Endothelial Dysfunction Improves in Patients with Rheumatoid Arthritis by Reducing Disease Activity. Lodewijk de Groot[1], Johanna Westra[2], Nynke Jager[1], Marcel D. Posthumus[2] and Marc Bijl[2]. [1]University Medical Centre Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: The incidence of cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA). Disease activity is supposed to be an important factor in the development of CVD in RA and reducing disease activity is one of the recommendations in the EULAR criteria for "cardiovascular risk management" in RA.

Aims of the study: To evaluate whether reduction of disease activity will influence markers of endothelial dysfunction, which is regarded an early marker of atherosclerosis.

Methods: In a prospective, longitudinal study 58 RA patients with recent onset of disease and 58 age and sex matched healthy controls were included. Endothelial dysfunction was measured by small artery elasticity (SAE), presence of atherosclerosis was determined by intima media thickness (IMT). Disease activity was measured by DAS-28. Patients were treated according to a predefined protocol. After one year all measurements were repeated in the RA patients and in 10 healthy controls.

Results: At entry endothelial dysfunction was increased in RA (median 3.4 ml/mmHg ×100, range 1.2–9.0) vs. HC (6.1, 1.7–12.9, P<0.0001). There was no difference in IMT between RA (0.70mm, 0.44–1.54) vs. HC (0.68, 0.49–1.46, P= 0.55). SAE had an inverse correlation with DAS-28 (r=-0.3066, P=0.0228). After 1 year SAE was improved in RA (3.9, 1.5–10.3, P=0.0115), in particular in patients who achieved remission (DAS-28 score < 2.6): in these SAE increased from 3.3, (1.2–7.7) to 5.7, (1.5–10.3), P=0.0269. In healthy controls SAE did not change after one year (6.8, (1.7–10.5) to 6.6 (1.6–10.0), P=0.56). DAS-28 scores decreased from 4.6, (2.1–7.8) to 2.1, (1.0–5.5), (P<0.0001). IMT showed no significant change after one year.

Conclusion: Endothelial dysfunction is present in early RA and is correlated inversely with disease activity. By reducing disease activity endothelial dysfunction improves, although not to normal values. This implicates that disease activity is probably not the only factor responsible for the increased risk for CVD in RA.

Statin Use Is Associated with Decreased Incident Coronary Artery Events in Rheumatoid Arthritis Patients. Chad P. Walker[1], Xiaoqin Tang[2], H. Lester Kirchner[2], Steven Steinhubl[3], Stephanie J. Morris[4], Jana L. Antohe[3] and Androniki Bili[5]. [1]Geisinger, Bloomsburg, PA, [2]Geisinger Center for Health Research, Danville, PA, [3]Geisinger Health System, Danville, PA, [4]Rose Tree Medical Associates—Riddle Memorial Hos, Danville, PA, [5]Geisinger Medical Center, Danville, PA

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased morbidity and mortality from cardiovascular disease (CVD). Statins have been associated with decreased coronary artery disease (CAD) events in the general population and have immunomodulatory effects, but this relationship has not been studied in RA. We examined the association of statin use with incident CAD in an inception cohort of RA patients.

Methods: Patients with newly diagnosed RA between 1/1/2001–12/31/2009 were identified through electronic health records (n=1881). Patients with preexisting CVD (CAD, cardiac revascularization procedure, abdominal aortic aneurysm, stroke, transient ischemic attack, peripheral artery disease, arterial revascularization procedure), primary care physician outside the institution, previous

statin use or liver disease were excluded (n=1331). The primary outcome was time to CAD (ICD-9 code ICD-9 410, 410.**-414.99 or revascularization procedure CPT codes 33510, 33548, 92982, 92984, G0290, G0291, 92930, 92981). Secondary analysis used time to development of CVD. Cox regression models were used to estimate the association between exposure to statin use and development of disease after adjusting for age, gender, race, hypertension, hyperlipidemia, diabetes, body mass index, low density lipoprotein level, systolic and diastolic blood pressure, rheumatoid factor, sedimentation rate and medications (TNF inhibitors, MTX, HCQ, steroids and NSAIDs).

Results: Analyses included 550 RA patients. Table 1 shows the patients' characteristics by statin use. Of the 39 cases developing CAD during observation, 14 were ever- and 35 were never-statin users. The median duration of statin exposure was 17.3 months. Of the 14 cases developing CAD in statin ever-users, 7 were exposed ≤ 17 months and 7 were exposed >17 months. The incidence rate ratio (95% CI) for statin use >17 months vs. ≤ 17 months vs. statin never use was 0.87 (0.39, 1.95; p-value=0.74) and 2.03 (1.06, 3.88; p-value=0.03) compared to never-use respectively. Results of the fully adjusted Cox model are shown in Table 2.

Table 1. Characteristics of RA patients by Duration of Statin Usage

		Post-RA Statin use[1]		
	Never (n = 432)	≤17 month (n = 58)	>17 month (n = 60)	P-value*
Male sex	105 (24.3%)	14 (24.1%)	16 (26.7%)	n.s.
White race	411 (95.1%)	54 (93.1%)	58 (96.7%)	n.s.

Hyperlipidemia	16 (3.7%)	49 (84.5%)	54 (90.0%)	<.001
DM	67 (15.5%)	20 (34.5%)	30 (50.0%)	<.001
Age at RA diagnosis	54 (44, 67)	59 (53, 68)	58 (52, 71)	.002
Median BMI (95.3% known)	28.4 (24.4, 32.3)	30.3 (27.6, 35)	32.1 (28.2, 36.2)	<.001
Median LDL (77.3% known)	107 (89, 128)	123 (102, 142)	103 (82, 120)	.001
Median SBP	74 (70, 80)	76.5 (72, 80)	72 (70, 80)	.047
Median DBP	124 (118, 132)	130 (122, 134)	131 (123, 139)	<.001
Pt Max CRP result (35.8% known)**	6.9 (2.4, 19)	7.4 (3.2, 19.7)	7.8 (3.1, 19.8)	n.s.
Pt Max Sedimentation Rate (81.3% known)	30 (16, 50)	34 (20, 54)	46 (21, 77)	.024

1. Ever Post-RA statin usage prior to DM diagnosis or censor date.
* P-values obtained either from Chi-square tests (frequencies) or Wilcoxon's test (medians)
** Not included in modeling due to the high percentage of missing data.
^ These are ever in time-frame. All else are post-RA.
n.s. = not significant

Table 2. Risk of developing CAD and CVD Based on Statin Use in RA patients

			HR (95% CI)	p-value
Coronary Artery Disease	Cumulative duration of statin exposure	Continuous (in months)	0.96 (0.96, 0.99)	.009
	Cumulative duration of statin exposure	≤17 months vs. never use	1.12 (0.42, 2.97)	n.s.
		>17 months vs. never use	0.30 (0.10, 0.94)	.039
Cardiovascular Disease	Cumulative duration of statin exposure	Continuous (in months)	0.97 (0.98, 0.10)	.021
	Cumulative duration of statin exposure	≤17 months vs. never use	1.52 (0.69, 3.31)	n.s.
		>17 months vs. never use	0.45 (0.16, 1.25)	n.s.
Coronary Artery Disease*	Cumulative duration of statin exposure	Continuous (in months)	0.963 (0.935, 0.991)	.009
	Cumulative duration of statin exposure	≤17 months vs. never use	1.121 (0.423, 2.974)	n.s.
		>17 months vs. never use	0.303 (0.098, 0.940)	.039
Cardiovascular Disease*	Cumulative duration of statin exposure	Continuous (in months)	0.971 (0.947, 0.996)	.021
	Cumulative duration of statin exposure	≤17 months vs. never use	1.515 (0.694, 3.306)	n.s.
		>17 months vs. never use	0.445 (0.159, 1.246)	n.s.

* Fully adjusted using time-variance where applicable for age, gender, race, hypertension, hyperlipidemia, diabetes, body mass index, low density lipoprotein level, systolic and diastolic blood pressure, rheumatoid factor, sedimentation rate and medications (TNF inhibitors, MTX, HCQ, steroids and NSAIDs)
n.s. = not significant

Conclusion: Statin use was associated with a 4% per month decrease in incident CAD risk in RA patients. For RA patients using statins for >17 months the risk of incident CAD decreased by 70%. Secondary analysis for incident CVD showed similar trends, although this did not reach statistical significance. This is a novel finding that may allow the study of statin use for primary CAD prevention in RA patients.

Endothelial Progenitor Cells and Cardiovascular Risk in Patients with Rheumatoid Arthritis. Nynke Jager, Steven Wenker, Lodewijk de Groot, Marcel D. Posthumus, Marc Bijl and Johanna Westra. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: The incidence of atherosclerosis and therefore cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA). The chronic inflammatory status is seen as an important factor in activation and damage to the endothelium. This leads to endothelial cell dysfunction and subsequently to atherosclerosis. Endothelial progenitor cells (EPCs) are stem cell like cells, and can be found in the peripheral blood. EPCs are supposed to play a role in repair of endothelial damage. The aim of this study is to evaluate whether the increased cardiovascular risk of RA patients is determined by lower EPC numbers, and whether these numbers correlate with endothelial dysfunction and atherosclerosis.

Methods: Thirteen RA-patients, with recent onset of disease (< 1 year), and thirteen healthy controls (HC) where included. EPC counts were measured in peripheral blood by flow cytometry using anti-CD34 en anti-CD133 antibodies. Colony-forming units (CFUs) were counted by culturing peripheral blood mononuclear cells on fibronectin coated plates (CFU-Hill) (1). In all participants SAE (small artery elasticity) was determined as measure of endothelial dysfunction and IMT (intima media thickness) was determined as measure for atherosclerosis.

Results: The numbers of circulating CD34 positive cells were lower in RA patients compared to HC (p=0.09), while CFU counts were significantly decreased in RA patients compared to healthy controls (p=0.005). The number of CD34 positive cells, the number of double positive cells (CD34/CD133) and the CFU counts were all significantly positively correlated to SAE measurement (p=0.02, p=0.02 and p=0.007 respectively). No correlations could be demonstrated between EPC or CFU numbers and IMT values.

Conclusion: Circulating EPCs and CFU counts are reduced in RA patients, and EPC numbers correlate with endothelial dysfunction. A shortage of EPCs in the peripheral blood could play a role in reduced repair and accelerated development of atherosclerosis in RA patients. As such, determination of the number of EPCs might be of value to predict the cardiovascular risk in RA patients.

Ischemic Stroke in RA—a Cohort Study of Risks, Relative Risks and Predictors. Marie Holmqvist[1], Emma Gränsmark[2], Solveig Wållberg Jonsson[3], Lennart TH Jacobsson[4], Lars Alfredsson[1] and Johan Askling[5]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Dept of Rheumatology, Umeå, Sweden, [4]Section of Rheumatology, Malmo, Sweden, [5]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Solna, Sweden

Background/Purpose: To investigate the risk of ischemic stroke (IS) in rheumatoid arthritis (RA) relative to the risk in the general population; to find out when after RA-diagnosis the risk is increased; to explore predictors of IS in the RA population.

Methods: RA-patients included in the Swedish Rheumatology Quality Register (SRQ) between 1 Jan 1995 and 1 Jan 2010 who had a symptom duration ≤12months when included and were free from ischemic stroke prior to inclusion were matched on sex, calendar period, county, and age to an ischemic stroke free general population comparator. 9,412 RA-patients and 46,242 general population comparators were identified. An index date was assigned to all individuals; date of inclusion in SRQ for RA-patients and corresponding in the matched comparators. Information on all first time hospitalizations for IS and potential predictors was retrieved from the Swedish Inpatient register. Information on deaths was retrieved from the census register. Follow-up with respect to hospitalization for IS ended at event, death, emigration or 31 Dec 2009. To estimate the relative risk (RR) and calculate 95% confidence intervals (CI), Cox models were constructed using time since RA-diagnosis as time scale. The models accounted for the matched design. To assess the impact of comorbidities such as hypertension (HT), diabetes mellitus (DM), atrial fibrillation/flutter (AF), peripheral venous events including deep venous thrombosis and pulmonary embolism (DVT/PE) and ischemic heart disease (IHD) on the risk of having an IS, Cox models were constructed and each potential predictor assessed separately using time-dependent covariates adjusted for age at index date and sex.

Results: Median follow-up was 4.7 years in RA and in comparators. Mean age at index date was 57.9 years in RA and 57.8 years in the comparators. 65.3% of the patients with RA were seropositive. 2.7% of RA-patients and 2.4% of the comparators were hospitalized with an IS after index date, corresponding to an age- and sex-adjusted RR of 1.14 (95% CI 0.99, 1.31). Women with RA had a significantly increased risk of IS compared to the general population (RR= 1.2, 95% CI 1.01, 1.44) but men did not. The risk increased compared to the general population after 10 years with RA (table). HT, IHD AF were statistically significant predictors of IS in RA. DVT/PE did not predict IS in RA but did in the general population (table).

Relative risk of ischemic stroke in RA stratified on time since RA-diagnosis

	<1 year since RA diagnosis	1–4 years since RA diagnosis	5–10 years since RA diagnosis	10–15 years since RA diagnosis
Relative risk (95% CI)	1.19 (0.84, 1.67)	1.06 (0.86, 1.30)	1.08 (0.84, 1.40)	2.00 (1.24, 3.22)
N events in RA/comp	45/190	110/516	73/336	27/78

Time-dependent covariates adjusted for age at index date and sex

	RA-patients RR (95% CI)	Comparators RR (95% CI)
Hypertension	1.74 (1.30, 2.32)	2.20 (1.92, 2.52)
Diabetes mellitus	1.34 (0.86, 2.10)	2.18 (1.82, 2.61)
Ischemic heart disease	1.64 (1.22, 2.22)	1.54 (1.33, 1.79)
Atrial fibrillation/flutter	1.91 (1.32, 2.75)	2.61 (2.22, 3.07)
Peripheral venous emboli	0.97 (0.55, 1.70)	1.32 (1.00, 1.75)

Conclusion: The risk of IS is increased in RA but first after 10 years with RA. Traditional risk factors might have a weaker association with IS in RA than in the general population, prompting us to search for other, RA-specific, predictors of IS.

1163

Myocardial Ischemia in Asymptomatic Patients with Rheumatoid Arthritis: A Comparative Study with Diabetes Mellitus. A. Karanasos[1], I. Felekos[1], C. Aggeli[1], E. Zampeli[1], A. Protogerou[1], C. Stefanadis[1], G. Kitas[2], K. Toutouzas[1] and PP Sfikakis[1]. [1]Athens University, Medical School, Athens, Greece, [2]The Dudley Group of Hospitals NHS Foundation Trust, Dudley, and Arthritis Research Campaign Epidemiology Unit, University of Manchester, UK, Manchester, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased ischemic events. The possible presence of myocardial ischemia, by dobutamine stress-contrast echocardiography was studied in asymptomatic patients and compared to patients with diabetes mellitus and a control group.

Methods: We prospectively enrolled 18 (12 women) consecutive non-diabetic RA patients with no evidence of coronary artery disease (68±7 years old with disease duration of 11±7 years, 50% smokers, 72% hypertensives, 33 % dyslipidemics) who developed new carotid plaques during the past 3 years. All underwent stress contrast echocardiography using the 17-segment model of the left ventricle for wall-motion and perfusion evaluation; consented patients with a positive stress test underwent coronary angiography. RA patients were compared to 18 asymptomatic patients with diabetes mellitus (matched 1:1 for traditional cardiovascular risk factors), as well with 36(matched 1:2) asymptomatic 'healthy' individuals.

Results: A positive stress result was found in 12 RA patients (67%), 14 diabetics (78%) and 11 controls (31%; $p<0.05$ for RA vs. control, $p<0.01$ for diabetes vs control group, p=NS for RA vs diabetes). Median number of myocardial segments with perfusion defect was 1 (interquartile range [IQR] 2) in RA, 2 (IQR 3) in diabetes and 0 (IQR 1.5) in controls ($p<0.05$ for RA vs. control, $p<0.01$ for diabetes vs control, p=NS for RA vs diabetes). Median wall motion score index was 1.05 (IQR 0.1) in RA, 1.1 (IQR 0.05) in diabetes and 1 (IQR 0.075) in the control group ($p<0.05$ for RA vs. control, $p<0.01$ for diabetes vs control, p=NS for RA vs DM). Among subjects with positive stress results either the number of segments with perfusion defect (median of 2) or wall motion score index (median of 1.1) was similar between RA, diabetes and controls. Of the 12 RA patients with positive stress result, coronary angiography performed in 8 revealed normal findings in 4, non significant coronary atheromatic lesions in 2 and lesions requiring angioplasty in 2 patients.

Conclusion: Asymptomatic patients with RA displayed high myocardial ischemic burden which was comparable to diabetes mellitus. In the absence of obstructive coronary artery disease myocardial ischemia, potentially caused by microvascular coronary dysfunction, was common in these patients.

1164

Radiographic Joint Damage in Rheumatoid Arthritis Is More Strongly Associated with Peripheral Arterial Stiffness Than with Peripheral or Carotid Artery Obstruction. Jose Felix Restrepo[1], Agustin Escalante[1], Daniel F. Battafarano[2], Daniel H. O'Leary[3] and Inmaculada Del Rincon[1]. [1]University of Texas Health Science Center, San Antonio, TX, [2]Brooke Army Medical Ctr, San Antonio, TX, [3]Tufts University-Boston Campus, Boston, MA

Background/Purpose: The mechanism for RA's increased cardiovascular(CV) morbidity and mortality are incompletely understood. One hypothesis is that shared mechanisms underlie joint damage and atherosclerosis in RA. The present study examined the association between radiographic joint damage, and markers of peripheral or carotid atherosclerosis and arterial stiffness in RA patients.

Methods: We studied RA patients using the ankle-brachial index (ABI), calculated as the systolic pressure of the lower limb arteries divided by that of the brachial arteries. The normal ABI varies from 0.91 to 1.3. An ABI ≤.9 indicates arterial obstruction, usually due to atherosclerosis, while an ABI ≥ 1.3 is incompressible, indicating arterial stiffness due to medial sclerosis or calcification. We used high resolution ultrasound to assess carotid plaque, a marker of atherosclerosis. We measured joint damage from radiographs of the hands and wrists, which we scored for erosions and joint-space narrowing using the method of Sharp and colleagues.

Results: We measured the ABI in 644 RA patients, among whom it was normal in 489 (76%), obstructed in 83 (13%) and incompressible in 72 (11%). Joint damage was significantly greater in the patients with obstructed arteries (Mean Sharp score = 72, SD = 71) and those with incompressible arteries (Sharp = 108, SD = 86), compared to the ones with normal arteries (Sharp score 52, SD = 58), $P \leq 0.001$ by one way ANOVA. The association between joint damage and incompressibility remained after age- and sex-adjustment, but was attenuated for obstruction, although it remained significant. Patients with carotid plaque also had significantly more joint damage (Sharp 73, SD = 74) than those without plaque (Sharp = 52, SD = 58), $P \leq 0.001$, but with age- and sex-adjustment the difference attenuated, loosing significance.

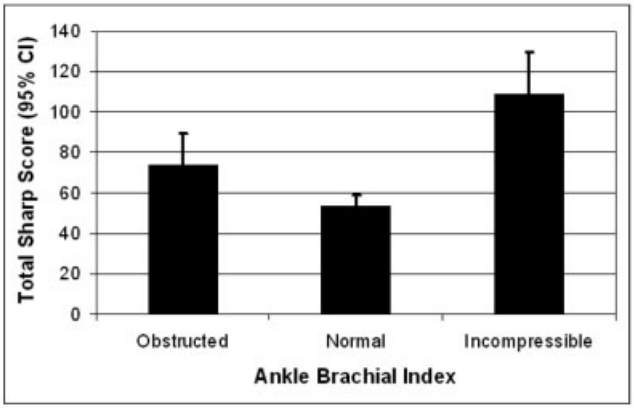

Figure. Sharp score in 642 RA patients, according to results on the ABI. Patients with either obstructed or incompressible peripheral arteries had significantly greater joint damage (ANOVA $P \leq 0.001$). With age- and sex-adjustment, the higher Sharp among incompressible patients remained highly significant ($P \leq 0.001$), but that with obstructed patients was attenuated ($P = 0.02$).

Conclusion: Radiographic joint damage in this group of RA patients was associated with peripheral arterial stiffness, and less so with markers of peripheral or carotid atherosclerosis. These findings support the hypothesis that CV disease in RA may share mechanisms with joint damage. Further research is needed to understand the mechanisms linking joint damage and arterial stiffness in RA.

Determinants of Insulin Resistance in Patients with Rheumatoid Arthritis. Seong Hu Park[1], SungIl Kim[1], Young Eun Park[1], Seung Geun Lee[1], SeungHoon Baek[1], Geun Tae Kim[2] and JoungWook Lee[3]. [1]Pusan Nationl University Hospital, Busan, South Korea, [2]Kosin University Gopsel Hospital, Pusan, South Korea, [3]Busan st. Mary's Medical Center, South Korea

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased cardiovascular events. These may be related to insulin resistance (IR). We evaluated status of IR and analyzed the relationship between IR and clinical and laboratory characteristics in patients with RA.

Methods: We examined 110 RA patients (93 females) and 110 age and sex matched healthy controls. We measured homeostasis model assessment (HOMA) IR, calculated according to fasting serum glucose and insulin. Univariate analysis was used to determine the relationship between baseline variables and IR (assessed by HOMA IR). Multiple linear regression analysis was used to select independent predictive factors.

Results: In patient group, age was 51.9±11.3 years old, disease duration was 58.5±43.2 months. HOMA IR was significantly high in patient group (1.73±2.07) compared with age and sex matched control group (0.88±0.69) ($p<0.001$). In patient group, 42 were early RA (disease duration less than 36 months) and 68 were established RA (more than 36 months). HOMA IR was significantly higher in patients with established RA (1.99±2.51) than those with early RA (1.31±0.90) ($p=0.001$), and correlated with disease duration ($r=0.393$, $p<0.01$), CRP($p=0.210$, $p=0.028$), age ($r=0.212$, $p=0.026$), triglyceride($r=0.236$, $p=0.023$), BMI ($r=0.231$, $p=0.015$). Disease duration and CRP were independent predictors for HOMA IR ($p\leq0.01$, $p=0.023$).

Conclusion: In patients with RA, IR measured by HOMA IR was significantly increased compared with that of healthy control. Independent predictive factors for HOMA IR in RA patients were disease duration and CRP.

Table 1. Clinical characteristics of patients with RA and controls

Variables	Controls (N = 110)	Patients with RA (n = 110)	P-value
Age, year	51.3 ± 9.0	51.8 ± 11.3	0.713
Women, n (%)	93 (84.5%)	93 (84.5%)	0.855
BMI, Kg/m2	23.3 ± 3.4	23.0 ± 3.1	0.534

Inflammation-Dependent Insulin Resistance Is Present in Rheumatoid Arthritis but it Is Not Associated with Retinol Binding Protein 4. Vanesa Hernandez-Hernandez[1], Esmeralda Delgado-Frías[1], Ivan Ferraz-Amaro[1], Jose A. Garcia-Dopico[2], Lilian Medina[2], Antonieta Gonzalez-Diaz[3], Maria A. Gomez-Rodriguez-Bethencourt[3], Jose Ramon Muñiz[4], Ana I. Rodriguez-Vargas[1], M. Angeles Gantes-Mora[1], M.Teresa Arce-Franco[1], M. Jesus Dominguez-Luis[5] and Federico Diaz-Gonzalez[1]. [1]Rheumatology Service, La Laguna, Spain, [2]Laboratorio Central, La Laguna, Spain, [3]Medicina Nuclear, Spain, [4]Resonancia Magnetica IMETISA, [5]Hospital Universitario de Canarias, La Laguna, Spain

Background/Purpose: Insulin resistance has been associated with rheumatoid arthritis (RA) disease activity. These correlation suggests that inflammation and hyperinsulinemia somehow interact and facilitate one another. Mechanistic data for inflammation-associated insulin resistance in RA are sparse. Retinol binding protein 4 (RBP4), an adipokie that contributes to insulin resistance, is increased in insulin-resistant states like diabetes and obesity. The role of this RBP4 has not been explored in inflammation-associated insulin resistance of RA patients. The purpose of this study was to estimate beta cell function, and resistance and sensitivity to insulin in patients with AR compared to controls, and to describe the potential relationship between peripheral bloods levels of RBP4 and inflammation-associated insulin resistance in RA patients.

Methods: 216 subjects, 101 RA patients and 115 age and sex matched controls were included in this cross-sectional study. Demographic data regard body mass index, presence of hypertension and corticosteroids intake were collected. Diabetes patients or controls were excluded. We measured in both groups fasting insulin and C-peptide, glucose, lipid levels, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), retinol binding protein 4, interleukin-6 (IL-6), and tumor necrosis factor alpha (TNFalpha). Insulin sensitivity was measured using the homeostasis model assessment index (updated HOMA model 2) to estimate beta cell function (%B), insulin sensitivity (%S) and insulin resistance index (IR). The Health Assessment Questionnaire Disability Index (HAQ) and the Disease Activity Score (DAS 28) were determined in RA patients.

Results: RA patients included were 55.2±10.0 years old, had a mean disease duration of 7.4±5.8 years and show a DAS28 3.99±1.41 and HAQ 0.80±0.76. In the univariate analyses the presence of RA was associated with a higher IR (β coefficient 0.8, 0.2–1.4 IC95%, $p=0.01$), and %B (β 20%, 2–39 IC95%, $p=0,03$). Insulinemia was also higher in AR patients, 73.3 vs 95.9 pmol/L, $p=0,04$ but they did not express higher levels of RBP4. This data remained statiscally significant when adjusted for body mass index, age, presence of comorbility and corticoids intake. DAS28 and HAQ did not correlate with insulin resistance indexes neither RBP4 levels. Similarly, ESR, RCP, IL6 and TNFalpha levels in RA patients were not associated with insulin resistance except for a strong positive association between RCP and %S ($r^2=0.48$, $p=0.00$). Multivariate analysis was perform to assess whether AR specific factors like ESR, RCP, corticoids intake, DAS28, HAQ, disease duration, and TNFalpha and IL6 levels were able to predict insulin sensitivity, resistance or beta cell function. DAS28, HAQ, corticoids, IL6, TNFa were capable to explain nearly the 20% of IR. For beta cell production, disease duration, corticoids, CRP and TNFalpha, IL6 levels predict 32% of %B variability.

Conclusion: Our data suggest that inflammation and IR interact and facilitate one another. IR states are presence in RA. RBP4 does not seem to play a role in IR related to RA.

1167

Low Serum Levels of Soluble Receptor for Advanced Glycation End Products Are Associated with Increased Augmentation Index in Patients with Early Rheumatoid Arthritis. Lai Shan Tam[1], Qing Shang[1], Edmund K. Li[1], Ka Lai Lee[2], Ying Ying Leung[3], King Yee Ying[4], Cheuk-wan Yim[5], Emily Kun[6], Alexander M. Leung[7], Martin Li[1], Tena K. Li[1], Tracy Y. Zhu[1], Ricky K. Chui[1], Lorraine Tseung[1], Shui Lian Yu[1], Woon Pang Kuan[8] and Cheuk-Man Yu[1]. [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Pamela Youde Nethersole Eastern Hospital, Hong Kong, Hong Kong, [3]North District Hospital, Hong Kong, Hong Kong, [4]Princess Margaret Hospital, Hong Kong, Hong Kong, [5]United Christian Hospital, Hong Kong, Hong Kong, [6]Tai Po Hospital, Hong Kong, Hong Kong, [7]Queen Elizabeth Hospital, Hong Kong, Hong Kong, [8]Hospital Selayang, Kuala Lumpur, Malaysia

Background/Purpose: There is growing evidence of premature atherosclerosis in patients with rheumatoid arthritis (RA), leading to a higher rate of cardiovascular events than in the general population. Recent evidence suggested that this phenomenon also occurs in patients with early RA. Whether the prevalence of subclinical atherosclerosis was increased in early RA patients

remained controversial. We assessed whether carotid intima-media thickness (IMT) and arterial stiffness indexes as determined by pulse wave velocity (PWV) and augmentation index (AIx) were increased in a cohort of early RA patients as compared to non-RA controls. We also ascertained the potential explanatory variables associated with an increased AIx in early RA patients.

Methods: Ninety-five early RA patients (age, 52.5 +/− 11.4 years; 85 female) and 70 age- and sex-matched (age, 52.4 +/− 10.5 years; 60 female) community controls were recruited for this cross-sectional study. Patients and controls were eligible for analysis if they had no overt cardiovascular (CV) diseases. PWV and AIx were assessed noninvasively during pulse wave analyses. For large artery remodeling the intima-media thickness (IMT) was measured in both common carotid arteries with ultrasound. Traditional CV risk factors were measured in patients and controls, while novel CV risk factors (soluble receptor for advanced glycation end products [sRAGE]) and inflammatory markers (ESR, CRP, IL-12p, TNF-alpha, IL-10, IL-6, IL-1beta, IL-8) were assessed in early RA patients.

Results: The mean disease duration for this group of early RA patient was 13.5 +/− 7.9 months and the DAS 28 score was 3.9 +/− 1.3. The prevalence of traditional CV risk factors was similar between the two groups, although the use of anti-hypertensives (26.5% versus 8.2%, $p<0.005$) and statins (7.1% versus 1.0%, $p<0.05$) were more prevalent in patients with early RA. Despite treatment, early RA patients had a significantly increased diastolic blood pressure (82 +/− 12 mmHg versus 77 +/− 11 mmHg, $p<0.005$). The levels of total cholesterol (4.6 +/− 1.1 mmol/L versus 5.3 +/− 0.8 mmol/L, $p<0.001$), HDL-cholesterol (1.5 +/− 0.4 mmol/L versus 1.7 +/− 0.4 mmol/L, $p<0.001$) and LDL-cholesterol (2.6 +/− 0.8 mmol/L versus 3.1 +/− 0.8 mmol/L, $p<0.005$) were significantly lower in early RA patients. AIx was statistically significantly higher in early RA patients as compared with controls (31.6 +/− 11.2 % versus 28.0 +/− 11.5%; $P<0.05$), while PWV (14.9 +/− 0.3m/s versus 14.9 +/− 0.3m/s, p=NS) and IMT (0.60 +/− 0.09mm versus 0.62mm +/− 0.08mm, p=NS) were similar between patients and control. Increased AIx in early RA patients was associated with the use of anti-hypertensives (36.3 +/− 8.7% versus 29.8 +/− 11.5%, $p<0.05$), older age ($r = 0.29$, $p<0.05$), higher glucose level ($r = 0.21$, $p<0.05$) and lower sRAGE level ($r = -0.24$, $p<0.05$).

Conclusion: AIx, a marker of arterial stiffness, is increased in early RA patients without overt CV diseases. Increase in AIx may be a sensitive indicator for early subclinical atherosclerosis in patients with early RA, which was associated with traditional as well as novel CV risk factors including a lower sRAGE level. Measuring AIx might assist in better assessing the increased cardiovascular risk in early RA patients.

1168

Prolonged Hydroxychloroquine Use Is Associated with Decreased Incidence of Cardiovascular Disease in Rheumatoid Arthritis Patients. Androniki Bili[1], Xiaoqin Tang[2], H. Lester Kirchner[2], Jana L. Antohe[1], Stephanie J. Morris[3] and Mary Chester Wasko[4]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Center for Health Research, Danville, PA, [3]Rose Tree Medical Associates—Riddle Memorial Hos, Danville, PA, [4]West Penn Allegheny Health System, Pittsburgh, PA

Background/Purpose: Hydroxychloroquine (HCQ) use has been associated with decreased incidence of diabetes (DM) and improved lipid profile in rheumatoid arthritis (RA) patients, but no studies have reported on the relationship between HCQ and cardiovascular disease (CVD) in RA. Given the long half-life of HCQ, we looked at the effect of long-term HCQ use (>36 mo.) and risk of incident CVD in RA patients.

Methods: 1,881 incident adult RA patients (ICD-9 code 714.0 at ≥ 2 outpatient encounters with a rheumatologist), diagnosed between 1/1/2001 – 3/31/2008 were identified. Prevalent cases of CVD [coronary artery disease (CAD), cardiac revascularization procedure, abdominal aortic aneurysm, stroke, transient ischemic attack, peripheral artery disease, arterial revascularization procedure] were excluded (n=52). Primary outcome was time to CAD [ICD-9 code 410, 410–414.99 or revascularization procedure (CPT codes 33510, 33548, 92982, 92984, G0290, G0291, 92930, 92981)]. Secondary outcome was time to development of CVD. Cox proportional regression models were used to calculate hazard ratios (HR) of exposure after adjustment for age, gender, race, BMI, LDL, BP, HTN, hyperlipidemia, DM, RF, ESR, TNF-α inhibitors, methotrexate, statin and corticosteroid use. Exposure to HCQ and all other variables were treated as time-variant in the models.

Results: Of the 1,829 patients included in the analysis, 684 (37.4%) patient were ever on HCQ, 138 on HCQ >36 mo. and 546 on HCQ ≤ 36 mo. Of the 166 cases developing CAD during observation, 102 were HCQ nonusers, 6 in the HCQ > 36 mo. and 58 in the HCQ ≤ 36 mo. user groups, yielding incidence of 25.4, 7.3 and 31.6 events per 1000 person-years (py), respectively, with incidence rate ratio (IRR) 0.29 (0.13–0.65, p=0.003) in the >36 months users vs. nonusers. HCQ use >36 months was associated with a reduction in the hazard for developing CAD (HR= 0.28, 95% CI:0.12–0.68, p=0.005) compared to nonusers. Of the 200 cases developing CVD during observation,126 were never on HCQ, 7 in the HCQ > 36 months and 67 in the HCQ ≤ 36 months users, yielding incidence of 31.7, 8.6 and 36.9 events per 1000 py, respectively, with IRR 0.27 (0.17–0.58, p=0.001) in the HCQ >36 mo users vs. nonusers. A similar association was found between HCQ use > 36 months, compared to nonusers, and hazard for developing CVD (HR 0.27, 0.12–0.60, p=0.005).

Conclusion: In patients with RA, HCQ use for >36 months is associated with a 72% and 73% reduction in the risk of incident of CAD and CVD respectively. These findings support the use of HCQ as an adjunct to other first line DMARDs in RA patients at high risk for CVD.

Vitamin D Deficiency, Interleukin 17, and Vascular Function in Rheumatoid Arthritis. Prabha Ranganathan[1], Shokoufeh Khalatbari[2], Srilakshmi Yalavarthi[3], Wendy Marder[4], Robert Brook[2] and Mariana J. Kaplan[4]. [1]Washington University School of Medicine, St. Louis, MO, [2]University of Michigan at Ann Arbor, MI, [3]University of Michgan at Ann Arbor, MI, [4]University of Michigan, Ann Arbor, MI

Background/Purpose: Although the effects of vitamin D deficiency on cardiovascular (CV) disease risk in health and in chronic kidney disease have been previously reported, no studies have examined the link between vitamin D deficiency and CV risk in rheumatoid arthritis (RA). Our aim was to determine the effects of vitamin D deficiency on vascular function, and

inflammatory markers potentially associated with CV risk, in a cohort of patients with RA.

Methods: Serum levels of 25 hydroxyvitamin D (25 [OH]D) were quantified in a cohort of 87 patients with RA, with an age of 55.2±12.1(mean ± standard deviation). The majority of this cohort was female (n=70 [80.5%]), and had been on stable doses of traditional disease-modifying anti-rheumatic drugs and/or biologics for at least 3 months. At the same visit, patients underwent assessment of flow mediated dilatation (FMD) of the brachial artery in response to reactive hyperemia to assess endothelium-dependent responses of conduit vessels; pulse wave velocity (PWV) to assess aortic compliance, and microvascular reactive hyperemia index (RHI) using Endopat-2000 device. Various markers of CV risk were quantified in plasma. RA disease activity was assessed by Disease Activity Score of 28 joints (DAS28). Serum interleukin 17 (IL-17) was quantified by enzyme linked immunosorbent assay (ELISA). Regression analysis was performed to determine the effects of vitamin D deficiency on vascular function and inflammatory markers in patients who were vitamin D insufficient ([25 (OH)D] < 30 ng/ml), and vitamin D deficient ([25 (OH)D] < 20 ng/ml).

Results: Of the 87 RA patients, 59 (68%) were vitamin D insufficient (25[OH]D <30 ng/ml) with 25(OH)D of 20.2±5.9 ng/ml. In univariate analysis, higher serum 25[OH]D levels were significantly associated with lower serum IL17 levels (p=0.004) in this group. This association persisted in multivariate analysis after adjusting for known confounders, including age, body mass index (BMI), gender, race/ethnicity and seasonal variation (p=0.02). In the subset of patients (n=25, 28.7%) who were vitamin D deficient (25[OH]D levels <20 ng/ml), with 25[OH]D of 14.4±3.4ng/ml, univariate analysis revealed that higher serum 25(OH)D levels were significantly associated with higher microvascular function, as assessed by RHI (p=0.04). This association persisted in multivariate analysis after adjusting for known confounders, including age, BMI, gender, and race/ethnicity (p=0.04).

Conclusion: Vitamin D deficiency in RA patients may affect Th17 responses and contribute to microvascular dysfunction. These results indicate that maintaining normal serum levels of vitamin D in patients with RA may protect against IL17 mediated inflammatory responses and provide a protective effect against vascular damage that afflicts patients with this disease.

1170

Asymptomatic Carotid Plaques in Rheumatoid Arthritis Results in Inadequate Treatment to Lipid Targets in Cardiovascular Prevention. Anne Grete Semb[1], Inge Olsen C[2], Sella Provan[1], Terje R. Pedersen[3], Einar Stranden[4], Désirée van der Heijde[5], Jonny Hisdal[4] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Smerud Medical Research, Oslo, Norway, [3]Oslo University Hospital-Ullevaal, Oslo, Norway, [4]Uslo University Hospital-Aker, Oslo, Norway, [5]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: One of the cornerstones in cardiovascular (CV) prevention is lipid lowering (LL), which is divided into primary (no CV disease) and secondary (known CV disease) prevention. The prevalence of asymptomatic carotid plaque (a-CP) is 2–3 times higher in rheumatoid arthritis (RA) patients compared to the general population. Patients with a-CP, which is equivalent of CV disease, should receive secondary CV preventive treatment, with intensive LL. Carotid ultrasound is not commonly used and the a-CP will therefore not commonly be taken into account in the CV risk stratification. There is therefore a high risk of treatment misclassification concerning LL in RA patients in that they wrongly will be categorized into either no preventive treatment or primary prevention instead of secondary preventive LL treatment. Our aim was to calculate the risk for preventive treatment misclassification by SCORE when a-CP was present.

Methods: We performed CV risk stratification by using SCORE in 86 RA patients and 56 controls without known CV disease. B-Mode ultrasound of the carotid arteries was performed. Cross- tabulations and Chi^2 were used for calculation of risk for treatment misclassification in patients with and without CP when SCORE < or > 5%.

Results: There were no differences between RA patients and controls concerning age (56.2±9.2 vs. 54.5±9.4 years), but slightly more females in the RA group (79 vs. 63%, p=0.05). Presence of CV risk factors, including lipids, was similar in the two groups, but a-CP was significantly more frequent in RA patients [n=39 (45.3%)] than in controls [15 (26.8%)] (p=0.003). In the RA group 75 patients had a SCORE<5% indicating no need for primary LL prevention. However, 30 (40.0%) of these patients had a-CP and should receive intensive LL treatment. In the RA group with SCORE >5% (n=11), indicating a need for primary prevention, 9 (81.8%) patients had a-CP and should therefore be categorized to more intensive LL treatment, as in secondary prevention. Of the 49 controls with SCORE<5%, indicating no need for LL therapy, 10 (20.4%) had a-CP and should have been categorized to secondary preventive LL treatment. Whilst of the 7 controls with SCORE >5%, 5 (71.4%) of those had a-CP and should have more intensive LL treatment as in secondary instead of primary preventive therapy. Thus, the risk for treatment misclassification (i.e. LL under treatment) in RA when SCORE <5% and >5% was 40.0% and 81.8% respectively.

Conclusion: RA patients with a-CP should receive intensive LL preventive treatment. There is also a high risk of a-CP when SCORE > 5%. Consequently, recommending more intensive LL treatment, as in secondary instead of primary preventive treatment may be preferable, when ultrasound of the carotid arteries is not feasible in cardiovascular risk stratification. Confirmation of these data is warranted in larger studies.

1171

Cardiac Involvement in Patients with secondary Amyloidosis Due to Rheumatoid Arthritis. Daisuke Kobayashi[1], Yoko Wada[1], Shuichi Murakami[1], Takeshi Kuroda[2], Masaaki Nakano[3] and Ichiei Narita[1]. [1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]Niigata University, Niigata, Japan, [3]Niigata University School of Medicine, Niigata, Japan

Background/Purpose: Rheumatoid arthritis (RA) is one of the major causes of amyloid A (AA) amyloidosis, the major organs affected being the kidneys and gastrointestinal tract. Although cardiac amyloidosis is the principal cause of death in patients with amyloid L (AL) amyloidosis, significant cardiac involvement in AA amyloidosis is thought to be rare. On the other hand, the survival rate of hemodialysis patients with AA amyloidosis associated with RA has been shown to be low, and our previous study revealed that cardiac failure accounted for more than half of all deaths in these patients. We examined the cardiac features of patients with RA associated with AA amyloidosis.

Methods: Twenty-one RA patients (2 males, 19 females) with AA amyloidosis who were followed up at our hospital between 2001 and 2010 were enrolled. Each patient fulfilled the 1987 American Rheumatism Association criteria for RA. All the patients had undergone GI tract (n=17), myocardium (n=2), or abdominal fat (n=2) biopsies, and had been confirmed to have reactive AA amyloidosis by histopathological examination. The patients' background data and echocardiographic features were analyzed retrospectively. Additionally, 14 patients whose left ventricular (LV) wall thickness exceeded 12 mm were assigned to a LV hypertrophy (LVH) group, and their clinical features were compared with a normal group (n=6).

Results: The mean period between the onset of RA and echocardiographic examination was 21.1 ± 9.9 years (range, 7 to 39 years), and the mean period between the onset of AA amyloidosis and echocardiographic examination was 3.7 ± 5.7 years (range, 0 to 16.2 years). Among the 21 patients, 19 were asymptomatic, and only 2 showed cardiac failure at the time of evaluation. Echocardiography demonstrated mild LVH, a low E/A ratio, and a normal ejection fraction (LV posterior wall thickness: 11.0 ± 2.1 mm, Interventricular septal thickness: 1.20 ± 0.25 mm, Ejection fraction: 66.8 ± 9.86%, E/A ratio: 0.80 ± 0.24). Patients in the LVH group had a significantly longer history of RA (24.3 ± 7.84 years vs. 14.8 ± 11.2 years, p=0.037), a lower estimated glomerular filtration rate (eGFR) (36.4 ± 18.3 ml/min vs. 54.2 ± 36.4 ml/min), and more severe poteinuria, than those in the normal group. Furthermore, we found a negative correlation between eGFR and LV wall thickness (R^2 =0.6647, p<0.001) and interventricular septal thickness (R^2 =0.40, p=0.006), but not the E/A ratio.

Conclusion: Thickening of the LV wall and myocardial diastolic dysfunction are the major cardiac features of patients with AA amyloidosis. Although cardiac involvement is said to be rare in AA amyloidosis, subclinical LV dysfunction may show insidious progression.

1172

Detection of Left Ventricular Regional Dysfunction by Using Cardiac Magnetic Resonance Imaging in Rheumatoid Arthritis Patients without Cardiac Symptoms; Comparison Between Non-Biologic DMARDs and Biologics Groups. Hitomi Kobayashi[1], Isamu Yokoe[1], Hiroshi Sato[1] and Yasuyuki Kobayashi[2]. [1]Itabashi Chuo Medical Center, Tokyo, Japan, [2]St Marianna Univ Sch of Med, Kawasaki, Japan

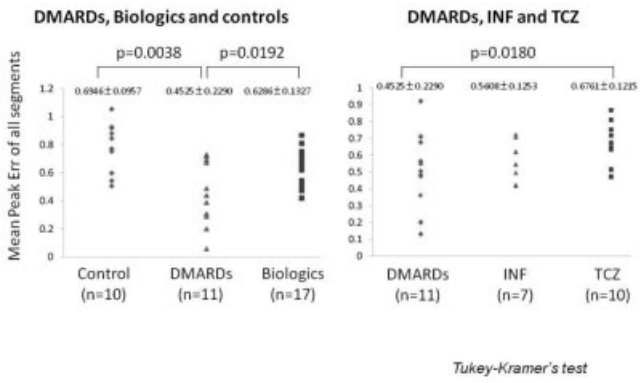
Background/Purpose: In patients with rheumatoid arthritis (RA), cardiac involvement is common and can contribute to worsening of patient outcome. Regional left ventricular (LV) dysfunction reflects myocardial abnormalities. Regional LV function in RA has not been systematically studied by cardiac

magnetic resonance imaging (CMR). We sought to detect LV regional dysfunction by using CMR in RA patients without cardiac symptoms.

Methods: Consecutive patients with RA and healthy control subjects were enrolled. RA patients received either non-biologic DMARDs or biologics. All subjects with no history and/or clinical findings of hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, dyslipidemia, or echocardiographic abnormalities underwent non-contrast CMR on a 1.5 T scanner. Peak systolic regional radial strain (Err, %) was calculated by feature tracking of cine MRI in six segments of the mid-slice of LV. We explored the associations of peak Err between the control and RA groups. Comparisons of peak Err between the DMARDs and the biologics groups, and the association of peak Err with disease activity and severity measures were determined.

Results: We compared 28 RA patients (92.9 % female; mean age 58.0±12.6 years) with 10 non-RA controls (100% female; mean age 55.7±4.6 years). RA patients received either DMARDs or infliximab (IFX; 3 mg/kg) or tocilizumab (TCZ; 8 mg/kg). DAS28-ESR was higher in the DMARDs group than in the biologics group, but not significantly different (4.08±1.12 vs. 2.09±1.60; p=0.06). Modified Health Assessment Questionnaire (mHAQ) scores were significantly higher in the DMARDs group than in the biologics group (0.61±0.25 vs. 0.18±0.22; p =0.01). Mean peak Err of all segments was lower in RA patients than in normal subjects but not significantly different (0.69±0.09 vs. 0.55±0.19; p=0.07). Peak Err in both the anterolateral and inferior wall was significantly lower in RA patients than in controls (p=0.01, p=0.01, respectively). In the DMARDs group, mean peak Err was significantly lower than in the biologics group (p=0.02). Mean peak Err was higher in the TCZ group than in the DMARDs group (0.67±0.12 vs. 0.45±0.22; p=0.01) [Fig1]. Abnormal peak Err in RA patients was associated with higher mHAQ scores (R^2=0.31).

Fig.1 Mean peak Err of all segments determined by MRI in patients with DMARDs, INF, TCZ and controls



Conclusion: Our findings suggested sub-clinical LV regional dysfunction in RA patients without cardiac symptoms. Evaluation of regional LV function by CMR appears useful for detecting subclinical myocardial involvement in RA patients. Higher mHAQ scores might be an independent risk factor for myocardial involvement in RA. Our results indicated that TCZ might affect the normalization of LV regional function compared with non-biologic DMARDs.

1173

Effect of Disease Activity on Lipoproteins Levels in Patients with Early Arthritis. Silvia Pérez-Esteban, Ana M. Ortiz, Ana M. Fernández-Ortiz, Santos Castañeda and Isidoro González-Alvaro. Hospital Universitario de La Princesa. IIS Princesa, Madrid, Spain

Background/Purpose: Persistent inflammatory activity in patients with rheumatoid arthritis (RA) is associated with an increased risk for cardiovascular complications. Risk factors for these complications include smoking, elevated C-reactive protein and dyslipidaemia. The two former risk factors are clearly related to the development or activity of RA. However, the relationship between lipoproteins levels and RA remains controversial. The objective of this work was to analyse the relation between total cholesterol (TCh) and its fractions, including oxidized LDL (oxLDL) and different variables in early arthritis (EA) patients.

Methods: We analysed data from 220 patients of our EA register: 76% women, age at onset: 53.6 [42–67] years (median [p25-p75]) and disease duration at entry: 5.9 [3.8 –8.6] months; 70% met RA 1987 criteria at two years of follow-up. Rheumatoid factor was positive in 46.4% of patients and anti-citrullinated peptide antibodies in 44%. The follow-up of patients ranged from 2 to 5 years with a total of 540 visits with lipid measurements available (mean 2.5 visits by patient). Demographic and disease related variables, as well as treatments prescribed were systematically recorded. TCh, LDL, HDL, VLDL and triglyceride (TG) levels were obtained from the routine laboratory results. oxLDL levels were assessed using a commercial ELISA kit (Mercodia AB, Uppsala, Sweden) in 157 patients. To determine the effect of independent variables on levels of TCh, its fractions HDL, LDL, VLDL and oxLDL and TG, we fitted population-averaged by generalized linear models, nested by patient and visit, using the *xtgee* command of Stata 10.1 for Windows (StataCorp LP, College Station, TX, USA).

Results: The table below shows the beta coefficients of the variables significant or nearly significant but relevant to the multivariate analysis models for each of the dependent variables.

	TCh	LDL	HDL	VLDL	TG
	βCoeff/p	βCoeff/p	βCoeff/p	βCoeff/p	βCoeff/p
Female	13.3 ± 5.6/0.017	—	13 ± 2.7/0.000	0.1 ± 0.05/0.008	—
Age (by year)	0.9 ± 0.1/0.000	0.3 ± 0.1/0.055	0.2 ± 0.1/0.025	—	0.7 ± 0.3/0.003
Smoking	11.1 ± 5.4/0.039	10.8 ± 5.6/0.054	—	—	—
Statin use	−26.8 ± 6/0.000	−25.9 ± 5.8/0.000	—	6.04 ± 2.2/0.007	—
BMI	1.5 ± 0.5/0.003	1.3 ± 0.5/0.018	—	0.70 ± 0.2/0.002	5.4 ± 1.3/0.000
HAQ	4.7 ± 3.3/0.16	—	−3.1 ± 1.8/0.095	—	28.7 ± 9.7/0.003
DAS28CRP	−5.5 ± 1.5/0.000	—	−1.9 ± 0.9/0.029	—	−16.3 ± 4.3/0.000
DMARDs					
Leflunomide	0.9 ± 0.3/0.000	0.6 ± 0.3/0.057	—	0.30 ± 0.1/0.019	—
Methotrexate	—	0.6 ± 0.2/0.005	—	—	−1.07 ± 0.6/0.07
Antimalarials	—	−0.04 ± 0.02/0.06	—	—	—

In addition, oxLDL levels were also analysed and were associated with female gender (beta coeff = −25 ± 9.3; p = 0.007), frozen time (−0.24 ± 0.02; p < 0.001), LDL level (0.38 ± 0.11; p = 0.001) and DAS28CRP (9.5 ± 3.3; p = 0.004).

Conclusion: TCh levels decrease significantly with increasing degree of arthritis activity. This finding was mainly due to the HDL fraction. Conversely, oxLDL levels significantly increased when the disease activity was greater. Higher HAQ values are related with increased lipid serum levels. These observations could contribute to the increased cardiovascular morbidity in RA.

Vascular Calcification On Hand and Wrist Radiographs Are Associated with Comorbidity and Overall Mortality In Rheumatoid Arthritis. Zachary Pruhs[1], Kaleb D. Michaud[2], Alan R. Erickson[3], Harlan Sayles[4], Gail S. Kerr[5], Angelo L. Gaffo[6], Liron Caplan[7], Grant W. Cannon[8], Deana M. Lazaro[9], Andreas M. Reimold[10], Dannette S. Johnson[11], Bogdan Cherascu[12], Pascale Schwab[13], Nasim A. Khan[14] and Ted R. Mikuls[15]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Univ of Nebraska Med Ctr & National Data Bank for Rheumatic Diseases, Omaha, NE, [3]UNMC Physicians - Brentwood, LaVista, NE, [4]University of Nebraska Medical School, Omaha, NE, [5]Washington DC VA and Georgetown University, Washington, DC, [6]Birmingham VA Medical Ctr, Birmingham, AL, [7]Denver VA and University of Colorado, Aurora, CO, [8]Salt Lake City VA and University of Utah, Salt Lake City, UT, [9]Brooklyn VA, Brooklyn, NY, [10]Dallas VA and University of Texas Southwestern, Dallas, TX, [11]University of Mississippi Med Center, Jackson, MS, [12]Iowa City VA and University of Iowa, Iowa City, IA, [13]Portland VA and Oregon Health & Science University, Portland, OR, [14]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [15]Omaha VA and University of Nebraska, Omaha, NE

Background/Purpose: There is an established relationship between the presence of vascular calcification (VC) on plain radiography and cardiovascular disease (CVD) in select patient populations without rheumatoid arthritis (RA). VC may be found incidentally in RA patients on hand and wrist radiographs obtained for diagnostic purposes or as an assessment of disease severity. This study was undertaken to determine the frequency of VC on hand and wrist radiographs and to examine the relationship of VC with CVD risk factors and all-cause mortality in RA patients.

Methods: Hand and wrist radiographs from 756 patients enrolled in the Veterans Affairs RA (VARA) registry were examined. The radiographs were read by an investigator and scored as either "positive" or "negative" for VC. A second investigator read a sample of the radiographs (n = 40) to confirm scoring accuracy. Inter-observer agreement was strong with a kappa coefficient = 0.7.

Patients with and without VC were compared in regards to demographics and the presence of CVD risk factors using the Student's t-test for continuous variables and chi-square test for categorical variables. The association of patient characteristics with VC were examined using backwards stepwise multivariable logistic regression. The association of VC with mortality was examined using multivariable Cox proportional hazards regression.

Results: VC was observed in hand and wrist radiographs in 88 (11%) patients. Patient characteristics for those with and without VC are shown:

	VC positive (n = 88)	VC negative (n = 668)	P-value
Age (years)	72 ± 8	63 ± 10	<0.001
Men	97%	90%	0.051
RA duration (years)	16 ± 14	13 ± 11	0.006
Anti-CCP positive	77%	78%	0.891
RF positive	81%	82%	0.818
Nodules	45%	45%	0.944
Diabetes	38%	15%	<0.001
Hyperlipidemia	43%	42%	0.780
Ever smoking	63%	83%	<0.001
Prevalent CVD	40%	21%	<0.001
Prednisone use	56%	42%	0.017

In multivariable analyses, factors independently associated with VC included diabetes (OR = 2.6; 95% CI 1.7 to 4.2; p<0.001), prevalent CVD (OR = 1.6; 95% CI 1.2 to 2.2; p=0.001), and patient global well-being (OR = 1.01; 95% CI 1.01 to 1.02; p<0.001). Compared to never smokers, former (OR = 0.3; 95% CI 0.2 to 0.6; p<0.001) and current smokers (OR = 0.2; 95% CI 0.1 to 0.3; p<0.001) were less likely to have VC. There was a non-significant trend toward an association of prednisone use (OR = 1.8; 95% CI 1.0 to 3.2, p = 0.065) with the presence of VC. Adjusting for age and gender, VC was associated with future all-cause mortality (HR = 1.4; 95% CI 1.0 to 1.9, p = 0.038). The association of VC with all-cause mortality is attenuated and no longer significant after adjusting for comorbidities and RA related measures.

Conclusion: The incidental finding of VC on hand and wrist radiographs may be informative as a means of CVD risk assessment in patients with RA. In addition to associations with higher overall mortality, VC is strongly and positively associated with established predictors of future cardiovascular events including prevalent CVD and diabetes. The inverse association of VC with ever smoking was not expected and could relate to 'left censoring', statistical chance, or other undefined biologic effects.

Cardiovascular Risk Models and Carotid Intima-Media Thickness Predict Cardiovascular Disease Events in Rheumatoid Arthritis. Inge A.M. van den Oever[1], Alper M. van Sijl[1], Hennie G. Raterman[2], Maarten Boers[3], Mike J.L. Peters[2], Yvo M. Smulders[2], Alexandre E. Voskuyl[3] and Michael T. Nurmohamed[4]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]VU University medical center, Amsterdam, Netherlands, [3]VU University Medical Center, Amsterdam, Netherlands, [4]Reade, Centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease with an increased cardiovascular (CV) risk. Carotid intima-media thickness (cIMT) independently predicts CV events in the general population, and hence, is used as a non-invasive screening tool to identify patients at high CV risk. In RA, it is still unclear whether estimated 10-year CV risk models, such as the Systematic Coronary Risk Evaluation (SCORE) and Framingham accurately predict CV disease incidence and whether cIMT measurement can improve the risk classification. Objective of this study is to investigate the predictive value of SCORE- and Framingham risk models and cIMT for future CV events in RA.

Methods: CARRÉ is an ongoing cohort study of CV disease in RA. In a subpopulation (n=141) we measured cIMT at baseline; 120 had no prior CV disease. In these 120 patients SCORE- and Framingham risk models calculated 10-year risk of fatal and nonfatal CV disease; we compared these calculations with actual CV events recorded in a mean follow-up of 9 years. Univariate logistic regression analyses investigated the extent to which individual CV risk factors, SCORE-, Framingham and cIMT predicted CV disease incidence.

Table 1. Baseline characteristics

	All patients (n = 120)	Patients with CV events (n = 13)	Patients without CV events (n = 107)
Demographic characteristics			
Age, in years	63 ± 7	67 ± 8	63 ± 7*
Males, %	34	54	31
CV-risk factors			
Systolic BP, in mmHg	143 ± 19	152 ± 20	141 ± 19
Hypertension, %	61	77	59
Current smoking, %	27	23	26
Total cholesterol, in mmol/L	5.74 ± 1.06	5.55 ± 0.82	5.77 ± 1.09
HDL-cholesterol, in mmol/L	1.48 ± 0.50	1.19 + 0.39	1.51 + 0.51*
LDL-cholesterol, in mmol/L	3.67 + 1.04	3.64 ± 0.79	3.68 ± 1.08
Atherogenic index	4.27 ± 1.52	5.22 ± 2.23	4.16 ± 1.38*
cIMT, in mm	0.82 ± 0.14	0.89 ± 0.13	0.81 ± 0.14
10-year CVD risk			
SCORE (mortality), %	6 (3–11)	9 (6–16)	5 (3–10)*
Modified SCORE (according to EULAR), %	7 (4–12)	11 (6–24)	7 (3–11)*
Framingham (morbidity and mortality), %	11 (7–15)	18 (10–27)	11 (7–15)*

* significant difference between patients with and without CV events p≤0,05

Results: Thirteen patients (incidence rate: 13.5 %, 95% CI: 7.8–23.2) developed a CV event, four of these events were fatal (incidence rate: 4.2 %, 95% CI: 1.6–11.1). Considering the 9-year follow up, SCORE- and Framingham predictions were very close to actual mortality and morbidity and consequently significantly predicted (fatal) CV events. cIMT also showed a trend in prediction of CV disease.

Table 2. Univariate logistic regression of CV disease incidence with CV risk factors, CV risk models and cIMT

	OR (95%-CI)	Standardized OR (95%-CI)	p
Age, 10-year increment	1.09 (1.00–1.18)*	1.80 (1.00–3.23)*	0.048
Male sex	2.37 (0.74–7.57)	—	0.15
Systolic BP, 1 mmHg increment	1.03 (0.99–1.06)	1.64 (0.94–2.86)	0.08
Hypertension, %	2.28 (0.59–8.75)	—	0.23
Atherogenic index, 1 point increment	1.47 (1.04–2.06)*	1.79 (1.06–3.01)*	0.03
Current smoking, %	1.11 (0.48–2.53)	—	0.81
IMT, 100 micrometer increment	1.44 (0.98–2.11)	1.67 (0.97–2.85)	0.06
10-year Framingham CV-risk (FRS), 1% increment	1.07 (1.01–1.13)*	1.82 (1.12–2.96)*	0.02
10-year SCORE CV-risk, 1% increment	1.08 (1.02–1.14)*	1.83 (1.17–2.88)*	0.009

* significant result p<0,05

Conclusion: This long term follow up study underscores the value of SCORE and Framingham in prediction of CV disease incidence, also in RA. In this study of RA patients the evidence for cIMT, a surrogate marker of CV disease in the general population, was inconclusive.

Insulin Resistance, a Non-Traditional Cardiovascular Risk Factor Influenced Both by Disease Activity and Adiposity in Rheumatoid Arthritis. Ronan H. Mullan[1], Susan Vankerkamp[1], Owen Sullivan[1], Oliver M. FitzGerald[2], Ursula Fearon[3] and Douglas J. Veale[3]. [1]St Vincent's University Hospital, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]Translation Rheumatology Research Group, Dublin, Ireland

Background: Rheumatoid Arthritis (RA) is associated with an increased cardiovascular (CV) mortality not fully explained by traditional cardiovascular risk factors. Insulin resistance (IR), which as a component of the metabolic syndrome is associated with central adiposity and cardiovascular disease, is also increased in RA. Adiponectin is an adipokine which is elevated and associated with radiographic progression in RA but which is suppressed in the metabolic syndrome. **Purpose.** To examine the associations of adiposity, disease activity and serum adiponectin levels with IR in RA.

Methods: Ninety-three RA patients were assessed at a single timepoint for CV risk factors, BMI and RA disease activity measures. Percentage Body fat and Android/Gynoid Fat ratio distribution was measured using Whole Body Dual X-Ray Absorptiometry. Fasting blood samples were taken for quantification of fasting lipoproteins, insulin and glucose. Paired sera were collected and stored at −80°C. Adiponectin was measured in serum by ELISA. IR was defined as Homeostasis Model Assessment (HOMA-IR)

measurement >1. Associations between IR with measures of obesity, adiponectin and disease activity were assessed. Spearman Rank Correlations and Mann Whitney U were used for univariate analysis. Statistical associations to HOMA-IR on univariate analysis were tested for independent associations by linear regression analysis using SPSS v11 software.

Results: IR was present in 84% patients (2.1 + 1.6 HOMA-IR, mean + SD). Obese patients (BMI > 30) when compared to patients with BMI 20–30 had higher levels of IR (3.4 + 2.2 vs 1.5 + 0.7 HOMA-IR, $P < 0.001$), CRP (12.0 + 15.9 v 6.0 + 10.9mg/dl, $P = 0.003$) and DAS28 (4.0 + 1.7 vs 3.2 + 1.3, $P = 0.06$) but lower levels of adiponectin (0.46 + 0.3 vs 0.73 + 0.5ng/ml, $P = 0.032$). IR was positively correlated with BMI ($r = 0.651$, $P < 0.001$), Android/Gynoid ratio ($r = 0.531$, $P < 0.001$), and percentage body fat ($r = 0.316$, $p = 0.04$) and negatively correlated with adiponectin ($r = -0.278$, $P < 0.04$). Using linear regression modelling controlling for age, gender, disease duration, RF status, pack year smoking history, and serum cholesterol, only BMI ($P = 0.012$) and SJC28 component of DAS28 ($P = 0.027$) were independently associated with IR.

Conclusion: Insulin Resistance (IR) is a highly prevalent and under-recognized cardiovascular risk factor associated both with increased disease activity and increased BMI in RA. Reduction of IR both through suppression of disease activity and weight loss may improve long-term cardiovascular outcomes in RA.

1177

Prevalence and Correlates of Metabolic Syndrome in Patients with Rheumatoid Arthritis. Maria Haye Salinas[1], Ana M. Bertoli[2], Francisco Caeiro[3], Luis Lema[4], Veronica Bellomio[5], Santiago Aguero[6], Federico Ceccato[7], Carla Saucedo[8], Javier Rosa[8], R. Quintana[9], Marcela Schmid[10], Walter Spindler[11], Natalia Tamborenea[12], Sergio Paira[7], Bernardo Pons Estel[13], Alberto J. Spindler[14], Enrique R. Soriano[8], Alejandro J. Alvarellos[15] and Veronica Saurit[16]. [1]Hospital Privado, Córdoba, Argentina, [2]Instituto Reumatológico Strusberg, Cordoba, Cordoba, Argentina, [3]Hospital Privado de Cordoba, Cordoba, Argentina, [4]Instituto Modelo de Cardiologia, Cordoba, Argentina, [5]Consultorio, Tucuman, Argentina, [6]Centro de Rehabilitación II, Catamarca, Argentina, [7]Hospital Jose Maria Cullen, Santa Fe, Argentina, [8]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [9]Hospital Provincial, Rosario, Argentina, [10]Hospital Cullen, Santa Fe, Argentina, [11]Centro Medico Privado, Tucuman, Argentina, [12]Consultorio, Buenos Aires, Argentina, [13]Sanatorio Parque, Rosario, Argentina, [14]Universidad Nacional Tucumán, Yerba Buena Tucuman, Argentina, [15]Hospital Privado, Cordoba, Argentina, [16]Hospital Privado Córdoba, Córdoba, Argentina

Background/Purpose: Patients with Rheumatoid Arthritis (RA) have increased morbidity and mortality due to cardiovascular (CV) disease. The screening of CV risk factors, metabolic syndrome (MS) among them, is therefore mandatory. The purpose of this study is to determine and compare the frequency of MS in patients with RA and a control group, and to assess the factors associated with MS.

Methods: This is a cross-sectional study involving 1033 (409 RA and 624 age and gender matched controls) patients, that were being followed at nine different medical institutions from Argentina. MS was defined according to the Adult Treatment Panel III (ATPIII) and International Diabetes Federation (IDF). The relationship between demographic variables (age, gender), clinical data (disease duration, disease activity as per the DAS28, presence of RF and/or ACCP antibody, presence of extra-articular manifestations), pharmacological treatment and MS was examined by descriptive statistics (the chi-square test for categorical variables and the Mann-Whitney test for continuous variables). Variables with $p \leq 0.10$ in these analyses were then examined by logistic regression.

Results: The frequency of MS in RA patients and the control group was 30% Vs 39%; $p = 0.002$ when defined with the ATPIII, and 35% vs 40%; $p = 0.1$ when defined with the IDF. When both definitions of MS were applied, patients with RA and MS tended to be older (60.6±10.9 age vs 54.3±13.7 age; $p<0.001$), to display higher values of erythrocyte sedimentation rate (22 mm/hr vs 18 mm/hr; $p=0.005$), to be positive for RF and/or ACCP antibody (92% vs 86%; $p=0.057$), to have extra-articular manifestations (35% vs 27%; $p=0.06$) and to use hydroxychoroquine (11% vs 18%; $p=0.03$). Other variables, such as gender, disease duration and activity and the use of methotrexate and biologic therapies did not differ between patients with and without MS. Variables independently associated with MS in RA patients were age (OR=1.03, 95%CI 1.01–1.06; $p=0.01$ for ATPIII- OR=1.03, 95%CI 1.01–1.05; $p<0.001$ for IDF), presence of RF and/or ACCP antibody (OR=2.91, 95%CI 1.11–7.61; $p=0.02$ for ATP III- OR=2.37, 95%CI 1.09–5.16; $p=0.02$ for IDF) and the use of hydroxychloroquine (OR=0.48, 95%CI 0.23–0.97; $p= 0.04$).

Conclusion: In this study, we were not able to demonstrate a higher frequency of MS in RA patients. However, among RA those older patients who also display features of a more severe disease such as a positive serology and extra- articular manifestations seem to be at a higher risk for the development of MS; while those on hydroxichloroquine seem to be at lower risk, probably reflecting the use of this drug in cases with a less severe disease.

1178

Rate of Progression of Subclinical Atherosclerosis in Femoral Versus Carotid Arteries in Patients with Rheumatoid Arthritis Over 3 Years. E. Zampeli[1], A. Protogerou[1], K. Stamatelopoulos[2], K. Fragiadaki[1], C. Katsiari[1], K. Kyrkou[2], C. Papamichael[2], M. Mavrikakis[2], G. D. Kitas[3] and P. P. Sfikakis[1]. [1]First Department of Propaedeutic and Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [2]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, Athens University Medical School, Athens, Greece, [3]The Dudley Group of Hospitals NHS Foundation Trust, Dudley, and Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) is associated with coronary artery disease (CAD). Subclinical femoral atherosclerosis has been suggested to be linked to the presence of CAD in the general population. We assessed prospectively subclinical atherosclerosis, as indicated by plaque presence and formation, in femoral and carotid arteries in RA patients to detect whether in these 2 arterial beds there are differences: (a) in the rate of atherosclerosis progression; (b) in the factors contributing to this.

Methods: Femoral and carotid plaques were identified by ultrasonography at baseline (2006–2007) and follow-up end (2009–2010), separated by an average of 3.6±0.2 years, in 64 non-diabetic RA patients without concomitant cardiovascular (CV) disease (53 women, aged 59.2±12 years; disease duration 7.8±6.2 years at baseline). Clinical evaluation and laboratory tests were performed every 3–6 months.

Results: At baseline, femoral plaques were significantly less frequent than carotid plaques (20.6% *vs* 46.9%, $p<0.001$). Sixteen patients (25%) developed at least one new femoral plaque and 19 (29.7%) at least one new carotid plaque during follow-up. Only 6 patients were common in these two subgroups (kappa test, $p=0.430$). Those having developed only carotid plaque(s) (n=13) were significantly older (70.6±6.7 years *vs* 61.8±4.6 years, $p=0.006$) than those who developed only femoral plaque(s) (n=10). No other significant differences were observed between the subgroups regarding classical CV risk factors and RA-related parameters. Binary logistic regression analysis revealed that of the classical CV risk factors only smoking associated independently with new femoral plaque formation, while for carotid atherosclerosis progression additionally age and duration of low-dose corticosteroid use were independent predictors. Disease related parameters (RA duration, stage, functional class, hs-CRP, ESR) did not predict either carotid or femoral plaque formation.

Conclusion: Despite baseline differences suggesting more advanced changes in the carotid rather than femoral arteries, the rate of new plaque formation in these two arterial beds was similar at follow-up, and predicted by different classical CV, but not RA-related risk factors.

1179

Rheumatoid Arthritis Patients Are Not At Increased Risk for 30-Day Cardiovascular Events or Infections Following Total Joint Arthoplasty. Kaleb Michaud[1], Edward Fehringer[2], Kevin Garvin[2], James R. O'Dell[3] and Ted R. Mikuls[3]. [1]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Although serious infection and cardiovascular disease are increased in patients with rheumatoid arthritis (RA), it is not known whether RA impacts the risk for these complications following total joint arthroplasty (TJA). We examined whether RA was associated with the occurrence of 30-day postoperative complications in a large population of patients undergoing TJA.

Methods: Analyses included data from the Veterans Affairs (VA) Surgical Quality Improvement Program (VASQIP) for fiscal years 1999–2006. ICD9 codes and medication dispensing data were obtained from the VA Pharmacy Benefits Management (PBM) database. RA was defined for those with a corresponding ICD9 (714.0) plus receipt of at least one DMARD

within 1 year before TJA. All other patients had an ICD9 (715.x) corresponding to osteoarthritis (OA). 30-day complications (major cardiovascular event, infection, and return to the operating room) were compared by diagnosis (RA vs. OA) using multivariate regression. Post-operative infections included systemic sepsis, pneumonia, urinary tract infection, superficial and deep wound surgical site infections. Cardiovascular events included cardiac arrest, myocardial infarction, stroke, pulmonary embolism, and deep vein thrombosis. All analyses were adjusted for age, sex, and clustering by site (n = 104 sites). Additional covariates included sociodemographics, comorbidities, health behaviors, and well defined operative risk factors (up to 44 covariates examined).

Results: There were 37,103 patients (n = 888 with RA) undergoing TJA, with total knee arthroplasty being most common (64%), followed by hip (33%), shoulder (2%), and elbow (0.2%). Patients were predominantly men (96%) with a mean (SD) age of 64 (11) years. Among RA patients, the most frequently used DMARDs included methotrexate (59%), hydroxychloroquine (40%) and sulfasalazine (23%) while 41% were taking glucocorticoids and 24% biologic DMARDs. The frequency of select complications based on diagnosis is summarized in the table below. Compared to OA patients, those with RA were significantly more likely to require a return to the operating room but had similar rates of postoperative infection and cardiovascular events.

Table. The frequency of select complications following TJA in patients with RA and OA

	RA (n = 888)	OA (n = 36,215)	RA OR (95% CI)
Infection	4.17%	4.12%	1.02 (0.72, 1.47)
Cardiovascular event	1.24%	1.98%	0.69 (0.37, 1.28)
Return to operating room	4.50%	3.01%	1.45 (1.08, 1.94)

Conclusion: RA patients are not at an increased risk for short-term infectious complications or cardiovascular events following TJA. RA patients did have an increased rate of return to the operating room. Reasons for this difference and strategies to address it require further study.

1180

High-Density Lipoprotein Subfractions HDL2 and HDL3 Are Reduced in Female Patients with Rheumatoid Arthritis and Do Not Appear to Be Affected by Disease Activity. Elke.E.A. Arts, Jaap Fransen, Heidi Lemmers, Leo A.B. Joosten, Piet L.C.M. Van Riel and Calin Popa. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: High-density lipoprotein cholesterol (HDL) is associated with anti-atherogenic properties. Higher levels of HDL subfractions HDL3 and particularly HDL2 protect for cardiovascular disease (CVD). Inflammation reduces HDL concentration and possibly impairs its anti-atherogenic effect. HDL composition and the impact of inflammation/disease activity on HDL subfractions in RA is still unknown. The objective of this study was to assess HDL2 and HDL3 concentrations in RA patients and their association with the level of disease activity.

Methods: Non-fasting blood samples were collected from 45 RA patients and 45 healthy controls, who did not suffer from inflammatory conditions (13 men and 32 women in both groups). None of the participants had a history of CVD or diabetes, or used lipid-lowering drugs. HDL2 and HDL3 concentrations were obtained by ultracentrifugation. Between-group comparisons were done using independent-sample t-tests, HDL2 concentration was compared between RA patients and healthy controls using analysis of covariance (ANCOVA) with exposure to RA (patients or controls) as independent variable, gender and age as covariates. The effect of disease activity on HDL2:HDL3 ratio was also analyzed in RA patients using ANCOVA, with age, gender, rheumatoid factor and disease duration as covariates.

Results: HDL2 and HDL3 were significantly lower in RA patients compared to healthy controls (p=0.01 and p=0.005, respectively). Mean±SD concentrations of HDL2 were 0.5±0.3 mmol/L in RA patients, compared to 0.7±0.4 mmol/L in the control group, a mean difference of 0.2 (95%CI 0.05–0.34). HDL3 levels were 0.8±0.2 mmol/L in the RA group and 0.9±0.2 mmol/L in the control group a mean difference of 0.1 (95%CI 0.04–0.19). The HDL2:HDL3 ratio was significantly lower in the patient group (0.5±0.3 mmol/L) compared to the control group (0.7±0.4 mmol/L) with a mean difference of 0.2 (95%CI 0.01–0.31) (p=0.04). Female gender was an effect modifier, HDL2 and HDL3 levels were primarily altered in women (fig.1). The HDL2:HDL3 ratio was only significantly different between groups in females, with a mean difference of 0.2 (95%CI 0.04–0.40, p=0.02) compared to a mean difference of 0.01 (95%CI −0.2–0.1, p=0.9) in males. HDL2 and HDL3 concentrations were similar for all categories of the DAS28 (low <3.2, medium 3.2–5.1, and high >5.1). Only after correcting for confounders; age and disease duration, was the effect of disease activity on HDL2 significant (p=0.04).

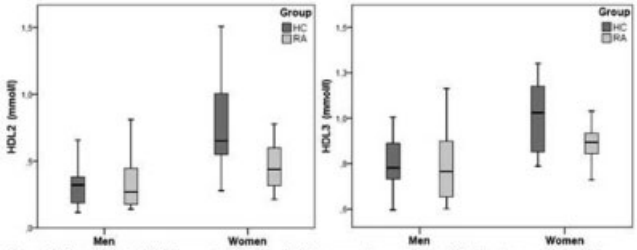

Figure 1. Mean HDL2 and HDL3 concentrations (mmol/L) for men and women in the RA patient group (RA) and the healthy control group (HC).

Conclusion: HDL2:HDL3 ratio is reduced in RA women, primarily due to lower HDL2 concentrations. This may contribute to accelerated atherosclerosis and CVD reported in RA. Height of disease activity does not appear to contribute to these modifications. Our results suggest that including HDL2:HDL3 ratio in CV risk assessment of RA patients may be of great importance. http://acr.confex.com/data/abstract/acr/2011/Paper_21969_abstract_16456_0.jpg

Association of Medicaons and Rheumatoid Arthritis Susceptibility Polymorphism with Lipid Profiles in Patients with Rheumatoid Arthritis. Lisa A. Davis[1], Lauren M. Pointer[2], Roger K. Wolff[3], Andreas M. Reimold[4], Gail S. Kerr[5], Ted R. Mikuls[6], Grant W. Cannon[7] and Liron Caplan[8]. [1]Univ of Colorado School of Med, Aurora, CO, [2]Denver Veterans Affairs Medical Center, Denver, CO, [3]University of Utah, Salt Lake City, UT, [4]Dallas VA and University of Texas Southwestern, Dallas, TX, [5]Washington DC VA and Georgetown University, Washington, DC, [6]Omaha VA and University of Nebraska, Omaha, NE, [7]Salt Lake City VA and University of Utah, Salt Lake City, UT, [8]Denver VA and University of Colorado, Aurora, CO

Background/Purpose: Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular disease (CVD), and though the mechanism is unknown, there are independent associations with RA-related factors (del Rincon I *Arth Rheum* 2005; Wolfe F, *Arth Rheum* 2008; Goodson *Arth Rheum* 2002). We examined whether single nucleotide polymorphisms (SNPs) linked with RA susceptibility and treatment are associated with low density lipoprotein (LDL) and triglyceride (TG) levels in subjects with RA.

Methods: Patients (n=1362) enrolled in the prospective Veterans Affairs RA (VARA) registry were genotyped for multiple SNPs with DNA samples derived from whole blood. Genes and associated SNPs included: REL (rs10203477, rs842647, rs13031237, rs9309331); DDAH2 (rs15574), interleukin-10 (rs3024493, rs1800872, rs1800896); methylenetetrahydrofolate reductase (rs1801131, rs1801133); tumor necrosis factor/ lymphotoxin A (rs3093662, rs1800629, rs3093668); and tumor necrosis factor receptor associated factor 1 (rs1014529, rs1014530). Covariates included: patient characteristics (age, ethnicity, gender, body mass index [BMI], diabetes, smoking status, education); RA severity markers (anti-CCP and rheumatoid factor status, C reactive protein level); lipid-lowering agent use (statin, fibrate, bile acid sequestrant); and lipid profile data. Multivariate linear regression was performed to determine factors associated with TG and LDLs. A p-value <0.01 was deemed significant in the final model.

Results: Factors associated with lower LDL level were age, diabetes, statin use, and the REL-related SNP (rs9309331), where the presence of CC conferred a 13 point lower LDL value compared to GG (see Table). The distribution of TG values required a lognormal transformation of the data, and results are interpretable as percentages relative to subjects without the described trait. For example, subjects using fibrates still demonstrated TG values 87% higher than subjects not taking fibrates, despite use of these agents. Factors associated with higher TG levels were Caucasian race, BMI, diabetes, smoking status, and fibrate use. There was an interaction term between diabetes and fibrate use that was associated with a decreased TG level.

Table. Predictors of LDL and TG levels in patients with rheumatoid arthritis

Variable		Parameter estimate	SE	Transformed percentage	p-value
Low density lipoprotein (LDL) model					
Age		−0.32	0.09	—	<0.001
Presence of diabetes		−7.25	2.42	—	0.003
rs9309331	*CC*	−12.92	4.89	—	0.008
	GC	−4.33	2.16	—	0.045
	GG	referent		—	—
Statin Use		−15.65	3.20	—	<.0001
Triglyceride (TG) model					
Caucasian		0.24	0.04	27.29%	<.0001
Body mass index		0.02	0.00	1.84%	<.0001
Presence of diabetes		0.17	0.04	18.04%	<.0001
Smoking status	*current*	0.15	0.05	16.59%	0.001
	former	0.08	0.04	8.87%	0.037
	never	referent			
Fibrate use		0.62	0.15	86.66%	<.0001
Diabetes fibrate interaction term*		−0.70	0.25	−49.50%	0.005

Conclusion: RA subjects on statins demonstrate lower LDL compared to RA subjects not receiving statins, but this was not found for fibrate use and TGs (unless the subject was also diabetic). A possible connection between rs9309331 and LDL levels should be further investigated.

1182

Urine Albumin Excretion Is Associated Differently with Cardiometabolic Risk Factors and Subclinical Atherosclerosis in Rheumatoid Arthritis (RA) Compared with Controls. Amanda Sammut[1], Joan M. Bathon[1], Roger Blumenthal[2], Moyses Szklo[3], Steven Shea[1], Joseph Polak[4], Russell Tracy[5] and Jon T. Giles[1]. [1]Columbia University Medical Center, New York, NY, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [4]Tufts University School of Medicine, Boston, MA, [5]University of Vermont, Colchester, VT

Background/Purpose: Albuminuria is a marker for subclinical cardiovascular disease (CVD) in the non-RA population. However, the associations of urine albumin excretion with measures of atherosclerosis have not been explored in RA, a population with increased atherosclerosis and CVD events.

Methods: Urine albumin excretion from a spot morning-collected urine sample was measured and the ratio of urine albumin to creatinine (UACR) calculated for men and women with RA and non-RA controls (frequency matched to the RA group on age, gender, and ethnicity) enrolled in a study of subclinical atherosclerosis, the Multi Ethnic Study of Atherosclerosis (MESA). Elevated UACR was defined as ≥ 25mg/g for women and ≥ 17mg/g for men. The associations of UACR with CVD risk factors [i.e. hypertension, diabetes, smoking, lipid parameters, insulin resistance assessed with the homeostatic model assessment (HOMA-IR)] and measures of atherosclerosis [coronary arterial calcification (CAC) quantified using 64-slice multidetector row computed tomography (MDCT) and maximal intima-medial thickness (IMT) of the common (CCA) and internal (ICA) carotid arteries, and presence of focal plaques in the ICA, assessed with bilateral B-mode ultrasonography] were compared cross-sectionally between the RA and control groups.

Results: A total of 196 RA patients [40% male, mean age 59±9 years, median RA duration 9 years, mean DAS28 3.7±1.1] were compared with 271 demographically matched non-RA controls. Median UACR did not differ between the RA and control groups (4.48 vs. 4.54 mg/g, respectively; p=0.40) and 21% in each group were found to have elevated UACR. In both the RA and control groups, higher age, waist circumference, hsCRP, IL-6, and the presence of diabetes, were associated with higher UACR. In contrast, hypertension and higher levels of HOMA-IR and homocysteine were significantly associated with higher UACR only in the control group (see Table). In both the RA and control groups, higher UACR levels were associated with a higher prevalence of any CAC (OR=1.25 per log unit increase in UACR, p=0.028). In contrast, UACR was associated with carotid measures only in the control group (see Table). Within both groups, adjustment for CVD risk factors reduced the magnitude and significance of the associations of UACR with CAC and carotid outcomes.

Table. Association of log UAC (log mg/g) with Cardiometabolic Risk Factors and Measures of Carotid Atherosclerosis, According to RA Status

Outcome	RA Group (n = 196) β	RA Group (n = 196) 95% CI	Controls (n = 271) β	Controls (n = 271) 95% CI	p-value for interaction by RA status
Hypertension*	1.37	(0.99, 1.90)	2.08	(1.52, 2.83)	0.040
log HOMA-IR**	−0.026	(−0.13, 0.075)	0.176	(0.096, 0.26)	0.002
log Homocysteine**	−0.011	(−0.055, 0.031)	0.039	(0.004, 0.073)	0.042
log CCA-IMT**	0.013	(−0.012, 0.039)	0.052	(0.025, 0.079)	0.025
log ICA-IMT**	0.016	(−0.043, 0.075)	0.098	(0.036, 0.16)	0.036
Carotid plaque (ICA/bulb)*	1.07	(0.75, 1.54)	1.65	(1.07, 2.55)	0.087

* β coefficients represent the average difference in the odds of the dichotomous outcome per each one unit higher log UACR (*modeled using ordinary logistic regression*)
** β coefficients represent the average difference in the continuous outcome per each one unit higher log UACR (*modeled using linear regression*)

Conclusion: Although the association of UACR with measures of subclinical coronary atherosclerosis was similar between RA and non-RA groups, we observed no association in the RA group of UACR with measures of carotid atherosclerosis, nor with several key cardiometabolic risk factors. This could suggest differing mechanisms linking urinary albumin excretion with cardiometabolic risk factors and atherosclerosis in RA compared to non-RA controls, and a lower utility for UACR as an indicator of subclinical CVD in RA.

1183

Atrial Fibrillation Is Not More Common in Patients with Rheumatoid Arthritis. A. Kirstin Bacani, Sherine E. Gabriel, Cynthia S. Crowson and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Patients with rheumatoid arthritis (RA) suffer from an excess burden of cardiovascular disease, but little is known about the incidence of arrhythmia in patients with RA. It has recently been suggested that the incidence of atrial fibrillation in increased in RA. The purpose of our study was to examine the incidence of atrial fibrillation among patients with RA and to compare the incidence to that in a non-RA cohort.

Methods: A population-based inception cohort of patients with RA who fulfilled 1987 ACR criteria for RA between 1/1/1980 and 12/31/2007 and a cohort of non-RA subjects from the same underlying population were assembled and followed until death, migration, or 12/31/2008. The occurrence of atrial fibrillation was ascertained from review of the medical record, defined as the first date of documented atrial fibrillation on electrocardiogram. Cumulative incidence of atrial fibrillation adjusted for the competing risk of death was estimated.

Results: The study included 813 RA patients (mean age [SD] 55.9 [15.7] years, 68% women). The average length of follow-up was 9.6 years [SD 6.9], and in 66% the rheumatoid factor was positive. There was no difference in the prevalence of atrial fibrillation among patients with RA diagnosed in 1995–2007 compared to non-RA subjects at RA incidence/index date (number, %) (n=20, 4% vs n=22, 5%), p=0.75, or in the incidence of atrial fibrillation during followup (n=47, 15% vs n=47, 12%), p=0.67; percentages are cumulative incidence at 10 years of follow-up. There was no change in the prevalence of atrial fibrillation among patients with RA diagnosed in 1980–1994 (n=13, 4%) compared to 1995–2007 (n=20, 4%) at RA incidence; p=0.68, or in the incidence of atrial fibrillation during followup (n=71, 13%) vs n=47, 15%), p=0.59. There was no statistically significant difference in development of atrial fibrillation in patients with RA and non-RA subjects without underlying coronary artery disease (p=0.83). Atrial fibrillation was associated with mortality equally in both patients with RA and non-RA subjects (interaction p=0.31).

Conclusion: The incidence and prevalence of atrial fibrillation are not increased in patients with RA diagnosed in 1995–2007 compared to non-RA subjects. The incidence and prevalence of atrial fibrillation in patients with RA has remained unchanged over the 30 year observation period. Arial fibrillation is not more strongly associated with mortality in patients with RA than in patients without RA.

1184

Hypothyroidism In Rheumatoid Arthritis and the Development of Cardiovascular Disease. Sara McCoy[1], Cynthia S. Crowson[2], Sherine E. Gabriel[2] and Eric L. Matteson[2]. [1]Mayo Clinic College of Medicine, Rochester, MN, [2]Mayo Clinic, Rochester, MN

Background/Purpose: To elucidate the association between rheumatoid arthritis (RA) and hypothyroidism in the development of cardiovascular disease.

Methods: A retrospective medical record review was performed using all incident cases of adult onset RA from a defined geographic population base that fulfilled criteria for RA in 1988–2007. A comparison cohort of patients without RA of similar age and sex was also examined. Cardiovascular disease (CVD) was defined as myocardial infarction, revascularization procedures, angina, or heart failure. Medical record and laboratory information regarding thyroid dysfunction were reviewed. The cumulative incidence of hypothyroid disease was estimated adjusting for the competing risk of death. Cox proportional hazards models were used to compare development of hypothyroid disease and CVD as well as associated risk factors.

Results: A cohort of 650 patients with RA and an age and sex matched comparison cohort of 650 patients without RA was assembled (both cohorts mean age 55.8; 69% female). There was no significant difference between cohorts in the presence of hypothyroid disease or subclinical hypothyroidism at time of RA diagnosis. Of patients with RA, 107 (16%) had hypothyroidism at RA incidence date. Of the cohort without RA, 88 (14%) of patients had hypothyroidism at the RA incidence/index date. No significant difference was found in the cumulative incidence of hypothyroid disease between the two cohorts. The cumulative incidence (%) of hypothyroidism among patients with RA was 7.7 ± 1.4 and in non-RA patients it was 6.7 ± 1.3 at 10 years after RA incidence/index date. Hypothyroid disease was found to be significantly associated with CVD in patients with RA (hazard ratio of 2; confidence interval 1.1,3.6). This difference remained significant after adjustment for traditional cardiovascular risk factors.

Conclusion: No significant difference was found in either incidence or prevalence of hypothyroidism between patients with or without RA. Hypothyroid disease was significantly associated with CVD in patients with RA, even after adjustment for cardiovascular risk factors.

The Burden of Autoimmunity and Risk for Coronary Artery Disease in Rheumatoid Arthritis. Katherine P. Liao[1], Fina Kurreeman[1], Raul N. Guzman P.[2], Jun Zhang[3], Tianxi Cai[3], Gang Li[1], Grant Duclos[1], Namrata Gupta[4], Sergey Goryachev[5], Vivian Gainer[2], Shawn N. Murphy[5], Susanne Churchill[5], Isaac Kohane[1], Elizabeth W. Karlson[6] and Robert M. Plenge[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Information Systems, Boston, MA, [3]Harvard School of Public Health, Boston, MA, [4]The Broad Institute, Cambridge, [5]Partners Healthcare Systems, Boston, MA, [6]Brigham and Womens Hospital, Boston, MA

Background/Purpose: RA patients are at a 2-fold risk of coronary artery disease (CAD) compared with the general population. Immune dysregulation is thought to contribute to this elevated risk of CAD, but the precise mechanisms are unknown. We hypothesized that the burden of autoimmunity, represented by the presence of autoantibodies, or autoimmune risk alleles are associated with increased risk of CAD in RA. We tested this hypothesis in RA and 2 diseases with pathognomonic autoantibodies and published genetic risk alleles, systemic lupus erythematosus (SLE) and celiac sprue. Both SLE and celiac also share genetic risk alleles with RA.

Methods: This study was conducted in a cohort of 1335 RA subjects identified from the electronic medical records of a large academic institution using our published algorithm. We identified RA subjects with prevalent CAD through medical record review. Subjects were identified with CAD if they had a CAD diagnosis by their treating physician and documentation of CAD after cardiac catheterization, stress test, EKG or if they underwent angioplasty, stent placement, or a coronary artery bypass graft.

We measured anti-nuclear antibodies (ANA), antibodies to tissue transglutaminase (tTG), and antibodies to cyclic citrullinated peptide (CCP) in all RA cases using commercial ELISA kits. We genotyped subjects for 34 SLE, 17 celiac, 29 RA validated risk alleles based on GWAS and meta-analyses, and 182 ancestry informative markers (AIMs). We conducted our analysis in European American (EU) subjects to minimize population stratification. We calculated a SLE, celiac, and RA count genetic risk score (GRS) by adding the number of disease specific risk alleles for each individual. We tested the association between ANA, tTG, CCP titers and CAD outcome using logistic regression in 3 separate models. The association between CAD outcome and disease-specific GRS was conducted using a student's t-test separately for SLE, celiac and RA.

Results: Among 1335 RA cases, 81% were female, 70% were CCP positive, 76% had bone erosions, and 8% (n=111) had CAD; 84% (n=1124) were EU by AIMs of which 9% (n=100) had CAD. In EU RA cases we observed an association between the celiac GRS and CAD outcome (p=0.03). There was a suggestive trend of higher tTG titers associated with increased risk of CAD (p=0.06). No association was observed between the SLE and RA GRS and CAD outcome. Similarly we found no association between ANA and CCP titers and CAD outcome in RA cases.

Conclusion: The unexplained risk for CAD in RA patients may be partially explained by the burden of autoimmunity, in particular genetic predisposition for celiac disease.

1186

Treatment to Lipid Targets in a Preventiv Cardio-Rheuma Clinic. Anne Grete Semb[1], Silvia Rollefstad[1], Terje R. Pedersen[2], Ingar Holme[2] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Oslo University Hospital-Ullevaal, Oslo, Norway

Background/Purpose: Even if cardiovascular prevention is established for the general population, only about 40% of individuals treated with lipid lowering (LL) agents reach recommended lipid targets.(1) Patients with inflammatory joint disease (IJD) have increased risk of cardiovascular (CV) disease. EULAR recommendations for CV primary prevention in patients with IJD (2) were published last year, but there is an unmet need of CV treatment results in this high risk patient population. Our objective was to perform cardiovascular risk stratification in patients with IJD and treat them with lipid lowering agents to lipid targets according to recommendations.(2)

Methods: Of the 239 patients with IJD referred to a preventive CV-rheumatologic clinique, 72 (30.1%) patients were not in the target group for treatment with statins (SCORE<5%). The rest, [167/239(69.9%)], were categorized to either primary or secondary LL preventive therapy with simvastatin, atorvastatin or rosuvastatin.

Results: At this reporting time, 55/167 (32.9%) of these patients are still under LL titration, whereas112 patients with rheumatoid arthritis (RA): n= 72, ankylosing spondylitis (AS): n= 27, and psoriatic arthritis (PsA): n=13) were treated to the nearest possible level of the lipid targets. Number of patient consultations needed to reach lipid goals vs. number of consultations used in patients still titrating LL treatment was (mean+SD) 2.96+1.19 vs. 1.19+0.59. There was no difference in age, blood pressure, smoking, inflammatory biomarkers (SR/CRP) and lipid levels between patients with RA/AS/PsA who reached lipid targets. A substantial number of the patients who were treated to lipid targets had known CVD (RA 43.1%, AS 25.9%, PsA 61.5%). In addition, asymptomatic carotid artery plaques were present in 42/72 (58.3%)/17/27 (63.0%)/ 6/13 (46.2%) among RA/AS/PsA respectively. Lipid changes in IJD patients from start to final consultation were significant; total cholesterol: 1.54 mmol/L (95%CI: 1.27, 1.80; p<0.0001), LDL: 1.32 (1.08, 1.56; p<0.0001), HDL: 0.07 (0.01, 0.14; p=0.02), TG: 0.34 (0.11, 0.57;p=0.004). The proportion of patients reaching at least 2 lipid goals was for RA/AS/PsA: 90.3/92.6/84.6% respectively. No serious adverse events were observed.

Conclusion: Patients with IJD referred to CV risk stratification have a high probability for the need of CV prevention. Treatment to lipid target goals was successful in almost 90% of patients with IJD. This experience supports the importance and relevance of establishing cardiovascular-rheumatologic prevention clinics.

Incidence and Time Trends of Herpes Zoster in Rheumatoid Arthritis: A Population Based Cohort Study. Bharath Manu Akkara Veetil, Eric L. Matteson, Sherine E. Gabriel and Cynthia S. Crowson. Mayo Clinic, Rochester, MN

Background/Purpose: To determine the risk factors, incidence, time trends and severity of herpes zoster (HZ) in a population based incidence cohort of patients with rheumatoid arthritis (RA) compared to a group of individuals without RA from the same population.

Methods: A population-based inception cohort of patients with RA who fulfilled 1987 American College of Rheumatology criteria for RA between 1/1/1980 and 12/31/2007 and a cohort of non-RA subjects from the same population base were assembled and followed until death, migration, or 12/31/2008. Incidence, risk factors and outcome data were collected by a retrospective chart review. The cumulative incidence of HZ adjusted for the competing risk of death was estimated. Cox proportional hazards models were used to compare the rate of development of HZ between patients with RA and the non-RA comparison cohort and to assess the association of risk factors on the development of HZ among patients with RA. Time-dependent covariates were used to model risk factors that developed over time.

Results: The study population consisted of 813 RA and 813 non-RA subjects. There was no difference in the presence of HZ prior to RA incidence/ index date between cohorts (p=0.85). Among patients who did not have HZ prior to incidence/index date, 84 RA patients and 46 non-RA subjects developed HZ during follow-up. The rate of development of HZ was 12.1 per 1000 person-years (95% CI: 9.6, 14.9) in RA patients and 5.6 per 1000 person-years (95% CI: 4.1, 7.5) in non-RA subjects. Thus, patients with RA were more likely to develop HZ during follow-up (hazard ratio [HR]: 2.3; 95% confidence interval [CI]: 1.6, 3.3). Patients diagnosed with RA in 1995–2007 had a higher likelihood of developing HZ than patients with RA diagnosed in 1980–1994 (HR: 1.9; 95% CI: 1.1, 3.2; p=0.013). Among patients with HZ, 13 (16%) patients with RA and 7 (15%) non-RA subjects were diagnosed with post-herpetic neuralgia (p=0.95). Hospitalization was required in 11 (13%) of RA patients and 1 (2%) of non-RA subject (p=0.055). Erosive disease, previous joint surgery, use of hydroxychloroquine and corticosteroids were significantly associated with the development of HZ in patients with RA. There was no significant association between the use of methotrexate or biologic response modifiers and the development of HZ.

Conclusion: The incidence of HZ is increased in RA and has risen in recent years. The increasing incidence of HZ in more recent years reflects the increase noted in the general population and does not appear to be associated with biologic use.

1188

Validation of An Infection Risk Score in Rheumatoid Arthritis. Cynthia S. Crowson, Deana D. Hoganson, Patrick Fitz-Gibbon and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased susceptibility for infections, which contributes to increased mortality. We previously developed a score to predict risk of serious infection in patients with RA in the pre-biologic era (1955–1994). The purpose of this study was to examine the performance of this infection risk score in patients more recently diagnosed with RA.

Methods: A population-based inception cohort of RA subjects who fulfilled 1987 ACR criteria for RA in 1995–2007 was assembled and followed through their complete medical records until death, migration, or 12/31/2008. The outcome measures included all serious infections (requiring hospitalization or IV antibiotics). Data were collected on use of biologic response modifiers and components of the risk score, which included age, sex, leukopenia, comorbidities (alcoholism, diabetes mellitus, chronic lung disease, cardiovascular disease), RA disease characteristics (extra-articular manifestations, rheumatoid factor, erythrocyte sedimentation rate) and glucocorticoid use. Calibration (i.e., ability to accurately predict the absolute risk level) of observed risk to predicted risk from our risk score was assessed using standardized incidence ratios (SIR; ratio of observed to predicted risk) and discrimination (i.e., accurately ranking risk from low to high) was assessed using the concordance (c-statistic).

Results: Among the 410 RA patients (mean age 55 years; 69% female; mean followup 5.6 years; 2,292 total person-years [py]), 79 had ≥1 serious infection (206 total serious infections). The rate of serious infections in these patients (9.0 per 100 py) was similar to the 1955–1994 time period (9.1 per 100 py). The infection risk score demonstrated very good discrimination for predicting serious infection in these patients (c-statistic=0.87). However, the predicted risk significantly underestimated the observed risk (SIR: 1.2; 95% confidence interval [CI]: 1.01, 1.3; p=0.037) indicating poor calibration. Biologics were used in 83 (20%) patients. The predicted risk of infections was higher among biologics users (p<0.001), but biologic use was not a significant predictor of serious infections (p=0.33 adjusted for the risk score). Among biologic users, the risk score showed good discrimination (c-statistic=0.91) and calibration (SIR: 1.02, 95% CI: 0.7, 1.4; p=0.90).

Conclusion: The risk score demonstrated good discrimination for serious infections among patients with RA. Re-calibration could improve accuracy of the risk predictions. Inclusion of biologic use in the risk score is unlikely to improve risk prediction. This risk score may alert clinicians to the potential occurrence of infection in their patients with RA.

1189

Risk for Herpes Zoster in Patients with Rheumatoid and Psoriatic Arthritis. Dimitrios A. Pappas[1], George Reed[2], Michele M. Hooper[3], Ying Shan[2], Bojena Bitman[4], Jeffrey D. Greenberg[5], Deborah Wenkert[3], Jie Zhang[6], Joel M. Kremer[7] and Jeffrey R. Curtis[6]. [1]Columbia University, College of Physicians & Surge, New York, NY, [2]UMass Medical School, Worcester, MA, [3]Amgen, Thousand Oaks, CA, [4]Amgen Inc., Thousand Oaks, CA, [5]New York University School of Medicine, New York, NY, [6]University of Alabama at Birmingham, Birmingham, AL, [7]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Opportunistic infections, including herpes zoster (HZ), occur more frequently in Rheumatoid Arthritis (RA) patients (pts) than in the general population. There is limited data on herpes zoster susceptibility in other inflammatory arthritides, such as psoriatic arthritis (PsA), despite an overlap in cellular and biochemical dysregulation underlying these diseases. It is also unclear, if the extent of immune dysfunction, as reflected by RA severity, also underlies the extent of vulnerability to opportunistic infections. We therefore investigated the incidence of HZ in PsA pts and, in RA pts, the disease severity, and other potential risk factors for HZ among pts participating in the Consortium of Rheumatology Researchers of North America (CORRONA) registry.

Methods: The CORRONA registry is a network of US private and academic rheumatology practices with data regarding ~ 25,000 RA and ~ 3500 PsA pts. We compared the incidence rate (IR) of physician-reported HZ in pts with RA and PsA. For RA pts, we investigated HZ risk vs. RA related factors (CDAI, mHAQ, RA duration, prednisone treatment), pt characteristics (age) and comorbidities including diabetes mellitus (DM), malignancy and cardiovascular disease (CVD). Baseline CDAIs were evaluated by category: remission (CDAI <=2.8), low (2.8–10) moderate (10–22), and high (CDAI >22). Analyses were adjusted for prevalent use of biologic and non-biologic DMARDs. Cox regression estimated hazardratios (HR) for incident HZ cases.

Results: 22,306 RA pts and 3,325 PsA pts had at least one follow up visit in the CORRONA registry and were included in the analysis. Age adjusted incidence rates (IR) of HZ were 6.8/1000 person-years (95% CI: 6.0–7.6) for pts with RA, and 5.3 (95% CI 3.8–6.8) for PsA, (crude IR were 8.1 and 5.3 respectively). In univariate models of RA pts, significant predictors of incident HZ were age (HR: 1.02, 95% CI 1.01–1.02), use of prednisone (HR: 1.28 95% CI 1.01–1.64), use of ≥2 prior biologics (HR: 1.43, 95% CI 1.02–2.01) and diabetes (HR: 1.54, 95% CI 1.03–2.30). In adjusted Cox models, each 5 year increase in age was associated with a HR of 1.11 (95% CI 1.06–1.17). Baseline CDAI categories yielded HR of: CDAI remission (HR=1), low (HR: 1.42, 95% CI 1.02–1.99) moderate (HR:1.17, 95% CI 0.80–1.70) and high (HR: 1.20, 95% CI 0.78–1.86). Prior use of > one biologic yielded a HR of 2.02 (95% CI:1.25, 3.26) for the development of HZ. Comorbidities and prednisone use were not significant in adjusted models.

Conclusion: HZ IR were high in both RA and PsA pts with a tendency towards higher IR in our RA study population. Among RA pts, HZ was associated with increasing age in our RA pts as is seen in the general population. A trend towards increased risk for pts with higher disease activity was observed. Greater use of prior biologics, perhaps reflecting more refractory disease, was also associated with increased risk. Ongoing analyses are evaluating drug-specific effects on the risk of developing HZ.

1190

Combining Tuberculin Skin Test and Interferon Gamma Release Assays for Latent Tuberculosis Infection Screening May Be Necessary for the Exclusion of Latent Tuberculosis in a High Risk Individuals with Rheumatoid Arthritis. Bella Mehta[1], Bret Sohn[2] and Petros V. Efthimiou[3]. [1]Lincoln Medical and Mental Health Center, New York, NY, [2]Lenox Hill Hospital,NY, New York, NY, [3]LM&MHC/Weill Cornell MC, New York, NY

Background/Purpose: Latent TB reactivation has emerged as a significant complication in patients with RA, especially with the increasing therapeutic use of biologic medications. RA patients were estimated to have a 4-fold increased risk for TB reactivation when compared to the general population. Current guidelines strongly recommend LTBI screening and treatment of positives with anti-tuberculous agents prior to biologics use. Interferon Gamma Release Assays (IGRAs) such as the Quantiferon-TB Gold test (QFT-G) have recently been introduced in clinical practice for LTBI screening. There is still limited evidence of their comparative efficacy in RA.

Methods: A retrospective, chart review, study was conducted in RA patients followed at the rheumatology outpatient clinic of an urban teaching hospital, serving an inner city, largely immigrant population. 116 RA patients who had both TST and QFT-G testing performed during their initial evaluation were included. QFT-G could be interpreted as positive, negative or indeterminate. All TST testing was performed and interpreted consistently by 2 qualified evaluators and defined as positive if >5mm induration was present. Patients were diagnosed with LTBI if TST and/or QFT-G were positive and were treated with 9 months of Isoniazid/B6 after active TB was ruled out by chest radiography. Additional LTBI screening tests, performed yearly, were recorded for a mean period of 2.54 (sd–1.35) years following the initial negative screen.

Results: Out of 116 patients studied, 88(77%) were classified as Hispanic, reflecting the community demographics served by the hospital.

Two patients had indeterminate QFT-G and negative TST and were excluded from our analysis. 45(39%) patients were diagnosed with LTBI with either a positive TST 37(32%) and/or QFT-G 21(18%). 13(11%) were positive and 69 (61%) were negative for both tests. The agreement between TST and QFT-G was 72 % (κappa =0.279, CI-95% 0.106–0.452, p=0.087). Disagreement between TST and QFT-G was 32(28%) which included both positive TST with negative QFT-G 24(21%) and negative TST with positive QFT-G 8(7%). In 69 patients with negative TST and QFT-G, 14 did not have subsequent TST and/or QFT-G. Of the remaining 55 patients, there were no TST conversions, whereas 3 patients experienced sero-conversions to QFT-G positive. None of the patients developed active TB, including one patient on TNF-inhibitor who converted to QTF-G positive.

Screening Test	TST (positive)	TST (negative)	Total
QFT-G(positive)	13	8	21
QFT-G(negative)	24	69	93
Total	37	77	114

Conclusion: There was low moderate agreement between TST and QFT-G in our high risk RA population. QFT-G identified 7% of patients that TST did not detect while TST identified 21% of patients that QFT- G didn't. In the absence of clearly defined gold standard and limitations associated with both tests, early screening with both tests and treatment of all identified cases, regardless of the test, may be an effective and safe approach with the aim to minimize the risk of LTBI reactivation.

1191

Cytomegalovirus (CMV) and Rheumatoid Arthritis (RA)—a Critical Role of CMV Specific T Cells? Kathrin Rothe[1], Dagmar Quandt[1], Matthias Pierer[2], Anett Schulz[1], Undine Meusch[1], Manuela Rossol[3], Roger Scholz[2], Christoph G. Baerwald[4] and Ulf Wagner[4]. [1]University of Leipzig, Leipzig, Germany, [2]Haertelstrasse 16–18, Leipzig, Germany, [3]Translationszentrum für Regenerative Medizin (TRM), University of Leipzig, Leipzig, Germany, [4]University Hospital, Leipzig, Germany

Background/Purpose: Herpes virus infections, such as cytomegalovirus infections are very common, affecting roughly about 50% of the European population. Initial CMV infections are typically asymptomatic but usually lead to a life-long virus persistence. Virus specific CD8 as well as CD4 memory T cell responses are found in infected persons with an extremely high frequency, described as the inflationary memory. In an inflammatory setting such as in rheumatoid arthritis, the changes in the overall reactivity of the T cell compartment maybe also affects the CMV reactivity and in turn this can contribute to the disease outcome.

Methods: We investigated whether a latent CMV infection is associated with the pathophysiology of RA patients. On the one hand retrospective analyses on clinical parameters were performed. In additiion, in vitro cell culture assays with PBMC derived from blood of CMV+ RA patients and CMV+ healthy donor (HD) were performed.

Results: First we were interested in the overall rate of CMV infections in RA patients as compared to healthy donor (HD). We found no difference in the number of CMV seropositive subjects in a retrospective analyses of 202 RA patients and 272 healthy donor (HD). Interestingly, more advanced joint destruction and increased surgical joint procedures could be detected in 102 CMV+ RA as compared to 78 CMV- RA patients by radiography.

CMV specific proliferation was analyzed on a single cell level with the use of a CFDA-SE proliferation assay. The results show a comparable level of proliferating CMV specific CD4 as well as CD8 T cells in CMV+ RA patients (mean CD4: 6.4%, mean CD8: 9.7%; n= 10) compared to CMV+ HD (mean: CD4 6.8%, mean CD8: 11.2%; n= 7). Additionally, activation markers like CD71 and CD25 correlated very well with the proliferative response of the T cells. In order to control the virus, IFNg production by T cells is very important. Using an IFNg secretion assay we found an increased frequency of CMV specific CD3+CD4+ IFNg producers with 2.1 % (n=4) in CMV+ RA patients as compared to 0.24% (n=6) IFNg producers among CD3+CD4+ T cells in CMV+ HD after CMV (pp65) peptide specific short time restimulation in vitro.

Conclusion: In conclusion, latent CMV infection amplifies joint damage in RA, in part due to an increased CMV specific effector function in the CD4+ T cell compartment.

1192

Outcome of Pulmonary NTM Disease in Patients with Underlying Rheumatic Disease:A Retrospective Observational Study. Jung Won Noh[1], Jiwon Hwang[1], Jaejoon Lee[1], Joong Kyong Ahn[2], Chan Hong Jeon[3], Jinseok Kim[4], Won-Jung Koh[1], Eun-Mi Koh[1] and Hoon-Suk Cha[1]. [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Soonchunhyang University College of Medicine, Bucheon, South Korea, [4]Jeju National University Hospital, Jeju, South Korea

Background/Purpose: The existing data suggest that the incidence and prevalence of pulmonary nontuberculous mycobacteria (NTM) infections are increasing. However, the effect of rheumatic disease itself and immunosuppressive therapy on the clinical significance and the outcome of NTM pulmonary disease are unknown. This study was undertaken to evaluate the clinical significance and the outcome of pulmonary NTM disease in patients with underlying rheumatic disease.

Methods: We performed a retrospective analysis using medical records at a single tertiary hospital from January 2002 to January 2011. The patients with pulmonary NTM disease with underlying rheumatic disease were identified. The demographic data, underlying rheumatic diseases, immunosuppressive regimen, isolated NTM organism, treatment regimen for NTM disease, and culture negative conversion rate of NTM were analyzed.

Results: A total of 24 patients with underlying rheumatic diseases who satisfied the criteria for pulmonary NTM disease as recommended by the American Thoracic Society were identified. Mean age was 60.9 ± 12.3 years and mean duration of follow up was 4.1 ± 3.2 years. The most common rheumatic disease was rheumatoid arthritis (58.3%), followed by systemic lupus erythematosus (8.3%), Sjogren's syndrome (8.3%), relapsing polychondritis (8.3%), ankylosing spondylitis (4.2%), mixed connective tissue disease (4.2%) and microscopic polyangiitis (4.2%). Immunosuppressive regimen included prednisolone (66.7%), methotrexate (33.3%), leflunomide (16.7%), cyclosporin (12.5%), azathioprine (8.3%), and TNF-α inhibitors (4.2%). The most commonly isolated NTM organism was mycobacterium avium complex (83.4%), followed by mycobacterium abscessus (12.5%) and mycobacterium fortuitum (4.2%). Seventeen patients (70.8%) required treatment for pulmonary NTM disease. Of these, 12 patients (70.6%) achieved culture negative conversion. The culture negative conversion rate in patients with rheumatic diseases was comparable to those without underlying rheumatic diseases from our institution. Furthermore, various immunosuppressive agents did not influence the rate of culture negative conversion. Dissemination or progression of pulmonary NTM disease was not observed.

Conclusion: Our study demonstrates that pulmonary NTM disease in patients with underlying rheumatic diseases may not have worse clinical consequences compared to those without. With proper treatment, the outcome of pulmonary NTM disease as assessed by culture negative conversion rate is comparable to those without rheumatic diseases despite the use of various immunosuppressive drugs.

Serodiagnosis of *Mycobacterium Avium*-Complex Pulmonary Disease with An Enzyme Immunoassay Kit That Detects Anti-Glycopeptidolipid Core Antigen IgA Antibodies In Patients with Rheumatoid Arthritis. Shogo Banno[1], Maiko Watanabe[2], Kanesige Sasaki[2], Taio Naniwa[2] and Yoshihito Hayami[2]. [1]Aichi Medical University, Aichi-prefecture, Japan, [2]Nagoya City University, Nagoya city, Japan

Background/Purpose: Rheumatoid arthritis (RA) has many pulmonary manifestations including bronchial abnormalities that can develop into *Mycobacterium avium*-complex (MAC)-pulmonary disease (PD). MAC-PD can be lethal in patients receiving tumor necrosis factor alpha-blockers despite the administration of antibiotics. Diagnosis of MAC-PD is often difficult because MAC is an environmental organism. In this study, we investigated the usefulness of the serodiagnosis of MAC-PD in RA patients by using an enzyme immunoassay (EIA) kit that detects anti-glycopeptidolipid (GPL) core antigen IgA antibodies.

Methods: Antibody levels were measured in 63 patients with RA; 14 with MAC-PD plus 3 cultured nontuberculous mycobacteria (NTM) other than MAC; and 16 with pulmonary abnormalities characterizing NTM but undetected in sputum culture; 30 control subjects.

Results: RA patients with MAC-PD showed significantly higher antibody levels than the controls ($p=0.02$). The cutoff point was set at 0.7 IU/l, making the sensitivity and specificity of the antibody in MAC-PD and control patients 43% and 100%, respectively.

Conclusion: The EIA kit is useful for the diagnosis of MAC-PD in RA patients because of its high specificity. This test is an easier and less invasive form of examination and could therefore replace bronchoscopy as the main diagnostic procedure for RA patients with MAC-PD.

1194

High Expression of Haptoglobin in the Peripheral Blood Mononuclear Cells From Methotrexate-Resistant Rheuamatoid Arthritis Patients. Wenfeng Tan, Fang Wang, Dunming Guo, Xiaoming Zhu, Yao Ke and Miaojia Zhang. the First Affiliated Hospital of Nanjing Medical University, Nanjing, CHINA., Nanjing, China

Background/Purpose: Starting with methotrexate (MTX) monotherapy is cost-effective in early Rheuamatoid arthritis (RA) patients. However, only 30–40% of the patients will experience a good response to MTX alone. Thus, it is important to identify the biomarker to predict MTX therapy response. Here, we investigate the gene expression profiles in peripheral blood mononuclear cell (PBMC) from methotrexate-resistant Rheuamatoid arthritis patients.

Methods: Baseline active RA patients treatment with MTX alone and RA disease activity was evaluated every 4 weeks until week 12 using a joint disease activity score (DAS28). Remission and treatment response were categorised using European League Against Rheumatism (EULAR) definitions. Gene expression profiles in PBMC from 10 MTX-resistant RA (MRR) and 5 MTX good-response (MGR) RA were analyzed by IIIumina microarray. Targeted gene mRNA expression levels in PBMC from 30 MRR, 20 MGR RA patients and 30 healthy controls (HC) were further analyzed using Real-time PCR.

Results: Multiple genes were up-regulated in PBMC from MRR RA patients compared to those in MGR patients. Differentially expressed genes involved in several overlapping pathways including immune responses (19%), signaling pathways (27%), transcription/translation regulators (26%), and metabolic functions (15%). Among those, Haptoglobin expression signal was 5.1 fold increased in MRR RA patients compared to those in MGR patients. Real-time PCR further indicated that Haptoglobin mRNA was higher in PBMC from MRR RA patients than those in MGR RA and HC. When stratifying RA patients into remission, low, moderate and high disease activity subgroup based on DAS28 score, the high disease activity subgroup displayed higher levels o Haptoglobin levels than those in the remission, low or moderate disease active subgroup as well as HC ($p<0.05$, respectively).

Conclusion: High expression of Haptoglobin in PBMC might predict MTX therapy response and could provide a new pathway invovled in RA pathogensies.

1195

Histological Analyses of Surgically Resected Synovial Tissues In Patients with Rheumatoid Arthritis Treated with/without Biological Agents. Yuichi Mochida[1], Katsushi Ishii[1], Kengo Harigane[1], Naoto Mitsugi[1] and Tomoyuki Saito[2]. [1]Yokohama City University Medical Center, Yokohama, Japan, [2]Yokohama City University School of Medicine, Yokohama, Japan

Background/Purpose: Recent treatment of rheumatoid arthritis (RA) was dramatically improved after introducing biological agents. Although there are several reports with small numbers of cases that analyzed the effect of biological agents from the view point of histopathology, the significance of biological agents on histological changes of joint synovium is remained uncertain. The purpose of this study was to compare the histopathological findings of surgically resected synovium in patients with RA between 2 groups with and without use of the biological agents.

Methods: Between January 2006 and December 2010, 59 biopsy specimens of synovium were obtained during joint surgery from 52 cases of RA. The obtained specimens were fixed in 10% neutral buffered formalin and routinely embedded in paraffin. Microscope slides were prepared, stained with hematoxylin and eosin, and reviewed. The histopathological findings of synovium in each specimen were evaluated and scored for detailed findings such as synoviocyte hyperplasia, fibrosis, proliferating blood vessels, perivascular infiltrates of lymphocytes, focal aggregates of lymphocytes, and diffuse infiltrates of lymphocytes using the histological score of the synovium by Rooney et al. The cases were divided into 2 groups. The group with the use of biological agents (Group A) included 25 cases with 32 joint specimens (24 female and 1 male). Seven cases underwent another joint surgery in different surgeries. In Group A, 10 cases (12 joints) used etanercept, 10 cases (12 joints) used infliximab, 3 cases (5 joints) used tocilizumab, and 2 cases (3 joints) used adalimumab at the time of surgery. The variations of surgery were total knee arthroplasty (TKA) in 17 cases, total hip arthroplasty (THA) in 4 cases, total elbow arthroplasty (TEA) in 4 cases, and others in 7 cases. The group without use of biological agents (Group B) included 7 cases with 27 joint specimens (25 female and 2 male). These cases underwent surgery during same study period as Group A. In Group B, the variations of surgery were TKA in 16 cases, THA in 2 cases, TEA in 3 cases, and others in 6 cases. The background data such as age, averaged duration of disease, CRP, DAS-28 score, and mean dose of methotrexate (MTX) and prednisolone (PSL) were not different between 2 groups.

Results: Group A showed significantly decreased scores in synovial hyperplasia, perivascular infiltrates of lymphocytes, focal aggregates of lymphocytes, diffuse infiltrates of lymphocytes and also total score than in the Group B. The scores of fibrosis and proliferating blood vessels did not show difference between 2 groups. No correlation between total Rooney's score and age, Larsen's classification, Steinblocker's classification, or the mean dose of MTX or PSL was found in each group. In Group A, no difference of total Rooney's score was found by variety of biologics, additionally, there was no correlation between total Rooney's score and the duration of disease or the duration of administration of biologics. In Group B, there was positive correlation between total Rooney's score and the duration of disease.

Conclusion: Based on these results, biological agents for RA clearly showed significant effects on histological findings of joint synovium.

1196

Induced Abortions in Women with Rheumatoid Arthritis on Methotrexate. Evelyne Vinet[1], Christian A. Pineau[2], Bindee Kuriya[3], Ann E. Clarke[1], Robert Platt[4] and Sasha Bernatsky[5]. [1]McGill University Health Centre, Montreal, QC, [2]McGill Univ Health Center, Montreal, QC, [3]University of Toronto, Toronto, ON, [4]McGill University, Montreal, QC, [5]McGill UHC/RVH, Montreal, QC

Background/Purpose: Statistics from North America and the United Kingdom suggest that up to half of pregnancies are unplanned; almost half of unintended pregnancies are terminated. In women with RA with unplanned pregnancies, those exposed to teratogenic drugs, such as methotrexate (MTX), may be more likely to undergo an induced abortion. Since there are few data examining these issues, we aimed to determine the rate of induced abortion in women with RA exposed to MTX compared to women with RA unexposed to this medication.

Methods: We performed a nested case-control study using Quebec's physician billing and hospitalizations databases (from 01/01/2000 to 31/12/2008), which cover all healthcare beneficiaries (~7.5 million). All women with RA, aged between 15–45 years, were identified based on ≥1 hospitalization with either a primary or secondary diagnosis of RA, or ≥2 physicians' claims for RA within any 2-year period (provided they were at least 8 weeks apart). Women who had an intra-uterine device, any procedures leading to sterilization, and/or any conditions causing infertility were excluded. Cases were defined as women having an induced abortion, based either on one procedure code and/or diagnostic code for induced abortion. Each case was matched to ≥1 controls for age, calendar time, and cohort entry. Exposure was defined as having filled at least one prescription of MTX in the 16 weeks prior to the index date. We performed a multivariate conditional logistic regression, including other potential predictors of induced abortion (i.e. exposure to anti-tumor necrosis factor (anti-TNF) agents in the previous 16 weeks, prednisone use, disease severity as indicated by extra-articular manifestations, and disease duration).

Results: We identified 112 cases of induced abortion in women with RA and 5855 corresponding RA controls. Exposure to MTX occurred in 10.7% of cases and in 21.7% of controls. Women exposed to MTX had a lower rate of induced abortion compared to unexposed women (adjusted rate ratio (RR) 0.47; 95% CI 0.25, 0.89). In multivariate analysis, there was a trend for an increased rate of induced abortions among women exposed to anti-TNF agents (RR 2.07; 95% CI 0.81, 5.27) and those with extra-articular manifestations (RR 2.17; 0.51; 9.35). We did not establish an independent effect of prednisone use (RR 0.78; 95% CI 0.41, 1.49) and disease duration on induced abortions.

Conclusion: Our findings suggest that women with RA exposed to MTX may be less likely to have an induced abortion compared to unexposed women. There are many potential reasons for this, such as more careful pregnancy counseling in these women, or possibly less sexual activity.

However, women with severe disease (i.e. on anti-TNF agents and/or with extra-articular manifestations) are potentially at increased risk for induced abortion, presumably for unplanned pregnancies. These results should prompt further research on contraceptive counseling and practices in women with RA.

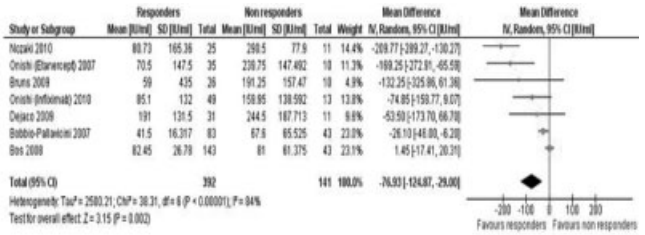
1197

Influence of Baseline Rheumatoid Factor on the Response to Tumor Necrosis Factor Antagonists of Rheumatoid Arthritis Patients: A Systematic Review and Meta-Analysis. Eva Salgado, Jose Ramon Maneiro, Loreto Carmona and Juan J. Gomez-Reino. Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain

Background/Purpose: To explore whether baseline titer or positivity of rheumatoid factor (RF) are predictors of the response of rheumatoid arthritis (RA) patients to tumor necrosis factor (TNF) antagonists.

Methods: A systematic review and meta-analysis using combined synonyms of the terms "rheumatoid arthritis", "Tumor Necrosis Factor-alpha/antagonists or inhibitors", "rheumatoid factor", and "response" (as MeSH terms and free-text)were conducted. Medline, Embase, Cochrane, and abstracts from the ACR and EULAR meetings were searched (up to June 2011). The search was limited to longitudinal observational studies in humans written in English, French, Spanish, Portuguese or Italian. Two independent reviewers did the selection by titer and abstract. All studies on association between baseline RF (titer and/or status) and response to any TNF antagonists, or with enough data to estimate this association were included.. Risk of bias was assessed using an adaptation of Quality Assessment for Prognostic Studies checklist. Qualitative data analysis by outcome and test was performed Meta-analysis with random effects models was run if sufficient homogeneity was present.

Results: The search produced 4163 hits. After selection by title and abstract, 18 articles were included for detailed analysis. Sixty-six associations between some measure of response and RF were tested: 44 on IgM RF (28 on RF titer, 16 on positivity), 10 on IgG RF (7 on titer, 3 on positivity) and 12 on IgA RF (8 on titer, 4 on positivity). Differences in time and method to assess response made some comparisons difficult. The majority of studies were of moderate to high quality. Six comparable studies with small sample sizes reported mean differences in baseline FR IgM titer between responders (EULAR good or moderate response) and non-responders at 14–48 weeks (see figure). Baseline RF IgM tends to be higher in the non-responder group (mean difference (responders- non responders) −76.93 [95%CI −124.87, −29.00]). Heterogeneity was very high (I^2=84%) in the studies showing this association. Comparison of other measures of outcomes in association with IgG RF and IgA RF tests showed contradictory results.



Conclusion: Studies that analyze the association between RF and response to treatment in RA are heterogeneous and show conflicting results. A positive association of IgM RF and response to treatment with TNF antagonists is hampered by the high heterogeneity of the studies.

1198

Factors Affecting Glucocorticoid Use in Early Rheumatoid Arthritis. Results from an Early Arthritis Cohort. Pooneh S.Akhavan[1], Glen S. Hazlewood[1], Ye Sun[2], Edward C. Keystone[3], Gilles Boire[4], Janet E. Pope[5], Carol A. Hitchon[6], Boulos Haraoui[7], Diane S. Ferland[8], V. Bykerk[9] and CATCH Investigators[10]. [1]University of Toronto, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]Rebecca MacDonald Centre for Arthritis and Autoimmune Disease, Mount Sinai Hospital, Toronto, ON, [4]CHUS - Sherbrooke University, Sherbrooke, QC, [5]St. Joseph's Health Care, University of Western Ontario, London, ON, [6]University of Manitoba, Winnipeg, MB, [7]Institut de Rhumatologie, Montreal, QC, [8]LaSalle, QC, [9]Brigham & Women's Hospital, Boston, MA, [10]Toronto, ON

Background/Purpose: Recent guidelines recommend early, short-term use of Glucocorticoids (GC) in patients with recently diagnosed active RA. Concerns over side effects, however have limited the use of these therapeutic agents. The pattern of GC therapy in real world setting may vary based on patients' clinical status, availability of other therapeutic agents, physician and patient preference. The objective was to determine the prevalence of GC use in patients with early RA and to identify the effect of baseline characteristics of patients and treatment center on GC use.

Methods: Patients with early RA were studied in the Canadian Early Arthritis Cohort (CATCH), a prospective cohort where data was collected according to a standardized protocol from 19 participating centers. For the present analysis we included any patient who had at least 3 months follow up. The primary outcome was any form of systemic GC (oral or parenteral) use during the first 3 months. Disease activity, using DAS28, was assessed at baseline and then every 3 months in each group. Univariate analysis compared baseline characteristics in two groups and a multivariable logistic regression analysis was used to model the use of GCs.

Results: 455 patients were included in the analysis who had at least 3 month follow up and were not treated prior to enrolment. 74% were women with a mean age of 52 (SD)(15) years, DAS28 5.5(1.4) and disease duration of 183(270) days. Rheumatoid factor (RF) was positive in 61%. 92 patients (20%) had received systemic GC (PO or IM) during the first 3 months. In univariate analysis two groups were not significantly different in their baseline DAS28 or HAQ. Steroid users were older (p=0.00018), had higher ESR (p=0.0006), CRP (p=0.0003) and erosion (p=0.045) but lower rheumatoid factor +ve (p=0.004). Multivariate regression analysis showed that patients' higher age and treatment center were associated with steroid use.

Conclusion: Despite recent guidelines recommending short-term use of GCs as part of initial management in patients with active recently diagnosed RA, most of these patients did not receive GC in this real word clinical setting. GC use was strongly influenced by the treating center. Younger patients were less likely to receive GC.The heterogeneity in practice patterns may represent a potential role for clinical practice guidelines to inform treatment decision making.

1199

No Evidence of Increased Mortality in Rheumatoid Arthritis Patients Treated with Biologics: Results From a Multicenter Cohort in Japan. Ayako Nakajima[1], Toshihisa Kojima[2], Wataru Fukuda[3], Taku Yoshio[4], Eisuke Inoue[1], Koichi Amano[5], Seiji Minota[4], Kazuyoshi Saito[6], Shigeki Momohara[1], Naoki Ishiguro[2], Yoshiya Tanaka[7], Tsutomu Takeuchi[8] and Hisashi Yamanaka[1]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Nagoya University, Nagoya, Japan, [3]Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan, [4]Jichi Medical University, Tochigi, Japan, [5]Saitama Medical University, Saitama Medical Center, Saitama, Japan, [6]University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan, [7]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [8]Keio University School of Medicine, Tokyo, Japan

Background/Purpose: To investigate the association between treatment with biologics and mortality in patients with rheumatoid arthritis in a multicenter cohort in Japan.

Methods: All patients with rheumatoid arthritis (RA) who received at least one dose of any biologic agent targeting tumor necrosis factor (TNF), interleukin 6 (IL-6) or others at six large rheumatology institutes in Japan (Biologics cohort) were included and monitored until May 15, 2010 or death, whichever occurred first. Death information about the date and cause was received from affiliated hospitals. Active monitoring by phone or mail was conducted for patients who stopped clinic visits. Mortality of the Biologics cohort was compared to the general Japanese population and to a practical RA cohort (the IORRA cohort), using standardized mortality ratio (SMR) determination. To evaluate the effect of lost to follow-up, sensitivity analyses were conducted. Factors associated with mortality were assessed by Cox model, in which age, sex, disease duration, DAS28, and doses of methotrexate (MTX) and corticosteroids were evaluated.

Results: Overall, 2,697 patients with RA were registered into the Biologics cohort; the median [IQD] age was 58.0 [47.2–66.1] years, 84.0% were women, and the median disease duration was 6.9 [2.3–14.8] years. Baseline disease activity indicated by dis DAS28 was 5.6 [4.8–6.4] and disability indicated by Japanese version of Health Association Questionnaire (J-HAQ) was 1.00 [0.50–1.75]. Biologics included infliximab (n=1,112), etanercept (n=1,053), adalimumab (n=345), and tocilizumab (n=173).

MTX and corticosteroids were prescribed in 77.7% and 54.2% of patients, respectively. Thirty-eight deaths were recorded among 6,940.9 patient-years of follow-up in the Biologics cohort, and 540 patients (20.0%) were lost to follow-up. With weighting for patients lost to follow-up, the weighted SMR in this Biologics cohort was 1.08 (95% confidence interval [95%CI], 0.77–1.47) compared to the Japanese general population, and 0.93 (95%CI, 0.66–1.28) compared to the practical RA cohort. The main cause of death was respiratory diseases, including pneumonia and interstitial lung diseases (Table). Risk factors for mortality included male gender (hazard ratio [HR], 3.01 [95%CI, 1.24–6.25]), older age (HR, 1.07 [95%CI, 1.03–1.11]), and corticosteroid dose (HR, 1.08 [95%CI, 1.01–1.17]).

Table. Underlying causes of death classified according to WHO International Classification of Disease (ICD)-10 chapter number

Chapter	Blocks	Chapter title	Deaths n = 38 (%)
I	A00-B99	Certain infections and parasitic diseases	6 (15.8)
II	C00-D48	Neoplasm	5 (13.2)
IV	E00-E90	Endocrine, nutritional and metabolic diseases	1 (2.6)
IX	I00-I99	Diseases of circulatory system	5 (13.2)
	I20-I25	Ischemic heart diseases	1
	I60-I69	Cerebrovascular diseases	3
X	J00-J99	Disease of respiratory system	18 (47.4)
	J10-J18	Influenza and pneumonia	7
XVIII	R00-R99	Symptoms, signs and abnormal clinical and laboratory findings, not elsewhere classified	3 (7.9)

Conclusion: Biologics treatment in RA patients was not associated with increased mortality in a multicenter registry in Japan.

Generalizability of Patients with Rheumatoid Arthritis in Biologic Clinical Trials. Priyanka Vashisht[1], Harlan Sayles[2], Grant W. Cannon[3], Gail S. Kerr[4], Pascale Schwab[5], Deana M. Lazaro[6], Andreas M. Reimold[7], Nasim A. Khan[8], Bogdan Cherascu[9], Angelo L. Gaffo[10], Dannette S. Johnson[11], Ted R. Mikuls[12] and Kaleb Michaud[13]. [1]Creighton University Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Salt Lake City VA and University of Utah, Salt Lake City, UT, [4]Washington DC VA and Georgetown University, Washington, DC, [5]Portland VA and Oregon Health & Science University, Portland, OR, [6]Brooklyn VA, Brooklyn, NY, [7]Dallas VA and University of Texas Southwestern, Dallas, TX, [8]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [9]Iowa City VA and University of Iowa, Iowa City, IA, [10]Birmingham VA Medical Ctr, Birmingham, AL, [11]Jackson VA and University of Mississippi Medical Center, Jackson, MS, [12]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [13]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Biologic response modifiers for the treatment of rheumatoid arthritis (RA) are efficacious and cost effective as determined by randomized clinical trials (RCTs), yet observational studies rarely show similar efficacy. RCTs have many criteria for participation which may limit the generalizability of their results. Our objective is to identify the proportion of clinical RA patients who would meet entry criteria for all RCTs of biological agents.

Methods: A nation-wide clinical cohort of 1522 patients in the Veterans Affairs RA registry who had met the 1987 ACR criteria for RA was evaluated at a random clinic visit. We reviewed 24 primary phase-III clinical trials for the 9 FDA-approved biologic treatments for RA and recorded all trial inclusion and exclusion criteria. Each participating patient was assessed for overall trial inclusion as well as four domains of inclusion: demographics, disease activity, medication exposure and comorbidities. For items not measured in the clinic as well as for all "wash-out" periods, we assumed a conservative 100% inclusion.

Results: Based on the review of criteria for 9 biologics in 24 RCTs, the mean percentage of patients meeting inclusion was 10.4 (SD 8.7). The domain most responsible for exclusion was disease activity, specifically joint count criteria which excluded patients on average 65.1% for tender and 63.2% for swollen joint counts. In comparison, biomarker criteria were much less restrictive as ESR excluded 22.2% and CRP excluded 5.5% patients. Disease duration was the most important factor of the demographic domain excluding 17.7% of patients. Previous treatment with methotrexate excluded about 52% patients for 6 trials and prior treatment with tumor necrosis factor inhibitor (TNFi) excluded 27% for 8 trials. Previous cancer history led to exclusion of about 35% patients for 3 trials. Comparing the non-TNFi and TNFi biologic agents, the RCTs for non-TNFi biologics were more restrictive than RCTs for TNFi (6.9% vs. 11.8% inclusion, $p=0.07$). There was no statistical trend in inclusion in RCTs by date published or date the drug was approved.

Conclusion: On average, 90% of our RA study patients did not meet criteria for inclusion for a given biologic RCT. Most trials require the patient to have moderate to severe disease activity, levels often associated with flares. While RCTs have shown these therapies to have high efficacy, it is possible that similar results are not seen in observational studies as those patients who are RCT eligible represent a small portion of those seen in the clinic.

Predictors, Features and Effects of First Biologic Switch in Rheumatoid Arthritis within GISEA register: Italian 10-Year Experience. Bernd Raffeiner[1], Costantino Botsios[1], Paolo Sfriso[1], Antonio Carletto[2], Domenico Biasi[2], Elisa Gremese[3], Gianfranco Ferraccioli[4], Clodoveo Ferri[5], Mauro Galeazzi[6], Roberto Gerli[7], Paola Cipriani[8], Roberto Giacomelli[8], Tamara Ziglioli[9], Roberto Gorla[9], Marcello Govoni[10], Antonio Marchesoni[11], Fausto Salaffi[12], Walter Grassi[13], Fabiola Atzeni[14], Piercarlo Sarzi-Puttini[15], AnnaRita Giardina[16], Giovanni Triolo[16], Florenzo Iannone[17], Giovanni Lapadula[17] and Leonardo Punzi[1]. [1]Rheumatology Unit, University of Padova, Padova, Italy, [2]Rheumatology Unit, University of Verona, Verona, Italy, [3]Rheumatology Unit, Catholic University, Roma, Italy, [4]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [5]Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy, [6]Rheumatology Unit, University of Siena, Siena, Italy, [7]Rheumatology Unit, University of Perugia, Perugia, Italy, [8]Rheumatology Unit, University of Aquila, L'Aquila, Italy, [9]Rheumatology Unit, University of Brescia, Brescia, Italy, [10]Rheumatology Unit, University of Ferrara, Ferrara, Italy, [11]Rheumatology Unit, Ospedale G Pini, Milano, Italy, [12]Rheumatology Unit, Polytechnic University of the Marche, Jesi, Italy, [13]Università Politecnica delle Marche, Jesi, Italy, [14]Rheumatology Unit, L Sacco University Hospital, MiIano, Italy, [15]Rheumatology Unit, L Sacco University Hospital, Milano, Italy, [16]Rheumatology Unit, University of Palermo, Palermo, Italy, [17]Rheumatology Unit, University of Bari, Bari, Italy

Background/Purpose: To identify predictors for first switch of biologic agents in real-life treatment of moderate to severe rheumatoid arthritis (RA) in Italy. To illustrate switch strategies adopted and to analyze results obtained this way.

Methods: Retrospective observational study was performed on RA patients who started biologic agents from 1999 to 2010 because of unresponsive moderate to severe RA within *GISEA* ("Gruppo italiano per lo studio dell'early arthritis") register including 14 tertiary rheumatology centers of Italy. Baseline parameters of patients maintaining and patients discontinuing first biologic agent were compared, and stepwise logistic regression model was calculated to find baseline parameters predictive for first switch. Switch strategies between biologics, time to and reason of first switch were analyzed. Efficacy of first switch was determined by EULAR response achieved at 6 and 12 months, and by rate of failure occurring with second line biologic divided for type of agent used and reason of switch. For statistical analysis the Kruskal-Wallis and chi-squared test were used as appropriate. $P < 0.05$ was considered statistically significant.

Results: 3,702 RA patients starting biologic treatment were included. Patients continuing first biologic had better EULAR responses at 6 and 12 months after starting biologic agent than those switching later on. Predictors for first switch were disease activity, glucocorticoids, lower age and disease duration, whereas concomitant DMARDS and the use of adalimumab and etanercept instead of infliximab resulted protective. Switching to second TNFα blocker was the strategy most applied, and showed greatest EULAR responses at 6 and 12 months. Etanercept performed better for response and failure rate than adalimumab and infliximab. As second line agents biologics with novel mechanisms of action presented lowest discontinuation rates, but were not significantly different from anakinra and etanercept. Switch because of inefficacy resulted in worse response and higher probability to fail again due to inefficacy.

Conclusion: Behavior in managing biologics is changing because more agents are available including those working on alternative pathways. Nevertheless, TNFα blockers confirmed their efficacy in first and second line, but possible superiority of new agents in long-term disease control has to be considered in further studies.

Sleep Disturbances and IL-6 Receptor Inhibition in Rheumatoid Arthritis. K. Fragiadaki[1], MG Tektonidou[1], M. Konsta[1], GP Chrousos[2] and PP Sfikakis[1]. [1]Laikon Hospital, Athens University Medical School, Athens, Greece, [2]First Department of Pediatrics, Athens University Medical School, Athens, Greece

Background/Purpose: Sleep quality has been recognized as a central component of health-related quality of life in patients with rheumatoid arthritis (RA) and sleep disturbances have been correlated with disease activity, pain and psychological distress. Indirect support for a possible link with the abundance of proinflammatory cytokines stems from sleep quality studies reporting an association between sleep problems and increased concentrations of TNF and IL-6 in healthy subjects. In this pilot 6-month study we examined whether administration of the IL-6 receptor antagonist tocilizumab affects sleep disturbances in RA.

Methods: Patients with documented sleep disturbances at baseline received monthly infusions of tocilizumab (8 mg/kg) for moderately or severely active RA. Sleep quality, by Pittsburgh Sleep Quality Index (PSQI) and daytime sleepiness, by Epworth Sleepiness Scale were evaluated at baseline, first, second, third and sixth month of treatment in 15 patients (13 women). RA disease activity, by DAS28 (ESR), functional status and disability, by Health Assessement Questionaire (HAQDi) and fatigue, by FACIT-Fatigue Scale (FFS) were evaluated in parallel. Medications used before enrollment, remained unchanged during follow-up.

Results: Sleep quality improved and daytime sleepiness decreased significantly at first-month assessment comparing to baseline, and these changes became more evident through 6 months ($p<0.00001$ and $p<0.004$ respectively, by repeated measures analysis). Moreover, disease activity decreased, fatigue decreased and functional status improved significantly. Further analysis revealed that individual changes in PSQI score over time were not associated with the corresponding individual changes in DAS28 ($r=0.37$, $p=0.17$) but correlated significantly with HAQDi changes ($r=0.60$, $p=0.02$) and marginally with changes in FSS scores ($r = -0.46$, $p = 0.08$)

Conclusion: Improvement of sleep quality after tocilizumab treatment in patients with RA does not appear to directly result from decreased disease activity, further suggesting that aberrant IL-6 regulation associates with sleep disturbances.

1203

Fatigue in Patients with Rheumatoid Arthritis: Examination of Contributory Factors Post Tumour Necrosing Factor Inhibitor Treatment. Patricia Minnock[1], Gabrielle McKee[2], Barry Bresnihan[3], Oliver M. FitzGerald[4] and Douglas J. Veale[5]. [1]Our Lady's Hospice & Care Services, Dublin, Ireland, [2]Trinity College Dublin, Dublin, Ireland, [3]St. Vincent's University Hospital, Dublin, Ireland, [4]St. Vincent's Univ Hospital, Dublin, Ireland, [5]Dublin Academic Medical Centre, University College Dublin, Dublin, Ireland

Background/Purpose: The nature of fatigue in patients with rheumatoid arthritis (RA) is poorly understood. The purpose was to determine contributory factors to persistent fatigue despite good disease outcome following six months of tumour necrosing factor inhibitor (TNFi) therapy.

Methods: Selection criteria included patients with RA assessed at baseline and six months post initiation of TNFi therapy, demonstrating a moderate / good disease response using the EULAR response criteria (ERC). This group was divided into two subgroups i) with poor fatigue outcome and, ii) with good fatigue outcome. The good fatigue outcome subgroup, selected to serve as a basis for comparison, were stratified to match gender, age range, disease duration, and functional status. Through postal survey, validated questionnaires: Short Form McGill pain questionnaire; Pittsburgh Sleep Quality Index; Profile of Mood States, Beck Depression Inventory and Beck Hopelessness Scale; Arthritis Self-Efficacy Scales, were used to capture information on possible contributory factors to persistent post treatment fatigue. Statistical analysis used chi-square test for nominal data (Rheumatoid Factor), parametric independent sample t-test for group means on the normally distributed scale variables, (HAQ-disability index, self-efficacy for pain), and the non-parametric Mann-Whitney *U* test for data which deviated from the normal (two-tailed).

Results: Twenty–eight patients with *Poor Fatigue Outcome*, despite demonstrating a moderate to good improvement in disease status (ERC$>0.6>1.2$) following six months of TNFi therapy, were identified for comparative study with 28 patients with *Good Fatigue Outcome*. The majority (80%) of the patients were female. The poor fatigue outcome subgroup differed significantly from the good fatigue outcome subgroup in the following parameters: RF positive 15 (54%), versus 5 (14%), $\chi^2 = 36.8$; exact $p\leq 0.001$; Ever failed synthetic DMARDS; 18 (64%) versus 24 (86%), $U = 285$; $Z=-2.331$, exact $p = 0.036$; Early morning stiffness duration (range) 0–180 minutes versus 0–30 minutes, $U = 0$ 85; Z –3.14; exact $p = 0.00$, Mean DAS28 ± SD (range), 3.3± 1.1 (1.7–5.8), and 2.4 ± 0.7 (1.2–4.4), $U=0$ 99; Z –3.051; exact p= 0.002, mean ± SD (range). The HAQ-disability index was higher in the poor fatigue outcome group 1.11 ± 0.6 (0–3) versus 0.76 ± 0.5 (1–3), this difference of 0.35 between groups which exceeds the known MCID of 0.22 was not statistically significant (t= 0.18; exact p= 0.07). Patients with *Poor Fatigue Outcome* experienced more pain (p=0.02–0.009), low arthritis self-efficacy for 'other symptoms' (p=0.022), and better sleep quality (p=0.014).

Conclusion: Despite demonstrating a moderate/good disease response patients with *Poor Fatigue Outcome* had a higher DAS28, more pain, less self-efficacy in relation to fatigue, more than symptoms related to pain and functioning; they also reported better sleep quality and lower mood than those with good fatigue outcome.

1204

Pregnancy and the Risk of Rheumatoid Arthritis In a High Risk North American Native Population. Christine A. Peschken[1], David B. Robinson[1], Irene Smolik[1], Carol A. Hitchon[1], Donna M. Hart[2], Charles N. Bernstein[1] and Hani El-Gabalawy[1]. [1]University of Manitoba, Winnipeg, MB, [2]Health Sciences Centre, Winnipeg, MB

Background/Purpose: Previous studies have examined rheumatoid arthritis (RA) risk and pregnancy history, with conflicting results. North American Natives (NAN) have a high birth rate, a high risk of RA, and develop RA at a younger age. We examined reproductive history and RA risk in this highly predisposed population with unique fertility characteristics.

Methods: We examined pregnancy history and RA risk using results from females enrolled in 2 studies: a study of RA in NAN RA patients (n=141) and their unaffected 1st degree relatives (n=197); and NAN RA patients (n=27) and unrelated healthy NAN controls (n=203) enrolled in a study of autoimmunity in NAN populations. All participants were interviewed using identical questionnaires detailing reproductive history. RA patients with onset before menarche were excluded. Only those pregnancies occurring prior to the diagnosis of RA were included. Age was defined as age at RA onset for RA patients, and age at study enrolment for controls.

Results: RA patients (n=168) and controls (n=400) were overall similar in age (37±12 vs. 36±12 years), high school completion (37% vs. 35%), frequency of shared epitope (one or more copies 78% vs. 81%) number of pregnancies (3.7 ±2.6 vs. 3.6± 2.7)and age at first pregnancy (19 ± 4.2 vs. 20 ± 4.1 years). Both groups had similarly high rates of smoking (81% vs. 77%), and low rates of breastfeeding (Duration 0–3 months; 65% vs. 67%). In multivariate analysis, for women who had 6 or more births the OR for developing RA was 0.43(95%CI 0.21–0.87) compared to women with 1–2 births *(p for trend = 0.046);* for women who gave birth for the first time after age 20 the OR for developing RA was 0.33 (95%CI 0.16–0.66) compared to women whose first birth occurred at age 17 or younger *(p for trend=0.001).* Most striking was the high risk of developing RA in the 1st postpartum year (OR 3.8; 95%CI 1.45–9.93) compared to subsequent years *(p for trend =0.004).*

Conclusion: We found a significantly lower risk of RA in multiparous women compared to those with only 1–2 pregnancies; however an early age at first birth strongly increased the risk of RA. In addition, our clinical impression of the postpartum period as very high risk for the development of RA in this population was also confirmed. The explanation for these findings is not known, but may relate to the protective effect of repeated exposure to the ameliorating hormonal levels of multiple pregnancies balanced against the effect of early exposure to postpartum hormonal changes.

1205

A Significant Proporcion of Patients with Palindromic Rheumatism and Positive Anti-Citrulinated Protein Antibodies Do Not evolve to Rheumatoid Arthritis after a Long Term Follow-up. S. Cabrera[1], J. A. Gomez-Puerta[1], M. V. Hernandez[1], V. Ruiz-Esquide[1], Georgina Salvador[2], M.E. Gomez-Caballero[1], J. Ramirez[1], J. D. Cañete[1] and R. Sanmarti[1]. [1]Hospital Clinic of Barcelona, Barcelona, Spain, [2]Hospital Mutua de Terrassa. Barcelona, Barcelona, Spain

Background/Purpose: A significant proportion of patients with palindromic rheumatism (PR) develop rheumatoid arthritis (RA) during follow-up.

Positive anti-citrullinated protein antibodies (ACPA) are frequently found in PR and have been suggested as a biomarker for the development of RA. However, in clinical practice, we have observed some patients with PR and positive ACPA, who do not evolve to chronic rheumatic disease after a long term follow-up.

Objectives: To analyze the long-term clinical evolution of patients diagnosed with pure PR according to the ACPA status at the time of the first serum measurement.

Methods: All patients with a diagnosis of PR according to the criteria of *Guerne et al* seen by our arthritis unit were analyzed; only patients with pure PR, defined as no evidence of associated rheumatic disease at the time of the first serum measurement of ACPA, were included. Some of these patients were analyzed in our previous study which was the first to describe positive ACPA in patients with PR*. Demographic characteristics, duration of PR until serum ACPA measurement and total follow-up time were recorded. ACPA in sera were measured using the CCP1 test until 2002 and the CCP2 test thereafter. All patients were followed until December 2010 in order to evaluate the development of chronic rheumatic disease. In some patients, serial ACPA determinations were made.

Results: We included 71 patients (27 from our original study) with pure PR (52 F/ 19 M) with a mean age at the time of the first ACPA serum measurement of 52.4 ±12.6 years and a duration of symptoms of 53.9 ± 9 months. Serum ACPA were positive in 37 patients (52.1%) with mean serum levels of 704.7 ± 592.5 UI. After a mean follow-up of 90.9 month ± 56.6 (range 1–213), 24 patients (33.8%) evolved to chronic rheumatic or systemic disease: RA 16 patients (22%), SLE 4 p (5.6%), other diseases: 4 p (5.6%) psoriatic arthritis, undifferentiated spondyloarthropathy, autoimmune hepatitis and familial Mediterranean fever. Development of RA during the follow-up was more frequently seen in ACPA positive than in ACPA negative patients, although the difference was not statistically significant, probably due to the small sample size (29.7% vs 14.7% p= 0.109). RA was diagnosed after a mean follow-up of 44.2 m ± 58.3 (44.2 ± 66.4 month in ACPA+ patients and 44.2 ± 41.9 month in ACPA- patients, p >0.05). No evidence of RA or other rheumatic disease was observed in 26 out of the 37 ACPA+ patients (70.3%) during the follow-up. ACPA serum levels of these patients were not significantly different from those of patients who evolved to RA (628.4±547.4 vs 736.9±618.1 p>0.05). Serial ACPA measurements were performed in 57 patients and in only two patients (one of them evolving to RA) a seroconversion from negative ACPA to positive ACPA was observed during the follow-up; the same serological status was demonstrated in the remaining patients

Conclusion: ACPA are frequently found in the sera of PR patients and may be considered as a biomarker for RA in these patients. However, a significant proportion of patients with PR and serum positive ACPA, even those with high titers, do not develop RA after a long term follow-up.

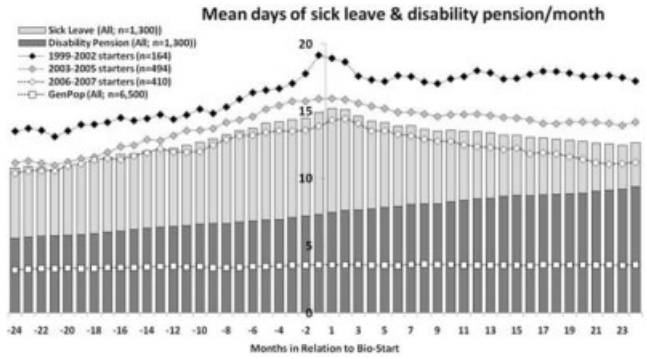
1206

Sick Leave and Disability Pension Before and After Initiation of Biologics in Psoriatic Arthritis Patients: Four-Year Nationwide Cohort Study. Martin Neovius[1], Jonas Eriksson[2], Julia F. Simard[2], Johan Askling[1] and ARTIS Study Group[3]. [1]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Solna, Sweden, [2]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Sweden

Background/Purpose: Productivity losses and biologic drugs are considered the major cost drivers in psoriatic arthritis (PsA), but long-term productivity data from PsA patients treated with biologics remain scarce. The aim of this study was to investigate changes in sick leave and disability pension in relation to start of biologic treatment in PsA patients.

Methods: PsA patients aged 19–60y initiating their first biologic (n=1,300; mean age 45y; 52% men) were identified in the Swedish Biologics Register ARTIS between 1999 and 2008. Five general population comparators per patient were sampled using age, sex, education and start year as matching factors. Sick leave and disability pension data (1997–2010) were retrieved from the Swedish Social Insurance Agency from two years before to two years after the day of biologic treatment start.

Results: Mean monthly days on disability pension increased monotonically from −24 months to +24 months after bio-start (5.6 to 9.4; p<0.001; **Figure**) with 25% and 39% on disability pension at the respective time points. The difference compared to the general population was large and increased from a mean of 3.6 to 6.7 days/month (Δmean 3.1; p<0.001), while the disability pension prevalence ratio increased from 3.5 to 4.0. Mean monthly sick leave days increased from 5.2 at −24 months to 7.7 at bio-start, but then decreased to 3.3 at +24 months. Mean total days of sick leave and disability pension was 14.9 at bio-start, significantly higher than at both −24 and +24 months (10.8 and 12.7 days, respectively; both p<0.001). The medians at −24, bio-start and +24 months were 0, 16 and 8 days/month, respectively. At bio-start the mean difference versus the general population was 11.6 total days/month (compared to 7.6 at −24 and 9.1 at +24 months). The distribution of days of sick leave and disability pension was skewed: 21% of patients accounted for >50% of total days at +24 months. Calendar period differences also existed with higher levels of sick leave and disability pension in the earlier compared to the later bio-start cohorts (Figure).



Conclusion: Mean and median monthly sick leave and disability pension days increased before bio-start. After bio-start, productivity improved but did not fully rebound to the −24 month level and remained significantly elevated compared to the general population. A small number of patients accounted for the bulk of the productivity losses.

1207

Treating to Target Matrix Metalloproteinase 3 Normalisation Together with Disease Activity Score Below 2.6 Yields Better Effects Than Each Alone In Rheumatoid Arthritis Patients: Treating to Twin Targets; T-4 Study. Yukitomo Urata[1], Ryoko Uesato[1], Dai Tanaka[1], Yoshihide Nakamura[2] and Shigeru Motomura[2]. [1]Seihoku Chuo Hospital, Gosyogawara, Japan, [2]Hirosaki University Graduate School of Medicine, Hirosaki, Japan

Background/Purpose: To assess whether therapy to achieve both disease activity score in 28 joints (DAS28) <2.6 and matrix metalloproteinase (MMP)-3 normalisation offers better outcomes than either target alone in early rheumatoid arthritis at 56 weeks; Treating to twine targets; T-4 study.

Methods: A total of 243 early RA patients were randomly allocated to one of four strategy groups: routine care (R group; n=62); DAS28-driven therapy (D group; n=60); MMP-3-driven therapy (M group; n=60); or both DAS28- and MMP-3-driven therapy group (Twin; T group; n=61). Specifically, medication was started with sulfasalazine (1 g/day) in all intervention groups. Targets were DAS28 <2.6 for D group, MMP-3 normalisation for M group, and both DAS28 <2.6 and MMP-3 normalisation for T group. If the value in question did not fall below the previously measured level, we intensified medication including methotrexate, other disease-modifying anti-rheumatic drugs and biologic agents. Primary, secondary, tertiary and quaternary outcome measures consisted

of the proportions of patients in clinical remission (DAS28 <2.6), showing radiographic nonprogression (Dmodified total Sharp score ≤0.5), showing normal physical function (modified Health Assessment Questionnaire score=0), and comprehensive disease remission defined as the combination of clinical remission, radiographic nonprogression, and structural normal physical function.

Results: Comprehensive disease remission at 56 weeks was achieved by more patients in T group (34%) than in R group ($p<0.001$), D group ($p<0.05$), or M group ($p<0.001$).

Conclusion: Results of the T-4 study revealed that comprehensive disease remission is an achievable goal in early RA with more aggressive therapy.

1208

Risk of Infections In Rheumatoid Arthritis Patients Treated with Tocilizumab—a Retrospective Data-Analysis. Veronika Lang[1], Matthias Englbrecht[1], Jürgen Rech[1], Bernhard Manger[2], Georg Schett[3] and Jochen Zwerina[4]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Medical School Erlangen, Erlangen, Germany, [3]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [4]University of Erlangen-Nuremberg, Germany, Erlangen, Germany

Background/Purpose: The human anti- interleukin 6 receptor (IL-6R) antibody tocilizumab is approved for the treatment of rheumatoid arthritis (RA) in patients who inadequately respond or are intolerant to therapy with DMARDs or TNF-alpha inhibitors. Infections are the most common adverse event during tocilizumab therapy. Therefore, we investigated the occurrence and risk factors for infections in rheumatoid arthritis (RA) patients treated with tocilizumab in clinical practice.

Methods: A cohort of all RA patients (N = 112) receiving tocilizumab therapy between October 2008 and March 2010 in Northern Bavaria, Germany, was assessed for the incidence of infections. Mild/moderate and severe infections were recorded. Multivariate logistic regression analysis was used to analyze risk factors for infection.

Results: In total, 26 patients developed infections (23.2%, 58.0/100py), 18 of them experienced mild to moderate infections (16.1%, 40.1/100py) and 8 faced severe infections (7.1%, 17.9/100py). One patient died. Concomitant use of leflunomide and prednisone, high disease activity and previous therapy with rituximab were associated with the occurrence of mild/moderate infections. Severe infections were related to age, longer disease duration, exposure to more than 3 previous DMARDs and concomitant therapy with proton pump inhibitors (PPI).

Conclusion: The rate of infection in RA patients treated with tocilizumab in clinical practice is higher compared with the populations in clinical trials. Increased awareness should especially be given to patients with higher age and longer disease duration, those concomitantly using leflunomide, prednisone or PPI as well as those with a previous exposure to rituximab.

1209

Bone Resorption, OsteoClastogenesis and Adalimumab. A Study On the Impact of Anti-Tumor Necrosis Factor Therapy On Osteoclastogenesis In Patients with Rheumatoid Arthritis. Sabrina Guay-Belanger[1] and Arthur J. Fernandes[2]. [1]Universite de Sherbrooke, Sherbrooke, QC, [2]Universite de Sherbrooke, Sherbrooke

Background/Purpose: Osteoclastic bone resorption depends on the capacity to generate osteoclasts (OCs) and on their individual activity. Our objective was to study the effect of anti-TNF therapy on the number of OC precursors in the peripheral blood of patients with RA, on *in vitro* osteoclastogenesis and on OCs activity before and during the treatment of patients with Adalimumab.

Methods: 25 patients with active RA diagnosed according to the ACR criteria and willing to sign an informed consent were recruited from the outpatient clinics at the Centre Hospitalier Universitaire de Sherbrooke. Adalimumab 40 mg sub-cutaneous was administered every two weeks. Primary outcomes were 1) the number of OC precursor (CD14+) cells in the peripheral blood, 2) the number of OCs generated *in vitro, and* 3) the amount of bone resorption *in vitro* before administration of Adalimumab and 3 and 6 months into the treatment. Secondary outcomes were disease *activity* defined as a DAS28 scoreand change in functional status by the M-HAQ. PBMCs were isolated from 50 ml of blood by Ficoll-Hypaque gradient and the number of CD14+ cells was determined by FACS. The whole population of PBMCs was plated in 48-well tissue culture plates and the cells were allowed to differentiate for 21 days in the presence of recombinant RANKL (75 ng/ml) and M-CSF (10 ng/ml). The cells were then stained for TRAP activity. The number of TRAP+ cells containing 3 or more nuclei was counted in each well. For bone resorption assays, cells differentiated for 30 days on bone slices were stained for 0.2% toluidine blue. Resorption surface was quantified using the image analysis program Simple PCI.

Results: Treatment with Adalimumab had no impact on the number of OC precursors in peripheral blood in any of the points studied. For the number of OCs generated *in vitro*, the medians with (25^{th} centile, 75^{th} centile) at first, 3 months and 6 months visits were 220.0 (109.5, 396.5), 201.0 (38.0, 387.0) and 58.0 (19.0, 386.5) OCs/well; these differences were not statistically significant. For the resorption assays, the medians with (25^{th} centile, 75^{th} centile) at first, 3 months and 6 months visits were 21466.0 (0.0, 855844.1), 0.0 (0.0, 411915.0) and 0.0 (0.0, 0.0) μm^2. Although there was a strong trend towards a decrease in the resorption area in visits 3 and 6 months, none of these results reached statistically significant difference when compared to the first visit (p = 0,057). Adalimumab induced a significant decrease in the DAS28 score and in the M-HAQ. For the DAS28 score, the difference between the medians was statistically significant for the first and 3 months visits (p = 0.0008) and for the first and 6 months visits (p = 0.0017). For the M-HAQ, the difference was statistically significant for the first and 6 months visits (p = 0,006).

Conclusion: Treatment with Adalimumab up to 6 months had no statistically significant impact on the number of OC precursors, osteoclastogenesis and resorption *in vitro* even if we can observe a trend toward a decrease in the number of OCs and bone resorption with treatment. For the clinical results, Adalimumab had a statistically significant impact in DAS28 and M-HAQ, decreasing both.

Golimumab's Efficacy in Patients with Very Active Disease in Methotrexate-naïve Rheumatoid Arthritis. Paul Emery[1], R. M. Fleischmann[2], Elizabeth C. Hsia[3], Stephen Xu[4], Weichun Xu[5] and Daniel G. Baker[6]. [1]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [2]University of Texas Southwestern Medical Center and Metroplex Clinical Research Center, Dallas, TX, [3]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA, [4]Centocor R & D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, [5]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, [6]Centocor R & D, a division of Johnson & Johnson Pharmaceutical Research and Development, LLC, Malvern, PA

Background/Purpose: To assess golimumab (GLM) treatment effect in patients with rheumatoid arthritis (RA) naïve to methotrexate (MTX) therapy with severe, active and progressive disease.

Methods: The GO-BEFORE trial studied GLM 50mg and 100mg + MTX in MTX-naïve patients. In the overall GO-BEFORE study population, patients exhibited lower disease activity (baseline ACR components and DAS28) than was observed in previous studies of biologic agents in MTX-naive patients[1]. This is a retrospective analysis of GO-BEFORE wk 52 data which compares efficacy outcomes in subsets of RA patients with severe, active disease to the overall study population. 637 MTX-naïve pts were randomized to PBO+MTX (Grp 1), GLM 100mg+PBO (Grp 2), GLM 50mg+MTX (Grp 3), or GLM 100mg+MTX (Grp 4). GLM/PBO received injections q4wks. Pts with <20% improvement in TJC/SJC at wk28 in Grps 1, 2, and 3 entered early escape to GLM 50mg+MTX, GLM 100mg+MTX, and GLM 100mg+MTX, respectively.(Grp4 had no change). The following baseline disease characteristics were used to define subsets of patients with severe, active, and progressive disease: SJC≥20 and TJC ≥12, EULAR DAS28 CRP >5.1, and CRP ≥3 mg/dL. Treatment effect for each subset and the overall population was defined as the differences between GLM 50mg or 100mg +MTX and MTX-alone in ACR50, DAS28 (CRP) remission, change in HAQ ≥ 0.25 and total vdHS score ≤0. Differences in the treatment effect between each subset of severe, active and progressive RA and the overall population was examined.

Results: Greater proportions of patients achieved the efficacy endpoints in the GLM+MTX groups versus MTX-alone and the difference between the treatment groups (tx effect) was generally larger in the severe, active and progressive subsets compared with the overall population (Table).

Table. Treatment effect between golimumab + MTX and MTX-alone at Wk 52

	Grp 1* MTX Alone N = 160	Grp 3** GLM 50mg + MTX N = 159	Tx effect Grp 3 vs Grp 1	Grp 4 GLM 100mg + MTX N = 159	Tx effect Grp 4 vs Grp 1
ACR50 % (n/N)					
All pts	35.6 (57/160)	42.1 (67/159)	6.5	48.4 (77/159)	12.8
CRP ≥3	29.3 (12/41)	52.4 (22/42)	23.1	48.8 (21/43)	19.5
SJC ≥20 and TJC ≥12	31.4 (11/35)	47.7 (21/44)	16.3	44.2 (19/43)	12.8
DAS28 CRP >5.1	33.9 (37/109)	45.6 (52/114)	11.7	43.6 (48/110)	9.7
EULAR DAS28 CRP remission %(n/N)					
All pts	26.3 (42/160)	35.8 (57/159)	9.5	39.6 (63/159)	13.3
CRP ≥3	14.6 (6/41)	35.7 (15/42)	21.1	30.2 (13/43)	15.6
SJC ≥20 and TJC ≥12	11.4 (4/35)	27.3 (12/44)	15.9	34.9 (15/43)	23.5
DAS28 CRP >5.1	18.3 (20/109)	33.3 (38/114)	15.0	30.9 (34/110)	12.6
HAQ ≥0.25 % (n/N)					
All pts	62.5 (100/160)	65.4 (104/159)	2.9	70.4 (112/159)	7.9
CRP ≥3	78.0 (32/41)	85.7 (36/42)	7.7	86.0 (37/43)	8.0
SJC ≥20 and TJC ≥12	68.6 (24/35)	75.0 (33/44)	6.4	88.4 (38/43)	19.8
DAS28 CRP >5.1	71.6 (78/109)	78.1 (89/114)	6.5	82.7 (91/110)	11.1
X-ray vdHS ≤0 % (n/N)					
All pts	53.9 (76/141)	71.4 (100/140)	17.5	61.2 (85/139)	7.3
CRP ≥3	34.1 (14/41)	64.3 (27/42)	30.2	51.2 (22/43)	17.1
SJC ≥20 and TJC ≥12	34.3 (12/35)	68.2 (30/44)	33.9	65.1 (28/43)	30.8
DAS28 CRP >5.1	52.3 (57/109)	72.8 (83/114)	20.5	60.0 (66/110)	7.7

*Includes pts who early escape at wk28 to GLM 50 mg + MTX; **Includes pts who early escape at wk28 to GLM 100 mg + MTX; For early escape pts, wk28 value carried forward to wk 52; Last observation carried forward for missing data, and treatment failure rules applied.

Conclusion: Overall, treatment effect in the efficacy parameters between GLM 50mg +MTX and GLM 100mg +MTX versus MTX-alone was greater for the severe, active and progressive subsets versus the overall population.

Impact of Rituximab On the Quality of Life and Physical Function of Patients with Rheumatoid Arthritis: Results From the British Society for Rheumatology Biologics Register. Moetaza M. Soliman[1], Kimme L. Hyrich[2], Mark Lunt[2], Kath D. Watson[2], Deborah PM Symmons[2] and Darren M. Ashcroft[1]. [1]School of Pharmacy and Pharmaceutical sciences, University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom

Background/Purpose: Improvements in the quality of life and physical function of rheumatoid arthritis (RA) patients receiving rituximab (RTX) have been shown in clinical trials. This study aimed to assess quality of life and physical function of RA patients six months after receiving RTX in routine clinical practice in the UK, and to identify factors that were associated with improvements in physical function.

Methods: The study included 448 RA patients registered with the British Society for Rheumatology Biologics Register, a national prospective cohort study, who were starting RTX and provided Health Assessment Questionnaire (HAQ) at baseline and six months after starting RTX. Changes in the HAQ scores and European Quality of life 5 Dimensions (EQ5D) ratings were used to evaluate improvements in physical function and quality of life. Multivariate regression models were used to identify factors that were associated with improvements in HAQ scores in patients receiving RTX who had failed at least one anti-tumour necrosis factor therapy. The models examined baseline demographic and disease characteristics, baseline physical function, concomitant drug therapies and previous biologic and non-biologic therapies.

Results: Six months after starting RTX, the mean HAQ, EQ5D utility, and EQ5D visual analogue scores had significantly improved (table 1). Over one third of patients (36%) achieved the minimal clinically important difference (MCID) in HAQ (improvement of 0.22 units at least). The multivariate analysis found that high baseline HAQ score was significantly associated with an improvement in HAQ (table 2). Patients receiving concurrent steroids were significantly less likely to show an improvement in HAQ. Older patients, females, and current smokers were also significantly less likely to show either HAQ improvements or achieving MCID in HAQ.

Table 1. Six months improvements

Outcome	Baseline	Six months
Mean HAQ (95% CI)*	1.96 (1.91, 2.02)	1.84 (1.78 to 1.90)
Mean EQ VAS (95% CI)†	45.6 (43.5, 47.7)	53.0 (51.1 to 54.9)
Mean EQ5D utility score (95% CI)§	0.29 (0.26, 0.32)	0.39 (0.36 to 0.42)

*HAQ range is 0 to 3, †EQ VAS range is 0 to 100, § utility score range is −0.59 to 1.00

Table 2. Significant predictors of HAQ improvements

Baseline factor	Linear Change in HAQ (Coefficient (95% CI))	Achieving MCID in HAQ (Odds ratio (95% CI))
Age (10 years)	0.07 (0.03 to 0.11)*	0.72 (0.55 to 0.93)*
Gender	0.14 (0.04 to 0.25)*	0.47 (0.25 to 0.91) *
Baseline HAQ	−0.13 (−0.20 to −0.06)*	1.49 (0.92 to 2.41)
Concurrent steroids	0.09 (0.01 to 0.18)*	0.63 (0.37 to 1.07)
Current smoking	0.13 (0.02 to 0.24)*	0.45 (0.21 to 0.96)*

*$P < 0.05$

Conclusion: In routine clinical practice, RTX was found to be effective in improving the quality of life and physical function of RA patients. Factors that influenced the degree of improvement in physical function included: baseline disability, smoking, concurrent use of steroids, age, and gender.

1212

Mortality and Cause of Death In Young Rheumatoid Arthritis Patients Treated with Anti-TNF Therapy: Results From the British Society for Rheumatology Biologics Register. Malack Alachkar, Kath D. Watson, Kimme L. Hyrich and Deborah PM Symmons. Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased mortality, with cardiovascular disease (CVD) being the leading cause of mortality and premature death. Any deaths observed in young RA patients are likely premature and possibly related to the underlying RA. In this study, we examined the cause of death in young RA patients aged 50 years or less who were treated with anti-TNF therapy.

Methods: The patients were selected from the British Society for Rheumatology Biologics Register (BSRBR), a UK national prospective cohort study to monitor the long-term safety of biologic therapy. The analysis included subjects with RA aged 50 years or less at registration with the BSRBR. Patients were followed either from the start of anti-TNF (adalimumab, etanercept or infliximab) therapy or from registration into the non-biologic disease modifying antirheumatic drug (nbDMARD) comparison cohort until 10/31/2009 or death, whichever came first. All patients were flagged with the UK national death register who provided copies of death certificates. We used student's t or chi-square (χ^2) tests to compare the baseline demographic characteristics and comorbidites between the two cohorts. Mortality rate per 1000 patient-years of observation (pyrs) with 95% confidence interval (95% CI) was estimated in each group and the two rates were compared. However, it was not possible to do baseline adjustment in the analysis because the numbers of death were too small.

Results: In total, 4883 young RA patients were recruited to this study; 4089 anti-TNF (21380 pyrs) and 794 nbDMARD (3206 pyrs) treated patients. Compared to the nbDMARD treated patients, anti-TNF treated patients were younger at RA onset, had longer RA duration and higher disease activity, and were more likely to be rheumatoid factor (RF) positive and to be receiving steroids (Table). Subjects in the biologic group were more likely to have hypertension (15% vs. 10.5%, p=0.003) but less likely to have chronic obstructive pulmonary disease (1.8% vs. 3.7%, p=0.0009) and a history of asthma (10% vs. 14%, p=0.0017). During the time of observation, 36 patients died in the anti-TNF cohort compared to 3 patients in the nbDMARD cohort (Table).

Table. Patient baseline characteristics, number of deaths and mortality rate.

Number of Patients	nbDMARD cohort n=794	Anti-TNF cohort n=4089
Patient-years of observation	3206*	21380*
Age at onset of RA years, mean (SD)	35.4 (8.9)*	30.7 (9.4)*
Age at registration years, mean (SD)	41.8 (7)	41.2 (7.3)
Disease duration years, mean (SD)	6.7 (6.1)*	15 (8)*
Female%	76%	79%
Steroid use, no (%)	64 (15.8)*	2042 (66.9)*
RF status positive, no (%)	429 (54.2)*	2472 (61.4)*
Baseline DAS28 mean (SD)	5.1 (1.1)*	6.4 (0.8)*
Baseline HAQ mean (SD)	1.5 (0.6)*	2.1 (0.5)*
Number of deaths	3	36
Mortality rate/1000 pyrs (95% CI)	0.94** (0.19–2.7)	1.68** (1.2–2.3)

*p value <0.001, **p value = 0.32 Causes of death in the anti-TNF group were infection (n=11), malignant neoplasms (n=7), CVD (n=6), interstitial lung disease (ILD) (n=4) and other (n=8). The causes of the death in the nbDMARD group were malignant neoplasm (n=1), CVD (n=1) and an intestinal vascular event (n=1).

Conclusion: There was no significant difference in mortality rate in this young cohort between those treated with anti-TNF and nbDMARD therapy. It is possible that the deaths due to infection and ILD may be attributable to the underlying RA or its treatment. RA may also have contributed to the CVD deaths.

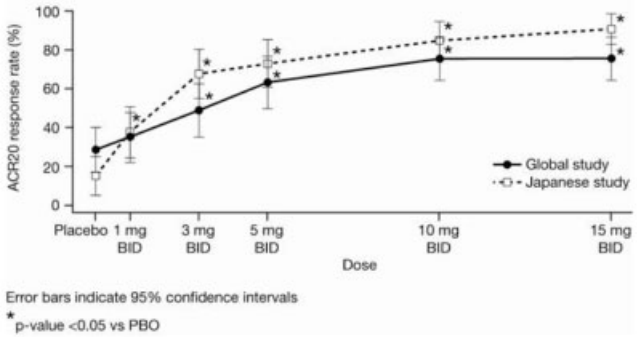
Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor, As Monotherapy in Patients with Active Rheumatoid Arthritis: A Comparison Between Japanese and Global Populations Over 12 Weeks of Dosing in Phase 2b Studies. T. Takeuchi[1], Y. Tanaka[2], H. Yamanaka[3], M. Suzuki[4], H. Nakamura[4], K. Yazawa[4], S. Toyoizumi[4], J. D. Bradley[5] and S. H. Zwillich[5]. [1]Keio University School of Medicine, Tokyo, Japan, [2]University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [4]Pfizer Inc., Tokyo, Japan, [5]Pfizer Inc., Groton, CT

Background/Purpose: To compare the efficacy, safety, and tolerability of tofacitinib monotherapy for the treatment of rheumatoid arthritis (RA) in Japanese (J) and global (G) pts with an inadequate response to DMARDs.

Methods: This was a planned comparison of J and G Phase 2 studies of tofacitinib monotherapy. The J study randomized 318 pts; the G study was conducted outside Japan and randomized 384 pts. Both were randomized, double-blind, placebo (PBO) controlled studies of tofacitinib 1, 3, 5, 10, and 15 mg twice daily (BID) enrolling pts with active RA (≥6 tender and swollen joints at baseline). The G study also included an active comparator arm and ran for 24 weeks (wks) in total. Inclusion and exclusion criteria and primary endpoints (ACR20 response rates at Wk 12) were matched to permit comparison. For the primary endpoint, a pair-wise Chi-Square Test with a 2-sided significance level of 0.05 was used to compare tofacitinib 1, 3, 5, 10, and 15 mg BID with PBO; type 1 error was protected using a step-down procedure in each study.

Results: In both studies the mean ages and durations of RA were similar. In contrast, the range of mean body weight was lower for J (52.9 to 57.4 kg) than G pts (65.7 to 75.7 kg). There were differences in baseline (pre-treatment) number of tender joints (J: 13.6–18.6 vs G: 24.1–27.1) but there was no major difference in DAS28-4(ESR) (J: 5.87–6.42 vs G: 6.30–6.57).

ACR20, ACR50, and AC70 response rates were dose-dependent in both studies and the dose response was similar across studies, although absolute response rates were higher in Japan (Figure).



The incidence of adverse events (AEs) was 44.2% (PBO), 55.5% (5 mg BID), 60.4% (10 mg BID), and 51.9% (15 mg BID) in the J study and 40.7% (PBO), 49.0% (5 mg BID), 50.8% (10 mg BID), and 52.6% (15 mg BID) in the G study. Categories of AEs occurring at an incidence of ≥10% were gastrointestinal disorders, infections and infestations, investigations, metabolism and nutritional disorders, nervous system disorders, skin and subcutaneous tissue disorders; the incidence rates of AEs were similar between the studies. Serious AEs were infrequent and had no apparent relationship to tofacitinib dose (Table).

Table. Summary of safety at 12 wk in the J and G studies

	NCT00687193 (J study) Tofacitinib						NCT00550446 (G study) Tofacitinib					
	1 mg BID N=53	3 mg BID N=53	5 mg BID N=52	10 mg BID N=53	15 mg BID N=54	PBO N = 52	1 mg BID N=54	3 mg BID N=51	5 mg BID N=49	10 mg BID N=61	15 mg BID N=57	PBO N = 59
Incidence of AEs (%)	21 (39.6)	23 (43.4)	29 (55.8)	32 (60.4)	28 (51.9)	23 (44.2)	19 (35.2)	19 (37.3)	24 (49.0)	31 (50.8)	30 (52.6)	24 (40.7)
Incidence of SAEs (%)	0	3 (5.7)	2 (3.8)	2 (3.8)	1 (1.9)	1 (1.9)	0	1 (2.0)	0	0	1 (1.8)	1 (1.7)
Incidence of severe AEs (%)	0	2 (3.8)	1 (1.9)	1 (1.9)	0	0	0	1 (2.0)	0	0	2 (3.5)	1 (1.7)
Incidence of discontinuation due to AEs (%)	0	1 (1.9)	2 (3.8)	3 (5.7)	0	2 (3.8)	2 (3.7)	2 (3.9)	0	1 (1.6)	2 (3.5)	1 (1.7)
Incidence of temporary discontinuation due to AEs (%)	1 (1.9)	3 (5.7)	2 (3.8)	2 (3.8)	4 (7.4)	3 (5.8)	1 (1.9)	2 (3.9)	1 (2.0)	2 (3.3)	3 (5.3)	0
Neutrophil ($\times 10^2/\mu L$)	0.06	−0.98	−1.44	−2.10	−1.66	0.47	0.04	−0.69	−1.00	−1.49	−1.59	−0.74
Serum creatinine (mg/dL)	0.01	0.02	0.04	0.05	0.06	−0.01	0.02	0.01	0.03	0.04	0.05	−0.01
HDL (mg/dL)	5.04	10.81	17.73	21.94	21.11	−0.94	4.06	5.86	7.98	9.7	9.12	0.84
LDL (mg/dL)	3.21	11.77	16.43	21.45	24.69	−0.24	4.28	12.27	16.78	24.64	28.3	−2.91

HDL, high density lipoprotein; LDL, low density lipoprotein

Dose-dependent decreases in neutrophil counts, dose-dependent increases in total, high and low density lipoprotein cholesterol and small increases in serum creatinine were observed in both studies (Table). Overall, the safety profiles in the two studies were similar.

Conclusion: The efficacy dose-response and safety of tofacitinib monotherapy at 12 wks was similar in J and G pts.

1214

Early Aggressive Intervention for Rheumatoid Arthritis Increases Rate of Remission Defined Using a Boolean Approach in Clinical Practice with Tocilizumab. Toshihisa Kojima[1], Atsushi Kaneko[2], Yuji Hirano[3], Hisato Ishikawa[4], Yuichiro Yabe[5], Hideki Takagi[6], Masatoshi Hayashi[1], Koji Funahashi[1], Daizo Kato[1], Hiroyuki Matsubara[7], Naoki Ishiguro[8] and TBCR Study Group[7]. [1]Nagoya Univeristy, School of Medicine, Nagoya, Japan, [2]Nagoya Medical Center, Nagoya, Japan, [3]Toyohashi Municipal Hospital, Toyohashi, Japan, [4]Nagano Red Cross Hospital, Nagano, Japan, [5]Tokyo Kosei Hospital, Tokyo, Japan, [6]Nagoya Kyoritsu Hospital, Nagoya, Japan, [7]Nagoya, Japan, [8]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan

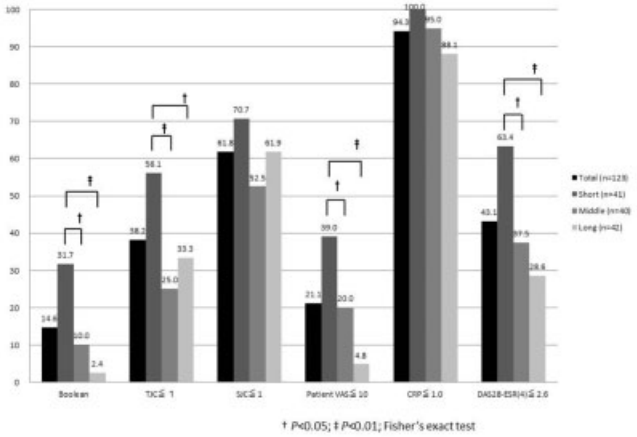
Background/Purpose: The goal of treating rheumatoid arthritis(RA) should be remission, for which a new definition was proposed in 2011. The efficacy of Tocilizumab for RA, a humanized monoclonal antibody that binds to and inhibits the interleukin-6 (IL-6) receptor, was demonstrated in several clinical trials, and its effectiveness in clinical practice is currently under investigation. To determine which patients can achieve the new Boolean-based definition of remission in clinical practice, we analysed factors associated with remission in 123 patients who received tocilizumab for 52 weeks.

Methods: All RA patients (n=134) who underwent tocilizumab treatment between May 2008 and September 2009 at Nagoya University Hospital and 12 other institutes (Tsurumai Biologics Communication Study Group) were enrolled in this study. Demographic data at the initiation of treatment (baseline) and the following parameters of disease activity (tender joint count (TJC) on 28 joints, swollen joint count (SJC) on 28 joints, patient global assessment of disease activity, erythrocyte sedimentation rate (ESR), and serum CRP levels) at baseline and 52 weeks later. We evaluated remission at 52 weeks using the 2011 definition of remission developed for use in RA clinical trials (Boolean approach). We analysed differences of baseline characteristics with disease duration and factors to determine those associated with remission using logistic regression analysis.

Results: Mean (SD) of age, disease duration and DAS28-ESR were 57 (13) years old, 10.5 (8.5) years and 5.8 (1.4). 52% of the patients had history of previous TNF-failure.

We found that patients with short disease duration (<4.8 years) had a significantly higher rate of remission (31.7%) than those with longer disease duration, and patient global assessment was the most important factor for achieving remission (Fig.1). Multivariate analysis revealed the following predictors of remission: short disease duration (<4.8 years; odds ratio [OR] 2.5, 95% confidence interval [CI] 1.4–4.7) and lower disease activity (DAS28-ESR<5.23; OR 2.5, 95% CI 1.2–5.1).

Figure 1 Boolean core measure set of patients categorized by disease duration at 52 weeks.



† $P<0.05$; ‡ $P<0.01$; Fisher's exact test

Conclusion: In this study, we showed that remission, as newly defined using a Boolean approach, is a realistic goal for patients with short disease duration in real-world clinical practice with tocilizumab.

1215

Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor, As Monotherapy or with Background Methotrexate in Japanese Patients with Rheumatoid Arthritis: A Phase 2/3 Long-Term Extension Study.

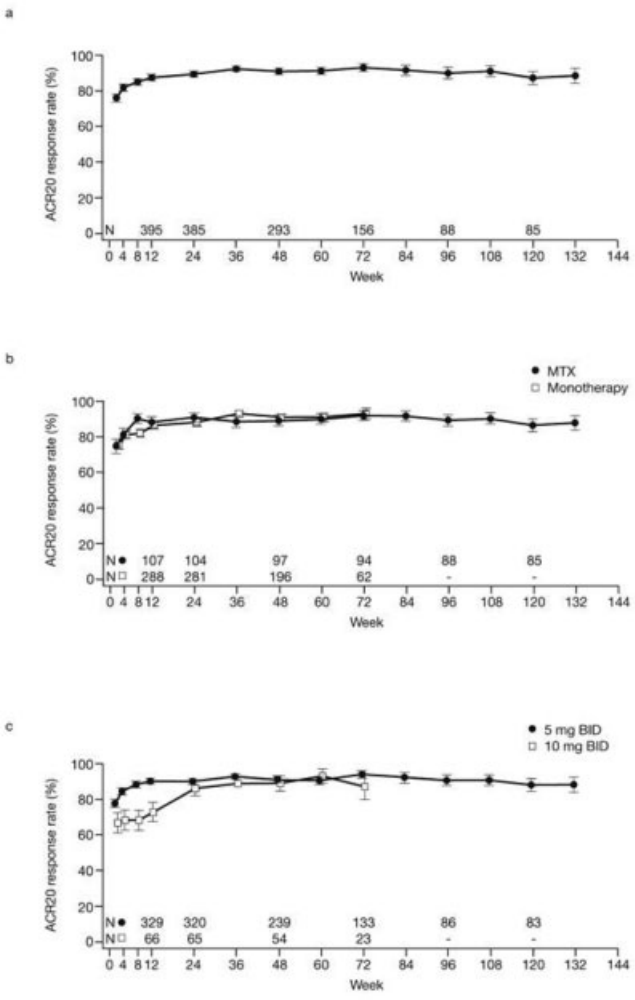
H. Yamanaka[1], Y. Tanaka[2], T. Takeuchi[3], M. Suzuki[4], H. Nakamura[4], Y. Komuro[4], S. Toyoizumi[4], J. D. Bradley[5] and S. H. Zwillich[5]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan, [3]Keio University School of Medicine, Tokyo, Japan, [4]Pfizer Inc., Tokyo, Japan, [5]Pfizer Inc., Groton, CT

Background/Purpose: Tofacitinib has previously shown efficacy and a manageable safety profile in 12-week (wk) randomized Phase 2 (P2) studies for the treatment of rheumatoid arthritis (RA) in Japan. Here we compare the safety and efficacy of tofacitinib in a long-term extension (LTE) study for Japanese pts with RA who received tofacitinib either as monotherapy or with background methotrexate (bkMTX).

Methods: This LTE study (NCT00661661) recruited pts completing P2 studies of tofacitinib either as monotherapy (NCT00687193) or with bkMTX (NCT00603512). LTE pts received tofacitinib 5 mg twice daily (BID) and could change or stop background DMARDs including MTX; inadequate responders could increase to tofacitinib 10 mg BID. For the purposes of this analysis pt groups were defined as follows: pts entering LTE on bk'MTX' (N=113) or 'monotherapy' (N=291); pts receiving tofacitinib '10 mg BID' for >12 wks (N=66), or all others, i.e. receiving tofacitinib '5 mg BID' (N=338).

Results: Results are presented for 404 pts whose tofacitinib exposure ranged from 8 months (mo) through 3 years (y). Efficacy was maintained over the long term in all pts (Figure 1a). Treatment with tofacitinib monotherapy for 1–2 y and with bkMTX for 2–3 y provided similar long-term efficacy. In both populations, the ACR20 response rate was maintained (Figure 1b). In total, 16% (66/404) pts received tofacitinib 10 mg BID for at least 12 wks. An increase in ACR20 response rate was apparent in those pts (Figure 1c).

Figure 1. Maintenance of efficacy (ACR20 +/-SE) during long-term treatment: a) all pts; b) monotherapy and MTX pts; c) tofacitinib 5 and 10 mg BID pts



There was no relationship between length of participation in the study and incidence of adverse events (AEs). Rates of discontinuation (DC) for AEs, DC for serious AEs (SAEs) and DC for serious infections (SIEs) also appeared stable over time (Table).

Table. Summary of safety during each time period in the Japanese LTE study

	Time (mo)				
	0 ≈ 6 N=404	7 ≈ 12 N=373	13 ≈ 18 N=224	19 ≈ 24 N=92	25 ≈ N=86
Incidence of AEs, n (%)	336 (83.2)	222 (59.5)	89 (39.7)	63 (68.5)	55 (64.0)
Incidence of DC due to AEs, n (%)	24 (5.9)	13 (3.5)	8 (3.6)	1 (1.1)	4 (4.7)
Incidence of DC due to SAEs, n (%)	10 (2.5)	14 (3.8)	5 (2.2)	3 (3.3)	1 (1.2)
Incidence of DC due to SIEs, n (%)	4 (1.0)	8 (2.1)	2 (0.9)	1 (1.1)	1 (1.2)

The most common AEs were infections such as nasopharyngitis (42.8%) and herpes zoster (9.9%). The most common AEs leading to DC were herpes zoster (1.5%), pneumonia (1.0%), and elevations in aspartate aminotransferase (0.5%) and alanine aminotransferase (1.0%) for which the protocol defined 3-fold elevation over the normal range as mandating treatment DC. SIEs were the category of SAEs most frequently leading to DC; the most common SIE was herpes zoster (1.5%).

Conclusion: Tofacitinib demonstrated sustained efficacy in the treatment of Japanese pts with RA when administered as monotherapy for 1–2 y or with bkMTX for 2–3 y. ACR response rates were similar in pts receiving tofacitinib as monotherapy or with bkMTX. The safety profile of tofacitinib, with or without bkMTX, was generally tolerable and consistent with that from P2 studies.

Baseline Predictors of Remission with Combination Etanercept-Methotrexate Therapy in Moderately Active Rheumatoid Arthritis: Interim Results of the PRESERVE Trial. Josef Smolen[1], Annette Szumski[2], Lisa Marshall[2] and Andrew S. Koenig[2]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Pfizer Inc., Collegeville, PA

Background/Purpose: Clinical remission is the aim of rheumatoid arthritis (RA) treatment [1] and baseline disease characteristics that predict an increased likelihood of reaching remission are of interest to clinicians. Patients with moderately active RA make up the majority of patients in the clinic [2] and achieve far better outcomes than patients with severe disease [3] but receive far less attention in clinical trials. The objective of this study was to analyze baseline characteristics that may predict remission in patients with moderately active RA (disease activity score in 28 joints [DAS28] >3.2 and ≤5.1) treated with combination etanercept (ETN) 50 mg once weekly (QW) + methotrexate (MTX) at Week 36 (Period 1) of the PRESERVE trial [4].

Methods: Patients with DAS28 >3.2 and ≤5.1, despite stable doses of oral MTX for ≥8 weeks, received open-label ETN 50 mg QW + MTX for 36 weeks. Remission was defined as DAS28 <2.6, simplified disease activity index (SDAI) ≤3.3, and clinical disease activity index (CDAI) ≤2.8. Predictors of remission were analyzed using logistic models and adjusted for geographic region and baseline DAS28, SDAI, or CDAI. Statistical tests were not adjusted for multiplicity.

Results: At Week 36, 67%, 25%, and 27% of patients achieved DAS28, SDAI, and CDAI remission, respectively. Younger age of patient (≤40 vs. >40) and lower health assessment questionnaire (HAQ) score (≤0.5 vs. >1.5) at baseline were significantly more predictive of SDAI, CDAI, and DAS28 remission (P<0.05 for all, Table). A lower HAQ score of ≤0.5 vs. 1.0–1.5 was predictive of CDAI and DAS28 remission (P<0.05 for both) and male gender was significantly predictive of SDAI and DAS28 remission (P<0.05 for both). Levels of rheumatoid factor (RF) and anticyclic citrullinated peptide (anti-CCP) levels at baseline were not predictive of remission response at Week 36 (P>0.10). Results for the continuous versions of these baseline predictors support the dichotomous results presented here. The only continuous baseline characteristic from DAS28, CDAI, and SDAI that was significantly predictive of all 3 remission measurement tools, after adjusting for baseline measurements, was DAS28 (P<0.05). However, baseline CDAI and SDAI were significantly predictive of CDAI and SDAI remission, respectively (P<0.05 for both).

Table. Baseline predictors of Week 36 remission in patients with moderately active RA

		DAS28 <2.6		SDAI ≤3.3		CDAI ≤2.8	
Baseline characteristic	N* (categ.1, categ.2)	Adjusted odds ratio (95% CI)†	P-value†	Adjusted odds ratio (95% CI)†	P-value†	Adjusted odds ratio (95% CI)†	P-value†

HAQ (1.0–1.5 vs. <=0.5)	233, 136	0.5 (0.3, 0.8)	0.005	0.6 (0.4, 1.1)	0.080	0.6 (0.4, 1.0)	0.040
HAQ (>1.5 vs. <=0.5)	174, 136	0.4 (0.2, 0.7)	0.001	0.5 (0.3, 0.9)	0.026	0.5 (0.3, 0.9)	0.019
Prior or current smoker (Y vs. N)	141, 622	0.9 (0.6, 1.3)	0.530	1.0 (0.6, 1.5)	0.955	1.0 (0.7, 1.6)	0.916
RF (> vs. <=median of 52)	385, 374	0.9 (0.6, 1.2)	0.442	1.0 (0.7, 1.5)	0.822	1.1 (0.8, 1.5)	0.750
RF (>3x ULN vs. <=3x ULN)	440, 319	0.9 (0.6, 1.2)	0.401	1.1 (0.8, 1.5)	0.642	1.1 (0.8, 1.5)	0.667
RF (POS vs. NEG)	552, 207	1.1 (0.8, 1.5)	0.705	1.2 (0.8, 1.7)	0.458	1.1 (0.8, 1.6)	0.605

* N values are based on DAS28 endpoints, the N values for SDAI and CDAI were similar. †Statistics from logistic regression model of Week 36 DAS2/SDAI/CDAI remission with baseline predictor, baseline DAS28/SDAI/CDAI and geographic region. Categ=category; CRP=C-reactive protein; ULN=upper limit of normal; M=male; F=female; ESR=erythrocyte sedimentation rate; Y=yes; N=no; POS=positive; NEG=negative.

Conclusions: Younger age, lower HAQ and lower DAS28 at baseline may be significantly predictive of SDAI, CDAI, and DAS28 remission in patients with moderately active RA on combined ETN-MTX therapy. Baseline RF and anti-CCP levels were not predictive of remission. These data may help clinicians manage patients according to the current treatment guidelines and more effectively treat patients to remission.

Is Long-Term Etanercept Monotherapy Ever An Option in a Patient with Moderate to Severe Rheumatoid Arthritis (RA)? Roy M. Fleischmann[1], Michael H. Schiff[2], Deborah Wenkert[3], Bojena Bitman[4], Sandeep Chaudhari[5], Jie Liu[6], Grace S. Park[7] and Debra J. Zack[8]. [1]University of Texas Southwestern Medical Center and Metroplex Clinical Research Center, Dallas, TX, [2]Rheumatology Division, University of Colorado, Denver, CO, [3]Amgen, Thousand Oaks, CA, [4]Amgen Inc., South San Francisco, CA, [5]KForce Clinical Research, Tampa, FL, [6]SimulStat Incorporated, San Diego, CA, [7]Amgen Inc., Thousand Oaks, CA, [8]Amgen Inc, Thousand Oaks, CA

Background/Purpose: Methotrexate is recommended as first-line therapy in patients with early RA. An improvement in efficacy has been demonstrated for all currently available tumor necrosis factor (TNF) inhibitors when used in combination with methotrexate. For the TNF inhibitors infliximab and adalimumab, methotrexate not only increases the response rate to the agent, but also appears to play a role in its continued efficacy by suppressing the formation of anti-drug antibodies. There are patients, however, for whom methotrexate is not an option. Since neutralizing anti-drug antibodies have not been seen with etanercept treatment, we examined long-term efficacy data in patients with moderate to severe early RA on the subset of patients who chose to remain on etanercept monotherapy.

Methods: We analyzed data from the Early Rheumatoid Arthritis (ERA) clinical trial of etanercept and up to 9 years of its subsequent long-term open-label extension. In the ERA study, patients were randomized to receive etanercept 10 mg or 25 mg twice weekly (BID) or methotrexate; after 1 year, patients continued on treatment unblinded. The current analysis examined patients who received and continued on etanercept 25 mg BID. Outcome measures included rates of remission and low disease activity based on disease activity scores using the 28-jount count with C-reactive protein as the indicator of inflammation (DAS28) and Simple Disease Activity Index (SDAI) scores, and Health Assessment Questionnaire Disability Index (HAQ-DI) scores.

Results: Of 114 patients receiving etanercept monotherapy, 61 patients had chosen to continue etanercept monotherapy through year 9. No discernable baseline characteristics (age, sex, race, rheumatoid factor status, disease severity) distinguished the 61 patients for whom 9-year data regarding etanercept monotherapy was available from the 114 patients originally placed on etanercept monotherapy. Low disease activity was achieved by 1 year in 64.9% and 62.5% of patients by DAS28 and SDAI, respectively, with 45.6% and 14.3% in DAS28 and SDAI remission. At year 9, 67.3% and 61.8% had low disease activity by DAS28 and SDAI with 54.5% and 32.7% in remission, respectively. Although SDAI scores varied widely from visit to visit for individual patients, most patients in SDAI remission at year 9 had been in SDAI low disease activity or better at each time point starting from year 1 or 2. HAQ-DI scores improved from mean (standard deviation [SD]) score of 1.41 (0.70) at baseline to 0.65 (0.74) at 6 months. HAQ-DI scores had improved to scores associated with the general population (score ≤ 0.5) in 54.1% of patients at year 1 and in 55.7% of patients at year 9.

Conclusion: Although combination therapy is the treatment of choice, some patients with moderate to severe RA can derive persistent, significant clinical benefit for at least 9 years from etanercept monotherapy.

Efficacy and Safety of Certolizumab Pegol Plus Methotrexate in Japanese Rheumatoid Arthritis Patients with An Inadequate Response to Methotrexate. Kazuhiko Yamamoto[1], Tsutomu Takeuchi[2], Hisashi Yamanaka[3], Naoki Ishiguro[4], Yoshiya Tanaka[5], Katsumi Eguchi[6], Akira Watanabe[7], Hideki Origasa[8], Toshiharu Shoji[9], Yoshiharu Sakamaki[10], Nobuyuki Miyasaka[11] and Takao Koike[12]. [1]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [2]Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan, [4]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [5]University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan, [6]Sasebo City General Hospital, Sasebo, Nagasaki, Japan, [7]Institute of Development, Aging and Cancer, Tohoku University, Sendai, Miyagi, Japan, [8]University of Toyama School of Medicine, Toyama, Toyama, Japan, [9]Otsuka Pharmaceutical Co., Ltd, Shinagawa-ku, Tokyo, Japan, [10]UCB Inc, Chiyoda, Tokyo, Japan, [11]Graduate School of Medicine and Dentistry, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan, [12]Sapporo Medical Center NTT EC, Sapporo, Japan

Background/Purpose: Certolizumab pegol (CZP) as add-on therapy to methotrexate (MTX) provided rapid and sustained efficacy in RA patients (pts) in multiple international clinical trials.[1,2] The objective of

this study was to investigate the efficacy and safety of CZP + MTX in Japanese pts with active RA and an inadequate response to MTX.

Methods: In this 24-week (wk), Phase II/III, multicenter, double-blind, randomized, placebo-controlled, study (NCT00791999), Japanese pts with active RA and an inadequate response to MTX were randomized (1:1:1:1) to 1 of 4 treatment groups: CZP 100, 200, or 400 mg or placebo (PBO) + MTX every 2 wks (Q2W). Per study design, pts in the CZP groups received induction dosing with 200 mg (100 mg group) or 400 mg (200 and 400 mg groups) at Wks 0, 2, and 4. Pts who did not achieve an ACR20 response at Wks 12 and 14 were withdrawn from the study at Wk 16 and were eligible to enter an open-label extension study, as were pts completing the study. Primary efficacy end point was ACR20 response at Wk 12.

Results: A total of 316 pts were randomized. Demographic and baseline (BL) characteristics were similar between treatment groups: RA disease duration ranged from 5.6 to 6.0 years, DAS28(ESR) from 6.19 to 6.46, HAQ-DI from 1.12 to 1.19, and MTX dose from 7.4 to 7.6 mg/wk across groups. The primary end point was met; ACR20 and ACR50 response rates were significantly higher in each CZP group compared with PBO at Wks 12 and 24 (Table). Differences in CZP ACR20 response rates vs PBO were significant as early as Wk 1 and sustained to Wk 24. At Wk 24, mean radiographic progression from BL was reduced, and more pts were mTSS non-progressors in the CZP-treated groups vs PBO; differences seen with the 100 mg Q2W dose were not significant vs PBO. Improvements in all ACR core set of disease activity measures, including physical function, were observed as early as Wk 1 and were sustained to Wk 24 at all CZP doses. CZP was well tolerated and no new safety signals were identified. SAEs ranged from 4.2% to 5.9% in the CZP groups (with 4 pts developing serious infections or infestations) vs 1.3% in the PBO group. There were no cases of TB or deaths.

Table. Efficacy of CZP + MTX at Wks 12 and 24 in Japanese RA pts

	CZP 100 mg n=72	CZP 200 mg n=82	CZP 400 mg n=85	PBO n=77

mTSS,% non-progressors[d,e,f]	62.9[g]	74.1**	70.2**	47.4

[a] NRI. [b]LOCF. [c]p Value not calculated. [d]The actual number of subjects in the summaries varies slightly from n=316 due to nonimputable missing data for each parameter. [e]Lin ext. [f]mTSS non-progressor: mTSS change from BL score at WK 24 <0.5. [g]Not significant compared with PBO. LS = least square.
* p<0.001, **p<0.01 each CZP group vs PBO. ACR response, DAS28(ESR) remission rate, mTSS non-progressors and EULAR response was assessed by logistic regression. DAS28(ESR), HAQ-DI, pain VAS and mTSS LS mean change from BL were assessed by analysis of covariance (ANCOVA).

Conclusion: Treatment with CZP + MTX resulted in a rapid and sustained reduction in RA signs and symptoms, inhibited progression of structural joint damage, and improved physical function in Japanese RA pts with an inadequate response to MTX. The 200 mg Q2W maintenance dose showed numerically greater clinical efficacy and better inhibition of radiographic progression compared with the 100 mg Q2W dose. No additional benefit was observed with the 400 mg Q2W dose vs the 200 mg Q2W dose. These results confirm the findings of the RAPID studies[1, 2] and substantiate 200 mg Q2W as the optimal maintenance dosing for CZP.

Integrated Safety Summary of Modified-Release Prednisone and Immediate-Release Prednisone Comparing Doses ≤5mg/Day Versus >5mg/Day.

Frank Buttgereit[1], Jacek Szechinski[2], Gisela Doering[3], Stephan Witte[4], Christine Knauer[4], Amy Y. Grahn[5], Kenneth G. Saag[6] and Rieke Alten[7]. [1]Charité University Medicine, Berlin, Germany, [2]Wroclaw Medical University, Wroclaw, Poland, [3]Merck KgaA, Darmstadt, Germany, [4]Horizon Pharma GmbH, Mannheim, Germany, [5]Horizon Pharma, Inc., Northbrook, IL, [6]University of Alabama at Birmingham, Birmingham, AL, [7]Rheumatology Schlossparkklinik, Berlin, Germany

Background/Purpose: Glucocorticoid (GC) chronotherapy with a modified-release (MR) prednisone tablet enables programmed delivery of prednisone during the night to target the circadian pattern of inflammatory mediators. This therapeutic approach has demonstrated both clinically relevant reduction of morning stiffness compared to conventional, immediate-release (IR) prednisone, as well as improvement in ACR response criteria (Buttgereit *et al Lancet* 2008, Buttgereit *et al Ann Rheum Dis* 2010, Alten *et al J Rheumatol* 2010). Adverse effects related to GCs increase with dose and duration of treatment (Da Silva *et al Ann Rheum Dis* 2006). The data here describe the integrated safety summary for low-dose glucocorticoid therapy in patients from two phase 3 clinical studies.

Methods: The CAPRA studies investigated safety and efficacy of MR prednisone in patients with RA, not adequately controlled by disease-modifying antirheumatic drug (DMARD) therapy. The CAPRA-1 study compared MR prednisone (3–10 mg/d, average of 6.8 mg/d) to conventional IR prednisone over 12 weeks in 288 patients, the CAPRA-2 study compared 5 mg/d MR prednisone + DMARD to placebo (PBO) + DMARD over 12 weeks in 350 patients. MR prednisone or PBO was administered once daily in the evening; IR prednisone or PBO once daily in the morning. An open-label extension of CAPRA-1 provided safety data for up to 12 months. All Adverse Events (AEs) were collected in a standardized manner and categorized according to the dose of prednisone received during the study (≤5 mg/d or >5mg/d).

Results: Overall, 41.9% of MR prednisone patients, 39.6% of IR prednisone patients, and 48.7% of PBO patients reported a treatment emergent adverse event (TEAE) during the 12 week blinded period showing comparable safety of the different formulations. In the MR prednisone group, discontinuations due to any TEAE were higher for the >5 mg/d dose, with 9.7% of patients discontinuing compared to 2.2% of patients receiving ≤5 mg/d. In the IR prednisone group, 5.3% of patients receiving ≤5 mg/d discontinued due to any TEAE compared to 4.4% of patients receiving >5 mg/d. The incidence of TEAEs in descending frequency are shown in Table 1. Safety data for the open label phase were consistent and similar (not shown).

		MR Prednisone			IR Prednisone		
	PBO (N=119)	≤5 mg/d (N=313)	>5 mg/d (N=62)	Total (N=375)	≤5 mg/d (N=76)	>5 mg/d (N=68)	Total (N=144)
Mean Daily Dose (mg ± SD)	NA	4.86 ± 0.37	8.45 ± 1.49	5.46 ± 1.50	4.93 ± 0.34	8.59 ± 1.48	6.66 ± 2.11
Any Adverse Event	48.7%	43.1%	35.5%	41.9%	42.1%	36.8%	39.6%
Frequency by Severity							
Mild	29.4%	20.4%	8.1%	18.4%	18.4%	16.2%	17.4%
Moderate	15.1%	20.8%	22.6%	21.1%	19.7%	19.1%	19.4%
Severe	4.2%	1.9%	4.8%	2.4%	3.9%	1.5%	2.8%
Preferred Term							
Rheumatoid arthritis flare	26.1%*	14.4%	4.8%	12.8%	11.8%	7.4%	9.7%
Nasopharyngitis	3.4%	4.8%	1.6%	4.3%	6.6%	4.4%	5.6%
Abdominal pain upper	1.7%	1.6%	1.6%	1.6%	7.9%	2.9%	5.6%
Headache	4.2%	4.5%	1.6%	4.0%	3.9%	2.9%	3.5%
Vertigo	0%	1.3%	0%	1.1%	3.9%	2.9%	3.5%

*p=0.0137 PBO versus MR prednisone; all other comparisons are nonsignificant; NA = not applicable, SD = standard deviation

Conclusion: Safety findings from the 12 week blinded period were similar between MR prednisone and PBO or IR prednisone, demonstrating that the MR formulation does not adversely impact the known safety profile of the active ingredient. MR Prednisone has been shown to be more effective than IR prednisone and PBO with regard to standard RA outcome parameters. Taken together, these data support that MR prednisone may improve the benefit/risk ratio of long-term low-dose GC treatment in patients with RA on standard DMARD therapy.

Efficacy and Safety of Certolizumab Pegol without Methotrexate Co-Administration in Japanese Patients with Active Rheumatoid Arthritis. Kazuhiko Yamamoto[1], Tsutomu Takeuchi[2], Hisashi Yamanaka[3], Naoki Ishiguro[4], Yoshiya Tanaka[5], Katsumi Eguchi[6], Akira Watanabe[7], Hideki Origasa[8], Koichi Iwai[9], Yoshiharu Sakamaki[10], Nobuyuki Miyasaka[11] and Takao Koike[12]. [1]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [2]Keio University School of Medicine, Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [4]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [5]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [6]Sasebo City General Hospital, Sasebo, Nagasaki, Japan, [7]Institute of Development, Aging and Cancer, Tohoku University, Sendai, Miyagi, Japan, [8]University of Toyama School of Medicine, Toyama, Toyama, Japan, [9]Otsuka Pharmaceutical Co., Ltd, Shinagawa-ku, Tokyo, Japan, [10]UCB Inc, Chiyoda, Tokyo, Japan, [11]Tokyo Medical and Dental University, Tokyo, Japan, [12]Sapporo Medical Center NTT EC, Sapporo, Japan

Background/Purpose: Certolizumab pegol (CZP) as monotherapy or as add-on to methotrexate (MTX) provided rapid and sustained efficacy in RA patients (pts) in international clinical trials.[1–3] The objective of this study was to investigate efficacy and safety of CZP in Japanese pts with active RA in whom MTX could not be administered.

Methods: In this 24-week (wk), Phase III, double-blind, randomized, placebo-controlled study (NCT00791921), pts were randomized to CZP 200 mg (following induction dosing of 400 mg at Wks 0, 2, and 4) or placebo (PBO) every 2 wks. Pts not achieving ACR20 at Wks 12 and 14 withdrew at Wk 16 and were eligible to enter an open-label extension, as were pts completing the study. Primary efficacy endpoint was ACR20 at Wk 12. ACR20 response rates and radiographic progression were also investigated in subgroups of pts receiving CZP monotherapy or concomitant DMARDs.

Results: Demographic and baseline (BL) characteristics of the 230 randomized pts were similar between CZP and PBO groups: mean RA disease duration 5.4 and 5.8 y, mean HAQ-DI 1.05 and 1.21, mean DAS28(ESR) 6.09 and 6.30, respectively. At BL, 53.4% of CZP pts (vs 57% PBO pts) received concomitant DMARDs and 46.6% received CZP monotherapy. The primary endpoint was met; ACR20 and ACR50 responses were significantly higher in all CZP groups vs PBO at Wks 12 and 24 (Table). Significant differences in ACR20 responses were seen as early as Wk 1 and sustained to Wk 24. At Wk 24, mean radiographic progression from BL was reduced and more pts were mTSS non-progressors in the CZP group (Table). At Wk 12, ACR20 responses were higher in CZP pts either on monotherapy or with concomitant DMARDs, with similar treatment differences of 51.1 points and 54.2 points, respectively (CZP vs PBO: monotherapy, 59.3% vs 8.2%; concomitant DMARDs, 74.2% vs 20.0%). Preliminary post-hoc analyses showed that at Wk 24, CZP significantly inhibited radiographic progression when administered as monotherapy (mTSS mean change from BL: 3.65 PBO vs 0.68 CZP, p=0.0087) or with concomitant DMARDs (mTSS mean change from BL: 1.61 PBO and CZP 0.24, p=0.001). CZP was well tolerated with no new safety signals. 11.2% of CZP pts experienced SAEs vs 2.6% in PBO (with 4 and 1 pts developing serious infections or infestations, respectively). There was 1 death in the CZP group and no cases of TB.

Table. Efficacy of CZP at Wks 12 and 24 in Japanese RA pts

	CZP 200 mg n=116	PBO n=114
Wk 12		
ACR20,% responders[a]	67.2*	14.9
ACR50,% responders[a]	37.9*	6.1
ACR70,% responders[a]	19.0[c]	0.0
DAS28, LS mean change from BL (SE)[b]	−2.01 (0.10)*	−0.29 (0.10)
HAQ-DI, LS mean change from BL (SE)[b]	−0.47 (0.05)*	0.03 (0.05)
Pain VAS, LS mean change from BL (0–100 mm) (SE)[b]	−26.4 (1.9)*	−1.9 (2.0)
DAS28 (ESR) remission rate[b],%	13.8**	0.9
Moderate or good EULAR response[b],%	82.7[c]	28.1
Wk 24		
ACR20,% responders[a]	63.8*	11.4
ACR50,% responders[a]	46.6*	6.1
ACR70,% responders[a]	25.9*	0.9
DAS28, LS mean change from BL (SE)[b]	−2.06 (0.12)*	−0.21 (0.12)
HAQ-DI, LS mean change from BL (SE)[b]	−0.48 (0.05)*	0.12 (0.05)
Pain VAS, LS mean change from BL (0–100 mm) (SE)[b]	−27.5 (2.1)*	−1.2 (2.1)
DAS28(ESR) remission rate[b],%	16.4**	0.9
Moderate or good EULAR response[b],%	77.6[c]	22.0
mTSS, LS mean change from BL (SE)[d,e]	0.48 (0.38)*	2.45 (0.38)
mTSS non-progressors,% responders[d,e,f]	76.3*	45.6

[a] NRI. [b]LOCF. [c]p Value not calculated. [d]The actual number of subjects in the summaries varies slightly from n=316 due to nonimputable missing data for each parameter. [e]Lin ext. [f]mTSS non-progressor: mTSS change from BL score at Wk 24 ≤0.5. LS = least square.
* p<0.001, **p<0.01, CZP vs PBO.
ACR response, DAS28(ESR) remission rate, mTSS non-progressors and EULAR response were assessed by logistic regression. DAS28(ESR), HAQ-DI, Pain VAS, and mTSS LS mean change from BL were assessed by analysis of covariance.

Conclusion: Treatment with CZP in Japanese RA pts in whom MTX could not be administered resulted in rapid and sustained improvement of RAsigns and symptoms, inhibited progression of structural joint damage, and ameliorated physical function. Efficacy and radiographic results were consistent regardless of use of concomitant DMARDs; notably, CZP showed significant inhibition of radiographic progression when used as monotherapy.

Dose Escalation Among Rheumatoid Arthritis Patients Treated with Infliximab or Abatacept: Comparison in Claims Data. Theodore Darkow[1], Benjamin Chastek[2], Lisa Rosenblatt[1], Digisha Trivedi[1], Tony Hebden[1], Henry Henk[2] and Fang Liu[2]. [1]Bristol-Myers Squibb, Plainsboro, NJ, [2]Innovus, an Optum Insight Company, Eden Prairie, MN

Background/Purpose: Published studies have documented dose escalation of infliximab in rheumatoid arthritis (RA) patients. We have previously demonstrated that abatacept-treated patients were significantly less likely to experience dose escalation than patients on infliximab[1].

Objectives: To determine whether previous findings of dose escalation with infliximab versus abatacept were reproducible in claims data using a larger sample size and longer follow-up.

Methods: Claims-based analysis of commercial enrollees of a large, US-managed care plan was conducted to examine treatment patterns among adult patients with RA. The identification period was January 1, 2006 through August 31, 2010. Patients newly initiated on infliximab or abatacept who had at least five infusions were included. Patients with evidence of other indications for biologic treatment (e.g. psoriasis) were excluded. Continuous plan enrollment for 6 months before initiation through the fifth infusion was required. Patients were followed until plan disenrollment, treatment termination, or August 31, 2010. Dose escalation was defined as two or more increases in either dose amount or frequency following the third infusion.

Results: A total of 1198 patients initiating infliximab and 799 patients initiating abatacept were identified, with a mean follow-up time of 477 and 275 days, respectively. The average increase in number of infused vials between the first and last infusion was 1.30 for the infliximab cohort and 0.12 for the abatacept cohort (p<0.001). The proportion of infliximab patients who experienced dose escalation during the follow-up period was 70.7%, with 56.6% having an increase in dose amount and 51.9% having an increase in frequency. In contrast, only 11.3% of the abatacept cohortexperienced escalation, with 10.5% having an increase in dose amount and 1.1% having an increase in frequency (p<0.001 for all comparisons). On average, time to first dose escalation did not differ between the two treatment groups (143.4 vs 149.0 days; p=0.68). Risk of escalation remained substantially lower for abatacept patients after controlling for patients' demographic and clinical characteristics in a multivariate survival model (hazard ratio=0.115; p<0.001).

Conclusion: The majority of patients treated with infliximab experienced dose escalation, whereas significantly fewer patients treated with abatacept had evidence of escalation. Furthermore, the escalation in dose seen with abatacept was relatively minor compared with that observed with infliximab and was consistent with previous analyses[1].

The Effectiveness of Abatacept in a Large Rheumatoid Arthritis Real World Practice: Changes in the HAQ Over Time and Durability of Response. Janet E. Pope[1], Emmanouil Rampakakis[2], John S. Sampalis[2] and Olivier Desjardins[3]. [1]St. Joseph's Health Care, University of Western Ontario, London, ON, [2]McGill University & JSS Medical Research, Montreal, QC, [3]Bristol Myers Squibb Canada, St. Laurent, QC

Background/Purpose: A large Canadian database was used to determine effectiveness of abatacept in real world RA patients by examining changes in health assessment questionnaire (HAQ), and the proportion of patients continuing abatacept over time.

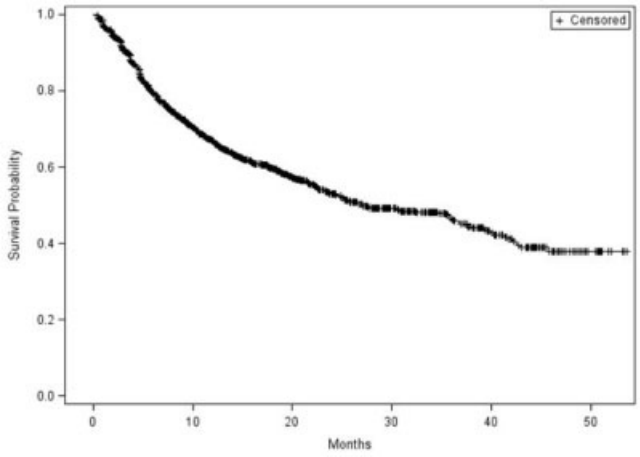
Methods: RA patients administered abatacept in routine practice via the Orencia Response Program network, between Aug. 2006 and Feb. 2011 who

received clinic or home infusions and had at least one follow-up evaluation were included. The number needed to treat (NNT) to improve HAQ by at least the minimally important difference (MID ≥ 0.22) and abatacept survival until last follow up were calculated overall, and for those post DMARD and post TNFi.

Results: Among the 2,929 patients enrolled, 1,771 (60.5%) were eligible for the study (mean age 57.6 years; disease duration 16.5 years (SD 11.0), 77% female, 79.2% had past TNFi) with a mean (SD) follow up of 13.8 (12.3) months. Mean (SE) durability of treatment was 26.8 (0.53) months; where 66% were still on abatacept at 12 and 53% at 24 months (Figure 1). The survival was longer where abatacept was the first biologic vs. post TNFi (P=0.0001) (Figure 1). In abatacept as 1st biologic, 70% achieved MID in HAQ vs. 71% if post TNFi (P=0.65) with NNT=1.4 in each group and there were also no differences in% achieving MID comparing no past biologic to 2, 3 or 4 pervious biologics. For those staying on abatacept, the mean improvement in HAQ increased over time; changing at 6,12, 18 and 24 months by −0.29, −0.41, −0.45 and −0.51 respectively with no difference between abatacept as first biologic vs. post TNFi (Table 1). Increased baseline HAQ (OR 2.13 (1.89, 2.39)) and less years of RA (OR 0.98 (0.97, 0.99)) were significant predictors of achieving the MID for HAQ.

Table 1. Characteristics and Patient Disposition

Parameter		Post DMARD N=369	Post TNFi N=1,402	Total Cohort N=1,771	P-Value	
Mean (SD) Age (years)			58.80 (13.65)	57.28 (13.10)	57.60 (13.23)	0.0496
Mean (SD) Time Since Diagnosis (years)			13.25 (10.83)	17.36 (10.92)	16.53 (11.02)	<0.001
Female Gender: n (%)			260 (70.46)	1,107 (78.96)	1,367 (77.19)	<0.001
Disease Severity: n (%)	Mild		1 (0.27)	4 (0.29)	5 (0.28)	0.736
	Moderate		22 (5.96)	104 (7.42)	126 (7.11)	
	Severe		346 (93.77)	1,291 (92.08)	1,637 (92.43)	
	NA		0 (0.00)	3 (0.21)	3 (0.17)	
Baseline HAQ			1.45 (0.71)	1.72 (0.69)	1.66 (0.70)	<0.001
	12 Months		−0.34 (0.66)	−0.43 (0.67)	−0.41 (0.67)	0.207
	24 Months		−0.48 (0.70)	−0.52 (0.70)	−0.51 (0.70)	0.786
	36 Months		−0.36 (0.69)	−0.60 (0.71)	−0.58 (0.71)	0.297
Mean (SD) Durability of Treatment			26.12 (0.86)	25.75 (0.58)	26.79 (0.53)	<0.001
% on Abatacept (Survival Estimate)	12 Months		74	64	66	
	24 Months		65	50	53	
	36 Months		56	43	46	



Parameter	Value
Total N	1,771
N (%) Failed	672 (37.94)
N (%) Censored	1,099 (62.06)
Mean (SE) Durability of Treatment (months)	26.79 (0.53)

Figure 1. Overall Durability of Abatacept

Conclusion: The results demonstrate that abatacept is effective in improving function in RA despite long disease duration. For those still on abatacept, HAQ continued to improve over the first 2 years. The real world durability of abatacept is better as first biologic; however the overall survival in this large study seems similar to other biologics despite 79% having previous TNFi exposure.

Drug Survival and Long-Term Dose Comparison of Etanercept and Infliximab in Rheumatoid Arthritis Patients. Brian D. Hanna[1] and Alpesh Shah[2]. [1]McMaster University, Ontario, Kitchener, ON, [2]Community Rheumatology Clinic, Etobicoke, ON

Background/Purpose: Reports from observational studies show that anti-TNF drug adherence rates in rheumatoid arthritis are higher for etanercept compared with infliximab. Clinical practice shows that not all rheumatoid arthritis patients respond to the 3 mg/kg dose of infliximab, leading some rheumatologists to use higher doses and/or reduce the dosing interval for infliximab. The purposes of this study are: 1) to compare dosing patterns and drug survival rates of etanercept and infliximab, and 2) to compare the initial dose with the optimal, any escalated and the last dose administered for infliximab in rheumatoid arthritis patients in a community based practice.

Methods: This study is a retrospective analysis of rheumatoid arthritis patients treated between June 2000 and December 2010 at community rheumatology clinic, starting treatment with either infliximab or etanercept, as a first biologic agent. Information was collected on age, sex, diagnosis, disease duration, previous and ongoing DMARDs, biologic dose, treatment start and termination dates as well as cause of withdrawal. Treatment groups were compared by baseline characteristics, dosing patterns and drug survival. The overall drug survival was compared using survival data with Kaplan-Meier plots. An optimal dose for infliximab was identified as the dose raised in mg/kg or a decrease in dosing interval by six months of treatment to achieve adequate response.

Results: A total of 116 patients (etanercept: 79 and infliximab: 37) were included in the analysis. All etanercept-treated patients were maintained with 50 mg per week therapy. Mean optimal dose of infliximab was 4.23 ± 1.29 mg/kg and majority of them given at every 8 week interval. Subsequently, 51.4% patients in the infliximab group required dose escalation to 4.51 ± 1.14 mg/kg. Of these, majority (73.8%) patients required infliximab at every 6 week intervals. Median drug survival time for the etanercept group was 58 months, for the infliximab group at optimal doses was 27 months and for the optimal plus escalated doses was 88 months.

Conclusion: In this study of real-world patients half of the patients in the infliximab group required dose escalation. Drug survival rate was higher with etanercept and the escalated infliximab groups compared with infliximab at initial and optimal doses over ten years of follow-up.

1224

Remission According to Different Composite Disease Activity Indices in Biologic-naïve Patients with Rheumatoid Arthritis Treated with Abatacept or Infliximab Plus Methotrexate. Josef S. Smolen[1], Maxime Dougados[2], Corine Gaillez[3], Coralie Poncet[4], Manuela Le Bars[3], Monica Mody[5] and Michael H. Schiff[6]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Hôpital Cochin, Paris, France, [3]Bristol-Myers Squibb, Rueil Malmaison, France, [4]Docs International, Sévres, France, [5]Bristol-Myers Squibb, Princeton, NJ, [6]University of Colorado, Denver, CO

Background/Purpose: Levels of acute phase reactants correlate with clinical disease activity in rheumatoid arthritis (RA)[1], and are weighted differently—or not included—in the calculation of disease activity indices such as SDAI, CDAI and DAS28. Biologics with different mechanisms of action (TNF blockers, anti-IL6 agent, T-cell costimulation modulator) may impact both acute phase reactants and disease activity measures differently[2]. We evaluated remission using the new definition of remission according to ACR/EULAR[3] versus DAS28-defined remission in RA patients (pts) treated with abatacept, infliximab or placebo plus MTX in the ATTEST trial, and investigated the contributions of the different core components.

Methods: In ATTEST, biologic-naïve pts with RA and an inadequate response to MTX were randomized to abatacept (~10 mg/kg every 4 wks), infliximab (3 mg/kg every 8 wks), or placebo (every 4 wks), plus MTX[4]. Remission according to DAS28 (CRP), SDAI and CDAI at Month 6 were evaluated for abatacept- infliximab- and placebo-treated pts, with missing data imputed by LOCF; SDAI and CDAI were evaluated post-hoc. Cut-offs for remission were <2.6 for DAS28; ≤3.3 for SDAI; and ≤2.8 for CDAI. Mean scores (with SD) from baseline at Month 6 in individual disease activity measures were assessed for pts in remission at Month 6.

Results: Baseline demographics and clinical characteristics were comparable between groups[4]. Mean (SD) DAS28, SDAI and CDAI scores, respectively, were 6.4 (0.9), 48.8 (13.2) and 45.7 (12.2) for abatacept, 6.4 (0.9), 48.4 (13.1) and 45.1 (12.3) for infliximab, and 6.3 (0.8), 48.3 (12.0) and 45.6 (11.2) for placebo. At Month 6, similar treatment effects for remission were observed for abatacept and infliximab, independent of indices used (Table). Among abatacept-treated pts in DAS28 remission, 46.7 and 56.7% also achieved SDAI and CDAI remission, respectively, compared with 43.6 and 43.6% of infliximab-treated pts. In patients reaching remission at Month 6, mean scores for core components, including ESR and CRP, were generally similar between the two active treatment arms (Table), although numerically lower SJC were seen with abatacept versus infliximab for patients in DAS28 remission.

	Abatacept, n=156			Infliximab, n=165			Placebo, n=110		
	DAS28	SDAI	CDAI	DAS28	SDAI	CDAI	DAS28	SDAI	CDAI
Remission at Month 6, n (%)*	30 (19.2)	14 (9.0)	18 (11.5)	39 (23.8)	17 (10.4)	20 (12.2)	6 (5.5)	4 (3.6)	5 (4.5)
95% CI	13.0–25.4	4.5–13.5	6.5–16.6	17.3–30.3	5.7–15.0	7.2–17.2	1.2–9.7	1.0–9.0	0.7–8.4
Mean (SD) scores at Month 6 for patients in remission									
SJC	0.3 (0.6)	0.2 (0.6)	0.2 (0.6)	1.0 (1.4)	0.2 (0.6)	0.2 (0.4)	1.7 (2.3)	0.3 (0.5)	0.2 (0.5)
TJC	0.2 (0.4)	0.1 (0.4)	0.2 (0.4)	0.3 (0.7)	0.1 (0.2)	0.2 (0.4)	0.0 (0.0)	0.3 (0.5)	0.4 (0.6)
PGA	12.4 (12.5)	5.0 (5.8)	6.4 (7.2)	13.6 (12.3)	6.5 (4.7)	7.3 (6.2)	9.2 (5.5)	7.0 (7.4)	6.6 (6.4)
EGA	8.3 (8.0)	3.2 (2.7)	3.5 (3.0)	8.7 (9.9)	3.8 (2.4)	3.4 (2.1)	10.7 (8.2)	5.0 (6.7)	4.8 (5.8)
ESR	21.2 (9.9)	17.9 (10.4)	19.6 (11.2)	26.6 (19.7)	27.5 (24.0)	30.8 (22.2)	33.3 (30.4)	41.0 (36.1)	51.2 (38.7)
CRP	7.9 (6.6)	6.8 (7.7)	14.4 (26.8)	5.3 (4.6)	4.9 (3.4)	9.2 (12.0)	9.2 (3.9)	9.8 (1.5)	12.3 (5.8)

CI=confidence intervals; SD=standard deviation; DAS28=Disease Activity Score 28; SDAI=simplified disease activity index; CDAI=clinical disease activity index; SJC=swollen joint count; TJC=tender joint count; PGA=patient global assessment; EGA=evaluator global assessment; ESR=erythrocyte sedimentation rate; CRP=C-reactive protein

Conclusion: Remission rates at Month 6 were similar for abatacept and infliximab, irrespective of the type of composite measure used. This remained true when more stringent remission criteria, such as SDAI, were applied. Furthermore, mean TJC and SJC for abatacept-treated patients in DAS28 remission were similar to patients in SDAI and CDAI remission, suggesting that these patients are not experiencing residual disease activity as has been seen for patients in DAS28 remission treated with other biologics[2].

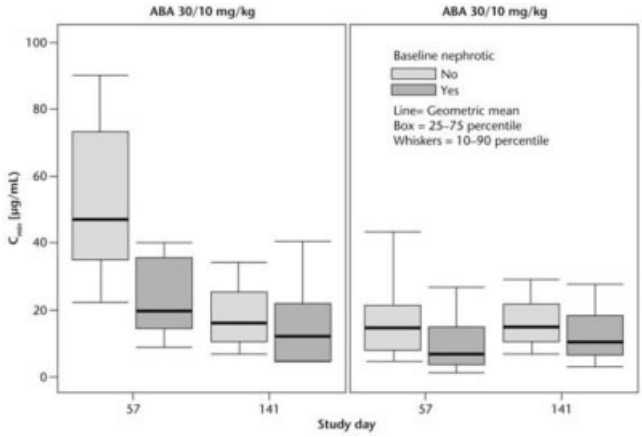
Pharmacokinetics of IV Abatacept in Systemic Lupus Erythematosus Patients with Active Proliferative Glomerulonephritis. Michael Tagen[1], Blisse Vakkalagadda[1], Neelima Thanneer[1], Stephanie Meadows-Shropshire[1], Martin Ullmann[1], Robert Wong[1], Richard Aranda[2] and Bindu Murthy[1]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb [at time of study], Princeton, NJ

Background/Purpose: Results from a dose-ranging study of abatacept (ABA) in systemic lupus erythematosus (SLE) patients (pts) with active proliferative glomerulonephritis (PGN) showed a larger reduction in urinary protein:creatinine ratio (UPCR) in nephrotic pts treated with ABA versus placebo[1]. Limited studies have shown differences in exposure to biologics due to renal damage in non-lupus pts[2,3]; therefore, the relationship between proteinuria and ABA systemic exposure was examined. We describe the pharmacokinetics of IV ABA in pts with active PGN due to SLE and evaluate the association with baseline nephrotic status (UPCR >339 mg/mmoL).

Methods: In Study IM101075, lupus nephritis pts with active PGN (UPCR ≥50 mg/mmoL) were randomized to receive placebo (n=100) or one of two IV ABA regimens: either 3 mths of ABA 30 mg/kg followed by ABA ~10 mg/kg for 9 mths (30/10; n= 99), or ~10 mg/kg for the entire 12 mths (10/10; n= 99). Mean (standard deviation [SD]) glomerular filtration rates at screening were 85 ± 36, 92 ± 36, and 88 ± 31 mL/min and mean (SD) UPCR values were 446 ± 381, 483 ± 954, and 403 ± 329, for the ABA 30/10, ABA 10/10, and placebo groups. A validated enzyme-linked immunosorbant assay (ELISA) was used to determine serum ABA concentrations. Measures of systemic exposure to ABA (maximum observed concentration [C_{max}], area under the concentration–time curve [AUC], and trough concentration [C_{min}]) were derived by model-independent analysis.

Results: Systemic exposure to ABA was 3-fold higher for the first 3 mths in the 30/10 regimen group compared with the 10/10 regimen group, demonstrating linear pharmacokinetics. After transitioning from 30 mg/kg to 10 mg/kg on Day 57, systemic exposure in the 30/10 group was comparable to that of the 10/10 regimen group by Day 141. Pts who were nephrotic at baseline (34% of ABA-treated pts) had 2.2-fold lower geometric mean C_{min} values at Day 57 (Figure) and 1.2-fold lower geometric mean AUC values than pts who were not nephrotic at baseline, suggesting that nephrotic pts clear ABA more rapidly. C_{max} values were similar in nephrotic and non-nephrotic pts, suggesting that distribution volume was not affected by renal damage. Pts who were nephrotic at baseline, but had improvement in proteinuria, had corresponding increases in ABA C_{min} values.



Conclusion: ABA systemic exposure is lower in nephrotic pts due to increased clearance secondary to active PGN. Nephrotic pts showed better improvement in UPCR compared with non-nephrotic pts despite having lower ABA exposure. Although these results were unexpected, they suggest that clinical response may be related to other factors besides ABA exposure in SLE pts with active PGN. Further investigation is needed to understand if this observation is due to different therapeutic trough levels or other factors.

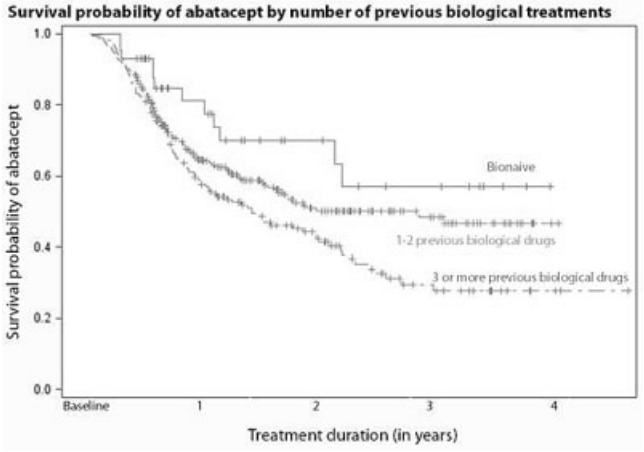
Clinical Effect of Abatacept in Patients with Rheumatoid Arthritis, Data From the Swedish Rheumatology Quality Registry. Ralph Nisell[1], Leszek Stawiarz[2] and Staffan Lindblad[1]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institutet and Carmona AB, Stockholm/Halmstad, Sweden

Background/Purpose: Abatacept is a biological T-cell modulation therapy used in RA. Data on diagnosis, preceding treatment as well as the reason for the discontinuation of the preceding treatment was derived from the Swedish Rheumatology Quality Registry.

Methods: Observational data from the Swedish Rheumatology Quality Registry was collected for the period from April 2006 to May 2011. Survival analysis (Kaplan Meier curves) with right censoring and log-rank test of equality across strata was performed. Comparisons between all pairs of curves (all strata) with Tukey-Kramer multiple-comparison adjustments were made.

Results: There were 606 patients started abatacept treatment from Apr 2006 to Dec 2010. Regarding the 473 RA patients (367 females or 78%), median and interquartile range of age at start of abatacept was 60 years (52–66) and median disease duration was 11 years (6–19). Median time since first given biological treatment to abatacept start was 3.3 years (1.3–6.3).

Abatacept was given as first biological treatment in 44 patients (9%), after one or two previous biological treatments in 263 (55%) patients, after three or more biological treatments in 167 (36%). Survival probability of abatacept in these groups is shown in Figure 1. After 1, 2 and 3 years drug survival was 78%, 70% and 57% respectively in bio-naïve patients, 64%, 50% and 49% in patients with 1–2 previous biological treatment and 57%, 41% and 29% in patients with 3 or more previous biological treatments. Bio-naïve patients had significantly longer drug survival time than patients with 3 or more previous treatments (p=0.0065), and patients with 1–2 previous biological treatments had longer drug survival time than patients with 3 or more previous treatments.



DAS28 was measured before treatment and after 3, 6 and 12 months of treatment. A per-protocol analysis was used. There was significant reduction of DAS28 at all time points compared with baseline. Median DAS28 at baseline was 5.5, at 3 months 4.5, at 6 months 4.3 and at 12 months 3.9. The effect of abatacept expressed in DAS28 was significantly better in men than in women at all time points except for 6 months. There was a significant tendency towards a longer drug survival in men compared to women (p=0.05). At 1, 2 and 3 years respectively drug survival was 69%, 57%, 52% in men and 61%, 46%, 37% in women.

Conclusion: In this cohort of 473 RA patients starting abatacept treatment during a time period of four years, drug survival time was longer for bio-naïve patients compared to patients treated with previous biological drugs. There was seen a gender difference in abatacept treatment outcome in favour of men.

1227

Sustained Clinical Response with Golimumab Administered Subcutaneously Every 4 Weeks in Ankylosing Spondylitis: 104-Week Results of a Randomized, Placebo-Controlled Study. Jürgen Braun[1], Desiree van der Heijde[2], Atul Deodhar[3], Anna Beutler[4], Michael Mack[4], Benjamin Hsu[5] and Robert D. Inman[6]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Oregon Health & Science University, Portland, OR, [4]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA, [5]Centocor R&D, a division of J&J Pharmaceutical R& D, LLC/Univ. of Pennsylvania, Malvern/Philadelphia, PA, [6]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON

Background/Purpose: The results through wk24 of the GO-RAISE study indicated that golimumab (GLM) significantly improved the signs and symptoms of ankylosing spondylitis (AS) vs. placebo (PBO). The purpose of this study was to assess the long-term clinical efficacy of GLM over 104 wks in pts with active AS who did and did not exhibit clinical improvement at wk24.

Methods: Pts (n=356) were randomly assigned (1:1.8:1.8) to subcutaneous injections of PBO, GLM 50 mg, or GLM 100 mg q4wks. At wk16, pts in the PBO or 50-mg groups with <20% improvement in both total back pain and morning stiffness entered early escape (EE) to GLM 50 or 100 mg, respectively. At wk24, patients still receiving PBO crossed over (CO) to GLM 50 mg. Among the subgroups of pts defined by clinical efficacy observed at wk24 (Yes vs. No for the individual variables, see Table), the proportions of pts achieving Assessment of SpondyloArthritis International Society (ASAS) partial remission (value < 2 on each of four 0- to 10-cm ASAS domains), AS Disease Activity Score based on C-reactive protein (ASDAS-CRP) remission (score <1.3), ASDAS-CRP major responder (decrease ≥2 from baseline), and ≥50% improvement from baseline in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50) were determined at wk104.

Results: After wk24 all pts were receiving GLM 50 or 100 mg. Among pts who demonstrated clinical improvement at wk24, the vast majority maintained their response to GLM through week 104, i.e., 88% of wk24 responders for ASAS partial remission, 91% of pts for ASDAS-CRP remission, 86% of pts for ASDAS-CRP major response, and 89% of pts for BASDAI50 response. No differences in wk104 response were observed among the randomized treatment groups (Table). Among pts who had not achieved clinical improvement at wk24, 22%, 29%, 27% and 44% of pts achieved ASAS partial remission, ASDAS-CRP remission, ASDAS-CRP major response, and BASDAI50 response, respectively at wk104. Among these wk24 nonresponders, the highest wk104 response rates were observed in pts who initially received PBO but EE/CO to GLM at wk16/24 (Table).

Table. Clinical response at wk104 by wk24 response status.

Responder at wk24	PBO	GLM 50&100 mg combined	All patients
ASAS partial remission (n=77)	88.9% (8/9)	88.2% (60/68)	88.3% (68/77)
ASDAS-CRP remission (n=106)	93.3% (14/15)	90.1% (82/91)	90.6% (96/106)
ASDAS-CRP major response (n=72)	85.7% (6/7)	86.2% (56/65)	86.1% (62/72)
BASDAI50 response (n=149)	86.4% (19/22)	89.8% (114/127)	89.3% (133/149)
Nonresponder at wk24			
ASAS partial remission (n=208)	30.8% (16/52)	18.6% (29/156)	21.6% (45/208)
ASDAS-CRP remission (n=158)	52.4% (22/42)	19.8% (23/116)	28.5% (45/158)
ASDAS-CRP major response (n=203)	40.4% (21/52)	21.9% (33/151)	26.6% (54/203)
BASDAI50 response (n=139)	65.9% (27/41)	34.7% (34/98)	43.9% (61/139)

Conclusion: Clinical response that was achieved by patients receiving golimumab through 24wks was sustained through wk104. In addition 22–35%of patients who had not yet responded well by week 24 to golimumab treatment acquired benefit later in the course of treatment.

1228

Fatigue and Morning Stiffness Are Correlated in Early Arthritis and Both Are Substantially Improved by Glucocorticoids. Gisela Westhoff[1], Angela Zink[2] and Frank Buttgereit[3]. [1]German Rheumatism Research Center Berlin, Berlin, Germany, [2]Deutsches Rheumaforschungszentrum and Charité University Medicine, Berlin, Germany, [3]Charité University Medicine, Berlin, Germany

Background/Purpose: Morning stiffness (MS) in rheumatoid arthritis (RA) is considered to be causally related to the circadian rhythms of pro-inflammatory factors and is ameliorated by glucocorticoids (GC). In contrast, the pathophysiology of fatigue, a similarly frequent and debilitating RA symptom, is still not well understood. We therefore investigated the association between MS and fatigue in patients with early arthritis and delineated the effects of GC on both manifestations.

Methods: Baseline data of 516 patients of an early arthritis inception cohort (disease duration <26 weeks, μ 13 ±8) were used. Morning stiffness was measured as duration (minutes) and severity (NRS 0–10). Dimensions of fatigue were assessed by the PROFAD items 'need rest', 'poor starting', 'low stamina', 'weak muscles' and 'poor concentration' (NRS 0–10). The patients with no GC, GC to be started and GC ≥1 week were compared with respect to the severity of MS and fatigue. The effects were adjusted for serological and immunological parameters, tender and swollen joint counts (0–28) and the duration under DMARDs (just started vs. ≥1 week).

Results: All patients were clinically diagnosed with either RA or undifferentiated arthritis (definite RA 56.1%, probable RA 36.1%, uA 7.8%) and 69.1% were classified as RA by the new ACR/EULAR RA classification criteria. 62% had just started a DMARD therapy with only 4% taking DMARDs for a week or more. 22% had oral GC (μ 16 mg/d, median 10) for at least one week (μ 2.7 ±3 weeks) and another 44% were designated to start GC. The patient-reported fatigue score (0–50) was significantly correlated with the physician-reported duration of MS (r = 0.246; P <0.001) and patient-reported severity of MS (r = 0.514, P <0.001) but was at the utmost weakly correlated with acute phase reactants and joint counts. Patients without GC yet and those designated to start GC were comparable in all measures considered, whereas patients taking GC for a week or more reported substantially less severe MS and fatigue, particularly less severe problems with "it is being hard to get going, things taking an effort or are a battle". Multivariate logistic regression analysis with below average-fatigue (PROFAD score ≤12) as target variable revealed that patients with GC for at least one week reported twice as likely low fatigue severity (adjusted OR 2.10, 95% CI 1.30–3.40; P = 0.002). Age, sex, diagnoses, blood parameters, joint counts and duration under DMARDs were not associated with the binary fatigue severity score.

Morning stiffness and fatigue by glucocorticoid therapy at baseline

	n	MS duration minutes	MS severity 0–10 phys.	MS severity 0–10 pts.	Need rest	Poor starting	Low stamina	Weak muscles	Poor concentration
No GC	174	58	4.1	5.2	3.6	3.6	2.9	3.4	2.4
GC to be started	226	77	4.8	6.1	3.9	4.2	3.0	3.6	2.5
GC >1 week	116	66	3.9	4.0	2.5	2.5	2.1	2.5	1.8
Total	516	68	4.4	5.3	3.5	3.6	2.9	3.3	2.3
P		0.011	0.007	<0.001	<0.001	0.002	0.003	0.075	

Conclusion: Our data indicate an association between MS and several dimensions of patient-reported fatigue. Since both RA manifestations are inter-correlated and ameliorated by GC, a common pathophysiology is suggested that may contribute to the understanding and treatment of fatigue in inflammatory arthritis.

1229

Different Remission Definitions Capture Different Proportions of Patients with Rheumatoid Arthritis Treated in Clinical Practice. Till Uhlig[1], Elisabeth Lie[1], Cecillie Kaufmann[2], Erik Rodevand[3], Knut Mikkelsen[4], Synnøve Kalstad[5] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Buskerud Central Hospital, Drammen, Norway, [3]St. Olav Hospital, Trondheim, Norway, [4]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [5]University Hospital in Northern Norway, Tromsø, Norway

Background/Purpose: Clinical remission is the treatment target in rheumatoid arthritis (RA) and several composite indices are available for evaluation of remission states, including the newly formulated ACR/EULAR definition. These definitions have not been applied in real life daily clinical practice.

The purpose of this study was to examine how often clinical remission is achieved in clinical practice using existing definitions, and to test how well patients in remission preserve physical function.

Methods: Data for this study were provided by the NOR-DMARD register in all 5788 patients with RA started with a synthetic (n=3875) or biological DMARD (n=1913). Age was mean (SD) 55.3 (29.9) yrs, disease duration was 8.2 (9.6) yrs, 73.3% of patients were females.

Applied definitions for clinical remission included the Disease Activity Score based on 28 joint counts (DAS28) <2.6, the Simplified Disease Activity Index (SDAI) ≤3.3, the Clinical Disease Activity Index (CDAI) ≤2.8, Routine Assessment of Patient Index Data (RAPID3, range 0–10) ≤1, and the preliminary ACR/EULAR remission definition where in the Boolean (BOOL) application tender joint count, swollen joint count, patient global assessment (scale 0–10), and CRP (mg/dL) all must be ≤1. ACR/EULAR remission is warranted if either ACR/EULAR BOOL is satisfied or SDAI ≤3.3. We also explored a practical definition of ACR/EULAR BOOL without CRP (ACR/EULAR PRAC). Data after 3 and 6 months of treatment were used for assessment of remission. Then patients with remission at 3 months were examined for deterioration of physical function (measured by the modified Health Assessment Questionnaire [MHAQ]) between months 3 and 12, likewise remission at month 6 for deterioration between months 6 and 12.

Results: The table shows percentages of patients in remission after 3 months and 6 months, and further among these patients with remission at 3 and 6 months percentages of patients with no deterioration in MHAQ until 12 months. SDAI, CDAI and the new ACR/EULAR definition for remission are most stringent and classify 7–8% as in remission after 3 months of DMARD treatment, and 9–11% after 6 months. DAS28 and RAPID3 classify most patients as in remission. All remission definitions performed similar in identifying patients with preserved physical function.

	DAS28	SDAI	CDAI	RAPID3	ACR/EULAR BOOL	ACR/EULAR	ACR/EULAR PRAC
3 mts	19.1	7.6	8.1	17.0	6.9	9.3	8.1
MHAQ non progr. 3–12 mts	65.7	63.9	64.9	65.2	64.2	63.6	65.6
6 mts	24.7	10.5	11.3	19.8	9.0	12.3	11.0
MHAQ non-progr. 6–12 mts	69.6	73.5	73.6	69.8	74.9	72.6	73.7

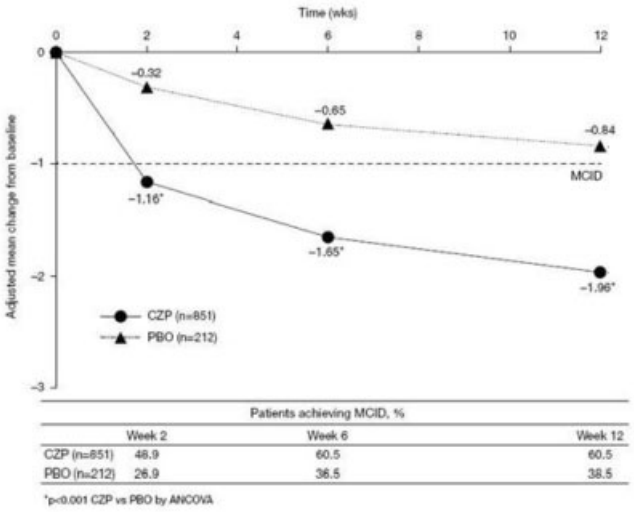
Conclusion: Definitions of remission differ regarding the proportion of patients classified as in remission after 3 and 6 months of DMARD treatment in clinical practice. However, no individual definition seems superior in identifying patients who preserve physical function until 12 months.

1230

Patient-Reported Disease Activity Including Joint Assessment: A Comparison of RADAI (Rheumatoid Arthritis Disease Activity Index) and RAPID3 (Routine Assessment of Patient Index Data 3) in Patients Treated with Certolizumab Pegol Over 12 Weeks. Michael E. Weinblatt[1], Janet E. Pope[2], Roy M. Fleischmann[3], Clifton O. Bingham[4], Geoffroy Coteur[5] and Maxime Dougados[6]. [1]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [2]St. Joseph's Health Care, University of Western Ontario, London, ON, [3]MCRC, University of Texas, Dallas, TX, [4]Johns Hopkins University, Baltimore, MD, [5]UCB, Brussels, Belgium, [6]Paris-Descartes University, Cochin Hospital, Paris, France

Background/Purpose: Self-reported disease activity (DA) indices such as RAPID3 (**R**outine **A**ssessment of **P**atient [pt] **I**ndex **D**ata 3) and RADAI (**R**heumatoid **A**rthritis [RA] **DA** **I**ndex)[1] offer a pt-focused approach to clinical management. RAPID3 is an index without formal joint counts, whereas RADAI includes a self-assessment of tenderness in 16 joint areas. This post hoc analysis of the REALISTIC (**RA** **E**v**AL**uation **I**n **S**ubjects receiving **T**NF **I**nhibitor **C**ertolizumab pegol [CZP]) study[2] assessed the performance of RAPID3 and RADAI to measure impact of treatment with CZP in a broad population of RA pts closely resembling routine clinical practice.

Methods: During the 12-week (wk), double-blind phase of REALISTIC (NCT00717236) 1063 pts with inadequate response to ≥1 DMARD were randomized 4:1 to CZP 400 mg at Wks 0, 2, and 4, followed by 200 mg at Wks 6, 8, and 10, or placebo (PBO), added to their current treatment. 75% pts were from North America. The RADAI (summarized as a joint tenderness score [JS] or the total score [TS], both ranging 0–10, with 10 indicating highest DA) was administered at 0, 2, 6, and 12 wks. Mean change from baseline (BL) in RADAI-TS was assessed using ANCOVA applying LOCF (CZP vs PBO). The% of pts achieving a minimum clinically important difference (MCID) for the RADAI-TS was evaluated (defined as a 1-point decrease). Correlations between RADAI-TS, RADAI-JS, RAPID3, and clinical DA measures (including DAS28[ESR] and total and swollen joint counts [TJC, SJC]) were examined using Pearson coefficients.



Patients achieving MCID, %

	Week 2	Week 6	Week 12
CZP (n=851)	48.9	60.5	60.5
PBO (n=212)	26.9	36.5	38.5

*p<0.001 CZP vs PBO by ANCOVA

Results: Mean BL RAPID3 and RADAI-TS were similar between groups (CZP vs PBO: RAPID3 14.75 vs 15.50, RADAI-TS 5.56 vs 5.68). Statistically significant improvements in RAPID3 and RADAI-TS were reported with CZP vs PBO from as early as Wk 2 up to Wk 12 (Figure). Significantly more CZP pts had improvements ≥MCID in RADAI and achieved RAPID3 low DA or remission from Wk 2 onward. Correlations between RADAI (TS and JS) or RAPID3 and DAS28(ESR) were high, while correlations between RADAI-TS and RAPID3 were very high (Table). Pt-reported scoring of the joint for tenderness in the RADAI highly correlated with physician-reported TJC and moderately with SJC. Responsiveness of RADAI and RAPID3 was good, especially in pts with moderate or high number of affected joints at BL.

Conclusion: Rapid and significant improvements in RAPID3 and RADAI were observed within the first 3 months of CZP treatment in a broad population of RA pts. RADAI and RAPID3 may represent reliable pt-reported measures of DA in RA pts.

Initial Combination Therapy with Adalimumab Plus Methotrexate Leads to Better Long-Term Outcomes Than with Either Monotherapy in Patients with Early Rheumatoid Arthritis: 8-Year Results of An Open-Label Extension of a Phase 3 Trial. Ferdinand C. Breedveld[1], Edward Keystone[2], Désirée van der Heijde[3], Robert Landewe[4], Josef Smolen[5], Benoit Guerette[6], Melissa McIlraith[6], Hartmut Kupper[7], Shufang Liu[8], Benjamin Wolfe[8] and Arthur Kavanaugh[9]. [1]Leiden Univ Medical Ctr, Leiden, Netherlands, [2]University of Toronto, Toronto, ON, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Academic Medical Center, Amsterdam, Netherlands, [5]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [6]Abbott, Rungis, France, [7]Abbott GmbH & Co KG, Ludwigshafen, Germany, [8]Abbott, Abbott Park, IL, [9]University of California San Diego, San Diego, CA

Background/Purpose: PREMIER was a phase 3, randomized, controlled trial (RCT) in MTX-naïve patients (pts) with early RA who received MTX, adalimumab (ADA), or ADA+MTX for 2 years (yrs) of blinded treatment. The RCT demonstrated the radiographic, clinical, and functional superiority of initial combination therapy over the individual monotherapies[1]; results were extended through an additional 3 yrs of open-label (OL) treatment in a 5-yr report[2]. This analysis aimed to evaluate long-term radiographic, clinical, and functional outcomes in pts treated with ADA, with and without MTX, for up to 8 yrs (i.e. 6 yrs beyond the 2-yr RCT).

Methods: Pts completing the RCT were eligible to receive OL ADA for a total of 10 yrs of treatment (this trial is ongoing); MTX could be added at the investigator's discretion during the OL extension. This post hoc analysis evaluated the 8-yr completers cohort with radiographic data available at baseline (BL) and yr 8; results are summarized overall and by initial treatment arms. Radiographic damage [mTSS, representing the sum of joint (jt) erosion (JE) and jt space narrowing (JSN)] was assessed at BL and yrs 2, 6, and 8; progressors were defined as a change (Δ) in mTSS from BL >0.5. Differences in ΔmTSS were assessed using a longitudinal ANCOVA following adjustment for BL damage. Clinical outcomes were assessed using the DAS28, and swollen (66 jts assessed) and tender (68 jts assessed) jt counts. Physical function was assessed using the HAQ-DI.

Results: A total of 299 (37.4%; 103, 96, and 100 from the initial ADA+MTX, MTX, and ADA arms, respectively) of the 799 pts initially randomized received OL ADA±MTX through yr 8. Following up to 8 yrs of ADA±MTX therapy, pts continued to demonstrate inhibition of radiographic progression and effective disease control (mean ΔmTSS=8.6; mean DAS28=2.6; mean HAQ-DI=0.6). Further, approximately half of pts experienced an absence of swollen (52.5%) and tender (47.9%) jts. Pts initially randomized to ADA+MTX demonstrated lower mean ΔmTSS, ΔJE, and ΔJSN at yr 8 (3.8, 1.4, 2.4) when compared with pts initially randomized to either MTX (11.4, 6.1, 5.2) or ADA (10.8, 5.6, 5.3) monotherapy (P <.001 for both mTSS comparisons) and were associated with fewer radiographic progressors (56.3% versus 72.9% and 73.0% for MTX and ADA monotherapy, respectively). OL ADA±MTX treatment inhibited radiographic progression in pts initially randomized to MTX or ADA monotherapy to levels that were comparable with those observed during OL treatment of pts from the initial ADA+MTX arm. Initial randomization to combination therapy also was associated with greater proportions of pts achieving high levels of disease control and normal physical function at yr 8 (DAS28 <2.6: 71.3%, 58.4%, 49.5%, and HAQ-DI <0.5: 60.2%, 55.9%, 47.4%, for ADA+MTX, MTX, ADA, respectively).

Conclusion: Following up to 8 yrs of treatment with ADA±MTX, pts with early, aggressive RA maintained effective disease control. Pts who initially received combination therapy with ADA+MTX demonstrated better long-term outcomes than those initially receiving either monotherapy.

Association Between Leptin, Adiponectin and TNF-α and Response to Treatment in Patients with Rheumatoid Arthritis. Daniel X. Xibille Friedmann[1], Sara Eugenia Hernandez Gongora[2], Carolina Bustos Bahena[3], Liliana Dominguez Hernandez[3], Ivan Martinez Rivera[3], Marisol Sandoval Rios[3], Jorge Eduardo Ortiz Panozo[4] and Jose Luis Montiel Hernandez[5]. [1]Hospital General de Cuernavaca, Cuernavaca Morelos, Mexico, [2]Postgraduate Research Coordination, School of Medicine, Universidad Latinoamericana, Cuernavaca, México, [3]Cytokines and Autoimmunity Laboratory, Faculty of Pharmacy, Universidad Autónoma del Estado de Morelos, Cuernavaca, México, Cuernavaca, Mexico, [4]Center for Population Health Research. Instituto Nacional de Salud Pública, Cuernavaca, México, [5]Cytokines and Autoimmunity Laboratory, Faculty of Pharmacy, Universidad Autónoma del Estado de Morelos, Cuernavaca, México

Background/Purpose: Response to treatment in Rheumatoid Arthritis (RA) determines the functional prognosis in affected patients. The development of predictors of response to therapy is essential in order to adequately treat patients with RA. Leptin and Adiponectin are white fat cell derived hormones that play an immunomodulatory role in RA and their levels have been associated with clinical activity in RA.Our objective was to determine whether baseline levels of leptin, adiponectin and TNF-α predict response to treatment in patients with RA at 6 months, 1, 2, 3 and 4 years of follow-up.

Methods: Patients were followed at the Rheumatology outpatient clinic of the Hospital General de Cuernavaca. Patients had been diagnosed with established RA by a Rheumatologist and fulfilled the 1987 ACR classification criteria. All patients were receiving treatment with steroids and/or DMARDs, both in combination or as monotherapy, and visited the clinic every three months where physical examination and routine lab testing was performed, which included RF (nephelometry), CRP (qualitative) and ESR (Westerngren). A blood sample was taken at a baseline visit between March 2006 and December 2008 in order to determine plasma anti-CCP, leptin, adiponectin and TNF-α levels (measured using ELISA). Patient follow-up occurred on visits at 6 months and every year afterward. Descriptive statistics were employed for demographic data while linear regression and ANOVA were employed in order to determine predictors of response to treatment. Response to treatment was assessed by a change in the DAS28 score from baseline to each time point. A p-value of <0.05 was considered as statistically significant.

Results: 147 patients were included of which 99 completed at least 6 months of follow up, 75 were followed for one year, 52 two years, 35 three years and 16 completed four years of follow up. All patients but 5 were women (94.9%). Mean age was 45.8 years (18–70) and mean time since onset of disease was 7.7 years (0–36). Mean body mass index was 26.95 (15–43). 92.5% of patients were RF positive and 79.7% were anti-CCP positive. Most patients received combination therapy at baseline, which included at least 2 DMARD (84.8%), the most common being methotrexate, 9.1% received methotrexate monotherapy and 6.1% received only prednisone and/or NSAIDs. No patients undergoing biologic therapy were included. Mean plasma levels for leptin were 0.27±0.8 ng/ml, for adiponectin 174.4±88.2 ng/ml, and for TNF-a 6.05±7.7 ng/ml. Higher baseline leptin levels predicted a good response to treatment at 6 months and one year (p=0.036 and 0.035, respectively), as did higher baseline TNF-α levels at one year (p=0.05). Neither leptin nor TNF-α were statistically significant predictors for long-term response to treatment (2 years and over). Higher baseline TNF-a and adiponectin levels, although not reaching statistical significance, did show a tendency to predict a poor response to treatment after 2 years (p=0.087) and 4 years (p=0.077) of follow-up, respectively.

Conclusion: Baseline levels of leptin and TNF-a predict a good response to treatment in RA patients at one year, but not in the longer term.

1233

Safety and Efficacy of Etanercept Over Five Years in a Large, UK Observational Cohort. C. D. Poole[1], Paul Emery[2], Adam Young[3], Duncan Porter[4], C. L. Morgan[1], H. Walker[5], C. J. Currie[6] and A. Reynolds[7]. [1]Pharmatelligence, Cardiff, United Kingdom, [2]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [3]City Hospital, St Albans, United Kingdom, [4]Gartnavel General Hosp, Glasgow, United Kingdom, [5]Pfizer UK Ltd, Tadworth, United Kingdom, [6]Cardiff University, Cardiff, United Kingdom, [7]Reynolds Clinical Sciences Ltd, Eastleigh, United Kingdom

Background/Purpose: Prospective observational registries have been established to monitor the long-term safety of TNF inhibitors and standard disease modifying antirheumatic drugs (DMARDs) in patients with rheumatoid arthritis (RA). The purpose of this study was to evaluate relative safety of etanercept (ETN) when compared with a DMARD

reference cohort and the efficacy of ETN over 5 years using data from a UK registry.

Methods: The British Society of Rheumatology Biologics Register (BSRBR) provided anonymised raw data on ETN and DMARD cohorts. No further data was provided if a patient switched to a non-ETN biologic. At baseline, patients underwent detailed clinical assessment by a rheumatologist. Follow-up questionnaires were completed every six months for three years by consultants and patients, then annually by consultants only for two more years. Health Assessment Questionnaire (HAQ) data were characterized for the first three years.

Patients with a potential for five years follow-up, a maximum window of ±90 days between RA treatment initiation and baseline registration were included. HAQ changes and DAS28 remission rates were calculated. Survival rates for serious adverse events were examined using Kaplan-Meier survival models and risk differences compared using the multivariate Cox proportional hazards model. These models were specified using a forward manual inclusion method for parameters where $P<0.05$. Subjects were followed to the date of last follow-up or death.

Results: ETN n=3,470, DMARDs n=1,365. Mean (median) follow-up 4.1 (4.9) years in both groups. Adjusted hazard ratios (aHR) for ETN vs. DMARDs and efficacy outcomes for ETN are detailed in Table 1. There were statistically significant differences in aHRs for malignancy and cardiovascular events. Of note was a significant reduction in mortality observed when deaths were restricted to on drug+90days with ETN aHR = 0.512 (95% CI 0.380–0.690, $p<0.001$), although this was not significant over the full observation period. Concomitant methotrexate therapy was associated with an increased likelihood of remission vs. ETN monotherapy (odds ratio [OR] = 1.69 (95%CI 1.32–2.14, $p<0.001$) at one year, and OR = 1.47 (95%CI 1.12–1.93, $p=0.006$) at five years). Subjects treated with ETN showed a significant improvement in HAQ compared with those receiving DMARDs at each timepoint during the first three years: −0.283 vs. −0.013 at 1yr; −0.305 vs. +0.008 at 2yrs, −0.272 vs. +0.101 at 3yrs (all $p<0.001$).

Table 1. aHR ETN vs DMARDs for safety outcomes

Safety parameters	aHR	95% CI	p-value		
Serious infection	1.01	0.81–1.26	0.943		
Malignancy	0.74	0.58–0.96	0.023		
Lymphoproliferative malignancy	0.64	0.30–1.40	0.266		
Cardiovascular events	0.64	0.49–0.85	0.002		
Death	0.80	0.62–1.04	0.096		
Efficacy outcomes for ETN					
Year	1	**2**	**3**	**4**	**5**
% patients remaining on ETN	71	61	54	49	40
% patients in remission (DAS28<2.6)	16	18	18	19	19

Conclusion: This evaluation at 5 years showed that ETN therapy was effective, whilst not associated with any increased risk of serious infection, malignancy, cardiovascular events or death when compared to a DMARD reference group; some risks may be reduced. While residual confounding may exist, this real-world data showed treatment with ETN was effective and as safe as treatment with DMARDs in patients with RA.

1234

Response with Combination Therapy—Methotrexate, Sulfasalazine, and Hydroxychloroquine—Appears Similar to the Response to Methotrexate and Anti-Tumor Necrosis Factor in US Veterans in the Veterans Affairs Rheumatoid Arthritis Registry. Grant W. Cannon[1], Brian C. Sauer[1], Candace L. Hayden[1], Stephen G. Pickard[1], Gail S. Kerr[2], J. Steuart Richards[2], Dannette S. Johnson[3], Liron Caplan[4], Ted R. Mikuls[5] and Andreas M. Reimold[6]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Washington DC VA and Georgetown University, Washington, DC, [3]Jackson VA and University of Mississippi Medical Center, Jackson, MS, [4]Denver VA and University of Colorado, Aurora, CO, [5]Omaha VA and University of Nebraska, Omaha, NE, [6]Dallas VA and University of Texas Southwestern, Dallas, TX

Background/Purpose: The linkage of pharmacy databases with objective clinical outcome measures provides an opportunity to compare the effectiveness and safety of rheumatoid arthritis (RA) therapies in real world clinical settings. Merging information from the Veterans Affairs RA (VARA) registry initiated in 2003 with assessment of disease activity and the VA Pharmacy Benefits Management (PBM) database with data from 1998 allows comparison of patients receiving combination therapy with methotrexate, sulfasalazine and hydroxychloroquine (MTX/SH) to patients receiving the combination of methotrexate and anti-tumor necrosis factor (TNF) therapy (MTX/TNF).

Methods: VARA routinely collects disease activity score (DAS28) on RA patients in this longitudinal prospective observational cohort study. For each prescription, PBM data was used to ascertain duration of the prescription, total dose dispensed, and anticipated date for refill of medication was recorded. Individual prescription courses were consolidated to determine regimens of combination therapy with MTX/SH and MTX/TNF. Regimens were defined as time from the initiation of the combination therapy regimen until the expected refill date for the last treatment before a 90 day gap or discontinuation. The average DAS28 and average ESR during each regimen of greater than 90 days was calculated during the observation period from 90 days after initial prescription to the end of the regimen.

Results: Of the 1382 patients in the VARA cohort, 443 (32%) received combination therapy with either MTX/SH or MTX/TNF; approximately half of these (n = 259) receiving treatment during observation. Of these 443 combination treated patients, 131 (30%) received only MTX/SH, 254 (57%) received only MTX/TNF and 58 (13%) received both combinations. A comparison of patients receiving only MTX/SH to MTX/TNF showed that patient treated with only MTX/SH were more frequently men and older than patients receiving only MTX/TNF. Among those with available DAS28 during VARA observation, measures of disease activity were similar across treatment groups (Table).

Characteristics of VARA patients receiving combination therapy with only MTX/SH, only MTX/TNF, and both MTX/SH and MTX/TNF for all patients and the subset of patients who had a treatment course ≥90 days and DAS28 measured - listed as DAS28 in the table below.

	Only MTX/SH		**Only MTX/TNF**		**MTX/SH & MTX/TNF**	
	All patients (n=131)	**DAS28 (n=56)**	**All patients (n=254)**	**DAS28 (n=163)**	**All patients (n=58)**	**DAS28 (n=40)**
Gender (% Male)	94%*	100%*	85%*	85%*	91%	93%
Age at diagnosis of RA	52 ± 11*	55 ± 10*	48 ± 16*	49 ± 13*	59 ± 12	52 ± 12
Age at enrollment	63 ± 11*	64 ± 8*	59 ± 12*	60 ± 10*	63 ± 11	64 ± 9
Age at 1st treatment (Rx)	62 ± 11*	63 ± 10*	59 ± 12*	59 ± 10*	60 ± 11	64 ± 9
Disease duration at 1st Rx	11 ± 10	8 ± 8	11 ± 14	10 ± 10	10 ± 10	9 ± 10
Nodules	43%	23%*	45%	48%	45%	42%
RF (+)	81%	82%	82%	86%	85%	84%
ACCP (+)	74%	77%	78%	77%	79%	73%
Erosion on hand X-ray	42%	36%	38%	32%	44%	47%
DAS28	—	3.5 ± 1.6	—	3.7 ± 1.4	—	3.9 ± 1.3
ESR	—	21 ± 16	—	21 ± 18	—	24 ± 20

* = $p<0.05$ for comparison between MTX/SH and MTX/TNF

Conclusion: Among U.S. veterans with RA, approximately half have received combination therapies with MTX/SH and/or MTX/TNF. In patients receiving these treatments, the combination of non-biologic DMARDs appears to be used more commonly than MTX/TNF in men and among older individuals. These differences may be related to channeling bias that could not be detected by the analysis for confounders. In this observational study, these treatment combinations do not appear to result in meaningful differences in disease activity over follow-up.

1235

Greater Physical Dysfunction Is a Negative Predictor for Achieving Boolean-Based Remission in Patients with Rheumatoid Arthritis Treated with Tocilizumab. Daisuke Hoshi, Kumi Shidara, Yohei Seto, Eiichi Tanaka, Ayako Nakajima, Shigeki Momohara, Atsuo Taniguchi and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: A new, Boolean-based definition of remission in the treatment of rheumatoid arthritis (RA) was proposed by the ACR/EULAR in 2010. Tocilizumab (TCZ) directly influences the function of IL-6 resulting in suppression of serum inflammatory markers, so it is necessary to evaluate the efficacy of TCZ by using the new remission criteria.

Methods: We analyzed the efficacy of TCZ treatment in 80 RA patients at 24 weeks after initial treatment with TCZ by using "DAS28 remission" defined to be DAS28-ESR < 2.6 and "Boolean remission" defined to be all criteria in the Boolean definition ≤ 1. We stratified the 80 RA patients by previous use of biologics, by concomitant use of methotrexate (MTX), by age

over or under 65 years, by disease duration and by physical dysfunction as measured by the Japanese version of the Health Assessment Questionnaire (J-HAQ). We compared the achievement of "DAS28 remission" by chi-square test and "Boolean remission" by Fisher's exact test. We further analyzed the predictive factors that influenced the achievement of "Boolean remission" at 24 weeks after initial treatment of TCZ by using stepwise multiple logistic regression analysis.

Results: Among the 80 RA patients, 88.8% were women. The median [25%, 75%] age was 60.0 [48.2, 65.0] years and disease duration was 100 [49, 176] months. MTX was used in 70% of patients and corticosteroid was in 77.5%. The number (percentage) achieving "DAS28 remission" and "Boolean remission" at week 24 were 40 (50.0%) and 10 (12.5%), respectively. There was no difference in reaching remission either defined by "DAS28 remission" or "Boolean remission" when patients were stratified by previous biologics use, concomitant MTX use, or age over or under 65 years. There were significant differences in achieving "Boolean remission", but not "DAS28 remission", when patients were stratified by disease duration ($p = 0.0368$) or by J-HAQ ($p = 0.0444$) in tertile. The predictive factor for not achieving "Boolean remission" at 24 weeks was a worse baseline J-HAQ score (odds ratio: 3.66, 95% confidence interval: 1.17–14.48).

Table. Risk factors at baseline for not satisfying "Boolean remission" at 24 weeks

	odds ratio	95% confidence interval	*P* value
Disease duration (month)	1.007	0.099–1.021	0.235
J-HAQ	3.655	1.174–14.475	0.039
ESR (mm/h)	0.98	0.954–1.005	0.121
Corticosteroid use (%)	2.952	0.617–14.085	0.163

Conclusion: This study showed that the achievement of "Boolean remission" was 12.5% and "DAS28 remission" was 50% in patients treated with TCZ. Greater physical dysfunction is a negative predictor for achieving "Boolean remission".

1236

Direct Comparison of Four Biologics in Biologic-naïve Rheumatoid Arthritis Patients. Yukio Yonemoto[1], Kimihiko Takeuchi[2], Koichi Okamura[1], Masatoshi Matsushita[2], Tsutomu Kobayashi[1], Tetsuo Aramaki[2], Tetsuya Kaneko[1] and Kenji Takagishi[1]. [1]Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [2]Isesaki Fukushima Hospital, Isesaki, Gunma, Japan

Background/Purpose: The treatment of rheumatoid arthritis (RA) has been transformed in recent years by the appearance of novel agents centered on biologics. The idea of "treat to target" has emerged, and the significance of remission has increased dramatically. However, few papers have compared different biologics under the same conditions at the same time, and no consistent view has emerged regarding the choice of agent. We compared treatment response to four biologics, infliximab (IFX), etanercept (ETN), tocilizumab (TCZ) and *adalimumab* (ADA), in biologic-naïve RA patients who had been started on treatment in the same period in the real clinical setting.

Methods: One hundred and forty-two biologic-naïve RA patients were started on a biologics (IFX 37, ETN 39, TCZ 27, ADA 39) from July 2008 onwards. Baseline and six months later, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), matrix metalloproteinase-3 (MMP-3), the swollen and tender joint counts, the Disease Activity Score in 28 joints using ESR (DAS28-ESR) and the European League Against Rheumatism (EULAR) remission criteria (DAS28-ESR$<$2.6) were examined. The drug survival rate on each agent was also surveyed.

Results: After 6 months, ESR, CRP, MMP-3, the swollen and tender joint counts and DAS28-ESR had fallen significantly from baseline with all four agents. Comparing the individual products, DAS28-ESR and MMP-3 fell significantly more with TCZ than with IFX and ETN. No significant difference was identified at 6 months in the DAS28-ESR remission rates (DAS28-ESR$<$2.6) and drug survival rate for each biologics.

Conclusion: In this study, DAS28-ESR was used whereas remission standards including clinical disease activity index (CDAI), simplified disease activity index (SDAI) and Boolean definition have been proposed at present. It has been reported that TCZ, which directly inhibits acute-phase reactant, can lead to an overestimation of the response to treatment. Another paper sets out a correlation between DAS28-ESR and CDAI, SDAI, and states that evaluation based on DAS28 is valid. The present study indicated a larger fall in MMP-3 with TCZ than with the other two agents, and suggested that TCZ may provide therapeutic efficacy at least comparable to TNF inhibitors in biologic-naïve RA patients.

1237

Impact of Tocilizumab Therapy for Remission Quartet in Rheumatoid Arthritis—the Result of 104 Weeks Follow up Data of REACTION study. Yoshiya Tanaka[1], Tsutomu Takeuchi[2], Koichi Amano[3], Eri Sato[4], Masao Nawata[5], Hayato Nagasawa[6], Daisuke Hoshi[7], Kazuyoshi Saito[8], Shunsuke Fukuyo[5], Kentaro Hanami[8], Hideto Kameda[2], Takahiko Kurasawa[6], Yuko Kaneko[9] and Hisashi Yamanaka[4]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [2]Keio University School of Medicine, Tokyo, Japan, [3]Saitama Medical Center, Saitama Medical University, Saitama, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [6]Saitama Medical Ctr, Kawagoe, Japan, [7]Tokyo Women's Medical University, Tokyo, Japan, [8]University of Occupational & Environmental Health, Japan, Kitakyushu, Japan, [9]Keio Univ School of Medicine, Shinjuku-ku, Japan

Background/Purpose: Biologics have changed dramatically the management of patients with rheumatoid arthritis (RA). Four levels of remission based on the concept of "treating to target" have been required, which is to achieve clinical, structural, and functional remission as well as to sustain remission over the long term. We evaluated those remissions and their sustainment in the REACTION Study, an observational study on tocilizumab (TCZ) in daily clinical practice.

Methods: The 229 patients were treated with TCZ 8 mg/kg every 4 weeks. The clinical remission (the disease activity score using the 28 joint count (DAS)28-ESR$<$2.6 and clinical disease activity index (CDAI)$\leq$2.8), structural remission (the estimated yearly progression of modified total Sharp score (ΔmTSS) $\leq$0.5), and functional remission (health assessment questionnaire (HAQ)$\leq$0.5) were evaluated. Sustained remission was defined as the remission sustainment rate at week 104 in patients who achieved remission at 52 weeks.

Results: Treatment with TCZ was continued for 2 years in 127 patients (55%). The patient characteristics who continued 2 years TCZ treatment were as follows. Mean age: 57.9 years; mean disease duration: 11.3 years; prior treatment with TNF inhibitor: 80 patients (63.0%); concomitant methotrexate (MTX): 80 patients (63.0%). The remission rates represented by DAS28$<$2.6 and CDAI$\leq$2.8 (measures of clinical remission) and HAQ$\leq$0.5 (measure of functional remission) tended to increase over time. At Week 104, 71.2% had achieved DAS28$<$2.6, 37.4% had achieved CDAI$\leq$2.8, and 38.2% had achieved HAQ$\leq$0.5. The main reason for discontinuation of TCZ was adverse drug reactions (47/229, 20.5%). In adverse drug reactions, pneumonia was 9 cases. Analysis of mTSS in 112 patients out of the 127 patients revealed ΔmTSS to be 20.1 at baseline, 1.1 at Week 52, and 0.6 at Week 104, indicating 97% inhibition compared to baseline. ΔmTSS$\leq$0.5 was about the same at Weeks 52 and 104, with ΔmTSS$\leq$0.5 at Week 104 in 52.9% (Table). Sustained remission: DAS28$<$2.6 in 85.5%, CDAI$\leq$2.8 in 70.0%, ΔmTSS$\leq$0.5 in 64.9%, and HAQ$\leq$0.5 in 83.3%. Multivariate analysis revealed predictive factors affecting total remission of DAS28, CDAI, TSS and HAQ at week 104 were disease duration (P=0.03) and CDAI (P=0.04) at baseline.

	0w	24w	52w	104w
DAS28-ESR$<$2.6	0 (0%)	67 (54%)	69 (59%)	89 (71%)
CDAI$\leq$2.8	0 (0%)	18 (15%)	30 (22%)	46 (37%)
ΔTSS$\leq$0.5	–	–	57(56%)	54(53%)
HAQ$\leq$0.5	16 (13%)	36 (29%)	38 (31%)	47 (38%)

Conclusion: Patients who could continue treatment with tocilizumab for 2 years were achieved significant remission of CDAI, which includes no measures for assessing inflammatory markers such as CRP. Moreover, structural remission and functional remission were both maintained over the long term in a high percentage of patients.

1238

Clinical Response At Months 1–6 Can Predict Likelihood of Achieving Remission in Abatacept Plus Methotrexate-Treated Patients with Early Rheumatoid Arthritis. Yusuf Yazici[1], Jurgen Wollenhaupt[2], Patrick Durez[3], Juan J. Gomez-Reino[4], Walter Grassi[5], Manuela Le Bars[6], Corine Gaillez[7], Coralie Poncet[8], Ayanbola Elegbe[9] and Rene Westhovens[10]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Schoen-Klinik Hamburg-Eilbek, Hamburg, Germany, [3]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium, [4]Hospital Clinico Universitario, Santiago de Compostela, Spain, [5]Università Politecnica delle Marche, Ancona, Italy, [6]Bristol-Myers Squibb, Rueil-Malmaison, France, [7]Bristol-Myers Squibb, Rueil Malmaison, France, [8]Docs International, Issy les Moulineaux, France, [9]Bristol-Myers Squibb, Princeton, NJ, [10]UZ Gasthuisburg, Leuven, Belgium

Background/Purpose: ACR/EULAR treat-to-target recommendations define remission as the goal for patients (pts) with early rheumatoid arthritis (RA), with appropriate therapeutic adaptation every 3–6 mths dependent on response[1]. In the AGREE study, a large proportion of methotrexate (MTX)-naïve pts with early RA achieved DAS28 remission over 1 yr; 41 (95% CI: 35–47) vs 23% (18–29) for pts treated with abatacept (ABA) + MTX vs MTX alone ($p<0.001$)[2]. Applying a threshold of a change from baseline (BL) in DAS28 of >0.6 (DAS28 response) or ≥1.2 (clinically meaningful DAS28 response) during the first few mths of therapy may help identify pts more likely to reach Low Disease Activity State (LDAS) or remission at a later time-point. We present *post-hoc* analyses examining if a DAS28 response or a clinically meaningful DAS28 response at Mths 1–6 can predict likelihood of achieving remission or LDAS at Yr 1, in pts treated with ABA + MTX.

Methods: In the 1-yr double-blind (DB) period of AGREE, MTX-naïve pts with early (≤2 yrs) RA, poor prognostic factors and high disease activity, as evidenced by tender (≥12) and swollen (≥10) joint counts, were randomized 1:1 to ABA + MTX or placebo + MTX (MTX alone)[2]. All pts completing the DB period entered the open-label (OL) period to receive ABA + MTX. Remission was defined as DAS28-CRP <2.6 and LDAS as ≤3.2. Likelihood of achieving remission at Yr 1 was evaluated for pts with a DAS28 response (change from BL >0.6) or a clinically meaningful DAS28 response (change from BL ≥1.2) at Mths 1–6. Data are as observed for pts treated with ≥1 dose of ABA in the OL period.

Results: Analyses included 459 pts; 232 treated with ABA + MTX and 227 with MTX alone. BL characteristics were similar between groups[1]; mean (SD) DAS28-CRP was 6.3 (1.0) in each group. Over 90% of ABA + MTX-treated pts experienced a DAS28 response (change from BL >0.6) from Mths 2 through 6, compared with ~73–88% of MTX-alone treated pts (Table). For pts with DAS28 response at Mths 2 through 6, approximately 50% of ABA + MTX-treated pts achieved remission at Yr 1, vs ~30% of MTX-alone treated pts (Table); for these pts, >60% of the ABA + MTX group vs 44–48% of the MTX alone group achieved LDAS at Yr 1 (data not shown). Through Mths 2 to 6, 76–88% of ABA + MTX-treated pts achieved a clinically meaningful DAS28 response (change from BL ≥1.2) vs 50–76% of MTX alone-treated pts (Table). Among these pts, ~50% of the ABA + MTX-treated group achieved remission at Yr 1 vs ~30% of MTX-alone treated group (Table); ~70% and 50–54% from each group, respectively, achieved LDAS (data not shown).

	Month 1	Month 2	Month 3	Month 4	Month 5	Month 6
DAS28 response (change from baseline >0.6), % (n/N)						
ABA + MTX	77.2 (173/224)	90.8 (208/229)	92.1 (211/229)	93.9 (215/229)	95.2 (216/227)	95.1 (213/224)
MTX alone	53.4 (119/223)	72.6 (162/223)	76.6 (170/222)	86.7 (195/225)	88.1 (192/218)	87.6 (191/218)
DAS28 remission at Year 1,% (n/N), according to achievement of DAS28 response each month						
ABA + MTX	49.1 (85/173)	48.1 (100/208)	47.9 (101/211)	47.4 (102/215)	46.8 (101/216)	47.9 (102/213)
MTX alone	32.8 (39/119)	30.2 (49/162)	27.6 (47/170)	27.7. (54/195)	29.2 (56/192)	29.8 (57/191)
Clinically meaningful DAS28 response (change from baseline ≥1.2),% (n/N)						
ABA + MTX	54.0 (121/224)	75.5 (173/229)	79.0 (181/229)	84.7 (194/229)	85.9 (195/227)	88.8 (199/224)
MTX alone	31.4 (70/223)	49.8 (111/223)	58.6 (130/222)	68.9 (155/225)	74.8 (163/218)	76.1 (166/218)
DAS28 remission at Year 1,% (n/N), according to achievement of clinically meaningful DAS28 response each month						
ABA + MTX	54.5 (66/121)	53.2 (92/173)	52.5 (95/181)	52.6 (102/194)	51.3 (100/195)	50.8 (101/199)
MTX alone	38.6 (27/70)	34.2 (38/111)	33.1 (43/130)	31.6 (49/155)	31.3 (51/163)	31.9 (53/166)

DAS28=Disease Activity Score 28; ABA=abatacept; MTX=methotrexate;

Conclusion: ABA + MTX-treated pts who achieve a DAS28 response (change from BL >0.6), or a clinically meaningful DAS28 response(change from BL ≥1.2), during the first 6 mths of therapy have a higher likelihood (~50%) of achieving remission at Yr 1 vs MTX-alone treated pts (~30%). These data support the concept of treating-to-target[1] with ABA + MTX in pts with early RA.

Impact of Tocilizumab Therapy After Switching From Tumor Necrosis Factor (TNF) inhibitors – Prevention of Joint Damage by Tocilizumab in Patients with Inadequate Response to Anti-TNF Therapies. Yoshiya Tanaka[1], Tsutomu Takeuchi[2], Koichi Amano[3], Eri Sato[4], Masao Nawata[5], Hayato Nagasawa[6], Daisuke Hoshi[7], Kazuyoshi Saito[8], Shunsuke Fukuyo[5], Kentaro Hanami[8], Hideto Kameda[2], Takahiko Kurasawa[6], Yuko Kaneko[9] and Hisashi Yamanaka[4]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [2]Keio University School of Medicine, Tokyo, Japan, [3]Saitama Medical Center, Saitama Medical University, Saitama, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [6]Saitama Medical Ctr, Kawagoe, Japan, [7]Tokyo Women's Medical University, Tokyo, Japan, [8]University of Occupational & Environmental Health, Japan, Kitakyushu, Japan, [9]Keio Univ School of Medicine, Shinjuku-ku, Japan

Background/Purpose: Anti-TNF agents are highly effective, but clinical remission is achieved in only about 40% of patients. In this study, we evaluated the efficacy of tocilizumab (TCZ) for preventing the joint damage as well as clinical and functional improvement in patients with inadequate response to anti-TNF agents by comparing the efficacy achieved during anti-TNF therapy one year prior to TCZ treatment.

Methods: Baseline characterisitics, efficacy as measured by disease activity score using the 28 joint count (DAS)28-ESR, clinical disease activity index (CDAI), health assessment questionnaire-disability index (HAQ-DI), and modified total Sharp score (mTSS) were assessed.

Results: In total, 145 patients with inadequate response to the anti-TNF therapies were analyzed. At baseline, mean age was 56.6±14.6 years (median [min-max]: 61.0 [15–88]), mean duration of disease was 12.4±10.5 years (median [min-max]: 10.0 [0.1–56.2]), methotrexate (MTX) was concomitantly used in 64.1%. The mean DAS28-ESR, CDAI and HAQ score was improved from 5.71±1.25 at baseline to 2.84±1.53 (% of <2.6=48.5) at week 52, from 26.7±13.1 to, 9.84±9.12 (% of ≤2.8=22.4), and 1.54±0.74 to 1.19±0.81 (% of ≤0.5=26.9), respectively..Analysis of 95 patients with available mTSS revealed the estimated yearly progression (ΔTSS) at baseline to be 16.7, but this had improved to 1.1 at 52 weeks, indicating 93.4% inhibition of joint destruction. Structural remission (ΔTSS≤0.5) was achieved in 53 patients (55.8%). The incidence of the patients who reached DAS28-ESR<2.6, CDAI≤2.8, and ΔTSS≤0.5 were improved significantly after switching from anti-TNF agents to tocilizumab (Table). Especially, Estimated ΔTSS after TCZ treatment (1.37) was significant improved from the EYP during one year anti-TNF treatment.

	−52w	0w	52w
Mean DAS28-ESR (% of <2.6)	5.24 (0%)	5.85 (0%)	2.87 (50%)
Mean CDAI (% of ≤2.8)	21.1 (0%)	27.4 (0%)	11.1 (18.9%)
Mean HAQ (% of ≤0.5)	1.24 (16.2%)	1.46 (7.9%)	1.12 (15.8%)
ΔTSS (% of ≤0.5)	3.55 (42.1%)	1.37 (63.2%)	

Conclusion: The clinical response and the efficacy in prevention of joint damage were significantly improved compared to pretreatment by switchin to tocilizumab from TNF-inhibitors in RA patients with inadequate response to TNF-inhibitors.

1240

Comparative Efficacy and Tolerability of Biologic Therapies in Early Rheumatoid Arthritis Utilizing a Bayesian Approach. Yusuf Yazici[1], Christopher Swearingen[2], Anagha Nadkarni[3] and Lisa Rosenblatt[3]. [1]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY, [2]University of Arkansas, Little Rock, AR, [3]Bristol-Myers Squibb, Plainsboro, NJ

Background/Purpose: Currently, five biologic disease-modifying antirheumatic drug (DMARD) therapies are used in MTX-naïve, early rheumatoid arthritis (RA). In the absence of head to head studies, indirect approaches are required in order to gain insight into the comparative efficacy and tolerability of these agents.

Objectives: To determine the relative efficacy and tolerability of biologic agents approved for the treatment of MTX-naïve early RA patients using mixed treatment comparison (MTC) methodology.

Methods: A systematic literature review was performed to identify RCTs published between January 1, 1990 and June 16, 2010 that measured efficacy and safety endpoints in an MTX-naïve, early RA population. Those RCTs that included any one of the approved biologics abatacept (ABA), adalimumab (ADA), etanercept (ETN), golimumab (GOL), and infliximab (INF), were included in the MTC that compared the following outcomes at 1 year: American College of Rheumatology (ACR) 20/50/70, Disease Activity Score 28 (DAS 28) remission, severe adverse events (AEs), serious infections and withdrawals due to an AE or due to any reason.

Results: No difference in the odds of achieving ACR 50 or ACR 70 scores was seen between the biologics, although both INF (odds ratio [OR]=0.48, 95% CI=0.27–0.82) and ADA (OR=0.53, 95% CI=0.29–0.94) had significantly lower odds of achieving ACR20 compared with ETN. The odds of achieving DAS28 remission was also found to be similar between all biologic therapies with the exception of INF which had significantly lower odds (OR=0.54, 95% CI=0.30–0.97) compared with ADA. Tolerability to the biologic agents was not significantly different with the exception of INF and GOL, as the former had significantly higher odds of experiencing serious infections compared with ETN (OR=5.12, 95% CI=1.20–24.80) and significantly higher odds of discontinuing treatment due to AEs compared with ABA (OR=4.80, 95% CI=1.45–17.08) and ETN (OR=4.28, 95% CI=1.75–11.35), while GOL had higher odds of discontinuing treatment due to AEs compared with those receiving ETN (OR=3.43, 95% CI=1.07–12.67).

Conclusion: In general, all biologic agents used in MTX-naïve early RA demonstrated similar efficacy and tolerability, except for INF which appeared to have less favorable efficacy and tolerability. For specific outcomes studied, ETN and ABA were not significantly different from each other and were the only biologics that did not demonstrate a significantly decreased likelihood of efficacy or tolerability compared with any of the other agents.

1241

Differences in Gene Expression Profiles in Rheumatoid Arthritis Peripheral Blood Mononuclear Cells Suggest Apoptosis As Relevant Mechanism for Response to Methotrexate Monotherapy. RD Oliveira[1], V. Fontana, C. Macedo, CM Junta, Eduardo A. Donadi[3], GA Passos and Paulo Louzada-Junior[1]. [1]School of Medicine of Ribeirao Preto - University of Sao Paulo, Ribeirao Preto, Brazil, [2]Faculty Med of Ribeirao Preto, Ribeirao Preto, Brazil

Background/Purpose: Methotrexate (MTX) remains the standard therapy for rheumatoid arthritis (RA), although about 30% of RA patients do not respond to MTX monotherapy. A better understanding of the mechanisms of MTX action may be useful in identifying those RA patients who are most likely to have benefit from MTX treatment. The aim of the study was to evaluate the gene expression profile in peripheral blood mononuclear cells (PBMC) in RA patients who did not respond to MTX monotherapy.

Methods: We evaluated 17 MTX-non-responders (MTX-NR) RA patients using MTX monotherapy (15–25 mg/week). As a control group, we also evaluated eight MTX-responders (MTX-R) RA patients, also under MTX monotherapy (15–25 mg/week). All patients were using stable dose of prednisone (5 mg/day). The classification in responders and non-responders to MTX fulfilled the EULAR response criteria for RA. Total blood was collected and RNA was extracted from peripheral blood mononuclear cells (PBMC) and the complementary DNA microarray was performed. We selected the genes presented at least in 80% of the microarray hybridizations.

Results: Clinical and laboratorial characteristics of the RA patients are shown in Table 1. Microarray analysis showed 535 differentially expressed genes when we compared MTX-NR with MTX-R and the hierarchical clustering analysis showed an unambiguous distinction. To identify general mechanisms of action, we selected genes whose magnitude of difference (fold change) in the gene expression between MTX-NR and MTX-R were higher than 1.3 or lower than 0.7. For the MTX-NR group, we observed four down-regulated genes involved in apoptosis induction, four up-regulated genes involved in apoptosis inhibition, and one up-regulated gene involved with immune response and inflammation (Table 2).

Table 1. Clinical and laboratorial characteristics of the RA patients.

Features	MTX-R (n=8)	MTX-NR (n=17)	p
Age, mean years (range)	54.7 (37–71)	51 (29–67)	Ns[a]
Female/Male	4/1	3/1	Ns[b]
Time of disease (years)	6.6	5.4	Ns[a]
Smoking (%)	38	53	Ns[b]
+ RF (%)	88	65	Ns[b]
+ ACPA (%)	75	82	Ns[b]
+ HLA-SE(%)	75.0	70	Ns[b]
DAS28 (mean ± SD)	1.87+0.76	6.47+1.1	<0.0001[a]

MTX-R: responders to methotrexate; MTX-NR: non-responders to methotrexate; +RF: positive rheumatoid Factor; +ACPA: positive antibodies to citrullinated protein antigen; + HLA-SE: presence of shared epitope of Human Leukocyte Antigen; DAS28: disease activity index including a 28-joint count; Ns= not significant.
Statistical tests: [a]two-sample t test,[b]exact Fisher test

Table 2. Differentially regulated genes in MTX non-responder group when compared with MTX responder group

Gene Symbol	Gene Name	Process involved	Fold change (MTX-NR vs MTX-R)
Apoptosis			
HTRA2	HtrA serine peptidase 2	Induction of apoptosis	0.69
CAV1	Caveolin 1	Induction of apoptosis	0.65
CASP8AP2	Caspase 8 associated protein 2	Induction of apoptosis	0.54
PRKDC	Protein kinase, DNA-activated, catalytic polypeptide	Induction of apoptosis	0.49
BCL2A1	BCL2-related protein A1	Inhibition of apoptosis	1.62
MXD1	MAX dimerization protein 1	Inhibition of apoptosis	1.43
TNIP1	TNFAIP3 interacting protein 1	Inhibition of apoptosis	1.35
BTG2	BTG family, member 2	Inhibition of apoptosis	1.32
Immune response			
CCL4	Chemokine (C-C motif) ligand 4	Inflammatory response	1.89

Conclusion: Using analysis of the gene expression profile from PBMC, we observed a unique distinction between MTX-NR and MTX-R patients. These results suggest apoptosis as relevant mechanism involved in the non-response to MTX, providing new gene insights in the pharmacological actions of MTX in the treatment of RA.

1242

Comorbidity and Cost Burden of Patients Prior to Initiating Abatacept or Infliximab As First Line Biologic Therapy for the Treatment of Rheumatoid Arthritis. Theodore Darkow, Digisha Trivedi, Brian Meissner, Lisa Rosenblatt and Tony Hebden. Bristol-Myers Squibb, Plainsboro, NJ

Background/Purpose: Patients with rheumatoid arthritis (RA) typically have significant comorbidity which, along with underlying RA severity, may impact both choice and response to treatment. Prior research has shown that, compared with patients initiating subcutaneous biologic therapy, patients who receive an intravenous (IV) biologic have higher baseline RA-related costs, suggesting more severe disease. However, a description of the characteristics of patients initiating IV biologic therapy has not been done.

Objectives: Characterize baseline healthcare costs and degree of comorbidity and disease severity in RA patients, prior to initiating first-line treatment with the IV administered biologic agents abatacept or infliximab.

Methods: Utilizing a large, managed care plan claims database, an analysis was conducted in adult RA patients during the 6 months prior to initiating first-line biologic treatment with abatacept or infliximab. The identification period was January 1, 2006 through August 31, 2010. Severity of overall comorbidity was described using Charlson Comorbidity Index (CCI) and all-cause health care costs, while RA-related healthcare costs were used as a proxy measure for severity of RA.

Results: A total of 1623 RA patients were identified who initiated abatacept or infliximab as first-line biologic therapy. Baseline RA-related healthcare costs for abatacept treated patients (n=411) were approximately twice those of patients treated with infliximab (n=1212). Baseline total all-cause health care costs and CCI were also significantly higher for abatacept treated patients (Table).

	Abatacept Mean (SD)	Infliximab Mean (SD)	p-value
Baseline Charlson Comorbidity Index	1.64 (1.17)	1.44 (0.92)	0.001
Baseline RA-related health care costs	$3,145 ($10,774)	$1,506 ($4,406)	0.003
Baseline all-cause health care costs	$7,491 ($16,886)	$4,548 ($8,529)	<0.001

Conclusion: In a commercially insured population, those patients initiating first-line abatacept appeared to demonstrate greater baseline severity of RA, as well as more comorbidity than those who received first-line infliximab. Further research is required to better understand how pre-existing conditions and severity of RA impact selection of intravenous biologic therapy and subsequent response in this patient population.

1243

Fatigue in Patients with Rheumatoid Arthritis Treated with Tocilizumab (Actemra®) in Real Life: Clinically Relevant Improvement in 62% of Patients At 4 Months and Rapid Onset of Action. the PEPS Study. Laure Gossec[1], Stephanie Rouanet[2], Ghislaine Steinberg[3] and Bernard G. Combe[4]. [1]Cochin Hospital, Paris, France, [2]Roche, Neuilly sur Seine, France, [3]Roche, Neuilly Sur Seine, France, [4]Hopital Lapeyronie, Montpellier, France

Background/Purpose: Fatigue is an important domain of health in rheumatoid arthritis (RA). Biologics and in particular Tocilizumab (TCZ) have demonstrated their efficacy on fatigue [1]. However, there is a lack of data in real life on the effects of TCZ on fatigue and its rapidity of appearance. The main objective was to describe TCZ real life effect on fatigue over the first 4 months of treatment in RA patients.

Methods: PEPS is a multicenter non-interventional study assessing fatigue in real life in patients starting TCZ. *Patients:* RA patients requiring TCZ according to their physician. *Treatment:* TCZ as prescribed in real life. The first 5 infusions (4 months) were assessed. *Primary endpoint*: percentage of patients with variation of fatigue (FACIT-fatigue scale, 0–52, higher results indicate less fatigue) from inclusion to 4 months, above the minimal clinically important difference (MCID: 4 points) [2]. *Secondary endpoints:* VAS fatigue, SF-36 vitality, HAQ, patient global, sleep, anxiety and depression by HADS, pain, DAS28, haemoglobin and tolerance. *Analysis*: patients with at least one TCZ infusion and FACIT score available at inclusion and at least once under TCZ were analysed. Last observation carried forward (LOCF) method was used to handle missing data on the primary criterion and DAS28. Survival analysis was performed to quantify the onset of action on fatigue. Univariate then multivariate logistic regressions were conducted to explain improvement of fatigue.

Results: 719 pts were included; 610 had analysable data: mean age 56±13 yrs, disease duration 12±10 yrs, 490 (81%) women, 463 (81%) rheumatoid factor or ACPA positive, 84% biologic IR. Mean (±SD) baseline DAS28 and FACIT-fatigue were respectively 5.3±1.1 and 24±10. At 4 months, TCZ reduced disease activity: mean DAS28 was 2.9±1.3, and improved fatigue: mean FACIT-fatigue was 33±11; 62% (n=378) patients reached MCID improvement for fatigue. Less fatigue was already observed at 2 weeks after treatment initiation. The mean percentage reduction of fatigue assessed by the FACIT score versus baseline was respectively 26% at week 2, and 37%, 52%, 61% and 59% at 1, 2, 3 and 4 months. The median time to reach FACIT-fatigue improvement >MCID with maintenance afterwards was 3 months.

In multivariate analysis, the only determinants of improvement of fatigue above MCID were high baseline level of fatigue (OR 3.2; 95% CI 2.0–5.1) and CRP (OR 1.01, 95% CI 1.00–1.03). When excluding baseline fatigue from the analysis, the significant determinants were baseline high levels of CRP (OR 1.01, 95% CI 1.00–1.03), of pain (OR 1.6, 95% CI 1.0–2.6) and baseline low SF36 vitality score (OR 2.0, 95% CI 1.2–3.2).

Safety profile was consistent with phase III results.

Conclusion: In these long-standing active RA patients, TCZ was efficacious on fatigue with rapid reduction seen as early as 2 weeks after the first infusion. Improvement in fatigue was mainly linked to high baseline fatigue, CRP and pain. In patients with disabling fatigue, TCZ may be a useful therapeutic option.

Treatment Satisfaction and Adherence of Patients on Biologic Monotherapy. Jörg Kaufmann[1], Anne-Eve Roske[2], Adrian Kielhorn[2], Eugen Feist[3] and Wolfgang A. Schmidt[4]. [1]Rheumatologist, Ludwigsfelde, Germany, [2]Roche Pharma AG, Grenzach-Wyhlen, Germany, [3]Charité Medical School, Berlin, Germany, [4]Med Ctr Rheumatol Berlin Buch, Berlin, Germany

Background/Purpose: The combination of a biologic DMARD (bDMARD) with methotrexate (MTX) is regarded as the gold standard for patients having not adequately responded to a conventional DMARD (cDMARD) therapy. Nevertheless, up to 40% of patients are receiving bDMARD monotherapy.

The aim is to compare treatment satisfaction and adherence in patients with rheumatoid arthritis on either TNF inhibitors or tocilizumab, both given as monotherapy.

Methods: Data from 254 patients treated with bDMARD monotherapy (TNF inhibitor or tocilizumab) between February and June 2010 were analyzed retrospectively in 23 centers across Germany. Analysis included drug adherence over a period of six months as well as patients and physicians global assessment on a 100 mm analogue scale. Selection criteria were confirmed diagnosis of RA; age > 18 years, and treatment initiation between February and June 2010. Patients had to be on their first or second bDMARD.

Results: Eighty-four percent of the patients were female; the mean age was 58 years (SD=18) and the mean weight was 70kg (SD 15.8). The mean time since diagnosis was 8.7 (SD 7.7) years. The tocilizumab and TNF inhibitor cohorts consisted of 126 and 128 patients, respectively.

Category	Tocilizumab (SD)	TNF inhibitors (SD)	All
Percentage still on treatment after 6 months (adherence)	90% (n=113)	76% (n=97)	83% (n= 210)
Patients global assessment after 6 months	75.3 (23.0)	66.8 (23.6)	71.0 (23.6)
Physicians global assessment after 6 months	74.9 (22.8)	67.1 (23.5)	70.9 (23.5)
General Health (VAS, change from baseline)	−32.0 (23.0)	−15.3 (30.5)	−25.2 (27.4)

*0= not satisfied, 100= satisfied, SD = standard deviation

Conclusion: Biologic DMARD mono-therapy is well tolerated by patients as expressed by the high adherence rate of 83%. The adherence rate of 90% shows tocilizumab to be an attractive treatment option in these patients.

1245

Baseline Tender Joint Count Scores Predict Long-Term Household Productivity in Patients with Rheumatoid Arthritis Treated with Certolizumab Pegol Plus Methotrexate. Arthur Kavanaugh[1], Oana Purcaru[2], Josef Smolen[3], Paul Emery[4], Vibeke Strand[5], Edward Keystone[6] and Ronald F. van Vollenhoven[7]. [1]University of California San Diego, San Diego, CA, [2]UCB, Brussels, Belgium, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [4]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [5]Stanford University, Palo Alto, CA, [6]University of Toronto, Toronto, ON, [7]Karolinska Institute, Stockholm, Sweden

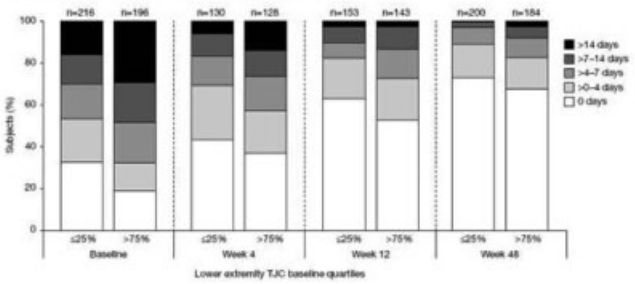
Background/Purpose: The impact of disease activity on household productivity has not been studied in detail. This analysis evaluated if baseline (BL) tender/swollen joint counts (TJC/SJC) are associated with and predict household productivity in patients (pts) with active rheumatoid arthritis (RA) receiving certolizumab pegol (CZP) plus methotrexate (MTX).

Methods: Pooled data at 1 year for CZP 200 and 400 mg completers from RAPID 1 (NCT00152386) and RAPID 2 and its open-label extension (NCT00160602/NCT00160641) were used. Household productivity (missed days of household work, days with reduced household productivity, days with outside help hired, missed days of family/social/leisure activities) was assessed using the Work Productivity Survey (WPS-RA).[1] Frequency distribution of WPS-RA scores over time was summarized by TJC/SJC BL 25% and 75% quartiles. Hand, large upper extremity (shoulder, elbow, hand), large lower extremity (hip [tender-

ness], knee, ankle), or total JC were assessed. Analyses were conducted on observed data (no imputation of missing data).

Results: At BL higher disease activity was associated with higher impairment in household duties and social activities (Table). Pts receiving CZP had rapid, sustained improvements in household productivity over time in all TJC/SJC quartiles. Over 1 year, fewer days of household work were missed per month in pts with lower (≤25% quartile) vs higher (>75% quartile) TJC BL scores in large lower extremity joints: by Week 4 (Wk) 69.2% vs 57.0% of pts missed ≤4 days of household work per month, increasing to 82.4% vs 72.7% by Wk 12 and by Wk 48, to 89.0% vs 82.6% (Figure). Although improvements in household productivity were reported by pts with higher BL TJC scores in the lower extremities, these were consistently smaller vs pts with lower BL TJC scores. Similarly pts with lower TJC BL scores in large lower extremity joints had greater reductions in days with reduced productivity and in days with outside help hired vs pts with higher BL scores. Fewer days of family/social/leisure activities were missed per month in pts with lower vs higher hand/total TJC BL scores. Pts with higher vs lower SJC BL scores had similar improvements in household productivity over time; there were no differences between the 2 groups at Wk 48.

Figure. Number of days with no household work per month (frequency distribution) in CZP patients, by large lower extremity TJC baseline scores (≤25% and >75% quartiles)



Conclusion: At BL higher TJC/SJC scores were associated with increased impairment in household productivity. Improvements in household productivity were seen with CZP treatment in both pts with lower vs higher BL TJC scores, with greater improvements in pts with lowest BL TJC scores.

Improvement & Maintenance of Hemoglobin Levels Among Rheumatoid Arthritis, Psoriatic Arthritis&Ankylosing Spondylitis Patients with Anemia of Inflammation After Treatment with Golimumab:3 Year Pooled Analysis.

Daniel E. Furst[1], Tim Gathany[2], Jonathan Kay[3], Mary Chester Wasko[4], Edward Keystone[5], Arthur Kavanaugh[6], Atul Deodhar[7], Frederick T. Murphy[8], Chenglong Han[9] and Mittie K. Doyle[10]. [1]UCLA, Los Angeles, CA, [2]Johnson & Johnson Pharmaceutical Services, LLC, Horsham, PA, [3]University of Massachusetts Memorial Medical Center/University of Massachusetts Medical School, Worcester, MA, [4]West Penn Allegheny Health System, Pittsburgh, PA, [5]University of Toronto, Toronto, ON, [6]University of California San Diego, San Diego, CA, [7]Oregon Health & Science University, Portland, OR, [8]Altoona Ctr for Clinical Research, Duncansville, PA, [9]Johnson & Johnson Pharmaceutical Services, LLC, Malvern, PA, [10]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC/University of Pennsylvania School of Medicine, Malvern/Philadelphia, PA

Background/Purpose: Previous analyses have shown that treatment with golimumab (GLM) for 6 months resulted in significant improvements in hemoglobin (Hgb) levels among patients with anemia at baseline, particularly for patients with anemia of inflammation. The purpose of this analysis was to determine the long-term effects of GLM on anemia of inflammation in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS).

Methods: Data through 3 yrs were pooled from 5 studies in the GLM rheumatology clinical program including: 3 RA studies (GO-BEFORE, GO-FORWARD, GO-AFTER), 1 PsA study (GO-REVEAL), and 1 AS study (GO-RAISE). Subcutaneous (SC) placebo (PBO) or GLM (50mg or 100mg) was administered q4wks in the randomized portions of the ongoing Phase3 trials. At 6 months/1 yr, pts remaining in the studies entered long term extensions (LTE) and received GLM 50mg or 100mg q4wks in an unblinded fashion. Dose escalation from 50mg to 100mg was allowed; no dose reduction was permitted. Primary endpoints for the studies compared patients treated with GLM±MTX with patients receiving placebo (PBO±MTX). Patients were defined as anemic if their Hgb were below the age- and sex-specific normal range of the central laboratory (Quintiles Laboratories, Smyrna, GA, United States). The normal Hgb range for the central laboratory was 11.6 to 16.2 g/dL for women aged ≤65 yrs, 11.0 to 16.1 g/dL for women aged ≥66 yrs, 13.0 to 17.5 g/dL for men aged ≤65 yrs, and 12.6 to 17.7 g/dL for men aged ≥66 yrs. A subset of patients with anemia of inflammation (anemic and ferritin ≥ 60 ng/mL), at baseline (BL) was analyzed for normalization and improvement of Hgb levels at 6 months; the long-term maintenance of these improvements were also analyzed at yrs 1, 2, and 3.

Results: At 6 months, among patients who had anemia of inflammation at baseline, patients treated with GLM±MTX showed greater Hgb improvements than patients treated with PBO±MTX (median improvement: 1.45 g/dL vs. 0.55 g/dL, $p < 0.001$) at 6 months. More GLM±MTX-treated patients achieved normal Hgb (67.9% vs. 42.3%, $p = 0.020$). Table 1 shows that 93.0% to 96.7% of these patients maintained normal Hgb at 1-, 2- and 3 years.

Table 1. Pooled Analysis of Data From GLM Rheumatology Clinical Trials-Maintenance of Normalized Hgb /Improvement From 6 Months to Years 1, 2, and 3 Among Pts With Anemia of Inflammation at BL

	Anemia of Inflammation at BL	Anemia of Inflammation at BL; Median Hgb improvement (g/dL)
Normalized Hgb at 6 months		
PBO	11/27 (40.7%)	0.55
GLM±MTX	55/84 (65.5%)	1.45
Maintenance of normalized Hgb*		
Year 1	58/62 (93.6%)	1.9
Year 2	59/61 (96.7%)	1.8
Year 3	53/57 (93.0%)	2.0

At 6 months all patients were receiving GLM (except in GO-BEFORE where all patients were receiving GLM at 1 year)
* Of all patients (including PBO- and GLM-treated patients) who had anemia of inflammation at BL and improved at 6 months

Conclusion: Among patients with RA, PsA and AS with anemia of inflammation at BL, patients treated with GLM±MTX achieved greater median improvements in Hgb and greater proportions had normalized Hgb levels at 6 months. Patients who achieved normal levels at 6 months and continued treatment with GLM, maintained the normal Hgb levels through 3 yrs. These improvements in anemia of inflammation support the hypothesis that anemia of inflammation responds to suppression of inflammation with GLM.

1247

Rheumatologists' Benefit-Risk Preferences for Biologic Treatments for Rheumatoid Arthritis.

A. Brett Hauber[1], James T. Cross[2], David E. Yocum[3], F. Reed Johnson[1], Jui-Chen Yang[1], Isidro Villaneuva[2] and Patricia P. Katz[4]. [1]RTI Health Solutions, Research Triangle Park, NC, [2]Genentech, Inc., South SanFrancisco, CA, [3]Genentech, Inc, South San Francisco, CA, [4]University of California San Francisco, San Francisco, CA

Background/Purpose: Little data exists on how physicians weigh benefit-risk tradeoffs of drugs, despite the impact on prescribing decisions. Biologic rheumatoid arthritis (RA) treatments can yield substantial benefits for patients, but can be associated with potentially serious, life-threatening risks. The aim of this study was to examine rheumatologists' preferences when weighing potential benefits and potential risks of biologic RA therapies.

Methods: US rheumatologists treating 10 or more RA patients monthly completed a web-enabled survey with a series of treatment-choice questions. These questions required choosing between two hypothetical RA treatments with differing levels of efficacy (defined as reduction in difficulty doing activities of daily living) and five potential treatment-related risks: annual risks of pneumonia, pneumocystis and progressive multifocal leukoencephalopathy (PML); 5-year risk of lymphoma; and risk of post-injection/-infusion anaphylaxis. An index of the importance of each treatment attribute was estimated using a mixed-logit choice model. The results of the model were used to calculate the

maximum level of each risk rheumatologists considered acceptable to achieve different improvements in patients' functioning.

Results: 190 rheumatologists completed the survey. The majority (77%) was male and in private practice (84%). Most (70%) had been in practice for at least 10 years.

Rheumatologists were willing to accept increases in treatment-related risks to improve a patients' ability to do daily activities. The most important risk was annual PML, followed in order of decreasing importance by 5-year risk of lymphoma, risk of post-injection/-infusion anaphylaxis, annual risk of pneumocystis, and annual risk of pneumonia. The maximum level of treatment-related risks that rheumatologists would accept for reduced limitations on daily activities from moderate to mild or from mild to none are presented in Table 1. Rheumatologists were consistently more willing to accept greater risks for greater benefits (improving RA from moderate to mild). Serious but rare risks such as PML, lymphoma and anaphylaxis were much less tolerated than more common risks with significant morbidity and mortality.

Table 1. Maximum percentage-point treatment-related risk rheumatologists would accept for different improvements in limitations on daily activities.

Treatment-Related Risk	Maximum Acceptable Risk for an Improvement in daily limitations from Moderate to Mild	Mild to None
Annual risk of PML	0.48% (0.36,0.60)	0.25% (0.15,0.34)
5-year risk of lymphoma	0.96% (0.57,1.35)	0.49% (0.28,0.70)
Risk of anaphylaxis after each injection or infusion	1.08% (0.71,1.45)	0.55% (0.32,0.79)
Annual risk of pneumocystis	2.23% (0.46,4.00)	1.14% (0.22,2.06)
Annual risk of pneumonia	3.78% (2.76,4.81)	1.94% (1.18,2.69)

Conclusion: Rheumatologists do not place uniform importance on different potential treatment-related risks. In order to reduce the impact of RA on patients' ability to conduct daily activities, rheumatologists appear willing to accept levels of treatment-related greater than those levels reported in the literature. PML was more unacceptable than we anticipated relative to risks such as lymphoma and pneumocystis that are associated with substantial morbidity, mortality and much greater frequency.

1248

Assessment of Immune Responses to Pneumococcal and Influenza Vaccines in Patients with Rheumatoid Arthritis Receiving Certolizumab Pegol. A. Kivitz[1], Joy Schechtman[2], Michele Texter[3], Andreas Fichtner[4] and Elliot Chartash*[3]. [1]Altoona Center for Clinical Research, Duncansville, PA, [2]SunValley Arthritis Center, Peoria, AZ, [3]UCB, Smyrna, GA, [4]UCB Biosciences GmbH, Monheim, Germany

Background/Purpose: The extent of antibody response to influenza and pneumococcal vaccination was evaluated in adult patients (pts) with rheumatoid arthritis (RA) receiving certolizumab pegol (CZP) or placebo (PBO).

Methods: This was a 6-week (wk) randomized, single-blind, PBO-controlled, phase IV trial followed by a 6-month open-label phase (NCT00993668). In the 6-wk phase, pts were randomized 1:1 and stratified by concomitant (MTX) use to receive CZP 400 mg or PBO at Wks 0, 2, and 4. All pts received commercially available 23-valent pneumococcal and 2009–10 trivalent subvirion influenza virus vaccines at Wk 2, prior to dosing with CZP. The co-primary endpoints (assessed independently) were the percentage of pts, in the per protocol set (PPS, included only those pts without protective titers at baseline [BL]) with a satisfactory humoral response defined as a ≥2-fold titer increase in ≥3 of 6 pneumococcal antigens (6B, 9V, 14, 18C, 19F, and 23F) and a ≥4-fold increase for each of 3 influenza antigens (H1N1 [nonpandemic], H3N2, and B), at Wk 6 (4 wks post-vaccination). Differences in proportions between groups were presented with a 95% confidence interval (CI). The results from 6-wk phase are reported.

Results: Of 224 randomized pts (CZP = 110; PBO = 114), 217 (96.9%) completed the 6-wk single-blind phase. BL demographics were similar between groups; 65.5% (72/100) of CZP and 68.4% (78/114) of PBO pts had concomitant MTX use (mean dose,16.6 mg/wk) at BL. In the PPS, following pneumococcal vaccination 53.3% of CZP pts (48/90) and 62.2% (56/90) of PBO pts achieved humoral response, at Wk 6 (–8.9; 95% CI: –23.3; 5.5). Following influenza vaccination, 54.0% (47/87) of CZP pts and 61.9% (52/84) of PBO pts achieved humoral response, at Wk 6 (–7.9; 95% CI: –22.7; 6.9). There was a >2-fold increase from BL to Wk 6 in titers in both treatment groups for each of the antigens tested in all pts including those with protective titers at BL (full analysis set, FAS). Following vaccination, 62.6% (67/107) of CZP and 65.5% (72/110) of PBO pts and 71.0% (76/107) of CZP and 77.1% (84/109) of PBO pts in the FAS developed protective pneumococcal and influenza antibody titers, respectively. Responses to pneumococcal and influenza antigens were reduced in both CZP and PBO pts who received concomitant MTX vs those who did not (CZP vs PBO: pneumococcal antigens, with concomitant MTX = 45.2% [28/62] vs 49.2% [30/61], without concomitant MTX = 71.4% [20/28] vs 89.7% [26/29]; influenza antigens, with concomitant MTX = 47.4% [27/57] vs 50.9% [29/57], without concomitant MTX = 66.7% [20/30] vs 85.2% [23/27]). Incidence of adverse events was comparable in CZP and PBO; most events were mild to moderate in intensity. There was 1 death in CZP group (bladder cancer diagnosed during study; unrelated to study drug) and none in the PBO group.

Conclusion: Humoral responses to pneumococcal and influenza vaccines were comparable in RA pts receiving treatment with CZP and PBO. Vaccine responses were reduced in both treatment groups with concomitant MTX therapy. These results indicate that RA pts receiving CZP can be effectively immunized with pneumococcal and influenza vaccines.

Number of Cardiovascular Risk Factors May be Associated with Higher Disease Activity Severity. Exploratory Analysis of Baseline Data from the Canadian Methotrexate and Etanercept Outcome Study: A Randomized Trial of Etanercept and Methotrexate vs Etanercept Alone in Rheumatoid Arthritis. Janet Pope[1], Edward Keystone[2], Boulos Haraoui[3], J. Carter Thorne[4] and Melanie Poulin-Costello[5]. [1]Univ of Western Ontario, London, ON, [2]University of Toronto, Toronto, ON, [3]Institut de Rhumatologie, Montreal, QC, [4]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [5]Amgen Canada Inc., Mississauga, ON

Background/Purpose: We designed a real-world rheumatoid arthritis (RA) non-inferiority trial to compare the proportion of patients with low disease activity while on etanercept (ETN) monotherapy vs ETN + methotrexate (MTX). The trial is still ongoing. Baseline data were explored to determine if cardiovascular (CV) risk factors such as hypertension (HTN), diabetes mellitus (DM), hypercholesterolemia, prior myocardial infarction (MI), and high body mass index (BMI) correlate with higher baseline disease activity. Two studies suggest increased erosions in those with low BMI in early RA.[1,2]

Methods: Baseline characteristics of established RA patients who, despite MTX therapy, had active disease (≥ 3 swollen joints), DAS28 ≥ 3.2, and were TNF inhibitor naïve were studied. A post-hoc exploratory analysis of baseline data examined the impact of CV risks on baseline DAS, adjusting for sex, age, prior RA medications, and duration of disease, using analysis of variance (ANOVA). Model selection was done by backwards elimination for $p < 0.1$.

Results: 258 patients with active RA (76% female; mean age, 54.7 ± 12.5 yrs; DAS28, 5.4 ± 1.1; duration of RA, 8.9 ± 8.4 yrs) were enrolled. Mean baseline health assessment questionnaire (HAQ) score was 1.38 ± 0.61. Mean duration of MTX treatment was 4.9 ± 4.7 yrs (mean dose, 20.5 ± 4.1 mg/wk). Higher baseline disease activity was statistically correlated with an increased number of CV risk factors ($p < 0.0001$), although each CV risk was not significant. No other factors had a significant statistical correlation with DAS28. In addition, BMI and DAS were not related statistically.

Limitations: Data on smoking and family history of CV events were not collected, and CV risk was determined from patient medical history. Only patients with active disease were selected for the study; which could bias the results compared to a prevalent RA population. Our study size is small and this was a post-hoc analysis, however numerically (but not statistically) it appears that many CV risk factors were associated with higher DAS.

Table 1. Cardiovascular Comorbidities and Disease Activity at Baseline

Comorbidity	Total Population (N = 258)	
	n	Mean DAS28 (95% CI)
Number of CV risk factors*, p = 0.0002[a]		
0	116	5.1 (4.9, 5.3)
1	75	5.6 (5.3, 5.8)
2	41	5.7 (5.4, 6.0)
≥ 3	26	6.0 (5.6, 6.4)
Gender, p = 0.0678		
Female	197	5.5 (5.3, 5.6)
Male	61	5.2 (4.9, 5.5)
Diabetes Mellitus, p = 0.2481		
Yes	18	5.7 (4.9, 6.5)
No	239	5.4 (5.3, 5.5)
Hypertension, p = 0.1417		
Yes	81	5.8 (5.6, 6.0)
No	154	5.2 (5.0, 5.4)
Hypercholesterolemia†, p = 0.9254		
Yes	43	5.7 (5.4, 6.0)
No	215	5.4 (5.2, 5.5)
Myocardial infarction, p = 0.7403		
Yes	11	5.9 (4.9, 6.8)
No	247	5.4 (5.3, 5.5)
BMI, kg/m^2, p = 0.3057[b]		
< 18.5	5	5.9 (5.4, 6.4)
≥ 18.5 to < 25	59	5.3 (5.0, 5.6)
≥ 25 to < 30	74	5.3 (5.1, 5.5)
≥ 30	63	5.8 (5.5, 6.1)
Other CV medical history, p = 0.5820		
Yes‡	27	5.6 (5.2, 6.0)
No	231	5.4 (5.3, 5.5)
Elevated CRP[c]		
≥ 3 mg/L	173	5.6 (5.4, 5.8)
< 3 mg/L	51	4.7 (4.5, 4.9)

[a] p-values from the multivariate ANOVA backwards elimination results. Age, duration of disease, and duration of methotrexate were also included in the model (p > 0.10) but are not shown here.
[b] BMI was a continuous variable in the ANOVA
[c] Not included in the ANOVA
* CV risk factors: hypertension, hypercholesterolemia, diabetes, prior MI, BMI ≥ 30
† Hypercholesterolemia includes dyslipidemia and high cholesterol
‡ 27 subjects had 46 cardiac-related medical histories including: angina attack, angina pectoris, angioplasty, cardiac catheterization, cardiovascular disease, carotid artery stenosis, carotid endarterectomy, coronary artery bypass graft, coronary arterial stent insertion, dyslipidemia (resolved at time of study start), hypertension (resolved at time of study start), ischemia, myocardial infarction, stent placement
Abbreviations: ANOVA = analysis of variance; BMI = body mass index; CI = confidence interval; CRP = C-reactive protein; CV = cardiovascular; MI = myocardial infarction

Conclusion: There is a statistical suggestion from this baseline data that an increase in the number of CV risks were associated with worse baseline DAS28 scores in this clinical trial of patients with active RA.

Effect on rheumatoid factor and anti-Cyclic Citrullinated Peptide Antibodies Levels of treatment with Infliximab and Adalimumab in patients with Rheumatoid Arthritis. Selene Baos, Chamaida Plasencia, Susana Ramiro, Rosario Moral, Jesús Díez, E. Martin-Mola, Alejandro Balsa and Dora Pascual-Salcedo. La Paz University Hospital, Madrid, Spain

Background/Purpose: Rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (ACPA) have been demonstrated to be useful in the diagnosis of rheumatoid arthritis (RA). Therapeutical monoclonal antibodies that inhibit tumour necrosis factor (TNF) activity, like infliximab (IFX) and adalimumab (ADA), have a demonstrated effect in the improvement of RA disease activity. IFX and ADA can induce the development of anti-drug antibodies (Abs) and this has been associated with a poor clinical response. Our aim was to study the effect of anti-TNF therapy (with IFX or ADA) on the variation of RF and ACPA levels in RA patients with a long-term treatment and if the formation of anti-drug Abs, concomitant treatment with MTX and the clinical response have any influence on RF and ACPA titers

Methods: We studied 83 patients with active RA treated with a TNF inhibitor (50 patients with IFX,and 33 with ADA), for a median of 4.3 (± 2.6) years. Clinical characteristics, serum trough drug levels and the presence of anti-drug Abs were evaluated. Clinical activity was measured by Disease Activity Score 28 (DAS28) and clinical response was evaluated by EULAR criteria. ACPA were measured by second generation ELISA, RF by nephelometry and the presence of anti-drug Abs by a bridging ELISA (1). Three time points (6 months, 1 year and 2–4 years) were chosen for the study. For the purpose of this study only patients with positive RF and/or ACPA were considered.

Results: RF was positive in 79 (95.2%) patients and ACPA in 76 (91.6%) patients. Both drug group (IFX and ADA) were analyzed together because no differences were seen in the decrease of RF (p=0.108) and ACPA (p=0.888) levels between groups. At baseline, there was no association between clinical activity and ACPA and RF levels (Pearson correlation (PC)=0.21 and PC=0.25, respectively). At 6 months RF but not ACPA, showed a significant decrease (320.66±393.53 at baseline vs 181.26±239.60 at 6 months, p<0.001 in RF and 1537.82±1263.87 at baseline vs 1428.59±1278.33 at 6 months, p=0.239 in ACPA). At 1 year and 2–4 years, both RF and ACPA titers had a significant decrease (p<0.05).The relative change (%) was significantly higher for RF than for ACPA during all the study (p<0.0001). More patients became negative in RF than in ACPA levels along the study [7 out of 79 (8.8%) vs 5 out of 76 (6.5%) at 6 months (p=0.4), 19 out of 79 (24%) vs 4 out of 76 (5.2%) at 1 year (p=0.001), 21 out of 79 (26.5%) vs 4 out of 76 (5.2%) at 2–4 years (p=0.0001), respectively]. EULAR clinical response was not associated by the lost of positivity of RF and ACPA at any studied point (p>0.1). RF and ACPA levels were not affected by the development of anti-drug Abs (p=0.2 and p=0.62, respectively), concomitant MTX therapy (p=0.858 and p=0.588, respectively) and clinical EULAR response at 4 years (p=0.165 and p=0.537, respectively).

Conclusion: The anti-TNF therapy has an influence on RF and ACPA levels. in RA patients in a long term treatment, being RF decrease more pronounced than the reduction of ACPA levels. The change in the RF and ACPA titers was not associated with a improvement in the clinical response.

Does Single Nucleotide Polymorphism in Folate Metabolic Pathway Contribute to Methotrexate Efficacy in Indian (Asian) Patients with Rheumatoid Arthritis? Yogita Ghodke[1], Arvind Chopra[2], Amrutesh S. Puranik[1], Pooja Shintre[3], Anjali Radkar[4], Kalpana Joshi[5] and Bhushan Patwardhan[5]. [1]University of Minnesota, Minneapolis, MN, [2]Centre for Rheumatic Diseases, Pune 411001, India, [3]Sinhgad College of Engineering, Pune, India, [4]Gokhale Institute of Politics and Economics, Pune, India, [5]Symbiosis International University, Pune - 411042, India

Background/Purpose: Folate antagonist MTX is preferred because of its cost and long term experience. However, ~50% patients experience good clinical response. Inconsistent non genetic prediction (treatment response) variables, significant variability in MTX response and expensive alternative biologic DMARDs demand better predictive markers for MTX response. We investigated SNPs in folate metabolic pathway in Indian (Asian) RA patients treated with MTX. We hypothesized that these SNP would affect MTX pharmacokinetics (PK) and MTX treatment outcome.

Methods: A total of 336 ACR classified RA patients (Female 85%, RF 79%) undergoing supervised MTX therapy for > 3 months were randomly selected from a community rheumatology clinic; 217 patients were analyzed; maximum (usually limited by tolerability) MTX dose 3.75–20 mg, median 17.5mg. We retrospectively analyzed standard CRF but recalled several patients to confirm events. Responders were classified as patients having ACR 50 at 12 months plus ACR 20 response at 6 months; ACR improvement response as per ACR. 12 SNPs in 9 genes of

folate-MTX metabolism (including transporters) were genotyped using PCR-RFLP and Real-time Taqman allelic discrimination that also included 144 healthy controls (HC). To evaluate the effect of SNPs on MTX PK; PK analysis was performed on 94 patients (weekly dose ranging 3.75 mg – 20 mg). Plasma MTX and its metabolite 7-OH MTX levels were determined at 0, 2 and 8 hr. by HPLC post column photoxidation-fluorescence detection and plasma homocysteine was estimated at 0 hr.

Results: (1) *MTHFR* A1298C 'C' allele (OR =2.6, 95% CI 1.9– 3.5, P<0.0001) and *RFC*1 G80A 'G' allele (OR=2.0, 95% CI, 1.5– 2.7, P<0.0001) were significantly associated with RA when compared to HC. (2) The table shows frequency distribution of genotypes associated with ACR 50 response. At 12 months patients with *MTHFR* 1298 CC genotype and *RFC*1 80 GG genotype were more likely to have poor MTX efficacy relative to *MTHFR* 1298 AA-AC (OR= 3.3, 95% CI 1.3–8.5, P=0.01) and *RFC*1 80 AA-GA (OR= 2.2, 95% CI 1.0–4.9, P=0.04) respectively. None of the other SNPs in folate-MTX pathway were associated with MTX efficacy in our RA population. (3) PK analysis revealed no significant difference in the plasma concentration of MTX, 7OH MTX and Hcy at 0hr, 2hr and 8 hrs between responders and non responders. However patients having 1298 CC genotype showed higher 7 OH MTX levels at 8 hrs.

Polymorphism	ACR 50 response	
	Responders (n=49)	Non responders (n=168)
***MTHFR* A1298C** AA + AC CC	0.840.16	0.680.32*
***RFC*1 G80A** AA + GA GG	0.730.27	0.600.40*

Conclusion: Patients with *MTHFR* 1298 CC and *RFC*1 80 GG showed poor clinical improvement with MTX. PK study show some associations with genetic polymorphisms but need to be further validated. SNPs in folate pathway may contribute to MTX efficacy in Indian RA patients. Large sample size validation cohort would be required to confirm our observations with an attempted higher dose to treat.

Association of ACR Clinical Responses with CDAI (Clinical Disease Activity Index) and RAPID3 (Routine Assessment of Patient Index Data 3) Indices of Disease Activity in Rheumatoid Arthritis Patients Treated with Certolizumab Pegol Plus Methotrexate. Michael H. Schiff[1], Kristel Luijtens[2], Owen Davies[2] and Yusuf Yazici[3]. [1]Rheumatology Division, University of Colorado, Denver, CO, [2]UCB, Brussels, Belgium, [3]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: CDAI (clinical disease activity index) and RAPID3 (routine assessment of patient index data 3) cut points defining responses that best match ACR20/50/70 response in rheumatoid arthritis (RA) patients (pts), are unknown. This study evaluates these cut points in a large study population treated with certolizumab pegol (CZP) plus methotrexate (MTX)[1].

Methods: ACR responders through Week (Wk) 12 from 393 pts treated with CZP (initial dose of 400 mg at Wks 0, 2 and 4 followed by 200 mg every 2 wks) plus MTX in RAPID 1 trial (NCT00152386) were categorized by proposed response cut points in CDAI (change from baseline CFB ≥6.7, ≥10.0, ≥13.9 and RAPID3 CFB ≥1.8, ≥3.6). ACR20/50/70 responses were compared with these proposed categorizations using cross-tabulations and kappa statistics. CART[2] (classification and regression trees) modeling was used to identify CDAI and RAPID3 cut points most closely associated with ACR20/50/70 responses.

Results: At Wk 12, almost all (93–100%) ACR20/50/70 responders achieved CFB in CDAI (≥6.7, ≥10.0, ≥13.9); however fewer pts (73–80%) with CFB in CDAI (≥6.7, ≥10.0, ≥13.9) achieved an ACR20 response (Table 1). CFB in CDAI≥13.9 was most closely associated with ACR20 response (κ=0.57). Association between proposed categorizations and ACR50/70 was weak (κ range: 0.05–0.29). Nearly all (90–100%) ACR20/50/70 responders achieved CFB in RAPID3 (≥1.8, ≥3.6); fewer pts (75–80%) with a CFB in RAPID3 (≥1.8, ≥3.6) also achieved an ACR20 response (Table 2). CFB in RAPID3≥3.6 was most closely associated with ACR20 response (κ=0.55); association between proposed categorizations and ACR50/70 was weak (κ range: 0.08–0.30). CART modeling identified CFB in CDAI ≥13.80, ≥20.15 and CFB in RAPID3 ≥5.46, ≥7.28 as the categorizations most closely associated with ACR50/70 responses. There was better association between ACR50 response and CART-defined CDAI of CFB ≥20.15 (κ=0.43) compared with proposed categorizations (κ range: 0.14–0.29) (Table 1) and better association with ACR70. CART-defined RAPID3 categorizations were more closely associated with ACR20/50/70 responses; with better association between ACR50 and CART-defined RAPID3 categorizations (κ=0.45) than with proposed categorizations (κ range: 0.21–0.30) (Table 2).

Table 1.

	ACR responders at Week 12 who also achieved CDAI CFB in patients[a] according to proposed cutpoints (Patients%) *Patients[a] (%) with CFB in CDAI who also achieved an ACR response at Wk 12* (kappa coefficient)			ACR responders at Wk 12 who also achieved CDAI CFB in patients[a] according to cutpoints defined by CART modelling (patients%) *Patients[a] (%) with CFB in CDAI who also achieved an ACR response at Wk 12* (kappa coefficient)	
	CDAI ≥6.7	CDAI ≥10.0	CDAI ≥13.9	CDAI ≥13.80	CDAI ≥20.15

ACR70	100.0	98.31		94.9	
	18.8 (0.08)	*21.0* (0.13)		*24.8* (0.20)	

CFB, change from baseline; CDAI, clinical disease activity index; RAPID3, routine assessment of patient index data 3; CART, classification and regression trees
[a] Patients who received an initial dose of CZP 400 mg Wks 0, 2 and 4 followed by 200 mg every 2 wks plus MTX

Conclusion: Thresholds for CDAI and RAPID3 CFB were identified that defined the closest associations with ACR responses in pts with inadequate response to MTX and high disease activity at baseline (mean DAS28 6.9). Responses based on cut points closely associated with ACR20 were identified, but association with ACR50 and ACR70 was not as strong. Further studies are needed to analyze different pt populations, including those with lower disease activity at baseline.

Efficacy and Safety of Certolizumab Pegol in a Broad Population of Patients with Active Rheumatoid Arthritis: Week 28 Results From a Phase IIIb Randomized Controlled Study. Michael Weinblatt[1], Roy M. Fleischmann[2], Ronald F. van Vollenhoven[3], Paul Emery[4], T.W.J. Huizinga[5], Maurizio Cutolo[6], Ruth Goldermann[7], Benjamin Duncan[8], Owen Davies[9] and Maxime Dougados[10]. [1]Brigham & Women's Hospital, Boston, MA, [2]MCRC, University of Texas, Dallas, TX, [3]Karolinska Institute, Stockholm, Sweden, [4]University of Leeds, Leeds, United Kingdom, [5]Leiden University Medical Centre, Leiden, Netherlands, [6]Research Laboratory and Academic Unit of Clinical Rheumatology, University of Genova, Genova, Italy, [7]UCB, Monheim, Germany, [8]UCB, Raleigh, NC, [9]UCB, Brussels, Belgium, [10]Rene Descartes University, Paris, France

Background/Purpose: In the 12-week (wk) REALISTIC (**R**A **E**v**AL**uation **I**n **S**ubjects receiving **T**NF **I**nhibitor **C**ertolizumab pegol) (NCT00717236) Phase IIIb trial, certolizumab pegol (CZP) was associated with rapid and consistent clinical responses, reduced disease activity, and improved physical function in a diverse group of rheumatoid arthritis (RA) patients (pts) irrespective of concomitant or prior therapy or disease duration.[1,2] We evaluated clinical responses in pts who completed the 12-wk double-blind (DB) phase and entered the open-label extension (OLE), up to Wk 28.

Methods: Following the 12-wk DB phase (CZP 400 mg/placebo [PBO] at Wks 0, 2, 4, then CZP 200 mg/PBO at Wks 6, 8, 10 plus current treatment) pts received open-label CZP 200 mg every other week

for ≥16 Wks. ACR responses, change from baseline (BL) in DAS28(CRP) and HAQ-DI, and DAS28(ESR) remission (DAS28 <2.6) at Wk 28 are shown in CZP and PBO Wk 12 completers receiving at least 1 dose of OL CZP at Wk 12 (OLE population). Pts who withdrew from the OLE for any reason had data imputed from that time point onward. For ACR responses, NRI and LOCF (from OLE visits only) were used for pts who withdrew due to AEs/lack or loss of efficacy and other reasons, respectively. Mixed model repeated measures (MMRM) was used for DAS28 and HAQ-DI. Safety data in DB phase and up to Wk 28 in OLE are presented.

Results: Of 851 CZP and 212 PBO pts in the ITT population, 771 (90.6%) and 184 (86.8%) completed the 12-wk DB phase and entered the OLE, respectively. BL disease characteristics and prior and concomitant therapy at randomization (Wk 0) were similar between CZP and PBO completers (Table). Percentage of pts with prior TNF inhibitor use was similar in OLE and DB phase (37.4% vs 37.6%, respectively). Clinical responses and improvements in DAS28 and HAQ-DI were comparable in CZP (28 wks CZP) and PBO (16 wks CZP) completers (Table). At Wk 28, DAS28(ESR) remission (DAS28<2.6) was achieved in 15.2% and 11.4% of CZP and PBO completers, respectively. CZP safety profile was similar to previous CZP trials. In the DB phase, incidence of AEs and serious AEs in CZP vs PBO groups was 522.05 and 26.68 vs 483.20 and 25.83 cases/100 pt-years, respectively; there were 2 deaths (1 case each of sigmoid diverticulitis and necrotizing pneumonia). In the OLE, incidence of AEs and serious AEs in CZP vs PBO completers was 239.12 and 13.03 vs 328.85 and 20.61 cases/100 pt-years, respectively; 2 deaths (1 case each of myocardial infarction and small-cell lung cancer) and 1 case of disseminated tuberculosis were reported.

Table. Disease characteristics at baseline and efficacy outcomes at Wk 28 for patients originally randomized to double-blind CZP or PBO for 12 weeks (CZP or PBO completers) followed by open-label CZP

Disease characteristics and prior and concomitant therapy in the OLE population at randomization (Wk 0)	Patients originally receiving CZP in the double-blind phase (CZP completers [28 wk CZP treatment]) n=770[a]	Patients originally receiving PBO in the double-blind phase (PBO completers [16 wk CZP treatment]) n=184
DAS28(CRP), mean (SD)	5.69 (0.90)	5.72 (0.84)
DAS28(ESR), mean (SD)	6.36 (0.94)	6.44 (0.85)
HAQ-DI, mean (SD)	1.48 (0.64)	1.60 (0.59)
Disease duration (years)		
Mean (SD)	8.53 (8.67)	8.85 (9.04)
Median (interquartile range)	5.30 (2.14–12.00)	6.43 (2.00–12.94)
Disease duration ≥2 years, n (%)	566 (76.1)	139 (75.5)
Prior TNF inhibitor use, n (%)	286 (37.1)	71 (38.6)
Concomitant MTX use, n (%)	533 (69.2)	128 (69.6)
Clinical assessment in the OLE population at Wk 26		
ACR20 responders,%	59.7	53.3
ACR50 responders,%	36.0	31.0
ACR70 responders,%	18.1	14.7
LS mean change from BL in DAS28(CRP)	−1.97	−1.82
LS mean change from BL in DAS28(ESR)	−2.18	−2.00
LS mean change from BL in HAQ-DI	−0.47	−0.40

NRI, non-responder imputation; LS, least square; DAS, disease activity score; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; HAQ-DI, health assessment questionnaire-disability index. [a]The number varies from n=771 CZP Wk 12 completers entering the OLE due to 1 CZP completer who discontinued the OLE after Wk 12 due to an AE, did not receive any study medication in the OLE, and was not included in the OLE analysis set.

Conclusion: In a diverse group of pts with RA, treatment with CZP was associated with rapid efficacy and improvements in disease activity and physical function up to 28 weeks, irrespective of concomitant DMARDs, prior TNF inhibitor therapy, or duration of disease.

No Change in Arterial Stiffness After 6 Months of Abatacept Treatment in Rheumatoid Arthritis. Sylvain Mathieu[1], Bruno Pereira[2], Emilie Rabois[1], Anne Tournadre[1], Jean Jacques Dubost[1] and Martin Soubrier[2]. [1]CHU Gabriel Montpied, Clermont-Ferrand, France, [2]CHU CLERMONT-FERRAND, Clermont-Ferrand, France

Background/Purpose: The excess cardiac risk found in rheumatoid arthritis (RA) has been attributed to biological inflammation. Effective control of inflammation and disease activity may be of benefit in reducing cardiovascular risk in RA patients.

Methods: and Objectives: To investigate the effects of 24 weeks of abatacept treatment in active RA on arterial stiffness measured by augmentation index (AIx) and pulse wave velocity (PWV) and on traditional cardiovascular risk factors (lipid profile, blood pressure).

Results: Twenty-one patients, of whom 17 (81.0%) were female; with a mean age of 65.2 ± 13.7 years and a mean disease duration of 21.5 ± 10.0 years, were included. Of the 21 RA patients, 10 (47.6%) had positive rheumatoid factors, 16 (76.2%) had positive anti-CCP antibody, and 90.5% (n=19) were erosive. Sixteen patients (76.2%) were non-responders to anti-TNF alpha treatments.

After 6 months of abatacept treatment, no change was observed in PWV and AIx (PWV: 8.5 ± 3.8 m/s at baseline, 9.3 ± 3.0 at 6 months; p=0.07 and AIx: 31.4 ± 10.7% at baseline, 31.6 ± 9.1 at 6 months; p=0.97). A significant increase in levels of HDL cholesterol (1.64 ± 0.45 mmol/l at baseline, 1.93 ± 0.62 at 6 months; p=0.01) and a decrease in atherogenic index (total cholesterol/HDL cholesterol), but not to a level of significance (3.14 ± 0.79 at baseline, 2.89 ± 0.96 at 6 months, 3.37 ± 1.03 at one year; p=0.14), were obtained. We found no modification in levels of total cholesterol (4.91 ± 0.99 mmol/l at baseline, 5.22 ± 0.86 at 6 months; p=0.33), LDL cholesterol (2.65 ± 0.65 mmol/l at baseline, 2.70 ± 0.63 at 6 months; p=1.0) or triglycerides (1.17 ± 0.53 mmol/l at baseline, 1.31 ± 0.73; p=0.72). No change was found in levels of blood pressure. DAS28 ESR (5.1 ± 1.0 at baseline, 3.5 ± 1.3 at 6 months; p<0.001) and DAS28 CRP (4.8 ± 0.9 at baseline, 3.4 ± 1.2 at 6 months; p<0.001) were significantly improved. We found a significant decrease in parameters of biological inflammation, significant for ESR (35.7 ± 38.9 mm/h at baseline, 26.6 ± 28.1 at 6 months; p=0.04) but not for CRP (21.5 ± 36.1 mg/l at baseline, 11.8 ± 15.1 at 6 months; p=0.61).

Conclusion: This study shows that arterial stiffness was not improved after 6 months of abatacept therapy. This lack of improvement might be due to insufficient decrease in biological inflammation in these 21 RA patients. However, the treatment did have a beneficial effect on lipid profile and so it would be interesting to have an assessment over a longer period.

Folate Metabolic Pathway Single Nucleotide Polymorphisms a Predictive Pharmacogenetic Marker of Methotrexate Related Adverse Events in Indian (Asian) Patients with Rheumatoid Arthritis. Yogita Ghodke[1], Arvind Chopra[2], Amrutesh S. Puranik[1], Pooja Shintre[3], Anjali Radkar[4], Kalpana Joshi[5] and Bhushan Patwardhan[5]. [1]University of Minnesota, Minneapolis, MN, [2]Centre for Rheumatic Diseases, Pune, India, [3]Sinhgad College of Engineering, Pune, India, [4]Gokhale Institute of Politics and Economics, Pune, India, [5]Symbiosis International University, Pune - 411042, India

Background/Purpose: Methotrexate (MTX) is a folate analogue and the best tolerated DMARD but is limited by major interpatient variability in clinical response and unpredictable toxicity. Though the increasingly recognized association of single nucleotide polymorphisms (SNPs) of the folate metabolic pathway is published little is known about Indian population. We present the results of a pharmacogenetic study in Indian RA patients on MTX. We hypothesized the role of SNPs in MTX pharmacokinetics (PK) and MTX related adverse events (AE).

Methods: 322 RA patients (Female 86%, RF 79%) undergoing supervised MTX therapy for > 3 months; were randomly selected from a community rheumatology clinic; maximum (usually limited by tolerability) MTX dose 3.75–20 mg, median 17.5mg. We retrospectively analyzed standard CRF but recalled several patients to confirm events. Hepatic, gastrointestinal (nausea, vomiting, gastritis, diarrhea), pain in abdomen, bone marrow, skin rash/aggravated nodules, mucositis, hair-loss and central nervous system related were identified as significant AE. Any one or combinations of above events were noted as "overall AE". 12 SNPs in 9 genes of folate metabolism (including transporters) were genotyped using PCR-RFLP and Real-time Taqman allelic discrimination. Toxicogenetic index was calculated as the sum of homozygous variant genotypes carried by an individual (Arthritis Rheum 2006; 54(2):607–12). The genotypes which showed significant association (P<0.05) in the binary logistic regression analysis were taken into consideration for calculating toxicogenetic index. The presence of the 4 genotypes was summed as a composite index to constitute a toxicogenetic index for each patient (index range 0–4). PK analysis was performed on 94 patients by determining plasma MTX and metabolite 7-OH MTX levels at 0, 2 and 8 hr by HPLC and plasma Hcy at 0hr.

Results: (1) The table shows occurrence of AE by risk genotype (Values are odds ratio (95% confidence interval: *P < 0.05). The toxicogenetic index

ranged from 0 to 4. An index of 4 was associated with ~3 fold higher likelihood of side effect compared with an index of 0 ($P = 0.0001$). (2) Pharmacokinetic analysis shows that the patients with risk genotype have significantly high plasma concentration of MTX at 2hr (*TS* 5UTR *2R/2R), 8hr (*TS* 6bp/6bp) and its active metabolite 7-OH MTX at 8 hr. (*SHMT*1 CC).

	No of patients	Hepatic	Bone marrow	Pain in abdomen	Overall AE
TS 5UTR 2R/2R vs. 3R/3R and 2R/3R	57 vs. 259	1.3 (0.6–2.8)	4.9 (1.7–13.6)*	0.8 (0.2–3)	1.5 (0.8–2.9)
TS 3 UTR 6bp/6bp vs. 6bp/6bp and 0bp/0bp	65 vs. 257	1.4 (0.7–3)	0.1 (0.3–3)	1.1 (0.3–4)	2.8 (1.4–5.6)*
GGH C401T TT vs. CC and CT	124 vs. 198	2.3 (1.3–4.1)*	1.1 (0.4–2.9)	1.0 (0.3–3)	1.7 (1.0–2.8)*
SHMT1 C1420T CC vs. CT and TT	8 vs. 304	0.7 (0.1–4.1)	1.3 (0.1–4.7)	6.9 (1.1–46.1)*	1.7 (0.3–9.7)

Conclusion: Our findings revealed newer risk association with MTX related AE in Indian (Asian) RA cohort. Pharmacokinetic studies do show some associations with genetic polymorphisms but need to be further validated. Our observations propose that a toxicogenetic index can provide a means of profiling patients who develop AE to MTX and may be useful in establishing the likelihood of occurrence of AE to MTX. However, prospective studies with large no of patients will be necessary to reveal the predictive value of this pharmacogenetic marker.

1256

Design of a High Potency CTLA4-Ig with Extended Half-Life for Improved Dosing Convenience. Matthew J. Bernett, Seung Y. Chu, Holly M. Horton, Erik Pong, Irene Leung, Gregory L. Moore, Umesh S. Muchhal, Greg A. Lazar, David E. Szymkowski and John R. Desjarlais. Xencor, Inc., Monrovia, CA

Background/Purpose: Biologics consisting of CTLA4 fused to the Fc domain of IgG (CTLA4-Ig), marketed as abatacept and belatacept, are immunosuppressive therapies approved for treatment of rheumatoid arthritis (RA) and kidney transplant, respectively. These biologics function by selectively modulating the CD80/CD86:CD28 costimulatory signal needed for full T-cell activation. CTLA4-Ig is significantly less potent at inhibiting CD86-dependent costimulation as opposed to CD80-dependent costimulation, due to CTLA4 binding with much higher avidity to CD80 than CD86. Abatacept is administered by a monthly IV infusion, which is less convenient than the subcutaneous self-injections of competing anti-TNF biologics. We have therefore developed a new optimized CTLA4-Ig with an engineered CTLA4 domain that binds preferentially and with higher affinity to CD86. In addition, by increasing affinity of the CTLA4-Ig Fc domain for the antibody salvage receptor FcRn, we generated a biologic with significantly longer half-life (Zalevsky et al. Nat. Biotech. 2010; 28:157). This biologic has the potential to increase efficacy, reduce dosing frequency, and enable more convenient subcutaneous dosing.

Methods: XENP9523 is a CTLA4-Ig with optimized affinity for CD86 and containing an extended half-life Ig domain. Using rational structure-based engineering, 21 positions in the extracellular domain of CTLA4 were identified as targets for mutagenesis. A total of 149 variants were constructed at these positions during two rounds of affinity optimization. After each round, CD80 and CD86 affinity was measured using SPR, and variants with higher CD86 affinity were identified. For mixed lymphocyte reaction (MLR) assays, PBMC at 1.2×10^6 per well from two different donors were mixed with CTLA4-Igs and incubated for 6 days, followed by measurement of IL2 release by ELISA. For PK studies, same-sex mice transgenic for human FcRn ($mFcRn^{-/-}$ hFcRn Tg 276 heterozygote on a B6 background) were obtained from The Jackson Laboratory and a single IV dose of CTLA4-Ig at 10 mg/kg given, followed by regular blood collection. PK parameters were determined for individual mice with a non-compartmental model using WinNonlin.

Results: CTLA4-Ig variants with 20-fold increased binding to CD86 were identified and variant XENP9523 was chosen based on favorable CD80/CD86 binding (improvement in CD86 >> CD80). This variant showed a 4-fold improvement in IC50 for the ability to inhibit IL2 production in MLR assays compared to abatacept. Variant XENP9523 when fused to our extended half-life Fc domain showed a 2-fold improvement in half-life and similar exposure compared to abatacept in a PK study using huFcRn transgenic mice.

Conclusion: We show that CTLA4-Ig engineered for enhanced binding to CD86 via its CTLA4 domain, and for extended half-life via its Ig domain, is a potent suppressor of T-cell activation in vitro. Our results demonstrate the importance of high affinity binding to CD86 for modulating the CD80/CD86:CD28 costimulatory signal. The combination of increased potency and extended in vivo half-life suggests that XENP9523 has potential clinical advantages compared to abatacept and belatacept, while simultaneously enabling the convenience of subcutaneous dosing.

1257

Campylobacter Fetus Infection In Three Patients Treated with Rituximab for Rheumatoid Arthritis. Alain Meyer[1], Arnaud Theulin[2], Emmanuel Chatelus[3], Christelle Sordet[2], Rose-Marie Javier[2], Helene Chifflot[4], Jacques-Eric Gottenberg[5] and Jean Sibilia[6]. [1]Hautepierre Strasbourg university, Strasbourg, France, [2]Hautepierre Strasbourg Hospital University, Strasbourg, France, [3]Hopital Hautepierre, Strasbourg, France, [4]Hautepierre Strasbourg Hospital University, 67000, France, [5]Strasbourg University Hospital, Strasbourg, France, [6]Service de rhumatologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France, Strasbourg, France

Background/Purpose: *Campylobacter fetus (C fetus)* is a rare microaerophilic pathogen in humans that usually causes prolonged or recurrent bacteraemia. Osteoarticular, prosthetic material infection or cellulitis have been more rarely described, mainly in immunocompromised patients.

Methods: We report three RA patients treated with RTX who developed osteoarticular and cutaneous infection due to *C fetus*.

Results: Age of the patients was 71, 53 and 80 years respectively with a median RA duration of 24, 13 and 19 years. All patients had history of diabetes mellitus. Patient n°2 also suffered of COPD and patient n°3 of BOOP and hypertensive cardiomyopathy. All patients were co-treated with corticosteroids, with a dosage of 10mg/D and DMARDs. Patients had received respectively 4, 1 and 2 RTX cycle before *C fetus* infection. Gamma globulin amount before the last RTX infusion was 5, 5.8 and 6.9 g/L. *C fetus* infection occurred within a delay of 4 month [0.75–36] before the last RTX infusion. Patient n°1 developed left knee prosthesis infection, patient n°2 cellulitis of the right leg, and patient n°3 arthritis of the right elbow. Only one patient had fever. CRP amount was 16.5, 2 and 50mg/dl and median WBC was 13 200, 15 400 and 13 200. All patients had severe B lymphopenia (respectively 0, 2 and 7 CD19+ B lymphocyte /mm3) and hypogammaglubulinemia (respectively 5, 5.8 and 3.2 g/L of gammaglobulin) at the onset of infection. Evolution was good in all patients after antibiotic therapy and discontinuation of RTX treatment (Table 1).

Table. Characteristics of the three RA patients treated with RTX with C fetus infection

Case	Age/ sex	Comorbidity	RA duration (years)	Biotherapy before RTX treatment	Treatment concomitant to RTX	N° of RTX cycle prior to C fetus infection	Gammaglobulin prior to RTX treatment (mg/L)	Delay between last RTX infusion and the beginning of infection	Nature of infection	Fever	CRP (mg/dL)	WBC count (/mm3)	CD19+ amount at the time of infection (/mm3)	Gammaglobulin amount at the onset of infection (g/L)	Site of isolation of C fetus	Antibiotic treatment	Evolution
N°1	71/F	diabetes mellitus, left total knee arthroplasty	24	infliximab	CS (10mg/D), MTX (15mg/W)	4	5	4 months	Left knee prothesis infection	No	16.5	13 000	0	5	Left knee arthrocentesis	clindamycin, doxycyclin	good
N°2	53/M	diabetes mellitus, COPD	13	No	CS (10mg/D), MTX (20mg/W)	1	5.8	3 weeks	Cellulitis of the right leg	No	2	15 400	2	5.8	Hemoculture	amoxicillin, ciprofloxacin	good
N°3	80/F	diabetes mellitus, hypertensive cardiomyopathy, BOOP	19	No	CS (10mg/D), leflunomid	2	6.9	3 years	Arthritis of the right elbow	yes	50	13 200	7	3.22	Right elbow artrocentesis	amoxicillin, clavulanic acid, levofloxacin	good

Conclusion: This represents the first report of a series of *C. fetus* infections in RA patients treated with RTX. Our observations highlight a crucial role of B cell in C fetus infection.

Interestingly, the 3 patients were treated with corticosteroids with a dosage of 10mg/d and had hypogammaglobulinemia, both before RTX infusion and when infection occurred which have been recently shown to be risk factors of severe infections in RA patients treated with RTX (1). The three patients had also diabetes mellitus that has probably promote the infection.

C fetus infections are certainly under diagnosed, mainly because this germ growth requires microaerophylic culture conditions (2). Our observations show that clinicians should be aware of the possibility of *C fetus* infection in RA patient treated with RTX and should ask for specific research of microaerophilic organism in case of "culture negative" monoartritis and/or cellulitis, especially when risk factors of severe infections such as hypogammaglobulinemia or diabetes mellitus are present.

Short- and Long-Term Effect of Unguided, Intra-Articular Injections with Betamethasone In Early Rheumatoid Arthritis. Impact of Joint Area, Repeated Injections, MRI Findings, Anti-CCP, IgM-RF and CRP. Merete L. Hetland[1], Mikkel Østergaard[2], Bo J. Ejbjerg[3], Søren Jacobsen[4], Kristian Stengaard-Pedersen[5], Peter Junker[6], Tine Lottenburger[6], Ib Hansen[7], Lis Smedegaard Andersen[8], Ulrik Tarp[9], Anders Svendsen[10], Jens Kristian Pedersen[6], Henrik Skjødt[11], Torkell Ellingsen[12], Hanne M. Lindegaard[6] and Kim Hørslev-Petersen[13]. [1]Copenhagen University Hospital at Glostrup, on behalf of DANBIO, Copenhagen, Denmark, [2]Copenhagen University Hospital in Glostrup, Glostrup, Denmark, [3]Hospital at Slagelse, Slagelse, Denmark, [4]Rigshospitalet - 4242, Copenhagen, Denmark, [5]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [6]Odense University Hospital, Odense C, Denmark, [7]Viborg Hospital, Viborg, Denmark, [8]Denmark, [9]Aarhus University Hospital, Aarhus, Denmark, [10]Odense, Denmark, [11]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [12]University Hospital, Silkeborg, Denmark, [13]University of Southern Denmark, Graasten, Denmark

Background/Purpose: To investigate in rheumatoid arthritis (RA) patients the short- and long-term efficacy of unguided intra-articularly injections with betamethasone, and the impact of joint area, repeated injections, magnetic resonance imaging (MRI) pathology, anti-cyclic citrullinated peptides (anti-CCP) and IgM-rheumatoid factor (RF) status on long-term efficacy.

Methods: 160 patients with early RA (<6 months' duration) received intra-articular betamethasone in all (max 4) swollen joints at each visit (2 week intervals for 8 wks, then every 4 wks) in combination with step-up DMARDs during 2 years. This was part of the CIMESTRA trial (1–2).

Short-term efficacy was assessed by EULAR good-response. Long-term efficacy by Kaplan-Meier plots of the joint-injection-survival (i.e. the time-span between injection and renewed synovitis).

Potential predictors of joint-injection-survival were tested.

Results: 1373 joints (wrists, knees, MCP, shoulders, ankles, PIP, elbows, MTP) were injected. Of these, 531 were 2nd injections in a previously injected joint, and 262 were 3rd. At baseline, the median DAS28 was 5.5 (IQR: 4.6–6.2), and the numbers of injections/dose of betamethasone given were: 4(3–4)/4 (3–4), declining to 0(0–2)/0 (0–1.5) at the following visits. At week 2, 4 and 6, respectively, 50.0%, 58.1% and 61.7% had achieved a good EULAR response.

After 1 and 2 years, respectively, 62.3%(95% C.I. 58.1–66.9%) and 55.5%(51.1–60.3%) of the joints injected at baseline had *not* relapsed. All joint areas had good 2-years' joint-injection-survival, longest for the PIP-joints (73.7%(79.4–95.3%), p<0.01.

2-year joint survival was higher for 1st injections 56.6%(53.7–59.8%) than for 2nd 43.4%(38.4–49.0%) and 3rd injections 31.3%(25.0–39.3%), p<0.0001.

The cumulated dose of betamethasone after 2 years was: 11ml (IQR 7–17ml). The median intraarticular betamethasone dose during the first 2 years corresponded to less than 1 mg prednisolone per day.

Adverse events were mild and transient. High MRI synovitis score of MCP joints and anti-CCP were associated with poorer joint-injection-survival, whereas CRP and IgM-RF were not.

Conclusion: In early RA, intra-articular unguided injections of betamethasone in small and large peripheral joints together with DMARD treatment resulted in very rapid, effective and long-lasting inflammatory control. The cumulative dose of betamethasone was low, and the injections were well tolerated.

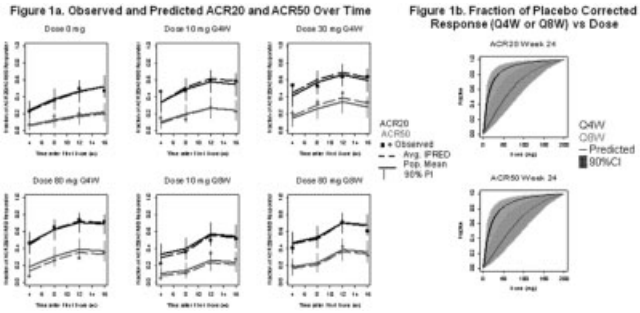
Pharmacokinetic-Pharmacodynamic Modeling of Ozoralizumab (ATN-103), a Novel Humanized Nanobody Tumor Necrosis Factor Inhibitor for Rheumatoid Arthritis. Chandrasekhar Udata[1], Arnab Mukherjee[2], Matt Hutmacher[3], Mark Peterson[1], Kai-Hsin Liao[1], Tina Checchio[2], Kathy Shields[4], Xu Meng[1] and Gail Comer[4]. [1]Pfizer, San Diego, CA, [2]Pfizer, Groton, CT, [3]A2PG, Ann Arbor, MI, [4]Pfizer, Collegeville, PA

Background/Purpose: Ozoralizumab (ATN-103), a novel tumor necrosis factor inhibitor (TNFi), is a humanized, trivalent, bi-specific nanobody containing two human TNF-binding domains linked to a human serum albumin-binding domain. Pharmacokinetic-pharmacodynamic (PK-PD) modeling of data from a seamless phase 1/2 study in subject with active rheumatoid arthritis (RA) was performed to understand the relationship of ATN-103 exposure to clinical efficacy measures ACR20 and ACR50, and to predict clinical responses at other doses and dose regimens.

Methods: In this seamless phase 1/2 study, subjects (253) received total 4 subcutaneous injections of placebo or ATN-103 doses of 10 mg, 30 mg, or 80 mg every 4 weeks (Q4W) or 10 mg or 80 mg every 8 weeks (Q8W) for 16 weeks. A total of 1988 serum ATN-103 samples, intensive first and last dosing cycle with troughs at other event, were analyzed using NONMEM. Longitudinal models of ACR20 and ACR50, data up to week 16, as ordered categorical were tested using published latent variable approach with direct, indirect, and effect-compartment PK-PD models. Simulations were performed to predict possible ACR responses at other doses, regimens, and for longer treatment durations.

Results: A 2-compartment open population PK model with first-order absorption and elimination adequately described the observed concentration-time data. For a typical patient weighing 70 kg, ATN-103 PK parameter estimates were: clearance = 0.325 L/d, central volume = 1.14 L, inter-compartmental clearance = 0.642 L/day, peripheral volume = 2.65 L and the absorption rate constant = 0.152 1/d. Between-subject variability was 38% and 33% for clearance and central volume, respectively. Body weight was identified as a significant covariate on clearance and central volume of distribution and included allometrically. Higher trough ATN-103 concentrations were associated with higher ACR responses, suggesting that exposure may be predictive of clinical response. Observed ACR responses over time were best described by the effect-compartment PK-PD model at all dose/regimens (Figure 1a). Week 16 ACR20 and ACR50 responses at 80 mg Q4W were estimated to be similar to that of other anti-TNFi. For a Q8W regimen, clinical response similar to that of TNFi was predicted at a 160 mg dose (Figure 1 b).



Conclusion: A longitudinal effect-compartment PK-PD model utilizing a latent variable approach was used to describe the ACR20 and ACR50 responses across a range of doses investigated and subsequently used for simulations of other desired treatment regimens. Analysis results suggest that a 160 mg Q8W regimen is likely to be as efficacious as the 80 mg Q4W regimen in terms of ACR20 and ACR50 responses.

1260

Correlation of CDAI and SDAI with DAS in a Large Real-Life Cohort of Rheumatoid Arthritis Patients Treated with Infliximab. Denis Choquette[1], William G. Bensen[2], Milton F. Baker[3], Sophie Elise Michaud[4] and Hayssam Khalil[5]. [1]University of Montreal, Notre-dame Hospital, Montreal, QC, [2]McMaster University, Hamilton, ON, Hamilton, ON, [3]VIHA, Victoria, BC, [4]Merck Canada Inc, Montreal, QC, [5]Merck Canada Inc, Kirkland, QC

Background/Purpose: In recent years, the efficacy of anti-TNF-alpha in the management of RA has been demonstrated in numerous controlled clinical trials. The Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI) have been recently designed as simplified disease activity scores. The purpose of this analysis is to evaluate the correlation between these simplified disease activity scores and routine clinical practice scores.

Methods: The data for this analysis were obtained from an observational study of adult RA patients initiated on treatment with infliximab and followed prospectively as per routine care since 2002. The majority of patients enrolled were biologic naïve.

Results: A total of 440 patients were included in this analysis. Mean (SD) age was 56.4 (13.6) years and mean (SD) disease duration at baseline was 11.0 (10.2) years. Mean SDAI, CDAI, DAS28-CRP and HAQ scores decreased significantly over 48 months (p< 0.001, for all parameters). A statistically significant strong positive correlation was observed between the DAS28-CRP and the SDAI (r=0.82; p< 0.001) or CDAI (r=0.94; p< 0.001). Differences in the proportion

of patients achieving low disease activity (LDA) and remission were observed between DAS28-CRP, SDAI and CDAI.

Parameter	Month 6 %	Month 12 %	Month 24 %	Month 36 %	Month 48 %
LDA (DAS 28 <3.2)	39.2	37.6	39.7	47.2	54.1
LDA (SDAI <11)	21.2	26.0	37.6	40.5	50.0
LDA (CDAI <10)	36.1	43.5	53.7	59.6	70.8
Remission (DAS 28 <2.6)	24.2	24.0	29.8	34.0	40.0
Remission (SDAI <3.3)	3.2	2.0	10.4	13.1	18.1
Remission (CDAI <2.8)	9.3	11.1	20.1	19.2	30.3

Conclusion: The results of this real-life observational study demonstrate that over four years of treatment infliximab is effective in reducing symptom severity and improving outcomes in patients with Rheumatoid Arthritis using different scores. Also, the data from this registry confirmed the validity of the SDAI and CDAI as disease activity measures in a real-life RA cohort.

1261

Development of a Whole Blood Assay to Determine Rituximab Mediated Complement Dependent Cytotoxicity of B Lymphocytes. Jonathan D. Jones[1], B. JoNell Hamilton[2], Whitney Hilton[3] and William F. C. Rigby[4]. [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Dartmouth College, Lebanon, NH, [3]Dartmouth Hitchcock Med Ctr, Lebanon, NH, [4]Dartmouth-Hitchcock Med Ctr, Lebanon, NH

Background/Purpose: Rituximab (RTX) is a monoclonal antibody targeting CD20, a marker found exclusively on B lymphocytes. RTX has shown efficacy in treating rheumatoid arthritis (RA). Although RTX depletes circulating B cells in all patients, less than half of RA patients achieve a high level of response. Moreover, the clinical response to RTX trails peripheral blood B cell depletion by weeks, if not months. Studies have suggested that synovial B cell depletion is important for clinical response, but the mechanism of B cell depletion in this compartment is not clear, particularly for non-circulating, resident synovial B cells. One possibility is that for clinical responses to occur, RTX must mediate synovial depletion of resident B cells via complement-dependent cytotoxicity (CDC) of B lymphocytes. By extension of this, non-responders fail to deplete synovial B cells by CDC. We report our development of a novel whole blood assay of RTX-CDC using hirudin anticoagulation and measurement of variable activity in normal volunteer donors.

Methods: Peripheral blood was drawn from healthy donors using hirudin, heparin or EDTA as an anticoagulant. Optimum hirudin concentration was found to be 50 μg/ml. Rituximab was added at varying concentrations and for various times and the percentage of CD19+ B cells as a function of all CD45+ cells determined by flow cytometry (FACScalibur, BD Biosciences).

Results: Using hirudin as an anticoagulant, we observed a rapid (15 minute) reduction in CD19 B cells with RTX concentrations as low as 0.01 μg/ml. No depletion was seen with RTX treatment when heparin or EDTA was employed as an anticoagulant, suggesting complement dependence. The role of complement activation was confirmed as B cell depletion was blocked by the addition of compstatin, which prevents the cleavage of C3 (Figure 1). The average percentage of B cell depletion was 35%, with an inter-donor variability of 11% to 60%. Only a portion of B cells deplete in this assay, and there is marked inter-donor heterogeneity of B cell depletion, findings which we are continuing to explore. These findings likely underlie the variability seen in RA response to rituximab.

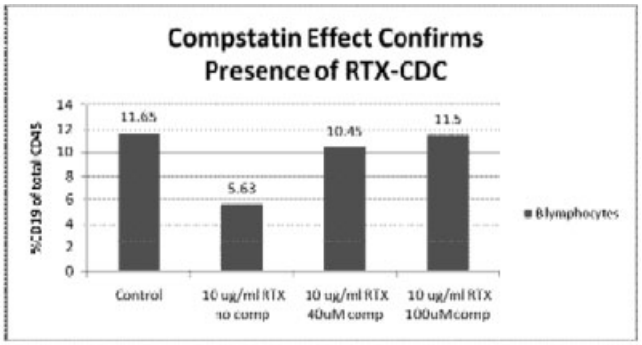


Figure 1. Addition of compstatin, a C3 inhibitor, blocked the reduction in CD19+ B cells following RTX addition, confirming the role of complement activation in the observed B lymphocyte depletion.

Conclusion: We have developed an assay that measures RTX mediated CDC of B cells. This assay presents a novel approach to assess the heterogeneity of RTX response, and will allow for increased understanding of the mechanisms of RTX effect. This may account for the variable success of RTX in various rheumatologic diseases, and has the potential to lead to a model to predict *a priori* RTX response. Additionally, these studies may provide insight into the success of other monoclonal antibodies currently in development.

1262

A Profile of Rheumatoid Arthritis Patients Treated with Tocilizumab in a United States Registry Population. Dimitrios A. Pappas[1], Alan Rathbun[2], George Reed[3], Joel M. Kremer[4], Isidro Villanueva[5], Jenny Devenport[6], Sarika Ogale[6], Ani John[6] and Jeffrey D. Greenberg[7]. [1]Columbia University, College of Physicians & Surge, New York, NY, [2]UMASS Medical School, Worcester, MA, [3]UMass Medical School, Worcester, MA, [4]Albany Medical College and The Center for Rheumatology, Albany, NY, [5]Viregen Macarena Hospital, Sevilla, Spain, [6]Genentech, South San Francisco, CA, [7]New York University School of Medicine, New York, NY

Background/Purpose: Tocilizumab (TCZ), a humanized anti-IL-6 receptor monoclonal antibody has demonstrated safety and efficacy in the treatment of RA across numerous randomized clinical trials (RCTs). The purpose of this abstract is to describe characteristics of patients initiating TCZ in usual care settings using the US CORRONA registry and to assess treatment response.

Methods: The CORRONA registry is a network of more than 100 private and academic rheumatology practices across the U.S., with data on approximately 27,000 RA patients. Descriptive analysis of baseline characteristics was summarized for all patients initiating TCZ. Response to TCZ treatment (change from baseline to 6 months) was summarized for the subset of patients who had data available at baseline and continued treatment for 6 months.

Results: In the CORRONA registry from August 23 2009 to May 2010, out of 2583 biologic initiations, 197 (7.6%) were treated with TCZ. Patients were predominately female, median age was 58 yrs (IQR 49–65), with median disease duration of 11 yrs (IQR 7–18) and baseline CDAI of 20.0 (IQR 12.1, 32.2). Some commonly reported baseline comorbidities were Cardiovascular Disease 13 (6.6%), Hypertension 61 (31.0%), Diabetes 13 (6.6%), Liver Disorder 15 (8.7%), Peptic Ulcer disease 24 (12.2%), Cancer 21 (10.7%), and hospitalized infection in last 12 months 1 (0.5%). 77% of the patients starting TCZ had discontinued their previous therapy for efficacy reasons and 8.8% for safety reasons. Almost all TCZ patients reported prior biologic use; 62 (31.5%) had 1 previous TNF exposure, 60 (30.5%) had 2 previous TNF exposure, 66 (33.5%) had ≥ 3 previous TNF exposure and 6 (3.0%) reported no previous biologic exposure.

At Baseline, most patients (62.4%) were initiated on TCZ at 4 mg, 35% of them were treated as monotherapy. In the subset of patients with available data for change from baseline up to 6 months of TCZ treatment (77 patients); median CDAI scores improved from 20.3 (IQR: 13, 32) at BL to 14.5 (IQR: 9.5, 27) [Table 1]; Swollen Joint Count (28) improved from 6 (IQR: 2, 10) to 4 (IQR: 1, 10) and Tender Joint Count (28) from 6 (IQR: 3, 10) to 3.5 (IQR: 1, 10).

Table 1. Response to Tocilizumab Treatment from Baseline to 6 month follow-up (N=77)

CDAI Disease Activity	Baseline Median (IQR) 20.3(13, 32)	6 month Follow Up Median (IQR) 4.5 (9.5, 27)
Remission	n = 2 2.6%	n = 8 10.4%
Low	n = 11 14.3%	n = 15 19.5%
Moderate	n = 28 36.4%	n = 28 36.4%
Severe	n = 36 46.2%	n = 26 33.8%

Conclusion: During the analysis period of 9 month, TCZ comprised 7.6% of all biologic initiations in the CORRONA registry. TCZ was mostly used in patients with long standing disease duration, with moderate to severe disease and for patients who had failed to respond to one or more prior TNF treatment. The majority of TCZ initiators were on combination therapy; with most on 4 mg/kg dose and for a one-third of these patients TCZ was used as monotherapy. In this real-world setting, patients treated with TCZ for 6 months showed a decrease in RA disease activity.

1263

SNP Algorithms for Prediction of Efficacy and Adverse Events of Abatacept. Tsukasa Matsubara[1], Satoru Koyano[2], Keiko Funahashi[2], Takafumi Hagiwara[1], Takako Miura[1], Kosuke Okuda[1], Takeshi Nakamura[1], Mitsuyoshi Iwahashi[3], Tomomi Tsuru[4], Shoichi Uchimura[5] and Shigeru Honjo[6]. [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]Higashi-Hiroshima Memorial Hospital, Higashi-hiroshima, Japan, [4]PS Clinic, Fukuoka, Japan, [5]Kanzaki Municipal General Hospital, Kanzaki, Japan, [6]Honjo Rheumatism Clinic, Takaoka, Japan

Background/Purpose: Abatacept (ABT), a CTLA4-Ig fusion protein agent targeted to T-cells, is a relatively new biological agent for RA treatment in Japan. However, there is no method for prediction of responders, non-responders, or adverse events which can occur during treatment. We established SNP algorithms for prediction of responders or non-responders, and adverse events in ABT-treated patients.

Patients and Methods: Forty-six RA patients treated with ABT were included in this study. Efficacy was assessed by DAS28 (CRP) at 48 weeks after the initial treatment. Any adverse events that may have been related to ABT administration and observed at 48 weeks of this long-term administration and during phase II were considered to be side effects. Genome-wide SNP genotyping was performed by Illumina Human610-Quad chip technology. Case-control analyses between 598,821 SNPs and responsiveness, remission or occurrence of adverse events were examined by Fisher's exact test. We selected 10 SNPs associated with ABT-responsiveness, remission, and adverse events ($p < 0.0001$). We scored the relationship between each SNP and responsiveness, the estimated total score of 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in responders: +1 point, hetero allele: 0 points, and homo allele in the majority of non-responders: −1 point), and then examined relationships between responders and non-responders, remission and non-remission, and occurrence of adverse events, plus or minus, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)), and sensitivity (true positive/(true positive+false negative)) of the algorithm for responsiveness of abatacept ranged from 90–96%. For remission, accuracy, specificity and sensitivity of the algorithm ranged from 91–97%. For adverse events, accuracy, specificity and sensitivity of the algorithm ranged from 95–100%. It is therefore suggested that the SNP algorithms can predict responders and adverse events prior to the initiation of treatment with abatacept.

Conclusion: These highly accurate algorithms using SNP analysis may be useful in the prediction of responsiveness and adverse events before treatment with abatacept, and in this way can contribute to future tailor-made treatment with biologic agents.

1264

Low Persistence of Methotrexate Monotherapy in the Veterans Affairs Rheumatoid Arthritis (VARA) Registry. Grant W. Cannon[1], Brian C. Sauer[1], Katherine L. Martin[1], Candace L. Hayden[1], Andreas M. Reimold[2], Liron Caplan[3], J. Steuart Richards[4], Gail S. Kerr[4], Dannette S. Johnson[5] and Ted R. Mikuls[6]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Dallas VA and University of Texas Southwestern, Dallas, TX, [3]Denver VA and University of Colorado, Aurora, CO, [4]Washington DC VA and Georgetown University, Washington, DC, [5]Jackson VA and University of Mississippi Medical Center, Jackson, MS, [6]Omaha VA and University of Nebraska, Omaha, NE

Background/Purpose: Several studies initiating disease modifying anti-rheumatic drugs (DMARDs) in DMARD naïve patients have suggested that a significant portion of rheumatoid arthritis (RA) patients will experience and sustain a significant clinical response to methotrexate (MTX) monotherapy (MTX-MON). Little information is available about the long term persistence of MTX-Mon in clinical practice.

Methods: A cross sectional analysis of RA patients in the Veterans Affairs Rheumatoid Arthritis (VARA) registry recorded DMARD history in the VA computerized patient record system (CPRS) and VA pharmacy records. Patients with RA of greater than 3 years duration who were currently receiving MTX-MON were identified and compared to VARA patients who had received MTX but had either discontinued the drug and/or received other DMARDs in addition to MTX.

Results: Of the 1039 RA patient reviewed, 912 (88%) had an RA disease duration >3years. Of these patients 832 (91%) had received MTX and 439 (48%) were continuing to receive MTX. Of the 832 patients treated with MTX-MON, 38 (5%) had continued MTX and not received other DMARDs over the duration of their disease (16 +11 years). An additional 98 (11%) patients had received other DMARDs alone or in combination with MTX in the past, but were currently only receiving MTX-MON at the time of the review. Many patients received MTX in combination with traditional DMARDs, anti-TNF drugs (TNF), or other biologic (OB) agents. A comparison of MTX-MON patients to other patients with >3 years of RA history treated with MTX did not identify any baseline factors associated with MTX-MON persistence, including patient demographics, serologic data for rheumatoid factor and anti-CCP, and shared epitope (SE). Pain score reported on a 10 point range at clinic visits and a cumulative composite measure of DAS28 over time calculated as DAS28 area under the curve (DAS28 AUC) were statistically significantly lower in MTX-MON patients naïve to other DMARDs in comparison to all other groups and all MTX currently on MTX alone in comparison to patient currently on DMARD combinations ($p<0.001$). A comparison of all patient currently on MTX to all patient currently on MTX in combinations with other DMARDs showed an older age at RA onset (54±14 versus 49±13, $p<0.001$) and age at evaluation (69±11 versus 64±11, $p<0.005$), but no other statistically significant differences.

History of RA greater than three years duration n = 912

Never Received MTX n=80 (9%) | History of MTX exposure n = 832 (91%)

MTX Stopped N=394 (45%) | Current MTX treatment n=438 (48%)

MTX alone n = 136 (15%) | MTX in Combination n = 302 (33%)

Prior non-MTX DMARD | MTX+DMARD n=143 (16%) | MTX+TNF n=149 (16%) | MTX+OB n=10 (1%)

			No n=38 (5%)	Yes n=98 (11%)			
Male Gender	74 (93%)	357 (91%)	37 (97%)	89 (91%)	132 (93%)	132 (88%)	10 (100%)
Age (years)	66 (11)	67 (10)	67 (10)	70 (11)	66 (11)	64 (12)	60 (8)
Age at RA onset	52 (15)	51 (13)	54 (14)	51 (14)	52 (12)	49 (14)	44 (11)
Disease Duration	16±12	17±11	13±12	18±12	18±10	15±10	15±11
RF-Positive (%)	59/60 (96%)	641/670 (96%)	24/25 (96%)	73/78 (94%)	109/115 (95%)	117/125 (94%)	9/9 (100%)
Anti-CCP Positive (%)	54/77 (70%)	289/366 (79%)	21/31 (68%)	81/90 (79%)	94/126 (75%)	118/148 (80%)	7/7 (100%)
Erosions Present	29 (39%)	152 (42%)	13 (37%)	42 (44%)	55 (40%)	53 (36%)	5 (50%)
SE-negative	25%	24%	30%	33%	32%	23%	0%
SE-1 allele	60%	49%	55%	48%	51%	51%	63%
SE-2 alleles	15%	27%	15%	19%	17%	26%	37%
Pain Score**	2.7 (3.2)	2.3 (3.1)	1.8 (2.4)	2.9 (3.4)	2.6 (3.1)	3.1 (2.9)	6.4 (2.2)
DAS28 AUC**	3.3 (1.2)	3.7 (1.2)	3.1 (1.1)	3.8 (1.2)	3.3 (1.1)	3.8 (1.1)	4.6 (0.7)
#DMARDs by Hx	2.4 (1.2)	4.5 (1.9)	1.0 (0)	3.5 (1.9)	3.1 (1.2)	4.4 (1.5)	6.5 (2.3)
Current DMARDs	1.3 (0.7)	1.2 (0.8)	1.0 (0)	1.0 (1)	2.3 (0.5)	2.3 (0.5)	2.1 (0.3)

** P < 0.001 for MTX-MON alone. #DMARDs by Hx = Total number of DMARDs taken over patient's RA course.

Conclusion: Long term persistence with MTX therapy alone is very uncommon with the majority of patients currently receiving MTX alone having a history of receiving other DMARDs during their past management. There were no baseline disease characteristics associated with long term persistent MTX-MON. While almost half of the patients with RA in our cohort continue to receive MTX, the vast majority of patients will receive additional DMARD therapy and/or discontinue MTX during the course of their disease.

1265

Effects of TNF-Alpha Inhibitors on Lipid Profile and on Sub-Clinical Atherosclerosis in Rheumatoid Arthritis. Systematic Review and Meta-Analysis. Sylvain Mathieu[1], Sarah Payet[1], Bruno Pereira[2], Eric Bruckert[3] and Martin Soubrier[2]. [1]CHU Gabriel Montpied, Clermont-Ferrand, France, [2]CHU CLERMONT-FERRAND, Clermont-Ferrand, France, [3]CHU Pitié-Salpêtrière, AP–HP, Paris

Background/Purpose: Rheumatoid arthritis is associated with an increased cardiovascular risk that has been recently reported to be decreased by anti-TNF alpha, whose mechanisms remain uncertain.

Methods: MEDLINE, EMBASE, the Cochrane Collaboration and congress abstracts were searched to identify all reports of interest published up to May 2010. All observational and case/controls studies assessing the short- (4 weeks), medium- (16 weeks) and long-term (52 weeks) effects of TNF alpha blockade (infliximab, adalimumab, etanercept) on lipid profile or intima-media thickness (IMT) or endothelial dysfunction in RA patients were included.

Results: Thirty publications and abstracts were included, which represented 1135 RA patients. We found no significant change in lipid profile, in both the short, medium and long term of treatment (Table 1). Anti-TNF alpha caused no significant change in the flow-mediated dilation and Augmentation Index, nor significant modification of IMT over time (0.73[0.68–0.79] mm at baseline, 0.68[0.54–0.82] after 16 weeks and 0.88[0.34–1.41] after one year; $p=0.83$). Anti-TNF alpha improved disease activity and systemic inflammation.

Table 1. Differences in parameters of lipid profile after TNF blockade treatment

	Baseline	4 weeks	16 weeks	52 weeks	p-value
TC, mmol/l	n=20	n=11	n=10	n=2	p=0.52
	5.10 [4.92–5.29]	5.31 [5.11–5.50]	5.19 [5.04–5.35]	5.17 [4.88–5.47]	
LDL, mmol/l	n=11	n=5	n=6	n=2	p=0.88
	3.21 [3.00–3.41]	3.24 [2.80–3.69]	3.15 [3.02–3.27]	3.07 [2.96–3.18]	
HDL, mmol/l	n=18	n=11	n=9	n=3	
	1.39 [1.30–1.48]	1.45 [1.35–1.55]	1.52 [1.35–1.70]	1.53 [1.45–1.62]	p=0.47
TG, mmol/l	n=14	n=8	n=5	n=1	p=0.48
	1.31 [1.15–1.46]	1.34 [1.14–1.55]	1.28 [1.05–1.50]	0.94 [0.82–1.06]	
Atherogenic index	n=11	n=6	n=5	n=2	p=0.34
	3.86 [3.64–4.08]	4.18 [3.57–4.79]	3.49 [3.14–3.83]	3.48 [2.93–4.04]	

n=number of included studies. TC=total cholesterol; LDL=low density lipoprotein cholesterol; HDL=high density lipoprotein cholesterol; TG= triglycerides.

Conclusion: Despite a significant decrease in biological inflammation, anti-TNF alpha caused no change in intima-media thickness, endothelial dysfunction or lipid profile in RA patients.

1266

Evaluation of A Novel Homogeneous Mobility Shift Assay for the Measurement of Human Antibodies-to-Infliximab and Infliximab Levels in Patient Serum. Shui Long Wang, Linda Ohrmund, Scott Hauenstein, Jared Salbato, Rukmini Reddy, Patrick Monk, Steven Lockton, Nicholas Ling and Sharat Singh. Prometheus Laboratories, San Diego, CA

Background/Purpose: The list of antibody-based drugs available for the treatment of autoimmune disease, such as rheumatoid arthritis, is steadily increasing. However, certain patients will generate anti-drug antibodies (ADA) that causes many consequences, including loss of drug efficacy and adverse reactions. Monitoring of patients for drug and ADA levels is not only required by the FDA, but also very important for patient management. Current methods for the assessment of ADA and drug levels include bridge ELISA, radioimmunoassay and SPR, which have many disadvantages such as low drug tolerance in the sample. We have developed a non-radio labeled homogeneous mobility shift assay to measure the antibodies-to-infliximab (ATI) and drug levels in serum from patients treated with infliximab (IFX). This method overcomes many of the limitations of the current methods.

Methods: To perform the mobility shift ATI assay, Alexa488 labeled IFX with Alexa488 internal control is incubated with ATI positive serum. After equilibration, the free Alexa488 IFX and bound IFX are resolved by size exclusion HPLC and the intensity of the fluorescence in each peak is measured by a fluorescent detector. The changes in the ratio of the internal control to the free IFX peak are proportional to the amount of ATI. The amount of ATI in the sample is calculated from a standard curve generated with different dilutions of ATI positive serum. Similar methodology and analysis are used to measure the IFX level in the serum. We have performed a full method validation on both ATI and IFX assays, and compared the clinical sample test results with those obtained from ELISA methods.

Results: Validation of the mobility shift ATI assay revealed a lower limit of quantitation of 35.4ng/mL in serum, lower than the industry requirement of 250–500ng/mL. The linear range of quantitation is 35.4–790ng/mL. The intra- and inter-assay precision is less than 15% of CV, and the accuracy of the assay is within 20%. IFX drug tolerance in the assay is 100μg/mL in the serum. Sera from 100 healthy subjects were tested to set up the cutoff point of 35.4ng/mL. ATI positive samples analyzed by bridge ELISA from 120 patients were also evaluated by the new method and the results showed a strong correlation between the two methods. However, the new method identified 23 false positive samples from the bridge ELISA. Similar results were obtained from the validation of the mobility shift IFX assay.

Conclusion: Results from this study demonstrated the superiority of the mobility shift assay in measuring ATI and IFX in patient serum. This method can also be applied to detect other antibody drugs and ADA in patient serum such as those treated with adalimumab.

1267

Tofacitinib Reduces Interferon-γ and Interleukin-17 Production From CD4+ T Cells in Patients with Rheumatoid Arthritis. Satoshi Kubo, Kunihiro Yamaoka, Koshiro Sonomoto, Keisuke Maeshima, Shintaro Hirata, Kazuhisa Nakano, Norifumi Sawamukai, Masao Nawata, Shigeru Iwata, Kazuyoshi Saito and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background/Purpose: Tofacitinib, a Janus kinase (JAK) inhibitor, has gathered attention in treatment of rheumatoid arthritis (RA), revealing the prompt clinical effects in randomized clinical trials. However, its mode of action remains uncertain, particularly when administered to RA patients. Therefore, we collected CD4+ T cells from RA patients treated with tofacitinib, and investigated the cytokine prolife from T cells in vitro and its relevance to clinical efficacy.

Methods: Patients who met the ACR criteria for RA and participated in the tofacitinib clinical trials and continued medication up to 52 weeks in our department were eligible. After the double blind period (12- or 24-weeks), during which patients were randomized to receive different doses of tofacitinib or placebo, all patients were treated with tofacitinib 5 mg or 10 mg BID open-label. CD4+ T cells from blood were collected by magnetic selection at 0 and 52-weeks and cultured under the stimulation with anti-CD3 and anti-CD28 antibodies for 3 days. Serum levels of IFN-γ and IL-17 in collected supernatants were measured by ELISA.

Results: (1) Patient background: 30 patients were assigned, mean age; 53.8 years, mean disease duration; 82.2 months, methotrexate was administered in 23 patients and the median dose was 9.2 mg/week, oral corticosteroids were administered in 7 patients and the median dose was 6.0 mg/day. At baseline, patients had a high degree of disease activity: -SDAI 37.6, DAS28 (ESR) 6.3, HAQ 1.8, CRP 20.3 mg/l, ESR 50.7 mm/h, MMP-3 229.4ng/ml, RF 208.0U/ml.

(2) The mean disease activity score was SDAI=7.7 and DAS28=3.1 at 52-weeks, which was significantly lower than that at baseline ($P<0.05$) and 73% achieved low disease activity (SDAI $<$ 11). HAQ was 0.7 at 52-weeks and 46% achieved HAQ-remission (HAQ$<=$0.5).

(3) Production of IFN-γ from CD4+ T cells at 52-weeks (1124.8 pg/ml) was significantly reduced, compared to that at baseline (1563.8 pg/ml) ($P<0.05$). Similar findings were noted in IL-17 production. IL-17 production at 52-weeks (1021.2 pg/ml) significantly decreased from that at baseline (1820.5 pg/ml) ($P<0.05$).

(4) There was no statistically significant correlation between the reduction of IFN-γ and IL-17 production from CD4+ T cells and improvement of clinical disease features including SDAI, CRP, ESR, MMP-3 and RF.

Conclusion: Tofacitinib acts on CD4+ T cells and suppress production of IFN-γ and IL-17 after 52 weeks of administration in patients with RA, suggesting the inhibitory effect on Th1 and Th17 differentiation. However, the reduction of cytokine production did not correlate with the clinical efficacy suggesting that tofacitinib acts not only on CD4+ T cells but also on other immune cells (such as dendritic cells, synovial fibroblast, and B cells) which may have direct or indirect connection with clinical efficacy.

A Phase 1, Randomized, Double-Blind, Placebo-Controlled, Multiple, Intravenous, Ascending-Dose Study of Sirukumab in Patients with Cutaneous or Systemic Lupus Erythematosus. Jacek C. Szepietowski[1], Surasak Nilganuwong[2], Anna Wozniacka[3], Annegret Kuhn[4], Filippa Nyberg[5], Jacek Szechinski[1], Ronald F. van Vollenhoven[6], Anders Bengtsson[7], Adam Reich[1], Dick de Vries[8], Bart van Hartingsveldt[8], Bei Zhou[9] and Benjamin Hsu[10]. [1]Wroclaw Medical University, Wroclaw, Poland, [2]Siriraj Hospital, Bangkok, Thailand, [3]Medical University of Lodz, Lodz, Poland, [4]University of Münster, Münster, Germany, [5]Karolinska Institutet, Danderyd Hospital, Stockholm, Sweden, [6]Karolinska Institute, Stockholm, Sweden, [7]Department of Rheumatology, Lund University Hospital, Sweden, [8]Janssen Biologics B.V., Leiden, Netherlands, [9]Centocor Research & Development, a Division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA, [10]Centocor R&D, a division of J&J Pharmaceutical R& D, LLC/Univ. of Pennsylvania, Malvern/Philadelphia, PA

Background/Purpose: Interleukin-6 may play a key role in the pathogenesis of cutaneous lupus erythematosus (CLE) and/or systemic lupus erythematosus (SLE).

Methods: This is a 2-part, phase 1, double blind, placebo controlled study to evaluate the safety and PK of multiple IV infusions of sirukumab, a human anti-interleukin-6 mAb in CLE/SLE pts. In Part A, pts with histologically-confirmed CLE were randomized to receive a total of 4 IV infusions of placebo or sirukumab 1, 4, or 10 mg/kg q2w. In Part B, pts with SLE diagnosed by ACR criteria and a SELENA-SLEDAI score of 5 to 12 were randomized to receive a total of 4 IV infusions of placebo or the highest well tolerated sirukumab dose in Part A (10 mg/kg) q2w. Primary evaluations were safety and PK. Secondary evaluations were PD, immune response, and preliminary clinical responses

Results: In Part A, 33 CLE pts were randomized (64% F; 31 Caucasian, 2 Asian; age 29–69; weight 49–100 kg), and 31 were treated. In Part B, 15 SLE pts were randomized and treated (87% F; 9 Caucasian, 6 Asian; age 19–58; weight 46–81 kg). More AEs were reported with sirukumab than placebo (Part A: 21/23 [91%] vs 5/8 [63%], Part B: 9/10 [90%] vs 4/5 [80%]). Sirukumab led to sustained, dose-independent decreases in WBC, ANC (neutropenia), platelets (thrombocytopenia); and minor elevations in total cholesterol. More skin-related AEs occurred with sirukumab 1 and 4 mg/kg than placebo; none occurred with 10 mg/kg. The majority of infectious AEs were mild upper respiratory infections reported similarly between groups in Part A but more often with sirukumab in Part B. More SAEs occurred with sirukumab than placebo (Part A: 3/23 [13%] vs 0/8 [0%], Part B: 2/10 [20%] vs 1/5 [20%]). SAEs reported with sirukumab were Horner's syndrome, epistaxis followed by iatrogenic wound infection and lung cancer, cholelithiasis, and pneumonia; none were possibly related to study drug except pneumonia. One pt on placebo had an unrelated myocardial infarction. One death occurred from a car accident. Sirukumab showed linear PK at IV doses of 1 to 10 mg/kg in CLE pts. Systemic exposure (Cmax and AUC[day 0–14]) and half-life were comparable between CLE and SLE pts. Sirukumab was not detected in urine samples from SLE pts. CRP and SAA decreased to low median levels by wk 1 and remained low through wk 14 with sirukumab in all pts. Complement C3 and C4 decreased with sirukumab in all pts without associated clinical disease flare. Of 32 pts with evaluable samples, none developed anti-sirukumab antibodies. Decreases in titers of ANA and anti-dsDNA and no other autoantibody changes occurred with sirukumab. No clinical improvement was detected by CLASI, overall BILAG global score, or SELENA-SLEDAI scores. In SLE pts, those treated with sirukumab improved in SF-36 physical scores and had stable DLQI scores while those treated with placebo had stable SF-36 and worsening DLQI.

Conclusion: Treatment with IV infusions of sirukumab was generally safe and well tolerated in both CLE and SLE pts. Sirukumab showed linear PK over the IV dose range of 1 to 10 mg/kg. Systemic exposure and half-life were comparable in CLE and SLE pts. Future studies in pts with more severe disease are needed to clarify the safety profile and efficacy potential of sirukumab.

1269

Meta-Analysis Suggests Intensive Non-Biologic Combination Therapy with Step-Down Prednisolone May Also 'Disconnect' Disease Activity and Damage in Rheumatoid Arthritis. Maarten Boers[1], Lilian H.D. van Tuyl[1], Marianne van den Broek[2], Piet J. Kostense[1] and Cornelia F. Allaart[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: In rheumatoid arthritis (RA) treatment with TNF inhibitors changes the relationship between disease activity and progression of radiological joint damage (the so-called 'disconnect' that allows arrest of damage progression even at moderate disease activity levels). In early RA intensive combination therapy of methotrexate and sulfasalazine with step-down prednisolone (COBRA schedule) has been shown to be equivalent to high-dose methotrexate and infliximab in suppression of damage progression (BeSt trial).[1] We investigated whether COBRA treatment also results in a 'disconnect' between disease activity and damage.

Methods: In a meta-analysis we combined the data of the COBRA trial[2] (COBRA v sulfasalazine monotherapy) with that of two arms of the BeSt trial (COBRA v sequential monotherapy). For each trial, 1-year progression of damage (Sharp van der Heijde score) was the dependent variable in a linear regression formula with the variables disease activity, treatment strategy (COBRA or control) and their interaction as independent factors. As estimates of disease activity we used the 1-year time-averaged Disease Activity Score (DAS44) and C-reactive protein (CRP) in separate analyses. The focus was on the interaction between disease activity and treatment strategy as proof of the existence of a 'disconnect'. Therefore we pooled the interaction terms of the two analyses, weighting by their inverse variance according to standard technique. Because of the directionality of the hypothesis and the relative insensitivity of regression for the detection of interaction, we used one-sided significance tests.

Results: For these analyses between 60 and 100% of original trial patients had complete data. In both trials analysed separately time-averaged DAS44 and CRP, respectively, were the only (strongly) significant independent factors related to damage progression. In the models that included disease activity, neither treatment group nor the interaction between treatment and disease activity entered as significant factors. However, pooling resulted in a (weakly) significant test for interaction:

Time-averaged-DAS44 × treatment interaction: one-sided $p = 0{,}027$.

Time averaged CRP × treatment interaction: one-sided $p = 0{,}044$.

Conclusion: This analysis has limitations inherent in metaanalysis, and a generic lack of power to detect interactions, especially in the context of low damage progression overall in a skewed distribution. Nevertheless, it gives some support to the suggestion that changes in the relationship between disease activity and damage progression are not limited to anti-TNF treatment, but a property of early, rapid and deep suppression of joint inflammation.

Clinical Response and B Cell Analysis by High-Sensitive Flowcytometry After the Second Course of Rituximab. Hans-Peter Brezinschek[1], Franz Rainer[2], Kerstin Brickmann[1], Raimund Lunzer[2] and Winfried B. Graninger[1]. [1]Medical University Graz, Graz, Austria, [2]Hospital Barmherzige Brueder, Graz- Eggenberg, Austria

Background/Purpose: Recently, we have shown that in an Austrian rituximab-registry RA-patients did not have a better clinical response when they completely depleted B cells 15 days after the first infusion. In addition, our results suggested that RA patients with a low number of transitional 1 B cells and/or low percentage of CD95+ post switch cells will benefit more profoundly from a B cell depleting therapy. The purpose of this study was to correlate the effect of a second course of rituximab (RTX) with the number of B cells after 15 days as well as B cell subsets.

Methods: Patients in the Austrian B Cell surveillance (ABS)-register were included in the study when they had a second course of RTX. DAS28 was determined before, 2 and 24 weeks after rituximab application. Peripheral blood mononuclear cells were isolated at the same time points and cells were stained with monoclonal antibodies directed towards CD19, CD24, CD27, CD38, CD45 and IgD. To exclude T cells and monocytes CD3 and CD14 were utilized. Five hundred thousand cells were acquired and analyzed using a seven-channel flow cytometry (BD Canto II cytometer, Software FACS-Diva). According to their surface staining B cells were divided in naive (CD19+, IgD+, CD27-); IgD memory (CD19+, IgD+, CD27+), post switch (CD19+, IgD-, CD27+) and double negative (CD19+, IgD-, CD27-) cells. In addition, B cells were further characterized using CD95 and CD80. Complete depletion was defined as 0,002%, i.e. 10 events or less in 500.000 CD45+ cells.

Results: Until now, 105 RA patients have been included in the ABS registry and 13 patients have undergone the week 24-analysis of a second course of RTX. There was a significant reduction in the DAS28 (mean ± SE) before the first and the second therapy course (5,92 ± 0.25 versus 4.23 ± 0.25, $p < 0.0001$). Interestingly, patients who did not respond to RTX after the 1st course still had a reduction in DAS28 after the second treatment, but it was smaller compared to 1st cycle responders (−0.8 ± 0.8 versus −1.9 ± 0.4; respectively). Similar to the results from the 1st cycle, no correlation between the EULAR response and complete depletion at day 15 was found. Thus, there was no significant difference in the mean number of B cells (mean ± SE) in responders and non-responders (33.0 ± 22.6 versus 19.5 ± 4.6, respectively). Interestingly, 2 out of four non-responder had an improvement of their DAS28 after the second cycle. Non-responder had an elevated frequency of post switch B cells compared to responders (29.8% 5.9 versus 15.0% ± 7.6; respectively). No significant differences were found for CD80 or CD95 expression on B cell subsets for responders and non-responders. Furthermore, in responders the numbers of transitional (T1) B cells were lower compared to non-responders or healthy controls (45 ± 23, 67 ± 40 and 384 83, respectively), but this was not significant.

Conclusion: Our preliminary results suggest again that the enumeration of B cells on day 15 will not help to discriminate Rituximab-responders from non-responders. Furthermore, a second cycle of RTX is warranted in RA-patient with an inappropriate response to the first therapy-course.

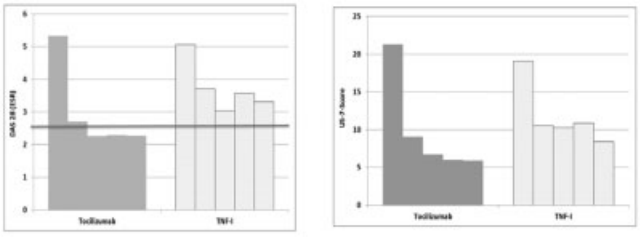
Comparison of Tocilizumab and TNF Inhibitor Therapy in Rheumatoid Arthritis. Jörg Kaufmann[1], Susanne Seel[2] and Anne-Eve Roske[3]. [1]Rheumatologist, Ludwigsfelde, Germany, [2]Ambulant Centres f. Rheumatology, Ludwigsfelde, Germany, [3]Roche Pharma AG, Grenzach-Wyhlen, Germany

Background/Purpose: The combination of a biologic DMARD (bDMARD) with methotrexate (MTX) is regarded as the gold standard for patients having not adequately responded to a conventional DMARD (cDMARD) therapy. There are no results from randomized controlled studies comparing different bDMARDs. Aim is to compare the effectiveness of TNF inhibitors with Tocilizumab with respect to clinical and sonographic parameters.

Methods: Data from 98 patients in whom bDMARD (TNF inhibitor or Tocilizumab) therapy had been initiated between September 2009 and September 2010 were retrospectively analysed. Selection criteria included confirmed diagnosis of RA and age >18 years. Patients had to be on their first bDMARD. Patients were examined sonographically at baseline and every 3 months using the US-7 score. The DAS28 score was recorded every 3 months.

Results: The Tocilizumab and TNF inhibitor cohorts consisted of 40 and 48 patients, respectively. Both groups were comparable in age, disease duration and gender distribution.

The following table shows the mean values for the DAS28 baseline and after 3, 6, 9 and 12 months compared to the biologics, which differ in their mode of action. The horizontal line marks the DAS28 remission threshold at 2.6.



Conclusion: Tocilizumab shows in the groups both clinically and sonographically significantly better effectiveness compared to TNF inhibitors. Prospective randomized controlled studies have been initiated to confirm these results.

1272

Efficacy Evaluation of Tocilizumab with the New ACR/EULAR Remission Criteria and DAS28-ESR. Tomonori Ishii[1], Yasuhiko Hirabayashi[2] and Michinoku Tocilizumab Study Group[3]. [1]Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Hikarigaoka Spellman Hospital, Sendai, Japan, [3]Senndai

Background/Purpose: New classification/remission criteria have been proposed to ensure the early diagnosis of rheumatoid arthritis (RA) and achieve remission or low disease activity according to strict criteria. As tocilizumab (TCZ) decreases the levels of acute phase proteins (e.g., CRP and ESR), it has been questioned whether it is appropriate to evaluate disease activity in patients on TCZ based on levels of acute phase proteins. In Japan, TCZ was approved in April 2008 as the third biological agent for the treatment of RA. The Michinoku Tocilizumab Study Group (MTSG) has registered RA patients receiving TCZ in 34 institutions in 6 prefectures in Tohoku area to analyze their clinical data. The usefulness of the new ACR/EULAR RA remission criteria (i.e., tender or swollen joint count (SJC/TJC) <1, patient global assessment <1, and CRP of <1 mg/dL; referred to as Criteria A) and Criteria A without CRP (Criteria B) was evaluated in patients receiving TCZ. Also, the association between these criteria and the conventional remission criteria (DAS28-ESR <2.6) was evaluated.

Methods: Patients with RA who were registered by the MTSG from May 2008 to November 2009 and received TCZ for 12 months were evaluated. Patients were assessed every 3 months by Criteria A and B and DAS-ESR, and the percentages of patients with remission at month 12 were obtained. The ROC analysis was performed to obtain cut-off values of DAS28-ESR score to achieve remissions according to the new criteria. Data were analyzed using the LOCF method.

Results: TCZ treatment was continued for 12 months in 81.8% of the patients registered by the MTSG. The data of 285 patients were analyzed in this study. The mean age at baseline was 59.6 years; 225 patients (79%) were female and the mean duration of RA was 10.2 years. Other biological agents had been used in 140 patients (49.1%), and methotrexate was used with TCZ in 145 patients (50.9%). At month 12, 71 (24.9%) and 72 (25.3%) patients achieved remission with Criteria A and B, respectively, and no significant difference was observed in the criteria with and without CRP (P=0.9230). Remission with DAS28-ESR was achieved in 164 patients (57.5%). RCO analysis revealed that the cut-off value to expect the achievement of remission with Criteria A was a DAS2-ESR score of <1.54 with sensitivity, specificity, positive predictive value and negative predictive value of 88.7, 85.5%, 67.0% and 95.8%, respectively. However, patients having RA for ^{3}10 years and patients in Stage 4 tended not to achieve remission even if the DAS2-ESR was <1.54.

Conclusion: In the clinical setting, the new remission criteria could confirm the remission with TCZ treatment without being affected by CRP level. The fact that the cut-off value to expect the remission according to the new criteria was DAS28-ESR <1.54 indicated that more stringent remission than the conventional criteria may be required for the new criteria in patients receiving TCZ.

Expectation of achievement of the new criteria of remission with a cut-off level of DAS28-ESR<1.54

Sensitivity	88.7%
Specificity	85.5%
Positive predictive rate	67.0%
Negative predictive rate	95.8%

1273

High Levels of Serum IL-6 but Not CRP or TNF-α During Tocilizumab Treatment Induces Myalgia Among the Patients with Rheumatoid Arthritis. Osamu Saiki[1] and Hiroshi Uda[2]. [1]Shiraishi Hospital, Imabari, Japan, [2]Keiseikai Hospital, Higashiosaka, Japan

Background/Purpose: Many biologics has been developed in recent years. Tocilizumab, IL-6 receptor antagonist, is one of essential biologics to treat RA patients. Several adverse reactions have been reported after tocilizumab injection, but occurrence of myalgia has rarely been discussed. We experienced RA patients who complained myalgia after tocilizumab treatment, so we conducted this study to examine the mechanism how the pain appears.

Methods: RA patients who had inadequate response to MTX and/or TNF inhibitor were treated by 8mg/kg of tocilizumab every 4 weeks. Serum IL-6 and CRP levels and DAS28 score of them were examined at baseline and every 4 weeks at tocilizumab injection. Patient's myalgia was evaluated everyday by themselves using 0 to 100 mm visual analog scales (VAS). The serum levels of creatine kinase (CK), aldolase, and TNF-α were also examined in addition to regular blood tests.

Results: Seventy-six RA patients were treated with tocilizumab every 4 weeks. Of these patients, 28 complained myalgia which started one or two days after receiving tocilizumab injection and decreased gradually, but the myalgia recurred by further tocilizumab injections. They suffered from severe myalgia of upper body such as neck, shoulder, and back muscles, but these pains were quite different from those of fibromyalgia nor polymyalgia rheumatica. When the patients complained myalgia, the levels of CRP had decreased to basal levels (less than 3 mg/L) and their activities of rheumatoid arthritis such as the number of swelling joints were rather decreased. RA patients with high disease activity at initial tocilizumab treatment developed myalgia more frequently than those with low disease activity. In the patients experienced myalgia, the serum IL-6 levels were significantly higher (107 $\pm$ 56 pg/L) than those in patients without myalgia (31 $\pm$ 18 pg/L) at 28 days after initial tocilizumab treatment. But the serum levels of high sensitive TNF-α and CRP were decreased to within normal limits, and the levels of CK or aldolase were within normal range. After initial tocilizumab treatment, the magnitude of myalgia decreased well paralleled with serum IL-6 levels.

Conclusion: During tocilizumab treatment, RA patients with high disease activities frequently experienced myalgia in spite of decreasing the disease activities. In the patients who complained myalgia, the levels of IL-6 but not CRP or TNF-α were selectively high. However, before tocilizumab treatment, the patients did not complain myalgia, when both IL-6 and CRP levels were high, suggesting the myalgia supposed due to interaction of IL-6 and tocilizumab.

1274

Development of a Novel Recombinant Biotherapeutic with Applications in Targeted Therapy of Human Arthritis. Panagiotis Kamperidis[1], Tahereh Kamalati[1], Mathieu Ferrari[1], Lewis Lee[1], Rita Jones[1], Toby Garrood[1], Malcolm D. Smith[2], Soraya Diez-Posada[1], Chris Hughes[1], Ciara Finucane[1], Stephen Mather[1], Ahuva Nissim[1], Andrew J. T. George[1] and Costantino Pitzalis[3]. [1]London, United Kingdom, [2]Adelaide, Australia, [3]Centre for Experimental Medicine and Rheumatology, QMUL, London, United Kingdom

Background/Purpose: To isolate recombinant antibodies with specificity for human arthritic synovium and to develop targeting reagents with joint specific delivery capacity for therapeutics and/or diagnostic applications.

Methods: *In vivo* single chain antibody (scFv) Phage Display screening using a human synovial xenograft model was used to isolate antibodies specific to the microvasculature of human arthritic synovium. scFv antibody tissue specific reactivity was assessed by immunostaining of: (i) synovial tissues from normal controls, RA and OA patients, (ii) normal human tissues arrays and (iii) tissues from other inflammatory diseases displaying neovasculogenesis. *In vivo* scFv antibody tissue specific targeting capacity was examined in the human synovial xenograft model using both ^{125}I labeled and biotinylated antibody.

Results: We have isolated a novel human, recombinant antibody, scFv A7, with specificity for the microvasculature of human arthritic synovium. We show that *in vivo*, this antibody can efficiently target human synovial microvasculature in SCID mice transplanted with human arthritic synovial xenografts. Our results demonstrate that scFv A7 antibody has no reactivity with the microvasculature or, other cellular components, found in a comprehensive range of normal human tissues including normal human synovium. Further, we show that the reactivity of the scFv A7 antibody is not a common feature of neovasculagenesis associated with chronic inflammatory conditions.

Conclusion: Here we report for the first time the identification of a scFv antibody, A7, that specifically recognizes an epitope expressed in the microvasculature of human arthritic synovium and has the potential to be developed as a joint specific pharmaceutical.

Gene Expression Profiling of Folate Pathway Related Genes in Methotrexate naïve- and Methotrexate-Treated Rheumatoid Arthritis Patients. Marjolein Blits[1], Gerrit Jansen[1], Yehuda G. Assaraf[2] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Technion, Haifa, Israel

Background/Purpose: The folate antagonist methotrexate (MTX) is an anchor drug in the treatment of rheumatoid arthritis (RA). Many attempts have been undertaken to predict response to MTX treatment, in particular by evaluating possible correlations with polymorphic variations of methotrexate/folate-related genes. Thus far, however, many of these studies were not elusive in providing robust predictive markers. The aim of this study was to explore whether analysis of expression of methotrexate/folate-related genes could provide information on the mechanism underlying (non)responsiveness of RA patients for MTX therapy.

Methods: Large-scale expression profiling by cDNA Stanford microarrays, containing 43000 elements, was performed on peripheral blood from 35 RA patients and 15 healthy individuals (van der Pouw Kraan, et al., Ann Rheum Dis 2007). The RA patient group included 25 patients treated with methotrexate (MTX^+ group) and 10 patients untreated for methotrexate (MTX^- group). As a control, a group of healthy, age and sex-matched, individuals (n=15) were arrayed. The array data was filtered and normalized in the Stanford microarray database. Subanalysis on this dataset was preformed for a set of genes involved in the methotrexate/folate pathway (van der Heijden, et al., Nat Clin Pract Rheumatol. 2007), in particular those involved in the cellular uptake (FR's) and efflux (MRP1–5, BCRP and P-gP) of MTX, as well as the metabolism and intracellular targeting of MTX (FPGS, GGH, DHFR, TYMS, and GART). Statistical analysis was performed using Student's *t* test or Mann-Whitney *U* test, p-values of ≤ 0.05 were considered to be statistically significant.

Results: Several folate/MTX-related genes were markedly and significantly altered between the three study groups. Interestingly, the metabolic enzymes FPGS and GGH were significantly up-regulated in the MTX^- RA group compared to the healthy control group (HC group), whereas GART expression was markedly down-regulated. Following MTX treatment, these alterations in expression levels were normalized to those observed in the HC group. Furthermore, the MTX-efflux transporters multidrug resistance protein-2 (MRP2) and MRP3 showed an increased expression in the MTX^+ group compared to the MTX^- group and the HC group, suggesting that cellular extrusion may contribute to a diminished MTX response in the MTX^+ group.

Conclusion: Collectively, these results indicate that, under inflammatory conditions basal folate metabolism is altered in blood cells of RA patients vs HC. Treatment with MTX restores expression of these genes to the levels within the range of the HC group. Finally, our results provide the first indication that multidrug resistance protein efflux transporters could contribute to an attenuated MTX response in MTX-based RA treatment.

1276

Retrospective Analysis of the Efficacy of Tacrolimus in Rheumatoid Arthritis: Suggestive Synergistic Effects with Methotrexate. Kenta Hoshi, Sumiaki Tanaka, Tatsuhiko Wada, Junichi Tanaka, Tatsuo Nagai and Shunsei Hirohata. Kitasato University School of Medicine, Sagamihara, Japan

Background/Purpose: Tacrolimus (TAC) is an immunosuppressant with a calcineurin inhibitory effect and has been shown to be beneficial in treating rheumatoid arthritis (RA). It's well known that the effects of biologics for treating RA are better in patients receiving biologics with methotrexate (MTX) than those in patient receiving biologics alone. It's therefore likely that MTX may enhance the effects of TAC for treating RA. To clarify the efficacy of combination therapy with TAC and MTX, we performed a retrospective cohort study of RA patients, who received TAC.

Methods: We selected all RA patients treated with TAC from 2006 to 2010 in our hospital and corrected clinical data from their medical records. To compare improvement of disease activity score of 28 joints (DAS28) during 12 months between MTX+TAC group (patients treated with TAC and MTX) and TAC group (patients treated with TAC with or without Disease-modifying antirheumatic drugs), we adjusted DAS28 for sex, age, dosage of prednisolone, and analysed using multivariate analysis of variance (MANOVA).

Results: 142 patients were treated with TAC for RA between 2006 and 2010 (Figure 1). Thirty-six patients were discontinued due to the lack of efficacy within 12 months, and 22 patients were discontinued due to adverse events including infection (4 patients), renal dysfunction(5) or hyperglycemia (2). 53 patients (TAC+MTX group: 21 patients, TAC group: 32 patients) were continued to receive TAC therapy over 12 months. As shown in Table, TAC significantly improved DAS28 during 12 months. Adjusted DAS28 before TAC and after 12months were summarized in Figure 2. MANOVA showed that the improvement adjusted DAS28 in 12 months was significantly greater in TAC+MTX group than in TAC group (p=0.0017).

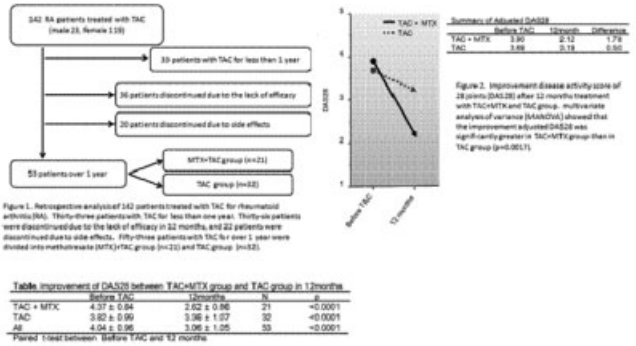

Figure 1. Retrospective analysis of 142 patients treated with TAC for rheumatoid arthritis (RA). Thirty-three patients with TAC for less than one year. Thirty-six patients were discontinued due to the lack of efficacy in 12 months, and 22 patients were discontinued due to side effects. Fifty-three patients with TAC for over 1 year were divided into methotrexate (MTX)+TAC group (n=21) and TAC group (n=32).

Summary of Adjusted DAS28

	Before TAC	12month	Difference
TAC + MTX	3.90	2.12	1.78
TAC	3.66	3.18	0.50

Figure 2. Improvement disease activity score of 28 joints (DAS28) after 12 months treatment with TAC+MTX and TAC group. multivariate analysis of variance (MANOVA) showed that the improvement adjusted DAS28 was significantly greater in TAC+MTX group than in TAC group (p=0.0017).

Table. Improvement of DAS28 between TAC+MTX group and TAC group in 12months

	Before TAC	12months	N	p
TAC + MTX	4.37 ± 0.84	2.62 ± 0.86	21	<0.0001
TAC	3.82 ± 0.99	3.96 ± 1.07	32	<0.0001
All	4.04 ± 0.96	3.06 ± 1.05	53	<0.0001

Paired t-test between Before TAC and 12 months

Conclusion: The results confirm that TAC has beneficial effects in treatment of RA. More importantly, the data demonstrate that combination therapy with TAC and MTX is more effective than TAC therapy.

1277

Anti-CCP Titers Are Predictive of the Response to Biological Agents in Patients with Rheumatoid Arthritis. Ryo Takahashi[1], Ryo Yanai[1], Hidekazu Furuya[1], Kuninobu Wakabayashi[1], Tsuyoshi Odai[1], Takeo Isozaki[2], Nobuyuki Yajima[1], Yusuke Miwa[3] and Tsuyoshi Kasama[1]. [1]Showa University School of Med, Shinagawa-ku Tokyo, Japan, [2]University of Michigan Medical School, Ann Arbor, MI, [3]Division of Rheumatology, Tokto, Japan

Background/Purpose: Biological agents have changed the therapy of rheumatoid arthritis (RA) dramatically last few years. But in some cases,

the effect is scarce, and there is also the risk to cause a serious infectious disease. Anti-cyclic citrullinated protein antibody (anti-CCP) is known as an important indicator for diagnosis of early RA and the positivity of anti-CCP is thought as one of the poor prognosis factors. To examine the relation between serum anti-CCP titer and patient responsiveness to biological agents in RA patients.

Methods: Anti-CCP was measured by ELISA. Disease activity and its clinical improvement were assessed using Disease Activity Scores [DAS28; erythrocyte sedimentation rate (ESR) 4] with European League Against Rheumatism (EULAR) response criteria.

Results: In the present study, 64 patients with RA treated with biological agents (infliximab; 30, etanercept; 19, tocilizumab; 7, adalimumab; 8) were included. The mean age was 36.0±18.0 yrs, mean disease duration was 7.8±4.1 yrs, and mean baseline DAS28 was 5.42±1.47. Among the 64 RA patients, 55 patients (85.9%) were positive for anti-CCP, and the mean antibody titer was 293.1±733.4 U/ml. After 14 weeks of treatment, 26 patients showed good responses and 30 moderate responses to biologic agents based on EULAR response criteria, while 8 showed no clinical improvement.

The anti-CCP titer was 73.7±112.1 U/ml in the good responders and 230.3±261.5 U/ml in the moderate responders, which were significantly lower than in the non-responders (1335±1791.5 U/ml). In addition, 100% of patients with low (<100 U/ml) basal anti-CCP titers showed moderate-good response, and 88.0% of those with moderate (100–499 U/ml) titers also showed a moderate-good response. Among those with higher (≥500 pg/ml) basal anti-CCP titers, 50% showed a moderate response and 50% no response. In addition, the anti-CCP titer was 85.9±879.1 U/ml in the group with remission at 14weeks, although significant higher titers of anti-CCP (396.8±129.2 U/ml) were seen in those had no remission.

Conclusion: The result suggests that anti-CCP titer might to be one of significant predictors of the efficacy of the biological agents in patients with RA.

1278

Abatacept Reduces N-Terminal Pro Brain Natriuretic Peptide Levels in Patients with Rheumatoid Arthritis: Results From a Prospective Cohort Study. Inge A.M. van den Oever[1] and Michael T. Nurmohamed[2]. [1]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [2]Reade, Centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk of heart failure (HF). The chronic inflammatory state in RA is associated with increased levels of N-terminal pro-brain natriuretic peptide (NT-proBNP), a clinical biomarker for HF. Recently a study has shown that NT-proBNP levels in RA patients decrease under TN-blocking therapy. It is not know whether this is also observed in biologics with another mode of action. Therefore, we investigated the association between EULAR response and change of NT-proBNP during abatacept treatment.

Methods: Of twenty-eight RA patients, treated with abatacept (10mg/kg) every 4 weeks and included in an observational cohort study, disease activity parameters and serum samples were collected at baseline and after 12 and 24 weeks of therapy. Clinical response to abatacept was assessed after 24 weeks of therapy using EULAR response criteria. Responding patients comprised both good and moderate EULAR responders. NT-proBNP levels were measured by the Elecsys 2010 electrochemiluminescence method (Roche diagnostics).

Results: Table 1 shows the baseline characteristics of the 28 RA patients. These characteristics did not differ significantly between EULAR responders and non responders. In all patients, NT-proBNP levels decreased (p= 0.09) after 12 weeks of therapy and decreased significantly (p=0.04) after 24 weeks of abatacept therapy (table 2). Out of 28, 19(68%) patients were EULAR responders after 24 weeks of therapy. At baseline NT-proBNP levels were higher in responding patients compared to non-responding patients. After 12 weeks of treatment more decrease in NT-proBNP levels was observed in responding patients compared to non-responders.(table 1). The same tendency was found after 24 weeks of therapy. Univariate analysis demonstrated a significant association between EULAR response and NT-proBNP levels (regression coefficient 1.18, 95%CI 2.18 to 0.19; p=0.022).

Table 1. Baseline characteristics of 28 patients with RA

Demographic variables	
Age (years)	53 (16)
Women	86%
RA-related variables	
RA duration (years)	16 (4–23)
IgM-RF ≥ 30 IU/ml	68%
erosions on radiographs	68%
nodules	29%
current methotrexate usage	39%
current prednison usage	41%
current usage of other DMARDs	25%
cardiovascular risk factors	
prior cardiovascular disease	18%
systolic blood pressure (mm Hg)	134 (17)
diastolic blood pressure (mm Hg)	85 (9)
body mass index (kg/m2)	26 (5)
diabetes mellitus type 2	11%
current smoker	21%
current usage of antihypertensives	36%
current usage of statins	14%

Values are mean (SD), median (IQR) or percentage

Table 2. changes in NT-proBNP levels

	baseline	12 weeks	24 weeks
all patients	9.3 (4.4 – 25.5)	10 (3.8 – 22.2)	9.0 (3.8 – 21.0)*
EULAR responders	22.0 (6.9 – 63.6)	13.3 (5.3 – 34.5)*	17.2 (6.0 – 39.5)*
EULAR non-responders	8.15 (3.5 – 9.7)	4.8 (3.0 – 17.9)*	5.9 (2.1 – 9.3)*

P<0.05

Conclusion: Decrease in NT-proBNP levels was more prominent in patients responding to abatacept therapy compared to non-responding patients. These findings underscore the importance of tight control of systemic inflammation in RA patients in order to decrease CV risk.

1279

Do Impared Memory, Cognitive Dysfonction and Distress Play a Role In Methotrexate-Related Pancytopenia In Rheumatoid Arthritis Patients? Salim Donmez[1], Yavuz Pehlivan[2], Omer Nuri Pamuk[1], Bunyamin Kisacik[2], Gulsum Emel Pamuk[1], Ahmet Mesut Onat[2], Mehmet Sayarlioglu[3] and Gözde Yildirim Çetin[3]. [1]Edirne, Turkey, [2]Gaziantep, Turkey, [3]Kahramanmaras, Turkey

Background/Purpose: Studies which investigate the risk factors for methotrexate (MTX)-related pancytopenia in rheumatoid arthritis (RA) patients conclude that the most important factors are age, the dose of methotrexate and genetic factors. In this study, we investigated the role of impaired memory and distress on the development of methotrexate-related hematological toxicity

Methods: Twentyfive RA patients (14 females, 11 males) who were being followed up at 2 centers and who developed pancytopenia and/or febrile neutropenia were included into the study. The control group included 3 RA patients whose hospital registration numbers were immediately after the RA patient of interest (72 cases; 61 females, 11 males). Patients' baseline clinical and sociodemographic features were recorded down from hospital files. RA patients who developed methotrexate toxicity were administered the mini mental test (MMT) and hospital anxiety and depression scale (HADS) one month after discharge from hospital. The controls were also administered the above-mentioned tests.

Results: Three of the patients (12%) with MTX toxicity died. Eight patients (32%) had concurrent hepatotoxicity, the ALT levels were 2–3 times higher than normal only in 2 patients. RA patients with MTX-related pancytopenia were more frequently males (56% vs. 15.3%, p<0.001), did not know how to read and write (52.4% vs. 16.2%, p=0.004), were more frequently living alone /24% vs. 7%, p=0.03), and higher creatinine levels (1.22+0.7 vs. 1.02+0.8, p=0.035) when compared to controls. The groups were similar in age, RF, anti-CCP positivity, HAQ scores, and annual income (all p values >0.05). When the questionnaires were interpreted, it was seen that MMT scores were significantly lower in the MTX toxicity group (22.6±4.3 vs. 26.08±4.8, p=0.002); HADS-A (10.4±4.7 vs. 7.5±3.8, p=0.016) and HADS-D (10.5±4.5 vs. 5.5±4.2, p=0.001scores were significantly higher.

Conclusion: The risk factors for the development of MTX-related pancytopenia in our study were male sex, high creatinine levels, having a low educational level, living alone and visual impairment. In addition, we observed that the presence of impaired memory, depression and anxiety played important roles for the development of methotrexate toxicity. As a result, we conclude that the administration of the MMT to RA patients with low education level, living alone and who are planning to be given MTX, might prove useful to decrease toxicity.

Acute Pain Relief by a Proprietary, Nano-Formulated Lower-Dose Oral Indomethacin. Roy D. Altman[1], Stephen Daniels[2] and Garen Manvelian[3]. [1]UCLA, Los Angeles, CA, [2]Premier Research Group, Austin, TX, [3]Iroko Pharmaceuticals, Poway, CA

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs), such as indomethacin, are commonly prescribed for the relief of arthritic, musculoskeletal, and postoperative pain. Because there is a direct relation between dose of NSAID and adverse effects (AEs), there is a need to develop a formulation which safely provides fast onset of acute pain relief at a reduced dose of medication while decreasing the potential gastrointestinal AEs. This study evaluated the time to onset of analgesia of an investigational, proprietary, lower dose nano-formulated, oral indomethacin (nano-formulated indomethacin) compared with placebo, as well as a loading dose of celecoxib, in subjects with acute dental pain.

Methods: This was a Phase 2, multicenter, randomized, double-blind, single-dose, parallel-group, placebo-controlled study. In total, 203 subjects were enrolled who were 18–50 years of age, had extraction of ≥2 third molars (at least 1 of which had to be a fully or partially impacted mandibular third molar), and experienced moderate to severe pain intensity (a score of ≥50 mm on a 100 mm Visual Analogue Scale [VAS]) ≤6 hours after surgery. Subjects assessed their baseline pain intensity (VAS) at Time 0 before receiving either nano-formulated indomethacin 20 mg or 40 mg, celecoxib 400 mg, or placebo. Efficacy variables included time to onset of analgesia and total pain relief. The Kaplan-Meier method was used to evaluate the treatment effect for each time to event endpoint. Time to onset of analgesia (measured as time to perceptible pain relief confirmed by meaningful pain relief) was based on data collected using the 2-stopwatch method.

Results: Data from the intent-to-treat population were included in the analysis. There was a statistically significant improvement in mean time to meaningful pain relief and mean time to peak pain relief for lower-dose nano-formulated indomethacin when compared with placebo (**Table**).

Parameter	Nano-formulated Indomethacin 20 mg Mean±SE (N=50)	Nano-formulated Indomethacin 40 mg Mean±SE (N=51)	Celecoxib 400 mg Mean±SD (N=51)	Placebo Mean±SE (N=51)
Mean Time to Meaningful Pain Relief (h)	2.4 ± 0.25[b]	1.8 ± 0.21[a]	2.6 ± 0.40[a]	3.4 ± 0.50
Mean Time to Peak Pain Relief (h)	3.4 ± 0.39	2.6 ± 0.30[c]	3.3 ± 0.36	4.4 ± 0.53

[a] $P<0.001$ compared with placebo
[b] $P=0.08$ compared with placebo
[c] $P<0.05$ compared with placebo
SE=standard error

Total pain relief over 8 hours (primary endpoint) for nano-formulated indomethacin was significantly ($P<0.001$) better compared with placebo (mean; 95% CI): 20mg (10.79; 2.66); 40mg (12.56; 2.64); placebo (3.02; 2.64). Tolerability data were comparable and there were no differences in treatment emergent adverse events between nano-formulated indomethacin 20 mg (38%; 19/50) or 40 mg (51%; 26/51), celecoxib (37.3%; 19/51), and placebo (56.9%; 29/51).

Conclusion: A lower dose, nano-formulated indomethacin demonstrated improved pain relief compared with placebo in this Phase 2 clinical trial, suggesting that use of this NSAID formulation may provide clinical benefit in the relief of acute arthritic/rheumatic and postoperative pain as a means of reducing AEs. Utilizing a lower dose, while maintaining efficacy, could result in an improved tolerability and safety profile and is in line with the FDA directive to use the lowest effective dose.

1281

A Phase 2 Study Evaluating the Acute Pain Relief of a Nano-Formulated Oral Naproxen. Garen Manvelian[1], Stephen Daniels[2], Allan Gibofsky[3] and Vibeke Strand[4]. [1]Iroko Pharmaceuticals, Poway, CA, [2]Premier Research Group, Austin, TX, [3]Hospital for Special Surgery, New York, NY, [4]Stanford University, Palo Alto, CA

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are commonly prescribed for the relief of a variety of painful rheumatologic and musculoskeletal conditions, despite concerns about the safety and tolerability of this class of drugs. The purpose of this randomized controlled trial was to evaluate the efficacy and safety of an investigational, nano-formulated, oral naproxen when compared with naproxen and placebo in a validated and standardized model of acute pain.

Methods: This was a Phase 2, multicenter, randomized, single-dose, active- and placebo-controlled trial. In total, 253 subjects 18–50 years of age were enrolled following extraction of ≥2 third molars (≥1 of which was a fully or partially impacted mandibular third molar) who experienced moderate to severe pain (a score of ≥50 mm on a 100 mm Visual Analogue Scale [VAS]) ≤6 hours after surgery) within 6 hours after surgery. Subjects received nano-formulated naproxen 200 mg or 400 mg, standard naproxen 250 mg or 500 mg, or placebo. The primary efficacy endpoint was the sum of total pain relief (TOTPAR) over 0–12 hours (TOTPAR-12). TOTPAR-8 and TOTPAR-4, secondary efficacy endpoints, were also evaluated along with VAS pain intensity difference (VASSPID).

Results: Nano-formulated naproxen 400 mg and 200 mg was significantly ($P<0.001$) better than placebo for TOTPAR-12 (**Table**).

	Nano-formulated naproxen 400 mg[a] N=51	Standard Naproxen 500 mg[a] N=51	Nano-formulated naproxen 200 mg[a] N=50	Standard Naproxen 250 mg[a] N=50	Placebo N=51
TOTPAR-12, mean; SD	31.9; 12.4	28.3; 13.0	25.7; 16.1	24.6; 15.3	9.6; 13.6
TOTPAR-8, mean; SD	21.5; 7.6	19.8; 8.1	17.3; 9.8	16.9; 9.8	6.8; 8.8
TOTPAR-4, mean; SD	10.1; 3.5	9.5; 3.8	8.2; 4.3	8.0; 4.5	3.5; 3.9

[a] $P<0.001$ compared with placebo
SD=standard deviation

Similarly, TOTPAR-4 and TOTPAR-8 values for nano-formulated naproxen 400 mg and 200 mg also demonstrated statistical significance in favor of the active treatments compared with placebo (**Table**). Additionally, VASSPID values over 4, 8, and 12 hours for each treatment group were significantly ($P<0.001$) better than placebo. Adverse events were reported in 13 subjects (5.1%): nano-formulated naproxen 400 mg (1, 2%); nano-formulated naproxen 200 mg (0), standard naproxen 500 mg (2, 3.9%), standard naproxen 250 mg (3, 6%), and placebo (7, 13.7%).

Conclusion: An investigational nano-formulated, lower dose, oral naproxen demonstrated efficacy and was well-tolerated in an acute pain model. These Phase 2 study results suggest that use of this nano-formulation could offer treatment of acute pain at a lower dose.

1282

Application of Nanotechnology to Improve Non-Steroidal Anti-Inflammatory Drugs. Garen Manvelian[1], Roy D. Altman[2] and Vibeke Strand[3]. [1]Iroko Pharmaceuticals, Poway, CA, [2]UCLA, Los Angeles, CA, [3]Stanford University, Palo Alto, CA

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are commonly prescribed for various conditions involving both acute and long-term pain. However, concerns exist about the safety and tolerability associated with NSAIDs. We have completed 3 Phase 2 clinical trials in acute pain models to assess the analgesic efficacy and safety of investigational, nano-formulated, oral NSAIDs: diclofenac, indomethacin, and naproxen.

Methods: All 3 Phase 2 trials were multi-center, randomized, double-blind, single-dose, parallel-group, active- and placebo-controlled studies. More than 200 subjects (N=202 [diclofenac], N=203 [indomethacin], and N=253 [naproxen]) were enrolled for each trial. Subjects were 18–50 years of age, had extraction of ≥2 third molars (at least one of which had to be a fully or partially impacted mandibular third molar), and experienced moderate to severe pain intensity within 6 hours after surgery.

Subjects received nano-formulated diclofenac, indomethacin, or naproxen, an active comparator (parent compound or celecoxib), or placebo. The sum of total pain relief (TOTPAR) was assessed at 4, 8, and 12 hours. The primary efficacy endpoints were TOTPAR 0 to 12 hours (diclofenac and naproxen) and 0 to 8 hours (indomethacin). Higher scores indicated better pain relief.

Results: All active treatments resulted in significantly ($P<0.001$) better TOTPAR values compared with placebo (**Table**).

	TOTPAR-12 Mean; SD	TOTPAR-8 Mean; SD	TOTPAR-4 Mean; SD
Nano-formulated Diclofenac 18 mg, N=49	17.8; 13.8[a]	14.3; 9.4[a]	8.2; 4.2[a]
Nano-formulated Diclofenac 35 mg, N=51	16.8; 12.8[a]	13.9; 8.8[a]	7.9; 4.3[a]
Celecoxib 400 mg, N=51	14.6; 15.1[a]	11.2; 10.5[a]	5.7; 5.0[a]
Placebo, N=51	5.7; 11.5	3.9; 7.2	2.1; 3.3
Nano-formulated Naproxen 400 mg, N=51	31.9; 12.4[a]	21.5; 7.6[a]	10.1; 3.5[a]
Standard Naproxen 500 mg, N=51	28.3; 13.0[a]	19.8; 8.1[a]	9.5; 3.8[a]
Nano-formulated Naproxen 200 mg, N=50	25.7; 16.2[a]	17.3; 9.8[a]	8.2; 4.3[a]
Standard Naproxen 250 mg, N=50	24.6; 15.3[a]	16.9; 9.8[a]	8.0; 4.5[a]
Placebo, N=51	9.6; 13.6	6.8; 8.8	3.5; 3.9
Nano-formulated Indomethacin 20 mg, N=50	Not assessed	10.8; 10.5[a]	5.5; 4.6[a]
Nano-formulated Indomethacin 40 mg, N=51	Not assessed	12.6; 10.7[a]	6.2; 4.8[a]
Celecoxib 400 mg, N=51	Not assessed	14.9; 9.9[a]	7.2; 4.2[a]
Placebo, N=51	Not assessed	3.0; 6.6	1.6; 2.8

[a]$P<0.001$ compared with placebo
SD=standard deviation

TOTPAR values for nano-formulated diclofenac and nano-formulated naproxen were numerically better than the active comparators, although the studies were not powered to assess this statistically. Additionally, visual analog scale pain intensity difference values for each treatment group were all significantly ($P<0.001$) better than placebo.

Conclusion: Investigational, nano-formulated, oral NSAIDs demonstrated efficacy in an acute pain model. These Phase 2 data indicate that nano-formulated diclofenac, indomethacin, and naproxen may offer efficacy at a lower dose and deserve further investigation in Phase 3 clinical trials. The aforementioned results are in line with the FDA directive to use the lowest effective NSAID dose.

1283

Demonstration of the Symptomatic and Structural Effect of Methotrexate in Daily Practice As the First RA-DMARD Despite Its Sub-Optimal Use: Results From the ESPOIR Early Synovitis Cohort. Cécile Gaujoux-Viala[1], Simon Paternotte[2], Bernard G. Combe[3] and Maxime Dougados[4]. [1]Paris 6 – Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France, [2]Hopital Cochin, Paris, France, [3]Hopital Lapeyronie, Montpellier, France, [4]Paris-Descartes University, Paris, France

Background/Purpose: Methotrexate (MTX) is recommended the first DMARD in rheumatoid arthritis (RA). Despite its widespread use and more than two decades of experience, considerable variations exist among rheumatologists in prescribing MTX, including its dose and its concomittent folic acid supplementation. Objective: To describe the use of MTX in early arthritis in daily clinical practice and to evaluate short-term (6 months) symptomatic efficacy and 12 months structural efficacy.

Methods: Patients: including in the French nationwide cohort of early arthritis (ESPOIR). Patients had to present with inflammatory arthritis lasting for 6 weeks up to 6 months, involving more than 2 joints and diagnosed by the referring physician as RA or RA-like (i.e. a high suspicion of RA).

- Data collected: at baseline patients characteristics and every 6 months symptomatic variables (DAS28,HAQ) and Xrays at baseline and 1 year.

- Analysis: a) Comparison of the patients characteristics with regard to the MTX intake (yes/no); b) The evaluation of the symptomatic and structural efficacy has been performed by generalized linear regression after adjustement on propensity score (by modelling the start of MTX by disease specific- and demographic variables obtained at baseline, using logistic regression analysis) in the group of patients receiving MTX versus the ones receiving any treatment except leflunomide or sulfazalasine or TNF inhibitors.

Results: Within the first 6 months of follow-up of 777 RA patients, 59% received a DMARD which was MTX in 68% (N=313). The mean dose of MTX was 12.7±3.8 mg/week. The folic acid supplementation was given in only 53.7% of the patients. MTX was initiated in patients with more active and severe disease (DAS28: 5.39±1.22 vs 4.83±1.30; HAQ: 1.11±0.68 vs 0.85±0.65; ACPA +: 50% vs 28%; erosion: 64.5% vs 53%; all $p<0.002$). After adjustment on the propensity score, MTX was found to be more efficient in terms of both symptomatic and structural end point than control group: change in DAS28 −1.81±1.50 vs −1.54±1.47, p=0.009; change in HAQ −0.51±0.65 vs −0.31±0.62,$p<0.0001$; radiographic progression score 0.88±0.23 vs. 1.60±0.22 units, p=0.031, respectively.

Conclusion: This study confirms the symptomatic and structural efficacy of MTX in early arthritis in daily practice.These data have been observed despite the non-optimal use of MTX including low doses and low frequency of folic acid supplementation.

Impact of Etanercept Therapy on Glycemic Control in a Cohort of Psoriatic Patients: The PRISTINE Trial. Andrew S. Koenig, Annette Szumski, Ronald Pedersen and Debbie H. Robertson. Pfizer Inc., Collegeville, PA

Background/Purpose: Psoriasis patients have an increased risk of systemic comorbidities, including cardiovascular disease and diabetes.[1] The mechanisms underlying these associations and the impact of systemic psoriasis therapy have not been well studied. In the PRISTINE trial (NCT00663052), a post hoc analysis was conducted of the effects of etanercept therapy on cardiometabolic biomarkers in subjects with psoriasis based on diabetes status.

Methods: Subjects ≥18 years with moderate-to-severe plaque psoriasis were randomised to receive either etanercept 50 mg once or twice weekly double blind for 12 weeks. Diabetes status was determined at baseline by patient history; subjects who were non-diabetic, pre-diabetic, and diabetic were also identified based on American Diabetes Association (ADA) diagnostic criteria (non-diabetic=glycosylated hemoglobin A1C [HbA1c] <5.7 with no medical history or diabetes medication; pre-diabetic=HbA1c 5.7–6.4%; diabetic=HbA1c >6.4% or medical history or diabetes medication). Median changes in cardiometabolic biomarkers were analysed based on diabetes status in subjects with both baseline and Week-12 visits for both treatment groups combined.

Results: At baseline, subjects (N=273) were 70% male, with mean age of 44 y, mean BMI of 28.3 kg/m^2 (males)/29.6 kg/m^2 (females), mean PASI of 21, and mean psoriasis duration of 17 y; 31% had a history of psoriatic arthritis (mean duration, 8 y). Overall 10% had a history of diabetes at baseline; 45% were identified as either pre-diabetic (32%) or diabetic (13%) based on ADA diagnostic criteria. In the non-diabetic, pre-diabetic, and diabetic subgroups, median changes in C-reactive protein from baseline to week 12 were −0.1*, −0.2*, −0.3* mg/dL, respectively (median baseline values: 0.3, 0.3, and 0.4 mg/dL; *$P<0.05$, change from baseline to Week 12); median changes in the apolipoprotein B/apolipoprotein A ratio were 0*, −0.1*, and 0 (median baseline values: 0.7, 0.8, 0.7; *$P<0.05$, change from baseline to Week 12). After-treatment changes in glycemic control markers are shown (table).

Effects of etanercept therapy on markers of glycemic control in subjects with psoriasis by diabetes status

	HbA1c* (%)		Plasma insulin† (mcU/mL)		Plasma glucose† (mg/dL)		HOMA-A*	
Subjects	Baseline	Change at Wk 12	Baseline	Change at Wk 12	Baseline	Change at Wk 12	Baseline	Change at Wk 12
Non-diabetic (n=152)	5.4	0‡	12.5	2.0‡	91.8	0.0	2.9	0.6‡
Pre-diabetic (n=86)	5.8	−0.1‡	14.0	2.0	95.4	2.7	3.6	0.4
Diabetic (n=35)	7.0	−0.3	14.0	3.0‡	122.4	1.8	5.3	1.1‡

All values shown are medians.
* Non-fasting; †fasting; ‡$P<0.05$, change from baseline to Week 12 (Wilcoxon Signed Rank Test)

Conclusion: Approximately 10% of subjects in the PRISTINE trial had a history of diabetes at baseline, whereas 45% were identified as being pre-diabetic or diabetic according to current diagnostic guidelines. Those with pre-diabetes or diabetes showed no overall worsening in glycemic control (HbA1c) and had slight increases in plasma insulin and the insulin-resistance measure HOMA-A. These findings suggest that etanercept therapy does not worsen glycemic control in these at-risk populations.

Long Term Results of a Remission Induction Approach to Early Axial Spondyloarthritis: Still Looking for the Window of Opportunity. Zoe R. Ash[1], Nick Barkham[1], Dennis McGonagle[1], Elizabeth Hensor[2], Paul Emery[1] and Helena Marzo-Ortega[1]. [1]University of Leeds, Leeds, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom

Background/Purpose: We have previously reported on an RCT assessing the efficacy of infliximab in very early axial SpA. Importantly, the clinical improvements correlated with resolution of MRI inflammatory spinal lesions. However, the key question is whether this early suppression of inflammatory activity translates into arrest of new bone formation, the hallmark of AS. We now report on the long term outcome of these patients, followed up at five years.

Methods: In the initial study patients received infliximab or placebo for 16 weeks. Subjects were then observed up to week 40 and were eligible for open-label treatment with infliximab on disease flare (BASDAI≥4). In the current phase subjects underwent a clinical assessment and laboratory investigations. Current imaging included whole spine and SIJ MRI to assess for ongoing disease activity and radiographs of the SIJs, lumbar and cervical spine to assess for disease progression including fulfilment of the modified New York criteria (mNYC).

Results: So far, 64% (25/39) of the patients who completed the original study have been assessed, 80% (20 patients) of whom are currently receiving an anti-TNF agent (8 adalimumab, 9 etanercept, 3 infliximab) and 52% are taking NSAIDs. The majority of patients have well controlled disease, with a median disease activity (BASDAI) of 0.65, median BASFI of 0.50. CRP is <5 mg/L in 88% (22/25) of the patients.

No substantive differences were seen in current disease activity or radiographic progression between patients who received infliximab in the initial randomised phase and those who received placebo. However, only 58% (7/12) of those who initially received infliximab are still on an anti-TNF agent, in comparison to 100% (13/13) of those who received placebo. Of those not on an anti-TNF agent, four remain well with minimal or no symptoms, one patient has active disease (BASDAI 4.52) but has defaulted from treatment.

Complete radiographic data was available for 15 patients (radiographs at baseline and follow up). Three patients fulfilled the mNYC for AS at baseline. The remaining 12 patients all have evidence of radiographic progression in the SIJs, with 8 patients now meeting the mNYC for AS. The median mSASSS score was low at 3.7, suggesting little progression within the spine. No patients have progressed to complete spinal ankylosis. Current MRI scans show very little active disease. No substantive differences were found in baseline disease activity scores or MRI findings between patients who now fulfil radiographic criteria for AS and those who do not. However a higher percentage of those with AS than those with non-radiographic axial SpA are now receiving NSAIDs (67% vs. 30%) and anti-TNF (92% vs. 70%).

Conclusion: A third of axial SpA patients treated early with a 3 month course of infliximab remain well and off treatment after 5 years, while all patients initially randomised to placebo continue to require anti-TNF treatment. Despite patients reporting a good clinical status with overall low disease activity and good function, it appears that there is ongoing SIJ radiographic progression in a significant proportion of patients. However this is a small study and these findings require confirmation in larger cohorts.

1286

High Prevalence of Coronary Heart Disease and Its Risk Factors In Veterans with Spondyloarthritides. Suhail Kumar, Trayton Mains and Vikas Majithia. University of Mississippi Medical Center, Jackson, MS

Background/Purpose: An increased prevalence of cardiovascular disease (CVD) and coronary heart disease (CHD) has been reported in patients with spondyloarthritides. This study investigated the prevalence of CVD risk factors, CVD including CHD and stroke in veterans at Jackson VAMC with spondyloarthritides (SpA) including PsA, ankylosing spondylitis (AS), and reactive arthritis (ReA).

Methods: A retrospective chart review, using ICD-9 codes for PsA, AS, and ReA was performed at Jackson, VAMC. Data including age, race, gender, medications, ESR, CRP, lipid panel, HbA1c, 25-OH vitamin D level, hypertension (HTN), smoking, statin use, and CVD events were tabulated. Comparisons of CHD, stroke, and CVD risk factors were made to a matched population from the American Heart Association data. Risk factors included smoking, dyslipidemia (DLD), HTN, and diabetes mellitus (DM). Prevalence ratio and odds ratio were calculated by standard method. Statistical significance (alpha<0.05) was calculated using Chi-square and Fisher's exact test.

Results: See Table. There were 81 patients, 79 male and 2 female, with mean age of patients with PsA, AS, and ReA being 61.8, 60.4, and 56, respectively. There was significant increase in the prevalence of CHD and the risk factors in the SpA, PsA and AS patients. There was an insufficient number of black patients in the cohort to assess effect of ethnicity.

	Control (%)	SpA (%)	PsA (%)	AS (%)	ReA (%)
CHD	9.1	23.46	25.00	26.09	14.29
PR		2.58	2.75	2.86	NS
OR		3.06	3.33	3.52	NS
p-value		*≤0.001*	*0.01*	*<0.05*	*NS*
CVA	2.5	3.70	6.82	0	0
PR		1.48 (NS)	2.73 (NS)		
DM	7.6	24.69	22.73	26.09	28.57
PR		3.25	2.99	3.43	3.76
HTN	34.4	74.07	77.27	73.91	64.29
PR		2.15	2.25	2.15	1.87
DLD	45.2	82.72	88.64	73.91	78.57
PR		1.83	1.96	1.64	1.74
Smoking	23.1	33.33	36.36	26.09	35.71
PR		1.44	1.57	1.13	1.55

PR, prevalence ratio; OR, odds ratio; NS, not significant

Conclusion: Our results further confirm that patients with SpA have an increased risk of developing CHD as well its risk factors. Our study is unique as increased risk and its quantification have not been previously reported in the U.S. veteran population. The increased CHD risk attributable to the increased prevalence of risk factors cannot be determined in this study but has been suggested to be over and above in previous studies.

1287

Clinical and Radiological Evaluation of Sacroiliac Joints (SIJ) Compared with Ultrasound (US) Examination in Early Spondiloarthritis. Francesca Bandinelli[1], Daniela Melchiorre[1], Francesco Scazzariello[1], Antonio Candelieri[2], Leonardo Giovannini[1], Giuliana Salvadorini[1], Francesco Porta[1] and Marco Matucci-Cerinic[1]. [1]University of Florence, Florence, Italy, [2]University of Calabria, Cosenza, Italy

Background/Purpose: BACKGROUND: The sacroiliac joint (SIJ) inflammation is the hallmark of all Spondiloartropathies (SpA) because it often takes several years before that the radiological damage can be demonstrated. The recent ASAS criteria for SpA have included Magnetic resonance (MRI) for early diagnosis, but other new imaging techniques, cheaper and more accessible, as SIJ ultrasonography (US), were not sufficiently investigated until now. In fact, US might have a promising role in detecting enthesitis and effusion of SIJ (1) in the next future. OBJECTIVE: To compare US with clinical examination and traditional radiography (XR) findings of SIJ in early SpA patients.

Methods: In 23 early SpA patients (42 [2,1] mean age, 4 male and 19 female, 11 Psoriatic Arthritis, 7 associated with inflammatory bowel disease and 10 undifferentiated SpA) diagnosed according to ASAS criteria (2), with active sacroileitis (bone oedema at MRI) and duration of disease lower than 3 years,

were investigated: disease activity (BASFI, BASDAI, pain VAS) scores, clinical examination (sacral sulcus tenderness), New York XR score for SIJ. Patients and 11 healthy controls (negative for axial symptoms, SIJ clinical examination and questionnaires) were examined with My Lab70 US 7–18 MHHz (Esaote, Genoa, Italy) the presence of effusion of SIJ and enthesopathy (thickness) of posterior sacroiliac and sacro-tuberosus ligaments.

Results: SIJC distension (right 2.2 ± 0.6 and left 2.3 ± 0.7 in SpA *vs* 1.7 ± 0.2 and 1.8 ± 0.2 in healthy controls, respectively) and ST thickness (right 3.9 ± 1.3 and left 3.4 ± 1.0 *vs* 1.9 ± 0.1 and 1.8 ± 0.1, respectively) were higher in SpA patients than in controls ($p<0,001$ and $p<0,05$ respectively). PS thickness was similar in patients and controls. Only ST thickness correlated with SIJ tenderness (15/23 patients painful at clinical examination [65,2%], $p<0,01$), pain VAS (21/23 with VAS>0 [91,3%], mean 6,5 [2,9], $p<0,001$), BASFI (18/23 with BASFI>0 [78,2%], mean 1,9 [1,6], $p<0,05$). XR SIJ evaluation (14/23 [60,8%] with New York score>1, mean [right] 0,86 [0,62] and [left] 0,65 [0,71]) did not correlate with US results

Conclusion: Our data confirm that SIJC distension and ST thickness were higher in early SpA but that only ST correlated with clinics. US is a promising imaging technique for SIJ more sensitive than clinical examination and XR.

Early Treatment of Psoriatic Arthritis Is Associated with Improved Outcomes: Findings From the Etanercept (Enbrel ®) PRESTA Trial.
Bruce W. Kirkham[1], Wenzhi Li[2], Robert Boggs[2], Henk Nab[3] and Miriam Tarallo[3]. [1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]Pfizer Inc., Collegeville, PA, [3]Pfizer Europe, Rome, Italy

Background/Purpose: Early detection of rheumatoid arthritis (RA) and a rapid therapeutic intervention reduces the risk of clinical progression, joint damage and subsequent irreversible loss of function. However, this has not been well investigated in patients with psoriatic arthritis (PsA). Importantly, the role of biologic agents in early PsA management is still unclear. The objective of this study was to explore the relationship between duration of PsA disease and improvement in health outcomes in patients treated with etanercept enrolled in the PRESTA trial.

Methods: Patients with both moderate/severe psoriasis and PsA who participated in the PRESTA trial and received etanercept 50 mg once weekly were included in the analysis. Subjects in this analysis had to be dosed at least once and have a post-baseline value. Change in baseline values of efficacy measures and Patient Reported Outcomes (PROs) at 24 weeks of treatment of patients with disease duration <2 years (defined as early treatment arm) was compared to change in patients with disease duration ≥2 years. Measures included the Health Assessment Questionnaire of physical function (HAQ), EQ-5D quality of life, Hospital Anxiety and Depression Scale (HADS), Psoriasis Activity and Severity Index (PASI), a Physician Global Assessment (PGA) of arthritis, swollen joint count, joint pain, patient-reported arthritis activity, duration of morning stiffness, and missed workdays. For each of the 12 efficacy variables and PROs, a linear regression of change on its baseline and PsA duration was performed. Age and gender were added as covariates.

Results: A total of 372 patients (103 with disease duration <2 years, 269 with disease duration ≥2 years) were studied. In both groups all outcomes measures at week 24 improved significantly from baseline and the change was similar in the two groups, however linear regression showed that early PsA disease was strongly associated with improvement in EQ-5D, PGA of arthritis, joint pain, and arthritis activity responses (Table). Improvement in EQ-5D, PGA of arthritis, joint pain, and arthritis activity was also associated with being younger, while quality of life and arthritis activity responses were also associated with being female. Improvement in HAQ, anxiety, depression, PASI, and morning stiffness was not associated with early treatment.

Table. The effect of disease duration, age, and sex on efficacy and PROs at Week 24 in patients with PsA

Variable	N	Disease duration <2 P value*	Age P value*	Female P value*
HAQ	371	0.5647	<.0001	0.5542
EQ5D	371	0.0457	<.0001	0.0006
EQ5D-VAS	368	0.0402	0.0002	0.5404
HAD anxiety	369	0.5977	0.0251	0.034
HAD depression	370	0.9493	0.0101	0.3317
PASI	370	0.5586	0.5676	0.2511
PGA arthritis	346	0.0269	0.002	0.3902
Swollen joint count	357	0.3086	0.2559	0.0864
Joint pain	367	0.0072	<.0001	0.0951
Arthritis activity	367	0.0148	<.0001	0.0527
Morning stiffness	360	0.6718	0.3673	0.3446
Sick days	207	0.8985	0.0787	0.9131

*Calculated using linear regression

Conclusion: Although PsA patients with early disease and with longer-duration disease both responded to etanercept treatment, PsA patients with early disease had better responses in several measures.

1289

Efficacy of a Shorter 6-Month Isoniazid treatment in Patients At High Risk for Tubercolosis Treated with Etanercept.
Salvatore D'Angelo, Michele Gilio, Maria Stefania Cutro, Pietro Leccese, Angelo Nigro, Carlo Palazzi, Angela Padula and Ignazio Olivieri. Rheumatology Department of Lucania, San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Potenza, Italy

Background/Purpose: Treatment with tumor necrosis factor (TNF) antagonists is associated with reactivation of latent tubercolosis infection (LTBI). Health authorities worldwide have proposed recommendations for screening of LTBI with purified protein derivative (PPD) and for the initiation of isoniazid (INH) therapy before starting anti-TNF therapy. Our objective was to evaluate the risk of developing active TB in PPD-positive patients on etanercept (ETN) therapy treated with shorter (6 instead of 9-month) course INH chemoprophylaxis.

Methods: All patients with a positive PPD test and candidate to anti-TNF treatment for rheumatoid arthritis (RA), psoriatic arthritis (PsA), or ankylosing spondylitis (AS) were treated with ETN (50 mg/week) and INH (300 mg/die for 6 months). LTBI therapy was scheduled to be started 1 month prior to the initiation of ETN therapy. Patients were carefully followed to reveal any active TB infection either while taking or after the 6 months discontinuating ETN treatment.

Results: From January 2006 to June 2010, 578 patients were evaluated for starting an anti-TNF treatment. Thirty-nine (6.75%) of these had a positive PPD and were enrolled in the present prospective study. The study cohort (24 men, 15 women; mean age 49.9 ± 9.0 years) included 10 patients with RA, 12 with PsA and 17 with AS. The mean follow-up after initiation of ETN was 43 months (median 47; range 5 to 73 mo). All but 4 patients completed the 6-month INH prophylaxis. Reasons for discontinuation of INH included abnormal liver enzymes in 2, peripheral neuropathy in 1, and rash in 1. All the discontinuating patients completed chemoprophylaxis with a 4-month rifampicin course. None of the studied patients experienced a LTBI reactivation.

Conclusion: A shorter 6-month INH chemoprophylaxis seems to be efficacious in preventing LTBI reactivation in a cohort of high-risk PPD-positive patients treated with ETN.

1290

Change in Back Pain Over Time As a Function of C-Reactive Protein Across Studies of Ankylosing Spondylitis.
Wenzhi Li[1], Michelle Stewart[2] and Andrew S. Koenig[1]. [1]Pfizer Inc., Collegeville, PA, [2]Pfizer Inc., Groton, CT

Background/Purpose: C-reactive protein (CRP) levels rise in response to inflammation and are often used to measure disease progress or effectiveness of treatment [1]. Ankylosing spondylitis (AS) is a chronic rheumatic disease that largely affects the spine leading to inflammatory back pain, physical disability, and a reduced quality of life [2]. The objective of this analysis was to investigate the relationship between CRP levels and change in back pain in patients with AS.

Methods: Data were pooled from four controlled clinical trials (placebo or sulfasalazine versus etanercept) [3–6]. Patients with at least one treatment dose, baseline data, and Week 12 data were analyzed. Subject nocturnal and total back pain was measured on the pain visual analogue scale (0–100). Each model was adjusted for baseline nocturnal back pain or baseline total back pain to control for any differences across studies. Pearson correlation coefficients for baseline and

Week 12 were calculated and linear regression controlling for study, treatment, geographic region, and Human Leukocyte Antigen (HLA)-B27 status was performed.

Results: Strong correlations were observed (Table) between nocturnal back pain and total back pain baseline values (r=0.7403, P<0.0001), Week 12 (r=0.9267, P<0.0001), and change from baseline at Week 12 values (r=0.8364, P<0.001). Correlations were very weak between CRP and nocturnal back pain baseline values (r=0.0190, P=0.5105), and weak for Week 12 (r=0.2319, P<0.0001) and change from baseline at Week 12 values (r=0.1852, P<0.0001); similar results were observed for the relationship between CRP and total back pain (Table). Based on the linear regression analysis results, CRP change was a statistically significant predictor of both nocturnal and total back pain change, even after adjusting for HLA-B27 status (both P < 0.0001), however, the contribution of CRP to the regression model was limited.

Table. Pearson correlation coefficients for nocturnal back pain, total back pain, and CRP at baseline, Week 12, and change from baseline

	Nocturnal back pain baseline	Total back pain baseline	CRP baseline
Nocturnal back pain baseline	1	0.7403	0.0190
		P<0.0001	P=0.5105
Total back pain baseline	0.7403	1	0.0107
	P<0.0001		P=0.7106
CRP baseline	0.0190	0.0107	1
	P=0.5105	P=0.7106	
	Nocturnal back pain Wk 12	Total back pain Wk 12	CRP Wk 12
Nocturnal back pain Wk 12	1	0.9267	0.2319
		P<0.0001	P<0.0001
Total back pain Wk 12	0.9267	1	0.2119
	P<0.0001		P<0.0001
CRP Wk 12	0.2319	0.2119	1
	P<0.0001	P<0.0001	
	Nocturnal back pain change	Total back change	CRP change
Nocturnal back pain change	1	0.8364	0.1852
		P<0.0001	P<0.0001
Total back pain change	0.8364	1	0.1889
	P<0.0001		P<0.0001
CRP change	0.1852	0.1889	1
	P<0.0001	P<0.0001	

Wk=Week; CRP=C-reactive protein.

Conclusion: These data show CRP levels alone may not be indicative of back pain levels in patients with AS. Focusing on CRP levels exclusively could be misleading; clinicians also need to ask patients about changes in nocturnal and/or total back pain to get a complete clinical picture of change with treatment.

PASE Tool for Early Screening of Psoriatic Arthritis: Association with Disease Biomarkers and Score Cutoffs. M. Elaine Husni[1], Abrar A. Qureshi[2], Ronald Pedersen[3], Andrew S. Koenig[3] and Debbie H. Robertson[3]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Brigham and Women's Hospital, Boston, MA, [3]Pfizer Inc., Collegeville, PA

Background/Purpose: Psoriatic arthritis (PsA) can lead to irreversible joint damage. The Psoriatic Arthritis Screening and Evaluation (PASE) questionnaire is a validated tool to screen for active PsA among individuals with psoriasis at the earliest possible stage. We assessed the association of PASE cutoff scores and the relationship with PsA disease biomarkers.

Methods: The PRISTINE trial (NCT0066305) evaluated the efficacy and safety of 2 etanercept doses for the treatment of psoriasis. Participants were randomized to receive etanercept 50 mg once or twice weekly for 12 weeks. At study entry, participants self-reported prior physician-diagnosed PsA and assessed their global joint pain (scale 1–5). The PASE questionnaire was administered at baseline. Receiver operating characteristics (ROC) analyses were performed on PASE scores based on prior diagnoses of PsA to determine optimal cutoff scores for best specificity and sensitivity. Logistic regression was used to examine the association of PASE total scores and subscores with serum CRP levels, Subject Global Assessment of joint pain (SGA-Joint), and the history of PsA diagnosis. PASE scores were examined for all patients and associations assessed for a sub-group that excluded patients treated with concomitant methotrexate. (PASE scores are sensitive-to-change with methotrexate).

Results: Of 273 participants at baseline, 30% (n=83) self-reported a physician-diagnosis of PsA. The mean PASE total score for these patients was 47.78 (standard deviation [SD] = 14.14), whereas patients without a diagnosis of PsA had a mean score of 28.26 (SD = 11.93). ROC analyses of baseline PASE total scores indicated that the optimal PASE total cutoff score for >50% probability of the presence of PsA is ≥47 (Table). SGA-Joint scores had a borderline strong correlation with PsA diagnosis (Pearson correlation coefficients 0.69 to 0.74). Interestingly, serum CRP levels showed low correlation with an historical diagnosis of PsA, PASE scores, or the SGA-Joint scores (coefficients ≤0.37 for all). The association results held for both the total population and the sub-group that was not treated with methotrexate.

Table. ROC analyses of baseline PASE scores based on prior diagnosis of PsA

		Characteristics of best scores		Possible PASE cutoff scores with best characteristics		
PASE Scale or subscale	ROC AUC	Proportion correct	Specificity/ Sensitivity*	Percent correct†	Specificity/ Sensitivity‡	>50% probability of PsA presence§
Total score	0.8447	83.92%	78.51	50	41	47
Symptom subscale score	0.8426	85.52%	77.71	23	23	23
Function subscale score	0.8235	82.52%	77.00	25	25	25

* 1/2 (sensitivity + specificity), maximum possible value = 100; †PASE scores that distinguish patient-reported PsA diagnoses from lack of diagnoses; ‡PASE scores that represent high specificity and sensitivity; §PASE scores that screen for a high probability of PsA, PASE, Psoriatic Arthritis Screening and Evaluation; PsA, psoriatic arthritis; ROC, receiver operating characteristic; AUC, area under the curve.

Conclusion: These findings confirm earlier work that the PASE tool is useful for screening for PsA symptoms early.[1] In this analysis, we compared PASE scores to patient-reported diagnoses of PsA in a clinical trial setting. The results support PASE as an informative tool, alerting physicians to the potential need for a rheumatologist's diagnosis for PsA.

Impact of Ankylosing Spondylitis on Sick Leave, Presenteeism and Work Satisfaction in Turkish People. Emel Ozcan[1], Ekin Sen[1], Sina Esmaeilzadeh[1], Aylin Rezvani[2], Tugba Baysak[1], Ayse Karan[1] and Annelies Boonen[3]. [1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Vakif Gureba University Hospital, Istanbul, Turkey, [3]Rheumatology-Medicine, Maastricht, Netherlands

Background/Purpose: The aim of this study is to evaluate the influence of Ankylosing Spondylitis (AS) on sick leave, presenteeism and work satisfaction and to explore the relationships between these outcomes and disease activity as well as physical function in Turkish patients.

Methods: A total of 68 consecutive and unselected patients with AS who were referred to the Rheumatologic Rehabilitation Units in the Departments of Physical Medicine and Rehabilitation in Istanbul University, Istanbul Faculty of Medicine and Vakif Gureba University Hospital between January and May 2011 were included in this study. Patients completed a self-reported questionnaire on socio-demographic characteristics and several patients reported outcomes among which Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Work Productivity and Activity Impairment Questionnaire (WPAI). The Turkish adaptation and test-retest reliability of the questionnaires was carried out successfully before beginning the study. The impact of AS on presenteeism, work satisfaction were examined with Visual Analogue Scale (VAS) and compared according to workload. Disease activity and physical function were assessed with the BASDAI and the BASFI, respectively. The relationships between BASDAI/BASFI scores and work outcomes as well as workload in paid work patients were analyzed by Spearman's correlation and Kruskal Wallis tests.

Results: The mean age of the patients was 37.7±7.3 (21–55) years, 94.1% (n=64) of the patients were male, 86.8% (n=59) of the patients had paid work. In patients with paid work 20.3% (n=12) had physical, 22.0% (n=13) had mental and 57.6% (n=34) had both physical and mental demanding works. There was not found any significant differences between patients with three types of work load and sick leave, presenteeism as well as work satisfaction (p>0.05). 13.6% (n=8) of patients with paid work had sick leave due to AS, average score of presenteeism was 3.1±2.9 and work satisfaction 6.2±2.9. There was a positive correlation between sick leave related to AS and BASDAI (r=0.287, p=0.028), and BASFI scores (r=0.269, p=0.040). There was a positive correlation between presenteeism and BASDAI (r=0.547, p<0.001), also between presenteeism and BASFI (r=0.584, p<0.001) scores. There was a negative correlation between work satisfaction and BASDAI (r=−0.280, p=0.032), and BASFI (r= −0.349,

p=0.007) scores. There was a positive correlation between difficulty in performing unpaid tasks in the last week and BASDAI (r=0.622, p<0.001), and BASFI (r=0.708, p<0.001) scores in paid work patients.

Conclusion: These findings suggest that disease activity and limitations in physical functioning are strongly associated with productivity, presenteeism and satisfaction in workplace. Also, patients with AS not only have substantial sick leave but also experience restrictions while being at work. Finally, in conjunction with treatment protocols, emphasis on the impact of AS on work status and productivity also any attempts to improve the working conditions in patients with AS will increase the efficacy of medical care and rehabilitation programs.

1293

Cardiovascular Outcome and High Dose Statin Treatment in Patients with Inflammatory Joint Disease. Anne Grete Semb[1], Tore K. Kvien[1], Rana Fayyad[2], David A. DeMicco[2], John LaRosa[3], John Betteridge[4], Terje R. Pedersen[5] and Ingar Holme[5]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Pfizer Inc, New York, [3]State University of New York health Science Centre, New York, [4]Middelsex Hospital, London, United Kingdom, [5]Oslo University Hospital-Ullevaal, Oslo, Norway

Background/Purpose: We examined the effect of intensive lipid lowering (LL) in patients with inflammatory joint disease (IJD): rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA) on a composite cardiovascular mortality and morbidity (CVMM) endpoint by a pooled analysis of TNT, IDEAL, and CARDS trials.

Methods: IDEAL (n=8888) compared atorvastatin 80 mg and simvastatin 20–40 mg in post-myocardial infarction patients with 4.8-year follow-up. TNT randomized 10001 CHD patients to double-blind 10 or 80 mg atorvastatin and followed for 4.9 years. CARDS (n=2838) assessed atorvastatin 10 mg versus placebo in patients with type 2 diabetes and no CVD; follow-up was 3.9 years. Of the 21727 patients, 222 had RA, 50 AS, and 36 PsA.

Results: Demographic data were similar between RA/AS/PsA and other participants (non IJD), except that those with IJD were older and more frequently females. Patients with AS had lower atherogenic lipids and apolipoprotein B (Table1) compared to non IJD. LL by statins was comparable in patients with and without IJD. Intensive lipid reduction reduced the rate of CVMM in patients with and without IJD; the lowest rate of CVMM was in AS (Table 2).

	Total cholesterol, mmol/L	LDL, mmol/L	ApoB, g/L
Patients with AS			
Mean ± SD	4.7 ± 0.9	2.8 ± 0.7	1.1 ± 0.3
LSMeans ± SE*	4.7 ± 0.1	2.7 ± 0.1	1.1 ± 0.04
p-value†	p=0.0186	p=0.0290	p=0.0600
Non IJD			
Mean ± SD	4.9 ± 0.9	2.8 ± 0.8	1.2 ± 0.3
LSMeans ± SE*	5.0 ± 0.008	2.9 ± 0.005	1.2 ± 0.002

*adjusted for age, gender, and study
†p-value versus non IJD

	Atorvastatin 80mg	Atorva10/ Simva40/ placebo	Interaction by treatment
RA (n=222)			
Incidence of CVMM	29/107 (27.10%)	25/115 (21.74%)	
HR (95% CI)	1.04 (0.60, 1.80)	-----	p=0.30
	p=0.90		
AS (n=50)			
Incidence of CVMM	4/31 (12.90%)	9/19 (47.37%)	
HR (95% CI)	0.26 (0.07, 0.91)	-----	p=0.02
	p=0.04		
PsA (n=36)			
Incidence of CVMM	4/18 (22.22%)	4/18 (22.22%)	
HR (95% CI)	0.81 (0.18, 3.55)	-----	p=0.97
	p=0.78		
Non IJD (n=21419)			
Incidence of CVMM	2043/9278 (22.02%)	2695/12141 (22.20%)	
HR (95% CI)	0.80 (0.76, 0.85)		
	p<0.0001		

Conclusion: Patients with IJD had comparable lipid lowering and a similarly reduced risk of CVMM after treatment with statins as those without IJD. Intensive LL with atorvastatin was most effective in reducing CVMM in AS, despite their lower levels of atherogenic lipids at baseline.

1294

Epidemiologic Results of Early Rheumatologic Evaluations in a Cohort of Psoriatic Patients Complaining of Musculo-Skeletal Symptoms. Gabriele De Marco[1], Angelo Cattaneo[2], Carlo Carrera[2], Simona Tavecchio[3], Massimo Ricci[4], Claudio Fracchiolla[5] and Antonio Marchesoni[6]. [1]Istituto Ortopedico Gaetano Pini, Milano, Italy, [2]Fondazione I. R. C. C. S. Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [3]Universita' delgli Studi di Milano, Milano, Italy, [4]Universita' degli Studi di Milano, Milano, Italy, [5]A. S. L. Desenzano del Garda, Desenzano del Garda, Italy, [6]Rheumatology Unit, Ospedale G Pini, Milano, Italy

Background/Purpose: Psoriatic arthritis (PsA) is a chronic rheumatism estimated to affect about 20% of psoriatic subjects. Initiatives such as rheumatologic consultations performed at dermatologic clinics are believed to be the key for PsA diagnostic latency reduction. PURPOSES: Describe the epidemiologic result of the rheumatologic evaluations performed in a dermatologic clinic dedicated to diagnosis and care of Psoriasis.

Methods: Between September 2008 and December 2010 the psoriatic subjects followed up at dermatologic clinic of the IRCCS Policlinico di Milano received a thorough rheumatologic evaluation, if they reported: a) muscolo-skeletal painful symptoms and/or b) articular swelling. The rheumatologic parameters evaluated encompass joint counts (tender, swollen, damaged), entheses counts and others as suggested in the GRAPPA international guidelines. The patients also underwent radiographic evaluation of the painful joints. Patient who were known for established PsA were evaluated only in case of active articular disease despite of appropriate treatment.

Results: Overall, among about 1200 subjects followed up at our center, 211 consecutive patients were evaluated (among these, 92 males). The mean age was 56.3 years (standard deviation 12.8 years; median 59, range 22–81), 73.5% suffered from plaque psoriasis (12.8% had nail disease). Only 18% of patients reported a previous diagnosis of PsA (documented by a rheumatologist or a dermatologist). In our cohort we diagnosed 80 PsA (37.9% of the sample, 57.5% of them were males). Sixty-two percent of PsA patients received the diagnosis for the first time and 25% reported the onset of inflammation within 2 years or less. PsA was classified in 66.2% of cases as peripheral arthritis, 28.7% of patients had dactylitis and 16.2% showed axial disease. Radiographic damage due to PsA was present in 36.2% of cases. In regard of age at the moment of evaluation, we did not notice differences between PsA subjects (mean 53.5 years) and the other members of the cohort (mean 57.9 years), as well as for the prevalence of nail disease (13.7%). Il 9.4% of the subjects in our cohort did not show signs or symptoms frankly attributable to inflammatory articular/entheseal disease, nor further investigations helped in diagnostic process. Therefore, these were not classified as PsA. One hundred and sixteen patients (55% of the cohort) were classified as Osteoarthritis, of whom 11 only (9.4%) suffered from PsA contemporarily.

Conclusion: We report that PsA is frequent (37.9%) among psoriatic subjects who complain of musculo-skeletal symptoms. The early rheumatologic consultation allowed us to identify mostly PsA in pre-radiographic stage, in 25% of cases with the onset of articular disease within 2 years.

1295

Proposal for An Adaptation of the Berlin Algorithm for Diagnosing Spa: Results of the SPondyloArthritis Caught Early (SPACE)-Cohort. R. van den Berg, M. Reijnierse, T.W.J. Huizinga and D.M.F.M. van der Heijde. Leiden University Medical Center, Leiden, Netherlands

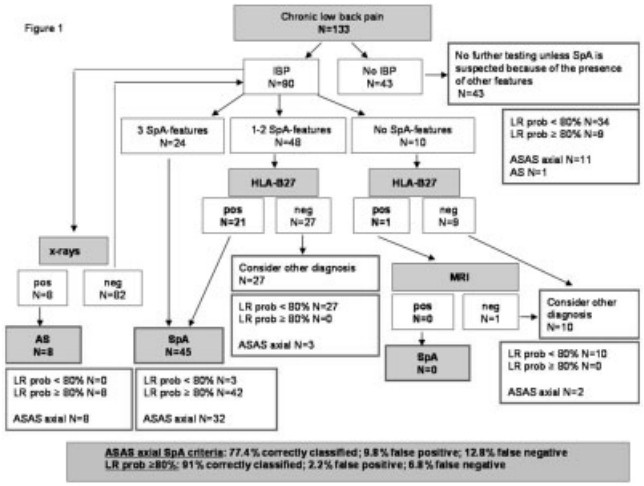
Background/Purpose: The recently developed Berlin algorithm is meant to assist clinicians in diagnosing early axial SpA. Inflammatory back pain (IBP) plays a dominant role. However, IBP is not a very specific symptom and might lead to misclassification. The goal is to validate the Berlin algorithm in the SPondyloArthritis Caught Early (SPACE)-cohort.

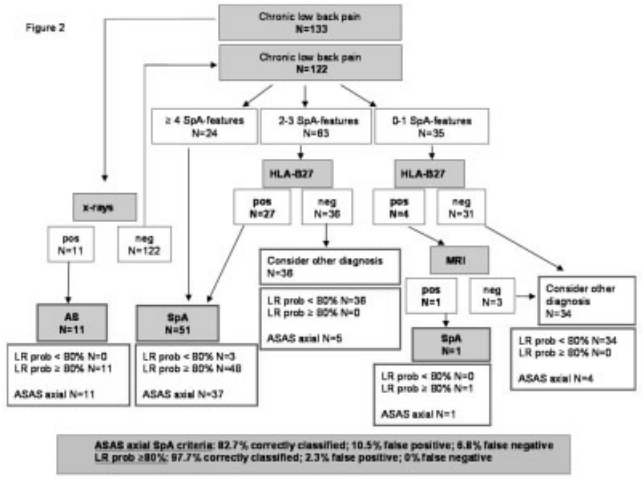
Methods: The SPACE-cohort is set-up in the Leiden University Medical Center (LUMC) to diagnose and treat axial spondyloarthritis (SpA)-patients early. All patients with back pain (>3 months, but <2 years; onset <45 years) were included and underwent a diagnostic work-up; MRI and X-rays of the SI-joints and laboratory assessments. All patients were classified according to the Berlin algorithm and to the ASAS axial SpA classification criteria. The LR-product was calculated based on

the present SpA-features; the cut-off ≥80% probability was used. Second, all patients were classified according to a modified algorithm, excluding IBP as entry criterion.

Results: In 6/133 patients no MRI is made, and in 1 patient also no X-ray is performed. These patients are analyzed as MRI- and X-ray-. 4/6 are diagnosed with axial SpA according to the algorithm. 40/53 (75.5%) patients diagnosed as axial SpA according to the algorithm fulfilled the ASAS axial SpA criteria and 50 (94.4%) had ≥80% probability of having SpA. The 3 remaining patients had a probability of 79.5% and 77.7% respectively. 17/80 (21.3%) patients not diagnosed as axial SpA fulfilled the ASAS axial SpA criteria and 9 (11.3%) had ≥80% probability of having axial SpA (figure 1).

The modified algorithm has IBP not as entry criterion but as additional SpA-feature. According to this modified algorithm, 63 patients (47.4%) could be diagnosed as axial SpA, of which 49 (77.8%) fulfilled the ASAS axial SpA criteria and 57 (95.2%) had ≥80% probability of having axial SpA. Again, these 3 additional patients had a probability close to 80%. 9/70 (12.9%) patients not diagnosed as SpA fulfilled the ASAS axial SpA criteria (figure 2).





The modified algorithm could classify 10 additional patients as axial SpA and no single patient with a probability >80% was excluded; the number of false classified patients is decreased. Some HLA-B27- patients are classified false negative by excluding them from the algorithm although they had MRI+ and other present SpA-features. Thus, in HLA-B27- patients with a high suspicion of SpA, we would advice to perform MRI as well.

Conclusion: We propose a slightly modified algorithm excluding IBP as an entry criterion that is better in accordance with the ASAS axial SpA criteria and the LR-product probability ≥80%, especially by reducing false negative classification.

Background/Purpose: There is a relative lack of qualitative studies in Psoriatic Arthritis (PsA). Such studies would help, to increase the knowledge of the patient's perspective in this disease.

The PsA impact of disease (PsAID) project is a EULAR initiative to elaborate a composite index reflecting the impact of PsA based on the patients' perception. The objective of this first step was to identify areas of health (domains) perceived most important for patients, that would be candidates for inclusion in such a composite index.

Methods: Eleven patient research partners (6 men, 5 women) from 11 European countries identified during a 1-day focus group meeting, 16 domains or areas of health important for the patient. In a subsequent survey, 139 patients from 13 countries ranked by decreasing importance the 16 domains of health and gave a priority rating to those domains they found to be a priority.

Results Were analysed as (a) mean rank of each domain, (b) percentage patients giving priority to each domain, and (c) percentage patients giving a high rank (within the first half of ranks i.e. rank 1–8) to each domain (Table).

Table. domains of health with ranks and priorities (lower mean ranks indicate greater importance)

		Mean rank	Priority	In top 8 ranks
1	Pain	2.56	84.4%	94.7%
2	Skin problems	6.23	52.7%	64.8%
3	Fatigue	6.43	43.4%	74.1%
4	Ability to work and/or to do leisure activities	6.67	50.4%	66.9%
5	Disability	7.23	45.7%	64.0%
6	Feeling of discomfort	7.58	25.6%	64.0%
7	Sleep disturbance	7.96	36.4%	56.1%
8	Anxiety, fear and uncertainty	8.42	33.3%	50.4%
9	Coping	8.45	34.9%	53.2%
10	Embarrassment and/or shame due to appearance	9.74	24.0%	39.6%
11	Social participation	10.01	23.2%	33.1%
12	Depression	10.06	24.0%	38.9%
13	Relationship with family	10.51	30.2%	34.5%
14	Concentration difficulties	10.61	18.6%	31.7%
15	Rejection and discrimination due to appearance	11.60	12.4%	22.3%
16	Sexual life	11.61	14.7%	25.1%

Results: The 16 domains selected by patients and reflecting the impact of PsA are in the Table and comprise physical domains (N=4), psychological domains (N=7), social/societal domains (N=2) and mixed/other domains (N=3). In the ranking survey, physical domains were rated as important; pain was by far the first domain in terms of impact; skin was considered the second domain; fatigue was also important since it was

rated as a priority by 43.4% of the participants. Psychological aspects were also considered important; foremost were anxiety and coping. Among social aspects, work and leisure activities obtained high priority. Discrimination and sexual life were considered the least important domains in this study.

Conclusion: This study gives insights into the patient's perspective in PsA and brings to light the importance of fatigue, but also of several previously under-estimated psychological aspects in PsA. This will form the basis of the development of a composite patient-reported outcome measure to better assess the patient's perspective in PsA.

Fully Quantitative Syndesmophyte Measurement in Ankylosing Spondylitis Using Computed Tomography: Reliability of Volume and Height Measures.

Sovira Tan[1], Jianhua Yao[1], John A. Flynn[2], Lawrence Yao[1] and Michael M. Ward[3]. [1]NIH, Bethesda, MD, [2]Johns Hopkins University, Baltimore, MD, [3]NIAMS/NIH, Bethesda, MD

Background/Purpose: Syndesmophyte progression at the margins of intervertebral disk spaces (IDS) is the hallmark of structural damage in ankylosing spondylitis (AS). Syndesmophyte growth is currently typically monitored by visual inspection of radiographs. The limitations inherent to the modality (2D projection of a 3D object) and rater (qualitative human judgment) entail a possibly important loss in sensitivity. We developed a 3D computer algorithm to measure syndesmophyte volumes and heights from computed tomography (CT) scans of the spine. In anticipation of longitudinal studies, we investigated the precision of this method using scans from 7 patients.

Methods: 7 patients with AS (6 men, 1 woman, mean age of 61 years) were scanned twice consecutively within minutes. Scans were done of the thoracolumbar junction (T10 to L4), providing 4 IDS for analysis. The algorithm segments the vertebral bodies from the scans, detects the 2 opposite end plates of each IDS and identifies as syndesmophyte the bone between those end plates. Syndesmophytes can then be quantified in terms of volume and height. The figure shows an example of IDS with segmented syndesmophytes. In each IDS, we calculated total syndesmophyte volume and height of the tallest syndesmophyte, and compared results of paired scans within patients. We evaluated reliability using the intraclass correlation coefficient (ICC). We examined the 95% limits of agreement using Bland-Altman analysis. For syndesmophyte volume, because the magnitude of the paired differences increased with the mean volume, the limits of agreement were evaluated on log transformed variables and converted back to the original scale.

Results: The 7 patients had IDS syndesmophyte volumes ranging from 0 to 1514 mm^3, and heights ranging from 0 to 8.14 mm (table). Differences between paired measures were very small, and ICCs for syndesmophyte volume and height measures were both 0.99. The limits of agreement for syndesmophyte volume were [$-0.04 \times$ volume, $0.04 \times$ volume] mm^3. For heights, the limits of agreement were independent of the mean and were [−0.2, 0.22] mm. Based on these results, a longitudinal increase in volume of more than 0.04 times the baseline volume, or an increase in height of more than 0.22 mm, represents changes beyond those expected by chance.

	VOLUME (mm3)			HEIGHT (mm)		
	1st Scan	2nd Scan	Differences (absolute value)	1st Scan	2nd Scan	Differences (absolute value)
Min	0	0	0	0	0	0
Max	1488	1514	27.3	8.02	8.14	0.42
Median	192.9	192.4	2.55	4.27	4.09	0.075
ICC	0.99			0.99		
95% limit of agreement	$-0.04 \times$ volume, $0.04 \times$ volume			−0.2, 0.22		

Conclusion: Based on analysis of 28 IDSs from the repeat CT scans of 7 patients, this computerized method that fully quantifies syndesmophytes in 3D space has excellent reliability and precision. The narrow limits of agreement are promising for application to longitudinal clinical studies of changes in syndesmophyte. None.

1298

Fully Quantitative Syndesmophyte Measurement in Ankylosing Spondylitis Using Computed Tomography: Validity of Volume and Height Measures.

Sovira Tan[1], Jianhua Yao[1], John A. Flynn[2], Lawrence Yao[1] and Michael M. Ward[3]. [1]NIH, Bethesda, MD, [2]Johns Hopkins University, Baltimore, MD, [3]NIAMS/NIH, Bethesda, MD

Background/Purpose: A sensitive method to monitor syndesmophyte growth is desirable for the clinical studies of drug efficacy against structural damage in ankylosing spondylitis (AS). The current standard, the scoring of radiographs, is limited by problems of poor visualization, use of 2D images to assess 3D structures and qualitative scoring system. To address these limitations we developed a computer algorithm that fully quantifies syndesmophytes in the 3D space of CT scans. We tested the validity of this method by comparing its measures to the readings of a physician on the scans of 36 patients.

Methods: Each patient had a CT scan of the thoracolumbar junction (T10 to L4), providing 4 intervertebral disk spaces (IDS) for analysis. The algorithm segments the vertebral bodies, detects the 2 end plates of each IDS and identifies as syndesmophyte the bone between the end plates. For each IDS, the algorithm computes the total syndesmophyte volume and height of the tallest syndesmophyte divided by the local IDS width.

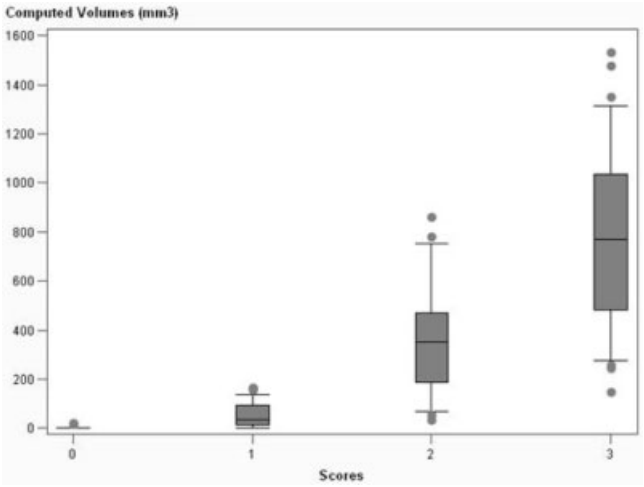
The IDS were scored for volume and height by visual ratings of the CT scans by a physician blinded to the algorithm results, using a 4 point scale. Scores for volume ratings were:

0 = no syndesmophyte
1 = non bridging syndesmophyte involving less than ¼ of vertebral rim
2 = syndesmophyte involving more than ¼ of vertebral rim or local bridging
3 = bridging involving more than ¼ of vertebral rim

The scores for heights were:

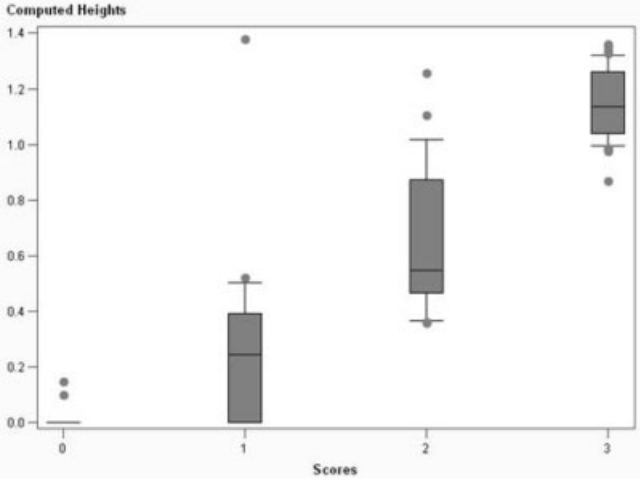
0 = no syndesmophyte
1 = syndesmophyte less than ½ IDS width
2 = syndesmophyte involving more than ½ IDS width
3 = bridging

We used the Kruskal-Wallis test to compare computed volumes and heights across the rating scores.



Results: We studied 36 patients with AS (30 men, 6 women; mean (SD) age 45.9 (11.5); mean duration of AS 20.5 (12.0) years). Among all patients, 144 IDS were scored. For volume, physician ratings of 0, 1, 2, and 3 were present in 32%, 26%, 20%, and 22% of IDS. Measured volumes by the algorithm increased with physician ratings (figure) ($p < .0001$), with little overlap in measured volumes between scores. The collapsed box at score 0 shows that the algorithm generated

few false positives. For height, ratings of 0, 1, 2, and 3 were present in 32%, 19%, 19%, and 30% of IDS. Measured heights also increased progressively with physician ratings (figure) (p <.0001).



Conclusion: An algorithm based on CT scans that fully quantifies syndesmophytes in 3D space accurately detected differences in syndesmophyte volume and height that were rated as different by visual ratings of a physician. Volume and height measures were higher in more severely involved disk spaces and the overlap between grades was small.

Impact of Tumor Necrosis Factor α, Infliximab, and Antibodies Toward Infliximab in Ankylosing Spondylitis Activities: Data From a Monocentric Crossectional Study. Elodie Constant[1], Florence Chopin[1], Béatrice Pallot-Prades[1], Thierry Thomas[1], Stéphane Paul[2] and Hubert Marotte[1]. [1]Inserm U1059, Saint-Etienne, France, [2]GIMAP, EA3064, University Hospital, Saint-Etienne, France

Background/Purpose: Infliximab is a chimaeric monoclonal antibody targeting tumour necrosis factor alpha (TNFα) indicated in ankylosing spondylitis (AS). We analyze association TNFα, infliximab, or antibodies toward infliximab (ATI) blood level with AS activity.

Methods: In a monocentric crossectional study, 30 AS patients treated with infliximab were collected. AS patients are the main characteristic of AS with 66% men, with a mean age of 44.4 years old (from 17 to 63) treated with infliximab since 37.4 months (from 0.5 to 106.4). Only 3 patients were treated with MTX and 2 with prednisone. AS activity was assessed by Ankylosing Spondylitis Disease Activity Score (ASDAS). TNFα, infliximab, and ATI serum concentrations were measured in the blood collected before the next infliximab infusion by enzyme-linked immunosorbent assay (LisaTracker, BMD, France). Data were analyzed using the Kruskall–Wallis one-way analysis of variance (ANOVA) test, followed by Dunnett's multiple comparison post hoc tests with $P<0.05$ chosen as the level of significance. Non-parametrict correlations were performed with Spearman test.

Results: We observe heterogeneity in TNFα concentration according to AS activity ($P < 0.001$). A dose TNFα effect was observed according to an increased AS activity assessed by ASDAS. Similarly, infliximab concentrations were heterogenous in the 30 AS patients ($P < 0.02$). Except for inactive AS, we observed an opposite dose effect between infliximab concentration and ASDAS ($P < 005$). Significant level of ATI were observed in 4 AS patients. One had a moderate activity and 3 had a very active disease. In this population, we also observed a positive correlation between TNFα concentration and ASDAS (Spearman correlation coefficient = 0.48, $P < 0.01$). Furthermore, a negative correlation between infliximab concentration and ATI was also observed (Spearman correlation coefficient = −0.47, $P < 0.01$).

Conclusion: Our study suggested that remaining circulating TNFα is associated with AS disease activity assessed by ASDAS. These confirm interest of a personal monitoring in arthritic patients treated by TNFα blockers. Furthermore studies including interventional approaches need to confirm impact of monitoring in the daily practice.

Ultrasound Assessment of Enthesis Thickening in Psoriatic Arthritis Patients Treated with Adalimumab Compared to Methotrexate. Irena Litinsky[1], Jonathan Wollman[2], Alexandra Balbir-Gurman[3], Uri Arad[2], Daphna Paran[4], Dan Caspi[2] and Ori Elkayam[2]. [1]Department of Rheumatology, Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine Tel Aviv University, Tel Aviv, Israel, [2]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Rambam Health Care Campus, Haifa, Israel, [4]Tel Aviv Souraski Medical Ctr, Tel Aviv, Israel

Background/Purpose: Enthesitis –inflammation of the origin and insertion of ligaments, tendons and aponeuroses is widely accepted clinical and imaging feature of Psoriatic arthritis (PsA). Clinical assessment of enthesitis by eliciting tenderness at the enthesis is inaccurate. Musculoskeletal ultrasound (MSUS) has become the gold standard for examination of tendons and has already been proved to be helpful in monitoring synovitis in RA patients treated with TNF-α antagonists. Evidence for the effect of TNF-α antagonists on ultrasonic features of inflamed enthesis and tendon is still limited. We aimed to assess the effect of adalimumab (ADA) compared to methotrexate (MTX) on the thickness of tendons and enthesis in PsA patients.

Methods: Thirty two PsA patients with active PsA were included. Group1: 21 PsA patients starting treatment with ADA: 14 women (66.6%), 7 men (33.4%), mean age 51.9+9.5 years. Group 2: 11 PsA patients beginning MTX: 5 (45.5%) women, 6(54.5%) men, mean age 45.1+14.3 years. The ultrasound (US) assessment and thickness measurement of the extensor (ET) and flexor tendons (FT) of the 2nd and 3rd finger of both hands, plantar aponeurosis (PA) and Achilles tendon (AT) bilaterally were performed on the day of initiating the therapy, 6 and 12 weeks after. Disease activity was assessed by the number of tender (TJ) and swollen joints (SJ), the number of inflamed enthesitis (IE), pain assessment (PA), patient (PDA) and physician (PGDAI) disease activity evaluation by VAS.

Results: Within each Group: In group 1, all disease activity parameters were improved at visit 3 and reached statistically significant for the number of TJ (10.38 vs 6.06 (P=0.0071)), SJ (8.19 vs 4.94 (P=0.04)), PA (71.52 vs 43.44(p=0.006)) and PGDAI (70.45 vs 40.95(p=0.0014)). Decreased thickness was observed for Achilles tendons bilaterally and was significant for the left side (Rt:0.35cm vs 0.33 (p=0.7) and lt: 0.38 vs 0.33 (p=0.02)), and for left plantar aponeurosis (0.13 vs. 0.1 (p=0.01))), while no significant changes were observed for the thickness of flexor and extensor hands tendons.A statistically significant positive correlation was found between the decrease of thickness of the extensor tendons and the number of TJ,number of IE, PGAD, PGA (3rd lt Et –PGA; 3rd rt ET-TJ, IE, PGA;2nd ET –TJ).In group 2, the disease activity parameters of IE (p=0.04), PA (p=0.0079), PGA (p=0.017) and PGDA (p=0.05) decreased significantly, while the number of TJ and SJ did not changed during the follow up period of 3 months. No change was observed in the thickness of both Achilles tendons and plantar aponeurosis, flexor and extensor tendons of hands after 12 weeks. **Comparison within groups:** Six weeks after initiating treatment with ADA, thickness of left Achilles tendon,2nd rt FT and the number of TJ, SJ, PA, PGA were significantly decreased in comparison to the MTX group (p=0.007;p=0.05 p=0.032; p=0.001;p=0.034 and p=0.003 respectively).

Conclusion: In patients with PsA, treatment with ADA, compared to MTX, significantly improved signs of diseases activity as well as several ultrasonic parameters of enthesis. The US assessment of enthesis is an additional useful tool in the monitoring of psoriatic enthesopathy.

1301

Characterization of a Colombian Cohort of Patientes with Reactive Arthritis. Wilson Bautista-Molano[1], John Londoño[1], Consuelo Romero-Sanchez[1], Paola Peña[1], Ana Santos[2] and Rafael Valle-Oñate[1]. [1]Spondyloarthritis Group. Rheumatology Division. Hospital Militar Central/Universidad de La Sabana., Bogotá, Colombia, [2]Facultad de Ciencias. Universidad de los Andes, Bogotá, Colombia

Background/Purpose: Reactive Arthritis (ReA) shares some clinical characteristics with others members of the Spondyloarthritis group of disorders, such as Ankylosing Spondylitis and Psoriatic Arthritis. It occurs after a preceding infection of the urogenital tract or the gout. It is associated with human leukocyte antigen HLA-B27 and patients present with asymmetric lower limb arthritis, enthesitis, dactylitis or inflammatory back pain. The mean disease duration has been reported to be between 3 and 6 months; however, a chronic course occurs in up to 20% of patients. Literature review do not report any study in our population to define if the characteristics are

similar to other regions. Given genetic susceptibility, environmental and socio cultural characteristics in our region, the clinical manifestations are different. Our objective is to describe clinical, demographic and laboratory findings of a cohort of patients with ReA in our country.

Methods: Data was collected from a Spondylarthritis Database of Rheumatology Service; which includes the information related to the disease. The patients were evaluated following the ASAS recommendations. Patient demographics, disease duration, family and personal history, clinical pattern, and HLA tipping were recorded. Questionnaires were administered for functional status (BASDAI- BASFI). All analyses were performed using SPSS software.

Results: 58 patients with ReA were identified. 46 were man (79.3%) and 12 woman (20.7%) with a mean age of 29 years and mean age at disease onset of 26.1 years. We found history of arthritis in 52 patients (89.7%), enthesopathy 44 (75.9%), back pain 34 (58.6%), buttock pain 15 (25.9%) and dactylitis 13 (22.4%). The duration of first episode was 3.79 months (0.5 – 12). Initial symptoms were: arthritis 26 (44.8%), several initial symptoms 23 (39.7%), back pain 4 (6.9%), enthesitis 3 (5.2%), buttock pain 1 (1.7), and uveitis 1 (1.7%). Taking into account the onset of disease, 32 patients (55.2%) had peripheral onset, 15 (25.9%) had mixed onset and 11 (19%) had axial involvement. There was history of infection in 57 (98.3%) mainly gastrointestinal. HLA typing was performed in 52 patients, of whom 32 were negative (61.6%) and 20 were positive (38.4%). 8 patients were B15 positive. At time of examination the main BASDAI score was 5.02 and main BASFI score was 4.92.

Conclusion: In our population we found predominantly young people, peripheral involvement and the pattern of asymmetric arthritis as initial symptom (similar than reported in the literature). The mean disease duration are also similar and enthesitis was found in higher frequency. However, the presence of HLA*B27 allele is less than reported in other papers and almost all of the patients had history of infection. This is remarkable, given not only by genetic susceptibility but also by environmental and socio cultural conditions in our region. This features influence the manifestation of the disease and the clinical pattern of presentation. Enrollment continues to increase the cohort and best characterize the population according to serological, microbiological and genetic tests.

1302

Anti-TNFα Efficacy Against Spondyloarthropathy without Associated Imaging Signs. Aurélia Bisson-Vaivre[1], Jean-François Menard[1], Didier Alcaix[2], Olivier Vittecoq[1], Xavier X. Le Loet[1], Charles Zarnitsky[2] and Vincent Goeb[1]. [1]Rouen University Hospital, Rouen, France, [2]Le Havre General Hospital, Le Havre, France

Background/Purpose: Some clinical presentations satisfy spondyloarthropathy (SpA)-diagnosis criteria without any detected imaging signs, sometimes posing the question of when early biotherapy should be started. Objective: To evaluate anti-TNFα efficacy in patients with clinical but not imaging (radiographic, computed-tomography scan, MRI) signs of SpA.

Methods: This retrospective study concerned patients with axial SpA followed in 2 hospitals, treated, according to EULAR recommendations, with anti-TNFα after failure of conventional therapies. Therapeutic responses, assessed according to BASDAI50 and ASAS20 or −40 definitions, were evaluated after 6 and 12 months. Factors associated with those responses were also sought.

Results: Among 385 patients included, 257 with imaging signs had significantly more frequent therapeutic responses and partial remissions ($p=0.0005$ and 0.03, respectively). The response rate of *HLA-B27* carriers with initial imaging sign(s) was significantly higher ($p=0.028$). Responders were younger at biotherapy onset, with lower BASFI and pain visual analog scale score, and higher CRP, compared to nonresponders. About 40% of the SpA patients without imaging sign(s) responded to anti-TNFα.

Conclusion: The initial presence of SpA imaging sign(s) seems to be a factor prognostic of the response to anti-TNFα, especially in *HLA-B27* carriers. However, the percentage of patients with exclusively clinical SpA signs and responding to anti-TNFα was far from negligible, thereby reinforcing the pertinence of ASAS criteria.

1303

Continuance of Non-Steroidal Anti-Inflammatory Drugs May Reduce Radiographic Progression in Ankylosing Spondylitis Patients on Biological Therapy. Nigil Haroon[1], Hua Shen[2], Adele Carty[3], Ammepa Anton[3], Richard J. Cook[2] and Robert D. Inman[1]. [1]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [2]University of Waterloo, Waterloo, ON, [3]Toronto Western Hospital, Toronto, ON

Background/Purpose: Anti-TNF therapy has brought significant improvement in symptoms and quality of life of patients with ankylosing spondylitis (AS). However a reduction in the rate of progression of radiographic damage has not been clearly demonstrated. The only therapy that has been shown to affect radiographic damage is the continuous use of non-steroidal anti-inflammatory drugs (NSAIDs). NSAIDs are commonly discontinued once symptoms are well controlled with biologics. We aimed to study the effect of continuous NSAID therapy in patients with AS who are already on biologics.

Methods: In this study 20 patients with AS (modified New York criteria) on anti-TNF therapy who continued their NSAIDS (B+N), were followed with X-rays at 2 years and clinical evaluation annually. For comparison, 20 AS patients on biological therapy (B) in whom NSAIDs had been discontinued were assessed. All patients were assessed on a regular basis on a longitudinal protocol. Disease activity was assessed by BASDAI, CRP and ESR. BASFI, BASG and BASMI were recorded. X-rays were obtained at baseline and follow up and scored using the mSASSS method. Absolute change in mSASSS and rate of change (change per year) were calculated and used as dependant variables. Mann-Whitney test and Fisher's exact test were used where appropriate.

Results: The mean (SD) age of onset of AS for B was 21 (9.1) years and for B+N 18.9 (8.5) years. There was no significant difference in the age of onset or diagnosis of AS between the two groups. There were three females in both groups. HLA B27 was positive in 12 and 15 patients respectively in the B and B+N groups. The baseline mSASSS scores were comparable (B: 12.35 ± 16.9; B+N:13.4 ± 18.5). The baseline BASMI, CRP and ESR were comparable in the two groups. The baseline BASDAI was higher in the B+N group (3.93 ± 2.1 vs 2.6 ± 2.2; $p=0.05$). There was a trend at baseline towards higher BASFI (3.5 ± 2.7 vs 2.1 ± 2.1) and BASG (4.1 ± 2.5 vs 2.6 ± 2.3) in the B+N group. The mean change in mSASSS over 2 yr was 3.05 ± 6.2 in group B compared to only 0.2 ± 3.4 units in group B+N ($p=0.08$). The rate of change in mSASSS also was similarly different with 2.508 ± 5.9 units change per year seen in group B compared to much lower progression at 0.05 ± 2.1 units per year in group B+T ($p=0.09$). There was no difference in the prevalence of extra-articular manifestations in the two groups.

Conclusion: The results point towards a trend reflecting less radiographic progression when NSAIDs are continued after the institution of biologic therapy in AS. Larger studies are needed to confirm this observation.

1304

Anti-TNF Therapy and Malignancy in Spondyloarthropathy-the Leuven Arthritis Biologics Register. Ine Westhovens, Rik Lories, Rene Westhovens, Patrick Verschueren and Kurt L. De Vlam. University Hospitals KULeuven, Leuven, Belgium

Background/Purpose: Tumor necrosis factor alpha (TNF-alpha) is a key member of a large family of cytokines and receptors that are crucial to cellular organization. The use of TNF-alpha antagonists has opened new perspectives for the treatment of patients with spondyloarthropathy (SpA), but concerns are rising about the occurrence of malignancy as a possible adverse event with this kind of therapy.

To report the malignancy incidence in a large single center cohort of patients with SpA treated with one or more anti-TNF therapies and to compare the results with the malignancy incidence in the Belgian population.

Methods: From September 2000 until March 2010, all SpA patients starting treatment with one or more anti-TNF therapies were included in this single center retrospective cohort study: 231 patients with a mean age of 47.86 were included for a total of 1020.74 patient years treatment and 1199.83 patient years follow-up after treatment start. The primary outcome of this study was the incidence of malignancy after starting anti-TNF treatment. Incidence rates were compared with the incidence rates of malignancy in Belgium in 2006 for the 45–50 year old population, registered by the Belgian Cancer Registry.

Results: In our study population, 6 out of 231 patients (2,6%) developed a malignancy after the start of anti-TNF treatment. The overall incidence rate of malignancy is 500,1 per 100000 patient years. The incidence rate for malignancy in female SpA patients is more than twice as high as in males (770.1/100000 versus 370.2/100000 patient years respectively), but standard-

ized incidence ratios are in the same range for male and female patients (156.1 for females and 147.8 for males) and indicate a higher incidence of malignancy in our study population compared to the Belgian population.

Conclusion: We see a tendency towards a higher incidence of malignancy in SpA patients treated with anti-TNF therapy. It is still not clear whether this increased risk is disease-related or treatment-related.

1305

Serum Biomarkers to Predict Clinical Response in Proof-of-Concept Trials in Spondyloarthritis. Maureen C. Turina, Nataliya Yeremenko, Jacqueline Paramarta, Bernard Vandooren, Paul-Peter Tak, Leen E. De Rycke and Dominique L. Baeten. Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: With the availability of TNF blockers for the treatment of spondyloarthritis (SpA), the clinical evaluation of new drugs requires quick "go/no go" signal in small scale, short term proof-of-concept (PoC) trials. The inclusion of a set of biomarkers complementing the clinical evaluations may help to reduce the length and size of these PoC. Therefore, we aimed to identify and validate serum biomarkers to predict clinical response at the group level in small-scale, short term, PoC trials in SpA.

Methods: Matrix metalloproteinase-3 (MMP-3), Pentraxin-3 (PTX-3), high sensitive C-reactive protein (hs-CRP), calprotectin, Interleukin-6 (IL-6), Vascular Endothelial Growth Factor (VEGF), and alpha-2 macroglobulin (alpha-2-MG) were selected as candidate biomarkers based on previous studies in SpA. Serum levels were determined by ELISA in healthy controls (n=20) as well as at week 0 and week 2 in SpA patients treated with either infliximab (5 mg/kg at week 0, 2, and 6) (n=18) or placebo (n=19). Clinical outcome parameters (patient and physician global assessment of disease activity and BASDAI) were evaluated at week 0 and 12.

Results: Whereas the baseline clinical parameters were similar in both SpA cohorts, treatment with infliximab but not with placebo induced a significant decrease in all clinical parameters at week 12 after initiation of treatment ($p<0.005$). Analysis of the baseline serum samples revealed similar levels of the selected biomarkers in the two SpA cohorts. In comparison with the healthy controls, however, levels of PTX-3 ($p<0.001$), hs-CRP ($p<0.001$), calprotectin ($p<0.001$) and VEGF ($p<0.001$) were significantly increased in SpA whereas IL-6 and alpha-2-MG were not elevated. Additionally, PTX-3 ($p<0.01$) was slightly increased in axial versus peripheral disease with a similar trend for hs-CRP ($p=0.08$).

In the placebo group, the levels of these biomarkers remained stable over 2 weeks. In contrast, infliximab induced a significant decrease of hs-CRP ($p<0.0001$), calprotectin ($p<0.001$), and IL-6 ($p=0.04$) with a similar trend for MMP-3 ($p=0.063$). VEGF and alpha-2-MG levels were not significantly modulated. The Standardized Response Mean (SRM), which reflects the ability to detect changes over time at the group level, was high for calprotectin (SRM 1.259) and good for hs-CRP (SRM 0.746) and MMP-3 (SRM 0.521). The SRM was low for the other biomarkers in the treated group and for all biomarkers in the placebo group. In contrast to the findings at the group level, linear regression to determine the biomarker value at the individual level revealed some significant but low correlations of changes in hs-CRP (r^2 between 0.24 and 0.36) and calprotectin (r^2 between 0.08 and 0.19) at week 2 with clinical outcome parameters at week 12.

Conclusion: Early changes in serum calprotectin, hs-CRP, and MMP-3 showed a good ability to predict longer term clinical response at the group level but have no predictive value at the individual level in SpA. These candidate biomarkers are currently validated in other small-scale, short term, PoC trials in SpA.

1306

Inflammation May Be Associated with An Unfavorable Lipid Profile in Psoriatic Arthritis Patients in the CORRONA Registry. Asena Bahce-Altuntas[1], Julie S. Schwartzman-Morris[1], Nicole Jordan[1], Jeffrey D. Greenberg[2], Chaim Putterman[1], George Reed[3] and Anna R. Broder[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]New York University School of Medicine, New York, NY, [3]UMass Medical School, Worcester, MA

Background/Purpose: Although TNF-α is pro-atherogenic (1), the long-term effects of TNF-α inhibition on lipid patterns are still unclear. Only a few small studies in Psoriatic Arthritis (PsA) have evaluated the relationship between TNF-α inhibitor (anti-TNF) use and the lipid profile, a major cardiovascular (CV) risk factor, with mixed results (2).

Methods: We performed a cross-sectional analysis of the relationship between anti-TNF and the lipid profile of PsA patients enrolled in the Consortium of Rheumatology Researchers of North America (CORRONA) registry. We included PsA patients who had at least one CORRONA visit with all lipid values available. The following cut-offs were used for the components of the lipid profile: (1) high Total Cholesterol, TC>200 mg/dl (5.17 mmol/L), (2) low High Density Lipids, males HDL<40 mg/dl (1.03 mmol/L), females HDL<50 mg/dl (1.29 mmol/L), (3) elevated Low Density Lipid, LDL>100 mg/dl (2.59 mmol/L) and LDL>130 mg/dl (3.36 mmol/L), and (4) high Triglycerides, TG>150 mg/dl (1.69 mmol/L), using previously established definitions for CV risk (3).

Results: Of the 4,015 PsA CORRONA patients, 274 met inclusion criteria, 157 anti-TNF-α users (anti-TNF+) and 117 non-anti-TNF-α users (anti-TNF-). Anti-TNF+ were younger than anti-TNF- [53.9 $\pm$ 10.5 years old vs. 58.7 $\pm$ 12.4 year old, $p=0.001$], included more males [62% vs. 46%, $p=0.01$], and had longer disease duration [13.2 $\pm$ 11.13 years vs. 8.9 $\pm$ 8.8 years, $p=0.001$]. Anti-TNF- had significantly more disease activity compared with anti-TNF+, as measured by CDAI [8.86 $\pm$ 8.1 vs. 6.54 $\pm$ 8.1, $p=0.02$]; log ESR [2.35 $\pm$ 1.2 vs. 1.89 $\pm$ 1.1, $p=0.05$]; log CRP [-0.39 ± 1.4 vs. -1.05 ± 1.3, $p=0.03$]; MD Skin Assessment [32.65 $\pm$ 33.4 vs. 23.93 $\pm$ 29.0, $p=0.03$]; and the presence of enthesitis or sausage digits [31% vs. 19%, $p=0.03$]. Statin use was similar in the two groups [32% vs. 24%, $p=0.17$]. There was no statistically significant difference in any lipid outcomes based on TNF use in the bivariate or in the multivariate analysis, adjusting for potential confounders such as demographics, disease activity markers and medications. Disease activity markers were associated with unfavorable lipid outcomes in the bivariate analysis. Low HDL associated with log ESR, OR 1.69 [95%CI: 1.14–2.52, $p=0.01$]; log CRP, OR 1.44 [95%CI: 1.04–1.99, $p=0.03$]; and CDAI, OR 1.04 [95%CI: 1.04–1.07, $p=0.03$]. Log CRP was also associated with both HDL levels $\beta-2.50$ [95%CI: -4.83–-0.17, $p=0.04$] and log TC/HDL ratio $\beta0.05$ [95%CI: 0.00–0.10, $p=0.04$]. There was a significant association between the presence of enthesitis or sausage digits with TG>150 mg/dl, OR 1.97 [95%CI: 1.13–3.46, $p=0.02$]. Limitations include the cross-sectional nature of the study.

Conclusion: We did not find an association between anti-TNF-α use and various lipid parameters in the CORRONA PsA study population. However, an unfavorable lipid profile may be associated with higher disease activity such as CDAI, ESR, CRP and presence of enthesitis or sausage digits. Further longitudinal studies are warranted to study whether controlling disease activity can improve the lipid profile of PsA patients.

Comparison of Screening Instruments for Psoriatic Arthritis in Patients with Psoriasis. Jessica Walsh[1], Daniel O. Clegg[2] and Kristina Callis Duffin[3]. [1]University of Utah Hospital, Salt Lake City, UT, [2]University of Utah Medical Ctr, Salt Lake City, UT, [3]University of Utah, Salt Lake City, UT

Background/Purpose: To compare the abilities of screening instruments to accurately predict a diagnosis of psoriatic arthritis (PsA) in patients with psoriasis.

Methods: Psoriasis Epidemiology Screening ProjecT (PEST), Toronto Psoriatic Arthritis Screen (ToPAS), and Psoriatic Arthritis Screening and Evaluation (PASE) instruments were assembled in random order into packets and distributed to 1194 participants of the Utah Psoriasis Initiative. Responding participants were evaluated by the principal investigator (PI). Previously established cutoff scores were used to designate positive and negative results for each screening tool. The sensitivities and specificities of the instruments were determined by comparing the results to the PI's diagnostic assessment.

Results: Evaluations were completed in 197 participants. Exclusions were made for unclear diagnoses (n = 22) and missing data (n = 17). Of the remaining 158 participants, 114 were diagnosed with PsA. The PI's diagnosis was corroborated by ClASsification of Psoriatic Arthritis (CASPAR) criteria in 90% of all participants and in 93% of participants with available laboratory and radiographic data relevant to CASPAR criteria. 44% of participants were on $\geq$1 disease modifying antirheumatic drug (DMARD) at the time of

evaluation. PEST and ToPAS were more sensitive and specific for the diagnosis of PsA than PASE (Table 1.) 37 participants had false negative scores on ≥ 1 instrument. Among these participants, 31 had synovitis documented by a rheumatologist, 16 had erosive peripheral arthritis, 3 had predominantly axial disease, and 2 had arthritis mutilans. Among the 23 participants with false positive scores on ≥ 1 instrument, 13 had osteoarthritis, 5 had fibromyalgia, 3 had crystal arthritis, and 2 had unclear alternative diagnoses.

Table 1

	Sensitivity	Specificity	PPV	NPV
PEST	0.89	0.64	0.86	0.71
ToPAS	0.93	0.64	0.87	0.78
PASE	0.68	0.49	0.78	0.36

PPV = positive predictive value NPV = negative predictive value

Conclusion: PEST and ToPAS performed better than PASE with higher sensitivities and specificities. Participants in this population may have had fewer active symptoms than patients in other psoriasis populations because of frequent DMARD use. PEST and ToPAS are theoretically more sensitive than PASE in patients with less active disease, because they include questions about current and past symptoms, whereas PASE questions pertain to current symptoms only. The high prevalence of PsA may be explained by histories of more burdensome musculoskeletal symptoms in patients motivated to enroll and/or by encouragement to participate from referring providers in patients with suspected PsA diagnoses. The specificities of the instruments were likely lowered by patients reporting that they participated in order to gain access to a rheumatologist, even when alternative diagnoses were suspected. Despite these limitations, ToPAS and PEST were useful in this population and may be better than PASE at predicting PsA in patients with less active symptoms at the time of evaluation.

1308

Burden of Delay to Diagnosis of Ankylosing Spondylitis. Sarah E. Grigg, Belinda J. Martin, Russell R. Buchanan and Lionel Schachna. Austin Health, Melbourne, Australia

Background/Purpose: Few studies have addressed the psychological, economic and health-related quality of life effects of the distinctively prolonged delay in diagnosis of ankylosing spondylitis (AS).

Methods: Based on the results of a pilot study, a structured self-administered questionnaire was designed to examine the global impact of delay to diagnosis among patients with AS. The questionnaire was completed by 127 of 219 patients attending an AS referral center and treated with a tumor necrosis factor (TNF) inhibitor.

Results: Mean ± SD age at symptom onset was 23.9 ± 9.3 and delay to diagnosis was 10.0 ± 8.9 years. The first symptom was axial in 76.4%, peripheral articular in 18.1%, and extra-articular in 5.5%. Over one-third (34.6%) delayed consulting a health care professional for more than 12 months after onset of symptoms, 70.9% assuming that their symptoms would resolve. The diagnosis of AS was established by a rheumatologist in 67.7%, family physician in 18.1%, and orthopedist in 5.5%. Prior to diagnosis, 68.2% consulted a physical therapist (15.8%, 3 or more), 43.6% a chiropractor (8.7%, 3 or more), and 27% an osteopath (3.2%, 3 or more). The diagnosis of spondyloarthritis was, however, suspected by an allied health professional among only 2 patients (1.7%). The first proposed musculoskeletal diagnosis was non-specific back pain in 55.1% and degenerative disc disease in 26.0%, while AS or a spondyloarthritis was the first presumptive diagnosis in only 21.3%. Estimated costs of treatment prior to diagnosis was greater than US3000 in 25.6% of AS patients with delay to diagnosis less than 5 years compared with 44.4% between 5 and 10 years (p=0.08), and 67.4% for greater than 10 years (p=0.002). Among these strata, employability was affected in 66.7% compared with 75.6% (p=0.37) and 90.7% (p=003), respectively. Eighty percent of respondents thought that physicians could devote more time to try to establish an AS diagnosis and 70.1% that their diagnosis could have been established earlier. Once a diagnosis was established, emotional relief was experienced by 69.3%, positive shift in perception of symptoms by 75.6%, and optimistic outlook for the future by 66.1%. Delay in diagnosis was not associated with long-term depressed mood as evidenced by current Beck Depression Inventory scores.

Conclusion: Delay in diagnosis of AS is associated with significant psychological and economic burden. Allied health professionals are an important target group for educational strategies, given early and often repeated contact with AS patients.

1309

Serum IL-23 Does Not Correlate with Disease Activity in Spondyloarthritis. Hanna Przepiera-Bedzak, Iwona Brzosko, Katarzyna Fischer and Marek Brzosko. Pomeranian Medical University, Szczecin, Poland

Background/Purpose: There are some data that IL-23 play an important role in pathogenesis of spondyloarthritis.

The aim of the study was to assess the association between serum concentrations of IL-23 and disease activity in spondyloarthritis (SpA).

Methods: We studied 184 SpA patients: 82 psoriatic arthritis (PsA) patients, 80 ankylosing spondylitis (AS) patients, 22 SAPHO syndrome patients and 20 healthy persons. We recorded: age, sex, disease duration. We assessed: BASFI, BASDAI, BASG, BASMI, VAS, SF-36, PASI scores. Blood was collected for analysis of IL-23, EGF, FGFb and FGFc by ELISA method. We assessed also CRP, ESR, WBC.

Results: Mean age of patients was: 52,8 years in PsA group, 48,0 years in AS group and 54,8 years in SAPHO group. Mean disease duration was 8,6 years in PsA group, 13,7 years in AS group and 6 years in SAPHO group. Mean serum IL-23 levels were: 4,1 pg/ml In PsA group, 2,6 pg/ml in AS group and 3,5 pg/ml in SAPHO group. There was no correlation between IL-23 and disease activity assessed by CRP and ESR in SpA patients. There was no correlation between IL-23 and disease activity assessed by BASMI, BASDAI, BASFI and BASG in SpA. There was no correlation between IL-23 and EGF and FGF in SpA. There was negative correlation between VAS score and IL-23 in SAPHO group (R = −0,46; p = 0,04). There was positive correlation between SF-36 and IL-23 in PsA group (R = 0,42; p = 0,003).

Conclusion: There is no association of serum concentrations of IL-23 with disease activity in SpA.

1310

Effect of Weight, Body Mass Index and Weight-Based Dosing on Persistency of Anti-TNFs in Psoriatic Arthritis. Jeffrey D. Greenberg[1], Rebecca Bolce[2], Ying Shan[3], Katherine C. Saunders[4], George Reed[3], Joel M. Kremer[5] and Dennis Decktor[2]. [1]New York University School of Medicine, New York, NY, [2]Janssen Services, LLC, Horsham, PA, [3]UMass Medical School, Worcester, MA, [4]CORRONA, Inc., Southborough, MA, [5]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Among approved anti-TNF agents for PsA, both fixed and weight-based dosing biologics are commonly prescribed. Despite the well-described higher body mass index (BMI) in PsA patients, there are few studies addressing whether patient weight and/or BMI influences patient outcomes on anti-TNFs. The effect of weight, BMI and weight-based dosing on persistency of treatment in anti-TNF biologic therapy among PsA patients was evaluated.

Methods: Patients with a diagnosis of PsA who were biologic naïve, initiated an anti-TNF biologic, and had at least one follow-up visit after this initiation were identified. Fixed dosing anti-TNFs (adalimumab and etanercept) versus weight-based (infliximab) dosing anti-TNFs were compared. Patients were considered persistent on treatment if they remained on the same drug therapy and did not switch or discontinue. Cox regression models adjusted for site clustering were used to estimate risk of discontinuation. Weight, BMI, and weight-based dosing were evaluated using Cox regression models and Kaplan-Meier survival analysis.

Results: Using data from CORRONA from 2/02–03/11, patients with a diagnosis of PsA (N=4,495) who were biologic naïve and initiated an anti-TNF biologic (N=428) and had at least one follow-up visit after this initiation (N=392) were identified. Obesity (BMI≥30) was significantly associated with a higher risk of discontinuation (unadjusted HR=1.8 [1.3, 2.5]; persistency 80% vs 63% at 18 months). PsA patients on fixed dosing anti-TNFs showed estimated higher risk of discontinuation compared to weight based dosing TNFi (unadjusted HR=1.3 [0.9, 2.0]; persistency 75% vs 70% at 18 months). Factors that were also associated with persistency were adjusted for—patient pain, gender, being disabled, duration of disease, history of CVD and year of initiation—BMI and fixed dosing anti-TNFs continued to show increased risk (Table 1). In separate models, weight showed similar effects on persistency as BMI.

Table 1. Multivariate Cox regression model for risk of discontinuation+.

	Hazard Ratio	95% CI	p-value
Fixed dosing (vs weight-based) anti-TNF	1.38	0.90,2.11	0.140
BMI (≥30) vs BMI <30	1.52	1.08,2.14	0.017
Pt. Pain (≥4 vs <4)	1.48	1.05,2.10	0.026
Female vs Male	1.64	1.17,2.29	0.004
Disabled	1.78	1.00,3.16	0.050
History of CVD	2.68	1.31,5.49	0.007
Duration of PsA	0.98	0.96,1.00	0.064

+ also adjusted for year of initiation

Conclusion: Increased BMI and weight were both significantly associated with risk of discontinuation of anti-TNFs in PsA patients. Infliximab, a weight-based dosing anti-TNF, was associated with a lower risk estimate of discontinuation than fixed dosing anti-TNFs although this did not reach statistical significance. Other determinants of risk of drug discontinuation included baseline patient pain level, gender, prior disability and CV comorbidity.

1311

Correlation Biomarkers of Cartilage and Bone Turnover with Disease Activity, Function, Quality of Life, Radiology and Magnetic Resonance Imaging in Patients with Early Spondiloarthritis. Raquel Almodovar[1], Valeria Ríos[2], Sara Ocaña[1], Milena Gobbo[3], Marisa Casas[1], Pedro Zarco[4] and Xavier Juanola-Roura[5]. [1]Hospital Universitario Fundación Alcorcón, Alcorcon. Madrid, Spain, [2]Hospital universitario Belvitge,, Barcelona, Spain, [3]Spanish Society of Rheumatology, Madrid, Spain, [4]Fundación Hopsital Alcorcon, Alcorcon, Madrid, Spain, [5]Hospital Universitario de Bellvitge, Barcelona, Spain

Background/Purpose: To analyse the influence of sex, HLA B27, psoriasis, osteitis in MRI and involvement pattern on biomarkers **of cartilage and bone turnover** [matrix metalloproteinase-3(MMP-3), high sensitivity C-reactive protein (hsCRP), C Telopéptide (CTX) and D-Pyridoline] in early spondiloarthritis (SpA) To determine the relationship between the biomarkers and activity, functional capacity, quality of life and radiology in early SpA.

Methods: A cross-sectional study of baseline visits from 60 patients included in Esperanza program was performed. Patients analyzed were under 45 years old, with onset symptoms within the range of 3 to 24 months. All patients included met the following criteria: a) inflammatory back pain, or b) symmetric arthritis, or c) back pain /articular pain, in addition to at least one of the following: a) psoriasis, b) inflammatory bowel disease (IBD), c) anterior uveitis (AU), d) radiographic sacroiliitis, e) family history of spondylitis, psoriasis, IBD, or AU, f) HLA-B27 positive. Data collected: social/demographic, ESR, CRP, HLA-B27, BASDAI, BASFI, total BASRI and ASQol. MRI of sacroiliac joints (SIJs) was performed on 23 patients and activity was defined according to the ASAS Group definitions for active lesions on MRI. Serum MMP-3 (ELISA), CTX (Cromatogrphic), hsCRP (Nefelometric) and urinary D-pyridoline (QLIA) were measured in all patients. Analysis: Chi square was used to compare rates and U de Mann-Whitney to analyze continuous variables. Pearson correlation coefficient analysis was performed to examine the contribution of differents biomarkers.

Results: At baseline, a total of 60 patients diagnosed of **early SpA** were included: 26 male (43%) and 34 female (56.6%), with age 32.3± 6.6 years and disease duration of 12.4± 6.7 moths. Eight percent of patients had axial affectation, 23% peripheral, 2% mixed and 3% enthesitic pattern. The HLA B27 was positive in 26.6% patients. Thirteen percent had psoriasis. Six patients (26%) had active sacroiliitis by MRI. The values (mean ± SD) were: nocturnal pain (cm) 4.5± 2.6; BASDAI (cm) 4.2 ± 2.4; ESR (ml/h)15± 14; CRP (mg/L) 5.3± 9.4; BASFI (cm) 2.7± 2.4; total BASRI 0.38 ±1 and ASQol 6.7± 5. Biomarkers showed no significant differences between HLA-B27 positive or negative patients, with or without psoriasis patients, with or without osteitis in MRI and type of involvement pattern. CTX **(0.53 mgr/L vs. 0.24mgr/L; p=0.001)** and MMP-3 **(0.53 mgr/L vs. 0.24mgr/L; p=0.001)** were significantly higher in male **than in female** with early **SpA.** Of the biomarkers examined, only the **h**igh sensitivity C-reactive protein (hsCRP) showed a significant correlation with the ESR level (r=0.3, p=0.04). MMP-3 and urinary D-pyridoline demonstrated a trend toward a positive correlation with ESR (r=0.2, p=0.08) and (r=0.3, p=0.08), respectively. hsCRP showed a trend toward a positive correlation with total BASRI (r=0.3, p=0.05).

Conclusion: In our study, the male sex is associated with higher levels of CTX and MMP-3 in early SpA, which may indicate higher radiographic damage in men. HLAB27, psoriasis and osteitis in MRI had no influence on any biomarkers. We found only a significant correlation between hsCRP and ESR.

1312

Effect of Adalimumab on Function, Health-Related Quality of Life, Work Productivity, and Daily Activities in Patients with Non-Radiographic Axial Spondyloarthritis. Walter P. Maksymowych[1], Philip J. Mease[2], Sumati Rao[3], Aileen Pangan[3], L. Steven Brown[3], Vipin Arora[3] and Mary A. Cifaldi[3]. [1]University of Alberta, Edmonton, AB, [2]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [3]Abbott Laboratories, Abbott Park, IL

Background/Purpose: To evaluate the effect of the anti–tumor necrosis factor agent adalimumab (ADA) on physical function and health-related quality of life (HRQOL) and productivity in patients with non-radiographic axial spondyloarthritis (SpA).

Methods: Biologic-naïve patients with non-radiographic axial SpA, excluding those meeting the modified New York criteria for AS, and inadequate response to or intolerance of ≥1 nonsteroidal anti-inflammatory drug were randomized to ADA 40 mg every other week (eow) or placebo for 12 weeks of double-blind treatment (Ability 1 trial). The blinded phase was followed by a 92-week open-label phase. Function was assessed using the Health Assessment Questionnaire for Spondyloarthropathies (HAQ-S) and HRQOL using the Short Form 36 Health Survey (SF-36) Physical Component Summary (PCS) score. Productivity was assessed using the 4 components of the Work Productivity and Activity Impairment Questionnaire (WPAI). Changes from baseline to Week 12 were compared between groups using ANCOVA with adjustment for baseline scores and treatment as a factor.

Results: Analyses were conducted on the full-analysis set, a subset of the intent-to-treat population (N=91 for adalimumab; N=94 for placebo). Mean age was 38 years, 55% were women, and duration of SpA symptoms averaged 10 years. Baseline HAQ-S scores were similar between ADA- and placebo-treated patients (0.99 and 1.05, respectively) and indicated moderate impairment. For both groups, baseline SF-36 PCS scores were lower than the general US population average of 49.1 (33.9 for ADA, 33.1 for placebo). Baseline WPAI scores indicated substantial total work productivity impairment (TWPI; 46% average reduction for ADA, 49% for placebo) and total activity impairment (TAI; 57% average reduction for both ADA and placebo) due to axial SpA. ADA therapy was associated with statistically significant improvements in HAQ-S, SF-36 PCS, absenteeism, and daily nonwork activity impairment scores (TAI) compared with placebo; presenteeism and TWPI showed no significant treatment group differences (table). Improvement in SF-36 PCS met the minimum clinically important difference of 3.0.

Mean Changes From Baseline to Week 12 in Function, HRQOL, and WPAI Scores in Patients With Non-Radiographic Axial SpA

	Placebo (N=94)	ADA 40 mg EOW (N=91)	P-Value
Physical Function			
HAQ-S	−0.1	−0.3	0.027[a]
HRQOL			
SF-36 PCS	2.0	5.5	0.001[b]
WPAI			
Absenteeism	2.3	−7.2	0.005[b]
Presenteeism	−5.8	−12.3	0.07[b]
TWPI	−5.7	−12.1	0.122[b]
TAI	−3.6	−14.9	0.002[b]

[a]Last observation carried forward.
[b]As observed.

Conclusion: Patients with non-radiographic axial SpA had substantial impairment of function, HRQOL, work productivity, and nonwork activities at baseline. After 12 weeks of therapy, the ADA group experienced clinically and statistically significant improvements in function and HRQOL and significantly less absenteeism from work and less impairment in daily nonwork activities compared with placebo.

1313

Are High Titers of Anti-CCP Antibodies in Psoriatic Arthritis Patients a Biomarker of Erosive Disease? Ignacio Garcia-Valladares[1], Raquel Cuchacovich[1], Antonio A. Iglesias-Gamarra[2] and Luis R. Espinoza[1]. [1]Louisiana State University, New Orleans, LA, [2]Universidad Nacional, Bogota, Colombia

Background/Purpose: The presence of positive anti-CCP antibodies (anti-CCP), especially at high titers, is characteristic of rheumatoid arthritis (RA) and predictive of the development of erosive disease. In contrast, anti-CCP antibodies may be present in PsA in less than <15% and usually at low titers.

The aim of this study was to compare the clinical, serological and radiologic characteristics of PsA patients with and without anti-CCP antibodies.

Methods: Serum anti-CCP antibodies were measured in 80 patients with PsA. Age, gender, family history, means disease duration, pattern of joint involvement, nail and skin involvement, and treatment were obtained. CASPAR criteria were used.

Results: Of the 80 patients with PsA, 38 were women and 42 men. The mean age 45.7-yrs (39–72), and the mean disease duration was 9.4-yrs (2–14). Anti-CCP antibodies were present in 10 patients, mean titer 174.9 IU. Most patients were female (9/1), had polyarticular involvement, and erosive disease. In contrast to anti-CCP negative PsA patients, PsA patients with positive CCP antibodies were older 53.2 –yrs vs 47.7-yrs, exhibited more RA-like polyarthritis, 8/10 (80%) vs 12/65 (18.4%), less nail involvement 4/10 (40%) vs 57/65 (87.6%), and less psoriatic spondyloarthropathy 0/10 vs 5/65 (7.7%). Anti-CCP negative PsA patients had predominant oligoarticular involvement 44/65 (67.7%) vs 2/10 (20%). Presence of enthesitis/dactylitis and PASI scores were similar in both groups. Rheumatoid factor was present in higher frequency in anti-CCP positive PsA patients, 4/10 (40%) vs 4/70 (5.7%), and anti-TNF-μ was given to 5/10 (50%) of anti-CCP antibodies positive patients as compared to 28.5% in negative anti-CCP antibodies PsA patients.

Conclusion: The clinical distinction between RA and PsA is often difficult to establish. Positivity for RF and anti-CCP antibodies is highly sensitive and to certain extent specific markers and can pre-date the onset of RA. Others and we however, have described the presence, albeit in low frequency (5–15%), of anti-CCP antibodies in patients with PsA but not in psoriasis.

These findings clearly demonstrate that a subset of PsA patients with positivity for anti-CCP is highly associated with RA-like polyarticular involvement, erosive changes and possibly a more severe progression of disease, and also higher use of anti-TNF-μ therapy; which lend support to the notion that anti-CCP antibodies should be considered a marker of disease severity in patients with PsA. Further studies, however, in larger number of patients are needed to define the role of these antibodies in PsA.

1314

Does the Change in Season Affect Disease Outcomes in Patients with Psoriatic Arthritis? Zahi Touma[1], Arane Thavaneswaran[2], Vinod Chandran[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Studies have shown a trend for worsening of psoriasis (Ps) in the winter and improvement in the summer. Patients with psoriatic arthritis (PsA) tend to report more joint pain during the winter time. We aimed to determine whether there is seasonal variation in disease activity of patients with PsA.

Methods: This retrospective study was conducted on all patients enrolled in a prospective longitudinal PsA cohort. Patients undergo a complete history, physical examination and laboratory evaluation at 6–12 month intervals. We defined the seasons as follows: June 22 to September 21 is summer, and December 22 to March 21 is winter. We identified the first available set of consecutive summer and winter visits on every patient. Comparisons between these repeated summer and winter visits from 1978 until 2011 for the same identified patients was conducted for the following outcomes: demographic, clinical data, inflammatory markers (ESR and CRP), treatment and Patient' Global Assessment (PGA).

We further categorized PsA disease activity into mild-moderate/severe for Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and mild/moderate/severe for active joints and Psoriasis Area and Severity Index (PASI) scores. Univariate and multivariate analyses using generalized estimating equations were conducted to account for repeated summer and winter visits per patient that included demographic/lifestyle and clinical variables.

Results: 253 patients with first available summer and winter visit were identified. Among these patients 1789 observations were analyzed. There was no statistically significant difference in patients' demographics, active and damaged joints, categorized joints disease severity, psoriasis (PASI) and categorized psoriasis severity, and treatment between summer and winter visits (Table 1–2).

Table 1. Patient's demographics and drug information for 253 patients in 1789 observations by season

Variable	Frequency (%) of Mean (sd) Summer N=917 visits	Winter N=872 visits	P-value
Sex: M/F	517 (59.0%)/360 (41.1%)	338 (39.1%)/527 (60.9%)	0.4095
Race:	—	—	0.5960
White:	779 (88.8%)	773 (89.4%)	
South Asian:	39 (4.5%)	29 (3.4%)	
Hispanic:	2 (0.2%)	2 (0.2%)	
Black:	—	—	
Chinese:	22 (2.5%)	23 (2.7%)	
Southeast Asian:	2 (0.2%)	3 (0.4%)	
Korean:	3 (0.3%)	3 (0.4%)	
Filipino:	5 (0.6%)	6 (0.7%)	
Aboriginal:	5 (0.6%))	4 (0.5%)	
Other:	20 (2.3%)	22 (2.5%)	
Age at visits	48.2 (12.7%)	47.4 (12.8%)	0.1185
Age at Diagnosis of Ps	27.8 (14.6)	27.4 (14.4)	0.6940
Age at Diagnosis of PsA	36.8 (12.5)	36.6 (12.3)	0.5358
Duration of Ps	20.3 (13.6)	19.9 (13.3)	0.1111
Duration of PsA	11.4 (9.8)	10.9 (9.3)	0.1276
Active Joints	629 (72.3%)	620 (71.7%)	0.5870
Active Joint Count	9.1 (9.8)	8.8 (9.6)	0.9677
Damage Joints	478 (54.6%)	465 (53.9%)	0.8096
Damaged Joint Count	10.9 (12.0)	11.5 (12.3)	0.0573
Medications			
NSAIDs	538 (85.9%)	541 (84.7%)	0.7851
DMARDs	576 (82.5%)	554 (81.0%)	0.1570
Biologic	146 (39.7%)	157 (42.4%)	0.4518
UVT	50 (7.8%)	43 (6.8%)	0.3272

Table 2. Measures of Disease Activity

Measures of Disease Activity			
BASDAI severity	—	—	0.0469
Mild-Moderate:	82 (56.6%)	70 (67.3%)	
Severe:	63 (43.4%)	34 (32.7%)	
BASDAI score			0.8012
Joint Severity	—	—	0.2131
Remission-Minimal:	375 (43.1%)	373 (43.1%)	
Mild-Moderate:	272 (31.3%)	296 (34.2%)	
Severe:	223 (25.6%)	196 (22.7%)	
PASI Severity	—	—	0.7209
Remission-Minimal:	327 (43.9%)	324 (45.1%)	
Mild-Moderate:	316 (42.4%)	294 (40.9%)	
Severe:	102 (13.7%)	101 (14.0%)	
PASI	4.5 (6.2)	4.7 (7.4)	0.1499
Patient Global	—	—	0.0462
Assessment	—	—	
Very good:	61 (15.6%)	48 (12.0%)	
Good:	175 (44.8%)	178 (44.5%)	
Fair:	118 (30.2%)	126 (31.5%)	
Poor:	30 (7.7%)	38 (9.5%)	
Very Poor:	7 (1.8%)	10 (2.5%)	
Inflammatory markers			
CRP	10.3 (18.0)	13.8 (20.4)	0.1803
ESR	17.5 (17.2)	17.8 (17.3)	0.6430

Although BASDAI scores were greater in summer visits as compared to winter visits in the univariate analysis, this difference did not hold in the multivariate analysis (OR=0.85, CI 0.34–2.13 p=0.73). Patients graded their disease worse in winter as compared to summer and this was statistically significant in the univariate analysis (p=0.04) but not in the multivariate analysis (OR=1.39; CI 0.99–1.94 =0.56).

Conclusion: The change in season doesn't affect PsA disease activity. Patients' disease activity as determined by active joints, inflammatory back pain, psoriasis and patients perspective of their disease doesn't change significantly between summer and winter.

1315

Changes in Psychological Status in Patients with Chronic Spondyloarthropathy Treated with Infliximab. Rosa M. Morlà[1], Hector Corominas[2], M. V. Hernandez[3], Mireia Moreno[4], Miquel Sala[5], Vera Ortiz-Santamaria[6], Patricia Reyner[6], Vicente Torrente-Segarra Jr.[7], Agusti Sellas Fernandez[8], Georgina Salvador[9], Elena Sirvent[10], Cristina Masuet[11] and Xavier Juanola-Roura[12]. [1]Hospital Sta Tecla, Tarragona, Spain, [2]Hospital Moises Broggi, Barcelona, [3]Hospital Clinic of Barcelona, Barcelona, Spain, [4]Servei de Reumatologia, Sabadell, Spain, [5]Rheumatology Unit, Figueres, Spain, [6]Unitat de Reumatologia, Spain, [7]Hospital General de Hospitalet, Barcelona, Spain, [8]Senior Consultant, Barcelon, Spain, [9]Hospital Mutua de Terrassa. Barcelona, Barcelona, Spain, [10]Hospital de Sant Boi, [11]Hospital de Bellvitge, Hospitalet de LLobregat, Spain, [12]Hospital Universitario de Bellvitge, Barcelona, Spain

Background/Purpose: Patients with chronic inflammatory rheumatic disease are known to present frequently associated psychological disorders. Several studies have reported the benefit of biological therapies in spondyloarthropathies (SpA), but there are few data regarding its impact on psychological symptoms and well-being.

To analyze the influence of infliximab as a anti-TNF therapy on self-reported indices of anxiety and depression in patients with chronic spondyloarthropathy, and their relation to the main disease activity parameters.

Methods: 62 patients with SpA according to the European Spondyloarthropathy Study Group (48 anchylosing spondilytis, 14 undifferentiated SpA) fulfilling Spanish Rheumatology Society criteria for biological therapy were enrolled in a prospective multicentric observational study. They received 5 mg/Kg infliximab iv infussion at 0,2,6 and every 8 weeks thereafter. At baseline and at 22 weeks patients were assessed for demographic variables, number of affected joints (NAJ), analytical parameters (ESR and C reactive protein), metrological indices (Schöber test and finger-floor distance), BASDAI (disease activity) and BASFI (functional status) questionnaires, visual analogic numeric scales for night and day pain and global self-reported pain. Patients were also assessed for self-reported anxiety (STAI-R and STAI-S questionnaires) and psychological disorder (HADS, with cutpoint at 12 points) and its subscales for anxiety (HADA, cutpoint at 8 points) and depression (HADD, cutpoint at 5 points). Continuous variables at baseline and 22 weeks were compared with Student or Wilcoxon tests, while categorical variables were compared with McNemar's or Wilcoxon's tests. A multivariate Binary Logistic Regression analysis was performed taking a $>$ 3 points decrease in the HADS score as the dependent variable.

Results: HADS score decreased significantly at 22 weeks. The median (interquartilic range) went from 16 (10–22) at baseline to 9 (3–15), $p<0.001$. The HADS anxiety and depression subscale scores decreased from 8 (5–12) to 6 (3–10), $p<$ 0,001, and from 8 (5–12) to 5 (3–10), $p<$ 0,001 respectively. Also a reduction was observed in the proportion of patients with psychological disorder (HADS $>=$ 12), from 71.2% to 48.1%, $p=0,029$, and with definite depression (HADD score $>=$ 5) from 59.7% to 44.6%, $p=0.01$. Other parameters improved significantly as expected, including NAJ, finger-floor distance, ESR, CRP, self-reported numeric scale of pain (at day, night and global), and disease activity (BASDAI) and functionality (BASFI) indices. In the multivariate analysis, only ESR (OR: 0.908 – 0.996) and BASFI (OR: 0,422–0,990) were found to contribute significantly to the variance of HADS. Low baseline values of both parameters were related to higher probability of psychological improvement.

Conclusion: Patients with chronic spondyloarthropathies receiving infliximab therapy presented a high incidence of psychological disorders that improved after 22 weeks of therapy, as assessed by the HADS validated self-reported test. Low values of VSG and BASFI were significant predictors of such improvement.

1316

Antibody Response to the Standard Hepatitis B Vaccination in Patients with Rheumatoid Arthritis and Ankylosign Spondylitis Treated with Infliximab. María Montoro Álvarez Sr.[1], Carlos Gonzalez Fernandez Sr.[2] and Ainhoa Gonzalez Expósito Sr.[2]. [1]Gregorio Marañón Hospital, Madrid, Spain, [2]Gregorio Maranon Hospital, Madrid, Spain

Background/Purpose: Measurement of antibody response to standar hepatitis B vaccination in patients with infliximab. Patients treated with infliximab are at an increased risk of infections, including many that are vaccine-preventable. Risk increases with the use of immunosuppressive medications, including corticosteroids and immunomodulators. It is important to assess vaccination status early on in the clinical care of patients who will have a possibility to receive infliximab as the best chance for administering all the indicated vaccines, and having the best chance of antibody response, is prior to the initiation of immunosuppressive medications. The viral hepatitis vaccines, hepatitis A and hepatitis B, are indicated in patients under infliximab therapy. There have been reports of HBV reactivation, and acute liver failure, in at-risk patients who receive anti-TNF therapy. Anti-TNF therapy are able to decrease immunogenic response to hepatitis B vaccine.

Methods: All rheumatoid arthritis (RA) and ankylosis spondylitis (Asp) patients receiving infliximab theraphy ($>$ 6 months), at rheumatology day care unit, with antiHBs negative were advice to received standar vaccination. Standar vaccination is given by receiving 3 intramuscular injections of the standard dose (20 μg) of recombinant HBV vaccine at weeks 0, 4, and 24. Percentage of responders at week 28, defined as patients with hepatitis B surface antibody (anti-HBs) of more than 10 mIU/mL who received at least 2 dose of vaccine. Patients with missing anti-HBs titer measurement at the final follow-up visit at week 28 were considered to be nonresponders. Post-vaccination titers should be obtained to confirm antibody response.

Results: Complete vaccination was administered in 52 patients (27 ASp, 25 RA). Titer of antiHBs $>$10 was achieved for 1 patient with RA and 3 patients with Asp. Nonresponders were 89% (24/27) in SpA and 96% (24/25) in RA. No serious adverse event possibly related to vaccine were reported.We observe in our patients on infliximab TNF treatment a decreased antibody response to HBV vaccination. It was measured by titers of anti-HBs antibody 28 week after first dosage of vaccine.

Conclusion: Antibody titer that define protection is not well know. Addressing HBV status, and vaccinating at-risk patients, should be a priority in patients who may require anti-TNF therapy. It is important to educate both physicians and patients regarding vaccination recommendations. Addressing these issues early on, gives more options in terms of ensuring optimal antibody response to the vaccination. Alternative schedules more immunogenic than the standard hepatitis B vaccine regimen are needed in patients under infliximab therapy

1317

Clinical and Radiological Manifestations of Ankylosing Spondylitis: Gender Differences. Fernando Pimentel-Santos[1], Ana F. Mourão[2], Célia Ribeiro[1], José Costa[3], Helena Santos[4], Anabela Barcelos[5], Patricia Pinto[6], Fátima Godinho[7], Margarida Cruz[8], Elsa Vieira-Sousa[9], Jorge Félix[10], J. E. Fonseca[11], Henrique Guedes-Pinto[12] and Jaime C. Branco[1]. [1]Centro Hospitalar de Lisboa Ocidental, Hospital Egas Moniz, Lisboa, Portugal, [2]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Rheumatology Department, Centro Hospitalar de Lisboa Ocidental, EPE, Hospital Egas Moniz, Lisbon, Portugal, [3]Centro Hospitalar do Alto Minho, Hospital de Ponte de Lima, Ponte de Lima, Portugal, [4]Instituto Português de Reumatologia, Lisboa, Portugal, [5]Hospital Infante D. Pedro, [6]Centro Hospitalar de Vila Nova de Gaia/Espinho EPE, [7]Hospital Garcia de Orta, [8]Centro Hospitalar Oeste Norte, Centro Hospitalar das Caldas da Rainha, [9]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [10]EXIGO Consultores, [11]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisboa, Portugal, [12]Universidade de Trás-os-Montes e Alto Douro

Background/Purpose: Ankylosing Spondylitis (AS) is a systemic inflammatory disorder with a men:women ratio of 2–3:1. There are evidence for differences in the expression of AS between the genders. To examine the clinical and radiographic features in men and women in the CORPOREA cohort, a large cross-sectional study of patients with AS, in order to understand the influence of gender in determining the severity of the disease.

Methods: Ankylosing Spondylitis (AS) is a systemic inflammatory disorder with a men:women ratio of 2–3:1. There are evidence for differences in the expression of AS between the genders. To examine the clinical and radiographic features in men and women in the CORPOREA cohort, a large cross-sectional study of patients with AS, in order to understand the influence of gender in determining the severity of the disease.

Results: A total of 369 patients were included, (62.3% men and 37.1% women), with a mean age of 45.4$\pm$13.2 years (range 20 – 79 years). Table 1 summarize the results for whole group and by gender. The mean delay between onset of symptoms and diagnosis was 7.6 $\pm$ 9.0 years. Compared with men, the mean BASDAI in women was 1.2 points higher (4.9 *vs* 3.7, $p<0.001$) and the mean BASFI was 0.7 points higher (4.5 *vs* 3.8, $p=0.01$),

but the mean BASMI was 0.8 points lower (3.5 *vs* 4.3, p=0.006) and the mean mSASSS was 17.6 points lower (10.2 *vs* 27, p<0.001).

Table 1. Characteristics of the overall cohort and analysis by gender.

	Total (n=369)	Male (n=232)	Female (n=137)	*p-value**
Gender	100%	62.8%	37.1%	—
Age (years)	45.4 ± 13.2	45.7 ± 13.5	44.9 ± 13.9	0.52
Age at onset (years)	26.5 ± 10.8	25.8 ± 10.8	27.5 ± 10.8	0.185
Age at diagnosis (years)	34.1 ± 13.4	33.0 ± 12.3	35.8 ± 12.4	0.040
Disease duration (years)	11.4 ± 10.5	12.6 ± 11.0	9.5 ± 9.3	0.022
Diagnosis delay (years)	7.6 ± 9.0	7.1 ± 9.0	8.3 ± 9.0	0.081
BASDAI	4.2 ± 2.3	3.7 ± 2.2	4.9 ± 2.3	<0.001
BASFI	4.1 ± 2.7	3.8 ± 2.6	4.5 ± 2.7	0.010
BASMI	4.0 ± 2.5	4.3 ± 2.6	3.5 ± 2.2	0.006
mSASSS	20.9 ± 23.1	27.4 ± 24.6	9.8 ± 14.7	<0.001
ESR (mm/h)	21.7 ± 17.7	20.1 ± 17.4	24.3 ± 18.2	0.012
HLA-B27 positivity	70.7%	73.5%	67.2%	—

Conclusion: The average age at symptom onset and the diagnostic delay were similar in both genders. However females reported greater disease activity (BASDAI) and functional impairment (BASFI), but had better metrology (BASMI) and better radiological evaluation (mSASSS). All of these findings suggest that the phenotype of AS differs between the genders, raising the question about the mechanisms underlying clinical manifestations of the disease.

1318

Anti-TNF Agents May Accelerate the Remodeling of Hip Cartilage in Ankylosing Spondylitis. Sang-Hoon Lee[1], Jaeho Choi[1], Somi Kim[2], Ran Song[1], Yeon-Ah Lee[2], Seung-Jae Hong[2] and Hyung-In Yang[3]. [1]Medical Center at Gangdong, School of Medicine, Kyung Hee University, Seoul, South Korea, [2]Kyung Hee University, Seoul, South Korea, [3]Kyung Hee University Hospital at KANGDONG, Kyung Hee University, Seoul, South Korea

Background/Purpose: Anti-TNF agents have been used for patients with ankylosing spondylitis (AS) that don't respond to anti-inflammatory drugs and DMARDs. Recently, it has been known that anti-TNF agents can prevent bone erosion but also delay the cartilage loss in rheumatoid arthritis patients. Therefore, we reviewed the effect of anti-TNF agents on hip joint cartilage, which is frequently involved in ankylosing spondylitis.

Methods: Through retrospective chart review, we investigated AS patients who were diagnosed according to the modified New York criteria and treated with anti-TNF agents. Patients are included who treated with TNF-alpha blockers during more than 12 months.We confirmed hip joint space changes before and after drug treatment by comparing the changes in simple X-ray, pelvis AP or CT scans.

Results: A total of 100 patients were enrolled. 86 out of 100 patients had no interval changes in hip joint space. The hip joint space of 4 patients decreased and 10 patients' hip joint space increased before and after anti-TNF agents. We analyze that the factors may influence changes of hip joint space such as the changes of BASDAI, ASDAS, CRP, ESR, IgA, anti-TNF agents with age, sex, and disease duration.

Factors that influence hip joint's Interval narrowing were not statistically significant because the number of patients was too small. 3 out of 4 patients were intermittently treated with anti-TNF agents though they were not in remission, and the hip joint space decreased. 1 patient used all three kinds of anti-TNF agents, but the effect was not enough. ESR, CRP, and BASDAI of the patient were consistently high and his symptoms were continued. 9 out of 10 patients have recently received the ongoing treatment regardless of their symptoms, and the hip joint space has significantly increased.1 patient treated only with medication such as NSAIDs and DMARDs reached remission after anti-TNF treatment of a year.

Conclusion: There have been no reports of anti-TNF agent that inhibits cartilage loss in hip joint until now. This study suggests anti-TNF agents have the protective effect of cartilage in AS. Although it is known that cartilage is not regenerated, some cases show actually the increase of hip joint space in this study. We suggest an additional large prospective case-control study will need anti-TNF agent's hip joint protective effect.

1319

Evaluation of Circulating Endothelial and Platelet Microparticles In Men with Ankylosing Spondylitis. Ismail Sari[1], Giray Bozkaya[2], Halil Kirbiyik[2], Ahmet Alacacioglu[2], Halil Ates[1], Gulten SOP[2], Gercek Sen[3], Ali Taylan[4], Ozden Piskin[1], Yasar Yildiz[2] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Izmir Bozyaka Training and Research Hospital, Izmir, Turkey, [3]Izmir Ataturk Training and Research Hospital, Izmir, Turkey, [4]Izmir Tepecik Training and Research Hospital, Izmir, Turkey

Background/Purpose: Microparticles (MPs) are molecules that are released from the various cells, most notably from platelets and endothelial cells, during the activation or apoptosis. MPs are involved in a wide range of physiological and pathological processes. MPs may modulate endothelial function by stimulating cytokine release, intervening in the production of nitric oxide and prostacyclin by endothelial cells as well as monocyte chemotaxis and adherence to the endothelium. Endothelial dysfunction has increasingly been studied in patients with ankylosing spondylitis (AS) with yet no clear mechanism to explain. In the present study, we aimed to evaluate the endothelial microparticle (EMP) and platelet microparticle (PMP) profiles in men with AS and healthy subjects to test whether PMPs and EMPs are altered in AS. We also aimed to determine whether the concentrations of MPs correlate with disease activity (BASDAI), function (BASFI), and spinal mobility (BASMI).

Methods: This descriptive, cross-sectional study comprised 82 men with AS according to the modified New York criteria and 53 healthy controls. Subjects with a history of chronic diseases including coronary artery disease, hypertension, diabetes mellitus, and dyslipidemia were excluded. MPs were isolated from plasma by ultracentrifugation. Following the isolation, MPs were stained with monoclonal antibodies against platelets, and endothelial cells, and quantified by using flow cytometry. MPs which are positive for both (CD31+/CD42+) and total CD42(+) are identified as PMPs; and MPs consisting (CD31+/CD42−), and total CD144(+) are considered as EMPs.

Results: Age, waist circumference, smoking status, fasting glucose and serum lipids were similar between the patient and control groups (p>0.05, Table 1). Mean disease duration was 13.2±8.9 years. There were no differences in regard with the concentration of EMPs and PMPs between the AS patients and healthy controls (p>0.05, Table 1). The comparison of active (BASDAI≥4) and inactive disease state AS patients showed that the concentration of EMPs and PMPs were not different between the groups (p>0.05). Correlation analysis revealed no correlation with BASDAI, BASFI or BASMI. However, that CRP, and HDL were significantly correlated with total CD42(+) PMPs (r=0.5, and −0.3), CD42(+)CD31(+) PMPs (r=0.4, and −0.3), and CD42(−)CD31(+) EMPs (r=0.3, and −0.2). Total CD144(+) EMPs showed significant correlations with fasting glucose and triglycerides (r=0.3 and 0.3).

Table 1. Clinical and laboratory results of the study group

	AS Patient (N=82)	Healthy Subjects (N=53)	P Value
Age (years)	39 (17–63)	35 (24–60)	0.7
Waist circumference (cm)	89 (64–10)	92 (62–112)	0.6
Fasting glucose (mg/dL)	88 (65–120)	87 (50–123)	0.2
LDL cholesterol (mg/dL)	106 (34–157)	116 (54–155)	0.07
Systolic blood pressure (mmHg)	110 (100–140)	115 (100–140)	0.6
Smoking status (%)	40.4	50.6	0.3
Platelet microparticles (*particle/μL*)			
Total CD42(+)	7371 (938–230565)	8472 (364–22552)	0.5
CD42(+)CD31(+)	5896 (390–21947)	6571 (158–21824)	0.7
Endothelial microparticles (*particle/μL*)			
CD42(−)CD31(+)	959 (107–3259)	1006 (72–3107)	0.07
Total CD144(+)	1125 (341–6912)	1391 (489–4038)	0.07

Conclusion: Circulating EMPs and PMPs, one of the indicators and mediators of vascular injury, are not significantly altered in male AS patients who do not have classical cardiovascular risk factors.

1320

Diagnostic Utility of Sacroiliac Joint MRI in Non-Radiographic Spondyloarthritis: Validation of Three Assessment Methods in Two Inception Cohorts. Ulrich Weber[1], Veronika Zubler[2], Susanne Juhl Pedersen[3], Stanley Chan[1], Kaspar Rufibach[4], Robert GW Lambert[1] and Walter P. Maksymowych[1]. [1]University of Alberta, Edmonton, AB, [2]Balgrist University Hospital, Zurich, Switzerland, [3]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [4]University of Zurich, Zurich, Switzerland

Background/Purpose: A systematic evaluation of sacroiliac joint (SIJ) MRI based on both active and structural lesions (global evaluation) has shown high diagnostic utility in axial spondyloarthritis (SpA) [1]. The incorporation of

erosions (ER) with bone marrow edema (BME) as defined by ASAS improved diagnostic utility compared to BME alone.

Objectives: To validate global and lesion-based (BME, BME plus ER) approaches to evaluation of SIJ by MRI in two inception cohorts of consecutive patients with back pain suspected of having SpA.

Methods: Cohort A comprised 88 consecutive patients, age ≤50, with acute anterior uveitis (AAU) and back pain referred by an ophthalmology centre. Cohort B comprised 69 consecutive patients ≤50 years referred by practising rheumatologists and primary care physicians to a tertiary care center for further assessment of suspected inflammatory back pain. They were classified according to clinical, laboratory and imaging evaluation as having non-radiographic SpA (nrSpA) (n=20; 65% HLAB27 positive, 55% male), ankylosing spondylitis (AS) by the modified New York criteria (mNYc) (n=10), and non-specific back pain (NSBP) (n=39). Scans from 20 local healthy controls (HC) were also assessed. SIJ MRI were scored independently in random order by 4 readers blinded to patient identifiers.

Results: The assessment of ER in addition to BME enhanced diagnostic utility in both cohorts despite differences in the prevalence of SpA. For the AAU cohort, AS by mNYc was diagnosed in 28/88 (31.8%) and 16/88 (18.2%) were diagnosed with NSBP. Of 44/88 (50%) that had suspected SpA (68% HLAB27 positive, 52% male), sensitivity/specificity of MRI according to 2 readers was 32%/100% by global assessment, 27%/100% for BME alone, and 36%/100% for BME plus ER, compared to NSBP. Similar data was noted in cohort B. Sensitivity/specificity (mean of 4 readers) of SIJ MRI for nrSpA compared to NSBP was 75%/96% by global assessment, 72%/85% for BME alone, and 81%/83% for BME plus ER. In cohort B, ER was detected in 75% of nrSpA patients. ER was not recorded in NSBP patients and HC, but both groups showed BME (NSBP in 23%, HC in 20%).

Table 1. Cohort B, nrSpA versus NSBP

Assessment method	Sens	Spec	LR+	LR-
Global	0.75	0.96	20.2	0.3
BME alone	0.72	0.85	4.3	0.3
BME + ER	0.81	0.83	7.0	0.2

Conclusion: In two unselected cohorts of consecutive patients we show that ER detected by MRI is highly specific for nrSpA and contributes to diagnostic utility beyond assessment of BME alone.

Multifocal Inflammatory Lesions in Ankylosing Spondylitis Patients Depicted by Whole Body MRI (WBMRI) Improve by a One Year Therapy with Etanercept. Martina Karpitschka[1], Daniel Theisen[1], Annie Horng[1], Christian Glaser[1], Maximilian Reiser[1], Sabine Weckbach[1] and Herbert Kellner[2]. [1]Munich, Germany, [2]Centre for Inflammatory Joint Diseases, Munich, Germany

Background/Purpose: In ankylosing spondylitis (AS) multifocal inflammatory manifestations of the musculoskeletal system are common. Whole-body magnetic resonance imaging (WBMRI) is known to detect widespread inflammatory lesions. Anti-tumor necrosis factor (TNF) therapy is highly effective in AS, however, expensive. Therefore, accurate assessment of therapy response is of clinical relevance. The purpose of this study was to evaluate WBMRI compared to clinical exam alone in patients during etanercept therapy.

Methods: 6 patients with AS underwent a 12 months therapy with etanercept (Enbrel ® 50 mg / week). Patients were examined by an established WBMRI protocol (1.5 T scanner, STIR and T1-w unenhanced and contrast-enhanced sequences) at 3 different points of time (0, 12 and 52 weeks) after application of the first dose of etanercept. WBMRI was evaluated in consensus by 2 experienced radiologists (blinded to clinical exam) for inflammatory lesions (e.g. spondylitis, sacroileitis, bursitis, enthesitis and synovitis). The lesions were counted and graded on a grading system (severe, moderate, mild, minimal). Simultaneously, clinical examination was performed by an experienced rheumatologist, including collecting data from BASDAI, BASFI and CRP. WBMRI and clinical scores were correlated.

Results: During etanercept therapy, symptomatic therapy with NSAID could significantly be reduced, (3.0±0.4 down to 1.5±0.2 (50%, $p<0.05$). The clinical examination scores showed significant improvement under therapy, e.g. the BASDAI-index decreased from 5.6±0.7 (week 0) to 1.6±0.5 (weeks 12, $p<0.05$) and to 1.4±0.6 (week 52, $p<0.05$). The patients' estimation of AS activity at week 0 averaged 6.8±1.1, physician assessment was 7.0+0.3 respectively. At week 12, the AS-activity averaged 1.2±0.5 by patients ($p<0.05$) and 2.0±0.3 ($p<0.05$) by the physician. The amount of pain diminished during therapy from 7.2±0.7 (BASDAI, week 0) to 1.3±1.0 (BASDAI, week 52).The morning stiffness significantly decreased from 72,0±18.0 (week 0) to 12.0±8.7 (week 52). In addition, clinical values improved under therapy, e.g. CRP averaged 15.9±4.7 at week 0 and declined to 2.1±21 at week 52 ($p=0.055$). In WBMRI, the sum of all lesions showed a significant decrease from week 0 (30.6±12.4) to week 12 (14.2±7.5), equivalent to a 59.2±13.8% reduction of lesions. Especially for spondylitis anterior and sacroileitis, there was a significant decline of inflammatory lesion, e.g. 9.5±2.6 in week 0 to 1.0±1.0 in week 52 for spondylitis anterior (reduction about 92.7±7.3, $p<0.05$) or 5.5±1.0 in week 0 to 0.0±0.0 in week 52 for sacroileitis (reduction of 100%, $p<0.05$). WBMRI detected significantly more areas of synovialitis and enthesitis than clinical examination ($p<0.05$).

Conclusion: Under etanercept therapy the activity of AS significanty decreased, which was proven by clinical examination, CRP and quality of life questionnaires (BASDAI) as well as by WBMRI. WB-MRI detected significantly more inflammatory lesions than clinical exam alone. The results suggest that WB-MRI improves the detection of inflammatory changes and the assessment of their course under therapy.

1322

Improvement in Ankylosing Spondylitis Disease Activity Score in Patients with Ankylosing Spondylitis Treated with Tumor Necrosis Factor-Alpha Blocking Therapy. Suzanne Arends[1], Eveline van der Veer[1], Pieternella M. Houtman[2], Martha K. Leijsma[1], Cees G.M. Kallenberg[1], Elisabeth Brouwer[1] and Anneke Spoorenberg[2]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]Medical Center Leeuwarden, Leeuwarden, Netherlands

Background/Purpose: The Ankylosing Spondylitis Disease Activity Score (ASDAS) has been developed to assess the full concept of disease activity with aspects of both subjective and objective nature. Recently, the cut-off values for ASDAS improvement were defined. Our aim was to assess the percentage of AS patients achieving ASDAS improvement, in comparison to ASAS and BASDAI response, after tumor necrosis factor-alpha (TNF-α) blocking therapy in daily clinical practice.

Methods: Between November 2004 and April 2010, 217 consecutive AS outpatients from the MCL and UMCG who started TNF-α blocking therapy because of active disease were included in the GLAS study, a prospective longitudinal observational cohort study. All patients fulfilled the modified New York criteria for AS or **the** ASAS criteria for axial spondyloarthritis. Infliximab (n=31) (5mg/kg) was administered intravenously at 0, 2, and 6 weeks and then every 8 weeks; etanercept (n=135) (50mg once a week or 25mg twice a week) and adalimumab (n=51) (40mg on alternate weeks) were given subcutaneously. After 3 and 6 months, response to treatment was defined using ASDAS clinically important improvement (≥1.1 improvement in ASDAS-CRP), ASDAS major improvement (≥2.0 improvement), ASAS20 (≥20% and ≥1 unit improvement in ≥3 of the 4 domains physical function, pain, patient's global disease activity, and inflammation, with no worsening ≥20% in the remaining domain), ASAS40 (≥40% and ≥2 units improvement in ≥3 of 4 domains, with no worsening in remaining domain), and BASDAI50 (≥50% improvement in BASDAI).

Results: Mean age of the 217 AS patients was 42.9 years (SD±11.9), median disease duration was 15 years (range 1–53), and 69% were male. Mean ASDAS was 3.8 (SD±0.8) at baseline, 2.1 (SD±0.9) after 3 months ($p=0.000$), and 2.0 (SD±0.8) after 6 months ($p=0.000$) of treatment. After 3 months, 67% and 35% of patients achieved ASDAS clinically important and major improvement, respectively. After 6 months, these percentages were 66% and 38%, respectively. For ASAS and BASDAI response see Table 1.

Table 1. Percentage of AS patients achieving response after 3 and 6 months of TNF-α blocking therapy (n=217)

	3 months	6 months
Missing data	6 (3%)	12 (6%)
ΔASDAS ≥1.1	142 (67%)	135 (66%)
ΔASDAS ≥2.0	74 (35%)	78 (38%)
ASAS20	142 (67%)	129 (63%)
ASAS40	101 (48%)	94 (46%)
BASDAI50	102 (48%)	101 (49%)

Conclusion: Approximately two-third of the AS patients achieved ASDAS clinically important improvement and approximately one-third ASDAS major improvement after 3 and 6 months of TNF-α blocking therapy. These data indicate that the response rate for ASDAS clinically important improvement is comparable to ASAS20 response, while ASDAS major improvement seems to reflect response in fewer patients than ASAS40 and BASDAI50 response.

1323

European SCORE May Underestimate the Cardiovascular Risk in Psoriatic Arthritis: Comparison of Two Indexes and Related Variables. César Magro-Checa, José L. Rosales-Alexander, Juan Salvatierra Sr., Jesús Cantero-Hinojosa, Jose Gonzalez-Dominguez and Enrique Raya-Alvarez. University Hospital San Cecilio, Granada, Spain

Background/Purpose: EULAR task force recommendations in the cardiovascular (CV) risk have been recently published. In contrast to RA, in patients (pts) with Psoriatic Arthritis (PsA) the the Systematic Coronary Risk Evaluation (SCORE) is not adapted by introducing a 1.5 multiplication factor. EULAR recommends the use of the SCORE when no local guidelines are available. In our country the SCORE table has been calibrated by the National Cardiology Society. The objective was to assess the CV risk in PsA pts using the SCORE for low risk European countries (eSCORE) and compare it with the calibrated SCORE (cSCORE) according to our local guidelines. Furthermore, we analyzed the correlation of several clinical and serological variables with these SCOREs indexes and the percentage of pts that received adequate therapy for the management of CV risk.

Methods: This cross-sectional study included 125 consecutive pts who fulfilled the Classification Criteria for Psoriatic Arthritis (CASPAR criteria) followed in our outpatient clinics. Patients with a previous CV event were excluded. The following data were recorded for analysis: sex, age, body mass index, duration in months since diagnose, clinical pattern of the disease, classic CV risk factors, lipid profile, treatment and inflammatory markers. Both the eSCORE function model calculated on the basis of atherogenic index and the cSCORE on the basis of total cholesterol, were compared. According to our national guidelines, a high CV risk has been defined by a SCORE $\geq$ 5%, the cutoff point recommended to start treatment.

Results: Based on the classic CV risk factors, the eSCORE was 1,21 $\pm$ 1,62% (mean $\pm$ standard deviation) and 4 pts (3.2%) were above the threshold of high or very high CV risk ($\geq$5%). After applying the cSCORE, the values were 2 $\pm$ 2,55% which meant a change in the eSCORE in almost 70% of the pts. Therefore, 17 pts (13,6%) were reclassified above the threshold of high and very high CV risk. Regression coefficient analysis showed that the average increased in the Spanish SCORE can be obtained by multiplying the SCORE function for low risk countries by 1.5 ($p < 0.000$). Multivariate regression analysis showed that the most important prognostic factor for predicting the SCORE was the age (Total R-square 68%, standardized beta 0,65; $p = 0,000$) followed by systolic blood pressure and smoking. Of notice, the ESR was also a prognostic factor of the SCORE. Analyzing the percentage of pts that received adequate therapy for the management of CV risk, according to the eSCORE 100% and 50% of high and very high risk pts respectively were treated adequately, but when pts were reclassified with cSCORE, this percentage decreases to 64,7% and 35,3% respectively.

Conclusion: Assessment of the CV risk in PsA pts applying the eSCORE leads to an underestimation of the risk in comparison with the application of the cSCORE, which may have an impact on the correct management of these pts. According to EULAR, it seems that PsA is not considered by itself as a CV risk factor, in contrast to RA, when using the eSCORE. Variable analysis showed that ESR, but not CRP, was a prognostic factor of the SCORE what suggests that sustained inflammation could play a role in the increase of CV risk.

1324

The Relation Between Daily Physical Activity Measured with the Accelerometer and Clinical Assessments in Patients with Ankylosing Spondylitis. Suzanne Arends[1], Marianne Hofman[1], Yvo P.T. Kamsma[1], Eveline van der Veer[1], Martha K. Leijsma[1], Pieternella M. Houtman[2], Cees G.M. Kallenberg[1], Anneke Spoorenberg[2] and Elisabeth Brouwer[1]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]Medical Center Leeuwarden, Leeuwarden, Netherlands

Background/Purpose: Intervention studies concerning exercise programs and physical therapy in Ankylosing Spondylitis (AS) have revealed positive effects on clinical assessments of disease activity, physical function, and spinal mobility. Until now, data concerning the amount of daily physical activity (i.e. household, work, transport, and leisure time activities) in relation to these clinical assessments are lacking. The aim of the present study was to investigate the relation between daily physical activity and clinical assessments of disease activity, physical function, and spinal mobility in patients with AS.

Methods: Fifty-five Dutch AS outpatients were included. All patients were over 18 years of age and fulfilled the modified New York criteria for AS or **the** ASAS criteria for axial spondyloarthritis. Clinical assessments of disease activity (BASDAI, CRP, ESR, and ASDAS), physical function (BASFI), and spinal mobility (occiput-to-wall distance, chest expansion, modified Schober test, lateral spinal flexion, and cervical rotation) were administered at the outpatient clinic. In succession, daily physical activity was assessed using the ActiGraph accelerometer during 7 consecutive days. The outcome of the accelerometer was expressed in average kilo counts per day (kcounts/day). Pearson and Spearman correlations were calculated between accelerometer outcome and clinical assessments.

Results: Mean age of the 55 AS patients was 44 years (SD$\pm$13), median disease duration was 17 years (range 2–54), and 62% were male. Median BASDAI was 3.2 (range 0.4–8.6), mean ASDAS was 2.2 (SD$\pm$1.0), and mean BASFI was 3.4 (SD$\pm$2.3), indicating mild disease activity and functional impairment. Daily physical activity, measured with the accelerometer, was negatively correlated with ESR ($\rho = -0.460$, $p<0.001$) and CRP ($\rho = -0.279$, $p<0.05$) and there was a trend suggesting a negative correlation with ASDAS ($r = -0.257$, $p=0.061$). Furthermore, daily physical activity negatively correlated with BASFI ($r = -0.274$, $p<0.05$) and positively correlated with the modified Schober test ($\rho=0.338$, $p<0.05$), lateral spinal flexion (left: $r=0.344$, $p<0.05$ and right: $r=0.385$, $p<0.01$), and cervical rotation (left: $\rho=0.358$, $p<0.01$ and right: $\rho=0.285$, $p<0.05$). No significant correlations were found between accelerometer outcome and BASDAI, occiput-to-wall distance, and chest expansion and accelerometer.

Conclusion: The present study indicates that higher daily physical activity, measured with the accelerometer, is related to lower disease activity, better physical function, and better spinal mobility in AS patients. Further studies are needed to investigate this relation.

1325

The Effectiveness of Leflunomide in Psoriatic Arthritis. Alhussain Asiri[1], Arane Thavaneswaran[2], Vinod Chandran[1], Gideon Kalman-Lamb[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: While the short term efficacy and safety of Leflunomide in psoriatic arthritis (PsA) was documented in a short term randomized controlled trial, its longterm effect and safety in "real life" clinical situation is not known. This study aimed to evaluate the effectiveness of Leflunomide alone and in combination with methotrexate in "real life" situation as well as their adverse effects.

Methods: At the PsA Clinic patients have been followed prospectively and are evaluated according to a standard protocol which includes a detailed clinical history including drug therapy, physical examination, laboratory and radiological assessments at regular intervals. All information is tracked on an oracle database. Leflunomide became available in 2002. PsA patients who received leflunomide alone and in combination with methotrexate were identified from the PsA clinic database. Effectiveness was defined by persistence on the medication, a $\geq$ 40% reduction in actively inflamed joint a $\geq$ 40% reduction in swollen joint count, and PASI50 and PASI75 response following treatment with leflunomide. Univariate and multivariate logistic regression analyses with stepwise selection were used for data analysis.

Results: 84 patients were identified in our cohort. 43 patients (50.6%) were on Leflunomide alone and 42 (49.4%) patients were on Leflunomide in combination with methotrexate. There were 38 females and 47 males with a mean age of 51.6 (12.6) and mean disease duration of 12.3 (9.1). The mean number (sd) of actively inflamed joints count was 16(12.9), swollen joint count was 5.4(5.8), damaged joint count was 12.3 (13.0) and the mean PASI score was 4.7(6.5). 30 patients discontinued leflunomide, 16 in the leflunomide alone group and 14 in those taking leflunomide and MTX. The main reasons for discontinuing the drug were toxicity, including diarrhea, alopecia, and renal toxicity. Of the 54 patients who continued the drug, 38% achieved a $\geq$ 40% reduction of actively inflamed joint count at 3 months, 48% at 6 months and 56% at 12 months. PASI50 was achieved by 27%, 28% and 38% at 3, 6 and 12 months, whereas PASI75 was achieved by 19% at 3 and 6 months and 32% at 12 months. No predictors were identified for the improvement in actively inflamed joint count. However, duration of PsA (OR 1.09 95% CI 1.00, 1.18, $p=0.03$) and the number of swollen joints (OR 1.35, 95% CI 1.00, 1.83, $p=0.003$) at baseline were predictive for improvement of the swollen joint count at 3 months. The number of swollen joints at baseline was also predictive for improvement at 12 months (OR 2.01 95% CI 1.23, 3.27, $p=0.005$). The use of concomitant MTX was predictive for achieving a PASI50 (OR 6.19 95% CI 1.20, 31.97) at 12 months.

Conclusion: Leflunomide eventually led to ≥ 40% reduction in tender and swollen joint counts in almost 50% of the patients by 1 year. Those also taking MTX were more likely to achieve a PASI50 response. There was no significant difference in side effects between the Leflunomide group and Leflunomide and Methotrexate group.

1326

Validation of the Patient Acceptable Work State: Establishing Thresholds for Patient-Reported Outcomes in a Longitudinal, Observational Study in Patients with Ankylosing Spondylitis. Walter P. Maksymowych[1], Sumati Rao[2], Annelies Boonen[3], Naijun Chen[4] and Mary A. Cifaldi[2]. [1]University of Alberta, Edmonton, AB, [2]Abbott Laboratories, Abbott Park, IL, [3]University Hospital Maastricht, Maastricht, Netherlands, [4]Abbott Laboratories, Abbott Park, Illinois, Abbott Park, IL

Background/Purpose: Restrictions in paid and unpaid work are a feature of ankylosing spondylitis (AS) and are measured using several instruments that score impairment on a continuous scale, although the significance of these scores is unclear. It may be helpful to define work performance on a dichotomous basis as either satisfactory or not satisfactory using the concept of patient acceptable work state (PAWS). This approach would help to more easily identify patients with problems while at work and at risk for sick leave and work disability. In this study, we validated 3 questions that assess PAWS in relation to patient-reported outcomes.

Methods: Data were obtained from the Patient-Reported Outcomes in Employment Study (PROSE), a longitudinal, observational study of AS and work productivity. Patients with AS completed questions on work status and disease characteristics (Bath Ankylosing Spondylitis Disease Activity Index [BASDAI] and Bath Ankylosing Spondylitis Functional Index [BASFI]) at baseline, 3 months, 6 months, 9 months, and 12 months (5 time points). Patients also answered the 3 PAWS questions (yes/no): "Considering all the different ways your disease is affecting you, if you would stay in this state for the next few months, do you consider that: 1) your ability to perform your current job is satisfactory?; 2) you will continue to work in your present job?; and 3) you may need to stop working and go on sick leave or disability leave?" PAWS was considered present (PAWS+) if patients answered "yes" to Questions 1 and 2 and "no" to Question 3. We calculated thresholds for the BASDAI, BASFI, and Work Productivity and Activity Impairment Questionnaire (WPAI) domains according to the 75th percentile of scores in PAWS+ patients and assessed the stability of these thresholds over time.

Results: Of 226 surveys obtained, 172 (76.1%) were from AS patients employed at baseline. At baseline, 143 (83.1%) patients indicated they would be satisfied with their current job in the next few months, given their current disease state; 158 (91.9%) indicated they would continue working in their present job; and 149 (86.6%) indicated they would not stop working, given their disease state. Results remained consistent at Months 3, 6, and 12**.** The number of patients considered PAWS+ was 135 (78.5%) at baseline and this remained stable over time (80.0%–89.4%). WPAI threshold scores were stable over the 5 time points, especially WPAI presenteeism (20%), overall work impairment (25%–30%), and activity impairment (30%). Although threshold scores were relatively stable for the BASFI (3.3–4.1), stability was less apparent for the BASDAI (3.6–5.0) (table).

75th Percentile (95% Confidence Interval) of WPAI Domain Scores, BASDAI, and BASFI for PAWS Responders (Employed Patients Only)

	WPAI Presenteeism	WPAI Overall Work Impairment	WPAI Overall Activity Impairment	BASDAI	BASFI
Baseline (N=135)	20 (20, 30)	30 (20, 30)	30 (30, 40)	5.0 (4.3, 5.6)	4.1 (3.1, 4.8)
Month 3 (N=110)	20 (20, 20)	20 (20, 30)	30 (30, 40)	4.2 (3.7, 4.9)	3.6 (2.8, 4.4)
Month 6 (N=101)	20 (20, 30)	20 (20, 30)	30 (30, 40)	4.2 (3.4, 4.8)	3.8 (3.3, 4.7)
Month 9 (N=93)	20 (20, 30)	20 (20, 30)	30 (20, 40)	4.2 (3.3, 4.5)	3.3 (2.9, 4.3)
Month 12 (N=76)	20 (20, 30)	25 (20, 33)	30 (20, 30)	3.6 (3.3, 4.4)	3.6 (2.6, 4.5)

Conclusion: The relationship between PAWS and work impairment and function remained stable over time in patients with AS. There was a less stable association with BASDAI, suggesting that factors other than disease activity may influence satisfaction at work.

1327

The Predictors of Infection in Psoriatic Arthritis—Results From a Longitudinal Observational Cohort. Amir Haddad[1], Arane Thavaneswaran[2], Vinod Chandran[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Many patients with psoriatic arthritis are treated with immunosuppressives and biologic agents. Infection is a reported adverse event. The purpose of this study is to identify factors that could predict infection in patients with psoriatic arthritis (PsA) in contrast to a control group of patients with psoriasis without arthritis.

Methods: The PsA cohort was initiated in 1978. Patients fulfil the CASPAR criteria and are followed at 6–12 month intervals according to a standard protocol. In 2006 a cohort of patients with psoriasis without arthritis (PsC) was initiated. Patients with psoriasis were all assessed by a rheumatologist to exclude the presence of inflammatory arthritis, and are followed at yearly intervals according to a standard protocol. Data are tracked in a computerized database. From these observational cohorts data on infection and disease characteristic variables were collected prospectively in the respective databases. Multivariate analysis using generalized estimating equations was used to relate the probability of infection to potential predictor variables such as age, sex, PASI score, functional comorbidity index, actively inflamed joint count and treatment with NSAIDs, DMARDs, Biologics and phototherapy. Survival analysis was used to distinguish individual contribution of these predictors to infection.

Results: The PsA cohort included 695 patients with 607 reported infections, the most prevalent infection was pneumonia at 19.2%. The incidence rate of infection was 0.33 (95% CI 0.31–0.36) per patient-year but was higher among patients treated with biologic agents (0.44 (95% CI 0.39–0.50)). Patients with infections were less likely to be males (OR=0.42 95% CI 0.31–0.55) and more likely to be treated with biologics (OR=1.43 95% CI 1.07–1.91). Patients with pneumonia were more likely to be older (OR=1.73 95%CI 1.02–2.96). Patients with serious infections (that required antibiotics or hospitalization) were more likely to have a higher PASI score (OR=1.1 95% CI 1.04–1.16). Older age at visit and treatment with biologics predicted more infections in the PsA cohort with an estimate of 0.05 (95% CI 0.065–0.036) and 1.42 (95% CI −0.006–2.85) respectively. The PsC cohort included 511 patients with a total of 176 observed infections, the most commonly reported infection affected the skin at 12.1%, the incidence rate of infection was 0.29 (95% CI 0.25–0.30) per patient-year and was higher (0.66 (95% CI 0.39–1.04)) in patients on biologics. Patients with all infections were more likely to be younger at visit (OR=0.97 95% CI 0.94–0.99), less likely to be males (OR=0.58 95% CI 0.36–0.93) and had a Higher FCI (1.33 95% CI 1.1–1.6), no predictor was found to be associated with skin infections.

Conclusion: The positive predictors for infection in patients with PsA are female gender and treatment with biologics. These data prove the association between infection and biologic treatment in PsA.

1328

A Retrospective Analysis of Anti-TNF Treatment of 146 Ankylosing Spondylitis Patients According to Gender. Yasemin Yalcinkaya, Özlem Pehlivan, Ahmet Omma, Bahar Artim-Esen, Burak Erer, Nihat Hüseyinsinoglu, Sevil Kamali, Murat Inanc, Orhan Aral, Ahmet Gul and Lale Ocal. Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey

Background/Purpose: To investigate disease characteristics according to gender differences in patients with ankylosing spondylitis (AS) receiving anti-TNF therapy.

Methods: This report evaluated retrospectively data of 146 patients with AS fulfilling modified New York criteria followed between 2001 and 2010, including demographics, symptoms, physical examinations, laboratory findings, complications and treatment details. Student's *t* test was used for comparison.

Results: The mean age of patients was 40.1 and 70% were males. Age at symptom onset, delay in diagnosis, disease duration(year) were 24.4, 5.8 and 15.8 respectively. The mean age at symptom onset(year) was significantly low in males (22.7 vs 28.3, $p<0.01$). The time interval between the onset of symptoms and anti-TNF therapy was >10 years in 89(61%), 5–10 years in 32(22%) and <5 years in 25(17%) patients. Females receiving anti-TNF therapy within 5 years were significantly high (23 vs 12%).

The mean duration of treatment (month) was 23.2 for infliximab(IFX)(n: 79), 21.4 for etanercept(ETN)(n:85) and 19.8 for adalimumab(ADA)(n:20). Switching to a second anti-TNF agent was 18%(n:26) and to a third agent 3%(n:5) for inefficacy (n:27), infusion reaction (n:5), uveitis (n:2), pulmonary tuberculosis(n:1) and psoriasis (n:1). Sixteen% of females and 19% of males required a second, 5% of females and 3% of males required a third agent (Table-1).

Initiation of anti-TNF agent due to axial involvement and high acute phase response were similar in females and males (96 vs 99% and 48 vs 52%). Peripheral arthritis and uveitis were more frequent in females (66 vs 37% and 4.5 vs 2%) whereas proteinuria/amyloidosis were more frequent in males(4 vs 2%).

In 12 patients (Table 1), dose reduction and cessation of anti-TNF therapy due to remission waspossible. Dose reduction was higher in males (7/102, 7% vs 1/44, 2%) and cessation was higher in females (3/44, 7% vs 1/102, 1%). The mean duration of treatment (month) in this group was 21 for infliximab(n:5) and 25.3 for etanercept (n:7); the time interval between the onset of symptoms and anti-TNF therapy was >10 years in 7(58%)(5 male), 5–10 years in 1(8%)(male) and <5 years in 4(33%)(2 male) patients. Termination due to complications (3 infusion reactions, 1 pulmonary tuberculosis, 1 hepatotoxicity, 1 pneumonia, 1 psoriasis) was significantly higher in males (n:6, 5.9% vs n:1, 2.3%).

Table 1. Details of anti-TNF treatment

	Females (n:44)	Males (n:102)
Dose reduction of anti-TNF therapy		
Satisfactory response	1 (2%)	7 (7%)
Cessation of anti-TNF therapy		
Remission	3 (7%)	1 (1%)
Complications	1 (2.3%)	6 (5.9%)
Switching to a second agent (n:26)	7 (16%)	19 (19%)
IFX → ETN (n:13)	3	10
ETN → IFX (n:6)	2	4
IFX → ADA (n:3)	–	3
ADA → IFX (n:2)	1	1
ETN → ADA (n:1)	1	–
ADA → ETN (n:1)	–	1
Switching to a third agent (n:5)	2 (5%)	3 (3%)
ETN → IFX→ ADA (n:3)	1	2
IFX → ADA→ ETA (n:1	–	1
IFX → ETA→ ADA (n:1)	1	–

Conclusion: In AS patients receiving anti TNF therapy, males were younger and had dominantly axial involvement. The mean duration of anti-TNF treatment was 27,8 months and similar for each agent (ETN /ADA / IFX). Females received anti-TNF therapy earlier but both male and female patients had satisfactory responses to anti TNF treatment. Switching between anti TNF agents was similar in males and females. Complications related with treatment were frequent in males.

1329

Differences in Clinical and Inflammation Outcomes in Patients with Axial Spondyloarthritis of Shorter and Longer Disease Duration After One Year Treatment with Etanercept. Anja Weiβ[1], In-Ho Song[2], Kay-Geert Hermann[3], Christian Althoff[3], Bruce Freundlich[4], Martin Rudwaleit[5], Joachim Listing[1] and Joachim Sieper[6]. [1]German Rheumatism Research Centre, Berlin, Germany, [2]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [3]Charite Medical School, Berlin, Germany, [4]University of Pennsylvania, Philadelphia, PA, [5]Ev. Krankenhaus Hagen-Haspe, Hagen, Germany, [6]Charité – Campus Benjamin Franklin, Berlin, Germany

Background/Purpose: To investigate the influence of the disease duration on the outcome in patients with axial spondylarthritis (SPA)

Methods: 62 patients with axial SpA with a symptom duration of less than 5 years were treated with Etanercept (ETA) for one year, either with ETA until week 48 (n=40) or they were switched from sulfasalazine treatment in the first year to ETA in the second year from week 48 until week 108 (n=26), as part of the ESTHER trial (1). 52% of these patients had a diagnosis of radiographic axial SpA and 48% had radiographic sacroiliitis. The patients were stratified into two groups: less than 3 years and more than 3 years of symptom duration before inclusion into the trial. These two groups were compared for clinical, CRP and magnetic resonance imaging (MRI)-outcome parameters using analysis of covariance (ANCOVA) with baseline status as covariable. Spearman correlation coefficients are calculated to analyse the relationship between two variables.

Results: Clinical parameters such as Bath ankylosing spondylitis disease activity index (BASDAI), Bath ankylosing spondylitis functional index (BASFI) and Bath ankylosing spondylitis metrology index (BASMI) showed significantly better improvement for short vs longer diseased patients (Table 1). The results for improvement of MRI inflammation score for sacroiliac joints (SIJ) and spine and for CRP showed no significant differences between the two groups (Table 1). In patients with SIJ score at baseline > 0 the change in BASDAI showed a correlation with the change in SIJ score in patients with a short disease duration (rho=0.4, p=0.05) and longer disease duration (rho=0.4, p=0.06). The correlation between spine score and BASDAI was weaker. Significant correlation between BASDAI and CRP was found for short diseased patients (rho=0.6, p=0.002) but not for longer diseased patients (rho=0.3, p=0.14). Interestingly, patients fulfilling the New York criteria for radiographic sacroiliitis did not differ from patients not fulfilling the criteria regarding change in BASDAI (p=0.97), BASFI (p=0.7), BASMI (p=0.21), CRP (p=0.93), MRI spine score (p=0.74) and MRI SIJ score (p=0.66).

Table 1. Mean outcome parameters at baseline, adjusted means under treatment with etanercept and adjusted mean changes from baseline. Adjustment was made for baseline status (95% confidence intervals (CI) were given).

	Means at baseline		Adjusted means under ETA therapy		Adjusted mean change (95% CI)		
Parameter	< 3 years n=32	>=3 years n=34	< 3 years n=32	>=3 years n=34	< 3 years n=32	>= 3 years n=34	p-value
BASDAI	5.0	5.4	2.5	3.4	2.7 (2.1, 3.3)	1.8 (1.2, 2.3)	0.028
BASFI	3.9	4.2	1.8	2.9	2.2 (1.7, 2.8)	1.2 (0.7, 1.7)	0.004
BASMI	1.9	2.1	1.4	1.9	0.6 (0.3, 0.9)	0.1 (−0.2, 0.4)	0.012
CRP	10.8	8.1	5.5	4.7	4.4 (1.6, 7.1)	5.3 (2.5, 7.8)	0.690
MRI spine score	1.3	2.2	0.99	0.7	0.9 (0.3, 1.4)	1.2 (0.6, 1.7)	0.470
MRI SIJ score	5.9	6.0	1.5	2.3	4.4 (3.7, 5.1)	3.6 (2.9, 4.3)	0.090

Conclusion: In patients with early axial SpA treated with ETA for one year short diseased patients showed a better improvement in all clinical parameters such as BASDAI, BASFI and BASMI than longer diseased patients, but such a difference was not present for objective parameters of inflammation such as MRI inflammation and CRP. These data indicate that patients with longer symptom duration respond less well to TNF-blockade for reasons which go beyond structural damage.

Profiling NSAID Responders in Ankylosing Spondylitis. Khalid A. Alnaqbi[1], Nigil Haroon[2], Hua Shen[3], Richard J. Cook[3], Adele Carty[2] and R. D. Inman[4]. [1]Toronto Western Hospital-EW 1–420, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON, [3]University of Waterloo, Waterloo, ON, [4]The Arthritis Program, Toronto Western Hospital and Division of Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: There is a substantial subset of ankylosing spondylitis (AS) patients in whom symptoms are well controlled with NSAID therapy alone. This is an important domain, since failure to achieve symptomatic control with NSAIDS is the operational prerequisite for biologic therapy in AS. The current study was undertaken to characterize that subset of AS patients who are responsive to NSAID therapy.

Methods: The longitudinal prospective database of an AS cohort (patients was analyzed on the basis of response to NSAIDs. NSAID-responders (NS-R) were defined as having a BASDAI<4 on the last clinic visit while be treated only with NSAIDs. NSAID-nonresponders (NS-NR) were defined as having a BASDAI>4 on the last clinic visit while be treated only with NSAIDs **OR** as having required biologic treatment. AS patients met the modified New York criteria for AS and demographic, clinical and radiographic variables including BASDAI, BASFI, BASG, metrology, CRP, ESR, extra- articular manifestations, and mSASSS scores were compared to see if NS-R and NS-NR could be differentiated.

Results: In the cohort of 524 AS patients there were 136 NS-R and 388 NS-NR.

Clinical assessment **(Table)** indicated that NS-R patients had milder disease as reflected in: (i) better spinal mobility (ii) lower BASFI scores (iii) absence of peripheral joint involvement. However, this was *not* reflected in differences in mSASSS scores.

Comparative Features of NSAID-responders vs NSAID-nonresponders

Variable (mean ±SD)	NS-R	NS-NR	p
Occiput to wall, cm	2.7 (5.5)	4.9 (7.8)	<0.001
Lateral spine flexion, cm	16.8 (5.6)	12.8 (6.1)	<0.001
Chest expansion, cm	5.1 (2.4)	4.1 (2.2)	<0.001
BASFI	1.9 (1.8)	4.6 (2.8)	<0.001
BASDAI	2.6 (1.6)	5.7 (2.2)	<0.001
mSASSS	16.9 (23.4)	15.9 (21.9)	0.8
CRP	10.9 (12.5)	13.2 (21.6)	0.2
ESR	13.1 (14.5)	15.5 (15.6)	0.2
Disease duration, yr	7.5 (9.5)	9.3 (10.1)	0.06
Age, yr	39.3 (14.0)	39.7 (12.8)	0.8

The following parameters examined failed to identify differentiating features between NS-R and NS-NR: age, gender, HLA-B27 status, use of methotrexate or sulfasalazine, concomitant uveitis or psoriasis or IBD, CRP or ESR. There was a trend toward shorter disease duration but this was not statistically significant.

Conclusion: In our AS cohort, 26% of patients were NS-R, achieving a satisfactory symptomatic state with NSAID therapy alone. Of interest, the radiographic severity was no different in NS-R vs NS-NR, suggesting a disconnect between symptoms and radiographic damage. While NS-R patients manifested a milder disease profile, there was no clinical feature which predicted response to NSAID, raising the possibility that genetic factors may dictate this difference.

Serum Kallikreins As Biomarkers in Psoriatic Disease. Azza Eissa[1], Dafna D. Gladman[2], Arane Thavaneswaran[2], Fawnda Pellett[3], Eleftherios Diamandis[1] and Vinod Chandran[3]. [1]Mount Sinai Hospital, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON, [3]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: There is high prevalence of PsA in patients with psoriasis seen in dermatology clinics. Biomarkers may be helpful in screening psoriasis patients for PsA. Kallikrein-related peptidases (KLKs) constitute a single family of 15 highly conserved trypsin- or chymotrypsin-like serine proteases that regulate important pathobiological processes such as skin desquamation, remodelling of extracellular matrix and innate immunity. Our purpose was to investigate serum KLKs as biomarkers of psoriatic disease and PsA.

Methods: In phase 1, 52 patients with psoriasis and 26 healthy controls were recruited. Psoriasis was diagnosed by a dermatologist. 26 of these patients had PsA satisfying CASPAR classification criteria, and in the remaining 26 (PsC), PsA was excluded by a rheumatologist. Patients with PsC and PsA were group matched for age, sex and psoriasis duration, while controls were matched for age and sex. Blood samples were drawn at the time of assessment and serum levels of KLK5, KLK6, KLK7, KLK8, KLK10, KLK11 and KLK13 was determined using Immunofluorometric ELISA. In phase 2, KLKs that showed promise were investigated in an independent cohort of 100 patients with severe psoriasis, 50 of who had PsA. Statistical methods used included logistic regression and correlation analysis.

Results: The 52 patients with psoriatic disease had a mean age of 46 years and psoriasis duration of 17 years. Compared to controls, only increased serum levels of KLK8 [Odds ratio per unit increase (OR) 2.56, 95% CI (1.08, 6.12) p = 0.03] independently associated with psoriatic disease in a multivariate reduced model. Polychotomous logistic regression analysis to identify biomarkers that have differential association between the three subject groups (PsC, PsA and controls) showed that increased levels of KLK8 have significantly different effects when modelling PsC and PsA separately, controlling for age, sex and the other KLKs. However, logistic regression analysis comparing PsC with PsA did not show a significant difference in the serum KLK8 levels between PsC and PsA. Since KLK8 was identified as a marker for psoriasis, KLK8 levels were further investigated in patients with severe psoriasis defined as PASI score >8 (with or without PsA). KLK8 levels were significantly elevated in patients with both PsA and PsC when compared to controls. There was no difference in KLK8 levels between PsA and PsC (p=0.21). KLK8 levels significantly correlated with PASI score in all 100 patients (r= 0.52, P = <0.0001) as well as when patients with PsC (r= 0.43, P = 0.002) and PsA (r=0.60, P <0.0001) were considered separately. Logistic regression analysis adjusting for age, sex and duration of psoriasis showed that KLK8 levels do not discriminate between patients with PsA and PsC. In patients with PsA KLK8 did not correlate with actively inflamed joint count (p=0.35) or swollen joint count (0.12).

Conclusion: Serum KLK8 is a soluble biomarker for psoriatic disease and psoriasis severity, but does not differentiate between PsA and PsC.

1332

Comparison Between Psoriasis and Psoriatic Arthritis in An International Cohort. Dafna D. Gladman[1], Renise Ayearst[2], Vinod Chandran[2], Jan P. Dutz[3], John T. Elder[4], Christopher Ritchlin[5], Cheryl Rosen[2] and Proton Rahman[6]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Univ of BC, Vancouver, BC, [4]University of Michigan, Ann Arbor, [5]University of Rochester, Rochester, NY, [6]St. Claires Mercy Hospital, St. Johns, NF

Background/Purpose: Genetic and longitudinal data on psoriasis and psoriatic arthritis patients will provide essential information regarding pathogenesis, risk factors and disease outcomes in these relatively prevelant and related disorders. We therefore established collaboration among several groups from Canada and the United States with the support of a New Emerging Team (NET) grant from the Canadian Institutes of Health Research (CIHR) in 2008. The overall goal of this research network is to improve outcomes for patients with psoriasis and PsA. A central aim of the initiative is to compare the clinical features in patients with psoriasis without arthritis (PsC) and patients with psoriatic arthritis (PsA) included in the database.

Methods: A central component of the NET is that aRheumatologists collaborates with a dermatologist at each site. Five sites formed the core group, including 3 sites in Canada and 2 in the USA, and subsequently 3 other Canadian sites, and sites in Australia and Argentina were added. A web-based database was developed that includes a physician, patient and an investigation component. The physician component includes a complete history, general physical examination and detailed musculoskeletal and skin examinations. All investigators and assessors were trained with proper assessments tools as well as database structure. The patient component includes 8 instruments including the HAQ, SF-36, DLQI, fatigue severity scale, FACIT-fatigue, ASQoL, BASDAI, BASFI and a patient global assessment of disease activity (PGA). Laboratory information includes routine tests, rheumatoid factor, antinuclear factor and radiographs. PsC as well as PsA pts are recruited in each site. Descriptive statistics, t tests and chi square tests were used to analyze the data.

Results: To date, the IPART database has accumulated 2649 patients of whom 1847 have PsA and 802 have psoriasis without arthritis. A comparison between patients with PsA and patients with psoriasis uncomplicated by arthritis demonstrated that patients with psoriasis had longer disease duration compared to PsA (17 vs 15 years p=0.03) while patients with PsA had higher PASI scores (6.4 vs 5.7, p=0.02) and more frequent nail involvement (68.4% vs 48.2% p<0.001). While hyperlipidemia was more common among patients with psoriasis (19.1% vs 14.5%, p<0.001), hypertension was more common among patients with PsA (30.1% vs 24.1%, p<0.001). Depression was slightly more prevalent among patients with psoriasis than those with PsA. No statistically significant differences in the prevalence of diabetes, cardiovascular morbidity, or cancer was noted between the two groups.

Conclusion: An international web based database has been established to follow patients with psoriasis and PsA. Several demographic and disease related differences between patients with psoriasis and those with PsA were observed. This program will allow for the identification of patients with PsA early stages, and will provide detailed skin and joint phenotypes, outcome data and essential ascertainment data for genetic and biomarker studies.

1333

Prevalence of Autoimmune Diseases and Other Comorbidities in Patients with Psoriatic Arthritis in the United States. Frank Zhang[1], Annie Guerin[2], Genevieve Gauthier[2], Robert Day[1] and Zeba Khan[1]. [1]Celgene Corporation, Summit,, NJ, [2]Analysis Group, Inc., Montreal, QC

Background/Purpose: Psoriatic arthritis (PsA) is an immune mediated disease involving skin manifestations (psoriasis) and joint disease. Limited information has been published on the comorbidity profile of patients with PsA. This retrospective study aimed to estimate the comorbidity burden of patients with PsA, with a particular focus on autoimmune diseases.

Methods: In a large US representative administrative claims database (2004–2008), we identified adult patients with ≥2 PsA diagnoses (ICD-9 code: 696.0). PsA-free patients (i.e., patients without any reported psoriasis (ICD-9 code: 696.1) or PsA diagnosis from 2004 to 2008) were selected and matched to PsA patients in a 1:1 ratio by age and gender. Proportions of patients with mild PsA (i.e., patients who were either not treated, used

non-steroidal anti-inflammatory drugs or corticosteroids) or moderate-to-severe PsA (i.e., patients receiving disease-modifying anti-rheumatic drugs, including biologics) were reported. Patient demographic characteristics and comorbidity profile information, including the Charlson comorbidity index (CCI) score, the prevalence of autoimmune diseases, and an exhaustive list of other physical and mental comorbidities were compared between PsA and PsA-free patients using Wilcoxon signed-rank tests for continuous variables or McNemar tests for discrete variables.

Results: Among the 21,332 selected matched pairs, 53% were female and the mean age was 52 years (SD=12 years). In the PsA population, 35% had mild PsA and 65% had moderate-to–severe PsA. PsA patients had a higher mean CCI score compared to PsA-free patients (1.47 vs. 0.71; p<.01). Compared to PsA-free patients, PsA patients had a significantly higher prevalence of autoimmune diseases, including rheumatoid arthritis (49.1% vs. 3.1%), ankylosing spondylitis (7.0% vs. 0.8%), ulcerative colitis (1.3 vs. 0.6%), Crohn's disease (1.2% vs. 0.5%), and Sjogren's syndrome (1.1% vs. 0.1%) (all p<.01). PsA patients also had higher prevalence of other comorbidities, including hypertension (46.3% vs. 35.3%), chronic pulmonary diseases (18.9% vs. 12.2%), diabetes (18.8% vs. 12.5%), hypothyroidism (15.0% vs. 9.7%), deficiency anemias (13.3% vs. 7.1%), depression (9.4% vs. 5.8%), valvular diseases (8.6% vs. 5.4%), psychoses (8.0% vs. 4.7%), fluid electrolyte disorders (7.7% vs. 4.4%), solid tumor without metastases (6.4% vs. 5.5%), and peripheral vascular disease (6.2% vs. 3.7%) when compared to PsA-free patients (all p<.01).

Conclusion: PsA was associated with a substantial comorbidity burden, including a significantly higher prevalence of autoimmune diseases and other physical and mental comorbidities.

1334

Does Clinical Examination Underestimate Joint Inflammation In Patients with Psoriatic Arthritis? Dafna D. Gladman[1], Richard J. Cook[2], Lihi Eder[1], Anupam Wakhlu[3], Claire Riddell[4], Mikkel Ostergaard[5], Arane Thavaneswaran[1] and Vinod Chandran[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]University of Waterloo, Waterloo, ON, [3]CSM Medical University, Lucknow, India, [4]Antrim Area Hospital, Northern Health and Social Care Trust, Antrim BT41 2RL, Northern Ireland, Ireland, [5]Copenhagen University Hospital at Glostrup, Glostrup, Denmark

Background/Purpose: We aimed to determine the correlation between clinical examination, magnetic resonance imaging (MRI) and ultrasound (US) evaluation of actively inflamed joints in psoriatic arthritis (PsA). We hypothesized that MRI and US will detect inflammation in the peripheral joints in PsA more often than clinical examination, and that MRI will detect inflammation more often than ultrasound.

Methods: PsA patients with variable degrees of inflammation and damage were identified from the PsA clinic. Each patient was reviewed clinically by 4 rheumatologists, who agreed for each joint of the wrists, MCPs 1–5 and MTPs 1–5 whether it was tender, swollen, both tender and swollen, and/or damaged (defined as limitation of range of movement >20% of the range not related to the presence of joint effusion, the presence of joint deformities, subluxation, flail joints or ankylosis). US examination of the same joints was performed by an expert ultrasonographer, for the presence of synovial hypertrophy; joint effusion and power Doppler signal which were considered evidence of inflammation. Each patient underwent an MRI examination of the most affected area – either hand/wrist, or foot. MRI images were reviewed by an expert reader for inflammation (bone marrow edema, synovitis, or periarticular inflammation). The sensitivity and specificity of MRI and US, respectively, were calculated with the clinical consensus as the "gold standard". The sensitivity/specificity of US with MRI as gold standard was also calculated.

Results: 13 patients (6M, 7F) participated in the study with mean age of 51.3 yr (SD9.9), PsA disease duration of 9.8 yr (7.7), 10.8 (9.0) actively inflamed joints, and 14.3 (15.2) damaged joints. Inflammation was detected in 13/26 wrists by clinical examination of which 10 were also detected by US. However, US detected inflammation in 6 additional wrists not considered inflamed by clinical examination. In MCP joints, US and MRI consistently identified more inflamed joints than did clinical examination. However, in the MTP joints, (except for the 1st MTP) clinical examination identified more inflamed joints than US and MRI. MRI identified the 8 wrist joints detected by clinical examination, but also an additional 3 wrists. While MRI detected more inflamed wrists than did US, both detected the same *inflamed* MCP joints; whereas MRI detected more inflamed MTPs than did US. The sensitivity/specificity is depicted in the table.

Modality - Site	Sensitivity	Specificity
US vs clinical		
Overall	0.91 (0.84, 0.95)	0.28 (0.21, 0.35)
Wrists	0.77 (0.46, 0.94)	0.54 (0.26, 0.80)
MCPs	1.00 (0.89, 1.00)	0.12 (0.06, 0.21)
MTPs	0.89 (0.78, 0.95)	0.44 (0.32, 0.57)
MRI vs Clinical		
Overall	0.60 (0.47, 0.72)	0.53 (0.42, 0.65)
Wrists	1.00 (0.60, 1.00)	0.25 (0.01, 0.78)
MCPs	0.64 (0.41, 0.82)	0.53 (0.36, 0.69)
MTPs	0.47 (0.29, 0.65)	0.57 (0.40, 0.73)
US vs MRI		
Overall	0.87 (0.74, 0.92)	0.25 (0.15, 0.37)
Wrists	0.64 (0.32, 0.88)	1.00 (0.06, 1.00)
MCPs	1.00 (0.87, 1.00)	0.00 (0.00, 0.15)
MTPs	0.76 (0.56, 0.89)	0.42 (0.26, 0.59)

Conclusion: US and MRI identified more inflamed joints than were detected on clinical examination. However, many joints considered inflamed on clinical examination did not appear inflamed by imaging. Further work is required to determine whether joints labelled 'inflamed' clinically but "uninflamed" by imaging are actually inflamed, and whether inflammation identified by imaging but not by clinical examination, has clinically significant consequences.

1335

The Natural Course of Radiographic Progression in Ankylosing Spondylitis – Differences Between Genders and Appearance of Characteristic Radiographic Features. Xenofon Baraliakos[1], Joachim Listing[2], Anna von der Recke[1] and Juergen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]German Rheumatism Research Centre, Berlin, Germany

Background/Purpose: Although male patients are believed to suffer more by clinical and radiographic signs in ankylosing spondylitis (AS), only a few studies with limited numbers of patients tried to assess differences between genders in this disease. We here systematically analyze the radiographic progression of AS patients, based on gender differences but also on different progression velocities over time in a large cohort of patients.

Methods: Overall, 146 AS patients were retrospectively blindly analysed in at least two time-points within 6 years by using the mSASSS. Radiographic progression between time points was compared by multivariat analysis, after adjustment for baseline radiographic status and symptom duration. The Mann-Whitney-U test was used to compare the data between subgroups at single time points. Moderate radiographic progression was defined as two new syndesmophytes, slow progression as not more than one new syndesmophyte and fast progression as more than 2 syndesmophytes every 2 years of follow-up (FU).

Results: 114 patients (78%) were male. Overall, this cohort was similar to other cohorts with patients with established AS but included patients with more advanced disease: the time since first symptoms was 23.6±11.2 years (range 5 – 58 years) and the mean time since diagnosis was 22.6±12.1 years (range 2 – 55 years). The mean FU time was 3.8±1.7 years (range 1–6 years), and the mean number of consecutive FU visits with x-rays was 2.7 (range 2–6). The mean mSASSS was 19.7±18.6 units at baseline (BL) and 25.8±20.9 units at FU (p<0.001). The mean mSASSS progression was similar between males (6.4±8.8) and females (5.4±6.6), p=0.670. However, females showed a trend for higher progression in the cervical spine (3.4±5.6 mSASSS units vs. 2.9±5.2 in males, p=0.374) and males in the lumbar spine (3.5±6.4 vs. 1.9±3.2 in females, p=0.154). More females (53.1%) vs. males (33.3%) (p=0.035) showed new cervical syndesmophytes and more males (40.4%) vs. female (25%) (p=0.111) showed new lumbar syndesmophytes. More females (38%) than males (13%) showed moderate radiographic progression and more males (14%) than females (3%) showed fast radiographic progression, while slow and no progression was similar for both genders.

Conclusion: Radiographic progression in AS is similar between male and female patients but female AS patients show more cervical structural lesions, while males show overall more rapid progress.

1336

Comparative Analysis of Outcomes in Ankylosing Spondylitis: 6 Year Data From the DISTILLER Biologic Registry. Leonard C. Harty, Ciara A. Murray, Conor Fearon, Mairead Dockery, Ursula Fearon and Douglas J. Veale. Translation Rheumatology Research Group, Dublin, Ireland

Background/Purpose: To examine the clinical and serological features of Ankylosing Spondylitis (AS) patients treated with TNF inhibitors (TNFi).

Methods: Data was prospectively collected on 147 consecutive, unse-

lected AS patients treated with TNFi's, from 2004–2011. Patients also received physiotherapy and were reviewed 3 monthly for the first year of therapy and then annually. BASMI, BASDI and BASFI, chest expansion, HAQ, ESR & CRP scores were assessed. Kruskal Wallis and Mann-Whitney U tests were used to compare non parametric categorical and continuous data. Results are given as the mean unless otherwise specified.

Results: 147 AS patients were registered commencing TNFi therapy with a mean age of 45 (IQR 15) and mean disease duration of 11 years (IQR 13). 72% were male. 61% were current or ex-smokers. 42% were in employment. 35% were treated with adalimumab, 50% with etanercept, 14% with infliximab, 1% with golimumab. Mean first recorded BASDI for the whole cohort was 4.7 (IQR 3), BASFI 4.3 (3.8), BASMI 3.7 (2.6). There was no difference between the TNFi's either in speed of response or outcomes measured. Current smokers presented with significantly more spinal pain than never / ex-smokers ($p=0.045$). Women had significantly lower BASMI scores (2.9 v 4, $p=0.012$) at baseline yet had worse patient global health (6.7 v 5.5, $p=0.033$). Post-TNFi therapy women had higher BASDI (3.7 v 2.7, $p<0.001$) and BASFI (3 v 2.4, $p=0.032$) scores compared to men. In addition, women had higher scores for HAQ (.6 v.2, $p<0.001$), ESR (21 v 9, $p<0.001$), CRP (8 v 6, $p=0.047$) and patient global (5 v 3, $p<0.001$).

Conclusion: Female AS patients present with higher pain and disability despite better mobility, following TNFi therapy they continue to have higher disease activity and functional scores compared to male AS patients. AS patients who smoke have more pain at baseline.

Association of Platelet Endothelial Cell Adhesion Molecule-1 and β1 Integrin Gene Polymorphisms with Uveitis Development in Ankylosing Spondylitis. Seung Cheol Shim, Donghyuk Sheen, Mi-Kyoung Lim, Jiyoung Kim, Soyoung Lee and Sangkwang Lee. Eulji University Hospital, Daejeon, South Korea

Background/Purpose: Genetic factors provide over 90% of the overall susceptibility to ankylosing spondylitis (AS) and recent studies have focused on non-major histocompatibility complex genes. The etiology of uveitis in AS has been suggested to involve two adhesion molecules including intercellular adhesion molecule (ICAM)-1 and leukocyte functional antigen (LFA)-1.

Platelet-endothelial cell adhesion molecule 1 (PECAM1) is a member of the immunoglobulin superfamily which is expressed on endothelial cells. There is emerging evidence to suggest that PECAM1 may be an important regulator of antigen induced cell activation of lymphocytes. The β1 integrin (ITGB1) can associate with different membrane proteins and cause signal transduction by interactions in the extracellular and trans-membrane domain. Therefore, we examined the association of PECAM1 and ITGB1 gene polymorphisms with development of uveitis in patients with AS.

Methods: We conducted a case–control study where 223 AS patients who met the Modified New York criteria and 239 ethnically matched controls were genotyped for 9 single nucleotide polymorphisms (SNPs) in the PECAM-1 promoter and gene. Genomic DNA was isolated from peripheral blood leukocytes by a standard phenol–chloroform method and a GoldenGate assay (Illumina, http://www.illumina.com) was used for genotyping.

Results: Conditional logistic regression was used to evaluate the association between the PECAM1 or ITGB1 SNPs with susceptibility to AS, and no significant association was found on both genes. However, in the subgroup analyses between AS patients with uveitis and those without, seven SNPs in PECAM1 gene were associated with the presence of uveitis, including rs1050382 (dominant model (DM), $p=0.022$), rs2812 (recessive model (RM), $p=0.013$), rs4968721 (DM, $p=0.016$), rs6808 (DM, $p=0.011$), rs6809 (DM, $p=0.013$), rs9899806 (DM, $p=0.013$) and rs9913080 (DM, $p=0.019$) (Table 1). In addition, seven polymorphisms in ITGB1 gene including rs11009147 (DM, $p=0.012$; co-dominant model (CDM), $p=0.034$), rs17468 (DM, $p=0.012$; CDM, $p=0.019$), rs2153875 (CDM, $p=0.030$), rs2230396 (DM, $p=0.012$; CDM, $p=0.034$), rs2488330 (DM, $p=0.004$; CDM, $p=0.017$), rs3780871 (DM, $p=0.031$) and rs7079624 (RM, $p=0.004$; CDM, $p=0.017$) were associated with uveitis development (Table 2).

rs3780871	0.268 (0.081–0.888)	0.031 (0.042)	0.745 (0.390–1.424)	0.374 (0.514)	0.662 (0.398–1.103)	0.113 (0.139)
rs7079624	1.403 (0.538–3.662)	0.488 (0.536)	2.560 (1.335–4.909)	0.004 (0.008)	1.830 (1.109–3.021)	0.017 (0.030)

Conclusion: This is the first analysis of the PECAM1 and ITGB1 gene polymorphisms in AS, demonstrating a clear association with uveitis in AS. Given the functional role of PECAM-1 and ITGB1 variants in the immune system, larger studies are now warranted to elucidate the association of PECAM-1 and ITGB1 in the pathogenesis of uveitis in AS.

1338

Predictive and Protective Value of Biomarkers in Patients with Ankylosing Spondylitis Who Are At High Risk of Radiographic Spinal Progression. Denis Poddubnyy[1], Kristina Conrad[2], Gisela Ruiz-Heiland[3], Uta Syrbe[2], Hildrun Haibel[2], Heiner Appel[2], Martin Rudwaleit[4], Georg Schett[3] and Joachim Sieper[2]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Charité – Campus Benjamin Franklin, Berlin, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Ev. Krankenhaus Hagen-Haspe, Hagen, Germany

Background/Purpose: In the recent years several biomarkers have been found to be associated with radiographic spinal progression/syndesmophyte formation in ankylosing spondylitis (AS): matrix metalloproteinase 3 (MMP-3) and C-reactive protein (C-RP) (positive association), sclerostin (SOST), Dickkopf 1 (DKK1), and periostin, (negative association). However, it is not clear, whether these biomarkers are also able to predict new bone formation in AS patients who are at high risk of radiographic progression due to a presence of syndesmophytes at baseline. The objective of the study was to to investigate the association of biomarkers with radiographic progression (new syndesmophytes formation or growth of the existing syndesmophytes) in patients with AS with and without radiographic damage at baseline.

Methods: Altogether 97 patients with AS from the German Spondyloarthritis Inception Cohort (GESPIC) were included in this analysis. Radiographs of the lumbar and cervical spine performed at baseline and after 2 years of follow-up were scored independently by two trained readers according to the mSASSS scoring system. Three groups of patients were defined according to the scoring results:

Group I (n=26): patients with syndesmophytes at baseline and new syndesmophyte or syndesmophytes growth after 2 years;

Group II (n=38): patients with syndesmophytes at baseline but without radiographic progression after 2 years;

Group III (n=33): patients without radiographic spinal damage at baseline and after 2 years.

Serum levels of the following biomarkers were examined: MMP-3, CRP, SOST, DKK1, periostin, C-terminal cross-linked telopeptide of type II collagen (CTX-II), bone alkaline phosphatase, sRANKL, osteoprotegerin, N-terminal telopeptide of type I collagen, procollagen type I and II N-propeptide (PINP and PIINP), bone sialoprotein and cartilage oligomeric matrix protein.

Results: There was a statistically significant difference between Group I and Group II in the serum levels of MMP3, CRP and PIINP (table), indicating that higher serum levels of these biomarkers might be associated with active progression of spinal structural changes in the patients who are at high risk of

such a progression. At the same time, higher levels of SOST, DKK-1, periostin, and CTX-II might be protective regarding radiographic spinal progression in AS since the highest level of these markers were found in patients without syndesmophytes neither at baseline nor after two years despite high levels of CRP, MMP3 and PIINP (table). None of the other investigated biomarkers showed an association with radiographic spinal progression.

Table. Baseline serum levels of biomarkers in three groups of patients AS defined according to the presence of syndesmophytes and their progression over 2 years.

Biomarkers	Group I: baseline syndesmophytes, progression	Group II: baseline syndesmophytes, no progression	Group III: no syndesmophytes, no progression	p (Kruskall-Wallis test)
MMP-3, ng/ml	30.3 ± 25.9*	14.4 ± 19.7	25.5 ± 34.2	0.020
CRP, mg/l	17.1 ± 17.1*	8.7 ± 9.9	11.7 ± 22.8	0.152
PIINP, ng/ml	175.4 ± 81.6*	133.5 ± 82.5	233.3 ± 237.7	0.099
CTX-II, ng/ml	1259 ± 1082	2464 ± 3078	7170 ± 11097*§	0.002
SOST, ng/ml	0.15 ± 0.4	0.8 ± 2.4	3.5 ± 6.3*§	0.002
DKK-1, ng/ml	4.7 ± 2.1	5.4 ± 5.3	9.8 ± 6.9*§	0.038
Periostin, ng/ml	46.3 ± 78.5	106.8 ± 151.8	243.7 ± 201.2*§	<0.001

* $p < 0.05$ vs. Group II; §$p < 0.05$ vs.Group I.

Conclusion: Higher levels of MMP-3, CRP and PINP may predict further radiographic spinal progression/new bone formation in patients with AS already having syndesmophytes, while higher levels of SOST, DKK-1, periostin and CTX-II might play a protective role.

1339

Increased T Cell Receptor Clonotype Sharing Among Ankylosing Spondylitis Patients Revealed by Deep Repertoire Sequence Analysis. Malek Faham[1], Victoria Carlton[1], Martin Moorhead[1], Jianbiao Zheng[1], Tom Asbury[1] and R. D. Inman[2]. [1]Sequenta, Inc., San Francisco, CA, [2]The Arthritis Program, Toronto Western Hospital and Division of Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Of all rheumatic diseases, ankylosing spondylitis (AS) exhibits the strongest HLA association, with over 90% of AS patients carrying the class I MHC allele HLA B27. Since the canonical role for class I MHC is peptide presentation to T cells, the HLA-B27 relationship in AS has implicated a T cell response restricted by this antigen presentation function. By implication, this has also suggested that a specific antigen is important in the pathogenesis of the disease. This hypothesis would predict that specific T Cell Receptor (TCR) sequences would be shared among different AS patients.

Methods: We have developed a technology for large scale sequencing of TCRβ to assess the repertoire profile in individual samples. All TCRβ sequences are amplified from peripheral blood samples and >1 million TCRβ sequences are obtained to generate a comprehensive profile of the blood TCR repertoire at that time point. We have applied this new technology to determine whether AS patients have excess sharing of TCR sequences.

Results: We assessed TCRβ repertoire data obtained from blood samples of 16 individual AS patients, all of whom met the modified New York criteria for AS. This profile was compared with 16 patients with systemic lupus erythematosus (SLE), representative of another autoimmune disease with much lower HLA association. We counted clonotypes that are shared among each patient set (present in >7/16 patients) and found a significantly higher number of shared clonotypes among AS patients ($p = 5 = 10^{-4}$). Many of the shared clonotypes can be anticipated to be shared by chance, due to the small number of added bases in these clonotypes during the recombination to form the specific TCRβ sequence. Therefore we used a TCRβ repertoire data from 50 blood samples from 21 healthy individuals to filter out clonotypes that seem to be present in an appreciable number of these samples. We filtered clonotypes present in more than 3 of the normal samples to identify a shared specific clonotypes for each of the SLE and AS patients. We observed a significantly higher number of shared non-generic clonotypes among AS when compared to lupus patients ($p = 1.0 = 10^{-4}$). A number of these clones, present in 9/16 AS patients, seem highly specific as they were not present in another set of 50 unrelated individuals.

Conclusion: Using a novel deep repertoire sequence analysis, we provide evidence that there is a distinctive set of shared clonotypes in the T cell repertoire in AS patients. This sheds light on the immunological role of HLA B27 in AS, and lays the groundwork for defining the antigenic stimulus for this T cell response, as well as the application of TCR profiling in the diagnosis and clinical assessment of AS.

1340

Family-Based Association Study of SPA3, a New Susceptibility Locus for Spondyloarthritis on 6p11-q11. Félicie Costantino[1], Brigitte Izac[1], Gilles Chiocchia[2], Roula Said-Nahal[3], Ariane Leboime[3], Elena Zinovieva[1], Diana Zelenika[4], Maxime A. Breban[3] and Henri-Jean Garchon[1]. [1]Institut Cochin, Paris, France, [2]Institut Cochin, 75014 Paris, France, [3]Ambroise Paré Hospital, Boulogne-Billancourt, France, [4]Centre National de Génotypage, Evry

Background/Purpose: Spondyloarthritis (SPA) is a highly heritable disease with a major genetic susceptibility factor, the HLA-B27 allele. Genome-wide association studies have revealed an involvement of other genes such as IL23R or ERAP1. Nonetheless, a significant fraction of the genetic predisposition to SpA remains to be explained. One major interest of linkage studies is their potential to capture loci with low-prevalence disease susceptibility alleles. However, to date, such studies have identified few non-MHC loci in SpA. Only one of these, called SPA2, could be replicated. More recently, in a new whole-genome linkage study, we mapped three novel loci on 6p11-q11, 13q13 and Xqter (LOD score of 5.21, 4.06 and 5.94 respectively; *Arthritis Rheum* 2009,60:S436). The aim of the present study was to investigate the 6p11-q11 region by means of association analyses.

Methods: The discovery cohort was the same as that used in the whole-genome linkage study and comprised 904 subjects from 154 families with multiples cases of SPA. A replication cohort comprised 136 independent trios. Demographic and disease characteristics were comparable between the 2 cohorts. Genotyping was performed using Affymetrix® 250K single-nucleotide polymorphisms (SNP) arrays in the discovery cohort and using Taqman® assays in the replication cohort. Family-based association analyses of the 6p11-q11 region were done using UNPHASED. In the discovery cohort, 1,494 SNPs located between 50Mb and 70Mb from the p-telomere were tested. Bonferroni correction was used to adjust for multiple comparisons (significance threshold: 3.3×10^{-5}).

Results: No SNP reached the significance threshold in the single-locus association analysis in the discovery cohort. We therefore re-analysed a subset of 87 trios drawn from the 53 families of the discovery cohort showing strongest linkage to 6p11-q11 (pLOD > 0.15). We identified a group of 4 SNPs (rs283552, rs9349565, rs6921803 and rs2273120) forming 2 significantly associated haplotypes, one predisposing (GTCC) and the other protective (GTTT). We confirmed these associations in the replication cohort (Table). The 4 SNPs were not in linkage disequilibrium with HLA-B27 that is 20 Mb away ($r^2<0.05$). They encompass the IL17A and F genes and other loci relevant for SpA pathogenesis. Fine mapping of the region covered by the 4 SNPs is underway.

	Linked families (87 trios) Global p = 8.7×10^{-8}			Replication cohort (136 trios) Global p = 0.05			Combined (223 trios) Global p = 2.4×10^{-5}		
Haplotype	T	U	p	T	U	p	T	U	p
GTCC	0.28	0.12	8.9×10^{-5}	0.16	0.07	0.005	0.21	0.10	2.4×10^{-5}
GTTT	0.005	0.10	0.004	0.06	0.10	0.06	0.04	0.11	6.0×10^{-4}

Conclusion: We identified 2 haplotypes associated with SPA in the recently linked 6p11-q11 region. These data extend the linkage findings and altogether, these provide evidence for a new SPA locus called SPA3. Our study emphasizes the interest of family-based studies to uncover new genetic factors in SPA.

1341

Highly Expressed HLA-B27 Accumulate in Subcellular Vesicular Compartments and Form Oligomers That Behave Differently From HLA-B7. Cindy Jeanty[1], Adèle Sourisce[1], Aurore Wielgosik[1], Maxime A. Breban[2] and Claudine André[1]. [1]Institut Cochin, 75014 Paris, France, [2]Hopital Ambroise Pare, Boulogne, France

Background/Purpose: The HLA-B27 molecule is strongly associated with spondyloarthritis (SpA). This association has been largely studied, but mechanisms of pathology remain unclear. The HLA-B27 has an enhanced propensity to misfold and form aberrant disulfide linked heavy chain dimers in the endoplasmic reticulum (ER). Animal studies have helped to go deeper understanding the mechanisms in which HLA-B27 exerts its effects. Indeed, development of a spontaneous inflammatory disease resembling human SpA in transgenic rats is specific of HLA-B27 and correlates with high levels of expression of this

molecule. Our goal was to determine if and to what extent B27 homodimers are involved in this requirement of overexpression. We therefore monitored the intracellular trafficking of HLA-B27 focusing on its overexpression level.

Methods: To perform these studies, HeLa cells transfected with HLA-B*2702, −05 and −06 proteins fused at their C-ter to Renilla Luciferase (RLuc) or YFP were used. These allowed applying the Bioluminescence Resonance Energy Transfer (BRET) technique to study HLA-B27/HLA-B27 interactions *in situ*. Further aspects of the HLA-B27 processing (e.g. subcellular distribution, folding state, relative abundance of mono- and homodimers) were studied using classical techniques, including immunoblot, microscopy and flow cytometry. Cells transfected with HLA-B*0702 fusion proteins were used as control.

Results: Monitoring the subcellular distribution of the HLA-B-YFP fusion proteins evidenced that misfolded HLA-B27 and -B7 proteins tend to accumulate in ERGIC-type (Endoplasmic Reticulum Golgi Intermediate Compartment) intracellular vesicles. This phenomenon correlated with an increased expression of the HLA-B proteins. For both, HLA-B7 and HLA-B27, BRET signals increased rapidly in HeLa cells cotransfected with HLA-B-YFP and -RLuc proteins due to heavy chain homodimerisation. Interestingly, at high levels of vesicle formation, BRET signals for HLA-B*2702 and −05 remained steady, whereas those for HLA-B*0702 and HLA-B*2706, a subtype weakly associated with SpA, strongly decreased in these high expression conditions.

Conclusion: Our results reveal that at a high expression levels, differences appear in the oligomerisation state between strongly SpA-associated HLA-B27 subtypes (B*2702, B*2705) and weakly or non-associated HLA-B alleles (B*2706, B*0702). The mechanisms underlying this differential behavior, possibly implying cellular responses such as UPR, autophagy or protein degradation, remain as yet unknown and are currently under investigation. These findings open new perspectives in understanding the pathogenicity of HLA-B27 proteins.

Exacerbated Uveitis in the Context of IFN-Gamma Deficiency Is Ameliorated by Blockade of the Th17 Response in a murine model of Proteoglycan-Induced Arthritis and Spondylitis. Holly L. Rosenzweig[1], Jelena M. Kezic[1], Michael P. Davey[2], Stephen R. Planck[1], Tibor T. Glant[3] and James T. Rosenbaum[1]. [1]Oregon Health & Science University, Portland, OR, [2]Veterans Affairs Medical Center, Portland, OR, [3]Rush University Medical Center, Chicago, IL

Background/Purpose: Uveitis, or intra-ocular inflammatory disease, frequently occurs in patients with spondyloarthropathies such as ankylosing spondylitis. Despite the co-occurrence of uveitis and arthritis very little is understood of how the eye is predisposed to disease. Our prior data demonstrated discordant mechanisms of disease in the eye versus joints with respect to IFN-gamma in a murine spondyloarthropathy model of cartilage proteoglycan (PG) aggrecan induced arthritis and spondylitis. Here, we sought to elucidate the extent to which the Th17-related cytokines contribute to uveitis in the absence of IFN-gamma.

Methods: Female BALB/c IFN-gamma knockout (KO) mice also transgenic for the T cell receptor specific for a dominant epitope of the G1 domain of PG (TCR-Tg mice) were immunized with PG. Mice received weekly intraperitoneal injections of blocking antibodies to IL-17, IL-23p19 (unique chain for IL-23), or IL-23p40 (common chain for IL-12/IL-23) or isotype control antibodies (n=8–10 mice/group). Uveitis was analyzed by intravital videomicroscopy and histology at 3 weeks following immunization (peak occurrence of uveitis). The corresponding effects on the severity of arthritis were examined by clinical scoring and histology. Splenocytes from naïve, IFN-gamma KO/TCR-Tg or TCR-Tg mice were stimulated with 20 μg/ml recombinant G1 domain of PG, and cytokines were measured by multiplex ELISA 48h later.

Results: Cytokine analysis of supernatants from G1 domain-stimulated splenocytes revealed a significant increase in IL-17 production in the absence of IFN-gamma compared to wild-type counterparts, implicating a Th17 skewed response. Assessment of the contribution of Th17-related cytokines to uveitis in IFN-gamma KO mice revealed that blockade of any of the 3 cytokines (IL-17, IL-23p19, or IL-23p40) significantly reduced the leukocyte rolling, adherence and infiltration within the iris vasculature and tissue as assessed by intravital videomicroscopy. Histological analysis confirmed the diminished uveitis. Somewhat surprisingly retinal phototoxicity from the anti-IL-17 antibody treatment was noted, in that the photoreceptors were obliterated in ~50% of these mice. The incidence of phototoxicity was less in mice treated with either of the anti-IL-23 antibodies (~10%), and was never observed in mice injected with isotype-matched control antibodies. Akin to uveitis, the remaining arthritis in IFN-gamma KO mice was diminished as a consequence of treatment with any of the 3 blocking antibodies.

Conclusion: The data here reveal a critical regulatory role for IFNg in suppression of a Th17 response in the eye. In contrast to arthritis, IFN-gamma deficiency worsens uveitis and inhibition of Th17-related cytokines ameliorated eye disease. However, retinal phototoxicity was observed with anti-IL-17 therapy but to a lesser extent with anti-IL-23 targeted antibodies.

1343

Identification of Immunogenic HLA-B*27:05 Restricted Peptides of Salmonella Outer Membrane Protein (OMP) in Patients with Reactive Arthritis and Undifferentiated Spondyloarthropathy. Ramnath Misra[1], Amit Singh[1] and Amita Aggarwal[2]. [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [2]Additional Professor Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Lucknow, India

Background/Purpose: We have earlier reported that Salmonella OMPs are major immunogenic targets of synovial fluid lymphocytes of patients with *Salmonella* induced ReA/uSpA[1]. Since these group of patients have genetic predisposition to HLA-B*27 and its subtype HLA-B*27:05, we sought to identify HLA-B*27:05 binding Salmonella OMP peptides which are immunogenic in patients with ReA/uSpA.

Methods: Crude lysates of E coli, Salmonella typhimurium, Shigella flexneri, Y enterocolitica and OMP of S typthimurium were prepared. 125 HLA-B*27:05 binding Salmonella OMP peptides identified using Propred1 software were synthesized and grouped in 23 pools. These panel of antigens (5 and 10 μg/ml) and peptide pools (10 μg/ml) were cultured with 1×10^5 synovial fluid or peripheral blood mononuclear cells (SF/PBMC) from 23 patients with ReA/uSpA, 10 patients with RA and PBMC of 10 healthy individuals (controls) for 5 days in 96 well culture plate. Lymphocyte proliferation was assayed by tritiated thymidine uptake and IFN-γ levels in culture supernatant. A stimulation index (SI) of >2.5 was considered significant. Individual peptides from pools having significant response were retested against cryopreserved SFMC/PBMC to identify immunogenic peptides. HLA-B*27 and its subtypes were done by PCR using allele specific primers. A BLASTp program was used to search for similar peptides from protein bank of arthritogenic bacteria and human.

Results: SFMC of 19/23 patients with ReA/uSpA showed a significant proliferative response to Salmonella OMP but there was minimal response in PBMC (1/10) of ReA/uSpA, SFMC of RA (1/10) or PBMC from control (1/10). Nine Salmonella OMP peptides QRAEMLPTL, SRSGLNIAL, LRFLYAKSL, RLEGTWVKL, ARCIAPYAL, KLFLTTAAL, YRNSDFFGL, QRPAVRVKL and YRVGPGDVL showed significant response (Table 1). Response to QRAEMLPTL was mainly restricted to HLA-B*27:05 positive (6/7) patients. All immunogenic peptides had sequence similarity with peptides derived from arthritogenic bacterial proteins while 5 immunogenic peptides had similarity with peptides from evolutionary conserved human proteins.

Table 1. Sequence of individual immunogenic peptides, its protein and number of patients SFMC responded

Peptide No.	Pool No.	Sequence	Protein Details	No. of Patients responded
100	13, 9	QRAEMLPTL	outer membrane efflux-like protein, OprM (53 kDa) (485 aa) NP-459345	7
47	5, 19	SRSGLNIAL	putative outer membrane protein (205 kDa) (1869 aa) NP-461450	3
43	5, 15	LRFLYAKSL	outer membrane usher protein, FimD, (95 kDa) (870 aa) NP-459541	3
33	13, 2	ARCIAPYAL	outer membrane usher protein, FimD, (95 kDa) (870 aa) NP-459541	3
55	13, 6	LRLEGTWVK	putative outer membrane protein (51 kDa) (468 aa) NP-459672	2
108	9, 20	QRPAVRVKL	multidrug efflux system subunit MdtB (1040 aa) NP-461072	2
110	9, 22	KLFLTTAAL	putative outer membrane protein (11 kDa) (94 aa) NP_459160	2
121	19, 10	YRNSDFFGL	outer membrane protein F (40 kDa) (368 aa) NP_459974	2
125	22, 2	YRVGPGDVL	putative outer membrane polysaccharide export protein (41 kDa) (379 aa) NP461063	2

Conclusion: A set of 9 novel HLA-B*27:05 binding peptides of Salmonella OMP were immunogenic to SFMC of patients with ReA/uSpA. Immune response to these peptide targets could be useful for diagnosis in undifferentiated spondyloarthropathy.

Endoplasmic Reticulum Aminopeptidase 1 Interaction with Human Leukocyte Antigen B27 Influences the Unfolded Protein Response. Nigil Haroon[1], Aifeng Lin[2], Ali Akram[1] and Robert D. Inman[1]. [1]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [2]Toronto Western Research Institute and University Health Network, Toronto, ON

Background/Purpose: Endoplasmic reticulum aminopeptidase 1 (ERAP1) is second only to HLA B27 in the strength of genetic association with ankylosing spondylitis. We have reported a functional interaction of ERAP1 with alteration in MHC-I free heavy chain and HLA-B27-peptide presentation. An aberrant UPR response has previously been reported in B27-positive cells, but the influence of ERAP1 on that response has not been resolved. Here we report the influence of ERAP1 on unfolded protein response (UPR) genes in HLA B27 transgenic mice.

Methods: HLA-B27 transgenic mice (B27tg) were developed on a MHC double knock out (DKO) strain which lacked endogenous murine class I MHC. These mice were crossed with ERAP1 −/− mice to generate the HLA-B27-ERAP-KO mice (B27tgE-). ERAP1 is known to have variation in tissue level of expression with high levels in the liver. Mesenteric lymph nodes (MLN), spleen and liver were obtained from age-matched B27tg and B27tgE- before and 5 days after intra-gastric Yersinia infection. Yersinia enterocolitica 0:8 was delivered to the mice by intragastric tube at a dose of 10^7 organisms. RNA was extracted from tissues and subjected to quantitative PCR with primers specific for the following markers of UPR: Bip, CHOP, XBP-1 and GADD45. β-actin expression was used a control.

Results: There was consistent expression of all 4 genes of UPR in the tissues tested except for GADD45 expression in the spleen. In the liver which has the highest expression of ERAP1, the UPR genes were expressed at significantly higher levels in the B27tgE- compared to B27tg. The fold expression of the respective genes in the B27tg *vs* B27tgE- were: Bip (15.4 *vs* 30.2), CHOP (3.05 *vs* 4.9), XBP-1 (19.9 *vs* 53.9) and GADD45 (7.6 *vs* 12.2). The fold expression of UPR genes in the spleen were comparable between B27tg and B27tgE-: BiP (1.84 *vs* 1.70); CHOP (2.41 vs 2.20), XBP-1 (3.79 vs 3.52). MLN demonstrated higher expression of UPR genes in B27tg compared to B27tgE-: Bip (2.07 *vs* 1.21), CHOP: (1.96 *vs* 1.52), XBP-1 (2.78 *vs* 1.22), GADD45 (3.20 *vs* 1.27).

Following Yersinia infection, there was a downregulation of the UPR response genes, seen in both strains. In MLN and spleen, the degree of downregulation of UPR genes was comparable. However, in the liver the decrease in CHOP and XBP-1 following infection was significantly more pronounced in the B27tgE- (CHOP: 2.20 to 1.55 and XBP-1: 3.52 to 2.16) than in the B27tg (CHOP: 2.41 to 2.04 and XBP-1: 3.79 to 3.02).

Conclusion: ERAP1 variations and interaction with HLA-B27 results in functionally significant alteration of the UPR and show differential effects after gastrointestinal infection. The effects seen may be especially prominent in those tissue with higher endogenous ERAP1 expression.

Phenotype of Resting and Activated Monocyte-Derived Dendritic Cells Grown From Peripheral Blood of Patients with Ankylosing Spondylitis. Gleb Slobodin[1], Aharon Kessel[1], Natalia Kofman[2], Elias Toubi[1], Itzhak A. Rosner[1] and Majed Odeh[1]. [1]Bnai Zion Medical Center, Haifa, Israel, [2]Technion, Haifa, Israel

Background/Purpose: Decreased levels of class II MHC expression and impaired formation of immunological synapse by dendritic cells (DCs) of HLA-B27 transgenic rats have been recently demonstrated. The resulting dysfunction of DCs may be implicated in the pathogenesis of the HLA-B27-related disease in transgenic animals. The phenotype of DCs in patients with ankylosing spondylitis (AS) has not been evaluated.

Methods: Monocyte-derived DCs (MDDCs) were grown from 5 HLA-B27 positive patients with active AS (mean BASDAI score 6.9, range 6.6–7.5) and 8 age-matched healthy volunteers. Surface expression of HLA-DR, co-stimulation molecules CD80, CD86 and CD40, as well as CD83 was assessed by flow cytometry and compared between the groups under 3 conditions: in resting state, after stimulation by lipopolysaccharide (LPS) and after stimulation by LPS in the presence of etanercept, a soluble receptor of tumor necrosis factor a.

Results: Lower baseline expression of class II MHC molecules (HLA-DR) was observed by MDDCs grown from AS patients, as compared to healthy subjects ($p=0.04$). A major increase in HLA-DR expression was observed in both AS and control groups upon LPS-induced activation ($p<0.01$ for both groups). However, the MDDCs grown from AS patients demonstrated higher rates of HLA-DR expression growth ($31.1\pm13.9\%$ vs $21.9\pm15.4\%$ growth in the control group), which minimized the difference between two groups as to the final levels of triggered HLA-DR expression. When added, etanercept decreased the rate of LPS-induced HLA-DR growth similarly in both groups ($8.7\pm6.3\%$ for AS and $7.5\pm4.7\%$ for control group). No difference between groups in the levels of expression of co-stimulation molecules and CD83 was observed.

Conclusion: Lower basic expression of class II MHC by the MDDCs grown from patients with AS may be associated with impaired regulation of their activity. Functional studies on DCs from patients with AS are needed to evaluate the integrity of their antigen-presenting function.

Chondrocalcin, C-Terminal Propeptide of Type II Collagen, Can Be Found in Sclerotic Lesions of Spine and Its Gene Expression Is Significantly Increased in Patients with Ankylosing Spondylitis. Yong-Jin Kwon, Tae-Yeon Kim, Sang-Won Lee, Yong-Beom Park, Soo Kon Lee and Min-Chan Park. Yonse University College of Medicine, Seoul, South Korea

Background/Purpose: It has been suggested that chondrocalcin, C-terminal propeptide of type II collagen encoded by *COL2A1* gene, shows calcium-binding capacity and induces calcification of cartilage matrix. It can be found in great concentration in calcifying cartilage, such as hypertrophic zone of growth plate and deep articular cartilage, and acts as a nucleation core by binding to proteoglycan aggregates and initiating calcification. Abnormal calcification and pathologic new bone formation are the hallmark of ankylosing spondylitis (AS), but the role of chondrocalcin in syndesmophytosis of AS has never been investigated. The purposes of this study were to detect the production of chondrocalcin at the sites of enthesial inflammation and syndesmophytosis in patients with AS, and to investigate whether the expression of chondrocalcin mRNA is elevated in patients with AS.

Methods: Fragments of vertebral bodies of lower cervical spines were obtained from patients with long-standing AS during decompressive cervical laminectomy and facetetctomy and control vertebral fragments were obtained from patients with spondylolytic spondylolisthesis who underwent total facetectomy. The production and localization of chondrocalcin in the vertebral fragments from patients with AS was assessed by H&E staining and immunohistochemical staining using anti-chondrocalcin antibody and compared to those in control vertebral bony fragments. Peripheral blood mononuclear cells (PBMCs) were harvested and isolated from 46 patients with AS. The mRNA expression of chondrocalcin from PBMCs was measured by real-time quantitative RT-PCR, and then compared to those from patients with rheumatoid arthritis (RA) and healthy controls.

Results: The histological evaluation of the bony fragments of vertebral bodies from patients with AS revealed signs of severe enthesitis and sclerosis. Immunohistochemical analysis showed remarkably increased chondrocalcin deposition in inflamed and sclerotic areas of their vertebral bodies, compared to control vertebrae from patients with degenerative spondylosis. Real-time PCR analysis exhibited that the mRNA expression of chondrocalcin was significantly increased in patients with AS, compared to those from patients with RA and healthy controls.

Conclusion: In this study, we found that chondrocalcin was detected at the sites of inflammation and sclerosis of vertebral bony fragments and that chondrocalcin gene expression was significantly increased in PBMCs from patients with AS. These findings suggest that chondrocalcin can have a certain role in the process of syndesmophytosis in AS.

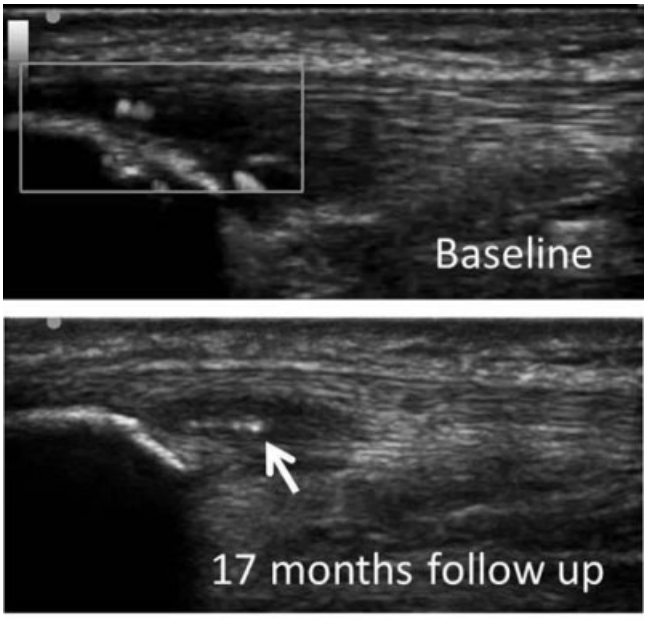
Serial Ultrasonography Documents New Bone Formation At Entheses in Spondyloarthritis. Ralf G. Thiele[1], Bethany A. Marston[1], Darren Tabechian[2], Allen P. Anandarajah[3] and Christopher Ritchlin[1]. [1]University of Rochester, Rochester, NY, [2]Univ of Rochester Schl of Med, Rochester, NY, [3]Univ of Rochester Medical Ctr, Rochester, NY

Background/Purpose: Entheseal inflammation is a hallmark feature of spondyloarthritis (SpA). New bone formation is thought to be part of the pathogenesis of joint damage and ankylosis in SpA. A progression from enthesitis to new bone formation and joint damage has been postulated but is difficult to assess as a process in vivo. Conventional radiography cannot visualize tendons, and MRI may be less sensitive in detecting small calcifications than ultrasound (US). The aim of this study was to assess development of enthesitis in vivo using serial high resolution US.

Methods: 144 images and video clips of 8 clinically symptomatic and sonographically abnormal entheses in 7 patients with SpA (psoriatic arthritis, n=4; reactive arthritis, n=2; ankylosing spondylitis (AS), n=1) were obtained over 2 years (long and short axis views in gray scale and power Doppler, and video clips to document pulsatile flow). The 8 entheses included: origin of patellar ligament: n=3; insertion of Achilles tendon, n=4; insertion of medial collateral ligament of first metatarsophalangeal joint, n=1. US criteria for enthesitis were: 1) cortical irregularity at interface of ligament or tendon and bone; 2) pulse synchronous Doppler signal at interface and within body of tendon or ligament; 3) loss of densely packed fibrillar pattern with decrease of hyperechogenicity and increased thickness of tendon or ligament at insertion or origin (edema). Criterion for entheseal new bone formation was: hyperechoic material within body of tendon or ligament that was not seen on prior studies. All studies were performed by a rheumatologist certified in musculoskeletal ultrasound, with 20 years' experience. Transducer frequencies of 10–18 MHz were used. All patients underwent treatment: NSAIDs alone, n=1; methotrexate and NSAIDs, n=1, methotrexate and TNF-inhibitor, n=5.

Results: Inflammatory changes by US criteria decreased in all 8 entheses followed after 15–24 months: No more Doppler signal was seen at the entheses, hypoechogenicity and thickness had decreased in all at the time of the last study. CRP and ESR levels had remained within normal limits in all patients throughout the observation period, and were not suitable as markers of entheseal inflammation in our patients. Clinical entheseal pain was present in all at study entry and none at the time of the last US study. Newly formed hyperechoic material was eventually seen in all entheses (mean time to development 17 months). This calcific appearing material was present at the site of previously seen Doppler signal in all cases (Figure). In the case of AS, enthesitis led to calcification of a collateral ligament.



Conclusion: Within entheses, sites of deposition of calcified material correlate with sites of prior hyperemia. In AS, enthesitis preceded collateral ligament calcification in our study. Serial US can document disease development from enthesitis to new bone formation.

Syndesmophyte Formation Is Associated with Low-Grade Spine Inflammation and Disconnected From Peripheral Arthritis in Mice Immunized with Recombinant Human Aggrecan G1 Domain. Mohamed Ramez, Toni S. Forde, Elena Kudryavtseva and Vyacheslav A. Adarichev. Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: The balance between inflammation-driven cartilage and bone erosion and new bone formation is set at different levels in rheumatoid arthritis and ankylosing spondylitis. Inflammation and tissue damage usually prepare the stage for the later repair process of new tissue formation like syndesmophytes and bone fusions in AS. To understand mechanisms of bone remodeling in inflammatory conditions, we developed a murine model of spondylitis induced with aggrecan immunizations.

Methods: Human aggrecan G1 domain (1–235 aa of ACAN-201) tagged with 6xHis was cloned using a baculovirus system, and the fusion protein was overexpressed in insect cells. Secreted rhAG1 protein was isolated using Ni-NTA resin. Protein identity and purity was characterized with SDS-PAGE and immunodetection. BALB/c females were immunized intraperitoneally with rhAG1 emulsified either in Complete Freund's adjuvant (CFA) or in dimethyldioctadecylammonium bromide (DDA) adjuvant or DDA alone. Mice were scored for visual signs of peripheral arthritis. Histopathology sections of paws and thoracic-caudal spines were stained with hematoxylin & eosin and alcian blue and examined for inflammation and intervertebral disk (IVD) afflictions.

Results: Mice immunized with rhAG1-DDA showed slightly higher arthritis severity than rhAG1-CFA group. Slowly progressive arthritis reached maximum after four immunizations. Histopathological examination of paw sections confirmed the presence of inflammatory cells, but severity of arthritis was rather mild. Despite the slow peripheral inflammation, histopathological assessment of spine sections revealed massive ventral chondroplasia of fibrocartilaginous annulus fibrosus-like cells that had been displacing anterior longitudinal ligament. Ventral aspects of enthesis, annulus fibrosus, and growth plate were mainly affected. Chondrophyte/syndesmophyte sizes reached up to 50% of the size of IVD. One to three syndesmophytes per every spine were observed in 20% of examined mice. The most affected regions were the junction of sacrum with lumbar and caudal parts of axial skeleton: S1-L6 and S4-Ca1. We observed consistent but low grade inflammation around afflicted skeletal regions that strongly correlated with spine chondrophytosis, r=0.81. Correlation between peripheral joints inflammation and syndesmophyte formation was much weaker, r=0.29.

Conclusion: A new murine model for syndesmophyte formation with disconnect between otherwise weak peripheral joints inflammation is developed. The balance between peripheral inflammation, spondylitis and chondrophytosis seems to be dependent on the source, biochemical properties and immunogenicity of the immunizing aggrecan antigen.

1349

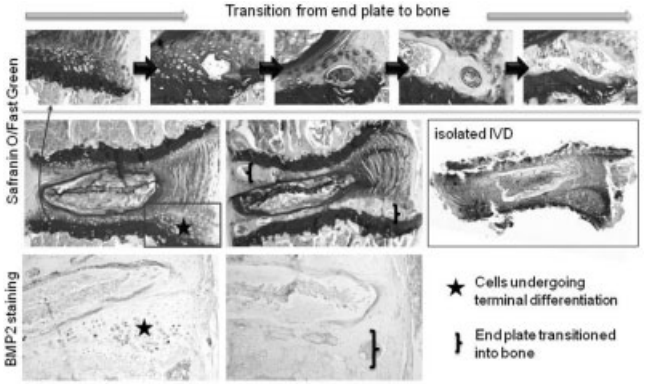
Transition From a Cartilage Phenotype Into Bone in the Intervertebral Disc End Plate in Ageing Mice: Role for Bone Morphogenetic Protein 2. Esmeralda N. Blaney Davidson[1], Elly Vitters[2], Wim B. van den Berg[1] and Peter M. van der Kraan[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands

Background/Purpose: Degeneration of the intervertebral disc (IVD) is considered an important source of back pain and affects 80% of the ageing population. The mechanisms underlying this age-related degeneration remain to be elucidated. Our present study is designed to study age-related changes in gene expression in IVD and to find clues whether changes in gene expression can explain age-related disc degeneration. We show that with age the end plate of murine lumbar spine undergo terminal differentiation followed by bone formation and accompanied by high mRNA expression of osteocalcin and intense BMP2 staining.

Methods: We isolated lumbar IVD of C57Bl/6 mice aged 4, 8, 12 and 20 months for RNA isolation and subsequent Q-PCR or whole spines for histology. A Q-PCR was performed evaluating the expression of aggrecan, collagen type I, collagen type II, collagen type X and osteocalcin and Id1. Values were corrected for GAPDH and calculated as a fold increase compared to 4 months of age. Paraffin sections were made from the whole spines and stained with Safranin O and Fast Green or immunohistochemistry was performed for BMP2.

Results: IVD used for RNA isolation partially contained the growth plate, the entire end plate, annulus fibrosus and nucleus pulposus (see figure). In these IVD aggrecan RNA decreased up to 1.9-fold by 20 months when compared to 4 months of age. Collagen type II increased 3.7 fold by 12 months of age and remained stable thereafter. Collagen type I also increased up to 4.5 fold by 12 months of age and reduced to 3.3 fold increase compared to 4 months of age. The most striking change was an increase in osteocalcin of 3.2 fold by 8 months, 5.4 fold by 12 months and even 6.1-fold by 20 months of age, indicated bone formation having its onset before 8 months of age.

To investigate the cause of this osteocalcin increase, we turned to histology and found hypertrophic differentiation in 6 month old end plate followed by replaced by bone eventually covering the entire growth plate (figure, middle part). As BMP2 is a major bone inducer we stained for BMP2 and found increased staining with age especially intense in the terminally differentiating end plate chondrocytes that are eventually replaced by bone (figure bottom left). On RNA level we found that Id-1 expression increased 1.4 fold at 8 months and 2.8 fold by 12 months of age and was stable after that when compared to 4 months of age.



Conclusion: We show age-related terminal differentiation in end plate chondrocytes which are eventually replaced by bone. This is accompanied by intense BMP2 staining in the hypertrophic cells and a sustained increase in osteocalcin and Id1 expression with age in the IVD. Our data strongly suggesting a role for BMP2 in bone formation in the IVD end plate with age. This phenomenon will contribute to age-related degeneration of the IVD.

1350

Simultaneous but Spatially Distinct Occurrence of Inflammation, Tissue Destruction and Osteoproliferation in the HLA-B27/Human beta2 Microglobulin Transgenic Rat Model of Spondyloarthritis. Leonie M. van Duivenvoorde[1], Martha L. Dorris[2], Nimman Satumtira[2], Paul P. Tak[1], Joel D. Taurog[2] and Dominique L. Baeten[1]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]UT Southwestern Medical Center, Dallas, TX

Background/Purpose: Spondyloarthritis (SpA) is characterized by inflammation as well as osteoproliferation of axial and peripheral joints. Clinical observations that TNF blockade halts inflammation and destruction but does not show a major impact on osteoproliferation raises the question of the exact relationship between these processes.

The objective of this study aimed to analyze the spatial and temporal relationship between inflammation, destruction and osteoproliferation in experimental SpA.

Methods: Histological samples were obtained from different stages of spontaneous tail spondylitis (n=10) and peripheral arthritis (n=9) in B27/hB2m tg rats[1]. Samples were formalin fixed and decalcified in EDTA. Paraffin sections were stained with H&E or toluidine blue and evaluated by two independent observers.

Results: In spondylitis, the first signs of mild inflammation were consistently found in loose connective tissue located at the junction of the annulus fibrosus with the vertebral bone. The inflammatory infiltrate contained numerous polymorphonuclear cells (PMNs). In moderately affected vertebral joints, inflamed tissue started to erode the bony endplate with appearance of multinucleated giant cells resembling active osteoclasts. In severe inflammation, this process gradually affected the cartilage growth plate and invaded the underlying bone marrow. Also here, numerous PMNs and multinucleated giant cells were observed. End-stage disease was characterized by an almost complete destruction of the intervertebral disc and the vertebral body, with persistence of inflammatory infiltration as well as osteoclastic bone resorption. Hypertrophic chondrocytes and new bone formation appeared at the stage of moderate inflammation and persisted at the stages of severe inflammation and end-stage destruction. Of interest, osteoproliferation was consistently found at the edge of the vertebral body, at a distance from the inflammatory and destructive process.

Peripheral arthritis was characterized by infiltration of synovial tissue with a similar predominance of PMNs. The inflamed pannus gradually invaded cartilage and bone and could also extend along the tendons, even though clear enthesitis was not observed. In contrast to the axial skeletal findings, pronounced infiltration of the bone marrow (osteitis) in the absence of synovitis was found in some cases. Both synovitis and osteitis contained multinucleated giant cells eroding the bone surfaces. Periosteal new bone formation was observed at different stages of inflammation.

Conclusion: Spontaneous spondyloarthritis in B27/hB2m tg rats is characterized by a destructive synovitis with PMNs and multinucleated giant cells rather than by enthesitis or osteitis. The simultaneous but spatially distinct appearance of inflammation and destruction versus osteoproliferation argues against the concept of reparative osteoproliferation after resolution of inflammation.

Inhibition of IL-17 by Antibody Administration Improves Onset of Tarsal Ankylosis In a Murine Model. Shin Ebihara and Masao Ono. Department of Pathology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background/Purpose: Ankylosis is a major joint pathology of spondyloarthropathy (SpA). Therapeutic intervention against spontaneous progression of ankylosis has been investigated. There is recent accumulating evidence that IL-17 is involved in the pathogenesis of SpA. The aim of this study is to evaluate efficacy of anti-IL-17 therapy on a spontaneous tarsal ankylosis in mice.

Methods: The onset of tarsal ankylosis observed in male DBA/1 mice was assessed on footpad swelling and, in part, histopathological examination. Serum IL-17 concentration was determined by enzyme-linked immunosorbent assay. The periodic administration of anti-IL-17 antibody to male DBA/1 mice started before or after the ankylosis onset and weekly continued until experimental end point. Pathological changes and mRNA expressions were assessed for joints and skins obtained at experimental end point.

Results: Footpad swelling of male DBA/1 was frequently observed as previously reported and histopathologically characterized by entheseal arthropathy. These mice developed psoriasis-like dermatitis with ankylosis. Circulating IL-17 was found to increase with the onset of ankylosis. Prophylactic administration of anti-IL-17 antibody significantly prevented the development of both the ankylosis and dermatitis. On the other hand, its administration after the onset of diseases has partial effect only on the ankylosis but not dermatitis.

Conclusion: Tarsal ankylosis of male DBA/1 mice occurs and develops in an IL-17-dependent manner. IL-17 is a potential therapeutic target of ankylosing arthropathy in human.

HLA Associations Reveal Genetic Heterogeneity in Psoriatic Arthritis and in the Psoriasis Phenotype. Robert Winchester[1], Gregory Minevich[1], Valeria Steshenko[1], Brian Kirby[2], David Kane[3], David A. Greenberg[4] and Oliver M. FitzGerald[2]. [1]Columbia University, New York, NY, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]Adelaide, Meath hospital Dublin (incorporating the National Children's hospital), Dublin 24, Ireland, [4]Mailman School of Public Health Columbia University, New York City, NY

Background/Purpose: Susceptibility to psoriasis (Ps) is clearly associated with *C*06:02,* but in psoriatic arthritis (PsA) the results of different studies on the role of HLA are quite disparate. Factors, contributing to the divergence in HLA allele frequencies in PSA include using serologic methods; the potential for case-control stratification and incomplete haplotype delineation in more admixed populations; and perhaps most importantly, the lack of proper case definition. We compared rigorously ascertained psoriatic arthritis cases presenting to a rheumatology unit with Ps cases without musculoskeletal features from a dermatology unit to address: (1) the extent to which the MHC contribution to PsA susceptibility resembles that of Ps; and (2) whether MHC genes determine quantitative traits within the PsA phenotype.

Methods: Separate discovery and validation cohorts for Ps (n=102 and 122) and PsA (n=197 and 162) recruited from the relatively homogeneous Irish population were studied by sequence-based HLA typing, comparing *HLA-B* and *HLA-C* allele and haplotype frequencies. In the Ps group musculoskeletal involvement was excluded by a rheumatology examination. Control cohorts included Irish blood donors, n=1000, and a local cohort (n=119) without family history of Ps. A significant association present in both discovery and validation cohort was considered definite, while an association in only one cohort was termed "preliminary".

Results: In PsA the frequency of *C*06:02* was lower, 28.7%, than in the Ps cohort, 57.5%, p=9.9exp-12. Three haplotypes containing *B*27:05* or *B*39:01* were significantly increased in frequency in PsA, but not in the psoriasis cohort allowing rejection of the hypothesis that the psoriasis phenotype is genetically homogeneous. Interestingly, the structurally related *B*39:06* allele was not increased. *B*27* was associated with an interval of 0.98 years between skin and musculoskeletal disease, p=2.05exp-6, versus 10.14 years for *C*06*. Preliminary evidence suggested *B*38:01* and *B*08* may be associated with susceptibility and that allotypes, including *B*40:01* and *B44:02*, but not *B*44:03*, encoding P2 pockets binding side chains opposite in charge from those encoded by *B*27* and *B*39* molecules exert a protective role.

Conclusion: The data suggest the psoriasis phenotype results from at least two patterns of MHC effect. The first involves the classic Ps susceptibility gene *C*06*, characterized by more penetrant skin disease with less prevalent and more time dependent musculoskeletal phenotype development. The second, appears mediated by HLA-B alleles, notably *B*27*, and includes temporally more coincident musculoskeletal involvement that is nearly equivalent in penetrance to skin disease.

Differential Human Leukocyte Allele Association Between Psoriasis and Psoriatic Arthritis—A Family-Based Association Study. Lihi Eder[1], Fawnda Pellett[2], Vinod Chandran[2], Sutharshini Shanmugarajah[2], Shelley Bull[3] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Mount Sinai Hospital, Toronto, ON

Background/Purpose: Our recent population based study has identified several HLA alleles as conferring an independent risk for PsA among patients with psoriasis. We aimed to validate these results using a family based association study.

Methods: PsA probands, psoriasis probands and their 1st degree family members (parents and siblings) were included in this study. The PsA probands were part of the University of Toronto PsA cohort and satisfied the CASPAR classification criteria. Psoriasis patients without arthritis were part of a prospective cohort of psoriasis patients and were evaluated by a rheumatologist to rule out inflammatory arthritis. All family members were evaluated for the presence of psoriasis and inflammatory arthritis by a rheumatologist. Extracted genomic DNA was amplified by PCR using locus specific primers for each of the HLA-B and -C loci. PCR amplicons were identified by Sequence Specific Oligonucleotide probes using a reverse line blot technique. In order to identify specific markers for PsA, PsA probands were compared to their siblings with psoriasis. Healthy siblings were excluded from the analysis. Since the disease status of the parents is not relevant for calculation of the Family Based Association Test (FBAT) statistics they were included in the analysis irrespective of their trait. FBAT version 2.0.3 software was used for the analysis. A family based test statistic (Z value) and p value were calculated. Z of more than 0 indicates over-transmission of the allele, while Z of less than 0 indicates under-transmission. An additive model was specified. Only alleles that were present in 10 or more families were included in the analysis.

Results: Altogether, 178 PsA and 30 psoriasis probands and 561 first degree family members belonging to 208 families were analyzed. Of those, 4 families were excluded due to Mendelian errors. 49.7% of the probands had a positive family history of psoriasis and 20.8% of the probands had a family history of PsA. The following HLA alleles were significantly associated and over-transmitted to PsA compared to psoriasis: HLA-C*12 (p=0.005), HLA-B*38 (p=0.04), HLA-B*39 (p=0.045), HLA-B*27 (p=0.002) (Table 1). HLA-C*06, the strongest risk allele for psoriasis, was not significantly associated with PsA. However, the test statistics (Z) indicates under-transmission of the allele to PsA compared to siblings with psoriasis.

Table 1. Family based association test Affected (PsA probands)—Unaffected (Psoriasis) sib-pairs and Trios ($N_{families}$ = 204, $N_{Pedigrees}$ = 234)

Allele	Allele frequency	No. Families	Z	P value
HLA-B*07	8.7%	29	−0.8	0.4
HLA-B*08	13.6%	36	−1.4	0.15
HLA-B*13	4.3%	14	−1.2	0.24
HLA-B*14	3.5%	11	−0.03	0.97
HLA-B*18	2.7%	10	0.6	0.52
HLA-B*27	8.5%	33	3.1	0.002
HLA-B*35	7.5%	31	−0.7	0.48
HLA-B*38	4.7%	15	2.0	0.04
HLA-B*39	3.5%	13	2.0	0.045
HLA-B*44	12.8%	41	−0.6	0.57
HLA-B*51	4.1%	15	−1.0	0.29
HLA-B*57	5.7%	23	0.6	0.57
HLA-B*60	5.3%	17	−0.4	0.65
HLA-C*01	4.7%	19	1.4	0.14
HLA-C*02	5.7%	22	1.1	0.27
HLA-C*03	8.9%	27	−1.2	0.22
HLA-C*04	10.9%	37	−1.7	0.09
HLA-C*05	8.2%	26	0.8	0.42
HLA-C*06	12.7%	35	−0.6	0.57
HLA-C*07	27.7%	69	−1.0	0.32
HLA-C*08	3.9%	13	0	1
HLA-C*12	8.7%	28	2.8	0.005
HLA-C*15	2.4%	13	−1.2	0.21
HLA-C*16	3.7%	11	−0.9	0.36

Conclusion: HLA-B*27, B*38, B*39 and C*12 alleles are potential specific genetic markers for PsA among patients with psoriasis.

1354

Enhanced Expression of KIR3DL2 in Natural Killer and CD3/CD4 Positive T Cells of Ankylosing Spondylitis Patients Compared to HLA-B*2705 or B*2709 Healthy Subjects. Alberto Cauli[1], Grazia Dessole[1], Giovanni Porru[1], Alessandra Vacca[1], Matteo Piga[1], Valentina Ibba[1], Pietro Garau[1], Simon Kollnberger[2] and Alessandro Mathieu[1]. [1]University of Cagliari, Cagliari, Italy, [2]Weatherall Institute of Molecular Medicine, Oxford, United Kingdom

Background/Purpose: The precise role of B27 in Ankylosing Spondylitis (AS) has still to be clarified. Among the possible explanation it has been proposed that the expression of beta2-microglobulin(β2m)-free homodimers ($B27_2$) on the cell surface may allow the interaction with KIR3DL2 (which does not bind the β2m-associated B27). Furthermore KIR3DL1 and KIR3DS1 recognise the Bw4 serological epitopes which is present in HLA-B27 and may thus also be relevant. The aim of this study was to evaluate the expression of KIRs possibly involved in the pathogenesis of AS in subjects bearing the HLA-B27 associated and non-associated alleles (B*2705 and B*2709).

Methods: Eighteen HLA-B*2705 AS patients, none on anti-TNF-α treatment, 12 HLA-B*2705 and 12 HLA-B*2709 positive healthy subjects (NC) were recruited from a bone marrow donors bank. No cases of spondyloarthopathy were reported in the family medical history of the NCs. Expression of KIR3DL2, KIR3DL1 and KIR3DS1 was evaluated on peripheral blood CD3−/CD56+ natural killer (NK) cells and CD3+/CD4+ T lymphocytes. KIR expression was evaluated as the percentage of positive cells and as the density of receptor expressed on the cell surface by cytofluorimetric analysis and quantified by comparison with standard beads (antibody binding capacity, ABC units, Dako Denmark). The differences between AS and NCs were analysed by one-way ANOVAs with Bonferroni post test and a two-tailed unpaired t-test with Welch's correction.

Results: KIR3DL2. We observed an increased number of NK cells expressing KIR3DL2 in AS 34.1%, IQR 23.4–47.2 compared with B*2705 NC 21.5%, IQR 13.9–25.9 (p=0.0004) and B*2709 NC 17.3%, IQR 9.0–25.5 (p=0.0007). Furthermore we also observed higher expression of the receptor on the cell surface in AS patients 1354 ABC units, IQR 1091–2048 compared with B27*2705 NC 1062, IQR 806–1244 (p<0.0035) and B*2709 NC 1004, IQR 816–1288 (p<0.0067). Lower percentages of cells staining positively for KIR3DL2 were found among CD4+ T lymphocytes in AS and healthy subjects, but the differences between patients and controls were still statistically significant; in details: AS 1.5%, IQR 1.1–2.2, compared with B*2705 NC 0.8%, IQR 0.5–1.1 (p=0.01) and B*2709 NC 0.9%, IQR 0.7–1.1 (p=0.01). Higher density of KIR3DL2 expression was also detected on the cell surface of CD4 T cells from AS patients 1134 ABC units, IQR 921.5–1134, compared with B*2705 NC 884, IQR 746.3–979.8 (p=0.01) and B*2709 NC 833, IQR 670.8–1042 (p=0.02). We also investigated levels of expression of KIR3DL1 in patients compared with

the NC group but the differences were not statistically significant, both as a percentage of positive cells and as the density of receptors on the cell surface of NK. KIR3DS1 was found to be expressed by 37% of NK cells in only one B*2709 healthy control from the the 42 B27 expressin subjects studied (this subject was negative for KIR3DL1).

Conclusion: This study demonstrates higher expression of KIR3DL2 receptors on NK and CD3/CD4 positive lymphocytes from B*2705 AS patients compared to B*2705 and B*2709 NCs, supporting the possible role of the KIR3DL2/B27$_2$ pair as relevant players in the pathogenesis of AS.

1355

Binding of Killer Immunoglobulin Receptors 3DL1 and 3DL2 Is Associated with Surface Expression of Major Histocompatibility Complex Class I Free Heavy Chains and Human Leukocyte Antigen B27 Presenting Abnormal Peptides. Nigil Haroon and Robert D. Inman. Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON

Background/Purpose: Ankylosing spondylitis (AS) is strongly associated with the HLA B27 subtypes B2704 and 2705 but not with 2706 and 2709. The basis for this important observation has not been defined. We have shown that the B27 subtypes differ in their interaction with ERAP1. Killer immunoglobulin receptors (KIR) KIR3DL1 and KIR3DL2 are known to bind MHC class I free heavy chain (FHC) dimers and could play a role in the pathogenesis of AS. The antibody MARB4 has been shown to detect HLA B27 presenting abnormally long peptides as well as FHC dimers. We addressed whether KIR3DL1 and KIR3DL2 binding correlates with the FHC expression on the cell surface, and whether that differs amongst the B27 subtypes. We also examined the correlation of KIR binding to MARB4 binding in the cell lines.

Methods: C1R cells transfected with different HLA-B27 subtypes (B2704, B2705, B2706, and B2709) were cultured in media till confluent. Cells were stained with the following antibodies: HC10 (for FHC), ME1 (for intact HLA B27), W6/32 (for intact MHC I) and MARB4 (for abnormal peptides). KIR3DL1-Fc and KIR3DL2-Fc chimeras were used in binding assays and detected using goat anti-human Fc IgG. Cells were acquired using a FACScalibur to analyse mean fluorescence intensity (MFI) and analysis performed using Flowjo software. Spearman's correlation was used to analyze the correlation of KIR3DL1 and 3DL2 binding to the binding of HC10, ME1, MARB4 and W6/32.

Results: Surface FHC expression was lower in B2706 and B2705 expressing cells than in the B2709 and B2704 cells: MFI of HC10 was 228 for B2704, 204 for B2705, 183 for B2706, and 262 for B2709. MARB4 MFI was higher in B2704, B2705 and B2709 cells than B2706 cells: 372 (B2704), 304 (B2705), 233 (B2706) and 461 (B2709). The correlations of KIR3DL1 binding with FHC and MARB4 expression were excellent at $R = 0.97$ ($p=0.01$) and $R = 0.96$ ($p=0.01$) respectively. KIR3DL2 bound cells also had excellent correlation with FHC ($R=0.98$; $p=0.01$) and MARB4 expression ($R=0.97$; $p=0.01$). There was no significant correlation of KIR3DL1 or 3DL2 binding cells with ME1 or W6/32 MFI. There was no clear differentiation of AS associated and non-associated B27 subtypes with regards to KIR3DL1 or 3DL2 binding.

Conclusion: KIR3DL1 and KIR3DL2 binding is associated with surface expression of FHC and with MARB4 staining. MARB4 might be detecting a subgroup of HLA B27-peptide complexes identified by KIR or might be reacting with FHC dimers. Further studies on functional impact of KIR binding in the pathogenesis of AS is required.

GDF15, a Distinct TGFb Family Member, Is Differentially Regulated in Spondyloarthritides Compared to Other Rheumatic Diseases. Stijn Lambrecht[1], Julie Coudenys[1], Filip De Keyser[2], Gust Verbruggen[3], Dieter Deforce[4] and Dirk Elewaut[5]. [1]Ghent University, Ghent, Belgium, [2]Universitair Ziekenhuis Gent, Gent, Belgium, [3]Universitair Ziekenhuis, B-9000 Gent, Belgium, [4]Laboratory for Pharmaceutical Biotechnology, Ghent University, Ghent, Belgium, [5]Gent University Hospital, Ghent, Belgium

Background/Purpose: The transforming growth factor-β (TGF-β) superfamily consists of a number of cytokines that regulate a variety of cellular processes. Growth differentiation factor 15 is a distant member of this TGF-β family with limited sequence homology to other members of this group. Its role in inflammatory arthritis is unclear. This study aims to evaluate the role of GDF15 across various inflammatory rheumatic diseases.

Methods: GDF15 levels were determined by ELISA in three different populations. An exploratory study included serum samples from a consecutive cohort of 555 patients where serum was collected initially during diagnostic investigation. A second population constituted of patients with an indication for an arthroscopic procedure for diagnostic purposes. A third consisted of a cohort of RA-patients in which the efficacy of infliximab was evaluated. Synovial tissue biopsies and peripheral blood mononuclear cells (PBMC) were collected, RNA isolated and qPCR for GDF15 conducted. The effect of IL-1 and LPS on GDF15 transcription in PBMC was measured.

Results: In all cohorts, inflammatory rheumatic diseases showed elevated GDF15 levels, except SpA. Interestingly, these patients showed near normal GDF15 serum levels. SpA, but not RA-patients, show a significant higher concentration of GDF15 in synovial fluid compared to serum, pointing to a local production of GDF15 in the synovial joint. In line herewith, GDF15 mRNA levels were markedly higher in synovial tissue versus PBMC, even when stimulated with IL-1 or LPS. In general, no significant correlations were observed between GDF15 serum levels and inflammation markers (CRP, ESR), indicating that GDF15 serum levels might be indicative for a distinct underlying disease process. Moreover, suppression of inflammation by anti-TNFa treatment does not affect GDF15 serum levels.

Conclusion: GDF15 shows an intriguing distribution profile in rheumatic diseases, which is markedly differentially regulated between SpA versus RA and other rheumatic disorders.

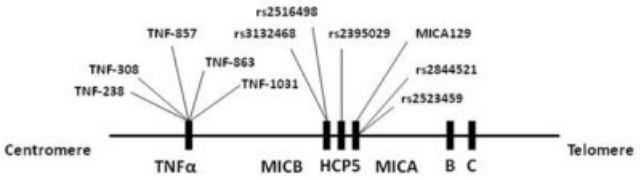
1357

Extended Haplotypes Between Human Leukocyte Antigen-C and Tumour Necrosis Factor A Gene Loci Reveal Psoriatic Arthritis Susceptibility Hotspots. Remy Pollock[1], Fawnda Pellett[2], Renise Ayearst[2], Al Amin P. Rahman[3], Dafna D. Gladman[1] and Vinod Chandran[2]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Memorial University, St Johns, NE

Background/Purpose: Evidence suggests that while psoriasis is strongly associated with alleles of HLA-C, psoriatic arthritis (PsA) susceptibility may lie within the region centromeric to HLA-C that includes HLA-B, *MICA, HCP5, MICB*, and *TNFA* loci. Extensive linkage disequilibrium in the major histocompatibility complex makes identification of the exact PsA disease locus difficult. In carefully phenotyped cohorts of PsA, psoriasis, and control subjects, we examined the linkage of these loci and their putative role in disease susceptibility.

Methods: The following SNPs were genotyped in 451 Caucasian patients with psoriatic disease (PsD) (264 patients with PsA satisfying CASPAR criteria and 187 patients without arthritis (PsC)) and 183 Caucasian controls: rs2523459, rs2844521 (MICA); rs2395029 (HCP5); rs2516498, rs3132468 (MICB); and rs1799964 (TNF-1031), rs1800630 (TNF-863), rs1799724 (TNF-857), rs1800629 (TNF-308), rs361525 (TNF -238) (Figure 1). HLA-B and C typing was performed by PCR-SSO and MICA129Met/Val was assigned from allelic typing performed by PCR-SSP. The Cochran-Armitage trend test was used to identify alleles associated with (PsD) and PsA compared to controls, and differentiate PsA from PsC. Haplotypes were estimated using the EM algorithm and differences between subject groups were analyzed using GoldenHelix® software. Logistic regression was used to test for independent effects of linked alleles.

Figure 1. Map of the psoriatic disease susceptibility region on chromosome 6p21.3



Results: Psoriatic disease was associated with HLA-C*02, *06, *12, B*27, *38, *57, rs2526459, rs2844521, MICA129, rs2395029, and TNF-238. The following haplotypes were significantly associated with PsD: HLA-C*06/B*57/rs2523459C/rs2844521A/MICA129Met/rs2395029G/TNF-238A ($P = 0.01$, $OR = 2.2$), 12/38/C/A/Met/T/G ($P = 0.01$, $OR = 3.7$), and 2/27/C/A/Met/T/G ($P = 0.003$, $OR = 11.5$). Compared to controls, PsA was associated with HLA-C*02, *12, B*27, *38, rs2523459, rs2844521, MICA129, and rs2395029 and the haplotypes: C*12/B*38/rs2523459C/rs2844521A/MICA129Met/rs2395029T ($P < 0.01$, $OR = 4.4$) and 2/27/C/A/Met/T ($P < 0.01$, $OR = 19.4$). When comparing PsA to PsC, PsA was associated with HLA-C*02, *06, *07,

B*08, *27, *57, rs3132468, TNF-1031, TNF-863, TNF-308, and TNF-238 and the haplotypes C*07/B*08/ rs3132468T/TNF-1031T/TNF-863C/TNF-308A/ TNF-238G (P = 0.02, OR = 1.9), 2/27/T/T/C/G/G (P = 0.001, OR = 4.9), and 1/27/T/T/C/G/G (P = 0.03, OR = 3.7). Logistic regression showed that compared to controls, MICA129Met and HLA-C*06 were independently associated with PsD, while MICA129Met, HLA-B*27 and *38 were associated with PsA. Compared to PsC, rs3132468 (MICB) and TNF-863 were associated with PsA, independent of HLA-C*07, B*08, and B*27.

Conclusion: This study suggests that susceptibility haplotypes for PsD extend from HLA-C to *TNFA*, while hotspots for PsA susceptibility exist at HLA-B, *MICB*, and *TNFA*.

1358

Synovial Cytokine Expression in Psoriatic Arthritis and Associations with Lymphoid Neogenesis and Clinical Features. Raquel Celis[1], Raimon Sanmarti[1], Julio Ramirez[2], Antonio Palacin[2], Jose L. Pablos[3] and Juan D. Cañete[4]. [1]Clinic Hospital, Barcelona, Spain, [2]Hospital Clinic, Barcelona, Spain, [3]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [4]Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain

Background/Purpose: Psoriatic arthritis (PsA) is an autoantibody-negative immune-mediated disease where synovial lymphoid neogenesis (LN) occurs. We determined whether LN is associated with specific patterns of inflammatory cytokine expression in paired synovial tissue (ST) and fluid (SF) samples and their potential correlation with the clinical characteristics of PsA.

Methods: ST and paired SF samples were obtained from the inflamed knee of 30 and 15 PsA patients, respectively. ST samples were immunostained with CD3 (T cell), CD20 (B cell), and MECA-79 (high endothelial vessels). Total ST mRNA was extracted and gene expression of CCR7, LT-b, IL-7, IL-10, IL-17A, IL-21, IL-22, IL-23, TNF-a, IL-1b, and IL-6 was measured by quantitative real-time PCR. IL-7, IL-10, IL-12, IL-17A, IL-22, IFN-g, IL-6, TNF-a and IL-23 levels in SF were quantified by ELISA. Clinical and biological data were collected at inclusion and after a median of 25 months follow-u

Results: 12 out of 30 patients (40%) had LN, which correlated with a significantly-higher expression of two molecular markers of LN, CCR7 and LT-b ($p<0.005$ and $p<0.038$, respectively). LN-positive patients had a non-significant trend towards higher IL-23 ($p=0.077$) and TNF-a ($p=0.075$) expression in ST and significantly-higher SF IL-6 levels ($p=0.048$). No other clinical or biological differences were identified in the LN group. In the whole study population, the expression of IL-1b, IL-6, IFN-g and IL-17 correlated with markers of disease activity.

Conclusion: PsA patients with LN show a trend towards higher expression of proinflammatory cytokines. The prognostic significance of this finding should be analyzed in prospective studies.

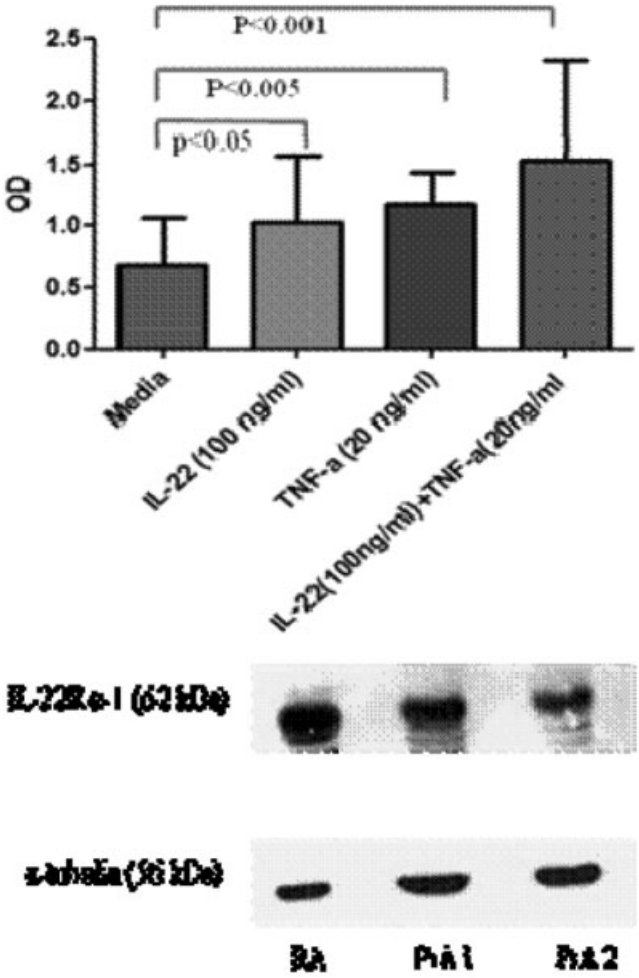
1359

Immunopathogenic Role of IL-22 and Its Receptor In Psoriatic Arthritis: Synergistic Effect of IL-22 and TNF-α In FLS Proliferation. Siba P. Raychaudhuri[1], Anupam Mitra[2], Ananya Datta Mitra[3] and Smriti K. Raychaudhuri[3]. [1]Sacramento VA Medical Center/ UC Davis School of Medicine, Mather, CA, [2]UC Davis School of Medicine/VA Sacramento Medical Center, Mather, CA, [3]VA Sacramento Medical Center, Mather, CA

Background/Purpose: Th17 cytokine IL-22 plays a key role in the proliferation of keratinocytes and fibroblast like synovial (FLS) cells. Based on these functions of IL-22, there are studies reporting its role in the pathophysiology of pannus formation in rheumatoid arthritis (RA) and induction of acanthosis in psoriasis. Synovial hypertrophy and the proliferation of FLS are also the key factors in the pathogenesis of psoriatic arthrthritis (PsA). Here we studied IL-22, IL-22 receptor (IL-22Rα1) and its functional significance in PsA

Methods: We collected synovial fluids (SF) and blood from PsA (n= 10); RA (n=12); and osteoarthritis (OA, n=12) patients. IL-22 in SF and blood was measured by ELISA. FLS were derived from synovial tissues (PsA, n=5; RA, n=5; OA, n=5). MTT and flow cytometric (CFSE) assays were performed to determine IL-22 induced proliferation of FLS. Recombinant TNF-α was used as a positive control for FLS proliferation assays. IL-22Rα1 expression in FLS was identified by western blotting (WB). Samples from RA and OA patients were used as positive and negative control respectively.

Results: IL-22 levels in SF were significantly elevated in patients with PsA (14.02 pg/ml ± 3.61), RA (14.11 pg/ml ± 2.50) in comparison to OA (4.98 pg/ml ± 0.35), $p<0.001$. Serum level of IL-22 was also elevated in patients with PsA (7.87 pg/ml ± 0.84) than in OA (4.45 pg/ml ± 0.50), $p<0.05$. After 5 days of incubation, we observed significant proliferation with recombinant human IL-22 (100 ng/ml) and TNF-α (20ng/ml) in FLS from PsA (OD=1.02±0.12 and 1.17±0.06) compared to media (OD=0.68±0.08), $p<0.05$ (Figure 1). In RA patients too, there was significant proliferation with IL-22 and TNF-α compared to media, $p<0.05$. Moreover in this study, we had a novel observation that IL-22 (100 ng/ml) and TNF-α (20 ng/ml) had a synergistic effect in proliferation of FLS (Figure 1). In the western blot, we found expression of IL-22Rα1 in FLS of PsA, RA and OA (Figure 2).



Conclusion: To our knowledge this is the first report to demonstrate the functional significance of IL-22 in PsA. Here we had a novel observation that IL-22 and TNF-α have a synergistic effect in proliferation of FLS. Pathogenic role of IL-22 and its receptor IL-22Rα1 in psoriatic arthritis opens a new field to develop IL-22/IL-22R targeted therapies in PsA.

1360

Association Between Human Leukocyte Antigen and Killer-Cell Immunoglobulin-Like Receptor Gene Variants and Type II Psoriasis and Dactylitis in Psoriatic Arthritis. Vinod Chandran[1], Fawnda Pellett[1], Arane Thavaneswaran[1], Remy Pollock[1], Renise Ayearst[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: HLA and KIR genes are associated with PsA. However, since the vast majority of patients with psoriatic arthritis (PsA) have associated cutaneous psoriasis it is difficult to determine whether the primary association is with musculoskeletal disease or with skin disease. Markers associated with Type II psoriasis (onset after age 40 years) as well as dactylitis are likely markers for musculoskeletal disease in PsA. We therefore conducted association studies to identify HLA alleles and KIR genes

associated with type II psoriasis as well as with dactylitis in subjects with PsA.

Methods: 135 PsA cases with type II psoriasis and 688 healthy ethnically matched controls were selected to study association between PsA and type II psoriasis. For the study on dactylitis, a case-only study comparing 378 subjects with dactylitis to 299 without dactylitis was performed. KIR typing was performed by PCR-SSP, and HLA typing by PCR-SSO with appropriate quality control. The difference in the frequency of individual markers in cases and controls were tested for significance using χ^2 test and Fisher's exact test. Trends for increasing susceptibility to PsA from combined genotypes (HLA-KIR and HLA) were evaluated by the Cochran-Armitage trend test. Multivariate analyses were conducted using logistic regression.

Results: When comparing PsA with type II psoriasis to controls, HLA-C*01, C*12, B*27, B*38 increased risk, whereas HLA-B*51 decreased risk in univariate analyses. Multivariate analysis showed that only HLA B*27 (OR 3.3, $p<0.0001$, 95% CI 1.94, 5.61) and HLA B*38 (OR 8.95, $p<0.0001$, 95% CI 4.33, 18.49) independently increased risk. HLA-B Bw4 and *KIR2DS2* was also associated with PsA and type II psoriasis. When comparing PsA with dactylitis to PsA without dactylitis only HLA-C *02 and -B*27 was associated with dactylitis in univariate analyses. Multivariate analysis confirmed that both HLA- C*02 (OR 1.85, $p=0.05$, 95% CI 1.01, 3.38) and -B*27 (OR 1.74, $p=0.03$, 95% CI 1.06, 2.85) were independently associated with dactylitis. *KIR2DS2* was also associated with dactylitis in univariate and multivariate analysis.

Conclusion: HLA-C*02, -B*27, -B*38 and *KIR2DS2* may be specific markers for musculoskeletal disease in PsA. These results need to be confirmed in large scale studies comparing well-phenotyped patients with PsA to those with psoriasis without PsA.

1361

Investigating the Association Between Endoplasmic Reticulum Aminopeptidase 1 Gene Variants and Psoriatic Arthritis. Vinod Chandran[1], Fawnda Pellett[2], Remy Pollock[1], Al Amin P. Rahman[3] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Memorial University, St Johns, NE

Background/Purpose: Endoplasmic reticulum aminopeptidase 1 (ERAP1) gene variants are associated with ankylosing spondylitis (AS) and interact with HLA-B*27. ERAP1 gene variants are also associated with psoriasis and interacts with HLA-C*06. Since psoriatic arthritis (PsA) is closely related to AS and psoriasis, and associated with HLA-C and -B alleles, we sought to investigate the association between ERAP1 variants with PsA and its interaction with HLA-C and -B alleles.

Methods: The following ERAP1 SNPs were genotyped in 666 Caucasian patients with PsA satisfying CASPAR criteria and 692 Caucasian controls-rs10050860, rs30187, rs26653. HLA-C and B typing was performed by PCR-SSO. Association between ERAP1 SNPs were investigated using the Armitage trend test. Interaction between the ERAP1 SNPs and HLA alleles B*27, B*38, B*57, C*01, C*02, C*06, C*12 previously shown to be associated with PsA was investigated using logistic regression. To further dissect the genetic relationship between skin and joint disease in PsA, ERAP1 and its interaction with HLA alleles was investigated in 333 Caucasian subjects with chronic plaque psoriasis who did not have PsA (PsC).

Results: The 3 ERAP1 SNPs were genotyped with a success rate of >98% and were in Hardy-Weinberg equilibrium. No association between the 3 SNPs and PsA were demonstrated (trend $p = 0.93, 0.86, 0.77$, respectively). Logistic regression analyses demonstrated interaction between rs10050860 and HLA B*27 (interaction $p < 0.01$), rs26653 and HLA B*57 ($p < 0.01$), rs26653 and HLA C*06 ($p < 0.01$) and rs26653 and HLA C*12 ($p = 0.02$). The association between rs10050860 and PsA was present only in B*27+ cases ($p = 0.01$), whereas the association between rs26653 and PsA was present in B*57+ ($p< 0.01$), C*06+ ($p < 0.01$) and C*12+ ($p = 0.03$) PsA cases and not in PsA cases without these HLA alleles. In patients with PsC, no association with the 3 SNPs was demonstrated (trend $p = 0.71, 0.15, 0.78$, respectively). No interaction between rs10050860 and HLA B*27 and rs26653 and HLA C*12 could be demonstrated. However, interaction between rs26653 and HLA B*57 ($p = 0.02$) and between rs26653 and HLA C*06 ($p = 0.05$) was demonstrated. The association between rs26653 and PsC was present in B*57+ ($p= 0.04$) and C*06+ ($p = 0.06$) PsC cases and not in PsC cases without these HLA alleles.

Conclusion: Our study demonstrated that although ERAP1 variants were not associated with PsA, there is genetic interaction between ERAP1 variants and HLA alleles B*27, C*06/B*57 and C*12 known to be associated with PsA, the associations being present only in those cases having these alleles. Unravelling the genetics of PsA may require investigating PsA subsets defined on the presence/absence of major genetic risk factors such as HLA*B27 or HLA C*06/B*57.

The Association Between Human Leukocyte Antigen and Killer-Cell Immunoglobulin-Like Receptor Gene Variants and the Development of Arthritis Mutilans in Patients with Psoriatic Arthritis. Vinod Chandran, Arane Thavaneswaran, Fawnda Pellett and Dafna D. Gladman. Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Genetic factors may influence the development of Arthritis Mutilans (AM) - the most severe form of psoriatic arthritis (PsA). We therefore conducted a case-only study to identify *HLA* and *KIR* polymorphisms associated with time to development of AM in patients with PsA.

Methods: Data on the presence of AM were obtained form a large cohort. In these cohort plain radiographs of the hands, feet and spine are obtained at baseline and 2-yearly intervals. The radiographs are scored using the validated modified Steinbrocker method by at least 2 rheumatologists by consensus. This methods scores each of 42 joints of the hands and feet on a 0–4 (0 = normal, 1 = soft-tissue swelling/osteopenia, 2 = erosion, 3 = erosion plus joint space narrowing, 4 = total joint destruction) scale. AM was defined as ≥5 joints with grade 4 radiographic damage. Data on the time when AM was first observed was obtained on 610 Caucasian subjects with PsA satisfying CASPAR criteria. HLA typing was performed by PCR-SSO, and KIR typing by PCR-SSP. Since AM is defined by the rapid onset of severe destruction, the principal outcome measure was the time to development of AM after diagnosis of PsA. Parametric survival analyses with interval censoring using a Weibull model adjusted for age at diagnosis of PsA and sex were conducted, HLA and KIR being predictor variables.

Results: The 610 subjects [352 (57.7%) males, mean age at diagnosis of 36 years, mean age at first visit is 43 years, mean duration of PsA 7 years, mean tender joint count 8.6, mean swollen joint count 4.9] had a median number of 3 radiographic assessments during a median follow up of 6.3 years. 97 (16%) subjects developed AM. The median time to development of AM was 1.3 years. Univariate analyses showed that HLA-B*27 and HLA-DQB1*02 alleles were associated with an increased hazard of developing AM whereas the allele HLA-A*11 and -C*04 were associated with a reduced hazard. A trend for association was noticed with HLA-C*02 and -A*29. Multivariate analysis with alleles significant at $p<0.1$ showed that HLA-B*27 (HR 2.14, 95% CI 1.35, 3.41, $p < 0.01$) and -DQB1*02 (HR 1.80, 95% CI 1.18, 2.75, $p < 0.01$) are independently associated with increased hazard whereas HLA- A*11 (HR 0.36, 95% CI 0.14, 0.91, $p = 0.03$) and -A*29 (HR 0.22, 95% CI 0.05, 0.910, $p = 0.04$) are independently associated with reduced hazard of developing AM. Among the KIR genes, only KIR3DS1 (HR 1.56, 95% CI 1.04, 2.36, $p = 0.03$) was associated with the hazard of developing AM. Since KIR3DS1 biologically interacts with HLA-B alleles that carry the amino acid isoleucine at position 80 (HLA- B Bw4 80ile) statistical interaction between KIR3DS1 and HLA-B Bw4 80ile was investigated in a multiplicative model. An interaction between the two genetic markers and the outcome was demonstrated (interaction $p = 0.05$). KIR3DS1 was associated with increased hazard (HR 2.13, 95% CI 1.26, 3.61, $p < 0.01$) of developing AM only in the absence of HLA –B Bw4 80ile.

Conclusion: PsA patients with HLA-B*27, -DQB1*02 and KIR3DS1 have an increased hazard of developing AM, whereas those with HLA-A*11 and A*29 have a reduced hazard. There is genetic interaction between KIR3DS1 and HLA-B Bw4 80ile, the risk associated with KIR3DS1 being present only in the absence of HLA-B Bw4 80ile.

1363

The Association Between Human Leukocyte Antigen and Killer-Cell Immunoglobulin-Like Receptor Gene Variants and the Development of Axial Arthritis Among Patients with Psoriatic Arthritis. Vinod Chandran, Arane Thavaneswaran, Fawnda Pellett and Dafna D. Gladman. Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Genetic factors may influence axial joint damage progression in psoriatic arthritis (PsA).Therefore we conducted a case-only study to identify *HLA* and *KIR* polymorphisms associated with

time to development of sacroiliitis and syndesmophytes in patients with PsA.

Methods: Data on the presence of radiographic sacroiliitis and syndesmophytes were obtained form a large cohort. Data on the time when at least unilateral ≥2 grade sacroiliitis and first syndesmophyte was observed on plain radiographs of the pelvis and spine was obtained on 633 Caucasian subjects with PsA satisfying CASPAR criteria. HLA typing was performed by PCR-SSO, and KIR typing by PCR-SSP with appropriate quality control. The principal outcome was the time to development of sacroiliitis/syndesmophytes after diagnosis of PsA. Univariate and multivariate parametric survival analyses with interval censoring using a Weibull model were conducted. The predictor variables were age at diagnosis of PsA, sex and genetic variables (HLA, KIR).

Results: The 633 subjects (362 (57.2%) males, mean age at diagnosis of 36 years, mean age at first visit 43 years, mean duration of PsA 7 years, tender joint count 8.7, swollen joint count 5.0, had a median number of 3 radiographic assessment during a median follow up of 6.0 years. 336 number of subjects developed sacroiliitis and 218 syndesmophytes. The mean time to development of sacroiliitis was 2.3 (4.9) years and that for syndesmophytes was 4.0 (6.7) years. Univariate analyses showed that HLA C*02, C*12, B*27 and DQB1*0609 alleles were associated with an increased hazard of developing sacroiliitis whereas the allele HLA A*29 was associated with a decreased hazard. Multivariate analysis showed that HLA C*02 [hazard ratio (HR) 1.83, 95% CI 1.34, 2.49, $p < 0.01$], C*12 (HR 1.33, 95% CI 1.01, 1.74, $p = 0.04$), and DQB1*0609 (HR 2.47, 95% CI 1.20, 5.11, $p = 0.01$) alleles were independently associated with an increased hazard of developing sacroiliitis whereas the allele HLA A*29 (HR 0.52, 95% CI 0.31, 0.88, p value = 0.02) was associated with decreased hazard. The activating KIR genes *KIR2DS1, KIR2DS5* and *KIR3DS1* were associated with increased risk of developing sacroiliitis in univariate analyses. Multivariate analysis however showed that only *KIR2DS1* (HR 1.32, 95% CI 1.05, 1.64, p = 0.02) was independently associated with time to development of sacroiliitis. A hierarchical risk depending on the presence/absence of *KIR2DS1* and its HLA-C C group 2 ligands was also demonstrated. With regard to time to development of syndesmophyte, in univariate analysis HLA C*01 and B*27 alleles were associated with an increased hazard; the alleles HLA A*29 and B*07 were associated with a reduced hazard. Multivariate analysis showed that only HLA B*27 (HR 1.66, 95% CI 1.21, 2.29, p value < 0.01) was independently associated with an increased hazard of developing syndesmophyte whereas HLA A*29 (HR 0.39, 95% CI 0.18, 0.85, p value 0.02) was associated with reduced hazard. Analyses of the KIR genes revealed only a marginal protective role for *KIR2DL3*.

Conclusion: Genetic factors are associated with development of sacroiliitis and syndesmophytes among patients with PsA.

1364

Family Based Association Study Confirms Human Leukocyte Antigen Allele Associations with Psoriatic Arthritis. Vinod Chandran[1], Fawnda Pellett[1], Proton Rahman[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]St. Claires Mercy Hospital, St. Johns, NF

Background/Purpose: We have shown in a population-based association study that the HLA alleles B*13, B*27, B*38, B*39, B*57 and DRB1*01 increases risk for PsA whereas the alleles A*03, C*03, B*49, B*51, DRB1*11 and DQB1*0602 are protective. Although less powerful than population-based designs, family-based designs have unique advantages over population-based designs, as they are robust to population stratification and allow both linkage and association to be tested. We therefore conducted a family-based association study to identify alleles in linkage and association with PsA.

Methods: A total of 283 families (202 from Ontario, 81 from Newfoundland, Canada) were recruited. Data from 263 nuclear families (1000 persons) were analyzed. Extracted genomic DNA was amplified by PCR using locus specific primers for each of the HLA-A, -C, -B, -DR and DQ loci. PCR amplicons were identified by Sequence Specific Oligonucleotide (SSO) probes using the reverse line blot technique. Alleles were examined for association with PsA using the family-based association test implemented in the FBAT program version 2.0.3. A family based test statistic (Z value) and p value were calculated. Z of more than 0 indicates over-transmission of the allele, while Z of less than 0 indicates under-transmission. An additive model was specified. Initially, association analyses were carried out using each individual allele. Alleles with < 10 informative families were excluded and significance level was set at $p<0.05$. Subsequently, haplotype based association tests using all 5 markers were also conducted.

Results: The significant results from the family-based association test using individual HLA alleles are given in the table. HLA alleles- A*02, B*27 and DRB1*07 increased risk for PsA, whereas the alleles A*03, A*28, B*51, DRB1*11 and DQB1*0301 were protective. A trend towards increased risk was found with HLA C*12, B*39, B*57, DRB1*16 & DQB1*0303 while a trend towards protection was found with the alleles C*15, B*07 and DQB1*0503. Haplotype analysis showed that A*02 C*06 B*57 DRB1*07 DQB1*0303 formed an extended haplotype that increased risk for PsA. HLA B*27 independently increased risk.

HLA allele	Allele frequency	Number of informative families	Z statistic	P value
A*02	0.309	120	2.783	0.0054
A*03	0.115	63	−2.281	0.0226
A*28	0.034	30	−3.376	0.0007
B*27	0.083	48	3.745	0.0002
B*51	0.035	26	−2.535	0.0112
DRB1*07	0.167	79	2.939	0.0033
DRB1*11	0.073	40	−3.822	0.0001
DQB1*0301	0.175	81	−2.659	0.0078

Conclusion: The results of this largest family-based association study in PsA show that the HLA alleles A*02, B*27 and DRB1*07 increases risk for PsA, whereas HLA A*03, A*28, B*51, DRB1*11 and DQB1*0301 decreases risk. These results partially confirm previously reported population-based study results.

1365

Proteomic Profiling of Synovial Fluid for the Identification of Psoriatic Arthritis Soluble Biomarkers. Daniel Cretu[1], Dafna D. Gladman[2], Fawnda Pellett[3], Eleftherios Diamandis[1] and Vinod Chandran[3]. [1]Mount Sinai Hospital, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON, [3]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: There is a high prevalence of undiagnosed psoriatic arthritis (PsA) in patients seen in dermatology clinics. Identifying soluble biomarkers for PsA will help in screening psoriasis patients for appropriate referral to a rheumatologist as well as provide further insight into disease pathogenesis. However, identification of novel protein biomarkers in peripheral blood is difficult and unreliable. Potential PsA biomarkers are likely to originate in sites of inflammation such as inflamed joints and subsequently enter systemic circulation. Therefore, we aimed to perform in-depth proteomic analysis of synovial fluid (SF) for the identification of putative biomarkers for PsA.

Methods: Using gel filtration and strong cation exchange chromatography, followed by LC-MS/MS on an LTQ-Orbitrap mass spectrometer, we extensively characterized the proteomes of SF from 3 individual PsA patients and 3 individual non-inflammatory (NI) (early OA) controls. All samples were analysed in triplicates. Two strategies were employed for identification of candidate biomarkers: (1) examination of differential protein expression between the PsA and NI controls, (2) tissue specificity analysis through mining of publicly available databases.

Results: Between 255 and 455 non-redundant proteins were identified with two or more peptides in each sample, with a false discovery rate <1.5%. A total of 591 high-confidence proteins were identified from all patient groups, 153 of which were PsA specific, 353 were common to PsA and NI, and 85 were unique to NI. Approximately 70% of proteins were extracellular, unannotated, or cell-membrane bound based on Genome Ontology classification. The three main functional categories of proteins represented in the PsA group based on STRING database are: extracellular matrix repair and destruction, collagen degradation, and complement activation. By applying specific filtering criteria, we obtained a preliminary list of ~40 potential PsA biomarkers, a number of which have been previously identified, such as Cartilage Oligomeric Matrix protein, Matrix Metalloproteinase 3, and S100A9 Protein.

Table 1.

Previously Investigated Biomarkers	Novel Identified Putative Biomarkers
CSF1R Macrophage colony-stimulating factor 1 receptor	NIF3L1 NGG1 Interacting Factor 3-like 1
MMP3 Matrix Metalloproteinase 3	PD3 Phospholipase D3
COMP Cartilage oligomeric matrix protein	ELA2 Elastase 2
COL1A1 Collagen alpha-1(I) chain	EFEMP1 EGF-containing fibulin-like extracellular matrix protein 1
CD14 Monocyte differentiation antigen CD14	ORM2 Alpha-1-acid glycoprotein 2
CRP C-reactive protein	MCAM Cell surface glycoprotein MUC18
CRTAC1 Cartilage acidic protein 1	MRC2 C-type mannose receptor 2

Conclusion: We have developed a high-throughput proteomics platform using LC-MS/MS allowing the delineation of the SF proteome from PsA patients and NI controls. Using this data and publicly available databases we have identified proteins that are differentially expressed, and may serve as putative PsA biomarkers. After validation, these markers will be investigated in the serum as soluble PsA biomarkers.

1366

Association of ERAP1, IL12B and IL23R Gene Polymorphisms with Subphenotypes of Psoriatic Arthritis. Deepak Jadon[1], William Tillett[1], Dinny Wallis[1], Charlotte Cavill[2], Anna Dixon[2], Nicola Waldron[1], Eleanor Korendowych[1], Anne Barton[3] and Neil J. McHugh[1]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]Bath Institute for Rheumatic Disease, Bath, United Kingdom, [3]University of Manchester, Manchester, United Kingdom

Background/Purpose: Genetic studies have demonstrated an association between interleukin-23 receptor (*IL23R*) and interleukin-12 beta (*IL12B*) gene variants and susceptibility to psoriatic arthritis (PsA)[1,2], ankylosing spondylitis (AS)[3] and psoriasis[4]. Endoplasmic reticulum aminopeptidase-1 (*ERAP1*) gene variants have shown association with AS[5] and psoriasis[6].

We now investigate whether single-nucleotide polymorphisms (SNPs) in the genes encoding *ERAP1*, *IL23R* and *IL12B* associate with specific clinical phenotypes within PsA, such as those with spinal involvement of PsA.

Methods: 262 PsA patients (131 males, median age at PsA onset 38 years) living in South-West England were compared with healthy controls derived from the Wellcome Trust Case Control Consortium; 3266 controls for *ERAP1* (rs30187), 5422 for *IL12B* (rs6887695) and 4941 for *IL23R* (rs11209026 and rs7530511) genes.

These SNPs were genotyped in PsA cases and controls using the Sequenom MassARRAY platform.

98.5% of cases fulfilled the CASPAR classification for PsA. The following clinical phenotypes were assessed; age at onset of psoriasis/PsA, number of arthritic joints, axial radiographic disease (defined as spondylitis/sacroiliitis or both), peripheral radiographic erosions, Psoriasis Area Severity Index, nail score and HAQ.

Statistical analysis was performed using the Pearson Chi-Square test or the Mann-Whitney-U test as appropriate.

Results: Genotype frequencies in cases and controls were in Hardy-Weinberg equilibrium.

There was a strong association between rs6887595 (*IL12B*) and PsA, with homozygosity for the major allele being more frequent in PsA than controls (odds ratio 1.7; 95% confidence interval 1.3–2.2; $p<0.001$).

A trend was demonstrated for the minor allele of rs11209026 to be less frequent in patients with erosive joint disease than in those without erosion or controls (6.9%, 13.3% and 12.8%, respectively).

None of the four SNPs associated with the presence of radiological axial disease or other clinical subphenotypes.

Conclusion: We have confirmed a strong association between rs6887595 (*IL12B* gene) and PsA. A trend has been demonstrated between an *IL23R* variant and peripheral erosive disease. Contrary to our hypothesis, no association was demonstrated between these known AS-associated SNPs and the presence of radiological axial disease, non-polyarticular or non-erosive disease that would suggest a PsA subphenotype towards the AS spectrum. *ERAP1* encodes a pair of trimming aminopeptidases located in the endoplasmic reticulum, that have complementary functions in human leucocyte antigen (*HLA*) class 1 peptide presentation. Therefore *ERAP1* in particular may exert an effect dependent on *HLA-B27* and *HLA-Cw6* status, as was demonstrated in a study of psoriasis[6]. We will now explore this with a larger sample size.

ACR/ARHP Poster Session B
Systemic Lupus Erythematosus - Clinical Aspects II
Monday, November 7, 2011, 9:00 AM–6:00 PM

Clinical and Laboratory Correlates in Responders (by the Systemic Lupus Erythematosus Responder Index) in Phase 3 Belimumab Clinical Trials. R.A. Furie[1], Z.J. Zhong[2], W. Freimuth[2] and M. Petri[3]. [1]North Shore-LIJ Health System, Lake Success, NY, [2]Human Genome Sciences, Inc., Rockville, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: To evaluate the clinical and laboratory correlates of SLE Responder Index (SRI) response irrespective of treatment assignment.

Methods: Data from BLISS-52 (NCT00424476) and BLISS-76 (NCT00410384) were pooled, and parameters of importance in week-52 SRI responders were compared with those in SRI non-responders. SRI response was defined as: 1) ≥4-point reduction in SELENA-SLEDAI, and 2) no new British Isles Lupus Assessment Group [BILAG] A or 2 new B scores, and 3) no Physician's Global Assessment worsening [<0.3 points] vs baseline.

Results: Of the 1684 patients enrolled in both studies, 761 were responders to treatment with belimumab (1 or 10 mg/kg) or placebo plus standard therapy and 923 were non-responders using an intention-to-treat analysis. At wk 52, SRI responders had statistically significant improvements in disease activity measures and in the number of improved SELENA-SLEDAI and BILAG organ domains vs non-responders. Significantly fewer responders had SFI flares (all and severe). Significantly more responders reduced corticosteroid use, and fewer increased corticosteroid use at wk 52 vs non-responders. Responders also had greater improvements in complement and anti-dsDNA antibody levels at wk 52 compared with non-responders. Results are summarized in Table 1.

Table 1. Clinical and Serologic Correlates at Week 52 in BLISS-52 and BLISS-76 SRI Responders (SRI R) and SRI Non-responders (SRI NR)

	SRI Response Status		
	SRI R	SRI NR	P value
Patients, n[a]	761	923	
≥4-point SLEDAI reduction, n (%)[a]	761 (100.0%)	35 (3.8%)	<0.0001
≥7-point SLEDAI reduction, n (%)[a]	307 (40.3%)	12 (1.3%)	<0.0001
BILAG improvement (no A's: ≤1B), n (%)[a]	699 (91.9%)	331 (35.9%)	<0.0001
Number of organ domains improved[a]			
SLEDAI, mean ± SE	2.00 ± 0.03	0.39 ± 0.02	<0.0001
BILAG, mean ± SE	1.45 ± 0.03	0.40 ± 0.02	<0.0001
% Change in PGA from baseline (among patients with no 0.3-point worsening at wk 52) (n = 1216), mean ± SE[b]	−58.31 ± 1.17	−34.90 ± 1.75	<0.0001
Prednisone >7.5 mg/d at wk 52, with baseline prednisone ≤7.5 mg/d, n/N (%)[b]	12/290 (4.1%)	89/418 (21.3%)	<0.0001
Prednisone ≤7.5 mg/d at wk 52, with baseline prednisone >7.5 mg/d, n/N (%)[a]	120/471 (25.5%)	70/505 (13.9%)	<0.0001
Patients with SFI flares (all), n (%)	532 (69.9%)	763 (82.7%)	<0.0001
Patients with SFI flares (severe), n (%%)	47 (6.2%)	269 (29.1%)	<0.0001
% Change in anti-dsDNA antibodies (among patients positive at baseline) (n = 913), median (Q1,Q3)[c,d]	−34.21 (−57.04, −0.50)	−26.06 (−50.81, 6.76)	0.014
Normalization of anti-dsDNA antibodies (among patients positive at baseline), n/N (%)[c,d]	69/479 (14.4%)	47/434 (10.8%)	0.10
% Change in C3 (among patients with low C3 at baseline) (n = 585), median (Q1,Q3)[c,d]	14.47 (1.25, 35.46)	8.96 (−4.88, 26.51)	0.0014
Normalization of C3 (among patients with low C3 at baseline), n/N (%)[c,d]	89/292 (30.5%)	74/293 (25.3%)	0.16
% change in C4 (among patients with low C4 at baseline) (n = 740), median (Q1,Q3)[c,d]	40.00 (13.33, 81.82)	28.57 (0.00, 63.64)	0.0035
Normalization of C4 (among patients with low C4 at baseline), n/N (%)[c,d]	134/361 (37.1%)	112/379 (29.6%)	0.03
% Change in CD20+ B cells (n = 542), median (Q1, Q3)[d]	−39.93 (−64.07, 3.56)	−30.20 (−56.28, 12.86)	0.072

[a]Based on dropout = failure; [b]based on last-observation-carried-forward analysis; [c]SRI excluding serology; [d]includes patients with data available at wk-52/primary visit. BILAG, British Isles Lupus Assessment Group; C, complement; PGA, Physician's Global Assessment; SE, standard error; SFI, SELENA-SLEDAI Flare Index; SLEDAI, Systemic Lupus Erythematosus Disease Activity Index.

Conclusion: The SRI is a novel composite endpoint that was created during the development of belimumab and served as the primary endpoint for the pivotal studies that led to approval by regulatory agencies. This analysis, undertaken to explore the clinical significance of an SRI response, demonstrated that patients who are SRI responders have a global benefit that extends well beyond those parameters included in the composite index.

1368

Retrospective Validation of the 3 Laboratory Organ Systems of Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K) Responder Index (SRI-50) Over 10 Years. Zahi Touma[1], Dafna D. Gladman[2], Dominique Ibanez[1] and Murray B. Urowitz[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: SRI-50, a valid and reliable index, measures partial ≥50% improvement in disease activity. A retrospective validation of SRI-50 required that the data is collected in a standardized way as is mandated by SRI-50 definitions and data retrieval form. The data was available on the 3 laboratory out of 9 organ systems of SLEDAI-2K. Our objective was to determine the frequency of ≥50% improvement in the 3 laboratory organ systems over 10 years as determined by SRI-50 definitions.

Methods: Patients who attended the Lupus Clinic from January 2000 to October 2010 and who had a minimum of 6 regular visits (every 4–6 months) were included. All items necessary to calculate the SLEDAI-2K are collected prospectively and tracked on an Oracle database.

Identification of patients with active descriptors at any point during the study period was based on SLEDAI-2K definitions. Identification of the patients who ever showed incomplete improvement, ≥ 50%, during the study, in descriptors at subsequent visits was based on SRI-50 definitions of improvement.

Table 1. SLEDAI-2K definitions and definitions of improvement by SRI-50

Descriptors	Definitions of SLEDAI	Weighted score	Definitions of SRI-50 Improvement	Weighted score
Urinary casts	Heme-granular or red blood cell casts.	‘4	Decrease by ≥50% in the total number of casts (heme-granular red blood cell casts).	‘2
Hematuria	>5 red blood cells/high power field. Exclude stone, infection, or other cause.	‘4	Decrease by ≥50% in the number of red blood cell/high power field	‘2
Proteinuria	New onset, recurrent, or persistent proteinuria of more than > 0.5 gram/24 hours.	‘4	Decrease by ≥50% in the range of proteinuria.	‘2
Pyuria	>5 white blood cells/high power field. Exclude infection.	‘4	Decrease by ≥50% in the number of white blood cells/ high power field.	‘2
Proteinuria	New onset, recurrent, or persistent proteinuria of more than > 0.5 gram/24 hours.	‘4	Decrease by ≥50% in the range of proteinuria.	‘2
Low Complement	Decrease in CH50, C3, or C4 below the lower limit of normal for testing laboratory.	‘2	≥50% increase in the level of any complement or normalization of one of them without a drop in either.	‘1
Increased anti-DNA antibodies levels	Increase in the level of anti-DNA antibodies above normal range for testing laboratory.	‘2	≥50% increase in the level of anti-DNA antibodies	‘1
Thrombocytopenia	<100,000 platelets/× 109/L. Exclude drug causes.	‘2	≥50% increase in the level of platelets but <100,000 platelets/mm3.	‘1
Leukopenia	<3,000 white blood cells/× 109/L. Exclude drug causes.	‘2	≥50% increase in the level of white blood cells but <3,000/ mm3/	‘1

We studied the renal (proteinuria, hematuria, pyuria and/or casts), immunological (complements and/or anti-DNA antibodies), and hematologic (thrombocytopenia and/or leucopenia) systems for which the needed data of SRI-50 was available through the database.

Results: 795 patients were identified. 88% were female, 64% Caucasian, 14% Black, 11% Asian. The length of the study period was 6.1 ± 3.1 years and Adjusted Mean SLEDAI-2K (AMS) was 4.66±3.42. Of the 795 patients, 748 patients (94%) had an active system at some point during the study period. 516 patients had renal, 667 immunological and 207 hematologic active system during the study period. 492 (66%) patients showed incomplete but ≥50% improvement in at least one descriptor as follows:

Of the 516 patients with active renal system, 174 (34%) met the definitions of SRI-50 and showed partial improvement. Of the 667 patients with active immunological system, 420 (63%) partially improved. Of the 207 patients with active hematological system, 52 (25%) partially improved.

Table 2. Frequency of incomplete but ≥50% improvement in active descriptors

Renal System Active Descriptors	Number of Active Patients	Patients who showed incomplete but ≥50% improvement
Overall	516	174 (34%)
Casts	324	32 (10%)
Hematuria	199	57 (29%)
Proteinuria	288	109 (38%)
Pyuria	308	60 (19%)
Immunological System Active Descriptors	Number of Active Patients	Patients who showed incomplete but ≥50% improvement
Overall	667	420 (63%)
Low complement	572	293 (51%)
Increased anti-DNA	542	288 (53%)
Hematological System Active Descriptors	Number of Active Patients	Patients who showed incomplete but ≥50% improvement
Overall	207	52 (25%)
Thrombocytopenia	69	10 (15%)
Leukopenia	166	42 (25%)

Conclusion: SLEDAI-2K scores descriptors as present or absent. None of these would be identified as responders using SLEDAI-2K. Although only the 3 laboratory organ systems were studied, 66% of the patients showed partial, ≥50%, improvement over the study period and thus would be considered responders. Thus, SRI-50 is good instrument to be used in clinical trials in SLE.

1369

Responders in the Phase 3 Belimumab Clinical Trials in Patients with Systemic Lupus Erythematosus Reported Improvements in Fatigue and Health-Related Quality of Life At Week 52. V. Strand[1], S. Cooper[2], Z.J. Zhong[2] and G. Dennis[2]. [1]Stanford University, Palo Alto, CA, [2]Human Genome Sciences, Inc., Rockville, MD

Background/Purpose: The effects of SLE on health-related quality of life (HRQOL) have been shown to be comparable to or worse than those of other chronic diseases such as AIDS, rheumatoid arthritis, diabetes, and congestive heart failure. In two phase 3 studies, patients with autoantibody-positive (antinuclear antibody ≥1:80 or anti-double-stranded DNA ≥30 IU/mL) systemic lupus erythematosus (SLE) and Safety of Estrogens in Lupus Erythematosus National Assessment–SLE Disease Activity Index (SELENA-SLEDAI) score ≥6 on stable standard therapy ≥30 days received belimumab 1 or 10 mg/kg, or placebo, plus standard therapy for 52 wk (BLISS-52 [N=865]; NCT00424476) or 76 wk (BLISS-76 [N=819]; NCT00410384). Primary endpoint: response rate at wk 52 by the SLE Responder Index (SRI): SELENA-SLEDAI improvement (≥4-point decrease), no new British Isles Lupus Assessment Group A or 2 new B scores, and no Physician’s Global Assessment worsening (<0.3-point increase). Wk-52 SRI response rates in patients with placebo, and belimumab 1 and 10 mg/kg, respectively, were 43.6%, 51.4% (p=0.013), and 57.6% (p=0.0006) in BLISS-52; 33.5%, 40.6% (p=0.089), and 43.2% (p=0.017) in BLISS-76; and 38.8%, 46.2% (p=0.006), and 50.6% (p<0.0001) in pooled analysis. Secondary endpoints included patient-reported outcomes (PRO) by Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue and by SF-36® Health Survey.

Objectives: To assess if SRI responses were clinically meaningful, improvements in PRO were compared in responders vs non-responders.

Methods: Pooled analyses of FACIT-Fatigue and SF-36 outcomes at week 52 were compared in patients with vs without an SRI response across all treatment groups.

Results: Baseline SF-36 physical (PCS) and mental (MCS) component summary and domain scores were lower than those of an age- and gender-matched US population. By pooled analysis, reported mean improvements at wk 52 in SF-36 PCS, MCS, and all domain scores in SRI responders were significantly greater than in non-responders, and exceeded minimum clinically important differences of 2.5 (summaries) and 5.0 (domains) points (table). This was also true for improvements in FACIT-Fatigue; improvements in fatigue were consistent with those in the SF-36 vitality domain. As assessed by the SF-36 transition question–“Compared with 1 year ago, how are you today?”—more than twice the number of responders reported they were “somewhat/much better” (76%) or “much better” (34%) compared with non-responders.

Table. Patient-Reported Outcomes: Pooled Analysis (N = 1684)

	SF-36 FACIT-Fatigue	PCS	MCS	VITAL
Baseline, mean score	30.08	39.06	40.81	43.33
Wk 52, mean Δ				
Responders (n = 761)	5.2*	4.9*	4.4*	10.4*
Non-responders (n = 923)	3.0	2.6	1.7	6.5

	SF-36 Domains							
	PF	RP	BP	GH	VITAL	SF	RE	MH
Baseline, mean SF-36 domain score	58.88	52.07	48.53	41.15	43.33	59.48	61.20	59.63
Wk 52, mean Δ								
Responders (n = 761)	10.3*	12.3*	14.9*	9.8*	10.4*	10.8*	9.3*	8.5*
Non-responders (n = 923)	4.5	6.8	7.1	4.9	6.5	3.7	3.3	3.3

	SF-36 Transition Question	
	Somewhat/Much Better (% Patients)	Much Better (% Patients)
Responders (n = 761)	76.1*	33.8*
Non-responders (n = 923)	33.5	14.6

* $p < 0.001$ (all p values are nominal): statistically significant mean changes also exceeded minimum clinically important differences. BP, bodily pain; GH, general health; MCS, mental component summary; MH, mental health; PCS, physical component summary; PF, physical functioning; RE, role-emotional; RP, role-physical; SF, social functioning; VITAL, vitality.

Conclusion: Regardless of treatment group, SRI responders reported statistically significant and clinically meaningful improvements in fatigue and HRQOL, and that their HRQOL was improved from 1 year ago compared with non-responders. The data indicate that SRI responders report improvements meaningful to them.

1370

Early Systemic Lupus Erythematosus Specific Antigens Predict Disease Characteristics. Jessica J. Hale[1], Jennifer A. Kelly[1], Chee Paul Lin[1], Stuart B. Glenn[1], Jourdan Anderson[1], Patrick M. Gaffney[2], Kathy L. Moser[2], John B. Harley[3], Judith A. James[4] and Courtney G. Montgomery[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH, [4]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease, most prevalent in women of child-bearing age. It is characterized by autoantibody production leading to inflammation and ultimately, tissue damage. Some autoantibodies precede clinical disease by several years, are unique to SLE and have antigenic peptide sequences that closely mimic that of a suspected environmental trigger Epstein-Barr Virus (EBV). The objective of this study was to assess the relationship between early humoral autoimmune responses, select viral responses and the varied manifestations of SLE in both European and African American (EA and AA) patients to better characterize SLE etiology.

Methods: Data were collected for 519 AA and 1210 EA female SLE patients. Individual and familial correlation analyses were performed to determine the extent early epitope and viral production are associated with lupus clinical and lab criteria. Data included quantitaive measures of antibodies against: SmB' amino acids (aa) 191–198 (GMR), SmD1 aa 95–119 (GRx4) and 60kDRo aa 169–182 (Ro169), EBV viral capsid antigen (VCA), EBV nuclear antigen 1 (EBNA-1) EBNA-1 aa 398–404 (GRR), ENBA-1 aa 58–72 (EBNA58) and EBNA-1 aa 1–90 and 409–497 (EBNA1M). We also evaluated the 11 ACR criteria, CH50, anticardiolipin (APL) IgG and IgM as well as the following autoantibodies: nuclear (ANA), double stranded DNA (dsDNA), Ro, La, P, nRNP. Transformations were applied where necessary to achieve normality. We assessed self and familial correlations using FCOR (S.A.G.E. software suite) and used a threshold for significance of $5 = 10^{-4}$. Significant correlations were confirmed using linear regression in SAS.

Results: In the EA females, increased levels of EBV-VCA corresponded to the presence of six of the 11 ACR criteria, including hematologic, immune, skin and renal systems ($p<2 = 10^{-4}$). We also found both EBV-VCA and GRR to be significantly correlated with levels of APL-IgG ($p=1.7 = 10^{-4}$ and $4 = 10^{-6}$). Anti-GMR was positively correlated with anti-Sm, -RNP, -dsDNA, -ssDNA, -ANA, as well as IgG antibodies in EAs ($p<1 = 10^{-4)}$ and with anti–Sm, -RNP and –dsDNA in AAs ($p<1 = 10^{-4}$). Anti-GMR was negatively correlated with CH50 titers in both EAs and AAs ($p=1.5 = 10^{-4}$ and $4.9 = 10^{-4}$). Also in both EAs and AA, anti-GRx4 was strongly, negatively correlated with renal involvement ($p=4.6 = 10^{-3}$ and $3.2 = 10^{-3}$). Sibling correlations were significant for anti-GMR in EAs and anti-EBV-VCA in AAs (p=1.2 = 10-5 and 7.5 = 10-4).

Conclusion: High levels of EBV-VCA antibodies predict multisystem involvement in EAs and perhaps AAs as well. Similarly, high levels of anti-GMR in both EAs and AAs are indicative of an array of autoantibodies and of disease severity (as indicated by low CH50 levels). Conversely, high anti-GRx4 levels indicate that a patient is less likely to have renal involvement, regardless of ethnicity. Significant sibling correlations support a genetic component to the interplay of EBV infection and autoimmune response. Finally, the results of this study highlight the potential to predict disease outcome based on early indicators of SLE and a suspected viral trigger.

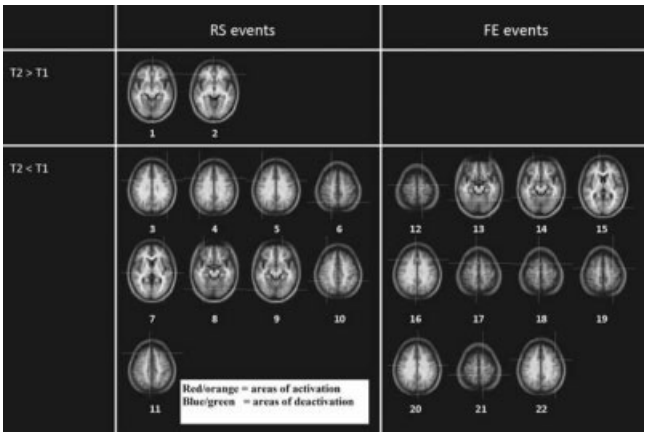
Inefficient Strategic Planning with Compensatory Recruitment of Neural Pathway for Conflict Processing and Error Detection Despite Sufficient Disease Control in Patients with New Onset Systemic Lupus Erythematosus: A Prospective Functional MRI Study. Anselm Mak[1], Tao Ren[2], Erin Hui yun Fu[1], Alicia AC Cheak[1] and Roger CM Ho[1]. [1]National University of Singapore, Singapore, Singapore, [2]National University of Singapore, Sinagpore, Singapore

Background/Purpose: Reliable tools which specifically probe the neuropsychopathology involved in cognitive functioning in patients with systemic lupus erythematosus (SLE) are lacking. Event-related functional magnetic resonance imaging (fMRI) allows excellent demonstration of real-time brain activation signal changes by utilizing the endogenous contrasting property of deoxyhaemoglobin which illuminates active brain areas as blood-oxygen-level-dependent (BOLD) fMRI signals under electromagnetic field. In this study, we used fMRI to address if differences in brain activation pattern existed between SLE patients and healthy controls (HC) and investigate whether unfavourable brain activation persisted even after sufficient control of lupus activity.

Methods: BOLD fMRI signals were recorded while 14 new-onset SLE patients (mean±SD age=39.38±13.9 years; 2 male, 12 female) without clinically-overt neuropsychiatric symptoms and 14 demographically and IQ-matched HC (mean±SD age=34.07±14.4 years; 2 male, 12 female) were performing the computer-based Wisconsin card sorting test (WCST) for assessing executive function which probes goal-directed task performance and strategic planning during response selection (RS) and feedback evaluation (FE) respectively. Composite beta maps were constructed by a general linear model to identify regions of cortical activation. BOLD fMRI signals were compared between (i) new-onset SLE patients and HC and (ii) SLE patients before and after sufficient control of their disease activity.

Results: Performance in WCST between SLE patients and HC, as well as within the SLE group before and after sufficient disease control was comparable. During RS, SLE patients demonstrated significantly higher activation than HC in both caudate bodies and Brodmann area (BA) 9 to enhance event anticipation, attention and working memory, in order to compensate for the reduced activation during FE in BA6, 13, 24 and 32 which serve complex motor planning and decision making, sensory integration, and error detection and conflict processing respectively. Despite significant reduction of SLE activity with conventional immunosuppressive therapies, BA32 was activated during RS to compensate for the reduced activation during FE in BA6, 9, 37 and 23/32, which serve motor planning, response inhibition and attention, color processing and word recognition, and error detection and conflict evaluation respectively (see Figure).



Conclusion: SLE patients recruited additional cortical areas to execute goal-directed tasks in order to compensate for their reduced strategic planning skill even their disease activity was significantly controlled. Targeted research and therapies towards these brain areas may therefore be attractive strategies to elucidate and manage cognitive dysfunction in SLE patients besides conventional therapies of SLE.

1372

The Effects of Smoking on Age of Onset, Autoantibodies and Interferon-α in Systemic Lupus Erythematosus. Kimberly Smith, Stephanie L. Green, Daniel F. Brandt, Beverly S. Franek, Timothy B. Niewold and Tammy O. Utset. University of Chicago, Chicago, IL

Background/Purpose: Environmental effects on SLE are poorly understood. Previous data suggests that smoking increased dsDNA antibody positivity in SLE. We wished to explore the impact of smoking on immunological aspects and age of onset in SLE.

Methods: 214 ambulatory patients fulfilling ACR criteria for SLE were enrolled in a clinical database at the University of Chicago. SLE history, smoking history, and demographics were obtained using standardized questionnaires. Serologic data was obtained by chart review; current titer was the titer performed nearest the time of study enrollment. In a subset of patients (N=72), interferon-α levels by WISH assay were also available. Associations between never-smokers/ever-smokers, current-smokers/other, high IFN-α, and autoantibodies were evaluated using Chi square, Fisher's exact test and multivariate regression. The association between smoking status, high IFN-α, and current/everpositive autoantibody titers were evaluated using Wilcoxon Rank-Sum analysis and logistic regression.

Results: Current anti-dsDNA titers were higher in never-smokers vs. ever-smokers (median 10 vs. 0, $p<0.01$). Never-smokers also had higher current titers of anti-Smith (mean 27 vs. 17, $p=0.01$), anti-SSA (mean 48 vs. 36, $p=0.01$), anti SSB (mean 14 vs. 7.7, $p=0.02$), and anti-RNP (mean 48 vs. 33, $p=0.01$) compared to ever-smokers. Additionally, the highest titers of anti-dsDNA were found in non smokers (median 160 vs. 22.5 in smokers, $p=0.02$). Similarly, the highest titers of anti-Smith (mean 35 vs. 26, $p=0.03$), anti-SSA (mean 54 vs. 40, $p=0.05$), and anti-RNP (mean 55 vs. 37, $p<0.01$) were found in never-smokers. IFN-α was lower in patients who had ever been smokers (high IFN-α in 44% of ever-smokers vs 69% of nonsmokers, $p=0.044$). However, total IgG did not differ between smoking groups. High IFN-α was not associated with current/ever-positive dsDNA, Sm or SSA, but both current and ever-positive RNP were associated with high IFN-α ($p=0.0008$ and $p=0.001$ respectively). On logistic regression of RNP positivity with pack-years, age and high IFN-α, smoking no longer correlated with RNP positivity (p=NS) while high IFN-α significantly correlated with RNP ($p=0.002$).

Furthermore, age of SLE onset appears to be later in smokers. In patients diagnosed after age 20 (N=164), the mean age of diagnosis in never-smokers was 34.6 vs. 39.2 in ever-smokers ($p=0.0013$). On multivariate regression of the age of onset by pack-years smoking, race/ethnicity, high IFN-α and education, the only significant relationship was between increased pack years and later age of SLE diagnosis ($\beta=0.22$, $p=.019$)

Conclusion: Smoking has been linked to numerous autoimmune diseases. In most diseases, smoking has a harmful effect. Our data suggests that smoking may suppress autoantibody production and delay age of onset in patients with SLE, similar to the protective effects seen in ulcerative colitis. As adjustment for high IFN-α obviates the association of smoking with RNP antibody, it is possible that the effects of smoking on autoantibodies is mediated by IFN-α.

1373

25-Hydroxyvitamin D Levels Are Inversely Correlated with Systemic Lupus Erythematosus Disease Activity Index, but Are Not Associated with Relapse-Free Survival During Six Months Follow-up of 171 Patients Included in a French Prospective Multicentric Cohor. Yoland Schoindre[1], Moez Jallouli[2], Benjamin Terrier[3], Marie-Laure Tanguy[2], Zahir Amoura[2], Jean-Charles Piette[2], Patrice Cacoub[2], Jean-Claude Souberbielle[4], Nathalie Costedoat-Chalumeau[2] and The group PLUS[5]. [1]Foch Hospital, Suresnes, France, [2]CHU Pitié-Salpêtrière, Paris, France, [3]Pitié-Salpêtrière Hospital, Paris, France, [4]CHU Necker, Paris, France, [5]Paris

Background/Purpose: Immunomodulatory actions of vitamin D, especially on self-tolerance and B-cell homeostasis, have been well documented, and growing evidence suggests the vitamin D plays a key role in the pathogenesis and progression of autoimmune diseases. Recent studies have found an association between lower serum 25-hydroxyvitamin D [25(OH)D] levels and higher systemic lupus erythematosus (SLE) disease activity. None of them studied the role of [25(OH)D] level in predicting SLE flares. The objectives of this study were to assess the relationship between serum 25(OH)D levels and disease activity and the disease flare during a follow-up of 6 months.

Methods: This study is ancillary to the PLUS study (ClinicalTrials.gov number n°NCT00413361), a randomized prospective, double-blind, placebo-controlled multicenter trial aimed at determining whether increasing the HCQ dosage to achieve an [HCQ] ≥1000 ng/mL reduces the risk of SLE flare. Serum 25(OH)D levels were measured in the M1 serum of the 171 randomised SLE patients who were followed-up 6 additional months.

Results: The mean SLEDAI score was 2.03 ± 2.43, and 12.3% patients had active disease defined by a SLEDAI ≥6. The mean 25(OH)D level was 20.6 ± 9.8 ng/mL. Thirty-one (18.2%) subjects had optimal vitamin D levels [25(OH)D ≥30 ng/mL], vitamin D deficiency [25(OH)D <10] was observed in 27 (15.9%) and vitamin D insufficiency [10 ≤25(OH)D <30] in 112 (65.9%) patients. In multivariate analysis, younger age (p = 0,016), higher body mass index (p = 0,007), photosensitivity (p = 0,034), absence of defined APS (p = 0,0004), and higher SLEDAI (p = 0,036) were associated with lower 25(OH)D levels. The mean SLEDAI scores were 2.6, 1.7 and 1.3 in subjects with deficiency, insufficiency, and optimal vitamin D levels, respectively. SLEDAI score was ≥6 in 3 (11.1%) patients with deficiency, 10 (8.9%) patients with insufficiency, and in 2 (6.5%) patients with optimal vitamin D status. The mean 25(OH)D level was not different in patients who developed flares during the 6 months of follow-up and in patients who did not (p = 0,8). Relapse-free survival was not statistically different in patients with 25(OH)D levels <10 ng/mL compared with those with 25(OH)D levels ≥10 ng/mL (p = 0,17), or in patients with 25(OH)D <30 ng/mL compared with those with 25(OH)D levels ≥30 ng/mL.

Conclusion: Similarly to others, we found a low vitamin D status in a vast majority of patients, and an inverse correlation between 25(OH)D levels and disease activity. These results raise the question of whether achieving and maintaining an optimal vitamin D status through adequate supplementation is associated with a reduction in the risk of SLE flare. Nevertheless, there was no association between 25(OH)D levels and relapse-free survival. Further studies should prospectively assess the effect of vitamin D supplementation on disease activity and outcomes in SLE.

1374

Association of Discoid Lupus with Clinical Manifestations and Damage Accrual in PROFILE: A Multiethnic Lupus Cohort. Yesenia C. Santiago-Casas[1], Luis M. Vila[1], G. McGwin Jr.[2], Michelle Petri[3], Rosalind Ramsey-Goldman[4], John D. Reveille[5], Robert P. Kimberly[2], Graciela S. Alarcon[2] and Elizabeth E. Brown[6]. [1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]Department of Medicine and Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Discoid lupus erythematosus (DLE) is the most common form of chronic cutaneous lupus and occurs in 15%–30% of patients with systemic lupus erythematosus (SLE). It is more common in African Americans and smokers. However, the association of DLE with other clinical features of lupus has not been clearly established. The aim of this study was to determine the association of DLE with clinical manifestations and disease damage in a large multiethnic SLE cohort.

Methods: SLE patients (per ACR criteria), age ≥ 16 years, disease duration ≤ 10 years at enrollment, and defined ethnicity (African American, Hispanic or Caucasian), from a longitudinal cohort were studied. Socioeconomic-demographic features, clinical manifestations and disease damage [as per the Systemic Lupus International Collaborating Clinics Damage Index (SDI)] were determined. The association of DLE with clinical manifestations and disease damage was examined using multivariable logistic regression adjusting for age, gender, race/ethnicity, disease duration, years of education, and smoking.

Results: A total of 2,228 SLE patients were studied. The mean (standard deviation, SD) age at diagnosis was 34.3 (12.8) years and the mean (SD) disease duration was 7.9 (6.0) years; 91.8% were females. Discoid lupus was observed in 393 (17.6%) of patients with SLE. In the multivariable analysis, patients with DLE were more likely to have malar rash (odds ratio [OR] 1.28, 95% confidence interval [95% CI] 1.02–1.62), photosensitivity (OR 1.66, 95% CI 1.30–2.13), oral ulcers (OR 1.35, 95% CI 1.07–1.70), leukopenia (OR 1.46, 95% CI 1.16–1.83) and vasculitis (OR 1.62, 95% CI 1.22–2.13), but less likely to have arthritis (OR 0.73, 95% CI 0.54–0.99), end-stage renal disease (ESRD) (OR 0.42, 95% CI 0.19–0.93), and antinuclear (OR 0.52, 95% CI 0.31–0.88), anti-dsDNA (OR 0.64, 95% CI 0.51–0.80) and anti-phospholipid antibodies (OR 0.71, 95% CI 0.52–0.98). No association was found with overall renal involvement. Patients with DLE had more damage accrual (OR 1.07, 95% CI 1.02–1.13), as well as some individual components of the SDI including chronic seizures (OR 1.84, 95% CI 1.08–3.13), alopecia (OR 5.71, 95% CI 3.91–8.35), scarring of the skin (OR 14.66, 95% CI 8.67–24.81), and skin ulcers (OR 2.43, 95% CI 1.06–5.60).

Conclusion: In this cohort of SLE patients, discoid lupus was associated with mucocutaneous manifestations, integument damage, leukopenia, vasculitis, and chronic seizures, but a lower frequency of arthritis, ESRD and immunologic abnormalities. Our findings highlight the importance of surveillance of SLE patients with DLE, particularly because of the association with serious manifestations such as vasculitis and seizures.

1375

Anti-C1q Antibody in Systemic Lupus Erythematosus. Ana-Maria Orbai[1], Gunnar K. Sturfelt[2], Ola Nived[3], Hong Fang[1], Graciela S. Alarcón[4], Caroline Gordon[5], Joan T. Merrill[6], Paul R. Fortin[7], Ian N. Bruce[8], David A. Isenberg[9], Daniel J. Wallace[10], Rosalind Ramsey-Goldman[11], Sang-Cheol Bae[12], John G. Hanly[13], Jorge Sanchez-Guerrero[14], Ann E. Clarke[15], Cynthia Aranow[16], Susan Manzi[17], Murray B. Urowitz[18], Dafna D. Gladman[19], Kenneth C. Kalunian[20], Melissa I. Costner[21], Laurence S. Magder[22], Systemic Lupus International Collaborating Clinics (SLICC)[23] and Michelle Petri[1]. Health, Montreal, QC, [16]Feinstein Institute for Medical Research, Manhasset, NY, [17]Allegheny Singer Research Institute, Pittsburgh, PA, [18]Toronto Western Hospital and University of Toronto, Toronto, ON, [19]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [20]UCSD School of Medicine, La Jolla, CA, [21]North Dallas Dermatology Assoc, Dallas, TX, [22]University of Maryland, Baltimore, MD, [23]Chicago

Background/Purpose: Anti-C1q antibody has been associated with SLE and SLE nephritis in single-center studies. We studied anti-C1q antibody specificity for SLE (vs. rheumatic disease controls) and its association with SLE manifestations in an international multi-center study.

Methods: Information and blood samples were obtained from 308 patients with SLE and 389 patients with other rheumatologic diseases from 25 clinical sites (84% female, 68% Caucasian, 17% African descent, 8% Asian, 7% other). Anti-C1q antibody was measured by an ELISA using IgG antibodies against the collagen-like region of C1q (anti-C1qCLR). P-values were calculated based on the chi-square test (SAS Institute, Cary, NC, USA).

Results: The prevalence of anti-C1q antibody was 28% (86/308) in SLE patients and 13% (49/389) in controls (P-value <.0001), odds ratio 2.7 (95% CI: 1.8, 4.0). By the submitting diagnosis, the frequency of anti-C1q antibody in controls was: 26% in scleroderma, 19% in rheumatoid arthritis, 15% in undifferentiated connective tissue disease, 15% in chronic cutaneous lupus, 14% in Sjögren syndrome, 8% in fibromyalgia, 7% in antiphospholipid antibody syndrome, 6% in dermatomyositis, and 5% in vasculitis.

Table 1. Association between Demographic Characteristics and Anti-C1q Antibody in SLE: Percentage of Patients with Anti-C1q Antibody, by Demographic Variables

		Percentage for Anti-C1q	P-value
Ethnicity	African Descent	21.7	0.15
	Caucasian	27.6	
	Asian	40.5	
	Other	30.0	
Gender	Female	26.9	0.25
	Male	36.4	
Age	≤30	35.5	0.017
	>30	23.0	

Table 2. Association between ACR Criteria and Anti-C1q Antibody in SLE: Percentage of Patients with Various Clinical Conditions, by Anti-C1q Status

	Positive Anti-C1q (%)	Negative Anti-C1q (%)	P-value	Odds Ratio (95% CI)	Adjusted P-value for Age
Malar Rash	47.7	46.9	0.90	0.9 (0.5, 1.5)	0.69
Discoid Rash	19.8	19.4	0.94	1.1 (0.6, 2.1)	0.71
Photosensitivity	53.5	53.2	0.96	1.0 (0.6, 1.7)	1.00
Oral Ulcers	38.4	46.4	0.20	0.7 (0.4, 1.1)	0.14
Arthritis	64.0	65.8	0.76	0.9 (0.5, 1.5)	0.70
Serositis	37.2	34.7	0.68	1.1 (0.6, 1.8)	0.84
Pleurisy	31.4	28.4	0.60	1.1 (0.6, 1.9)	0.74
Pericarditis	14.0	12.2	0.67	1.2 (0.6, 2.5)	0.66
Proteinuria	50.0	22.5	<.0001	3.0 (1.7, 5.1)	<.0001
Urinary casts	18.6	7.2	0.0033	2.6 (1.2, 5.4)	0.015
Seizure	5.8	4.1	0.51	1.2 (0.4, 3.8)	0.72
Psychosis	3.5	0.5	0.035	9.5 (0.9, 98.5)	0.059
Hematologic	64.0	58.1	0.35	1.2 (0.7, 2.0)	0.49
Leukopenia	40.7	35.1	0.36	1.2 (0.7, 2.0)	0.48
Lymphopenia	38.4	36.5	0.76	1.1 (0.7, 1.8)	0.73
Thrombocytopenia	15.1	12.2	0.49	1.1 (0.5, 2.2)	0.86
Anti-dsDNA	77.9	47.8	<.0001	3.4 (1.9, 6.1)	<.0001
Anti-Smith	33.7	14.4	0.0001	2.8 (1.5, 5.0)	0.0007
Antiphospholipid	57.0	54.5	0.70	1.1 (0.7, 1.8)	0.70

Table 3. Association with Renal Lupus: Percentage of Patients with SLE Serologies among those with and without Lupus Nephritis

Variable	Renal Lupus (%)	No Renal Lupus (%)	P-Value	Odds Ratio (95% CI)	Adjusted P-value for Age and Race
Anti-C1q	45.5	19.3	<.0001	3.2 (1.8, 5.6)	<.0001
Anti-dsDNA	80.2	44.4	<.0001	4.7 (2.5, 8.6)	<.0001
Anti-Smith	29.7	15.0	0.0023	1.9 (1.1, 3.6)	0.03
Low complement	78.2	50.2	<.0001	2.8 (1.5, 4.9)	0.0006

Conclusion: Anti-C1q antibody was found in 28% of SLE patients, although it was also found in other rheumatologic diseases. It was more common in Asians than in Caucasians or patients of African descent. In terms of SLE manifestations, it was associated with renal lupus, anti-dsDNA antibody, low complement and anti-Smith antibody. Anti-C1q antibody was more highly associated with renal lupus than anti-Smith antibody was. Although complexities of the assay have limited its introduction as a routine test, these data clearly point to its utility in SLE, especially in lupus nephritis.

1376

Comparison of Health-Related Quality of Life, Disease Damage, Disability, Age and Disease Duration in Pediatric Lupus Across Different Continents: An Expanded Sample. Lakshmi Nandini Moorthy and the International SMILEY Collaborative Group[1]. [1]UMDNJ/RWJ Medical School, New Brunswick, NJ

Background/Purpose: Simple Measure of Impact of Lupus Erythematosus in Youngsters© (SMILEY©) is a brief, 24-item health-related quality of life (HRQOL) assessment tool for pediatric systemic lupus erythematosus (SLE). Responses are in the form of a 5-faces scale for easy comprehension. SMILEY© is valid in US-English and we are conducting cross-cultural validation of SMILEY©. Our objective was to compare SMILEY© scores in different countries from North (N) and South (S) America, Europe and Asia.

Methods: Children ≤18 years with SLE and their parents completed the appropriate SMILEY© translation, as well as gold standard quality of life (QOL) and physical function scales. Demographic, medication and SLE–related data were obtained. We compared the means of age, child reports of SMILEY© total score and domain scores, PedsQL™ generic module total score, Child Health Assessment Questionnaire (CHAQ) disability index, and Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI). Depending on the data distribution of the above variables, we used one-way ANOVA or the Kruskal-Wallis (KW) test. Because of the limited sample size for some countries, we have combined data by continents.

Results: 436 children (356 girls) and 407 parents participated from: N. America (US=170, Mexico=10, Puerto Rico=7), S. America (Brazil= 89, Argentina=11), Europe (Italy=16, Spain=15, Denmark=14, Netherlands=10, France=8, UK=7), and Asia (China=29, Japan=17, Turkey=17, Saudi Arabia=5, India=10, Israel=1,). The mean disease duration was

37±36 months (median=26 months; range=1 – 188 months, n=397). Table 1 shows the comparison of the means/medians of child/parent reports of the SMILEY© (total/domain scores), PedsQL™ total score, parent CHAQ disability index, and SDI. There were significant differences found in damage and HRQOL score (PedsQL™ and SMILEY©). The children from Asia had the best child-reported generic and disease-specific HRQOL and the children from N. America had the worst HRQOL. Further, there were differences in the domains, Effect on self and Social, across the countries; but no differences in the domains of Limitation and Burden of SLE suggesting that these aspects may be similar across the world in children with SLE. The parent-report of HRQOL did not always follow the trend of the child-report HRQOL.

Table 1. HRQOL, SLE-damage, duration and age

	North America	South America	Europe	Asia	P Value
SDI	0.72 ± 1.4 (0–10, 181)	0.43 ± 1.0 (0–5, 87)	0.25 ± 0.7 (0–4, 69)	0.34 ± 0.8 (0–3, 44)	0.03 (KW)

Child					
Parent					

Conclusion: In the analysis, differences in HRQOL, disease duration and damage are found. Disease status, age, attitudes, and cultural differences can influence HRQOL. Although there are far more patients from the N. America, these results provide interesting patterns of HRQOL differences across the world. We are continuing to enroll from the above centers and from additional centers to expand our sample and exploring these differences further.

Systemic Lupus Erythematosus (SLE) and Vitamin D (Vit D) Deficiency Are Associated with Shorter Telomere Length. Brett M. Hoffecker[1], Laura M. Tonks[2], Tamara K. Nowling[1] and Diane L. Kamen[1]. [1]Medical University of SC, Charleston, SC, [2]UNC Chapel Hill, NC

Background/Purpose: Premature shortening of telomere length, a marker of cellular senescence, has been observed in patients with SLE and in a population deficient in vit D. Vit D deficiency, alarmingly prevalent among African Americans with SLE, has important implications for health. Our study tested whether leukocyte telomere length (LTL) shortens more rapidly with SLE and if this would be compounded by vit D deficiency. Gullah African Americans enrolled in the SLE in Gullah Health (SLEIGH) case-control study are ideal to address this hypothesis because of genetic homogeneity with low non-African admixture.

Methods: Comparisons were made between female SLE patients (n=59, age 39.9 +/−11.6 years) and age- and gender-matched controls (n=59, age 39.9 +/− 11.6 years) from SLEIGH. Relative LTL was determined in triplicate by monochrome multiplex qPCR using stored DNA, with human Jurkat T cell line DNA used as standard on each plate. Serum 25-hydroxyvitamin D (25-D) was determined by RIA. Disease activity (SLEDAI), damage (SLICC) scores and SLE criteria (ACR) were compared among patients at baseline (n=59) and follow-up visits (n=29).

Results: SLE patients had shorter LTL (0.526 +/−0.166) compared to matched controls (0.581 +/−0.017), p=0.049. Age was inversely correlated with LTL (N=118, rho=−0.2, p=0.031) and higher baseline age predicts shorter (<=0.56) LTL, p=0.004. At baseline, subjects with deficient serum 25-D (<20 ng/mL, n=62) had shorter LTL (p=0.003). Among SLE patients, 25-D increased from 19.8 +/−12.9 to 29.3 +/−12.7, p<0.001, over a mean of 2.8 +/−1.9 yrs, without a significant change in LTL detected. Among patients with SLE no significant correlations between LTL and SLEDAI score, SLICC score, presence of end-stage renal disease (n=8), or number of ACR SLE criteria were found.

Conclusion: We found that Gullah African American SLE patients have shorter LTL compared to Gullah controls matched for gender and age. We found also that 25-D deficiency correlates with shorter LTL. These observations are consistent with autoimmunity and low vit D status contributing to cellular aging. Further studies are needed to determine if replacement of vit D can impact clinical expression of SLE and/or LTL shortening.

1378

Systemic Lupus Erythematosus Responder Index Assessment of Responders in EMBLEM, a Phase IIb Study in Patients with Moderate to Severe Systemic Lupus Erythematosus. Michelle Petri[1], Marilyn C. Pike[2], Lexy Kelley[3], Brian Kilgallen[4] and Caroline Gordon[5]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Med Pharm Consulting Inc, Cambridge, MA, [3]UCB, Smyrna, GA, [4]UCB, Brussels, Belgium, [5]Medical School, Birmingham, United Kingdom

Background/Purpose: Epratuzumab is an anti-CD22 monoclonal antibody under development for SLE. EMBLEM (SL0007 [NCT00624351]) was a randomized, multicenter, placebo-controlled, double-blind, phase IIb study. SLE is complex and challenging to evaluate. EMBLEM used a novel composite endpoint, the BILAG-based Composite Lupus Assessment (BICLA). Efficacy was seen at Week 12 after 4 doses of i.v. epratuzumab 600 mg weekly and 2 doses of 1200 mg every other week (treatment effect 24.8% and 19.4%). Another composite endpoint, the SLE Responder Index (SRI), was developed from the belimumab phase II program for use in phase III. The aim of this post-hoc analysis was to better understand drivers of response, by assessing subject response in EMBLEM using the SRI.

Methods: BICLA responders required: 1) BILAG-2004 improvement (BILAG A to B/C/D, BILAG B to C/D, and no BILAG worsening); 2) no deterioration in SLEDAI total score; 3) no worsening in physician's global assessment (PGA) by > 10%; and 4) must not have received non-protocol treatment. SRI responders required: 1) a reduction in total SLEDAI score of ≥ 4 points; 2) no new BILAG A or no more than 1 new BILAG B domain score; 3) no worsening in PGA by > 10%; and 4) must not have received non-protocol treatment. For both endpoints, patients not fulfilling all criteria or dropping out early were considered non-responders.

Results: Baseline mean total SLEDAI and BILAG scores in the whole study population were 14.8 and 15.2. Baseline characteristics were comparable between arms except for the number of SLEDAI 8-point items. SRI responder rate was higher than BICLA responder rate in all arms, with pronounced differences in the placebo, 1200 mg EOW and 1800 mg EOW arms (Table). Responder classification matched for most (166/227, 73%) subjects. Of subjects who differed (61/227, 27%), most (47/61, 77.0%) were BICLA non-responders but SRI responders. Of these, in 77% of cases response was due to improvement from baseline in a single item (SLEDAI 8 points, vasculitis [n = 7] or lupus headache [n = 15]; 4 points, arthritis [n = 14]), Overall SRI improvement requirement (≥ 4 point SLEDAI improvement) was more frequently achieved than BICLA improvement requirement (BILAG improvement): 121 [53.3%] pts vs 81 [35.6%] pts. Increasing SLEDAI cutoff to ≥ 6 and ≥ 8 points lowered placebo response to 39.5% and 31.6% but did not discriminate active therapy better.

Table. Comparison of responder rates and treatment effect in EMBLEM™ seen with BICLA and SRI endpoints

	Placebo (n = 38)	Epratuzumab 100 mg EOW (n = 39)	Epratuzumab 400 mg EOW (n = 38)	Epratuzumab 800 mg EOW (n = 37)	Epratuzumab 1200 mg EOW (n = 37)	Epratuzumab 1800 mg EOW (n = 38)
BICLA response rate	8 (21.1%)	12 (30.8%)	10 (26.3%)	17 (45.9%)	15 (40.5%)	9 (23.7%)
SRI response rate	19 (50.0%)	14 (35.9%)	12 (31.6%)	18 (48.6%)	23 (62.2%)	18 (47.4%)
Difference	+11 (+28.9%)	+2 (+5.1%)	+2 (+5.3%)	+1 (+2.7%)	+8 (+21.7%)	+9 (+23.7%)

EOW = every other week ×2 doses; QW = every week ×4 doses

Conclusion: BICLA and SRI are composite endpoints developed to improve SLE trial assessment. In this analysis of EMBLEM data, disagreement in BICLA and SRI response rates was driven by baseline distribution of items with high SLEDAI weights: greatest difference was seen in groups with more 8-point SLEDAI items at baseline. In SLE trials, assessment of individual SLEDAI and BILAG items should be monitored for consistency. Further work on the application of composite endpoints to SLE trials is warranted.

1379

Corticosteroid Use and Associated Risk of Adverse Events in Patients with Systemic Lupus Erythematosus: A Retrospective Claims Analysis.
Manan Shah[1], Sham Chaudhari[1], Trent McLaughlin[1], Hong Kan[2], Benno Bechtel[3] and Charles T. Molta[4]. [1]Xcenda, LLC, Palm Harbor, FL, [2]GlaxoSmithKline, Research Triangle Park, NC, [3]GlaxoSmithKline, Munich, Germany, [4]GlaxoSmithKline, Philadelphia, PA

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by acute and chronic inflammation of various body tissues. Corticosteroids (CS) are often required to reduce inflammation and organ damage. However, CSs are associated with potential adverse events (AEs) when given in high doses or for prolonged periods. Little to no data are currently available on what the true risk of AEs might be among CS users within an SLE population.

Methods: A retrospective, cohort design using administrative claims data (study period: 1/1/2000–6/30/2010) was employed. Patients ≥18 years having at least 2 outpatient medical claims or 1 inpatient/emergency room claim with a primary/secondary SLE diagnosis (ICD-9-CM code 710.0x) from 07/01/2000–12/31/2007 were identified, with the index date deemed as date of first SLE diagnosis. Patients were required to have a prescription for CS within 6 months of their index date. Occurrence of CS-related chronic and acute AEs (Table 1) was assessed during the 24 months following CS initiation and compared to SLE patients with no exposure to CS during the same time period. CS users and non-users were required to be free of AEs during the 6-month period prior to index date. Risk differences in the development of each AE were determined using multivariate Cox proportional hazards models. To attenuate residual confounding, each model accounted for all measurable confounders including patient characteristics, SLE severity, other SLE treatments and risk factors (other than CS) associated with AEs.

Results: 989 SLE patients received CS and 1728 SLE received no CS in the sample. Patients receiving CS were younger (47.9 vs 49.7 years, $P=0.003$) and more likely to be female (88.8% vs 85.4%, $P=0.013$) than SLE patients with no CS use during the study period. After adjusting for baseline differences, the risk of each AE associated with CS use is highlighted in Table 1. SLE patients receiving CS were more likely to develop pneumonia, herpes zoster, fungal infections, cataracts, sleep disturbances, hypertension, type II diabetes, migraines and nausea/vomiting than SLE patients with no exposure to CS. There was no significant association between CS use and the remainder of AEs studied (Table 1). Under-coding of AE and short follow-up time may be contributors to the lack of association.

Table 1. Results of Adjusted Cox Proportional Hazards Models (Risk of AEs in CS Users Compared to Non-Users)

Adverse Event	CS Use Relative to No CS Use Hazard Ratio (95% Confidence Interval)
Chronic Adverse Events	
Depression	1.21 (0.959, 1.52)
Bipolar	1.48 (0.672, 3.24)
Osteoporosis	1.13 (0.849, 1.50)
Sleep disturbances*	2.01 (1.51, 2.66)
Metabolic syndrome	1.10 (0.516, 2.33)
Hypertension*	1.39 (1.14, 1.69)
Obesity	1.23 (0.831, 1.83)
Type II diabetes*	1.76 (1.27, 2.45)
Cataracts*	1.67 (1.26, 2.20)
Avascular necrosis	1.77 (0.652, 4.78)
Migraine*	1.59 (1.13, 2.25)
Dyslipidemia	1.16 (0.957, 1.41)
Acute Adverse Events	
Urinary tract infection	1.22 (0.99, 1.51)
Herpes zoster*	1.77 (1.06, 2.98)
Fungal infection*	1.97 (1.39, 2.79)
Gastrointestinal ulcers/bleeds	1.12 (0.832, 1.50)
Fracture	1.19 (0.86, 1.64)
Pneumonia*	2.50 (1.80, 3.46)
Nausea/vomiting*	1.89 (1.45, 2.49)
Sepsis	1.55 (0.787, 3.05)
Tuberculosis	1.59 (0.71, 3.55)

*$P<0.05$

Conclusion: While CS is frequently prescribed to control symptoms of SLE, the results highlight the potential risks associated with its use in this subset. Due to the retrospective, non-randomized nature of this study, a true causal link cannot be made between CS use and AEs. Although further work is necessary to quantify the relationship between amount of steroid use and risk of AEs, these results support the potential benefits of reducing CS use wherever possible.

1380

Prevalence and Associated Factors for Asymptomatic Pulmonary Arterial Hypertension in Patients with Systemic Lupus Erythematosus.
Ki-Jo Kim[1], Ji-Young Kim[2], Su-Jung Park[2], Hosung Yoon[3], Yun-Jung Park[4], Chong-Hyeun Yoon[1], Jin-Jung Choi[5], Wan-Uk Kim[6] and Chul-Soo Cho[1]. [1]College of Medicine, Catholic University of Korea, Seoul, South Korea, [2]Research Institute of Bone & Joint Diseases, Catholic University of Korea, Seoul, South Korea, [3]The Catholic University, Incheon, South Korea, [4]The Catholic University of Korea, Suwon, South Korea, [5]CHA University, Bundang CHA General Hospital, Seongnam, South Korea, [6]St. Vincent's Hospital, Suwon, South Korea

Background/Purpose: Pulmonary arterial hypertension (PAH) is one of the rare but devastating complications in connective tissue diseases. PAH in systemic lupus erythematosus (SLE) is underrecognized in the clinical field. Early identification of PAH is important and can alter the natural course. The purpose of this study is to estimate point prevalence of asymptomatic PAH and determine the associated factors for PAH in a cohort of SLE patients.

Methods: A prospective cross-sectional study of 103 patients with SLE were recruited in a single tertiary centre. Transthoracic echocardiography was performed to estimate the pulmonary arterial pressures. PAH was defined as resting systolic pulmonary artery pressure (sPAP) ≥ 40 mmHg, in the absence of left heart disease. The patients were also evaluated with respect to their clinical and serologic features, and disease treatment.

Results: PAH was identified in eight patients (8.74%) who had no history of interstitial lung disease. Fourteen patients (13.59%) had sPAP of 30–40 mmHg. Higher SLEDAI score (11.7 ± 8.4 vs. 5.9 ± 5.1, $p = 0.004$ and lower positivity of anti-Ro/SSA antibody (22.2% vs. 65.9%, $p = 0.010$) was observed in patients with PAH than patients without PAH. Of note, serum uric acid (UA) was significantly higher in patients with PAH than in those without PAH (7.72 ± 0.70 vs. 5.45 ± 0.22 mg/dl, $p = 0.001$). However, no significant differences in disease duration, Raynaud's phenomenon, antiphospholipid antibodies were found between these groups. In multivariate analysis, higher serum UA level was independently associated with the presence of PAH. Interestingly, serum UA level correlated significantly with plasma B-type natriuretic peptide level ($r = 0.439$, $p < 0.001$). Serum monocyte chemoattractant protein-1 (MCP-1) levels were also elevated in patients with PAH (592.38 ± 165.51 vs 274.71 ± 26.48 pg/ml, $p = 0.001$). Crystal-free UA dose-dependently increased MCP-1 production in endothelial cells and enhanced monocytes chemotaxis by MCP-1.

Conclusion: Clinically asymptomatic PAH is not uncommon in SLE patients. Serum UA level may be useful as a surrogate marker for screening of PAH. Uric acid stimulates endothelial MCP-1 production and monocyte chemotaxis, potentially contributing to the pathogenesis of PAH.

1381

Feasibility of Implementing a Lifestyle Intervention and Its Effects on Metabolic Parameters and Adipokines in Overweight and Obese Patients with Systemic Lupus Erythematosus.
Nehal Shah[1], Amy D. Rickman[2], Anne E. Mishler[2], Nicole L. Wilson[3], John M. Jakicic[2], Susan Manzi[4] and Amy H. Kao[4]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, PA, [3]W Penn Allegheny Health System, Pittsburgh, PA, [4]Allegheny Singer Research Institute, Pittsburgh, PA

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at increased risk for cardiovascular disease, more likely to be sedentary, have chronic inflammation and altered metabolic parameters and adipokines. Few studies have evaluated the feasibility of a lifestyle intervention and its effects on metabolic parameters and adipokines in overweight/obese patients with SLE. Thus, it is important to examine interventions that can positively impact weight and physical activity in SLE patients. The purpose of this pilot study was to investigate the effect of a 16-week lifestyle intervention on weight loss and physical activity, in addition to its effects on metabolic parameters and adipokines in overweight/obese SLE patients.

Methods: A lifestyle program included a reduced calorie diet (1200/1500 kcal/d) and a progressively increased physical activity from 100 to 300 min/wk by week 16. Paired t-tests were used to determine significant differences between measurements at baseline and week 16.

Results: Fifteen SLE female subjects (mean age=39.7±10.4yrs, 53% Caucasian, mean body mass index/BMI=30.8±3.7 kg/m^2). Measurements were assessed at baseline and 16 weeks in 9 subjects (60% completion rate). The majority (88%) was insulin resistant by HOMA-IR at baseline (mean HOMA-IR: 2.82±1.03). Mean% weight change was −9.8±2.8%, mean weight lost was 8.2±2.0 kg, and self-reported physical activity was 190±59.4 min/wk (90% of subjects reached the 20 min/session goal in weeks 1 and 2 and 57% of subjects reached the goal of 60 min/session in weeks 15 and 16). All 9 subjects achieved significant reduction ($p<0.05$) in weight (−8.2±2.0 kg), BMI (−3.04±0.7 kg/m^2), waist circumference (−10.8±4.9 cm), leptin (−9.4±4.6 ng/mL) and adiponectin (−0.1±0.1 ug/mL) levels. Mean self-reported physical activity minutes/session significantly increased from weeks 1 and 2 to weeks 15 and 16 (+25.6 min/session). Significant correlations were observed between changes in weight and leptin (Spearman's correlation/r= −0.77, p=0.02), between changes in waist and adiponectin (r= 0.83, p= 0.01) and between changes in weight and fasting insulin (r=0.58, p=0.05).

Conclusion: These results demonstrate the feasibility of a pilot lifestyle program on weight loss and increased physical activity that can lead to significant improvements in metabolic profiles and adipokines in overweight/obese SLE patients. Additional research is needed to improve subject completion rate and compliance to physical activity goals in future programs. Moreover, research with a larger sample and compared to a control group should examine how a lifestyle program may impact SLE patients longer term and other health parameters (i.e. SLE-specific and psychosocial factors).

1382

Renal Mir-150 As Potential Biomarker of Chronicity in Lupus Nephritis. Hua Zhou[1], Sarfaraz A. Hasni[2], Mayank Tandon[1], Ilias Alevizos[1], Howard A. Austin[3], James E. Balow[3] and Gabor G. Illei[1]. [1]NIDCR, Bethesda, MD, [2]NIH/NIAMS, Bethesda, MD, [3]NIH/NIDDK, Bethesda, MD

Background/Purpose: Histological variations of kidney injury in lupus nephritis are associated with different renal outcomes. Novel quantitative biomarkers which can mirror the degree of renal damage may be useful to help clinical decision making and assist in the choice of optimal therapy. microRNAs (miRs) are involved in many biologic processes and have shown promise as biomarkers in other settings. In this study we assessed the association of miR expression profiles with histologic features of chronicity of kidney biopsies from proliferative lupus nephritis patients.

Methods: MicroRNA expression profiles were analyzed on total RNA obtained from 18 formalin fixed paraffin embedded (FFPE) kidney biopsies from 8 patients by Affymetrix miR microarray. The expression of miR-150 was assessed by Taqman qRT-PCR on 10ng of total RNA in 16 of these samples and an additional 7 samples from 6 patients. miR150 levels are expressed as their relative expression (deltaCt) compared to U48 used as an endogenous control. Repeat biopsies from the same patient were done based on clinical indication, primarily for nephritis flares. The association between miR-150 and histological chronicity index (CI) was analyzed using the Prism 5 statistical software package.

Results: miR-150 was the most differentially expressed miR on microarrays between the renal biopsies with high CI (CI >4, n=9) compared to low CI (n=9). miR-150 signal intensity was 4-fold increased in the high CI group by microarray analysis. deltaCt values of renal miR-150 obtained by qRT-PCR were significantly higher in the high CI (mean 2.83, SD 1.6) vs the low CI (mean 0.65, SD 1.2; p= 0.0017 Student's t test) groups. Moreover, the miR-150 deltaCt values showed strong positive correlation with CI scores (Pearson's r=0.73 $p<0.0001$).

Conclusion: microRNA can be isolated from archived FFPE specimens with good enough quality for miR microarray and qRT-PCR. Renal miR-150 level was differentially expressed in kidney biopsies from patients with proliferative lupus nephritis with either low or high degree of chronicity. The positive correlation of miR-150 with chronicity index suggests that it may be a useful quantitative biomarker for evaluating kidney injury in lupus nephritis.

Health, Montreal, QC, [16]Feinstein Institute for Medical Research, Manhasset, NY, [17]Allegheny Singer Research Institute, Pittsburgh, PA, [18]Toronto Western Hospital and University of Toronto, Toronto, ON, [19]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [20]UCSD School of Medicine, La Jolla, CA, [21]North Dallas Dermatology Assoc, Dallas, TX, [22]University of Maryland, Baltimore, MD, [23]Chicago

Background/Purpose: To determine the prevalence of the direct Coombs in SLE and controls with other rheumatologic diseases, and to characterize its clinical associations.

Methods: The Systemic Lupus International Collaborating Clinics Revision of SLE Classification Criteria derivation and validation datasets were merged for the purpose of this study. The analyses were based on 868 patients with both direct Coombs measured and physician consensus diagnosis available (456 SLE and 412 controls). Of the 456 SLE patients, 412 (90.4%) were female, 279 (61.2%) Caucasian, and 89 (19.5%) African descent. Their mean age was 37.7±13.4. The results were based on the chi-square test (SAS Institute, Cary, NC, USA). A p-value ≤0.05 was considered statistically significant.

Results: The prevalence of the positive direct Coombs test was 21% (96/456) in SLE patients and 6% (25/412) in controls (P-value <.0001), sensitivity 21%, and specificity 94% for SLE. Of 96 SLE patients with positive direct Coombs, 79 (82.3%) had never had hemolytic anemia.

Table 1. Association between Demographic Characteristics and Direct Coombs in SLE

Variable		Positive Direct Coombs (%)	P-value
Ethnicity	African descent	16.8	0.39
	Caucasian	16.5	
	Asian	25.0	
	Other	12.5	
Gender	Female	17.7	0.46
	Male	13.6	
Age	≤30	21.1	0.15
	>30	15.6	

Table 2. Association between ACR Criteria and Direct Coombs Status in SLE, Excluding Patients with Hemolytic Anemia

Variable	Positive Direct Coombs (%)	Negative Direct Coombs (%)	Odds Ratio (95% CI)	P-value
Malar Rash	40.5	42.7	0.9 (0.6, 1.5)	0.72
Discoid Rash	12.7	18.3	0.6 (0.3, 1.3)	0.23
Photosensitivity	41.8	49.1	0.7 (0.5, 1.2)	0.24
Oral Ulcers	39.2	40.3	1.0 (0.6, 1.6)	0.86
Arthritis	69.6	61.3	1.4 (0.9, 2.4)	0.16
Serositis	36.7	31.8	1.2 (0.7, 2.1)	0.40
Pleurisy	32.9	25.2	1.5 (0.9, 2.5)	0.16
Pericarditis	15.2	12.2	1.3 (0.6, 2.6)	0.47
Renal criterion	36.7	34.2	1.1 (0.7, 1.8)	0.67
Neurologic	10.1	6.4	1.7 (0.7, 3.8)	0.23
Hematologic	60.8	47.5	1.7 (1.0, 2.8)	0.032
Leukopenia	36.7	26.8	1.6 (0.9, 2.6)	0.08
Lymphopenia	34.2	28.1	1.3 (0.8, 2.2)	0.28
Thrombocytopenia	21.5	13.8	1.7 (0.9, 3.2)	0.08
Immunologic	94.9	81.2	4.4 (1.5, 12.3)	0.0027
Anti-dsDNA	76	62.1	1.9 (1.1, 3.4)	0.02
Anti-Smith	34.2	23.6	1.5 (0.9, 2.8)	0.049
Antiphospholipid	64.6	52.8	1.6 (0.9, 2.7)	0.055
Anticardiolipin IgG	27.9	17	1.9 (1.1, 3.3)	0.025
Low complement	81	60.5	2.8 (1.5, 5.1)	0.0005

Conclusion: The great majority of patients with SLE and a positive direct Coombs had never had hemolytic anemia. A positive direct Coombs test was highly associated with SLE versus other rheumatologic diseases. It was associated with the ACR hematologic criterion, anti-dsDNA, anti-Smith, anticardiolipin IgG and low complement. These data justify the decision by SLICC to include direct Coombs in the new classification criteria for SLE.

1384

Predictors of Earlier Time to Renal Failure Among Those with Biopsy-Proven Lupus Nephritis. Alí Duarte-García[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Prevention of renal failure is the ultimate goal of therapy of lupus nephritis (LN). Determination of risk factors and protective factors requires long-term follow up, not available in the clinical trial setting. We determined predictors of earlier time to renal failure in a longitudinal cohort of biopsy-confirmed LN.

Methods: Based on combined retrospective and prospectively collected data, we estimated the probability of renal failure within 10 and 20 years of biopsy based on 422 SLE patients with LN biopsy of either ISN Class I, II, III, IV, V, of VI. Based on prospectively collected cohort data, we used Cox regression methods to assess the relationship between time-varying clinical variables and progression to renal failure in the subset of these patients (393) who did not have renal failure before active follow-up in our cohort. The patients were 91% female, 50% African-American, 6% "other", with mean age at biopsy of 33 years of age.

Results: In our cohort, the risk of renal failure within 10 years of a positive LN biopsy was 16% (Table 1). Risk was substantially higher among those with Class IV LN than those with other classes of LN. During cohort follow-up, adjusting for Cockcroft-Gault eGFR at the start of follow-up, those who were younger or those who were more often positive for anti-dsDNA were at increased risk of renal failure (Table 2). After adjusting for age and ISN Class, the strength of association between anti-dsDNA and risk of failure was diminished (Rate Ratio comparing those with frequent anti-dsDNA to those with none, 2.6, p=0.13).

Table 1. Relationship between LN class and risk of renal failure, considering those with combined biopsy results as a separate class.

Subgroup	Estimated percent chance of developing Renal Failure within 10 years (95% CI)	Estimated risk of developing renal failure within 20 years (95% CI)
Any Class (n=422)	16.3 (12.4, 21.3)	25.7 (19.0, 34.4)
Class II (n=37)	13.3 (4.5, 35.7)	25.9 (18.8, 35.1)
Class III (n=63)	3.7 (1.0, 24.5)	32.9 (12.3, 70.3)
Class IV (n=129)	38.3 (20.0, 39.1)	38.9 (26.6, 55.1)
Class V (n=86)	3.7 (1.2, 11.2)	3.7 (1.2, 11.2)
Combination (n=105)	17.8 (11.1, 27.7)	22.4 (13.1, 36.7)

[1] This p-value assesses the degree of evidence against the hypothesis that failure probabilities in the two groups are equal at all time points.

Table 2. Association between predictors and kidney failure during cohort participation based on separate models for each variable, controlling for GFR at start of follow-up.

Variable		Rate Ratio (95% CI)	P-value
Gender	Male (vs. female)	1.1 (0.3, 3.6)	0.88
Age	30–39 (vs. < 30)	0.4 (0.2, 1.1)	0.076
	40+ (vs. < 30)	0.3 (0.1, 0.7)	0.0056
Race	African-American (vs. Caucasian)	1.4 (0.6, 2.9)	0.44
	Other (vs. Caucasian)	0.7 (0.1, 3.1)	0.62
Anti-dsDNA	Some but <50% of follow-up (vs. none)	0.9 (0.2, 3.7)	0.92
	50%+ (vs. none)	3.5 (1.2, 10.6)	0.024
Low Complement	Some but <50% of follow-up (vs. none)	1.8 (0.3, 9.3)	0.49
	50%+ (vs. none)	1.8 (0.7, 4.9)	0.25
Systolic Blood Pressure at start of follow-up	130+ mmHg (vs. <130)	0.9 (0.5, 1.9)	0.86
Plaquenil Use	Some, but <50% of time (vs. none)	1.2 (0.5, 3.3)	0.70
	>50% (vs none)	1.0 (0.4, 2.2)	0.94
ACE or ARB	Some, but <50% of time (vs. none)	1.3 (0.4, 3.7)	0.67
	>50% (vs none)	0.9 (0.4, 2.1)	0.90
Class II LN		0.9 (0.4, 2.1)	0.77
Class III LN		0.4 (0.2, 1.3)	0.12
Class IV LN		3.3 (1.5, 7.4)	0.0027
Class V LN		0.8 (0.4, 1.7)	0.56

Conclusion: These prospective cohort data indicate a 16.3% chance of renal failure at 10 years and 25.7% at 20 years, with Class IV having the worst prognosis. There was no evidence that Plaquenil or ACE-inhibitor use was protective. Those who were younger were at increased risk, and there was some evidence that those more often positive for anti-dsDNA were at increased risk. These data suggest that normalization of anti-dsDNA might be an important therapeutic target to reduce renal failure.

1385

Do Active Lupus Patients Continue to Improve At 12 Months by Systemic Lupus Erythematous Disease Activity Index 2000 Responder Index 50 (SRI-50)? Zahi Touma[1], Murray B. Urowitz[1], Dominique Ibanez[1], Shahrzad Taghavi-Zadeh[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: A previous study showed that SRI-50 detects partial but clinically important improvement, ≥50%, in disease activity between visits in response to standard of care treatment. Patients are deemed improved (responders) if their SLEDAI-2K decreases by ≥4. We aimed to determine if lupus patients continue to improve at 12 months as determined by SRI-50. To evaluate if SRI-50 identifies more responders at 6 and 12 months as compared to SLEDAI-2K.

Methods: This study was conducted on active lupus patients with SLEDAI-2K≥6 at baseline visit who attended the Lupus Clinic from September 2009 to April 2011. Patients were followed regularly every 3–4 months over 12 months. SLEDAI-2K scores were determined at baseline and at follow-up visits and SRI-50 scores were determined at follow-up visits. Patients received standard of care treatment. A patient was defined as responder when the total score on follow-up visit decreased by ≥4. We determined the percentage of responders at follow-up visits, using SLEDAI-2K definitions and scores and using SRI-50 definitions and scores.

Results: 66 patients with SLEDAI-2K≥6 at baseline visit were identified and followed over 12 months. Patient demographics are presented in table 1.

Table 1. Patients' characteristics

Sex	Female 60 (91%)/6 (9%)
Age at diagnosis (years)	28±12
Age at 1st visit in the study (years)	42±14
Disease Duration at 1st visit in the study (years)	14±11
Race	
Caucasian	36 (55%)
Black	36 (55%)
Asian	36 (55%)
Others	2 (3%)
SDI at 1st visit in the study	1.43±5.47
Prednisone at baseline visit: patients number (%)	51 (77%)
Anti-malarial number: patients number (%)	47 (71%)
Immunosuppressants: patients number (%)	44 (67%)

SLEDAI-2K at baseline was 10.36±4.77. SLEDAI-2K at 12 months was 6.34±4.69 and SRI-50 was 5.53±4.58 (Table 2).

Table 2. Results of disease activity assessment of 66 patients with active lupus at baseline visit (SLEDAI-2K ≥6)

Visits	SLEDAI-2K	SRI-50	SLEDAI-2K difference	SRI-50 difference	P values
Baseline	10.36±4.77	10.36±4.77	0±0	0±0	<0.001
3–6 months	6.75±4.12	5.90±3.82	3.64±5.25	4.50±5.17	<0.001
12 months	6.34±4.69	5.53±4.58	4.01±5.46	4.82±5.57	<0.001

More importantly the number of responders at 3–6 months as determined by SRI-50 was greater then SLEDAI-2K, 36(55%) and 39 (60%), respectively. Similarly, at 12 months SRI-50 identified more responders as compared to SLEDAI-2K, 39 (59%) and 42 (64%), respectively.

Conclusion: Lupus patients with moderate to severe disease activity continue to improve at 1 year as determined by SRI-50 and SLEDAI-2K. SRI-50 was able to indentify more responders at 6 and 12 months as compared to SLEDAI-2K. SRI-50 showed superiority over SLEDAI-2K in identifying responders throughout the study period.

1386

Lupus Disease Activity Does Not Improve Significantly in One System and Worsen in Another System. Zahi Touma[1], Dafna D. Gladman[2], Dominique Ibanez[1], Shahrzad Taghavi-Zadeh[1] and Murray B. Urowitz[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K) is a global index that generates a score describing overall disease activity in 9 systems. The British Isles Lupus Assessment Group (BILAG) index generates scores for each organ system separately. It has been suggested that disease activity may improve in some systems while worsening in others making it difficult to interpret outcomes using a global activity index. We aimed to determine 1) if disease activity improves significantly in one system while worsening in another system. 2) if the global disease index SLEDAI-2K, is valid to identify patients who had a clinically important improvement with no worsening in other systems.

Methods: This is a cross-sectional study conducted on active lupus patients who attended the Lupus Clinic from September 2009 to May 2011. Patients were included if at baseline visit their SLEDAI-2K was ≥6. All patients had at least one follow-up. SLEDAI-2K and the BILAG index were determined initially and follow-up visit. Patients were treated with standard of care. We identified the first visit available in which patients had improved by decreasing their SLEDAI-2K ≥4. The assessment of the 8 systems was determined using the BILAG index grade (BLIPS V4.0.). In the group of patients who improved we identified any patients who had new A or new B score on BILAG on the follow-up visit as compared to the baseline visit. Descriptive statistics were used to describe the characteristics of the patients.

Results: The patient population included 103 lupus patients. The length of time interval between baseline and last visit was 5.3±3.5 months. Of the 103 patients studied 71 patients had improved their SLEDAI-2K score by ≥4 on follow-up visit. Patients' demographics are presented in table 1.

Table 1. Characteristics of 71 patients who improved

Sex	F 62 (87%)/M 9 (13%)
Age at diagnosis (years)	28.2±11.2
Age at 1st visit in the study (years)	40.8±13.8
Disease Duration at 1st visit in the study (years)	12.7±10.3
Race	
Caucasian	39 (55%)
Black	18 (25%)
Asian	4 (6%)
Others	10 (14%)
SDI at 1st visit in the study	1.4±1.8
Prednisone at baseline visit: patients number (%)	56 (79%)
Anti-malarial number: patients number (%)	51 (72%)
Immunosuppressants: patients number (%)	43 (61%)

Among the 71 patients who improved the mean SLEDAI-2K scores were at baseline visit 11.7±5.3 and 6.4±4.9 at follow-up visit. More importantly among the patients who improved none had a new A on follow-up visit as compared to baseline visit. 2 patients had each a new B on follow-up visits. In both patients new B resulted from a drop in hemoglobin to $<11\times10^9$/ liter (10.3×10^9/ liter and 10×10^9/ liter, respectively) despite the absence of active hemolysis and in the setting of a negative Coombs test. The change in the hemoglobin level was not clinically important to require a change in lupus medications and this change was not related to lupus disease activity.

Conclusion: In this study we showed that if disease activity improves significantly in one system it is unusual to have clinically important worsening in another system. SLEDAI-2K 30 days can be used as an independent single measure to determine improvement in disease activity in lupus patients.

1387

Low Placebo Responses and Clinical Components of the Biomarkers of Lupus Disease (BOLD) Study May Provide Useful Insights for Systemic Lupus Erythematosus Clinical Trial Design. Sudhakar T. Sridharan[1], T. Zhou[1], F. Immermann[1], M. Lehmann[1], J.L. Masferrer[1], M. Honczarenko[1], J.C. Rawdon[2], J.A. James[2] and J.T. Merrill[2]. [1]Pfizer Inc, Collegeville, PA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Interpretation of lupus clinical trials may be confounded by background immune suppressants (IS) promoting high placebo response rates, and challenges defining efficacy in a heterogenous disease population. The BOLD study addresses whether withdrawal of background IS would be safe and lessen time to flare in a placebo group and also compares current trial measures as endpoints.

Methods: Discriminatory capacity of outcome measures and impact of IS are being assessed cross sectionally in 100 patients (pts) and longitudinally in 50 pts in whom IS are withdrawn, brief steroids given and subsequent flares evaluated. This interim report includes 80 active patients entered with >/=2 BILAG B or 1 BILAG A or SLEDAI >6.

Results: Of 80 subjects in this interim analysis, mean age was 40.9 (11.9) yrs, majority female (91%), Caucasian (60%) African American (21.25%), American Indian (17.5%), and Asian (1.25%). Ethnicity had no impact on baseline disease activity or outcomes. Disease activity was higher in pts on prednisone (n= 27 mean dose 11.4 mg/d) than not (n=53]: SLEDAI 10.0 vs 8.0 p=0.036, Classic BILAG 12.0 vs 8.0 p = 0.009) confirmed in a multivariate model including other IS (p=0.035 SLEDAI, p <0.001 BILAG). 31 pts have completed follow up after IS withdrawal and brief steroid burst (up to three 160mg IM Depomedrol injections within 2 weeks)..Median time to flare was 72 days (CI 43–91), and 100% flared by week 24. Significant differences between baseline, improving, and flare visits were detected by PGA (mean 1.889, 0.882, 1.857 p <0.001), SLEDAI (mean 8.2, 4.2, 7.7 p <0.001) BILAG (mean 9.4, 3.7, 9.2 p <0.001) and CLASI (skin) scores (median 4.0, 1.0, 2.0 p<0.001). Independent safety adjudication findings were 42 total AEs including 20 mild/moderate infections, one serious (bleeding ulcer) and one unexpected event (perianal abcess). 15 patients had flares exceeding baseline disease with 4 severe flares and no serious adverse events related to flare. All flares resolved within 6 weeks after treatment.

Relative Performance of Outcome Measures in Detecting Improvement

BASELINE versus:	SRI-4	SRI-5	SRI-BILAG	BOLD Criteria*
Week 4 n=31	**15** (p=0.068)	**8** (p<0.001)	**21**	23
Week 8 n=21	14	8	9	11
Imp Visit n=31	17 (p<0.001)	**11** (p<0.001)	**27**	31
Flare Visit n=31	4	2	0	0

* (>/= drop of one BILAG grade or SLEDAI 4 pt)
SRI-4/5 (from BLISS trials) SRI-BILAG (from EMBLEM trial)
Analysis by Fisher's exact test compared to BOLD criteria

Conclusion: Withdrawal of IS may be safe and well tolerated in SLE trials and produces rapid endpoints for placebo pts who can then receive early rescue therapy without confusing outcomes. The compound endpoint SRI-BILAG may be more sensitive to change than SRI when anchored to the simpler BOLD improvement criteria. These differences could be clinically meaningful given the known effectiveness of steroid treatment used in BOLD.

1388

Frequency and Characteristics of Prolonged Remission in Systemic Lupus Erythematosus. Amanda J. Steiman[1], Murray B. Urowitz[1], Dominique Ibanez[1], Anjali Papneja[2] and Dafna D. Gladman[3]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, incurable autoimmune disorder, classically characterized by a relapsing/remitting course. However, a small subset of SLE patients display a prolonged clinical remission. These patients represent a clinically important group that may provide further insights into SLE pathophysiology. In this study we characterize the clinical course of SLE patients, followed at a single centre, who have achieved prolonged remission.

Methods: Patients followed regularly in the Lupus Clinic between July 1970 and May 2011 were identified in our database. We defined a prolonged remission as SLEDAI-2K = 0 (serologically quiescent clinically quiescent (SQCQ)), or = 2 or 4 on the basis of active serology alone (serologically active clinically quiescent (SACQ)) for at least five consecutive years, with visits ≤ 18 months apart, during which time the patients could be taking antimalarials, but not steroids or immunosuppressives. Flare was defined as any clinical activity on SLEDAI-2K, or by the initiation of steroids or immunosupressives. Each patient's pre-remission clinical course was classified as monophasic (single flare followed by remission), relapsing/remitting (≥2 fluctuations in SLEDAI-2K of ≥4 on the basis of clinical activity), or chronic active (persistent clinical activity with SLEDAI fluctuating by ≤3 at

each visit). Adjusted mean SLEDAI (AMS) was calculated for each patient for the three years leading up to remission. Descriptive statistics were used.

Results: 38 of 1613 (2.4%) patients achieved prolonged remission. One patient experienced two discrete prolonged remission periods, thus 39 periods were studied. 32 (84.2%) patients were female. Mean duration of SLE clinic follow up was 21.8 ± 10.3 years, and the average time to remission from clinic entry was 9.1 ± 8.8 years. The mean prolonged remission duration was 11.6 ± 6.4 years. 17 remission periods were SQCQ, 11 were SACQ and 11 were mixed SQCQ/SACQ. When subdivided by type, mean remission duration was 9.7± 5.7, 9.7 ± 3.5 and 17.0 ± 6.9 years for SQCQ, SACQ and mixed remissions, respectively. All but one of the 28 patients who continue to be followed contemporarily were in remission at their last clinic visit. Antimalarials were being used by 16 (42.1%) of patients at remission onset, with a further 5 (13.1%) using them at some point during their remission. Twenty-three (60.5%) patients had relapsing/remitting disease, 7 (18.4%) had monophasic illness, and 3 (7.9%) had chronic active disease prior to remission; a further 5 (13.2%) were in remission on transfer to the clinic, with 4 maintaining their remission until their most recent clinic visit. Mean AMS over the three years prior to onset of remission was 2.9 ± 1.7.

Conclusion: Prolonged clinical remission is an infrequent outcome among SLE patients, lasts more than a decade, and is preceded by an atypically monophasic clinical course in a significant minority. These occurrences may be reflective of unique pathophysiologic mechanisms, and warrant further investigation.

1389

Comparison of the SF-36 Vs. Lupus Qol in Measuring Health-Related Quality of Life in Systemic Lupus Erythematosus Women with and without Activity. Claudia Mendoza-Pinto[1], Mario Garcia-Carrasco Sr.[1], Socorro Mendez-Martinez[1], Oscar Pazarán[1], Mario H. Cardiel[2] and Aurelio Lopez-Colombo[3]. [1]HGR 36 CMN Manuel Ávila Camacho, Instituto Mexicano del Seguro Social, Puebla, Mexico, [2]Hospital, Morelia, Mexico, [3]Delegación Estatal, Instituto Mexicano del Seguro Social, Puebla, Mexico

Background/Purpose: The Lupus QoL questionnaire was developed in the United Kingdom as a disease-specific health-related quality of life instrument for adults with systemic lupus erythematosus (SLE). The Short Form-36 (SF-36) is a valid, reliable tool that captures the physical, psychological, and social impact of SLE. The purpose was to compare health-related quality of life (HRQL) in women with and without SLE activity using the Lupus Qol vs. SF-36.

Methods: We conducted a comparative study of women aged ≥ 18 years, attended by our Lupus Clinic. HRQL was assessed by administration of the Lupus QoL and SF-36. In both surveys, each question is evaluated using a 5-point Likert response. Each of the 8 domain scores range from 0 to 100. Lupus activity was measured using the Mex-SLEDAI and chronic damage using the Systemic Lupus Collaborative Clinics Damage Index (SDI). Data were analyzed using descriptive statistics, the chi-square test and Spearman's correlation.

Results: A total of 106 were included with a mean age of 41.46 ± 13.32 years. The mean disease duration was 8.55 ± 5.7 years, the mean activity score was 2.6 ± 2.47, and the mean SDI score 0.75 ± 1.03.The mean SF-36 score was 60.43 ± 20.63 and the mean Lupus QoL 71.03 ± 20.75. The correlation between the SF-36 and Lupus QoL was rho = 0.748. The correlation between lupus activity and the SF-36 and the Lupus QoL was −0.376 and −0.336, respectively. The correlation between the SDI and the SF-36 and the Lupus QoL was 0.354 and 0.429, respectively. Correlations for comparable domains of the SF-36/LupusQoL were: physical health /physical function: 0.784, emotional health/mental: 0.651, pain/bodily pain: 0.648, fatigue/vitality: 0.554. Correlations for non-comparable domains were mental component score (MCS)/planning: 0.557, MCS/body image: 0.470, MPC/burden to others: 0.409, physical domain/intimate relationship: 0.421, and all $p < 0.001$. The correlation between activity and the SF-36 was 0.748, $p = 0.026$, while the correlation with the Lupus Qol was not statistically significant.

Conclusion: The SF-36 and Lupus QoL HRQL questionnaires showed a moderate correlation between comparable and non-comparable domains. However, the Lupus QoL was not superior to the SF-36 in assessing HRQL in lupus patients. The utility of the Lupus QoL should be evaluated in studies in patients with moderate-to-severe disease activity.

1390

Cognitive Dysfunction and Diffusion Tensor Imaging in Systemic Lupus Erythematosus. Elizabeth Kozora[1], Aziz Ulug[2], Doruk Erkan[3], Glendalee Ramon[3], An Vo[4], Robert Zimmerman[5], Emily Duggan[1], JoAnn Vega[3], Christopher Filley[6] and Michael D. Lockshin[3]. [1]National Jewish Health, Denver, CO, [2]The Feinstein Institute for Medical Research, Manhasset, NY, [3]Barbara Volcker Center for Women and Rheumatic Diseases: Hospital for Special Surgery, New York, NY, [4]The Feinstein Institute for Medical Reearch, Manhasset, NY, [5]Weill Cornell Medical College, New York, NY, [6]University of Colorado School of Medicine, Aurora, CO

Background/Purpose: Cognitive dysfunction is common in Systemic Lupus Erythematosus (SLE) patients and has been associated with microstructural cerebral white matter (WM) abnormalities (Kozora & Filley, 2011). Diffusion tensor imaging (DTI) provides an index of the structural integrity of WM by using quantitative directional diffusion properties of water molecules for each voxel. The technique is based on the principle of anisotropy, a term referring to the propensity for water in the normal state to diffuse along the direction of WM tracts. The purpose of this pilot project is to examine WM microstructure with DTI in relation to cognitive function in SLE.

Methods: SLE patients fulfilling the ACR Classification Criteria with no history of overt neuropsychiatric (NP) disorders such as stroke, seizures, or major depression were: a) interviewed regarding detailed neuromedical histories and perceived cognitive impairment; b) administered the ACR-SLE neuropsychological battery; c) and received MR images with a 3T MR scanner. The DTI protocol included 60 slices of 2.6mm thickness with field of view of 240mm and image matrix of 128χ128 zero filled to 256χ256.

Results: We enrolled 20 patients (40% Caucasian) with a mean age of 36.5 +/−11.7, mean education 15.6 +/− 2.4 years, mean disease duration 154.8 +/− 122.9 months, and mean SLEDAI score 3.7 +/− 4.6. Forty-seven percent of the patients were on prednisone (mean dosage 8.3 +/− 1.6 mg). During the formal neuromedical interview, 11/20 (55%) reported cognitive difficulties in aspects of attention and memory. Based on the neuropsychological assessments, 60% of the SLE patients had global cognitive impairment. On specific tests, SLE patients were impaired on immediate visual recall (65%), delayed visual recall (65%), visuomotor sequencing (50%), visuomotor speed (45%), visual attention (40%), verbal learning (35%) verbal fluency to letter cues (35%), verbal fluency to a semantic cue (35%) and complex auditory attention (32%). Using objective cut-off scores, SLE patients with cognitive impairment had lower fractional anisotropy (FA) in the left inferior longitudinal fasciculus (ILF) ($p<0.001$), an occipitotemporal association tract related to memory and language (Shinoura et al., 2007; Kantarci et al., 2011).

Conclusion: This is the first study to demonstrate abnormal DTI in SLE patients without overt NP activity but with significant cognitive dysfunction. Based on DTI analysis, the objectively impaired SLE patients had abnormalities in the ILF. Our study suggests that disruption of WM tracts may underlie aspects of cognitive dysfunction in SLE.

1391

Impaired Responses to Aspirin in Patients with Systemic Lupus Erythematosus: The Role of Inflammation and Oxidative Stress. Vivian K. Kawai[1], Ingrid B. Avalos[2], Annette M. Oeser[1], John A. Oates[1], Ginger L. Milne[1], Cecilia P. Chung[3] and C. Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]Harvard University, Boston, MA, [3]Vanderbilt Medical Center, Nashville, TN

Background/Purpose: Aspirin is a widely used effective therapy for decreasing the risk of thrombosis. However, in some patients aspirin does not adequately suppress platelet thromboxane formation, a phenomenon termed "aspirin resistance". Many patients with lupus (SLE) have increased risk of thrombosis and thus receive aspirin. We previously reported that 15% of patients with SLE have impaired response to aspirin, and that this was associated with features of the metabolic syndrome (obesity, diabetes, and hypertension). The mechanism is unknown, but oxidative stress, which is associated with obesity and inflammation, has been implicated as contributing to this impaired response. Therefore, we tested the hypothesis that impaired response to aspirin in SLE is associated with increased oxidative stress.

Methods: We prospectively studied 34 patients with SLE who had stable disease and no contraindication to aspirin therapy. Patients received immediate-release aspirin 81 mg/day for 7 days. NSAIDs were withdrawn for 7 days before and during the study. We collected blood and urine before and after aspirin treatment to measure concentrations of serum TxB_2 (in whole blood allowed to clot at 37°C) and urinary 8-iso prostanglandin $F_{2\alpha}$

(F_2-isoprostanes) excretion, a robust measure of oxidative stress. We defined an impaired response to aspirin as the inability to suppress serum TxB_2 concentrations to <10 ng/ml. We compared urinary F_2-isoprostane excretion in patients with and without impaired responses to aspirin. Continuous data are described as median with interquartile ranges [IQR].

Results: Impaired response to aspirin was present in 15% (5/34) of patients with lupus. Patients with impaired aspirin response (n=5) were 60% female, age 45 [34–46 years], and those who were aspirin sensitive (n=29) were 86% female, age 40 [29–48 years]) (p>0.05). SLE patients with impaired response to aspirin had higher BMI (36.2, [28.9–36.6 kg/m^2] vs. 24.5, [22.3–27.7 kg/m^2]), p=0.055) and serum CRP concentrations (17.2, [1.8–19.9 mg/L] vs. 0.9,[0.6–4.0 mg/L], p=0.018) (Fig 1), and were more likely to be obese (60% vs. 14%, p=0.018) and have diabetes (40% vs. 7%, p=0.034). However, urinary F_2-isoprostane excretion did not differ significantly in aspirin insensitive (1.48, [1.37–2.82 ng/mg of creatinine]) and sensitive patients (1.56, [1.24–2.71 ng/mg of creatinine]) (p=0.933) (Fig 2).

Fig 1: C reactive protein (mg/L) concentrations in aspirin resistant and sensitive SLE patients

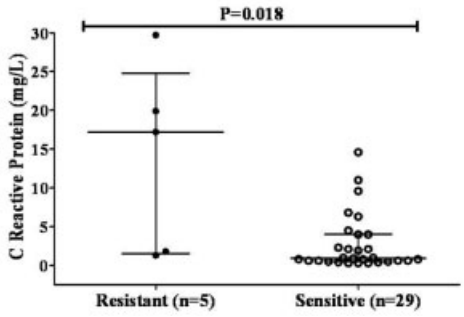

Fig 2: Urinary 8-iso PGF2α distribution in aspirin resistant and sensitive SLE patients

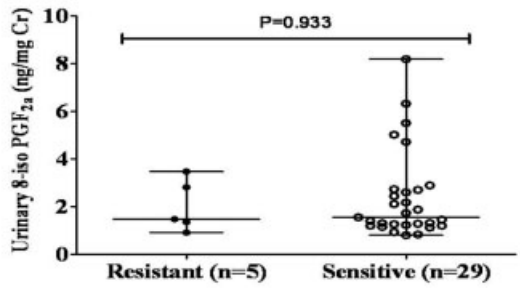


Conclusion: Oxidative stress, measured by urinary F_2-isoprostane excretion, was not associated with variability in sensitivity to aspirin in patients with SLE. However, decreased sensitivity to aspirin was associated with inflammation, as measured by CRP concentrations.

1392

Infection As a Predictor of Organ System Damage Accrual and/or Death in Systemic Lupus Erythematosus. Amanda Eudy[1], Deanna Hill[2], Qinggong Fu[2], Hong Fang[3] and Michelle Petri[3]. [1]UNC Chapel Hill, Chapel Hill, NC, [2]GlaxoSmithKline, Collegeville, PA, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that can affect many organ systems. Among individuals with SLE, infections are a leading cause of morbidity and mortality. Active SLE disease, deficiencies in the complement system, use of immunosuppressant therapy or prednisone and disease manifestations such as renal disease have been associated with an increased risk of infection. The majority of studies to date have focused on the risk factors for infection and subsequent death, but the association between incident infections as predictors of organ system damage has yet to be analyzed. Data from a prospective SLE cohort study were analyzed to determine the association between an infection during a 12-month period and risk of organ system damage accrual and death in SLE.

Methods: This study was comprised of 1,168 SLE patients from a prospective cohort. All patients had at least 24 months of follow-up during 1987–2010 and met the ACR criteria for SLE diagnosis. Patients were seen at least every three months at an academic tertiary medical center clinic. Disease activity was measured at each visit by SLE Disease Activity Index (SLEDAI), and organ system damage accrual was measured annually using the SLICC/ACR Damage Index (SDI). The analysis consisted of a 12-month observation period (OP) beginning 1 year after a patient's first clinic visit (index date) and a successive follow-up period (FP) of variable time lengths for each patient. The association between occurrence of any infection (viral, bacterial, thrush, or opportunistic) in the OP and death or subsequent organ system damage accrual in FP was measured by time-to-event analysis with Cox proportional hazard ratios (HR) and 95% confidence intervals (CI). Organ damage accrual was defined as a 1-unit increase in SDI score from start of FP. Multivariable analyses adjusted for age at cohort entry (years), gender, ethnicity, duration of disease at cohort entry (years), SDI at start of follow-up, adjusted mean SLEDAI (AMS) in OP, and oral prednisone use (>7.5 mg/day) during OP. Damage analyses were restricted to patients who did not have damage in the organ system of interest prior to the start of the FP.

Results: Thirty-two percent of SLE patients (n=374) experienced an infection during OP. Any infection during the OP increased the risk of subsequent overall organ damage accrual by 30% (HR= 1.30, [95% CI: 1.03, 1.64], Table 1). There was a lack of association between any infection during the OP and death in the FP (HR= 1.11, [95% CI: 0.71, 1.73]), as well as specific organ damage accrual.

Table 1. Any infection during the OP as a predictor of death or organ system damage accrual during follow-up

Outcome	Adjusted HR	95% CI	p-value
Death	1.11	(0.71,1.73)	0.665
Organ System Damage Accrual			
Overall	1.30	(1.03,1.64)	0.028
Renal	0.95	(0.44,2.08)	0.897
Neuropsychiatric	1.34	(0.90,1.99)	0.151
Pulmonary	1.19	(0.77,1.85)	0.439
Cardiovascular	1.54	(0.96,2.46)	0.074
Peripheral Vascular	1.16	(0.52,2.62)	0.714
Musculoskeletal	1.06	(0.76,1.47)	0.749
Stroke	1.27	(0.67,2.38)	0.465
Seizure	0.63	(0.17,2.28)	0.479

Conclusion: Our findings suggest that a prior infection is an important predictor of overall organ system damage accrual in SLE. However, a prior infection did not appear to predict death. (Study number: WEUKBRE4566) None.

1393

Low Prevalence of Use of ACEI/ARBS and Lipid Lowering Agents In African American (AA) Systemic Lupus Erythematosus Patients. Asha Thomas, Madhu-Kalyan Pendurthi and Vikas Majithia. University of Mississippi Medical Center, Jackson, MS

Background/Purpose: Cardiovascular (CV) and renal involvement in systemic lupus erythematosus (SLE) is common (up to 75%) and frequently associated with morbidity and mortality (31%). Blockage of ACE pathway and lipid lowering has been shown to have significant benefits in a number of systemic diseases. Previous evidence suggests that they may be associated with reduced risk of overall disease activity, renal and CV morbidity in SLE. Their role in SLE is not well defined, and their use by rheumatologists as a standard of care is not known. There are no specific studies addressing their usage and quantifying the benefits. We did this study to evaluate the prevalence and benefits of using ACEi/ARBs and lipid- lowering agents among AA lupus patients in the Rheumatology clinic at University of Mississippi Medical Center (UMMC).

Methods: Cross-sectional study using retrospective chart reviews of 204, AA SLE patients was done. Data collected includes demographics, BMI, past medical history, medications, antibody panel, complete blood counts, metabolic panel, lipid panel, complement levels, and spot urine Pr:Cr (protein, creatinine ratio). Data was de-identified and collected using Google forms and tabulated to Excel. All analyses were performed using SAS 9.2.

Results: Average age of the population was 38.51{13.255}. 91%(185) were females, 61.69% had hypertension, 9% had diabetes and 23.5% had LN. ANA was positive in 99% of patients and dsDNA was positive in 65%. Average BMI was 31.93{9}. 92% of the population was on hydroxychloroquine and 20% were taking aspirin. Results are summarized in the table below:

ACEi/ARB use	No	Yes
Overall use (n=204)	125 (61.58%)	78 (38.42%)
Hypertension (n=124, 61.69%)	51 (41.12%)	73 (58.87%)
		OR=2.29 (p=0.0003)
Proteinuria status		
Spot urine Pr:Cr>0.5 (n=44)	27 (61.37%)	17 (38.63%)
Spot urine Pr:Cr<0.5 (n=157)	118 (75.15%)	39 (24.85%)
		OR=1.009 (p=0.97)
Lupus nephritis (n=43, 21.07%)	15 (34.88%)	28 (65.22%)
		OR=2.99 (p=0.001)
Dyslipidemia		
Total screened = 196/204 (96%)		
Prevalence (LDL >129 or on treatment) = 51 (26%)		
Lipid-Lowering agents	**No**	**Yes**
Overall use (n=51, 26.02%)	22 (43.14%)	29 (56.86%)
LDL>100 & <129 (n=26)	22 (84.62%)	4 (15.38%)

In this analysis, 38.42% were on ACEI/ARBS as compared to 21% in the LUMINA study, showing that overall use is better but still low. They were more frequently used ($p<0.05$), if participants had hypertension (62%) or history of LN (21%). Presence of proteinuria did not lead to an increased use. Dyslipidemia was common in our participants, seen in about 26%. Use of lipid-lowering agents was low at about 55% of these patients and only 15% for LDL>100 &<129. In most cases, no clear reason for non-prescription was documented.

Conclusion: Despite potential benefits on the renal and CV complications in SLE, use of ACEi/ARBS and lipid-lowering drugs in SLE patients remains low. Possible explanations include lack of scientific studies addressing these medications' role, clear consensus or guidelines for their use in SLE. Lack of focus on treatment of concomitant conditions, cost, compliance and other administrative factors also probably contribute. Further studies and expert consensus guidelines to clearly establish the role of these drugs are needed. In the interim, awareness of their potential benefits may increase their use.

1394

Population Pharmacokinetics of Sifalimumab, An Investigational Anti-Interferon-α Monoclonal Antibody, in Systemic Lupus Erythematosus Patients. Rajesh Narwal, Lorin Roskos, Wendy White, Warren Greth and Gabriel Robbie. MedImmune, Gaithersburg, MD

Background/Purpose: Sifalimumab is a fully human immunoglobulin (Ig) G1κ monoclonal antibody (mAb) that binds to and neutralizes a majority of the subtypes of human IFN-α. Sifalimumab is being evaluated as a treatment for systemic lupus erythematosus (SLE). The primary objectives of this analysis were to (a) model the population pharmacokinetics (PK) of sifalimumab; (b) to identify and quantitate the impact of patient/disease characteristics on PK variability; and (c) to evaluate fixed versus body weight based dosing regimens.

Methods: Sifalimumab serum concentration-time data were collected from a phase 1b study (Study # MI-CP152) designed to evaluate the safety and tolerability of multiple IV doses of sifalimumab in adult patients with SLE. Sifalimumab was administered every 14 days as a 60-minute IV infusion with escalating doses of 0.3, 1.0, 3.0 and 10 mg/kg and trough serum concentrations were collected every 14 days. A total of 120 patients provided evaluable PK data with a total of 2370 serum concentrations (average of 20 samples per patient). Sifalimumab serum concentrations were determined using a validated colorimetric enzyme-linked immunosorbent assay (ELISA) with a lower limit of quantitation (LLOQ) of 1.25 μg/mL. The population PK of sifalimumab was performed using a non-linear mixed effects modeling approach in NONMEM VII software. Impact of patient demographics, clinical indices and biomarkers on PK parameters were explored using a step wise forward selection and backward elimination approach. The appropriateness of the final model was tested using visual predictive check (VPC). The final population PK model was utilized for phase II dosing projections.

Results: Sifalimumab PK was best described using a 2-compartment linear model with first order elimination. Following IV dosing, the typical clearance (CL) and central volume of distribution (V_c) were estimated tobe 176 mL/day and 2.9 L, respectively. The estimates of between-subject variability for CL and V_c were 28% and 31%, respectively. Patient baseline body weight, IFN gene signature (21 genes), steroid use and sifalimumab dose were identified as significant covariates for CL, whereas only baseline body weight was significant covariate for V_c and V_p. Although the above mentioned covariates were statistically significant, they did not explain variability in sifalimumab PK parameters to any relevant extent. Thus no dosing adjustments are necessary. VPC results demonstrated good predictability of the final population PK model. Simulation results demonstrate that both fixed and body weight based dosing regimens yield similar median steady state concentrations (C_{ss}) and variability. Fixed sifalimumab doses of 200, 600 and 1200 mg monthly (with a loading dose at day 14) were selected for phase II clinical trial.

Conclusion: A population PK model of sifalimumab was developed and validated. The estimated typical PK parameters were similar to other monoclonal antibodies without a target sink. The population PK analysis also demonstrated the feasibility of evaluating fixed doses of sifalimumab in phase II clinical trials.

1395

Do Race/Ethnicity and Geography Affect Outcomes in An Inception Cohort of Patients with Systemic Lupus Erythematosus Followed for at Least 5 Years? D. D. Gladman[1], Murray B. Urowitz[1], Dominique Ibanez[1], Nicole Anderson[1] and Systemic Lupus International Collaborating Clinics (SLICC)[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto, ON

Background/Purpose: We have previously demonstrated that there are differences in the features of SLE at inception when studied by geographic and race/ethnicity origins. In this study we examined the influences of ethnicity and geography on outcomes in patients followed for at least 5 years.

Methods: An international research network comprising 27 centres from 11 countries has followed an inception cohort of SLE patients yearly according to a standardized protocol between 2000 and 2011. Of these, 537 patients followed for a minimum of 5 years constitute the study population. Disease activity was measured by SLEDAI-2K and Adjusted Mean SLEDAI-2K (AMS) at 5 years, damage using the SLICC/ACR Damage Index (SDI). Multivariate proportional hazards model were evaluated adjusting for age, sex, SLEDAI-2K, and use of medications at enrolment. AMS was analysed by linear regression.

Results: Of the 537 patients there were 469 (87.3%) females. At enrolment the mean age was 35.3 $\pm$ 14.1 years, SLEDAI-2K was 5.7 $\pm$ 5.6 and disease duration 0.5 $\pm$ 0.3 years. 70% were on glucocorticosteroids, 63% on antimalarials, and 38% on immunosuppressive medications. The average length of follow up was 7.2 $\pm$ 1.5 years. At 5 years, mean AMS was 3.8 $\pm$ 3.2, and SDI scores $\geq$ 1 were found in 240 patients, while the SDI was $\geq$ 3 in 87 patients.

Site	N	AMS-5 Mean	SDI $\geq$ 1 P	SDI $\geq$ 3 HR	95% CI	HR	95% CI
Asia	52	2.52	0.08	**0.37**	0.20, 0.69	0.54	0.18, 1.65
Canada	146	3.29		1.00		1.00	
Europe	150	3.03	0.40	0.81	0.57, 1.15	0.97	0.52, 1.82
Mexico	78	**4.14**	0.03	1.14	0.74, 1.77	1.88	0.93, 3.79
USA	111	2.95	0.31	1.14	0.79, 1.65	**1.87**	1.02, 3.45
Ethnicity							
Asian	78	3.30	0.69	**0.58**	0.36, 0.93	0.68	0.30, 1.52
African decent	81	3.64	0.15	1.33	0.93, 1.90	1.66	0.93, 2.97
Caucasian	277	3.16		1.00		1.00	
Hispanic	85	**4.31**	0.001	1.41	0.96, 2.07	1.60	0.85, 3.00

Conclusion: At 5 years of follow up the AMS is higher in Hispanics by ethnicity and in Mexicans by country. Presence of any damage is lowest among Asians and in Asia. High levelsof damage accrual is associated with country (USA) but not necessarily with race/ethnicity.

1396

Microstructural Abnormalities in White and Deep Gray Matter Visualized within the First Year of Diagnosis in Adolescents with SLE: A Pilot Magnetization Transfer Imaging Study. Eyal Muscal[1], Elfrides Traipe[1], Elisabeth Wilde[1], Douglas R. Bloom[1], Barry L. Myones[1], Zili D. Chu[1], Robin L. Brey[2] and Jill Hunter[1]. [1]Baylor College of Medicine, Houston, TX, [2]UTHSCSA, San Antonio, TX

Background/Purpose: White and gray matter (WM, GM) damage may be early sequelae of SLE-mediated neuroinflammation and vasculopathy. Novel MRI modalities such as magnetization transfer imaging (MTI) may detect tissue alterations prior to the appearance of discrete lesions on

conventional imaging. We postulated that WM and deep GM abnormalities would be detected by MTI early in the disease course of adolescents with SLE.

Methods: Right handed-adolescents with SLE and age-matched healthy controls completed 3T MRI scans with conventional anatomic and MTI sequences. The average signal intensity of 5 mm regions of interest (ROIs) without discrete lesions was calculated from images with (M_S) and without (M_0) an MT pulse in bilateral WM and GM regions. The magnetization transfer ratio (MTR) for an ROI was calculated as $MTR = 100\% \cdot (M_0 - M_S)/M_0$. MTI metrics were calculated by researchers blinded to clinical status. We compared the MTR values of a priori WM and deep GM ROI of SLE and control subjects. Descriptive statistics were expressed as medians. Continuous variable group differences were assessed via non-parametric testing. Assuming that larger sample size values would be normally distributed unadjusted effect sizes were calculated as Cohen's *d* using observed group means and SD values.

Results: MTR values were generated for 10 SLE subjects and 10 healthy controls. Median age at imaging was 14.7 for SLE cohort and 14.9 for controls (range 13–18). Both cohorts had a female predominance (SLE 80%, controls 90%) and multi-ethnic composition (SLE: 50% Caucasian, 30% Hispanic, 10% bi-racial, and 10% Asian; CONTROL: 40% Caucasian, 30% Hispanic, and 30% African-American). Median duration from SLE diagnosis was 4.7 months (range 2.7–22.0 months), and the SLEDAI median score was 2.0 (range 0–8). LAC positivity was 40%, aPL positivity 50% and history of biopsy-proven nephritis 20%. Median prednisone dose at imaging was 30 mg (range 5–40 mg). There were no previous NPSLE events documented.

Discrete WM hyperintensities were observed in frontal or prefrontal regions in 70% of the SLE subjects (1–2 mm lesions). Mild cerebral and cerebellar volume loss was seen in 60% of SLE subjects. MTR reductions suggestive of WM and deep GM tissue alterations were apparent when comparing SLE subjects to controls. Effect sizes for MTR reductions ranged between 0.35–1.37. Statistically significant lower MTR values were observed in bilateral **WM** (frontal, centrum semi-ovale, and posterior internal capsule) and bilateral deep **GM** regions (caudate and globus pallidus) of the SLE subjects. Significant effect sizes were all large (Cohen's $d > 0.78$, p values $<$ 0.01). SLE group MTR values did not correlate with SLEDAI scores, cumulative prednisone dose, or disease duration since diagnosis.

Conclusion: Microstructural brain tissue alterations were visualized by MTI in adolescents with mild disease (non-NPSLE). Microstructural alterations were visualized even in regions that appeared normal on conventional anatomic sequences. Significant MTR reductions were in regions supplied by small perforator arteries of the anterior and middle cerebral arteries and may represent a early and indolent vascular or inflammatory injury.

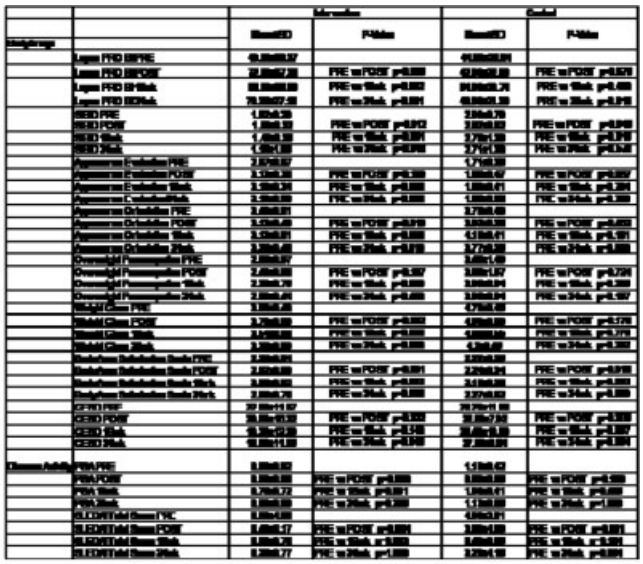
1397

Lupus and Body Image: An Intervention That Works. Meenakshi Jolly[1], Kristin Peters[2], Rachel A. Mikolaitis[1], Kali Evans-Raoul[3], Thomas F. Cash[4] and Joel A. Block[1]. [1]Rush University Medical Center, Chicago, IL, [2]University of Missouri Health Care, Columbia, MO, [3]The Image Studios, Chicago, [4]Old Dominion University, Norfolk, VT

Background/Purpose: Systemic Lupus Erythematosus (SLE) can be potentially disfiguring, involve multiple organs and adversely affect their physical and emotional health. Our previous work shows Body Image (BI) is poor among women with SLE and is predictive of poor health outcomes. This study aimed at determining the feasibility and effectiveness of a novel BI intervention in improving (1) BI and (2) Health outcomes, among women with cutaneous SLE.

Methods: Body Image Intervention comprising of education, cognitive behavioral therapy (tailored for SLE) and cosmetic training (tailored for SLE) was offered to 10 SLE patients (inactive to mildly active) once a week for 10 weeks, along with standard of care as a pilot study. Each session lasted 1hr-45 minutes. Five SLE patients (inactive to mildly active) were followed with standard of care but without any active intervention. Multi Dimensional Body Relations Satisfaction –Appearance Scale (MBRSQ-AS), Situational Inventory of Body Image Dysphoria (SIBID-SF) and Body Image in Lupus Screen (BILS) were used to measure BI. Center for Epidemiological Studies Depression (CES-D), Self Esteem (SE), Coping (Brief), Anxiety and Lupus-PRO were used for health outcomes. Data was obtained baseline, post intervention, followed by 18 and 24 weeks post intervention. Descriptive statistics and paired t tests analysis were performed. P value of ≤ 0.05 was considered significant on two-tailed test.

Results: Mean age (SD) was 42.4 (13.2) yrs. 25/29 had SLE. Ninety seven percent were women and 46% had a flare at the time of the study. Mean (SD) total scores were CLASI activity 8.8 (5.6), CLASI damage 9.6 (9.1), PGA 1.1 (0.8), SLEDAI 4.5 (4.1) and SDI 1.8 (2.2). Fifty-nine percent patients were on prednisone and 66% on hydroxy-chloroquine. Mean (SD) EQ5D VAS was 73 (15.1), and BIQLI 0.39 (1.5). CLASI activity score correlated with SLEDAI-rash item (r 0.46, p=0.01), LupusPRO Lupus Symptom item on skin flare (r 0.37, p=0.05), EQ5D VAS (r −0.49, p=0.04), but not with PGA (r 0.35, p=0.08) or total SLEDAI (r 0.19, p=0.33). CLASI damage score correlated with age (r 0.45, p=0.02), SDI items on cutaneous skin scarring/alopecia (r 0.51, p=0.001), skin extensive scarring/panniculum (r 0.51, p=0.01) and skin ulceration (r 0.37, p=0.05) and total SDI score (r 0.53, p=0.001). BIQLI was not associated with CLASI activity or damage score. However, CLASI face activity adversely affected patient's interactions with people of their own sex (r −0.53, p=0.001), interactions with people of opposite sex (r −0.49, p=0.01), experiences when they met new people (r −0.36, p=0.05), experiences at work/school (r −0.45, p=0.01), relationships with friends (r −0.40, p=0.03) and relationships with family members (r −0.39, p=0.04).



Conclusion: Body Image is modifiable in SLE. The proposed intervention was successful; improvements in BI persisted at 24 weeks after the intervention and lead to significant improvements in other health outcomes in this study.

1398

Clinical-Pathological Correlates of Proliferative Lesions in Lupus Nephritis. Claire Barber[1], Murray B. Urowitz[2], Dafna D. Gladman[3], Joan E. Wither[4], Carolina Landolt-Marticorena[2], Heather Reich[5], Wendy Lou[6], Jiandong Su[7], Jonathan Yip[8], Gan Qian[6], David Thomas[9], Samih Nasr[10], Rohan John[8], Ellie Aghdassi[8] and Paul R. Fortin[7]. [1]Mount Sinai Hospital, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON, [4]Toronto Western Research Institute, University Health Network, Toronto, ON, [5]The Toronto Western Hospital, Toronto, ON, [6]Dalla Lana School of Public Health, Toronto, ON, [7]Toronto Western Hospital, Toronto, ON, [8]University Health Network, Toronto, ON, [9]Nephrocor, Long Island, NY, [10]Division of Anatomic Pathology, Mayo Clinic, Rochester

Background/Purpose: To examine the clinical-pathological correlates at time of renal biopsy in patients with lupus nephritis according to the 2003 International Society of Nephrology and Renal Pathology Society (ISN/RPS) classification.

Methods: We studied a large prospectively followed cohort of SLE patients from a single centre with renal biopsy slides available and matched clinical follow-up. Demographic and clinical data collected at time of renal biopsy included age, gender, disease activity (SLEDAI-2K) and damage (SLICC damage index). Renal biopsies were reviewed by two expert pathologists independently and by a third pathologist where disagreement occurred to determine a consensus score. The degree of agreement between pathologists on individual items of the ISN/RPS score was measured. We included only pathologic variables with at least moderate agreement (kappa ≥ 0.6). The variables included ISN/RPS class I-VI of nephritis. For class III, the subclasses of active (A), active and chronic (A/C) and chronic (C) had poor agreement and were considered as a single class. For class IV, the

agreement was poor for the segmental versus global subclasses but acceptable or the active A, A/C or C lesions. Correlates between these variables and clinical characteristics at time of biopsy were determined using chi-square or Fisher's exact test. Univariate and multivariate regression models were generated to examine the outcomes of complete remission (CR) defined as serum creatinine (sCr) $<$ 1.4 mg/dl and proteinuria of $<$ 0.33 g/d, partial remission (PR) defined as a $<$ 25% increase in baseline sCr and $>$ 50% reduction in baseline proteinuria to $<$ 1.5 g/d and no remission at 6, 12 and 24 months post-biopsy.

Results: 137 patients had biopsy slides available for review. The average age at time of biopsy was 37.2 $\pm$ 12.0 years, 81.5% were female and 64.2% were Caucasian. The majority of biopsies showed class III (24.8%) or class IV nephritis (IV-A: 12.4%, IV-A/C: 22.6%, IV-C: 4.4%) and 14.6% were pure class V. The estimated glomerular filtration rate (eGFR) was lower in patients with class IV- A/C (42.8 mL/min/1.73m^2) compared to all other groups (85.1 mL/min/1.73m^2, $p < 0.001$) and higher in class III (91.6 mL/min/1.73m^2, $p = 0.002$). The mean arterial pressure (MAP) was higher in patients with class IV-A/C compared to other classes (107.6 $\pm$ 18.4mmHg versus 98.1 $\pm$ 13.5mmHg, $p = 0.02$). The SLEDAI-2K and a non-renal SLEDAI-2K were no different between classes; however the anti-dsDNA levels by Farr assay at time of biopsy were highest in class III (40 U/mL versus 16 U/mL, $p = 0.02$) and lowest in class IV-C biopsies (5 U/mL versus 22.5 U/mL, $p = 0.01$) and C3 levels were lowest in class IV-A and IV-A/C (0.4 $\pm$ 0.2 vs 0.8 $\pm$ 0.30 $<$ 0.001; 0.6 $\pm$ 0.3 vs 0.8 $\pm$ 0.4, $p = 0.04$). On univariate analysis the presence of a higher C3 levels at time of biopsy was associated with CR at 24 months (OR 6.18, 95% CI: 1.33, 28.69). On multivariate analysis none of the pathologic variables was independently associated with CR or PR at any time point.

Conclusion: Distinct clinical features at the time of renal biopsy are associated with specific ISN/RPS subclasses of lupus nephritis however no pathologic features were independently associated with renal outcome.

1399

Chronicity Index, Especially Glomerular Sclerosis, Is An Independent Predictor of Renal Response Following Immunosuppressive Treatment in Patients with Lupus Nephritis. Dong-Jin Park[1], Sung-Ji Lee[1], Tae-Jong Kim[2], Yong-Wook Park[2] and Shin-Seok Lee[1]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Chonnam National University Medical School and Hospital, Gwangju, South Korea

Background/Purpose: Renal responses to immunosuppressive agents in patients with lupus nephritis (LN) differ widely depending on ethnicity, follow-up duration, disease severity, and treatment. Activity and chronicity indices seem to be better predictors of renal response than other factors. However, these results have not been uniformly confirmed by other studies. Thus, we evaluated the predictors of renal remission at the first year following immunosuppressive treatment in patients with LN.

Methods: We studied 79 patients who had kidney biopsy prior to the start of induction treatment, and who subsequently were treated with immunosuppressive drugs for at least 6 months and followed-up for more than a year. Sociodemographic, clinical, laboratory, and treatment-related data at the time of kidney biopsy and during follow-up were obtained by reviewing patients' charts. Renal response was defined as an inactive urinary sediment, a decrease in urinary protein to creatinine ratio $<$ 0.5, and normal or stable renal function. Multivariate analyses were performed using the logistic regression model to identify independent predictors of renal response in LN patients.

Results: After 1 year, renal response was achieved in 39 of 79 patients (49.4%) treated with immunosuppressive drugs. Intravenous cyclophosphamide was most commonly used as a treatment, followed in descending order of frequency by mycophenolate mofetil, azathioprine, and cyclosporine. Renal response was associated with disease duration at the onset of LN ($P<0.05$), chronicity index on renal histology ($P<0.05$), glomerular sclerosis ($P< 0.001$), tubular atrophy ($P<0.05$), interstitial fibrosis ($P<0.05$), and the use of hydroxychloroquine at the onset of LN ($P<0.05$). In multivariable regression analysis, glomerular sclerosis in the chronicity index ($P<0.01$) and disease duration at the onset of LN ($P<0.05$) were significant predictors of the renal response in LN patients.

Conclusion: Our findings suggest that glomerular sclerosis in the chronicity index is an independent predictor of renal response after the start of therapy in LN patients.

1400

Asian Ethnicity Is Associated with Increased Disease Severity in An Urban Australian SLE Cohort. Alberta Y. Hoi, Vera Golder and Eric F. Morand. Monash University, Melbourne, Australia

Background/Purpose: Limited information is available to describe disease differences between Asian and Caucasian SLE patients. We sought to investigate the hypothesis that Asian ethnicity is associated with increased disease severity, using prospectively collected clinical data from an Australian clinic in which patients of diverse ethnicities are managed.

Methods: Data was collected prospectively from all consenting patients seen at the Lupus clinic of an urban teaching hospital, between May 2007 and April 2011. ACR criteria, disease activity (SELENA SLEDAI), disease related damage (SLICC-SDI) were documented as published. Ethnicity was self-assigned, and was defined according to common heritage, often consisting of same country of birth, ancestry, linguistic and cultural traits. Analyses were done comparing Asians vs non-Asians. Persistently active disease was defined as $\geq$2 consecutive visits where SLEDAI was $\geq$6.

Results: 131 subjects, mean age 44 years (range 20–78), with mean disease duration 11 years (range 1–33) were prospectively followed for an average of 33 months (range 5–37). All fulfilled $\geq$4 ACR diagnostic criteria. Asian SLE patients (n=52, 40%) differed significantly to non-Asian patients (n=79, 60%) in multiple domains. Asians were significantly less likely to have photosensitivity (OR 0.44 95%CI 0.20–0.95 p=0.04), and significantly more likely to have renal disease (OR 2.89 95%CI 1.40–5.98 p=0.01). Asian SLE patients were significantly more likely to have anti-dsDNA (OR 4.15 OR 1.66–10.37 p<0.01), anti-RNP (OR 4.12 95%CI 1.68–10.12 p<0.01), anti-Sm (OR 4.44 95%CI 1.46–13.50 p=0.01), anti-Ro (OR 3.59 95%CI 1.72–7.51 p<0.01) and hypocomplementemia (OR 2.64 95%CI 1.04–6.71 p=0.04). In this cohort, 47% had persistently active disease, as defined; 24% had persistently active disease for over 6 months in duration. Asians SLE patients were significantly more likely to have persistently active disease (OR 2.14, 95%CI 1.05–4.38 p=0.04). Asians also had a higher maximum SLEDAI score (mean 10.82 vs 7.73, p<0.01), and time-adjusted mean SLEDAI (5.94 vs 4.26, p=0.01). There was no significant difference in disease activity according to household incomes or education levels. During the observed period, Asian patients were significantly more likely to be treated with prednisolone (OR 2.93, 95%CI 1.25–6.85 p=0.01), azathioprine (OR 2.16, 95%1.05–4.44 p=0.04), and mycophenolate (OR 2.48 95%CI 1.06–5.81 p=0.03), and trended towards greater likelihood of cyclophosphamide treatment (OR 3.94, 95%CI 0.97–16.02 p=0.04). Asians were significantly more likely to have had avascular necrosis (OR 22.23 95%CI 1.22–403.9 p<0.01), and trended towards greater likelihood of persistent nephrotic proteinuria (OR 8.30 95%CI 0.94–73.25, p=0.03) and cardiomyopathy (OR 11.24 95% CI 0.57–222.5 p=0.03).

Conclusion: In a single urban teaching-hospital lupus clinic in Australia, Asian ethnicity was significantly associated with serologically more active and clinically more severe SLE. Evidence of greater autoantibody positivity and a lack of correlation with socioeconomic factors suggest genetically-based regulation of autoimmune responses play an important role in disease severity.

1401

Incidence and Prevalence of Systemic Lupus Erythematosus in Buenos Aires, Argentina: A 11 Years Health Management Organization Based Study. Soledad M. Valeiras[1], Martin F. Marchese[1], Alejandro S. Talani[1], Nicolas L. Avellaneda[1], Alvaro Etchepare[1], Patricio Etchepare[1], Maria S. Plou[1] and Enrique R. Soriano[2]. [1]Instituto Universitario, Escuela de Medicina, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Background/Purpose: There are differences in the epidemiology of autoimmune diseases in different countries. Studies regarding the epidemiology of systemic lupus erythematosus (SLE) are lacking in Argentina. The purpose of this study was to estimate the incidence and prevalence of SLE in a University Hospital based Health Management Organization in Buenos Aires (HIMCP).

Methods: *Population*: For incidence calculation the population at risk was all adult members of the IHMCP (>18 years old), with continuous affiliation for at least one year from January 1998 to January 2009. Each person was followed until he/she voluntarily left the IHMCP, death or finalization of the study (final dates) contributing time at risk since January 1998 or enrollment date (whichever occurred later) to that final date. *Case ascertainment*: multiple methods for case finding were used to ensure complete ascertainment: a) patients with the problem SLE, undifferentiated autoimmune disease or mixed connective tissue disease in the IHMCP problem oriented Computer-based Patient Record System, b) patients with positive Antinuclear antibody test (ANA titule>1/160) and/or positive anti-sm antibodies and/ or anti dsDNA antibodies in the Hospital laboratory database, and c) patients who consumed hydroxichloroquine, chloroquine, azathioprine, cyclophosphamide, mycophenolate mofetil, cyclosporine, and or rituximab, from the administrative IHMCP drugs database. Medical records of all patients found were reviewed, and only patients fulfilling ACR criteria for SLE were included. *Statistical analysis:* Global and by gender incidence rate (IR) was calculated with 95% confidence intervals (CI). Prevalence was estimated at 1/1/ 2009, and the denominator population was the number of active members > 18 years at that date (n= 127,959).

Results: In the study period 186,086 persons contributed a total of 1,082,817.6 person-years, of whom 68 developed SLE: IR: 6.28 (CI: 4.9 – 7.7) cases per 100,000 person-years. There were 57 females: IR: 8.95 (CI: 6.6 – 11.2) cases per 100,000 person-years; and 11 males: IR: 2.55 (CI: 1.2 – 3.9) cases per 100,000 person-years. On January 1/ 2009, 75 prevalent cases were identified: prevalence: 58.6 (CI: 46.1 – 73.5) cases per 100,000 inhabitants (females: 83.2 (CI: 63.9 – 106.4) and males: 23 (CI: 11.9 – 40.1) per 100,000 members).

Conclusion: This is the first report of incidence and prevalence of SLE in Argentina. Incidence and prevalence rates were similar to those from large series in Europe and lower than in other Latin American countries, perhaps reflecting the mainly European origin of this population in Buenos Aires. As expected incidence and prevalence of SLE was higher in females.

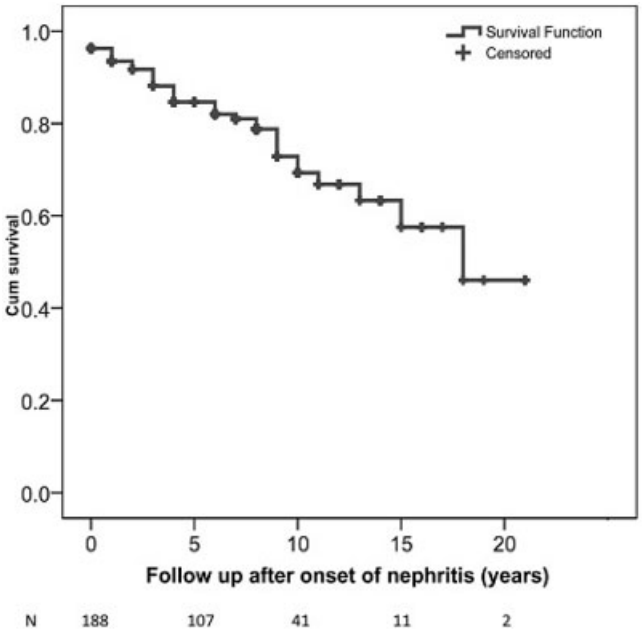
1402

Long-Term Outcome of Lupus Nephritis in Asian Indians Using Standard Therapy. Varun Dhir, Amita Aggarwal, Able Lawrence, Vikas Agarwal and Ramnath Misra. Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Lucknow, India

Background/Purpose: Lupus nephritis is an important complication in SLE. There have been impressive gains in outcome with current immunosuppressive regimens in developed countries. However, there is sparse data on the long-term outcome from developing countries including India. This study looked at outcome in Asian-Indians.

Methods: Retrospective study of SLE patients (fulfilling ACR 1997) with nephritis (unexplained proteinuria >=500mg with or without active sediments) seen at single Indian center over 20 years. They were treated as per standard regimens. Treatment response assessed by remission at 1 year (proteinuria<=2g/day with at least 50% reduction from baseline, no active sediments and serum creatinine<=1.5mg/dl). Primary outcome was development of chronic renal failure (CRF, serum creatinine>1.5mg/dl) or death. Secondary outcome was end-stage renal disease or death. Survival analysis was done using Kaplan-Meier and differences in survival by log rank test. Risk factors for poor outcome were assessed by cox-proportional hazards.

Results: The study included 188 patients of lupus nephritis, female: male ratio 11:1, mean age 23.6±10.5 years. Of these 136 patients had renal biopsy. Renal histology was: class II in 22, class III in 36, class IV in 61, class V in 16 and class VI in 1. Intravenous cyclophosphamide pulses (NIH) used as induction in most cases of proliferative nephritis: class III (85.3%), class IV (94.8%) and non-biopsied (71.1%). Most with non-proliferative nephritis received steroids with or without azathioprine: class II (73.7%) and class V (80%). The 1-year remission rate was 84.6%, with no statistical difference by class of nephritis. Median duration of follow up was 6 years (IQR 3–9). Survival with normal renal function was 84, 69 and 57% at 5, 10 and 15 years as shown in the figure (N= numbers at risk).



Survival curves were not different for various histological classes, however non-biopsied patients had lower survival compared to class II and class III or IV ($p<0.05$). Risk factors and hazard ratio (95% CI) for primary outcome on univariate analysis was number of infections 1.5 (1.1–2.0), initial serum creatinine 1.8 (1.4–2.2), hypertension 2.3 (1.0–5.1), hematuria 2.8 (1.3–6.1), low C3 3.0 (1.1–7.6) and absence of remission 13.8 (5.2–36.7). Only hematuria and absence of remission were significant on multivariate analysis. Renal survival at 5, 10 and 15 years was 91, 81 and 76%. Of 130 patients analyzed for complications, 45 (34.6%) had at least one serious infection, including tuberculosis in 17 (13.1%). There were 16 deaths, half due to infections (half of these were due to TB).

Conclusion: Outcome of lupus nephritis in Asian-Indians on standard treatment is comparable to developed nations. Lack of remission at 1 year and hematuria were risk factors for poor outcome. There was a high rate of infections especially tuberculosis; these were also a major cause of death.

1403

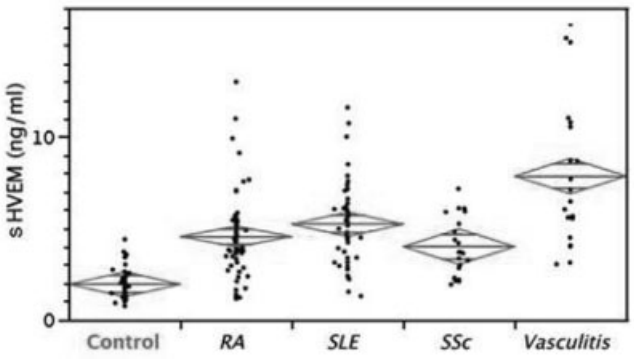
Soluble Form of Herpesvirus Entry Mediator (HVEM) Is Elevated in Sera of Active Collagen-Vascular Diseases and Might Be a New Biomarker of Disease Activity. Satoko Arai, Kazuhiro Kurasawa, Harutsugu Okada, Takayoshi Ohwada, Reika Maezawa and Takeshi Fukuda. Dokkyo Medical University, Mibu-machi, Tochigi-ken, Japan

Background/Purpose: Herpesvirus entry mediator (HVEM), a member of TNF receptor superfamily, regulates immune-responses. HVEM binds to LIGHT to activate both interacting cells. In addition, HUVEM interacts with BTLA and CD160 to deliver negative signals. Animal studies have shown that HVEM/ LIGHT/ BTLA/ CD160 interactions are involved in the development of autoimmune diseases. However, role of these molecules in human collagen-vascular diseases are not fully clarified.

The aim of this study are to determine whether there exists soluble form of HVEM (sHVEM) in sera from CVDs, and to clarify clinical importance of sHVEM in CVDs.

Methods: We developed a EIA system for detection of sHVEM and examined sera before treatment from SLE(n=44), RA(n=63), scleroderma(SSc)(n=21), vasculitis(n=21), and healthy controls(n=42). Clinical features of the patients were examined by reviewing medical records.

Results: Serum levels of sHVEM in controls were 1.93+0.85ng/ml. Soluble HVEM levels were significantly elevated in sera from CVDs (Fig.). The levels were 5.27+2.31 (average+ s.d.) in SLE, 4.50+2.23 in RA, 3.99+1.57 in SSc and 7.84+3.99 ng/ml. When cut-off level was determined as 3.63 ng/ml (average +2SD), elevation of s HVEM was found in 72.7% of SLE, 66.6% of RA, 52.3% of SSc and 95.2% of vasculitis.



In SLE, patients with low complement levels or high anti-DNA titers showed high sHVEM levels compared to those without the abnormalities. No significant relation was found between sHVEM levels and organ involvements. In RA, sHVEM levels from patients with moderate to high disease activity were higher than those with remission or low disease activity. In vasculitis, patients with more extended organ involvements had higher sHVEM levels. Moreover, immunosuppressive therapy reduced sHVEM levels significantly in SLE, RA and vasculitis.

Conclusion: Soluble form of HVEM exists in human sera. Serum levels of sHVEM were significantly elevated in varieties of CVDs compared to controls. The elevation of sHVEM reflects disease activity and treatment reduced titer of the molecules. Soluble form of HVEM could be a candidate of new biomarker of disease activity of CVDs.

1404

Utility of IFN-α As Biomarker in Central Neuropsychiatric Involvement in SLE. Hilda Fragoso-Loyo, Yemil Atisha-Fregoso, Carlos Nuñez-Alvarez, Luis LLorente-Peters and Jorge Sánchez-Guerrero. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico

Background/Purpose: An accurate indicator of central nervous system (CNS) involvement in SLE has not yet been identified. Aim: To assess the utility of interferon (IFN)-α in serum and cerebrospinal fluid (CSF) as biomarker of disease activity in central neuropsychiatric systemic lupus erythematosus (cNPSLE).

Methods: In 34 patients with cNPSLE, 44 non-NPSLE, 16 surgical-SLE, 4 primary-neuropsychiatric, and 25 non-autoimmune, serum and CSF samples were drawn at hospitalization, except non-NPSLE in whom only serum was studied. Six-months later, serum/CSF and serum samples were taken in 20 cNPSLE and 35 non-NPSLE patients. All patients were evaluated by the study rheumatologists and neurologists, at hospitalization and six months later using a standardized protocol. SLE activity (SLEDAI-2K) was assessed at hospitalization in all patients, and six-months later in cNPSLE and non-NPSLE. The central NP manifestations included: seizure disorders 13, severe refractory headache 7, acute confusional state 8, cerebrovascular disease 4, psychosis 1, and transverse myelitis 1. Interferon-a was detected by xMAP milliplex technology according to the protocol of milliplex MAP (Millipore) kits (LINCO, Millipore, Billerica, MA.).

Results: The mean $\pm$ SD age of cNPSLE patients was 31.4$\pm$12.2 years, which was similar across study groups (p=0.46). SLEDAI-2K scores among cNPSLE, non-NPSLE, and SLE-surgical patients were 15.3$\pm$8.2, 12.4$\pm$8.2, 3.8$\pm$1.5, respectively.

INF-α levels in serum were higher in cNPSLE than non-autoimmune patients (P=0.02), but were similar to non-NPSLE and SLE-surgical groups. In CSF, IFN-a levels were higher in cNPSLE than in non-autoimmune patients (P = 0.03), and non-significantly higher than SLE-surgical and primary-neuropsychiatric.

Six months later, serum levels of IFN-α did not vary from baseline values despite a significant decrease in SLEDAI-2K score in cNPSLE and non-NPSLE patients. CSF levels of IFN-α in cNPSLE also remained stable. IFNa levels in serum and CSF showed a fair correlation rs = 0.25 (P = 0.07), but the correlation of both of them with cNPSLE activity was poor.

Conclusion: Serum and CSF IFN-a levels in cNPSLE are not higher than in patients with non-NPSLE hence, IFN-a is not a useful biomarker of CNS involvement in SLE.

1405

Peripheral Arterial Disease in Systemic Lupus Erythematosus. Jose-Gabriel Erdozain[1], Irama Villar[2], Javier Nieto[2], María-Victoria Egurbide[2] and Guillermo Ruiz-Irastorza[2]. [1]Hospital de Mendaro, Mendaro, Spain, [2]Hospital de Cruces, UPV/EHU, Barakaldo, Spain

Background/Purpose: The prevalence of peripheral arterial disease (PAD) in lupus patients is unknown. An ankle-brachial index (ABI) < 0.9 has a good correlation with the presence of PAD. The aims of the study are: 1) To analyze the prevalence of PAD, cardiovascular disease (CVD) and cardiovascular risk factors in a cohort of systemic lupus erythematosus (SLE) patients. 2) To identify potential predictors of PAD in patients with SLE.

Methods: Two hundred seventeen SLE patients from the Lupus-Cruces prospective observational cohort were recruited. The ABI was determined in every patient. The relation of a low ABI with demographic and clinical variables, the presence of traditional risks factors and cardiovascular events, the cardiovascular risk calculated by SCORE and the treatments received by each patient was analysed.

Results: Ninety two percent of patients were women. The mean age (SD) was 49 years (15) at the time of the study and 36 years (16) at lupus diagnosis. Mean follow-up (SD) was 12 years (10). The prevalence of low ABI was 47 (21.7%). The mean cumulative dose of prednisone (SD) was 22 gr. (56). Twenty one patients (11%) had never received antimalarials. 22 patients (10.1%) had antiphospholipid syndrome and 74 (34%) had antiphospholipid antibodies. Lupus nephritis was present in 60 (27.6%) patients. Cardiovascular risk factors distribution was as follows: smoking 65 (30%), high blood pressure (HBP) 70 (32%), diabetes 7 (3.2%), dyslipidemia 74 (34%) and family history 25 (11.5%). Previous symptomatic arterial disease was present in 27 patients (12.4%).

Patients with low ABI were older (57 vs. 46 years, p<0.0001), and had more frequent HBP (34% vs. 15%, p=0.002), diabetes (57% vs. 20.5%, p=0,041), dyslipidemia (31% vs. 16%, p=0.015) and previous cardiovascular events (52% vs. 17.5%, p<0.0001). A high SCORE identified patients with low ABI (p=0.006). A history of lupus nephritis, antiphosphoiipid syndrome or positivity for antiphospholipid antibodies was not different between patients with low and normal ABI. Regarding lupus treatments, only a lower cumulative dose of cyclophosphamide was related to a low ABI (1.1 vs. 2.7, p=0.023). Patients with low ABI had higher levels of fibrinogen (425 mg/dl vs. 378 mg/dl, p=0.003).

Conclusion: The prevalence of PAD is higher in SLE patients than in the general population. Traditional risk factors are be associated with PAD in patients with SLE. The influence of lupus itself and lupus treatments is still unclear.

1406

Characteristics of Disease Activity and Organ System Involvement in a Cohort of patients with Systemic Lupus Erythematosus Followed for More Than One Year. Marta Mosca[1], Chiara Tani[2], Linda Carli[1], Grazia Maria Rizzelli[1], Rossella Neri[1], Antonio Tavoni[3], Anna d'Ascanio[4] and Stefano Bombardieri[4]. [1]University of Pisa, Pisa, Italy, [2]University of Pisa, Italy, [3]Via Roma 67, Pisa, Italy, [4]Rheumatology Unit, Pisa, Italy

Background/Purpose: The clinical picture of systemic lupus erythematosus (SLE) is very complex due to the wide variety of clinical manifestations, to the alternance of flares and remission and to damage accrual. It is common clinical experience the fact that in some patients many organ systems will be involved by active inflammation over disease history, while in some patients disease activity is mainly observed in few organ systems.

Aim of the present study was to evaluate the characteristics of disease activity and organ system involvement in a cohort of SLE patients regularly followed at a single Unit.

Methods: Patients regularly followed at our clinic with a disease duration of more than one year were selected for this analysis. Clinical charts were reviewed to obtain epidemiological and clinical data. A diagnosis of flare was based both on the judgement of the treating physician and on changes in the therapeutic approach. The predominant type of organ involvement at each flare was recorded. The disease was defined as "*monomorphic*" if during the disease course flares involved the same organ system, "*complex*" if different organ/systems have been involved in different flares.

Results: One hundred and sixty five patients were included in this

analysis, mean disease duration was 15.8 years ± 8.7 (min 2 max 41). During the disease course 121 patients (73%, mean disease duration 17.3 years) presented at least one disease flare; based on the previously reported definition 66 patients had a "*complex*" disease characterized by the sequential accrual of different organ involvement, while 99 patients had a "*monomorphic*" disease. More specifically we could identify three more common patterns of "*monomorphic*" disease which were those with predominant articular, cutaneous and renal manifestations. No differences were observed if patients were subdivided on the basis of disease duration (more or less than 15 years).

Conclusion: These observations support the general concept of SLE a single disease in which potentially any system might be involved by disease activity during the disease course, but highlight also the fact that subtypes of the disease also exist which are characterized by a less wide clinical picture. These differences might be related with differences in patient's genetic background and in environmental factors. Prospective studies to better clarify this aspect and characterize these subpopulations could allow the identification of biomarkers, specific therapeutic targets and help optimizing and possibly personalizing patients treatment.

1407

Medication Impact on Gene Expression Patterns May Depend on Biologic Subgroups in the Biomarkers of Lupus Disease (BOLD) Study. Margot O'Toole[1], Ying Zhang[1], Attila Seyhan[1], Frederick W. Immermann[2], Andrew A. Hill[3], Padmalatha S. Reddy[3], Sudhakar T. Sridharan[2], Monique Lehmann[2], Jaime L. Masferrer[4], Tianhui Zhou[2], William M. Mounts[3], Maryann Whitley[3], Terry Walker[1], Stan Kamp[5], Judith A. James[6], Marek Honczarenko[1] and Joan T. Merrill[7]. [1]Pfizer, Cambridge, MA, [2]Pfizer Inc, Collegeville, PA, [3]Pfizer, Cambridge, [4]Pfizer Inc, Cambridge, MA, [5]Oklahoma Medical Research Fund, Oklahoma City, [6]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK, [7]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Background immunosuppressives (IS) may augment or interfere with responses to targeted therapies in SLE patients, and be potent confounders in clinical trials and practice. The BOLD study examines the clinical-biological effects of medications commonly used in SLE.

Methods: An interim analysis of the first 55 patients and 15 healthy controls has tested expression levels of 270 known lupus or inflammation associated genes by TaqMan PCR.

Results: Significant ($p < 0.05$) expression differences vs controls were detected for 51% of assayed genes. Patients segment into an *IFN High* group (n=31) expressing IFN signature genes at levels higher than controls, and *IFN Low* (n = 24), who express many genes, including some IFN and IL21 pathway genes, at levels **lower** than control. Associations between medication use and gene expression were found in analyses of 34 patients on antimalarials, 15 on AZA, 11 on MTX, and 6 on MMF. The two IFN groups differ with respect to impact of medications on expression levels of genes associated with lupus. Examples include:

		Change with Medication in Lupus Patients	
Gene	**Medication**	***IFNHigh*Group**	***IFNLow*Group**
TBX21	Antimalarials	**Decreased (p = 0.02)**	NS (p = 0.47)
NOD2	Antimalarials	NS (p = 0.87)	**Increased (0.0006)**
IL1RL1	AZA	NS (p = 0.53)	**Increased (0.04)**
IFNGR2	MTX	NS (p =0.12)	**Decreased (0.02)**
USP18	MTX	**Increased (p = 0.02)**	NS (p = 0.42)
ITGAX	MMF	**Increased (p = 0.02)**	NS (p = 0.67)

To date 23 patients have completed the BOLD protocol: withdrawn from background IS, briefly treated with steroids, then followed until flare. Expression levels of 17 genes increased (eg. KLRG1, p = 0.0029), and 22 decreased (eg, CXCR2, p = 0.0017) with flare. Patients tend to remain within their IFN group irrespective of successful treatment or subsequent flare ($p<0.001$).

Conclusion: BOLD suggests there may be distinct lupus subsets characterized by IFN inducible gene expression, and that these groups may differ with respect to the impact of commonly used medications.

1408

Treatment Regimens of Patients Enrolled in the Lupus Clinical Trials Consortium (LCTC). Alana B. Levine[1], Doruk Erkan[2], Jill P. Buyon[3] and Michael D. Lockshin[2]. [1]Hospital for Special Surgery, New York, NY, [2]Barbara Volcker Center for Women and Rheumatic Diseases, Hospital for Special Surgery, New York, NY, [3]NYU School of Medicine, New York, NY

Background/Purpose: Systemic lupus erythematosus (SLE) has a wide spectrum of clinical manifestations requiring varied treatment regimens. The LCTC, an organization affiliated with 18 academic institutions across the United States and Canada, collects clinical information on SLE patients. Each center aims to follow 100 patients for five years. This study compares LCTC physicians' predictions to actual past and current treatment of LCTC patients and assesses variance of current treatment among centers.

Methods: *Phase 1:* We conducted a multiple choice survey of LCTC physicians regarding treatment expectations for the entire cohort. The expectation survey was performed without respondents' knowledge of full registry content. *Phase 2:* We assessed past and current treatment of patients enrolled in LCTC.

Results: *Phase 1:* 29 physicians from 18 institutions completed the survey (Table). *Phase 2:* We analyzed treatment regimens of 1242 patients, of whom 1136 (91.5%) are female, 599 (48.2%) Caucasian, 423 (34.1%) Black, 135 (10.9%) Asian, and 85 (6.8%) other; 146 (11.7%) are Hispanic. The mean age at the time of registry entry was 40.5 ±13.2 years (range 18–78) and mean disease duration 9.5 ±8.1 years (range 0–56). Since diagnosis, 93%, 76%, and 15% of patients had been treated with systemic corticosteroid, immunosuppressive, and biologic medications, respectively. At the time of enrollment in LCTC, 77%, 57%, 55%, and 5% of patients were currently receiving antimalarial, systemic corticosteroid, immunosuppressive, and biologic medications, respectively (Table). Frequency of use of these medications varied among participating centers. 79% of physicians accurately predicted rate of systemic corticosteroid use since diagnosis, 21% immunosuppressive use, and 74% biologics use. For treatment at the time of enrollment, 62%, 52%, 48%, and 79% of physicians correctly predicted antimalarial, systemic corticosteroid, immunosuppressive, and biologic medication use, respectively. Among centers, the ranges of frequency of actual current use of corticosteroids were 40–83%, immunsuppressants 30–80%, antimalarials 55–89%, and biologics 0–10%.

Physicians' (n: 29) Predictions of & Actual Medication Use (AMU) in LCTC Cohort (n: 1242)

	# of Physicians Based on *Prediction* Choices				% of LCTC Patients (*AMU*) (% range amongst centers)
Medication–Past Use	0–25%	25–50%	51–75%	>75%	
Antimalarial	0	1	3	25	—
Systemic corticosteroid	0	1	5	**23**	93% (75–100%)
Immunosuppressive	1	9	13	**6**	76% (49–100%)
Biologic	**20**	5	2	0	15% (3–27%)
Medication–Current Use	0–25%	25–50%	51–75%	>75%	
Antimalarial	0	1	10	**18**	77% (55–89%)
Systemic corticosteroid	1	3	**15**	10	57% (40–83%)
Immunosuppressive	3	11	**14**	1	55% (30–80%)
Biologic	**23**	5	1	0	5% (0–10%)

Conclusion: LCTC physicians accurately predicted the frequency of antimalarial, corticosteroid, and biologic use for the entire cohort. Centers varied in rate of actual use of these medications, a circumstance that may reflect differences in patient selection, disease severity, or prescribing practices across participating institutions and that will be further explored. LCTC offers a real-life look at treatment of SLE patients today; the variances among centers have important implications for comparisons of translational and outcome data as well as for treatment trials.

Hydroxychloroquine-Induced Hyperpigmentation in Patients with Systemic Lupus Erythematosus. A Series of 23 Cases. Moez Jallouli, C. Francès, Jean-Charles Piette, Du Le Thi Huong, M. Miyara, D. Saadoun, A. Mathian, J. Haroche, C. De Gennes, G. Leroux, C. Chapelon, Bertrand Wechsler, Patrice Cacoub, Zahir Amoura and Nathalie Costedoat-Chalumeau. CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: To describe the clinical features and outcome of hydroxychloroquine-induced pigmentation in patients with systemic lupus erythematosus (SLE).

Methods: This was a retrospective, monocentric (SLE clinic, Pitié-Salpêtrière, Paris) study of SLE patients with pigmented lesions considered to be related to hydroxychloroquine (HCQ). All patients fulfilled the 1997 ACR revised criteria for SLE. The medical files of patients were analysed and all patients were interviewed. Pictures of skin lesions were systematically reviewed by a dermatologist. In five patients, the concentration of iron was

measured on samples of skin biopsy performed both in healthy skin and pigmented lesions.

Results: We found 23 patients who developed HCQ-induced pigmentation. All were women. Mean age at pigmentation development was 33.8 ± 13.1 years. Skin pigmentation appeared after a median duration of HCQ therapy of 64 months (range: 3 months-22 years). At the time of cutaneous pigmentation development, the median cumulative dose of HCQ was 657 grams (range: 36–3,168). During follow-up, 21 patients had measurements of blood HCQ concentration [HCQ]. The median number of measurements in a patient was 3 (range: 1–11). The mean [HCQ] was 1,189 ± 436 ng/ml. This value was not significantly different from that in a group of 143 unselected SLE patients who had been receiving HCQ 400 mg daily for at least 6 months [1].

Hyperpigmentation was localized on the anterior side of the legs (n=23), on the arms (n=5), and on oral mucosa (n=1). Twenty one patients (91.3%) reported that appearance of pigmented lesions was preceded by the occurrence of ecchymotic areas, which gave way to a localized blue-gray or black pigmentation that persisted.

Twenty two patients (95.6%) had at least one condition predisposing them to easy bruising: at the onset of pigmented lesions, 1 patient had persistent thrombocytopenia, 14 patients were treated with platelet antiagregants and 8 with oral anticoagulants. Four patients recalled a previous severe trauma to their legs (accident in 3 cases and combat sport in 1 case).

Six patients also presented HCQ retinopathy, that occurred before (n=4) or after (n=2) skin pigmentation. One patient developed an atrioventricular block of first degree which was reversible after discontinuation of HCQ.

HCQ was discontinued definitively because of skin pigmentation in 2 patients who reported a gradual incomplete fading of hyperpigmentation. Among patients who continued HCQ (n=21), an improvement of pigmented lesions was reported in 6, despite the maintenance of a similar daily dose of HCQ. Pigmentation was found stable in the other 15 patients.

The median concentration of iron in the skin samples taken from five patients was higher in pigmented lesions (4115 nmol/g) compared to normal skin (413 nmol/g).

Conclusion: we report a large single-center series of SLE patients with HCQ-induced skin pigmentation. These lesions were often secondary to ecchymosis. They were not clearly related to duration, cumulative dose or blood concentration of HCQ.

Response to Hydroxychloroquine in Japanese Patients with Cutaneous Lupus Erythematosus Using the Cutaneous Lupus Erythematosus Disease Area and Severity Index. Naoto Yokogawa[1], Takaharu Ikeda[2], Kyo Aizawa[3], Akiko Tanikawa[4], Masayuki Amagai[4], Yukihiko Kato[5], Yoko Momose[6], Satoru Arai[6], Hikaru Eto[6], Fukumi Furukawa[2] and Japanese Hydroxychloroquine Study Group[7]. [1]Tokyo Metropolitan Tama Medical Center, Section of Rheumatology, Tokyo, Japan, [2]Wakayama Medical University, Department of Dermatology, Wakayama, Japan, [3]Sanofi-Aventis K.K. Biostatistics & Programming, Tokyo, Japan, [4]Keio University School of Medicine, Department of Dermatology, Tokyo, Japan, [5]Tokyo Metropolitan Tama Medical Center, Section of Dermatology, Tokyo, Japan, [6]St. Luke's International Hospital, Department of Dermatology, Tokyo, Japan, [7]Japan

Background/Purpose: To evaluate the the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) in Japanese cutaneous lupus erythematosus (CLE) patients to design a clinical trial of Hydroxychloroquine (HCQ) in Japan.

Methods: This is a prospective cohort study of CLE patients with or without systemic lupus erythematosus (SLE) who started HCQ at four major institutions of Japanese Hydroxychloroquine Study Group: Tokyo Metropolitan Tama Medical Center, Wakayama Medical University, Saint Luke's Hospital, Keio University. All institutions obtained the Institutional Review Board approval for the use of HCQ. Ophthalmologic exams were mandated before starting HCQ and every six months after starting HCQ. The dose of HCQ was 200–400mg/d, and less than 6.5mg/kg/d. The therapeutic responses are assessed at four months by the change of CLASI activity score. Patients were categorized into responders (improved) or non-responders (unchanged or worsened) using the criteria of 4-point or 20% decrease in the CLASI activity score.

Results: Thirty patients, 17 with SLE, were included. Median dose of prednisolone (PSL) before HCQ was 3.75 mg/d. Five patients experienced minor adverse reactions (3 pts with transient eye symptoms, 2 pts had mild gastrointestinal symptoms, 1 pt with possible eruption) but all patients tolerated HCQ. Twenty-six patients (87%) were categorized as responders. The median (range) CLASI activity score of all patients changed from 9.6 (2–24) to 4.1 (0–11). Treatment effect of HCQ was consistent across subgroups with regards to baseline characteristics [Table1]. We performed multivariable analysis including severity of CLE (CLASI activity score: 9 or more), presence of SLE, types of CLE (acute CLE, subacute CLE, annular erythema, discoid LE) duration of CLE (5 year or longer), dose of PSL (5mg or more), and smoking. Among them, only CLASI activity score before HCQ revealed statistically significant (F= 30.1 p<0.0001) [Table 2].

Table 1.

Pared t-test	n	CLASI Activity (Pre)	CLASI Activity (Post)	Difference	t	p value
total	30	9.6	4.1	−5.3	−6.17	<.0001
SLE	17	9.2	4.2	−5.0	−4.37	0.0005
not SLE	13	10.2	4.0	−6.2	−4.27	0.0011

not smoking	13	8.7	3.7	−5.0	−5.199	<0.0001
CLASI Pre <9	17	4.9	2.8	−2.1	−2.9756	0.0089
CLASI Pre =>9	13	15.8	5.8	−10.0	−12.2747	<0.0001

* median of PSL was 3.75mg/d

Table 2.

Multivariable analysis	F	p value
Full model	3.64	0.0138
SLE	0.05	0.834
ACLE	0.63	0.4443
SCLE	0.33	0.5744
DLE	0.92	0.3557
Annular erythema	1.23	0.2887
Duration	1.08	0.3201
PSL	1.00	0.4899
Smoking	0.09	0.7749
Pre CLASI Activity	30.11	<.0001

Conclusion: The cutaneous aspects of SLE can be measured by the CLASI. The CLASI activity score may be a reasonable primary endpoint when performing a clinical trial of HCQ.

1411

Systemic Lupus Erythematosus and Sickle Cell Disease (SCD) As Comorbid Conditions. Asha Thomas, Madhu Kalyan Pendurthi, Robert W. McMurray and Vikas Majithia. University of Mississippi Medical Center, Jackson, MS

Background/Purpose: Systemic lupus erythematosus (SLE) and sickle cell disease (SCD) are chronic diseases with multisystem manifestations including arthritis, chest pain, proteinuria, and autoantiboides. The prevalence of SLE in an African-American (AA) population is about 1: 750 and that of SCD is 1:625. The exact prevalence of SCD in SLE is not known because most of the published studies are case reports. Surprisingly 20% of SCD patients have positive ANA. We aimed to measure the incidence of SCD among SLE patients at University of Mississippi Medical Center (UMMC) caring predominantly for African American population and characterize SCD complicated by SLE.

Methods: To characterize the incidence of comorbidity, we analyzed 115 clinic patients with SLE (> 4 ACR SLE criteria) with hemoglobin electrophoresis (HE) in consecutive patients seen between 2010 to2011. To further characterize the comorbid presentation of SLE/SCD we performed a retrospective chart review summary of SCD/SLE patients at our institution (7 patients identified) in addition to 39 cases reported in the literature. Data included demographic information, clinical features, medication history, hematologic and SLE parameters. Data was deidentified and tabulated.

Results: Based on HE, 2 SLE patients (1.5%) were HbSS and 11 SLE patients (13%) were heterozygotes, both of which are higher than the accepted population incidence of 0.25% HbSS and 8% SCD trait respectively. These are higher than accepted population prevalence of 0.25% HbSS and 8% SCD trait respectively. A summary result of the retrospective review of SCD with SLE is shown below:

Presenting Symptom/sign	n=46 cases
Age	24 + 2 years (mean + SD)
Sex	76% female
HbSS or Sickle positive	100%
ANA positivity	96%
Arthritis present	78%
Pleurisy present	39%
Proteinuria present	43%
Low C3/C4	22%
Anti-dsDNA positive	57%
APL positivity	24%

The majority of cases were successfully treated with corticosteroids and/or hydroxychloroquine, although some required azathioprine (17%) or cyclophosphamide (11%).

Conclusion: While the co morbid prevalence is rare, it is important to recognize the possibility of SCD complicated by or masquerading as SLE, especially in AA population. Surprisingly few cases of SCD/SLE were receiving hydroxyurea prophylaxis for SCD, although one report suggests a successful outcome for SLE/SCD co morbidity. Recognition of SCD in concurrence with SLE may be important to treatment strategies. A high index of suspicion is necessary as there did not appear to be markedly distinguishing characteristics of SLE/SCD disease manifestations. Further, the higher than expected incidence of SCD and SCD trait in our clinic population suggests that more rigorous epidemiologic and genetic investigation is necessary.

1412

Ultrasonographic Evaluation of Hand and Wrist in Systemic Lupus Erythematosus without Arthralgia. Hosung Yoon. The Catholic University, Incheon, South Korea

Background/Purpose: Articular involvement is one of the most common features of systemic lupus erythematosus (SLE) and includes joints and tendons, ranging from minor arthralgia to erosive or deforming arthropathy.[1, 2] Arthritis is typically non-erosive, non-deforming, and symmetric polyarthritis that usually involves the small joints of hands and wrists. Most SLE patients with arthritis have mild, transient course, a minority of SLE patients with chronic course may develop deformities, which could be erosive or non-erosive. Tendinopathies occur in SLE, leading to tendinitis, tenosynovitis, tendon rupture and tear.[3, 4] High resolution ultrasound (HRUS) is a sensitive imaging technique in evaluating joints and tendons. The addition of power Doppler ultrasound can detect active inflammation and are correlated with joint inflammatory activity.[5, 6] The purpose of this study is to evaluate ultrasonographic abnormalities in SLE without arthralgia in hand and wrist joints, and to correlate those with clinical parameters.

Methods: Eighty-two SLE without arthralgia (76 female, 6 male) were enrolled. Age and sex-matched 18 healthy volunteers (17 female, 1 male) and 13 SLE with arthralgia (12 female, 1 male) were included as controls. Physical examination of hand and wrist was recorded as tenderness and swelling. Disease activity was assessed using the SLEDAI (SLE Diseas Activity Index) score. MSUS using an 5– 13MHz linear array probe was used for imaging wrist, 2nd and 3rd MCP joints, and flexor tendons of 2nd, 3rd and 4th finger of nondominant side.

Results: Of Eighty-two SLE without arthralgia, wrist synovitis was found in 34 patients (41.5%) and MCP synovitis was noted in 45 patients (54.9%). Tendinitis and tenosynovitis were detected in 33 patients (40.2%) and 12 patients (14.6%), respectively. These abnormalities were observed more frequently in selected SLE with arthralgia (n=13). Synovitis thickness in joints and tendon thickness were greater in patients with arthralgia compared to those without ($p<0.002$ and $p<0.001$). Sum of synovitis grading score was positively correlated with SLEDAI ($r=0.49$, $p<0.001$) and anti-dsDNA antibody ($r=0.27$, $p=0.009$). Tendon thickness was positively correlated with sum of synovitis grading score ($r=0.22$, <0.031).

Conclusion: Synovitis or tendinopathies are common in SLE patients who do not suffered from arthralgia. Longitudinal study is needed to determine the meaning of sonographic abnormalities in SLE patients who do not suffered from arthralgia. SLE patients with high SLEDAI may need to take musculoskeletal sonography.

1413

Pregnancy Outcomes and Fetal Complications in Patients with Systemic Lupus Erythematosus: a Retrospective Analysis in Korea. Eun-Jung Park[1], Jiwon Hwang[1], Jaejoon Lee[2], Joong Kyong Ahn[3], Chan Hong Jeon[4], Hoon-Suk Cha[1] and Eun-Mi Koh[1]. [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Samsung Medical Center, Sunkyunkwan University School of Medicine, Seoul, South Korea, [3]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [4]Soonchunhyang University College of Medicine, Bucheon, South Korea

Background/Purpose: Systemic lupus erythematosus (SLE) predominantly affects women in reproductive year. The effect of pregnancy on the SLE disease activity and the influence of SLE activity on pregnancy outcomes are major concerns in the management of SLE. The aim of this study is to evaluate the pregnancy outcomes in SLE patients and to investigate the impact of pregnancy on disease activity and the effect of lupus activity on pregnancy with respect to fetal complications.

Methods: All pregnancies with SLE seen at Samsung Medical Center between November 1994 and December 2010 were included and retrospectively analyzed. Demographics, clinical manifestations, laboratory data and fetal outcomes were evaluated. SLE flare was determined by Lupus Activity Index-Pregnancy (LAI-P) score. Logistic regression analysis was used to determine the predictive factors for fetal complications.

Results: Sixty-two pregnancies were observed among 50 patients. Of these, 51 (82.3 %) live births and 11 (17.7%) fetal losses were seen. Of live births, 38 (74.5 %) full-term births and 13 (25.5 %) preterm births occurred. Thirteen cases of low birth weight and 9 intrauterine growth retardations were noted. Fetal losses included 3 spontaneous abortions, 2 stillbirths, and 6 therapeutic abortions. Proteinuria, 0.5g per day or more, during pregnancy was found to be a predictive factor for fetal complications adjusting for age, history of previous lupus nephritis, and history of steroid use (adjusted OR 5.59; $P = 0.024$). LAI-P score measurement was available in 36 pregnancies. Of these, SLE flare occurred in 12 pregnancies (33.3 %), mainly during the second trimester (37.5%). Renal involvement (69.2 %) was found to be the most common SLE flare during pregnancy, followed by thrombocytopenia (15.4 %), serositis (7.7 %) and vasculitis (7.7%). All flares were classified as severe flare according to LAI-P score. As expected, fetal losses, prematurity and low birth weights were observed more frequently in the flare group whereas live births and full-term births were observed more frequently in those without SLE flare.

Conclusion: Our data demonstrated a relatively higher rate of live births and lower rate of fetal losses in patients with SLE compared to previous reports. The rate of lupus flares during pregnancy was also lower and renal flare was the most common manifestation. Proteinuria, 0.5g per day or more, during pregnancy was found to be the sole predictive factor for fetal complications.

1414

Relationship Between Age of Onset and Clinical Profile In Systemic Lupus Erythematosus Patients. Julia Martínez-Barrio, Juan G. Ovalles, Francisco J. López-Longo, Inmaculada de la Torre, Lina Martínez-Estupiñán, Juan C. Nieto and Luis Carreño. Gregorio Marañón Hospital, Madrid, Spain

Background/Purpose: Several studies have shown that the clinical and immunological profiles of SLE are related to the age of onset[1]. However, other authors have not found any link between them[2]. To describe the clinical and immunological differences between Early, Adult and Late onset SLE.

Methods: 445 patients diagnosed with SLE between 1986 and 2006 were included in an inception cohort and followed up for a minimum time of one year (median 11, 1–20). Demographic, clinical and laboratory features were collected at recruitment time and every 12 months. Patients were divided into three groups: Early onset ≤ 18 years (n=92), Adult onset 19–50 years (n=276) and Late onset >50 years (n=77). Damage was scored at the end of the study using SLICC/ACR Damage Index. Sera samples were tested for autoantibodies, complement and immunoglobulins. Chi-square test and ANOVA with Bonferroni correction was applied for quantitative variables with a normal distribution, otherwise Kruskal-Wallis test was used.

Results: The sex ratio (F/M) was significantly higher in the Adult onset patients ($p=0.021$). At disease onset, the Early onset group presented more renal and skin manifestations ($p=0.023$; $p=<0.001$). During follow-up Early

onset group continued to have higher frequency of renal disease (p=<0.001), malar rash (p=<0.001), Raynaud's phenomenon (p=0.008), cutaneous vasculitis (p=0.006) and neurological manifestations (p=0.044) than the other two groups. Whereas arthritis was more frequent in the Adult onset group than in the others (p=0.031), the Late onset group had significantly more hypertension (p=0.048), neoplasias (p=0.017), disease duration (p=0.028), mortality (p<0.001) and accrual damage (p=0.037). As for laboratory data, lymphopenia was more frequent in Adults (p=0.005) and low serum complement (p=<0.001), anti-dsDNA, anti-U1RNP and anti-Sm were more common in Early onset patients.

Conclusion: Early onset SLE is clinically and immunologically different with more renal and neurological manifestations, cutaneous vasculitis, malar rash and Raynaud's phenomenon than Adult and Late onset SLE. The Early onset group presented higher frequency of low serum complement, anti-dsDNA, anti-U1RNP and anti-Sm antibodies. The accrual damage and mortality proportion observed in the Late onset patients may be related to the consequences of aging.

STATISTICALLY SIGNIFICANT FINDINGS

CHARACTERISTICS n=445	Early Onset ≤18 years (n=92)	Adult Onset 19–50 years (n=276)	Late Onset >50 years (n=77)
At Disease Onset

Serum Cystatin C Is Affected by Inflammation and Renal Dysfunction in Patients with Systemic Lupus Erythematosus. Christine LY Chew[1], Awal Al-M Husain[1], Philip Pemberton[2], Sahena Haque[1], Allen Yates[2] and Ian N. Bruce[3]. [1]University of Manchester, Manchester, United Kingdom, [2]Manchester Royal Infirmary, Manchester, United Kingdom, [3]A, Manchester, United Kingdom

Background/Purpose: Systemic lupus erythematosus (SLE) patients have increased mortality due to complications, such as renal failure and cardiovascular disease. In clinical practice, glomerular filtration rate (GFR) is usually estimated using the modified Cockcroft-Gault (mCG) or the Modification of Diet in Renal Disease (MDRD) equations. Serum cystatin C (sCysC) has been suggested to be a more stable marker of renal dysfunction. We aimed to compare sCysC in SLE patients and healthy controls, to assess its agreement with standard tests of renal dysfunction and investigate factors contributing to higher sCysC in SLE patients.

Methods: Women with SLE patients (≥4 ACR criteria) were recruited from our Lupus Clinic and healthy women were recruited from the general population. Subjects underwent clinical assessment of their SLE as well as lifestyle factors, blood pressure and body mass index (BMI). We also ascertained their history of lupus nephritis and/or nephrotic syndrome, serum creatinine, and eGFR using the mCG an MDRD equations. Serum CysC was measured using R&D Systems' ELISA development method (working range up to 2ng/mL; intra-assay coefficient of variation (CV) = 6.49%, inter-assay CV = 12.70%). We assessed the agreement between different estimates of GFR using Deming plots. Univariate and multivariate linear regression analyses were applied to ascertain the predictors of sCysC in SLE patients.

Results: 178 patients and 68 controls were recruited with a median (IQR) age of 50 (39–60) and 53 (46–61) years old respectively. SLE patients had higher systolic blood pressure (P<0.05), and higher sCysC (Controls vs. SLE (median [IQR]) = 120 [110–130] vs. 127 [115–143], P=0.02; 0.950 [0.727–1.134] vs. 1.161 [0.980–1.359], P<0.0001; respectively). In both groups, sCysC correlated positively with serum creatinine, and inversely to both measures of eGFR (r= −0.530; p<0.0001 (mCG), and r= −0.620; p<0.0001 (MDRD)). Using Deming plots, there was closer agreement between the mCG and MDRD estimates of eGFR (P<XX) than these individual tests with sCysC (P= X and Y for sCysC and mCG and MDRD respectively). In a univariate analysis of SLE patients, sCysC also had significant correlations with age (β-coefficient, P value) (0.009; 0.05), hs-CRP (0.04; 0.001), SLEDAI (0.04; 0.007), SLICC damage index (0.18; <0.0001), serum creatinine (0.01, <0.0001), eGFR (0.01, <0.0001) and past history of nephritis (0.3, 0.004). BMI (0.003, 0.7) was included in the analysis due to its influence on plasma CysC. In multivariate analysis (β, P), age (0.0039, 0.06), hs-CRP (0.01, <0.0001) and serum creatinine (0.01, <0.0001) were all independently associated with sCysC in SLE.

Conclusion: SCysC is increased in SLE and in SLE patients with a history of nephritis. While 2 standard methods of estimating GFR agree well with each other they have lower levels of agreement with sCysC. This is supported by our observation that in SLE, sCysC is also influenced by BMI and low grade inflammation. SCysC should therefore not supplant current methods of assessing renal dysfunction in SLE patients.

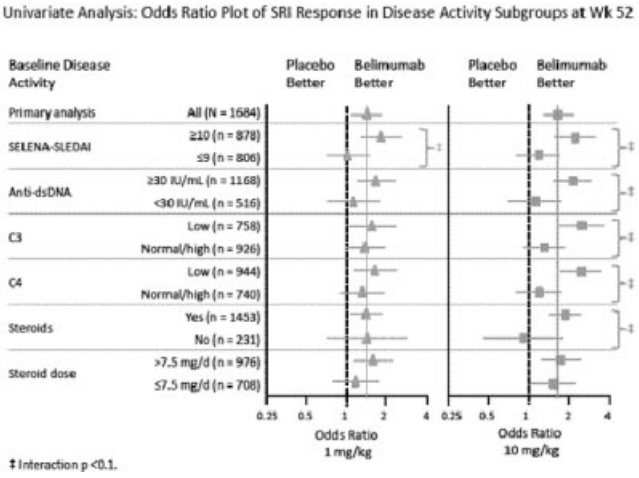
Factors Associated with Belimumab Treatment Benefit: Results From Phase 3 Studies in Patients with Systemic Lupus Erythematosus. R.F. van Vollenhoven[1], M. Petri[2], R. Cervera[3], C. Kleoudis[4], Z.J. Zhong[5], D. Roth[6], W. Freimuth[5] and BLISS-52 and BLISS-76 Study Groups[7]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Hospital Clinic, Barcelona, Spain, [4]GlaxoSmithKline, Durham, NC, [5]Human Genome Sciences, Inc., Rockville, MD, [6]GlaxoSmithKline, King of Prussia, PA, [7]Multicenter

Background/Purpose: To identify baseline systemic lupus erythematosus (SLE) disease characteristics that predicted belimumab treatment response in BLISS-52 (NCT00424476)/BLISS-76 (NCT00410384).

Methods: 1684 autoantibody-positive (antinuclear antibody ≥1:80 or anti-double-stranded DNA [anti-dsDNA] ≥30 IU/mL) SLE patients with SELENA-SLEDAI (SS) score ≥6 received belimumab 1 or 10 mg/kg, or placebo, plus standard therapy, for 52 wk (BLISS-52) or 76 wk (BLISS-76). Primary endpoint of both trials was response rate at wk 52 by the SLE Responder Index (SRI): SS improvement (≥4-point decrease), no new BILAG A or 2 new B scores, and no Physician's Global Assessment worsening (<0.3-point increase). Patients were classified as non-responders if they withdrew from study or received prohibited/restricted medication beyond protocol-specified limits. Subgroup analyses of SRI response at wk 52 were performed to evaluate the consistency of belimumab treatment effect. Multivariate logistic-regression analysis was performed on the pooled dataset to identify baseline characteristics associated with greater treatment benefit. The model was built using a stepwise forward selection process.

Results: Overall wk-52 SRI rates with placebo, and belimumab 1 and 10 mg/kg were 38.8%, 46.2% (odds ratio [OR]: 1.4; p = 0.006), and 50.6% (OR: 1.7; p <0.0001), respectively. Univariate analysis by baseline characteristics generally demonstrated positive treatment effects for belimumab in subgroups with odds ratios >1; patients with higher baseline disease activity (SS score ≥10, OR: 1.8 and 2.2 for belimumab 1 and 10 mg/kg, respectively; positive anti-dsDNA, OR: 1.7 and 2.1; and low complement [C3/C4], OR: 1.6 and 2.4) had greater response to belimumab vs placebo than those with lower disease activity (figure). Steroid use did not appear to be a predictor of a differential response to belimumab vs placebo when categorizing patients by a steroid dose of <7.5 and ≥7.5 mg/d. It did appear to be a predictor of a differential response when categorizing patients by no steroid use vs any steroid use, although the group using no steroids was small. In patients with baseline low C3/C4 and positive anti-dsDNA, wk-52 SRI response rates were 31.7% with placebo, and 41.5% (OR: 1.8; p = 0.002) and 51.5% (OR: 2.7; p <0.001) with belimumab 1 and 10 mg/kg, respectively. Results of the multivariate analyses were consistent with the univariate results with low C3/C4, steroid use, and SS ≥10 as predictors of better

outcome with belimumab. In patients with baseline SS ≥10, wk-52 SRI response rates were 44.1%, 58.0% ($p < 0.001$), and 63.2% ($p < 0.001$) with placebo, and belimumab 1 and 10 mg/kg, respectively.



Conclusion: Measures of high baseline disease activity in SLE patients, including high SS score, low C3/C4, positive anti-dsDNA, and steroid use, predicted better outcome with belimumab (10 mg/kg) treatment compared with standard of care alone.

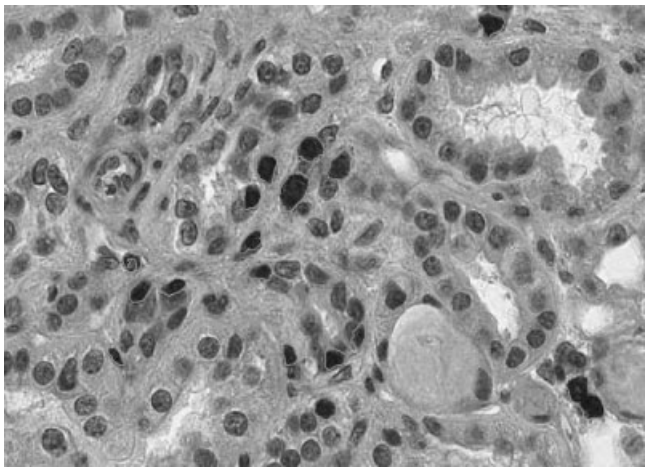
Towards a Quantitative Assessment of Renal Biopsies for Lupus Nephritis. Siddharth S. Samsi[1], Brad H. Rovin[2], Sara Cole[3], Don Stredney[1] and Wael N. Jarjour[4]. [1]Ohio Supercomputer Center, Columbus, OH, [2]Ohio State University Medical Center, Columbus, OH, [3]The Ohio State University, Columbus, OH, [4]Ohio State University, Columbus, OH

Background/Purpose: Systemic lupus erythematosus of the kidneys is associated with high morbidity and mortality. Despite advances in treatment, significant variation in response to treatment exists. While some of this variation is undoubtedly related to genetic and environmental factors, inter-observer variation and sampling bias continue to confound the accurate interpretation of kidney biopsies, contributing to variations in treatment. Underestimating the severity of renal involvement or inaccurately assessing reversibility of lesions can result in significant morbidities related to under or over-treatment. Therefore, there is a need for additional, objective tools that pathology experts can use to assist in the evaluating kidney biopsy.

Methods: We present two approaches for quantification of tissue components in renal biopsies as the first step towards an automated image analysis system for quantifying histological findings associated with progression to renal failure, such as cellular crescents, extensive fibrinoid necrosis, glomerular sclerosis, fibrous crescents, tubular atrophy and interstitial fibrosis. The first approach is used to analyze H&E stained tissue for glomeruli identification. The second approach analyzes fluorochrome-conjugated monoclonal stained human renal biopsies to identify positively stained infiltrating cells.

Results: First, our approach was applied to the analysis of H&E stained renal biopsies to develop the techniques required to identify glomeruli. This preliminary work was carried out using mouse kidneys due to the availability of entire kidney for the study. Tissue biopsies were scanned at 40x microscope resolution. Regions containing glomeruli were extracted from the images and used to develop and test the proposed algorithm. Using computer aided image analysis, it is possible to isolate glomeruli in renal biopsies. Analysis of glomeruli in a sample mouse renal tissue showed average thickness of Bowman's capsules around one glomeruli to be 3.32 microns with the major axis of the glomeruli being 140.28 microns. Second, techniques developed above were applied to the analysis of CD3 stained human kidney biopsy scanned at 40x microscope resolution. Ten random regions of 250 micron^2 were extracted from two whole slide images. A total of 543 CD3 positive cells were counted using automated image analysis as demonstrated in the figure.



Conclusion: Through the use of computer-aided image analysis, it is possible to isolate and measure physical dimensions of structures in renal biopsies. This approach will be further developed for quantification of fibrosis in the glomeruli. Furthermore, immunohistochemistry will allow for quantitation of various cellular infiltrates and their localizations. By correlating findings with clinical outcomes, this approach has the potential to advance the understanding of Lupus Nephritis and improve treatment outcome.

The Relationship Between Pain Coping Skills and Pain, Fatigue, Mood, and Lupus Activity. Preethi Kurakula, Tamara J. Somers, Lisa G. Criscione-Schreiber, Francis J. Keefe and Megan E. B. Clowse. Duke University Medical Center, Durham, NC

Background/Purpose: Patients with systemic lupus erythematosus (SLE) experience distressing physical and psychological symptoms that are often not relieved by current pharmaceutical options. In this study, we sought to examine how two forms of pain appraisal (self-efficacy for pain and pain catastrophizing) are related to pain, stiffness, fatigue, mood, and self-reported memory problems in patients with SLE. Pain self-efficacy and pain catastrophizing are particularly salient because they have been shown to be modifiable through psychosocial interventions improving outcomes in patients with other rheumatological conditions.

Methods: We conducted a cross-sectional study of consecutive patients who met the 1997 ACR classification criteria for SLE. All participants completed a questionnaire that included symptom ratings (i.e., pain, stiffness, fatigue), mood, memory problems, and pain coping strategies (i.e., self-efficacy for pain control and pain catastrophizing). SLE disease activity was rated by the treating rheumatologist using the SELENA-SLEDAI. Correlational analyses were used to examine bivariate relationships between pain appraisals and SLE outcomes, followed by hierarchal regression (HLR) analyses to examine the independent contributions of self-efficacy for pain control and pain catastrophizing to the outcomes after controlling for demographic variables and disease severity. In each HLR, age and race were entered on Step 1, disease severity was entered on Step 2, and self-efficacy for pain control and pain catastrophizing were entered on Step 3.

Results: The 74 SLE patients in this study were 91% female with a mean age of 39 (SD=13) years; 59% Black and 38% White. Both self-efficacy for pain and pain catastrophizing correlated with pain, fatigue, stiffness, and mood (all $p < 0.05$). Results of our HLR showed that patients with lower levels of self-efficacy reported higher levels of symptoms of SLE including pain ($p<.001$), stiffness ($p=.001$), and fatigue ($p<.001$). Additionally, patients with higher levels of pain catastrophizing reported lower positive mood ($p=.003$) and showed a trend toward reporting more problems with memory ($p=.06$). Disease activity measured with the SELENA-SLEDAI was not associated with physical symptoms, mood, memory, or self-efficacy for pain control or pain catastrophizing.

Conclusion: Our results suggest that in patients with SLE, low self-confidence to control pain (self-efficacy) was related to a high level of physical symptoms and pain catastrophizing was related to mood and memory problems. Importantly, the effects of these pain appraisals do not appear to be explained by standard disease activity ratings. This finding suggests that pain coping skills training, which is designed to decrease

catastrophizing and enhance patients' ability to control pain and has been shown to be effective in other rheumatological conditions, may similarly help improve physical and psychological symptoms in SLE patients.

Memory Complaints in Lupus Patients: Relationship to Lupus Activity, Symptoms, Quality of Life, Psychological Distress, and Coping. Megan E. B. Clowse[1], Lisa G. Criscione-Schreiber[1], Meenakshi Jolly[2], Francis J. Keefe[1] and Tamara J. Somers[1]. [1]Duke University Medical Center, Durham, NC, [2]Rush University Medical Center, Chicago, IL

Background/Purpose: Patients with systemic lupus erythematosus (SLE) often report distressing symptoms of cognitive impairment. Rheumatologists working with SLE patients are often unsure how such complaints are related to core outcomes such as SLE activity and emotional health. This study aimed to understand how reports of memory complaints are related to SLE disease activity and patient-reported physical symptoms, quality of life, and psychological distress.

Methods: We conducted a cross-sectional study of consecutive patients who met the 1997 ACR classification criteria for SLE. Participants completed the Multiple Sclerosis Neuropsychological Questionnaire (MSNQ) to assess memory complaints. SLE disease activity was rated by the treating rheumatologist using the SELENA-SLEDAI and physician's global assessment (PGA). Patient reported symptoms of pain, fatigue, stiffness, and pain were recorded on a visual analog scale (VAS). The LupusPRO was used to assess lupus-related quality of life; a low score on a LupusPRO domain indicates increased distress. Additionally, psychological health was assessed using the Positive and Negative Affect Schedule (PANAS). Correlational analyses were used to examine bivariate relationships between memory complaints and outcome measures. A correlation with a p-value <0.05 was considered statistically significant.

Results: The 74 SLE patients in this study were 91% female with a mean age of 39 (SD=13) years; 59% Black and 38% White race. The average score on the MSNQ was 23.12 (SD=15.07), indicating that half of our sample is at high risk for neuropsychiatric impairment (score > 23) based on standardized scoring of this measure. Physician-reported SLEDAI and PGA did not correlate with memory complaints, nor did VAS based patient-reported measures of fatigue, stiffness, and rash. Memory complaints did correlate with the patient-reported pain VAS and the physical symptom LupusPRO domains (lupus symptoms (r=-0.27), pain (r=-0.39), physical health (r=-0.41)) and LupusPRO summary health-related quality of life (r=-0.62) and overall quality of life (r=-0.44) scores. In addition, memory complaints correlated with the LupusPRO emotional health (r=-0.48) domain and PANAS (low positive mood (r=-0.34) and high levels of negative mood (r=0.47)).

Conclusion: This study found that SLE patients varied in their reports of memory complaints with half of our sample reporting high levels of memory problems. Results showed that memory complaints were not related with physician measured disease activity, but were associated with outcomes important to SLE patients, including pain and psychological distress. Based on our cross-sectional study, it is not clear whether memory problems lead to lower quality life, pain, and more psychological distress, or vice versa. Future longitudinal studies could help identify the causal relationship between memory complaints and patient outcomes. An interesting direction for future research would be to explore how behavioral intervention designed to enhance how patients cope with memory problems could impact patient outcomes such as quality of life, physical symptoms, and psychological distress.

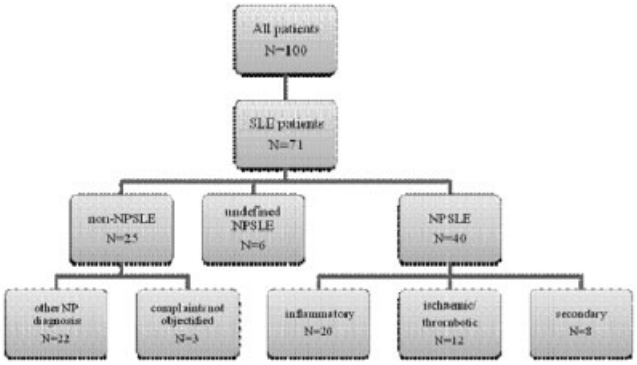
The Leiden Neuropsychiatric Systemic Lupus Erythematosus Clinic; Establishing Clinical Phenotypes. E. Zirkzee, G. Steup-Beekman, H. Middelkoop, E. Bollen, N. Van der Wee, E. Baptist, R. Van der Mast, M. Huisman, J. Luyendijk, M. Van Buchem and T. Huizinga. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Understanding of pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE) is emerging and recent animal studies show a link between auto-antibody activity and cognitive dysfunction[1]. To optimally correlate information derived from experimental research with findings in human NPSLE, well described clinical phenotypes are essential.

Methods: The Leiden NPSLE clinic is a tertiary referral clinic that evaluates patients suspected of NPSLE and leads to a prospectively collected database. Diagnosis and treatment are based on consensus of an experienced multidisciplinary team of medical specialists and a neuropsychologist. NPSLE phenotype is based on the clinically suspected putative pathogenetic mechanism and subsequently advised therapy. Cognitive dysfunction is objectified by neuropsychological tests. Sociodemographic and clinical characteristics of three phenotypes; inflammatory, ischemic/thrombotic and secondary NPSLE are described.

Results: From September 2007 until December 2009 we evaluated one hundred patients. The figure shows outcome of evaluation and attribution of NP manifestations. Twenty patients had inflammatory NPSLE of whom twelve (60%) patients had cognitive dysfunction. Mood disorder, seizure disorder and psychosis were present in three (15%) patients in this group. Mean age of patients was 42 years, mean disease duration 8.0 years and symptom duration 1.8 years. Clinical systemic activity was present in 80% of patients, antiphospholipid antibodies in 60% and MRI abnormalities in 75% of patients. Twelve patients had ischemic/thrombotic NPSLE of whom six (50%) patients had cognitive dysfunction. Eleven (92%) patients had cerebrovascular disease with various clinical manifestations. Mean age of patients was 47 years, mean disease duration 8.6 years and symptom duration 2.7 years. Clinical systemic activity was present in 25% of patients, antiphospholipid antibodies in 67% and MRI abnormalities in 100% of patients. Eight patients had secondary NPSLE of whom three (38%) had cognitive dysfunction. Mean age of patients was 34 years, mean disease duration 14 years and symptom duration 2.7 years. Clinical systemic activity was present in 25% of patients, antiphospholipid antibodies in 25% and MRI abnormalities in 50% of patients.



Conclusion: We identified three clinical phenotypes in NPSLE; inflammatory (50%), ischemic/thrombotic (30%) and secondary (20%) NPSLE and described their characteristics. Cognitive dysfunction was highly prevalent in all patients, especially in inflammatory NPSLE. High prevalence and emerging pathogenetic understanding make cognitive dysfunction an interesting target for further research. Furthermore, this study showed the feasibility of establishing a prospective database in NPSLE by means of a dedicated multidisciplinary clinic.

Limited Value of Soluble Urokinase Plasminogen Activator Receptor As a Disease Activity Marker in Patients with Systemic Lupus Erythematosus. Helena Enocsson, Jonas Wettero, Thomas Skogh and Christopher Sjowall. Linkoping University, Linkoping, Sweden

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic rheumatic disease characterized by multiorgan involvement and varying degree of activity over time. Although measurements of anti-dsDNA antibodies, complement, blood cell counts and erythrocyte sedimentation rate (ESR) can be helpful, distinction of disease activity from organ damage remains a challenge. The urokinase plasminogen activator receptor (uPAR; CD87) is expressed *e.g.* on endothelial cells, monocytes, granulocytes and smooth muscle cells. During inflammation, cell surface uPAR expression and shedding increases, and the soluble form, suPAR, accumulates in the circulation. It has been shown that suPAR predicts disease outcome of infectious diseases and malignancies, and correlates to disease activity in inflammatory diseases, such as rheumatoid arthritis (RA). The aim of this study was to examine suPAR as a potential biomarker in SLE.

Methods: Cross-sectional sera from 100 healthy controls and 198 SLE

patients fulfilling the 1982 ACR classification criteria (80%) or the Fries (ANA positive + ≥2 typical organ manifestations) criteria (20%) were analyzed for suPAR by ELISA (suPARnostic®), kindly provided by Electra-Box Diagnostica AB, Tyresö, Sweden. In addition, 19 of the 198 patients (all with ≥4 ACR criteria) were selected on the basis of raised disease activity (SLEDAI score or physician's global assessment, PGA) for consecutive suPAR analysis (2–13 visits per patient). Routine analyses at all visits included blood cell counts, ESR, C-reactive protein (CRP), complement (C3, C4, C3d and classical function), creatine kinase, urinalysis and anti-dsDNA (*Crithidia luciliae* IF test, CLIFT). Disease activity was assessed by SLEDAI and PGA.

Results: In cross-sectional analysis, no significant difference was found between controls and patients regarding suPAR levels; and no correlations were found between suPAR and disease activity measures (SLEDAI, PGA or CLIFT). However, correlations between suPAR and CRP (r=0.33), ESR (r=0.25), C3d (r=0.27), leukocyte (r=0.36) and platelet count (r=0.19) were identified. In addition, thrombocytopenia and leukopenia were the only lupus manifestations where suPAR levels differed significantly between patients exhibiting *vs* not exhibiting the manifestation (p=0.048 and p=0.031, respectively). A linear regression analysis of the impact of platelet count and differential white blood cell count on suPAR levels revealed that neutrophils were the only cells with significant impact (38%, p<0.001). Comparing suPAR levels in controls with SLE patients at peak disease activity (consecutive samples), statistical significance was only reached when patients with cytopenia at flare had been excluded.

Conclusion: In contrast to RA, suPAR is not strongly associated with disease activity in SLE. The reason hereto may, at least partially, be explained by muted suPAR levels in patients with hematological activity, such as leukopenia.

1422

Caregiver Burden Is Associated with Worse Dyadic Relationship and Health Outcomes in Lupus. Amita Thakkar, Rachel A. Mikolaitis, Joel A. Block and Meenakshi Jolly. Rush University Medical Center, Chicago, IL

Background/Purpose: Systemic Lupus Erythematosus (SLE) inflicts young women and adversely impacts their quality of life (QOL). Informal caregivers of patients with chronic illness are generally their intimate partners. SLE, may impose care giver burden (CGB), and adversely impact the quality of dyadic relationship & caregiver's QOL. CGB and its recognition may be important in designing interventions to improve health outcomes in SLE.

Methods: Dyad is a unit consisting of the SLE patient & their caregiver. Ten SLE patients and his/her primary informal caregiver (n=10) were recruited from the Lupus Clinic. Data collected included demographics, CGB (caregiver burden scale, screen for caregiver burden), QOL (SF-36), & quality of dyadic relationship (Dyadic Adjustment Scale-DAS). Data were collected from dyads separately to avoid confounding. Correlation coefficients between CGB with DAS and Dyadic QOL were calculated.

Results: The mean (SD) age of caregivers was 37.3 (SD 9.64) yrs. Sixty percent of caregivers were employed and were providing care for 3.95 (SD 2.65) yrs. 9/10 were patient's intimate partner. Caregivers provided informal care for a mean of 10 hours/wk. All caregivers provided emotional support, while 70% assisted with activities of daily living, 30% dispensing medications, 70% transportation and 80% financially. Half of the caregivers reported other dependents, with a mean of 1.4 (SD 0.96) additional dependent members/household. Mean (SD) caregiver scores were: total CGB Scale score 9.1 (5.8), Subjective burden 8.3 (9.5), Objective burden 4.4 (4) & total DAS 94.4 (15.5). Mean (SD) age and disease duration of SLE patients was 35.2 (9) yrs and 7.9 (7.7) yrs. Mean (SD) Total DAS for SLE was 94.6 (17). Agreement between DAS scores was significant (R 0.96, p 0.001). Total CGB was inversely related to caregivers employment status, own QOL (Bodily pain (r −0.61, p 0.06)) and patients QOL (Physical Function (r −0.66, p 0.03), Role Physical (r −0.82, p 0.004), Social Functioning (r −0.65, p 0.06), Role Emotional (r −0.86, p 0.003)) & patients DAS (r −0.66, p 0.08).

Objective burden was associated with caregivers age (r 0.68, p 0.03), own QOL (Bodily pain (R −0.58, P 0.08), General Health (r −0.64, p 0.04), Vitality (r −0.56, p 0.09), Social Function (r −0.61, p 0.06), Mental Health (r −0.58, p 0.08)) & patient's QOL (Role Emotional (r −0.63, p 0.07)). Subjective burden was associated with caregiver age (r 0.79, p 0.007), own QOL (Physical Function (r −0.67, p 0.03), Bodily Pain (r −0.64, 0.05), General Health (−0.76, p 0.01), Vitality (r −0.62, p 0.06), Social Function (r-0.67, 0.04), Mental Health (r −0.75, 0.01)), & patients QOL (Role Emotional (r −0.73, p 0.03).

QOL of the patient and the caregiver were correlated. Caregiver DAS scores were associated with patients QOL, while patients DAS scores were associated with their own QOL (Data not shown).

Conclusion: This exploratory data shows that caregiver burden in SLE is associated with caregiver's own and their SLE partners QOL. Though dyadic QOL is interrelated, Dyadic DAS is linked primarily to patient's QOL. To optimize patient's health outcomes in SLE, focus should be on the dyadic unit rather than the patient in isolation.

Genetic Ancestry, Serum Interferon-α Activity and Autoantibodies in Systemic Lupus Erythematosus. Kichul Ko, Beverly S. Franek and Timothy B. Niewold. University of Chicago, Chicago, IL

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous disease that has different clinical and serological manifestations amongst various self-reported ancestral backgrounds. High levels of interferon-α (IFN-α), which plays an important pathogenic role in SLE, have been associated with positive serology and self-reported non-European ancestry. We aimed to explore and refine these relationships using quantitatively defined genetic ancestry in place of self-reported ancestry.

Methods: Data from 220 lupus patients were analyzed from a majority African-American multiancestal cohort. A panel of more than 300 ancestry informative markers (AIM) selected throughout the genome was genotyped, and principal component analysis was used to analyze the AIM data, providing quantitative variables representing continental ancestry. Univariate and multivariate logistic regression models were used to detect associations between serum IFN-α, autoantibodies, and genetic ancestry. Age and gender were included as co-variates.

Results: In univariate models, African American genetic ancestry (AA) was associated with positive anti-Ro, anti-Smith and anti-ribonucleoprotein (anti-RNP) antibodies and high levels of IFN-α (p-values 0.0194, 0.0112, 0.0002 and 6.1×10^{-6} respectively). Hispanic American ancestry was linked to presence of anti-La (p-value 0.0397). In multivariate models, AA ancestry was associated with positive anti-RNP antibody (p-value 0.0026). High levels of IFN-α were linked to presence of anti-RNP antibody (p-value 2.8×10^{-5}), but AA ancestry was not directly associated with IFN-α (p-value 0.1565), supporting a sequential relationship between these variables. Similar to previous work, younger age was independently associated with higher IFN-α (p-value 0.0014).

Conclusion: Our data support a model in which AA ancestry increases the likelihood of SLE-associated autoantibody formation, which subsequently results in higher levels of serum IFN-α. The relationship between higher IFN-α and younger age in SLE continues to be robust across multiple analyses and cohorts.

1424

Analysis of Longitudinal Gene and Protein Expression Data Classifies SLE Patients Based on Molecular Profiles Associated with Disease Activity, Serology and Specific Organ Manifestations. Mikhail Olferiev[1], Kyriakos A. Kirou[2], Dorthe Lundsgaard[3], Klaus S. Frederiksen[3], Jan Fleckner[3] and Mary K. Crow[1]. [1]Mary Kirkland Center for Lupus Research, Hospital for Special Surgery, New York, NY, [2]Mary Kirkland Center for Lupus Care, Hospital for Special Surgery, New York, NY, [3]NovoNordisk, Copenhagen, Denmark

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are highly heterogeneous and are characterized by variable clinical manifestations and outcome. In order to define the immunopathogenic mechanisms that underlie this heterogeneity, with the goal of predicting clinical course and identifying therapeutic targets, we simultaneously identified mRNA profiles in longitudinal PBMC samples and determined the levels of pro-inflammatory cytokines and autoantibodies in plasma of patients with SLE.

Methods: One hundred sixty-nine PBMC and plasma samples were collected longitudinally (up to 3 years) from 23 SLE patients and 5 healthy donors (HD). All SLE patients fulfilled ACR criteria for the disease. PBMC mRNA transcriptional profiles for each visit were obtained using Affymetrix Human Genome U133 Plus 2.0 GeneChips. Plasma levels of 44 autoantibodies and 56 pro-inflammatory cytokines were evaluated using Multi-Analyte Profiling (MAP) technology (Rules-Based Medicine, Austin, TX). Data were analyzed using the significance analysis of microarrays algorithm and clustering analysis.

Results: Unsupervised hierarchical clustering demonstrated that gene expression in SLE patients was distinct from HD. The two most prominent gene signatures in peripheral blood of SLE patients, type I interferon-inducible genes (IFN-I) and neutrophil granule-related genes, classified SLE patients into three distinct groups. Clinical and serologic characteristics were significantly different among the groups. Group A patients, with neither the IFN-I nor neutrophil gene expression signatures, had only mild disease. Groups B and C had more frequent disease flares, but were distinguishable from each other based on gene expression, clinical manifestations, and cytokine profile: 8/11 SLE patients with both IFN-I and neutrophil signatures (group B) had increased anti-SSA/Ro autoantibodies ($p<0.02$) and significantly more frequent vascular involvement (by BILAG; $p<0.05$) compared to Group C. Group C expressed the IFN-I signature but not the neutrophil signature and was characterized by mucocutaneous manifestations ($p<0.02$) and 1.8 fold higher plasma TNFα compared with Group B.

Conclusion: Gene expression analysis of longitudinal PBMC samples classified SLE patients based on IFN-I and neutrophil gene signatures into three distinct groups that differ in clinical manifestations, autoantibodies and pro-inflammatory mediators. Interestingly, anti-SSA/Ro autoantibodies are associated with the neutrophil gene signature in PBMC, consistent with a recent demonstration of neutrophil activation by RNA-containing immune complexes. Comprehensive examination of molecular pathways associated with clinical features of lupus will help to unravel the heterogeneity of this complex autoimmune disease.

Estrogen Stimulation of Endosomal Toll-Like Receptor Expression Lowers the Threshold of Activation in Peripheral Blood Mononuclear Cells and Contributes to the Gender Bias of Systemic Lupus Erythematosus. Nicholas A. Young, Alexandra Friedman, Benjamin Kaffenberger and Wael N. Jarjour. The Ohio State University Medical Center, Columbus, OH

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disorder with significant predilection for women. While disease pathogenesis remains an active area of investigation, correlation studies have shown that genetic, environmental, and hormonal factors all play a role in the development and progression of this immunological disorder. Gender bias can not be more clearly displayed than when simply looking at the SLE patient population. Childbearing age females are nine times more likely to be diagnosed with SLE than corresponding males of the same age range. Furthermore, this ratio drops dramatically when considering post-menopausal or pre-adolescent females. Recent work with large patient cohorts and high-throughput genetic analyses has led to the identification of several genetic susceptibility markers. Among these genes, toll-like receptors (TLRs) appear to have strong association with SLE in multiple studies. TLRs have been a great focus of recent scientific effort due to their close relationship to many diseases and potential as targets for immunomodulatory drugs.

Methods: In this work, we set out to examine the hormonal relationship between TLRs in influencing SLE pathology. Peripheral blood mononuclear cells (PBMCs) were isolated from both SLE and healthy patients. Healthy subject PBMCs were treated with a physiological dose of testosterone, 17b-estradiol (E2), and/or TLR agonist. Cells were incubated and harvested for collection and analysis of protein and mRNA expression.

Results: E2-induced expression was confirmed in healthy PBMCs *in vitro* with the endosomal TLRs; TLR3, TLR7, TLR8, and TLR9, while no effects were observed with testosterone treatment. Using TLR agonists to treat these cells, we identified an autocrine-mediated control over expression. This mechanism was observed in all endosomal, nucleic acid-binding TLRs. TLR4, which is located on the surface of the cell, was not subject to this pathway. Further, when SLE patients were analyzed, higher levels of TLR3, TLR4, TLR7, TLR8, and TLR9 were observed when compared to resting PBMCs of healthy subjects. A significant synergistic response between estrogen and TLR8 agonist-induced TLR8 expression was also displayed in healthy PBMCs. In order to examine gender differences further, PBMCs from healthy male and female volunteers were treated with estrogen and TLR8 ligand. Both male and female PBMCs increased the expression of TLR8 and enhanced cytokine (INF-g, IL-12 and MIP-1b) production in a synergistic response to these stimuli; however greater upregulation of TLR8 expression was observed in PBMCs from healthy females compared to males.

Conclusion: Taken together, these observations suggest a mechanism that explains, in part, the female bias in SLE through heightened sensitivity of TLR expression in response to E2. This novel mechanism may be relevant in other autoimmune disorders with female predominance, and could be targeted therapeutically to decrease autoinflammatory responses in women.

Genome-Wide Analyses of IRF1 and H4 Acetylation in SLE Monocytes. Kathleen E. Sullivan[1], Lihua Shi[1], Li Song[1], Michelle Petri[2] and Zhe Zhang[3]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Johns Hopkins Hospital, Baltimore, MD, [3]Bioinformatics, Children's Hospital of Philadelphia, Philadelphia, PA

Background/Purpose: SLE is characterized by chronic inflammation and multisystem end-organ dysfunction related to inflammation. Although treatments have improved morbidity and mortality, the disease continues to be associated with chronic cumulative organ damage. Disease chronicity could be impacted by changes to the epigenome, leading to durably dysregulated changes in gene expression. Patients with SLE have evidence of type I interferon effects but the expression of genes downstream of type I interferons is typically higher than the expression of the type I interferon genes themselves. We previously reported that H4 acetylation marks on genes from SLE monocytes were globally increased and the gene set characterized by increased H4 acetylation was enriched in potential IRF1 binding sites. IRF1 is of interest because it can be induced by exposure to type I interferons and can drive a set of pro-inflammatory genes.

We investigated epigenetic changes in SLE monocytes from patients with low disease activity to define epigenetic changes that could be attributed to ongoing exposure to type I interferons.

Methods: To directly examine the role of IRF1 in SLE, we performed ChIP-seq for IRF1 on monocytes from 8 SLE patients with low disease activity and 8 control subjects. The SOLiD platform was used and reads were mapped to the human genome using Bioscope.

Results: 89 IRF1 sites were identified unique to SLE patients and 445 IRF1 sites were found which were had increased peak height in the SLE group compared to the controls. IRF1 targets were validated using a standard ChIP assay. 70% of the IRF1 sites identified directly through ChIP-seq overlapped those identified bioinformatically based on increased H4 acetylation and a potential IRF1 binding site.

Conclusion: IRF1 binding is substantially altered in monocytes from SLE patients. The finding of increased IRF1 binding in SLE monocytes provides a potential link between the type I interferon signature and the pro-inflammatory milieu.

1427

Poly (ADP-Ribose) Polymerase 1 and Special AT-Rich Sequence Binding Protein 1 Bind to the TT>A System Lupus Erythematosus Associated Regulatory Downstream of TNFAIP3. Feng Wen[1], Michael Kinter[1], Joel Guthridge[1], Mary Beth Humphrey[2] and Patrick M. Gaffney[3]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by dysregulated interferon responses and loss of tolerance of self-antigens resulting in systemic inflammation and organ failure. The tumor necrosis factor alpha inducible protein 3 (TNFAIP3) gene encodes the ubiquitin-modifying enzyme A20, which negatively regulates NF-kB activity. We recently described a functional TT>A polymorphic dinucleotide, 42kb downstream of the TNFAIP3 promoter, as a prime candidate causal polymophism responsible for association with SLE in subjects of European and Korean ancestry that demonstrates reduced affinity for a nuclear protein complex that includes NF-kB.

Methods: In order to further characterize this nuclear protein complex we affinity purified proteins from LPS stimulated THP-1 cells using oligonucleotide probes specific for the wild type (TT) or polymorphic (A) sequence followed by mass spectrometry. Western blot was used for validation.

Results: Two primary proteins poly (ADP-ribose) polymerase 1 (PARP-1) and special AT-rich sequence binding protein 1 (SATB-1) were

isolated. The identities of these proteins were confirmed by Western blotting in independent experiments.

Conclusion: PARP-1 functions in DNA replication and chromatin remodeling, and also facilitates diverse inflammatory responses by promoting pro-inflammatory gene expression. SATB1 functions in tethering chromatin to the nuclear membranes at matrix attachment regions thus facilitating long-range regulation of gene transcription. These results suggest that the TT>A polymorphism may predispose to SLE through the recruitment of chromatin modifying proteins that modulate long-range transcriptional regulation of A20.

1428

IRF5 Activation in Monocytes of SLE Patients Is Triggered by Circulating Autoantigens Independent of Type I IFN. Rivka Stone[1], Di Feng[1], Jing Deng[1], Sukhwinder Singh[1], Lisong Yang[1], Patricia Fitzgerald-Bocarsly[1], Maija-Leena Eloranta[2], Lars Ronnblom[3] and Betsy Barnes[1]. [1]University of Medicine and Dentistry of New Jersey, Newark, NJ, [2]Section of Rheumatology, Uppsala University, Uppsala, Sweden, [3]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden

Background/Purpose: Genetic variants of interferon regulatory factor 5 (*IRF5*) are associated with susceptibility to systemic lupus erythematosus (SLE). IRF5 regulates the expression of proinflammatory cytokines and type I interferons (IFN) believed to be involved in SLE pathogenesis. The aim of this study was to determine the activation status of IRF5 by assessing its nuclear localization in immune cells of SLE patients and healthy donors, and to identify SLE triggers of IRF5 activation.

Methods: IRF5 nuclear localization in subpopulations of peripheral blood mononuclear cells (PBMC) from 14 genotyped SLE patients and 11 healthy controls was assessed using imaging flow cytometry. IRF5 activation and function were examined after *ex vivo* stimulation of healthy donor monocytes with SLE serum or components of SLE serum. Cellular localization was determined by ImageStream and cytokine expression by Q-PCR and ELISA.

Results: IRF5 was activated in a cell type-specific manner; monocytes of SLE patients had constitutively elevated levels of nuclear IRF5 compared to NK and T cells. SLE serum was identified as a trigger for IRF5 nuclear accumulation; however, neither IFNα nor SLE immune complexes could induce nuclear localization. Instead, autoantigens comprised of apoptotic/necrotic material triggered IRF5 nuclear accumulation in monocytes. Production of cytokines IFNα, TNFα and IL6 in monocytes stimulated with SLE serum or autoantigens was distinct yet correlated with the kinetics of IRF5 nuclear localization.

Conclusion: This study provides the first formal proof that IRF5 activation is altered in monocytes of SLE patients that is in part contributed by the SLE blood environment.

1429

Large Scale Analysis of Serum Tumor Necrosis Factor Alpha Levels in Systemic Lupus Erythematosus. Corinna E. Weckerle[1], Dorothy Imbuka[1], Beverly S. Franek[1], Jennifer A. Kelly[2], Marissa Kumabe[1], Kathy L. Moser[3], Judith A. James[4], John B. Harley[5] and Timothy B. Niewold[1]. [1]University of Chicago, Chicago, IL, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK, [5]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH

Background/Purpose: SLE disease manifestations are highly variable between patients, and the prevalence of individual clinical features differs significantly by ancestry. Serum tumor necrosis alpha (TNF-α) is elevated in some SLE patients, and may play a role in disease pathogenesis. We used logistic regression modeling to establish the network of associations between serum TNF-α, autoantibodies, serum interferon alpha (IFN-α), and clinical manifestations in large SLE cohorts from several different ancestral backgrounds.

Methods: We studied 653 SLE patients from the Lupus Family Registry and Repository at OMRF, including 214 African-American patients, 298 European-Americans and 141 Hispanic-American subjects. TNF-α was measured using an ELISA, and IFN-α was measured with a functional reporter cell assay. TNF-α and IFN-α levels were binned as a high versus low categorical variable using a cut-off value of 2 standard deviations above the mean of healthy controls. Logistic regression models were used to detect associations in each ancestral background separately, and meta-analyzed when appropriate.

Results: High levels of TNF-α were associated with high serum IFN-α activity across all ancestral backgrounds (OR=1.8, $p=1.2\times10^{-3}$). The proportion of high TNF-α/high IFN-α subjects was highest in African-Americans and lowest in European-Americans ($p=5.0\times10^{-3}$). Similarly, the proportion of low TNF/low IFN subjects was highest in European-Americans and lowest in African-Americans ($p=2.7\times10^{-4}$). TNF-α levels were not significantly associated with autoantibodies, clinical manifestations, or age at recruitment. Consistent with previous studies, IFN-α was closely correlated to autoantibodies, younger age, and non-European ancestry.

Conclusion: This represents the largest study of cross-sectional serum TNF-α levels in SLE patients, and we observed a positive correlation between TNF-α and IFN-α. While IFN-α was closely correlated with SLE-associated features such as characteristic autoantibodies and non-European ancestry, TNF-α was only associated with IFN-α in SLE patients, suggesting a secondary relationship between TNF-α and SLE disease characteristics.

Low Programmed Death Ligand-1 Gene Expression in SLE Monocytes Coregulated by IL-10, TNF-α and TGF-β May Contribute to Chronic T Lymphocyte Activation. Jing-Ni Ou[1], Gretchen R. Henstorf[1], Matthew Crabtree[1], Alice Wiedeman[2] and Anne M. Stevens[1]. [1]Seattle Children's Research Institute, Seattle, WA, [2]University of Washington, Seattle, WA

Background/Purpose: Programmed death ligand 1 (PD-L1) expressed on monocytes and myeloid dendritic cells plays an important role in controlling T lymphocyte responses to self antigen released by apoptotic cells. We previously demonstrated poor PD-L1 expression in patients with SLE during an autologous MLR, in contrast to the reported high PD-L1 expression found in infection, malignancy, and rheumatoid arthritis. Normally induced by IL-10 and TNF-α while suppressed by TGF-β, PD-L1 gene expression may be a key step in the downregulation of T lymphocytes upon exposure to apoptotic cells. Lack of PD-L1 may contribute to the hyperstimulatory properties of SLE monocytes, leading to chronic T cell activation.

Methods: PD-L1 expression on $CD11c^{+}$ $CD14^{high}$ monocytes was assayed by flow cytometry in cultured peripheral blood cells from pediatric patients with SLE and age-matched controls. PD-L1 mRNA expression was assayed by RT-PCR. Early T cell activation was assayed by quantification of Calcium flux in CD4+ T cells by flow cytometry.

Results: Both PD-L1 surface protein and mRNA expression were induced by TNF-α, and TNF-α production correlated with PD-L1 expression in SLE patients in remission. IL-10, however, induced surface expression without an increase in mRNA, suggesting post-translational regulation. TGF-β suppressed both mRNA and surface expression, and correlated with PD-L1 expression during active SLE. Isolation of CD14+ myeloid DC and monocytes resulted in decreased PD-L1 expression, suggesting that lymphocytes may regulate PD-L1 on APC. Depletion of CD16+ NK and NKT cells resulted in a 50% drop in PD-L1 expression, whereas no significant differences were detected with depletion of CD19+, CD4+, or CD25+ lymphocytes. Early T cell activation was inhibited by CD14+ APC expressing PD-L1, but not by those with low or absent PD-L1.

Conclusion: Cytokine-mediated induction of PD-L1 expression on antigen presenting cells may be an important step in normally controlling the lymphocyte response to apoptotic cells. SLE monocytes fail to upregulate PD-L1 during active disease, because of a low ratio of stimulatory TNF-α to inhibitory TGF-β. Lack of PD-L1 on monocytes exposed to apoptotic cells may in part explain the hyperstimulatory phenotype in SLE.

1431

Impact of Aberrations In Xenobiotic Metabolism On the Susceptibility to Systemic Lupus Erythematosus. Yedluri Rupasree, Liza Rajasekhar, Addepalli Pavani, Shaik Mohammad Naushad and Vijay Kumar Kutala. Nizam's Institute of Medical Sciences, Hyderabad, India

Background/Purpose: The rationale of the study is to investigate whether aberrations in xenobiotic metabolism influence pathophysiology of Systemic Lupus Erythematosus (SLE) by inducing catechol estrogen mediated DNA-adduct formation that serves as better epitope for binding of anti-nuclear antibodies.

Methods: Six putatively functional polymorphisms in xenobiotic metabolism and three most common polymorphisms in one-carbon metabolism

were studied in 105 SLE cases and 106 healthy controls using PCR-RFLP and PCR-AFLP approaches.

Results: Among the Phase I enzymes, cytochrome P450 (CYP) 1A1 m1 and m4 variants that increase catechol estrogen production were associated with 2.11- (95% CI: 1.33–3.35) and 4.85- (0.96–32.89) folds risk for SLE. Among the Phase II enzymes, glutathione-S-transferase (GST) T1 null variant showed significant association with SLE (OR: 4.28, 95% CI: 1.96–9.50). Genetic variants of one-carbon metabolism i.e. edmethylene tetrahydrofolate reductase (MTHFR) C677T, thymidylate synthase (TYMS) 5′-UTR 28bp tandem repeat polymorphism, methionine synthase (MTR) A2756G showed no direct association with SLE. Correlating these variants with clinicopathological features of SLE showed positive association of CYP1A1 m1 variant with photosensitivity (r=0.20); and m4 variant with hemolytic anemia (r=0.24). Psychosis (r=-0.18) was inversely correlated with CYP1A1 m1 and positively correlated with GSTT1 null variant (r=0.18). Total glutathione levels in SLE cases were found to be low (362±113 μmole/L vs. 466±79 μmole/L), which will further augment the risk associated with GSTT1 null variant.

Conclusion: Aberrations in xenobiotic metabolism were found to inflate the risk for SLE through estrogen mediated oxidative stress and also to explain phenotypic heterogeneity in SLE.

1432

Metabolic Underpinnings of Systemic Lupus Erythematosus. Tianfu Wu[1], Chun Xie[1], Jie Han[1], Irene Blanco[2], Nancy J. Olsen[3], Chaim Putterman[2], Ramesh Saxena[4] and Chandra Mohan[4]. [1]University of Texas, Southwestern Medical Center at Dallas, Dallas, TX, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Penn State MS Hershey Medical Center, Hershey, PA, [4]University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: Although several genomic, transcriptomic and proteomic studies have been carried out in SLE, the metabolic disturbances that underlie SLE are largely unknown, prompting us to examine serum metabolites in SLE globally.

Methods: We executed a global metabolomic analysis of serum from 29 subjects (9 healthy controls, 10 SLE patients with SLEDAI 0–5, and 10 "active" SLE with SLEDAI>5) and active lupus nephritis, all drawn from UT Southwestern at Dallas, using a combined LC/MS and GC/MS based platform. Validation of key differences using orthogonal platforms was performed using an independent cohort of SLE patients (N=38; average age=38; average BMI=28.7; average SLEDAI=7), 14 matched healthy controls and RA disease controls, drawn from the Albert Einstein College of Medicine, New York.

Results: SLE sera revealed reduced levels of >100 metabolites, supportive of dampened glycolysis, Krebs cycle, fatty acid oxidation and amino acid metabolism. Whereas long-chain fatty acids, including the n3 and n6 essential fatty acids were significantly reduced, medium chain fatty acids and serum free fatty acids were elevated. The SLE metabolome exhibited a profound degree of lipid peroxidation, with 9-HODE and 13-HODE levels being significantly higher ($P < 0.01$), reflective of oxidative damage. Conversely, deficiencies were noted in the cellular anti-oxidant, glutathione (0.5±0.2μM, vs 2.9±0.7μM, P<0.0001), and all methyl group donors, including cysteine, methionine, and choline, as well as phosphocholines. SLE sera exhibited significantly elevated levels of multiple gamma-glutamyl peptides and the mediating enzyme GGT1 (1360±142 U/L vs 181±49 U/L, P<0.001; 459±235 U/L, P<0.01, respectively), compared to the healthy or RA disease controls, possibly alluding to a vigorous attempt to regenerate glutathione. Significant elevations were also seen in the levels of pro-inflammatory metabolites leukotriene B4 (966±142 ng/ml vs 132 ± 37 ng/ml, P<0.001) and 5-HETE (974350±116779 vs 2139±2016, P<0.0001). Random forest analysis and receiver operating curves revealed the best discriminators of SLE to be serum levels of lipid peroxidation products, MDA (AUC=0.92, P<0.0001), leukotriene B4 (AUC=0.99, P<0.0001), GGT1 (AUC=0.97, P<0.0001), and glutathione (AUC=0.84, P<0.0001). Importantly, these elevations were not observed in another chronic inflammatory autoimmune disease, rheumatoid arthritis (RA).

Conclusion: Comprehensive profiling of the SLE metabolome reveals heightened oxidative stress, inflammation, altered lipid profiles and a prothrombotic state. The observed reductions in multiple sources of cellular energy allude to reduced energy generation in SLE. Although further studies are warranted to dissect out the origins and consequences of the observed alterations, the completed studies have sprung forth several potential disease biomarkers that await longitudinal validation, and also novel opportunities for disease modulation, including targeted dietary support.

1433

Interferon Alpha Strikes Again: Modulation of Inflammasome Activity Results In IL-18 Mediated Vascular Dysfunction In Systemic Lupus Erythematosus. J. Michelle Kahlenberg[1], Seth G. Thacker[1], Celine C. Berthier[1], Jeffrey Hodgin[1], Clemens D. Cohen[2], Matthias Kretzler[1] and Mariana J. Kaplan[1]. [1]University of Michigan, Ann Arbor, MI, [2]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Individuals affected by systemic lupus erythematosus (SLE) develop heterogeneous manifestations including severe organ damage and complications from premature atherosclerosis and vascular dysfunction. Interferon-alpha (IFN-α) likely plays an important role in the development of lupus and lupus-related cardiovascular disease (CVD). IFN-α has a deleterious effect on the viability and function of endothelial progenitor cells (EPC)/circulating angiogenic cells (CAC), leading to impaired vascular repair. This disruption of EPC/CAC function by IFN-α is in part mediated by repression of IL-1β. Counter-intuitively, SLE patients also have increased levels of IL-18 and the IL-1β/IL-18 processing machinery, the inflammasome. This study attempted to understand this dichotomy and the potential role of inflammasome activation on SLE-related CVD.

Methods: Cultures of human and murine lupus and control EPC/CACs were used to assess the role of the inflammasome machinery in EPC/CAC differentiation. The role of specific caspase-1 inhibitors, recombinant IL-18 or IL-8 blockade in endothelial differentiation was analyzed. Serum levels of IL-18 and SLE-related autoantibodies were evaluated and correlated to EPC/CAC dysfunction. Microarray analysis of control and lupus kidney biopsies was completed to examine inflammasome regulation in SLE *in vivo.*

Results: In the presence of ac-YVAD-cmk, an inhibitor of caspase-1, a significant improvement in SLE EPC/CAC differentiation was evident. Additionally, inhibition of caspase-1 blocked IFN-α-mediated repression of EPC/CAC differentiation, implicating inflammasome activation as a downstream pathway of IFN-α signaling. Neutralization of IL-18 in SLE EPC/CAC cultures restored normal endothelial differentiation, while exogenous IL-18 inhibited differentiation of control EPC/CAC cultures in a dose-dependent manner. These observations suggest that IL-18 may have deleterious effects on vascular repair *in vivo* in SLE. Additionally, patients with anti-Ro antibodies, but not anti-ds DNA, anti-Sm or anti-RNP antibodies were significantly more likely to have elevated IL-18 levels and EPC/CAC dysfunction, indicating a putative link between autoantibody production and inflammasome activation. Inflammasome changes were operational *in vivo* in lupus nephritis, as evidenced by transcriptional upregulation of mRNA of inflammasome components in lupus kidney biopsies.

Conclusion: IFN-α impairs EPC/CAC function through modulation of the inflammasome to promote IL-18 over IL-1β production. This is detrimental to vascular repair and may be an important mechanism leading to increased CV risk in SLE. The role that inflammasome activation plays in atherosclerosis development and renal dysfunction in SLE warrants further examination. Additionally, the finding that anti-Ro antibodies correlate with serum IL-18 levels and EPC/CAC dysfunction indicates that cross talk between auto-reactive B cells and the inflammasome may result in premature vascular damage in SLE.

1434

Retroviral Vector System Identified FLRT2 As a Novel Cell Surface Autoantigen Against Anti-Endothelial Cell Antibodies in Systemic Lupus Erythematosus. Tsuyoshi Shirai[1], Hiroshi Fujii[1], Masao Ono[2], Kyohei Nakamura[1], Ryu Watanabe[3], Yumi Sasaki[1], Naruhiko Takasawa[1], Tomonori Ishii[1] and Hideo Harigae[1]. [1]Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Department of Pathology, Tohoku University Graduate School of Medicine, Sendai, Japan, [3]Tohoku University Hospital, Sendai, Japan

Background/Purpose: Anti-endothelial cell antibodies (AECA) are detected in a number of patients with connective tissue diseases (CTD), and they have a potential to induce vascular lesions. Although targets of AECA have been intensively studied, most molecules reported so far are intracellular proteins and their pathogenic mechanisms for vascular injury remain unclear. The aims of this study are to identify autoantigens expressed on endothelial cell surface using retroviral vector system and to clarify their pathogenic roles.

Methods: Sera from systemic lupus erythematosus (SLE) patients were screened for AECA activity with human umbilical vein endothelial cells (HUVEC) by flow cytometry, and we selected one serum with high AECA activity for following cell sorting. cDNA library of HUVEC were generated and inserted into retroviral vector, pMx. Using retroviral vector system (Figure 1),

cDNA library was stably transfected to rat myeloma cell line. HUVEC cDNA expressing cells were FACS sorted with IgG that had high AECA activity and cloned by limiting dilution.

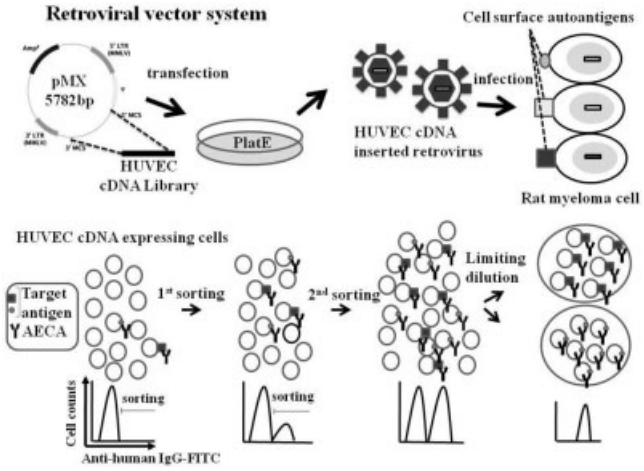

Figure 1. Retroviral vector system.

Results: Serum from one patient with active lupus nephritis had IgG that bound strongly to HUVEC. The patient's serum after treatment showed remarkably reduced binding activity, indicating this AECA activity correlates with disease activity. By expression cloning with FACS sorting, two distinct clones were isolated (Figure 2a). Polymerase chain reaction (PCR) (Figure 2b) and microarray analysis revealed both clones have an identical membrane protein, fibronectin leucine rich transmembrane 2 (FLRT2). We confirmed HUVEC express FLRT2 on cell surface. We also showed that 9 % of lupus patients had anti-FLRT2 activity, whereas normal control and other CTD did not have anti-FLRT2 activity except for one patient with Wegener's granulomatosis.

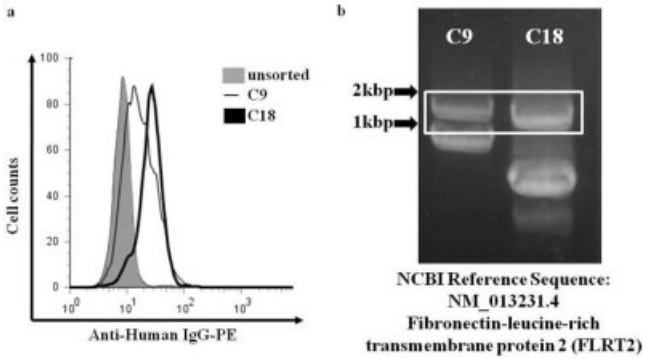

Figure 2. Isolated two distinct clones, C9 and C18. a: C9 and C18 were stained with IgG from the active lupus patient. b: PCR of genomic DNA to amplify inserted sequence. DNA sequencing of given bands in white box revealed both had FLRT2 mRNA coding sequences.

Conclusion: We identified cell membrane protein FLRT2 as a novel autoantigen against AECA in lupus patients. Autoantibody against FLRT2 might play roles in the pathogenecity of vascular injury and thus this retroviral vector system is a strong tool for identification of cell surface autoantigens.

1435

Binding of Serum IgG to Human Mesangial Cells and Its Correlation with Disease Activity in Patients with Lupus Nephritis. Desmond YH YAP[1], Susan Yung[2], Owen Chan[2], Florence Q. Zhang[2] and Tak Mao Chan[2]. [1]Queen Mary Hospital, Hong Kong, Hong Kong, [2]The University of Hong Kong, Hong Kong SAR, Hong Kong

Background/Purpose: Lupus nephritis is hallmarked by mesangial deposition of immunoglobulins, which result in subsequent glomerular injury and altered renal functions. Our group had previously demonstrated that human anti-dsDNA antibodies could bind to human mesangial cells (HMC) and this binding activity correlated with disease activity. In this study we assessed the binding activity to HMC by the serum IgG and its subclasses in lupus nephritis patients. Their associations with clinical and laboratory parameters in lupus nephritis patients were also evaluated.

Methods: Serial serum samples were retrieved from 23 patients with biopsy-proven diffuse proliferative lupus nephritis over a mean follow-up of 74 months. Binding activity (expressed as OD) of total serum IgG and its subclasses (IgG_1, IgG_2, IgG_3, IgG_4) to HMC was ascertained with a cellular ELISA and its correlation with clinical or laboratory parameters examined. Sera from 23 healthy individuals were used as controls. Sensitivity/specificity of total IgG or IgG_1 binding to HMC in the prediction of renal flare was calculated and ROC curves constructed.

Results: A total of 189 samples were analyzed - 48 samples during active and 141 during inactive disease, defined according to clinical assessment (SLEDAI >=10 as active and <=4 as inactive). Binding of serum total IgG to HMC was 0.12±0.09, 0.59±0.37 and 0.74±0.42 OD for healthy controls, inactive lupus, and active lupus respectively (P=0.023 active vs inactive, P<0.001 controls vs active or inactive disease). Binding of serum IgG_1 to HMC was 0.05±0.05, 0.41±0.38 and 0.55±0.40 OD for the three groups respectively (P=0.037 active vs inactive, P<0.001 controls vs active or inactive disease). Controls and lupus patients did not vary in the binding of serum IgG_2, IgG_3 or IgG_4 to HMC. Total IgG and IgG_1 HMC-binding activity correlated with anti-dsDNA levels (r=0.26 and 0.39 respectively, P<0.001 for both), and inversely with C3 levels (r=-0.17 and −0.45 respectively, P<0.05 for both). No correlation was observed between IgG binding to HMC and clinical parameters such as serum creatinine, albumin, or proteinuria. Sensitivity/specificity of total IgG or IgG_1 binding to HMC in the prediction of renal flare was 81.3%/39.7% (ROC AUC 0.61, P=0.03) and 83.8%/41.8% (AUC 0.63, P=0.009) respectively.

Conclusion: There is significant total IgG and IgG_1 mesangial cell-binding activity in the sera of patients with lupus nephritis, especially during active disease, and this binding correlated with the anti-dsDNA antibodies levels.

1436

Cardiovascular Disease and Cognitive Dysfunction in Systemic Lupus Erythematosus. Sara Murray, Jinoos Yazdany, Rachel Kaiser, Lindsey A. Criswell, Edward H. Yelin, Patricia P. Katz and Laura J. Julian. University of California, San Francisco, San Francisco, CA

Background/Purpose: Cognitive dysfunction and cardiovascular (CV) disease are common and debilitating manifestations of systemic lupus erythematosus (SLE). While there is substantial evidence linking CV disease and Framingham-type risk factors with cognitive dysfunction in the general population, these relationships have not been fully explored in SLE. In this study, we evaluated CV events, traditional CV risk factors, and SLE-specific risk factors (antiphospholipid antibodies (aPL), disease activity, disease duration) as predictors of cognitive dysfunction in a large cohort of patients with SLE.

Methods: Subjects included 694 participants from the Lupus Outcomes Study (LOS), an annual telephone survey querying demographic and clinical variables. The Hopkins Verbal Learning Test – Revised (HVLT-R) and the Controlled Oral Word Association Test (COWAT) were administered to assess cognitive function, and cognitive impairment was defined by a composite z-score average worse than −1.0 standard deviation below age-stratified normative values. CV risk factors and events were obtained from self-report, disease activity was assessed using the Systemic Lupus Activity Questionnaire (SLAQ), and patients were considered to be positive for aPL if they had at least one laboratory result indicating the presence of anticardiolipin antibodies (IgG or IgM), anti-beta2 glycoprotein-1 antibodies (IgG or IgM), or a lupus anticoagulant measured by an abnormal Russell viper venom test at least one point in time. Multiple logistic regression was used to investigate the cross-sectional relationship between self-reported CV events (myocardial infarction (MI), stroke), traditional CV risk factors (hypertension, hyperlipidemia, diabetes, obesity, smoking), and SLE-specific risk factors and cognitive impairment. Analyses also controlled for gender, education, poverty status, and depression.

Results: The prevalence of cognitive impairment was 15%. In multiple logistic regression analyses, aPL (OR=2.1, 95% CI 1.3–3.4), hypertension (OR=2.1, 95% CI 1.2–3.6), and a history of stroke (OR=2.3, 95% CI 1.2–4.4) were each significantly associated with cognitive dysfunction. In additional analyses evaluating the association between these predictors and severity of cognitive impairment, stroke was significantly more prevalent in subjects with severe impairment compared to those with mild or moderate impairment (p=0.036).

Conclusion: Our results suggest that aPL, hypertension, and stroke likely play a significant role in cognitive dysfunction in SLE and may serve as potential targets for therapeutic interventions to improve cognitive outcomes.

Atherosclerosis and Cardiovascular Disease in Systemic Lupus Eryhematosus Are Related to An Inflammatory /Oxidative Status Linked to the Autoimmune Condition and the Clinical Activity of the Disease. Effect of Statins Treatment. Chary Lopez-Pedrera[1], Patricia Ruiz-Limon[1], Carlos Perez-Sanchez[1], M[a] Angeles Aguirre[1], Nuria Barbarroja[1], Antonio Rodriguez-Ariza[1], Eduardo Collantes-Estevez[1], Jose Manuel Villalba[2], Francisco Velasco[1], Munther A. Khamashta[3], Maria Laura Bertolaccini[3] and M[a] Jose Cuadrado[4]. [1]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [2]University of Cordoba, Cordoba, Spain, [3]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [4]The Rayne Institute, London, United Kingdom

Background/Purpose: Atherosclerosis (AT) and cardiovascular disease (CVD) are enhanced in autoimmune diseases, such as antiphospholipid syndrome (APS) and systemic lupus erythematosus (SLE).Characterization of the molecular and cellular basis of signalling abnormalities within the immune system that lead to auto reactivity and inflammation and their relationship to early AT and CVD development remain critical for understanding the pathogenesis of APS and SLE. Although there is evidence that statins have anti-inflammatory properties, their mechanism of action remains incompletely understood. Aims: i) To determine if the proinflammatory SLE profile is related to their oxidative status, and associated to the autoimmune condition and the clinical disease activity; ii) to test the anti-inflammatory effectiveness of fluvastatin.

Methods: The study was conducted in 64 SLE patients and 47 healthy donors. Flow cytometry, ELISA and enzymatic assays were used to evaluate markers of inflammation and oxidative stress in white blood cells and plasma. Carotid-intimate media thickness (CIMT) was used as surrogate parameter of AT. Microarray expression profiling was used in paired samples of SLE monocytes from 21 patients before and after one month of in vivo fluvastatin treatment. Real-Time RT-PCR of selected genes was used to validate microarray data.

Results: Increased TF and PAR2 levels were found in monocytes from SLE patients, which also displayed higher plasma levels of VEGF, IL8, MCP-1, TNFα and tPA. SLE monocytes displayed a decreased mitochondrial membrane potential (MMP) and increased levels of peroxides, GSH, and antioxidant enzymes (SOD2, catalase and GPx). aPL-IgG and anti-dsDNA levels significantly correlated with SLEDAI, markers of inflammation, thrombosis and oxidative stress. CIMT was associated to increased aPL-IgG, TF, VEGF and tPA, as well as to decreased MMP. The occurrence of cardiovascular events was associated with reduced MMP and SOD2, and increased catalase and GPx activity, as well as with increased levels of inflammatory markers. A total of 726 genes displayed significant changes in expression after 1 month of fluvastatin treatment, of which 30% were found associated to inflammation and CVD. Fluvastatin treatment led to downregulation of many genes related to inflammation, angiogenesis and the atherosclerosis pathways. Genes related to mitochondrial activity, NO, and oxidative stress signalling pathways were also found significantly altered. The expression changes in selected cytokines, associated intracellular pathways, and markers of oxidative stress were further confirmed at protein level.

Conclusion: i) SLE-related auto-antibodies significantly contribute to the development of AT and CVD. ii) A redox-sensitive pathway (in which mitochondrial membrane alterations seem to perform a main part) might play a key role in the elicitation of those pathologies in the setting of SLE. iii) Fluvastatin has significant anti-inflammatory effects on SLE monocytes, downregulating the expression of molecules mediating angiogenesis, AT and inflammatory signalling. Analysis of Endothelium from Systemic Lupus Erythematosus Patients Demonstrates a Marked Interferon Inducible Signature and an Associated Decrease in Transforming Growth Factor Beta Signaling Genes. Diana Goldenberg[1], Mikhail Olferiev[1], Duygu Onat[2], Ante Harxhi[2], Danieli Andrade[1], Mary K. Crow[1], Paolo Colombo[2] and Jane E. Salmon[1]. [1]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [2]Columbia University College of Physicians & Surgeons, New York, NY

Background/Purpose: Endothelial dysfunction may promote premature atherosclerosis in patients with systemic lupus erythematosus (SLE). Using a novel approach of endothelial sampling coupled with microarray analysis of amplified endothelial RNA, we have previously shown upregulation of interferon inducible genes in SLE patients compared with healthy controls. Herein, we used quantitative real time polymerase chain reaction (RT-PCR) and quantitative immunofluorescence microscopy i) to further validate our initial interferon findings and ii) to investigate the interaction between the interferon and transforming growth factor beta (TGFβ) signaling pathways.

Methods: Fourteen patients with SLE (age 30.9 $\pm$ 9.4 yrs, SLEDAI score 6.2; range 0–20) and 12 age-matched healthy subjects were studied. Endothelial cells were collected from arm veins using endovascular wires then separated using magnetic beads coated with endothelial specific antibodies. Analysis of the microarray profiles was performed on amplified RNA using GeneSpring GX 11 software. Student T test analysis was performed and differentially expressed genes with >1.5 fold expression and $p<0.05$ were selected. Microarray findings were further validated using RT-PCR and quantitative immunofluorescence microscopy (Scion Image Software 4.0).

Results: Microarray analysis showed that several interferon-inducible genes (i.e. IFIT3, IFI44L, IFI6, MX2, IFITM1, OAS1 and OAS2) were upregulated and that several genes in the TGFβ signaling pathway (i.e. TGFBR2, TGFBR3, SMAD2 and SMAD3) were downregulated in SLE patients compared with controls. RT-PCR confirmed upregulation of IFIT3 and downregulation of TGFBR2, TGFBR3 and SMAD2 in the SLE patients. Immunofluorescence analysis demonstrated increased protein levels of IFIT3 and ISG15 in SLE patients compared with controls.

Conclusion: We used a novel in-vivo approach of venous endothelial sampling coupled with gene expression and protein analysis to study the molecular events that promote endothelial dysfunction in SLE. Our results indicate an opposite expression pattern of interferon and TGFβ signaling pathways in the venous endothelium of SLE patients, the former being upregulated and the latter downregulated. These findings further characterize processes that appear relevant to the pathobiology of endothelial dysfunction in SLE.

Anti NMDAR and Anti-P/NSPA Antibodies Contribute to Cognitive Dysfunction in Lupus Patients. Loreto Massardo[1], Patricia Flores[2], Jorge Calderón[2], Marcela Bravo-Zehnder[2], Angel Jurado[2], Carla Henríquez[2], Oslando Padilla[2], Marcela Babul[2], Andrea Slachevsky[3], Sergio Jacobelli[4], Betty Diamond[5] and Alfonso Gonzalez[6]. [1]Catholic University of Chile, Santiago 114-D, Chile, [2]Pontificia Universidad Catolica de Chile, Santiago, Chile, [3]Universidad de Chile, Santiago, Chile, [4]Universidad Catolica de Chile, Santiago, Chile, [5]Feinstein Institute Med Rsch, Manhasset, NY, [6]Marcoleta 367, Santiago, Chile

Background/Purpose: Cognitive dysfunction (CD) in SLE patients has been linked to psychosocial factors, including major depression (MD), autoantibodies and corticosteroids.

Purpose: To assess the contribution of autoantibodies (*anti N-methyl-D-aspartate receptor (NMDAR), anti-ribosomal P protein/neuronal surface P antigen (anti-P/NSPA)* antibodies in contrast with psychosocial factors and corticosteroids, to CD.

Methods: Eighty-four Chilean SLE consecutive patients and 24 controls, all female, median age 36 (range 17–64) had cognitive function assessment using *Cambridge Neuropsychological Test Automated Battery* system, CANTABeclipse™ (2006) assessing attention, visual memory, working memory, executive function, and decision making and response control domains. Lower than 2 SD test performances in ≥ 2 domains were considered CD (32% in patients and 0% in controls). Multivariate models analysis ANCOVA accounting for the effects on CANTAB tests were performed, considering psychosocial factors (*age, education, employment, MD, anxiety, suicidal risk)* and lupus factors such as autoantibodies (*anti-NMDAR, anti-P/NSPA, anti-NSPA, anti DNA Farr, anti phospholipids and anti La/Ro/Sm/Rnp),* SLEDAI-2k, prednisone, antimalarials and cytotoxics. $P<0.05$ was considered significant. Patients had median disease duration of 2 years (0.1–30), SLEDAI-2k score: 6 (0–28), 82% with >5 mg prednisone, and 21% with MD.

Results: Antibody frequencies: anti-*NMDAR* 17%, anti-P/NSPA 8%, anti-NSPA 5%, lupus anticoagulant 15%, anti-DNA 57%. Contributors to lower performances per domain: 1. Attention: anti-NMDAR, education, employment, age and prednisone; 2. Visual memory: anti-P/NSPA, age, SLEDAI-2K, education, and anti-DNA; 3. Executive function: anti-NMDAR, anti-P/NSPA, antiphospholipids, anti-RNP, antimalarials, anticoagulant, age, education, cytotoxics, prednisone and employment. Decision making and response control domain: anxiety, anti-NSPA, antiphospholipid, age and prednisone.

Conclusion: Both NMDAR and anti-P/NSPA antibodies, but not MD or any other psychiatric disorders, contribute to CD affecting specific task domains. Anti-NMDAR alone contributes to dysfunctions on attention domain and together with anti-P/NSPA affects executive function. Anti-P/NSPA antibodies alone contribute to visual memory and decision making and response control domain impairment. This is the first report of antiNMDAR and antiP/NSPA autoantibodies impact on neuropsychological performance in SLE patients.

A Central Role of Plasmin in Cardiac Injury Initiated by Fetal Exposure to Maternal Anti-Ro Autoantibodies. Paraskeyi Briasouli[1], Joanne Reed[1], Jill P. Buyon[1], Robert M. Clancy[1], Mark Halushka[2] and Lucas Buyon[3]. [1]New York University School of Medicine, New York, NY, [2]John Hopkins Pathology, Baltmore, MD, [3]New York University School of Medicine, new York, NY

Background/Purpose: Cardiac neonatal lupus (cardiac NL) is thought to be initiated by surface binding of anti-Ro60 autoantibodies to apoptotic cardiocytes during physiological remodelling of the heart. Binding increases the expression of urokinase plasminogen activator receptor (uPAR) which acts as a 'don't eat me signal" resulting in accumulation of apoptotic cardiocytes and activation of uPA and plasmin protease activity. The latter may facilitate increased binding of anti-Ro60 by disrupting and cleaving the protective effect of factors such as circulating beta2-glycoprotein I (β2GPI). To further examine the significance of components of the uPA/uPAR system in cardiac NL, levels of soluble uPA, uPAR and plasminogen proteins were evaluated in umbilical cord blood as well as expression of these proteins in an autopsy specimen.

Methods: Enzyme linked immunosorbent assays (ELISA) were conducted to measure total uPA, uPAR, plasminogen, and plasmin inhibitory complex plasmin-anti-plasmin (PAP) in the umbilical cord blood from non-cardiac NL (n=26) and cardiac NL (n=35) anti-Ro exposed infants.

Results: uPA, uPAR and plasminogen levels were significantly higher in cardiac NL compared to non-cardiac NL children (3.3 ng/ml±0.1 vs 1.9±0.05 ng/ml; p<0.0001), (6.6±0.3 ng/ml vs 2.1 ±0.2 ng/ml; p<0.0001), (435±34 ng/ml vs 220±19 ng/ml; p<0.0001) respectively. In contrast, the plasmin-anti-plasmin (PAP) complex was significantly decreased in the cardiac compared to non-cardiac NL group (15±2 ng/ml vs 32±1 ng/ml; p<0.0001) suggesting that in the affected fetuses, circulating plasmin was accessible for activation. In 3 twin pairs discordant for cardiac NL, the twin with cardiac NL had higher levels of uPA (3.1±0.1 ng/ml vs 1.9±0.05 ng/ml; p=0.0086) and lower levels of PAP compared to the non-cardiac NL twin (15±2 ng/ml vs 27±2 ng/ml; p=0.034). Levels of uPAR and plasminogen were also higher in the cardiac NL twin but the differences were not significant (6.2±1.4 ng/ml vs 2.2±0.7 ng/ml; p=0.147) and (412±61 ng/ml vs 260±27ng/ml; p=0.152) respectively. There was no association between levels of uPA, uPAR, plasmin, PAP and gender, dexamethasone use, delivery, birth weight, or gestational age of the fetuses. uPAR levels were higher in cardiac NL children with higher titers of anti-Ro60, consistent with in vitro data demonstrating increased uPAR expression in Anti-Ro60 bound apoptotic cardiocytes. Immunohistologic evaluation of a heart from a fetus dying with cardiac NL, revealed an extensive inflammatory infiltrate in the AV node. Macrophages, giant cells and endothelial cells expressed uPA. Plasminogen was expressed in macrophages and giant cells. An age-matched fetal heart only stained endothelial cells for uPA and plasminogen.

Conclusion: The finding of increased soluble uPA, uPAR, and plasminogen in umbilical cord blood of fetuses with cardiac NL and expression of uPA and plasminogen in affected tissue supports the hypothesis that fetal cardiac injury is mediated, at least in part, by plasmin generation initiated by anti-Ro binding to the apoptotic cardiocyte.

Vascular Events and HLA-DRB1 Genotypes in Systemic Lupus Erythematosus. Elisabet Svenungsson[1], Emelie Lundstrom[1], Johanna Gustafsson[1], Andreas Jonsen[2], Dag Leonard[3], Agneta Zickert[1], Kerstin Elvin[4], Gunnar K. Sturfelt[2], Gunnel Nordmark[3], Anders Bengtsson[5], Lars Ronnblom[3], Iva Gunnarsson[1] and Leonid Padyukov[1]. [1]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [2]Department of Rheumatology, Lund University Hospital, Lund, Sweden, [3]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden, [4]Department of Clinical Immunology and Transfusion Medicine, Unit of Clinical Immunology, Karolinska University Hospital and Karolinska Institutet /Karolinska University Hospital, Stockholm, Sweden, [5]Department of Rheumatology, Lund University Hospital, Sweden

Background/Purpose: Vascular events are common in systemic lupus erythematosus (SLE) and SLE patients with antiphospholipid antibodies (aPL) are at particularly high risk. Genotypes in the HLA-DRB1 region on chromosome 6 are associated with SLE per se and genetic associations in this region have also been reported with the occurrence of pro-thrombotic aPL. We investigated if HLA-DRB1 genes are associated with vascular events in patients with SLE.

Methods: A total of 664 unrelated SLE patients of Caucasian origin from three different clinics (n = 364 + 160 +140) were included in this study. All fulfilled four or more of the 1982 American College of Rheumatology revised criteria for SLE. Two-digit HLA-DRB1 typing was performed by sequence-specific primer-polymerase chain reaction. Previous manifestations of objectively verified ischemic heart disease (IHD, myocardial infarction or angina), ischemic cerebrovascular disease (ICVD, stroke or transient ischemic attack) and venous thromboembolic events (VTE, deep venous thrombosis or pulmonary emboli)) were retrieved through patient interviews and medical files. aPL were measured with ELISA. Matched controls (n=1403) were genotyped. Odds ratios (OR) with 95% confidence intervals (CI) were calculated with the software JMP 9.0. Meta-analyses, presented below, of the combined results were calculated with RevMan 5.

Results: SLE per se was, as expected, strongly associated with HLA-DRB1*03 (OR: 2.75 95% CI: 2.32–3.26). After excluding HLA-DRB1*03 positive patients (due to common co-occurrence of DR*03 and DR*15) there was also an association with HLA-DRB1*15 (OR 2.02 95% CI 1.59–2.56), on the contrary HLA-DRB1*04 (OR: 0.81 95% CI: 0.64–1.02) was not associated with SLE. Yet, the HLA-DRB1*04 allele was associated with ICVD (OR: 1.68 95% CI: 1.00–2.82), but not with IHD or VTE. The HLA-DRB1*04 allele was furthermore consistently associated with the occurrence of aPL of all measured specificities: anticardiolipin IgG (OR: 1.96 95% CI: 1.32–2.90), and IgM (OR: 1.79 95% CI: 1.22–2.63), b2 Glycoprotein-1 IgG (OR: 2.73 95% CI: 1.81–4.10) and with a positive lupus anticoagulant test, performed in one cohort, (OR: 2.57 95% CI: 1.53–4.31, n=363).

Conclusion: The HLA-DRB1*04 genotype is not associated with SLE per se but it confers an increased risk for ischemic cerebrovascular disease among patients with SLE. Furthermore we confirm that the HLA-DRB1*04 genotype is consistently associated with the presence of pro-thrombotic aPL of different specificities. Our results demonstrate that genetic susceptibility merits further investigation as a possible cause of both aPL and the enhanced risk of cardiovascular disease, in particular stroke, among patients with SLE.

Insulin-Like Growth Factor Binding Protein-4 As a Marker of Chronic Lupus Nephritis. Chun Xie, Tianfu Wu, Jie Han, Ramesh Saxena and Chandra Mohan. University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: Renal involvement is the leading cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE). Kidney biopsy remains the mainstay of Lupus Nephritis (LN) diagnosis and prognostication. In particular, the chronicity index (CI) on renal pathology is highly predictive of renal and patient mortality. Since renal biopsy is invasive, there is an urgent need for the identification of non-invasive, surrogate biomarkers that closely parallel renal pathology in SLE. Previously, we have been able to identify markers that predict renal pathology "activity" but not "chronicity". Hence, we sought to identify novel surrogates of this aspect of the disease.

Methods: The sera from adult patients with LN (N = 5, average SLEDAI = 8) were screened for ~280 molecules using an array-based proteomic platform. The molecules with increased serum levels were then validated by ELISA in 86 patients with LN. Normal healthy adults (N = 23) and patients with other glomerular diseases (N = 20) served as controls.

Results: Insulin-like growth factor binding protein-4 (IGFBP-4) was one of the several molecules that were elevated in the sera of patients with LN compared to normal healthy controls in the array-based screen (arbitrary unit, mean +/− SE, 878,825 +/− 305,430 vs 143,926 +/− 23,927, $P = 0.06$). Serum IGFBP-4 levels of 86 biopsy-proven LN patients were then validated by ELISA. Compared to healthy (442 +/− 62 ng/ml) or other glomerular disease controls (725 +/− 204 ng/ml), serum IGFBP-4 levels were significantly higher in the patients with LN (1422 +/− 109 ng/ml, $P < 0.01$ and < 0.0001, respectively). Serum IGFBP-4 did not correlate well with systemic lupus erythematosus disease activity index (SLEDAI), renal SLEDAI or proteinuria, but it did correlate with serum creatinine ($R = 0.6124$, $P < 0.0001$). Interestingly, in 19 patients with proliferative LN (ISN/RPS Class III or IV) whose blood samples were obtained at the time of renal biopsy, serum IGFBP-4 level correlated strongly with the chronicity index on renal pathology ($R = 0.742$, $P < 0.001$).

Conclusion: IGFBP-4 emerges a relatively specific biomarker of lupus nephritis, strongly reflective of renal chronicity changes in lupus nephritis. Taken together with previously identified activity biomarkers, IGFBP-4 may help predict prognosis and guide treatment in LN, hence supplanting renal biopsy. Mechanistic studies are in progress to understand the biology of IGFBP-4.

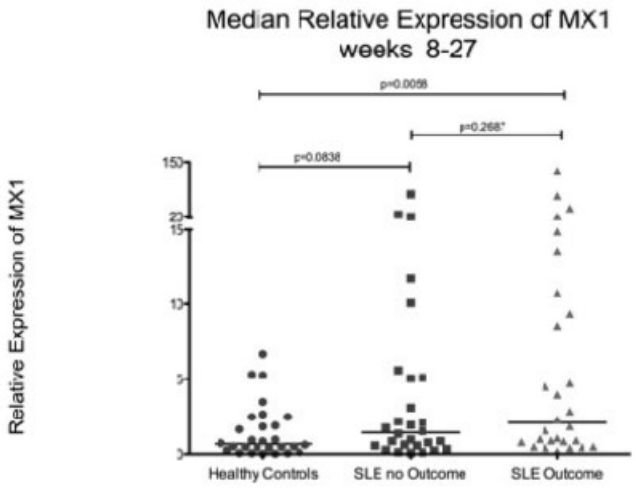
Increased Relative Expression of the Interferon-Responsive Gene MX1 Is Present in Pregnant SLE Patients and May Distinguish Flare of SLE From Preeclampsia. Danieli Andrade[1], Gloria Koo[1], Patricia M. Redecha[1], Kyriakos A. Kirou[2], Mimi Kim[3], Mary K. Crow[1] and Jane E. Salmon[4]. [1]Hospital for Special Surgery, New York, NY, [2]Mary Kirkland Center for Lupus Care - Hospital for Special Surgery, New York, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY

Background/Purpose: Type I IFN (IFN-I) contributes to the pathogenesis of SLE. Elevated levels of IFN-I stimulated genes have been associated with increased disease activity. That IFN-α has anti-angiogenic effects raises the possibility that it may be deleterious for developing placenta in pregnant SLE patients. We hypothesized that MX1 (myxoma resistance protein 1), an IFN -I responsive gene, could be used as a single gene to determine the presence of IFN signature and predict outcomes in pregnant lupus patients.

Methods: We performed a nested case-control study of SLE patients in the PROMISSE Study- Predictors of Pregnancy Outcome: Biomarkers In Antiphospholipid Antibody Syndrome and Systemic Lupus Erythematosus. Patients met ACR criteria for SLE. Exclusions were: prednisone >20mg, proteinuria >1gm/24 hr and creatinine >1.2 mg/dl. Each month, beginning at <12 wks gestation, SLEPDAI was measured and blood was collected. Poor pregnancy outcome was defined as: fetal death >12 wks; placental insufficiency or preeclampsia (PE), severe IUGR or severe hypertension. Each of 28 patients with SLE and poor pregnancy outcomes were matched 1:1:1 by age and ethnicity to an SLE patient with an uncomplicated pregnancy and a healthy pregnant control. Serum samples from 3 matched pregnancies were assayed simultaneously for IFN-α activity using a reporter cell assay. Real-time quantitative polymerase chain reaction was used to determine the RE of MX1 from samples obtained each month. To assess IFN-α activity in non-autoimmune patients destined for PE, we examined RE of MX1 through pregnancy in 11 healthy patients who developed PE and compared values to patients with SLE and PE as a pregnancy outcome. All analyses for Relative Expression (RE) of MX1 were done at 8–27 weeks of gestation and were expressed as medians.

Results: In early pregnancy, RE of MX1 is higher in SLE patients with outcome than controls (p=0.0058) and tended to be higher in SLE patients with no poor outcome (p=0.08). SLE patients with PE showed higher levels of RE MX1 than controls, (p=0.0052) and than SLE patients with no outcomes (p=0.0094). There was no correlation between SLEPDAIs and RE MX1 before the outcome. RE of MX1 was not different in patients who were positive for anti-Ro. Hydroxychloroquine use was not associated with decreased expression of RE MX1 (p=0.529). SLE patients with PE showed higher RE MX1 compared to non-autoimmune patients with PE (p=0.0002).



Conclusion: RE of MX1 may be used as a single gene to detect the IFN signature in pregnant SLE patients. RE of MX1 can distinguish pregnant SLE patients from those without SLE. Pregnancy does not abrogate induction of IFN-α genes. Our data show that PE, in and of itself, is not associated with increased IFN-α, and that high levels of RE of MX1 may differentiate lupus nephritis from PE in pregnant patients with hypertension and proteinuria.

Immune Complexes (ICs) From Systemic Lupus Erythematosus (SLE) and Complement Activate ERK1/2 and PI3K/Akt Pathway in Primary Human Mesangial Cells. Anil K. Chauhan[1] and Terry L. Moore[2]. [1]Saint Louis University, St. Louis, MO, [2]Saint Louis University, Saint Louis, MO

Background/Purpose: In SLE patients, antibodies against nuclear antigens and other self-antigens ICs and activate the complement system. This results in type III hypersensitivity reaction. To better understand the physiology of the tissue damage from these immune reactants, we purified the ICs from SLE patients and studied the signaling events triggered by them in the presence of the fluid phase terminal complement complex (TCC) in the primary human mesangial cells.

Methods: The plasma from SLE patients with high disease index was collected with informed consent. ICs were purified from plasma of SLE patients using Proceptor™ affinity resin. These purified ICs were analyzed using 2D SDS-PAGE and their antigen composition was obtained using nano-LC/MS/MS. 1×10^6 primary mesangial cells were treated with purified ICs (2μg) and fluid phase TCC (2.5 μg) isolated from zymogen activated human serum. The cell lysate prepared from treated cells were probed for phosphorylation of ERK1/2 and PI3K/Akt in Western blot analysis.

Results: The nono-LC-MS/MS analysis of the ICs revealed the presence of proteins from several functional categories, such as signaling, protein-protein interaction, and protein transport. The ICs from SLE patients triggered phosphorylation of ERK1/2 at 2 h time interval, and this phosphorylation was over by 4 h. Activation of ERK1/2 is required for cellular proliferation, thus suggesting a role for ICs and TCC in inducing the proliferation of cells lining the mesangium. This proliferation will contribute to the tissue fibrosis such as observed in lupus nephritis. PI3K/Akt/mTOR is an important signaling pathway that is a therapeutic target and act by impacting apoptotic pathways. We observed over 396% increase in PI3K/Akt phosphorylation at the 4 h time interval in cells treated with ICs and TCC. These signaling events implicate the ICs and complement in cell survival. This suggests that ICs and TCC trigger both proliferative and cell survival responses. We also observed presence of a number of KIAA proteins within these ICs. In addition, we also identified C3, C4A, CD5L, hemopaxin, alpha-1B glycoproteins. The KIAA 1542 gene was identified as a risk factor in genome wide association studies. We will present the protein composition of ICs isolated from SLE patients obtained using nano-LC/MS/MS analysis.

Conclusion: Our results define two signaling events activated by ICs and complement in tissue where immune deposits are formed.

1445

Quantitative Analysis of Pathologic Cell Subsets Involved in Tubulointerstitial Inflammation in Human Lupus Nephritis. Vladimir M. Liarski, Daniel F. Brandt, Christine Hsieh, Natalya Kaverina, Christine Labno and Marcus R. Clark. University of Chicago, Chicago, IL

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease, the most frequent severe manifestation of which is nephritis. Pathologically, lupus nephritis (LN) is characterized by immune complex deposition and inflammation in both glomeruli and the tubulointerstitium. We have previously shown that tubulointerstitial inflammation is a usual feature of LN and the infiltrate is organized into either well-circumscribed T:B cell aggregates or germinal center (GC)-like structures.

Methods: To investigate the cellular make-up of the tubulointerstitial inflammation, we used multicolor confocal microscopy. These studies revealed that the infiltrate was composed of CD4+ICOS+ and CD4+PD-1+ cells, consistent with a T follicular helper [T_{FH}] subtype as well as CD20+ and Ki67+ cells, consistent with activated and proliferating B cells. We next sought to understand how these different subsets of cells could be cooperating to mediate inflammatory damage but were limited by the absence of quantitative tools for this purpose. Therefore, we

developed a novel proprietary algorithm based on ImageJ (W Rasbrand, NIH, http://rsb.info.nih.gov/ij/) to transform the obtained immunofluorescent images into binary form. From this, we were able to derive a data-rich analysis of inter-cell relationships across 40 human lupus nephritis biopsies.

Results: Our analysis demonstrated that CD20+ B cells were much more likely to be close to CD4+PD1+ (56% of cells within 0–3 microns, $p=1\times10^{-4}$) or CD4+ICOS+ (59% of cells within 0–3 microns, $p=2.46\times10^{-5}$) T cells than to other CD20+ B cells (<8% within 0–3 microns). This association remained unchanged after correction for cellular density. The relationship was also present but not as robust when compared with Ki67+ B cells (38% of cells within 0–3 microns, $p=1\times10^{-3}$), which may reflect the fractionation of the latter into centroblasts within GCs and plasmablasts or other intermediate cell types within less organized T:B aggregates. As expected, comparison with CD8+PD-1+ T cells failed to reveal an association ($p=0.1$).

Conclusion: Our data reveals that T_{FH} cells are more likely to form conjugates with naïve and activated B cells. This example indicates that our novel quantitative approach enables the identification of important cell-cell interactions within human tissues and serves as a powerful analytical tool that may be generalized to other cell types and human tissues.

Gene Expression Profiles in Monocytes and Macrophages From Systemic Lupus Erythematosus Patients and Healthy Controls with and without An Atherosclerosis Phenotype. Benjamin Korman[1], Carly Skamra[1], Peggy Wu[1], Alexander Sandhu[1], Qi Quan Huang[1], Chiang-Ching Huang[1], William Pearce[1], Kim Sutton-Tyrrell[2], George Kondos[3], James Carr[1], Daniel Edmundowicz[2], Richard Pope[1] and Rosalind Ramsey-Goldman[1]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]University of Pittsburgh, [3]University of Illinois at Chicago, Chicago, IL

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk of atherosclerosis. Given that monocytes and macrophages play an essential role in the pathogenesis of SLE and in the initiation and progression of atherosclerosis, we examined differential gene expression profiles of monocytes and macrophages in patients with SLE and controls with and without an atherosclerotic phenotype.

Methods: Monocytes and macrophages were isolated from 36 individuals: 20 with SLE and 16 healthy controls of whom 10 SLE patients and 8 healthy controls had an atherosclerosis phenotype with at least 3 of the following 4 abnormalities: plaque index [PI] >0, intima media thickness [IMT] > mean of the study group, coronary calcium score [CAC] >10, or aorta calcium score [ACS] > 100. RNA was extracted and whole genome expression profiling was performed on the Sentrix Human (Illumina) platform to measure expression of >47,000 transcripts in each sample. Cluster analysis was performed to identify gene expression patterns. The PANTHER database was used for gene ontology analysis.

Results: Cluster analysis demonstrated that, in monocytes, 9/20 SLE patients had an interferon-inducible signature compared to only 2/16 controls (OR 5.7, 95% CI = [1.02, 32.0]). 3 additional patients had a signature with upregulation of pro-inflammatory cytokines and chemokines, while 8 SLE patients could not be clearly differentiated from controls. In macrophages, there were no clear gene expression signatures. Expression profiling in monocytes and macrophages was unable to clearly distinguish individuals with and without atherosclerosis. However, in a stratified analysis of monocytes of SLE patients with atherosclerosis compared with patients without an atherosclerosis phenotype, we were able to reproduce our previous observation that individuals with subclinical atherosclerosis (defined by CAC > 100) had a substantial enrichment in the expression of 344 genes including those involved in TLR/IL-1R signaling (OR 9.3, 95% CI = [1.2, 72.9]). Furthermore, we identified genes with both a fold change >2 and $p<0.05$ that were differentially expressed during monocyte to macrophage differentiation between SLE patients and controls. There was significant ($p<0.001$) enrichment of genes involved in signal transduction, immune system processes, carbohydrate and lipid metabolic processes, and apoptosis. Further analysis of the signal transduction genes demonstrated differences between patients and controls in downregulated genes including *JAK2, STAT6, TLR8,* and *TLR2* and upregulated genes including *VEGFB, TGFB1, FN1, IL-1R2, SCARB1, MSR1,* and *CD163* all of which have previously been shown to be potentially involved in the pathogenesis of atherosclerosis.

Conclusion: Whole genome expression data analyzing monocytes supports the importance of the interferon-inducible signature in SLE. Furthermore, our results also suggest that the TLR/IL-1R-associated immune gene signature and other signal transduction molecules may be involved in the pathogenesis of SLE or associated with atherosclerosis development in patients with SLE.

ACR/ARHP Poster Session B

Systemic Sclerosis Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics II

Monday, November 7, 2011, 9:00 AM–6:00 PM

1447

Treatment of Systemic Sclerosis: What to Use When First-Line Treatment Fails. A Consensus of Experts. Kyle M. Walker[1], Janet E. Pope[2], Scleroderma Clinical Trials Consortium (SCTC)[3] and Canadian Scleroderma Research Group (CSRG)[4]. [1]Trinity College Dublin, Dublin, Ireland, [2]St. Joseph's Health Care, University of Western Ontario, London, ON, [3]Boston, MA, [4]Montreal, QC

Background/Purpose: There is a need for standardization in systemic sclerosis (SSc) management, particularly after usual (1st-line) treatment.

Methods: SSc experts (n=118) were sent 4 surveys to gain consensus for SSc management. Cases were given for mild and severe organ involvement and experts chose treatments and the % of each drug chosen was recorded, and used to construct treatment algorithms which were voted on re: agreement from 0–9; (consensus was 7, 8 or 9).

Results: 55 (47%) responded to all surveys. After ACEi use for mild scleroderma renal crisis (SRC){97% agreement}, 2nd-line was to add either a CCB {37%} or ARB {35%}, then an alpha blocker (20%) in severe SRC. Treatment of mild and severe SRC was similar (75% agreement) {Fig 1}. ERAs were 1st-line in mild PAH (72%) and proceeded by adding PDE5i (77%) and then a prostanoid (73%). For severe PAH, treatment was any of: prostanoid (49%), combination of ERA and PDE5i (19%) or ERA and prostanoid (16%) {71% agreed} (Fig 2). For mild Raynaud's (RP), CCB (92%) were followed by adding a PDE5i (35%), then an ARB (32%) and finally a prostanoid (23%). For more severe RP, 54% agreed on adding a PDE5i or a prostanoid (32%) {Fig 3}. For prevention of digital ulcers (mild history) treatment was a CCB (73%), then to add a PDE5i (57%) then an ERA (47%), and a prostanoid (38%) {50% agreed}. A severe history was similar (Fig 3). For ILD, induction was usually IV cyclophosphamide (65%) or occasionally oral (64%) or mycophenylate mofetil (MMF) (48%) or azathioprine (45%). For maintenance, MMF was chosen by ¾ (56% agreed). For skin involvement after methotrexate, MMF was usually chosen (38% agreed). For GERD, half would exceed the maximum recommended PPI dose if required (72% agreed). For joint involvement after methotrexate (60%), corticosteroids (37%) or hydroxycholoroquine (31%), then biologics (20%) should be considered (62% agreed).

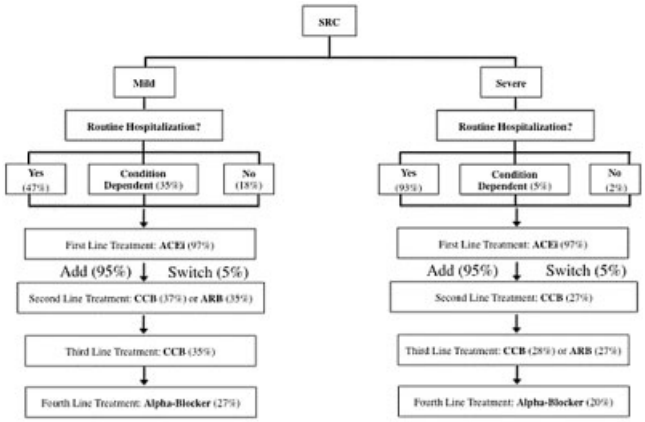

Figure 1. Algorithm for the treatment of mild and severe SRC

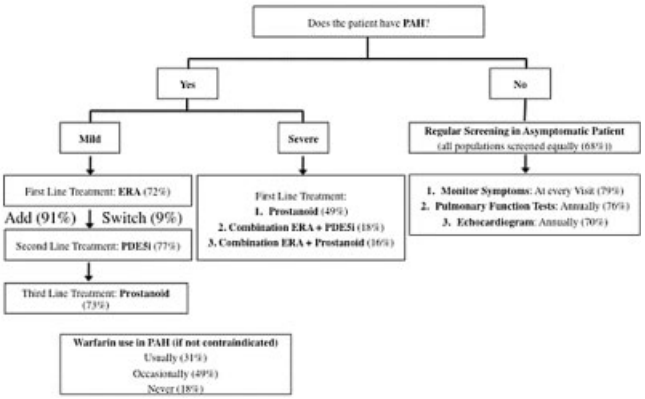

Figure 2. Algorithm for the management of PAH

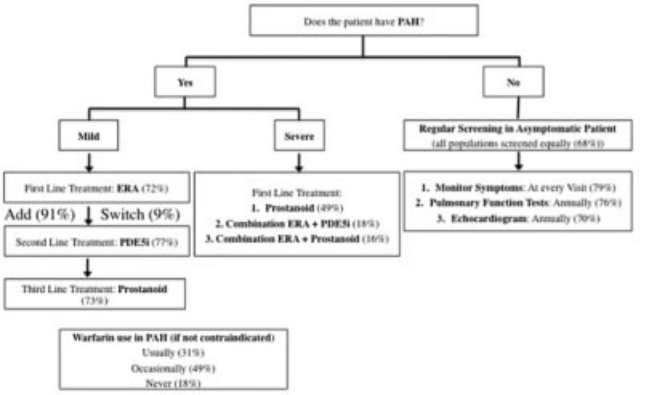

Figure 3. Algorithm for the treatment of RP and the treatment/prevention of DU

Conclusion: Discrepancies in drug choices occurred after 1st-line treatment in SSc. Not all algorithms had good agreement. This study provides some guidance for SSc management.

1448

Two Years Follow-up Results After Rituximab Treatment (baseline and month 6) in Patients with "Early" Systemic Sclerosis with Diffuse Skin Involvement. Vanessa Smith[1], Yves P. Piette[1], Saskia Decuman[1], Jens T. Van Praet[1], Ellen De Schepper[2] and Filip De Keyser[1]. [1]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [2]Biostatistics Unit, Ghent University, Ghent, Belgium

Background/Purpose: Systemic sclerosis (SSc) with diffuse skin involvement (DcSSc) has a bad prognosis. As yet, no treatment has been shown through randomized controlled trials to halt the natural progression of skin involvement in SSc. Nevertheless, it has been shown recently that in patients with early DcSSc who showed improvement of their skin score during two years of follow-up, survival was significantly better than in patients without such improvement. The purpose of this study is to examine safety and potential efficacy of rituximab in patients with "early" DcSSc.

Methods: Two years follow-up in an open-label study of eight patients with early DcSSc. Patients received an infusion of 1000 mg rituximab at baseline (w0 and w2) and at month 6 (w24 and w26), together with 100 mg methylprednisolone at each infusion. Clinical read outs, disease activity score and functional status were performed at month 0, 3, 6, 12, 15, 18 and 24, except for echocardiography which was performed at month 0, 3, 6, 12 en 24. Assessments included modified Rodnan skin score (mRSS), evaluation of internal organ functioning (lung function, echocardiography, creatinine clearance), the health assessment questionnaire disability index, the Medical Outcome Study Short Form 36 and CD 19+ peripheral blood count. Mixed models analyses (MMA) with random intercept for patients were used to evaluate changes in clinical parameters over time.

Results: There was a clinical significant change in skin score throughout the study with a mean mRSS of 24.8 at baseline (SD: 3.4) and 13.6 at month 24 (SD: 5.6) ($p<0.001$). There was also a significant decrease in Disease Activity Score (DAS), with a mean of 4.5 at baseline (SD: 1.9) and 2.1 at month 24 (SD: 2.4) ($p<0.001$). Indices of internal organ involvement remained stable throughout the study (Table 1). Rituximab induced effective B-cell depletion in all patients both at baseline and month 6 (<5 CD19+ cells/μl blood). Three serious adverse events (SAE) occurred (in addition to two SAE already previously described in the 6 months report of this study)[1], which were thought to be unrelated to the rituximab treatment.

Table 1. Changes in clinical and laboratory parameters in the study upon treatment with rituximab

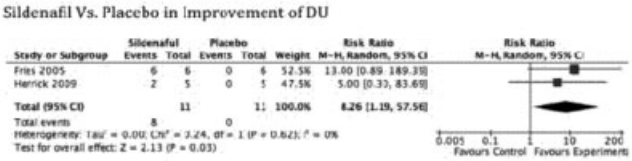
A Meta-Analysis of Randomized Trials in the Treatment and Prevention of Digital Ulcers (DU) in Systemic Sclerosis (SSc). Theresa Tingey[1], Joseph Smuczek[1] and Janet E. Pope[2]. [1]McMaster University, Hamilton, ON, [2]St. Joseph's Health Care, University of Western Ontario, London, ON

Background/Purpose: Digital ulcers (DU) in SSc occur in 50% and may be quite severe. Assessing data from DU trials in SSc may provide guidance for treatment.

Methods: The objective of this meta-analysis was to assess the efficacy of various pharmacologic therapies in treating and preventing DU in SSc including DU trials and Raynaud's Phenomenon (RP) SSc trials which recorded DU. MEDLINE, EMBASE (to November, 2010) and ACR and EULAR abstracts (2009–10) were searched for trials dealing with DU. Randomized trials comparing pharmacologic therapy with placebo or another agent were eligible. Inclusion criteria and trial quality were assessed by 2 reviewers. Quality was scored based on randomization, blinding, statistical methods, intention to treat analysis, and method of randomization. RevMan 5 software was used for analyses.

Results: 40 studies were found, and 19 excluded. Main reasons for exclusion were non-randomisation (7), no DU outcome (8) or insufficient data

(4). Quality score for trials was moderate (mean 2.9/5). Prostacyclins overall when combined were not effective, but intravenous (IV) iloprost was associated with significant prevention (reduction in new DU by standardized mean difference {SMD} of −0.77; 95% CI −1.46 to −0.08; P=0.03); oral prostaglandins were ineffective. Atorvastatin decreased the number of new DU (SMD −0.85; 95% CI −1.32 to −0.38; P=0.0004). Nifedipine was associated with an insignificant decrease in the number of patients developing new DU (RR 0.50; 95% CI 0.17 to 1.46) and no significant differences in overall number of DU and mean number of new DU. Sildenafil was not significant in complete DU healing but for improvement of DU in two trials (P=0.03) and tadalafil had healing and prevention of DU in one trial. In a head to head trial, iloprost was not superior to nifidipine for healing or prevention of DU. Two large bostentan trials were associated with a reduction in the number of new DU (SMD −0.36; 95% CI −0.59, −0.13, P=0.0002) but no difference in the proportion of people with DU healing (P=0.6). Antiplatelet treatment, heparin, dimethyl sulfoxide, ketanserin, prazosin, PGE1, beraprost, cicaprost, and cyclofenil were not statistically different from placebo.



Conclusion: Small sample size, secondary data from RP trials, variable definitions of improvement and prevention and few comparative trials limit the conclusions. The results suggest that there is evidence to support the use of IV iloprost in healing DU in SSc. Bosentan can decrease the number of new DU (prevention). PDE5 inhibitors may have benefit.

Digital Ulcers in Patients with Systemic Sclerosis: Prevalence, Location, Nailfold Capillaroscopy and Functional Impact. Holly Ennis[1], A. Vail[2], Elizabeth Wragg[3], Adrienne Taylor[3], Tonia Moore[1], Andrea Murray[1], Lindsay Muir[4], Christopher E.M Griffiths[5] and Ariane L. Herrick[1]. [1]School of Translational Medicine, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [2]School of Community Based Medicine, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [3]Rheumatology Directorate, Salford Royal NHS Foundation Trust, Salford, United Kingdom, [4]Hand Surgery, Salford Royal NHS Foundation Trust, Salford, United Kingdom, [5]Dermatology Centre, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom

Background/Purpose: Although digital ulcers are a common manifestation of vascular abnormality in patients with systemic sclerosis (SSc) their prevalence, functional impact and pathophysiology have been relatively little studied. Our aim was to investigate point prevalence of active digital ulcers in a cohort of SSc patients and to assess ulcer location, associated findings on quantitative nailfold videocapillaroscopy, and impact on hand function.

Methods: Over a 12 month period, patients attending for routine annual review at a specialist SSc clinic were assessed by a tissue viability nurse who documented all active digital ulcers and performed the Hand Mobility in Scleroderma (HAMIS) test. Patients completed the Cochin Hand Function Scale (CHFS) and the Scleroderma Health Assessment Questionnaire (SHAQ) (both self-assessments), and underwent quantitative nailfold capillaroscopy.

Results: Clinical and demographic features of the 148 participants (74% of those approached) are shown in Table 1. A total of 25 ulcers (9 digital-tip and 16 extensor surface) were found in 15 patients, giving an overall point prevalence (95% CI) of 10% (6–16%) and a point prevalence of 6% (3–11%) for each ulcer type. There was a trend for intercapillary distance to be higher (and therefore density lower) in patients with active ulcers (log [distance], p=0.03). The presence of ulcers was associated with higher pain visual analogue scores (VAS), CHFS and HAQ scores but this was statistically significant only for pain VAS (mean difference 0.45 [0.04–0.88], p=0.04).

Variable	Total study population n=148	No digital ulcers n=133	Digital ulcers n=15
Female, n (%)	125 (84)	133 (85)	12 (80)
LcSSc, n (%)	109	100 (75)	9 (60)
Age, median (range), yrs	60 (21–88)	60 (21–83)	50 (36–88)
Disease duration, median (range), yrs	11 (1–54)	11 (1–43)	13 (1.54)
Capillary density (inter–capillary distance), median (range)	27821 (574–149840)	26914 (574–149840)	49924 (26540–74242)
Pain VAS, median (inter–quartile range)	0.8 (0.1–1.5)	0.8 (0–2.4)	1.2 (0.8–2.1)
CHFS, median (range)	17 (0–80)	13.5 (0–80)	24.5 (3–64)
HAQ, median (range)	1.4 (0–3)	1.3 (0–3)	1.75 (0–2.25)

All 15 patients with ulcers were right-handed. 5 had ulcers only on their left hand, 6 only on their right hand and 4 on both hands. The presence of ulcers on the left hand was associated with significantly reduced HAMIS left scores (mean difference 8.8 [3.2–14.5], p=0.002). This was similar regardless of location. There was a similar association with extensor surface, but not fingertip, ulcers on the right (dominant) hand.

Conclusion:

1. In this prospective study in which active digital ulcers were all identified in a standardised manner by a specialist nurse, the point prevalence was 10% overall and 6% for each of digital-tip and extensor surface ulcers.
2. Digital ulcers were associated with reduced capillary density (reflecting severity of microvascular disease).
3. The burden of pain and functional impairment associated with active digital ulcers was confirmed.
4. The finding that fingertip ulcers of the right (dominant) hand may have a less detrimental impact than others is unexplained but may reflect coping mechanisms in patients with chronic disabling disease.

Elevation of Aldolase in Eosinophilic Fasciitis. Jennifer Nashel[1] and Virginia D. Steen[2]. [1]Washington, DC, [2]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Eosinophilic fasciitis (EF), is a rare, localized, fibrosing disorder of the fascia that was first described in 1974. The diagnosis of EF is often suspected based on skin findings and laboratory values such as peripheral eosinophilia, increased erythrocyte sedimentation rate (ESR) and hypergammaglobulinemia. These traditionally associated laboratory abnormalities may be transient in early disease and even absent in many confirmed cases. There are some reports that an increased aldolase with normal creatine phosphokinase (CPK) is seen in EF. We have reviewed a case series of patients to assess the presence of laboratory abnormalities in EF.

Methods: We performed a retrospective review of EF patients seen at Georgetown University Hospital in the Division of Rheumatology between 2009 and 2011.

Results: This review included 12 adult patients with EF with a mean age at diagnosis of 45 years (range 24 to 77 years). The majority of patients (10/12) had typical skin changes on all four extremities without evidence of systemic sclerosis. Only six patients had peripheral eosinophilia ranging between 8 and 38%. In these patients, the peripheral eosinophilia was an early and transient finding. The ESR was elevated in 4 out of 11 and C-reactive protein was elevated in 4 out of 8. At disease presentation only 1 of 11 patients had an elevated CPK, however the aldolase levels were elevated in 9 out of 10 patients. While the eosinophilia and inflammatory markers declined rapidly with initiation of steroid treatment, aldolase gradually normalized and more closely followed the clinical disease response.

Conclusion: In this case series of EF patients, aldolase was more likely to be abnormal than peripheral eosinophilia, hypergammaglobulinemia, and ESR. We suspect that aldolase elevation in the setting of a normal CPK is a reflection of perimysial fascial and focal muscle enhancement as illustrated on MRI and en bloc surgical biopsy. An elevated aldolase with a normal CPK may be a unique marker in EF. It may also play a useful role in following disease activity.

HLA *DQB1*03:02* Is a Marker for Severity of Interstitial Lung Disease in Systemic Sclerosis. Shervin Assassi[1], Filemon K. Tan[1], Jun Ying[2], Olga Y. Gorlova[2], Brock E. Harper[3], Hilda T. Draeger[4], Emilio B. Gonzalez[5], Rosa M. Estrada-Y-Martin[1], Julio Charles[1], Xiaodong Zhou[1], Frank C. Arnett[1], John D. Reveille[1] and Maureen D. Mayes[1]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]UT M. D. Anderson Cancer Center, Houston, TX, [3]University of Texas Medical Branch, Galveston, TX, [4]University of Texas Health Science Center, San Antonio, TX

Background/Purpose: Interstitial lung disease (ILD) is associated with significant morbidity and mortality in systemic sclerosis (SSc). The major histocompatibility region (MHC) showed the strongest association with SSc in the first genome-wide association study, making it the prime genetic locus for studying the pathogenesis of SSc and biomarker development. The goal of the current study was to examine the association of MHC genetic markers with severity of ILD in SSc.

Methods: Patients with SSc were recruited from two US cohorts, GENISOS and the Scleroderma Family Registry. HLA Class II genotyping (*DRB1, DQA1, DQB1, DPB1*) was performed on extracted and purified genomic DNA. Furthermore, anti-centromere (ACA), anti-topoisomerase (ATA), and RNA Polymerase III were detected utilizing commercially available kits. The primary outcome was forced vital capacity (FVC)% predicted at enrollment. A two-step approach was used for the analysis in order to limit the number of performed comparisons. Initially, the top 10 most discriminating, independent clinical and genetic variables were identified in a random forest analysis. Subsequently, these variables were analyzed by linear regression following a forward variable selection strategy. A final multivariable model was constructed with independent variables, significantly associated with the outcome.

Results: A total of 793 patients with SSc were examined, from which 38 % had moderate (FVC=50%–80%) and 6% severe (FVC<50%) restrictive lung disease. Diffuse cutaneous involvement was present in 47% of patients. The mean disease duration was 6.2 years.

HLA *DQB1*03:02* (p=0.0001, b= 6.9, 95% C.I.: 3.4–10.4), disease duration, as well as presence of ACA and ATA were significantly associated with FVC in the multivariable model (adjusted for ethnicity). Addition of disease type (limited versus diffuse) did not significantly change the overall fit of the model. No other HLA Class II allele was associated with FVC.

In our multiethnic sample, 19.6% of patients had at least one HLA *DQB1*03:02* allele. In the multivariable model, patients with this HLA allele had on average 6.9% higher FVC levels, indicating that this HLA allele was a predictor of milder ILD, independent of autoantibody profile and disease duration (Table 1).

We also repeated the entire analysis with only Caucasian patients (n=553). HLA *DQB1*03:02* was again the only HLA Class II allele, significantly associated with FVC. HLA *DQB1*03:02* was present in 19% of Caucasian patients. The same clinical variables were the independent predictors of FVC among these patients in the final model (Table 1).

Table 1. Final Multivariable Model

	Caucasian Patients		All Patients*	
Variable	**b, 95% (C.I.)**	**p-value**	**b, 95% (C.I.)**	**p-value**
DQB1*03:02	6 (2.2,9.8)	0.002	**6.9 (3.4,10.4)**	**<0.001**
ATA	−4.1 (−7.7,−0.4)	0.031	−4.3 (−7.7,−0.9)	0.013
ACA	11.3 (7.6, 15)	<0.001	12.3 (8.6, 15.9)	<0.001
Disease Duration, yrs	−0.4 (−0.6,−0.2)	<0.001	−0.4 (−0.6,−0.2)	<0.001

* Adjusted for ethnicity

Conclusion: This is the first study linking an MHC locus/allele to severity of SSc-ILD. HLA *DQB1*03:02* is an independent predictor of milder ILD in SSc. Because of its high frequency, this allele can be used for risk stratification in patients with SSc beyond the known clinical predictors.

1453

Treatment of Idiopathic Retroperitoneal Fibrosis: A Single Center Experience. Pietro Tartaro and Renzo Marcolongo. Hematology and Clinical Immunology Unit, Padova, Italy

Background/Purpose: Idiopathic Retroperitoneal Fibrosis (IRF) is a rare collagen vascular disease of unclear origin, characterized by the development of fibro-inflammatory tissue in retroperitoneal space around the abdominal aorta, iliac arteries, vena cava and ureters. IRF has been associated with HLA-DRB1*03. The optimal treatment of IRF has not yet been established. Therapeutic options include periodic ureteral stenting, ureterolysis/omental wrapping and/or medical therapy with corticosteroids, alone and in combination with tamoxifen or an immunosuppressive agent. We evaluated our clinical experience on IRF, with particular attention to the response to therapy.

Methods: Retrospective review of clinical records of IRF patients observed over 25 years and followed for at least 6 months. Descriptive statistics were used.

Results: We found data about treatment of 67 patients; 56 received corticosteroids (84%), 5 prednisone alone (7,5%), 17 in combination with tamoxifen (26%), 21 with azathioprine (32%), 10 with cyclophosphamide (15%) and 33 with periodic ureteral stenting (49,2%); 6 underwent ureterolysis/omental wrapping (9%); 46 patients achieved complete remission (67%), with the removal of ureteral stents, and are currently off treatment; 16 patients are still under treatment (24%); 9 (13,4%) had important therapy-related side effects (1 azathioprine-related pancreatitis, 2 severe leucopenia, 3 intolerance to tamoxifen, 1 HBV reactivation, 2 sepsis). The disease recurred in 12 patients (32%) from 6 months to 5 years (average 26 months) after treatment discontinuation.

Additional clinical information was also available for 37 patients; 21 had the involvement of abdominal aorta (57%), 12 with periaortitis (33%) and 9 with aneurysm (24%); 16 (43%) had systemic symptoms (fatigue, weight loss, abdominal and/or back pain), 10 arterial hypertension (27%) and 1 thrombosis of vena cava (2.7 %). In single cases, we found IRF in association with autoimmune diseases such as morfea, retrobulbar fibrosis, Hashimoto's thyroiditis, Raynaud's phenomenon, primary sclerosing cholangitis and psoriasis. PET scan, performed in 15 patients, showed abnormal retroperitoneal uptake in 7 cases. Average follow-up was of 71 months.

Conclusion: In our experience, medical treatment with corticosteroids, alone and in combination with tamoxifen or azathioprine and, when the case, together with ureteral stenting, is usually safe and well tolerated. We conclude that, to make a correct therapeutic choice, it is first worth excluding every identifiable cause retroperitoneal fibrosis, in particular hidden malignancy. For this reason, as starting therapy, we usually prefer prednisone, ranging from 0.5 to 1 mg/Kg/day, alone or in combination with tamoxifen. In case of treatment failure or intolerance, after having carefully excluded every possible contraindications, we add to prednisone an immunosuppressive agent such as azathioprine. Nevertheless, since many IRF patients are aged people with a fragile metabolic condition or concomitant chronic diseases, for their potential side effects, immunosuppressive agents should be used carefully and only in cases non responsive to less aggressive treatments.

Prevention of Digital Ulcers in Systemic Sclerosis Patients: A Proposal of Risk Chart. Andreina Manfredi[1], Marco Sebastiani[1], Roberto D'Amico[1], Valeria Carraro[2], Mario Bocci[3], Sheila Moscatelli[4], Michele Iudici[5], Michele Colaci[1], Dilia Giuggioli[1] and Clodoveo Ferri[6]. [1]University of Modena and Reggio Emilia, Modena, Italy, [2]Rheumatology Clinic, University of Padova, Padova, Italy, [3]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [4]University of Perugia, Perugia, Italy, [5]Second University of Naples, Naples, Italy, [6]Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease mainly characterized by fibrosis of skin and internal organs and by diffuse microangiopathy, responsible for digital ulcers (DU) in about 50% of patients. Management of DU is very challenging; it includes combined systemic and local treatments. Risk factors for the appearance of scleroderma DU are not defined and data from literature are discordant.

Recently, our group proposed a capillaroscopic index (CSURI: Capillaroscopic Skin Ulcer Risk Index), able to identify patients with high risk to develop DU within 3 months from capillaroscopic evaluation, with a positive and negative predictive value of 62.3% and 97.2%, respectively.

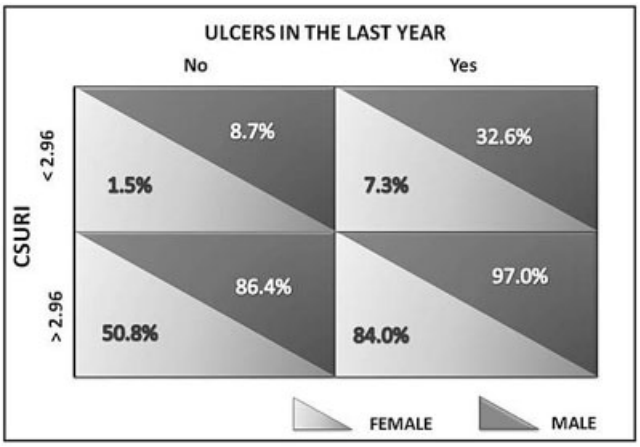
Aim of the study was to develop a predictive model, including CSURI, demographic, and clinico-serological parameters, in order to estimate the total risk of developing DU over next six months.

Methods: One hundred and seventy-two unselected SSc patients (male/female 19/153, limited/diffuse cutaneous SSc 121/51, mean age 53.4 years ± 13.8 SD, mean SSc duration 108.2 months ± 97.8 SD) from 5 Italian Rheumatology Centers were consecutively enrolled. Capillaro-

scopic parameters were defined and collected according to our previous study. All patients underwent videocapillaroscopy at baseline; 3 and 6 months later patients were investigated for the development of DU.

The main demographic, clinical, and serologic features were evaluated for the possible association with the occurrence of DU. Possible correlations among the variables and DU were investigated by multivariate logistic regression.

Results: The development of DU was significantly associated with CSURI (Odds Ratio [OR] - 66.8, confidence interval [CI] 17.9 to 248.7; $p < 0.001$), history of previous DU within the last year (OR 5.1, CI 1.7 to 14.9; $p = 0.003$), and male gender (OR 6.2, CI 1.1 to 34.5; $p = 0.039$). The proposed risk chart based on these three parameters is reported in the figure (the percentages are referred to the cumulative risk for DU).



Conclusion: Among different SSc parameters CSURI, recent history of DU, and male gender showed to be strictly associated with the appearance of DU within the next six months from baseline. Our composite predictive model, which must be opportunely validated, represents an attempt to classify patients with different risk levels to develop DU; a correct patient's classification may optimize the needed preemptive and therapeutical strategies.

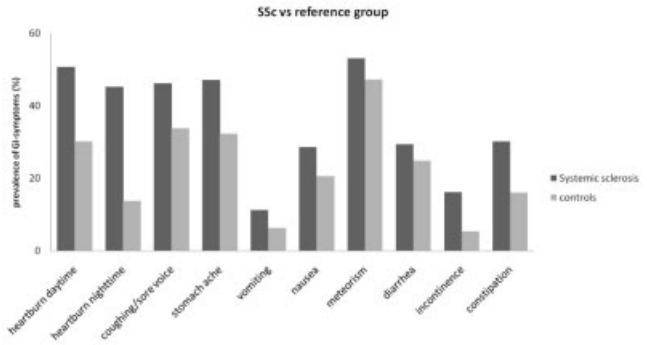
Clinical Features of Gastrointestinal Involvement in Patients with Systemic Sclerosis. Christiane Strohbeck[1], Florian MP Meier[1], Gabriela Riemekasten[2], Christiane Pfeiffer[3], Andrea Himsel[4], Ilka Herrgott[5], Norbert Blank[6], Jorg HW Distler[7], Matthias Seidel[8], Nicolas Hunzelmann[9] and Ulf Müller-Ladner[10]. [1]Justus-Liebig Universität Gieβen, Kerckhoff-Klinik GmbH, Bad Nauheim, Germany, [2]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany, [3]University Hospital Ulm, Ulm, Germany, [4]University Hospital Frankfurt, Frankfurt am Main, Germany, [5]University Hospital Münster, Münster, Germany, [6]University of Heidelberg, Eppelheim, Germany, [7]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [8]University Hospital of Bonn, Bonn, Germany, [9]University of Cologne, Cologne, Germany, [10]Justus-Liebig-University of Gieβen, Bad Nauheim, Germany

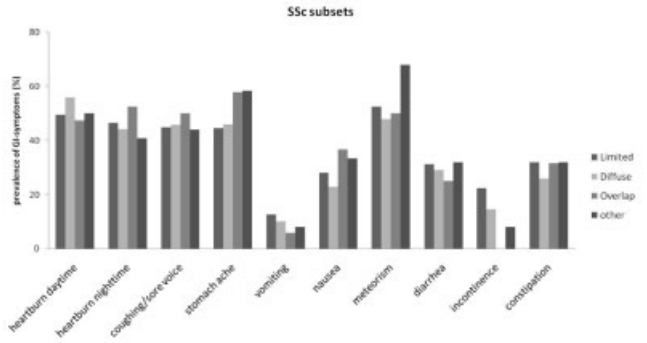
Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune connective tissue disease affecting various organ systems. A common feature of SSc is the involvement of the oesophagus, the stomach and the intestine. Our objective was to gather information about the extent and frequency of gastrointestinal (GI) symptoms in SSc patients. Therefore, the GI-expert center of the DNSS (German Network of Systemic Sclerosis) designed a questionnaire including patient characteristics, disease duration, symptoms and medications.

Methods: In detail, the questionnaire consisted of ten items about GI-symptoms and their occurrence, general aspects of the disease (e.g. time of occurrence), patient characteristics, questions about nicotine or alcohol abuse and about medications for either GI-symptoms or SSc in general. The questionnaire was approved by the local ethics committee. Throughout Germany, the questionnaire was distributed to SSc-patients in DNSS centers. Patients suffering from other rheumatic diseases served as control group. Altogether, 390 patients were included in this study, 222 in the SSc-group and 168 in the reference group.

Results: The results showed that only 5.4% of the SSc-Patients did not suffer from GI-symptoms at all, compared with 8.4% of the reference group. 87.4% were severely affected by clinically relevant GI sequelae, regardless of the SSc disease subset, compared to 73.8% in the reference group. The first diagram displays the distribution and frequencies of the symptoms.



All symptoms occurred more often in SSc-patients. The difference was most prominent for heartburn at nighttime and daytime, as well as for incontinence.



The second diagram demonstrates that the GI-symptoms were independent of the disease subsets. Besides, significant differences between the SSc-group and the reference group could be observed for weight ($p = 0.025$) and the body-mass index ($p < 0.001$). Of interest, only 55.9% of the SSc and 24.7% of the patients of the reference group received medication for their gastrointestinal involvement ($p < 0.001$).

Conclusion: The involvement of the upper and lower gastrointestinal tract in patients with SSc is clinically challenging. Our results demonstrate that almost every SSc-patient is affected by gastrointestinal disorders. Furthermore, these problems occur with higher frequency and severity in SSc patients than in other rheumatic diseases. Therefore, a detailed anamnesis with distinct attention to GI-symptoms is recommended as early as possible.

1456

Trends in Mortality in Patients with Systemic Sclerosis Over 40 Years: A Systematic Review and Meta-Analysis of Case-Control and Cohort Studies. Muriel Elhai[1], Christophe Meune[2], Jerome Avouac[1], Andre Kahan[1] and Yannick Allanore[1]. [1]Rheumatology A, Paris Descartes University, Cochin Hospital, APHP, Paris, France, Paris, France, [2]Paris Descartes University, Cardiology department, Cochin Hospital, Paris, France

Background/Purpose: Among the many different immune-mediated rheumatic diseases, Systemic Sclerosis (SSc) stands out as a severely incapacitating and life-threatening disease, the pathogenesis of which is largely unknown and for which therapeutic options are few and insufficient. Nevertheless, a recent cohort study has suggested a decrease in mortality with 10-year survival rates of 60% in the subgroup of patients included before 1985 as compared to 77% in the subgroup included later one. Thus we set out to determine whether mortality rate in SSc patients has decreased over the past 40 years through a meta-analysis of cohort studies.

Methods: We performed a systematic review and a meta-analysis of literature in MEDLINE and EMBASE databases from January 1960 to June 2010. All cohort studies or case-control studies reporting SSc mortality risk were included. Articles had to report enough data to compute a standardized mortality ratio (SMR). Eligibility of references retrieved by the search was assessed independently by two of the authors and disagreements resolved at each step. We then calculated pooled SMRs of SSc mortality and determined their evolution with time using meta-regression analysis. We also conducted adjusted meta-regression analyses, for the methodology of the studies and for relevant covariates (i.e. age, gender and cutaneous form), respectively.

Results: Among a total of 721 identified references, 637 were excluded on the basis of their title or abstract resulting in 84 articles examined for full text. There were finally 9 independent studies in which SMR was available. They were analyzed corresponding to a total of 2691 patients: mean age: 50.1 years, 2230 (83%) were women, 713/2691 (26%) had diffuse SSc. Mid-cohort year ranged from 1977 to 1995 (<1980: two studies; 1980–90: five studies; >1990: two studies). 732 deaths occurred during a mean follow-up of 7.3 years. The overall pooled SMR was 3.53 [95% CI: 3.03–4.11]. Among 732 deaths, 389/612 deaths (64%) were considered as related or possibly related to SSc whereas 223/612 deaths (36%) were defined as not related to SSc. Cardiac deaths were the most frequent causes of deaths (29%) followed by lung involvement (23%). All adjusted meta-regression analyses did not show any significant change in SMR over time ($p=0.523$). Exclusion of the studies before 1980 revealed a trend for a decrease in SMR but not significant ($p=0.112$).

Conclusion: Our results confirmed that SSc is a devastating condition associated with a high risk of mortality reflected by a pooled SMR of 3.5. Despite some data suggesting a decrease in the mortality risk in SSc, SMR has not significantly changed over the last40 years. Further studies are needed to assess the effect of recent available therapies on mortality in SSc.

Comparison of Wide Field Nailfold Capillaroscopy and Videocapillaroscopy in the Assessment of the Microcirculation in Patients with Raynaud's Phenomenon. Juliana Sekiyama, Cintia Camargo, Luis Eduardo C. Andrade and Cristiane Kayser. Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: Capillaroscopy is a well established method for the assessment of the microcirculation in patients with Raynaud's phenomenon (RP). Several equipments such as wide field nailfold capillaroscopy (NFC) and digital videocapillaroscopy are currently used. This study aimed to compare the different parameters evaluated by wide field NFC with those obtained by videocapillaroscopy, as well as to evaluate the reliability of both methods in the assessment of the microcirculation in patients with RP.

Methods: Fifty-six consecutive patients with primary RP (PRP; n = 14), and RP secondary to systemic sclerosis (SSc; n = 28) and undifferentiated connective tissue disease (n = 14) (three men and 53 women in total) were included. A control group of 14 healthy controls matched for sex and age was also included. Wide field NFC was performed using a stereomicroscope (Olympus - SZ40) under 10–25 x magnification. The following parameters were analyzed in eight digits of the hands (excluding the thumb): number of capillaries/mm, number of enlarged loops (about four times the normal capillary width) and giant capillary loops (10 or more times the normal capillary width), number of microhaemorrhages, and vascular deletion score (score 0–3). NFC parameters were calculated as the average obtained in all analyzed fingers. Videocapillaroscopy was performed under 200 x magnification contact lens connected to an imaging analysis software (Videocap 8.14, DS-Medica, Italy). The following parameters were measured over 32 fields (4 fields per finger in 8 fingers, excluding the thumb): number of capillaries/mm, presence of enlarged (capillary diameter >20 μm) and giant capillaries (diameter >50 μm), microhaemorrhages, and capillary loss. Except for the number of capillaries/mm, a score based on a semiquantitative rating scale (score 0–3) was used for each videocapillaroscopy parameter. Intra- and inter-observer reliability was evaluated by performing both exams in 20 individuals in two different days and with two different observers, respectively. Observers were blinded about patients' clinical diagnosis.

Results: There was a significant correlation ($p<0.000$) between wide field NFC and videocapillaroscopy in the comparison of all parameters: number of capillaries/mm ($r=0.817$), enlarged capillaries ($r=0.902$), giant capillaries ($r=0.689$), microhaemorrhages ($r=0.506$), and vascular deletion/capillaries loss ($r=0.784$). Inter- and intra-observer reliability (kappa-coefficient or intra-class correlation coefficient) was good for most parameters evaluated by wide field NFC and videocapillaroscopy.

Conclusion: In the present study both wide field NFC and videocapillaroscopy showed to be reproducible and reliable methods and could be equally useful for the evaluation of peripheral microangiopathy in patients with RP.

Measuring Vascular Burden in Scleroderma and Raynaud Phenomenon. Laura K. Hummers[1], Stefan Zimmerman[1], Fredrick M. Wigley[1], John Carrino[2], Erik Schwetje[3], Warren Greth[4] and Ami A. Shah[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins Medical Institute, Baltimore, MD, [3]MedImmune, LLC, Gaithersburg, MD, [4]MedImmune LLC, Gaithersburg, MD

Background/Purpose: Patients with scleroderma (SSc) have various degrees of peripheral vascular disease including vasoreactivity and obliterative vasculopathy that may lead to significant morbidity in a subset of patients. Our goal in this study was to simultaneously determine blood flow, temperature, clinical features and vascular anatomy of the hand in patients with SSc and primary Raynaud phenomenon (RP).

Methods: Subjects were included in 3 groups: SSc with active digital ulcers (DU) and/or critical digital ischemia; SSc without DU or inactive DU; and primary RP. Subjects underwent MRI/MRA of the hand to determine vessel caliber, collateralization, and level of contrast filling of radial, ulnar, superficial palmar arch (SPA), deep palmar arch (DPA) and digital vessels. On the same day, subjects also had laser Doppler perfusion imaging (LDI) of the same hand and digital temperature measurements performed serially at 4 time points (0, 5, 15 and 45 minutes). Subjects also completed Raynaud Condition Score (RCS), Physician Global Assessment of Digital Ulcers Visual Analog Scale (VAS), Patient Global Assessment of Raynaud's VAS, and Patient Global Assessment of Digital Ulcers VAS. A telangiectasia score was also measured by the physician, and clinical data about their SSc and concomitant vascular disease were collected.

Results: Twenty-five subjects were enrolled (10 SSc without active DU, 11 SSc with active DU and/or critical ischemia, 4 primary RP). Two subjects could not tolerate the MRI study (both in the SSc with active DU group). Subjects were mostly female (21/25) and there was no significant difference in age between the groups although SSc patients without active DU were slightly older (Table 1). No subject had a history of other vascular disease. There were no significant differences in skin temperature or perfusion between the 3 groups when the 4 time points were averaged. There were no noted radial artery abnormalities in any subject, but more subjects with active DU had decreased opacification of the ulnar artery (44%, vs. 10% SSc without DU, 20% in primary RP, $p=0.213$). Also 3/9 patients with active DU had diminished SPA opacification compared to only 1 in each of the other groups ($p=0.8$). Perfusion was decreased in those with either ulnar artery or SPA abnormalities compared to those without, although this was not statistically significant. Subjects with SSc and active DU had a higher mean number of digital arteries with poor flow (either no fill or fill only to the proximal phalanx) than primary RP or no DU subjects, but did not reach statistical significance. However, there was a significant inverse correlation between perfusion and mean number of digits with poor flow ($p=0.003$).

	SSc without active DU	SSc with actitve DU and/or critcal ischemia	Primary RP
Age at visit 1, yrs	56.9 ± 3.7	47.5 ± 3.6	45.8 ± 14.7
Gender F:M	7:3	10:1	4:0
SSc duration, yrs	13.8 ± 9.6	17.3 ± 14.3	NA
Race, W:B	8:2	8:3	4:0
Diffuse subtype, %	70	45	NA
Current vasodilator use, %	20	55	0

Conclusion: All patients with RP have impaired perfusion on LDI, but SSc patients have more structural vascular disease, particularly if they have active DU, which correlates with diminished perfusion.

1459

Watermelon Stomach in Systemic Sclerosis: A EUSTAR Case-Control Study. Etienne Ghrenassia[1], Jérôme Avouac[1], Chris T. Derk[2], Paolo Airo[3], Dinesh Khanna[4], Alice Berezne[5], Kiet Tiev[6], Francesca Ingegnoli[7], Edoardo Rosato[8], Paola Caramaschi[9], Roger Hesselstrand[10], Valeria Riccieri[11], Sharon Bae[12], Virginia D. Steen[13] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [2]Jefferson Medical College, Philadelphia, PA, [3]Brescia, Italy, [4]University of Michigan, Ann Arbor, MI, [5]Paris Descartes University, Internal Medicine department, Cochin Hospital, Paris, France, [6]Internal Medicine Department, Saint Antoine Hospital, Paris, France, [7]University of Milan, Milan, Italy, [8]Department of Clinical Medicine, La Sapienza University, Rome, Italy, [9]Rheumatology Unit, Department of Medicine, Verona, Italy, [10]Lund University & Skåne University Hopsital, Lund, Sweden, [11]University of Rome, Medical Clinic and Therapy Department, [12]Division of Rheumatology, Department of Medicine, Geffen School of Medicine, University of California at Los Angeles, Los Angeles, CA, [13]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Watermelon stomach (WS) or Gastric Antral Vascular Ectasia (GAVE) is a very rare gastric complication of Systemic Sclerosis (SSc). It has a unique endoscopic appearance that is characterized by multiple longitudinal stripes of red vessels which radiate in a spoke-like fashion from the pylorus to the antrum. In SSc, WS seems to be a component of the general microangiopathy that characterises the disease and it is thought as a severe complication. However, despite the large use of gastroscopy, prevalence of SSc-GAVE remains poorly known. Furthermore, the characteristics of SSc-GAVE remain poorly described and based on the few available data, SSc features of SSc-GAVE patients remain unclear. The aim of this study was to determine the subgroup at risk together with the outcomes of SSc patients with GAVE.

Methods: We performed a retrospective, multicenter, international, case/control study. We collected cases of SSc-GAVE cases through EUSTAR network. Every case was matched with 2 SSc controls recruited from the same center, matched for age, sex, cutaneous subtype and disease duration. Disease characteristics were recorded at the time of GAVE occurrence and the last observation was used to defined the outcomes.

Results: We included 23 cases of SSc patients with GAVE, who were compared to 42 SSc controls. These 23 SSc patients (20 women, 87%) had a mean ± standard deviation (SD) age of 58±13 years and a mean ± SD disease duration of 6±3 years; 13 had the diffuse cutaneous subset and 10 the limited. Among these patients, 22 (96%) had anaemia, 10 (43%) needed red blood cell transfusion, and 12 (52%) required endoscopic treatment. In addition, SSc patients with GAVE were more likely to have anti-RNA polymerase-III antibodies (14/23, 60% vs. 9/42, 21%, p=0.009), decreased frequency of anti-topoisomerase-I antibodies (1/23, 4% vs. 11/42, 26%, p=0.02) and DLCO/AV<75% predicted (16/23, 68% vs. 12/42, 28%, p=0.01) compared to SSc patients without GAVE. The likelihood of other SSc-related disease characteristics were not different between cases and controls. After a follow-up of 35±27 months, 7 (30%) SSc patients had a relapse of bleeding requiring new local endoscopic treatment. Among these 7 patients, 4 needed red blood cell transfusion.

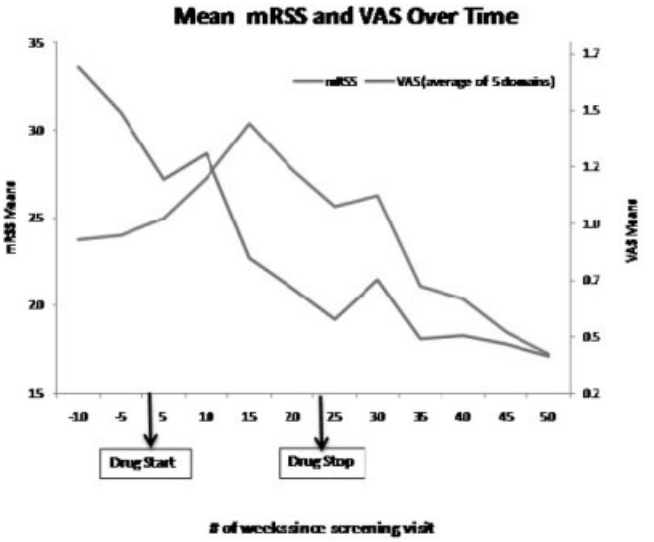
Conclusion: Absence of antitopoisomerase I antibodies and presence of antibodies to RNA-Polymerase-III antibodies may be useful to identify the subset of SSc patients with increased risk for GAVE. Despite it was described as a late complication, SSc patients with GAVE had early disease duration. GAVE appears as a cause of anaemia that clinicians should be aware of. This complication often requires local endoscopic therapy, which is usually efficient, despite frequent recurrent events. The inclusion of further cases in this ongoing project may help to better characterise the features of this rare complication.

1460

Patient Reported Measures of Skin Activity Associate with Disability in Diffuse Scleroderma. Julie J. Paik[1], Laura K. Hummers[1], Fredrick M. Wigley[1], Sharon R. Ghazarian[1], Natalie R. Daya[1], Ami A. Shah[1] and for the Imatinib Study Group[2]. [1]Johns Hopkins University, Baltimore, MD, [2]CH-4002 Basel, Switzerland

Background/Purpose: The modified Rodnan skin score (mRSS) is the current gold standard tool to assess skin disease severity in patients with diffuse cutaneous systemic sclerosis (SSc). While this physician-centered metric may reflect damage from the SSc disease process, it may not correlate with patient perceptions of disease activity and disability. Thus, the purpose of this study was to determine if a patient driven assessment of skin disease activity correlated with disability.

Methods: 27 subjects with early diffuse cutaneous SSc were enrolled in a multi-center, open-label study evaluating the efficacy of imatinib in the treatment of skin fibrosis. Subjects were older than 18 years, had disease duration of less than 18 months from the first non-Raynaud's symptom, and had a minimum mRSS of 20 without trunk involvement or 16 with trunk involvement. Imatinib was titrated to a goal dose of 600mg/day until Week 24 if safety and tolerability permitted. The Johns Hopkins Skin Scales Questionnaire (JHSSQ), scleroderma health assessment questionnaire (SHAQ), and the mRSS were assessed longitudinally in all subjects. The JHSSQ is a patient centered assessment consisting of 5 domains measured on a visual analogue scale (VAS): pain, itching, softening, flexibility, and global skin score. An overall patient score was obtained by averaging the 5 VAS domains for each subject at each time point. The mean mRSS and mean VAS scores were analyzed graphically, and the mean VAS score was correlated over time with our outcomes, disability (HAQ disability index) and generalized pain (HAQ Pain Score).



Results: The subjects had a mean age at enrollment of 45 years (SD 11.9), and 77.7% were female. The average mRSS at enrollment was 24.7 (SD 5.6), and the average JHSSQ score was 1.54 (SD 0.55). As shown in Figure 1, from baseline to week 15 the mean mRSS progressively worsened from a mean of 23.7 to 30.4 while the mean JHSSQ score decreased from 1.6 to.8, demonstrating subject perception of improvement. After week 30, the mean mRSS and JHSSQ continued to decline to a nadir of 16 and 0.4, respectively.

There were statistically significant correlations between the mean JHSSQ VAS score and mean HAQ disability index at visits 2, 6, 9, 10, 12, and 18 (Pearson correlation coefficients ranging from 0.40 to 0.63)and between the mean JHSSQ VAS score and mean HAQ pain score at visits 6, 8–12, and 18 (correlation coefficient range 0.59–0.89).

Conclusion: A patient driven assessment of skin disease activity (JHSSQ score) correlates moderately well with disability and pain in SSc patients with active, diffuse skin disease. The JHSSQ score may be used as an early indicator of disease activity. Initial improvement in the JHSSQ VAS was discordant with the mRSS early in the course of imatinib administration.

1461

Identification of Mesenchymal Cells Expressing Endothelial Markers in Small Pulmonary Arteries of Systemic Sclerosis Associated Pulmonary Fibrosis: Possible Role of Endothelial-Mesenchymal Transition. Fabian A. Mendoza[1], Sonsoles Piera-Velazquez[1], John L. Farber[2] and Sergio A. Jimenez[1]. [1]Scleroderma Center and Jefferson Institute of Molecular Medicine, Philadelphia, PA, [2]Department of Pathology and Cell Biology Thomas Jefferson University, Philadelphia, PA

Background/Purpose: Several pulmonary disorders including interstitial pulmonary fibrosis (IPF), systemic sclerosis (SSc)-associated interstitial lung disease (ILD) and some forms of pulmonary arterial hypertension (PAH) display a prominent fibroproliferative vasculopathy characterized by the accumulation of mesenchymal cells and abundant deposition of extracellular matrix in the subendothelial space of small and medium sized pulmonary arteries. The origin of the mesenchymal cells responsible for the subendothelial fibrosis and subsequent obliteration of the vessel lumen in these disorders is not known. The purpose of this study was to examine the possibility that endothelial to mesenchymal transition (Endo-MT) is involved in the accumulation of activated mesenchymal

cells in the subendothelial space of pulmonary arteries in systemic sclerosis (SSc) associated interstitial lung disease (ILD).

Methods: Lung tissues from 3 patients with SSc and pulmonary fibrosis were examined by histopathology, immunohistochemistry, and confocal laser microscopy for the simultaneous expression of markers of endothelial cells (CD-31) or hematopietic progenitor cells/ small vessel endothelial cells (CD-34) and myofibroblasts (alpha smooth muscle actin or type I collagen).

Results: Expression of the endothelial cell marker CD-31, or the hematopoietic progenitor cell/ small vessel endothelial cell marker, CD-34, was observed in mesenchymal cells embedded within the subendothelial neointima of small pulmonary arteries in the three SSc lung specimens. Co-expression of CD-31 with the mesenchymal markers, collagen type I or alpha smooth muscle actin was demonstrated employing confocal laser microscopy in numerous mesenchymal cells present in the subendothelial region of small pulmonary arteries.

Conclusion: The results indicate that mesenchymal cells bearing endothelial cell-specific markers are present in the subendothelial space of small pulmonary arteries from patients with SSc-associated ILD. These mesenchymal cells of endothelial origin are likely to be responsible for the production and accumulation of subendothelial fibrotic tissue in the affected vessels that in turn results in their luminal obliteration. Understanding of the mechanisms responsible for the transition of endothelial cells into mesenchymal cells (EndoMT) in SSc associated ILD may provide novel therapeutic approaches for this devastating and incurable disease.

Outcomes of Systemic Sclerosis Associated Polyarthritis Patients Treated by Biotherapies Tocilizumab or Abatacept: A EUSTAR Observational Study. Marine Meunier[1], Marco Matucci Cerinic[2], Britta Maurer[3], Gabriela Riemekasten[4], Raffaele Pellerito[5], Carlos Alberto von Mühlen[6], Alessandra Vacca[7], Paolo Airo[8], Francesca Bartoli[2], Ginevra Fiori[2], Oliver Distler[9] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [2]Department of Internal Medicine, Rheumatology Section, Transition Clinic, University of Florence, Firenze, Italy, [3]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [4]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany, [5]Ospedale Mauriziano, Torino, Italy, [6]Rheumatology Department, Saint Lucas Hospital, Pontifical Catholic University of Rio Grande do Sul, Porto Alegre, Brazil, Porto Alegre, Brazil, [7]Chair of Rheumatology II, Department of Medical Sciences, University of Cagliari, Italy, Cagliari, Italy, [8]Brescia, Italy, [9]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Joint involvement is frequent in systemic sclerosis (SSc) and up to 30% can develop clinical signs of synovitis or tenosynovitis (1). Treatment is not standardized and polyarthritis is not uncommonly refractory to DMARDS. Biologic agents are increasingly used in inflammatory rheumatic conditions. Among them, tocilizumab and abatacept have proven to be effective in rheumatoid arthritis but no trial has been performed SSc. The aim of this study was to evaluate the safety and effectiveness of tocilizumab and abatacept in SSc-polyarthritis, in a prospective multicenter observational study.

Methods: By querying the EUSTAR network, 13 SSc patients with active polyarthritis and insufficient response to DMARDS were included. Patients received tocilizumab or abatacept upon the decision of their physician in routine practice: 9 patients received tocilizumab at 8 mg/kg/month and 4 patients abatacept at 10 mg/kg/month. Clinical and biological assessments were carried out at treatment initiation and before the last infusion.

Results: The majority of patients were followed 6 months (9/13) but the last data were only obtained at 3 months for 4 patients. Mean age was 50±10 years, mean disease duration 10±5 years, 46% of patients had a diffuse cutaneous sub-type, 4 patients had positive anti-CCP antibodies. 3 out of 12 patients had severe lung fibrosis. Patients received biotherapy in association with DMARDs (n=9) or alone (n=4).

Tocilizumab induced a significant response for joint involvement with a mean DAS28 decrease of 2.2±1.2 (2.8±1 before the last infusion versus 5.0±0.9 at baseline, $p<0.0001$) a mean tender joints decrease of 6.5 (4.7±7 versus 11.2±7) and a mean swollen joints decrease of 4 (1.2±1.8 versus 5.2±5). 6/9 patients receiving tocilizumab achieved EULAR good response. Rodnan's skin score did not significantly change (8±8 versus 9±9, p=0.8) and neither quality of life (HAQ 1.4±0.5 versus 1.7±0.7, p=0.6). Treatment was stopped for three patients: two because of insufficient improvement and one for elevation of liver enzymes.

Abatacept induced a significant response for joint involvement with a mean DAS28 decrease of 1.8±0.9 (2.6±0.6 versus 4.4±1.1 at baseline, p=0.03), a mean tender joints decrease of 2.8 (1.2±0.9 versus 4.0±1.8) and a mean swollen joints decrease of 3.8 (0.2±0.5 versus 4.0±1.8). 3/4 patients receiving abatacept fulfilled EULAR good response criteria. Rodnan's skin score did not significantly change (10±7.6 versus 9±7.4, p=0.8) and neither quality of life (HAQ 0.7±0.2 versus 0.9±0.3, p=0.2).

Conclusion: In this very preliminary pilot study, both tocilizumab and abatacept appeared to be safe and to improve joint involvement after 3 to 6 months in refractory SSc arthritis patients. The follow-up is too short to estimate the impact on the fibrotic lesions. A larger number of cases is expected to be included with the support of EUSTAR network. Larger studies with longer follow-up are warranted to further determine the safety and efficacy of these drugs in SSc, and potentially raise the opportunity of developing randomised controlled trials.

Features of Acute Denervation in Scleroderma Myopathy. Julie J. Paik, Fredrick M. Wigley, Laura K. Hummers and Andrew L. Mammen. Johns Hopkins University, Baltimore, MD

Background/Purpose: Coexisting myopathy is poorly understood in systemic sclerosis (SSc). We sought to determine the histological characteristics of myopathy in SSc.

Methods: SSc patients with proximal muscle weakness and a muscle biopsy read at our institution were identified in our longitudinal database. Clinical and laboratory data including Medsger muscle severity score, modified Rodnan skin score (mRSS), autoantibodies, creatine kinase (CK), aldolase, electromyography and nerve conduction studies (EMG/NCS), and Magnetic Resonance Imaging (MRI) of affected proximal muscles were obtained. Biopsies were contrasted to patients with dermatomyositis. Fisher's exact test was used to determine if there was any statistical association between different histological categories on muscle biopsy to clinical data ($p<0.05$ was considered statistically significant).

Results: 29 patients were included with a mean ±standard deviation age of 42 ±13 years. 82.7% were female, 55% Caucasian, 34% African-American, 34% limited and 65.5% diffuse SSc. The mean mRSS was 8.6 ±10.3. 41.3% of the patients had a Medsger muscle severity score of only 1 (4/5 proximal weakness); 10.3% had a severity score of 4 (requiring assistive device). Autoantibody profile was: anti-centromere (18.5%), Scl-70 (3.8%), RNP (25.9%), and RNA-polymerase III (15.3%). The mean ± standard deviation CK at biopsy was 2078 ±3544, and aldolase at biopsy was 23.2 ± 21.3. On EMG, 15/26 (57.6%) had irritable myopathy while 10/26 (38.4%) had non-irritable myopathy. MRI showed that 17/18 (94.4%) patients had edema.

Muscle biopsy histology Total N=29

Inflammation only	0
Necrosis only	8 (27.6%)
Inflammation and necrosis	14 (28.2%)
Esterase positivity	14 (48.2%)
Presence of Fibrosis with inflammation and/or necrosis	11 (37.9%)

Higher CK values showed a statistically significant association with the presence of necrosis on muscle biopsy (p=0.006) but did not associate with inflammation. The presence of fibrosis on muscle biopsy did not associate with diffuse skin disease and was seen in patients with shorter disease duration (mean 3 years; p=0.016).

Almost 50% of the biopsies had esterase positive angular atrophic fibers, a specific marker of acute denervation. In contrast to the SSc patients, only 1 out of 10 analyzed dermatomyositis muscle biopsies had features of acute denervation (p=0.057). Esterase positivity did not associate with neuropathy on NCS.

Conclusion: Acute denervation, not previously described, is a unique and common finding in SSc patients with myopathy. In addition, muscle fibrosis is rarely seen in isolation, is apparent in early disease, and not isolated to diffuse skin disease.

1464

Medium and Large Vessel Involvements Contribute to Digital Ulcers in Systemic Sclerosis. Christophe Meune[1], Marine Meunier[2], Jérôme Avouac[2], Andre Kahan[2] and Yannick Allanore[2]. [1]Paris Descartes University, Cardiology department, Cochin Hospital, Paris, France, [2]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France

Background/Purpose: Digital ulcers are a burden in systemic sclerosis (SSc). Microangiopathy is a cardinal feature of SSc that has a critical role in the development of DU. However, whether injury of the medium or large vessels also contributes to DU in SSc has been poorly investigated. The importance of large artery stiffening has been highlighted by

the observation that aortic pulse wave velocity (PWV), which is inversely related to distensibility, and central augmentation index (AIx), a composite measure that depends on the site and degree of wave reflection, are independent predictors of cardiovascular and total mortality in selected patient groups. In addition, previous reports suggested that Aix is a more sensitive marker of arterial stiffening and risk in younger individuals. Our aim was to measure PWV and Aix in SSc patients stratified according to the presence of digital ulcers.

Methods: Reflected waves assessed by radial applanation tonometry and PWV were measured and compared in a prospective cohort of consecutive SSc patients with and without active digital ulcers, recruited during a 6-month period.

Results: 63 consecutive SSc patients were included (male 14, age 57±12 years, diffuse cutaneous form 10, disease duration 9.7±7.1 years). Among these, 10 SSc patients (15.9%) had active digital ulcer. Systolic, diastolic aortic pressure, as well as aortic pulse pressure, were similar in patients with versus without active ulcers (p=0.104, 0.531 and 0.143 respectively). Regarding our primary criteria, when compared to patients without ulcer, SSc patients with active digital ulcer had increased AIx_75 (35% [28–38] versus 29% [21–34], p=0.048) without any significance difference in PWV (7.3 m/s [6.7–10.1] versus 7.6 m/s [6.7–8.6], p=0.913). By univariate analysis, age (p=0.002), the existence of active ulcer (p=0.048) and ESR (p=0.010) are the only associated factors with Aix_75. In bivariate analysis, after adjustment for age, the presence of active ulcer remained a strong determinant of AIx_75 (p=0.038). In addition, the AIx_75 of the reflected wave correlated with age (r=0.76, p=0.035) and NT-proBNP concentration (r=0.388, p=0.004), whereas PWV correlated only with age (r=0.520, p=0.001).

Conclusion: SSc patients with active ulcer have increased Aix_75 but similar PWV when compared to patients without active ulcer. These data suggest that patients with active ulcer have a different arteriolar site of reflection, possibly due to increased peripheral arteries vasoconstrictor tone. If confirmed this could suggest that this vascular component should be targeted by the drug regimen in SSc patients with active DU.

1465

Juvenile Systemic Sclerosis Outcomes After Treatment of Pulmonary Fibrosis with Cyclophosphamide or Methotrexate. Gretchen R. Henstorf[1] and Anne M. Stevens[2]. [1]Seattle Children's Research Institute, Seattle, WA, [2]University of Washington, Seattle, WA

Background/Purpose: Children with systemic sclerosis (SSc) usually develop alveolitis with progressive, potentially fatal interstitial fibrosis. Adult trials suggest stabilization of pulmonary function with cyclophosphamide (CY) therapy, though with significant risk for adverse events. There are no controlled trials for treatment of juvenile SSc. As part of a larger study to develop objective clinical and radiological measures for outcomes in juvenile SSc, we reviewed the courses of patients with SSc lung disease who were treated with extensive courses of CY or methotrexate.

Methods: Medical records were reviewed for all patients diagnosed with scleroderma at Seattle Children's Hospital between 1994 and 2010 to identify children who fulfilled ACR criteria for SSc. Twenty-four patients were identified: 20 girls and four boys. Medical records were reviewed for 13 patients who developed pulmonary fibrosis and/or alveolitis detected by high resolution CT scan. Patients were followed for a mean of 8 years (range 1.4–16.8, SD 4.1). The mean age at diagnosis was 10.4 years (range 2.4–14.7, SD 4.3).

Results: The DLCO adjusted for alveolar volume (DLCO) prior to therapy averaged 84.3%, ranging from 68–105% of normal. Nine patients (mean DLCO 83%, range 64–105%) were treated with CY at the first sign of alveolitis; three with less severe alveolitis were treated with methotrexate (DLCO 88% range 81–94%), and one received both CY and methotrexate. The treatment regimens were oral CY (1–3 mg/kg/day) and/or IV CY (750 mg/m2) for an average of 3 years (range 0.5 to 11.5 intermittently), with cumulative CY doses averaging 21.2 grams (range 7 to 29.5 grams, SD 9) or methotrexate 1 mg/kg, maximum 40 mg, subcutaneously once a week. All patients received corticosteroids.

We found that five of the nine CY patients had improved pulmonary function at the last test, with a mean increase DLCO of 2.2% (range −15 to +11%, mean increase 2% per year). Patients on methotrexate were stable with DLCO improving in two patients (88 to 91% and 81 to 102%) and decreasing in one (94% to 81%). Serial CT scans showed stable or improved disease (by estimated area of alveolitis and/or fibrosis) in all patients. There was two serious infections during the CY therapy, and one case of antibiotic-induced pneumonitis. One patient had mild gastritis that resolved with a reduction in oral CY dose. Of five cases of pulmonary hypertension three resolved; the two others died of restrictive lung disease and heart failure.

Conclusion: Juvenile patients with severe SSc lung disease can stabilize and even improve with cyclophosphamide or methotrexate and corticosteroid therapy. The low short-term rate of adverse events and high rate of morbidity and mortality of SSc reported without treatment argues for the benefit of cyclophosphamide or methotrexate in children with SSc lung disease. Long-term studies will be required to determine the true cost and benefit of aggressive cyclophosphamide therapy in juvenile SSc.

1466

The N-Terminal Fragment of Brain Natriuretic Peptide As An Outcome Predictor in Scleroderma Renal Crisis. Cecilia B. Chighizola[1], Henry Penn[2], Pier Luigi Meroni[1], Christopher D. Denton[3] and Voon Ong[4]. [1]University of Milan, Milan, Italy, [2]Northwick Park Hospital, Harrow, United Kingdom, [3]Royal Free Hospital, Medical School, London, England, [4]UCL Medical School, London, England

Background/Purpose: Scleroderma renal crisis (SRC) is a life-threatening complication of Systemic Sclerosis (SSc), clinically characterised by acute renal failure and hypertension. Although the outcome has improved with ACE inhibitors, there remains significant mortality and morbidity. Therefore, novel biomarkers to identify patients at high risk of poor renal outcome would be invaluable.

The N-terminal fragment of Brain Natriuretic Peptide (N-TproBNP), a neuroprohormone released from cardiomyocytes in response to pressure overload, is an important biomarker in heart failure and pulmonary arterial hypertension. Notably, N-TproBNP has shown clinical utility in renal impairment. Aim of this study was to assess the role of N-TproBNP in a retrospective cohort of SRC patients.

Methods: 19 SRC patients (16 dcSSc, 3 lcSSc) were enrolled in this study. Three patient subgroups were identified based on renal outcomes (no dialysis, temporary dialysis and permanent dialysis). Kruskal-Wallis test was used to compare N-TproBNP levels among the subgroups.

ROC curves were generated to identify N-TproBNP levels with optimal sensitivity and specificity to predict requirement for renal replacement therapy. Logistic regression analysis was performed to investigate the relationship between N-TproBNP levels and renal outcome, with adjustment for creatinine. N-TproBNP levels were compared at SRC presentation and at six-month follow up using Wilcoxon matched-pair test. Associations between N-TproBNP and clinical variables were determined by Spearman's coefficient.

Results: There was significant difference in N-TproBNP levels among three subgroups of patients based on renal outcome (median in the 3 subgroups: 'no dialysis' 119, 'temporary dialysis' 1729.5 and 'permanent dialysis' 3373 pg/ml; p= 0.003). Analysis of the ROC curves of N-TproBNP to predict requirement for dialysis provided a sensitivity of 87.5% at a cut-off N-TproBNP level of 1494 pg/ml with a specificity of 90.9% (95% CI 0.73–0.99, area under ROC curve 0.9545). At logistic regression analysis, N-TproBNP > 1494 pg/ml was strongly predictive of requirement for dialysis (OR 70, p <0.005, 95%CI 3–1317). In the logistic regression model adjusted for creatinine, N-TproBNP levels >360 pmol/L still significantly predicted renal outcome (p=0.019). Among the eleven patients (57.9%) who had N-TproBNP levels repeated at six-month follow up, there was a significant reduction in N-TproBNP values (p=0.0029). As expected, N-TproBNP levels strongly correlated with serum creatinine (r=0.6105, p=0.0055) and negatively with eGFR (r=-0.7446, p= 0.0009), Hb levels (r=-0.7123, p=0.0006) and disease duration (r=-0.7083, p=0.0007). Similar correlation was observed between N-TproBNP levels and left ventricular ejection fraction but this did not quite meet significance (r=-0.4594, p=0.0734).

Conclusion: These data strongly suggest N-TproBNP peptide may be a useful biomarker in risk stratification of renal outcome among SRC patients. Measurement of N-TproBNP may therefore complement assessment of renal function and selectively identify those patients likely to require renal replacement therapy.

1467

Systemic Sclerosis-Related Digital Ulcers: Influence of Location, Calcinosis and Perfusion on Time to Healing. Andrea Murray[1], Tonia Moore[1], Elizabeth Wragg[2], Holly Ennis[1], Andy Vail[3], Adrienne Taylor[2], Graham Dinsdale[1], Lindsay Muir[4], Charles Hutchinson[1], Christopher E.M Griffiths[5] and Ariane Herrick[1]. [1]School of Translational Medicine, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [2]Rheumatology Directorate, Salford Royal NHS Foundation Trust, Salford, United Kingdom, [3]School of Community Based Medicine, University of Manchester, Manchester Academic Health Science Centre, Salford, United Kingdom, [4]Hand Surgery, Salford Royal NHS Foundation Trust, Salford, United Kingdom, [5]University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom

Background/Purpose: Relatively little is known about pathophysiology of systemic sclerosis (SSc) related digital ulcers and of their healing. Our aim was to determine whether time to ulcer healing was related to location on the finger, the presence of underlying calcinosis, or perfusion.

Methods: Patients attending for annual review at a specialist SSc clinic were asked to report any ulcers occurring within the following 12 months and if so to attend regularly for specialist wound care and comprehensive assessment until ulcer healing. If more than one ulcer was present, then each ulcer was assessed and included in the study. The ulcer location was documented, photographed and an x-ray taken to identify the presence of any underlying calcinosis. To measure perfusion the ulcer site, an adjacent area of skin and an area of skin away from the ulcer (representing normal perfusion) were imaged using laser Doppler imaging (LDI). LDI data was measured as a ratio of perfusion at the ulcer site/normal (U) and adjacent/normal (A), where U or A <1 represents ischaemia and U or A >1 hyperaemia.

Results: 17 patients (median age 61, [range 41–88] years, duration of disease 16 [1–44] years, 82% female, 41% limited cutaneous SSc, 29% anticentromere antibody positive, 18% anti-Scl70 positive, 18% smokers) attended with ulcers over the 12 month period. A total of 61 ulcers was documented (number of ulcers per patient ranged from one [8 patients] to 13). Location data were available for 54 ulcers (61% were on the right hand, 15% occurred on a thumb, 35% were digital tip and 65% extensor surface). Site-specific calcinosis (clinical or radiographic) was reported in 33 ulcers (data available for 55 ulcers) and calcinosis was most common in digital tip (53%) and least common in extensor surface ulcers (23%).The median (95% confidence interval [CI]) time to ulcer healing was 62 (31–147) days for digital tip ulcers and 56 (36–78) days for extensor ulcers ($p=0.41$). Time to healing was longer for those ulcers with underlying calcinosis (83 [33–216 days]) compared to no calcinosis (49 [35–62 days], $p=0.06$). Median (range) LDI measurements (data available for 53 ulcers) for U and A at baseline were 0.79 (0.11–2.92), reflecting ischaemia, and 3.22 (1.22–24.01), reflecting hyperaemia, respectively. 32 ulcers (60%) were ischaemic ($U<1$, 19 fingertip, 13 extensor). Ischaemic ulcer healing time was 97 (CI 56–138) days compared to 43 (30–56) days for non-ischaemic ulcers.

Conclusion: The location of digital ulcers and the presence of underlying calcinosis or ischaemia affect digital ulcer healing time, with digital tip ulcers, ulcers overlying areas of calcinosis and ischaemic ulcers taking longest to heal.

1468

Spectrum of Muscle Disease in Scleroderma. Huma Sohail[1], Ann J. Impens[2], Elena Schiopu[2] and Kristine Phillips[3]. [1]University Of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan Medical School, Ann Arbor, MI

Background/Purpose: Skeletal muscle disease commonly occurs in scleroderma, either alone or in combination with other autoimmune diseases. Neither the spectrum of muscle abnormalities associated with scleroderma, nor the prevalence of co-existing autoimmune diseases has been well defined. We conducted this study 1) to classify scleroderma patients based on their characteristic skeletal myopathy and 2) to determine the clinical, biochemical and histological characteristics of these patients.

Methods: We used electronic medical records to identify patients with a diagnosis of scleroderma evaluated at the University of Michigan Hospital from January 2000 to July 2010. Using structured medical record abstraction, we collected the following variables; autoimmune disease diagnosis, age, BMI, sex, EMG, muscle strength testing, histopathology and organ system involvement. Patients were identified based on abnormal muscle enzymes. Myopathy was defined as presence of muscle weakness, abnormal muscle enzymes and positive muscle biopsy. The time of onset of myopathy relative to development of scleroderma features was determined. The study protocol was approved by local IRB.

Results: Of the 1340 patients seen with a referral diagnosis of scleroderma, we identified 370 patients with abnormal muscle enzymes (CPK >180 or Aldolase >7). 206/370 satisfied criteria for a diagnosis of scleroderma. 5 had CPK elevation due to other causes (cardiomyopathy $n=2$, myocardial infarction $n=1$, rhabdomyolysis $n=1$, metastatic lung cancer $n=1$). 150/201 (75%) patients had no evidence of an additional autoimmune disease, while 51 (25%) had the following additional diagnoses; MCTD (30), SLE (5), Dermatomyositis/Polymyositis (10), possible Sjogren's (anti Ro positivity and sicca) (7), RA (1), and unclear diagnosis (2).

150 patients were classified as; morphea ($n=9$), limited or diffuse cutaneous systemic sclerosis ($n=139$) and sine scleroderma ($n=2$). Patients with morphea and incomplete documentation were excluded leaving us with 115. Mean CPK in this group was 407 (37–1706*)* and mean aldolase 9.85 (2–40). 29/115 (25.5%) had muscle weakness, 6/115 (5.2%) had myalgias only. 14/115 (12%) underwent muscle biopsy and were included in the final analysis. Myopathy was observed within the first year of diagnosis in 10/14 (71%). Mean age at onset of myopathy was 46years (30–88y), mean BMI 25.7, ANA positivity 13/14(92.9%). 14/14(100%) patients lacked muscle inflammation on histopathology. Predominant histopathological feature included muscle fiber atrophy 14/14(100%). Other systemic manifestations included ILD 12/14 (85.7%), GERD 14/14 (100%), esophageal dysmotility 7/9 (77%), lower GI involvement 5/14(35.7%), pulmonary HTN 4/14(28.6%) and renal crisis 1/14(7.1%).

Conclusion: Despite muscle enzyme abnormalities, not all patients with scleroderma undergo complete evaluation for myopathy. The risk of life threatening scleroderma related complications may shift a clinician's attention to the management of more severe manifestations. MCTD or clinical overlaps require a careful consideration. Muscle histopathology is critical in therapeutic considerations

1469

Circulating Endothelial Cells and Capillaroscopic Skin Ulcer Risk Index (CSURI) As Biomarkers of Scleroderma Microvascular Injury. Silvia L. Bosello, Mario Bocci, Giacomo De Luca, Annunziata Capacci, Barbara Tolusso and Gianfranco Ferraccioli. Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: Videocapillaroscopy is a non invasive technique useful to identify early microvascular abnormalities in patients with systemic sclerosis (SSc) and to predict the possible occurrence of ulcers (1). Increased levels of circulating endothelial cells (CEC) have been reported as a marker of vascular damage in various diseases, including SSc, and circulating endothelial precursors (CEP) are impaired in SSc patients. The purpose of this study was to assess the levels of CEC and CEP in a group of scleroderma patients, relating them to the capillaroscopic pattern and capillaroscopic skin ulcer risk index (CSURI).

Methods: 26 SSc consecutive patients underwent blood sample and videocapillaroscopy. Twelve patients presented digital ulcers. CSURI index was calculated, considering the number and size of megacapillaries and the number of total capillaries, as previously reported.

CEP were isolated in the peripheral blood by positive selection of CD34-expressing cells and quantified by flow cytometry as CD45-negative, CD133 and VEGFR2-positive cells. CEC were identified as CD45-negative, CD31-positive and CD146-positive cells.

Results: The mean percentage of CEC in SSc patients was of $6.7\pm7.5\%$, while the mean percentage of CEP was $4.9\pm3.1\%$. CSURI mean score in this cohort of SSc patients was 4.5 ± 5.2. A significant direct correlation emerged between the percentage of CEC and the CSURI score ($R = 0.53$, $p = 0.006$). When SSc patients were divided in patients with and without ulcers, the percentage of CEC was significantly higher in patients with ulcers ($8.6\pm8.8\%$) with respect to patients without ulcers (4.8 ± 4.7), ($p=0{,}008$). The percentage of CEP was comparable in both groups, while the ratio of CEC/CEPC was significantly increased in patients with ulcers (9.6 ± 15.8) than in patients without ulcers (3.3 ± 8.1), ($p<0.0001$). Furthermore CSURI score was lower in patients with SSc and ulcers(5.9 ± 7.2) than in SSc patients without ulcers (2.2 ± 1.6), ($p=$ns).

Conclusion: The results of this study suggest that the CSURI, proposed as a new prognostic tool for digital skin ulcer development in systemic sclerosis patients, may reflect persistent and widespread microvascular injury in SSc patients, characterized by increased circulating endothelial cells. On the other hand CEC values seems to be a possible biomarker of endothelial-vascular loss in SSc.

Living with Connective Tissue Related Interstitial Lung Disease: Patient Experiences of the Disease Process Over Time. Shikha Mittoo[1], Lesley Ann Saketkoo[2], Jeffery J. Swigris[3], Daphne LeSage[4], Aryeh Fischer[3] and Sid Frankel[5]. [1]University of Toronto, Toronto, ON, [2]LSU Health Science Center, New Orleans, LA, [3]National Jewish Health, Denver, CO, [4]Center for CCH at State of Louisiana, New Orleans, LA, [5]University of Manitoba, Winnipeg

Background/Purpose: Very limited information is available about the patient experience of connective tissue disease-related interstitial lung disease (CTD-ILD), in terms of global effects on functioning in various psychological and social spheres or of the patients' approaches to coping with the disease and secondary problems related to it. Such information from the patients' perspective would be useful in informing clinical practice and in developing patient reported outcome measures.

Methods: Data were collected through a focus group interview, involving nine patients. After institutional review board approval a purposeful sample was recruited from a tertiary-referral hospital in Manitoba, Canada. Inclusion criteria involved English speaking adults with a diagnosis of ILD based on at least one of: histology, chest imaging, presence of shortness of breath or cough, restrictive pulmonary physiology and/or impaired DLCO, resting or exertion-related peripheral oxygen desaturation. Patients with pulmonary hypertension or hypersensitivity pneumonitis were excluded. The interview schedule included two questions ("How have you experienced your disease since the diagnosis of ILD?", "How has the disease changed?"), and the moderator used the WHO-100 domains to develop prompts to insure comprehensiveness. Data were analyzed through inductive development of analyst-constructed themes. The thematic structures of two independent analysts were triangulated.

Results: Of the 9 participants, 8 were female and 8 were Caucasian. Their mean age was 53.56 (SD =16.02); 4 out of 8 were smokers. The following CTD sub-types were represented: idiopathic inflammatory myositis, rheumatoid arthritis, scleroderma, and undifferentiated connective tissue disease; one had an overlap of scleroderma and lupus.

Three main themes emerged. One focused upon Living with Uncertainty in a Marginal Situation. Uncertainty flowed from areas of confusion between patients and physicians related to diagnosis, evaluation, prognosis, and therapeutic plan. Communication seemed to stagnate after diagnosis. Future disease course and the origin of current symptoms were not easily delineated. A second theme emerged on the Struggle Over the New Self, attempting to maintain an autonomous voice in resisting social and family pressures to relinquish normal roles and fully assume the sick role. Parenting and grand-parenting roles were especially important to many participants. The third theme involved the development of resilience through coping skills. These skills allowed the patients to actively manage their situation, and thus were empowering.

Conclusion: This is the first known effort to report patient reported qualify of life related outcomes (patient experience) in this population. These findings hold important implications for physicians related to enhancing and continuing communication, supporting competence and reinforcing empowered coping. Communication protocols might be developed, and advice might be given as to how patients might maintain as many normal roles as possible. Patient developed coping skills might be studied to identify their effectiveness.

1471

Functional Class Change in Patients with Connective Tissue Disease-Associated Pulmonary Arterial Hypertension: Associations with Survival and Exercise Capacity. Lorinda Chung[1], Lori S. Parsons[2], Paul M. Hassoun[3], Michael D. McGoon[4], David B. Badesch[5], Dave P. Miller[2], Mark R. Nicolls[6] and Roham T. Zamanian[6]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]ICON Late Phase & Outcomes Research, San Francisco, CA, [3]Johns Hopkins University, Baltimore, MD, [4]Mayo Clinic, Rochester, MN, [5]University of Colorado Denver, Aurora, CO, [6]Stanford University, Stanford, CA

Background/Purpose: Patients with connective tissue disease-associated pulmonary arterial hypertension (CTD-APAH) have multi-organ system involvement with several factors contributing to their assessment of functional class (FC). A recent study including all PAH subtypes showed that improvement in FC within 1 year is associated with improved survival. We sought to investigate the effect of FC change on survival and exercise capacity in CTD-APAH patients.

Methods: The **R**egistry to **EV**aluate **E**arly **A**nd **L**ong Term PAH Management (REVEAL) is a prospective registry of >3,500 patients with PAH from 55 US centers. CTD-APAH patients diagnosed by right heart catheterization (mean pulmonary artery pressure > 25mmHg and pulmonary capillary wedge pressure ≤ 15mmHg) who did not have significant interstitial lung disease (ILD) (chest imaging with severe fibrosis, OR moderate fibrosis AND total lung capacity < 60% predicted) were included in our analyses. Only those who were assessed as FC III at enrollment and had at least one follow-up FC assessment within the first year after enrollment were included. We classified patients as: 1) improved if FC III improved to FC I/II; 2) stable if remained FC III; or 3) deteriorated if worsened to FC IV based on their first FC follow-up assessment after enrollment. Kaplan-Meier curves were estimated for survival from the time of the first follow-up FC assessment and differences between the groups were assessed by the log-rank test. The change in six minute walk distance (6MWD) between enrollment and the follow-up FC assessment was compared between the groups with ANOVA.

Results: Of the 275 CTD-APAH patients, 186 (68%) had systemic sclerosis, 44 (16%) had lupus, 8 (3%) had rheumatoid arthritis, 20 (7%) had mixed connective tissue disease, 4 (1.5%) had Sjögren's, and 4 (1.5%) had myositis. The follow-up FC assessment occurred 4.2±2.8 months after enrollment. 69% (n=189) of patients remained FC III at follow-up (stable), 24% (n=66) improved, and 7% (n=20) deteriorated. There were no differences among the groups with regards to presence of pericardial effusions, mild ILD, anemia, or brain natriuretic peptide levels at enrollment or at the follow-up assessment. Two-year survival from the follow-up FC assessment was 79±5%, 68±4%, and 22±11%, for the improved, stable, and worsened groups respectively (P=.022 for improved vs. stable; P<.001 for stable or improved vs. worsened) (Figure). The change in 6MWD was minimal in the stable group (−1.8±60.9 m), increased in the improved group (+25±63 m) and decreased in the worsened group (−29±51 m).

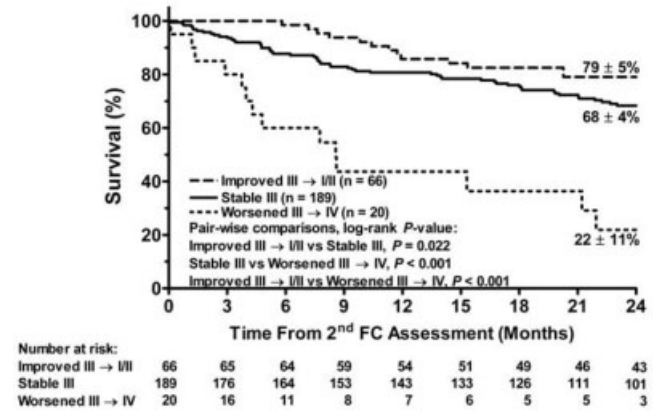

Figure 1. Two-year survival from second functional class assessment of CTD-APAH patients who are FC III at enrollment

Conclusion: Improvement in FC can provide prognostic information with regards to survival and change in exercise capacity in patients with CTD-APAH. Despite multiple factors contributing to the assessment of FC in CTD-APAH patients, FC should be monitored on a routine basis.

1472

Serum Interleukin-9 Levels Are Increased In Patients with Systemic Sclerosis: Association with Lower Frequency and Severity of Pulmonary Fibrosis. Koichi Yanaba and Shinichi Sato. The University of Tokyo, Tokyo, Japan

Background/Purpose: Systemic sclerosis (SSc) is a generalized connective tissue disorder characterized by sclerotic and vascular changes in the skin and various internal organs. It is generally regarded as an autoimmune disorder because of the presence of antinuclear antibodies. Although the pathogenesis of SSc remains unclear, many previous studies have suggested that cytokines or growth factors regulate its induction by stimulating the synthesis of extracellular matrix components, which may injure endothelial cells and modulate the function of leukocytes. These cytokines or growth factors are produced in part by inflammatory cells infiltrating the affected tissues, such as skin or lungs, of patients with SSc.

Interleukin (IL)-9 is a T cell-derived pleiotropic cytokine that was initially identified as a T helper (Th) 2 cytokine. A number of $CD4^+$ T cell subsets, named Th9, have recently been shown to share the capacity to secrete IL-9. IL-9 targets cells of the lymphoid, myeloid and mast cell lineages, as well as lung epithelial cells, and is likely to contribute to the development of allergic and autoimmune diseases such as asthma, silica-induced lung fibrosis, and experimental autoimmune encephalomyelitis. However, it is unclear whether IL-9 exerts mainly proinflammatory or anti-inflammatory activities.

We suggest that IL-9 plays a role in the pathogenesis of SSc and, in this study, examined serum IL-9 levels in SSc patients, and evaluated the results with respect to clinical features.

Methods: Serum IL-9 levels were examined by enzyme-linked immunosorbent assay in 71 patients with SSc, 15 patients with systemic lupus erythematosus, 15 patients with dermatomyositis, 39 patients with atopic dermatitis, and 28 healthy individuals. Furthermore, we also evaluated the results with respect to clinical features.

Results: Serum IL-9 levels were significantly elevated in SSc patients compared with healthy individuals, and patients with systemic lupus erythematosus or dermatomyositis or atopic dermatitis. Among SSc patients, there were no differences in serum IL-9 levels between those with limited cutaneous SSc and those with diffuse cutaneous SSc. Patients with SSc and raised IL-9 levels less often had pulmonary fibrosis and decreased percent vital capacity than those with normal IL-9 levels. IL-9 levels were positively correlated with percent vital capacity in patients with SSc. Thus, elevated IL-9 levels may be protective against the development of pulmonary fibrosis in SSc.

Conclusion: The current study suggests that elevated IL-9 levels may be protective against the development of pulmonary fibrosis in SSc. Further studies examining the contribution of IL-9 to the regulation of interstitial lung disease and other organ involvement in SSc are required. Nonetheless, the results of our study suggest that the administration of IL-9 might be a possible treatment in patients with SSc who have severe interstitial lung disease.

High-Dose I.v. N-Acetylcysteine Increases Peripheral Tissue Perfusion and Improves Clinical Symptoms of Systemic Sclerosis Patients. A Pilot Study. Alberto Sulli, Barbara Ruaro, Giuseppe Zampogna, Carmela Ferrone, Francesca Ravera, Bruno Seriolo and Maurizio Cutolo. Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy

Background/Purpose: Systemic sclerosis (SSc) is characterised by progressive tissue hypoperfusion and morphological anomalies of the microcirculation, inducing functional and organic clinical manifestations. This is a pilot study to evaluate clinical efficacy of a single i.v. cycle of N-acetylcisteine (NAC) treatment at a high dosage in patients affected by severe Raynaud's phenomenon (RP) secondary to SSc with digital ulcers and non-responders to either calcium channel blockers or prostacyclin.

Methods: Ten SSc patients (mean age 67±11SD years, mean disease duration 9±4SD years) with the aforementioned characteristics were enrolled into the study after having obtained written informed consent. At baseline and at 5 days after continuous i.v. NAC infusion (20 g/24 hrs/day for 5 days) the following evaluations were carried out: laser Doppler flowmetry (LDF), nailfold videocapillaroscopy (NVC), biochemical assessments (routine haematochemicals, homocysteine, osteocalcin, pyridinoline, deoxypyridinoline, telopeptide, factor VIII), along with clinical parameter assessment. Peripheral digital perfusion (PDP) was assessed by LDF at basal temperature and after heating the probe at 36°C analysing the central area of the fingertips from 2nd to 5th finger bilaterally (1–2). NVC was performed at the level of the same fingers to establish the pattern of microangiopathy and quantify the morphological anomalies (3). Both frequency and severity of the RP attacks, pain intensity tied to digital ulcers, and the subjective elasticity of the skin were evaluated by visual analogical scales (VASs). Statistical analysis was carried out by non-parametric Wilcoxon signed rank test.

Results: Eight patients showed a "Late pattern" of microangiopathy at NVC, whilst two had an "Active pattern". A statistically significant increase of PDP was observed after NAC treatment in 8/10 patients, both at basal temperature (median from 72 to 95 PU) and at 36°C (median from 106 to 134 PU) ($p=0.05$). NAC administration did not interfere with capillary dilation capacity, as the magnitude of PDP rise was about 30% as at basal temperature assessment, as at 36°C. No change was observed in the score for the NVC parameters during the brief observation period. The blood concentrations of telopeptide and factor VIII showed statistically significant increase ($p<0.05$), whilst there was a statistically significant decrease in concentrations of homocysteine, osteocalcin, and phosphorus ($p<0.05$). When VASs were analysed, there was a notable reduction in both the frequency and severity of RP attacks when compared to pre-treatment values, as was the case for intensity of pain due to ulcers and the subjective cutaneous elasticity ($p=0.04$). The treatment was well tolerated and no side effects were observed.

Conclusion: Continuous i.v. infusion of high-dose NAC increases peripheral tissue perfusion, induces modifications in some biochemical parameters and improves clinical symptoms in SSc patients, possibly by interfering with the fibrotic skin process.

Progression of Microvascular Damage Through Different Nailfold Capillaroscopic Patterns in Systemic Sclerosis Patients. Alberto Sulli[1], Francesca Ravera[1], Barbara Ruaro[1], Vanessa Smith[2], Carmen Pizzorni[1], Giuseppe Zampogna[1], Elisa Alessandri[1] and Maurizio Cutolo[1]. [1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

Background/Purpose: Systemic sclerosis (SSc) is characterised by early nailfold capillary anomalies and progressive internal organ involvement. This is a longitudinal study to investigate the transition of nailfold microangiopathy through different patterns of microvascular damage, looking for possible correlation with organ involvement, in patients with systemic sclerosis (SSc).

Methods: Forty patients (median disease duration 81 months) showing at baseline the "Early" scleroderma-pattern of microangiopathy were followed-up for a median time of 7.3 years. Transition from "Early" to "Active" to "Late" SSc patterns was evaluated by nailfold videocapillaroscopy (NVC) (to establish the pattern of microangiopathy and quantify the morphological anomalies) (1–2). In addition, organ involvement was yearly assessed as follows: oesophageal involvement by manometry, pulmonary function by lung volume tests, DLCO and CT; cardiac performance by Doppler echocardiography, renal function by laboratory tests and arterial Doppler echography; active or recent history of ulcers by both clinical interview and examination. Statistical analysis was performed by non-parametric tests.

Results: At the end of the follow-up, the NVC pattern was found still "Early" in 44%, "Active" in 36%, "Late" in 15%, and "Normal" in 5% of SSc patients. In the subgroup of patients whose microangiopathy progressed from "Early" up to "Late" NVC pattern, the mean time of progression from "Early" to "Active" pattern was only 8±1 months ($p=0.01$), significantly shorter when compared with the mean time of progression from "Early" to "Active" pattern of the other patients (28±20 months), identifying a subset of subjects with fast progression of the microangiopathy. Clinical signs/symptoms progressed in accordance with morphological nailfold changes in 60% of the SSc patients. Both digital ulcers and oesophageal, skin, and lung involvement were found more frequently in SSc patients with either "Active", or "Late" pattern at the end of follow-up, when compared with organ involvement al baseline ("Early" NVC pattern). Both oesophageal involvement and lung disease correlated with higher NVC scores for loss of capillaries and disorganization ($p<0.04$); pulmonary arterial hypertension with higher scores for loss of capillaries, ramifications and disorganization ($p=0.04$); digital ulcers with higher scores for loss of capillaries, ramifications and disorganization ($p=0.02$), as well as with lower scores for giant capillaries ($p=0.002$).

Conclusion: The results confirm a dynamic transition of the nailfold microvascular damage through different patterns of microangiopathy. Patients showing a rapid progression from "Early" to "Active" NVC pattern (lower than one year) should be strictly monitored since at risk of rapid progression to the advanced ("Late") NVC pattern of microangiopathy that is associated with greater organ involvement.

Serum Brain Natriuretic Peptide is a Reliable Marker for Survival of Pulmonary Arterial Hypertension Associated with Connective Tissue Diseases, Including Systemic Sclerosis, Mixed Connective Tissue Disease and Systemic Lupus Erythematosus. Sumiaki Tanaka[1], Kenta Hoshi[1], Junichi Tanaka[1], Tatsuhiko Wada[1], Jun Okada[2], Tatsuo Nagai[1] and Shunsei Hirohata[1]. [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Kitasato University, Sagamihara, Japan

Background/Purpose: Under the current circumstance where several potent effective drugs of therapy for pulmonary arterial hypertension (PAH), it is important to set attainment target of therapy for PAH improvement of survival. Because PAH is frequently complicated and is still a life-threating organ involvement in patients with connective tissue diseases (CTD), we studied to confirm the most reliable predictive factor for survival.

Methods: We performed a retrospective-cohort study among 75 PAH patients with CTD, including 37 patients with systemic sclerosis, 20 patients with systemic lupus erythematosus, and 18 patients with mixed connective tissue disease, who were followed between January 1980 and May 2011 in our hospital. We have used beraprost sodium for 56 patients, sildenafil for 20 patients, bosentan for 19 patients, epoprostenol for 8 patients, tadalafil for 7 patients, ambrisentan for 3 patients and treprostinil for 1 patient. Serum levels of brain natriuretic peptide (BNP) (pg/ml) were sequentially measured in these patients 2139 times, and systolic pulmonary artery pressures (sPAP) were estimated by Doppler echocardiogram 861 times. Based on the character of distribution, serum levels of BNP were converted logarithmic values with which the patients were grouped into R1, R2, R3 and R4 (Table 1 and 2). To assess which of serum levels of BNP or sPAP is more reliable predictive factor for survival, we paid attend to the maximum values of serum BNP (logBNPmax) and sPAP (sPAPmax) during observation periods. Mortality odds ratio of these factors adjusted with sex, age, variation of CTD, presence or absence of interstitial lung disease, and WHO-functional class at the start of PAH treatment were evaluated using stepwise logistic regression analysis.

Results: Table 1 showed the distributions of serum levels of BNP and systolic PAP. Twenty-two patients (29.3%) were died during observation. Shown in Figure 1, no patients whose logBNPmax was in R1 and R2 died. The results of stepwise logistic regression analysis disclosed that logBNPmax in R4 was independent risk factor for death, but sPAPmax. Adjusted mortality odds ratios were significant correlated with logBNPmax, but not with sPAPmax in univariate as well as multivariate analysis (Table 3).

Table 1. Distributions of serum levels of BNP and systolic PAP

point	logarithmic values of serum BNP levels	reversed BNP (pg/ml)	systolic PAP (mmHg)
minimum	0.415	2.60	21
1st quartile	1.471	29.58	43
median	1.861	72.61	53
3rd quartile	2.277	189.23	59
maximum	3.490	3020.30	143

Table 2. Definition of group for logarithmic values of serum BNP levels

group	range
R1	0.415–1.471
R2	1.471–1.871
R3	1.361–2.277
R4	2.277–3.490

Table 3. Logistic regression analysis for mortality of PAH in patients with CTDs

factor	mean	mortality odds ratio 95%CI	p
univariate analysis			
logBNPmax in R4	23.34	3.45–495.3	0.0004
sPAPmax (mmHg)	1.01	0.98–1.03	0.5021
multivariate analysis			
logBNPmax in R4	25.17	3.50–553.23	0.0005
sPAPmax (mmHg)	1.00	0.97–1.02	0.7519

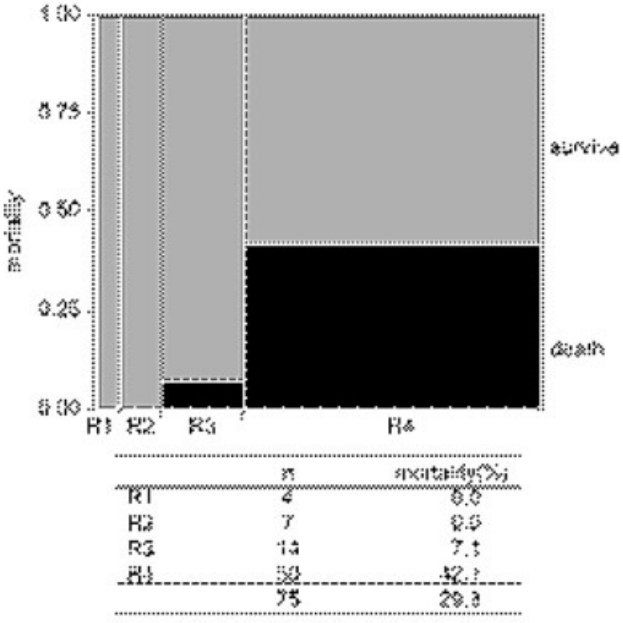

Figure. Mosaic graph showing mortality depend on logBNPmax in PAH patients associated with CTD (Cochran-Armitage trend test, p=0.0017).

Conclusion: These results confirm that serum level of BNP is a reliable marker for management of PAH in CTD. More importantly, maximal serum BNP level, but not sPAP, is critical parameters for prognosis of PAH.

1476

Long Term Safety and Effectiveness of Tumour Necrosis Factor Inhibitors In Systemic Sclerosis Patients with Arthritis. Mohammed Omair[1], Veerapong Phumethum[2] and Sindhu R. Johnson[3]. [1]Mount Sinai hospital, Toronto, ON, [2]Prapokklao Hospital, Chantaburi, Thailand, [3]Toronto Western Hospital, Toronto, ON

Background/Purpose: To assess the long term safety and effectiveness of Tumour Necrosis Factor (TNF) inhibitors in the treatment of systemic sclerosis (SSc) patients with inflammatory arthritis.

Methods: SSc patients who fulfilled the American College of Rheumatology criteria and had inflammatory arthritis followed in the Scleroderma Program at the Mount Sinai and Toronto Western Hospitals, Toronto, Canada who received a TNF inhibitors for 12 months or more were retrospectively reviewed. Safety outcomes included infection, allergic reaction, development of neurologic symptoms, malignancy, drug induced lupus, and death. Effectiveness outcomes included swollen joint count, tender joint count, and self-reported pain numeric analogue scale score (0 = no pain, 10 = worst pain) at 12 months, compared to baseline.

Results: Eleven SSc patients were identified: 7 (64%) were female and 4 (36%) had diffuse disease. The median age and disease duration at the time of starting TNF inhibitors were 49 years and 24 months respectively. At 12 months, the median swollen joint count and tender joint count significantly decreased from 9 to 0 ($p<0.01$) and 15 to 3.5 ($p = 0.02$), respectively. The median pain score decreased from 4.5 to 3 ($p = 0.10$). One patient developed uncomplicated herpes zoster. After 30 months, 4 out of eleven (36%) developed malignancy. No death, allergic reaction, serious infection, neurologic symptoms, or drug induced lupus was reported.

Conclusion: TNF inhibitors appear to be effective in the treatment of SSc-associated inflammatory arthritis. However, malignancy occurred in one third of our patients. Further studies are required to confirm these findings.

Fascicular Block: A Predictor of Mortality In Early Systemic Sclerosis. Hilda T. Draeger[1], Shervin Assassi[2], Roozbeh Sharif[3], Emilio B. Gonzalez[4], Brock E. Harper[4], Richard A. Lange[1] and Maureen D. Mayes[3]. [1]Univ of TX Health Science Center-San Antonio, San Antonio, TX, [2]Univ of Texas Health Science, Houston, TX, [3]University of Texas Health Science Center at Houston, Houston, TX, [4]University of Texas Medical Branch, Galveston, TX

Background/Purpose: Previous data from the Genetics versus Environment in Scleroderma Outcome Study (GENISOS) indicated that abnormal electrocardiogram (EKG) findings at an early stage of disease are an independent predictor of mortality in patients with systemic sclerosis (SSc). The objective of this study was to examine the frequency of specific EKG abnormalities in these patients, their serological correlates, and their predictive significance for mortality.

Methods: SSc patients with disease duration of ≤ 5 years from their first non-Raynaud's phenomenon symptom were enrolled in the GENISOS cohort. At enrollment, a standard 12-lead EKG was obtained along with demographic, clinical and autoantibody information. All baseline EKGs were reviewed by a cardiologist (RAL). Although not routinely done, echocardiogram data were recorded when available. Social Security death search and the National Death Index database were used to determine vital status. Chi square (χ^2) was used to examine the correlation between EKG abnormalities and serologic findings. A Cox proportional hazards model was used to investigate the predictive significance of EKG abnormalities for survival after adjusting for age at enrollment. This was extended to include potential confounders for non-SSc related cardiac disease (i.e. gender, hypertension, smoking, diabetes mellitus, and known coronary artery disease).

Results: Of 265 SSc patients (222 women and 43 men with average age of 48.8 vs. 48.0 years, respectively) with average disease duration of 2.5 years, 50.6% had abnormal ECG findings. A detailed list of observed EKG abnormalities is provided in Table 1. The EKG findings were not associated with SSc disease type (i.e., limited or diffuse) or autoantibody profile. Survival analysis showed that over 9 years average follow-up, patients with fascicular block (i.e., LBBB, RBBB, LAFB or LPFB) were at increased risk of mortality (hazard ratio: 2.3; 95% CI:1.1, 4.6, $p=0.02$), after adjustment for age at enrollment (Table 1). In the multivariable model, the predictive significance of fascicular blocks for survival was independent of non-SSc related cardiac risk factors (hazard ratio: 2.1; 95% CI: 1.02, 4.28, $p=0.04$). Moreover, fascicular block was not associated with cardiac disease (i.e., decreased ventricular function or pulmonary arterial hypertension) found on echocardiogram.

Table 1. EKG findings in the GENISOS cohort: Frequency and survival analysis after adjustment for age at enrollment

ECG findings	Number of cases (Frequency)	Hazard Ratio (95% CI)	*p value**
Sinus bradycardia	19 (7.2)	0.75 (0.3, 1.89)	0.551
Sinus tachycardia	7 (2.6)	1.7 (0.54, 5.42)	0.530
First degree AV block	14 (5.3)	1.83 (0.8, 4.23)	0.217
Premature atrial contractions	7 (2.6)	0.38 (0.05, 2.74)	0.227
Premature ventricular contractions	8 (3.0)	1.61 (0.39, 6.59)	0.696
Left axis deviation	18 (6.8)	1.37 (0.59, 3.15)	0.683
Right axis deviation	13 (4.9)	0.77 (0.24, 2.46)	0.915
Delayed transition	8 (3.0)	1.15 (0.28, 4.69)	0.995
Fascicular block	**20 (7.6)**	**2.27 (1.12, 4.58)**	**0.022**
Widened QRS complex	25 (9.4)	1.23 (0.57, 2.69)	0.559
Left atrial enlargement	2 (0.8)	2.80 (0.39, 20.22)	0.254
Right atrial enlargement	3 (1.1)	N/A	1.000
Left ventricular hypertrophy	15 (5.7)	2.33 (1.16, 4.68)	0.103
Right ventricular hypertrophy	3 (1.1)	1.74 (0.24, 12.53)	0.480
Non-specific ST-T wave changes	32 (12.1)	1.52 (0.8, 2.89)	0.448
Prominent U wave	4 (1.5)	1.65 (0.41, 6.75)	0.568
ST elevation	18 (6.8)	1.28 (0.56, 2.96)	0.470
Prolonged QTc	6 (2.3)	0.41(0.06, 2.92)	0.341
Low voltage	20 (7.6)	1 (0.36, 2.76)	0.993
Previous myocardial infarction	11 (4.2)	1.54 (0.56, 4.24)	0.396
EKG findings consistent with PAH	30 (11.3)	1.48 (0.76, 2.89)	0.223

* *p-value adjusted for age; PAH:*pulmonary arterial hypertension

Conclusion: This is the first study reported to date, on correlation of EKG abnormalities with mortality in SSc. EKG abnormalities are common in patient with early SSc. We observed that fascicular block is an independent predictor of mortality. This EKG abnormality may be a surrogate for scleroderma heart disease.

1478

The Risk of Cancer in Japanese Patients with Systemic Sclerosis. Atsushi Hashimoto[1], Hirahito Endo[2], Toshihiro Matsui[3], Shigeto Tohma[3], Sumiaki Tanaka[4] and Shunsei Hirohata[4]. [1]Kitasato University School of Medicine, and Sagamihara National Hospital, National Hospital Organization, Sagamihara, Kanagawa, Japan, [2]Toho University School of Medicine, Tokyo, Japan, [3]Sagamihara National Hospital, National Hospital Organization, Sagamihara, Kanagawa, Japan, [4]Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan

Background/Purpose: Systemic sclerosis (SSc) is a chronic and multisystemic autoimmune disease of which pathogenesis is still unclear. In addition to severe organ involvement, including that of the lungs, heart and kidneys, cancer is a major cause of death in patients with SSc. To evaluate incidence and identify risk factors of cancer in SSc patients, we investigated Japanese cohort.

Methods: A cohort of 405 Japanese patients with SSc, who attended Kitasato University hospital during the period from 1973 to 2008, was retrospectively analyzed until the end of 2009. Clinical data containing autoantibody profile and overlap of other connective tissue diseases were obtained from medical records or autopsy reports. The standardized incidence ratio (SIR), the ratio between the observed incidence of the cohort in this study and the expected incidence in a comparable age- and sex-matched Japanese population, was calculated.

Results: In the cohort representing 6730 person-years of total disease duration of entire 405 SSc patients, 35 malignancies were found in 34 patients (16 diffuse cutaneous SSc and 18 limited cutaneous SSc) before or after onset of SSc, or at autopsy. Lung cancer, especially adenocarcinoma was the most frequent followed by gastric or breast cancer, which were the most common cancers in Japan. The Kaplan-Meier method with the log-rank test revealed a significant worse survival in patients with cancer than that without it ($p=0.0074$). Univariable analysis for risk factors of cancer detected lung involvement for lung cancer (odds ratio (OR) 5.7, $p=0.0252$). Similarly, multivariable analysis revealed heart involvement for breast cancer (OR 22.2, $p=0.0116$) in addition to lung involvement for lung cancer (OR 7.6, $p=0.0211$). SIR analysis demonstrated that only lung cancer in females had significantly elevated incidence in SSc patients (SIR 8.45; 95% confidence interval (CI) 3.67–13.23), whereas overall cancer (SIR 1.32; 95% CI 0.87–1.76) or another type of cancer did not when compared with the general population.

Conclusion: Except for lung cancer in females, the overall incidence of canser in SSc patients was almost equal to that in the general population. Because lung cancer was significantly correlated with lung involvement, in other words interstitial lung disease (ILD), ILD could play a causal role in developing lung cancer and carcinogenic effect of SSc itself might be little.

ACR/ARHP Poster Session B

Systemic Sclerosis Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics I

Monday, November 7, 2011, 9:00 AM–6:00 PM

1479

Topical Vitamin D Analogue Calcipotriol Superinduces TSLP and IL-13 Expression in the Bleomycin Scleroderma Model but Does Not Modify Fibrosis. Alicia Usategui, Manuel J. Del Rey, Elena Izquierdo, Vanessa Miranda, Gabriel Criado and Jose L. Pablos. Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain

Background/Purpose: Patients with different autoimmune diseases, including systemic sclerosis (SSc), have low vitamin D (vitD) concentrations compared to healthy controls. Therapy with systemic vitD or topical vitD analogues has been reported as potentially beneficial in localized scleroderma. Topical vitD may induce atopic dermatitis-like skin irritation, a side effect that has been linked to strong induction of the potent Th2 polarizing cytokine thymic stromal lymphopoietin (TSLP) in the epidermis. We analyzed the potential effects of topical vitD non-calcemic

analogue calcipotriol on the expression of TSLP and Th2 cytokines, and skin fibrosis in the bleomycin model of scleroderma.

Methods: Skin fibrosis was induced in female CH3 mice aged 6 wk by subcutaneous injection of bleomycin (1mg/ml) into the shaved back skin every day for 4 weeks. Groups of 10 mice were given a daily topical application of 3 nM of the non-calcemic vitD analogue calcipotriol or control vehicle cream on the bleomycin injected skin area. Treated skin was harvested and histological examination and collagen content were determined by Masson's trichrome staining and total hydroxyproline content. TSLP, IL-4, IL-13, IL-17 and IFN-gamma mRNA expression were quantified by quantitative RT-PCR. Quantitative data were analysed by Mann-Whitney U-test.

Results: In bleomycin injected mouse skin, significantly increased expression of TSLP, IL-13 and IL-17, and a modest, non-significant increase in IL-4 and IFN-gamma mRNA expression were observed. Skin irritation with strong desquamation and intense inflammatory cell infiltration was observed in calcipotriol but not vehicle treated mice. In bleomycin injected mice treated with calcipotriol, a significantly higher increase in TSLP and IL-13 mRNA expression compared to vehicle treated mice was observed. Other Th cytokines were not modified by calcipotriol treatment. Skin fibrosis, measured as the increase in Masson′s trichrome stained collagen dermal area was similar in both bleomycin/vehicle and bleomycin/calcipotriol treated groups compared to control group. Collagen protein measured as hydroxyproline content was also similar in calcipotriol and vehicle treated groups.

Conclusion: Topical calcipotriol increases inflammatory infiltration and enhances the expression of TSLP and the Th2 cytokine IL-13 in the bleomycin induced model of skin fibrosis. Despite these effects, calcipotriol does not modify the development of fibrosis in this model. These observations suggest that vitD may induce complex effects, perhaps of different sign, that collectivelly do not result in changes on skin fibrosis in this model.

Bosentan Reverses the Profibrotic Phenotype of Systemic Sclerosis Dermal Fibroblasts Through Increasing the DNA Binding Ability of Transcription Factor Fli1. Kaname Akamata[1], Yoshihide Asano[2] and Shinichi Sato[3]. [1]University of Tokyo, Bunkyo-Ku, Japan, [2]University of Tokyo Graduate School of Medicine, Tokyo, Japan, [3]The University of Tokyo, Tokyo, Japan

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by vascular injuries and fibrosis of skin and certain internal organs. Although the pathogenesis of SSc still remains unknown, mounting data have demonstrated the possible contribution of endohtelin-1 (ET-1) to the development of fibrosis and vasculopathy in SSc. ET-1 is indispensable for the profibrotic effect of transforming growth factr-b on fibroblasts and bosentan, a dual ET receptor antagonist, reverses the profibrotic phenotype of SSc fibroblasts. Clinically, bosentan prevents the development of new digital ulcers in SSc. Thus, ET-1 may be involved in the mechanism responsible for the constitutive activation of fibroblasts and endothelial cells in SSc.

Fli1 is a member of Ets transcription factor family, which functions as a potent repressor of type I collagen gene in dermal fibroblasts and as a pivotal regulator of angiogenic process in endothelial cells. In SSc skin, Fli1 levels are constitutively downregulated in these cells, especially through the epigenetic mechanism in dermal fibroblasts, suggesting that Fli1 is one of the genetic factors in SSc. Supporting this idea, gene silencing of Fli1 activates fibroblasts and endothelial cells *in vitro* and a series of Fli1 mutant mice reproduce the histopathological features of SSc skin, including collagen deposition and abnormal vascular structure.

Based on these backgrounds, the purpose of this study is to clarify the mechanism by which bosentan exerts its anti-fibrotic effect on SSc fibroblasts, especially focusing on Fli1, by using SSc dermal fibroblasts and SSc animal models.

Methods: Five strains of SSc dermal fibroblasts and closely matched healthy dermal fibroblasts were used in *in vitro* studies. Bleomycin-induced SSc mouse model was used to evaluate the anti-fibrotic effect of bosentan *in vivo*.

Results: mRNA levels of COL1A2 gene were increased by ET-1 around 15 minutes in normal fibroblasts. A responsive element of ET-1 was located between −353 and −264 bp of the COL1A2 promoter, where Fli1 binding site is included, suggesting that ET-1 increases the promoter activity of COL1A2 gene by decreasing the DNA binding ability of Fli1. Consistent with the previous finding that the DNA binding ability of Fli1 is diminished by phosphorylation at threonine 312, ET-1 stimulation increased the phosphorylation levels of Fli1 at threonine 312. In SSc fibroblasts, phosphorylation levels of Fli1 were constitutively elevated compared with normal fibroblasts. Furthermore, a responsive element of bosentan was located between −353 and −264 bp of the COL1A2 promoter in SSc fibroblasts. Moreover, bosentan decreased the phosphorylation levels of Fli1 and increased the DNA binding ability of Fli1 in SSc fibroblasts. Collectively, these results indicate that bosentan reverses profibrotic phenotype of SSc fibroblasts at least partially by increasing the DNA binding ability of Fli1. We also demonstrated that this mechanism is involved in the anti-fibrotic effect of bosentan *in vivo* using SSc animal models.

Conclusion: Bosentan reverses profibrotic phenotype of SSc fibroblasts at least partially by increasing the DNA binding ability of Fli1.

Expression Profiling of Skin and Lung Tissue and Explanted Fibroblasts in a Transgenic Mouse Model of Scleroderma. Emma Derrett-Smith[1], Rachel Hoyles[1], Pia Moinzadeh[1], Cecilia B. Chighizola[1], Korsa Khan[1], Voon Ong[2], David J. Abraham[1] and Christopher P. Denton[1]. [1]UCL Medical School, London, United Kingdom, [2]UCL Medical School, London, England

Background/Purpose: Gene expression profiling of skin or lung tissue and fibroblasts in explant culture have been used to study intrinsic subsets and pathogenic mechanisms in systemic sclerosis (SSc) [1]. There are technical challenges integrating the results of whole tissue and fibroblasts, although the methods are often complementary. We have applied a similar strategy to analysis of a transgenic mouse model that is a phenocopy of many of the histological and biochemical features of SSc. This mouse strain has ligand-dependent upregulation of TGFb signalling due to altered TbRII receptor expression in fibroblasts.

Methods: In the present study we have analysed gene expression profiles of whole skin and lung from littermate TbRIIdk-fib mice and fibroblasts cultured from neonatal or adult skin and lung tissue ($n \geq 3$ in each group) using the illumina microarray platform. RNA was extracted, quantified and assessed for quality using standard methods. Technical validation of the data and additional quantitation of key gene expression was performed using quantitative RT-PCR assay using replicate samples.

Results: Cluster analysis identifies key gene profiles that are specific for skin or lung fibroblasts and also that are altered in whole tissues. In general the differential gene expression was much more marked in whole tissue and differences were more marked in neonatal compared with adult fibroblasts consistent with the higher levels of transgene expression previously described in younger mice. In particular, genes related to cytoskeletal and extracellular matrix structure and function (aSMA, troponin, tropomyosin 1, collagens type I, III, VI, VIII, XVII, matrix metalloproteinases 3, 9, 10, 13, 17, Timp3), endothelin (endothelin-1, Ednrb, Ednra), TGFb (Ltbp1, TGFb1, 2, 3, Ctgf), BMP (Bmp2, 4, Bmpr1) and VEGF (Vegfa, Vegfc) signalling axes and innate immunity (Il-6, Il-11, Il-13, Il-1r, Crp, Saa) were found to be differentially expressed both in transgenic whole skin, lung and explanted fibroblasts. In addition, genes coding for Pecam1 ($p=0.03$) and Elastin ($p=0.003$) were upregulated strongly in whole lung and skin. Some of these key genes that demonstrated significantly dysregulated expression in transgenic mouse skin and lung are summarised in more detail in Table 1.

Table 1. Representative genes that demonstrate dysregulated expression in transgenic skin and lung

Gene	Target tissue	Relative transgenic expression	P value
Mus musculus matrix metalloproteinase 3 (Mmp3), mRNA	Lung fibroblast	1.94	0.02
Mus musculus transforming growth factor beta 1 (Tgfb1), mRNA	Lung fibroblast	1.14	0.01
Mus musculus pleiotrophin (Ptn), mRNA	Skin fibroblast	−0.59	0.1
Mus musculus dual specificity phosphatase 1 (Dusp1), mRNA	Skin fibroblast	0.28	0.0004
Mus musculus homeo box B7 (Hoxb7), mRNA	Skin fibroblast	−0.49	0.01
Mus musculus annexin A1 (Anxa1), mRNA	Whole lung	−0.43	0.05
Mus musculus integrin alpha 6 (Itga6), mRNA	Whole lung	−1.89	0.02
Mus musculus collagen, type XII, alpha 1 (Col12a1), mRNA	Whole skin	0.82	0.01
Mus musculus similar to Fibrillarin, transcript variant 1 (LOC100044829)	Whole skin	0.40	0.02
Mus musculus vascular endothelial growth factor (Vegfa) transcript variant 2, mRNA	Whole skin	−1.86	0.05

Conclusion: These data are reminiscent of studies of human SSc tissue and illustrate another potential complementary strength for mouse models in better understanding the disease.

The Effect of Trichostatin A, One of the Histone Deacetylase Inhibitor, on Skin Fibrosis Mouse Model. Fumihide Ogawa[1], Hajime Tomita[1], Yutaka Kuwatsuka[1], Kazuhiro Shimizu[1], Shinichi Sato[2] and Atsushi Utani[1]. [1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]The University of Tokyo, Tokyo, Japan

Background/Purpose: Systemic sclerosis (SSc) is connective tissue disorder characterized by severe fibrosis of the skin and various internal organs. Tight skin (TSK/+) mouse is a putative murine model of SSc characterized by excessive collagen deposition in skin. Bleomycin-induced SSc model mouse, which is another model of SSc, is established using subcutaneous bleomycin treatment. Acetylation and deacetylation of histones play an important role in transcriptional regulation of eukaryotic cell. Histone deacetylases (HDACs) can act as transcription regressors and consequently promote chromatin condensation. Thus, HDACs play a key role in the regulation of gene transcription. Recently, trichostatin A (TSA), one of the HDAC inhibitor, was postulated as a therapeutic agent for fibrosis. Therefore, we investigated the role of TSA in the development of TSK/+ mice fibrosis and bleomycin-induced SSc model mouse.

Methods: TSA was injected subcutaneously into the back of the TSK/+, bleomycin-induced SSc model mice, and wild type mice daily for 4 weeks. Skin sections were assessed histologically. Skin thickness was assessed by hypodermal thickness in TSK/+ mice and by total skin thickness in bleomycin-induced SSc model. The mRNA levels of interleukin (IL)-4, IL-6, transforming growth factor (TGF)-β, type I collagen, fibroblast growth factor (FGF), and interferon (IFN)-γ were measured using real-time reverse transcription polymerase chain reaction (RT-PCR). Autoantibody and several cytokine levels in sera were assessed by enzyme-linked immunosorbent assay. In addition, cultured fibroblasts from mouse skin were stimulated with TSA. The mRNA expressions of collagen and fibrogenic cytokines were evaluated by real-time RT-PCR.

Results: TSA significantly decreased the development of TSK mouse skin fibrosis by reducing the hypodermal thickness. Furthermore, skin mRNA expressions of type I collagen and fibrogenic cytokines, including FGF, TGF-β, IFN-γ, IL-4, and IL-6, were markedly attenuated by TSA administration. However, serum levels of anti-topoisomerase I autoantibody, IL-4, IL-6, and IFN-γ were not affected by TSA percutaneous administration. In addition, TSA significantly down-regulated mRNA levels of collagen, FGF, and IL-6 in cultured fibroblast from mice skin. However, TSA could not decrease the skin sclerosis of bleomycin-induced SSc model.

Conclusion: These results suggest that TSA decreases skin fibrosis only in TSK mouse by regulating expression of collagen and fibrogenic cytokines and does not affect systemic immune level. The effect of TSA for skin sclerosis may depend on the pathogenesis of sclerosis.

1483

Notch Pathway Is Activated in Systemic Sclerosis (SSc). Kae Takagi[1], Yasushi Kawaguchi[1], Yuko Ota[1], Akiko Tochimoto[1], Chikako Fukasawa[1], Masanori Hanaoka[1], Hisae Ichida[1], Takahisa Gono[1] and Hisashi Yamanaka[2]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Systemic sclerosis is a chronic disease of unknown etiology characterized by autoimmunity, vascular damage, and progressive fibrosis of the skin and internal organs. However, it has not been elucidated how the fibrosis is achieved. Therefore, any effective treatments have not been established. Recently it has been reported that Notch signaling pathway was activated in lesional skin of SSc patient. Notch signaling pathway has been known to be associated with human development process and differentiation. Alterations in Notch signaling are implicated in the pathogenesis of several human diseases such as T-cell acute lymphoblastic leukaemia, melanoma. On the other hand, Notch pathway is context dependent, and the effects for fibrosis may depend on the cellular and physiologic environment in which fibroblast or connective tissue is placed. The aim of our study is to investigate whether Notch signaling pathway contributes to the uncontrolled activation of fibrosis in SSc.

Methods: The expression of Notch receptor and its ligand was determined by RT-PCR, Western blot analysis (WB) and flowcytometory (FCM) in cultured skin fibroblasts derived from SSc and healthy controls (HC). To investigate functional significance of Notch signaling pathway, Notch intracellular domain (NCID) was retroviraly transduced with SSc derived fibroblast. Then, concentrations of type I procollagen in the fibroblast supernatants were measured using EIA kit. After stimulating by TGFβ and PDGF, the expression of Notch was determined by real-time PCR and WB.

Results: Expression of Notch 1, 2, and 3 mRNA was lower in SSc derived fibroblast than HC. WB and FCM analysis revealed that SSc derived fibroblasts showed reduced expression of Notch1 than fetal derived control fibroblast. However, even in healthy control derived fibroblasts, Notch expression was variable. These indefinites results prompt us to investigate procollagen type 1C levels in supernatants of cultured mock or NICD transduced SSc derived fibroblasts. NICD transduction into SSc derived fibroblasts slightly augmented procollagen type 1C production. Expression of Notch was upregulated after TGFβ stimulation, but not by PDGF stimulation.

Conclusion: Importance of Notch signaling pathway for etiology of fibrosis in SSc was provided. Nevertheless, obvious relationship between Notch signaling pathway and fibrosis was not elucidated. Complexity and context dependency of Notch signaling pathway contributing to fibrosis was speculated.

Mice Lacking the Receptor-Like Protein Tyrosine Phosphatase CD148 Are Protected From Bleomycin-Induced Pulmonary Fibrosis. Tamiko R. Katsumoto[1], Kevin K. Kim[2], Alexis N. Brumwell[1], John X. Nguyen[1], Connor E. Rosen[1], Elliott Callahan[1], Jing W. Zhu[1], Mark R. Looney[1], Harold A. Chapman[1] and Arthur Weiss[3]. [1]UCSF, San Francisco, CA, [2]University of Michigan, Ann Arbor, MI, [3]UC San Francisco, San Francisco, CA

Background/Purpose: Studies using the bleomycin (BLM) model of pulmonary fibrosis suggest that inhibitors of the later fibrotic phase rather than the early inflammatory phase of disease development may have a higher likelihood of clinical antifibrotic efficacy for diseases such as scleroderma. Protein tyrosine phosphatases and kinases regulate the equilibrium of tyrosine phosphorylation signaling pathways important in cell growth and differentiation. Tyrosine kinases have been implicated in fibrosis, and studies testing the anti-fibrotic activity of tyrosine kinase inhibitors in scleroderma patients are underway. The receptor-like protein tyrosine phosphatase (RPTP) CD148 is widely expressed on various hematopoietic and non-hematopoietic lineages, including lung epithelial cells, endothelial cells, and fibroblasts. Given the importance of tyrosine phosphorylation pathways in fibrosis, we explored the role of CD148 in the BLM model of pulmonary fibrosis.

Methods: Mice with a targeted deletion of the CD148 transmembrane domain (CD148KO) generated by our lab were used. Intratracheal bleomycin was instilled using standard methods. Acute lung injury was measured using extravasation of radioactive iodine-labeled albumin and wet-to-dry ratios. Fibrosis was evaluated by both Masson Trichrome staining of lung sections as well as by the Sircol Collagen Assay.

Results: CD148KO mice showed improved survival following intratracheal BLM administration, (WT 37% vs. CD148KO 92%, $p=0.0135$). Masson Trichrome staining of lungs demonstrated markedly attenuated lung fibrosis in CD148KO mice. Lung collagen content was increased 4.2-fold over saline controls in WT mice, compared with only 1.7-fold increase in CD148KO mice. Acute lung injury was induced 2-fold in both WT and CD148KO mice, suggesting no attenuation of the acute inflammatory response in CD148KO mice. Additionally, evaluation of cells obtained from bronchoalveolar lavage (BAL) at day 7 following bleomycin administration showed no attenuation in BAL cell counts in CD148KO mice. CD148, the predominant RPTP on platelets, positively regulates platelet aggregation via the GPVI collagen receptor. However mice lacking the GPVI receptor showed no attenuation of BLM-induced fibrosis, suggesting that CD148 on platelets was unlikely mediating this phenotype. Furthermore, mice in which CD148 was specifically deleted in lung epithelial cells showed no differences in survival, suggesting that CD148 on epithelial cells was not responsible for the phenotype observed.

Conclusion: Mice lacking CD148 show improved survival following intratracheal BLM administration. Attenuation of bleomycin-induced fibrosis does not appear to be the consequence of a diminished early acute lung injury response to bleomycin. CD148 on platelets or lung epithelial cells does not appear to explain the attenuation of fibrosis observed in CD148KO mice. Future studies will interrogate other specific cell types mediating this response, as well as elucidate the pathways regulated by CD148 underlying this phenotype. These data suggest that inhibition of the RPTP CD148 may present an attractive anti-fibrotic therapeutic strategy.

Absence of Epithelial to Mesenchymal Transition Despite Activation of Keratinocytes in Scleroderma Skin. Joanna Nikitorowicz Buniak, Xu Shiwen, David J. Abraham, Christopher D. Denton, Carol M. Black DBE and Richard J. Stratton. UCL Medical School, London, United Kingdom

Background/Purpose: We have recently shown that scleroderma (SSc) epithelial cells exhibit an activated phenotype similar to wound healing. The interplay between keratinocyte-fibroblast is important in health and disease including epithelial to mesenchymal transition (EMT). EMT is regarded as an important mechanism potentially contributing to lung, liver, and kidney fibrosis. In the SSc epidermis we found active HGF signalling via c-Met and SMAD phosphorylation consistent with TGFβ signalling, both mechanisms implicated in driving EMT. Also we found increased vimentin levels in whole skin biopsy by proteomics. Therefore, we decided to look for evidence of EMT in the skin of scleroderma patients to determine if the skin fibrosis in scleroderma might involve EMT process.

Methods: Forearm skin biopsies taken from scleroderma patients diffuse subset (n=6) and age matched healthy controls (HC) (n=6) were analysed by immunohistochemical staining using antibodies against epithelial markers, K14 and E-cadherin as well as mesenchymal cell and cellular motility markers such as: vimentin, S100A4/FSP-1, α-SMA. Collagen IV was also identified in the sections to determine integrity of the basement membrane. The epidermal thickness and cell area was measured using Axiovision 4.8 software.

Results: Immunohistochemistry results showed activated skin phenotype. Epidermal thickness was increased from 51.27 μm in HC to 88.85 μm in SSc skin, (p=0.005). The mean area of basal cells was 73.37 μm^2 in HC and 111.71 μm^2 in SSc (p=0.0016). While spinous layer keratinocytes were 89.26 μm^2 in healthy control and 173.6 μm^2 in systemic sclerosis (p=0.0038). However, higher numbers of ki67 positive cells in SSc epidermis (8.48) were not significant (p=0.08) when compared with HC (5.62). We did not observe any loss of E-cadherin or gain of vimentin in basal keratinocytes. However, healthy control sub-epidermal cells in a 50μm area adjacent to epidermis had increased vimentin staining. The collagen IV layer in the basal membrane was not compromised. Although we observed increased levels of FSP-1 expression in scleroderma skin when compared with healthy control skin, the level of smad2/3 activation in the area showed no difference.

Conclusion: Our results indicate that despite keratinocytes activation and HGF signalling, EMT is not taking place in scleroderma skin. Although, FSP-1 was increased the marker is not specific to fibroblasts and also detects dendritic cells and macrophages. EMT process is an important step in tumour development and the findings are consistent with the clinical observation that skin cancers are not seen at increased frequency in scleroderma patients. However, more investigations should be done to fully explore the cell and molecular mechanisms underlying the activated epidermis seen in SSc.

Abnormal Morphology and Excessive Synthesis of Collagen V Affects Skin Thickness and Disease Activity in Systemic Sclerosis. Patricia Martin[1], Walcy R. Teodoro[1], Ana Paula P. Velosa[2], Jymenez de Morais[1], Solange Carrasco[3], Francine F. R. Braga[1], Romy Christmann[4], Claudia Goldenstein-Schainberg[5], Edwin R. Parra[1], Vera L. Capelozzi[1] and Natalino H. Yoshinari[2]. [1]Universidade de São Paulo, São Paulo, Brazil, [2]Univerdidade de São Paulo, São Paulo, Brazil, [3]Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [4]Boston University, Boston, MA, [5]University of São Paulo, São Paulo, Brazil

Background/Purpose: Physiological and mechanical properties of skin, one of the primary organs affected in systemic sclerosis (SSc), depends on collagen types I, III and V assembly, forming heterotypic fibers. Collagen V (COLV) regulates fibril diameter and maintenance of its properties is important to keep normal tissue architecture and function. Based on experimental model of SSc discovered in our laboratory, in which over expression of abnormal COLV was a prominent feature, we assumed that this abnormality could be also present in SSc patients.

Methods: skin biopsies of 18 patients (5 at early and 13 at late disease stage) and 10 healthy controls were studied for histological, molecular and biochemical profiles of COLV. Assessment of skin thickness was performed using the Modified Rodnan Skin Score (MRSS) and disease activity was calculated by Valentini Disease Activity Index. Quantification of COLV was obtained by histomorphometry done in dermis and quantitative RT-PCR of dermal fibroblasts culture. Additionally, fibroblasts culture supernatant immunoblotting and tridimentional reconstruction of COLV were performed.

Results: The COLV content in the dermis was higher in early-SSc (44.60 + 10.63%) when compared to controls (24.61 + 5.61%, p<0.01) and late-SSc (33.30 + 4.38%, p<0.01) A positive correlation between COLV and MRSS (r=0.42, p=0.04) as well as disease activity (r=0.45, p=0.03) was observed. The gene expression of COLV alpha 1 and COLV alpha 2 was increased in SSc patients when compared to controls (2.2-fold, p=0.02 and 5.9-fold, p<0.01; respectively). Higher expression of both chains were observed in SSc dermal fibroblasts culture supernatant. Tridimensional reconstruction of collagen fibers confirmed expression of thickened and distorted COLV in SSc patients, different from thin fibrils observed in healthy controls.

Conclusion: Increased synthesis of structurally abnormal COLV is observed in dermis of SSc patients. Since this collagen participates of heterotypic fiber assembly, morphological changes of COLV could explain histoarchitectural disarrangement and skin thickening, mainly at early SSc stage. The positive correlation between dermal COLV expression and disease activity, suggests that besides structural role and loss of regulatory function, COLV may be involved in additional pathophysiological mechanisms.

The Association Between the PTPN22 C1858T Polymorphism and Systemic Sclerosis: A Meta-Analysis. Young Ho Lee, Sung Jae Choi, Jong Dae Ji and Gwan Gyu Song. Korea University Medical Center, Seoul, South Korea

Background/Purpose: The 1858C→T SNP (single nucleotide polymorphism) of PTPN22 (rs2476601) changes the amino acid at position 620 of Lyp from arginine (R) to tryptophan (W) and disrupts binding between Lyp and Csk, which suppresses T cell activation. The aim of this study was to determine whether the functional protein tyrosine phosphatase nonreceptor 22 (PTPN22) C1858T polymorphism confers susceptibility to systemic sclerosis (SSc) in different ethnic populations.

Methods: A meta-analysis was conducted on the PTPN22 C1858T polymorphism across thirteen comparative studies. We examined the contrast of the allelic effect of T (the variant allele) versus C (the common allele). The random effects model was used in the presence of significant between-study heterogeneity. Otherwise, the fixed effects model was applied.

Results: A total of 13 separate comparisons were considered in this meta-analysis, which in total involved 4,488 SSc patients and 4,874 controls (9,362 study subjects). The analysis showed an association between the PTPN22 1858T allele and SSc in all study subjects (OR [odds ratio] 1.179, 95% confidence interval [CI] 1.016, 1.3662, $p = 0.030$). Analysis after stratification by ethnicity indicated that the PTPN22 1858T allele was significantly associated with SLE in Europeans (OR 1.210, 95% CI 1.042, 1.405, $p = 0.012$), and analysis showed an association between the T allele and SSc in anti-centromere antibody (ACA)-positive subjects (OR 1.210, 95% CI 1.042, 1.405, $p = 0.012$). However, no association was found between the allele and anti-topoisomerase antibody (ATA)-positive SSc European patients (OR 1.136, 95% CI 0.947, 1.364, $p = 0.169$). In addition, African Americans were found to have a much lower prevalence of the T allele (1.5%) than any other population studied, and Europeans had the highest prevalence (8.4%).

Conclusion: This meta-analysis confirms that the PTPN22 C1858T polymorphism is associated with SSc susceptibility and ACA status in Europeans, and that its prevalence is dependent on ethnicity.

1488

Augmented Expression of Inducible Costimulator (ICOS) and Its Ligand (ICOSL) in Patients with Systemic Sclerosis. Minoru Hasegawa, Manabu Fujimoto, Takashi Matsushita, Yasuhito Hamaguchi and Kazuhiko Takehara. Kanazawa University Graduate School of Medical Science, Kanazawa, Japan

Background/Purpose: Although the pathogenesis of systemic sclerosis (SSc) remains unclear, tissue infiltrating leukocytes likely have critical roles via inducing fibrogenic growth factors and Th2 cytokines. Inducible co-stimulator (ICOS), expressed on activated T cells, and its ligand, ICOS ligand (ICOSL), expressed on antigen-presenting cells and other cells, have been considered a single receptor-ligand pair. The ICOS-ICOSL pathway promotes T cell activation, differentiation, and effector responses, and T cell-dependent B cell responses. ICOS-mediated costimulation of T cells leads predominantly to the production of effector cytokines such as interleukin (IL) −4 and IL-10 and, to a lesser extent, IL-2, interferon-gamma, and tumor necrosis factor-alpha, thereby playing a more important role in Th2 responses than Th1 responses. Recently, we have reported that ICOS-ICOSL signaling significantly affects the development of bleomycin-induced lung and skin fibrosis in mice. To investigate the role of ICOS-ICOSL signaling in the pathogenesis of SSc, we assessed its expression in patients with SSc.

Methods: Expression of ICOS on peripheral blood CD4 or CD8-positive T

cells and expression of ICOSL on CD19-positive B cells or CD14-positive macrophages were determined by flow-cytometry in 20 SSc patients. Expressions of ICOS and ICOSL were also assessed by immunohistological staining and real-time PCR in the legional skin of 20 patients with SSc. Serum levels of soluble ICOS were measured by enzyme-linked immunosorbent assay in 68 patients.

Results: ICOS expression levels were significantly increased on both CD4+ T cells and CD8+ T cells, especially on activated or memory T cells from early diffuse cutaneous SSc (dcSSc) patients compared with that from healthy controls. ICOSL expression was also significantly increased on both CD19+ B cells and CD14+ macrophages from early dcSSc patients than that in healthy controls. Expression levels of ICOS and ICOSL were significantly reduced after the immunosuppressive treatment. ICOS-expressed T cells and ICOSL-expressed B cells or macrophages were increased in the lesional skin tissues of patients with early dcSSc compared with normal skin. mRNA levels of ICOS and ICOSL were augmented in the lesional skin of early dcSSc patients. Soluble ICOS levels were significantly increased in sera from SSc patients than that from healthy controls. Increased soluble ICOS levels were associated with involvement of diffuse skin sclerosis and interstitial lung diseases (ILD).

Conclusion: Augmented ICOS-ICOSL signaling, via overexpressed ICOS and ICOSL, may be contributing to the development of SSc. Soluble ICOS levels may be used as a serum biomarker for skin sclerosis or ILD in patients with SSc.

1489

Impaired *In Vivo* Neovascularization Capacity of Endothelial Progenitor Cells In Patients with Systemic Sclerosis. Masataka Kuwana, Yuka Okazaki, Hidekata Yasuoka and Tsutomu Takeuchi. Keio University School of Medicine, Tokyo, Japan

Background/Purpose: It has been proposed that defective vasculogenesis with reduced and/or dysfunctional endothelial progenitor cells (EPC) plays a role in the pathogenesis of systemic sclerosis (SSc), but whether the number of $CD45^{-}CD34^{+}CD133^{+}VEGFR2^{+}$ 'real' EPC is reduced in SSc patients is a matter of debate. In this study, we established a system for evaluating *in vivo* EPC's capacity to promote neovascularization, and used it to assess functional properties of EPC in SSc patients.

Methods: Peripheral blood mononuclear cells were obtained from 16 patients with SSc (9 diffuse and 7 limited cutaneous SSc) and 12 healthy controls. For evaluating capacity of EPC to promote new blood formation *in vivo*, murine colon carcinoma line CT-26 cells were transplanted beneath the skin of severe combined immunodeficient mice in conjunction with or without immunomagnetically sorted human $CD133^{+}$ cells. The tumor volume and the density of tumor blood vessels were measured at 10 days. The efficiency of EPC incorporation into the vascular wall was evaluated by double-staining of tumor sections with anti-mouse CD31 and anti-human CD31 antibodies, followed by observation under a confocal microscopy.

Results: Co-transplantation of CT-26 cells with $CD133^{+}$ cells, but not with $CD133^{-}$ cells, markedly promoted tumor growth. In addition, histological examinations of the tumors showed that co-transplantation of $CD133^{+}$ cells increased the density of blood vessels compared with transplantation of CT-26 cells alone. These effects were lost when $VEGFR2^{+}$ cells were depleted from the $CD133^{+}$ cells before transplantation, indicating a primary role of $CD133^{+}$ $VEGFR2^{+}$ EPC in neovascularization in our system. Comparisons between SSc patients and controls showed that tumor growth was slower and blood vessel formation was inferior in SSc-derived $CD133^{+}$ cells ($P = 0.004$ and 0.009, respectively), while there was no difference in the proportion of $VEGFR2^{+}$ cells in the $CD133^{+}$ cell fraction between these two groups. The tumor size was correlated with the density of tumor vessels, and a correlation coefficient was 0.9 when SSc patients and healthy controls were combined together ($P < 0.001$). Finally, tumor vessels incorporating human endothelial cells expressing human CD31 but did not express mouse CD31 were significantly fewer in transplantation of SSc-derived $CD133^{+}$ cells than in transplantation of control-derived $CD133^{+}$ cells ($P = 0.01$). The majority of human endothelial cells expressed von Willebrand factor, a mature endothelial marker.

Conclusion: We have established a system to evaluate *in vivo* angiogenic and vasculogenic properties of human EPC. The EPC's ability to promote new vascular formation by being incorporated into vessel walls and differentiating into mature endothelial cells is impaired in patients with SSc.

1490

A Membrane-Associated Adaptor Protein DOK5 Is Upregulated in SSc and Associated with IGFBP-5-Induced Fibrosis. Hidekata Yasuoka, Yukie Yamaguchi and Carol A. Feghali-Bostwick. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Systemic sclerosis (SSc) is characterized by excessive fibrosis of the skin and internal organs due to fibroblast proliferation and excessive production of extracellular matrix (ECM). We have shown that insulin-like growth factor binding protein (IGFBP)-5 is upregulated in primary skin and lung fibroblasts of SSc patients, and IGFBP-5 induces fibrosis *in vitro* and *in vivo*. Using gene expression profiling of primary fibroblasts expressing IGFBP-5, we have identified a membrane-associated adaptor protein, DOK5, as an IGFBP-5 target gene. DOK5 is a tyrosine kinase substrate and signaling molecule. Our objective is to determine the role of DOK5 in fibrosis and specifically in IGFBP-5-induced fibrosis.

Methods: Primary human lung fibroblasts were infected with replication-deficient adenovirus expressing human DOK5, human IGFBP-5, or control adenovirus. Cells were also treated with recombinant IGFBP-5. DOK5 mRNA and protein levels were examined by RT-PCR and immunobloting, respectively. DOK5 levels were examined *in vivo* in mouse tissues expressing IGFBP-5 using immunohistochemistry. Intracellular DOK5 expression was measured using immunocytostaining and densitometric measurement of signal intensity. Intracellular localization of DOK5 was assessed using immunoblotting of cytoplasmic and nuclear cellular fractions. To determine the effect of DOK5 on fibrosis, DOK5 was expressed *ex vivo* in human skin in organ culture. Levels of DOK5 mRNA and protein were compared in primary fibroblasts and lung tissues of patients with SSc and healthy donors.

Results: DOK5 mRNA and protein levels were increased *in vitro* by endogenous and exogenous IGFBP-5. DOK5 protein levels were induced *in vivo* by IGFBP-5. DOK5 upregulation required activation of the MAP kinase signaling cascade. IGFBP-5 triggered nuclear translocation of DOK5. Furthermore, expression of DOK5 in human skin resulted in a significant increase in dermal thickness. Lastly, both DOK5 mRNA and protein levels were significantly increased in fibroblasts and skin tissues of patients with SSc compared with those of healthy controls, as well as in lung tissues of SSc patients.

Conclusion: IGFBP-5 induces DOK5 expression, and DOK5 exerts pro-fibrotic effects. DOK5 levels are increased *in vivo* in skin and lung tissues of patients with SSc. Our findings sugget that IGFBP-5 induces its pro-fibrotic effects, at least in part, via DOK5. Furthermore, IGFBP-5 and DOK5 are both upregulated in SSc fibroblats and tissues, and may thus be acting in concert to promote fibrosis.

1491

A Genome-Wide Association Study Follow-up Strategy Reveals the Association of *IL12RB2* Gene with Systemic Sclerosis in Caucasian Populations. Lara Bossini-Castillo[1], Jose Ezequiel Martin[1], Jasper Broen[2], Carmen Pilar Simeon[3], Lorenzo Beretta[4], Madelon C. Vonk[2], Patricia E. Background/Purpose: Recently, our group published the first genome-wide association study (GWAS) conducted to date in Caucasian SSc patients. In the previously mentioned GWAS study, a single nucleotide polymorphism (SNP) at the *IL12RB2* locus showed a suggestive association signal.

IL12RB2 encodes IL-12Rβ2, which constitutes the transducing component of the IL-12 receptor heterodimer. Moreover, IL12Rβ2 knockout models develop autoimmune events and polymorphisms in the *IL12RB2* gene region have been related to several human autoimmune disorders.

Aiming to reveal the possible implication of *IL12RB2* gene in SSc, we conducted fine-mapping GWAS follow-up study in different Caucasian cohorts.

Methods: The whole analyzed set comprised 15,474 individuals of Caucasian Ancestry (5,991 SSc patients/9,483 controls). Ten GWAS genotyped single nucleotide polymorphisms (SNPs) in the *IL12RB2* region were analyzed. Then, we included three relevant SNPs in a first follow-up step comprising 7,192 European individuals (3,344 SSc / 3,848 controls). Only the most associated SNP was considered for a second follow-up phase comprising 1,736 US individuals (597 SSc/1,139 controls). Both follow-up cohorts were genotyped using TaqMan SNP genotyping assays in a real-time PCR System.

Significance was calculated using 2×2 contingency tables and Fisher's exact test or χ^2 when necessary, to obtain *p*-values, odds ratios (OR) and 95% confidence intervals (CI) using PLINK (v1.07) software. The logistic regression and conditioned logistic regression analyses, were performed using PLINK software. Linkage disequilibrium patterns across the region in the HapMap Project Phase I and II (CEU population) defined the haplotype tagging SNPs using Haploview (v.4.2) software.

Results: Ten SNPs in the *IL12RB2* region were included in the initial GWAS analysis set, six of them were found to be significantly associated with SSc. However, conditioned logistic regression revealed that the significance of the initially observed associations relied on the rs3790567 association. Both the most associated SNP (rs3790567) and its unique tag-SNP (rs3790566) were selected for replication. We also included rs924080 in the first follow-up phase due to its localization in a recombination hotspot in the intergenic region between *IL12RB2* and *IL23R*.

After the first follow-up phase, only the association of rs3790567 was consistent ($P_{MH} = 4.84\times10^{-3}$ OR = 1.12) (*Table 1*).

Interestingly, the second follow-up phase confirmed this finding ($P_{\chi2} = 2.82\times10^{-4}$ OR = 1.34) (*Table 1*). It is remarkable that rs3790567 pooled analysis in the whole set of individuals reached a highly statistically significant association ($P_{MH} = 2.82\times10^{-9}$ OR = 1.17) (*Table 1*).

Table 1. Genotype and allele distribution of *IL12RB2* rs3790567 genetic variant in SSc patients and controls in a three-step association study.

Population (CTRL/SSc)	CTRL				SSc							
	AA (N)	AG (N)	GG (N)	MAF	AA (N)	AG (N)	GG (N)	MAF	P_{MH}	OR	95% CI	P_{BD}
GWAS cohort (5,161/2,309)	0.06 (332)	0.37 (1,911)	0.57 (2,918)	0.25	0.08 (196)	0.40 (919)	0.52 (1,194)	0.28	1.92×10^{-5}	1.19	1.10–1.29	NS
European follow-up (3,183/3,085)	0.08 (241)	0.37 (1,169)	0.56 (1,773)	0.26	0.09 (282)	0.38 (1,187)	0.52 (1,616)	0.28	4.48×10^{-3}	1.12	1.04–1.22	NS
GWAS + European follow-up (8,344/5,394)	0.07 (573)	0.37 (3,080)	0.56 (4,691)	0.25	0.09 (478)	0.39 (2,106)	0.52 (2,810)	0.28	5.19×10^{-7}	1.61	1.09–1.22	NS
US follow-up (1,139/597)	0.05 (60)	0.37 (417)	0.58 (662)	0.24	0.10 (59)	0.39 (231)	0.51 (307)	0.29	2.82×10^{-4}*	1.34	1.14–1.57	NA
GWAS + European + US follow-up (9,483/5,991)	0.07 (633)	0.37 (3,497)	0.56 (5,353)	0.25	0.09 (537)	0.39 (2,337)	0.52 (3,117)	0.28	2.82×10^{-9}	1.17	1.11–1.24	NS

Controls are used as reference for all comparisons. CTRL: healthy controls; SSc: Systemic sclerosis; MAF: Minor allele (A) frequency; P_{MH}: allelic Mantel-Haenszel fixed effects model *p*-value; *: Allelic Chi-square uncorrected *p*-value; OR: odds ratio; 95% CI: 95% confidence interval; P_{BD}: Breslow-Day test *p*-value; NS: not statistically significant; NA: not applicable.

Conclusion: Our data clearly support *IL12RB2* rs3790567 association with SSc, and suggest a relevant role of IL-12 signaling pathway in SSc pathogenesis.

1492

The IRF7 Region Is Associated with Anti-Centromere Autoantibody Production in Systemic Sclerosis Patients. F. David Carmona[1], Ramana Gutala[2], Carmen P. Simeón[3], Patricia E. Background/Purpose: The interferon (IFN) pathway plays a key role in the susceptibility to autoimmunity. For instance, type I IFNs were reported to have a central aetiopathogenic role in the development and progression of systemic lupus erythematosus (SLE), and a type I IFN signature has been also observed in patients with systemic sclerosis (SSc). Recent studies have reported an association between *IRF7* and autoantibody production in SLE. To further explore the potential role of this genomic region in SSc, we studied whether five single-nucleotide polymorphisms (SNPs) within this locus were implicated in the susceptibility to the disease and its main specific features.

Methods: Two case-control sets of Caucasian origin from the US and Spain were analysed, comprising a total of 2316 SSc cases and 2347 healthy controls. A meta-analysis was performed to test the overall effect of these genetic variants on SSc.

Results: The Mantel-Haenszel test under an allelic model revealed strong association signals in the ACA analysis for rs1131665 ($P_{FDR}=6.14\times10^{-4}$, OR=0.78, CI 95% 0.68–0.89), rs4963128 ($P_{FDR}=6.14\times10^{-4}$, OR=0.79, CI 95% 0.70–0.90), rs702966 ($P_{FDR}=3.83\times10^{-3}$, OR=0.82, CI 95% 0.72–0.93) and rs2246614 ($P_{FDR}=3.83\times10^{-3}$, OR=0.83, CI 95% 0.73–0.94). Significant *P*-values also were obtained when the global disease was tested; however, the statistical significance was lost when the ACA+ patients were excluded from the study, suggesting that these associations rely on ACA positivity. In addition, the combined analysis of the ACA+/ACA- comparison showed statistically significant differences between both SSc subgroups for rs1131665 ($P_{FDR}=0.015$, OR=0.80, CI 95% 0.69–0.93), rs4963128 ($P_{FDR}=0.035$, OR=0.85, CI 95% 0.74–0.98), and rs702966 ($P_{FDR}=0.029$, OR=0.83, CI 95% 0.72–0.96). Conditional logistic regression and allelic combination analyses suggested that the functional *IRF7* SNP rs1131665 is the most likely causal variant.

Conclusion: Our data show that variation in the *IRF7* genomic region is clearly associated with ACA susceptibility in SSc patients and, hence, it may represent a common risk factor for autoantibody production in autoimmune diseases.

1493

Atherosclerosis Biomarkers in Systemic Sclerosis—A Multiplex Analysis. Dinesh Khanna[1], Anagha A. Divekar[2], Ram Raj Singh[2], Mariana J. Kaplan[1], Maureen A. McMahon[3], Daniel E. Furst[2], Nagesh Ragavendra[3], Paul Maranian[2], Wenpu Zhao[1] and Karen M. Au[2]. [1]University of Michigan, Ann Arbor, MI, [2]UCLA Medical School, Los Angeles, CA, [3]UCLA David Geffen School of Medicine, Los Angeles, CA

Background/Purpose: Increasing evidence suggests that atherosclerosis is increased in systemic sclerosis (SSc) compared to healthy individuals. However, the pathogenesis of atherosclerosis in SSc remains unknown. This study aimed to identify markers of fibrosis, vasculopathy, and inflammation that may be involved in the pathogenesis of atherosclerosis in a female SSc cohort.

Methods: The multiplex antibody array, based upon enzyme-linked immunosorbent assay (ELISA) technology, can measure multiple proteins simultaneously within a single sample. We utilized a microplate-based multiplex platform (Aushon Biosystems SearchLight) to identify 100 proteins in plasma samples from females with SSc with no history of atherosclerosis (N=46). In addition, circulating type I Interferon (IFN) activity was quantified by exposing epithelial cells to SSc serum and quantifying IFN-inducible genes by real-time PCR. All subjects underwent bilateral carotid ultrasounds to quantify plaque and intima-medial thickness (IMT) and were read by a single reader (NR). Statistical analysis was performed using Wilcoxin rank-sum test and Spearman's correlation. Significance was determined at $P<0.05$; no statistical adjustment was performed for multiple-testing as this analysis was hypothesis generating.

Results: Mean age (+/− SD) of the subjects was 48.6 (+/− 13.3) years. Carotid plaque was detected in 21 (46%) of the SSc subjects. Multiplex analysis detected significant associations between biomarkers of inflammation, vasculopathy, and fibrosis with atherosclerosis in the SSc subjects. IL-2, IL-6, CRP, KGF, ICAM-1, endoglin, PAI-1, and IGFBP3 were associated with carotid plaque ($P<0.05$, Table 1). MPIF1, A-SAA, thrombomodulin, NTpBNP, and CC16 were correlated with carotid IMT ($P<0.5$, Table 2). Type I IFN signatures were not associated with plaque or CIMT in SSc.

Table 1. Proteins associated with carotid plaque in SSc

	BIOMARKER (pg/ml)	NO PLAQUE, mean(SD)	PLAQUE, mean(SD)	*P*-value
Inflammation	IL-2	3.0 (2.6)	5.0 (3.8)	0.03
	IL-6	11.0 (13.5)	25.2 (48.5)	0.05
	CRP	1627772 (2437838.6)	3856899.5 (4734651.2)	0.01
Vasculopathy	KGF	0.8 (2.1)	1.6 (2.1)	0.02
	ICAM-1	403423.3 (131159.9)	539301.8 (242768.3)	0.04
	Endoglin	22444.1 (9253)	28156.3 (8860.8)	0.04
Fibrosis	PAI-1	9607.8 (6527.1)	6680 (5898)	0.05
	IGFBP3	404848.8 (116838.8)	322117.3 (93709)	0.01

Table 2. Correlation of proteins with carotid IMT in SSc

	BIOMARKER	IMT (r)	*P*-value
Inflammation	MPIF-1	0.31	0.04
	A-SAA	0.31	0.04
Vasculopathy	Thrombomodulin	0.32	0.04
	NTpBNP	0.42	0.01
Fibrosis	CC16	0.37	0.01

Conclusion: Distinct biomarkers of inflammation, vasculopathy, and fibrosis are associated with carotid plaque and IMT in SSc. Factors associated with carotid IMT differ from those associated with plaque in SSc. Further studies are needed to confirm the validity of these associations in another SSc cohort and their putative role as biomarkers of vascular events in this disease.

Hummers[7], Marilyn Perry[1], Carmen Pilar Simeon[8], Patricia Carriera[9], Norberto Ortego-Centeno[10], Miguel Gonzalez-Gay[11], the Spanish Scleroderma Group[12] and Javier Martin[13]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]UT M. D. Anderson Cancer Center, Houston, TX, [3]Consejo Superior de Investigaciones Científicas (CSIC), Armilla (Granada), Spain, [4]Instituto de Parasitología y Biomedicina López-Neyra, IPBLN-CSIC, Armilla (Granada), Spain, [5]Feinstein Institute Medical Reschearch, Manhasset, NY, [6]Feinstein Institute Med Rsch, Manhasset, NY, [7]Johns Hopkins University, Baltimore, MD, [8]Hospital Valle de Hebron, Barcelona, Spain, [9]Madrid, Spain, [10]Hospital Clínico San Cecilio, Granada, Spain, [11]Hospital Marques De Valdecilla, Santander, Spain, [12]Granada, Spain, [13]Instituto de Parasitologia y Biomedicina Lopez-Neyra (CSIC), Granada, Spain

Background/Purpose: The goal of this study was to identify which single nucleotide polymorphisms (SNPs) were truly associated with systemic sclerosis (SSc) and to identify shared susceptibility loci between SSc and other diseases represented on the Immunochip.

Methods: Genotyping: Genotyping was performed using the Immunochip, which is a custom chip developed by the Immunochip Consortium and which contains 196,524 polymorphisms that provide deep coverage of loci previously reported from genome-wide association studies (GWAS) and candidate gene studies of major autoimmune and inflammatory diseases.

Cases and Controls: SSc was diagnosed on the basis of fulfillment of the 1980 criteria for the classfiication of systemic sclerosis or if 3 of 5 CREST features (Calcinosis, Raynaud's phenomenon, Esophageal dysfunction, Sclerodactyly, Telangiectasia) were present. Data on healthy controls were obtained from the Immunochip Consortium.

Data Analysis: After quality control measures were applied, a total of 1,884 SSc cases and 4,325 controls were included in the analysis. Case samples included white European-American subjects from the U.S. Scleroderma Registry (n=981, 88.6% female) and from the Spanish Scleroderma group (903 cases, 89.3% female). Control data on 3,993 race-matched U.S. subjects and 332 Spanish subjects were obtained from the Immunochip Consortium. P-values reported are adjusted for multiple comparisons by FDR-BH (False Discovery Rate using the step-up procedure of Benjamini and Hochberg).

Results: After quality control measures, the genotyping rate was 99.8% and 124,001 SNPs were included in the analysis.

As expected and previously reported in the SSc GWAS, the most highly associated loci (adjusted p-values ranging from 8.9×10^{-12} to 7.38×10^{-5}) included the major histocompatibility complex region (MHC) region on chromosome 6, *STAT4* on chromosome 2, *TNPO3/IRF5* on chromosome 7, and *BLK* on chromosome 8.

Aside from the regions noted above, 16 SNPs in 8 additional genes/intergenic gene regions were significantly associated with SSc with adjusted p-values ranging from 5.34×10^{-9} to 3.24×10^{-5}. These include *FAM69A* at 1p22 ($p=6.05\times10^{-7}$ for the most significant SNP), *IL12RB2* at 1p31 ($p=3.24\times10^{-5}$), *PARK7* at 1p36 ($p=6.73\times10^{-7}$), *DENND1B* at 1q31 ($p=1.75\times10^{-6}$), the intergenic region *LOC100121216/CXCR4* at 2q21 ($p=5.96\times10^{-7}$), *KIAA1109* at 4p27 ($p=5.34\times10^{-9}$), the intergenic region *LOC286016/LOC407835* at 7q32 ($p=2.32\times10^{-7}$) and *DDC* at 7p11 ($p=4.30\times10^{-6}$)

In addition, significant associations were seen with rare variants in 3 genes (*PER3, CD6*, and *IKZF4*) and 2 intergenic areas (*FCGR3A/FCGR2C* and *SMARCC2/RNF41*) but the numbers of subjects with these was quite small making estimates unreliable.

Conclusion: The Immunochip analysis has provided confirmation of previously reported genetic loci in SSc. In addition 8 genes/gene regions have been identified as potential susceptibility regions. The identification of rare variants, although affecting only a small number of subjects, deserves additional studies.

1495

Systemic Sclerosis As Prototypic Disease for Functional Antibodies Against Vascular Receptors: From Beside to Bench and Mouse Models. Angela Kill[1], Reinmar Undeutsch[2], Christoph Tabeling[3], Martin Witzenrath[4], Wolfgang M. Kuebler[5], Sebastian Bock[6], Rudi Samapati[5], Harald Heidecke[7], Ivo Lukitsch[3], Duska Dragun[4] and Gabriela Riemekasten[8]. [1]Charité University Hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany, [2]Charité University hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany, [3]Charité University Hospital, Berlin, [4]Charité University Hospital, Berlin, Germany, [5]Charité University Hosptial, Berlin, Germany, [6]Charité University Hospital and German Rheumatism Research Centre, a Leibiz, Berlin, Germany, [7]CellTrend GmbH, Luckenwalde, Germany, [8]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany

Background/Purpose: We have recently discovered functional cross-reacting autoantibodies against the angiotensin-II type-1 receptor (AT1R) and against the endothelin-1 receptor type A (ETAR) in the majority of patients with systemic sclerosis (SSc) linked with vascular and fibrotic complications and predicted disease-related mortality (Riemekasten et al. ARD 2011). The strong association between the presence of these antibodies with clinical SSc symptoms suggests a contribution of these antibodies in SSc pathogenesis. Due to the high homology of the receptors in different species we hypothesized comparable effects of the human antibodies in different species. Our aim was to test direct involvement of AT1R-Abs and ETAR-Abs on pathogenesis of SSc-lung involvement in vivo, ex vivo, and in vivo.

Methods: Biological effects of autoantibodies were studied *in vitro* in human microvascular endothelial cells and in human fibroblasts for induction of collagen synthesis, cytokines, and signaling pathways known to play a role in SSc. Blockers of AT1R and ETAR were used to determine the specificity of the effects. Small vessel myography of rat lung vessels was performed in the presence or absence of the natural ligands angiotensin II and endothelin-1. Direct effect of the antibodies on endothelial Ca influx was studied in vivo by using real-time fluorescence imaging (RFI). Finally, IgG from SSc patients with PAH and lung fibrosis highly positive for the presence of anti-AT1R and anti-ETAR antibodies as measured by a sandwich ELISA (CellTrend, Luckenwalde, Germany) were injected into C57BL/6 mice. BAL was performed 7 days after adoptive transfer.

Results: In microvascular endothelial cells, expression of different SSc-related cytokines and chemokines was induced that was partially ameliorated by AT1R or ETAR blockers. In fibroblasts, antibody-mediated induction of collagen-1 was completely ameliorated by both AT1R and ETAR blockers. The antibodies also amplified the vasoconstrictive responsiveness towards endothelin-1 and angiotensin II in pulmonary resistance vessels that could be blocked by corresponding receptor antagonists. There was no direct effect of the antibodies on vasoconstriction. Real-time fluorescence imaging revealed increased endothelial Ca influx in the presence of SSc-IgG not found in the presence of IgG from controls negative for anti-AT1R/ETAR antibodies. Finally, neutrophilic alveolitis was induced seven days after adoptive transfer.

Conclusion: Our data suggest a contribution of anti-AT1R and ETAR antibodies in SSc pathogenesis and revealed effects on different cells and species. Long-term in vivo experiments and long-term blockade will be performed to identify the full spectrum of the effects.

1496

Evidence for the Contribution of the X Chromosome to Systemic Sclerosis Susceptibility: Association with the Functional *IRAK1* 196Phe/532Ser Haplotype. Philippe Dieude[1], Matthieu Bouaziz[2], Gabriela Riemekasten[3], Paolo Airo[4], Martina Müller[5], Daniele Cusi[6], Gilles Chiocchia[7], Catherine Boileau[8], Yannick Allanore[9] and Genesys Consortium[10]. [1]Hopital Bichat, Paris, France, [2]Evry-genopole, France, [3]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany, [4]Brescia, Italy, [5]München, Germany, [6]Milano, Italy, [7]Institut Cochin, 75014 Paris, France, [8]Boulogne, France, [9]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [10]Paris

Background/Purpose: Several autoimmune disorders, including systemic sclerosis (SSc), are characterized by a strong sex bias. Until now, nothing is known about whether genes on the sex chromosomes can influence SSc susceptibility. Recently, an *IRAK1* haplotype that contains the 196Phe functional variant (rs1059702), located on Xq28, was found to confer susceptibility to systemic lupus erythematosus (SLE). OUr objective was to test for association with SSc the *IRAK1* SLE-risk haplotype.

Methods: We tested for association the *IRAK1* SLE-risk haplotype in a discovery set of 849 SSc and 625 controls. *IRAK1* rs1059702 was further genotyped in a replication set, which includes individuals from Italy (493 SSc, 509 controls) and Germany (466 SSc, 1083 controls), all individuals being of European Caucasian origin and of female gender.

Results: Association between the *IRAK1* haplotype and SSc was detected in the discovery set. In both discovery and replication sets the rs1059702 TT genotype was found to be associated with specific SSc subsets highlighting a potential contribution in disease severity. A meta-analysis provided evidence for an association between both T allele and TT genotype and the overall disease: OR 1.20 95%CI[1.06–1.35], P=0.003 and OR 1.49 95%CI[1.06–2.10], P=0.023, respectively. However, the most remarkable associations were observed with diffuse cutaneous, anti-topoisomerase I antibodies positive and SSc-related fibrosing alveolitis subsets: OR 2.35 95%CI[1.51–3.66], $P=1.56\times10^{-4}$, OR 2.84 95%CI[1.87–4.32], $P=1.07\times10^{-6}$ and OR 2.09 95%CI[1.35–3.24], $P=9.05\times10^{-4}$, respectively.

Conclusion: Our study provides the first evidence for an association between *IRAK1* and SSc, demonstrating that a sex chromosome gene directly influences SSc susceptibility and its phenotypic heterogeneity.

1497

Identification of Novel Genes Associated with Systemic Sclerosis Through Genome Wide Association Study Follow-up. Jose Ezequiel Martin[1], Jasper Broen[2], Olga Y. Gorlova[3], Madelon C. Vonk[4], Spanish Scleroderma Group[5], Alexandre Voskuyl[6], Annemie Schuerwegh[7], Marie Vanthuyne[8], Vanessa Smith[9], Rene Westhovens[10], Elfride de Baere[11], Alexander Kreuter[12], Gabriela Riemekasten[13], Roger Hesselstrand[14], Annika Nordin[15], Oyvind Palm[16], Paolo Airo[17], Nicolas Hunzelmann[18], Lorenzo Beretta[19], Filemon K. Background/Purpose: Systemic sclerosis (SSc) is complex autoimmune disease affecting the connective tissue; influenced by genetic and environmental components. Recently, we performed the first successful GWAS of SSc. Here, we perform a large replication study to better dissect the genetic component of SSc.

Methods: We selected 768 polymorphisms from the previous GWAS carried out in Caucasian individuals from Europe and US; and genotyped them in nine replication cohorts from Europe. Overall significance was calculated for replicated significant SNPs by meta-analysis of the replication cohorts and replication-GWAS cohorts (3,790 cases and 6,831 controls). Finally, we searched for differential association in the main SSc subgroups of limited (lcSSc) and diffuse (dcSSc) subtypes, and autoantibody positive for anti-centromere (ACA) and anti-topoisomerase I (ATA).

Results: We found evidence for replication and overall genome wide significance for one novel SSc genetic risk locus: *PSD3* (P value = 5.38×10^{-8}, OR = 1.451). Additionally, we found suggestive association in the loci *TMEM163* (P value = 4.50×10^{-7}, OR = 1.169) and *ADAMTS17* in the ATA+ subgroup (P value = 4.95×10^{-7}, OR = 1.392). As expected we strengthened the evidence for previously confirmed associations in the *CD247*, *STAT4*, *TNFAIP3*, *TNPO3*/*IRF5* and *IRF8* loci. Additionally, we shed new light on the association of *IRF5* with SSc, which suggests that this is a shared genetic risk factor with systemic lupus erythematosus.

Conclusion: This study significantly increases the number of known putative genetic risk factors for SSc, including the genes *PSD3*, *TMEM163* and *ADAMTS17*, and further confirms five previously described ones.

1498

Gut Fibrosis with Associated Diminished Colonic Contractility in a Transgenic Mouse Model of Scleroderma. Nora Thoua, Korsa Khan, Audrey Dooley, Emma Derrett-Smith and Christopher P. Denton. UCL Medical School, London, United Kingdom

Background/Purpose: Clinically significant gastrointestinal involvement occurs in up to 90% of patients with systemic sclerosis (SSc). Animal models of SSc mimic some of the pathophysiological disease processes of SSc and can help in the development of effective therapies. Animal models have helped to study different disease aspects such as systemic disease manifestations as well as organ damage such as lung fibrosis and pulmonary arterial hypertension. There is no mouse model to date that has specifically investigated the GI tract. The transgenic mouse strain TβRIIΔk-fib is characterized by ligand-dependent upregulation of TGF-β signalling and has been shown to develop skin fibrosis, lung fibrosis and diminished aortic ring contractility associated with adventitial fibrosis. We investigated if similar changes are observed in gut tissue in this mouse model.

Methods: Colonic tissue was examined using histology, immunohistochemistry and isolated organ bath studies. Gross tissue architecture was examined by haematoxylin and eosin stain (H&E), picrosirius red (staining for collagen) and immunohistochemical markers for alpha-smooth muscle actin (aSMA), phospho-Smad 2/3 (pSmad2/3) and Ki-67 (cell proliferation marker). To investigate the enteric nervous system, tissue was stained with PGP 9.5 (marker for general neural tissue) and S-100 (glial marker). Fibrosis was quantified using the NIS Elements BR 2.30 system (Nikon) allowing for quantification of the various colour wavelengths with pixels as the unit of measure. Colonic strip contractile responses to potassium chloride (KCl) and carbachol (a cholinergic agonist) were assessed in isolated organ baths and data was presented as % of maximal contraction.

Results: H&E staining showed no architectural differences between transgenic and wild-type mice gut tissue. However, a marked increase in collagen deposition in the transgenic mice compared to wild-type controls (% of tissue stained red: WT: 3.95±0.7 vs TG: 9.71±2, p=0.05). No significant difference was observed immunostaining for aSMA, Ki-67, pSmad2/3 between transgenic and wild-type control mice. There was no obvious difference in neural tissue staining. The organ bath studies showed colonic strip contractility was diminished in transgenic (TG) mice compared with wild-type (WT) controls to both KCl 80mM (WT: 53.5 ± 14.2 vs TG: 13.5 ± 12.8, p=0.022) and carbachol at the higher concentrations (10^{-5}: WT: 90.4 ± 8.7 vs TG: 50.6 ± 17.8; p=0.025 and 10^{-4}: WT: 64.6 ±7.2 vs TG: 31.97 ± 13.9; p=0.023).

Conclusion: We have shown that this transgenic mouse model previously shown to develop skin, lung and cardiac fibrosis also develops colonic fibrosis with associated effect in colonic tissue contractility. This may offer further insight in pathologic processes leading to the development of gut fibrosis as well as the effect in the gastrointestinal tract of therapies targeting fibrosis.

Angiogenic Biomarkers Predict the Development of Digital Ulcers in Patients with Systemic Sclerosis. Jérôme Avouac[1], Christophe Meune[2], Andre Kahan[1], Gilles Chiocchia[3] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [2]Paris Descartes University, Cardiology department, Cochin Hospital, Paris, France, [3]Institut Cochin, 75014 Paris, France

Background/Purpose: To evaluate the possible merit of different endothelial markers for the prediction of ischaemic digital ulcers (DU). These biomarkers were also evaluated for the prediction of other microvasuclar complications that are pulmonary hypertension (PH), left ventricular (LV) dysfunction and scleroderma renal crisis (SRC).

Methods: Endothelial markers were assessed in a prospective cohort of 100 SSc patients without known cardiovascular involvement or severe comorbidities at presentation. Circulating endothelial progenitor cells (EPCs) and circulating endothelial cells (CECs) were quantified in peripheral blood by flow cytometry after cell sorting. Serum levels of placenta growth factor (PlGF), soluble vascular adhesion molecule (sVCAM) and vascular endothelial growth factor (VEGF) were measured by quantitative sandwich ELISA technique (Quantikine kits, R&D systems). The primary outcome was the occurrence during a planed 3-year follow-up of one or more new ischemic DU, defined by a painful area ≥2mm in diameter with visible depth and loss of dermis localized on fingertips. Secondary endpoint was the occurrence of at least one cardiac/vascular event, assessed by an exploratory composite index defined by the occurrence of at least one of the following event: a) one or more new ischemic DU, b) pre-capillary PH confirmed by RHC, c) left ventricular (LV) dysfunction, defined by a LV ejection fraction (EF)<50% d) SRC, defined by a sudden and marked increase in systemic blood pressure and acute renal failure.

Results: The mean ± standard deviation (SD) age of the 100 patients (89 women) was 56±13 year old and the mean ± SD disease duration was 9±8 years at baseline. Forty patients had the diffuse cutaneous subset, and 60 the limited. During the planned follow-up, seventeen patients developed new ischaemic DU (8 patients with a history of previous DU and 9 patients with no previous DU). Regarding other vascular complications, PH occurred in 5 patients, LV dysfunction in 4 and SRC in a single patient. By univariate analysis, low EPC counts (p=0.009), high PlGF (p=0.007) and sVCAM (p=0.04) serum levels were identified as predictive biomarkers of the occurrence of at least one new DU. Multivariate analysis including these three biomarkers and SSc-related disease characteristics identified high PlGF serum levels (HR: 5.04, 95% CI: 1.19–21.09) and a history of DU (HR: 9.51, 95% CI 1.54–58.77) as independent predictors of new DU. In an alternate model excluding patients with a history DU at baseline, low EPC counts (HR: 7.95, 95% CI 2.09–30.09) and high PlGF serum levels (HR: 13.46, 95% CI 1.58–114.73) were found as predictors of new DU. Regarding secondary outcome, Low baseline EPC counts (HR: 4.56, 95% CI 1.04–20.06, p=0.03) and elevated PlGF serum levels (HR 5.85 95% CI 1.42–24.15, *P*=0.02) were independent predictors in multivariate analysis of the occurrence of cardiac/vascular events, according to our exploratory index.

Conclusion: This study identified low circulating EPC counts and high PlGF serum levels as predictors of new DU in SSc. It highlights the critical role of angiogenesis in this vascular outcome. These markers may improve DU risk stratification and therefore allow earlier therapeutic intervention.

Background/Purpose: To analyze the efficacy and tolerance of infliximab in refractory Takayasu disease.

Methods: French multicenter retrospective study which included patients with Takayasu disease. Clinical disease activity was considered if the patient presented one of the following features: (1) new onset of carotodynia, pain over other large vessels or new ischemic vascular claudication, (2) transient ischemic episodes not attributed to other factors, (3) new bruit or asymmetry in pulses or blood pressure, (4) systemic features in the absence of infection or other factors. Biological activity was defined if the patient presented 2 of the following features: (1) VS>30 mm/h, (2) CRP>10 mg/l, (3) fibrinogen>3 g/l, (4) leukocyte count>10 10^3/mm^3 without any infection. Radiological activity was defined as the presence of at least 2 of the following features: (1) arterial wall thickening at angioscanner, (2) arterial wall thickening with mural enhancement in resonance magnetic imaging, (3) arterial hypermetabolism on PET-scan. Corticodependence was defined as prednisone≥20mg/day before infliximab.

Results: Fifteen patients with Takayasu disease (median age 41 years [17–61], 13 women) were included. At the time of infliximab beginning, 14 patients were treated with steroids (median dose 20 mg/day [5–35]), methotrexate (n=7) or azathioprine (n=4). Infliximab was used at 5 mg/kg [3–5] every 6 weeks [4–8]. Median follow-up after initiation of infliximab was 43 months [4–71]. A partial or good overall response was noted in 13/15 cases (87%), 10/13 (77%) and 8/11 cases (73%) at 3, 6, 12 months respectively. Clinical and biological activities were significantly decreased within 3 months (from 11 at baseline to 4 patients at 12 months; p<0.05), and similarly for corticosteroid dose (from 20 mg/day [5–35] at baseline to 6 mg/day [2.5–30] at 12 months; p<0.05). Only 1 patient was still steroid-dependent at 12 months (vs 8 cases before infliximab). C-reactive protein regressed from 30 mg/l [4–70] to 5 mg/l [0–57] and 6 g/l [0–50] at 3 and 6 months respectively (p<0.05). Side effects were 2 infusion-related reactions, 1 pulmonary tuberculosis, 1 severe bacterial infection and EBV reactivation. At the last visit, infliximab was continued in 7 patients (47%), and was discontinued in the 8 patients because of remission (n=3), inefficacy (n=2) or adverse reactions (n=3). In 3/8 patients infliximab was switched to adalimumab, which was effective in 1 case.

Conclusion: This study confirms the interest of infliximab in terms of clinical and biological response, as well as steroid-sparing agent.

Takayasu Arteritis: Treatment and Outcome. An American Cohort of 126 Patients. Jean Schmidt[1], Tanaz A. Kermani[2], A. Kirstin Bacani[2], Cynthia S. Crowson[2], Eric L. Matteson[2] and Kenneth J. Warrington[2]. [1]Amiens University Hospital, Amiens, France, [2]Mayo Clinic, Rochester, MN

Background/Purpose: Takayasu arteritis (TA) is a rare inflammatory condition affecting the aorta and its branches. This chronic, relapsing disease is associated with significant morbidity, and treatment can be challenging. The aim of this study is to report the treatment and outcomes of a large cohort of patients with TA seen at a referral center in the USA.

Methods: We retrospectively studied a cohort of patients with newly diagnosed (within a year) TA evaluated at our institution between 01/01/1984 and 12/31/2009. ACR criteria for TA were used for inclusion (modified to include patients diagnosed between age 41 and 50 years). Disease activity was assessed according to the NIH (Kerr) criteria. Data are reported using descriptive statistics (median and [1^{st}-3^{rd} quartile of the distribution]); predictors of outcome were examined using Cox models.

Results: The cohort included 126 patients, predominantly white (82.5%) and female (91%). The median age at diagnosis was 31.5 years [22.9–39.6]. All patients had arteriographic abnormalities compatible with TA.

Eighty six percent of patients were treated with oral corticosteroids (CS). A CS sparing agent was prescribed in 56 % of patients, mainly methotrexate.

The longitudinal cohort was comprised of 79 patients followed for more than 1 year. The median length of follow up was 5.5 years [2.9–10.1]. After five years of follow up, 96 % of these patients had experienced remission of any duration, and 71 % sustained remission (remission of at least 6 months, while on <10 mg / day of prednisone). Among patients achieving remission (n = 77), 46 % experienced at least one relapse by 5 years after remission. The median time to achieve remission was 5 months [1.9–12.5]. The median time to achieve

sustained remission was 32 months [16.7–49.9]. The median time to first relapse was 8 months [3.4–23.3]. Factors associated with achieving a sustained remission were: an age at diagnosis above 40 (HR 9 (95 % confidence interval (CI) 1.4–55.3), p = 0.017), and a lower ESR at diagnosis (HR 0.88 per 10 mm/h (95 % CI 0.82–0.94), p < 0.001).

Vascular intervention was performed in 55% of the patients. The procedure success rate for open surgery (56 procedures) was 57%, and percutaneous angioplasty (20 procedures) was 35 %, p = 0.08.

Thirteen pregnancies were recorded in 10 women: 9 term deliveries, 2 preterm deliveries (newborns in good health), 1 miscarriage, and 1 medical abortion.

Among the 79 patients followed longitudinally, 10 developed infections, 9 cerebral ischemic disease, and 5 ischemic heart disease.

Survival at 10 years was 96.9 % ± 1.7, and survival at 15 years was 85.9 % ± 6.5. There were 6 deaths. The median age at death was 45.5 years [29–52], after a median follow up of 38 months [12–140].

Conclusion: Medical treatment achieves remission induction in most patients with TA, but almost half of the patients experience relapse. Open surgery may have better results than angioplasty. In this study, age at diagnosis above 40 years and a lower ESR at diagnosis were associated with increased likelihood of sustained remission.

1502

Tumor Necrosis Factor Inhibitors in Patients with Takayasu Arteritis: Experience From a Referral Center with Long-Term Follow-up. Jean Schmidt[1], Tanaz A. Kermani[2], A. Kirstin Bacani[2], Cynthia S. Crowson[2], Eric L. Matteson[2] and Kenneth J. Warrington[2]. [1]Amiens University Hospital, Amiens, France, [2]Mayo Clinic, Rochester, MN

Background/Purpose: Takayasu arteritis (TA) is a rare, primary vasculitis affecting the aorta and its branches, often characterized by a chronic course with disease relapses. There have been no randomized clinical trials to evaluate optimal therapy. A few case reports and small pilot studies suggest that tumor necrosis factor inhibitors (TNFi) may be effective for treating TA. We report our experience with use of TNFi in patients with TA seen at a major referral center in the USA.

Methods: We retrospectively studied a cohort of patients with newly-diagnosed TA evaluated at our institution between 01/01/2004 and 12/31/2009 and who received some TNFi in this period. The ACR criteria for TA were used for inclusion (modified to include patients diagnosed between age 41 and 50 years). Disease activity was assessed according to the NIH (Kerr) criteria: Sustained remission was defined as an inactive disease for at least six months while on a treatment regimen including prednisone <10 mg/day. Data are reported with descriptive statistics (mean (± SD), median [first-third quartile of the distribution]).

Results: We included 20 patients (19 women, 16 Caucasians), with a mean age of 33 years (± 10.2), and a median duration of disease of 15.9 months [2–32.7] at initiation of TNFi. The median total follow up for these patients was 54 months [34–82].

The indication for starting TNFi was active/relapsing disease in 19 patients (of whom 6 had new arterial lesions), and adverse effect of a previous treatment for 1 patient (alopecia due to mycophenolate mofetil).

Before use of TNFi, all 20 patients received prednisone at a median maximum daily dose of 60 mg [60–60]. Other prior immunosuppressive therapy included methotrexate in 18 patients, azathioprine in 5 patients, mycophenolate mofetil in 3 patients, and cyclophosphamide in 3 patients.

The TNFi used were infliximab in 17 patients, adalimumab in 2 patients, and etanercept in 1 patient. The median duration of treatment with TNFi was 15.24 months [8.45–31.96]. Eleven patients discontinued TNFi: 3 for treatment failure (1 relapse, 1 lack of steroid sparing effect, and 1 persistently active disease), 4 due to adverse effects (1 infection after hand surgery, 2 reactions to infusion, and 1 pancreatic cancer), 4 for other reasons.

Treatment with TNFi resulted in disease remission in 19/20 patients (time to achieve remission while on TNFi 3.6 months [1.4–6.2]), and sustained remission in 11 patients (time to achieve sustained remission 24.9 months (± 20)). Of 12 patients receiving 10 mg of prednisone or more at the time of starting a TNFi, 10 patients were able to taper prednisone below 10 mg, and 7 were able to stop prednisone. However 5/19 patients experienced relapse while on TNFi (time to relapse 2.9 months [2.9–4.1]). Despite good tolerance, two patients discontinued their treatment while in remission. Both experienced relapse with a new arterial stenosis, and both achieved remission again once the TNFi was resumed.

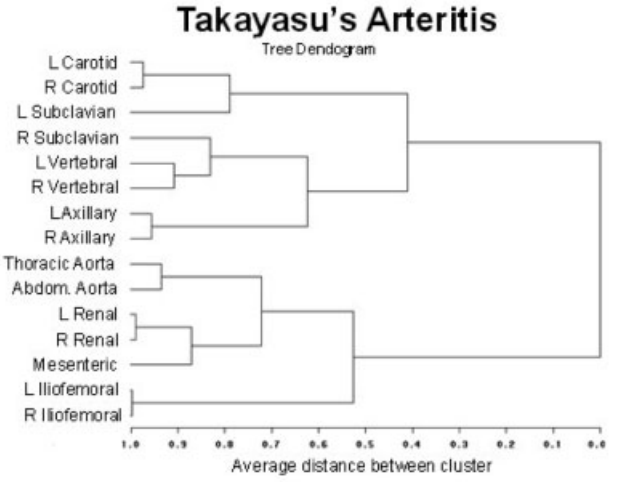
Conclusion: Treatment with TNFi can induce remission and even sustained remission in patients with refractory TA. However, drug continuation in our population was low and about 25% of our patients experienced disease relapse while on TNFi.

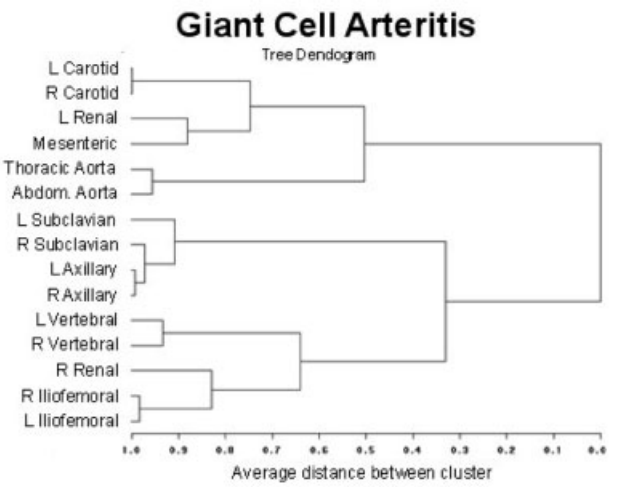
1503

Distribution of Large Artery Lesions in Takayasu's Arteritis Compared to Giant Cell Arteritis. Peter C. Grayson[1], Kathleen Maksimowicz-McKinnon[2], Tiffany M. Clark[3], Gunnar Tomasson[4], David Cuthbertson[5], Simon Carette[6], Nader A. Khalidi[7], Carol A. Langford[8], Paul A. Monach[9], Philip Seo[10], Kenneth J. Warrington[11], Steven R. Ytterberg[11], Gary S. Hoffman[12] and Peter A. Merkel[4]. [1]Boston University Medical Center, Boston, MA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Cleveland Clinic Foundation, Cleveland, [4]Boston University School of Medicine, Boston, MA, [5]University of South Florida, Tampa, FL, [6]Toronto Western Hospital, Toronto, ON, [7]McMaster University, Hamilton, ON, [8]Cleveland Clinic, Cleveland, OH, [9]Boston University, Boston, MA, [10]Johns Hopkins Vasculitis Center, Baltimore, MD, [11]Mayo Clinic, Rochester, MN, [12]Cleveland Clinic Found A50, Cleveland, OH

Background/Purpose: To compare the occurrence of aortic and primary branch arteriographic lesions in patients with large vessel vasculitis [Takayasu's arteritis (TAK) and giant cell arteritis (GCA)]; to determine if patterns of arteriographic disease differ between patients with TAK and GCA and between patients categorized by age at the time of disease onset; and to explore novel ways to classify large vessel vasculitis using computer-generated models of disease classification based upon patterns of arterial involvement.

Methods: Patients with arterial lesions (stenosis, occlusion, or aneurysm) on magnetic resonance angiography were selected from two North American cohorts of TAK and GCA. The frequency of lesions was calculated for 15 arteries: bilateral carotid, vertebral, subclavian, axillary, renal, and iliofemoral arteries; thoracic and abdominal aorta; and mesenteric arteries. Agglomerative, hierarchical cluster analysis was used to cluster arterial involvement. Tree diagrams were created to visualize clustering patterns in TAK and GCA and in subgroups defined by age at disease onset (<40 years; 40–55 years; and > 55 years). Latent class analysis was used to identify computer-derived subgroups of patients with large vessel vasculitis based upon patterns of arterial disease.





Results: Large arterial lesions were identified in 145 patients with TAK and 62 patients with GCA. There was significantly more left carotid ($p=0.03$) and mesenteric ($p=0.02$) artery disease in TAK and more left and right axillary ($p<0.01$) artery disease in GCA. There were no significant differences in involvement between disease subgroups in the 9 other large arteries studied. Similarities and differences in cluster patterns of arterial pathology were observed between the TAK and GCA subgroups (**Figure**). Arterial involvement was contiguous in the aorta and tended to be symmetric in paired branch vessels in both TAK and GCA. Subclavian involvement was different between TAK and GCA. Asymmetric subclavian disease with frequent left subclavian involvement was observed in TAK, and symmetric subclavian disease with concomitant axillary involvement was observed in GCA. Patterns of arterial disease for patients in the < 40 and the 40–55 year age groups at the time of disease onset resembled TAK and arterial patterns for patients in the > 60 year age group resembled GCA. Latent class analysis identified 3 subgroups of patients. Two subgroups, defining 26% and 18% of the dataset, were associated with the traditional diagnoses of TAK and GCA respectively. The majority of patients (56%), however, were classified into a subgroup that did not differentiate between TAK and GCA.

Conclusion: Strong similarities and subtle differences in the distribution of arterial disease were observed between TAK and GCA. These findings suggest that TAK and GCA may exist on a spectrum within the same disease.

1504

Outcome of Vascular Interventions in Takayasu Arteritis Using the Takayasu Arteritis Damage Score. Sivakumar M. Rajappa. Cerebrovascular and Vasculitis Research Foundation, Chennai, India

Background/Purpose: Takayasu's aorto-arteritis (TA) in India tends to present with vascular complications over time. We devised a clinical index to measure damage related to TA called the Takayasu Arteritis Damage Score (TADS). In North America, despite providing short term benefit, endovascular revascularization procedures are associated with a high failure rate in patients with TA. Using the TADS, we analyzed a large series of TA patients who underwent vascular interventions.

Objectives: To analyze the outcomes of vascular interventions in 232 patients with Takayasu's arteritis (TA) from India who were seen at the Cerebrovascular and Vasculitis Research Foundation (CVRF) at Chennai between 1988 and 2010.

Methods: TA database at CVRF were reviewed for the period 1988 to 2010. All patients received pre/post procedures immunosuppressive treatment with any combination of: corticosteroids, Azathioprine, Methoterate or Mycophenylate Mofetil and inteventions were performed when the arteritis was considered inactive with low Indian Takayasu's Arteritis Scores (ITAS). The primary outcome measure was patency of vessels as determined by repeated Digital Subtraction angiography or Computerized Tomography/ magnetic resonance angiography. The secondary outcome measures were: periprocedural complications, morbidity and mortality. Vascular Interventions performed were: Percutaneous transluminal angioplasty (PTA) with or without stenting for Carotids, Vertebrals, Subclavians, Renal arteries and Aorta; bypass grafts to Carotids, Inguinal and abdominal aorta/Inguinal arteries; Carotid endarterectomy, Coronary artery bypass surgery and Coronary angioplasty and stenting.

Results: 82 TA patients, underwent 122 vascular interventions. There were 31 men and 51 women. Mean age at onset of TA symptoms was 33.54 years with a mean disease duration of 8.9 years. The procedures performed were: Carotid angioplasty and stenting- 24, vertebral angioplasty and stenting-4, grafts from ascending aorta to Carotids-3, subclavian angioplasty and stenting- 16, renal angioplasty and stenting-26, angioplasty and stenting of Aorta- 14, coronary angioplasty and stenting- 24 and CABG Surgeries-11. The Mean follow up period was 136 months. Associated clinical features and drug therapy were recorded. Peri-operative complications included (infections- 5.3%, stroke- 8%, myocardial infarction-3.6%, renal failure-3.5%). There were no peri-procedural deaths. The patency of stents at 5 years was 92% and at 10 years was 83%. 18% of the total number of patients died and the TADS scores in fatal disease were higher than in non-fatal cases with good correlation between the duration of TA and total TADS scores.

Conclusion: Vessel occlusion is a major feature of TA. Recording a damage score (TADS) helps to delineate features associated with pulse loss and with long-term patency of stent procedures. Unlike the reports from North America, there is good long term patency of vascular interventions performed in TA patients treated with adequate immunosuppressive treatment pre/post interventions and when these interventions are done when the TA is inactive, as seen with low Indian Takayasu's Arteritis Scores.

1505

Tocilizumab: A Novel Therapy for Patients with Large-Vessel Vasculitis. Maria Grazia Catanoso[1], Luca Magnani[1], Nicolo Pipitone[1], Annibale Versari[1], Lucia Dardani[1], Lia Pulsatelli[2], Riccardo Meliconi[3], Luigi Boiardi[1] and Carlo Salvarani[1]. [1]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [2]Istituto Ortopedico Rizzoli, Bologna, Italy, [3]Istituto Ortopedico Rizzoli and University of Bologna, Bologna, Italy

Background/Purpose: Treatment of large vessel vasculitis (LVV) remains challenging. Patients usually respond to glucocorticoid (GC) therapy, but often relapse on tapering of the GC dose or after GC withdrawal. In addition, GC are fraught with numerous adverse events. The aim of this study was to assess the efficacy and safety of the anti-IL-6 receptor (IL-6R) antibody tocilizumab (TCZ) in patients with LVV.

Methods: Six patients with active LVV (one with giant-cell arteritis, four with Takayasu arteritis, and one with thoracic aortitis and retroperitoneal fibrosis) received monthly TCZ (8 mg/kg/ bodyweight) infusions for six consecutive months. Two patients were treatment-naïve patients (both with Takayasu arteritis), while the other four had relapsing disease which had failed to respond to immunodepressive drugs, including TNF-α blockers and abatacept. Disease activity and drug tolerability were assessed clinically and by laboratory tests at study entry and subsequently every month, while ^{18F}-Fluorodeoxyglucose positron emission (PET) was performed before and after TCZ treatment. In addition, a semiquantitative clinical evaluation was performed at baseline and at 3 and 6 months as well as every 3 months during follow-up using the ITAS (Indian Takayasu Activity Score) and the Kerr indices. After TCZ treatment, methotrexate was started as maintenance therapy in the two treatment-naïve patients, while the other patients continued with their previous treatments (three methotrexate and one mofetil mycophenolate).

Results: All patients treated with TCZ therapy had a satisfactory clinical and laboratory response (Table 1), while PET findings significantly improved in all cases. No serious adverse events were noted. Follow-up data are available for 5/6 patients. Three patients remain in clinical and laboratory remission, while two patients suffered a clinical relapse associated with an increase in inflammatory markers.

Table 1. Clinical data and laboratory findings before/after TCZ therapy

	ESR (mm/1h)	CRP (mg/dl)	ITAS	KERR
PT 1	45/3	4.02/0.06	4/0	4/0
PT 2	67/2	0.99/0.05	3/0	4/0
PT 3	84/2	4.80/0.01	8/0	4/1
PT 4	95/4	5.42/0.07	3/0	4/2
PT 5	33/6	4.27/0.12	3/0	3/1
PT 6	69/12	0.88/0.04	2/0	4/0

PT: patient; Normal values: Erythrocyte Sedimentation Rate (ESR) <40 mm/1st h; C-Reactive Protein (CRP) <0.5mg/dl; ITAS <1; Kerr ≤2

Conclusion: In this small group of patients with LLV, treatment with TCZ was effective and well tolerated. Further, larger studies are required to confirm our findings.

1506

Leflunomide in Takayasu Arteritis—Results from an Observational Study. Alexandre W. S. de Souza[1], Morgana D. da Silva[1], Luiz Samuel G. Machado[1], Ana Cecilia D. Oliveira[1], Frederico A. G. Pinheiro[1] and Emilia I. Sato[2]. [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil

Background/Purpose: Takayasu arteritis (TA) is a large vessel vasculitis that affects the aorta, its main branches, pulmonary and coronary arteries. Use of immunosuppressive agents such as methotrexate, azathioprine, mycophenolate mofetil and cyclophosphamide has been evaluated in TA either in open-label studies or in several cohort studies with positive results. Leflunomide was first reported in a patient resistant to corticosteroid and methotrexate with a successful result and it was used by 6% of patients with TA followed-up in a cohort study. The objective of this study is to evaluate the efficacy of leflunomide to control disease activity in patients with TA refractory or intolerant to conventional treatment.

Methods: Prospective open-label study, where TA patients with active disease based on clinical assessment, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and magnetic resonance angiography

(MRA) received leflunomide 20mg/day for at least 6 months. Adverse events attributable to leflunomide were also recorded.

Results: The study comprised 15 patients with TA with a mean age of 36.2 years followed for a mean of 9.1 months. At baseline, 14 TA patients had active disease despite therapy with corticosteroids and immunosuppressive agents, while intolerance to current treatment was observed in one patient. In the follow-up visit, we found a significant decrease in the frequency of patients with active TA (93% vs. 20%; $P = 0.002$), in the mean daily dose of prednisone (34.2 mg vs. 13.9 mg; $P < 0.001$) and in the median values of ESR (29.0 vs. 27.0 mm/hour; $P = 0.012$) and of CRP (10.3 vs. 5.3 mg/L; $P = 0.012$). Two patients (13.3%) developed new angiographic lesions in the follow-up MRA. Three patients (20%) experienced mild adverse events during the study and none discontinued therapy.

Conclusion: this the first open label study showing improvement of disease activity and acute phase reactants with 20 mg/day of leflunomide in TA patients who are refractory or intolerant to conventional therapy with corticosteroids and immunosuppressive agents. Leflunomide was safe and a steroid sparing effect was also observed. A double blind controlled study is desirable to confirm this finding.

1507

Tocilizumab for the Treatment of Large Vessel Vasculitis (Giant Cell Arteritis, Takayasu Arteritis) and Polymyalgia Rheumatica: A Case Series. Sebastian Unizony[1], Luis Arias-Urdaneta[1], Eli Miloslavsky[2], Sheila L. Arvikar[1], Arezou Khosroshahi[1] and John H. Stone[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hopsital, Boston, MA

Background/Purpose: Glucocorticoids (GC) are still the mainstay of therapy for giant cell arteritis (GCA), polymyalgia rheumatica (PMR), and Takayasu arteritis (TA). A sizeable percentage of these patients experience disease exacerbations upon GC tapering and require repeated GC courses, resulting in prolonged GC exposure and adverse effects. Interleukin (IL)-6 is an attractive target for therapy in these conditions because patients with GCA, TA, and PMR have increased levels of this cytokine in their peripheral circulation and inflamed tissues, and serum IL-6 concentrations correlate with disease activity. We retrospectively assessed the outcomes of 7 patients with large-vessel vasculitis (GCA and TA) and PMR treated with tocilizumab (TCZ), an anti IL-6 receptor humanized monoclonal antibody.

Methods: Patients with GCA, TA and PMR refractory to conventional therapy received monthly infusions of TCZ (8 mg/kg). Six subjects had failed at least one disease-modifying anti-rheumatic drug (methotrexate, azathioprine, or cyclophosphamide) or infliximab in addition to prednisone. Clinical improvement was assessed by evaluating symptoms of disease activity, inflammatory markers, ability to taper prednisone, and serial cross-sectional imaging when necessary before and during TCZ therapy. IL-6 level was measured at baseline and before each TCZ infusion.

Results: Seven patients with GCA (n = 4), TA (n = 2), or PMR (n = 1) received TCZ. The mean duration of disease at the time of anti-IL6R therapy initiation was 18 months (range 11–28), and the mean follow up on TCZ was 5.1 months (range 4–6). Clinical signs of active inflammation disappeared in all patients following the initiation of TCZ. Within eight weeks, all subjects were able to taper their prednisone dose to a mean of less than 5 mg. Before TCZ, the patients had experienced an average of 2 flares per year. Since the initiation of TCZ, all patients have entered and maintained remission. The mean erythrocyte sedimentation rate (ESR) declined from 36.8 mm/h (range 10.6–66) to 7.6 mm/h (range 3.2–14.6) after the start of TCZ (P = 0.001). The mean C-reactive protein (CRP) concentration declined from 22.4 mg/L (range 5.6–32.7) at baseline to 2.8 mg/L (range 0.28–13.4) after anti-IL-6R therapy (P = 0.001). The mean prednisone dose was tapered from 18.3 mg/day (range 7–34.3) to 4.9 mg daily (range 0–6.5) following the initiation of TCZ (P = 0.007). Baseline IL-6 levels were elevated in all except one TA patient [Mean 13.8 pg/ml (range 2.8–18.4)]. In 6 cases, the IL-6 concentration increased after the initiation of TCZ [mean 128.3 pg/ml (range 30.9–308)]. Serial positron emission tomography (PET) studies in one TA patient revealed complete resolution of fluorodeoxyglucose uptake in the great vessels after 4 TCZ infusions. No patient required treatment with other immunosuppressive medications while on TCZ. Adverse effects related to TCZ included mild neutropenia (n=2) and transaminitis (n=3).

Conclusion: IL-6 is important in the pathogenesis of GCA, TA and PMR. TCZ led to prompt clinical, serological and radiographic improvement in a group of patients with persistent disease who were unable to taper prednisone below acceptable doses despite concomitant second-line immunomodulatory agents.

1508

Results of a Randomized Controlled Study of Adalimumab for Steroid Sparing in Patients with Giant-Cell Arteritis. Xavier Mariette[1], Gabriel Baron[2], Eric Hachulla[3], Michel DeBandt[4], C. Larroche[5], Xavier Puéchal[6], Francois Maurier[7], B. de Wazieres[8], T. Quemeneur[9] and Philippe Ravaud[10]. [1]Université Paris-Sud, Le Kremlin Bicetre, France, [2]Epidemiology, Paris, France, [3]Internal Medicine, Lille CEDEX, France, [4]Abstract Medical Int'l, Boulogne, France, [5]Hospital University Bobigny, France, [6]Le Mans General Hospital, Le Mans, France, [7]Division of internal Medicine, CHR Metz, Metz, Metz, France, [8]CHU de Nimes, Nimes, France, [9]CHR de Valenciennes, Valenciennes, France, [10]Hopital Hotel Dieu, Paris Descartes University, Paris, France

Background/Purpose: Steroid is the basis of treatment of giant-cell arteritis (GCA) with very good efficacy but frequent drug dependence leading to side effects. Some case reports suggest that anti-TNF therapy could be useful in case of steroid dependence. Last, in rheumatoid arthritis, anti-TNF therapy given in very early disease associated with DMARDs can induce remission which may be sustained even after withdrawal of biologic therapy.

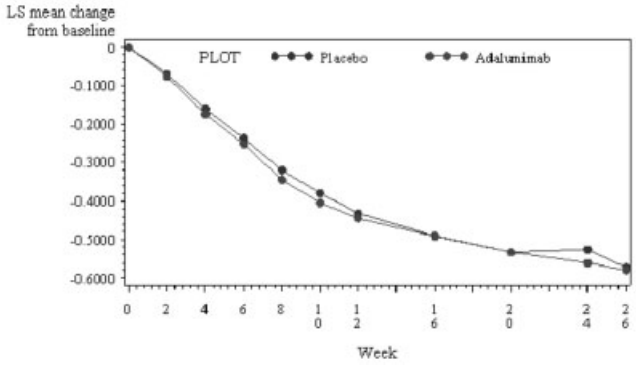
We evaluated the possibility that the association to steroids of a 10-week treatment of adalimumab (ADA) at the beginning of the treatment of GCA could allow a more rapid decrease of steroids without any increase risk of relapse.

Methods: Patients with GCA fulfilling 1990 Hunder criteria were randomized at diagnosis in 2 groups: prednisone (PDN) 0.7mg/kg + adalimumab 40mg or PDN 0.7mg/kg + placebo (PLA) SC at W0, W2, W4, W6, W8, W10. In responder patients, PDN was tapered progressively according to a fixed protocol and the primary end-point was the percentage of patients with less than 0.1 mg/kg of PDN at W26.

Results: 70 patients were included, 34 in the ADA arm, 36 in the PLA arm. 10 patients did not receive the 10-week procedure, 7 in the ADA arm (4 consent withdrawals, 1 serious adverse event (SAE) and 2 unknown reasons), 3 in the PLA arm (2 SAE and 1 death at W4). Analysis was done in intention to treat. At baseline, data were comparable between the ADA and the PLA groups: mean age 73.9 +/− 7.8 years and 73.9 +/− 9.2 years; mean CRP 66 +/− 66 mg/l and 61 +/− 68 mg/l; 1st hour ESR 69 +/− 34 mm and 69 +/− 34 mm; mean Hb level 11.6 +/− 1.6 g/dl and 11.5 +/− 1.4 g/dl.

Serious adverse events occurred in 20.8% and 48.6% of patients in ADA and PLA arms, respectively. 2 patients died in the PLA arm at W4 and W26 (from septic shock and from cancer) and 1 patient died in the ADA group from septic shock but without having received any injection of ADA. Serious infections occurred in 3 patients with ADA (septic shock, shingle and pneumonia) and in 5 patients with PLA. Cancer was observed in 1 patient in each group.

The primary end-point was not achieved: the percentage of patients in remission at 6 months with less than 0.1 mg/kg of PDN was 47.1% and 47.2% in the ADA and PLA arm, respectively. A sensitivity analysis on the 60 patients having effectively received the 10-week procedure gave identical non significant results: 60.0% and 47.2% in the ADA and PLA arm, respectively, p=0.20.The dose decrease of steroids with time was the same in the 2 groups:



Conclusion: In patients with GCA, a 10-week treatment of ADA, associated with a classical dose of steroids does not allow to decrease the percentage of patients in remission at 6 months with less than 0.1 mg/kg of steroids. The safety profile was the same between both groups with no unusual side effects observed with ADA in this group of aged patients with co-morbidities.

1509

Impairment of the Elastic Properties of Aorta and the Carotid Artery System in Patients with Takayasu's Arteritis. Selen Yurdakul[1], Fatma Alibaz Oner[2], Yelda Tayyareci[1], Haner Direskeneli[2] and Saide Aytekin[1]. [1]Florence Nightingale Hospital, Istanbul, Turkey, [2]Marmara University, School of Medicine, Istanbul, Turkey

Background/Purpose: Takayasu's arteritis (TA) is a chronic, inflammatory vasculitis of the aorta and its major branches. In this study, we aimed to evaluate aortic and carotid artery elastic properties and to assess carotid arterial mechanics by using a novel strain imaging method, "velocity vector imaging" (VVI).

Methods: We studied 20 patients with TA (F/M:18/2, mean age: 34.8±7.9 years) and 15 healthy controls (HC)(F/M: 14/1, mean age: 33.9±7.0 years). All patients and HC were assessed for aortic strain, stiffness, distensibility, carotid artery stiffness index and carotid artery intima-media thickness (CIMT) measurements. Additionally, VVI analysis was performed to determine longitudinal and radial tissue motion of the common carotid arteries (CCA), by off-line analysis of standard B-mode ultrasound images.

Results: Aortic strain was significantly impaired in patients with TA, compared to the control group (4.8±3.0% vs 14.4±5.5%, p=0.0001), whereas aortic stiffness (8.8±5.1 vs 2.3±1.4, p=0.0001) and carotid artery stiffness index (5.4±2.6 vs 1.7±0.6, p=0.0001) were markedly increased. Similarly, we observed a significant decrease in aortic distensibility in patients with TA (0.9±0.5 vs 1.3±0.5, respectively, p=0.03). Peak longitudinal strain and strain rate values were also significantly impaired in TA (Strain: 1.1±0.3% vs 5.9±0.7%, p=0.011; Strain rate: 0.3±0.1% vs 0.5±0.3, p=0.008). Total longitudinal displacement measurements were similar between the patient group and HC (p=0.13). However, peak radial velocity was decreased (0.1±0.02 cm/s vs 0.3±0.1 cm/s, p=0.02), while time to peak radial velocity was markedly increased in the patient group (208±49 ms vs 139±40 ms, p=0.0001). CIMT was also significantly increased in the patient group (0.1±0.02 cm vs 0.06±0.01 cm, p=0.0001).

Conclusion: TA is associated with reduced elasticity of the aorta and the carotid artery system. Longitudinal and radial wall motion of CCA is also impaired in patients with TA, possibly due to the vascular involvement. VVI is a feasible, novel "strain" imaging method in assessing the mechanical properties of the large arteries in systemic vasculitides.

Giant Cell Arteritis with or without Suspicion of Aortitis At Diagnosis. A Retrospective Study of 22 Patients with a 12-Year Follow-up. Olivier Espitia[1], Antoine Néel[1], Christophe Leux[2], Jerome Connault[3], Thierry D. Ponge[4], Benoît Dupas[2], Mohamed Hamidou[3] and Christian Agard[1]. [1]Internal Medicine, Nantes University Hospital, Nantes, France, [2]Nantes University Hospital, Nantes, France, [3]Service de médecine interne, Hôpital Universitaire de Nantes, Nantes, France, Nantes, France, [4]Hotel-Dieu, Nantes CEDEX 1, France

Background/Purpose: During giant cell arteritis (GCA), aortitis is frequently suspected, up to 30–50% of cases, using different medical imaging techniques. Images of aortic involvement may be non symptomatic and their real outcome remain elusive. The objective of this study was to describe the long-term outcome of patients with or without suspicion of aortitis at the time of diagnosis of GCA.

Methods: In 1999, 22 patients with newly diagnosed biopsy-proven GCA were explored using aortic computed tomodensitometry (CT). Ten patients (group 1) had aortic inflammatory thickenings ≥ 3mm (n=7) and/or aneurism (n=3), whereas 12 patients had no suspicion of aortitis (group 2). A retrospective study of these 2 groups was conducted in 2011. We contacted and questioned the patients, their family and general practitioner, and analysed each medical file. The following items were investigated: demographic data, cardio-vascular risk factors, total and cardio-vascular mortality, cardio-vascular events, GCA relapses, corticosteroids regimen. Satistics were made using R development Core Team (2009) software.

Results: Seventeen women and 5 men (mean age at diagnosis=73.7±7.2y) were included. Inflammatory parameters and cardio-vascular risk factors were similar in group 1 and 2. The mean follow-up was 94.8 months. Twelve years after diagnosis of GCA, the total mortality was 50% without differences between group 1 (7/10) and group 2 (5/12). However, the 12y cardio-vascular mortality was statistically higher in patients with initial suspicion of aortitis (50%), than in patients without (0%, p=0.029, Log rank test). In group 1, the causes of deaths of cardiovascular origin were: rupture of abdominal aortic aneurism (n=1), thoracic aortic dissection (n=1), stroke (n=1), heart failure (n=1), peripheral arterial disease (n=1). Twelve cardio-vascular events occured in 7/10 patients of group 1 whereas only 5 occured in 4/12 patients of group 2. Stroke were statistically more frequent in group 1 (40% vs 0% in group 2, p=0.03). Recurrent GCA relapses were noted in 5/10 patients of group 1, 0/12 patients of group 2 and this difference was statistically significant (p=0.01). Moreover, definitive steroid treatment discontinuation was more frequent in group 2 (n=2) than in group 1 (n=8, p<0.05).

Conclusion: Despite the limitations due to its retrospective character and its small number of patients, our study suggests that GCA clinical course may differ according to initial CT signs of aortic involvement. CT suspicion of aortitis may lead to aortic fatal events and aortic thickenings deserve to be monitored. Initial aortic CT involvements seem to sign a particular form of GCA, with higher rate of cardio-vascular events and mortality, and with frequent relapses requiring longer steroids treatment.

1511

Increased Mortality in Giant Cell Arteritis with Large Vessel Disease: A Population-Based Cohort Study. Tanaz A. Kermani, Kenneth J. Warrington, Cynthia S. Crowson, Steven R. Ytterberg, Gene G. Hunder, Sherine E. Gabriel and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: To evaluate all-cause mortality in a population-based incident cohort of patients with giant cell arteritis (GCA) with large vessel disease.

Methods: A population-based cohort of patients diagnosed with GCA between January 1, 1950 and December 31, 2004 was studied. Cases of large vessel involvement were identified from medical records. We defined large vessel involvement as large artery stenosis, aortic aneurysm and/or aortic dissection that developed in the 1 year prior to GCA diagnosis or any time after. Diagnosis was based on imaging studies, pathology or autopsy. Patients were followed until death, last contact, or December 31, 2009. We evaluated mortality in GCA patients with large vessel disease compared to GCA patients without this manifestation, and then evaluated survival of GCA patients with large vessel disease to that expected in the general population. Cox proportional hazards models with time-dependent covariates were used to evaluate the influence of large vessel involvement on death after adjusting for age, sex and calendar year. Overall survival was estimated using Kaplan-Meier methods and compared to expected survival for the US population.

Results: Our study included 204 patients; 163 women (80%) and 41 men (20%). Mean age at diagnosis of GCA was 76.0 years (± 8.2 years) with a median length of follow-up 8.8 years (1996 total person-years). We observed 63 large vessel events including 27 large artery stenoses and 36 aortic aneurysms and/or dissections. Twelve patients had an aortic dissection.

Compared to GCA patients without this manifestation, patients with large vessel disease had an increased mortality (HR: 2.4; 95% CI: 1.6–3.6). This was significantly increased in the subset of patients who developed aortic aneurysm (HR: 3.4; 95% CI: 2.2, 5.4) and aortic dissection (HR: 155; 95% CI: 60–400). While there was a trend toward increased mortality in GCA patients with large artery stenosis (HR: 1.5; 95% CI: 0.9, 2.5), this did not achieve statistical significance.

Overall survival of the patients in the cohort was similar to that expected in the general US population (p=0.19). However, compared to the general population, GCA patients who developed any large vessel manifestation had a significantly decreased survival, p<0.001 (Figure). All-cause mortality was increased in the subset of GCA patients with an aortic aneurysm (p<0.001) and aortic dissection (p<0.001) but not in patients with large artery stenosis (p=0.11).

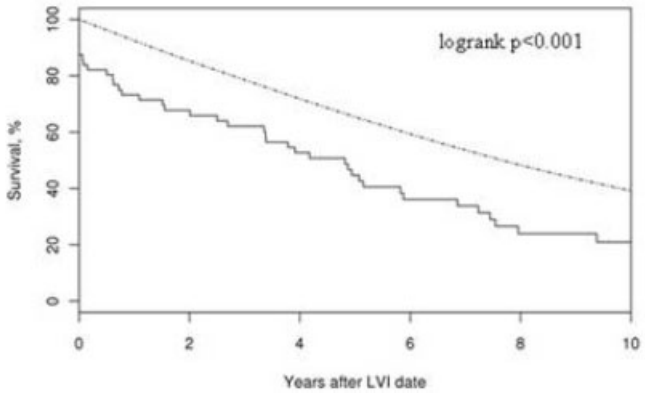

Figure. Survival in 56 patients with GCA who developed large vessel involvement (solid line) compared to expected survival in the US population (dashed line).

Conclusion: Development of aortic aneurysm and/or aortic dissection is associated with increased mortality in GCA. Screening efforts should focus on this serious complication but further studies are needed to determine the optimal screening modality and frequency.

1512

Statin Exposure and Risk of Giant Cell Arteritis: A Case Control Study. Jean Schmidt[1], Tanaz A. Kermani[2], Cynthia S. Crowson[2], Eric L. Matteson[2] and Kenneth J. Warrington[2]. [1]Amiens University Hospital, Amiens, France, [2]Mayo Clinic, Rochester, MN

Background/Purpose: In addition to their lipid-lowering properties, statins are known to have immunomodulatory and anti-inflammatory effects. A recent study reported that statin exposure is associated with a reduced risk of developing rheumatoid arthritis. Statins may influence other inflammatory conditions such as giant cell arteritis (GCA). The primary goal of this study was to examine a potential association between statin exposure and the risk of developing GCA. The secondary goals were to compare the clinical features and course of patients with GCA with/without statins.

Methods: Using a retrospective case-control study design, we reviewed the medical records of all patients with biopsy-proven GCA who fulfilled ACR criteria diagnosed between January 1, 1998 and December 31, 2008.The index date was the date of the temporal artery biopsy. Statin use at index date was recorded; statin use after diagnosis of GCA was not considered. Population-based controls (without GCA) were randomly selected. One control was matched with each case by sex, age, and calendar year. Data is presented as medians with first and third quartile of the distribution. The association between statin exposure and the risk of GCA was analyzed using a conditional logistic regression model, with adjustment for cardiovascular risk factors.

Results: We studied 297 patients with GCA (73 % female; mean age at diagnosis 75 years). At index date the rate of statin exposure was 18.1 % for the cases, versus 33.3 % for the controls ($p < 0.001$). Statin exposure was associated with a marked reduction in the risk of GCA: crude odds ratio (OR) 0.37 (95 % CI 0.27–0.58), $p < 0.001$. The OR was 0.31 (95 % CI 0.15–0.6), $p < 0.001$ after adjustment for comorbidities including hypertension, diabetes mellitus, dyslipidemia, cigarette smoking, personal history of myocardial infarction, stroke, lower limb claudication, body mass index > 25 kg/m^2, and family history of ischemic heart disease.

In patients with GCA the presenting clinical features were similar between patients receiving statins compared to those who were not on statins at diagnosis (i.e. headache, abnormal temporal artery, jaw claudication, polymyalgia rheumatica symptoms, visual symptoms, constitutional signs). There was no significant difference in the acute phase reactants at diagnosis of GCA between patients on statins or not (ESR 64 [53–96] mm/h versus 69 [43–95] mm/h, $p = 0.92$; CRP 48.7 [35–94] mg/L versus 56.5 [27–100] mg/L, $p = 0.88$ respectively).

Follow-up data were available for 197 patients with GCA. In this sub-group the median follow-up was 56 [34–88] months. There was no statistically significant difference between the exposed (to statins) and non-exposed patients with GCA in relapse-rate, number of relapses, and relapse-free survival.

Conclusion: In this study, statin exposure was associated with a marked reduction in the risk of GCA, even after adjustment for cardiovascular risk factors. While it is unknown how statins reduce the risk of GCA, statin use at the time of diagnosis does not appear to modify the clinical presentation or the course of the disease.

1513

Relapses Among Patients with Giant Cell Arteritis. Tanaz A. Kermani[1], Kenneth J. Warrington[1], David Cuthbertson[2], Simon Carette[3], Gary S. Hoffman[4], Nader A. Khalidi[5], Curry L. Koening[6], Carol A. Langford[7], Kathleen McKinnon-Maksimowicz[8], Carol McAlear[9], Paul A. Monach[9], Philip Seo[10], Peter A. Merkel[9] and Steven R. Ytterberg[1]. [1]Mayo Clinic, Rochester, MN, [2]University of South Florida, Tampa, FL, [3]Toronto Western Hospital, Toronto, ON, [4]Cleveland Clinic Foundation, Cleveland, OH, [5]McMaster University, Hamilton, ON, [6]University of Utah, Salt Lake City, UT, [7]Cleveland Clinic, Cleveland, OH, [8]University of Pittsburgh, Pittsburgh, [9]Boston University School of Medicine, Boston, MA, [10]Johns Hopkins Vasculitis Center, Baltimore, MD

Background/Purpose: To evaluate the frequency, timing and clinical features of relapses in a prospective, multicenter, longitudinal cohort of patients with giant cell arteritis (GCA).

Methods: Patients with GCA enrolled in a prospective, multicenter, longitudinal study were included in the analysis. At each quarterly visit, standardized forms were used to collect clinical information. We defined relapse as either new disease activity after a period of remission or worsening disease activity. Kaplan-Meier method was used to evaluate time to first relapse in the subset of patients with newly diagnosed GCA.

Results: The study included 128 subjects – 102 women (80%) and 26 men (20%). Mean (±SD) age at diagnosis of GCA was 69.9 (±8.6) years. Mean follow-up for the cohort was 21.4 (±13.9) months. Median duration of disease at study enrollment was 4.6 (interquartile range (IQR): 1.2, 16.8) months.

At baseline evaluation, 49 patients with GCA (39%) reported at least 1 prior relapse. During follow-up 59 relapses were observed in 44 patients (34%); 10 patients (8%) experienced 2 or more relapses. Symptoms at relapse are summarized in the Table. At relapse 34 patients were receiving glucocorticoids. Other medications at the time of relapse were methotrexate (13 patients), anti-TNF therapy (2 patients), and mycophenolate mofetil (2 patients).

Disease activity at the time of relapse was rated as "low" in 30 flares and "moderate" in 15 flares. In 42 flares with active disease at the time of evaluation, mean ESR at relapse was 32 (±16) mm/hour with mean CRP of 13.5 (±12.9) mg/L. ESR was elevated during 25 flares (60%) while C-reactive protein was elevated in 22 flares (52%) ($p > 0.05$ for difference). Both test results were normal in 14 relapses (33%) despite active symptoms.

Sixty-nine patients (53%) were enrolled within 4 months of diagnosis. Time to first relapse in this subset is shown in the Figure with 24% of subjects experiencing a first relapse within 12 months after diagnosis.

Table. Clinical manifestations of giant cell arteritis during 59 relapses

Symptom	Number (%)
Cranial	32 (54%)
Headache	25
Scalp tenderness	19
New temporal artery pain	6
Carotidynia	2
Jaw/tongue claudication	8
Visual	3 (5%)
Partial vision loss	1
Diplopia	1
Ischemic retinopathy	1
Musculoskeletal	38 (64%)
Polymyalgia rheumatica	24
Arthralgias	19
Limb claudication	5 (9%)
Upper extremity claudication	5
Lower extremity claudication	1
Constitutional (weight loss, fatigue)	8 (14%)

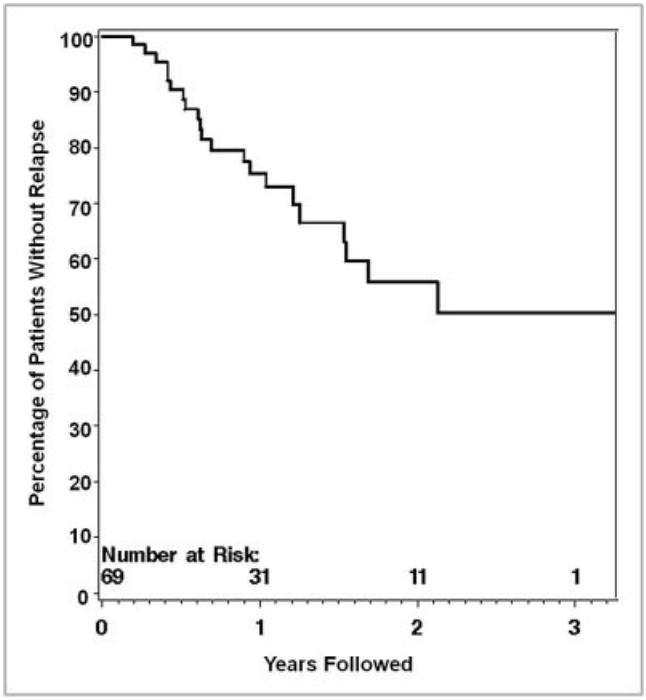

Figure. Time from diagnosis to first relapse in 69 patients with newly-diagnosed GCA

Conclusion: Relapses are common in GCA, occurring even 24 months after diagnosis. While headache and polymyalgia rheumatica were the most common manifestations at relapse, 2% of patients developed new visual symptoms and 4% had limb claudication. Both ESR and CRP were normal in one-third of the flares, highlighting the need for better biomarkers to assess disease activity. There remains an unmet need for more effective therapeutic alternatives to glucocorticoids.

1514

The Relationship Between the Polymyalgia Rheumatica Activity Score and Patient Reported Outcomes in Polymyalgia Rheumatica. EM McCarthy, Paul A. MacMullan, S. Al-Mudhaffer, A. Madigan, S. Donnelly, Cj McCarthy and G. M. McCarthy. Mater Misericordiae University Hospital, Dublin 7, Ireland

Background/Purpose: Patient reported outcomes(PROs) are increasingly being used for the assessment and monitoring of patients with rheumatic diseases. Standard PROs include the Health Assessment Questionnaire (HAQ),Visual Analogue Scale(VAS) for patient assessment of disease activity(VASDA) and VAS quality of life(VASQoL). PROs suitable for use in clinical care should be feasible with minimum respondent and administrative burden. In PMR, disease activity is measured using the PMR-AS as indicated by Leeb and Bird – PMR-AS = CRP(mg/dl) + VAS pain(0–10scale) + VASphysician (0–10scale)+Morning stiffness([min]x.1)+ Upper Limb Elevation (0–3 scale). Little data is available on how the PMR-AS reflects PROs.

Objectives: To prospectively evaluate the strength of correlation between PROs and PMR-AS in patients with known PMR and identify the best PRO measure for use in the clinical setting.

Methods: 60 patients with PMR were divided into Active disease (group 1, n=25) or Inactive disease(group 2,n=35), based on symptoms, physician assessment and ESR. Both groups underwent clinical and laboratory assessment at baseline and week 6. The following disease activity data were collected: PMR-AS, VasDA, VASQoL and HAQ. Between group disease activity data were assessed using Wilcoxon Signed Rank Test. Spearman's rank correlation coefficient(Spearman's rho) was used to directly compare the PMR-AS to the HAQ, VASDA and VASQoL. Measures of responsiveness including Standardised response means and effect size statistics were calculated for all outcome measures. Receiver operator curves (ROC) were calculated for the PROs.

Results: Demographic data was similar in all groups. Mean values for each disease measure are shown in Table 1. Disease activity scores improved significantly in the active group between week I and week 6 reflecting response to steroid treatment. There was no significant difference between the mean disease scores at week 6 in the Active group and the Inactive group.

Table 1. Mean disease measures at Weeks I and 6 in Active and Inactive Groups

	Active PMR-Week 1	Active PMR-Week 6	Wilcoxon p value	Inactive PMR –Week 1	Inactive PMR – Week6	Wilcoxon p value
PMR-AS	26.18	6.8	<.0001	5.16	4.8	n/s
HAQ	1.51	.51	<.0003	.53	.49	n/s
VASDA	7.38	2.78	<.0001	2.19	2.14	n/s
VASQoL	7.58	3.13	<.0001	2.08	2.19	n/s

Analysis of PMR-AS *vs* VASDA, VASQoL and HAQ showed correlation coefficients of 0.87(p<.001), 0.80(p<.001) and 0.68(p<.001), respectively.

VasDA and VasQoL are more responsive to change in disease activity than HAQ and PMR-AS (Table 2).

Table 2. Measures of responsiveness

	Standardised Response Means	Effect Size
VasDA	1.76	2.52
VasQoL	1.74	2.27
PMR-AS	1.54	1.84
HAQ	1.36	1.65

ROC analysis revealed VASDA to be more specific than either HAQ(.95 vs.85, p<.001) or VASQoL (.95 vs.93, p<.001) for the detection of response to treatment in active PMR.

Conclusion: VASDA, VASQoL and HAQ are strongly correlated with the PMR-AS. VASDA is more responsive to change in disease activity than the VASQoL, PMR-AS and HAQ. VASDA is inexpensive and easily administered in rheumatology clinics. We recommend its routine use in clinical practice.

1515

Plasma Fibrinogen Better Reflects patients' Functional Ability in Polymyalgia Rheumatica Than Either ESR or CRP. EM McCarthy, Paul A. MacMullan, S. Al-Mudhaffer, Anne M. Madigan, S. Donnelly, C. J. McCarthy and G M. McCarthy. Mater Misericordiae University Hospital, Dublin 7, Ireland

Background/Purpose: Measurement of disease activity in PMR is challenging due to the subjective nature of symptoms and absence of consistent physical signs in an elderly population.Previously we have demonstrated the enhanced specificity of fibrinogen over the standard biomarkers ESR and CRP for the detection of treatment response in patients with active PMR. The usefulness of patient reported outcomes(PROs) is increasingly being recognised in rheumatic disease. PROs reflect the impact of disease and its trearment from the patients perspective.Any biomarker that accurately reflects PROs in PMR would be of benefit in the clinical setting.

Objectives: To assess the correlation between patient reported outcomes(PROs) and the biomarkers fibrinogen, ESR and CRP in PMR.

Methods: 60 patients with PMR were divided into Active disease (group 1, n=25) or Inactive disease (group 2, n=35), based on symptoms, physician assessment and the standard biomarkers, ESR and CRP. Plasma fibrinogen was also measured. Groups underwent clinical and laboratory assessment at baseline and 6 weeks. PRO data collected included: Visual Analogue Scale(VAS) for patient assessment disease activity (VasDA), VAS for patient assessment of Quality of Life (VasQoL) and Health Assessment Questionnaire(HAQ). Demographic data were assessed using Fischers Exact Test and between group disease activity by Wilcoxon Signed Rank Test. Spearman's rank correlation coefficient was used to compare all biomarkers with the PROs. Standardised response means, a measure of a tests responsiveness to change, with a higher score indicating greater responsiveness were calculated for all 3 biomarkers.

Results: Demographic data was similar in all groups.There were significant differences in steroid dose between groups (15mg v 5mg) reflecting the institution of steroid therapy in the active group (p<.001). Mean scores for all PROs and biomarkers improved significantly in the

Active group between week 1 and week 6($p<0.001$).There was no significant difference between week 1 and 6 scores in the Inactive group (Table 1).

Table 1. Mean Scores for Patient Reported Outcomes and Biomarkers

	Active PMR-Week 1	Active PMR-Week 6	Wilcoxon p value	Inactive PMR – Week 1	Inactice PMR – Week 6	Wilcoxon p value
HAQ	1.51	.51	<.001	.53	.49	n/s
VASDA	7.38	2.78	<.001	2.19	2.14	n/s
VASQoL	7.58	3.13	<.001	2.08	2.19	n/s
Fibrinogen(g/L)	5.2	3.49	<.001	3.23	3.24	n/s
ESR(mm/hr)	59.6	24.3	<.001	17.6	18.3	n/s
CRP (mg/L)	45.9	12.6	<.001	5.2	5.3	n/s

All biomarkers showed significant correlation with the PROs ($p<.005$). Overall Fibrinogen showed superior correlation coefficients with the various PROs than either of the standard biomarkers ESR or CRP.

Table 2. Correlation coefficients of Patient Reported Outcomes and Biomarkers

	HAQ	VASDA	VASQoL
Fibrinogen	.51	.64	.61
ESR	.45	.57	.57
CRP	.39	.62	.64

Standardised Response Means for Fibrinogen, ESR and CRP were 1.63,1.2 and 1.05 respectively, indicating that plasma fibrinogen is the most responsive biomarker for assessment of change in disease activity.

Conclusion: Plasma fibrinogen better reflects PROs in PMR than the standard biomarkers ESR or CRP. It is also more responsive to changes in disease activity than either ESR or CRP. None.

1516

Sensitivity of the New EULAR/ACR Classification Criteria for Polymyalgia Rheumatica in Comparison with the Former Ones: A Single Centre Study. Pierluigi Macchioni, Maria Grazia Catanoso, Luigi Boiardi and Carlo Salvarani. Arcispedale S Maria Nuova, Reggio Emilia, Italy

Background/Purpose: To evaluate the diagnostic ability of the new ACR/EULAR classification criteria for PMR in a consecutive series of new onset PMR patients from a single centre.

Methods: All patients with suspected PMR seen at our centre are followed according to a standardized protocol which include clinical examination, determination of laboratory parameters, QOL questionnaire and US examination of shoulders and hips. Consecutive patients seen in our rheumatological centre with recent onset PMR and followed for at least 12 months were included prospectively during a 5 year period. Patients entered the study if diagnosis of PMR were confirmed at 12 month follow-up period according to rheumatologist opinion (PM). Diagnostic performance of new ACR/EULAR classification criteria were evaluated and compared to the sensitivity of the former diagnostic/classification criteria (Hunder's, Hazleman's, Bird's, Healey's criteria

Results: 112 patients entered the study (mean age 73.9+7.45y, female 72.3%, mean disease duration 13.8+2.8 w, mean ESR 62.6+20.9 mm/1sth, mean CRP 4.88+3.64 mg/dl, mean Leeb's index of disease activity 42.2+14.1). 103 (92%) pts had bilateral shoulders complains, 109 pts (97.3%) had increased levels of ESR/PCR, 74.1% had hip pain or LRM, 98.2% had normal RF and anti-CCP, 67% did not have peripheral joint involvement. At US examination 73.2% had bilateral shoulder involvement and 43.8% had US signs of at least one shoulder and one hip inflamed. 102 pts (91.1%) could be defined to have PMR according to the new ACR/EULAR classification criteria. Ninety-six pts (85.7%) satisfied the US criteria and no new patient could be diagnosed after US examination. Applying the former classification/diagnostic criteria 78.6% satisfied Hunder's criteria, 78.6% Healey's criteria, 59.8% Hazleman's criteria and 79.5% Bird's criteria.

Conclusion: In our series of recent onset PMR patients the new ACR/EULAR criteria seems to have higher sensitivity as compared to the previous criteria. US examination do not seem to have any impact to the sensitivity of these criteria.

1517

Annexin-A1: A Potential Novel Biomarker in Giant Cell Arteritis. Suchita Nadkarni[1], Jane Hollywood[2], Justin C. Mason[3], Bhaskar Dasgupta[4] and Mauro Perretti[1]. [1]Barts and the London School of Medicine, London, United Kingdom, [2]Southend Hospital, Southend, United Kingdom, [3]Imperial Coll/Hammersmith Hosp, London, United Kingdom, [4]Southend University Hospital, Essex, United Kingdom

Background/Purpose: Diagnosis of giant cell arteritis (GCA) relies on a multitude of parameters, including age of onset (>50yrs), temporal artery abnormalities (pulse) and abnormal temporal artery biopsies (ACR classification criteria 1990). Elevated ESR and CRP levels in serum are used as the gold standard laboratory diagnostic for GCA. However, these biomarkers are disease non-specific presenting the challenge to identify a GCA-specific biomarker. Annexin-A1 (AnxA1) is a 37-kDa glucocorticoid-regulated protein, abundant within the neutrophil, and rapidly mobilized to cell to the surface upon cell activation. Once mobilized, AnxA1 is able to exert anti-inflammatory actions including inhibition of leukocyte adhesion to the vessel wall during inflammation. Following activation, neutrophils (as well as other cells) are also capable of releasing microparticles (MP) into the plasma; these are small ($<1\mu m$), heterogeneous structures, which can induce cellular cross-talk and regulate inflammatory responses. Little is known about the role of neutrophils in GCA, classically identified as a T-cell-mediated disease. In the present study we report elevated AnxA1 on neutrophils and MP from patients with biopsy-positive GCA but not in disease controls, including polymyalgia rheumatica (PMR) and rheumatoid arthritis (RA). Thus, expression of AnxA1 on circulating neutrophils may be a potential biomarker for GCA.

Methods: Blood samples from GCA (n=8; F:M 6:2), were taken at week 1 post steroid commencement and every 4 weeks up to 24 weeks. Initial GCA steroid doses were 60mg/day, falling to 40mg, 20mg and 10mg at weeks 4, 12, and 24, respectively, with week 1 mean CRP levels at 106 mg/L, falling to 6mg/L at week 24. Using whole blood flow cytometry we have longitudinally measured AnxA1 protein expression on neutrophils and neutrophil-derived plasma microparticles, and used real-time PCR to detect AnxA1 gene expression in this cell type.

Results: Analyses revealed 50% of circulating neutrophils from GCA patients expressed AnxA1 on their surface 1-week post steroid treatment. Levels of expression steadily declined during the 24-week observation period, with only 20% of neutrophils expressing AnxA1 at 24-weeks post-steroid intervention. High AnxA1 expression was not observed on neutrophils from patients with PMR or RA: only 20% of circulating neutrophils expressing AnxA1 in either control patients. Furthermore, AnxA1 expression was largely confined to the neutrophils, as neither monocytes nor lymphocytes displayed high levels of AnxA1 on their surface.

AnxA1 levels were also detected in GCA patient plasma MP, with neutrophil-derived MP expressing high AnxA1 at week 1. The expression profile correlated with their circulating cell counterparts during the 24-week period. Finally, real-time PCR analysis revealed a 3-fold decrease in AnxA1 gene expression at week 24 when compared to week 1.

Conclusion: Taken together, we propose high AnxA1 expression on neutrophils could be a potential and novel disease-specific biomarker for GCA.

1518

Prospective Evaluation of Aortic Structural Damage (aneurysm/dilatation) Using a Predefined Screening Protocol in Biopsy-Proven Giant-Cell Arteritis Patients with Extended Follow-up. Ana García-Martínez, Pedro Arguis, Sergio Prieto-González, José Hernández-Rodríguez, Georgina Espígol, Marc Corbera, Marco Alba, Itziar Tavera-Bahillo, Ester Planas and María Cinta Cid. Vasculitis research unit. Hospital Clínic. University of Barcelona. IDIBAPS, Barcelona, Spain

Background/Purpose: In a previous cross-sectional evaluation of 54 patients with biopsy-proven giant-cell arteritis (GCA) we found that 22.2% (12 patients) had significant aortic structural damage (ASD) (aneurysm/dilatation) after a median follow-up of 5.4 years. Development of ASD was not related to persistence of clinically apparent disease or elevation of acute-phase reactants or pro-inflammatory cytokines during follow-up (García-Martínez A et al. Arthritis Rheum 2008). The outcome of ASD after longer follow-up has never been prospectively evaluated.

Methods: Patients from the previously evaluated cohort who continued their follow-up visits in our department were subjected to the same screening protocol every four years approximately. The aim was to assess the development of new ASD and the outcome of previously detected abnormalities. The screening protocol consisted of a chest X-ray and a CT scan if aortic

aneurysm was suspected or changes respect to the baseline X-ray were observed. The abdominal aorta was evaluated by ultrasonography (US). ASD was defined when the ascending aorta measured > 4 cm in diameter, the aortic arch or the descending aorta ≥ 4cm, the abdominal aorta > 3 cm or, when the aorta exhibited a fusiform dilatation. Results were compared to those obtained from the previous screening.

Results: Eighteen of the 54 patients from the original cohort had died or were lost of follow-up before they could be evaluated a second time. The remaining 36 patients were subjected to a new screening (median follow-up at the time of second screening 8.5 years, range 8–12). In 7 of these patients ASD had been detected in the previous evalutation (1 involving the abdominal aorta and 6 the thoracic aorta). In the second screening the abdominal aneurysm remained stable whereas thoracic ASD increased in diameter. Three patients had newly discovered thoracic ASD not detected in the first screening. One of them died of an aortic dissection 9 years after the diagnosis of GCA. The remaining 26 patients did not show changes in the chest X-ray when compared to the baseline X-ray, or, if changes were suspected, the CT scan did not evidence significant aortic abnormalities. No new abdominal aneurysms were observed by US. To date, six patients have been subjected to a third screening, with no evidence of new ASD in any of them. Overall, 27.7 % of patients from the original cohort developed ASD after a median follow-up of 10 years (range 4.3–15).

Conclusion: Our study suggests that GCA-patients develop ASD mainly but not exclusively, within the first 5 years of follow-up. Once ASD occurs, dilatation increases over time, particularly in the thoracic aorta underlining the need for periodic evaluation. These results should be confirmed in a larger series of patients.

1519

Clinical Profile and Therapeutic Approaches in Polymyalgia Rheumatica: Is hydroxychloroquine a Useful Steroid-Sparing Agent in the Management of the Disease? Rosaria Talarico, Nicolò Giusti, Anna d'Ascanio, Pasquale Pepe, Maurizio Mazzantini and Stefano Bombardieri. Rheumatology Unit, Pisa, Italy

Background/Purpose: Polymyalgia rheumatica (PMR) is a relatively common syndrome of the elderly, characterized by severe pain and stiffness in the neck shoulder and pelvic girdles, along with increased acute phase reactants. The therapeutic approach to PMR remains mainly based on glucocorticoids (GC); however, growing studies suggest a steroid-sparing effect of some DMARDs in PMR.

The primary aim of this study was to retrospectively study the clinical findings in a cohort of patients with PMR. A secondary aim was to evaluate the therapeutic approaches used, comparing the efficacy of GC alone versus GC plus DMARDs.

Methods: We carried out an analysis by review of the medical documentation of all consecutive patients with a diagnosis of PMR seen in the last twenty years. Epidemiological and clinical data as well as drugs administered were evaluated. In order to evaluate the efficacy of the therapies received, we evaluated the number of disease relapse observed during the follow-up, defining relapse any further clinical manifestations compatible with the clinical spectrum of PMR and/or an increase of ESR ≥ 40 mm/hour, not otherwise justifiable, that required higher doses or new introduction of GC therapy.

Results: Five hundred patients (157 males and 343 females, mean age 77.6±8 years, mean age at disease onset 70±8 years; mean disease duration 34.5±30 months) were studied. The most frequent clinical features at disease onset were: pain of the shoulder and pelvic girdle 93%, stiffness of the neck 51%, peripheral arthritis 30%, fever 25%, fatigue 22%, anorexia and weight loss 7%; moreover, 89% of the patients had presented at the onset an erythrocyte sedimentation rate (ESR) higher than 40 mm/1st hr ± abnormal C reactive protein (CRP), while 7% presented isolated increased levels of CRP. A diagnosis of giant cell arteritis (GCA) was made in 25 patients, of which 65% at the onset of PMR and 35% during the follow-up. Any epidemiological difference was noted between isolated PMR and PMR/GCA patients. Fifty-nine percent of patients received GC alone, while the others were treated with GC plus DMARDs (methotrexate 48%, hydroxychloroquine 42%, others 10%). A significant difference was observed in the number of disease relapse, that was 305 in the group of GC alone and 196 in the group of GC plus DMARDs; specifically, the lower number of relapses was observed in those patients who received hydroxychloroquine.

Conclusion: The clinical spectrum of PMR seems quite typical, but on the other hand we certainly need large trials and longer observational studies to make more clear the therapeutic algorithm of the disease. According to the literature data, our results had shown that antimalarials brought the disease under control in the majority of patients, therefore it could be appropriate to study their early introduction in PMR management.

1520

Does Ultrasonography Guidance Increase the Yeld of Temporal Artery Biopsy in Patients with Giant Cell Arteritis? Preliminary Results From a Single-Blinded Randomized Study. Giuseppe Germanò, Nicolo Pipitone, Luigi Boiardi, Ilaria Chiarolanza, Luca Cimino, Maria Grazia Catanoso, Andrea Caruso and Carlo Salvarani. Arcispedale S Maria Nuova, Reggio Emilia, Italy

Background/Purpose: Temporal artery (TA) biopsy (TAB) is the gold standard to diagnose giant cell arteritis (GCA), but is negative in approximately 20% of patients. Aims: The study aimed to establish whether Color-doppler-ultrasonography (CDS)-guided TAB might provide a greater yield compared to standard TAB technique.

Methods: We enrolled 76 consecutive patients with suspected GCA from September 2009 through May 2011. Patients were randomized to undergoing CDS-guided TAB (group 1), or to undergoing TAB performed according to conventional technique (group 2). All patients were evaluated by physical examination of the temporal arteries (PETA), CDS and TAB. 2 patients were excluded because biopsy showed no evidence of arterial walls. 43/74 patients were taking prednisone at a mean dose of 17.3 mg/day and 7/43 had been taking steroids for <2 weeks. CDS was carried out by a physician blinded to the clinical data of the patients. CDS was performed using a ESAOTE MyLab 70 device fitted with a LA435 probe set on "standard" CDS vascular examination mode. The common trunk and the main branches of the TA were screened in a longitudinal and transverse plane along the entire vessel. In patients from group 1 the ultrasonographist marked with a dermographic pen the segment of the TA which showed the largest halo (if present). In the absence of a clear-cut halo, a site with doubtful halo, stenosis, occlusion, or wall thickening was marked. The surgeon performed the TAB in the segment marked by the ultrasonographist in patients from group 1, while TAB was carried out according to standard procedure in patients from group 2. PETA was performed before CDS. PETA was considered positive in the presence of tenderness or decreased/absent pulse of the TA. Fisher's exact test was used for statistical analysis. Informed consent from the patients and approval from the local Ethics Committee were obtained.

Results: TAB was positive in 13 patients in group 1 and 12 in group 2 (NS). In total, the halo was detected in 20 patients from group 1 and 12 in group 2 (NS). The full results are shown in Table I.

Conclusion: CDS-guided TAB was associated with a significally greater probability of being positive (OR 3..4, 95% CI=1.1–10.4). However, the percentage of TAB-positive patients was similar regardless of whether TAB was performed under CDS guidance or not.

Table 1.

	Group 1 (n=35)	Group2 (n=39)	p	OR (95% CI)
	CDS-guided TAB	Standard TAB		
Gender	M:12; F:23	M: 10; F:29	—	—

Incidence of Peripheral Vascular Disease and Myocardial Infarction Among Patients with Giant Cell Arteritis. Gunnar Tomasson[1], Christine Peloquin[1], Thorvardur Love[2], Aladdin Mohammad[3], Yuqing Zhang[1], Hyon K. Choi[1] and Peter A. Merkel[1]. [1]Boston University School of Medicine, Boston, MA, [2]Landspitali University Hospital, Reykjavík, Iceland, [3]Skåne University Helsingborg, Lund, Sweden

Background/Purpose: Involvement of the primary branches of the aorta is well documented among subjects with giant cell arteritis (GCA), but few studies have explored the association between GCA and peripheral vascular disease (PVD) or myocardial infarction (MI). The objective of this study was to determine the association of GCA with incident PVD and MI in a large population cohort.

Methods: Data from The Health Improvement Network (THIN), a medical record database of 7.3 million patients from general practices from across the United Kingdom, were used. Subjects with GCA were identified as those with diagnostic codes for GCA followed by prescription for glucocorticoids occurring at least one year after enrollment into the database. For each subject with GCA, five subjects free of GCA at the time of diagnosis of GCA for the index subject were selected to a reference group, matched on age, sex, and entry-time to the database. Outcome was defined as having a diagnostic code for PVD or MI respectively. Information on cardiovascular risk factors: smoking, hypertension (HTN), diabetes mellitus (DM), blood lipids, and body mass index (BMI) was obtained from health records for the period prior to the diagnosis of PVD or MI. Subjects with PVD or MI at baseline were excluded from the analysis. Subjects were followed until the occurrence of study outcomes or the time of censoring; censoring occurred when subject exited the database, developed GCA (for reference subjects only), or reached the study's common close out date of June 2010. Cox proportional hazards models were constructed to determine the association between GCA and study outcomes adjusted for cardiovascular risk factors. The analyses were stratified according to age and sex to account for matching in the data.

Results: There were 3,676 subjects that met criteria for incident GCA between January 1990 and January 2010. Median follow-up time was 4.2 years (IQR: 1.8–7.7), for both exposed and reference subjects. Current smoking, HTN, and DM were somewhat more common among exposed compared to reference subjects. During the follow-up time 80 (2.2%) of 3,676 subjects with GCA developed PVD and 204 (1.1%) of 18,430 reference subjects (1.2%) developed PVD. Subjects with GCA had a greater than two-fold increased risk of PVD, HR=2.12 (95% CI: 1.60–2.80), this effect estimate was almost identical among the 13,978 subjects (63.2%) with complete data with respect to smoking, BMI and blood lipids. After adjustment for cardiovascular risk factors there was no attenuation in the risk estimate for PVD, HR=2.44 (95% CI: 1.58–3.75). Out of 3,676 subjects with GCA, 194 (5.3%) had MI compared with 472 (2.6%) of 18,430 reference subjects, HR=2.26 (95% CI: 1.88–2.72), this effect estimate was slightly lower among those with complete data with respect to respect to smoking, BMI, and blood lipids, HR=1.91 (95% CI:1.50–2.43). After adjustment for cardiovascular risk factors there was no attenuation in the risk estimate for MI, HR=1.85 (95% CI: 1.45–2.36).

Conclusion: Patients with GCA have a two-fold elevated risk of PVD and MI compared to a reference group, even after adjustment for cardiovascular risk factors

1522

Incidence of Cerebrovascular Accidents Among Patients with Giant Cell Arteritis. Gunnar Tomasson[1], Christine Peloquin[1], Thorvardur Love[2], Aladdin Mohammad[3], Yuqing Zhang[1], Hyon K. Choi[1] and Peter A. Merkel[1]. [1]Boston University School of Medicine, Boston, MA, [2]Landspitali University Hospital, Reykjavík, Iceland, [3]Skåne University Helsingborg, Lund, Sweden

Background/Purpose: Giant cell arteritis (GCA) generally spares intracranial arteries but an increased incidence of cerebrovascular accidents (CVA) has been reported among patients with GCA. The objective of this study was to determine the association of GCA with incident CVA in a large patient cohort, after adjustment for cardiovascular risk factors.

Methods: Data from The Health Improvement Network (THIN), a medical record database of 7.3 million patients from general practices from across the United Kingdom, were used. Subjects with GCA were identified as those with diagnostic codes for GCA followed by prescription for glucocorticoids occurring after at least one year after enrollment into the database. For each subject with GCA, five subjects free of GCA at the time of diagnosis of GCA for the index subject were selected to a reference group, matched on age and sex and entry-time to the database. Outcome was defined as having a diagnostic code for vaso-occlusive-, hemorrhagic- or unspecified CVA. Information on cardiovascular risk factors, including smoking, hypertension, diabetes mellitus, blood lipids, and body mass index, were obtained from corresponding diagnostic and additional health records codes, and medications codes, occurring prior to the diagnosis of CVA. Subjects with no codes for hypertension or diabetes mellitus were considered free of those diseases. Subjects with CVA at time of diagnosis of GCA or, for the reference group, at the time of diagnosis of GCA for the index subject, were excluded from the analysis. Subjects were followed until the occurrence of CVA or the time of censoring; censoring occurred when subjects exited the database, developed GCA (for reference subjects only), or reached the study's common close out date of June 2010. Cox proportional hazards models were constructed to determine the association between GCA and CVA, adjusted for cardiovascular risk factors. The analyses were stratified according to age and sex to account for matching in the data.

Results: There were 3,811 subjects that met criteria for incident GCA between January 1990 and January 2010, included. Median follow-up time was 4.2 years (inter-quartile range: 1.8–7.7), for both exposed and reference subjects. Current smoking, hypertension, and diabetes mellitus, were slightly more common among exposed compared to reference subjects. During the follow-up time, 160 of 3,811 subjects with GCA (4.2%) had CVA and 626 of 18,763 subjects in the reference group (3.3%) had CVA. Subjects with GCA had a significantly increased risk of CVA, HR=1.40 (95% confidence interval (CI) 1.17–1.69), this effect estimate was somewhat higher among the 14,573 subjects (63.7%) with complete data with respect to cardiovascular risk factors, HR=1.70 (95% CI: 1.28–2.27). After adjustment for cardiovascular risk factors there was no attenuation in the risk estimate, HR=1.71 (95% CI: 1.27–2.29).

Conclusion: Patients with GCA have an elevated risk of CVA, after adjustment for cardiovascular risk factors.

1523

Age At Onset and Gender Are Associated with Differences in Giant Cell Arteritis (GCA) Initial Presentation and Outcome. Marco A. Alba, Ana García-Martínez, Itziar Tavera-Bahillo, Sergio Prieto-González, Georgina Espígol, Jose Hernandez-Rodriguez and Maria C. Cid. Vasculitis research unit. Hospital Clínic. University of Barcelona. IDIBAPS, Barcelona, Spain

Background/Purpose: GCA is a chronic inflammatory disease involving large and medium-sized arteries. It is considered the most frequent primary vasculitis with higher incidence in women. Mean age of onset in different cohorts ranges between 72–74 years. Former studies have observed certain differences in GCA clinical spectrum depending on age at disease presentation and gender. Particularly polymyalgia rheumatica has been found to be more frequent in women and in patients younger than 70 years. The purpose of this study was yo evaluate differences in initial clinical manifestations, ischemic complications and clinical course according to age at onset and gender in a prospectively followed cohort of patients with biopsy-proven giant cell arteritis.

Methods: Between 1995 and 2005, 170 patients were diagnosed with biopsy proven GCA at our institution. Among them, patients with the following criteria were selected: prospective treatment by the authors according to uniform criteria, prospective recording of GCA-presentation, related complications, relapses, periodic screening for aneurysm, glucocorticosteroid doses, and follow-up duration of at least 4 years.

Based on the mean ± standard deviation (SD) of age at disease onset, patients were classified in 3 groups: age equal or below 67 years (mean -1SD) (early onset), age between 68 and 80 years, and age equal or older than 81 (mean+1SD) (late onset). Ninety-four patients fulfilled the selection criteria and were eligible for this study. Although retrospective in design, the study was performed on a prospectively followed cohort. Chi-square test, ANOVA test and Kaplan-Meyer survival analysis/log-rank test were used for statistical comparison.

Results: Mean age (±SD) at diagnosis was 74±7 years (58–89). Patients with early onset GCA (≤67 years) presented more frequently fever (p=0.002), and had higher erythrocyte sedimentation rate (0.039) than patients >68 years. Subsequent clinical course of this group did not differ from patients with disease onset between 68–80 years and >81 years. In contrast, late onset GCA (≥81 years) was characterized by higher prevalence of severe ischemic complications in the form of amaurosis fugax (6% for ≤67 years vs 9% for 68–80 vs 29% for ≥81 years, p=0.046) and blindness (6% for ≤67 years vs 7% for 68–80 vs 33% for ≥81 years, p=0.006). During follow-up, late onset GCA patients relapsed less frequently (p=0.027). Concerning to gender, we found no differences in the initial clinical presentation between men and women but men developed more frequently aortic aneurysm during follow-up (p=0.003).

Conclusion: Age at onset and gender are associated with differences in clinical presentation and outcome in patients with GCA

1524

Development of Ischemic Complications In Patients with Giant Cell Arteritis Presenting with Apparently Isolated Polymyalgia Rheumatica. Paula Estrada, Javier Narvaez, Laura Lopez-Vives, Irene Martín-Esteve, Carmen Gomez-Vaquero and Joan Miquel Nolla. Hospital Universitario de Bellvitge, Barcelona, Spain

Background/Purpose: Controversy exists over the risk of ischemic complications in patients with giant cell arteritis (GCA) presenting with apparently isolated polymyalgia rheumatica (PMR). Recent studies that have

analyzed this issue give conflicting results. Our objective was to investigate the frequency and type of GCA-related ischemic complications in a series of patients with GCA who, for a substantial period of time (at least 2 months), lacked vascular symptoms and presented with apparently isolated PMR.

Methods: Between 1986 and 2010, 159 patients were diagnosed with GCA by the Department of Rheumatology within the Hospital Universitario de Bellvitge (Barcelona, Spain), a referral, tertiary care hospital. Patients were diagnosed with GCA if they had a positive temporal artery biopsy (TAB) or, in cases with negative or no biopsy, if the fulfilled the remaining four ACR criteria for the classification of GCA and had a prompt and persistent response to corticosteroid treatment.

Patients that developed GCA on a background of a prior history of PMR were selected for the study. The diagnosis of PMR was based on the criteria proposed by Chuang et al *(Ann Intern Med 1982;97:672–80).* Patients were considered to have *severe ischemic manifestations* if they suffered visual ischemic manifestations, cerebrovascular accidents (stroke and/or transient ischemic attacks), jaw claudication, or large-artery stenosis of the extremities that caused signs of occlusive manifestations (limb claudication) of recent onset. For the purpose of this study, severe ischemic complications were attributed to GCA if they occurred within the time between the onset of GCA symptoms and 4 weeks after the onset of corticosteroid therapy

Results: Sixteen patients (10%) developed GCA on a background of a prior history of PMR. These 16 patients were diagnosed as having isolated PMR because they did not have clinical evidence of GCA at the time of diagnosis and showed a prompt response to low-dose steroid therapy (10 to 20 mg/d of prednisone), with normalization of the acute-phase reactants. Despite this observation, they later experienced an arteritic relapse during the course of steroid treatment. The median time to arteritic relapse from initiation of therapy was 214 ± 173 days and the total dose of prednisone received was 1707 ± 1268 mg (average daily dose, 7.2 ± 1.3 mg/d). Relapses usually occurred during the tapering of the prednisone dose or as a consequence of an unauthorized discontinuation of treatment (one case). Temporal artery biopsy was positive in 75% (12/16) of these cases.

Severe GCA-related ischemic complications were observed in 37.5% (6/16) of the patients (4 patients presented with 2 or more events): jaw claudication in 2 patients (12%); visual manifestations in 6 (35%), including 4 cases of amaurosis fugax and 2 cases of permanent visual loss; strokes in 2 (12%); and 1 case (6%) of upper limb claudication due to reversible stenosis of the axillary artery.

Conclusion: Patients with GCA presenting with apparently isolated PMR are not a benign subset and have a significant risk of developing severe ischemic complications (37.5% of the cases).

1525

Frequency of Pulmonary Arterial Hypertension Is Not Increased in Takayasu's Arteritis. Melike Kalfa[1], Oktay Musayev[2], Hakan Emmungil[1], Ozgul Soysal[3], Zevcet Yilmaz[1], Vedat Inal[1], Servet Akar[3], Nurullah Akkoc[3], Fatos Onen[3], Meral Kayikcioglu[2], Gokhan Keser[1] and Kenan Aksu[1]. [1]Dept. of Internal Medicine, Division of Rheumatology, Ege University, Izmir, Turkey, [2]Dept. of Cardiology,Ege University, Izmir, Turkey, [3]Dept. of Internal Medicine, Division of Rheumatology, Dokuz Eylül University, Izmir, Turkey

Background/Purpose: Takayasu's arteritis (TA) is an inflammatory disease that affects large and medium-sized arteries, especially the aorta and its branches. Although pulmonary artery involvement is common, the clinical manifestation is rare. In this study, we examined the presence of pulmonary arterial hypertension (PAH) in TA patients by using transthoracic Doppler echocardiography.

Methods: Seventy patients with TA (mean age 42.07±10.44 years; F/M: 63/7) diagnosed according to the 1990 American College of Rheumatology criteria were enrolled in this study. The control groups included 67 systemic sclerosis (SSc) patients (56.66±11.57 years; F/M:59/8) and 68 healthy controls (39.50±9.53 years; F/M: 61/7). Transthoracic Doppler echocardiography was performed by the same cardiologist to all the participants, and systolic pulmonary artery pressure (SPAP) was calculated for each individual. In accordance to ESC-ERS guideline, possible diagnosis of PAH was considered only in patients having SPAP>50 mmHg, with or without additional echocardiographic findings suggestive of PAH. SPSS 15.0 was used for statistical analysis. P value <0.05 was accepted as statistically significant.

Results: Mean SPAP values in TA, SSc and healthy control groups were 20.93±6.06, 31.57±12.75, and 18.88±5.385 mmHg, respectively. While SPAP values in SSc group were significantly higher than the other two groups ($p<0.001$), there were no differences between TA and healthy groups ($p=0.167$). Based upon the ESC-ERS guideline definition, possible PAH was present in 5 out of 67 SSc patients (7.4%). However, although pulmonary artery involvement was present in 4 out of 70 TA patients (5.6%), none of these had PAH.

Conclusion: Using transthoracic Doppler echocardiography and the ESC-ERS guideline, none of our TA patients, including those with pulmonary artery involvement fulfilled the criteria of possible PAH. Although the exact diagnosis of PAH requires classical angiography, our echocardiographic findings suggest that frequency of PAH is not increased in TA.

Lower Respiratory Tract Involvement In Relapsing Polychondritis. Elisa Perry[1], Shirish Sangle[2], Rebecca Preston[1] and DP. D'Cruz[3]. [1]St Thomas' Hospital, London, United Kingdom, [2]Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom, [3]St. Thomas' Hospital, London, United Kingdom

Background/Purpose: Relapsing polychondritis (RP) is a rare autoimmune condition characterized by cartilaginous inflammation, degeneration and destruction. Airway involvement in RP is associated with high morbidity and mortality. Our purpose is to present the clinical and imaging features of airway involvement in patients with RP.

Methods: We retrospectively reviewed 28 patients with a diagnosis of RP who fulfilled Adam's criteria for RP. The studies were performed on 16 slice helical computer tomography (CT) scanners with collimation of 0.625 and 1.5mm, pitch of 0.98 and 1.074mm and reconstruction interval of 1mm respectively. All patients had inspiratory and expiratory images performed from thoracic inlet to diaphragm with or without intravenous contrast medium. All images were available in both soft tissue and lung window settings. All patients underwent Computed Tomography (CT) scan of the thorax in inspiratory and expiratory phase. Two radiologists reviewed all studies simultaneously with consensus agreement.

Results: Nineteen of 28 (68%) patients had abnormal imaging and 9/28 (32%) had normal imaging. The median age of patients with abnormal imaging was 50 years (26–68) at the time of imaging and disease duration was 7.1 (0.9–24.2) years. There were 24 Caucasians, 3 Afro-Caribbean and 1 Indian Asian in origin. Other clinical manifestation in this group were: auricular involvement (18/28), respiratory tract/thoracic symptoms (19/28), ocular involvement (17/28), nasal chondritis (15/28), arthritis (9/28) and constitutional symptoms (4/28). Of those with respiratory manifestations, symptoms included dyspnoea, tracheitis, stridor, sore throat, hoarse voice, costochondritis, chest pain, laryngeal cartilage tenderness and lower respiratory tract infective symptoms. One patient also had pulmonary emboli.

Characteristic changes seen in patients with abnormal imaging were: airway malacia (79%), increased wall attenuation (74%), airway wall thickening (68%), gas trapping (57%) and airway narrowing (53%). In one patient increased wall thickening and attenuation involved the posterior tracheal membrane, which has not been previously reported.

Conclusion: The most prevalent airway abnormalities seen in RP were of airway malacia (79%) and increased wall attenuation (74%). Respiratory tract involvement (68%) may be more extensive and prevalent than previously thought.

1527

Ischemic Colitis (IC) Associated with Rheumatic Diseases; A Colonoscopic Study of 23 IC Cases. Ikuko Masuda[1], Masako Hara[1], Hisae Ichida[2], Kae Takagi[2], Takahisa Gono[2], Yasuhiro Katsumata[2], Yasushi Kawaguchi[2] and Hisashi Yamanaka[2]. [1]International University of Health and Welfare, Sanno Hospital, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Ischemic colitis is caused by various predisposing factors such as arterosclerosis. Although patients with connective tissue disorders, such as systemic lupus erythematosus (SLE), are at risk for various ischemic events due to wide-spread vasculitis of small vessels, ischemic colitis is not common gastrointestinal complication. We herein reported 23 cases of ischemic colitis associated with various rheumatic diseases.

Methods: This retrospective colonoscopy study was performed on 600 consecutive patients with various rheumatic diseases from 2004 to 2008. Diagnosis of ischemic colitis was established from colonoscopic and pathologic findings. Written informed consent was obtained from each patient before colonoscopic examination. Clinical variables were obtained for all patients including age, gender, presenting symptoms, and associated risk factors.

Results: We have identified twenty-three cases of ischemic colitis, including 7 SLE, 5 rheumatoid arthritis/rheumatoid vasculitis, 4 scleroderma, 3 myositis, and 2 vasculitis syndrome, out of 600 patients. Twelve of twenty-three cases had gastrointestinal ischemic episodes such as abdominal pain or hematochezia. Ischemic colitis had been reported to be an uncommon gastrointestinal complication in patients with SLE. However, seven out of 74 SLE patients (9.4%) examined were diagnosed as ischemic colitis, which was significantly higher frequency than those with rheumatoid arthritis/rheumatoid vasculitis (5 out of 177 patients; 2.8%). Also, the age group of ischemic colitis with SLE was much younger than ischemic colitis with other rheumatic diseases (35 year old vs 76 year old). One of the SLE patients developed near-circumferential rectal ulcer and perforation in later year, where is very rare as a location of regular ischemic colitis.

Conclusion: Ischemic colitis with rheumatic diseases may not be uncommon as had been reported since half of our patients were asymptomatic. Colonoscopic screening may be useful to discern ischemic colitis associated with hidden intestinal vasculitis in patients with rheumatic diseases.

1528

Presentation and Outcome of Hepatitis C Virus-Related Mixed Cryoglobulinemia Cardiomyopathy. Benjamin Terrier[1], Alexandre Karras[2], Philippe Cluzel[3], Jean-Philippe Collet[4], Damien Sène[5], David Saadoun[6] and Patrice Cacoub[5]. [1]Pitié-Salpêtrière Hospital, Paris, France, [2]Nephrology, HEGP, Paris, France, [3]Radiology, Pitié-Salpétrière, Paris, France, [4]Cardiology, Pitié-Salpétrière, Paris, France, [5]CHU Pitié-Salpêtrière, Paris, France, [6]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France

Background/Purpose: Hepatitis C virus (HCV) infection may be responsible for mixed cryoglobulinemia vascultitis, ranging from mild clinical symptoms to fulminant life-threatening complications. In primary systemic vasculitides, cardiac manifestation is associated with a poor outcome and treated with immunosuppressive therapy. Cardiac involvement during HCV-related systemic vasculitis has never been evaluated. Objective: To describe clinical presentation and to evaluate clinical outcome of cardiac manifestation during HCV-related systemic vasculitis in the antiviral therapy era.

Methods: Data from 165 patients with HCV-related systemic vasculitis were retrospectively reviewed to describe the clinical presentation of HCV-related systemic vasculitis with cardiac manifestation and to compare clinical outcome of patients with (n=7) and without cardiac (n=158) involvement.

Results: The prevalence of cardiac manifestation was low (n=7.4%) and revealed by thoracic pain and congestive heart failure manifestations mostly (n=4 each, 57%). Cardiac imaging showed dilated cardiomyopathy in 5 patients and hypertrophic cardiomyopathy in 1. In multivariate analysis, patients with cardiac manifestations had more frequently B-cell non-Hodgkin lymphoma [odds-ratio (OR) 18.1; 95% CI, 2.8–116.7; P=0.0023)] and gastrointestinal involvement (OR 14.6; 95% CI, 2.0–104.9; P=0.0078). All cardiac manifestations were reversible early after the initiation of corticosteroids and agressive immunosuppressive therapy. However, after a median follow-up of 19 months, 3 patients (43%) died. Respective 6-month, 1-year and 2-year survival rates in patients with and without cardiac involvement were 86 and 99%, 71 and 96%, and 48 and 90%. Overall survival was significantly associated with cardiac involvement (HR 5.01, P=0.003). The analysis of causes of death, however, showed that they were more frequently related to extra-cardiac manifestations.

Conclusion: Cardiac damage is a rare manifestation of HCV-related vasculitis, associated with B-cell lymphoma and life-threatening manifestations. Despite a favorable early outcome, patients with cardiac damage had a poorer survival than those without.

1529

Lymphoma Prevalence in Patients with Serum Cryoglobulins with or without Cryoglobulinemic Vasculitis: Data Extrapolated From the Cryoglobulinemic Vasculitis Classification Criteria Database. Orsola-Malpighi Hospital, Bologna, Italy, [11]Dipartimento Apparato Locomotore, AOU Policlinico di Modena, Modena, Italy, [12]Section of Internal Medicine and Clinical Oncology, Department of Biomedical Sciences and Human Oncology, University of Bari, Medical School, Bari, Italy, [13]CHU Pitié-Salpêtrière, Paris, France, [14]University Medical Centre Ljubjana, Ljubljana, Slovenia, [15]Via Roma 67, Pisa, Italy, [16]Internal Medicine Unit, Policlinico San Marco, Bergamo, Italy, [17]viale Morgagni 85, Florence, Italy, [18]Rheumatology Unit, M. Scarlato Hospital, Scafati, Salerno, Italy, [19]Hematology, S.Gerardo Hospital, Monza, Italy, [20]Clinique Saint-Jean, Brussels, Belgium, [21]Oskar-Alexander-Street 26, Bad Bramstedt, Germany, [22]Rheumatology Unit, Pisa, Italy, [23]Istituto di Malattie Infettive e Tropicali, Università di Milano c/o Ospedale L. Sacco, Milano, Italy

Background/Purpose: Patients with cryoglobulinemic vasculitis (CV) or serum cryoglobulins without CV (CwV) a have an increased risk of lymphoma development. We compared the prevalence of lymphoma in HCV-positive or -negative patients with cryoglobulinemia.

Methods: Fifty hundred patients with positive serum cryoglobulins were studied. Mean age was 60.77±13.75 years, they were 356 females (71.2%) and 144 males (28.8%), and the first cryoglobulin positivity occurred thirty-four months before the last evaluation (range 3–290 months). 272 patients had CV (54.4%). The other 228 patients (45.6%) had other diseases associated with CwV. One hundred and seventeen HCV negative patients were collected and they were 42/272 (15.4%) among CV, while they were 75/228 (32.9%) among CwV.

Results: Globally, a lymphoma was diagnosed in thirty-two patients (32/500, 6.4%). Of them, fourteen patients were HCV negative (14/32, 43.7%). Furthermore, lymphoma was diagnosed in 18/383 HCV positive patients (4.7%), and 14/117 HCV negative patients (11.9%) (p=0.005, Pearson). Among the 18 HCV positive patients with lymphoma, a CV was present in 16/18 (88.9%), while among the 14 HCV negative patients with lymphoma, a CV was present in 10/14 (71.4%). In HCV positive, as well as in HCV negative patients, the diagnosis of a CV increases the risk of almost 5–6 times the risk of lymphoma (p=0.022, OR 5.7, 95% CI 1.3–25.1, and p=0.006, OR 5.5, 95% CI 1.6–19.0 for HCV positive and HCV negative patients, respectively). Among HCV negative patients, a Sjögren's syndrome (SS) was diagnosed in 55/117 (47%).

Conclusion: CV, much more than CwV, is associated with lymphoma prevalence. Lymphoma prevalence is higher in CV without HCV infection than in CV associated with HCV infection. Thus, lymphoma should be suspected with much higher attention in HCV negative CV patients, who often suffered from SS.

1530

Comparison of Clinical and Laboratory characteristics of Cryoglobulinemic Vasculitis Associated with Primary Sjögren's Syndrome and Hepatitis C Virus Infection. Svetlana G. Palshina[1] and Vladimir I. Vasiljev[2]. [1]Scientific research institute of rheumatology of RAMS, Moscow, Russia, [2]Scientific research institute of rheumatology of RAMS, Moscow, Russia, Moscow, Russia

Background/Purpose: To compare the clinical manifestations and laboratory data of cryoglobulinemic vasculitis (CV) in patients with primary Sjögren's syndrome (pSS) and hepatitis C virus (HCV) infection.

Methods: There were 54 patients with authentic CV included in the research, of whom 22 patients had HCV infection (group 1) and 32 - pSS

(group 2). The mean age in the cohort was 53,4 ±11,9 years, median duration of CV was 5 years (range, 0,75 −31), without statistical differences in the groups (p> 0,1). Females prevailed in both groups (92.6%). Kidney and liver involvement was confirmed morphologically. Electroneurophysiological methods evaluated the character of peripheral neuropathy. pSS/sSS fulfilled Russian criteria of SS. Real-time PCR, ELISA were performed for HCV. Lymphoma was confirmed morphologically/immunomorphologically after affected organ biopsy + bone marrow biopsy. Type of monoclonal secretion was assessed with high-resolution electrophoresis in agarose gel with subsequent immunofixation of sera and concentrated urine.

Results: There were no statistical differences (p> 0,05) in two groups in frequency of clinical symptoms such as purpura (81,8% vs. 93,8%), ulcers (18,2% vs. 25%), peripheral neuropathy (50% vs. 46,9%), glomerulonephritis (40,9% vs. 31,3%), lung involvement (18,2% vs. 18,8%), non-hodgkin lymphoma (NHL) (13,6% vs. 25%). We found no statistical differences (p>0,05) between groups in frequency of mixed monoclonal cryoglobulinemia (MMC) - (72,7% vs 74,2%), in median rheumatoid factor (RF) titer (337.8 IU/ml (9.5– 4890) vs. 147,4 IU/ml (9.5– 1714), and the percentage of seropositive patients (90,9% vs. 87,5%), mean levels of IgG (139,9±75,5 IU/ml vs. 161,6±107,7 IU/ml), median IgM (356,5 IU/ml(81–1900) vs. 333 (67–1607 IU/ml)), low levels of C4 (81% vs. 61,1%), median CRP (2,4 (0,2–44,9 mg/l) vs. 3,9 (0,2–101), ANA (81,8% vs. 84,4%), the median CD19+ (14,9% vs. 5,3%) and BAFF (0,64 vs 0,8 ng/ml). High levels of aRo (median 4,5 IU/ml (1,7–200) vs. 154 IU/ml (7,1–200)), aLa (median 6,6 IU/ml (0,8–33) vs. 36 IU/ml (1,2–200)), ANA>1/320 (27,8% vs 63%), increased IgA (9,1% vs 31,3%) were statistically more frequent in group 2 (p <0,05), while arthralgia/ arthritis (50% vs 28%) - in group 1 (p <0,05). 78.6% patients of group 1 had mild inflammatory grade of hepatitis, while 42.1% patients had severe liver fibrosis. 1b genotype of HCV prevailed (84.2%), the median viral load was 7,2 $\times 10^5$ cop / ml ($0–10^6$). 18.2% patients were chronic HCV-carriers with persistently normal liver enzymes. pSS/sSS was diagnosed in 27.3% patients of group 1. Of the 3 NHL associated with HCV, 2 patients had SS.

Conclusion: CV associated with pSS and HCV infection on the main clinical manifestations and laboratory parameters (MMC, RF, C4) doesn't differ significantly. Differences exist only in laboratory parameters such as aRo, aLa and ANA titer and arthralgia. The presence of pSS/sSS is one of the risk factors for NHL in patients with HCV-associated CV.

1531

Childhood Granulomatosis with Polyangiitis: Prevalence and Treatment of Airway Stenosis. Nicole M. Fowler[1], Jocelyn M. Beach[2], Paul Krakovitz[1] and Steven J. Spalding[1]. [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH

Background/Purpose: Granulomatosis with polyangiitis, previously known as Wegener's granulomatosis (WG), is a necrotizing granulomatous vasculitis affecting the upper and lower respiratory tract, kidneys, and other small vessels throughout multiple organ systems. Recently, classification criteria for childhood WG (cWG) have been proposed and include the addition of airway stenosis. Airway inflammation occurs more frequently in children than adults and often proves difficult to diagnose and treat. Our objectives were to 1) determine the prevalence of airway involvement in a cohort of children with WG as defined by the European League Against Rheumatism/Pediatric Rheumatology European Society (EULAR) criteria, 2) document the frequency of specific airway findings and 3) review our treatment approach to children with WG-related airway disease.

Methods: Retrospective chart review performed on patients under 18 years old with a diagnosis of vasculitis evaluated at our institution between 2004 and 2010.

Results: 28 patients fulfilling EULAR classification criteria for the diagnosis of cWG were included in the analysis. Mean follow-up of 3.1 years. Larynotracheobronchial (LTB) disease occurred in 50% of patients. LTB disease was present at diagnosis in 36%, while in the remaining 14% it developed on immunosuppressive therapy. The development of airway disease or its progression occurred regardless of the immunosuppressant medication administered. In addition, medical management was inadequate for management of airway disease in 71% of patients. All patients underwent successful endoscopic intervention.

Conclusion: Airway manifestations frequently occur in cWG. Inflammatory changes can occur at any point in the disease course, necessitating diligent surveillance. Endoscopic interventions for LTB stenotic lesions represent a safe and effective therapeutic option.

1532

Comparison of CNS Vasculitis in Children and Adults: Is This the Same Disease Entity? Marinka Twilt[1], Tania Cellucci[2], Carlo Salvarani[3], Gene G. Hunder[4] and Susanne M. Benseler[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]Hospital for Sick Children, Toronto, ON, [3]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [4]Mayo Clinic, Rochester, MN

Background/Purpose: Primary vasculitis of the central nervous system (CNS) is a devastating inflammatory disease restricted to the brain and spinal cord. Previously healthy children and adults can develop life-threatening neurological deficits including stroke and seizures. Recently distinct phenotypes have been proposed for childhood CNS vasculitis. However, clinical phenotypes have never been explored throughout the age spectrums. The aim of this study was to describe the presenting features of children and adults with CNS vasculitis, to compare distinct entities and their treatment regimens and to analyze disease progression and/or relapse.

Methods: Two cohorts of consecutive patients with primary CNS vasculitis based on Calabrese criteria were identified: 1) adult patients (Mayo Clinic, Rochester) and 2) pediatric patients (Sickkids, Toronto). Patient demographic characteristics, presenting clinical features, neuroimaging characteristics, brain pathology results, clinical course including progression and relapse and treatment regimens were recorded. Characteristics of cohorts were analyzed using descriptive statistics. Comparative analysis assessed distinct disease phenotypes and treatment regimens.

Results: A total of 227 patients were included in the study; 101 adult patients and 126 pediatric patients. In children the median age was 8 years (1–17 years) and in adults 47 years (17–84 years). Pediatric patients showed a male predominance (F: M = 1:1.5) in contrast with the adult cohort (F:M = 1.3: 1). In the children with angiography positive CNS vasculitis (n=97) there was a male predominance (F:M=1:2.2) and the main presenting clinical symptoms were hemiparis (74%) and speech problems (28%), while the adult patients with angiography positive CNS vasculitis (n=70) show a more female predominance (F:M= 1.6:1) and the main clinical features in adults were headache (69%) and visual symptoms (47%). Brain biopsy positive patients in the pediatric cohort (n=29) showed an almost exclusive female predominance (F: M = 4.2:1) and the presenting features in these children were mainly, seizures (83%), fever (38% and speech problems (21%), in the adults with biopsy positive CNS vasculitis (n=31) there was an equal gender distribution (F:M=1:1) and altered cognition (71%) and headache (52%) were most frequent. Histology showed exclusively lymphocytic inflammation in children (100%)and predominantly a granulomatous pattern in adults (58%). Treatment strategies: in children prednisone in 59 (47%) and cyclophosphamide in 34 (27%), in adults prednisone in 97 (96%) and cyclophosphamide in 46 patients (46%). Relapse or progression of the disease was seen in adults in 26% and in children in 15%.

Conclusion: Primary CNS vasculitis in adults and children encompassed distinct phenotypes across the age spectrum. Gender predominance varies significantly between subtypes. Presenting clinical features differed as well with more seizures, speech problems, hemiparesis and fever in the children and more altered cognition, visual symptoms and headaches in the adults. Although adults are treated significantly more frequently with steroids and cyclophosphamide, relapse rates are lower in children.

Circulating Levels of Klotho In Kawasaki Disease: A Possible New Marker of Vascular Damage? Fernanda Falcini[1], Laura Masi[2], Francesco Franceschelli[2], Gigliola Leoncini[2], Serena Capannini[1], Francesco La Torre[3], Marco Matucci Cerinic[1] and Maria Luisa Brandi[2]. [1]Department of Internal Medicine, Rheumatology Section, Transition Clinic, University of Florence, Firenze, Italy, [2]Department of Internal Medicine, Endocrinology Unit, University of Florence, Firenze, Italy, [3]DIMIMP-University Rheumatologic Section, Policlinico of University, Bari, Italy

Background/Purpose: Vascular endothelial cell damage is critical in KD pathogenesis. FGF23/FGF23 receptor complex and its cofactor Klotho play an important role in the regulation of phosphate homeostasis, bone mineralization, control of vascular damage and atherosclerosis. Klotho is a circulating protein expressed in several tissues including vasculature. Pts with chronic renal failure have low serum levels of Klotho protein and develop vascular calcifications, and VEGF-mediated angiogenesis is impaired in Klotho-deficient mice. Several studies have shown that Klotho is a vasoprotective protein acting through multiple pathways. We previously demonstrated that KD pts have high serum levels of FGF23 indicating this factor as a potential predictor of atherosclerosis.

Aims: 1. To measure Klotho serum levels of in a cohort of KD pts. 2. To look for an association between Klotho levels and coronary damage.

Methods: Serum from 109 consecutive KD pts, median age 30.5 mnths, were collected for the measurement of Khloto protein using an ELISA method (Uscn Life Science Inc.). The intact assay is standardized to measure Klotho in nanograms per milliliter (ng/ml). 66 sex- and age-matched healthy children were studied as controls. In all pts data were recorded about familial predisposition to atherosclerosis.

Results: We found significant high amount of Klotho protein both in KD and healthy children. However, a trend characterized by lower levels of Klotho in KD *vs* healthy children was observed (KD: mean 246,97 +/− 174,6 vs. 302,3 +/−100 ng/ml). No significant differences in the serum Klotho levels between KD pts. with and without CA (235+/− 120 vs. 244+/−133 ng/ml) was detected.

Conclusion: The serum Klotho values in our subjects (both in KD and controls) was about 1000-fold higher than those reported in the literature. This may be due to the fact that our population was younger than that previously studied. The few data published in the literature indicate that serum alpha-Klotho correlated negatively with age. Indeed, alpha-Klotho is higher in prepubertal children in comparison with adults. In addition in umbilical cord blood klotho level is very high followed by a reduction after 4 days of life. It is plausible to hypothesize that the postnatal reduction of serum Klotho could be followed by an increment until the prepubertal age. This could in part explain the high values found in our population. Klotho is a pivotal vasoprotective protein and is considered an important factor attenuating atherosclerosis by several pathways. KD pts have a trend characterized by lower Khloto levels in comparison with health subjects. These preliminary results might open the way to a new marker of vascular damage in KD pts.

1534

Vessel Remodeling in Childhood Primary CNS Vasculitis: Impact of Corticosteroid Therapy. Gordon S. Soon, Ivanna Yau, Derek Armstrong, Pascal N. Tyrrell, Suzanne Laughlin, Gabrielle deVeber and Susanne M. Benseler. The Hospital for Sick Children, Toronto, ON

Background/Purpose: Childhood non-progressive primary CNS vasculitis (NPcPACNS) accounts for the single most common cause of vascular strokes in children. The aims of the study were 1) to describe the cerebral vessel imaging at presentation in children with NPcPACNS and 2) to determine whether corticosteroid therapy had any impact on follow-up imaging.

Methods: A single-centre cohort study of consecutive children diagnosed with cPACNS based on Calabrese criteria between January 1990 and December 2009 was performed. Children were included if they 1) had non-progressive cPACNS (unilateral proximal stenoses and no evidence of progression >3 months) and 2) had serial cerebral vessel imaging, including either Magnetic Resonance Angiography (MRA) or conventional angiography. The study excluded progressive cPACNS and angiography negative cPACNS. Data collection: Serial MRA and conventional angiography were blindly reviewed by two independent neuroradiologists following a previous developed protocol. Parenchymal lesions were characterized by number, size, and location (laterality, arterial territory, grey/white matter involvement). Cerebral vessel involvement was characterized by location and features of stenoses, including artery name, number affected, severity, laterality, and appearance (beading, dilatation, smooth, irregular). Analysis: frequencies were compared using descriptive statistics.

Results: A total of 44 children with NP-cPACNS were included. Initial cerebral vessel imaging included conventional angiography in 39 children (89%). Proximal middle cerebral artery (MCA) was involved in 35 children (80%), distal internal carotid artery (ICA) in 25 (57%), and proximal anterior cerebral artery (ACA) in 17 (39%). Left-sided vascular disease was detected in 28 children (64%). Sixteen children (36%) had a maximal stenosis of >75%, including 13 (30%) with complete occlusion. Children treated with corticosteroid therapy had a significantly higher degree of stenosis on initial imaging (p=0.02). At 3 month follow-up imaging, there was no statistical difference in the number of affected vessels, degree of stenosis, or maximum length of stenosis compared between children treated with and without corticosteroid therapy.

Conclusion: NPcPACNS likely represents an inflammatory attack on the arterial wall thus providing the rationale for considering immunosuppressive therapy on presentation. At our institution, corticosteroid therapy was not uniformly provided in children with NPcPACNS but was typically reserved for children with the most severe arteriographic abnormalities. Nonetheless, cerebral vessel imaging at 3 month follow-up was similar in children treated with and without corticosteroid therapy, thereby suggesting a possible role for immunosuppressive treatment of this disease.

1535

Systemic Vasculitis and Pregnancy: Maternal and Neonatal Outcome of 20 Prospectively Followed Pregnancies. Micaela Fredi[1], Marta Mosca[2], Tamara Ziglioli[1], Chiara Tani[2], Matteo Filippini[1], Francesca Strigini[2], Laura Andreoli[1], Cinzia Casu[1], Mario Motta[3], Andrea Lojacono[4] and Angela Tincani[1]. [1]Rheumatology Unit, University of Brescia, Brescia, Italy, [2]University of Pisa, Pisa, Italy, [3]Neonathology and NICU, Spedali Civili, Brescia, Italy, [4]Obstetric and Gynecology of Brescia, Brescia, Italy

Background/Purpose: The increasing knowledge in diagnosis and management of primary systemic vasculitis (SV) has led to an earlier detection and treatment of such diseases with the consequent improvement of survival rate and quality of life. SV are rare diseases and, unlike other autoimmune conditions, they do not preferentially affect women. Therefore our understanding of the relationship between pregnancy and SV is limited. The aim of this study was to describe pregnancy outcome in patients with diagnosis of SV followed in our Institution; to evaluate the influence of pregnancy on maternal disease.

Methods: Analysis of 20 pregnancies (prospectively followed by a multispecialistic team) in 15 patients with diagnosis of SV, according to Chapel Hill Consensus Conference and/or ACR Criteria for SV. Two patients were affected by Takayasu arteritis (TA), 3 by Churg-Strauss syndrome (CS), 2 by Polyarteritis nodosa (PA), 8 by Behcet's disease (BD). Data regarding the duration of disease, serological and clinical features, pregnancy outcome, neonatal and maternal complications and therapy during pregnancy were collected from clinical charts.

Results: All the patients conceived during clinical and serological remission of the disease. The median age of the patients at the conception was 33 (range 27–40); 13 patients were Caucasian, 1 from North Africa and 1 from South America. The mean duration of SV before pregnancy was 8 years (range 1–17). Reproductive history of each patient is detailed in the table. There were 2 miscarriages and 2 fetal death in 2 patients (20% of all pregnancies); 4 pregnancies (20%) had complications: 1 preeclampsia, 3 premature deliveries (before 34 week), 1 post-partum haemorrhage and a post-partum disseminated intravascular coagulation (DIC). Flares of the disease appeared in 5 patients (33,3%): 1 PA, 2 TA and 2 BD. We had 18 live births: 5 premature (28%), in particular 1 newborn small for gestational age (SGA), 1 suffered from necrotizing enterocolitis (NEC) and 1 from respiratory insufficiency.

Conclusion: Our data show that conceiving during the remission of the disease and strictly monitoring of the pregnancy seem to be not sufficient to prevent flare of the disease, maternal and neonatal complications. In particular we want to emphasize the elevated frequency of preterm delivery before the 34th week among the live births (28% vs 5% of the general obstetric population of our hospital).

Table.

Pt	Disease	N° pregnancy	Outcome	Week of delivery or loss	Maternal complications	Neonatal complications	Treatment
1	TA	3	a) miscarriage b) miscarriage c) live birth (twins)	a) 7 b) 8 c)32	Flare of the disease 2nd trimester, abruptio placentae	—	LDA, PDN
2	TA	1	a)live birth	a) 38	Flare of the disease 3rd trimester, PROM	—	LDA AZA LMWH
3	PA limited	2	a) live birth b) live birth	a)38 b)40	—	—	LDA
4	PA systemic	1	a)live birth	a)30	Flare of the disease 2nd trimester, preclampsia	SGA	LDA, PDN, antihypertensive therapy
5	CS	1	a) live birth (twins)	a)31	Abruptio placentae; post-partum haemorrhage	1 with NEC, 1 with RI	PDN, asthma therapy
6	CS	1	a)live birth	a)39	—	—	PDN, asthma therapy,
7	CS	1	a)live birth	a) 40	—	—	—
8	BD	1	a)live birth	a)38	Flare of the disease 1st trimester; post partum DIC	—	LDA cyclosporine, PDN
9	BD	1	a)live birth	a)39	—	—	LDA
10	BD	1	a)live birth	a)38	—	—	LDA, LMWH
11	BD	3	a) fetal death b) fetal death c) live birth	a) 12 b) 15 c)38	—	—	LDA, LMWH
12	BD	1	a)live birth	a)40	Flare of the disease 2nd trimester	—	LDA, M-PD
13	BD	1	a)live birth	a)40	—	—	—
14	BD	1	a)live birth	a)37	—	—	PDN, LDA
15	BD	1	a)VIP	—	—	—	MMF, LMWH, antihepileptic drug

LDA= low dose aspirin, LMWH= low-molecular-weight heparin, PDN= prednisone, M-PD=methyl prednisolone, MMF= mycophenolate mofetil, NEC= necrotizing enteritis, IR= respiratory insufficency, VIP= voluntary interruption of pregnancy, DIC= disseminated intravascular coagulation, SGA= small for gestational age

Infertility Among Patients with Vasculitis. Megan E. B. Clowse[1], Rachel Richesson[2], Carl Pieper[1], Peter A. Merkel[3] and Vasculitis Clinical Research Consortium[4]. [1]Duke University Medical Center, Durham, NC, [2]University of South Florida, Tampa, FL, [3]Boston University School of Medicine, Boston, MA, [4]Boston

Background/Purpose: Fertility may be impaired in men and women with vasculitis due to morbidity from the disease and the high prevalence of cyclophosphamide (CYC) use. This study assessed the rate of infertility in patients who had and had not completed childbearing before the diagnosis of vasculitis, the frequency of discussions about the risks to fertility, and interventions to prevent infertility from CYC.

Methods: All participants in the Vasculitis Clinical Research Consortium Patient Contact Registry were invited to participate in an internet-based anonymous questionnaire about reproductive health. Participants were divided into two groups based on interest in having children at the time of diagnosis: i) childbearing completed; and ii) childbearing not completed. Other data collected included CYC exposure, infertility, whether the patient recalled discussing fertility prior to CYC dosing, and if they took steps to prevent infertility.

Results: 450 participants completed the questionnaire and reported a diagnosis of vasculitis by a specialist and/or received immunosuppressive medications other than prednisone. 304 of 450 (68%) had completed childbearing at the time of their diagnosis of vasculitis; this group had a mean age almost 20 years older at diagnosis than the 146 participants who had not completed childbearing at the time of diagnosis (Table).

	WOMEN		MEN	
	Completed childbearing prior to vasculitis	Not completed childbearing prior to vasculitis	Completed childbearing prior to vasculitis	Not completed childbearing prior to vasculitis
Number	221	122	83	24
Current Age (years)	54.1*	35.9	59.1*	41.4
Age at diagnosis (years)	47.9*	27.0	53.7*	30.1
Infertility	11.6%	17%	9.6%*	33.3%

* p-value <0.0001 comparing completed and not completed childbearing.

Infertility was not significantly different between women who had and had not completed childbearing. However, among women diagnosed before age 40, those who received CYC had an almost 3-fold higher rate of infertility compared to women without CYC (24.3% vs 8.8%, $p<0.01$). A discussion of the impact of CYC on fertility was recalled by 67.8% of women who hadn't completed childbearing, of whom 17 (43%) took steps to preserve ovarian function during treatment including using GnRH-agonists (7), oral contraceptives (8), both methods (1), and depot medroxyprogesterone (1).

Infertility was significantly higher among men who had not completed childbearing at vasculitis diagnosis, but receiving CYC did not impact this rate. Future fertility was discussed with 83.3% of men interested in having children prior to CYC, half of whom stored sperm for future use.

Conclusion: The rate of infertility was increased in young women with vasculitis exposed to CYC. A significant minority of women did not recall being informed of the risk of infertility at the time of treatment; of those informed, less than half took steps to prevent infertility. Interestingly, infertility did not appear to be associated with CYC in men, but a higher percentage of them had been informed of this risk and half took measures to protect against infertility. This data confirm that infertility is an important concern for patients with vasculitis and that physicians need to be more vigilant about discussing the risk of infertility with their patients with vasculitis.

1537

Pregnancy in Men and Women with Vasculitis. Megan E. B. Clowse[1], Rachel Richesson[2], Carl Pieper[1], Peter A. Merkel[3] and Vasculitis Clinical Research Consortium[4]. [1]Duke University Medical Center, Durham, NC, [2]University of South Florida, Tampa, FL, [3]Boston University School of Medicine, Boston, MA, [4]Boston

Background/Purpose: The outcome of pregnancies in men and women with vasculitis is unknown because of the relative rarity of the condition, but is an area of great concern to patients and physicians. In a survey of a large population of patients with vasculitis, this study assessed the pregnancy outcomes before and after a diagnosis of vasculitis.

Methods: All participants in the Vasculitis Clinical Research Consortium (VCRC) Patient Contact Registry were invited to participate in a one-time, internet-based anonymous questionnaire about reproductive health. Participants were asked to report the total number of pregnancies they had carried (women) or fathered (men), as well as the outcomes (live birth, pregnancy loss, preterm birth) of those pregnancies, the timing of pregnancy relative to the diagnosis of vasculitis, and medications taken during pregnancy or at the time of conception. Elective abortions and current pregnancies (4) were excluded from the analysis. Outcomes from pregnancies before and after vasculitis were compared, taking into account the effect of the individual propensity for a given outcome in the analysis.

Results: A total of 65 pregnancies after a diagnosis of vasculitis were reported by women and 17 by men. The rate of pregnancy loss was statistically higher in pregnancies in women after the diagnosis of vasculitis compared to prior to vasculitis (34% vs 23%, $p=0.03$). Among women with vasculitis, there was a non-significant increase in the rate of preterm births in pregnancies after vasculitis than before (23% vs 13%, $p=0.1$). For pregnancies that followed the diagnosis of vasculitis, 59% reported that vasculitis activity was not impacted by pregnancy, 23% reported improvement in vasculitis during pregnancy, and 18% reported worsening of disease during pregnancy. For men, the pregnancy loss rate was 59% in 17 pregnancies conceived after vasculitis, compared to 75% of 130 pregnancies prior to vasculitis ($p=0.7$). Pregnancy outcomes and vasculitis activity in pregnancy did not differ significantly between diagnoses for men or women, although the power to detect such differences was low.

24 pregnancies were exposed to prednisone (39% of the pregnancies after the diagnosis of vasculitis). The pregnancy loss rate and preterm birth rates were not statistically different between pregnancies with and without prednisone exposure. 7 pregnancies were exposed to azathioprine resulting in 1 elective abortion, 2 miscarriages, 2 live term births, with 2 pregnancies ongoing. 2 pregnancies were exposed to methotrexate, one was electively aborted and one ended in a miscarriage. One pregnancy resulted in a live term birth after exposure to cyclophosphamide. The pregnancy loss rate was not elevated in the 15 pregnancies conceived by women with prior exposure to cyclophosphamide.

Conclusion: Pregnancies conceived by women following the diagnosis of vasculitis had a higher rate of pregnancy loss compared to those conceived prior to diagnosis. Vasculitis was not worsened during the majority of pregnancies conceived after diagnosis. A larger study will be required to determine the impact of medications in pregnancy success among women with vasculitis.

The Impact of Pain on Successful Ageing. Ross Wilkie[1], Abdelouahid Tajar[2] and John McBeth[1]. [1]Keele University, Newcastle-under-Lyme, United Kingdom, [2]University of Manchester, Manchester, United Kingdom

Background/Purpose: With population ageing there is growing drive to promote a healthier old age and ways to age successfully. Successful ageing is a multi-faceted state, which involves preservation of biomedical, physical, psychosocial and lay components to enable cognitive, physical and mental well-being, social participation and quality of life. Musculoskeletal pain is common in older adults and is considered as a stressor which impacts on a number of body functions. This is the first longitudinal study to investigate the relationship between musculoskeletal pain and successful ageing in the general population.

Methods: A population-based prospective cohort study of adults aged 50 years and over, the North Staffordshire Osteoarthritis Project (NorStOP) was conducted. Subjects were those who had completed questionnaires at base-

line, 3 and 6-year follow-ups. Based on their reports of pain, subjects (n = 2949) were classified into those reporting no pain, regional pain and widespread pain (American College of Rheumatology criteria). Using published methodology a 33-item successful ageing index (SA) was constructed by summing the number of deficits (health deficits across biological, psychological and functional domains). The SA score was calculated for each subject at baseline, 3 and 6 years by dividing the number of deficits by the total number of potential deficits and was expressed as a score from 0 to 100. Linear regression models were used to test the association between SA at each time point and pain status at baseline, first unadjusted and then adjusting for age, gender, education and social network. Mixed modelling was used to explore the longitudinal trends in SA across six years; pain was included as a time varying variable to examine the impact of change in pain on SA.

Results: The median age of the subjects was 61(inter-quartile range: 55 to 67) and 54% were female. At baseline 834 (28.7%) had no pain, 1296 (44.5%) had regional pain and 780 (26.8%) had widespread pain. Compared to those with no pain, subjects with regional pain had a higher SA score at all three time points ($p<0.01$). Those with widespread pain had the highest scores. Baseline regional and widespread pain were associated with SA scores after adjusting for covariates. Increasing pain was associated with increasing SA scores over time (Table1); an increase from none to regional and regional to widespread pain resulted in a 19% and 17% increase in SA scores respectively. An increase from none to widespread pain lead to a 40% increase in SA score.

Table 1. Longitudinal relationship between pain and Successful ageing index*

	M (I): Empty model	M (II): Adding time to M (I)	M: (III) Adding pain to M (II)	Model (IV): Adding age, gender education and social network to M (III)
βeta coefficients (95% CI)				
Intercept	3.07 (3.05, 3.09)**	2.94 (2.91, 2.96)**	2.76 (2.73, 2.79)**	2.68 (2.59, 2.76)**
TIME	—	0.07 (0.06, 0.08)**	0.06 (0.06, 0.07)**	0.06 (0.05, 0.07)**
Regional pain	—	—	0.18 (0.16, 0.21)**	0.19 (0.16, 0.21)**
Widespread pain	—	—	0.34 (0.31, 0.36)**	0.33 (0.30, 0.36)**

* Index scores have been log transformed. ** $p<0.001$. CI Confidence interval

Conclusion: The results from this study indicate that pain has a significant adverse affect on successful ageing. The cross-sectional results indicate that at baseline, individuals with regional and widespread pain have accumulated significantly more signs of less successful ageing than those with no pain. The longitudinal results indicate that increasing pain significantly accelerates the rate of less successful ageing.

1539

Not So Golden Years: Older (≥65 years) Women with Arthritis Are Employed Least and Disabled Most. Kristina A. Theis[1] and Sylvia Furner[2]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]University of Illinois at Chicago, Chicago, IL

Background/Purpose: Employment of older workers (≥65 years) increased >100% between 1977 and 2007; the U.S. Bureau of Labor Statistics projects further increases as Baby Boomers age. Employment is lower among working-age (18–64 years) adults with arthritis compared with non-arthritis peers. The purpose of this study is to estimate the prevalence and change over time of employment and work disability among older adults (≥65 years) with and without arthritis by sex.

Methods: Data were obtained from the 2002–2009 National Health Interview Surveys (mean n = 27,729; mean response rate = 70%), an annual, multistage probability survey by in-person interview designed to represent the U.S. civilian, non-institutionalized population. Arthritis diagnosis was identified by "Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" We analyzed respondents ≥65 years who self-identified as employed or work disabled (unable to work due to disability). Weighted proportions and prevalence ratios with 95% confidence intervals (CI) were calculated accounting for complex sample design (SAS 9.2).

Results: The proportion of employed women with arthritis was significantly lower than that of men with or without arthritis in all years and significantly lower than for women without arthritis in all years except 2002 and 2007. The proportion of work disability among women and men without arthritis was lower than for men and women with arthritis. All groups had a higher probability of being employed compared with WA+ in all years (Table).

Table. Prevalence ratios (PR) and 95% confidence intervals (CI) for employment and work disability among older adults (≥65 years) with and without arthritis, by sex, NHIS, 2002–2009

	MALE Arthritis				FEMALE Arthritis			
	No		Yes		No		Yes (referent)	
	Employed							
Year	PR	95% CI	PR	95% CI	PR	95% CI	PR	95% CI
2002	2.3	(1.8–2.9)	1.9	(1.4–2.4)	1.3	(1.0–1.6)	1.0	(1.0–1.0)
2003	2.3	(1.9–2.9)	2.2	(1.7–2.9)	1.7	(1.3–2.1)	1.0	(1.0–1.0)
2004	2.4	(2.0–3.0)	1.6	(1.3–2.1)	1.5	(1.2–1.9)	1.0	(1.0–1.0)
2005	2.6	(2.1–3.2)	1.8	(1.5–2.3)	1.8	(1.4–2.2)	1.0	(1.0–1.0)
2006	2.2	(1.7–2.9)	2.0	(1.5–2.6)	1.6	(1.2–2.0)	1.0	(1.0–1.0)
2007	1.8	(1.4–2.2)	1.6	(1.2–2.1)	1.3	(1.0–1.7)	1.0	(1.0–1.0)
2008	2.4	(1.9–3.2)	1.8	(1.3–2.4)	1.6	(1.2–2.0)	1.0	(1.0–1.0)
2009	1.9	(1.5–2.3)	1.7	(1.4–2.2)	1.4	(1.1–1.8)	1.0	(1.0–1.0)
	Work Disabled							
2002	0.6	(0.4−0.8)	0.7	(0.5–1.1)	0.5	(0.3−0.7)	1.0	(1.0–1.0)
2003	0.4	(0.3−0.6)	0.9	(0.6–1.2)	0.5	(0.4−0.7)	1.0	(1.0–1.0)
2004	0.5	(0.3−0.7)	1.0	(0.8–1.4)	0.7	(0.5−0.9)	1.0	(1.0–1.0)
2005	0.5	(0.4−0.7)	0.6	(0.4−0.9)	0.3	(0.2−0.5)	1.0	(1.0–1.0)
2006	0.5	(0.3−0.7)	0.8	(0.5–1.2)	0.4	(0.3−0.7)	1.0	(1.0–1.0)
2007	0.7	(0.5−0.9)	0.9	(0.6–1.3)	0.5	(0.4−0.8)	1.0	(1.0–1.0)
2008	0.4	(0.2−0.5)	0.6	(0.4−0.9)	0.4	(0.3−0.6)	1.0	(1.0–1.0)
2009	0.4	(0.3−0.7)	1.0	(0.6–1.4)	0.5	(0.3−0.8)	1.0	(1.0–1.0)

Conclusion: Older women with arthritis are at an employment disadvantage compared with other groups. High work disability in women with arthritis ≥ 65 years suggests these women want or need to be working and may benefit from evidence-based public health programs shown to reduce and delay disability. Vocational rehabilitation and job accommodations may also help. The aging of the population and projected employment trends suggest these adverse employment and work disability disparities will continue to grow unless addressed.

1540

A Population-Based Study Comparing the Impact of Arthritis and Chronic Joint Symptoms: Are There Implications for Arthritis Education and Health Care? Mayilee Canizares[1] and E. M. Badley[2]. [1]Toronto Western Research Institute, Toronto, ON, [2]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON

Background/Purpose: Arthritis is one of the most common conditions, affecting 15%-20% of the population. Surveys suggest that a further 10%-15% of the population report chronic joint symptoms (CJS). CJS have been considered as an indication of possible arthritis with studies showing conflicting results. Most of these studies have compared predictors of CJS and arthritis but only a minority have considered health-related outcomes. This study compares predictors and health outcomes for individuals with self-reported arthritis and those without arthritis reporting chronic or sporadic joint symptoms.

Methods: Data from the 2008 Canadian Community Health Survey (15+; n=66,013) were used for analyses. Respondents were asked about arthritis as a long-term chronic health condition diagnosed by a health professional. Participants not-reporting arthritis were further asked about joint symptoms excluding the back and neck over the past 12 months. Analyses were conducted for the following mutually exclusive groups: arthritis, chronic joint symptoms (symptoms present on most days in the past month), sporadic joint symptoms (other joint symptoms in the past 12 months (SJS)), and no arthritis and no joint symptoms (NJS). Log-Poisson regression was used to examine risk factors for each of these groups. Similar regressions, adjusting for socio-demographic, lifestyle factors, and comorbidities were used to

estimate the risks of reporting physical inactivity, three health outcomes (poor/fair overall health, poor/fair mental health, activity limitation), and five measures of healthcare use.

Results: 16.0% of the population reported arthritis, 10.1% reported CJS and 11.6% reported SJS. Individuals with arthritis were older than those with CJS or SJS. Women reported arthritis and CJS more often while men reported SJS. Other than age, the profile of risk factors for arthritis and CJS was similar, notably obesity and overweight. After adjusting for age, sex, SES, lifestyle factors and comorbidities, prevalence ratios showed similar risks for physical inactivity, and all health outcomes and health care use measures for the arthritis and CJS groups, and these were higher than those for SJS group.

Conclusion: CJS was reported by one-in-ten of the adult population. The similarities in risk factors, other than younger age, for CJS and arthritis suggest that the CJS group might represent people in early stages of arthritis who have not yet been diagnosed. The similar impact of CJS and arthritis on health outcomes and increased healthcare use, suggests that arthritis education and management interventions are likely to be beneficial for the CJS group with possible unrecognized arthritis.

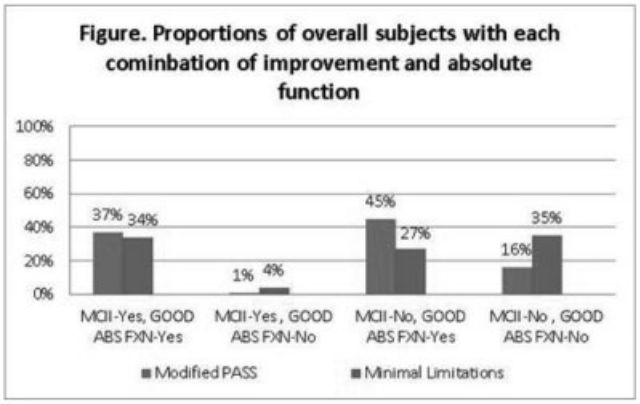
Does Important Improvement in Function After Knee Replacement Guarantee Good Absolute Function. Jessica L. Maxwell[1], David T. Felson[2], Jingbo Niu[2], Barton Wise[3], Michael C. Nevitt[4], Jasvinder Singh[5], Laura Frey-Law[6] and Tuhina Neogi[2]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Ctr for Healthy Aging-UC Davis, Sacramento, CA, [4]University of California-San Francisco, San Francisco, CA, [5]University of Alabama at Birmingham and Birmingham VA Medical Center, Birmingham, AL, [6]University of Iowa, Iowa City, IA

Background/Purpose: Improvement in function is a goal of knee replacement (KR) surgery and the focus of prior studies. However, how relative improvement relates to absolute levels of functioning post-KR is important from a patient perspective as persons with knee OA care more about their absolute functional state than improvement (Tubach, 2006). It is possible that despite improvement, some may be limited in function post-KR. We investigated whether the attainment of a minimal clinically important improvement (MCII) in function indicates good absolute function post-KR.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded longitudinal cohort study of persons with or at high risk of knee osteoarthritis. A person-specific WOMAC physical function (PF) questionnaire was administered at each study visit (baseline, 30, and 60 months). We focused on those who had a KR during follow-up with pre- and post-KR data. Pre-KR function data was obtained from the clinic visit immediately prior to KR, and post-KR data was at the next immediate clinic visit, typically between 6 and 24 months post-KR. We examined the frequency of MCII post-KR (WOMAC-PF improvement of $\geq$14.2/68 (Escobar, 2007)) and good absolute function using 2 separate definitions: i) modified Patient Acceptable Symptom State (PASS) for knee OA using WOMAC-PF $<$25.9/68 (Tubach, 2006) ["modified PASS"]; ii) WOMAC-PF score $<$17/68 representing an average score of "mild" impairment on each of the 17 items ["mild limitations"]. The proportion of subjects who had pre-KR function sufficiently high so that they were unable to attain an MCII were analyzed separately.

Results: There were 245 subjects with pre- and post-KR data (mean age 65 years, 29% male). Overall, 44% achieved a MCII post-KR, and good absolute function post-KR was attained by 80% and 57% based on modified PASS and mild limitations, respectively. The majority of those with a MCII attained a good absolute function post-KR ($\sim$ 1/3 of total sample) (see Figure). A substantial proportion who did not attain a MCII had good absolute function by the modified PASS and to a lesser extent by the mild limitations definition. Good pre-KR function in 33 subjects precluded their ability to attain a MCII. Of these, 94% (modified PASS) and 79% (mild limitations) had good absolute function post-KR, indicating that some may have had a decline in function post-KR.



Conclusion: Improvement in function and absolute functional status post-KR are not necessarily related. While attainment of MCII is related to good absolute function, substantial proportions may have good absolute function without attaining an MCII. More research is needed to determine what measure of absolute function indicates good status post-KR as the PASS may represent functional status with greater-than-mild limitations and thereby overestimate the proportion with a good absolute level of function post-KR.

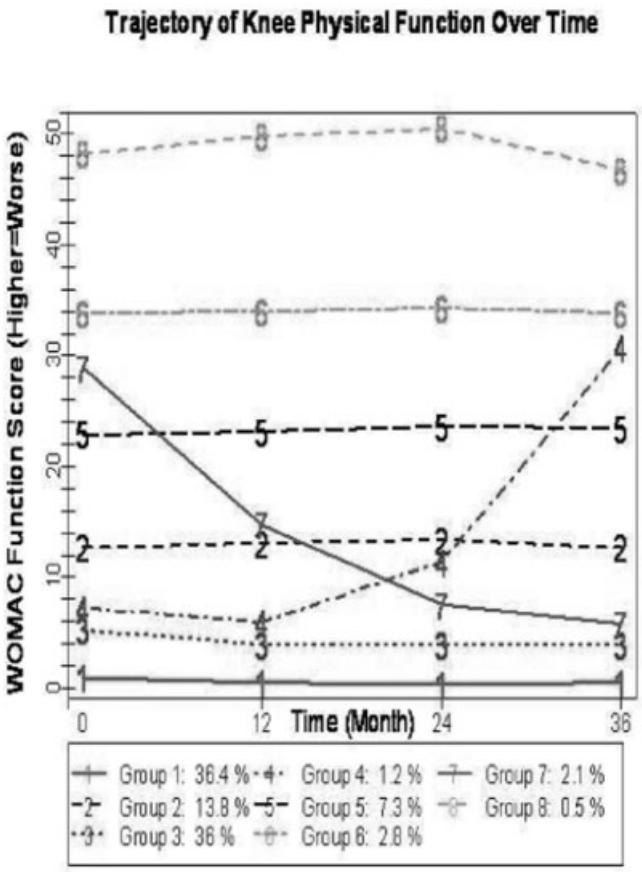
1542

Patterns of WOMAC Function in People with or At High Risk of Knee Osteoarthritis: The Osteoarthritis Initiative. Uyen Sa D. Nguyen[1], Bin Zhang[2], Jingbo Niu[1], Daniel K. White[1] and Yuqing Zhang[1]. [1]Boston University School of Medicine, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA

Background/Purpose: Despite people with knee osteoarthritis (OA) being at high risk of poor physical function, little is known of changes in physical function over time. Understanding these patterns of change and identifying risk factors of decline could help in preventing the development of poor physical function. We described the trajectories of change in physical function over time and evaluated factors associated with these trajectories of change.

Methods: Knee-specific WOMAC physical function scores were assessed in the participants at baseline and at three subsequent annual visits in the Osteoarthritis Initiative. We restricted this analysis to knees with 3 or 4 WOMAC function scores. We used SAS PROC TRAJ, a group-based finite mixture modeling, to identify distinctive sub-groups of knees that follow similar trajectories of physical function over time. The PROC TRAJ procedure, using likelihood estimation, assigned each knee into a discrete group according to its function trajectory within the population. Model fit was assessed using Bayesian Information Criteria. We compared characteristics across the sub-groups using χ^2 or ANOVA.

Results: Among 4,379 participants (58% women, 17% African Americans, mean age: 61, mean BMI: 29, mean WOMAC function at baseline: 8), we identified 8 distinctive trajectories of knee-specific WOMAC function over 3 years. As shown (Figure), 96.7% of the knees (Groups 1, 2, 3, 5, 6, 8) had stable physical function over time--average score changed $\leq$ 2 points or $\leq$ 10% from year to year; 1.2% of the knees had worsened function (Group 4), and 2.1% of the knees had improved function (Group 7). Two pairs of trajectories had similar baseline function scores but diverged over follow-up (Table, Group 3 vs. 4, and Group 6 vs. 7). Group 4 worsened over time compared with Group 3, and had a higher proportion of African Americans (32% vs. 14%) and people who were morbidly obese (25% vs. 8%), knees with severe ROA (47% vs. 32%) and replacement therapy (5% vs. 2%). Conversely, Group 7 improved over time compared with Group 6, and had fewer females (65% vs. 73%) and African Americans (35% vs. 57%), people with morbid obesity (19% vs. 36%) and major depressive symptoms (6% vs. 18%), but higher proportion of knee replacement therapy (9% vs. 5%). We repeated the analyses using worst function in the two knees and found similar results.



Conclusions: The majority of knees had stable function over three years; however, a small proportion had substantial change in function. Several factors such as socio-demographic, anthropometric, structural lesions and medical interventions may explain differences in the trajectories of function over time.

1543

Disease Impact of Osteoarthritis in Hands, Hip, Knee or Generalized Osteoarthritis—a Cross Sectional Study. Rikke Helene Moe[1], Margreth Grotle[1], Ingvild Kjeken[2], Kåre Birger Hagen[1], Tore K. Kvien[3] and Till Uhlig[3]. [1]National Resource Centre for Rehabilitation in Rheumatology, Diakonhjemmet Hospital, N-0319 Oslo, Norway, [2]Diakonjemmets Hospital, Oslo, Norway, [3]Diakonhjemmet Hospital, Oslo, Norway

Background/Purpose: Osteoarthritis (OA) is a leading cause of pain and disability. Knowledge is limited concerning disease impact and the localization of OA and. Therefore, we aimed to describe demographic characteristics, health status and disease impact in patients with hand OA compared to hip, knee or generalized OA.

Methods: We included 409 patients who were referred to a specialized rheumatology outpatient clinic with a clinical diagnosis of OA. Patients were examined clinically by a rheumatologist and classified into hand, hip, knee and/or generalized OA (defined as OA in at least two extremity localizations) based on the primary localization of complaints. Demographic variables included age, gender and body mass index (BMI). The patients completed questionnaires including pain, fatigue, and stiffness and patient global disease activity on numeric rating scales (NRS, range 0–10, 0 is best health), Hopkins Symptom Checklist-25 (HSCL-25, 1–4, 1 is best), Arthritis Self-Efficacy Scales (ASES, 0–100, 100 is best), Western Ontario and McMaster index (WOMAC) (0–30, 0 is best) and Australian/Canadian hand index (AUSCAN, 0–10, 0 is best) and SF-36 physical and mental component summary scores (PCS and MCS, 0–100, 100 is best).

Results: The 408 patients (86% women) had a mean (SD) age of 63.1 (8.0) years. Hand OA was the most frequent diagnosis (n=270, 66%), while hip (n=33, 8%), knee (n=75, 18%) and generalized OA (n=30, 7%) were less frequent. Patients with hand or generalized OA were significantly older and had lower BMI compared to patients with isolated knee OA (table). Frequent co-morbidities for all groups were allergies, hypertension, ischialgia and chronic inflammatory diseases.

All groups reported moderate to severe pain with mean values >5 on NRS. Hip and knee OA patients had highest scores for WOMAC and hand OA and generalized OA patients for on AUSCAN. Patients with hand OA and generalized OA scored overall better on physical functioning (SF-36 PCS) than patients with knee and hip OA. All groups reported high HSCL scores (mean value >1.5), indicating high levels of psychosocial symptoms (table).

Scale, Mean (SD) (range)	Hand OA n=270	Hip OA n=33	Knee OA n=75	Generalized OA n=30
Age (years)	63.18 (0.5)	61.0 (1.4)	60.8 (1.1)	63.2 (1.5)
BMI	25.9 (0.3)	26.3 (0.6)	27.7 (0.66)	24.1 (0.9)
Pain (1–10, NRS)	5.2 (0.1)	6.1 (0.4)	5.2 (0.26)	5.1 (0.4)
Fatigue (1–10, NRS)	3.9 (0.19)	4.9 (0.6)	4.8 (0.3)	4.5 (0.6)
Stiffness (NRS)	5.1 (0.17)	5.9 (0.5)	5.0 (0.3)	6.0 (0.4)
Disease act (NRS)	4.6 (0.14)	5.7 (0.4)	5.2 (0.3)	5.0 (0.5)
AUSCAN sum	5.11 (0.2)	3.7 (0.4)	3.8 (0.3)	5.1 (0.4)
Pain	5.04 (0.2)	4.0 (0.4)	3.9 (0.3)	4.9 (0.4)
stiffness	5.1 (0.2)	3.8 (0.6)	3.8 (0.4)	5.4 (0.4)
physical	5.2 (0.17)	3.3 (0.5)	3.7 (0.3)	4.8 (0.5)
WOMAC sum	10.4 (0.6)	11.9 (1.2)	13.5 (0.8)	11.6 (1.3)
Pain	3.3 (0.2)	3.9 (0.4)	4.8 (0.3)	3.7 (0.4)
stiffness	4.1 (0.2)	4.5 (0.4)	4.6 (0.3)	4.6 (0.5)
physical	3.0 (0.2)	3.5 (0.5)	4.1 (0.3)	3.3 (0.5)
HSCL-25	1.63 (0.0)	1.5 (0.1)	1.7 (0.0)	1.6 (0.1)
ASES pain	58.4 (1.7)	60.4 (3.09)	53.3 (2.6)	56.8 (6.0)
ASES symptoms	67.7 (1.53)	73.4 (1.9)	62.8 (2.1)	70.9 (5.0)
SF-36				
Physical functioning	68.78 (1.3)	50.2 (3.6)	50.0 (2.5)	65.46 (4.0)
Role physical	61.50 (1.9)	50.6 (5.6)	51.38 (3.4)	57.62 (5.4)
Pain	47.60 (1.5)	37.60 (3.2)	41.56 (2.1)	42.63 (1.7)
General health perception	46.39 (1.2)	37.59 (3.2)	42.11 (2.0)	41.79 (3.3)
Vitality	55.63 (0.7)	51.82 (1.5)	55.25 (1.1)	56.03 (2.1)
Social functioning	49.01 (0.7)	45.70 (1.2)	50.00 (1.1)	47.85 (2.2)
Role emotional	82.61 (1.6)	85.68 (4.6)	77.05 (3.2)	82.47 (4.6)
Mental health	68.83 (0.5)	69.22 (1.4)	67.82 (1.3)	69.27 (2.0)
PCS	38.5 (0.7)	37.5 (1.8)	35.9 (1.2)	36.6 (1.9)
MCS	46.5 (0.5)	47.5 (1.3)	46.7 (1.1)	46.2 (1.9)

Conclusion: OA patients who were referred to specialist care had high age and demonstrated considerable disease impact. Patients with hand OA reported especially pain and disability in hands but also disease impact for the lower extremities. Similarly, patients with lower extremity OA reported poor functioning of the lower extremities, but also of the hands. These findings indicate considerable disease impact with reduced health-related quality of life regardless of the OA localization.

1544

Association of Depressive Symptoms and Helplessness with Socioeconomic Status in People with Hip Osteoarthritis. My-Linh Luong, Leigh F. Callahan, Rebecca J. Cleveland, Britta L. Schoster, Jordan Renner and Joanne M. Jordan. University of North Carolina, Chapel Hill, NC

Background/Purpose: Individual and community socioeconomic status (SES) variables have demonstrated associations with psychosocial outcomes in self-report and other types of arthritis, but these associations have not yet been examined in hip osteoarthritis (OA). The purpose of this study is to evaluate the role of both individual and community-level SES as determinants of psychosocial outcomes of African Americans (AA) and Caucasians with hip OA.

Methods: A cross-sectional analysis was performed on 735 participants with hip radiographic OA (rOA) (defined as Kellgren-Lawrence (KL) grade ≥2) from the first follow-up evaluation and new enrollees (1999–2003) of the Johnston County Osteoarthritis Project. Psychosocial outcomes included depressive symptoms using the Center for Epidemiologic Studies Depression (CES-D) scale (range 0–60), and perceived helplessness using the Rheumatology Attitudes Index (RAI) (range1–5). SES measures included educational attainment (<high school diploma (<HS), or ≥HS), occupational status (managerial or non-managerial), and community poverty (defined from the U.S. Census household poverty rate for the block group in which the participant resided). Poverty rate was trichotomized as <12% (referent), 12–25%, and >25%. Separate analyses were performed for those with symptomatic hip OA (sOA) (defined rOA with pain or stiffness in the same hip). Regression analyses were used to examine the association between CES-D and RAI outcomes with all SES variables while adjusting for age, gender, race, and body mass index (BMI).

Results: Participants' average age was 67 years (45–94), 46% had a BMI≥30, 65% were female and 28% were AA. 35% of the population had <HS, 55% were in non-managerial occupations, and 72.4% of individuals resided in communities where more than 12% of the population live below the poverty rate. Average CES-D score was 6.09 and the average RAI was 2.45. Of those with hip rOA, 252 also met the definition of hip sOA. In covariate adjusted analyses of individual SES measures among those with hip rOA, those with <HS and non-managerial occupation had significantly higher CES-D (β=2.89, C.I. = [1.83, 3.95]); β=1.74, C.I. = [0.72, 2.76], respectively) and RAI scores (β=0.29, C.I. = [0.18, 0.41]; (β=0.25, C.I. = [0.14, 0.37] respectively). In multivariate regression analyses mutually adjusting for all SES variables and covariates, most associations remained, however occupation was no longer associated with CES-D. Results for hip sOA were similar to those for rOA, although we did not observe associations for education with CES-D or occupation with RAI. Community poverty showed little association with either depression or feelings of helplessness.

Conclusion: Low educational attainment is associated with higher levels of depression and feelings of helplessness in people with hip OA. Non-managerial occupation may also play an independent role, particularly for helplessness. These data highlight the importance of individual-level SES measures as risk factors for depression and feelings of helplessness in persons with OA.

Current Social Position Associated with Rheumatoid Arthritis Severity and Self-Reported Health Outcomes in African Americans. Leigh F. Callahan[1], Rebecca J. Cleveland[1], Xia Li[1], Todd A. Schwartz[1], Beth L. Jonas[1], Ted R. Mikuls[2], Britta L. Schoster[1], Graciela S. Alarcon[3], Richard Brasington[4], Doyt L. Conn[5], Edwin A. Smith[6], George Howard[3], Larry W. Moreland[7] and S. Louis Bridges Jr.[8]. [1]University of North Carolina, Chapel Hill, NC, [2]Omaha VA and University of Nebraska, Omaha, NE, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Washington Univ School of Med, St. Louis, MO, [5]Emory Univ School of Medicine, Atlanta, GA, [6]Med Univ of South Carolina, Charleston, SC, [7]University of Pittsburgh, Pittsburgh, PA, [8]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Socioeconomic status (SES), has been shown to be associated with rheumatoid arthritis (RA) prevalence as well as physical and psychosocial outcomes. Ethnicity is sometimes used as a surrogate for SES, but recent findings suggest this may not be appropriate. The purpose of this study is to evaluate whether SES is associated with RA disease severity and patient reported outcomes (PROs), independent of ethnicity, in a population of African Americans (AA) with RA.

Methods: A cross-sectional analysis was conducted on 855 AA patients with RA who were enrolled from medical centers in the southeastern US. SES measures were educational attainment (≤ high school [HS] diploma, or >HS); occupation (OCC) (professional or non); home ownership (yes or no); and annual household income (INC) (≤$30,000 (30K) or >$30K). Outcomes were joint severity (tenderness, swelling and malalignment); radiographs (erosion, JSN score); laboratory measures (C-reactive protein [CRP] levels, rheumatoid factor [RF], and anti-cyclic citrullinated protein antibodies [anti-CCP]); and PROs (HAQ, pain and fatigue visual analog scales [VAS], helplessness Rheumatology Attitudes Index [RAI], and counts of poor physical, poor mental, and limited activity days). Covariates included gender, age, RA disease duration, current Methotrexate/Leflunomide and biologic agent use, clinical comorbidity index, and pack-years of cigarette smoking (0, <10, 10-<20, ≥20). Bivariate analyses were performed to examine mean values of RA severity markers according to SES. Regression models were used to determine associations of each RA severity outcome and PROs with SES measures, adjusting for covariates. All analyses were also performed in a subset of those with RA ≤2 years (N=413).

Results: The mean age was 54 years, 84% were female, and average RA disease duration was 84 months. Approximately 57% had ≤HS, 51% non-professional OCC, 52% non-homeowners, 71% INC≤$30K and 52% had ever smoked. In bivariate analyses, all measures of low SES were associated with poorer outcomes, with the strongest associations seen for ≤$30K and non-homeowners with PROs (P<0.01). In a covariate-adjusted multivariable regression model examining all SES measures, significant independent associations with joint severity measures and most PROs were limited to INC ≤$30K and homeowners. Similar results were seen in analyses limited to those with RA ≤2 years.

Conclusion: In AA with RA, disease severity and low PROs are associated with low levels of SES, particularly for those with low household income and not owning a home. These data support the importance of SES with clinical and self-reported RA disease severity measures. Our finding that SES is a significant predictor of RA severity in a population limited to AA highlights the importance of SES outside of racial context.

1546

Early Consultation with a Rheumatologist for Rheumatoid Arthritis: Does It Reduce Subsequent Use of Orthopaedic Surgery? Debbie Ehrmann Feldman[1], Sasha Bernatsky[2], Michelle Houde[3], Marie-Eve Beauchamp[2] and Michal Abrahamowicz[2]. [1]Université de Montréal, Montréal, QC, [2]McGill UHC/RVH, Montreal, QC, [3]Public Health Department of Montreal, Montreal, QC

Background/Purpose: Optimal care in rheumatoid arthritis (RA) includes early use of disease-modifying anti-rheumatic drugs to prevent joint damage and hopefully decrease surgical interventions. Our objective was to determine if persons with RA who saw a rheumatologist early in the disease course had a reduced rate of orthopaedic surgery.

Methods: All persons with a diagnosis of RA confirmed by a rheumatologist and based on billing code data in the province of Quebec, in 1995 were followed until 2007. Patients were classified as "early consulters" if they were seen by a rheumatologist within 3 months of being diagnosed with RA by their referring physician, "late consulters" if they were seen by more than 3 months after the initial RA diagnosis, and "undetermined" if they were first diagnosed with RA by a rheumatologist. Time to orthopaedic surgery, defined using ICD9 and ICD10 procedure codes, was compared with Cox's proportional hazards regression.

Results: There were 3,890 patients with a confirmed RA diagnosis: mean age at diagnosis was 56.3 years and 69.4% were female. Most (73%) were "undetermined consulters"; 13.7% were "early" consulters and 13.3% "late" consulters. Among all patients, 15.3% (610) had an orthopaedic surgery during the observation interval. Patients in the early consultation group were less likely to undergo orthopaedic surgery over the 12 year follow-up period than those in the late consultation group (adjusted hazard ratio: 0.63; 95% confidence interval: 0.46, 0.85).

Conclusion: Persons diagnosed with RA who consult a rheumatologist later in the disease course have a worse outcome in terms of eventual orthopaedic surgery. In addition to improving patient outcomes, appropriate medical treatment under the supervision of a rheumatologist may also decrease costly interventions such as orthopaedic surgery. Our results add more credence to support early treatment guided by a rheumatologist in patients with rheumatoid arthritis.

Tumor Necrosis Factor Blocker Treatment Patterns After Discontinuation within the First Year of Therapy Initiation in Rheumatoid Arthritis Patients in a Real-World Managed Care Setting. Machaon Bonafede[1], Crystal Watson[2], Kathy M. Fox[3], Nicole Princic[1] and Shravanthi R. Gandra[2]. [1]Thomson Reuters Healthcare, Cambridge, MA, [2]Amgen Inc, Thousand Oaks, CA, [3]Strategic Healthcare Solutions, LLC, Monkton, MD

Background/Purpose: Clinical guidelines and published literature do not offer specific recommendations for treatment options after discontinuing a tumor necrosis factor (TNF) blocker for rheumatoid arthritis (RA). Some clinical trials have tested the efficacy of switching among TNF blockers, but patterns of TNF-blocker use after discontinuation in a real-world setting are not well characterized. The purpose of this study is to estimate the percentage of patients and time to restart the initial TNF blocker or switch to another biologic within the first year of therapy initiation among RA patients discontinuing etanercept (ETN), adalimumab (ADA), or infliximab (INF) in a real-world managed care setting.

Methods: MarketScan Commercial Database was used to identify biologic-naïve adult (18–64 years) RA patients with ≥1 claim for ETN, ADA, or INF between January 1, 2005 and June 30, 2009. Patients were followed for 1 year after the initial TNF blocker claim (index date) and had to be continuous enrolled 6-months prior to index (pre-index period) and 1-year after index. Patients diagnosed with psoriasis, psoriatic arthritis, ankylosing spondylitis, juvenile idiopathic arthritis, Crohn's disease, or ulcerative colitis in the pre-index period were excluded. Discontinuation from index therapy was defined as either a >45 day gap in therapy or switch to another biologic. Time to restart or switch was measured in days from index date of initial TNF-blocker therapy.

Results: Overall, 2,933 ETN, 2,094 ADA, and 1,099 INF RA patients were included. Patient characteristics were similar between the treatment groups with a mean age (SD) of 50 (10) years and 76% female. The percentage of patients who discontinued within 1-year for ETN, ADA and INF were 59%, 57%, and 48%, respectively. The percentage of patients who discontinued and restarted initial TNF-blocker therapy were 23% for ETN, 18% for ADA, and 11% for INF. Mean (SD) time to restart from index date was 219 (79) days for ETN, 223 (82) days for ADA, and 241 (77) days for INF. Switch to any non-index biologic occurred in 15% of ETN, 14% of ADA, and 13% of INF patients. Of the patients who switched, the majority (84%) switched to one of the other TNF-blockers (ETN, ADA, or INF) with a mean time to switch between 170–207 days.

Conclusion: Among RA patients initiating a TNF-blocker therapy in a managed care setting, 11–23% of patients discontinued and restarted the initial TNF-blocker therapy and approximately 13–15% switched to another biologic in the first year. In the first year, the mean time to restart after discontinuing index therapy was between 219–241 days, whereas switching to another TNF blocker therapy occurred around 170–207 days from initiation of index therapy.

1548

Analysis of Radiographic Changes in Patients with Early Psoriatic Arthritis. Majed M. Khraishi[1], Rana Aslanov[2], Emmanouil Rampakakis[3], Anh Duong[4] and John S. Sampalis[3]. [1]Memorial University of Newfoundland, St Johns, NF, [2]Memorial University of Newfoundland, St.John's, NF, [3]McGill University & JSS Medical Research, Montreal, QC, [4]JSS Medical Research, Westmount, QC

Background/Purpose: Psoriatic arthritis (PsA) is a seronegative arthropathy characterized by axial involvement, peripheral arthritis, and enthesitis. Disease duration and severity of joint inflammation significantly affect the radiographic outcome which can be used as a prognostic factor for PsA progression. Radiography at early PsA (EPsA) stages can play a vital role in the patient evaluation, differential diagnosis from other arthritis types and management. The aim of this study was to describe the radiographic changes in EPsA, defined as <2 years since symptom onset

Methods: EPsA patients (pts) were assessed at a rheumatology clinic specializing in PsA. Standard clinical and laboratory assessments including conventional radiography of peripheral (hands, wrists and feet) and sacroiliac joints were conducted at baseline. All detected radiographic changes were classified as normal, abnormal-not clinically relevant-, and abnormal-clinically relevant-, and their association with patient demographics and baseline characteristics was analyzed

Results: A total of 84 pts with EPsA (mean (SD) disease duration = 1.0 (0.8) yrs) were included in this analysis. Table 1 shows the cohort baseline characteristics. The most common joint involvement was polyarticular (59.5% of pts) presentation (symmetric or asymmetric) and Distal Interphalangeal Predominant (DIP) involvement (57.1% of pts).

Among the 79 pts with available baseline radiological assessment until now, radiological damage was identified in 25 (31.6%) pts, of whom 10 (40%) had changes in 2 joints and 3 (12%) in ≥3 joints. The vast majority of these pts (n=19, 76%) experienced joint damage within the 1st year of PsA onset. The observed radiographic changes included new bone formation (often interpreted by radiologists as degenerative), slight to moderate narrowing of the joint space, and marginal and central bone erosions, with the majority of abnormalities appearing in the hands, feet and sacroiliac (SI) joints. Among the 66 pts evaluated, 15 (23%) had abnormal hand images, of whom 9 (60%) in both hands. Furthermore, 10% of the evaluated pts (5/50) had radiographic abnormalities in feet (3 (60%) in both legs) and 10.4% (7/67) in SI joints (2 (30%) in both sides).

Mean (SD) CRP was higher in pts with radiological damage compared to the rest of the cohort (8.8 (7.7) vs 5.8 (5.5);P=0.053). Mean (SD) SJC was also higher in former pts (4.4 (6.2) vs 3.0 (3.7)), although without reaching statistical significance. All other parameters were comparable between the groups

Conclusion: Radiological damage was detected in 32% of patients with EPsA, which was associated with increased CRP. Among these, 76% acquired the damage within the 1st year of symptom onset. Asymmetric oligoarthritis was not a dominant pattern in our cohort as was previously reported. The increased incidence of axial and DIP joint involvement are in agreement with previous studies showing that they represent the most common sites in PsA.

Table 1. Baseline Characteristics and Patient Disposition

Parameter	N=84
Mean (SD) Age (years)	48.04 (10.55)
Female Gender: n (%)	44 (52.4%)
Mean (SD) Age at PSO Diagnosis (years)	38.73 (14.17)
Mean (SD) Age at PsA Diagnosis (years)	47.85 (10.66)
Mean (SD) PASQ score	11.33 (4.83)
Mean (SD) PASI score	3.51 (5.94)
Mean (SD) CRP	6.71 (6.36)
Mean (SD) ESR	15.99 (18.43)
Mean (SD) TJC	8.32 (8.48)
Mean (SD) SJC	3.42 (4.60)
PsA Treatment n (%)	
NSAIDs	68 (81.0)
MTX	26 (31.0)
Sulfasalazine	9 (10.7)
Anti-TNFá	8 (9.5)

Patients with Polymyositis, Dermatomyositis and Inclusion Body Myositis Have Activity Limitations Despite Low Disease Activity: A Registry Study. Li Alemo Munters[1], Malin Regardt[2], Therese Jansson[3], Susanna Johansson[3], Christina Ottosson[4], Maryam Dastmalchi[5], Ingrid E. Lundberg[3] and Helene Alexanderson[3]. [1]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden, [4]Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden, [5]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Polymyositis (PM), dermatomyositis (DM) and inclusion body myositis (IBM) are rare diseases characterized by slowly progressive muscle weakness. Although patients with PM and DM respond to treatment with clinical improvement several develop a sustained disability that increase during the disease course, limiting activities in daily life. The knowledge of activity limitations in PM, DM and IBM is limited. All patients with PM, DM and IBM at Karolinska University Hospital are registered annually in the Swedish Myositis Network Registry (SWEMYONET). The aims of this registry study were to investigate activity limitation in a cohort of patients with PM, DM and IBM and to evaluate correlations between two activity limitation measures and disease activity.

Methods: All patients registered in SWEMYONET from Karolinska University Hospital during 2009 were included. Activity limitation was measured by Health Assessment Questionnaire (HAQ) (score range, 0–3.00) and Myositis Activities Profile (MAP) (score range, 1–7). The cohort consisted of 84 patients of whom 33 had PM (73% women), 40 had DM (55% women) and 11 had IBM (55% women). Median disease duration for PM was 9 years (range, 1–28), for DM 10 years (1–41) and IBM 6 years (2–11). Median of Physician's global assessment of disease activity (0–100mm) was 5 mm (range, 0–50). Mann Whitney U-test was applied to test the sub-groups differences, level of significance was set to <0.05. Spearman rang correlation (r_s) was used to test correlations between measures.

Results: Median HAQ values indicated mild activity limitation for both PM, Md=1.00 (range, 0–2.50) and DM 0.25 (0–1.88) and moderate for IBM 1.5 (0.5–2.75). Activity limitation measured by MAP in PM indicate moderate limitation Md=3.75 (range, 1–7), in DM mild limitation 2 (1–7) and for IBM moderate limitation 4 (1–7).The most limited activity domains measured by MAP in PM were *work/school work* and *leisure,* in DM *moving around, work/school work and leisure* and in IBM *moving around, work/school work* and *leisure*. Patients with DM had significantly less activity limitation compared to PM and IBM whereas IBM had significantly higher activity limitation than PM and DM. High correlations (r_s= 0.70 – 0.79) were revealed between HAQ and four domains of MAP (*Movement, Self Care, Moving around, Domestic*). There were low correlations between HAQ/MAP and Physician's global assessment of disease activity (r_s=0.39 / 0.21–0.41).

Conclusion: Although low disease activity was revealed in the cohort, patients still perceived mild to moderate activity limitation. Patients with DM had less activity limitation than patients with PM and IBM while

patients with IBM had greater activity limitation than PM and DM. The most limited activity domain in the cohort was *leisure*. The correlations between HAQ and MAP are equivalent to findings in a previous study (1).

Influenza Vaccine Intervention in a Rheumatology Clinic Population. Sherece Black[1], Sarabjit Brar[1], Lee Chang, Sylvia Chico[1], Donald Makowski[1], Virginia Haiduc[1], Steven K. Magid[3], Julie A. Pollino-Tanner[1], Julita C. Reyes-Canu[1], Ann M. Rakowicz[1] and Monica C. Richey[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hosp for Special Surgery, New York, NY

Background/Purpose: The Center for Disease Control (CDC) recommends annual influenza vaccination for all immunosuppressed individuals. Persons with rheumatologic conditions are immunocompromised not only due to disease, but also because of the medication they take. As a consequence they have an increased risk of developing infections than the healthy individuals. In spite of the recommendation by the Advisory Committee on Immunization (ACIP) and the American College of Rheumatology (ACR), rheumatology patients overall have lower influenza and pneumococcal vaccination rate compared to the general population. During the 2009–2010 Influenza vaccine season, out of 1514 clinic patient visits to our Division of Rheumatology, only 100 (6%) clinic patients were vaccinated.

Objectives: The objective was to increase the number of patients who receive the influenza vaccine during the 2010–2011 Influenza season in our Rheumatology clinic.

Methods: In order to increase the vaccination rates for our patients, a nurse specific intervention was designed. Posters and flyers promoting the health benefits of the influenza vaccine were posted in the patient reception areas, and exam rooms. Using a paper survey in both English and Spanish, a registered nurse queried all patient: a) if they have been vaccinated b) if they wanted to be vaccinated c) the reason for refusal of the vaccine. Asking patients the "why not" question was thought to be helpful in organizing future strategies for patient education with the goal to increase the vaccination rate. To prevent duplication of surveys, stickers were attached to all charts, indicating patient acceptance or refusal of the vaccine. Patients that refused the vaccine were educated on the importance of receiving the influenza vaccine by the registered nurse.

Results: Of 1195 patients who visited our clinic during the 2010–2011 Influenza vaccine season, 440(36.8%) completed the survey. The survey results indicated that a) 256(21.4%) patients received the vaccine in our clinic, b) 133(11%) patients were previously vaccinated by their primary care physician (PCP), and c) 51(4.25%) patients refused.

Conclusion: The nurse specific intervention designed to increase the number of patients who received the Influenza vaccine in our Rheumatology Division was proven effective. The percentage of patients vaccinated during the 2010–2011 Influenza season increased from 6% (2009–2010 Influenza season) to 21.4%. Based on these results, we learned that a nurse specific intervention is an important step in promoting influenza immunization in our clinic. Our next year efforts will focus on improving our strategy and further patient education about the importance of receiving this particular vaccine

1551

What Is the Health Literacy and Numeracy in a Rheumatology Veterans Population? Janine A. Galasso. Philadelphia VA Medical Center, Philadelphia, PA

Background/Purpose: As defined in Healthy People 2010 (US HHS 2000), health literacy is: "the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions. Low health literacy has been shown to negatively impact patient well being and medication adherence. Health numeracy is the use of quantitative skills in the context of healthcare, and can negatively impact medication adherence as well. Patients with rheumatic disease who have limited health literacy are at higher risk for adverse outcomes due to the number of medications and complex treatment regimens often prescribed. The purpose of this project was to evaluate the health literacy and numeracy of Rheumatology patients in a Veterans rheumatology clinic

Methods: This prospective, cross-sectional, single center study was approved by the institutional review board at the Philadelphia VA Medical Center. Subjects were enrolled that met the inclusion criteria of; at least 18 years of age, English as the primary language and a diagnosis of one or more of the following: RA, OA, SLE, Gout or other rheumatic disease. Patients completed a validated Literacy Questionnaire (STOHLA), and a Rheumatology Numeracy Questionnaire previously published by one of the authors (JMVF;Rheum Disease 67 (supII):673, July 2008).

Results: Thirty-three subjects were enrolled in the study. 85% were male with a mean age of 54 (27–77 years) 51% self-identified as African American, 42% as Caucasian and 12% as Hispanic. The rheumatologic diagnosis distribution was:: gout 12%, RA 42%, OA 24%, SLE 6%, other 6%. The average number of medications per electronic health record was 7.9 (5.07174 SD). Completed level of educations were: $<6^{th}$ grade 0%, $7–11^{th}$ grade 3%, high school 21%, technical/vocational school 9.3%, some college 37.5%, B.S. degree 18.75% and Masters or above 6.25%. The majority of patients (88%) had adequate health literacy, The average score on the numeracy test was 56% (24.45927 SD), on a scale of 0–100%, suggesting that most subjects struggled with quantitative skills.

Conclusion: The majority of Veteran patients had adequate literacy, but inadequate health numeracy, In patients with low health numeracy and an average number of medications of 7.9, patient safety can be compromised and medication errors can occur If validated in a larger population, intervention strategies can be developed to improve patient education about medications, and circumvent health numeracy deficits.

1552

Factors Associated with Hallux Valgus: The Johnston County Osteoarthritis Project. Yvonne M. Golightly[1], Marian T. Hannan[2], Alyssa B. Dufour[3], Jordan Renner[4] and Joanne M. Jordan[1]. [1]UNC Thurston Arthritis Research Center, Chapel Hill, NC, [2]Hebrew SeniorLife & Harvard Med Sch, Boston, MA, [3]Hebrew SeniorLife & Boston Univ, Boston, MA, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: Prevalence of hallux valgus (HV) differs by gender and by race, but underlying factors that explain these differences are not well understood. This cross-sectional analysis examined 1) whether HV is associated with foot pain, and 2) potential factors associated with HV in a large, bi-racial cohort of men and women 50 years of age or older.

Methods: Of the 1,670 Johnston County Osteoarthritis Project participants clinically evaluated in 2006–2010, 1,416 had complete foot exam, foot symptoms, and clinical and demographic data available for analysis (mean age 68 years, mean body mass index [BMI] 31.7 kg/m^2, 66.2% women, 31.1% African American [AA]). Trained examiners used the validated Foot Assessment Clinical Tool to assess HV (present/absent based on angle of hallux toward lesser toes $>15°$), pes planus (present/absent), and presence of foot symptoms ("on most days, do you have pain, aching or stiffness in your [right/left] foot?"). Multivariate logistic regression models for the total sample and by each gender and race group (AA men, AA women, Caucasian men, Caucasian women) were performed to examine the effect of age (in 10 year increments), BMI (categorized as <25, 25–30, 30–35, and >35 kg/m^2), foot symptoms, pes planus, and presence of knee or hip radiographic osteoarthritis (OA) on HV.

Results: HV was present in 64.3% of the total sample (AA men=70.4%, AA women=69.0%, Caucasian men=55.4%, Caucasian women=65.5%). Table shows risk factors for HV for the total sample and by gender-and-race groups. In the total sample, female gender, AA race, older age, pes planus, and the presence of knee/hip OA elevated the odds of HV, and greater BMI lowered the odds of HV, adjusting for all other factors. When pes planus was present, the odds of HV in AA men were 2.6 times higher (adjusted odd ratio [aOR] =2.60, 95% confidence interval [95% CI] =1.09, 6.19). AA women, Caucasian men, and Caucasian women had non-significantly elevated ORs for HV and pes planus. A BMI of 25–30 kg/m^2 was inversely associated with HV among Caucasian men (aOR = 0.39, 95% CI = 0.16, 0.94). This association between BMI and HV was observed across other BMI categories, although it was not statistically significant. When radiographic knee/hip OA were present, the odds of HV were higher across groups, particularly in Caucasian men (aOR = 2.05, 95% CI = 1.28, 3.29).

Factors Associated with Hallux Valgus (adjusted for all other covariates)

	Total Sample (N=1416)	AA Men (N=135)	AA Women (N=306)	Caucasian Men (N=343)	Caucasian Women (N=632)
	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)
Gender (referent= male)	1.28 (1.01, 1.61)	—	—	—	—
Race (referent= Caucasian)	1.33 (1.03, 1.71)	—	—	—	—
Age (10 year increment)	1.19 (1.05, 1.35)	1.24 (0.80,1.93)	1.26 (0.94, 1.68)	1.15 (0.89, 1.50)	1.19 (0.98, 1.43)
BMI <25 (referent)	1.00	1.00	1.00	1.00	1.00
BMI 25–30	0.66 (0.46, 0.95)	0.33 (0.10, 1.09)	0.82 (0.26, 2.62)	0.39 (0.16, 0.94)	0.89 (0.55, 1.43)
BMI 30–35	0.75 (0.51, 1.10)	0.76 (0.21, 2.71)	0.48 (0.16, 1.46)	0.48 (0.19, 1.19)	1.09 (0.64, 1.85)
BMI >35	0.57 (0.39, 0.84)	0.36 (0.10, 1.25)	0.44 (0.15, 1.32)	0.46 (0.18, 1.18)	0.76 (0.45, 1.29)
Foot symptoms	1.27 (0.98, 1.67)	0.99 (0.38, 2.59)	1.64 (0.84, 3.20)	1.19 (0.67, 2.12)	1.25 (0.86, 1.81)
Pes Planus	1.69 (1.27, 2.24)	2.60 (1.09, 6.19)	1.64 (0.97, 2.77)	1.69 (0.89, 3.21)	1.52 (0.95, 2.41)
Knee or Hip osteoarthritis	1.41 (1.11, 1.79)	1.25 (0.55, 2.81)	1.54 (0.85, 2.79)	2.05 (1.28, 3.29)	1.20 (0.84, 1.70)

Conclusion: HV and pes planus were associated, most notably among AA men, and HV and knee/hip OA were associated, especially among Caucasian men. Higher BMI was generally inversely associated with HV. We believe this is the first report of the association between HV and knee/hip OA. Future studies should examine possible effects of genetics, shoe wear (especially toe box structure), multi-joint OA (joints in addition to knee and hip), and occupational factors to explain these differences and inform early intervention approaches.

1553

Foot Type Is Linked to Falls in Older Adults: The Framingham Foot Study. Jody L. Riskowski[1], Thomas J. Hagedorn[2], Alyssa B. Dufour[3], Virginia A. Casey[2] and Marian T. Hannan[4]. [1]Hebrew SeniorLife, Boston, MA, [2]Hebrew Senior Life, Boston, MA, [3]Hebrew SeniorLife & Boston Univ, Boston, MA, [4]Hebrew SeniorLife & Harvard Med Sch, Boston, MA

Background/Purpose: In the US, 30% of community-residing older adults fall each year. Although the causes of falls are multifactorial, few studies have investigated foot type (i.e., high, low and rectus arch) and fall risk, despite it being the main or only base of support. Therefore, the purpose of this study was to evaluate foot type and fall risk in a population-based study of older adults.

Methods: This study included participants in the Framingham Foot Study who were members of the Framingham Study Original and Offspring cohorts who had a valid standing and walking plantar pressure scan of each foot and information on falls between 2002 and 2008. Foot pressure scans were collected using Tekscan Matscan (Boston, MA). Participants walked barefoot at a self-selected pace across a 3.5m walkway, using the two-step method to collect a pressure scan for each foot. Foot type was assessed using the Modified Arch Index (MAI) from the dominant limb (as determined from the foot scan as leg with greater propulsive force, not self-report). Cut-points for foot type were based on sex-specific quartiles of MAI. The highest and lowest 25% of the MAI values categorized foot type (i.e., low arch was highest MAI quartile and high arch was lowest MAI quartile). The middle 50% was the referent (rectus foot type). Falls were recorded as yes/no based on participant self-report of falling in the past year. Sex-specific logistic regression models were used to examine foot type and fall risk relative to the referent. A second model further adjusted for age and body mass index (BMI).

Results: Of the 2131 participants, there were 954 men (age: 66.0 ± 9.9 years; BMI: 27.7 ± 6.0 kg/m^2) and 1177 women (age: 65.6 ± 10.6 years; BMI: 28.7 ± 4.6 kg/m^2). 236 men (14.8%) and 456 (22.7%) women reported falling in the past year.

The unadjusted and adjusted odds ratios showed that men who had high arches had a ~55% decreased fall risk (Table). Men who had low arches had an increased fall risk, although not statistically significant. No association was noted in the unadjusted model for women; however, the adjusted model showed a 12% decrease in fall risk for women with low arches.

	Unadjusted OR		Adjusted OR	
	Men	Women	Men	Women
MAI Rectus (referent)	1.00	1.00	1.00	1.00
MAI High Arch	**0.43 (0.25, 0.74)**	0.95 (0.69, 1.34)	**0.46 (0.29, 0.75)**	0.90 (0.81, 1.21)
MAI Low Arch	1.33 (0.88, 2.00)	1.08 (0.78, 1.37)	1.27 (0.92, 1.77)	**0.78 (0.68, 0.96)**

Conclusion: Both the unadjusted (clinically relevant) and adjusted (biologic mechanism relevant) models showed an association between foot type and falls, especially in men. Future studies should examine foot type and its role in balance and gait to understand how foot type influences fall risk in risk in older adult populations.

1554

The Effect of Foot Pain on Mobility Disability in Older Adults: The Framingham Foot Study. Virginia A. Casey[1], Alyssa B. Dufour[2], Jody L. Riskowski[3], Thomas J. Hagedorn[1], Robert R. McLean[4] and Marian T. Hannan[5]. [1]Hebrew Senior Life, Boston, MA, [2]Hebrew SeniorLife & Boston Univ, Boston, MA, [3]Hebrew SeniorLife, Boston, MA, [4]Hebrew Senior Life/Harvard Medical School, Boston, MA, [5]Hebrew SeniorLife & Harvard Med Sch, Boston, MA

Background/Purpose: Studies have shown that BMI is a strong and persistent predictor for mobility disability in older adults. Additionally, foot pain is also known to be more prevalent in obese individuals. The purpose of this study is to evaluate the independent relations between foot pain and mobility disability in a population of community-dwelling older adults.

Methods: A subset of participants from the Framingham Foot Study (2002–2008) who had performance measures of physical limitations and disability assessed were included in this cross-sectional analysis (n=1332). Mobility disability was assessed using the Short Physical Performance Battery (SPPB). The SPPB is a composite of 3 timed performance tests with each test scored on a scale of 0 to 4; the highest possible score of 12 indicates better physical function. Studies in healthy older adult populations have shown the SPPB to be predictive of physical limitations, disability and mortality. For this analysis, the SPPB score was dichotomized using 1–10 as an indicator of mobility disability and 11–12 as a good score. Foot pain (y/n) was queried by a trained examiner "On most days, do you have pain, aching or stiffness in either foot?" Age, sex, body mass index (BMI, grouped <25, 25–30, >30 kg/m^2), physical activity (PASE score from validated Physical Activity Scale for the Elderly), current smoker (y/n) and depression score (CES-D scale) were also obtained or assessed. Sex-specific multivariate logistic regression models were performed to examine the effect of the above factors upon mobility disability.

Results: Our study sample of 1332 older adults had a mean age of 70yrs (±SD 12.0) and mean BMI of 28 kg/m^2 (±5.3) with an age range of 41–98y in men and 36–100y in women. The 550 men had mean age of 70 yrs (± 11.3) and BMI of 29 kg/m^2(± 4.6) while women had mean age of 70 yrs (± 12.4) and mean BMI of 27 kg/m^2 (± 5.7). As age increased, both men and women had a greater probability of being in the poor mobility disability group (OR=1.2; p<0.0001). 26% of the men and 35% of the women had foot pain. Males with foot pain had greater than a two-fold odds of being in the poor mobility disability group (OR=2.5; p<0.007) even after controlling for the effects of age and BMI. The relation between disability and foot pain was less pronounced in females (OR=1.4) with only a trend toward significance. Surprisingly, physical activity, smoking status and depression score did not contribute to the models in either sex.

Conclusion: Presence of foot pain increased the odds of having mobility disability in our study of older adult men from the Framingham Foot Study with a similar, but not statistically significant relation, seen in women. As foot conditions and related foot pain are mostly easily treatable, clinicians should consider assessment of foot pain in general examinations of older adults who are at risk for mobility disability.

1555

Lesser Toe Deformities Are Highly Heritable in Older Men and Women: The Framingham Foot Study. Marian T. Hannan[1], Yi-Hsiang Hsu[1], Virginia A. Casey[2], Gouri Vadali[2] and Joanne M. Jordan[3]. [1]Hebrew SeniorLife & Harvard Med Sch, Boston, MA, [2]Hebrew Senior Life, Boston, MA, [3]UNC Thurston Arthritis Center, Chapel Hill, NC

Background/Purpose: Foot disorders affect 20–60% of adults and are often linked to physical limitations. Although genetics are commonly suspected in foot disorders, only two studies have been done: a family aggregation study showing that family history of hallux valgus may have an autosomal dominant transmission, and our work in 2010 that reported high heritability of hallux valgus and pes cavus. To our knowledge, no other studies have examined foot disorders and genetics in humans. Our purpose was to examine further heritability of several common foot conditions, linking data on specific foot disorders to a wealth of genetic data in the community-based Framingham Study, using their pedigree structure.

Methods: The Framingham Foot Study (n=2179 participants examined in 2002–2005) was designed to examine common foot disorders and functional limitations. A trained examiner used a validated foot exam to assess specific foot disorders in participants. Genotyping has been obtained in 959 men and 1220 women. We estimated overall, sex-specific and age (< 60, 60+y) heritability of lesser toe deformities (hammer toes, claw toes, overlapping toes), heel fat-pad atrophy (present/absent), forefoot fat-pad atrophy (present/absent), and pes planus in the Framingham participants. Pes planus was defined using a digital recording of foot pressure while walking (MatScan device, Tekscan, Inc. Boston MA), that

allowed calculation of the ratio of arch width (medial to lateral, to nearest 0.01 cm) to heel width. Pes planus (present/absent) was defined as either foot as having a weight-bearing arch width ≥ 75% of the heel width (previous work showed that this cut-point encompassed those with clinician impression of flat feet). We estimated heritability of the foot conditions by a standard quantitative genetic variance-components model implemented in the Sequential Oligogenic Linkage Analysis Routines (SOLAR) package.

Results: Mean age was 66y (range 39–99y); 57% were female. The prevalence of lesser toe deformities was 35% (753 toe deformity cases with available pedigree structure). The overall heritability of lesser toe deformities was 0.79 for women and 0.61 for men (both p-value < 0.01) and 0.56 for both sexes combined ($p = 4 \times 10^{-7}$) For persons aged < 60y, the heritability was 0.63. The prevalence of heel fat-pad atrophy was 13%, of forefoot fat-pad atrophy was 30%, and of pes planus was 8%. Of these foot conditions, none showed significant heritability overall or by group. Thus, only lesser toe deformities were highly heritable for both men and women.

Conclusion: This study reveals new findings in an area that has received little attention, yet is critically important to general populations. We documented for the first time, the high heritability (strongly suspected by many) of a structural foot disorder phenotype: lesser toe deformities. As foot disorders are common, it is important to identify those at high risk, as effective interventions exist. Also, especially for lesser toe deformities, identification of individuals close to onset may lessen the impact of foot disorders or prevent development of physical limitations. Genome-wide association analyses are planned to identify potential genetic determinants for this common foot disorder.

1556

Factors Affecting Dynamic Foot Function in Older Adults: The Framingham Foot Study. Thomas J. Hagedorn[1], Alyssa B. Dufour[2], Yvonne M. Golightly[3], Jody L. Riskowski[4], Howard J. Hillstrom[5], Virginia A. Casey[1] and Marian T. Hannan[6]. [1]Hebrew Senior Life, Boston, MA, [2]Hebrew SeniorLife & Boston Univ, Boston, MA, [3]University of North Carolina, Chapel Hill, NC, [4]Hebrew SeniorLife, Boston, MA, [5]Hospital Special Surgery (HSS), New York, NY, [6]Hebrew SeniorLife & Harvard Med Sch, Boston, MA

Background/Purpose: Excessive pronation and supination of the foot are thought to be linked to worse physical function. The center of pressure excursion index (CPEI), a measure that characterizes pronation and supination, may be a useful indicator of dynamic foot structure and function. A larger CPEI value indicates supination, while a smaller CPEI indicates pronation. The purpose of this study was to identify important risk factors for CPEI or subsets with different CPEI among a large cohort of community-dwelling, ambulatory men and women with a wide age spectrum, as the initial step in understanding foot function and outcomes.

Methods: 2094 participants were included from the population-based Framingham Foot Study, examined between 2002 and 2008. Participants walked at a self-selected pace over a Tekscan Matscan system (Boston, MA) using the two step method, and plantar pressure scans were recorded for each foot. Bilateral CPEIs were averaged due to similarities between feet. Factors included sex, age (< 65 or ≥ 65 years), BMI (≥ 30 or < 30 kg/m^2), physical activity (PASE score from questionnaire dichotomized at the mean as ≥ 127, < 127), and type of shoewear. ("bad"= sandals, slippers, or high heels; "good"= athletic shoes, sneakers, leather shoes, rubber soled shoes, or work boots, based on previous work). We used Students t-Test to identify those factors associated with CPEI separately by sex. The effect of continuous age and BMI and sex were also evaluated using a linear regression model.

Results: Participants (55% female) had a mean age of 66.8 ± 10.16 yrs, and a mean BMI of 28.43 ± 28.4 kg/m^2. Results of t-Tests are shown in Table 1. The mean CPEI was smaller among women than men ($p < .0035$). Older men had smaller mean CPEI ($p = .0001$), and a similar, borderline significant, difference was seen in older women ($p = 0.0569$). Mean CPEI did not differ by BMI, PASE score, or shoewear. The regression model showed significant contributions by age and sex ($p < .0001$), but not BMI ($p = 0.17$).

Table 1. T-Tests for risk factors and CPEI in men and women: Framingham Foot Study

Males	N	Mean CPEI	Standard Deviation	p	Females	N	Mean CPEI	Standard Deviation	p
Sex	952	16.057	6.35		Sex	1142	12.87	6.45	<.0001
Age < 65	415	16.74	6.32	0.003	Age < 65	543	13.25	6.34	0.06
Age ≥ 65	537	15.53	6.33		Age ≥ 65	599	12.53	6.53	
BMI < 30	603	16.08	6.48	0.90	BMI < 30	794	12.72	6.52	0.23
BMI ≥ 30	341	16.03	6.13		BMI ≥ 30	348	13.22	6.27	
PASE <127	269	14.63	7.50	0.86	PASE <127	392	12.09	7.71	0.70
PASE ≥ 127	293	14.74	7.28		PASE ≥ 127	308	11.85	8.03	
Bad Shoes	932	15.76	7.95	0.78	Bad Shoes	1000	11.45	8.15	0.28
Good Shoes	17	15.21	7.68		Good Shoes	142	12.24	7.95	

Conclusion: We found significant differences in CPEI by age and sex, while noting that CPEI did not differ by BMI, physical activity, or shoewear. Sex differences may likely be due to anatomical differences in the lower extremity that give women a more pronated gait. The differences in older men might be the result of changes to the foot with age, such as an increased prevalence of flat feet but more research is needed to examine this possibility. Physical activity, BMI, and shoewear did not significantly influence CPEI in our analyses, suggesting that foot function is may be driven more by local anatomical than systemic considerations. This study is the first to show age and sex differences in foot function in a large population-based cohort. Future work will evaluate the relationship between CPEI and outcomes such as falls, sarcopenia, and lower extremity function.

Non-Pharmacological Interventions for Fatigue in Rheumatoid Arthritis: A Cochrane Review. Fiona Cramp[1], Sarah Hewlett[1], Celia Almeida[1], John R. Kirwan[2], Ernest Choy[3], Trudie Chalder[4], Jon Pollock[1] and Robin Christensen[5]. [1]University of the West of England, Bristol, United Kingdom, [2]University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom, [3]Cardiff University, Cardiff, ENGLAND, United Kingdom, [4]Department of Psychological Medicine, London, United Kingdom, [5]Copenhagen, Denmark

Background/Purpose: Fatigue is a common and potentially distressing symptom for patients with rheumatoid arthritis with no accepted evidence based management guidelines. Non-pharmacological interventions, such as physical activity and psychosocial interventions have been shown to help people with a range of other long term conditions manage subjective fatigue. The purpose of the review was to evaluate the effectiveness and safety of non-pharmacological interventions for the management of fatigue in people with rheumatoid arthritis.

Methods: Randomised controlled trials were included that evaluated a non-pharmacological intervention in people with rheumatoid arthritis, with self-reported fatigue as an outcome measure. To identify relevant studies the following electronic databases were searched: Cochrane Central Register of Controlled Trials; Cochrane Database of Systematic Reviews; Current Controlled Trials Register; The National Research Register Archive; The UKCRN Portfolio Database; MEDLINE; EMBASE; AMED; CINAHL; PsycINFO; Social Science Citation Index; Web of Science; Dissertation Abstracts International. In addition reference lists of articles identified for inclusion were checked for additional studies and key authors were contacted. Two reviewers selected relevant trials, assessed methodological quality and extracted data. Where appropriate, data were pooled using meta-analysis with a random-effects model.

Results: Nineteen studies met the inclusion criteria with a total of 2240 participants with rheumatoid arthritis. Included studies investigated physical activity interventions (k=5), psychosocial interventions (k=10), herbal medicine (k=1), omega-3 fatty acid supplementation (k=1), Mediterranean diet (k=1) and the provision of Health Tracker information (k=1). The quality of the studies varied from low to moderate. Meta-analyses of available data demonstrated that physical activity was statistically more effective than the control with a small effect (SMD −0.29, 95% CIs −0.53 to −0.05) and psychosocial interventions were statistically more effective than the controls with a marginal effect (SMD −0.14, 95% CIs −0.28 to 0.00).

Conclusion: This review provides some evidence that physical activity and psychosocial interventions may provide benefit in relation to self-reported fatigue in adults with rheumatoid arthritis. There is currently insufficient evidence of the effectiveness of other non-pharmacological interventions. Further high quality research is still required to confirm the optimal non-pharmacological interventions and inform future clinical guidelines. Better understanding of the mechanisms of fatigue would also help to further develop effective interventions.

1558

Relationship Between Beliefs, Motivation and Worries about Physical Activity and Physical Activity Participation in Persons with Rheumatoid Arthritis. Linda S. Ehrlich-Jones[1], Jungwha Lee[2], Pamela A. Semanik[3], Cheryl Cox[4], Dorothy D. Dunlop[5] and Rowland W. Chang[2]. [1]Rehabilitation Institute Chicago, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Rehabilitation Institute Chicago, Oak Park, IL, [4]St. Jude Children's Research Hospital, Memphis, TN, [5]Northwestern Univ Med School, Chicago, IL

Background/Purpose: Among persons with arthritis, engaging in physical activity can help maintain or increase mobility, improve function, decrease pain, and decrease disability. In 2000, Behavioral Risk Factor Surveillance System surveys conducted by state health departments reported about 31% of people with arthritis were inactive. A sedentary lifestyle is associated with cardiovascular disease, osteoporosis, decline in physical function (strength, endurance, flexibility), and an increased risk of all-cause mortality. The interrelationships between beliefs, motivation and worries about physical activity are complex. Each factor contributes to behavior change; they are measurable and can be modified. The development of interventions that target potential predictors, moderators and/or mediators of physical activity have the potential to increase physical activity participation. Currently, there is a knowledge gap in persons with rheumatoid arthritis (RA) regarding the relationship between beliefs, motivation, and worries about physical activity in relation to physical activity participation. The objective of this study is to determine if stronger beliefs that physical activity can be beneficial (cognitive appraisal), increased motivation for physical activity (perceived competence) and increased levels of worry that not doing physical activity can be detrimental (affective response) are associated with higher levels of physical activity participation in a sample of patients with RA.

Methods: A cross-sectional study used baseline data from 185 adults with RA enrolled in a randomized clinical trial assessing the effectiveness of an intervention to promote physical activity. Data included patients' self-reported beliefs that physical activity can be beneficial for their disease, motivation for physical activity participation, worries about physical activity participation, and average daily accelerometer counts of activity over a week's time. The relationships between physical activity and beliefs, motivation and worries about physical activity were examined by multiple regression models adjusting for body mass index, gender, age, race and disease activity.

Results: Physical activity participation was greater for adults with higher scores on scales measuring beliefs that physical activity is beneficial for their disease (p for trend= 0.032) and motivation for physical activity participation (p for trend= 0.007) when adjusted for age, gender, body mass index, race and disease activity. There was a positive but non-significant trend in physical activity participation in relation to worries.

Conclusion: Stronger beliefs that physical activity can be helpful to manage disease and increased motivation to engage in physical activity are related to higher levels of physical activity participation. These data provide empiric rationale to promote development of interventions that target these factors with the goal of improving physical activity participation in adults with RA.

1559

A Qualitative Study of Exercise Habits of Individuals with Rheumatoid Arthritis Taking Anti-TNFαMedication Sixteen Weeks Following Participation in a Randomised Controlled Trial. Angela Reid[1], Audrey Brady[1], Catherine Blake[2], Anne-Barbara Mongey[3], Douglas J. Veale[3], Oliver M. FitzGerald[3] and Tara Cusack[2]. [1]Our Lady's Hospice and Care Services, Dublin, Ireland, [2]University College Dublin, Dublin, Ireland, [3]St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: A recent randomized controlled trial (RCT) investigated the effect of dynamic exercise programs (land-based or water-based) on function in people with rheumatoid arthritis (RA) taking anti-TNFα medication. The results of the RCT demonstrated that beneficial effects of the exercise interventions did not persist 16 weeks beyond completion of the exercise programs. Consistent engagement in exercise is essential in order for individuals with RA to maintain improvements in fitness and physical well-being. The qualitative component of this study sought to examine the exercise habits and adherence to exercise of participants 16 weeks following completion of the RCT.

Methods: A convenience sample of RCT participants (n=17) was recruited for the qualitative study. Semi-structured telephone interviews were undertaken 16 weeks following completion of the eight-week exercise programs. The interview schedule consisted of a series of questions designed to explore the exercise habits of participants since completion of the RCT. The factors that influenced their adherence to the exercise programs were also examined. Interviews were digitally recorded and transcribed verbatim. The data were coded and analyzed using the methods developed in grounded theory. A coding system was developed in order to facilitate the identification of recurrent patterns and themes.

Results: Of the 17 interviews conducted, nine were with land-based program participants (three male and six female) and eight were with water-based program participants (two male and six female). Their ages ranged between 27 and 70 years and the duration of their disease ranged between 1 and 39 years. Fourteen interviewees had not continued to carry out the exercise program while the three who continued to exercise had all completed the land-based intervention. Themes that were identified in terms of failing to continue to exercise included lack of access to suitable facilities or equipment (in particular hydrotherapy or suitable swimming pools), lack of motivation and time constraints. Six of the 14 interviewees who had not continued the exercise programs had changed their exercise habits by taking up more exercise while eight individuals had not altered their exercise habits. The main themes identified that might have aided participants in continuing to exercise included; access to facilities, and support in terms of exercising in a supervised group setting or at an organized time.

Conclusion: The results of these interviews demonstrate that few of this sample of RCT participants continued to engage in dynamic exercise programs on completion of the study. While some individuals reported changing their exercise habits the majority did not. Improved access to appropriate facilities and support in terms of organized, supervised exercise classes within the community may enable this population to continue to participate in dynamic exercise on a more regular basis thereby improving and maintaining functional abilities in the long term.

1560

Muscle Area and Muscle Quality Relate to Physical Activity in Subjects with Rheumatoid Arthritis. Samannaaz S. Khoja, Gustavo JM Almeida, Bret H. Goodpaster and Sara R. Piva. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: People with Rheumatoid Arthritis (RA) experience a reduction in lean muscle mass and an increase in fat mass due to metabolic abnormalities caused by the disease. Low lean muscle mass associates with decreased muscle strength and physical function, and may play a role in the low levels of physical activity (PA) reported in this population. To our knowledge, direct associations between lean muscle mass and PA have not been established in RA. Investigating this relationship may help optimize strategies to improve PA participation. In addition to muscle mass, muscle quality may also affect PA. Muscle quality may be characterized by its muscle attenuation (MA) coefficient and provides information about amount of fatty tissue present within the muscle. Studies in other populations suggest that increased intramuscular fat affects overall muscle function. The aim of this study was to investigate the association of thigh muscle area and muscle quality and PA in subjects with RA

Methods: Cross-sectional study on 17 subjects with RA (age 61.5$\pm$ 10.6 yrs; RA duration 17.2 $\pm$ 3 yrs; BMI 30.6 $\pm$ 7.6 kg/m^2; 13 female). PA was measured at several low intensity levels by the Sense Wear armband, a multi-sensor portable activity monitor that provides data on energy expenditure (EE) of PA performed above 1 metabolic equivalent level (PAEE$\geq$1MET), EE of PA performed above 2METs (PAEE$\geq$2METs), and EE of PA performed above 3METs (PAEE$\geq$3METs). Mid-thigh cross-sectional area (CSA) of each leg was measured by computed tomography (CT), and averaged for both sides. The mean MA of the mid-thigh CSA was calculated for each leg using the Slice-O-matic software, and averaged for both sides. MA coefficient ranges from 0 to 100 Hounsfield units (HU), higher numbers indicate lower intramuscular fat and better muscle quality. We calculated the correlations between mid-thigh CSA and MA with PAEE above 1, 2 and 3 METs. We accounted for body size in the analysis by controlling for BMI.

Results: Total mid-thigh CSA and mean MA both showed positive associations of moderate strength with PAEE$\geq$1MET, PAEE$\geq$2METs and PAEE$\geq$3METs after controlling for BMI. Results suggest that subjects with higher area of thigh muscle and lower amount of intramuscular fat have higher levels of PA. Variable descriptives and semi-partial correlation coefficients are depicted in the Table.

Table. Associations between Muscle Cross-sectional Area (CSA) and Mean Muscle Attenuation (MA) Coefficients with Physical Activity Energy Expenditure (PAEE)

Variables	Medians (IQ:25–75)	Semi-Partial Correlation Coefficients After controlling BMI		
		PAEE≥1MET	PAEE≥2METs	PAEE≥3METs
Mid-Thigh CSA (sq cm)	94.2 (84.2–111.3)	0.64*	0.59*	0.65*
Mid-Thigh mean MA (HU)	41.7 (38.9–44.5)	0.44	0.45*	0.52*
PAEE≥1MET (kcal/min)	913.0 (449.0–1212.5)			
PAEE≥2METs (kcal/min)	488 (165.5–773.5)			
PAEE≥3METs (kcal/min)	128.0 (29.0–332.0)			

* significant at α–level of 0.05.

Conclusion: The findings suggest that perhaps improving muscle mass and muscle quality may lead to an increase in PA participation in patients with RA. An increased participation in physical activities reduces cardiovascular risk, which is an important predictor of morbidity and mortality in RA. In order to optimize interventions to promote PA participation, future longitudinal trials should consider the effects of muscle mass and quality while investigating changes in PA.

1561

Associations Between Changes in Physical Function and Physical Activity in Response to An Exercise Program in Patients with Rheumatoid Arthritis. Gustavo JM Almeida and Sara R. Piva. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Measures of physical function (PF) characterize patient's ability to perform functional activities whereas measures of physical activity (PA) informs about the amount of activities patients perform. Cross-sectional studies in patients with Rheumatoid Arthritis (RA) have reported conflicting evidence about the associations between these two domains of PF and PA. Longitudinal studies investigating how well changes in PF associate with changes in PA are lacking. If changes in these two domains are associated targeting exercise to improve PF can result in increases in PA participation in patients with RA. The aim of this study was to explore the associations between changes in PF and changes in PA in patients with RA.

Methods: This is an interim analysis from a randomized controlled trial on the effect of a 12-week strengthening exercise for the lower extremities on muscle function in patients with RA. At this point, data from 12 subjects (9 females, age 65.1±9.5, BMI 30.4±8, disease duration 20.4±11.1 years, and Health Assessment Questionnaire-HAQ.82±.75) were analyzed. PF was measured by the Lower Extremity Functional Scale (LEFS), quadriceps strength measured in an isokinetic dynamometer, timed 5-chair rise, and time to go up and down a flight of stairs. PA was measured by the Physical Activity Scale for Individuals with Physical Disabilities questionnaire (PASIPD) and by the SenseWear armband, a multi-sensor portable activity monitor that provided data on energy expenditure (EE) of PA performed above 1 metabolic equivalent level (PAEE≥1MET), EE of PA performed above 2 METs (PAEE≥2METs), EE of PA performed above 3 METs (PAEE≥3METs). Spearman or Pearson correlation coefficients were calculated between changes in PF and changes in PA according to data distribution.

Results: The associations between changes in PF and changes in PA are shown in the Table. Results indicated that the associations between changes in PF and changes in PA were higher for the more demanding functional tasks such as chair rise and climbing stairs, and lower for changes in quadriceps strength and PA. Changes in self-reported PF and real-time PA did not associate, whereas the association between changes in self-reported PF and self-reported PA was moderate, which may have occurred due to both measures being self-reported.

Table. Associations between changes (Δ) in physical function (PF) and physical activity (PA) variables. Associations represent Pearson Correlations, unless otherwise indicated.

Variables explored	Correlation coefficients between PF and PA variables			
	Δ Quad Strength	Δ Chair time†	Δ Stair time†	Δ LEFS
Δ PAEE≥1MET	0.37	−0.70*	−0.51*	0.09
Δ PAEE≥2MET	0.27	−0.68*	−0.55*	0.10
Δ PAEE≥3MET	0.21	−0.43	−0.41	0.01
Δ PASIPD score	0.64*	−0.32	−0.88**	0.41

Quad Strength = quadriceps strength; Chair time = timed 5-chair rise; Stair time = time to go up and down a flight of stairs; † Spearman Rho Correlation Coefficients; *p≤.05; **p≤.01.

Conclusion: The clinical relevance of this study is that improvements in PF to perform demanding functional tasks seem to play a role in increasing PA in patients with RA. Perhaps targeting exercises to improve patient's ability to perform more demanding functional tasks may increase the participation in PA. Increasing participation in regular PA is important for patients with RA because it can prevent several co-morbidities associated with the disease, and maintain mobility that is also reduced in these patients.

1562

Sensorimotor Training Versus Resistance Training in Patients with Knee Osteoarthritis. Aline B. Gomiero[1], Virginia M. Trevisani[2], Andrea H. Kayo[2], Maria Stella Peccin[3] and Marcelo Abraão[4]. [1]Federal University of Sao Paulo, São Paulo, Brazil, [2]Federal University of São Paulo, São Paulo Brazil, Brazil, [3]Federal University of São Paulo, São Paulo, Brazil, [4]Federal University of São Paulo, Brazil

Background/Purpose: People with knee osteoarthritis (OA) have functional instability and defective neuromuscular function, it was recently suggested that sensorimotor exercises are important and may be needed to improve the effectiveness of training programs for these patients. This study objective was to compare the effectiveness of a supervised resistance muscular training (RT) versus sensorimotor training (SMT) for patients with Knee OA, on decrease of pain and functional improvement.

Methods: Randomized single blind clinical trial with 96 patients, 50–75 years old, with knee OA according to ACR criteria, were randomized into one of 3 groups. SMT group (n=32), RT group (n=32), and control group (CG n=32) for a 16-weeks intervention. The intervention for the RT group consisted in orientation plus quadriceps and hamstring strength training followed by stretching of this muscles. The SMT group consisted in orientation plus stability and agility training followed by stretching, and the CG received the same orientations, warm-up and stretching exercises made by the interventional groups without the intervention. Evaluations were made before (T0) and after intervention (T16). Outcomes measured included: Visual Analogue Scale of pain (VAS); electromyographic analysis of quadriceps muscle (EMG); isometric quadriceps strength with dynamometer (miotec medical supplies) and Timed-Up-Go test (TUG). Patients also completed 2 self-report measures of physical function and disability; the Medical Outcomes Study – Short Form (SF-36) and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Data were analyzed using repeated measures ANOVA with Bonferroni corrections.

Results: There were no significant differences in age, gender distribution, height, or weight among groups ($p > .05$). There were significant differences between the two time points in RT group for the variable WOMAC $p=0.004$ and SF-36 subscales physical functioning $p<0.001$, vitality $p=0.001$ and role emotional $p<0.001$. We also observed significant improvement on quadriceps strength on RT group $p=0.006$ and on SMT group $p<0.001$. There were no differences among the groups or between the two time points for the variables VAS, EMG, TUG, and for SF-36 sub-scales role-physical and mental health.

Conclusion: Although our results showed no improvements on function and pain after resistance training or sensorimotor training in patients with knee osteoarthritis, experts recognize the importance of mechanical loading for maintaining healthy cartilage. Furthermore, more studies are necessary to demonstrate changes in performance-based physical function after a functional intervention.

1563

Reductions in Knee Joint Loading After Focused Hip Muscle Training. Laura E. Thorp, Markus A. Wimmer, D. Rick Sumner and Joel A. Block. Rush University Medical Center, Chicago, IL

Background/Purpose: The purpose of this investigation was to analyze the effects of a focused hip muscle training program on knee joint loading in subjects with medial compartment knee OA. We hypothesized that focused hip musculature training in individuals with mild to moderate knee OA would produce favorable changes in dynamic loading of the medial knee during walking, as evidenced by decreased external knee adduction moments.

Methods: 17 subjects with mild to moderate medial compartment knee OA ranging in age from 35–69 years of age completed the study protocol. Subjects underwent gait analysis walking barefoot at self-selected normal walking speeds. Both the peak external knee adduction moment and the knee adduction angular impulse were calculated for the index knee (more painful knee) before and after participation in a 4-week supervised, physical therapy intervention targeted at the hip abductor musculature. Additionally, subjects wore an accelerometer-based activity monitor for 7 days after the baseline visit.

Results: While there were no significant differences in the peak external knee adduction moment or the knee adduction angular impulse for the group as a whole, over half the subjects (10 of the 17) had a decrease in both the peak external knee adduction moment and the knee adduction angular impulse. For these subjects, the peak external knee adduction moment decreased from 2.7 to 2.5%BW*Ht ($p=0.03$) and the knee adduction angular impulse decreased from 0.9889 to 0.8850%BW*Ht*sec ($p=0.004$). Load reductions as high as 28% were observed in those who responded to therapy. As a group, the responders tended to be more active than the non-responders (8339 step/day vs. 6128 steps/day), though this difference was not significant ($p=0.125$).

Conclusion: Existing literature is controversial regarding the effect of lower extremity exercise on joint loading in individuals with knee osteoarthritis. Indeed in the present study, no significant effect was noted for the group as a whole. Targeted exercise interventions may not be ideal for all individuals, due to compliance, motivation, and baseline level of fitness. What cannot be overlooked is that for some individuals, targeted hip muscle training reduced knee joint loading. As with other conservative, biomechanically-based therapies, the challenge is how to identify appropriate candidates for treatment.

A Survey of Physical Therapists' Use of Outcome Measures In Total Hip and Knee Arthroplasty. Catherine A. McAuley[1], Marie D. Westby[1], Alison Hoens[2], Ronda Field[3], UBC 2011 MPT Students[4] and W. Darlene Reid[2]. [1]Mary Pack Arthritis Centre, Vancouver, BC, [2]University of British Columbia, Vancouver, BC, [3]Richmond Hospital, Richmond, BC, [4]Vancouver, BC

Background/Purpose: Over 77,500 total hip and knee joint arthroplasty (TJA) surgeries are performed in Canada each year – almost 12,000 in British Columbia (BC). Physical therapists (PTs) play a key role along the continuum of care of these patients (pre-op through post-op rehabilitation) and have identified a need for standardized outcome measures (OMs) to assess treatment effectiveness, inform clinical decision-making, and facilitate communication across health care settings and providers. The aim of this study was to identify PTs' use of OMs with TJA patients in BC. It is part of a larger project to recommend and promote the use of standardized OMs along the TJA continuum.

Methods: We surveyed a stratified (according to practice area), random sample of PTs registered to practice in BC on their use of 18 OMs that were free, valid, reliable, and responsive in osteoarthritis and TJA care. Respondents indicated familiarity and experience with each measure on a 4-point ordinal scale. Open-ended questions invited comments and suggestions for other measures. Questionnaires were pilot tested with a representative sample and then mailed to 694 PTs with self-addressed stamped envelopes. Postcard and e-mail reminders were used to increase response rates. The survey was carried out over a 4-month period. We used descriptive statistics to examine use of measures and respondent demographics. Measures were grouped by type (patient reported outcome measures (PROM), performance-based or prognostic indicators) and by ICF domains (body structure/function and activity/participation) for further analysis. Chi-square tests were used to compare PTs who treat TJA patients and completed the full questionnaire to PTs who do not treat TJA and returned only demographic information. The McNemar test was used to compare use of OMs for clinical decision-making versus program evaluation.

Results: A total of 298 (43%) questionnaires were returned. Of these, 172 (58%) respondents worked with TJA patients. Respondents who work with TJA patients were more likely to work in an urban setting ($p=.04$) and to have graduated less than 10 years previously ($p=.008$). Of the 18 measures in the survey, eight were used by a majority (>50%) of respondents for clinical decisions compared to three for program evaluation purposes. This difference in purpose of outcome measurement was statistically significant ($p<.001$ to $p=.04$) for all but four measures. Performance-based measures were used more often (53%) than prognostic indicators (38%) or PROMs (36%). Of the nine listed PROMs, respondents were most experienced with the numeric pain rating scale (97.7%) in ICF 'body function' domain and the Lower Extremity Functional Scale (59.1%) in ICF 'activity and participation'. The most commonly used performance-based measure was the Timed Up and Go (75%). Less than half of the respondents used the prognostic measures - body mass index and waist circumference.

Conclusion: There is varied use of OMs for clinical-decision making and program evaluation by PTs treating TJA patients in BC. This finding provides a foundation to develop a standardized approach for OMs that is clinically meaningful for TJA patients along their continuum of care.

1565

Describing the Interventions in Home Care Physical Therapy for Patients Following Total Knee Replacement. Kimberly Nanovic[1], Amy Phillips[1], Elizabeth Childs[1], Patricia D. Franklin[2] and Carol A. Oatis[1]. [1]Arcadia University, Glenside, PA, [2]Univ of MA Med Schl, Worcester, MA

Background/Purpose: Total knee replacement (TKR) is one of the most common procedures performed; however, current literature on interventions used in home care PT following this surgery is understudied. This study describes the PT interventions used in the home care setting following TKR.

Methods: We requested 40 and received 27 home care physical therapy (PT) records for patients participating in a clinical trial. Eligible records were from patients who had received a primary TKR, completed their PT rehabilitation, used no outpatient PT services post-operatively and had completed the 6-month study assessment. All 27 records contained complete information for use of modalities, functional training, ROM, and quadriceps exercises; only 17 records contained complete information for strengthening exercises. PT records were used to determine the number of patients receiving modalities, functional training, ROM or strengthening exercises. Exercise progression was defined as increased difficulty of an exercise or the addition of a more difficult exercise. Documented interventions were compared to post-TKR interventions recommended in the literature. Descriptive statistics were used to describe home care PT interventions.

Results: Out of the 27 records, all received passive and/or active knee ROM exercises as well as quadriceps exercises. Of these records, 14 used cold packs and 11 used a CPM. 6 patients received one or more of the following modalities: joint mobilizations, patellar mobilizations, scar massages or soft tissue massages. 26 received gait training on even surfaces, 23 received stair training, and 12 performed gait training outdoors or on uneven surfaces. One-third or fewer performed bed mobility, sit to stand transfers and car transfers. All of these are recommended in the literature. In the 17 complete records, strengthening exercises were reported for: knee flexion (13), hip extension (13), hip flexion (14), hip abduction (15), and plantarflexion and dorsiflexion (10). These exercises target the same muscle groups recommended in the literature. Straight leg raises were reported in 15 of 17 records and 10 records reported squats. 6 or fewer records documented use of marches, lunges, step ups/downs, or wall slides, all of which are recommended in the literature. 15/17 records showed progression of multiple exercises, 1 progressed one exercise and 1 had no documented progression. 5 records had no documented quadriceps strengthening progression.

Conclusion: Much variability exists in the interventions performed in home care PT for patients post TKR. There is variable use and limited progression of recommended interventions. The variability in use of recommended interventions may contribute to variability in patients' functional outcomes. Further research is needed to examine these interventions and their contributions to functional outcomes. Limitations in the data resulting from unclear documentation demonstrate the necessity of a uniform documentation system in home care PT.

1566

Dysautonomia and Chronotropic Incompetence in Fibromyalgia. Roberta P. C. Ribeiro[1], Thalita Dassouki[2], Luiz A. Perandini[2], Guilherme G. Artioli[1], Ana L. G. Calich[3], Ana Lucia S. Pinto[4], Hamilton Roschel[5], Fernanda R. Lima[6], Eloisa Bonfa[7] and Bruno Gualano[8]. [1]University of Sao Paulo,, Sao Paulo, Brazil, [2]University of Sao Paulo, Rheumatology Division, LACRE, Sao Paulo, Brazil, [3]University of Sao Paulo, Sao Paulo, Brazil, [4]University of Sao Paulo, School of Medicine, Rheumatology Division, LACRE, Sao Paulo, Brazil, [5]University of Sao Paulo, School of Physical Education and Sport, Sao Paulo, Brazil, [6]University of Sao Paulo, School of Medicine, Rheumatology Division, Sao Paulo, Brazil, [7]Faculdade de Medicina da Universidade de São Paulo (FMUSP), Sao Paulo, Brazil, [8]University of Sao Paulo,School of Physical Education and Sport, Sao Paulo, Brazil

Background/Purpose: The understanding regarding fibromylgia (FM) physiopathology has substantially advanced, with a growing body of evidence suggesting that autonomic nervous system dysfunction (also called dysautonomia) plays a role in this disease. We aimed to gather knowledge on the autonomic modulation in patients with fibromyalgia (FM) in response to

exercise and to investigate whether this population suffers from chronotropic incompetence.

Methods: Fourteen women with FM (age: 46 ± 10 years; BMI: 26.6 ± 5.2 kg/m^2) and 14 gender-, BMI- (25.4 ± 4.9 kg/m^2), and age-matched (age: 41 ± 14 years) healthy individuals (CTRL) took part in this cross-sectional study. A treadmill cardiorespiratory test was performed and heart-hate (HR) response during exercise was evaluated by the chronotropic reserve (CR). HR recovery (ΔHRR) was defined as the difference between HR at peak exercise and at both first (ΔHRR1) and second (ΔHRR2) minutes after the exercise test.

Results: FM patients presented lower peak VO_2 when compared with healthy subjects (22 ± 3 *vs.* CTRL: 32 ± 9 mL/kg/min, respectively; $p<0.001$). Additionally, FM patients demonstrated lower CR (72.5 ± 19.4 *vs.* CTRL: 106.1 ± 21.7, $p < 0.001$), ΔHRR1 (24.5 ± 12.2 *vs.* CTRL: 32.6 ± 9.1, $p = 0.059$) and ΔHRR2 (34.3 ± 14.2 *vs.* CTRL: 50.8 ± 10.8, $p = 0.002$) than their healthy peers. The prevalence of chronotropic incompetence was 57.1% among patients with FM.

Conclusion: The majority of the patients with FM undertaken a graded exercise test presented chronotropic incompetence and delayed HR recovery, both being indicative of dysautonomia and higher risk of events.

1567

Participation in Household and Community Activities by Persons with Systemic Sclerosis. Janet L. Poole[1], Betty Skipper[2], Kristal Hildebrand[1] and Annandhi Chandrasekaran[1]. [1]University of New Mexico, Albuquerque, NM, [2]University of New Mexico, NM

Background/Purpose: Pain, finger ulcers, Raynaud's phenomenon, and internal organ involvement, particularly decreased pulmonary function, make it difficult for people with systemic sclerosis (SSc) to participate in daily activities. Most outcomes measures used in scleroderma research measure perceived difficulty or importance of various activities. However, frequency of participation might be a more accurate indication of what people can do and actually do. Therefore, the purpose of this study was to examine frequency of participation in household and community activities by persons with SSc.

Methods: A convenience sample of 69 persons with SSc was recruited from the Scleroderma Foundation website and national conference. Participants completed a demographic questionnaire, questions regarding presence and severity of symptoms, the Health Assessment Questionnaire (HAQ), the Center for Epidemiologic Studies Depression Scale (CES-D), and the Adelaide Activities Profile (AAP). The AAP consists of 21 items divided into 4 subscales representing distinct domains of participation in household or community activities: domestic chores, household maintenance, service to others and social activities. Participants rate the frequency of participating in an activity during the previous three-month period, on a 4 point scale from 0 (never) to 3 (once a week or more). Items are summed to yield subscale scores and a total score (0–63). Higher scores indicate higher levels of participation.

Results: Participants were primarily female (94 %), married (65 %), and white (88 %). Mean age was 53.7 years, mean disease duration was 9.9 years and mean education level was 15.5 years. Fifty percent had diffuse SSc and 43% had limited SSc. The primary symptoms reported were Raynaud's phenomenon (98 %), finger ulcers (46 %), and lung involvement (52%). Participants had moderate pain (VAS = 4.2) and fatigue (VAS = 5.5). Mean HAQ and CES-D scores were 1.1 and 16.2 respectively. On the AAP, the mean total score was 37.4. Subscale scores were 16.2 for domestic chores, 9.5 for household management, 7.2 for service to others and 4.6 for social activities. There were no significant differences in AAP subscale or total scores between the types of SSc (limited and diffuse). However, having more fatigue ($p <.05$), and higher HAQ ($p <.001$) and CES-D ($p =.006$) scores resulted in higher total AAP scores. A three factor ANOVA on the AAP total score using the HAQ, CES-D and fatigue as independent variables showed that only the HAQ was statistically significant ($p <.005$) after adjusting for the other variables.

Conclusion: Persons with SSc reported participating in domestic chores, such as meal preparation and housework, more frequently than household maintenance, service to others and social activities. Reduced time spent in home maintenance and community activities has been shown to be related to lower life satisfaction in persons with other rheumatic diseases. Thus, strategies to help people manage domestic chores may free up time to engage in other activities.

1568

Effect of Physical Exercise in Systemic Sclerosis—a Pilot Study. Jenny Bergegård[1] and Helene Alexanderson[2]. [1]Karolinska University Hospital, Solna, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden

Background/Purpose: A few studies have reported improved aerobic capacity following aerobic exercise in systemic sclerosis patients without lung involvement. No previous studies have examined the effect of intensive physical exercise for patients with systemic sclerosis and pulmonary impairment. The aim of the study was to examine the effect of an 8-week exercise program for patients with systemic sclerosis and 50–100 % in vital capacity.

Methods: A single subject experimental design with repeated systematic measures during a six week A-phase (baseline-period) and an eight week B-phase (intervention-period) was used. Three women and one man with median age 66 years and median disease duration of four years completed aerobic exercise on a stationary bike corresponding to 15 on Borg RPE (strenuous) and muscular endurance training of shoulder flexors and hip flexors / knee extensors three times a week for eight weeks. Physical capacity (six minute walk test), aerobic capacity (sub maximal treadmill test) and muscle endurance in shoulder- and hip flexion (Functional Index 2) were assessed every other week. Level of activity limitation (Health Assessment Questionnaire), perceived health (Short Form 36), Raynaud, Fatigue and Global Health during the recent week (Visual Analouge Scale) were assessed at weeks 0, 6, 14. A mean value and 2 standard deviations (2SD) of measure time points in the A-phase were calculated. A statistically significant difference was defined as two consecutive measure points in the B-phase above or below the 2SD. Measures producing ordinal data were analyzed visually for trends and slopes.

Results: Three participants improved statistically significantly in muscular endurance and two participants improved significantly in aerobic capacity. There was a visual trend with three patients rating less fatigue after 8 weeks of exercise compared to measures in the A-phase. One patient rated between 83–91 mm on the VAS during the A-phase and dropped down to 47 mm after eight weeks of exercise, one rated 50 mm in the A-phase and dropped down to 22 mm, and one rated 41 mm and then dropping to 23 mm while one patient remained unchanged. All other variables remained unchanged.

Conclusion: This eight week exercise program was well tolerated with positive effects on aerobic capacity and muscular endurance. These preliminary results of an ongoing study need to be confirmed in a larger population ($n>10$).

1569

Mobility and disease Activity but Not Aerobic Capacity Relate to Functional Disability in Ankylosing Spondylitis. Fabio Jennings, Hilda A. Oliveira, Marcelo C. Sousa, Vaneska G. Cruz and Jamil Natour. Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Background/Purpose: Ankylosing spondylitis (AS) is an inflammatory disease characterized by progressive stiffness and eventual fusion of the skeleton, restrictive ventilatory defect and functional limitations. The purpose of this study was to investigate the relationship between clinical variables, mobility, disease activity, aerobic capacity and functional disability in patients with AS.

Methods: A cross-sectional study enrolled thirty patients (23 male, 7 female) with definite AS (New York modified criteria) with no other cardiopulmonary disease. All the necessary information regarding clinical features was recorded. Mobility was measured using the BASMI (Bath Ankylosing Spondylitis Metrology Index) and disease activity was evaluated using the BASDAI (Bath Ankylosing Spondylitis Disease Activity Index). Levels of C reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were measured. BASFI (Bath Ankylosing Spondylitis Functional Index) was used to evaluate functional disability. Aerobic capacity was evaluated using an incremental cardiopulmonary exercise testing protocol by treadmill. Additionally, the 6-minute walking test was apllied.

Results: the AS patients had the mean age of 42.1 ±10.1 years and disease duration of 17.5±8,4 years. The mean BASMI score was 5.46 ±2.00, mean BASDAI score was 3.65 ±1.95 and the mean BASFI was 4.95 ±2.41. Levels of CPR and ESR were elevated (9.27 ±11.23 and 16.23 ±15.32, respectively). The mean peak VO2 was 30.8 ±6.37 ml.kg^{-1}.min^{-1}. The

BASFI score was correlated with BASMI (r=0.766; p< 0.01) and BASDAI (r=0.574; p=0.01). There was weak negative correlation between BASFI and peak VO2 (r=-0.366; p=0.47). Multivariate linear regression analysis showed that BASMI and BASDAI accounted for 58.7% (r^2) and 33% (r^2) of the total BASFI variance. BASMI and BASDAI together accounted for 67.4% (r^2 p< 0.001) of the total BASFI variance. The addition of peak VO2 to the model did not improved the explained variability in BASFI score.

Conclusion: this study shows that mobility and disease activity are the most important determinants of functional disability in patients with AS. The findings suggest that adequate control of inflammation and interventions to avoid joint stiffness are necessary to prevent disability in AS.

1570

A Multidisciplinary and Multidimensional Program for Hand Osteoarthritis Is Not Effective: Results of a Randomized Controlled Study. Mirelle J. Stukstette[1], Joost Dekker[2], Alfons A. den Broeder[1], Willemijn Noort van der Laan[3], Johannes W.J. Bijlsma[4] and Cornelia H.M. van den Ende[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]VU University Medical Centre, EMGO Institute, Amsterdam, Netherlands, [3]Maartenskliniek Woerden, Woerden, Netherlands, [4]UMC Utrecht, Utrecht, Netherlands

Background/Purpose: Although research on the efficacy of non-pharmacological interventions is very limited and mainly based on low quality studies, international guidelines for management of hand osteoarthritis (OA) strongly recommend to treat all patients with hand OA with a combination of pharmacological and non-pharmacological interventions. The aim of this study was to examine the efficacy of a multidisciplinary, multidimensional non-pharmacological intervention in patients with hand OA.

Methods: a single blinded randomized multicenter trial was conducted. Patients were recruited at three Rheumatology outpatient clinics in the Netherlands. Included were patients with Hand OA according to the ACR classification Criteria for clinical hand OA with limitations in activities (AUSCAN function > 25). Patients were randomly assigned to immediate start of multidisciplinary intervention (four weekly sessions, including individual goal setting, exercises, education, and splints if considered necessary) or 30 minutes of education followed by waiting time of 3 months. Data at baseline and 3 months were collected by a research assistant who was blinded for treatment allocation. Primary outcome measures after three months were pain and limitations in activities as measured with the AUSCAN and the OARSI-20 responder criteria. Secondary outcome measures included grip strength, self-efficacy, pain coping and quality of life. (Dutch Trial Register trial number NTR1191).

Results: 151 patients (83% female, mean (SD) age 59.2 (7.7)) were included. At baseline and after 3 months no significant and no relevant differences were observed between the treatment group (n=75) and the control group (n=76) in any of the primary and secondary outcome measures. About one third of patients were classified as responder (OARSI 20 responder criteria) (32% and 37% in the treatment group and control group, respectively).

Outcome measure	Groups				
	Experimental		Control		Difference*(95% CI) at 3 months
	Baseline (mean(sd))	3 months (mean(sd))	Baseline (mean(sd))	3 months (mean(sd))	exp-contr
Pain^	52.1 (16.8)	47.2 (14.0)	51.9 (16.0)	45.1 (18.4)	1.98 (−2.49;6.45)
Function^	58.4 (19.5)	51.6 (20.4)	60.8 (17.7)	52.2 (17.8)	1.35 (−2.81;5.52)

^normalised AUSCAN score (0–100); *adjusted for baseline

Conclusion: Patients with hand OA do not benefit on the short term from a multidimensional and multidisciplinary non pharmacological treatment program.

1571

Association of Pinch Strength with Hand Dysfunction, Finger Deformities and Contact Points In Patients with Rheumatoid Arthritis. Kenrin Shi[1], Akihide Nampei[2], Kosuke Ebina[1], Tsuyoshi Murase[1], Hideki Yoshikawa[1], Makoto Hirao[3] and Jun Hashimoto[3]. [1]Osaka University Graduate School of Medicine, Osaka, Japan, [2]Osaka Rosai Hospital, Sakai, Japan, [3]Osaka Minami Medical Center, Osaka, Japan

Background/Purpose: Among disabilities in rheumatoid hands, weakness of pinch strength severely deteriorates hand function. This study aimed to investigate the association of pinch strength with hand dysfunction in patients with rheumatoid arthritis (RA), as well as with several factors concerning thumb and index finger, such as deformities and contact points during pinch.

Methods: Eighty-one hands of 42 outpatients with RA were examined. Hand dysfunction was evaluated by Japanese version of Stanford Health Assessment Questionnaire in part, focusing on hand and finger function, as Hand Disability Index (HDI). Pinch strength was measured by pinch gauge, and was analyzed in relation to HDI as well as deformities and contact points during tip pinch in thumb and index finger.

Results: Average pinch strength was 1.05 kg in tip pinch, 1.55 kg in key pinch, and 1.48 kg in three-digit pinch, all of which demonstrated significant negative correlations with HDI. Tip pinch strength was significantly weaker in hands with volar dislocation of metacarpophalangeal joint of index finger than in those without, while that in hands with mutilated deformity of thumb demonstrated significant weakness. Tip pinch strength was the maximum with thumb contact at the pulp and with index finger at the apex, whereas abnormal contact points demonstrated significant weakness.

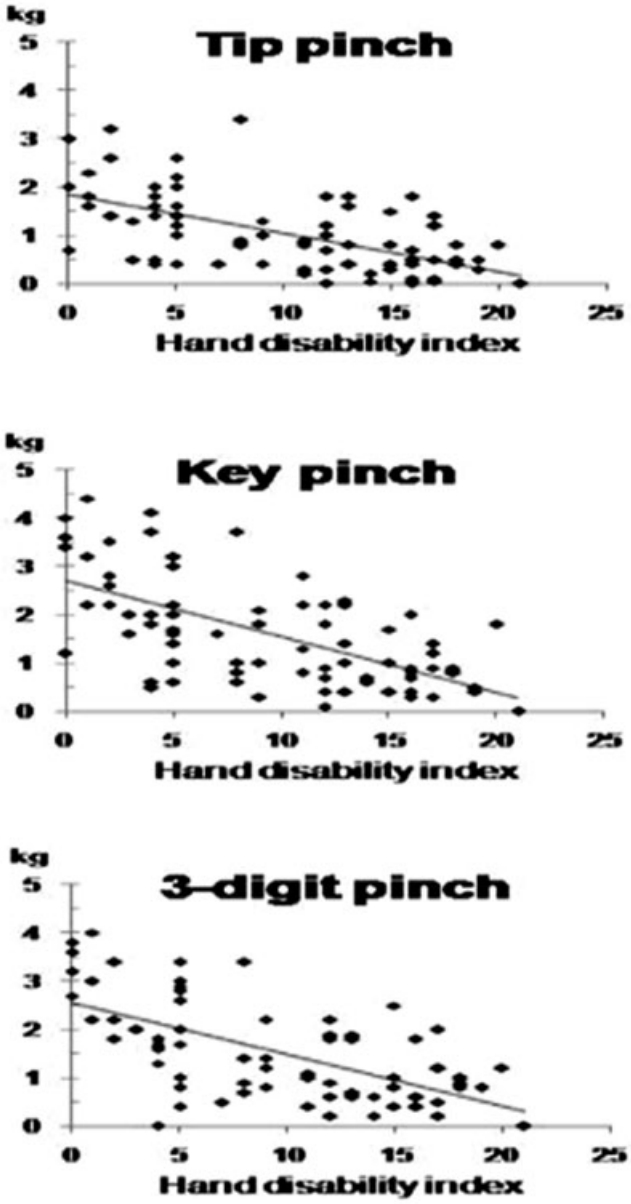

Figure. Correlation of hand disability index and pinch strength.

Conclusion: Since pinch strength significantly correlated to hand function, it is important to arrange good alignment with favorable contact points in thumb and index finger, not only in conservative management but also in planning of reconstructive surgeries of rheumatoid hands.

Effects of Maximal Acute Physical Exercise on Prothrombin Time in Patients with Primary Antiphospholipid Syndrome (PAPS) Under Oral Anticoagulation with Warfarin and Exercise Capacity. Carolina B. Garcia[1], Luciana N. J. Matos[2], Carlos E. Negrao[2], Hamilton Roschel[3], Ana Lucia S. Pinto[4], Jozelio F. Carvalho[5], Eloisa Bonfa[6] and Fernanda R. Lima[1]. [1]Rheumatology Department, Sao Paulo, Brazil, [2]University of Sao Paulo, InCor, Sao Paulo, Brazil, [3]University of Sao Paulo, School of Physical Education and Sport, Sao Paulo, Brazil, [4]University of Sao Paulo, School of Medicine, Rheumatology Division, LACRE, Sao Paulo, Brazil, [5]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [6]Faculdade de Medicina da Universidade de São Paulo (FMUSP), Sao Paulo, Brazil

Background/Purpose: The aim of this study was to evaluate the effect of acute physical exercise on prothrombin time (PT) in patients with primary antiphospholipid syndrome (PAPS) under oral anticoagulation therapy with warfarin.

Methods: Nineteen premenopausal sedentary women with PAPS (Sapporo and Sidney criteria with exclusive deep venous thrombosis(mean age: 32.4 ± 8.90 years; mean BMI 24.4 ± 3.77 Kg/m^2) were enrolled in the study. All of the PAPS patients were undergoing chronic anticoagulation therapy. PT was stable (INR between 2–3) for at least the past 2 weeks prior to the test. Also, other drugs administration and dietary intake were stable for 2 months prior to testing. Exclusion criteria were: chronic obstructive pulmonary disease, smoking, cardiovascular disease, diabetes, systemic hypertension, secondary antiphospholipid syndrome, body mass index (BMI) >30, and stroke. Capillary blood samples were drawn during a maximum cardiopulmonary stress test (RAMP protocol) at: baseline (B), anaerobic threshold (AT), immediately after the test (Im) and 1 hour after the test (1h). PT was assessed by a Coaguchek XS,(Roche Diagnostics, Indianapolis, USA). Data were analyzed by a one-way repeated measures ANOVA procedure. Significance level was set at $p<0.05$.

Results: PT did not significantly change between any of the time points (B: 2.29 ± 0.32; AT:. 2.33 ± 0.36;,Im: 2.29 ± 0.35; 1h: 2.37 ± 0.37), demonstrating that the PT was stable during and after (1h) exercise. Additionally, none of the patients presented any adverse symptoms or any thrombosis or bleeding events during the exercise or in a one month follow-up period.

Conclusion: This is the first study to demonstrate that an acute exercise bout of maximal intensity is safe and did not affect PT in patients with PAPS under oral coagulation therapy with warfarin.

1573

Applying the New Classification Criteria for Rheumatoid Arthritis to Patients (pts) with Early Rheumatoid Arthritis Treated with Abatacept Plus MTX—Insights From AGREE (Abatacept study to Gauge Remission and joint damage progression in MTX naïve patients with Early Erosive Rheumatoid Arthritis). Tanaka Ngcozana[1], Cecilia B. Chighizola[2], Louise Parker[1], Carol M. Black DBE[1], Voon Ong[3] and Christopher D. Denton[4]. [1]UCL Medical School and Royal Free Hosp, London, United Kingdom, [2]UCL Medical School, London, United Kingdom, [3]UCL Medical School, London, England, [4]Royal Free Hospital, Medical School, London, England

Background/Purpose: Sexual dysfunction is a great concern for many patients with scleroderma. Previous studies suggest that the prevalence of erectile dysfunction (ED) in male scleroderma (SSc) patients ranges from 12 to 81%. The objectives of this study were to (a) determine the prevalence of sexual dysfunction (b) evaluate its psychological impact on relationships (c) explore the interaction of these patients with key health professionals in sexual health.

Methods: 100 men with limited (lcSSc) or diffuse cutaneous scleroderma (dcSSc) were invited to complete a validated International Index of Erectile Function Questionnaire (IIEF). The questionnaire was expanded to evaluate the psychological effects of sexual difficulties in SSc patients' relationships and interaction with health professionals. IIEF assesses five domains of sexual function: erectile function, orgasmic function, sexual desire, intercourse satisfaction and overall satisfaction. Potential confounding factors including smoking were analysed with logistic and linear regression.

Results: 62 patients responded to the questionnaire of which the mean age (mean ±SD, year) was 54 ±11.1. The mean disease duration (mean ±SD, years) was 8.4 ± 8.0 and 11.4 ± 7.3 for patients with dcSSc and lcSSc respectively. 71% of the respondents reported sexual difficulties in at least one of the domains. 39% of this cohort were considered as severe in all 5 domains of which half had diffuse disease. Interestingly, 34% developed sexual difficulties before they were diagnosed with SSc. For those who developed ED after the onset of SSc, the mean duration (mean±SD, years) from disease onset to emergence of ED was 4.0 ±3.1. As shown in the table below, intercourse satisfaction fared the worst of all the five domains with a score of 45% in the severe dysfunction category. Past or present smoking did not predict ED or severity of ED.

Domain	Severe Dysfunction n (%)	Moderate n (%)	Mild-Moderate Dysfunction n (%)	Mild Dysfunction n (%)	No Dysfunction n (%)
Erectile Function	23 (37)	4 (6)	3 (5)	11 (18)	16 (26)
Orgasmic Function	22 (35)	8 (13)	5 (8)	1 (2)	21 (34)
Sexual Desire	6 (10)	11 (18)	10 (16)	16 (26)	6 (10)
Intercourse Satisfaction	28 (45)	5 (8)	11(18)	3 (5)	10 (16)
Overall Satisfaction	24 (39)	3 (5)	5 (8)	16 (26)	9 (15)

55% of the respondents reported that their sexual difficulties had caused a significant strain on their relationships with their partner and 48% of these individuals did not discuss the difficulties with their partners. 45% of the patients reported that they had never been asked about their sexual health by a health professional. However 65% of the men would have discussed these issues had they been given the opportunity to do so.

Conclusion: ED is a common yet unexplored complication in scleroderma. It is a difficult subject to discuss, yet our results suggest that sexual functioning is an integral parameter in the assessment of quality of life for the affected men. Our results suggest that ED may occur even before diagnosis of SSc, implying that it could be an early feature especially in diffuse subset. Therefore multidisciplinary teams treating scleroderma patients should be aware of and actively enquire about sexual dysfunction.

1574

"Lo Que Me Diga El Doctor": Patient Reported Interpersonal Processes of Care in An Urban Rheumatology Clinic. Alice Fike[1], Katherine Kline[2], Jorel Martinez[3] and Mark F. Gourley[4]. [1]National Institutes of Health, Bethesda, MD, [2]NIH/NIAMS, Bethesda, MD, [3]Chicago, [4]Bldg 10, Room 6N216F, Bethesda, MD

Background/Purpose: To employ a patient-reported interpersonal processes of care (IPC) survey instrument to describe and assess the care of patients to the National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS) Community Health Center (CHC), an urban rheumatology clinic serving a majority foreign born, Hispanic population. We wondered whether foreign birth and/or the need for an interpreter would influence patient reports of their care.

Methods: Between March 2009 and December 2010, a total of 204 IPC surveys, validated in Spanish and English, were administered to established CHC patients. All patients were cared for by rheumatology fellows. The IPC instrument was designed to compare three key aspects of the patient-physician relationship: Communication, Decision-Making, and Interpersonal Style, across racial and ethnic groups. For each question, patients were asked to report their experiences over the past six months on a five-point scale ranging from "never" (1) to "always" (5). Domain scores were calculated and reported as positive or negative by dichotomizing the scales based upon the direction of the question. Patients were grouped by U.S. or foreign birth and foreign born patients were further grouped based on need for interpreter. Significance of associations was calculated using Chi-square analysis.

Results: Of the 196 individuals who reported ethnicity, 125 self-identified as Hispanic. Patients reported the highest scores for interpersonal style, followed by communication, and then decision making. Refer to Table 1 for scores by domain.

	Positive ratings (%)	Negative ratings (%)
DOMAIN		
Subdomain		
COMMUNICATION		
Lack of clarity	85	15
Elicited concerns	95	5
Explained results	90	10
DECISION MAKING		
Decided together	76	24
INTERPERSONAL STYLE		
Compassionate, respect	93	7
Discrimination/ethnicity	93	7

While 21% of foreign-born patients using an interpreter and 14% of foreign-born patients without an interpreter reported a high frequency of physicians speaking unclearly, only 10% of U.S.-born patient reported this ($p=0.252$). In their evaluation of decision making, 27% of U.S.-born patients reported negative scores for physicians, while 23% of foreign patients without an interpreter and 19% of foreign patients with an interpreter reported negative scores in this domain($p=0.553$).

Conclusion: Physician-patient communication is an important marker of healthcare quality. Assessing patient reports of interpersonal processes of care identifies areas of improvement for targeted intervention to assist in training fellows. This is especially important in our understudied, majority Hispanic cohort. The results of the IPC survey suggest physicians need to be more cognizant of sharing the results of physical exams and tests with their patients, attempt to involve patients in their own treatment plan, and speak more clearly to their patients. The differences in expectations related to participatory decision making are perhaps mediated by acculturation. Because communication between patients and physicians influences health outcomes, it is important to measure and evaluate patients' impressions of their care.

1575

Pilates in Juvenile Idiopathic Arthritis. Tania Mendonça IV. Osvaldo Marques da Silva e Valda Maria da Silva, Sao Paulo, Brazil

Background/Purpose: The incorporation of measures that evaluate the health-related quality of life (HRQL) of pediatric patients after the use of interventions will assure a better evaluation of the therapeutic program set to this population.To assess the HRQL of the JIA patients after an exercise program of the Pilates method.

Methods: Clinical trial of a consecutive sample of 26 JIA (ILAR) patients of the Oligoarticular (57.7%), Polyarticular (15.4%) and Systemic (26.9)% subtypes, with an average 10.6 ± 4.7 years of age. The patients participated in Pilates sessions twice a week for 6 months. The degree of satisfaction of the patients in relation to the intervention has been assessed by means of a Likert-type question with options for patients that are totally, very or little satisfied and those slightly or totally unsatisfied with the intervention using Turkey's variance analysis with *post hoc* in order to identify the differences. The HRQL has been assessed by means of the comparison between the PedsQL 4.0 in the baseline and end-of-6-months period after the intervention.

Results: 73.1 % of the patients were totally satisfied with the attributed exercise program ($p<0.05$). In the comparison between the PedsQL 4.0 scores averages in the baseline and end-of-6-months period a significant difference has been noted ($p<0.05$) in the *physical* (50.7 ± 18.1 vs. 90.3 ± 15.5), *emotional* (44.8 ± 18.2 vs. 88.7 ± 13.9), *social* (54.6 ± 15.3 vs. 66.0 ± 15.9), *school-related* (44.4 ± 17.7 vs. 80.0 ± 12.6), psychosocial summary (47.8 ± 14.7 vs. 85.4 ± 15.4) and total score (48.8 ± 12.7 vs. 83.6 ± 12.9).

Conclusion: The Pilates exercise program has promoted a positive impact in the HRQL of JIA patients in the domains, summaries and total scores of the PedsQL 4.0. These results call for the reflection of health professionals on the elaboration of projects intended for the release of funds for the modernization of the rehabilitation methodology of the pediatric population in general.

1576

Ambivalent Attitudes, Accessing Information and Decision-Making: An Interview Study of Medication Use in Early Rheumatoid Arthritis (RA). Anne F. Townsend[1], Paul M. Adam[2], Catherine L. Backman[3], Linda C. Li[3] and ERAHSE Team[4]. [1]Arthritis Research Centre of Canada, Vancouver, BC, [2]Mary Pack Arthritis Centre, Vancouver, BC, [3]University of British Columbia, Vancouver, BC, [4]Vancouver & Toronto

Background/Purpose: Timely treatment is important to control RA, prevent irreversible joint damage and limit impact on daily life. Prompt intervention with DMARDS is associated with improved outcome but delays exist between disease onset and effective medication use. Evidence shows that multiple factors delay early treatment including diffuse symptom onset, access to health care services, and difficulties in gaining a diagnosis. However, little is known of the patient perspective about early decisions and medication use. The current study investigates patient: 1) attitudes to and experiences of medication use; 2) information-seeking; 3) the decision-making process.

Methods: Participants were recruited from rheumatologist and family physician offices, and from newsletters of patient advocacy groups. We conducted in-depth interviews with 38 people (37 women, 1 man), with an RA diagnosis $\leq$12 months. The interviews were organized around 3 distinct but overlapping areas: 1) Pre-diagnosis symptoms, impact and management; 2) Experiences with health professionals leading up to the diagnosis; 3) Post-diagnosis experiences of symptoms, management and the health care system. Follow-up phone calls were made to check and elaborate on the interview generated data. Analysis was informed by grounded theory and a narrative approach.

Results: Medications were core to people's disease management. There was a both a reluctance to take medications and a need for them. Participants expressed ambivalence to medication use in a range of ways: 1) They identified an aversion to medications but required them; 2) They accessed information from multiple sources e.g. the Internet, health professionals and social networks, which was wide-ranging and contradictory; 3) There was little perceived opportunity to discuss options and patient knowledge in the rheumatologist consultation 4) There was post diagnosis delay in and resistance to, taking prescribed medications, and a desire to be 'weaned off' or reduce medications, but an ongoing search for relief and disease control.

Conclusion: A number of interrelated factors continued to hamper prescribed medication regimens, once diagnosis was confirmed. The obstacles to effective and timely medication treatment illustrated the importance of patient-physician communications. More opportunities for shared decision-making, based on dialogue and exchange of knowledge and information in the rheumatologist consultation may reduce some of the tensions around medication use and facilitate ongoing and effective treatment plans

1577

Conception, Family Size and Miscarriages in Fibromyalgia Patients. Robert S. Katz[1], Sharon M. Ferbert[2], Patricia Kuenzi[1], Jessica L. Polyak[3] and Susan Shott[1]. [1]Rush University Medical Center, Chicago, IL, [2]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL, [3]Rheumatology Associates, Chicago, IL

Background/Purpose: Fibromyalgia (FMS) imposes significant handicaps on patients. We asked female fibromyalgia patients about their experiences with childrearing because we anticipated that the patients' pain, fatigue, cognitive problems might create unique difficulties in raising a family and could affect their ability and/or desire to have more children.

Methods: As a part of an Internet survey administered by the volunteer community fibromyalgia organization, AFFTER, 763 female self-identified FMS patients and 115 female controls without FMS responded to questions about their desire and ability to have children. Only women's responses were analyzed to eliminate confounding by gender..

To validate the Internet Survey an identical rheumatology office questionnaire was administered to 115 FMS patients and 63 control patients with other rheumatic diseases. The chi-square test of association and Fisher's exact test were used to compare percentages and the Mann-Whitney test was done to compare FMS and control respondents with respect to the number of biological children. A 0.05 significance level was used and all tests were two-sided.

Results: In the Internet survey the mean respondent age was 49.8 ± 11.4 years. There was no statistically significant difference between FMS and control respondents with respect to the number of biological children (FMS 1.7 ± 1.3 vs. control 1.7 ± 1.6, $p = 0.88$). There were no apparent problems with conception among the FMS patients. Of the respondents who had tried to conceive, 59.6% of FMS patients and 68.8% of controls reported no difficulty conceiving ($p = 0.088$). In the rheumatology office questionnaire The mean age was 48.1 ± 12.3 years for FMS patients and 50.7 ± 13.6 for control patients ($p = 0.092$). 81.7% of the FMS patients and 61.9% of the control patients were women ($p = 0.004$). There was no statistically significant difference between FMS and control respondents

with respect to the number of biological children (FMS 1.5 ±1.4 vs. control 1.4 ±1.3, p = 0.78). Only 19.0% of FMS patients reported that they were raising or had raised their desired number of children with no particular difficulty, compared to 62.9% of control patients (p < 0.001). Of the respondents who had tried to conceive, 28.8% of FMS patients and 15.6% of control patients reported difficulty conceiving (p = 0.10). 15.1% of FMS patients and 4.4% of the control patients reported that they had miscarriages but were eventually successful in having a baby (p = 0.13)

Conclusion: Fibromyalgia does not appear to limit family size because of limitations imposed by the illness or problems with conception.. However, child rearing was frequently challenging in fibromyalgia patients.There was a trend toward more miscarriages reported in the fibromyalgia patients.

1578

Participation in Hospital Influenza Collaborative Is "inFLUential" in Improving Vaccination Rates in Patients with Juvenile Idiopathic Arthritis and Systemic Lupus Erythematosus. Janalee Taylor[1], Elaine F. Haddix[2], Kim Badinghaus[3], Mary Beth Burns[1], Terry M. Moore[4], Julie V. Ranz[1], Amy Anneken[1], Pam Fiorini[1], EVA Spiegel[1], Esi Morgan-Dewitt[1], Michael Henrickson[1], Hermine Brunner[1] and Jennifer L. Huggins[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital MC, Cincinnati, OH, [3]Cincinnati Children's Hospital Center, Cincinnati, OH, [4]Cincinnati Chiildren's Hospital Medical Center, Cincinnati, OH

Background/Purpose: Influenza (flu) is a contagious respiratory illness caused by influenza viruses. It can result in mild to severe illness, with noted reports of pediatric influenza related deaths. Influenza related morbidity and mortality can be decreased by improving flu vaccination rates. Children with rheumatic disease and those who are on immunosuppressive medications are at increased risk of complications related to influenza. The purpose of this study is to increase flu vaccination rates in patients with Juvenile Idiopathic Arthritis (JIA) and Systemic Lupus Erythematosus (SLE) through participation in hospital-wide influenza collaborative.

Methods: 2010–2011 CDC Influenza Vaccine Recommendations were reviewed. Target populations for pediatric rheumatology clinic were identified. Inclusion criteria for JIA consisted of: Rheumatology patients seen in the last year with a Primary DX code of 714.3, 714.32, 714.33 taking immunosuppressive medications of: methotrexate, sulfasalzine, leflunomide, cyclosporin, mycophenolate mofetil, azathioprine, etanercept, adalimumab, anakinra, infliximab, rituximab, abatacept, canakinumab, tocilizumab, rilonocept, or corticosteroids. SLE patients included rheumatology patients seen in the last year with a Primary DX code for Lupus is 710. Cohorts for JIA and SLE were pulled using Epic Clarity reports and lists were examined for appropriateness of eligibility criteria. Interventions included: reminder cards mailed to target patient population, Epic Influenza Best Practice Alert for target populations, standardized order sets, RN order placement for influenza, and process education for staff.

Results: Two hospital-wide goals for 2010 season were set: 1) 87% of divisions would achieve an 80% immunization goal (vaccinated or actively declined) by January 15, 2011; 2) 75% of target populations would achieve at least 75% actual vaccination (through clinic or PMD). 18 divisions participated in the collaborative with identification of 35 high risk populations. Collaborative-wide results revealed 72% of divisions achieving immunization goal. 80% of identified target populations received actual vaccine. The pediatric rheumatology 2010 patient cohort consisted of 313 and 124 JIA and SLE patients respectively. 94% of JIA and 89% of SLE patients achieved immunization goal of vaccination or decline. Percent of JIA and SLE receiving actual vaccination was 94% and 80% respectively. Comparison of vaccination rates from 2009 to 2010 revealed implementation of Best Practice Alert resulted in 20–25% improvement. Insurance status had no effect on immunization rates in rheumatology patients.

Conclusion: Participation in hospital-wide flu collaborative is valuable program to increase influenza vaccination rates for high risk pediatric rheumatology populations. Key interventions included involvement of front-line nurses with process and Epic implementation, development of Epic Best Practice Flu Alert system and standardized order sets. Consistent data feedback to teams/divisions and automated Best Practice Alerts are useful tools for driving performance.

1579

Incorporating the Patient Perspective: Developing a Patient-Focused Evaluation for An Early Rheumatoid Arthritis Support and Education Program. Meredith K. Wolrich, Adena Batterman, Roberta Horton, Linda Leff, Theodore R. Fields and Vanima Lalsa. Hospital for Special Surgery, New York, NY

Background/Purpose: OMERACT's work has inspired a paradigm shift in rheumatology research, emphasizing the need for the patient perspective in identifying and measuring RA treatment outcomes. Hewlett's (2003) research reveals that patients and clinicians often have different views concerning outcome prioritization. Without patient input, providers may fail to consider issues of paramount importance in making treatment decisions.

We previously reported on a free monthly support and education program designed to meet the disease-related psychosocial and educational needs of newly diagnosed (<1 yr.) RA patients. The Program is part of a hospital-based early arthritis initiative and was developed from a multi-level needs assessment. Consistent with OMERACT philosophy, format and content are driven by patient input obtained through biannual focus groups. However, our monthly written evaluations, consisting of Likert scale and open-ended questions, were developed *without* patient input. Thus, they may not measure outcomes most important to participants or in language that they find relevant. Our goal is to describe our process for ensuring the inclusion of this essential feedback and its outcome.

Method: Data was collected in 3 stages:

1) We reviewed psychosocial assessments of all past participants (n=40), completed prior to their entering the Program, to identify patient-centered outcomes. Based on the most frequent responses to questions regarding expectations of the Program and RA-related concerns, we created a list of themes and organized them into 3 key domains.

2) Volunteers from our group (n=8) were given a Likert scale survey to rate importance of the listed themes to confirm their relevance.

3) Two MSWs ran a two-hour focus group (n=8) that was recorded and transcribed. Participants were asked 3 questions, modeled on a study by Carr et al (2003), to identify the most important Program outcomes within the 3 domains and obtain patient language to describe them: 1) Which Program outcomes are most important to you? 2) What makes you satisfied? 3) How do you decide it is working for you?

Result: Demographics: *Gender* – Female 88%; Male 12%. *Ethnicity* – Caucasian 50%; Asian-American 25%; African-American 12.5%; Latino 12.5%. *Mean Age* – 53. *Education* –17+ yrs. 75%; 13–16 yrs. 25%.

Within the 3 domains – 1) managing/living with RA; 2) connecting with others with RA, and 3) coping with the emotional impact of RA – the most salient patient-identified outcomes include: obtaining information about RA; enhancing communication with MD; sharing experiences with others; feeling less anxious; feeling more hopeful and confident about managing RA; and not feeling alone with RA. Patient language was also obtained, giving us further insight into the meaning of these outcomes.

Conclusion: This data will drive the creation of new evaluation questions to reflect outcomes and patient language identified in the focus group. Next, we will conduct individual cognitive interviews – a technique used to gather information on how respondents think about and answer survey questions – to ensure these questions reflect patient intention. We will review responses to revise and finalize the evaluation, and assess its efficacy in meeting patient needs.

1580

Preferences for Arthritis Interventions: Comparison Between Blacks and Whites with Arthritis. Chivon A. Mingo[1], Jessica M. McIlvane[2] and William E. Haley[2]. [1]University of North Carolina, Chapel Hill, NC, [2]University of South Florida, Tampa, FL

Background/Purpose: Arthritis disproportionately affects Blacks in comparison to Whites. Blacks consistently report more pain, and more activity limitations. It is imperative to have effective interventions and treatment options for Blacks. The purpose of this study is to begin to identify factors needed to design arthritis interventions that will reduce barriers and increase appeal to Blacks.

Methods: Using a needs assessment survey, intervention preferences, barriers to healthcare, knowledge about interventions and care, utilization, and health beliefs among Black and White adults with self-reported physician-diagnosed OA were examined. Frequencies were examined to determine perceived needs related to arthritis healthcare of Blacks and Whites recruited from the community. Independent samples t-tests and Pearson's Chi-square analyses were computed to determine group differences between Blacks and Whites.

Results: Blacks were more likely to report cost, lack of trust, fear of being the only person of their race, lack of recommendation from their doctor, and lack of recommendation from a family member or friends as barriers to participating in arthritis interventions. There were also many commonalities across race. In addition, Blacks were more likely to prefer the intervention content, intervention structure and delivery methods, and arthritis resources presented in the needs assessment in comparison to Whites.

Conclusion: Findings suggest that similar interventions are needed across racial groups, but some minor practical adaptations could be made to existing arthritis interventions to minimize barriers, increase cultural sensitivity, and offer programs that would be appealing to Blacks and Whites with arthritis.

1581

Increased Awareness of Arthritis May Result in Earlier Diagnosis of Rheumatoid Arthritis. Sara Zafar[1], Humeira M. Badsha[2], Ayman Mofti[2], Arlene Delosantos[2], Janice Altares[2], Gerald Matudio[2] and Kok Ooi Kong[3]. [1]University of Edinburgh, Edinburgh, United Kingdom, [2]Al Biraa Arthritis Center, Dubai, United Arab Emirates, [3]Tan Tong Seck Hospital, Singapre, Singapore

Background/Purpose: Patients with Rheumatoid Arthritis (RA) in the United Arab Emirates (UAE) have been found to have a long delay in diagnosis, in addition to a low utilization of DMARD therapy (1, 2). Over the past 5 years, in addition to the establishment of support groups such as the Emirates Arthritis Foundation, a number of awareness programs and PR campaigns have also been instituted in the UAE. The aim of our study is to assess whether initiatives to increase awareness of arthritis among the general public have resulted in a shorter lag time to diagnosis.

Methods: We collected demographic, disease and treatment data on the first 100 patients who met ACR criteria for RA, and who were presenting to our practice for the first time. This data was compared with similarly collected data, on the first 100 patients presenting to our musculoskeletal clinic, 5 years previously.

Results: A total of 100 patients were seen with an average age of 40.2 ± 11.0 years (42.2 ± 12.3 years in previous data set, not statistically significant by Student's t-test); female 87% (as before); Arabs 28% and Indians 48% (Arabs 38% and Indians 36% previously). 62% were rheumatoid-factor positive, whereas 73% were titre positive in the previous study (not statistically significant, chi-square test). There was a mean reduction in lag time between symptom onset to diagnosis by 45.8%, from 14.4 ± 15.6 months to 7.8 ± 12.1 months (Student's t-test p=0.001). Furthermore, the lag to the first DMARD was also reduced by a mean of 34.9%, from 19.2 ± 24 months to 12.5 ± 21.7 months (Student's t-test p=0.04). There was no statistically significant difference between the mean DAS 28, ESR and patient global assessment of disease activity (VAS) score amongst the two groups (current data: ESR 36 ±28 mm/h, DAS 28 5.0 ± 1.4, VAS 58.0 ± 26.7 mm; 5 years prior: ESR 33 ±25 mm/h, DAS 28 5.2 ± 1.6, VAS 57.4 ± 25.0 mm).

Conclusion: These data suggest that there has been a reduction in both the lag to diagnosis and the initiation of DMARD therapy among patients in the UAE, as compared with 5 years prior. This may be attributed to the inception of patient support groups and a general drive towards increasing public awareness about RA. Studies of larger cohorts may be needed to substantiate our findings. In addition subsequent studies must address if the shorter lag time to diagnosis and first DMARD can result in higher levels of disease remission and improved quality of life for our patients with RA.

Table 1.

	2006 Data	2010 Data	p-values
	100 patients seen (average ± SD)		
Age:	42.2 ± 12.3	40.2 ± 11.0	
Gender: Female	87%	87%	
Arab	38%	28%	
Indian	36%	48%

Effects of a Telephone Based Osteoarthritis Self-Management Program on Communication with Health Care Providers. Kelli D. Allen[1], Hayden B. Bosworth[1], Cynthia Coffman[1], Jennifer H. Lindquist[1], Nina R. Sperber[1], Morris Weinberger[2] and Eugene Z. Oddone[1]. [1]Duke and Durham VA Medical Center, Durham, NC, [2]University of North Carolina at Chapel Hill & Durham VA Medical Center, Durham, NC

Background/Purpose: Osteoarthritis (OA) self-management programs aim to improve patients' communication with health care providers about their OA and its treatment, but little is known about how effectively these programs meet this goal. These analyses examined whether a telephone-based OA self-management program improved patients' self-reported communication with providers and perceptions of participation in OA treatment decisions. We also examined whether there were differential program effects according to patient race and education level, since these characteristics have been associated with differences in communication with providers.

Methods: Participants (n=515, mean age = 60 years, 93% male, 46% non-white-primarily African American) were involved in a randomized controlled trial of a telephone-based OA self-management program, compared to health education (HE; attention control) and usual care control (UC) groups. The self-management program included education materials and 12 monthly calls from a health educator to facilitate personal goals for OA management. Outcomes for these analyses, collected at baseline and 12-month follow-up, included the Communication with Physicians Scale (CPS; range 0–5, higher scores indicate more active communication behaviors such as discussing OA-related problems) and the Medical Outcomes Survey Participatory Decision-Making Scale (PDMS; range 0–100, higher scores indicate greater participation). Linear mixed modeling was used to assess differential improvement in CPS and PDMS scores between the OA arm and control arms (HE and UC), between white vs. non-white participants and participants with some college vs. no college.

Results: At baseline mean CPS and PDMS scores were higher for those with some college than those with no college (2.6 vs. 2.2; p<0.01 and 77.4 vs. 72.5;p=0.05) There were no overall intervention effects on change in CPS scores over 12-months and no differences in change by race. However, compared with the UC group, OA intervention effects on CPS differed according to education (p=0.03). In the OA group, CPS scores improved by 0.4 points for those with no college education compared to 0.1 points for those with some college education. There were no overall intervention effects on change in PDMS scores and no differences in effects according to education. However, there were differences in OA intervention effects on PDMS according to race, compared with both HE (p=0.04) and UC (p=0.06) groups. In the OA self-management group, whites improved by 7.5 points, whereas non-whites declined by 4.3 points. In both the HE and UC arms there were small improvements in PDMS scores for both whites and non-whites.

Conclusion: Patients in this OA self-management program who had lower education levels improved in their self-reported communication with physicians about their OA (about a 20% increase in score), and this is a key demographic group for targeting these programs. Non-whites' decline in participatory decision-making scores may be due to a change in perception of how actively they participate in OA treatment decisions; a more robust intervention may be needed to increase participatory behaviors.

1583

How Do Self-Directed Participants Follow the Arthritis Foundation's *Walk with Ease* Program? Kirsten A. Nyrop, Britta L. Schoster, Mary Altpeter, Betsy Hackney and Leigh F. Callahan. University of North Carolina, Chapel Hill, NC

Background/Purpose: Our research team established the efficacy of the *Walk With Ease (WWE)* program for both a self-directed and an instructor-led group format. Self-directed participants were encouraged to walk at least 3 days/week for 30 accumulated minutes/day, and to follow the program at their own pace using the *WWE* workbook. The workbook includes basic facts about arthritis and exercise, motivational tools (e.g. self-check lists, walking diary), and warm-up and cool-down exercises. This study examines how self-directed participants followed the *WWE* components, throughout the 6-week intervention and 1 year later.

Methods: At the end of the 6-week trial, self-directed participants completed a self-assessment survey and at 1 year a follow-up survey of their continued use of the *WWE* program. Survey responses were analyzed using descriptive statistics to examine how participants followed the program.

Results: 270 *WWE* study participants opted for the self-directed format, of which 225 (83%) completed the 6-week and 204 (91%) the 1-year survey.

At the end of the *WWE* program, 52% reported walking an average of 3.7 (±1.8) days/week and 31.7 (±15.3) minutes/walk. 38% described themselves as more physically active, 76% would continue walking, and 97% would recommend *WWE* to a friend. At 1 year, 69% reported continued walking for exercise, 61% walked about the same amount of time/minutes, 54% about the same number of times/week, and 96% would recommend *WWE* to a friend.

Table 1 is an overview of how participants reported following components of the *WWE* program. Despite wide variation in self-reported use of the workbook and related tools, 81% found the workbook somewhat/very helpful with reaching their walking goals. 58% found the walking diary helpful, and 47% read 4 or more of the 6 workbook chapters. Although participants did not do the exercises regularly, 49% found the stretching and 53% the strengthening exercises somewhat/very helpful. At 1 year, 69% continued walking for exercise, 61% walked about the same number of minutes, and 54% the same number of walks/week.

Table 1. Use of the *Walk With Ease* Program by Self-Directed Participants at 6 Weeks

USE OF PROGRAM MATERIALS	Percent
WWE workbook	
Read 4 or more of the 6 chapters	47
Considered the workbook somewhat or very helpful with reaching walking goals	81
Self-Assessment Tools	
Used the Starting Point Self-Test	39
Used the Ending Point Self-Test	12
Used the Knowledge and Confidence Self-Check	27
Walking diary	
Used to keep track of times/distances walked	39
Tracked amount of time spent walking	57
Tracked distance walked	25
Used the walking diary to strengthen motivation to walk	22
Considered the walking diary somewhat or very helpful	58
Exercises	
Did the warm-up and cool-down stretches a couple of times a week	28
Thought the stretches were somewhat/very helpful	49
Did the strengthening exercises regularly	19
Thought the strengthening exercises were somewhat or very helpful	53
OVERALL ASSESSMENT OF THE PROGRAM	
Physical activity level	
Moderately or a lot more active now compared to before starting *WWE*	38
Key items learned from WWE	
The relationship between arthritis, exercise and pain	94
How to overcome physical and mental barriers to walking	81
How to exercise safely and comfortably	90
How to make a walking plan with realistic goals	88
Strategies to keep my motivation	80

Conclusion: Self-directed participants reported high satisfaction with and benefits from the *WWE* program, both at 6 weeks and 1 year. However, there was considerable variability in how they used specific program components. These findings indicate that the self-directed *WWE* format is acceptable and provides a flexible option for adults with arthritis symptoms who prefer to exercise on their own.

1584

Improving Doctor-Patient Communication Through Let's Talk Rheumatoid Arthritis. Arlene Vinci, Emily L. Creek and Cindy McDaniel. Arthritis Foundation, Atlanta, GA

Background/Purpose: In 2004, a telephone survey of 500 self-identified individuals with rheumatoid arthritis (RA) was conducted for the Arthritis Foundation (AF) by Harris Interactive. The study revealed:

- 70% of people in the survey with RA still experience pain, stiffness and fatigue on a daily basis
- The majority of RA participants taking either BRMs or DMARDs are very or extremely interested in having their physician:
- Spend more time explaining the RA medications
- Provide materials such as brochures about RA
- Talk about new RA therapies
- Talk about new RA clinical trials for which they may qualify

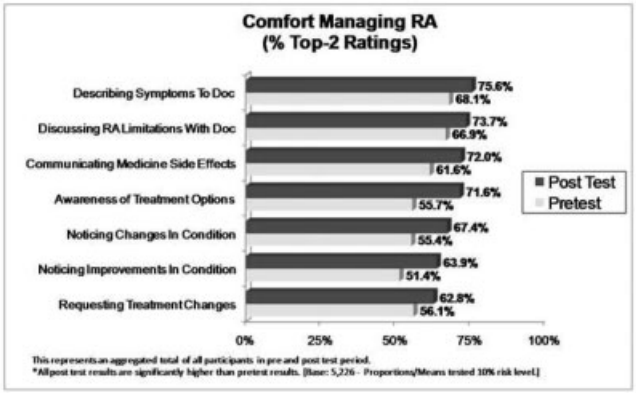
To address these unmet needs, the AF developed a communication guide designed to help RA patients improve the dialogue with their physicians. Three focus groups with both rheumatologists and patients were conducted to determine reaction, efficacy, and level of buy-in.

Methods: Using the communication guide as the centerpiece, a fulfillment kit containing RA educational materials, a health assessment questionnaire and a participant survey was developed and launched in 2006. A national year-round media campaign serves to promote the free Let's Talk RA Communication Kit to RA patients and their caregivers. In addition, 77 Let's Talk RA Town Hall meetings and Roundtable discussions featuring local rheumatologists have been conducted for some 3,600 RA patients nationwide.

The impact of Let's Talk RA is continuously assessed through the use of a pre-test survey found in the Kit and a post-test survey mailed six months later to all pre-test participants. A total of 5,226 surveys have been collected as of December 31, 2010 which includes 3,960 pretest and 1,266 post-test surveys. The participation rate is around 7% for the pretest period and 41% for the post test period. Resulting data was tabulated and tested for differences between the pre and post-test periods.

Results: Results of the surveys indicate that post-test participants are more likely than those in the pre-test period to report higher comfort levels in managing rheumatoid arthritis six months after they begin participation in Let's Talk RA:

- higher ratings for describing specific symptoms, discussing RA limitations, requesting treatment changes and communicating about medication side effects with doctors, and
- higher comfort levels in noticing improvements and changes in their condition.



In addition to increased comfort in managing RA, post-test participants are more likely to say that they are satisfied with their treatment changes and that the Let's Talk RA kit provides help in communicating with doctors than are those in the pre-test period.

Conclusion: Based on the research results, it is evident that Let's Talk RA is having a positive impact on program participants and their treatment experience.

1585

A Needs Assessment of Hospital for Special Surgery's Charla De Lupus/Lupus Chat® Teen and Parent Support Group: Gaining a Community Perspective on Nutritional Health to Inform Implementation of a Nutrition Education Intervention. Jillian A. Rose[1], Christie Carlstorm[2], Roberta Horton[1], Sandra Goldsmith[1], Robyn Wiesel[1] and Lisa F. Imundo[3]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital For Special Surgery, New York, NY, [3]Childrens Hospital of New York, New York, NY

Background/Purpose: Our national lupus support and education program is offered to people with lupus and their families in underserved Latino and African American communities. As part of our community service plan, we have collaborated with an affiliated urban medical center's pediatric rheumatology department, and our internal department of public and patient education's nutrition education program, designed to provide culturally sensitive education to children and their families. Health disparities (our targeted community is 71% Hispanic, with higher rates of obesity and lower SES than overall city rates) combined with increased risks (CVD, osteoporosis) related to SLE and its treatment indicate the need for sound nutritional practice. The goal of our needs assessment was to get a better understanding of teens and their parents' nutritional choices, knowledge and values, along with potential barriers, to assess the efficacy of a further intervention.

Methods: Written surveys were administered through telephone interviews (English/Spanish), with 48 questions (teens) and 55 questions (parents) of our lupus support program. The survey design incorporated assessment tools from the Dept. of Agriculture for a better understanding of the nutritional value, knowledge and practices of teens. The survey had 7 sections: demographics, home environment, food intake, knowledge of food pyramid /healthy diet/food labels, exercise, and interest in an educational intervention. Also, teen and parent focus groups were conducted for a more detailed understanding of survey results.

Results: We contacted 90 teens and parents; 35 (11 parents: mean age 46 and 24 teens: mean age 17) completed the phone interview. 46% were Latino; 83% female. 60% reported household income < $30,000/yr. and 34% reported Spanish as the primary language spoken at home. Although 63%of parents and 42% of teens say "the things I eat and drink now are healthy so there is no reason for me to make changes" 82% of parents and 33% of teens eat at fast food places 1–3 times per week. Importantly, 55%of parents strongly disagree that what one eats or drinks can affect lupus, yet 100% of parents know of health conditions related to eating too much fat (i.e Obesity, CVD). Almost 40% of teens did not know of any health conditions related to insufficient calcium; one quarter of teens did not know of any health conditions related to eating too much salt. Although 88% of teens felt reading food labels is important, many teens in our focus group felt that price and taste were more important, and food labels were hard to understand. They also felt that their neighborhoods didn't have a lot of "healthy" foods. Our phone survey and focus group results indicated a desire for a nutritional intervention that parents and teens they would attend together.

Conclusion: These findings, revealing incongruities between conveying socially acceptable responses and actual behaviors, as well as gaps in knowledge and access, are the first step in informing the development of an educational intervention that meets our community's needs.

1586

Citizen Engagement in Arthritis Research for Patient Centered Research: A Model of Success. Louise Bergeron, Dawn Richards, Linda Wilhelm, John Coderre, Delia Cooper, Janet Gunderson, Louise Crane, Christopher DeBow, Simone Hughes, Marie-Eve Veilleux, Iris Maurstad, Neil White, Elaine Wychreschuk and Katy Miller. Canadian Arthritis Network, Toronto, ON

Background/Purpose: The Canadian Arthritis Network's (CAN) Consumer Advisory Council (CAC) is a model of Citizen Engagement in Arthritis Research. The Council is comprised of Canadians living with various forms of arthritis. CAN consumers represent a wide range of professional experiences, ages, cultures, and languages. CAN consumers are Chronic Disease and Arthritis Self-management Program Facilitators, members of Health Canada's Expert Advisory Committees, Patient Partners in medical schools, community reviewers for the Canadian Institutes of Health Research, involved in consultative input into the Canadian Agency of Drugs and Technologies in Health reviews, Cochrane Musculoskeletal group and members of regional, national and international community groups and organizations.

Methods: In 1998, the Canadian Arthritis Network, funded by the Federal Government's Networks Centres of Excellence Program, a national, federally- funded, not-for-profit organization that supports integrated, multidisciplinary and multi-institutional research and training, struck a committee of people living with arthritis to provide advice on the priorities of arthritis research from the perspective of those living with the disease. Since arthritis receives only a small percentage of research funding in Canada, the goal was to spend dollars focused on areas that would have the most impact on improving health outcomes.

Results: The Canadian Arthritis Network's most basic methods of engaging citizens consist in giving consumers voting privileges as part of the governance structure of the organization, together with a budget supporting the activities of the Consumer Advisory Council. The Council in turn engages the larger citizen community by presenting CAN CARES, The Canadian Arthritis Network Research Exchange Seminar, where a slate of researchers presents their findings, followed by a discussion with the audience. The Canadian Arthritis Network involves consumers in all of its committees, funded research, and training programs. This citizen engagement model has been successful because of the following criteria:

Membership of the council on all committees & integration in the governance structure of the Canadian Arthritis Network.

Equal collaboration on research projects.

Participants and leaders in training activities

Participation in knowledge translation & exchange activities, both-internal and external.

Ongoing yearly financial budget dedicated to the operations of the council.

Validation, by the Canadian Arthritis Network, of the importance of the council in the pursuit of arthritis research.

Conclusion: Patient engagement is an integral part of the Canadian Arthritis Network; a unique model. Patients play an integral role in the Knowledge Translation process helping to choose research direction, ensuring research is translated into better health outcomes. Involving patients in health research creates champions who advocate the value of health research and demystify science to other Canadians so they will understand the importance of health research. Consumer participation increases the legitimacy of health research which is primarily pursued for the benefit of the public.

Monday, November 7, 2011, 11:00 AM–12:30 PM

1587

Evidence for a Direct Role of Anti-Signal Recognition Particle Antibodies in the Pathogenesis of Necrotizing Myopathies. Coralie bloch-Queyrat[1], Laurent Drouot[2], Jean- Luc Charuel[3], Erika Yada[4], Dominique Langui[5], Saik Urien[6], Serge Herson[1], Lucie Musset[3], Gillian Butler Browne[4], Olivier Boyer[2] and Olivier Benveniste[1]. [1]Centre de Référence des Maladies Neuro Musculaire, Pitié Salpêtrière, Paris, France, [2]INSERM U905, University of Rouen, Rouen, France, [3]Laboratoire d'immunochimie, Pitié- Salpêtrière, Paris, France, [4]UMRS 974 INSERM UPMC, Paris, France, [5]Plateforme d'Imagerie Cellulaire, INSERM UMRS 975/CNRS UMR 7225/ UPMC ICM Centre de Recherche Pitié-Salpêtriere, [6]URC Cochin Necker CIC901-INSERM, France

Background/Purpose: Signal Recognition Particle (SRP) is a ubiquitous protein complex which mediates the transport of newly synthesized proteins to the endoplasmic reticulum in eukaryote cells. Anti-SRP auto-antibodies (Abs) are associated with a severe necrotizing myopathy. We have previously shown (Arthritis Rheum. 2011 Mar 11. doi: 10.1002/art.30344) that serum titers of anti-SRP Abs closely correlate with CK level and muscle weakness in patients. The aim of this study is to investigate a possible direct role of anti-SRP Abs in the development of this form of myopathy.

Methods: Muscle deposits of anti-SRP Abs were assessed by immunohistochemistery on normal mouse or human muscle tissues, by both light- and electron-microscopy, using different sources of anti-SRP Abs (sera from 5 patients, purified anti-SRP from a patient's plasma exchange on affinity column charged with SRP54 recombinant protein, goat anti-mouse SRP (SRP54, SANTA CRUZ BIOTECHNOLOGY), chicken anti-human SRP (SRP54, USBIOLOGICAL)). Cytopathic effect of anti-

SRP Abs was assessed on cultured primary human muscle cells (myotubes). Myotubes were cultured with purified anti-SRP Abs (200 μg/ml) or control polyclonal IgG (200 μg/ml). After 4 days of culture, cells were processed for scanning microscopy. Total area covered by myotubes was calculated using NIH Image J image analysis software.To appreciate the *in vivo* effect of anti-SRP Abs on muscle strength, serum (400 ml) from anti-SRP+ patient or healthy donor was injected intraperitonealy daily for 14 days to C57BL/6 mice and muscle strength was assessed by rotarod.

Results: Similar histological aspects were found by light microscopy after incubation with the different sources of anti-SRP Abs. Immunostainings appeared as a punctuated intracellular signal within the endomysium with reinforcement at the membranes of myocytes. Preincubation of purified anti-SRP54, or commercial anti-SRP54 Abs, with excess recombinant SRP54 led to signal disappearance. Immunogold staining followed by electron-microscopy revealed immunoreactivity located in the endoplasmic reticulum. When cultured with purified anti-SRP Abs, myotubes showed a dramatic decrease of their diameter as compared to those cultured with control polyclonal IgG or no Abs, leading to a 60% decrease in the surface they covered (surfaces (in arbitrary unit) respectively of 1.4 10^6(anti SRP); 3.6 10^6(polyclonal IgG) and 3.0 10^6(no Abs); p=0.003, Kruskal-Wallis test with Monte-Carlo resampling). In vivo injection of anti-SRP Abs (compared to normal serum) resulted in weight loss (−4 g in average) and significant decrease in muscle strength as attested by rotarod results (25 sec. vs. 130 sec. ($p<0.01$)).

Conclusion: In muscle, anti-SRP Abs deposited on the endoplasmic reticulum. This was associated with a direct cytopathic effect as observed *in vitro* on cultured primary human muscle cells and *in vivo* by a rapid decrease in muscle strength. These results provide the first experimental evidence that anti-SRP Abs may play a direct role in the pathogenesis of necrotizing myopathies.

1588

β-Catenin Is a Central Mediator In Systemic Sclerosis. Christian Beyer[1], Amelie Schramm[1], Alfiya Akhmetshina[1], Trayana Kireva[1], Clara Dees[1], Sonia C. Schindler[1], Makoto M. Taketo[2], Oliver Distler[3], Georg Schett[4] and Jorg HW Distler[4]. [1]Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany, [2]Kyoto University Yoshida-Konoé-cho, Kyoto, Japan, [3]University Hospital Zurich, Zurich, Switzerland, [4]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: β-catenin is the central integrator of canonical Wnt signaling. Binding of Wnts to their receptors causes stabilization of β-catenin, which translocates into the nucleus and regulates the transcription of target genes. Since recent evidence suggests a central role of Wnt signaling in fibrosis, we examined the Wnt pathway in SSc and focused on the role of β-catenin in fibroblast activation.

Methods: We performed qPCR for several Wnt ligands and axin-2 to examine Wnt expression in SSc skin. We further studied protein levels of Wnt-1, −4, −10b and β-catenin by IHC. To establish the effects of Wnt signaling on collagen release, we used fibroblasts with either stabilization of β-catenin (ΔEx3 β-catenin$^{wt/ex}$) or fibroblasts carrying a deletion of both β-catenin alleles (Ctnnb1$^{ex/ex}$). Finally, we created mice with fibroblast-specific stabilization of β-catenin (ΔEx3 β-catenin$^{wt/fl}$ × Col1a2;Cre-ER) as well as mice carrying fibroblast-specific deletion of β-catenin (Ctnnb1$^{fl/fl}$ x Col1a2;Cre-ER). We studied spontaneous fibrogenesis in ΔEx3 β-catenin$^{wt/fl}$ × Col1a2;Cre-ER mice 8 weeks after Cre-activation and challenged activated Ctnnb1$^{fl/fl}$ × Col1a2; Cre-ER mice with bleomycin for 4 weeks.

Results: We could demonstrate mRNA overexpression of Wnt-1, −10b, and −16 as well as increased Wnt-1 and Wnt-10b protein levels in SSc skin. The overexpression of several Wnt ligands resulted in a prominent nuclear accumulation of β-catenin in fibroblasts. Finally, increased mRNA levels of the target gene axin-2 confirmed the activation of canonical Wnt signaling.

In ΔEx3 β-catenin$^{wt/ex}$ fibroblasts, we addressed the consequences of enhanced Wnt signaling and increased accumulation of β-catenin for SSc fibrogenesis: In vitro stabilization of β-catenin resulted in an increase of collagen release by 112 ± 7 % ($p < 0.05$). By contrast, deletion of β-catenin in Ctnnb1$^{ex/ex}$ fibroblasts reduced collagen production by 55 ± 17 % ($p < 0.05$). Collagen mRNA levels were altered accordingly.

To confirm the crucial role of β-catenin in dermal fibrosis in vivo, we selectively targeted β-catenin in fibroblasts. Cre-activated ΔEx3 β-catenin$^{wt/fl}$ × Col1a2;Cre-ER mice showed massive and spontaneous dermal thickening with increases of 3.98 ± 0.1–fold ($p < 0.05$). Hydroxyproline content and myofibroblast counts were also increased prominently. In contrast to the pro-fibrotic effects of β-catenin stabilization, deletion of β-catenin in Ctnnb1$^{fl/fl}$ x Col1a2;Cre-ER mice protected from bleomycin-induced dermal fibrosis (reduction of skin thickness by 54 ± 4 %; $p < 0.05$).

Conclusion: We demonstrated a prominent activation of canonical Wnt signaling in SSc with nuclear accumulation of β-catenin in fibroblasts and activation of the target gene axin-2. Our results showed that fibroblast-specific stabilization of β-catenin resulted in enhanced collagen release in vitro and in vivo, whereas deletion of β-catenin potently reduced collagen production. Together, our findings highlight a key-role of β-catenin in fibroblast activation and fibrosis. Thus, β-catenin may be promising molecular targets for anti-fibrotic therapies.

1589

A Combined Fc-OPG/hPTH(1–34) Therapy to Restore Impaired Skeletal Growth and Bone Loss in a Mouse Model of IL-6 Dependent Juvenile Inflammatory Diseases. Andrea Del Fatore[1], Marta Capannolo[2], Barbara Peruzzi[2], Alfredo Cappariello[1], Nadia Rucci[2], Fabrizio De Benedetti[1] and Anna Teti[2]. [1]Children Hospital Bambino Gesù, Rome, Italy, [2]University of L'Aquila, L'Aquila, Italy

Background/Purpose: Premature osteoporosis and stunted growth are common complications of childhood chronic inflammatory diseases and have a significant impact on patients' quality of life. Presently no treatment regimens are available for these defects in juvenile diseases. To test a new therapeutic approach, growing mice overexpressing the pro-inflammatory cytokine IL-6 (TG) showing a generalized bone loss and stunted growth were used. Since TG mice present increased bone resorption and impaired bone formation, we hypothesized that a combined therapy with the antiresorptive modified osteoprotegerin, Fc-OPG, and the anabolic PTH could counteract their skeletal alterations and improve growth.

Methods: We therefore treated TG mice with Fc-OPG 0.25 mg/Kg once at the 4th day of life and with 80 μg/Kg hPTH(1–34) everyday from the 16th to the 30th day of age. No toxic effects were observed on vital organs.

Results: The treated mice presented a complete rescue of growth, as showed by a body weight of 93% and a tibia length of 92% of WT mice ($p<0.05$ *vs* TG vehicle), and of bone phenotype (BV/TV %; WT vehicle 6.38+2.46; TG vehicle 3.12+0.82; TG Fc-OPG/hPTH 5.24+0.66$^{\#}$; $^{\#}p<0.02$ *vs* TG vehicle), with a normalization of osteoclast and osteoblast parameters. Restoring of normal bone turnover was confirmed by RT-PCR on femurs of Fc-OPG/hPTH-treated mice that showed normalization of TRAcP, ALP and RUNX2 expression compared to vehicle-treated TG mice, with levels similar to WT mice. *In vitro* cultures from Fc-OPG/hPTH-treated mice confirmed the full rescue of osteoclast number and bone resorption and an increase of osteoblast ALP staining to levels similar to cultures from WT mice, with normal osteoblast progenitors determined by CFU-F-ALP assay. The phenotypic rescue of TG mice was due to the combined treatment, because TG mice treated once at the 4th day of life with Fc-OPG 0.25 mg/Kg alone showed an increase of body weight (WT vehicle 14.61+1.72 g; TG vehicle 7.64+0.7 g*; TG Fc-OPG 10.4+1.12 g*; *$p<0.03$ *vs* WT vehicle), tibia length (WT vehicle 1.59+0.14 cm; TG vehicle 1.30+0.05 cm*; TG Fc-OPG 1.40+0.04 cm*; *$p<0.05$ *vs* WT vehicle) and bone volume to intermediate levels between those observed in WT and in TG vehicle-treated mice. Similar intermediate rescue was observed treating TG mice with hPTH alone since the 16th day of life. Moreover, intermittent injections of hPTH since the 4th day of age caused distress of the mice with no effects on the somatic growth.

Conclusion: In conclusion, our results identified the sequential Fc-OPG/hPTH as a treatment regimen to rescue the somatic growth and bone disorder in TG mice, thus providing the proof of principle for a new therapeutic approach to correct these defects in juvenile inflammatory diseases.

1590

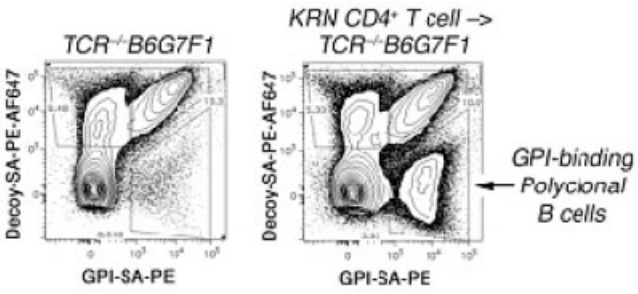
The Absence of CD4$^+$ T Cell Help Underlies the Maintenance of B Cell Tolerance to Glucose-6-Phosphate Isomerase and the Avoidance of Arthritis. Justin J. Taylor, Laura O. Barsness, Ryan J. Martinez, Stephanie R. Thomas and Daniel L. Mueller. University of Minnesota Medical School, Minneapolis, MN

Background/Purpose: Rheumatoid Arthritis (RA) in individuals expressing certain HLA DR4$^+$ (shared epitope) alleles is highly associated with the production of autoantibodies, including rheumatoid factors and anti-citrullinated protein antibodies. Mice carrying the H-2^{g7} MHC allele are also prone to the development of arthritis as a consequence of CD4$^+$ T cell autoimmunity directed against glucose-6-phosphate isomerase (GPI)/I-A^{g7} complexes and production of anti-GPI IgG1 autoantibodies. In both cases, those mechanisms responsible for the breakdown of natural B cell tolerance, such as a failure of peripheral clonal

deletion or restoration of functional responsiveness (e.g., reversal of clonal anergy), are not well understood because of our inability to easily identify and directly characterize low frequency polyclonal autoreactive B cells.

Methods: We now report the development of a B cell "antigen tetramer" system for use with multiparameter flow cytometry that can accurately detect and phenotype self antigen-specific B cells. Purified proteins of interest were biotinylated and multimerized using streptavidin (SA)-phycoerythrin (PE) conjugates. "Decoy tetramers" were also created using SA-PE-Alexa Fluor 647 (AF647) conjugates and biotinylated control proteins, to facilitate exclusion gating of B cells that bind biotin, SA, or PE.

Results: Using a combination of GPI and decoy tetramers, we observed in healthy mice a population of phenotypically naive B cells with the capacity to specifically bind GPI (*figure left*). Remarkably, an adoptive transfer of GPI/I-A^{g7}-specific KRN TCR-transgenic $CD4^+$ T cells into TCR-deficient B6G7F1 (H-$2^{b \times g7}$) mice caused these GPI–binding B cells to robustly proliferate and differentiate into both germinal center cells as well as anti-GPI IgG1–secreting plasmablasts, in association with the development of arthritis (*figure right*). Consistent with this breakdown in natural self tolerance to GPI, naive-appearing OVA–binding B cells in transgenic mice that ubiquitously express a soluble form of chicken ovalbumin (OVA) underwent a similar clonal expansion and differentiation when mice were immunized with antigen in the presence of normal OVA-specific $CD4^+$ T cells. In contrast, OVA–binding B cells that persisted in mice despite transgenic expression of a membrane-bound OVA protein did not respond to immunization with OVA, thus indicating that they were in an anergic state.



Conclusion: Membrane-bound self antigens lead to a clonal anergy in polyclonal self-reactive B cells that cannot easily be broken with $CD4^+$ T cell help, whereas B cell tolerance to cytosolic and soluble self proteins often relies solely on $CD4^+$ T cell tolerance.

1591

Identification of Robust and Disease-Specific Stromal Alterations in Spondyloarthritis Synovitis. Nataliya Yeremenko[1], Gemma M. M. Rigter[1], Iris Simon[2], Juan D. Cañete[3], Paul P. Tak[1] and Dominique L. Baeten[1]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Agendia BV, Amsterdam, Netherlands, [3]Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain

Background/Purpose: The cellular and molecular pathways driving synovial inflammation and stromal remodeling in spondyloarthritis (SpA) remain largely unknown. As SpA and rheumatoid arthritis (RA) show clearly distinct patterns of structural remodeling and since stromal pathways of remodeling may be specific to the target tissues, systematic comparison of the inflamed synovial tissue in both conditions may help to identify disease-specific pathogenic mechanisms. We conducted this study in order to identify cellular and molecular pathways specific for SpA synovitis by an unbiased microarray screening approach.

Methods: Synovial tissue samples were obtained by arthroscopy from untreated individuals with SpA (n=55), RA (n=45) and gout (n=10). RNA was extracted and gene expression profiling was performed on a test cohort of 12 SpA versus 8 RA samples using microarrays (Agilent 44K). Top differentially expressed genes were validated on three independent cohorts of SpA versus control samples by qPCR and confirmed on the protein level by immunohistochemistry. qPCR was also performed on paired SpA synovial biopsies before and after TNF blockade.

Results: Using very stringent analysis and statistical criteria, the microarray experiments identified a signature set of 359 genes that discriminated with high certainty (a cut-off >1.5-fold change, $p<0.001$) between patients with SpA and RA. Technical validation by qPCR on the same samples yielded a strong correlation between the microarray and qPCR data (r=0.93, p= 1.95e-009) with 25 of the top genes being confirmed as differentially expressed ($p < 0.05$). Reanalysis of the top 25 genes in an independent cohort of early, untreated SpA and RA confirmed the differential expression of the genes with again a very good correlation with the original microarray results (r=0.97. p= 0.00004). The gene signature was not only reproducible but also consistent as pathway analysis revealed that almost all top-ranking upregulated transcripts in SpA were related to myocyte/myofibroblast biology. Several of these genes, including the alpha smooth muscle form of actin, showed up to 100-fold upregulation in SpA versus RA synovitis. Additional analysis of gout versus SpA samples confirmed that these genes were specifically upregulated in SpA synovitis rather than downregulated in RA. Immunohistochemistry for α-smooth muscle actin and smooth muscle myosin heavy chain identified expression of these proteins not only around the vessel walls but also in fibroblast-like cells in the intimal lining layer and synovial sublining. Expression in the latter two regions, but not in the vessels, was significantly increased in SpA versus RA. Double immunofluorescence and FACS analyses revealed a colocalization of α-smooth muscle actin and fibroblasts marker CD90. Finally, paired analysis of SpA samples obtained before and after 12 weeks of TNF blockade showed that the expression of these genes was not altered by this treatment.

Conclusion: This study identified a robust and disease-specific increase in myofibroblasts in SpA synovitis. The reason for this increase and the potential role of these cells in inflammation and, more importantly, structural remodeling in SpA are currently under investigation.

1592

Identification of Specific Amino Acids in the Uric Acid Transporter URAT1 Required for Uricosuric-Mediated Inhibition. Philip K. Tan, David Hyndman and Jeffrey N. Miner. Ardea Biosciences, San Diego, CA

Background/Purpose: Uricosuric agents are used for the treatment of gout and lower serum uric acid levels by blocking uric acid reabsorption in the kidney proximal tubule through inhibition of the uric acid transporter URAT1. We have identified a compound RDEA3170 that specifically binds to and inhibits URAT1 with nanomolar potency and examined its interaction with wild type and URAT1 mutants. We also compared the interaction of RDEA3170 with that of other known primary uricosuric agents.

Methods: Wild type and URAT1 site-directed point mutants were prepared and expressed in transfected cultured cells for cell-based uric acid transport and binding assays. Transport assays were performed by incubating the cells with ^{14}C-labeled uric acid in the absence or presence of URAT1 inhibitors, and the cell associated label was measured. Binding assays were performed by measuring binding of tritiated RDEA3170 to membranes prepared from URAT1-transfected cells in the absence or presence of unlabeled URAT1 inhibitors. For oocyte transport assays, wild type and URAT1 mutants were expressed by injection of URAT1 cRNA. Transport of ^{14}C-labeled uric acid was measured and URAT1 inhibitors were tested for extracellular or intracellular activity.

Results: RDEA3170 inhibits URAT1 activity with a half maximal inhibition constant of 24 nM, which is equipotent to the uricosuric benzbromarone and 200-, and 500-fold more potent than the uricosurics sulfinpyrazone and probenecid, respectively. Binding of radiolabeled RDEA3170 to URAT1 in membranes was specific, saturable, competitive with other uricosurics, and has a dissociation constant of 30 nM. To investigate the compound interactions in more detail, we analyzed URAT1 point mutants in the uric acid transport assay. URAT1 residues were mutated to the corresponding residues in the rat URAT1 ortholog (rRST) that has 75% sequence identity to URAT1 but is less sensitive to inhibitors. Mutation of human URAT1 F365 to Y decreases the potency of RDEA3170 by 100-fold, while mutation of rRST Y365 to F results in a gain of function, increasing the potency of RDEA3170 by 10-fold compared to wild type rRST. URAT1 mutants with conservative amino acid substitutions in the presumed substrate binding pocket were prepared and compared to wild type URAT1. URAT1 R477 to K decreases the potency to RDEA3170 and benzbromarone but responds similarly to sulfinpyrazone; URAT-F241Y decreases the potency to RDEA3170 and sulfinpyrazone but responds similarly to benzbromarone; and URAT-F448Y decreases the potency to benzbromarone and sulfinpyrazone but responds similarly to RDEA3170. From Xenopus oocyte experiments, RDEA3170 inhibits URAT1 activity extracellularly and intracellularly with similar potency.

Conclusion: RDEA3170 showed high potency, direct binding, and functional inhibition of URAT1. All inhibitors likely interact in the same general binding site within URAT1. However, each inhibitor likely utilizes a distinct but overlapping set of residues for URAT1 inhibition.

1593

A Controlled Pilot Study On the Use of Active Learning Techniques During a Rheumatology Elective for Medical Residents. Joshua Scheers-Masters[1], David R. Blumenthal[2], Jeanne Macrae[3], Matthew Avitable[3] and Deana M. Lazaro[4]. [1]SUNY Downstate, Brooklyn, NY, [2]VA NY Harbor Healthcare System, Brooklyn, NY, [3]SUNY Downstate Medical Center, NY, [4]Brooklyn VA, Brooklyn, NY

Background/Purpose: There is a need to train physicians to evaluate musculoskeletal (MSK) complaints. Previously, we found that providing passive learning materials to residents attending rheumatology clinic had no impact on measures of rheumatology knowledge and clinical exam proficiency. The purpose of this study was to examine the impact of active learning based upon Kolb's experiential theoretical framework on rheumatology knowledge, MSK physical exam skills, and subjects' attitudes towards rheumatology.

Methods: Forty SUNY Downstate medical and neurology interns were enrolled in the study and completed a 45 question multiple choice (MC) pre-test and questionnaire. All residents were randomly assigned to participate in either an ambulatory rheumatology elective or another subspecialty experience for four weeks although all Neurology residents were assigned to the control arm due to administrative constraints. 24 residents completed the study after 6 months. All residents received a copy of the Primer on the Rheumatic Diseases. Residents assigned to the rheumatology group were given 12 case-based learning modules and 12 quizzes; each quiz was reviewed and discussed with a rheumatology attending. The rheumatology group had additional instruction on the MSK exam using active learning techniques and arthrocentesis and injection techniques using simulators. They participated in 3 out-patient Rheumatology clinic sessions and journal club weekly. At the end of the elective month, both groups completed a 45 question MC post-test, a 4 station objective structured clinical examination (OSCE) on the evaluation and treatment of MSK diseases, and a post- questionnaire.

Results: No significant difference was seen on the pre-test between the two groups (0.508 vs 0.504, $p=0.913$), however, the rheumatology group had a significantly higher score on the post-test (0.716 vs 0.598, $p=0.011$). On the OSCE, the rheumatology group had a significantly better performance on all four stations, including arthrocentesis (0.776 vs 0.519, $p<0.0005$), lower extremity exam (0.684 vs 0.553, $p=0.019$), upper extremity exam (0.615 vs 0.479, $p=0.039$), and clinical cases (0.628 vs 0.424, $p=0.001$). On the questionnaires, the rheumatology group had a significantly greater change in confidence in their ability to treat arthritis compared with the controls (1.393 vs 0.167, $p=0.004$). Similarly, the rheumatology group had greater increase in confidence in their ability to treat as a specialist (1.014 vs 0.089, $p = 0.016$). No significant differences were found for questions relating to who should treat arthritis (primary care physicians or rheumatologists) or enthusiasm for the field of rheumatology.

Conclusion: In this small study, we found that integrating active learning techniques based upon Kolb's experiential theoretical framework into a rheumatology elective had a significant impact on interns' rheumatology knowledge as measured on a multiple choice examination, MSK clinical skills as measured on a 4 station OSCE, and confidence in treating arthritis based on a questionnaire.

Funding for this project was provided by the American College of Rheumatology Research and Education Clinician Scholar Educator Award.

Rheumatology Decision 2011: Factors Influencing Career Decisions Among Rheumatology Fellows. Saira Sheikh[1], Michael Smith[1], Tony Ning[2], Erin Shiner[3], Dijana Christianson[4], Lisa G. Criscione-Schreiber[5], Marcy B. Bolster[6], Kenneth S. O'Rourke[7], Deb MacDonald[1], Leigh F. Callahan[8] and Beth L. Jonas[9]. [1]University of North Carolina Chapel Hill, Chapel Hill, NC, [2]Duke University, Durham, NC, [3]Wake Forest Univ. Baptist Med. Ctr., Winston-Salem, NC, [4]Medical University of South Carolina, Charleston, SC, [5]Duke University Medical Center, Durham, NC, [6]Medical Univ of South Carolina, Charleston, SC, [7]Wake Forest Univ School of Med, Winston-Salem, NC, [8]University of North Carolina, Chapel Hill, NC, [9]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: There is a growing concern that fewer rheumatology fellowship graduates are entering academic medicine. Academic rheumatologists are critical to the development of an adequate workforce. The impending shortage of practicing rheumatologists in the United States makes it crucial to understand the factors involved in fellows' career choices. Here we present data on current and former rheumatology fellows regarding factors influencing their career decisions.

Methods: This project was a collaborative effort between the four programs of the Carolinas Fellows Collaborative (CFC). Fellows and faculty of the CFC developed a survey to assess career decision-making among rheumatology trainees. IRB approval was obtained. This survey was sent electronically, using Constant Contacts®, to current rheumatology fellows and recent graduates (previous 5 years) of the four programs. Data collected included demographic information, magnitude of student loan debt, views on fellowship training, and factors influencing career choice. Participants were asked to identify why they made their respective career choices and point out factors that might influence them to choose a career in academic medicine.

Results: The response rate was 46% ($N=67$). Of our respondents, 70% were female, 71 % were married, and 50% were fellows currently in training. Nearly three quarters of fellows (73%) had student loan debt of greater than $100,000. Responses indicated that at the initiation of fellowship 73% of current fellows aspired to pursue a career in academic medicine; however that number dropped to 40% during training. Those with plans to continue in academic medicine stated that personal choice (46%) was the most important factor leading to this decision. Among those choosing private practice, the majority stated that workplace flexibility (46%), debt burden (38%) and earning potential (38%) were most important in their decision. Respondents indicated that improved research mentoring (67%), protected research time during fellowship (60%), improved funding opportunities (47%), formal training in clinical education (60%), loan repayment plan (67%) and higher salaries(67%) were important factors that would have informed a decision to choose a career in academic medicine.

Conclusion: In this pilot study, we have identified trends and variables that may influence career choices by rheumatology fellows. We have also identified potentially modifiable aspects of fellowship training and other factors that may encourage fellows to pursue a career in academic medicine. Using this preliminary data, we are conducting a larger survey targeting fellows in training nationwide.

1595

Knowledge of Clinical Anatomy by Rheumatology Fellows and Rheumatologists in Latin America. José E. Navarro-Zarza[1], Cristina Hernández-Díaz[2], Miguel A. Saavedra-Salinas[3], Robert A. Kalish[4], Juan J. Canoso[5] and Pablo Villaseñor-Ovies[2]. [1]Mexican Taskforce for the Advancement of Clinical Anatomy, Mexico, Mexico, [2]Instituto Nacional de Rehabilitación, Mexico City, Mexico, [3]Centro Médico Nacional, México, Mexico, [4]Tufts Medical Center, Boston, MA, [5]ABC Medical Center and Tufts University, Mexico City, Mexico

Background/Purpose: It is generally agreed that knowledge of musculoskeletal anatomy is a prerequisite to performing an adequate rheumatologic physical examination. However, little information is available regarding the level of anatomical knowledge of rheumatology fellows (RF) and practicing rheumatologists (PR).

Methods: All participants in a series of musculoskeletal clinical anatomy seminars held in 5 Latin American countries under an ILAR grant in 2010 and 2011 had a one-to-one, standardized, pre-seminar evaluation in which they were asked to demonstrate or identify the structures or functions in the bodies of the participants and instructors of 20 anatomic structures (Table). The average duration of the evaluations was 7 minutes. This exercise was accepted by the national societies, participating rheumatology services and seminar attendees. Standard summary statistics are presented. Differences between groups were tested with T test or ANOVA.

Table. Anatomic Structures Tested. (D= demonstration, I= Identification of)

1	Anat. snuffbox, palmar limit I	11	Supraspinatus D
2	Anat. snuffbox, dorsal limit I	12	Infraspinatus D
3	Radial styloid I	13	Occipital-atlas motion D
4	Lister′s tubercle I	14	Atlas-axis motion D
5	Dorsal hand interossei D	15	Tensor fascia lata D
6	Palmar hand interossei D	16	Gluteus medius D
7	Thumb adduction D	17	Hoffa′s fat I
8	Thumb abduction D	18	Pes anserinus I
9	Biceps brachii I	19	Tibiotalar joint D
10	Brachialis I	20	Talocalcanean joint D

Results: There were 191 participants in the study. These included 113 (59.1%) RF from 15 training programs, 55 (28.7%) PR and 23 (12%) non-rheumatologist health care professionals (NRHP). PR had a median experience of 10 (range 3–46) yrs. Mean number of correct answers (out of 20 questions) was 9.04 (95CI: 8.49 to 9.53) for all participants. Of these, 37.7% answered correctly <5 questions, 56.7% 5–15 questions and 5.8% >15 questions. Correct answers in RF averaged 9.24 (95CI: 8.55 to 9.92), in PR 9.03 (95CI: 8.05 to 10.03) and in NRHP 7.91 (95CI: 6.47 to 9.36) (ANOVA p = 0.439). When 1st year fellows were compared with 2nd, or 2nd plus 3rd (one program) year fellows, a significant difference was found favoring the latter [8.38 (95CI: 7.37 to 9.40) vs 9.91 (95CI: 8.9 to 10.7), $p = 0.02$]. Anatomical knowledge in PR was unrelated to length of experience (Pearson's r= 0.21, p=0.11), [0–5yr 8.59 (95CI: 6.94 to 10.24), 6–10yrs 7.67 (95CI: 5.12 to 10.21) and >10yrs 9.70 (95CI: 8.2 to 11.21) (ANOVA p = 0.363].

Conclusion: Anatomical knowledge is far from satisfactory for most RF, PR and NRHP tested in Latin America. Although RF fared better in the 2nd plus 3rd year of training most fellows failed to correctly identify the majority of structures or functions and only 9.3% obtained >15 of the 20 correct answers. For PR length of practice had no bearing on anatomical knowledge. The lowest scores were found in NRHP. Efforts should be made to improve anatomical knowledge early during rheumatology training to improve physical examination skills and understanding of the anatomic basis of regional pain syndromes. Also, clinical anatomy should be emphasized in continuing medical education activities for PR and NRHP. Improved clinical skills in anatomic diagnosis and the resulting decreased dependence on technology may ultimately result in societal cost saving. Data from other parts of the world should be obtained as the knowledge gap we perceived may not be limited to Latin America.

1596

Development of a Novel Interactive Case Based Educational Website In Rheumatology. Christopher E. Collins. Washington Hospital Ctr, Washington, DC

Background/Purpose: With increasing utilization of the internet, online based e-learning has quickly risen to take a prominent role in medical education. Internet based education is easily available to a large audience, can provide a template for direct interaction with an individual, and can potentially eliminate the passive user experience. While a number of subspecialties have embraced the internet as a vessel for medical e-learning and medical education research, relatively few websites dedicated to rheumatology education exist. Furthermore, most of these have limited opportunities for interaction and even fewer have integrated methods for measuring outcomes for medical education effectiveness. Recently, through grant supported time under the ACR REF Clinician Scholar Educator Award, a new web-based educational website in rheumatology was developed.

Methods: An interactive rheumatology focused medical education website called the "Web-based Interactive Rheumatology Experience" or "WIRE" (www.rheumwire.com) has been developed and recently completed formative assessment. The content of the site draws from interesting cases presented by Rheumatology Fellows participating in the District of Columbia (DC) Intra-City Grand Rounds, a monthly conference attended by Rheumatology Fellows and staff from several DC area training programs. The site incorporates the concepts of basic web-design principles, an interactive user experience, built in elements for participant data gathering, and a variety of outcome measures. A pilot validation study (summative assessment) is currently underway utilizing internal medicine (IM) residents from several regional IM training programs. Measured outcomes include post test knowledge assessments as well as Likert based user satisfaction surveys.

Results: Currently, the WIRE has 59 unique pages incorporating a total of 295 unique files. Approximately 43,000 lines of code have been generated so far. The core structure of the website has been established including a login system to capture demographics of the participant as well as the ability to tailor user content. Imbedded interactions based in JavaScript and PHP provide a high level of participant interaction and two unique cases with accompanying didactics have been completed. Additional presentations and didactics are under development. Formative assessment of the WIRE was useful in identifying a few content and design specific problems as well as some cross-browser compatibility issues. Overall, the website was well reviewed and felt to have high value for a novel medical education experience.

Conclusion: The WIRE is an interactive online learning tool currently undergoing summative evaluation. Once validated as an effective educational tool, the WIRE website will serve not only as a valuable asset for medical education, but as a potential template for medical education research oriented design.

1597

Revision of Existing Osteoporosis Curriculum in Response to Fellows Feedback: 2011 Curriculum. Thomas P. Olenginski and Thomas M. Harrington. Geisinger Medical Center, Danville, PA

Background/Purpose: A formal Osteoporosis Curriculum was integrated within our institution's Rheumatology Fellowship in 2007 responsive to the ACGME's requirements for formal curriculum documentation. Responding to fellow feedback, staff evaluation and overall program needs as well as a unique system-based opportunity in osteoporosis care, we revised this curriculum and so report our 2011 curriculum changes.

Methods: Our previous curriculum was presented at ACR 2007 and is published in the abstract supplement (Arthritis Rheum Sept 2007, vol. 56: (9) s538). As fellows are evaluated, they offer feedback to program director and staff. Similarly, we appraise our fellowship program annually. We decided to make changes in curriculum structure to adapt to identified fellow needs as well as to enhance fellow education and osteoporosis exposure as we integrated our outpatient and inpatient High-Risk Osteoporosis Clinic (HiROC). HiROC potentially 'overexposed' our fellows to an already robust osteoporosis experience within reported curriculum.

Results: The overall curriculum is similar to that previously reported, with necessary additions of educational materials relative to Zoledronic Acid, Denosumab, FRAX, and atypical femur fractures, and 'drug holiday concept'. Additionally, fellows now see outpatient and inpatient consults related to system-wide HiROC program(begun 2008), enhancing the system-based care competency. Curriculum changes made responsive to fellow feedback include: our fellows requested more didactic sessions related to Biologic DMARD's, as well as to Xray study and interpretation and to expanded CARE Program study. We modified our teaching calendar to incorporate these needs. We deleted 4 hrs of 'blocked osteoporosis sessions' and inserted the 4 new sessions above (Table 1). Using the 'new' dedicated session times within teaching calendar, we have expanded our overall teaching curriculum (new Biologic sessions and dedicated Xray sessions as well as ongoing CARE Program sessions) without affecting overall osteoporosis education or clinical exposure.

Week	Monday	Tuesday	Wednesday	Thursday	Friday
1	Core Curriculum Conf		Fellow Conference	Best Practice	CARE
2	Core Curriculum Conf	Medical Student Lecture	Research Conf	**Rheum/Radiology Conf**	**CARE**
3	Core Curriculum Conf		Fellow Conference		CARE
4	Core Curriculum Conf		Journal Club	**Biologic Conf**	**CARE**

* Bold/underline indicate changes in curriculum calendar.

Since formal osteoporosis curriculum inception, every fellow has become ISCD-certified. Performances on ABIM Rheumatology Certification Exam since 2007 in Osteoporosis section is 75 percentile (6 fellows) and ACR in-training exam performance in Osteoporosis and Metabolic Bone Disease in 2011 was 82 percentile (4 fellows).

Conclusion: In summary, an osteoporosis curriculum has continually been implemented in our fellowship program. We have enhanced and expanded our teaching curriculum responsive to documented fellow needs. A defined curriculum structure, feedback, and fellowship annual review have allowed these refinements and modifications.

1598

Blog Versus traditional Seminar: A Comparative Trial in Rheumatology. Elaine L. M. Bezerra[1], Francisco A. Bezerra Neto[1], Maria J. Vilar[1] and Grupo de Estudos e Pesquisas em Educação Médica - UFRN[2]. [1]Federal University of Rio Grande do Norte, Natal, Brazil, [2]Natal, Brazil

Background/Purpose: New teaching methodologies have been adopted in medical education, nevertheless with little data on their effectiveness or on how they were compared with the traditional ones. The objective of this comparative study was to assess student learning in Rheumatology contents using either an innovative electronic (blog) or a traditional seminar format.

Methods: A randomized crossover study was carried out at the Federal

University of Rio Grande do Norte, in the city of Natal in north-eastern Brazil. All participants, fourth year medical students, signed terms of informed consent. During the Rheumatology discipline they were divided aleatorily in two groups (blog / group 1 or traditional seminar / group 2). At the first phase, the topic discussed was *Spondyloarthritis (Ankylosing Spondylitis, Psoriatic Arthritis, Reactive Arthritis and Enteropathic Arthritis).* At the second moment, the groups were crossovered to discuss some *Diffuse Disease of Connective Tissue (Systemic Sclerosis, Dermatopolimyositis, Sjögren's Syndrome and Mixed Connective Tissue Disease)*. Students of the blog group were required to post at least two writings to a faculty-moderated group blog and provide at least one comment on a peer's posts. Measurement of learning outcomes with a mixed cognitive assessment (multiple choice, short-answer and true-false questions) was done after both discussions resulting in a score ranging from 0 to 10. Anonymous surveys at the end of the study assessed student perceptions of teaching practices. The possibility that some of them could also observe the blog discussion of their friends (group 1) when they were in the group 2 ("contamination") was also questioned. Student's t-test was used to compare the means achieved by students.

Results: A total of forty four students (22 in the blog arm / group 1, 22 in the traditional seminar arm / group 2) completed this study. At the end of the first topic discussion, the means of assessment scores of groups 1 and 2 were, respectively, 8,44 and 8,29 (P= 0,6729). At the end of the second phase, the means of groups 1 and 2 were, respectively, 7,79 and 7,32 (P= 0,2949). About 81% of the students stated their experience with blogs as good or excellent. The majority of them also indicated that the blogs were either equally (38,64%) or more (31,82%) efficient than traditional seminars. The "contamination" of this educational intervention was 6,8% (3/44), which was not considered a great problem of approach transferability.

Conclusion: Our study suggests there is no statistically significant difference in themes learned when discussed by blog or traditional seminar. Given this, faculty staff should consider balancing the formats employed across their curricula to address different learning styles of students and avoid fatigue with any given method. Additional studies with a larger number of participants and combinations of the two methods are needed.

ACR Concurrent Abstract Session
Epidemiology and Health Services Research I: Gout
Monday, November 7, 2011, 2:30 PM–4:00 PM

1599

Allopurinol Initiation and the Risk of Death in the General Population. Yanyan Zhu[1], Yuqing Zhang[2], John D. Seeger[3], Young Hee Rho[4], Christine Peloquin[1] and Hyon K. Choi[1]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University Clinical Edpidemiology Reserach and Training Unit, Boston, MA, [3]Brigham and Women's Hospital/Harvard Medical School, Boston, MA, [4]Vanderbilt Medical Center, Nashville, TN

Background/Purpose: Allopurinol is an effective urate-lowering medication that might also have certain cardiovascular benefits; however, it is not free of adverse effects. Its rare but potentially fatal adverse effects have led to reluctance among some physicians to prescribe allopurinol, even when clinically indicated. If the impact of these severe side effects is substantial, it may shorten the survival of patients who were started on allopurinol. However, a recent VA study (98% males) suggested that allopurinol use may lower the risk of death (relative risk = 0.77). In this study, we evaluated the impact of allopurinol initiation on the risk of death among individuals with hyperuricemia in the general population.

Methods: We conducted an incident user cohort study with propensity score matching, using The Health Improvement Network (a UK general population database) data between January 2000 and May 2010. The source population included individuals aged ≥40 years who had a record of hyperuricemia (serum urate level >6 mg/dL for women and >7 mg/dL for men) at any time within the study period. Study cohort members are required to have ≥2 years of enrollment with the general practice before entering the study cohort. We constructed propensity score matched cohorts of allopurinol initiators and comparators (non-initiators) within 6-month cohort accrual blocks (to adjust for potential secular trends of allopurinol use). The index date was defined as the date of first allopurinol prescription for allopurinol initiators and a randomly assigned date within the cohort accrual block for comparators. The variables used in propensity score estimation were assessed over the 2 years prior to the index date, including demographics, comorbidities, medications, and laboratory data (**Table**). In order to approximate the 'intent-to-treat' design of a randomized trial, subjects were analyzed according to whether or not they initiated allopurinol at baseline, regardless of whether they stopped or started allopurinol during follow-up. We estimated the hazard ratios (HRs) using Cox proportional hazard model stratified by cohort accrual blocks.

Results: Of 5,927 allopurinol initiators and 5,927 matched comparators (70% males and mean age 67 years), 1,372 died during the follow-up. The mean follow-up time was 3.1 years. The majority of baseline characteristics were well balanced in two comparison groups (**Table**) through propensity score matching. Allopurinol initiation was associated with a lower risk of all-cause mortality (HR, 0.89 [95% CI, 0.80, 0.99]). Further multivariate adjustment did not change the estimate materially (adjusted HR, 0.86 [0.77, 0.95]).

Baseline Characteristic in the Propensity-Score Matched Cohort

	Allopurinol Initiators (N=5,927)	Non-Initiators (N=5,927)

Increased Gout Risk Related to Diuretic Use Only Exists for Those with a Higher Genetic Risk: Detection of A Urate Gene-by-Diuretic Interaction in the Atherosclerosis Risk in Communities Cohorty. Mara McAdams DeMarco[1], Janet W. Maynard[2], Alan N. Baer[2], Anna Kottgen[3], Linda Kao[1] and Josef Coresh[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University Hospital Freiburg, Freiburg, Germany

Background/Purpose: Diuretics and urate share renal tubular transport mechanisms. No cohort studies have quantified the association of diuretic use and gout risk among hypertensive adults with genetic susceptibility for higher serum urate levels.

Methods: Atherosclerosis Risk in Communities (ARIC) is a prospective population-based cohort recruited in 1987–1989 from 4 US communities, consisting of 4 visits. Gout was self-reported. Participants with hypertension (self-report of medication to treat hypertension, or a measured blood pressure ≥ 140/90 mm Hg) were included in this analysis if they had available SNP genotype data on urate handling genes.

Trained interviewers recorded diuretic use and type. A genetic urate score was created using common SNP for 8 genes shown in GWAS studies to be highly associated with serum urate levels [5 encode renal urate transporters or regulators thereof (*SLC2A9, ABCG2, PDZK1, SLC22A11, and SLC17A1*); three with unclear biological mechanisms related to serum urate levels (*GCKR, R3HDM2-INHBC*, and *RREB1*)]. Using logistic regression, we estimated the odds ratio (OR) of incident gout by diuretic use, stratified by the median of the genetic urate score.

Results: There were 3,529 hypertensive participants and 33% used a diuretic. The mean age at cohort entry was 55 years old and 47% of the participants were male. Over 9 years of follow-up, 109 (3.1%) developed gout. The 9-year cumulative incidence in those whose genetic urate score was below the median was 2.76% for those not taking a thiazide or loop diuretic and 1.03% for those taking either a thiazide or loop diuretic. For those above the median, the cumulative incidence was 3.08% for those not taking a thiazide or loop diuretic and 6.49% for those taking a thiazide or loop diuretic. Results are presented in the table. Compared with no thiazide or loop diuretic use, use of these diuretics was not associated with gout (OR=0.37, 95% CI: 0.13, 1.03) among those with a genetic urate score below the median but was associated with incident gout among those with a genetic urate score above the median (OR=2.18, 95% CI: 1.31, 3.64; p-value for interaction=0.003). Results were similar when adjusted for confounders.

Odds ratio (OR) for incident gout comparing those taking a diuretic to those not taking a diuretic by the median the genetic urate score (−0.29) in the ARIC cohort (n = 3,529)

	Genetic urate score		
Model	**Below median** (n = 1,764)	**Above median** (n = 1,758)	**p-value for interaction**
Any diuretic use	*OR (95% CI)*	*OR (95% CI)*	
Unadjusted	1.18 (0.63, 2.22)	2.07 (1.27, 3.38)*	0.168
Sex- and age-adjusted	1.43 (0.75, 2.73)	2.37 (1.44, 3.90)†	0.220
Adjusted for confounders	1.27 (0.66, 2.45)	2.11 (1.25, 3.54)*	0.247
Thiazide or loop diuretic use			
Unadjusted	0.37 (0.13, 1.03)	2.18 (1.31, 3.64)*	0.003
Sex-and age-adjusted	0.42 (0.15, 1.20)	2.42 (1.44, 4.08)†	0.004
Adjusted for confounders	0.42 (0.14, 1.15)	2.24 (1.31, 3.84)*	0.005

* p-value < 0.05.
† p-value <0.001
Adjusted for age, sex, body mass index, estimated glomerular filtration rate.
CI=Confidence Interval.

Conclusion: The increased risk of gout related to diuretic use in hypertensive subjects of the ARIC cohort was only observed among those with a higher genetic risk score for elevated serum urate levels, suggesting a urate gene-by-diuretic interaction. These findings delineate an important interaction of genetic traits influencing urate metabolism and handling with diuretic use in hypertensive subjects.

1601

Mortality Due to Coronary Heart Disease and Kidney Disease Among Middle-Aged and Elder Men and Women with Gout In the Singapore Chinese Health Study. Gim Gee Teng[1], Li-Wei Ang[2], Jian-Min Yuan[3] and Woon-Puay Koh[4]. [1]National University Health System, Singapore, Singapore, [2]Ministry of Health, Singapore, Singapore, [3]Masonic Cancer Center, University of Minnesota, Minneapolis, MN, [4]Department of Epidemiology and Public Health, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background/Purpose: Impact of gout on mortality is underrated despite increasing evidence of gout being an independent mortality risk factor in Caucasian populations. Whether the link is causal or confounded by lifestyle factors or comorbidities remains unclear. Studies in the Asia are warranted due to rapid modernization, population growth and aging. We examined the association between gout and mortality in a prospective cohort of Chinese men and women in Singapore.

Methods: The Singapore Chinese Health Study comprised of 63,257 Chinese, ages 45–74 years, living in housing estates and enrolled in 1993–98 by in-person interview of lifestyle, dietary patterns and medical history. At follow up-I (1999–2004), 52,322 reported if they had a history of physician-diagnosed gout. Mortality in the cohort was identified via record linkage with death registry, through December 2009. Cox regression analyses examined the associations between gout and mortality risk, adjusted for age, body mass index (BMI), gender, dialect, education, alcohol drinking, physical activity, smoking, saturated fat and cholesterol intake, hypertension, coronary heart disease (CHD), stroke and diabetes.

Results: Among 52,322 subjects eligible for the present analysis, 2,117 (4.1%) had a history of physician-diagnosed gout. The mean age at diagnosis of gout was 54.7 (SD 10.0) years. Compared to subjects without a history of gout, subjects with gout were more likely to have diabetes, hypertension, stroke and CHD. People with gout were more educated, had higher BMI, and consumed more alcohol, saturated fat and cholesterol. After a mean follow-up period of 8.1 (SD 1.9) years, there were 6,660 total deaths, of which 33% were cardiovascular deaths. Relative to those without a history of gout, subjects with gout were at increased mortality from all causes [hazard ratio (HR) 1.17; 95% confidence interval (CI) 1.05–1.31], CHD (HR 1.34, 95%CI 1.07–1.68) and kidney disease (HR 6.08, 95%CI 3.76–9.84). Early age at initial diagnosis of gout was associated with higher mortality from all causes as well as CHD. Stroke mortality was also higher in subjects with gout but the increased risk did not reach statistical significance. The risk estimates associated with gout were higher among women compared to men for mortality from all causes, as well as from CHD, stroke and kidney disease.

Conclusion: Gout is moderately associated with total and CHD mortalities, and a strong risk factor for kidney disease mortality among Chinese in Singapore. Patients with gout should be screened and managed for CHD and kidney disease. Further research is needed to investigate if optimizing care for gout, especially for patients with younger age of onset, may improve survival.
None.

1602

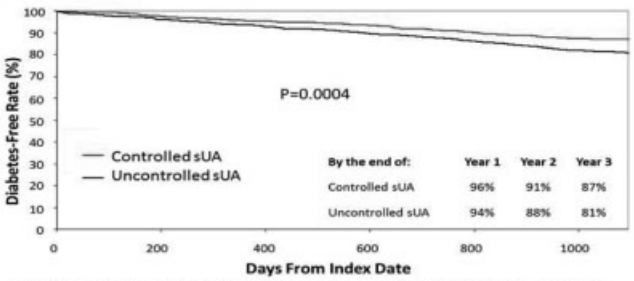
Uncontrolled Serum Uric Acid In Veteran Gout Patients Is Associated with a Higher Risk of Diabetes. Bhavik J. Pandya[1], Maryna Marynchenko[2], Hari Sharma[2], Andrew Yu[2], Eric Wu[2], Lizheng Shi[3], Jinan Liu[3] and Eswar Krishnan[4]. [1]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [2]Analysis Group, Inc., Boston, MA, [3]Tulane University, New Orleans, LA, [4]Stanford University, Stanford, CA

Background/Purpose: The association between high serum uric acid (sUA) levels and diabetes is not clear, with many studies claiming a positive connection, and other studies finding no such relationship. The goal of this study was to evaluate the association between uncontrolled sUA and the risk of developing diabetes among veteran gout patients (pts) in the United States.

Methods: Using the Veterans Integrated Services Network 16 (VISN 16) database, adult male pts (age ≥18 yrs) with at least 2 gout diagnoses (ICD-9 CM: 274.xx) and 2 sUA measurements between January 1, 2002 and January 1, 2011 were selected. Pts were required to be continuously eligible for at least 6 months prior to and 12 months after the index date (first sUA test date). Diabetes was identified using ICD-9-CM codes, or use of anti-diabetic medications, or HbA1c≥6.5. Pts with claims for inflammatory diseases at any point in their history (rheumatoid arthritis, lupus, scleroderma, vasculitis, psoriatic arthritis, autoimmune diseases, pseudogout, and other inflammatory arthritis) or those with diabetes prior to the index date were excluded. The study period for each pt (from index date until the end of eligibility) was broken into 6-month cycles to allow for a longitudinal design. sUA levels were assessed for each cycle; any cycle with sUA level >7 mg/dLwas considered to have an uncontrolled sUA level (sUA ≤7 was considered to be controlled). Time to first diabetes diagnosis was compared between pts with uncontrolled vs controlled sUAs. Average area under the curve (AUC) connecting sUA levels during the study period was used to classify pts into uncontrolled vs controlled sUA cohorts for Kaplan-Meier survival (K-M) analysis. Relative risk of diabetes associated with uncontrolled sUA levels was estimated using a Cox proportional hazard model with sUA levels as time-varying covariates, after controlling for: age at index date; year of index date; race; region; body mass index (BMI); and other risk factors at baseline (eg, hypertension, hyperlipidemia, and tobacco use).

Results: Among the 1,923 pts selected for the study, 52% were white; average age was 62.9 years; average BMI was 30.6; and average follow-up time was 80 months. Major comorbidities at baseline included hypertension (93%), hyperlipidemia (64%), cardiovascular diseases (30%), and smoking (8%). K-M analysis (Figure 1) found that pts with controlled sUA had significantly higher diabetes-free rates at year 1, 2, and 3 compared with pts with uncontrolled sUAs (96% vs 94%; 91% vs 88%; and 87% vs 81% respectively; p<0.001). In addition, uncontrolled sUA was associated with a significantly higher risk of developing diabetes, after adjusting for confounding factors (hazard ratio: 1.19, 95% confidence interval: [1.01–1.41]).

Figure 1. Kaplan-Meier Survival Curve for Time to First Diabetes Diagnosis: Controlled sUA vs Uncontrolled sUA



Interpretation: Pts with uncontrolled sUA have a significantly higher diabetes diagnosis rate than those with controlled sUA. sUA level was considered uncontrolled if average AUC was >7 during the study period.

Notes: Time to diabetes was measured from index date until: a) diabetes diagnosis; b) death; or c) the end of data, whichever comes earlier. Pts with diabetes prior to index date were excluded.

Sample size at the end of:	Baseline	Year 1	Year 2	Year 3
Controlled sUA	785	750	677	612
Uncontrolled sUA	1,138	1,065	939	789

Conclusion: Among VISN 16 pts with gout, uncontrolled sUA was associated with a higher risk of a new diagnosis of diabetes when compared with controlled sUA.

1603

Does Treatment of Asymptomatic Hyperuricemia Improve Cardio and Neurovascular Outcomes? A Decision-Analytic Evaluation. Roopa Akkineni[1], Alexandra Lee[2], Katherine L. Miller[3], Anna N A. Tosteson[4], Hyon K. Choi[5], Yanyan Zhu[5] and Daniel A. Albert[1]. [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Veterans Affairs National Center for Patient Safety, White River Junction, VT, [3]Northeastern Ohio Universities College of Medicine, Rootstown, OH, [4]Dartmouth Medical School, Lebanon, NH, [5]Boston University School of Medicine, Boston, MA

Background/Purpose: Recent studies suggest that elevated serum uric acid level is associated with increase in coronary and cerebrovascular disease. Treatment for asymptomatic hyperuricemia with urate lowering drugs like Allopurinol may reduce vascular events. However, some patients have experienced adverse drug reactions when treated with Allopurinol. A decision analysis was designed to identify the optimal treatment strategy for patients with asymptomatic hyperuricemia.

Methods: A Markov state-transition model was constructed to assess the occurrence of cardiovascular and neurovascular events and to estimate life expectancy in patients undergoing urate-lowering treatment with Allopurinol. The model simulated three hypothetical cohorts of male patients 50-years and older having asymptomatic hyperuricemia, each with different serum urate concentrations (4–5.9mg/dl, 6–6.9mg/dl and 7–7.9mg/dl). Age-specific incidences of gout, cardio- and neurovascular events were modeled across different serum urate concentrations.

Sensitivity analyses were conducted for probability of adverse drug reactions, incidence of gout, incidence and death from a vascular event. Probabilities and quality adjustment values were obtained from published literature. Number needed to treat (NNT), number needed to harm (NNH) and hypothetical trial sample size calculations were performed.

Results:

	Serum Urate (mg/dl)		
Decision	**4–5.9 mg/dl**	**6–6.9 mg/dl**	**7–7.9mg/dl**
Treat (QALYS)	31.837	**31.190**	**30.749**
Don't Treat (QALYS)	**32.152**	31.162	30.201

A serum urate level greater than 7mg/dl favored treatment and yielded the maximum gain in quality-adjusted-life-years [QALYs] compared to watchful waiting at 0.55 QALYs or 6.6 months.

Sensitivity analysis showed treatment with Allopurinol was favored even with drug reaction rates up to 27% (6–6.9mg/dl) and 84% (7–7.9mg/dl). Treatment strategy was most effective at higher serum urate levels in preventing incidence and death from vascular events.

The NNT to prevent one stroke and one fatality from myocardial infarction were 170 and 141 patients respectively. Treatment of 250 patients with Allopurinol would result in one case of Allopurinol hypersensitivity syndrome. A hypothetical trial of Allopurinol treatment versus placebo would involve 2,291 individuals with a serum urate level greater than or equal to 7.0mg/dl followed for one year in order to validate the prevention of cardio and neurovascular events.

Conclusion: Treatment with Allopurinol was an effective strategy for patients with asymptomatic hyperuricemia at serum urate concentrations above 6mg/dl based on QALY comparison with watchful waiting. Based on the results of our sample size calculation, a clinical trial evaluating the effectiveness of Allopurinol treatment to prevent cardio and neurovascular events in individuals with asymptomatic hyperuricemia would be both feasible and useful in validating these results.

1604

Comparative Effectiveness of Allopurinol and Febuxostat In Controlling Serum Uric Acid In a Large US Commercially Insured Population. Jasvinder A. Singh[1], Bhavik J. Pandya[2], Gabriel Gomez Rey[3] and Brett W. Pinsky[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [3]Innovus, Eden Prairie, MN, [4]Innovus, Lenexa, KS

Background/Purpose: The study goal was to assess the comparative effectiveness of allopurinol (ALLO) vs febuxostat (FEB) in lowering serum uric acid (sUA) level in a real-world managed-care setting in the US.

Methods: This retrospective study utilized 2009–2010 medical and pharmacy claims along with laboratory data from adults with gout enrolled in a large US commercial health plan. Study patients (pts) had at least 1 medical claim with a diagnosis of gout and 1 fill for ALLO or FEB. The date of first cohort medication fill was identified as the index date. Pts were also required to have at least 1 sUA measurement a minimum of 14 days post-index date. Pts had ≥6 months of continuous enrollment prior to their index date (baseline period) and were followed for ≥90 days after start of treatment. Effectiveness of lowering sUA was examined as both change in sUA from baseline to first available follow-up sUA, and percentage of pts achieving sUA goal (<6 mg/dL).

Results: The study sample included 451 pts taking FEB and 5,880 pts taking ALLO. More than 82% of FEB patients received an index dose of 40 mg and more than 95% of patients had an index dose ≤300mg (ALLO <300mg, 41% and ALLO = 300mg, 54%). At baseline, FEB pts had a higher Quan-Charlson comorbidity Index score (1.4 vs 1.0; $p<0.01$) and a higher mean sUA level (8.53 vs 7.80 mg/dL; $p<0.01$) compared with ALLO pts. FEB-treated pts had an average 2.2 mg/dL sUA decrease vs 1.3 mg/dL ($p<0.01$) for ALLO-treated pts. After controlling for baseline patient demographics, baseline sUA, and comorbidities, FEB was associated with a 0.50 mg/dL greater drop in sUA vs ALLO from baseline ($p<0.01$). Additionally, more FEB pts attained sUA goal at both <6 mg/dL (60.5% vs 48%) and <5 mg/dL (36.7% vs 22.7%) [Table 1]. After controlling for comorbidities (hypertension, peripheral artery disease, heart failure, rheumatoid arthritis, osteoarthritis, hyperlipidemia, kidney failure); presence of tophi; geographic region; gender; age; and insurance type, FEB-treated pts had 71% higher odds ratio of attaining sUA goal <6 mg/dL (OR 1.71 [1.39–2.11]; $p<0.01$) and 2x higher odds ratio of attaining sUA <5 mg/dL (OR 2.06 [1.65–2.57]; $p<0.01$). The mean dose at time of goal attainment was slightly higher in patient achieving an sUA goal of <5 mg/dL (FEB=55.6 mg; ALLO=308.3 mg) than <6 mg/dL (FEB=54.4; ALLO=288.5 mg). Median time to achieving sUA goal <6 mg/dL and <5 mg/dL was shorter for FEB-treated pts (157 and 194 days) than ALLO-treated pts (264 and 323 days; $p<0.01$ and $p<0.01$, respectively)

Table 1. Patients Attaining sUA Goal

	% of Patients Attaining Goal (<6.0 mg/dL)		% of Patients Attaining Goal (<5.0 mg/dL)	
	Unadjusted	*Adjusted*	*Unadjusted*	*Adjusted*
FEB-Treated Patients	56.1	60.5	32.6	36.7
ALLO-Treated Patients	48.4	48.0	23.0	22.7
p-value*	<0.01	<0.01	<0.01	<0.01

*Adjusted p-value represents the p-value associated with the logistic regression parameter estimate.

Conclusion: FEB lowered sUA in gout pts significantly more than ALLO as demonstrated by both the absolute value of the change in sUA, % of pts getting to sUA goal of <6 mg/dL and <5 mg/dL, and odds ratio of pts achieving sUA goal.

1605

Continued Opioid Use in Fibromyalgia Is Associated with Negative Health Related Outcomes. Peter A. Ste-Marie[1], Mary-Ann Fitzcharles[2], Marc-Olivier Martel[2], Ann Gamsa[2], Pantelis Panopalis[2] and Yoram Shir[2]. [1]University of Montreal, Montreal, QC, [2]McGill University, Montreal, QC

Background/Purpose: Opioids are not recommended for the treatment of fibromyalgia (FM), but are used by up to $^1/_3$ of patients, and were identified by patients as giving best symptom relief in an Internet survey. The effect of opioids on pain needs to be balanced with negative health and psychosocial effects, and similarity between adverse effects of opioids, such as sleep disturbance, poor energy and mood disturbance, and symptoms of FM need to be appreciated. Long-term risks are also unclear. We have examined the outcome in FM patients followed in a multidisciplinary setting stratified according to opioid use.

Methods: FM patients being followed prospectively in a multidisciplinary pain clinic were stratified according to opioid use at follow-up. Demographic information, work status and history of substance abuse were recorded. Outcome measures included: Patient Global Impression of Change (PGIC), employment and disability status, Fibromyalgia Impact Questionnaire (FIQ), Health Assessment Questionnaire (HAQ), Pain Disability Index (PDI), patient global status and pain by Visual Analog Scale (VAS), and anxiety and depression by Arthritis Impact Measurement Scale (AIMS). Univariate comparisons of continuous variables were made using Student's t-tests, and for categorical variables using chi-squared tests. Logistic regression was used to model the association between selected variables.

Results: One hundred and thirty one of 159 patients (82%), mean age 50±10, 92% female, had at least one follow up visit at mean (SD) of 26±15months. Opioid use vs. non use was reported in 43 (33%; Group 1) vs. 88 (67%; Group 2). Twelve patients in Group 2 were given a trial of opioids, followed by discontinuation. Opioid use was significantly associated with poorer outcome for multiple measures of symptoms and function, including unemployment and disability benefit payments (Table 1). Change scores from baseline to follow-up only achieved significance for HAQ, with deterioration in group 1 (p=0.011). A logistic hierarchical regression analysis revealed that baseline level of pain was a significant predictor of opioid status at follow-up, even after controlling for demographic and substance abuse-related variables (p=0.007).

Table 1. FM patients stratified according to opioid use at follow-up.

	ALL at baseline n=131	Group 1 Opioid users Follow up n=43	Group 2 Non-users Follow up n=88
PGIC (Likert) ± SD		4.8 ± 1.6*	5.4 ± 1.6
Employed, n (%)	39 (30)	10 (23)*	36 (41)
Disability, n (%)	42 (32)	14 (33)*	13 (15)
Pain			
Pain VAS ± SD	6.4 ± 2.3	6.5 ±2.5*	5.4 ± 2.9
MPQ ± SD	42 ± 15	43 ± 17***	32 ± 18
Body Map ± SD	27 ± 10	27 ± 12*	22 ± 13
Function			
FIQ ± SD	66 ± 18	66 ± 20**	54 ± 23
PDI ± SD	37 ± 15	38 ± 16**	28 ± 18
HAQ ± SD	1.14 ± 0.66	1.27 ± 0.71**	0.87 ± 0.68
Patient global VAS ± SD	6.4 ± 2.4	6.7 ± 2.7**	5.5 ± 2.6
AIMS anx ± SD	6.1 ± 1.9	5.6 ± 2.1	5.4 ± 2.0
AIMS dep ± SD	5.0 ± 1.6	3.9 ± 2.1	3.3 ± 1.8

Group1 FU vs Group2 FU: *p≤0.05, ** p≤0.01, ***p≤0.001
SD: Standard deviation, PGIC: 1=much worse, 4= no change, 7=much better

Conclusion: In this first study reporting on health related outcomes and opioid use in FM, opioid users had poorer symptom, functional and occupational outcome compared to non users. Although opioids may have been initiated due to more severe symptoms, we have no evidence that these agents improved function, and rather may have contributed to this less favourable outcome. Only a formal study of opioid use in FM will clarify this issue, but until then physicians must be vigilant regarding the multiple adverse consequences of opioid therapy.

1606

5-HT2C Receptor Agonists Attenuate Muscle Pain in a Rat Model of Fibromyalgia. Shinichi Ogino, Mina Tsukamoto, Yukinori Nagakura, Tomonari Watabiki, Yasuaki Shimizu and Hiroyuki Ito. Astellas Pharma Inc., Tsukuba, Japan

Background/Purpose: Fibromyalgia (FM) is a chronic disorder believed to involve the dysfunction of biogenic amine-mediated pain control and is characterized by widespread pain, muscle tenderness, and decreased pain threshold to pressure and other stimuli. Interruption of 5-hydroxytryptamine (5-HT) transmission, a main neurotransmitter in the descending pain inhibitory system, results in hypersensitivity of the spinal nociceptive neurons. 5-HT2C receptors are present in the dorsal horn of the spinal cord and mediate 5-HT-induced analgesia in animal pain models. Here, we examined the effects of several 5-HT2C receptor agonists on muscle hyperalgesia using the reserpine-induced FM model rats.

Methods: Reserpine (1 mg/kg) was administered subcutaneously once daily for three consecutive days to male SD rats. Muscle pressure threshold of the gastrocnemius muscle was determined using the Randall-Selitto test, and extracellular 5-HT content in the spinal cord was measured using a microdialysis system. The effect of 5-HT2C (lorcaserin, vabicaserin, and YM348), 5-HT1A (buspirone), and 5-HT2A (TCB-2) agonists on muscle pressure threshold was evaluated 5 days after the final injection of reserpine. In addition, the effect of the 5-HT2C receptor selective antagonist SB242084 was examined by injecting the agent 15 min before the administration of lorcaserin.

Results: Reserpine treatment significantly reduced extracellular content of 5-HT in the spinal cord and the muscle pressure threshold in rats. Lorcaserin (1 and 3 mg/kg, p.o.), vabicaserin (1 and 3 mg/kg, s.c.), and YM348 (0.1 and 0.3 mg/kg, p.o.) dose-dependently and significantly attenuated the reserpine-induced decrease in muscle pressure threshold, while no effect was observed with either buspirone (10 mg/kg, i.p.) or TCB-2 (2 mg/kg, i.p.). The analgesic effect of lorcaserin was significantly reversed by pretreatment with SB242084.

Conclusion: Our findings indicate that 5-HT2C receptors play a critical role in pain transmission in the reserpine-induced muscle hyperalgesia and suggest the therapeutic potential of 5-HT2C receptor agonists in treating FM.

1607

Mechanisms of Improvement in Fibromyalgia Symptoms in a Clinical Trial of Exercise: Increased Fitness or Hawthorne Effect? Steven A. Mazzuca[1], Anthony Kaleth[2], Chandan Saha[3], James Slaven[3] and Dennis C. Ang[4]. [1]Indiana Univ Schl of Medicine, Indianapolis, IN, [2]Indiana University Purdue University Indianapolis, [3]Indiana University, [4]Indiana University, Indianapolis, IN

Background/Purpose: We have previously shown that initiation of supervised aerobic exercise for fibromyalgia (FM) patients, whether followed by a course of motivational interviewing (MI) to promote maintenance or standard instruction in FM self-care, was associated with an overall increase in self-reported physical activity levels and improvement in FM symptoms. To rule out the possibility that self-reported improvements reflected the generalized effects of attention, we explored whether the association between increased moderate-vigorous physical activity (MVPA) and improved clinical outcomes was mediated by an objective increase in physical fitness.

Methods: Subjects were 201 FM patients who completed the 36-week Research to Encourage Exercise for Fibromyalgia (REEF) trial. We measured changes in MVPA (CHAMPS), physical fitness [6-minute walk test (6MWT)], pain [Brief Pain Inventory (BPI)], and severity of FM symptoms [Physical Impairment (PI) subscale of the Fibromyalgia Impact Questionnaire (FIQ) and the FIQ global]. General linear models were used to perform a mediation analysis, following the approach described by Baron and Kenny (J Personal Soc Psych 1986;51:1173–82). All analyses were controlled for REEF treatment group (T).

Results: Subjects were divided into 3 subgroups, based on the achievement and/or maintenance of ≥90 min/wk increase in MVPA: Group A, achieved and maintained at week 36 (n=51); Group B, achieved but not maintained (N=80); Group C, not achieved (n=70). Groups A and B exhibited significantly greater improvements in fitness (6MWT) than Group C (P = 0.0069 and 0.0199, respectively). Changes in fitness correlated with changes in symptoms (P<0.05 for all outcomes). The table below character-

izes the association between MVPA and clinical outcomes, with and without adjustment for changes in 6MWT.

		Parameter Estimate (*P*-Value)			
Outcome	Adjusted for 6MWT	Group A vs. C	Group B vs. C	R^2 (MVPA|T)	ΔR^2 (%)
BPI	No	−1.03 (0.004)	−0.40 (0.199)	0.0434	
	Yes	−0.89 (0.017)	−0.44 (0.188)	0.0312	−28%
FIQ-PI	No	−1.74 (<0.001)	−0.85 (0.024)	0.0824	
	Yes	−1.39 (0.002)	−0.76 (0.054)	0.0522	−37%
FIQ Global	No	−13.64 (<0.001)	−4.94 (0.102)	0.0794	
	Yes	−10.20 (0.005)	−2.69 (0.404)	0.0470	−41%

Conclusion: The magnitude of the association (parameter estimate) between a maintained increase in self-reported MVPA and improved FM symptoms was diminished 14–25% by adjustment for a concurrent, objective measure of change in physical fitness (6MWT). Adjustment for fitness reduced the % of variance in outcomes associated with MVPA levels by 28–41%. These data suggest that while the Hawthorne Effect cannot be totally discounted, post-intervention changes in FM symptoms in the REEF trial were mediated, in part, by fitness-related changes in MVPA.

Study of the Measurement Properties of the Arnold Fibromyalgia Diagnostic Screen: Results From a Cross-Sectional Study. Susan Martin[1], Cheryl Coon[2], Lori McLeod[2], Arthi Chandran[3] and Lesley M. Arnold[4]. [1]RTI-Health Solutions, Ann Arbor, MI, [2]RTI-Health Solutions, Research Triangle Park, [3]Pfizer, New York, [4]University of Cincinnati College of Medicine, Cincinnati, OH

Background/Purpose: The primary objectives of this study were to 1) conduct confirmatory analyses of the performance of a new patient- and physician-completed fibromyalgia (FM) screener, the Arnold Fibromyalgia Diagnostic Screen (AFDS), using the 1990 American College of Rheumatology (ACR) diagnostic criteria as the gold standard comparison and 2) select the AFDS scoring model that maximizes accuracy in predicting an ACR FM diagnosis. Secondary objectives included 1) evaluating the screening ability of the London Fibromyalgia Epidemiology Study Screening Questionnaire (LFESSQ) and the ACR Diagnostic Criteria (ACR-FDC) and 2) documenting time to completion and participant preference among the AFDS, LFESSQ, and the ACR-FDC.

Methods: 150 adult participants with chronic pain, half of whom had received a physician diagnosis of FM, were enrolled in this multicenter cross-sectional study. The study visit included a physician-conducted evaluation to capture the clinician-reported components of the AFDS, assessment of whether the patient met the ACR criteria for FM, and assessment of whether the patient had FM based on clinical judgment. Additionally, the study visit included patient completion of the three screening questionnaires and venipuncture. The sensitivity and specificity for an FM diagnosis based on the ACR criteria was tabulated for each of six AFDS scoring models. Kappa, Youden's index, overall accuracy, and a likelihood ratio were also calculated. Chi-square contingency tables with odds ratios were created predicting the dependent variable (0 = no ACR FM diagnosis, 1 = ACR FM diagnosis) for two of the AFDS models (the primary scoring model and the scoring model with the highest Youden's index) as well as for the LFESSQ and ACR-FDC. The three patient preference items were summarized using counts and percentages; means, medians, and standard deviations (SD) were calculated for the participant time to complete each questionnaire. All analyses were conducted using SAS. All statistical tests were 2-tailed. A conservative type 1 error rate of 1% ($\alpha = 0.01$) was applied to each individual hypothesis test.

Results: Item-level analyses provided support for the response categories and the predictive ability of most of the individual AFDS items. Additionally, the evaluation of the AFDS scoring models demonstrated that the greatest accuracy in predicting an FM diagnosis was provided by a combination of AFDS patient items and the AFDS clinician items that included an abbreviated (8 point) tenderpoint exam (sensitivity = 0.68, specificity = 0.82). Sensitivity of the ACR-FDC and the LFESSQ was 0.87 and 0.86, respectively, with specificity of 0.62 for the ACR-FDC and 0.49 for the LFESSQ. Most participants reported an overall preference for the AFDS (49%) over the ACR-FDC (22%) or LFESSQ (16%). Mean (SD) time to completion for each questionnaire was 5.2 minutes (3.9) for the AFDS patient items, 2.7 (2.8) for the ACR-FDC, and 1.8 (3.4) for the LFESSQ.

Conclusion: The study results indicate that the AFDS holds promise for identifying patients with FM and has measurement properties better than or similar to existing tools. The AFDS warrants further evaluation for use in the primary care setting.

A Multicenter, Randomized, Double-Blind, Placebo-Controlled Switch Study to Evaluate the Safety, Tolerability, and Efficacy of Milnacipran in Patients with An Inadequate Response to Duloxetine for the Treatment of Fibromyalgia. Lucinda Bateman[1], Allan Spera[2], Robert H. Palmer[2], Joel M. Trugman[2] and Jennifer Lin[2]. [1]The Fatigue Consultation Clinic, Salt Lake City, UT, [2]Forest Research Institute, Jersey City, NJ

Background/Purpose: As fibromyalgia (FM) treatments often do not have the same effectiveness in all FM patients; it is frequently necessary to switch therapies to achieve greater benefit or to avoid side effects. This study evaluates the safety, tolerability, and efficacy of milnacipran (MLN) following a direct switch from duloxetine (DLX) in FM patients with inadequate response to DLX. Although both compounds are serotonin/norepinephrine reuptake inhibitors, their pharmacologic properties differ, which may result in different responses and adverse-effect profiles in some FM patients.

Methods: Patients with FM were eligible for this study if they were currently receiving a stable dosage of DLX (60 mg/d) for ≥4 weeks at screening. After 2 weeks of open-label treatment with DLX 60 mg/d, patients with VAS pain scores ≥40 (range, 0–100 mm) and dissatisfied with DLX were randomized 4:1 to receive MLN 100 mg/d (n=86) or placebo (PBO, n=21) for 10 weeks. The purpose of the small PBO group was to minimize expectation bias rather than provide a comparator arm, since patients would be discontinuing a treatment that may have been partially efficacious. In keeping with anecdotal clinical practice, patients randomized to the MLN group were directly switched from DLX to MLN with no tapering or titration periods. MLN dosage could be adjusted if necessary (required to be ≥100 mg/d by Week 5). The primary efficacy parameter was the percentage of patients who rated themselves "much improved" or "very much improved" on the Patient Global Impression of Change (PGIC) scale. The secondary efficacy parameter was 1-week recall VAS pain score. Efficacy parameters were analyzed by using last observation carried forward.

Results: Among patients switched from DLX to MLN, 59.3% completed the double-blind treatment period, and 17.4% discontinued due to adverse events (AEs) (in patients switched to PBO, 52.4% completed the double-blind period and 9.5% discontinued due to AEs). At Week 10, 32.9% of patients switched from DLX to MLN were PGIC responders and the overall MLN group had a mean decrease from baseline in VAS pain of 12.3 mm (in the group switched to PBO, 23.8% of patients qualified as PGIC responders, but the mean decrease from baseline in VAS pain was only 1.3 mm). 34.2% of patients switched from DLX to MLN showed ≥30% improvement in VAS pain, whereas 29.1% of patients had ≥40% improvement, and 25.3% had ≥50% improvement. Treatment-emergent AEs in patients switched to MLN were similar to those reported in previous PBO-controlled trials. The most common TEAEs in those patients were nausea (21% of patients switched to MLN and 29% in patients switched to PBO) and dizziness (15% MLN, 5% PBO). For comparison, in previous studies conducted in patients not switching from another SNRI, at a dosage of MLN 100 mg/d, the incidence of nausea was 35% and dizziness was 11% (Savella package insert). There were 2 SAEs among patients switched from DLX to MLN: suicidal ideation and hypersensitivity.

Conclusion: These results suggest that FM patients with an inadequate response to DLX treatment may benefit from a switch to MLN for management of their symptoms. Additionally, a direct switch from DLX to MLN was safe and well tolerated in this study.

1610

An 11-Year Longitudinal Study of Pharmacologic Therapy in Fibromyalgia. Frederick Wolfe[1], Brian T. Walitt[2], Robert S. Katz[3], Yvonne C. Lee[4], Kaleb D. Michaud[5] and Winfried Häuser[6]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Washington Hospital Center, Washington, DC, [3]Rush University Medical Center, Chicago, IL, [4]Brigham and Women's Hospital, Boston, MA, [5]Univ of Nebraska Med Ctr & National Data Bank for Rheumatic Diseases, Omaha, NE, [6]Technische Universität München, Munich, Germany

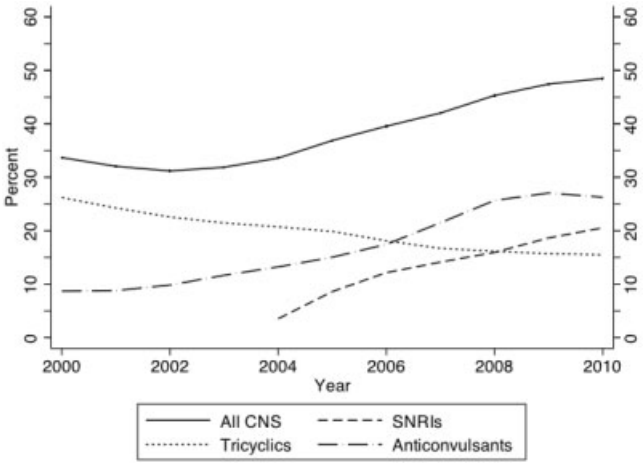
Background/Purpose: Fibromyalgia pharmacotherapy has undergone significant changes in the last decade with recommendations regarding opioids and the introduction of FDA-approved serotonin-norepinephrine reuptake inhibitors (SNRI) such as duloxetine and milnacipran and narcoleptic drugs such as pregabalin and gabapentin. SNRIs

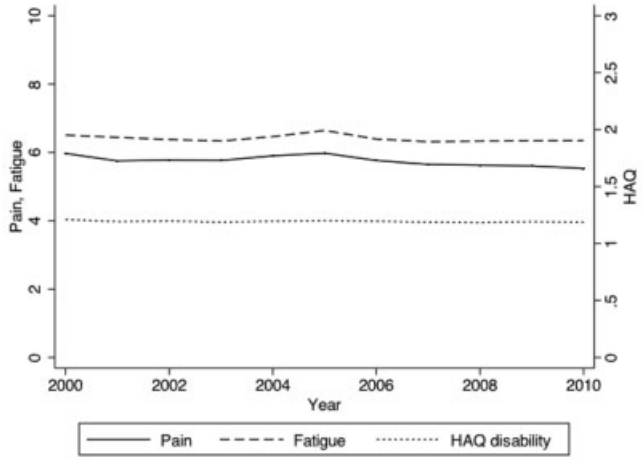
and anticonvulsants are heavily promoted to physicians and direct-to-patient advertising. However, there are few data on the prevalence of use of fibromyalgia treatments and their effect on the outcome of fibromyalgia. We report here the results of an 11 study of fibromyalgia pharmacotherapy.

Methods: We used a longitudinal fibromyalgia databank that assessed drug use and outcome variables at semi-annual intervals on 2,870 patients during 18,452 observations. We assessed outcomes by VAS pain and fatigue scales, and the HAQ functional disability index. Prevalence estimates were based on generalized estimating equations (GEE), and adjusted for demographic and severity variables.

Results: NSAID use fell from 73% in 2000 to 44% in 2010. At similar intervals strong opioids increased from 6% to 12% and weak opioids from 35% to 40%. Overall, non-NSAID analgesic use increased from 63% to 68%. During the same period the group of tricyclic antidepressants, SNRIs and anticonvulsants increased from 34% to 49% (Figure 1). These changes were brought about by a decrease in tricyclic use from 26% to 16% and increases in anticonvulsants from 9% to 26% and in SNRIs from 0% to 21%.

The mean pain, fatigue and HAQ disability scores were 5.6 (SD 2.6), 6.3 (2.8) and 1.2 (0.7), respectively, and these scores remained high and changed almost not at all over the 11-year period (Figure 2). In addition, the total drug cost ($2007) increased from $459 to $1,345.





Conclusion: Strong and weak opioid use remains high in fibromyalgia despite recommendations against opioids. Switching from inexpensive generic trycyclics to newer and expensive SNRIs and anticonvulsant agents was common. Drug costs increased substantially, but despite changes in therapy, no clinically significant changes in pain, fatigue or function were noted during 11 years of follow-up.

Comparative Analysis of Bone Erosions and Cysts in Rheumatoid Arthritis, Psoriatic Arthritis and Erosive Hand Osteoarthritis. Stephanie Finzel[1], Christian Ernet[1], Juergen Rech Sr.[1], Christian M. Stach[1], Klaus Engelke[2], Matthias Englbrecht[1], Jochen Zwerina[1] and Georg Schett[1]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Rheumatoid arthritis (RA), psoriatic arthritis (PSA) and erosive hand osteoarthritis (EHOA) all lead to joint destruction via formation of erosive lesions but may differ substantially in their quality and distribution pattern. This study was performed in order to investigate the differences in the pattern of erosion formation in patients with RA, PSA and EHOA by a high-resolution micro-computed tomography scanner (μCT) designed to visualize bone architecture.

Methods: 25 patients with RA, 25 patients with PSA and 25 patients with EOHA (age- and sex-matched) received a micro- computed tomography scan of the dominantly affected hand to compare structural bone changes in the metacarpophalangeal joints. Number, size and distribution of bone erosions and prevalence of cystic lesions were recorded. In addition, joint space narrowing was measured.

Results: The number of bone erosions was similar in RA, PSA and EHOA, whereas their size was smaller in PSA and EHOA than in RA. Moreover, erosions in EHOA showed a specific distribution pattern affecting the ulnar and radial sites of the metacarpal heads (MCH). In EHOA patients, the MCH were far more frequently and more severely affected than the phalangeal bases. Cystic bone lesions, defined as the absence of trabecular structure in a circumscript area without cortical break were highly prevalent in EHOA (92%) and were localized in peripheral and central subchondral areas of periarticular bone, whereas they were significantly less frequent in RA (24%) and PSA (36%) ($p < 0.01$). Higher age, male sex and postmenopausal state were associated with bone cysts, subchondral erosions and joint spase narrowing (JSN) in EHOA Patients; MCP joints 2 and 3 were much more affected by JSN than MCP joint 4.

Conclusion: High-resolution μCT imaging shows profound differences in periarticular bone changes between RA, PSA and EOHA. The differential pattern of erosive lesions and bone cysts in the three different forms of arthritis and in particular the almost complete absence of bone cysts in RA and PSA suggest different mechanisms to be involved in bone remodeling in RA, PSA and EOHA. Our data indicate that it is possible to differentiate between inflammatory and degenerative bone erosion by advanced imaging technology.

Baseline Levels of the Inflammatory Biomarker C-Reactive Protein Are Significantly Correlated with Magnetic Resonance Imaging Measures of Synovitis At Baseline and After 26 Weeks of Treatment in Patients with Early Rheumatoid Arthritis. Charles G. Peterfy[1], Boulos Haraoui[2], Arthur Kavanaugh[3], Josef S. Smolen[4], Sourav Santra[5], Hartmut Kupper[6], Tracy F. Nicholson[7] and Paul Emery[8]. [1]Spire Sciences LLC, Kentfield, CA, [2]Institut de Rhumatologie, Montreal, QC, [3]University of California San Diego, San Diego, CA, [4]Krankenhaus Lainz, Vienna, Austria, [5]Abbott GmBH & Co KG, Abbott Park, IL, [6]Abbott GmBH & Co KG, Ludwigshafen, Germany, [7]Abbott Laboratories, [8]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease, which results in joint inflammation and destruction. Early detection of inflammation and structural damage by magnetic resonance imaging (MRI) has been demonstrated to be a sensitive predictor of disease progression.[1,2] This sub-analysis assessed MRI scores after 26 wks of treatment with adalimumab plus methotrexate (ADA+MTX) or placebo (PBO)+MTX and the correlation of baseline disease characteristics with MRI scores at baseline, wk 26, and change over 26 wks.

Methods: OPTIMA was a phase 4 trial of MTX-naïve patients (pts) ≥18 years old with RA <1 year and active disease (DAS28 >3.2, ESR ≥28 mm/h or CRP ≥1.5 mg/dL, and either >1 erosions, RF+, or anti-CCP+) who were randomized to ADA+MTX (N=515) or PBO+MTX (N=517) for 26 wks. High-field 1.5-Tesla MRI was conducted on the metacarpophalangeal and wrist joints of the most clinically severe extremity per patient before and after i.v. gadolinium-based contrast. Synovitis, osteitis, and erosions were scored by 2 independent blinded radiologists using a modified OMERACT-RAMRIS scoring system. The changes in observed MRI measurements were compared between treatment groups using an ANCOVA model adjusted for baseline. The relationship between MRI scores and baseline disease traits was assessed for CRP, TJC68, SJC66, DAS28, and HAQ using Pearson correlation.

Results: The MRI substudy included 70 pts with at least 1 MRI; there were 59 pts (27 ADA+MTX, 32 PBO+MTX) with both baseline and wk 26 MRI. Mean MRI baseline values were similar between treatment groups: 6.22/6.77 (synovitis), 5.37/3.33 (osteitis), and 6.13/4.14 (erosion) for ADA+MTX and PBO+MTX pts, respectively. ADA+MTX pts showed significantly greater mean decreases in MRI scores from baseline to 26 wks for synovitis (−3.61/−2.03, *P*=.003), osteitis (−3.98/0.00, *P*=.006), and erosion (−0.78/1.41, *P*=.004) compared with PBO+MTX pts. MRI scores were all highly correlated with one another (*P*<0.001), both at baseline and wk 26, as were the changes in these scores. Baseline CRP levels were significantly correlated with all synovitis measures and the absolute erosion score at wk 26, while baseline osteitis demonstrated a significant correlation with baseline TJC68 (table).

Table. Correlation of Baseline Disease Variables with MRI Scores at Baseline and Week 26, and the Change in MRI Score (r values)

	Synovitis			Osteitis			Erosion		
	BL	Wk 26	ΔBL-wk 26	BL	Wk 26	ΔBL-wk 26	BL	Wk 26	ΔBL-wk 26
CRP	0.38**	0.30*	−0.34**	0.04	0.16	−0.02	0.12	0.27*	0.03
TJC68	−0.03	−0.05	−0.10	−0.24*	−0.09	0.10	−0.07	0.05	0.02
SJC66	0.09	0.02	−0.17	−0.18	−0.08	0.06	0.02	0.11	−0.08
DAS28	0.15	0.12	−0.24	−0.13	0.02	0.03	−0.05	0.14	0.08
HAQ	0.13	0.04	−0.25	−0.12	−0.12	0.01	0.02	−0.01	−0.05

* *P*<.05; ** *P*<.01; BL, baseline; ΔBL-wk 26, change in MRI score from baseline to week 26.

Conclusion: Treatment with ADA+MTX resulted in greater reductions in synovitis, osteitis, and bone erosion MRI scores compared with PBO+MTX at 26 wks in pts with early RA. Particularly striking was the lack of effect of MTX alone on osteitis. The strong correlation between change in osteitis and change in erosion corroborates the current view that osteitis is a precursor of erosion. That baseline CRP correlated with responsiveness of MRI synovitis to treatment supports the utility of CRP in pt selection.

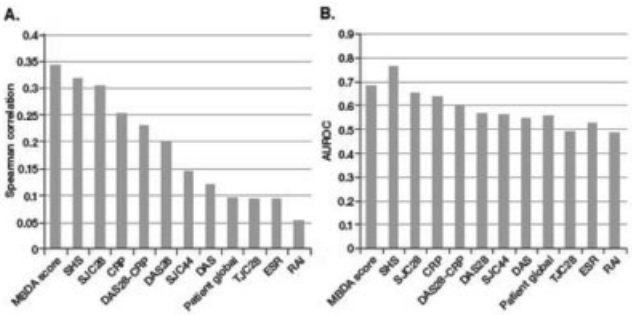
A Multi-Biomarker Disease Activity (Vectra DA) Algorithm Score for Rheumatoid Arthritis Predicts Radiographic Progression in the BeSt Study. Cornelia F. Allaart[1], Linda Dirven[1], Shintaro Hirata[2], P.J.S.M. Kerstens[3], B.A.C Dijkmans[4], David Chernoff[5], Guy Cavet[5], Michael Centola[6], Lyndal K. Hesterberg[5], Yoshiya Tanaka[2], T.W.J. Huizinga[7] and Yijing Shen[5]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [3]Jan van Breemen Research Institute|Reade, Amsterdam, Netherlands, [4]VU Medical Center, Amsterdam, Netherlands, [5]Crescendo Bioscience, Inc., South San Francisco, CA, [6]Oklahoma Medical Research Fdn, Oklahoma City, OK, [7]Leiden University Medical Centre, Leiden, Netherlands

Background/Purpose: A novel multi-biomarker disease activity (MBDA) score for rheumatoid arthritis (RA) was significantly associated with DAS28CRP in multiple studies. Since disease activity is associated with structural damage, we set out to examine whether the MBDA algorithm score can also help predict progressive joint damage.

Methods: We analyzed 126 patients from the BeSt trial, which demonstrated the efficacy of early aggressive intervention in RA. The MBDA algorithm combines serum biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL40, Leptin, Resistin, CRP, SAA) into a single score. Serum samples from baseline (BL) and year 1 were examined. Total Van der Heijde Sharp Scores (SHS) and DAS28CRP were available at BL, year 1, and year 2. The performance of the MBDA algorithm score and continuous clinical variables at BL or year 1 was evaluated by Spearman correlation to change in SHS over the next 12 months (ΔSHS) and by Area under the receiver operating characteristic curve (AUROC) for identifying joint damage progressors (ΔSHS>0). For binary clinical variables, C-indices (comparable to AUROC) were used. The MBDA score and other variables at year 1 (presence of erosions, CCP status, CRP, DAS28CRP, and 28 joint counts) were assessed as independent predictors of ΔSHS by multivariate ordinary least squares regression.

Results: Among individual continuous measures from year 1 assessed for their ability to predict ΔSHS, the MBDA algorithm score had the highest correlation with ΔSHS (r=0.34), followed by starting SHS (r=0.32), SJC28 (r=0.31), CRP (r=0.25), DAS28CRP (r=0.23), and TJC28 (r=0.1, Figure panel A). Correlations of MBDA algorithm scores and other variables to 12-month ΔSHS were higher at year 1 than at BL. The MBDA algoirhtm score at year 1 had the second highest performance at identifying joint damage progressors (AUROC = 0.69) following SHS at 1 year (AUROC = 0.77, Figure panel B). In multivariate regression, only the MBDA algorithm score was a significant predictor of ΔSHS (p<0.05). Median MBDA algorithm scores dropped markedly from BL to year 1 (57 to 36, p<0.001).



Conclusion: A pre-defined, multi-biomarker algorithm for RA disease activity can also predict joint damage progression, suggesting that the combination of biomarkers accurately reflects underlying disease processes.

1614

Tocilizumab (TCZ) Inhibits Progression of Joint Damage in Rheumatoid Arthritis (RA) Irrespective of Its Antiinflammatory Effects: Disassociation of the Link Between Inflammation and Destruction. Josef Smolen[1], José Martinez-Avila[2] and Daniel Aletaha[3]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, Vienna, Austria, [2]Medical University of Vienna, Austria, [3]Medical University of Vienna, Vienna, Austria

Background/Purpose: Joint damage in RA correlates with disease activity (DA) by composite scores, swollen joint counts or acute phase reactants during its natural course or during therapy with synthetic drugs like methotrexate (MTX). In contrast, treatment with TNF blockers (TNFi) plus MTX inhibits joint damage progression even in patients (pts) with higher DA, disassociating this link. Such disassociation implies a profound direct interference with the events eliciting joint damage beyond effects on disease activity and has not been shown for other biologics. Here we evaluated if IL-6 inhibition with TCZ interferes with joint destruction beyond its effects on DA.

Methods: We used a random 90% sample of data from the LITHE trial on active RA despite MTX[1] with complete clinical and radiologic data at baseline (BL) and 1 year (yr) treated with placebo (PL; n=117), 4mg/kg TCZ (n=197) and 8mg/kg TCZ (n=217) every 4 weeks, pooling the TCZ groups because of similar radiographic effects[1]; all patients continued MTX. We calculated the SDAI, CDAI, DAS28 at BL and 1yr. We correlated BL and 1yr values of clinical and serologic variables with changes to 1yr of the Genant modified total Sharp score (TGSS) using Spearman test and also compared TGSS progression in low and high DA groups for PL and TCZ (Kruskal-Wallis).

Results: BL DA variables were similar among the groups. In line with published results[1], change of TGSS in this dataset was significantly lower in pts on TCZ than PL (TCZ:0.29±0.96; PL: 0.90±1.92; p=0.0007). In patients treated with PL, the correlation with TGSS change was low but significant for BL SDAI (r=0.18, p=0.047) and SJC28 (r=0.22, p=0.019) with similar trends for CRP (r=0.15, p=0.106) and CDAI (r=0.17, p=0.061), in line with previous notions mentioned above. Similar correlations were seen for SDAI, CDAI, DAS28 at 1yr with x-ray change during that year (r=0.26–0.28, p=0.002 – p=0.006). In contrast, none of the BL or 1yr variables showed significant correlation with x-ray

changes in pts on TCZ+MTX, suggesting a reduction or even abrogation of the link between DA and damage by TCZ.

Progression of TGSS was similar between treatment groups when remission or low DA was reached: PL: 0.4±1.1 (n=41); TCZ: 0.2±0.7 (n=217) (p=n.s). In contrast, when only moderate or high DA was reached after 1yr, PL treated patients had significantly higher TGSS change (1.2±2.2; n=76) than those treated with TCZ (0.4±1.2; p=0.0009).

Conclusion: IL-6 receptor inhibition with TCZ, in combination with MTX, appears to inhibit joint damage progression independent of its impact on disease activity. Similar effects have hitherto been reported only for TNF-i. These data indicate that the effects of IL-6 inhibition on progression of joint damage in RA are among the most profound currently attainable.

Evidence for Limited Repair of Existing Bone Erosions in Rheumatoid Arthritis Patients Treated with the Interleukin-6 Receptor Blocker Tocilizumab. Stephanie Finzel[1], Juergen Rech Sr.[1], Sarah Schmidt[1], Klaus Engelke[2], Matthias Englbrecht[1], Christian M. Stach[1] and Georg Schett[1]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany, [2]Institute of Medical Physics, University of Erlangen, Erlangen, Germany

Background/Purpose: The detection and quantification of bone erosion is an important outcome parameter in both clinical studies and clinical practice. This study was performed in order to investigate whether bone erosions in patients with rheumatoid arthritis (RA) treated with the interleukin-6 receptor blocker tocilizumab (TCZ) show evidence for repair.

Methods: A total number of 245 erosions were identified in the metacarpophalangeal (MCP) joints 2 to 4 of the right hand of 20 rheumatoid arthritis patients treated with TCZ in combination with methotrexate (MTX; mean dose 12.88 mg) and 21 sex-, age- and disease activity- matched patients treated with MTX monotherapy (mean dose 15.56 mg). All erosions were assessed for their exact maximal width and depth by high-resolution μCT imaging at baseline and after one year of treatment.

Results: All erosions detected at baseline could be found at follow-up after 1 year. At baseline, the mean width of bone erosions in the TCZ group was 1.57 mm, their mean depth was 1.67 mm, which was slightly less severe than in the MTX-treated group (width: 2.4mm; depth: 2.4 mm). In those patients reaching either clinical remission (DAS <2.6) or a DAS28 response of more than 1.5, the mean depth of erosions significantly ($p < 0.01$) decreased after 1 year of treatment with TCZ (−0.23 mm), whereas their mean width remained unchanged (−0.12 mm). In contrast, the mean depth (+2.16 mm) and width (+0.17 mm) of erosive lesions significantly increased in the MTX- treated group after 1 year. The reduction in depth of lesions was confined to joint areas containing spongiosal structure and associated with sclerosis at the base of the lesion.

Conclusion: Bone erosions in RA patients treated with TCZ show limited evidence for repair, which is in contrast to RA patients treated with MTX alone. Repair is associated with decreased depth of lesion and sclerosis at the bases of the erosion. These data indicate that TCZ can facilitate repair of existing bone erosions in RA, however repair is still incomplete after 1 year of treatment.

1616

Co-Localization of Non-Cartilaginous Articular Pathology and Cartilage Damage in Regard to Subsequent Cartilage Loss in Subjects with or at Risk for Knee Osteoarthritis - the MOST Study. Frank Roemer[1], David T. Felson[2], Ke Wang[1], Michel Crema[1], Monica D. Marra[1], Yuqing Zhang[3], Michael C. Nevitt[4], Cora E. Lewis[5], James Torner[6] and Ali Guermazi[7]. [1]Boston University, Boston, MA, [2]Department of Clinical Epidemiology, Boston University School of Public Health, Boston, MA, USA, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]University of California-San Francisco, San Francisco, CA, [5]University of Alabama, Birmingham City, Birmingham, AL, [6]University of Iowa, Iowa City, Iowa City, IA, [7]Boston Medical Center, Boston, MA

Background/Purpose: One of the strongest predictors of subsequent cartilage loss seems to be prevalent cartilage damage. Abnormally loaded areas of the knee joint are at increased risk of cartilage loss. Ipsi-compartmental meniscal damage and extrusion and prevalent bone marrow lesions (BMLs) may be considered markers for increased load to an adjacent cartilage subregion. The aim was to evaluate the impact of directly underlying BMLs and meniscal damage (called 'associated') pathology on the risk of subsequent cartilage loss at 30 months follow-up stratified by baseline cartilage damage severity.

Methods: The Multicenter Osteoarthritis (MOST) Study is an observational study of subjects with or at risk of developing osteoarthritis (OA). The MRI protocol (1.0 T) included axial and sagittal proton density-weighted fat-suppressed fast spin-echo and a coronal STIR sequence. MRIs were assessed according to the modified WORMS scoring system. Included were all knees with available baseline and 30 months MRI readings of the tibio-femoral joint (10 subregions). Ordinal logistic regression was used to estimate the risk of cartilage loss in each subregion, stratified by the severity of baseline cartilage damage. Cartilage loss was defined as at least within-grade progression in the same subregion. Subregions with associated articular pathology were stratified in subregions with one, two or three associated risk factors (i.e. meniscal damage, meniscal extrusion and BMLs). Subregions without adjacent pathology but with the same degree of prevalent cartilage damage (graded from 0 to 6) were the reference. Additional adjustment was performed for possible confounders.

Figure 1. Cartilage loss in the tibio-femoral joint by grade in regard to adjacent pathology

	Cartilage status in subregion (tibiofemoral joint – 10 subregions)						
Subregions and adjacent risk factor status	All Grades	Grade 0	Grade 2	Grade 2.5	Grade 3	Grade 4	Grades 5 and 6
Subregions included (%)	13524 (100.0)	9747 (72.1)	476 (3.5)	173 (1.3)	1983 (14.7)	49 (0.3)	1096 (8.1)

[3] two of three adjacent features: BML, meniscal damage, meniscal extrusion)
[4] three adjacent features: BML and meniscal damage and meniscal extrusion)
* significant at p < .05
95% CI - 95 % confidence interval

Results: 13524 subregions of 1365 knees were included. Subregional baseline cartilage scores were distributed as follows: grade 0: 9747 (72.1%); grade 2: 476 (3.5%); grade 2.5: 173 (1.3%); grade 3: 1983 (14.7%); grade 4: 49 (3.6%); grades 5 and 6 combined: 1096 (8.1%). 1119 (8.3%) subregions showed progressive cartilage loss at follow up. The risk of progressive cartilage loss was significantly increased for most grades in subregions where associated pathology was present when compared to subregions without adjacent pathology as the reference (Figure 1). For all grades of baseline cartilage damage combined, risk of cartilage loss increased significantly with number of associated features (test for trend $p<0.0001$).

Conclusion: For all prevalent grades of cartilage damage in the WORMS scale, the risk of cartilage loss is markedly increased for subregions with associated pathology indicative of abnormal loading conditions. Risk is further increased for subregions with more than one type of associated pathology. Integrity of meniscal structure/position and subchondral bone marrow is paramount for cartilage preservation.

ACR Concurrent Abstract Session

Metabolic and Crystal Arthropathies I: Concurrent Session on Pathogenesis of Gout, a Potential Novel Therapy, and Validity of Dual Energy Computed Tomography

Monday, November 7, 2011, 2:30 PM–4:00 PM

1617

Diagnosis of Gout Using Dual-Energy Computed Tomography: An Accuracy and Diagnostic Yield Study. Tim Bongartz[1], Katrina N. Glazebrook[1], Steven J. Kavros[2], Clement J. Michet[1], Stephen P. Merry[3], Naveen S. Murthy[1], Bharath Manu Akkara Veetil[1], John M. Davis III[1], Thomas G. Mason II[4], Kenneth J. Warrington[1], Nisha J. Manek[1], Tanaz A. Kermani[1], Deana D. Hoganson[1], A. Kirstin Bacani[1], Hailong Wang[1] and Cynthia H. McCollough[2]. [1]Mayo Clinic, Rochester, MN, [2]Rochester, MN, [3]Mayo Clinic, Rochester, [4]Mayo Clinic Rochester, Rochester, MN

Background/Purpose: Dual energy computed tomography scanning (DECT) is highly accurate in detecting and classifying renal uric acid stones. This technology has recently been modified to detect intra- or peri-articular monosodium urate (MSU) deposits. We aimed to formally assess the accuracy of this new imaging method to diagnose gout and explore whether it may have any substantial impact on clinical decision making beyond the established diagnostic approach using polarizing microscopy of synovial fluid.

Methods: To assess the sensitivity and specificity of DECT for diagnosis of gout, we included patients into two prospective cohorts: A control cohort of subjects without any history of gout who underwent arthrocentesis for other types of joint disease, and a second cohort of subjects with active gout diagnosed with a combined reference method of polarizing and electron microscopy. Accrual was stratified according to joint location and duration of symptoms (≤6 weeks>/6 weeks) in order to capture a wide spectrum of disease. All study participants underwent dual source, dual energy (80 and 140 kVP) CT scanning of the aspirated joint. Images were classified by a musculoskeletal radiologist as positive or negative for MSU deposition. To explore the diagnostic yield of DECT scanning, we assembled a third cohort of subjects who had clinical suspicion for gout but from whom an appropriate synovial fluid specimen for analysis could either not be obtained, or polarized microscopy was negative for the presence of MSU crystals. These subjects then had DECT imaging of the affected joint area. If the imaging findings suggested the presence of MSU deposits, we performed an ultrasound (US) guided aspiration of these areas with subsequent polarizing microscopy.

Results: The sensitivity and specificity of DECT for diagnosing gout was 0.93 (95%CI 0.79–0.98) and 0.95 (95%CI 0.82–0.99), respectively. These estimates were based on 40 patients with confirmed gout according to the reference method and 40 control patients with other types of joint disease. All 3 false negative subjects were observed in the stratum of 10 patients with acute podagra and no prior episodes of joint pain. The 2 false positive patients had advanced knee osteoarthritis with a DECT signal indicating intracartilaginous uric acid deposition. The diagnostic yield cohort consisted of 30 subjects with a clinical suspicion for gout but a negative synovial fluid aspiration. DECT imaging showed evidence for uric acid deposition in 14 of these 30 patients (46.7%). US guided aspiration of areas with positive DECT findings confirmed presence of MSU crystals.

Conclusion: DECT imaging provides high sensitivity and specificity for detection of MSU crystal deposits in subjects with gout. Sensitivity appears to be lower in patients with acute symptoms and no prior history of gout. DECT is a high-yield test with significant impact on clinical decision making when gout is suspected based on clinical presentation but polarizing microscopy of synovial fluid fails to demonstrate MSU crystals.

1618

Assessment of Tophus Size; A Comparison Between Physical Measurement Methods and Dual Energy Computed Tomography Scanning. Nicola Dalbeth, Opetaia Aati, Angela Gao, Meaghan House, Qiliang Liu, Anne Horne, Anthony Doyle and Fiona M. McQueen. University of Auckland, Auckland, New Zealand

Background/Purpose: A number of methods have been used to assess tophus size in clinical studies of chronic gout, from simple physical measurement techniques to complex advanced imaging methods. Dual energy computed tomography (DECT) has recently been described as a sensitive method to detect urate deposits in patients with gout. The aim of this study was to compare the reliability and validity of various physical methods with DECT assessment of tophus size.

Methods: Twenty-five patients with a history of gout according to ACR classification criteria and at least one subcutaneous tophus were recruited. For each patient, up to three index tophi were selected for analysis. Sites in the feet were preferentially selected. Tophus location was recorded in detail using a diagram and written description (n=64 tophi, 55 in the feet). Each tophus was assessed by two independent observers using Vernier calipers (longest diameter) and tape measure (area). The total number of subcutaneous tophi was also counted. All patients proceeded to DECT scanning of both feet. Index tophus DECT volume was assessed by two independent observers using automated volume assessment software (n=55 tophi). Five patients returned within one week for repeat physical assessment of tophus size. DECT scans from the returning patients were scored twice by both observers. Intra- and inter-observer reproducibility was assessed by intraclass correlation coefficient and limits of agreement analysis (Bland and Altman).

Results: Table 1 summarises the reproducibility analysis. Overall, DECT was more reproducible than the physical methods with an interobserver ICC of 0.95 [95% CI 0.92–0.97]. Vernier caliper and tape measurements correlated highly with each other (r_s=0.84, p<0.0001) but less well with DECT (for index tophi, r_s=0.46, p=0.004 for both). Variation was observed in the amount of urate deposits documented by DECT in tophi of similar physical size (Figure).

Table. Summary of reproducibility analysis for various methods of tophus size.

	Measurement, mean (SD)	Intraclass correlation coefficient, mean (95% CI)	Bias, mean (SD)
Interobserver reproducibility (Assessor 1 vs. Assessor 2)			
Vernier caliper longest diameter	25.7 (8.8) mm	0.78 (0.66–0.86)	2.1 (6.2) mm
Tape measure area	895 (713) mm^2	0.88 (0.82–0.93)	133 (320) mm^2
Tophus count	10 (8)	0.58 (0.25–0.79)	1.8 (8.5)
DECT volume	0.62 (1.15) cm^3	0.95 (0.92–0.97)	−0.07 (0.36) cm^3
Intraobserver reproducibility (Assessment 1 vs. Assessment 2)			
Vernier calipers longest diameter	28.1 (13.4) mm	0.75 (0.54–0.87)	−0.4 (10.1) mm
Tape measure area	1244 (1186) mm^2	0.91 (0.82–0.96)	64 (519) mm^2
Tophus count	14 (12)	0.94 (0.77–0.98)	−1.5 (4.3)
DECT volume	1.66 (2.1) cm^3	1.00 (1.00–1.00)	0.02 (0.13) cm^3

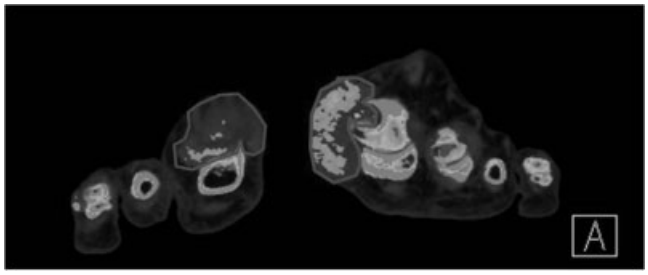

Figure. Example of two similar sized tophi from a single patient showing large variation in urate volume (green).

Conclusion: DECT scanning is a highly reproducible method for assessing tophus volume. This imaging modality reveals the composition of tophi which contain variable urate deposits embedded within soft tissue.

1619

A Novel Role for Monosodium Urate Monohydrate Crystals and Gouty Synovial Fluids in Monocyte Migration in Gout. M. Asif Amin[1], Qiang Shu[1], Jonathon W. Vargo[1], Jeffrey H. Ruth[1], Takeo Isozaki[1], Solhee Lee[1] and Alisa E. Koch[2]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]Department of Veteran's Affairs and University of Michigan, Ann Arbor, MI

Background/Purpose: Gout is characterized by intra-articular deposition of monosodium urate monohydrate (MSU) crystals. The role of neutrophil influx in acute gouty arthritis is well established, while the contribution of monocytes (MNs) and their secreted inflammatory mediators is not. Here we demonstrate the role of MSU in MN migration.

Methods: To examine the role of MSU crystals in normal human peripheral blood (PB) MN migration, we performed MN chemotaxis in a modified Boyden chamber *in vitro* using either MSU crystals or gouty synovial fluids (SFs) as stimuli. To examine mechanisms of MN migration, we performed MN chemotaxis with MSU in the presence or absence of chemical signaling inhibitors. We determined the *in vivo* role of MSU crystals or gouty SFs in homing of dye-tagged MNs using normal human

synovial tissue (ST)-severe combined immunodeficient (SCID) mouse chimeras. Gout often occurs after ingestion of rich foods, so to understand MN migration *in vivo*, we injected MSU crystals with fatty acid FFA C18:0 (FFA) into C57BL/6 mouse knees and examined them for MN ingress after 48 hours. To investigate the contribution of MSU to production of leukocyte chemoattractants macrophage migration inhibitory factor (MIF) and epithelial neutrophil activating factor-78 (ENA-78/CXCL5), and the signaling molecules involved in secretion of these cytokines, we stimulated MNs with MSU crystals, and performed ELISAs on conditioned medium. We also assayed for MIF in gouty SF by ELISA.

Results: We found that there was a significant 2 fold increase in *in vitro* MN migration in response to MSU crystals, while gouty SFs increased MN migration 5 fold compared to negative control ($n=3$, $p<0.05$). MSU crystal induced MN migration was significantly decreased by inhibitors of p38 MAPK, Src, and NFκB, suggesting that crystal induced MN migration occurs via these pathways. To determine if MSU crystals or gouty SFs induce MN migration *in vivo*, we engrafted SCID mice with normal human STs. After 4 weeks, we injected dye-tagged human PB MNs via tail vein. Simultaneously, we injected MSU crystals or gouty SFs into ST grafts. After 48 hours, we harvested the STs and found an increase in MN homing to the grafts injected with MSU crystals or SFs ($p<0.05$), indicating that either of these stimuli could recruit MNs *in vivo*. Likewise, we found a marked increase in mouse MN ingress in knees when these mice were injected with MSU crystals and FFA. Human MNs stimulated with MSU for 24 hours released significantly higher quantities of the potent leukocyte chemoattractants MIF and ENA-78/CXCL5 compared to nonstimulated MNs. MIF was a mean of 6 fold higher in gouty SFs compared to osteoarthritic fluids, suggesting the importance of MIF in gouty arthritis. Next, we examined the role of signaling molecules in the production of MIF and ENA-78/CXCL5 by stimulating MNs with MSU crystals in the presence of chemical signaling inhibitors. We found that MIF or ENA-78/CXCL5 secretion depended on the p38 MAPK pathway.

Conclusion: This data suggests an intriguing role for MSU crystals and gouty SFs in MN migration *in vitro* and *in vivo*. This data also provides evidence that MNs and their secreted products such as MIF and ENA-78/CXCL5 may be potential therapeutic targets for the treatment of diseases like gout.

1620

Bone Destruction by RANKL-Expressing T Cells in Chronic Gouty Arthritis. Sung-Ji Lee, Hye-Mi Jin, Young-Nan Cho, Seong-Chang Park, Dong-Jin Park, Tae-Jong Kim, Shin-Seok Lee, Seung-Jung Kee and Yong-Wook Park. Chonnam National University Medical School and Hospital, Gwangju, South Korea

Background/Purpose: To analyze the cellular expressions of pro-resorptive cytokines in gouty tophus tissues, to determine the capacity of monosodium urate monohydrate (MSU) crystals to induce these cytokines, and to understand the mechanisms of bone destruction in chronic gout.

Methods: Fourteen fixed, paraffin-embedded, uninfected tophus samples were analyzed immunohistochemically. Peripheral blood mononuclear cells (PBMCs) were cultured *in vitro* with MSU crystals, and gene expression was assessed by reverse transcription-polymerase chain reaction. *In vitro* osteoclastogenesis was performed using PBMCs and synovial fluid mononuclear cells (SFMCs).

Results: CD4+ T cells, CD8+ T cells, CD20+ B cells, and mast cells infiltrated tophus tissues. Tartrate-resistant acid phosphatase (TRAP)+ osteoclasts were present around tophi and in osteolytic lesions. Interleukin (IL)-1, IL-6 and tumor necrosis factor (TNF)-α were produced from infiltrated mononuclear cells, whereas receptor activator of nuclear factor κB ligand (RANKL) was strongly expressed in T cells. However, osteoprotegerin (OPG) was not or weakly expressed in tophus tissues. MSU crystals induced the expressions of IL-1, IL-6, TNF-α and RANKL in PBMCs, but inhibited OPG expression. In addition, the pro-resorptive cytokines were highly expressed in SFMCs of gouty arthritis patients. Furthermore, *in vitro* osteoclastogenesis was enhanced in SFMC cultures, but inhibited in T cell-depleted SFMC cultures.

Conclusion: Our study demonstrates that RANKL-expressing T cells and TRAP+ osteoclasts are present within gouty tophus tissues, and that infiltrating cells express pro-resorptive cytokines. Furthermore, our data show that MSU crystals have the potential to induce pro-resorptive cytokines, and T cells are involved in osteoclastogenesis in chronic gout.

1621

Pharmacological Inhibition of Interleukin-1 Receptor-Associated Kinase-4 Reduces Inflammation in a Murine Model of Gout and Is Consistent with IL-1 Signaling Blockade. Andrea Bree[1], Kathleen Phillips[1], Micah Benson[1], Ken Dower[1], Marina Shen[2], Katherine Lee[1], Vik Rao[1], Cheryl L. Nickerson-Nutter[2] and Melanie Ruzek[1]. [1]Pfizer, Inc., Cambridge, MA, [2]Pfizer, Cambridge, MA

Background/Purpose: Gout is an inflammatory disease associated with crystalline uric acid deposition within joints of affected patients. In a mouse model of this disease, where intraperitoneal injections of monosodium urate (MSU) crystals result in a neutrophilic peritonitis, IL-1 receptor signaling has been demonstrated to play a key role in this inflammatory response. As interleukin-1 receptor-associated kinase 4 (IRAK-4) is a critical signaling molecule downstream of the IL-1 receptor, we were interested in whether a highly specific IRAK-4 small molecule kinase inhibitor would be effective in this model system.

Methods: The IRAK-4 inhibitor was tested for activity in vitro on IL-1-induced cytokine responses in human whole blood and peripheral blood mononuclear cell (PBMC) cultures. In vivo we evaluated the cellular inflammation and cytokine responses to intraperitoneal injection of MSU crystals in IRAK-4-deficient/kinase inactive IRAK-4 transgenic mice, in wildtype mice treated with the IRAK-4 inhibitor and in IL-1R-deficient mice alone and upon coadministration of the IRAK-4 inhibitor. The IRAK-4 inhibitor was injected subcutaneously in a nanocrystal formulation to ensure adequate exposure over the course of the studies in mice.

Results: In vitro, the IRAK-4 inhibitor blocked interleukin (IL)-1-induced IL-6 production by human whole blood and peripheral blood mononuclear cells (PBMC) as well as the production of tumor necrosis factor-a by PBMCs. In vivo, MSU-treated IRAK-4-deficient/kinase inactive IRAK-4 transgenic mice showed a significant reduction in peritonitis compared to wildtype (WT) and heterozygous mice. A similar level of inhibition of MSU-induced peritonitis was observed upon treatment of WT mice with the IRAK-4 inhibitor. In addition, IL-6 levels in the peritoneal lavage fluid of MSU-treated mice were reduced by the IRAK-4 inhibitor treatment, suggesting that downstream cytokine responses are similarly affected by blockade of IRAK-4 signaling. To explore whether the IRAK-4 inhibitor mediates its effects through the IL-1 pathway in this model, we compared the IRAK-4 inhibitor treatment in WT mice to the response in IL-1 receptor (IL-1R)-deficient mice and found that the inhibition of peritonitis to MSU crystal injection was similar with IRAK-4 inhibitor treatment and in IL-1R-deficient mice. Furthermore, there was minimal additional inhibition observed when IL-1R-deficient mice were treated with the IRAK-4 inhibitor.

Conclusion: These results demonstrate that specific pharmacological inhibition of IRAK-4 can block human IL-1 responses in vitro as well as ameliorate the gout-like peritonitis in mice and indicates that IRAK-4 inhibitors have potential therapeutic application in IL-1-mediated diseases in humans.

1622

Association Between Sugar-Sweetened Beverage Consumption and Gout in the New Zealand Population. Tony R. Merriman[1], Nicola Dalbeth[2], Lisa K. Stamp[3], Marilyn E. Merriman[1], Ruth Topless[1], Peter J. Gow[4], Andrew Harrison[5], John Highton[6], Peter B. B. Jones[7] and Caitlin Glue[1]. [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Otago, Christchurch, Christchurch, New Zealand, [4]Middlemore Hospital, Auckland, New Zealand, [5]Hutt Hospital, Lower Hutt, New Zealand, [6]Univ of Otago Med Sch, Dunedin, New Zealand, [7]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand

Background/Purpose: Association between the consumption of high fructose corn syrup (HFCS; 55% fructose)-sweetened beverages and fruit, and the risk of hyperuricaemia and gout, has been reported in North America. The objective was to examine the association of gout with sugar-sweetened beverages in a New Zealand (NZ) population. The population of NZ has a unique composition, and soft-drinks and fruit juices in NZ are predominantly sweetened with sucrose (50% fructose), rather than HFCS.

Methods: Survey data from 753 people with, and 633 people without, gout as determined by ACR criteria, were used to examine the association between gout and intake of sugar-sweetened beverages, including fruit juice, and fruit. One unit of drink was defined as a can or large glass. Three ethnic

groups were analysed; NZ Maori, Caucasian and Western Polynesian (Samoa, Tonga, Niue). STATA v8.0 statistical software was used.

Results: Significantly increased risk was apparent only in those drinking four or more sugar-sweetened beverages per day (Table). In all population groups, ingestion of 4 or more such drinks per day is associated with a 3–4-fold increased risk of gout. We observed a protective effect from daily fruit intake in the Caucasian participants (1 piece, adjusted OR=0.32, P=0.08; 2–3 pieces, OR=0.23, P=0.02; ≥4 pieces, adjusted OR=0.15, P=0.007). There were no significant associations with fruit intake in other ethnic groups.

Table. Analysis of frequency of sugar sweetened beverage intake and gout

	Frequency of sugar-sweetened beverage intake (servings/day)			
	0	1–1.99	2–3.99	4+
Caucasian				
Adjusted OR (95% CI)*	1.00	1.05 (0.51,2.15)	1.67 (0.66,4.24)	4.48 (1.22,16.50)
P Value	–	0.90	0.28	0.024
NZ Maori				
Adjusted OR (95% CI)*	1.00	0.70 (0.30,1.63)	1.61 (0.65,4.00)	3.46 (1.35,8.86)
P Value	–	0.41	0.30	0.010
Western Polynesian				
Adjusted OR (95% CI)*	1.00	1.72 (0.65,4.49)	1.66 (0.71,3.91)	4.34 (1.69,11.19)
P Value	–	0.27	0.24	0.002

* Adjusted by sex, body mass index, age, hypertension, kidney disease, alcohol intake, seafood intake and fruit intake.

Conclusion: These results demonstrate association between increased intake of sugar-sweetened beverages and gout in all NZ ethnic groups studied. A possible mechanism for this association is the direct effect of fructose on serum urate concentrations through production of AMP and subsequently urate, as well as the long-term effects of fructose on insulin resistance and the renal excretion of urate. The observed protective effect of fruit intake in Caucasian was consistent with one North American study (Williams PT. Am J Clin Nutr. 2008;87:1480) but not a second North American study (Choi H and Curhan G. Br Med J. 2008;336:309). The protective effect of fruit, despite its fructose content, may be due to fruit containing gout-protective chemicals, or to fruit intake being a marker of a gout-protective diet.

ACR Concurrent Abstract Session
Osteoarthritis - Clinical Aspects II
Monday, November 7, 2011, 2:30 PM–4:00 PM

1623

MRI-Detected Synovitis and Bone Marrow Lesions Are Associated with Joint Tenderness in Hand Osteoarthritis. Ida K. Haugen[1], Pernille Bøyesen[1], Barbara Slatkowsky-Christensen[1], Sølve Sesseng[1], Désirée van der Heijde[2] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Previous studies in knee osteoarthritis (OA) have shown that bone marrow lesions (BMLs) and synovitis are important for the experience of pain. No studies have explored the role of MRI features in relation to pain and physical function in patients with hand OA. The aim was therefore to explore the association between MRI features and joint tenderness, patient-reported pain, physical function and grip strength in hand OA.

Methods: 107 patients (98 women) with mean (SD) age of 68.9 (5.6) years underwent MRI and clinical joint examination of dominant hand. The interphalangeal joints were scored according to the preliminary Oslo hand OA score for MRI and assessed for tenderness upon palpation. Pain and physical function was assessed by self-reported questionnaires (AUSCAN pain/physical function, FIHOA and AIMS-2 hand/finger) and grip strength (Jamar dynamometer). We used Generalized Estimating Equations (GEE) to explore the association between the presence of MRI features and joint tenderness, and linear regression for the association between the amount of MRI features (i.e., MRI sum scores and number of affected joints) and patient-reported outcomes and grip strength of the same hand that was imaged by MRI. We adjusted for age and sex, and features with $p<0.25$ were introduced in a multivariate model (backward selection). In a second model we also adjusted for radiographic severity (Kellgren-Lawrence).

Results: Presence of most MRI features was significantly associated with tenderness upon palpation in the corrected univariate analyses (adjusted for age and sex) (table). The final multivariate model included osteophytes, erosions, bone attrition, moderate/severe synovitis and BMLs (table). Moderate/severe synovitis (OR 1.8;p=0.002) and BMLs (OR 1.8;p=0.007) remained significantly associated with joint tenderness after additional adjustment for radiographic severity (multivariate model).

The sum score of osteophytes was significantly associated with FIHOA (beta=0.22;p=0.002) and grip strength (beta=-0.33;p<0.001), malalignment was associated with AIMS-2 hand/finger (beta=1.19;p=0.03), while no significant associations were found for AUSCAN pain/physical function (corrected univariate analyses). Analyses with the number of affected joints as predictor variables provided similar results as the analyses with MRI sum scores (data not shown).

Table. The odds ratios (95% confidence interval) for tenderness upon palpation in joints with MRI pathology (adjusted for age and sex) compared to joints without the MRI feature.

	Separate models: OR (95% CI); p-value	Final multivariate model: OR (95% CI); p-value
Osteophytes	2.0 (1.4–2.7); p < 0.001	1.4 (1.0–2.0); p = 0.07
Joint space narrowing	1.6 (1.2–2.2); p = 0.002	—
Erosions	1.8 (1.4–2.4); p < 0.001	1.5 (1.1–1.9); p = 0.008
Bone attrition	2.6 (1.7–3.9); p < 0.001	2.5 (1.6–4.0); p < 0.001
Cysts	1.8 (1.0–3.3); p = 0.07	—
Malalignment	2.1 (1.3–3.3); p = 0.002	—
Synovitis #	2.1 (1.5–2.9); p < 0.001	1.9 (1.3–2.9); p = 0.001
Flexor tenosynovitis	1.3 (0.9–1.8); p = 0.20	—
Bone marrow lesions (BMLs)	2.4 (1.7–3.4); p < 0.001	1.6 (1.1–2.4); p = 0.02
Collateral ligament (CL) absence	1.9 (1.4–2.5); p < 0.001	—
BMLs at CL insertions	2.2 (1.4–3.4); p < 0.001	—

joints with synovitis grade 0–1 serve as reference.

Conclusion: Synovitis and BMLs were associated with joint tenderness independent of each other, other MRI features and also radiographic severity, and may represent potential targets for symptom-modifying treatment in hand OA.

1624

Breaking the Law of Valgus: The Surprising and Unexplained Prevalence of Medial Patellofemoral Cartilage Damage. K. Douglas Gross[1], Jingbo Niu[2], Joshua J. Stefanik[3], Ali Guermazi[4], Frank Roemer[3], Leena Sharma[5], Michael C. Nevitt[6], Neil Segal[7], Cora E. Lewis[8] and David T. Felson[2]. [1]MGH Institute of Health Professions, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Boston, MA, [4]Boston Medical Center, Boston, MA, [5]Northwestern University, Chicago, IL, [6]University of California-San Francisco, San Francisco, CA, [7]University of Iowa, Iowa City, [8]University of Alabama, Birmingham City, Birmingham, AL

Background/Purpose: The Law of Valgus dictates that patellofemoral (PF) osteoarthritis (OA) involves excessive lateral loading and lateral PF cartilage damage. Many treatments for PF OA, including surgeries and braces, assume that disease affects the lateral compartment. Medial PF OA is expected to occur only rarely in the presence of varus knee malalignment. Yet, the assertion that medial PF OA is less prevalent than lateral PF OA has not been corroborated in large-scale studies or using MRI to detect cartilage damage. Thus, we compared the prevalence of medial and lateral PF cartilage damage in 3 large OA studies and determined the relationship of PF cartilage damage to varus, neutral, and valgus knee alignment.

Methods: In the Boston Osteoarthritis of the Knee Study (BOKS), the Framingham Osteoarthritis Study (FOA), and the Multicenter Osteoarthritis Study (MOST), MRIs were read for cartilage morphology at the medial and lateral patella and trochlea femoris by 2 experienced musculoskeletal radiologists using Whole-Organ MRI Scoring (WORMS). WORMS scores >2 (any cartilage thickness defect), >3 (areas of partial thickness loss), >4 (widespread partial thickness loss), and >5 (areas of full thickness loss) were all variously considered as thresholds to identify of cartilage damage that might indicate OA. Weighted kappa for inter-rater reliability in WORMS scoring was 0.80 in BOKS, 0.73 in FOA, and 0.78 in MOST. Using a standard protocol, standing long-limb radiographs were measured for mechanical axis alignment and varus (<-2 degrees), neutral (-2 to 2 degrees), and valgus (>2 degrees) aligned knees were identified.

Table. Prevalence of medial and lateral patellofemoral (PF) cartilage damage in BOKS, FOA, and MOST studies

		Definition of PF Cartilage Damage							
		Patellar Cartilage Morphology Score				Either Patellar or Trochlear Cartilage Morphology Score			
		≥ 2	≥ 3	≥ 4	≥ 5	≥ 2	≥ 3	≥ 4	≥ 5
BOKS (baseline)	Medial PF Damage % (n /N knees)	75.00 (168/ 224)	68.75 (154/ 224)	48.21 (108/ 224)	26.79 (60/ 224)	84.38 (189/ 224)	79.02 (177/ 224)	55.80 (125/ 224)	30.36 (68/ 224)
	Lateral PF Damage % (n /N knees)	61.61 (138/ 224)	58.04 (130/ 224)	45.54 (102/ 224)	24.11 (54/ 224)	73.66 (165/ 224)	68.75 (154/ 224)	54.46 (122/ 224)	28.57 (64/ 224)
FOA	Medial PF Damage % (n /N knees)	64.72 (277/ 428)	50.00 (214/ 428)	23.36 (100/ 428)	17.76 (76/ 428)	69.95 (298/ 426)	57.51 (245/ 426)	27.00 (115/ 426)	21.13 (90/ 426)
	Lateral PF Damage % (n /N knees)	50.93 (218/ 428)	43.22 (185/ 428)	16.59 (71/ 428)	10.98 (47/ 428)	55.40 (236/ 426)	47.65 (203/ 426)	21.60 (92/ 426)	16.43 (70/ 426)
MOST (baseline)	Medial PF Damage% (n /N knees)	62.74 (1017/ 1621)	51.63 (837/ 1621)	20.30 (329/ 1621)	18.63 (302/ 1621)	69.19 (1116/ 1613)	56.11 (905/ 1613)	21.64 (349/ 1613)	19.78 (319/ 1613)
	Lateral PF Damage % (n /N knees)	45.34 (735/ 1621)	38.43 (623/ 1621)	19.74 (320/ 1621)	16.59 (269/ 1621)	51.08 (824/ 1613)	43.15 (696/ 1613)	23.56 (380/ 1613)	20.52 (331/ 1613)

Results: The prevalence of medial PF cartilage damage exceeded that of lateral damage in all 3 OA studies and according to nearly every threshold definition (see table). This was true whether the patella alone was considered (left of table), or the trochlea femoris was also considered (right of table). Only when consideration was limited to severely involved knees (WORMS > 4 or >5) did the prevalence of lateral PF cartilage damage approximate that of medial PF damage. Moreover, the high prevalence of medial PF cartilage damage persisted within all strata of knee alignment. Even among knees with valgus malalignment, it was only when the threshold used to identify cartilage damage was specific to the most severely involved knees (WORMS > 4 or >5) that the prevalence of lateral PF cartilage damage surpassed that of medial PF damage.

Conclusion: Contrary to the Law of Valgus, these findings indicate that medial PF cartilage damage may be more prevalent among older adults than lateral PF cartilage damage. These findings are likely to have major implications for the treatment of PF OA since many surgical and rehabilitative interventions attempt to unload the lateral PF compartment by medially realigning the patella. Such interventions may be contraindicated in the presence of medial PF disease.

Change in Knee Cartilage Volume and Incident Meniscal Extrusion As Predictors of Change in Joint Space Width of the Tibiofemoral Joint: 5 Year Longitudinal Study. Joanna Hall[1], Laura Laslett[1], Johanne M. Pelletier[2], Jean Pierre Pelletier[2], François Abram[3], Chang-Hai Ding[4], Flavia Cicuttini[5] and Graeme Jones[1]. [1]University of Tasmania, Hobart, Australia, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [3]ArthroVision Inc., Montreal, QC, [4]University of Tasmania & Monash University, Hobart, Australia, [5]Monash University, Central and Eastern Clinical School, Melbourne, Australia

Background/Purpose: Joint space width (JSW) on X-ray is the current gold standard for assessing osteoarthritis disease modification. Recently, concerns have been raised about this measure. However, there are limited longitudinal data comparing the predictive validity of MRI cartilage volume change and incident meniscal extrusion (IME) for X-ray change. The aim of this study was to determine whether change in these MRI indices over 2.6 years predicted change in JSW over 5 years in randomly selected community dwelling older adults.

Methods: Participants (N=180) had X-rays and MRI's of the right knee at baseline and after 2.6 years for MRI and 5 years for X-ray. IME as well as articular cartilage volumes at baseline and 2.6 years were determined at the medial and lateral tibial and femoral compartments by MRI. Sagittal T1-weighted fat-suppressed MR images were obtained and processed on an independent computer work station. X-ray was performed using a standard fixed semi-flexed view and scored only on those with adequate alignment (N=150).

Results: Participants were aged 50–80 years (mean 62 years, range 51–78), 49% were male. Medial and lateral cartilage volume reduced over time (medial −612 μL/year, p=<0.001, lateral −392μL/year, p<0.001), as did JSW (medial −0.048 mm/year, p=0.0043, lateral −0.12 mm/year, p<0.001). IME occurred in 7% (primarily medial). In multivariate analysis, change in compartment specific cartilage volume was a weak but significant predictor of change in JSW in both the medial ($R^2$5%, p=0.008) and lateral compartments ($R^2$2%, p=0.05). In the medial compartment, IME was a stronger predictor of change in JSW than cartilage volume loss (R^2=14%, p<0.001).

In subgroup analysis by cartilage measurement site, change in tibial cartilage volume was not a significant predictor of change in JSW at the medial or lateral compartments ($R^2$0.4%, p=0.37; $R^2$2%, p=0.056). Change in femoral cartilage volume was weakly predictive of change in JSW in the medial ($R^2$2.5%, p=0.05) but not lateral compartments ($R^2$1.2%, p=0.17). In patients with prevalent radiographic osteoarthritis (n=84), change in cartilage volume had a better goodness of fit but was not significantly predictive of JSW change at the medial or lateral compartments, ($R^2$9.6%, p=0.132; $R^2$2.6%, p=0.16).

Conclusion: Despite both outcome measures decreasing significantly from baseline, change in JSW was only weakly predicted by change in cartilage volume. This provides some evidence of face validity for X-ray. However, incident meniscal extrusion was a stronger contributor to change in JSW than cartilage volume loss at the medial compartment while over 80% of the variation in JSW change remains unexplained. Given that MRI examines cartilage directly while radiographs examine it indirectly, these results cast doubt on the validity of radiographs as a proxy measure of cartilage loss, suggesting it is time for a re-evaluation of the choice of key outcome measure for disease modifying trials.

Novel MRI Ultrashort TE Enhanced T Mapping Shows Subsurface Cartilage and Meniscus Changes Clinically in Human Subjects After Anterior Cruciate Ligament Tear (ACLT). Constance R. Chu. Ashley A. Williams and Yongxian Qian, University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Joint injury leads to accelerated development of OA. Human subjects with ACL and meniscus injuries provide a unique clinical opportunity to study early OA and potential intervention strategies for early-stage disease modification. Improved ability to diagnose and stage subsurface cartilage and meniscus injury and degeneration are critical to this effort. Ultra-short TE-enhanced T2* (UTE-T2*) mapping is a novel, non-invasive, and quantitative MRI technique we have shown potentially discerns subsurface cartilage degeneration confirmed by microscopy (1) with high clinical reproducibility (2). This study was performed to test the hypothesis that UTE-T2* changes can be quantified in surface-intact human menisci and articular cartilage after ACL tear (ACLT).

Methods: Thirty-five human subjects were imaged on a 3T Siemens MRI scanner using an 8-channel knee coil according to IRB-approved protocols. Ten asymptomatic subjects, with no known knee problems (mean age = 27 yrs), and 25 consecutive human subjects with ACLT who completed UTE scans (mean age = 30 yrs) were studied. Images were acquired at eleven echo times (TE range 0.6–40 ms) with the acquisition-weighted stack of spirals (AWSOS) sequence (3). UTE-T2* maps were generated with a mono-exponential T2 fit (1,2). All ACLT subjects underwent arthroscopy for clinical treatment where Outerbridge cartilage grading and confirmation of meniscal tear status were performed. Non-parametric statistics were used as appropriate.

Results: Of the 25 ACLT subjects, 80% (20/25) had intact articular surfaces to the central weight-bearing study area of the medial femoral condyle, and 60% (15/25) had intact menisci. The UTE-T2* values in the deep articular cartilage of ACLT subjects with both intact medial menisci and intact articular surfaces (n=13) were higher than that of the same regions of asymptomatic (n=10) subjects (14.5 *v* 10.4 ms, P=0.009). Meniscus UTE-T2* values in subjects with ACLT and surface intact medial menisci (n=15) were higher than that of asymptomatics (P=0.001). Meniscus UTE-T2* in subjects with ACLT and medial meniscus tear (n=10) were higher than both ACLT with intact medial menisci (18.3 *v* 13.1 ms, P=0.01) and asymptomatics (18.3 *v* 9.8 ms, P<0.0001).

Conclusion: This human clinical study shows quantitative and noninvasive MRI evidence for subsurface cartilage and meniscus matrix changes following ACL tear, a substantial joint injury associated with rapid OA development. Continued longitudinal study is needed to determine whether elevated meniscus and cartilage UTE-T2* are potential markers of subsurface injury that lead to OA. The ability to diagnose, stage and quantify meniscus and cartilage injury prior to visible surface breakdown are important for identifying early disease states that may be amenable to molecular, biological, and mechanical interventions to delay the onset of OA.

Pressure Pain Threshold and Knee Pain in Osteoarthritis: The Multicenter Osteoarthritis Study. Tuhina Neogi[1], Jingbo Niu[1], Lars Arendt-Nielsen[2], Joachim Scholz[3], Laura Frey-Law[4], Clifford Woolf[5], Yuqing Zhang[1], Larry Bradley[6], Michael C. Nevitt[7] and David T. Felson[1]. [1]Boston University School of Medicine, Boston, MA, [2]Aalborg University, Aalborg, Denmark, [3]Columbia University, New York, NY, [4]University of Iowa, Iowa City, IA, [5]Children's Hospital, Boston, MA, [6]University of Alabama, Birmingham, AL, [7]University of California-San Francisco, San Francisco, CA

Background/Purpose: Mechanisms contributing to knee pain in osteoarthritis (OA) are not well understood. Sustained mechanical and inflammatory stimuli in the joint may lead both to changes in the peripheral threshold of nociceptors (peripheral sensitization) and a central amplification of signals in the CNS (central sensitization), resulting in heightened pain sensitivity. We hypothesized findings of sensitization, as assessed by pressure pain threshold, may be associated with symptomatic knee OA (SxOA) and knee pain severity.

Methods: The Multicenter Osteoarthritis (MOST) Study is cohort study of persons with or at high risk of knee OA. At the 60-month clinic visit, participants underwent knee radiography, answered pain questionnaires, and had pressure pain threshold (PPT) assessed, which is a marker of peripheral +/− central sensitization at sites of disease/inflammation, or of central sensitization when assessed at an otherwise normal area. PPT was assessed with an algometer (1cm^2 tip) at the patella (site of pathology: peripheral +/− central sensitization) and wrist (free of pathology: central sensitization) as the point at which the participants indicated that the pressure first changed to slight pain. The average of 3 trials was used to calculate the PPT, which was then categorized into tertiles. Knees were categorized according to presence of SxOA based on KL≥2 and presence of consistent frequent knee pain (answering yes to a question about frequent knee pain at a telephone screen and a subsequent clinic visit within 30 days). Pain severity was categorized as the maximum of none, mild, or at least moderate pain on any of the 5 knee-specific WOMAC pain questions. We evaluated the association of PPT with SxOA and presence of frequent knee pain using logistic regression with GEE, and with knee pain severity using proportional odds logistic regression with GEE, adjusting all analyses for age, sex, BMI, race, clinic site, KL grade, depressive symptoms, catastrophizing, and widespread pain.

Results: 2033 subjects (3823 knees) had all measures performed (mean age 68±8, mean BMI 30.6±5.9, 60% female). The range of PPT at the wrist was 0.38 to >9 kg/cm^2 and at the patella was 0.30 to >9 kg/cm^2. The lowest tertile of PPT assessed at the wrist (central sensitization) was significantly associated with presence of SxOA, presence of frequent knee pain, and greater knee pain severity, and at the patella (peripheral +/− central sensitization) was significantly associated with frequent knee pain and greater pain severity (Table).

Table: Association of PPT with Knee Pain in Knee OA

	Symptomatic Knee OA		Frequent Knee Pain		Knee Pain Severity	
PPT tertiles:	Crude OR	Adj* OR (95% CI)	Crude OR	Adj* OR (95% CI)	Crude OR	Adj* OR (95% CI)
Patella						
Lowest	1.87	1.26 (0.94-1.69)	2.11	1.53 (1.19-1.95)	2.72	1.93 (1.59-2.34)
Middle	1.23	1.00 (0.75-1.32)	1.20	1.03 (0.81-1.30)	1.60	1.45 (1.22-1.72)
Highest (referent)	1.0	1.0	1.0	1.0	1.0	1.0
P for trend		0.1		0.001		<0.0001
Wrist						
Lowest	1.65	1.44 (1.08-1.91)	1.56	1.31 (1.02-1.68)	2.07	1.84 (1.51-2.24)
Middle	1.25	1.40 (1.04-1.87)	1.34	1.37 (1.08-1.76)	1.44	1.53 (1.26-1.85)
Highest (referent)	1.0	1.0	1.0	1.0	1.0	1.0
P for trend		0.01		0.03		<0.0001

*adjusted for age, sex, BMI, race, clinic site, ROA severity, depression, catastrophizing, widespread pain

Tertile categories (kg/cm^2):
Patella: lowest: 0.30-3.79; middle: 3.80-5.64; highest: >=5.65
Wrist: lowest: 0.38-2.63; middle: 2.64-3.71; highest: >=3.72

Conclusion: Low pressure pain threshold was associated with pain in knee OA, as assessed by presence of symptomatic knee OA, frequent knee pain, and greater knee pain severity. These findings support the contribution of both peripheral and central sensitization in the pain experience of knee OA.

Association of Knee Pain Patterns Determined From the Intermittent and Constant Osteoarthritis Pain Instrument with Knee Pain Severity: The Multicenter Osteoarthritis Study. Tuhina Neogi[1], Jingbo Niu[1], David T. Felson[1], Michael C. Nevitt[2], C.E. Lewis[3], James Torner[4], Melissa French[5] and Gillian A. Hawker[5]. [1]Boston University School of Medicine, Boston, MA, [2]University of California-San Francisco, San Francisco, CA, [3]University of Alabama, Birmingham City, AL, [4]University of Iowa, Iowa City, Iowa City, IA, [5]Women's College Hospital, Toronto, ON

Background/Purpose: Knee OA-related pain changes over time as disease progresses, related both to frequency and severity of pain. At the early stages, OA-related knee pain is thought to be activity-related (intermittent) only, while as disease progresses, the pain becomes more constant, and eventually is constant punctuated with intermittent episodes of greater pain. A new pain assessment tool for knee OA, the Intermittent and Constant OA Pain (ICOAP) instrument, can be used to describe these intermittent and constant knee pain patterns. We evaluated whether ICOAP-defined pain patterns were associated with knee pain severity.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded cohort study of persons with or at high risk of knee OA. Knee-specific WOMAC, VAS (0–10) and ICOAP scores were ascertained at the same study visit. The ICOAP assesses presence and severity of intermittent and constant pain, and for intermittent pain, its frequency (5-point Likert scale for each). Using the knee-specific ICOAP, pain patterns were defined as increasing in severity as: 1) no intermittent or constant pain; 2) intermittent pain only (of at least mild severity occurring at least sometimes); 3) constant pain only (of at least mild severity); and 4) a combination of constant + intermittent pain, as defined above. We evaluated the relationship between ICOAP pain patterns (exposure) and knee pain severity (WOMAC, VAS as outcomes) using proportional odds logistic regression with generalized estimating equations. We also assessed the relation of knee pain severity (exposure) to presence of constant or constant plus intermittent pain *vs.* intermittent pain alone.

Results: We studied 2322 participants (4632 knees) with ICOAP data (mean age 68±8, mean BMI 31±6, 60% female). On ICOAP, the majority of knees (62%) had no intermittent or constant pain, 30% had intermittent pain, 4% had constant pain, and 4% had both by ICOAP. By WOMAC and VAS, ~55% of knees had mild-moderate pain, and ~11% had severe/extreme pain. Higher ICOAP pain pattern categories were associated with greater pain severity by WOMAC and VAS (Table). Further, greater WOMAC and VAS pain severity were more likely to be associated with constant rather than intermittent only pain (Table).

Table: Association of ICOAP pain patterns with Knee Pain Severity

Crude Knee Pain severity by ICOAP Pain Pattern Category:	Mean (SD) WOMAC pain (0-20)	Mean (SD) VAS pain (0-100)
ICOAP pain pattern:		
1) No intermittent/constant pain (n=2874)	1.2 (2.0)	6.0 (11.0)
2) Intermittent pain (n=1409)	4.9 (3.1)	27.5 (19.3)
3) Constant pain (n=167)	8.2 (3.8)	43.5 (25.6)
4) Constant + intermittent pain (n=182)	9.0 (3.9)	53.2 (24.4)
Outcome: Knee Pain Severity by WOMAC and VAS (proportional odds logistic regression model)	Maximal WOMAC knee pain [adj OR* (95% CI)]	Maximal VAS knee pain [adj OR* (95% CI)]
ICOAP pain pattern:		
5) No intermittent/constant pain (n=2874)	1.0 (ref)	1.0 (ref)
6) Intermittent pain (n=1409)	16.0 (12.7-20.1)	16.0 (12.5-20.5)
7) Constant pain (n=167)	40.2 (26.4-61.3)	45.9 (28.9-72.7)
8) Constant + intermittent pain (n=182)	43.2 (28.5-65.5)	71.2 (45.7-110.9)
p for linear trend	p<0.0001	p<0.0001
Outcome: ICOAP constant *vs.* intermittent knee pain (logistic regression model)	ICOAP constant vs intermittent pain [adj OR* (95% CI)]	
Maximal WOMAC knee pain:		
1) None (n=1638)	1.0 (ref)	
2) Mild/moderate pain (n=2471)	1.4 (0.6-3.3)	
3) Severe/extreme pain (n=514)	3.8 (1.5-9.4)	
	p for linear trend <0.0001	
Maximal VAS knee pain:		
1) 0 (n=1560)	1.0 (ref)	
2) 1-4 (n=2529)	1.2 (0.5-3.3)	
3) >4 (n=534)	4.7 (1.7-12.6)	
	p for linear trend <0.0001	

*adjusted for age, sex, BMI, catastrophizing, depressive symptoms, widespread pain, clinic site, race, Kellgren and Lawrence grade

Conclusion: Knee pain patterns defined by the ICOAP instrument, thought to be related to disease duration, were associated with greater knee pain severity. These findings support the hypothesis that knee pain patterns (intermittent, constant, constant+intermittent) are meaningful patterns that are associated with overall pain severity and likely stage of disease.

Risk Factors Associated with Incident Hip Fractures in 9,720 Japanese Patients with Rheumatoid Arthritis: A Prospective Observational Cohort Study. Takefumi Furuya[1], Eisuke Inoue[1], Takayuki Hosoi[2], Atsuo Taniguchi[1], Shigeki Momohara[1] and Hisashi Yamanaka[1]. [1]Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan, [2]National Center for Geriatrics and Gerontology, Obu, Aichi, Japan

Background/Purpose: Patients with rheumatoid arthritis (RA) have a high risk of hip fracture. Limited data exist in the literature concerning risk factors for incident hip fractures in patients with RA. Previously, utilizing data from our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort study, we reported clinical risk factors for both incident vertebral and non-vertebral fractures in Japanese patients with RA. However, we did not evaluate the risk factors for hip fractures alone, because in our previous studies, the number of hip fracture patients was small. In this study, we evaluated the association between potential risk factors and incident hip fractures in Japanese patients with RA.

Methods: IORRA is a prospective observational cohort study of Japanese RA patients at the Institute of Rheumatology, Tokyo Women's Medical University (Tokyo, Japan) that was begun in 2000. A total of 9,720 patients (82% female, mean age 56 years) with RA were enrolled in the IORRA cohort study from 2000 to 2010. Self-reported hip fractures were verified with patient medical records. Cox proportional hazards models with time-dependent covariates were used to analyze independent contributions of various risk factors to hip fracture incidence.

Results: During a mean (SD) follow-up of 5.2 (3.3) years, 152 patients (male 22, female 130) reported 152 hip fractures. Among these 152 patients, 107 hip fractures in 107 patients (male 16, female 91) were verified with medical records. Japanese version of the Health Assessment Questionnaire (J-HAQ) score (hazard ratio [HR], 2.35; 95% confidence interval [CI], 1.86–2.97; $P = 1.1 \times 10^{-12}$), age (per 10 years; HR, 1.60; 95% CI, 1.31–1.94; $P = 2.4 \times 10^{-6}$), history of total knee replacement (TKR) (HR, 3.25; 95% CI, 1.37–7.74; $P = 0.0076$), and body mass index (BMI) (HR, 0.93; 95% CI, 0.87–0.99; $P = 0.021$) were significantly associated with hip fractures (model (1) in Table). Among the scores on the 8 domains of the J-HAQ, HAQ (arising) (HR, 1.65; 95% CI, 1.29–2.11; $P = 7.0 \times 10^{-5}$) and HAQ (hygiene) (HR, 1.49; 95% CI, 1.11–2.00; $P = 0.0076$) were significantly correlated to incident hip fractures (model (2) in Table). While inconclusive, past fracture history appeared to be associated with hip fracture risk (model (1) and (2) in Table). We did not find significant associations of incident hip fractures with gender, smoking, RA duration, the Disease Activity Score in 28 joints, visual analog scale (VAS) for pain, VAS by physician, daily prednisone dose, weekly methotrexate dose, bisphosphonate use, active vitamin D_3 use, biologic use, folic acid use, or proton pump inhibitor use.

Hazard ratios (95% CI) for incident hip fractures: Cox regression models with stepwise selection.

Risk factor	Model (1)	Model (2)
J-HAQ score	2.35 (1.86–2.97)	N/A
J-HAQ score (arising)	N/A	1.65 (1.29–2.11)
J-HAQ score (hygiene)	N/A	1.49 (1.11–2.00)
Age, per 10 years	1.60 (1.31–1.94)	1.61 (1.33–1.96)
History of total knee replacement	3.25 (1.37–7.74)	2.86 (1.20–6.80)
Body mass index, kg/m^2	0.93 (0.87–0.99)	0.91 (0.86–0.97)
Past fracture history	1.51 (0.99–2.30)	1.49 (0.98–2.27)

CI, confidence interval; HAQ, health assessment questionnaire.

Conclusion: High HAQ disability score, old age, history of TKR, and low BMI appear to be associated with incident hip fractures in Japanese patients with RA. Among the 8 domains of the J-HAQ, disabilities of arising and hygiene appear to correlate to incident hip fractures in Japanese RA patients.

The Impact of MKK6 and MKK3 on Physiological Bone Architecture and Postmenopausal Bone Loss. Jean-Paul David[1], Meghan Edgar[2], David L. Boyle[2], Georg Schett[3] and Gary S. Firestein[2]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]UCSD School of Medicine, La Jolla, CA, [3]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: The p38 MAP kinases are known regulator of bone homeostasis. In particular the alpha isoform of p38 (p38a) regulates bone formation by osteoblasts and bone resorption by osteoclasts. The two upstream activators of p38 MAP-kinases, namely MKK3 or MKK6, are interesting targets for bone disease. Recent studies showed that MKK6 deficiency protects from bone destruction in arthritis. We therefore analyzed the bone structure of mice deficient for MKK3 and MKK6 before and after ovariectomy.

Methods: Structural bone parameters, i.e. bone volume per tissue volume (BV/TV), trabecular number and thickness were MKK3 and MKK6 deficient mice were compared to wild type controls using micro-computed tomography analysis. Effect of estrogen withdrawal on the bone parameters of these mice were compared following ovariectomy (OVX) performed on 10 week old mice. All mice were sacrificed at 14 weeks of age. The efficiency of the surgery was confirmed by measuring the levels of circulating luteinising hormone (LH) in the sera of the mice.

Results: A significant increase in bone mass (BV/TV) (MKK3−/−: 61.3±9.8%; MKK6−/−: 87.6±7.3% increase compared to wild type) and trabecular number (MKK3−/−: 46.7±2.6%; MKK6−/−: 84.7±9.6% increase compared to wild type) were found in MKK3- and MKK6-deficient mice, the phenotype being more pronounced in the latter ($p<0.001$ for each). Ovariectomy was performed in order to determine the potential involvement of MKK3 and MKK6 in post-menopausal bone loss. A significant increase in the level of circulating LH was found in the sera of all ovariectomized mice confirming the success of the surgery. In all groups of mice, bone loss was found in the ovariectomized compared to the sham operated mice of the same genotype (MKK3−/−: 51.7±3.7%; MKK6−/−: 37.6±7.5%; wild type: 48.8±3.0% decreased bone mass). Due to the original increase in bone mass, the effect of ovariectomy was less pronounced in MKK6 deficient mice (MKK3−/−: 52.2±11.8%; MKK6−/−: 128.8±27.4% increased bone mass compared to ovariectomized wild type; $p<0.01$) showing a partial protection from bone loss.

Conclusion: MKK3 and MKK6 are negative regulators of bone homeostasis indicating that both kinases mediate the function of p38 MAP-kinases in bone. The pronounced increase in bone mass as well as the resulting partial protection against OVX-induced bone loss in MKK6-deficient mice suggest a more promising potential for pharmacological inhibitors of MKK6 in the treatment of bone loss.

Denosumab Decreases Cortical Porosity in Postmenopausal Women with Low Bone Mineral Density. C. Libanati[1], S. K. Boyd[2], K. K. Nishiyama[2], R. M. Zebaze[3], D. A. Hanley[2], J. R. Zanchetta[4], Thierry Thomas[5], S. Boutroy[6], C. E. Bogado[4], M. Austin[1] and E. Seeman[7]. [1]Amgen Inc., Thousand Oaks, CA, [2]University of Calgary, Calgary, AB, [3]University of Melbourne, Melbourne, Australia, [4]Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina, [5]INSERM U1059 and University Hospital, Saint-Etienne, France, [6]INSERM U831 and Université de Lyon, Lyon, France, [7]Austin and Repatriation Medical Centre, University of Melbourne, Melbourne, Australia

Background/Purpose: Intracortical remodeling, particularly in the cortex adjacent to the marrow cavity, is responsible for most of the bone lost during advancing age.[1,2] Indeed, patients who suffer a hip fracture have large coalescent pores that precipitously compromise bone strength as porosity increases.[3] Denosumab reduces bone remodeling and ovariectomy-induced intracortical porosity in subhuman primates. In postmenopausal women, denosumab rapidly reduces bone remodeling intensity and increases cortical density.[4–6] We propose that this increase in cortical density is the result of (i) partial reversal of intracortical porosity that is present prior to treatment, (ii) reduction in the appearance of new pores by suppression of remodeling, and (iii) more complete secondary mineralization of osteons (which would be

removed had remodeling continued at the same intensity). We now present evidence to support several of these mechanisms.

Methods: Postmenopausal women (N=247) aged 61 ± 5 years with low bone mineral density were randomized in a double-blind, double-dummy fashion to denosumab 60 mg every 6 months (N=83), alendronate 70 mg weekly (N=82), or placebo (N=82). Porosity was evaluated in the compact-appearing cortex of the distal radius at baseline and month 12 from HRpQCT scans using an enhanced method that accurately[7] and reproducibly[8] identifies the cortex with automatic threshold segmentation.[9] Pores above ~82 μm were quantifiable; porosity was expressed as a percent of the total cortical volume.

Results: Baseline cortical porosity at the distal radius was 2.6%. Over 12 months, cortical porosity (mean [95% CI]) increased with placebo (5.19% [1.41, 8.98]) and alendronate (2.86% [–2.32, 8.04]) but decreased with denosumab (–2.98% [–6.39, 0.43]) (Figure). Denosumab reduced cortical porosity by 8.18% ($P < 0.01$) compared with placebo and by 5.84% ($P = 0.06$) compared with alendronate.

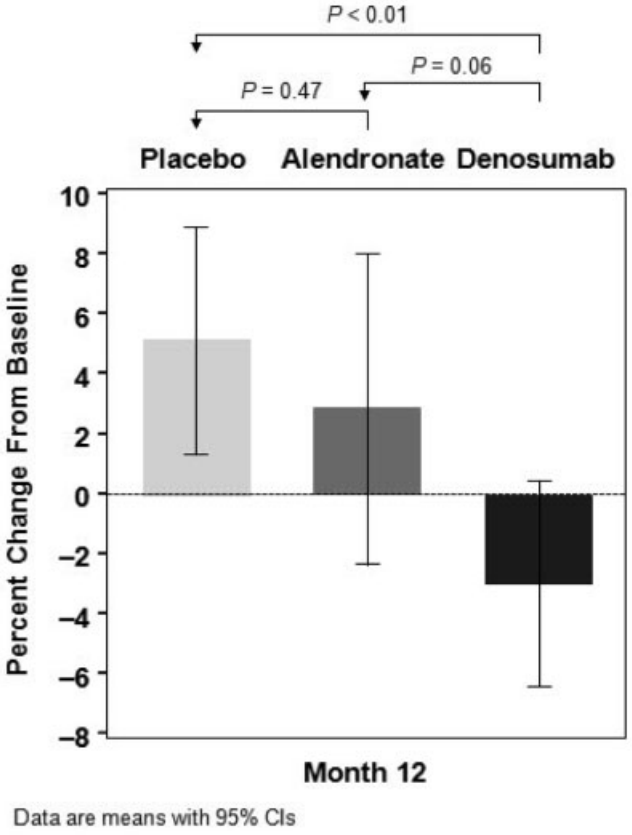

Figure. Denosumab Decreases Cortical Porosity at the Distal Radius in Postmenopausal Women With Low Bone Mineral Density

Conclusion: In summary, denosumab prevented the progression of porosity seen with placebo, an effect that differs from that of alendronate. The changes in porosity are likely to partly reverse bone fragility and prevent its progression and thus reduce fracture risk. Ongoing work exploring non-threshold methods and assessing porosity over the entire cortex, including the trabecularized cortex is underway and may improve quantification of bone morphology and differences between therapies.

Fracture Risk Is Increased in Young Women with Rheumatoid Arthritis. Shreyasee Amin, Sherine E. Gabriel, Sara J. Achenbach, Elizabeth J. Atkinson and L. Joseph Melton III. Mayo Clinic, Rochester, MN

Background/Purpose: Rheumatoid arthritis [RA] is the only cause of secondary osteoporosis singled out in the WHO's fracture [fx] prediction algorithm, FRAX®. Nevertheless, the risk for fx among younger women and men with RA is not well established. We examined the risk for fx by sex and by age at diagnosis in a population-based RA cohort.

Methods: We studied a population-based inception cohort of women and men with RA (age ≥18 yrs) who fulfilled 1987 ACR criteria for RA between 1955–2007 and an equal number of age- and sex-matched controls from the same underlying population, who were followed until death, migration or the present. All incident fxs were identified through a complete review (inpatient and outpatient) of medical records. Excluding fxs resulting from severe trauma, the risk for first osteoporotic fx [OP fx] (hip, spine, wrist and proximal humerus), and for any first fx following their RA diagnosis was compared with their matched control, stratified by sex, using a Cox proportional hazards model, where follow-up time (until death or last follow-up) ended at the first date reached by either within a pair. We then stratified by age at RA diagnosis (<50 yrs, ≥50 yrs). For those <50 yrs with RA, we examined their risk for fx over all available follow-up as well as until age 50 yrs.

Results: In 1155 RA cases, (810 women and 345 men, mean age at RA diagnosis ± SD: 56 ± 16 yrs and 58 ± 14 yrs, respectively), followed for 12,585 person-yrs [p-y], 205 women, (25%, 23 per 1000 p-y), and 67 men, (19%, 19 per 1000 p-y), had an OP fx, while 276 women, (34%, 31 per 1000 p-y), and 87 men, (25%, 24 per 1000 p-y), had any fx. Women and men with RA were at increased risk for fx relative to controls, regardless of age stratification at diagnosis, although did not reach statistical significance in men when stratified by age (see table). When follow-up was limited to age 50 yrs in the 304 women <50 yrs with RA (mean age at RA diagnosis: 39 yrs), the hazard ratio [HR] for OP fx was 6.7 (95% CI:1.5, 29.5), with 13 women having at least one OP fx (7 per 1000 p-y) vs. 2 (1 per 1000 p-y) in matched controls; the HR for any fx was 1.9 (95% CI: 1.04, 3.4), with 31 women with RA having at least one fx (16 per 1000 p-y) vs. 17 (9 per 1000 p-y) in matched controls. In men <50 yrs with RA (N=109, mean age: 41 yrs), too few had a fx before age 50 yrs (N=2 with OP fx; N=5 for any fx) for robust conclusions on fx risk relative to controls.

	Hazard Ratio (95% CI) by Age at RA Diagnosis		
Women	**All**	**<50 yrs**	**≥50 yrs**
OP Fx*	1.7 (1.4, 2.2)	4.3 (2.4, 7.8)	1.4 (1.1, 1.8)
Any Fx*	1.6 (1.3, 1.9)	2.4 (1.6, 3.5)	1.4 (1.1, 1.7)
Men			
OP Fx*	1.6 (1.1, 2.4)	1.4 (0.7, 3.0)	1.8 (1.1, 2.8)
Any Fx*	1.4 (1.02, 1.9)	1.7 (0.9, 3.2)	1.4 (0.9, 2.0)

*excludes any severe trauma fx

Conclusion: Men <50 yrs with RA appear to be at increased risk for future fx, but few fxs occurred before age 50 yrs. Women <50 yrs with RA are not only at high risk for future fx, but their fx risk is increased even before they reach age 50 yrs. Fx prevention strategies for young women with RA are thus important to consider.

Incident Vertebral Fractures (VF) 12 Months After Glucocorticoid (GC) Initiation in Children with Rheumatic Disorders (RD). Bianca A. Lang[1], Celia Rodd[2], David A. Cabral[3], Peter B. Dent[4], Janet E. Ellsworth[5], Adam M. Huber[1], Kristin M. Houghton[3], Roman Jurencak[6], Maggie Larché[4], Claire MA LeBlanc[5], Brian Lentle[3], MaryAnn Matzinger[6], Paivi M. Miettunen[7], Kiem Oen[8], Johannes Roth[6], Claire Saint-Cyr[9], Rosie Scuccimarri[2], Nazih Shenouda[6], Leanne M. Ward[6] and the Canadian STOPP Consortium[10]. [1]Dalhousie University, Halifax, NS, [2]McGill University, Montréal, QC, [3]University of British Columbia, Vancouver, BC, [4]McMaster University, Hamilton, ON, [5]University of Alberta, Edmonton, AB, [6]University of Ottawa, Ottawa, ON, [7]University of Calgary, Calgary, AB, [8]University of Manitoba, Winnipeg, MB, [9]Université de Montréal, Montreal, QC, [10]National Pediatric Bone Health Working Group

Background/Purpose: Compromised bone health is recognized as an important source of morbidity in children with RD. The aims of this study were to determine the frequency of incident vertebral fractures (VF) 12 months after starting GC treatment in a prospectively-followed cohort of children with RD, characterize these VF and examine risk factors for their development.

Methods: Children initiating GC for treatment of RD between January 2005 and December 2007 in ten participating Canadian tertiary pediatric

centers were enrolled in the Steroid-Associated Osteoporosis in the Pediatric Population (STOPP) study. Enrolled patients had baseline (within 30 days of GC initiation) and six monthly BMD studies, as well as x-rays of the thoracolumbar spine at baseline and at 12 months which were evaluated using the Genant semi quantitative method. An incident VF was defined as a new VF or worsening of an existing VF. Patients also had baseline and 3 monthly assessment of medications, including cumulative GC dose, and clinical status including disease activity (10 cm visual analog scale), physical activity (HAES questionnaire), presence of back pain, and vitamin D/calcium intake. Clinical features, including cumulative GC dose, back pain, disease and physical activity, calcium and vitamin D intake, and spine aBMD Z-scores were analyzed for association with incident VF.

Results: Of 136 patients enrolled, data were available on 118 (64% female, median age 10.8 y) at 12 months. Diagnoses included juvenile dermatomyositis (JDM) (23%), juvenile idiopathic arthritis (JIA) (36 %), systemic lupus erythematosus (SLE) and related conditions (18%), systemic vasculitis (14%), and other (9%). At 12 months, 7 patients (6%, 95% CI 2–11%) had 12 incident VF (3 SLE, 2 JDM, 1 vasculitis, 1 mixed connective tissue disease). All incident VF were new fractures; 5 patients had a single VF, one had 2 VF and one had 5 VF. Nine (75%) of the incident VF were thoracic and 11 (92%) had wedge morphology. One child was excluded from the natural history of bone health analyses after 4 months because she received osteoporosis treatment for symptomatic VF. Patients with and without incident VF did not differ with respect to age, gender, pubertal status, disease activity, physical activity, vitamin D/calcium intake or presence of back pain. Children with incident VF received on average 50% more GC than those without ($p=0.030$), had a greater increase in BMI at 6 months ($p=0.010$), and had greater decrements in spine aBMD Z-scores in the first 6 months ($p=0.048$). Four of 6 children (67%) with incident VF and natural history data to 12 months had spine aBMD Z-scores less than −2.0 at 12 months compared to 16% of children without VF ($p=0.011$).

Conclusion: Children with rheumatic diseases exhibited an incident VF rate of 6% at 12 months following GC-initiation. Children with incident VF received more GC, had greater increases in BMI and greater declines in spine aBMD Z-scores in the first 6 months of GC treatment.

Does Identification of Prevalent Vertebral Fracture on Densitometric Vertebral Fracture Assessment (VFA) in Clinical Practice Influence Physician Prescribing Behavior? John T. Schousboe. Park Nicollet Health Services, Minneapolis, MN

Background/Purpose: Densitometric vertebral fracture assessment (VFA) improves estimation of subsequent vertebral fracture risk, and the presence of a vertebral fracture on a lateral spine image is widely considered to be an indication for pharmacologic fracture prevention therapy. Previous studies have shown that selected use of VFA in those having bone densitometry does identify significant numbers of individuals with previously unknown vertebral fracture who otherwise would not be considered candidates for pharmacologic fracture prevention therapy. No prior study has examined whether or not physician prescribing behavior is actually influenced by use of or results of VFA. We hypothesized that in those who do not have osteoporosis by BMD criteria, that performance amd results of VFA will be associated with new prescriptions for pharmacologic fracture medication.

Methods: All individuals who had a VFA with a bone density test between 7/1 2005 and 6/31/2010 were identified from billing records of a large multispeciality clinic. Among the subset of osteopenic individuals (worst T-score between −1.5 and −2.49), we did a nested case control analysis to estimate the association between results of the VFA and commencement of pharmacologic fracture prevention therapy within 90 days of the date of the test. All 108 treatment naïve individuals who were started on therapy to prevent fractures were selected as cases, and 142 who remained off of drug therapy were selecgted as controls. A manual medical record review of the VFA report was done by a person blinded to changes in the person's medications to assess whether or not a possible or definite vertebral fracture was diagnosed. Logistic regression models were done to estimate the association of prevalent vertebral fracture identified on VFA and subsequent commencement of drug therapy to prevent fractures.

Results: Among 9,250 patients with osteopenia, 3,223 treatment naive patients with T-score >-1.5 and ≤ −2.5 also had a VFA at the time of their DXA. Within the nested case control cohort, the associations of predictors with start of drug therapy to prevent fractures were as follows:

Predictor	Odds Ratio (95% C.I.)
Age Category: <65 (reference) 65-74 75+	 1.0 0.31 (0.15 – 0.64) 0.50 (0.24 – 1.07)
Sex (reference is female)	2.65 (1.12 – 6.26)
Prior Fracture	0.80 (0.42- 1.53)
Current Use of Glucocorticoid Rx	1.55 (0.57 – 4.24)
VFA negative (reference) Possible Vertebral Fracture Definite Vertebral Fracture	1.00 2.89 (1.18 – 7.05) 2.08 (0.98 – 4.41)

Of an estimated 158 patients in the entire cohort of 3223 who had a prevalent vertebral fracture, only 24 (14.3%) were started on drug therapy to prevent fractures.

Conclusion: Diagnosis of a possible or definite prevalent vertebral fracture at the time of a bone density test among those without osteoporosis is associated with subsequent prescription of drug therapy to prevent fractures, but the majority of those with a prevalent vertebral fracture but without osteoporosis by BMD criteria are not being treated.

Impaired Lymphatic Vessel Maturation in Mice with TNF-Induced Inflammatory Arthritis. Qianqian Liang[1], Ronald Wood[2], Brendan Boyce[1], Edward M. Schwarz[1] and Lianping Xing[1]. [1]University of Rochester, Rochester, NY, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY

Background/Purpose: Lymphangiogenesis occurs in response to joint inflammation, limiting the severity of synovitis. Arthritis overwhelms this process, but the mechanism is unknown. Lymphatic vasculature is composed of primary capillaries and mature vessels, which have different morphology, structural composition, and functions. Lymphatic capillaries are composed of LYVE-1+ endothelial cells, while mature lymphatic vessel endothelial cells are LYVE-1-, covered by smooth muscle actin+ cells, and contain valves for the uni-directional lymph flow. Thus, proper lymphatic vessel maturation is essential for efficient lymph drainage. The effects of joint information on lymphatic vessel maturation have not been studied. We hypothesize that lymphatic vessels in arthritic joints are abnormal, resulting in insufficient lymphatic drainage to local lymph nodes, which aggravates chronic synovitis. We tested this hypothesis using a combination of functional, morphologic, and biochemical approaches in TNF-Tg mice that develop chronic inflammatory arthritis.

Methods: TNF-Tg mice (1, 2.5 and 5-m-old, N=4–10 mice/genotype) and WT littermates were used. Lymphatic draining function from the footpad to popliteal lymph nodes (PLN) were assessed by near-infrared (NIR) indocyanine green (ICG) lymphatic imaging. Lymphatic capillaries (LYVE-1+), mature lymphatic vessels (SMA+/CD31+), and lymphatic valves (Intergrin-9+) in ankle tissues were identified using whole mount immunostaining. Expression of *angiopoietin 1 and 2*, and *forkhead box protein C2*, genes that are known to regulate lymphatic vessel maturation and valve formation were examined by real time qPCR.

Results: NIR-ICG imaging showed no difference in lymphatic draining function between pre-arthritic 1-month-old TNF-Tg and WT mice. However, a clear defect in lymphatic drainage was observed in 2.5-month-old TNF-Tg mice with severe ankle arthritis. The time to initial ICG detection in lymphatic vessels following footpad injection (T-initial) was significantly longer in TNF-Tg mice (13±5 vs 8±2 min in WT; $p<0.05$). The ICG clearance from the footpad was significantly decreased (%clearance: 64±12 vs 92±5

p<0.05) in TNF-Tg vs WT mice. ICG leakage from the lymphatic vessels was observed in 7 of 9 legs of TNF-Tg mice >5-month old, but not in WT mice. Whole mount immuno-staining revealed altered lymphatic vasculature in the foot of TNF-Tg mice: increased diameter of LYVE-1+ lymphatic capillaries (48±5 vs 37±4 μm p<0.05) and decreased smooth muscle actin+ cell coverage of mature lymphatic vessels (65±2 vs 86±1% p<0.05) vs WT. No differences in structure of lymphatic valves between TNF-Tg and WT mice were observed. Real-time qPCR demonstrated a 6-fold reduction in *angiopoietin 2* expression in foot skin of TNF-Tg vs WT mice, while changes in *angiopoietin 1* were reduced 2-fold.

Conclusion: Ankle inflammation in TNF-Tg mice inhibits lymphatic vessel maturation, resulting in decreased smooth muscle actin+ cell coverage and leakage, thereby reduced draining function. Identification of factors and mechanisms that regulate lymphatic vessel maturation in inflammation may lead to a new lymphatic-based therapy for chronic inflammatory arthritis.

A Distinct Tolerogenic Subset, Splenic IDO+CD11b+Dcs From Orally Tolerized Mice Suppresses Collagen-Induced Arthritis. Min Jung Park[1], Kyung-Su Park[1], Mi-La Cho[1], Ji-Min Kim[2], Sang Heon Lee[3] and Ho Youn Kim[4]. [1]The Catholic University of Korea, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, South Korea, [3]Division of Rheumatology, Seoul, South Korea, [4]Rhematism Research Center, Seoul, South Korea

Background/Purpose: To define the systemic immunoregulatory effect of dendritic cells (DCs) expressing Indoleamine 2,3-dioxygenase (IDO), we examined the characteristics of splenic DCs after induction of oral tolerance in collagen-induced arthritis (CIA) mice.

Methods: Oral tolerance was induced by feeding bovine CII 6 times, beginning 2 weeks before the first immunization to induce CIA. Splenic cells, DCs and Tregs purified by magnetic-activated cell sorting (MACS) were analyzed by FACS. IDO activity was measured by enzyme assay, and its expression was assessed by 1-methyl tryptophan (1-MT) treatment. CD11b+DC and IDO expression on splenic tissues were examined by a confocal microscopy.

Results: CD11b+ subset of the splenic DCs was a major contributor to IDO expression in tolerized CIA group. The IDO+DCs which express low level of CD80 were strongly induced after stimulation with CII antigen. The IDO+CD11b+DCs effectively induced the differentiation of Tregs, along with increased expression of CTLA-4 and programmed death 1 (PD-1), in the presence of CII antigen. When adoptively transferred into untolerized CIA mice, tolerized CD11b+DCs suppressed the development of arthritis. The suppression was correlated with the increase in IDO expression and Treg/Th17 ratio, and with the decrease in serum levels of IL-1b, IL-6, IL-21 and TNF-a.

Conclusion: A distinct splenic subset, IDO+CD11b+DC was induced after induction of oral tolerance and exerted tolerogenic effect in the systemic immune regulation.

Collagen Triple Helix Repeat Containing 1 Protein Is a New Synovial Lining Biomarker Overexpressed in Antibody-Mediated Arthritis. Mohammed Talha Shekhani[1], Toni S. Forde[1], Anne S. Cuttler[2], Volkhard Lindner[2] and Vyacheslav A. Adarichev[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Maine Medical Center Research Institute, Scarborough, ME

Background/Purpose: Hypertrophy of the synovial membrane accompanied by enhanced cell invasiveness and boosted production of cartilage and bone degrading enzymes are a hallmark of rheumatoid arthritis (RA). To find new synovial biomarkers whose expression is affected by sex, and to dissect mechanisms of higher female preponderance in RA, we generated congenic murine strain carrying sex-affected arthritis-protective locus Pgia8a.

Methods: To induce arthritis, mice were injected i.p. with cocktail of mAbs to collagen type II followed by LPS stimulation. Differential gene expression analysis of RNA isolated from arthritic paws was performed using Affymetrix GeneChip® Mouse Gene 1.0 ST Array. Collagen Triple Helix Repeat Containing 1 (Cthrc1) transgenic mice FVB-Tg[Cthrc1] were crossed to BALB/c strain to generate mice carrying the discovered sex-affected differentially-expressed Cthrc1 gene in inflammatory-susceptible genetic background. Immunohistochemical staining was performed to identify Cthrc1 in synovial joints and investigate whether the protein expression co-localizes with fibroblast-like and macrophage-like synoviocyte markers.

Results: Using transcriptome analysis, we found that arthritis severity in congenic males is under the control of Cthrc1, Adamts12 and C1qtnf3 locus-specific genes whose expression was tightly correlated with inflammation, r>0.87. Genetic association between Cthrc1 and arthritis was replicated in F1(BALB/c x FVB-Tg[Cthrc1]) mice that showed 30% stronger inflammation than Tg-negative F1 hybrids. Even naïve Tg[Cthrc1] mice exhibited pre-inflammatory phenotype of neutrophilia (30% up, p<0.014) accompanied with peripheral monocytopenia (50% down, p<0.025) and longer blood coagulation time. Immunohistochemical staining of sections of articular joints confirmed a highly inducible pattern of Cthrc1 protein expression, which we observed initially at RNA level using RT-PCR. Importantly, Cthrc1 was localized in synovial lining of arthritic mice, and protein expression was co-localized with pannus development. In synovium of naïve mice, Cthrc1 was almost undetectable. In transgenic mice, protein was expressed in synovial lining even in naïve mice, which might partially explain a stronger arthritis in F1-Tg[Cthrc1] mice when compared to Tg-negative F1 hybrids. Co-localization of Cthrc1 with fibroblast, macrophage and T cell markers is in progress.

Conclusion: Secreted promigratory protein Cthrc1 is a novel biomarker for inflammatory arthritis and hypertrophic synovial lining. When Cthrc1 protein is overexpressed in transgenic mice, it affects multiple systems including blood cell composition, and both normal and inflamed synovium.

1638

Intra-Articular Injection of the Selective IκB Kinase β Inhibitor NEMO-Binding Peptide Ameliorates Collagen Induced Arthritis by Inducing Regulatory T Cells and Alternatively Activated Macrophages. Soyoun Min[1], Mei Yan[1], Yong Du[1], Cristina Arriens[1], Tianfu Wu[1] and Chandra Mohan[2]. [1]University of Texas, Southwestern Medical Center at Dallas, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: Nuclear factor (NF)-kB is a transcription factor that is critical in the pathogenesis of various autoimmune disorders including rheumatoid arthritis (RA). To examine whether local NF-κB inhibition had efficacy in reducing inflammation in collagen induced arthritis (CIA) without systemic immune suppression, we tested intra-articular delivery of an IKK inhibitor, NEMO-binding domain peptide (NBP).

Methods: NBD peptides were injected intra-articularly into the knee joint of DBA1 mice (N = 6) (150ug/joint) at the onset of disease, while the control mice were administered a scrambled peptide. The severity of arthritis was determined by visual examination of the paws, and the mice were sacrificed 6 weeks after the first immunization. Joint specimens were examined for pathology. Serum levels of anti-collagen antibodies and cytokine production were measured by ELISA. The induction of regulatory T cells and macrophage were assessed by flow cytometry analysis and immunofluorescence staining.

Results: Intra-articular NBD injection ameliorated the severity of arthritis scores (9.0 ± 1.1 vs 5.5 ± 0.7 U, P < 0.01) and reduced bone destruction on histological analysis, compared to vehicle injected mice. The serum concentrations of type-II collagen-specific IgG2a antibodies were significantly lower in NBD-treated mice compared to vehicle-treated mice (0.379 ± 0.05 vs 0.125 ± 0.01 OD units, P < 0.05), whereas the levels of type-II-collagen-specific IgG1 antibodies were mildly increased by NBD treatment. NBD treatment also diminished serum pro-inflammatory cytokines including IFN-g and IL-17 while the regulatory cytokine IL-10 was increased in sera. NBD-treated CIA mice had significantly higher percentages and numbers of $CD4^+CD25^+$ cells in dLN compared to the control (4.1 % ± 0.3 vs 0.41 % ± 0.1, P < 0.01). Furthermore, $CD4^+$ cells from dLN of NBD-treated CIA mice expressed higher levels of Foxp3than those isolated from dLN of control CIA mice. Immunohistochemical analysis of NBD treated mice revealed that Foxp-3 and Ym-1 (a marker of alternatively activated macrophages) were present and adjacent to each other within dLNs, compared to control CIA-subjected mice.

Conclusion: These results indicate that IKK-β-targeted NF-κB blockade using the NBD peptide appears efficacious as a local intra-articular therapy for arthritis, potentially reducing unwanted systemic effects. Together these data demonstrate that NF-kB inhibition promote induction of $CD4^+CD25^+$ T reg cells and alternatively activated macrophages, which together may confer therapeutic benefit in inflammatory arthritis.

1639

Inflammatory Arthritis in Mice Is Dependent on the Mast Cell-Restricted Signaling Protein Ras Guanine Nucleotide Exchange Protein 4 (RasGRP4). Richard Stevens[1], Roberto Adachi[2], Peter A. Nigrovic[3], Matthew J. Hamilton[3] and Steven Krilis[4]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]University of Texas M. D. Anderson Cancer Center, Houston, TX, [3]Brigham and Women's Hospital, Boston, MA, [4]St George Hospital, Kogarah NSW, Australia

Background/Purpose: Ras guanine nucleotide exchange protein-4 (RasGRP4) is a calcium-regulated, guanine nucleotide exchange factor and diacylglycerol/phorbol ester receptor that is expressed in human, rat, and mouse mast cells (MCs), and their circulating progenitors. Although the other three members of this family of intracellular signaling proteins participate in the development of T cells, B cells, and platelets, the importance of RasGRP4 in the development and function of MCs has not been elucidated. We created a transgenic RasGRP4-null C57BL/6 mouse to deduce the possible role(s) of this evolutionarily conserved signaling protein in MC-dependent inflammatory diseases.

Methods: A targeting construct was prepared in which the Cre gene was placed at the translation-initiation site of the 17-exon, 19-kb mRasGRP4 gene. To ensure that no functional RasGRP4 protein could be expressed in the resulting transgenic mice, the first 8 exons of the gene were deleted, including those nucleotides that encode the protein's guanine nucleotide exchange domain. Using homologous recombination methods and C57BL/6 mouse embryonic stem cells, a RasGRP4-null mouse was obtained which was then backcrossed 10 times with wild-type (WT) C57BL/6 mice to eliminate possible nonspecific mutations created during the homologous recombination step. The resulting transgenic mouse line was characterized and then subjected to inflammatory arthritis induced by K/BxN mouse serum.

Results: RasGRP4-null C57BL/6 mice were healthy and contained normal numbers of granulated MCs in their tissues that histochemically resembled those in WT C57BL/6 mice. Thus, RasGRP4 is not essential for the Kit-dependent development of tissue MCs. Immature MCs (mBMMCs) could be generated from RasGRP4-null mice by culturing their bone marrow cells for 4–6 weeks in IL-3 enriched conditioned media in the presence or absence of Kit ligand. Nevertheless, microarray analysis of IL-3-developed mBMMCs revealed altered expression of numerous transcripts compared with WT mBMMCs. Exposure of IL-3-developed RasGRP4-null mBMMCs to calcium ionophore resulted in the release of the cell's preformed mediator β-hexosaminidase and increased expression of tumor necrosis factor-α and other cytokines and chemokines, as occurs in calcium ionophore-treated WT mBMMCs. Although the latter data revealed that signaling pathways downstream of RasGRP4 are intact and functional in MCs, arthritis was reduced >90% in RasGRP4-null mice that had received K/BxN mouse serum relative to similarly-treated WT mice. In support of these inflammatory arthritis data, MC-dependent colitis also was reduced in RasGRP4-null mice.

Conclusion: The exciting finding that RasGRP4 is essential in inflammatory arthritis in mice suggests that the pharmaceutical inactivation of this signaling protein might be of efficacy in the treatment of patients with inflammatory arthritis and other MC-dependent disorders.

The CYLD/IKKbeta Axis Functions in Synovial Fibroblasts to Regulate TNF-Driven Arthritis. Maria Armaka[1], Manolis Pasparakis[2], George Mosialos[3] and George Kollias[1]. [1]Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece, [2]Institute for Genetics, Centre for Molecular Medicine, University of Cologne, Cologne, Germany, [3]School of Biology, Aristotle University of Thessaloniki, Thessaloniki, Greece and Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece

Background/Purpose: Synovial fibroblasts (SFs) are major cellular players in rheumatoid arthritis. We have shown previously in the human TNF transgenic (TghuTNF, Tg197) model of inflammatory polyarthritis that SF targeting by TNF is sufficient for the orchestration of the complete pathogenic process. Here, we have sought to identify SF-specific TNF-driven signaling pathways with physiological roles in the arthritogenic process. The deubiquitinating enzyme (DUB) CYLD is a tumor suppressor protein known for its role in repression of NF-kB and MAPK activation. The aim of this study was to assess the role of SF-specific ablation of the DUB CYLD and/or the NF-kappaB-related kinase, IKKbeta, in the development of arthritis in the TghuTNF model.

Methods: ColVI-Cre mice providing floxed-allele recombination specificity for SFs were crossbred into the TghuTNF, CYLD and/or IKKbeta conditional knock-out backgrounds. Histological analysis of synovial inflammation, as well as cartilage and bone destruction was performed in week 4, 8 and 14. SF cultures were generated in order to study the TNF-mediated responses of gene-deficient SFs by RT-PCR, western blot and FACS analysis.

Results: TNF stimulation of CYLD-deficient SFs revealed that CYLD negatively regulates NF-kappaB whereas it does not affect MAPK responses of SFs. As a consequence, the expression profile of arthritis-related NF-kappaB-regulated genes was affected. Notably, the TghuTNF ColVI-Cre CYLD$^{f/f}$ mice show exacerbations of the arthritic phenotype over controls as early as 4weeks of age with profound synovial inflammation and cartilage degradation. Significant exacerbations over controls were also evident at the age of 8 weeks with intense TRAP activity in the joint area and complete loss of joint architecture. SFs from these mice showed a stronger activation phenotype exhibiting upregulation of VCAM-1, ICAM-1, high gelatinase activity and deregulated inflammatory gene expression compared to their non-Cre littermate controls. Furthermore, we show that TghuTNF ColVI-Cre IKKbeta$^{f/f}$ mice exhibit attenuated arthritic manifestations and that concomitant loss of both CYLD and IKKbeta expression in SFs from TghuTNF mice also results in the amelioration of the arthritic phenotype.

Conclusion: Our results demonstrate a physiologically significant role of the CYLD/IKKbeta pathway in modeled arthritis by showing that in TghuTNF mice the CYLD/IKKbeta axis regulates SF–specific arthritogenic responses downstream of TNF.

Background/Purpose: Rituximab (RTX) might result in decreased serum immunoglobulin levels, in a proportion of patients with rheumatoid arthritis (RA) increasing with the number of RTX cycles. Very limited real life data are available regarding the risk of serious infections in patients who develop hypogammaglobulinemia after RTX. The present study aimed to investigate the association between low gammaglobulin levels after RTX and the occurrence of serious infections.

Methods: The 5-year prospective and multicenter AIR registry has been set up by the French Society of Rheumatology in 2006. Serious adverse events, including serious infections (which require either hospitalization or intravenous antibiotics) are validated by two investigators using chart copies.

Results: Among the 2000 patients with RA included in the AIR registry, gammaglobulin, IgM or IgG after RTX levels were collected in 1146 (57.3%), 1148 (57.4%) and 1150 (57.5%) patients, respectively. Low levels after RTX (gammaglobulins <6g/l, IgM<0.5g/l, or IgG<6g/l) were observed in 178 (15.5%), 306 (26.6%), and 139 (12.1%) patients. Serious infections occurred in 24 patients (13.5%) with a low gammaglobulin level after RTX and in 85 (8.8%) patients with a normal gammaglobulin level, resulting in 6.3 vs 4.6 serious infections/100 patient/years (4.9 serious infections/100 patient/years in the whole population who had a gammaglobulin assessment after RTX). Serious infections occurred in 36 (11.8%) patients with a low IgM level and in 68 (8.1%) patients with a normal IgM level, resulting in 5.5 vs 4.3 serious infections/100 patient/years (4.7 in all patients

with IgM assessment after RTX). Serious infections occurred in 21 patients (15.1%) with a low IgG level and in 83 (8.2%) patients with a normal IgG level, resulting in 10.0 vs 3.8 serious infections/100 patient/years (6.2 serious infections/100 patient/years in all patients with IgG assessment after RTX). In univariate analysis adjusted on follow-up duration, only low IgG after RTX was associated with an increased risk of serious infections(OR 1.99 95% CI [1.2–3.3], P= 0.008), but not low gammaglobulin (OR 1.5 95% CI [0.9–2.5], P= 0.09) or low IgM level (OR 1.5 95% CI [0.9–2.3], P= 0.08). Preliminary results showed that hypoIgG after RTX was associated with an older age, history of cancer or of serious or recurrent infections. In multivariate analysis taking into account these latter parameters, low IgG after RTX remained associated with the risk of serious infections.

Conclusion: Converse to low gammaglobulin or low IgM level, low IgG after RTX is associated with a significant increase in the risk of serious infections in common practice. This had not been reported in long term extension phases of controlled trials, maybe due to the limited comorbidities of patients included. These results confirm that serum IgG level should be checked after RTX and the benefice/risk balance of retreatment with RTX discussed for each patient with low IgG level after RTX.

1642

Risk Factors for Major Adverse Cardiovascular Events in Rheumatoid Arthritis Patients Treated with Tocilizumab. Vijay Rao[1], Andrey Pavlov[2], Micki Klearman[1], David Musselman[3], Jon T. Giles[4], Joan M. Bathon[4], Naveed Sattar[5] and Janet S. Lee[3]. [1]Genentech, San Francisco, CA, [2]Everest, Toronto, [3]Roche, Nutley, NJ, [4]Columbia University Medical Center, New York, NY, [5]University of Glasgow, Glasgow, United Kingdom

Background/Purpose: To examine the associations of lipids, inflammation, and rheumatoid arthritis (RA) disease activity measures with risk for cardiovascular events in moderate to severe RA patients treated with tocilizumab (TCZ).

Methods: Post-hoc analyses of the combined data from 5 pivotal TCZ phase-III trials and long-term extension periods were conducted in a stepwise fashion. First, demographic, laboratory, and disease characteristics were compared for patients with (n = 42) and without (n = 3944) major adverse cardiovascular events (MACE: non-fatal myocardial infarction, non-fatal stroke, or death due to cardiovascular cause) determined by independent, blinded adjudication. Univariate Cox proportional hazard modeling was performed to evaluate potential risk factors for MACE at baseline (BL) and post-BL (wk 24) with time to MACE as the time variable. Multivariate Cox proportional hazard models were also fit to obtain best prediction of time to MACE. Statistically significant predictors were considered as those with $P<0.05$.

Results: For all MACE events occurring during TCZ exposure including open-label extension treatment, univariate modeling revealed BL age, history of coronary artery disease (CAD), disease activity (DAS28), total cholesterol/HDL ratio, and albumin as predictive characteristics (P<.05), but only age and history of CAD consistently remained predictive in a series of multivariate sensitivity analyses. Neither reductions in measurements of inflammation (CRP and ESR), nor increases in lipid parameters at 24 wks were associated with MACE on TCZ therapy. Additional Cox models employing single predictors and adjusting for BL age revealed that the following wk 24 outcomes were statistically significant predictors of future MACE: DAS28 based scores (DAS28, AUC of DAS28, EULAR response), TJC, SJC, and Patient Global Assessment (Table). Additionally, greater reductions in DAS28 score from BL to wk 24 were inversely associated with MACE, after adjusting for age and BL DAS28 score (Table).

Univariate Associations Between RA Parameters and MACE, Adjusted for Age at Baseline

Disease Activity Assessments at Week 24	Age-adjusted Hazard Ratio (95% CI)	P Value
# Swollen Joints (28)*†	1.101 (1.055, 1.149)	<0.0001
DAS28 score†	1.482 (1.201, 1.828)	0.0002
# Tender Joints (28)†	1.069 (1.030, 1.110)	0.0005
EULAR (Good vs. No Response)	0.219 (0.084, 0.569)	0.0018
Reduction from baseline in DAS28†‡	0.704 (0.556, 0.891)	0.0036
AUC of DAS28 to week 24, score-years	2.154 (1.208, 3.840)	0.0093
Patient Global Assessment Score, mm†	1.015 (1.002, 1.028)	0.0256

* Interpretation of HR: After adjustment for age, one additional SJC at week 24 is associated with an increased 10.1% hazard for MACE.
† Observed values; LOCF for missing SJC or TJC at Week 24
‡ Also adjusted for baseline DAS28 score.

Conclusion: Traditional cardiovascular risk factors at BL (history of CAD, total cholesterol/HDL ratio, and albumin), as well as disease activity parameters are associated with MACE for patients on TCZ therapy. Only age and CAD history remained statistically significantly associated with MACE on multivariate analysis of BL characteristics. Further, in this on-treatment analysis, risk of MACE was broadly linked to elevated disease activity at BL and a less robust therapeutic response at week 24. There was no association between lipid change and risk for MACE. We hypothesize that mitigating cardiovascular risk in RA patients may require a multifaceted approach that includes effective control of RA disease activity.

Role of study sponsor: This study was funded by Roche. Support for third-party writing assistance for this abstract was provided by F. Hoffmann-La Roche Ltd.

B Cell Repopulation and Rheumatoid Factor Predict Duration of Response to Rituximab in Rheumatoid Arthritis. Edward M. Vital[1], Sudipto Das[2], Shouvik Dass[1], Maya H. Buch[3], Frederique Ponchel[1], Andrew Rawstron[1] and Paul Emery[4]. [1]NIHR Leeds Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom

Background/Purpose: Duration of response to rituximab in rheumatoid arthritis is variable. It is currently unclear whether fixed or on-demand retreatment produces better overall long term outcomes. Predictors of time to relapse may therefore be valuable. We investigated known predictors of response to rituximab to test whether they could predict sustained response to 12 months.

Methods: 104 rituximab-treated patients pooled from 3 clinical trials were analysed and results from 78 patients with EULAR response at 6 months used. All protocols restricted NSAID and corticosteroid use similarly. DAS28 and EULAR response criteria were measured at 0, 14, 26 and 40 weeks. Patients who had relapsed by worsening EULAR criteria were retreated. Naive and memory B and plasmablast subsets were measured by highly sensitive flow cytometry (as previously described) at 0, 2, 6, 14, 26 and 40 weeks.

Results: Of the 78 patients with response at 6 months, 57% had moderate response (MOD) and 43% had good response (GOOD). In patients with detectable B cells at 6 months DAS28 worsened by mean(SD)0.45(1.06), whereas in patients with undetectable B cells DAS28 improved by mean 0.44(0.45), p<0.001 between groups. At 12 months NR/RT, MOD, GOOD rates were 51, 28, 21%. We tested a binary logistic regression model including B cell detection, level and RF, IgG and DAS28 for prediction of continued EULAR response at 12 months, which produced a significant model (p=0.001) with overall accuracy 70.4% (see table).

Prediction of EULAR Moderate or Good Response at 12 months

Variable	Odds Ratio	CI	p
Rheumatoid Factor (per IU/mL)	0.996	0.992–0.999	0.02
IgG (per g/L)	0.990	0.828–1.183	0.91
DAS28	0.582	0.343–0.988	0.04
B cells detectable (Y/N)	0.211	0.033–1.363	0.10
Plasmablast count	1.271	0.844–1.914	0.25

Based on these results we also tested a simplified two-variable categorial model with RF and DAS28 using thresholds of 108 IU/mL and 3.7 (derived from ROC analysis) as predictive of relapse, which also produced a significant model with overall accuracy 69%(p=0.001). Response rates at 12 months by these two criteria were as follows: DAS28<3.7 and RF<108 (n=30): 73%; DAS28>3.7 and RF<108 (n=15):53%; DAS28<3.7 and RF>108:35%; DAS28>3.7 and RF>108:8%.

Conclusion: Following an initial response to rituximab at 6 months, many patients lose response over the next 6 months. This may be predicted at 6 months by B cell repopulation and rheumatoid factor, after correcting for disease activity. These findings need to be validated, but may allow for selection of retreatment regime based on B cell biomarkers.

1644

Is Screening for JC-Polyomavirus by PCR or Detection of Antibodies Useful in Patients with Rheumatic Diseases Who Are Treated with Rituximab? Jens Verheyen[1], Eugen Feist[2], Kseniya Maizus[1], Zebulon Tolman[1], Elena Knops[1], Tim Waterboer[3], Gerd R. Burmester[4], Michael Pawlita[3], Herbert Pfister[1] and Andrea Rubbert[1]. [1]University of Cologne, Cologne, Germany, [2]Charité Medical School, Berlin, Germany, [3]German Cancer Research Center, Heidelberg, Germany, [4]Charité University Medicine, Berlin, Germany

Background/Purpose: Monoclonal antibodies like Natalizumab and Efalizumab have been associated with an increased risk of progressive multifocal leukoenzephalopathy (PML), which is caused by reactivation of the human JC-polyomavirus (JCPyV). However, the impact of Rituximab (RTX) treatment on JCPyV replication and the development of PML is less clear. The present study was undertaken to analyse patterns of JCPyV infections in patients with rheumatic diseases treated with Rituximab.

Methods: Urine and blood samples were obtained from 64 patients with rheumatic diseases receiving RTX treatment. None of the patients developed neurological symptoms suggestive of PML at any timepoint during the observation period. In 49 cases multiple urine samples could be anaylsed, including baseline samples before the start of RTX treatment (n=20). Blood samples were tested for the presence of JCPyV-DNA and serum antibodies in most patients at a single time point. Antibodies to JCPyV VP1 were detected using a GST-capture ELISA in combination with fluorescent bead technology. JCPyV genotyping (n=23) was performed by amplifying and sequencing the control region and VP1.

Results: In patients, from whom samples were available at baseline (before the start of rituximab treatment) and during follow-up, JCPyV DNA detection stayed either negative (n=13) or positive (n=5) during the observation period (2.0+/−0.9 RTX cycles, 630+/−323 days) in most patients. Interestingly, in two patients, even though initially tested positive, JCPyV DNA detection was negative after the start of RTX treatment.

Urine samples from patients already pretreated with Rituximab (n=44, 3.1+/−1.9 RTX cycles) were tested positive in 17 cases. During the follow up period before and after additional RTX cycles (n=29, 1.1+/−0.3) JCPyV DNA detection remained stable either positive (n=11) or negative (n=15) in most patients. In two patients after one RTX cycle, one negative and multiple positive JCPyV DNA results were obtained. Only in one patient the JCPyV DNA detection switched to positive after two additional RTX cycles.

Patients constantly shedding JCPyV DNA in the urine (n=15) had significant higher JCPyV antibody titers in the blood than patients who always tested negative (n=24). Nevertheless in two cases antibody titers were low despite the detection of JCPyV in the urine and vice versa high in six patients without detectable JCPyV DNA.

JCPyV DNA was only once detected in the blood of one patient. JCPyV isolates obtained from urine and blood could be assigned to four different genotypes according to the VP1 sequences but did not harbour any mutational patterns in the control region associated with PML.

Conclusion: The patterns of JCPyV infections do not seem to be influenced by the Rituximab treatment in patients with rheumatic disorders. According to our results, routine screening of patients for the presence of replicating JCPyV or serum antibodies does not seem to be warranted.

1645

Efficacy of Different Doses of Rituximab for the Treatment of Rheumatoid Arthritis: Data From the CERERRA Collaboration. Katerina Chatzidionysiou[1], Elisabeth Lie[2], Evgeny L. Nasonov[3], Galina Lukina[3], Merete L. Hetland[4], Ulrik Tarp[5], Ioan Ancuta[6], Karel Pavelka[7], Dan C. Nordström[8], Cem Gabay[9], Helena Canhao[10], Matija Tomsic[11], Piet LC van Riel[12], Juan J. Gomez-Reino[13], Tore K. Kvien[2] and Ronald F. van Vollenhoven[1]. [1]Karolinska Institute, Stockholm, Sweden, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]ARBITER, Institute of Rheumatology, Moscow, Russia, [4]Copenhagen University Hospital at Glostrup, on behalf of DANBIO, Copenhagen, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Cantacuzino Hospital, Bucharest, Romania, [7]1Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [8]ROB-FIN, Helsinki University Central Hospital, Helsinki, Finland, [9]for the SCQM registry, University Hospitals of Geneva, Geneva, Switzerland, [10]Lisbon Medical Academic Medical Center on behalf of Rheumatic Diseases Portuguese Register, Lisbon, Portugal, [11]University Medical Centre Ljubjana, Ljubljana, Slovenia, [12]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [13]Hospital Clinico Universitario, Santiago, Spain

Background/Purpose: The approved dose of RTX in RA is 1000mg ×2, but some data have suggested similar clinical efficacy with 500mg ×2. The purpose of this analysis was to compare the efficacy of the two dosages given as first or second treatment course.

Methods: Ten European registries submitted anonymized datasets with demographic, efficacy and treatment data for patients who had started RTX. Efficacy of treatment and retreatment was assessed based on DAS28 reductions and EULAR responses after 6 months.

Results: Data on RTX dose were available for 2873 out of 3266 patients in CERERRA. 2625 (91.4%) and 248 (8.6%) patients received 1000mg ×2 and 500mg ×2, respectively. Patients who were treated with the lower dose (LD) were significantly older (mean±SD: 55.2±15.8 vs. 52.6±12.6, yrs, p=0.002), had longer disease duration (13.6±11.9 vs. 10.9±8.2, yrs, p<0.0001), higher number of prior DMARDs (2.6±1.3 vs. 2.4±1.4, p=0.04) but lower number of prior biologics (0.7±0.9 vs. 1.0±1.0, p<0.0001) and lower baseline DAS28 (5.7±1.3 vs. 5.9±1.3, p=0.02) than those treated with the higher dose (HD). Additionally they were less likely to receive concomitant DMARDs (72.6% vs. 83.1%, p<0.0001) but more likely to receive concomitant corticosteroids (65.7% vs. 59.3%, p=0.03).

Both dosages lead to significant clinical outcomes at 6 months. Patients with the HD achieved numerically slightly greater DAS28 reductions at 6 months compared to those treated with the LD (mean DeltaDAS28±SD = 1.9±1.4 vs. 1.7±1.4, p=0.5 corrected for baseline DAS28). Similar percentages of patients achieved EULAR good response (55.2% vs. 50%, p=NS) and remission (10.5% vs. 10.7%, p=NS) in the HD and LD groups, respectively.

At 6±1.5 months 579 patients received retreatment with HD RTX and 26 patients with LD. Patients who received a different dose at retreatment than at first treatment, as well as patients who were retreated at different time points during the first year, were disregarded from the analysis. Retreatment with HD led to even greater DAS28 reductions at 12 than at 6 months (DeltaDAS28 6m = 1.85±1.19, DeltaDAS28 12m = 2.52±1.47, p by paired t-test <0.0001), while retreatment with LD led to no significant further DAS28 reduction (6m = 1.61±1.41, 12m = 1.27±1.78, p=0.2). A significantly higher good responders rate was observed for the HD of RTX in retreated patients (60.7% vs. 32.1%, p=0.003).

Conclusion: In this large observational cohort initial treatment with RTX at 500 mg ×2 and 1000 mg ×2 led to comparable clinical outcomes. The HD was associated with further DAS28 reductions when given as a second treatment course.

1646

Seropositivity and Response to RTX: Data From the CERERRA Collaboration. Katerina Chatzidionysiou[1], Elisabeth Lie[2], Evgeny L. Nasonov[3], Galina Lukina[3], Merete L. Hetland[4], Ulrik Tarp[5], Ioan Ancuta[6], Karel Pavelka[7], Dan C. Nordström[8], Cem Gabay[9], Helena Canhao[10], Matija Tomsic[11], Piet LCM Van Riel[12], Juan J. Gomez-Reino[13], Tore K. Kvien[2] and Ronald F. van Vollenhoven[1]. [1]Karolinska Institute, Stockholm, Sweden, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]ARBITER, Institute of Rheumatology, Moscow, Russia, [4]DANBIO, Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Cantacuzino Hospital, Bucharest, Romania, [7]1Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [8]ROB-FIN, Helsinki University Central Hospital, Helsinki, Finland, [9]for the SCQM registry, University Hospitals of Geneva, Geneva, Switzerland, [10]Hosp Santa Maria, Lisbon, Portugal, [11]University Medical Centre Ljubjana, Ljubljana, Slovenia, [12]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [13]Hospital Clinico Universitario, Santiago, Spain

Background/Purpose: Predictors of response to biologic therapy in rheumatoid arthritis (RA) are needed to achieve a more individualized therapy. Seropositivity has been associated with better response to rituximab (RTX). The purpose of this study was to assess the 6-month response to the first RTX course in RA according to RF and ACPA status.

Methods: Ten European registries submitted anonymized datasets from RA patients who had started RTX, and datasets were pooled and analysed. Chi-square test for comparison of categorical variables and t-test for continuous data were used. Predictors of response were identified by logistic regression analysis.

Results: 3266 patients were included in the cohort. 79.9% of patients were RF (+) (2041 out of 2553) and 73.2% were ACPA (+) (877 out of 1198). 718 patients were double positive (DP) and 147 double negative (DN).

2200 patients were RF (+) and/or ACPA (+). Improvements of DAS28 (ΔDAS28) at 6 months were significantly better for RF (+) than RF (−) patients as well as for ACPA (+) than ACPA (−), DP vs. DN and RF and/or ACPA (+) vs. DN (table 1). A significantly higher percentage of ACPA (+) and DP patients achieved EULAR Good Response at 6 months compared to ACPA (−) and DN, respectively (table 1). The completeness of data was very similar for seropositive and seronegative patients, with the percentages of missing data at 6 months being approximately 50% in all groups. A significantly higher percentage of seronegative patients received retreatment by 6 months than seropositive patients. In univariate analyses adjusted for age and gender ACPA positivity (OR=2.03, p=0.016) and DP (OR=2.43, p=0.03) but not RF positivity (OR=1.53, p=0.07) predicted EULAR good response to therapy with RTX at 6 months after the first treatment.

Table 1. Clinical outcomes at 6 months for RTX treated patients according to RF and ACPA status.

	RF (+)	RF (−)	p-value	ACPA (+)	ACPA (−)	p-value
Baseline DAS28	5.85 ± 1.36	5.63 ± 1.34	0.02*	5.8 ± 1.35	5.68 ± 1.32	NS
DeltaDAS28 6m	1.94 ± 1.5	1.65 ± 1.34	0.005	1.93 ± 1.51	1.40 ± 1.47	<0.0001
EULAR Good/Moderate/ No 6m	21.5/62/16.5%	17.4/63.4/19.2%	0.06	23.9/58.7/17.4%	14.9/62.9/22.2%	0.009
Remission 6m	13.8%	11.3%	NS	13.5%	10.9%	NS
	DP	**DN**	**p-value**	**RF and/or ACPA (+)**	**DN**	**p-value**
Baseline DAS28	5.81 ± 1.36	5.65 ± 1.36	NS	5.84 ± 1.35	5.65 ± 1.36	NS
DeltaDAS28 6m	1.95 ± 1.54	1.41 ± 1.51	0.007	1.93 ± 1.49	1.41 ± 1.51	0.005
EULAR Good/Moderate/ No 6m	24.7/58.4/ 16.9%	13.8/65/21.2%	0.06	21.4/61.9/16.7%	13.8/65/21.2%	0.038
Remission 6m	13.9%	12.5%	NS	13.7%	12.5%	NS

* Corrected for baseline DAS28.

Conclusion: In this large observational cohort of RA patients treated with RTX, seropositive patients achieved significantly greater reductions in DAS28 at 6 months compared to seronegative patients. Baseline ACPA positivity may be a better predictor for good response to RTX than RF positivity.

Sclerostin As Marker of Bone Formation in Ankylosing Spondylitis Under Anti-TNF Therapy: A 12-Month Longitudinal Analysis. Carla G.S. Saad[1], Ana C. M. Ribeiro[1], Julio C. B. Moraes[1], Liliam Takayama[1], Celio Goncalves[1], Ricardo M. Oliveira[2], Clovis A. A. Silva[1], Eloisa Bonfa[1] and Rosa M.R. Pereira[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]RDO Diagnosticos Medicos, São Paulo, Brazil

Background/Purpose: Sclerostin was reported to be low in AS patients and associated with bone formation. However, there is no data regarding anti-TNF therapy effect in this natural inhibitor of Wnt signaling and its possible association with bone mass. The present study longitudinally evaluated serum levels of sclerostin and lumbar spine bone mineral density (BMD) in Ankylosing Spondylitis (AS) patients under TNF blockage.

Methods: Thirty active AS patients according the modified New York classification criteria were assessed at baseline (BL), 6 (6M) and 12 months (12M) after anti-TNF therapy. Thirty aged- and sex-matched healthy individuals comprised the control group. Patients were evaluated for clinical parameters (BASDAI, BASFI, BASMI, AsQol), inflammatory markers (ESR, CRP, MMP3), baseline radiographic damage (mSASSS). BMD and laboratory analysis of sclerostin (ELISA-SCLEROSTIN; *Biomedica*, *Vienna*, Austria) and sclerostin binding to LRP6 (using recombinant human LRP6-Fc chimera; R&D Systems and human anti-sclerostin biotinylated antibody; *Biomedica*, *Vienna*, Austria) were performed in patients and controls.

Results: At entry, AS patients had lower sclerostin levels (60.5 ± 32.7 vs. 96.7 ± 52.9 pmol/l, $P=0.004$) with comparable sclerostin binding to LRP6 to controls ($P=0.387$). Baseline lumbar spine, femoral neck and total femur BMD were alike in both groups ($P>0.05$). A significant clinical improvement of BASDAI ($P<0.001$), BASFI ($P<0.001$), BASMI ($P=0.003$) and AsQoL ($P=0.001$) was observed evaluating BL vs. 6M vs. 12M. Concomitantly, a significant gradual increase in lumbar spine BMD was observed analyzing baseline vs. 6M vs. 12M of anti-TNF therapy ($P<0.001$) suggesting bone formation, since baseline mSASSS and lumbar spine BMD values were positively correlated (r=0.61, $P<0.001$). A significant reduction in ESR, CRP and MMP-3 levels was observed after TNF therapy comparing baseline vs. 6M vs. 12M ($P<0.001$). These inflammatory markers remained stable comparing 6M and 12M ($P>0.05$). Serum levels of sclerostin progressively increased from baseline to 6M and 12M after biological treatment ($P<0.001$), these increase was sustained between 6M and 12M of anti-TNF therapy ($P=0.024$). Of note, at 12M sclerostin levels remained significantly lower compared to controls (72.7 ± 32.3 vs. 96.70 ± 52.85 pmol/l, $P=0.038$). No change in sclerostin binding to LRP6 was observed from baseline to 12M of anti-TNF treatment ($P=0.472$).

Conclusion: The persistent low levels of sclerostin, in spite of its gradual increase after resolution of inflammation, may underlie the syndesmophyte bone formation in AS patients under anti-TNF therapy.

Serum Leptin Levels Are Associated with the Presence of Syndemophytes in Male Patients with Ankylosing Spondylitis. Ki-Jo Kim[1], Ji-Young Kim[2], Su-Jung Park[2], Hosung Yoon[3], Chong-Hyun Yoon[1], Jin-Jung Choi[4], Wan-Uk Kim[5] and Chul-Soo Cho[1]. [1]College of Medicine, Catholic University of Korea, Seoul, South Korea, [2]Research Institute of Bone & Joint Diseases, Catholic University of Korea, Seoul, South Korea, [3]The Catholic University, Incheon, South Korea, [4]CHA University, Bundang CHA General Hospital, Seongnam, South Korea, [5]St. Vincent's Hospital, Suwon, South Korea

Background/Purpose: Osteoporosis is detected more frequently in patients with ankylosing spondylitis (AS) with syndemophytes and is associated with bone-marrow adiposity. Leptin is produced in adipose tissue and modulate bone metabolism and phenotypes in animal model. However, the association between leptin and syndemophytes has not yet been elucidated in AS. The purpose of this study is to determine the association between serum leptin concentration and the presence syndemophytes and bone metabolic markers in male patients with AS.

Methods: Seventy-two consecutive male patients with AS and nineteen sex- and age-matched healthy controls were included. Baseline assessment included age, disease duration, treatment, clinical, radiologic and laboratory data. Bone mineral density (BMD) at the spine and femur was measured by dual-energy x-ray absorptiometry (DEXA). Radiographs of the lumbar spine were used to detect syndesmophytes. Serum concentration of leptin and bone metabolic markers including bone specific alkaline phosphatase, osteocalcin and telopeptide of type I collagen were measured. Serum leptin levels are adjusted for body mass index (BMI). Multivariate logistic regression model was used to evaluate the independent effect of clinical and laboratory variables on the presence of syndemophyte.

Results: Serum leptin/BMI levels were not significantly higher in male patients with AS than in healthy individuals (169.94 ± 21.80 vs 131.21 ± 18.22 $pg*m^2/ml*kg$, $p = 0.339$). However, 30 male AS patients with syndemophytes have significantly higher serum leptin/BMI levels than 42 male AS patients without syndemophytes and 19 healthy controls, respectively (222.45 ± 38.59 vs 129.78 ± 22.89 and 131.21 ± 18.22 $pg*m^2/ml*kg$, $p = 0.010$ and 0.040). In multivariate analysis including age, disease duration, c-reactive protein, and serum TNF-α level, higher serum leptin/BMI levels were independently associated with the presence of syndemophytes ($p = 0.029$). Interestingly, serum leptin/BMI level correlated positively with serum bone-specific alkaline phosphatase (Pearson correlation = 0.279, $p = 0.039$). But, there was no significant association between serum leptin/BMI levels and BMD.

Conclusion: Serum leptin levels are elevated in a substantial fraction of male patients with ankylosing spondylitis and are associated with the presence of syndemophytes, suggesting a potential role of leptin on new bone formation in AS.

Eotaxin: A Novel Biomarker in Ankylosing Spondylitis That Predicts Less Structural Damage. Walter P. Maksymowych[1], Nigil Haroon[2], Nathalie Morency[1], Richard J. Cook[3], Ker-Ai Lee[3], Stephanie Wichuk[1], Proton Rahman[4], Dafna D. Gladman[2] and Robert D. Inman[2]. [1]University of Alberta, Edmonton, AB, [2]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [3]University of Waterloo, Waterloo, ON, [4]St. Claires Mercy Hospital, St. Johns, NF

Background/Purpose: About a third of patients with ankylosing spondylitis (AS) have been shown to exhibit radiographic progression over 2 years

but there is limited prospective data on the factors that predict progression. We have previously identified 22 high priority candidate biomarkers from a panel of 58 biomarkers reflecting inflammation and joint tissue turnover that were assessed in a multiplex assay of a subset of The Spondyloarthritis Research Consortium of Canada (SPARCC) prospective cohort[1]. In this subsequent study, we aimed to identify which of the 22 biomarkers was predictive of progression in the entire study cohort.

Methods: The SPARCC cohort comprises patients with AS followed prospectively with clinical and radiographic outcomes. Readers scored X-rays obtained at baseline and year 2 using the mSASSS method. Pre-specified dependent variables were: 1) change in mSASSS >0 and >2 units from baseline through 2 years, 2) development of new syndesmophytes at year 2, 3) spur and ankylosis score (SAS: score for ankylosis = 3 and spur = 2 per vertebral corner). Multivariate analyses were controlled for age, sex, disease duration, biologic treatment, baseline and 2-year change in CRP, and baseline radiographic score.

Results: Baseline and 2-year radiographs were available on 241 patients with AS according to the modified New York criteria. Mean (SD) age was 40.5 (13.3) years, males 81.1%, mean (SD) disease duration 20 (11.2) years), 48.9% received biologics, and 51.1% received standard therapies. At baseline, mean (SD) mSASSS was 15.1 (20.7) and mean (SD) SAS was 12.3 (20.7). Mean (SD) change in mSASSS and SAS over 2 years was 1.8 (3.8) and 1.9 (4.9), 20.6% had mSASSS progression > 2 units, and 28.6% developed ≥1 new syndesmophyte. Multivariate linear regression analysis with either the mSASSS or the SAS as dependent variable showed that only baseline eotaxin was significant in the model so that higher levels predicted lack of progression (Table). Metalloproteinase 3 was also a significant independent predictor in patients on biologics (Est = 0.03 (95% CI 0.003–0.064), p = 0.03).

		Univariate Model			Multivariate Full Model		
Dependent variable	**Treatment**	**Est**	**95%CI**	**P value**	**Est**	**95%CI**	**P value**
SAS	All	−1.09	−1.89, −0.28	0.0085	−1.09	−1.89, −0.28	0.0085
SAS	Standard	−1.60	−3.01, −0.19	0.026	−1.60	−3.01, −0.19	0.026
mSASSS	All	−1.12	−1.87, −0.36	0.0037	−1.12	−1.87, −0.36	0.0037
mSASSS	Biologic	−1.25	−2.59, 0.082	0.066	−1.45	−2.74, −0.15	0.029

Conclusion: Higher levels of eotaxin, a biomarker previously unconnected with SpA, predict less progression irrespective of treatment.

Smokers in Early Axial Spondyloarthritis Have An Earlier Disease Onset, More Inflammation and Damage: Results From the *DEvenir Des Spondyloarthropathies Indifferenciées Récentes* Cohort. Pedro Machado[1], Ho Y. Chung[2], Désirée van der Heijde[3], Maria-Antonietta D'Agostino[4] and Maxime Dougados[5]. [1]Leiden University Medical Center, Leiden, Netherlands & Coimbra University Hospital, Coimbra, Portugal, [2]Leiden University Medical Center, Leiden, Netherlands & Queen Mary Hospital, Hong Kong, China, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Versailles-Saint Quentin en Yvelines University-APHP, Ambroise-Paré Hospital, Boulogne-Billancourt, France, [5]Paris-Descartes University, Cochin Hospital, Paris, France

Background/Purpose: Few studies have investigated the influence of smoking in axial spondyloarthritis (SpA) and previous analyses have focused on ankylosing spondylitis (AS) rather than the early disease stage of axial SpA. In patients with AS, it has been shown that smokers have more limited physical function (1–3) and increased radiographic damage (4). Our aim was to investigate the associations of smoking with various clinical and imaging outcomes in early axial SpA patients.

Methods: Seven hundred and eight patients with IBP of less than 3 years duration defined by Calin or Berlin criteria were recruited in the DESIR (*DEvenir des Spondyloarthropathies Indifferenciées Récentes)* cohort, a multicenter study in France. Six hundred and fifty four fulfilled at least one of the SpA criteria sets (Modified New York (mNY), European Spondyloarthropathy Study Group (ESSG), Amor, and/or ASAS axial SpA) and were included in the analyses. Clinical, demographic and imaging parameters were compared between smokers and non-smokers and variables with significant differences in univariate analyses were used as dependent variables in multivariate linear and logistic regression models adjusted for age, gender, duration of inflammatory back pain, race, HLA-B27 status and other potential confounders.

Results: Our study population was characterized by young age (mean 33.6, median 33.0 years) and short duration of symptoms (mean 1.5, median 1.4 years). Thirty seven percent of the patients were smokers. In multivariate analysis, smoking was associated with earlier onset of inflammatory back pain (IBP) (regression coefficient (B)=-1.46; p=0.04), higher disease activity reflected both by the Ankylosing Spondylitis Disease Activity Index (ASDAS-CRP) (B=0.20; p=0.03) and BASDAI (B=0.50; p=0.003), worse functional status reflected by the BASFI (B=0.38; p=0.02), more MRI inflammation of the sacroiliac (SI) joints (odds ratio (OR)=1.57; p=0.02) and of the spine (OR=2.33; p<0.001), MRI structural lesions of the SI joints (OR=1.54; p=0.03) and of the spine (OR=2.02; p=0.01) and higher modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) (B=0.54; P=0.03). Smoking was also associated with poorer health-related quality of life (HRQoL), assessed both by the AS Quality of Life (ASQoL) score (B=1.38; p<0.001) and by the Short Form 36 (SF-36) physical (B=-4.89; p<0.001) and mental (B=-5.90; p<0.001) component scores.

Conclusion: In patients with early axial SpA, smoking was independently associated with earlier onset of IBP, higher disease activity, poorer functional status, increased axial inflammation on MRI and axial structural damage on MRI and radiographs, and worse HRQoL. These observations may have important implications in the education of patients with axial SpA and highlight the need to consider smoking as one of the potential prognostic factors in axial SpA as well as one of the environmental factors potentially involved in the pathogenesis of the disease.

The Incidence of Infection in Psoriatic Arthritis - Results From a Longitudinal Observational Cohort. Amir Haddad[1], Arane Thavaneswaran[2], Vinod Chandran[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Many patients with psoriatic arthritis are treated with biologic agents. The main adverse event is infection. However, the rate of infection among patients with psoriatic disease is unknown. The purpose of this study was to investigate the rate, type and characteristics of illness in patients with psoriatic arthritis (PsA) in contrast to a control group of patients with psoriasis without arthritis (PsC).

Methods: The PsA cohort was initiated in 1978. Patients are followed at 6–12 month intervals according to a standard protocol which includes history, physical examination laboratory evaluation and radiographic assessment. It collects documentation of the presence, site and type of infection at each visit. In 2006 a cohort of patients with PsC was initiated. Patients with psoriasis are all assessed by a rheumatologist to exclude the presence of inflammatory arthritis, and are followed at yearly intervals according to the same standard protocol. Data are tracked in a computerized database. Descriptive analyses were conducted using t tests and chi-square tests. Only infections observed after 2006 were included.

Results: 695 patients with PsA and 511 patients with PsC and were followed up in our respective clinics since 2006. A total of 607 infections were detected among 318 patients with PsA, and 176 observed infections among 144 patients with PsC. The incidence rate of infection was similar in both groups with 0.33 (95% CI 0.31, 0.36) per patient-year in the PsA cohort and 0.29 (95% CI 0.25, 0.30) per patient-year in the PsC cohort (p=0.15). The incidence rate of infection for patients on biologics was higher at 0.44 (95% CI 0.39–0.50) and 0.66 (95% CI 0.39–1.04) in the PsA and PsC cohorts respectively. Patients with PsA were more likely to have 4 or more infections during the course of follow-up compared to patients with PsC (p=0.0001). Among patients with PsA the most common infections were lung, sinus, skin (cellulitis) and upper respiratory whereas among PsC patients skin, genitourinary, lung and upper respiratory were most prevalent. Patients with PsA had less bacterial infections compared to PsC (62% vs. 77.1% p=0.005), and were less likely to have been treated with antibiotics than patients with PsC (73.6% vs. 87.1% p=0.0003). Patients with PsA and PsC with infection shared similar background comorbidities. In the PsA group patients were older (51.8 vs. 46.7 yrs, p=0.0002) and as expected required more treatment with NSAIDs, DMARDs and biologics (p<0.0001), while patients with PsC were more likely to be treated with phototherapy (p<0.0001). Patients with PsA had a lower prevalence of smoking and alcohol consumption than patients with PsC (p=0.0002 and 0.0015, respectively).

Conclusion: The incidence rate of infection was similar in PsC and PsA cohorts at 29–33 infections per 1000 patient-years. Patients with PsA suffered from recurrent infections more commonly than patients with PsC. Patients in the two cohorts were more likely to have a bacterial etiology for infection and required in the majority of cases antibiotic treatment. The most commonly reported infection was pneumonia in the PsA group and cellulitis in the PsC group.

1652

Efficacy and Safety of Apremilast, An Oral Phosphodiesterase Inhibitor, in Ankylosing Spondylitis. E. Pathan[1], S.M Abraham[1], L. Van-Rossen[2], Robin Withrington[3], AC Keat[4], Peter J. Charles[5], E. Paterson[5], Muslima Chowdhury[6], L. Hastings[1], A. Fox[1], C. McClinton[1] and Peter Taylor[7]. [1]Kennedy Institute of Rheumatology, London W6 8RF, United Kingdom, [2]Kent and Canterbury Hospital, Canterbury, Kent CT1 3NG, United Kingdom, [3]Kent & Canterbury Hosp, Canterbury, United Kingdom, [4]Northwick Park Hospital, Harrow, United Kingdom, [5]Kennedy Institute of Rheumatology, Imperial College, London, United Kingdom, London, England, [6]Imperial College London, London, United Kingdom, [7]Kennedy Institute of Rheumatology, London, United Kingdom

Background/Purpose: Apremilast (APR) is a novel, orally available small molecule that specifically inhibits phosphodiesterase-4, increasing intracellular cAMP and thus modulates multiple pro- and anti-inflammatory mediators. APR has been shown to significantly improve PASI-75 and ACR 20 in subjects with psoriasis and psoriatic arthritis, respectively.

Objectives: To evaluate the efficacy and safety of APR by monitoring changes in signs and symptoms in a pilot study of patients with ankylosing spondylitis (AS) and to investigate the effect of APR on blood levels of sclerostin, Receptor Activator of NFκB Ligand (RANKL) and Osteoprotegrin (OPG) as biomarkers of bone biology in this cohort.

Methods: This was a double-blind, Placebo (PBO)-controlled Phase II unpowered pilot study in AS patients, symptomatic for ≥2 years, uncontrolled on conventional non-steroidal anti-inflammatory drugs and with daily spinal pain and stiffness for ≥2 weeks before being randomised equally to oral APR 30 mg BID, titrated over 5 days, or PBO. Treatment was assessed using Bath indices over 12 weeks, followed by a 4-week observation phase. Results were compared at each time point using analysis of co-variance (ANCOVA).

Plasma levels of sclerostin and serum levels of RANKL and OPG were measured by ELISA at baseline and after 12 weeks of therapy. Differences in the 2 treatment groups were expressed as percentage change from baseline and compared using the Mann Whitney U test.

Results: 38 subjects were randomised (safety population) and 36 subjects had ≥1 post-baseline assessment (intent-to-treat population) and completed the study. At week 12, APR was associated with a trend to greater mean improvement from baseline for all clinical assessments compared with PBO (Table). There was a significant mean percentage change from baseline in levels of Sclerostin and RANKL, but not of OPG levels, in the APR group vs PBO.

Clinical Parameter	Mean change from baseline (SD)		p value (ANCOVA)
	Apremilast (n = 17)	Placebo (n = 19)	
BASDAI	−1.59 (1.48)	−0.77 (1.47)	0.139
BASFI	−1.74 (1.91)	−0.28 (1.61)	0.108 (non-parametric)
BASMI	−1.36 (2.35)	−0.17 (2.83)	0.166
BASG	−0.51 (1.02)	−0.21 (0.67)	0.617
Laboratory marker	**Mean percentage change from baseline (SD) [No change = 100%]**		**p value (Mann Whitney U test)**
RANKL	73.2 (30.9)	108.2 (32.01)	0.016
OPG	97.8 (18.3)	92.8 (18.8)	0.41
RANKL:OPG	78.3 (33.8)	108.5 (34.6)	0.08
Sclerostin	84.8 (23.03)	110.1 (32.68)	0.011

More APR-treated vs PBO subjects reported loose stools (26.3% vs 10.5%) and headache (42.1% vs 26.3%), but there was no relevant difference in the incidence of diarrhoea, nausea and upper respiratory tract infections: 10.5%, 15.8% and 31.6%, respectively. There were no serious AEs reported.

Conclusion: Although a small pilot study, these results show that APR may be effective and well tolerated in AS and modulates biomarkers of bone biology. Given the current lack of oral DMARDs for AS, these encouraging pilot data support further research of APR in axial inflammation.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects: Renal

1653

Incident Lupus Nephritis: Predictive and Protective Factors. Ana-Maria Orbai[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: To assess predictive and protective factors (hydroxychloroquine and ACE inhibitors/ARBs) for incident lupus nephritis.

Methods: This analysis was based on 1300 patients in a longitudinal cohort from 1987 to the present who did not have renal involvement prior to or at the time of cohort entry. Incident lupus nephritis was defined as proteinuria of 3 or 4+ on dipstick urinalysis or urine protein > 500 mg (on spot urine or 24h collection), reproducible at 3 months. Using this definition, we estimated rates of incident nephritis, in subgroups defined by clinical and demographic characteristics. Pooled logistic regression was used to estimate the association between characteristics and rates, adjusting for confounding by other variables (SAS Institute, Cary, NC, USA). A p-value ≤0.05 was considered statistically significant.

Results: There were 55 incident cases of lupus nephritis (7.6/1000 person-year). The incidence was significantly higher in African-Americans (RR 4, p<0.0001), those with history of low C3 (RR 10.6, p<0.0001), low C4 (RR 2.6, p=0.0011), anti-dsDNA (RR 3.4, p=0.0015), anti-Smith (RR 4.5, p=0.0001), anti-Ro (RR 2.3, p=0.0017), anti-La (RR 2.3, p=0.011), anti-RNP (RR 3, p<0.0001), high titer anticardiolipin IgG (RR 2.4, p<0.0038) or leukopenia (RR 2.3, p=0.003). Use of hydroxychloroquine for more than 6 months was associated with a reduced incidence (RR 0.5, p=0.043). ACE inhibitor or ARB use was not significantly protective against incident lupus nephritis.

In the multivariable model (Table), predictors significantly associated with incident lupus nephritis were African-American ethnicity (RR 3, p=0.0009), history of low C3 (RR 6.5, p<0.0004), anti-Smith antibody (RR 2.2, p=0.0076), anti-Ro antibody (RR 1.8, p=0.036) and history of cutaneous lupus (RR 2.3, p=0.014). In the multivariable model, current use of Plaquenil for more than 6 months was protective (RR 0.3, p=0.0024).

Table. Association of various predictors and incident nephritis, controlling for each other in a multivariable model.

Variable		Rate Ratios (95% CI)	P-value
Ethnicity	Caucasian	1.0 (Ref. Gp)	0.0009
	African-American	3.0 (1.6, 5.7)	
History of low C3	No	1.0 (Ref. Gp)	0.0004
	Yes	6.5 (2.3, 18.5)	
Testing positive for anti-Smith	No	1.0 (Ref Gp)	0.0076
	Yes	2.2 (1.2, 3.9)	
Testing positive for anti-Ro	No	1.0 (Ref. Gp)	0.036
	Yes	1.8 (1.0, 3.1)	
History of Cutaneous Lupus	No	1.0 (Ref. Gp)	0.014
	Yes	2.3 (1.2, 4.4)	
History of Leukopenia	No	1.0 (Ref. Gp)	0.15
	Yes	1.5 (0.9, 2.9)	
Plaquenil Use	Never	1.0 (Ref. Gp)	0.17
	Past, not current	0.5 (0.2, 1.3)	0.89
	Current < 6 months	1.0 (0.5, 2.5)	0.024
	Current > 6 months	0.3 (0.2, 0.7)	
Proportion of cohort time on	<20%	1.0 (Ref Gp)	0.57
	20–79%	0.8 (0.3, 2.0)	0.10
	80%+	2.0 (0.9, 4.5)	

Conclusion: Predictors significantly associated with incident lupus nephritis were African-American ethnicity, history of low C3, anti-Smith antibody, anti-Ro antibody and history of cutaneous lupus. In the multivariable model, current use of Plaquenil for more than 6 months was protective (RR 0.3, p=0.0024). The results strongly support early and consistent use of Plaquenil, in that it must be used for 6 months or more to be protective. Our results do not support a previous cohort study that ACE inhibitor use was protective.

Urinary and Serum Monocyte Chemotactic Protein-1 and Interferon Gamma-Induced Protein-10 Are Good Markers to Assess Lupus Activity. Bonnie Abujam, Satyanarayana Swamy and Amita Aggarwal. Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Lucknow, India

Background/Purpose: Interferon gamma-induced protein-10 (IP-10) and Monocyte chemoattractant protein-1 (MCP–1) are pro-inflammatory chemokines. IP-10 promotes the recruitment of monocytes, T and NK cells bearing CXCR3 receptor into inf lamed sites whereas MCP-1 plays a role in recruitment of monocytes and lymphocytes. These chemokines may be involved in the immunopathogenesis of lupus nephritis. Data on urinary MCP-1 and IP-10 are limited in human SLE.

Methods: SLE patients fulfilling ACR 1997 criteria and providing consent were included. SLEDAI was assessed and blood and urine samples collected. Active lupus was defined as SLEDAI>=4. Active patients were divided into active renal lupus if they had proteinuria >=500mg/day or active sediment (>=5 RBC or 5 WBC or any cellular casts per hpf) and

active non-renal lupus. 'Renal SLEDAI' was calculated using four urinary parameters of SLEDAI. Patients with active renal lupus were followed till the nephritis became inactive when a second sample of urine and blood were collected. Serum and urinary levels of MCP-1 and IP-10 (pg/ml) were measured by ELISA (BD Opt EIA). Urinary values were normalised for urinary spot creatinine (pg/mg creatinine).

Results: The study included 78 active and 58 inactive lupus patients. Of 78 active patients, 46 were active renal whereas 32 were active non-renal. Their median age was 25 (IQR 10–55) years and SLE duration was 23 (IQR 6–48) months. The levels of MCP-1 and IP-10 in different groups is given below:

Parameter	Active renal (N = 46)	Active non renal (N = 32)	Active total (N = 78)	Inactive (N = 58)
Urinary MCP-1	46.2 (19.9–125.3) ##	12.7 (5.8–43.9)	35.1 (12.7–71.8)**	9.5 (4.4–17)
Urinary IP-10	12.5 (5.6–22.7) #	5.2 (2.9–12.1)	9.5 (4.4–17.9)**	3.9 (1.9–9.3)
Serum IP-10	690 (465–1000)	477 (327.5–1307.5)	665 (387–1189.3)**	334 (220–512.3)
Serum MCP-1	703.5 (542.5–1000)	680 (455–987.5)	700 (500–1000)*	520 (354.5–789.5)

[Values are median (Inter Quartile Range); *p<0.05, ** p<0.001 as compared to inactive lupus, #p=0.01,##p<0.001 as compared to active non-renal lupus]

Most markers had good correlation with SLEDAI, urinary MCP-1 (r= 0.57, 95% CI 0.38–0.70), urinary IP-10 (r= 0.40; 95% CI 0.19–0.57), serum IP-10 (r=0.51; 95% CI 0.32–0.66) and serum MCP-1 (r= 0.21; 95% CI 0.01–0.38). On longitudinal follow (n=24) of active renal patients, there was a significant decrease in urinary levels of MCP-1 and IP-10 (p=0.005) as well as serum levels of IP-10 (p=0.003) however there was no difference in serum MCP-1 levels.

Conclusion: Urinary and serum IP-10 and urinary MCP-1 are good markers of lupus activity. Further, urinary MCP-1 and IP-10 can differentiate between renal and non-renal active disease. Urinary MCP-10 and IP-10 can also be used for follow up of lupus nephritis patients. Thus, urinary levels seem to be specific for renal inflammation whereas serum levels are reflective of generalised lupus activity.

1655

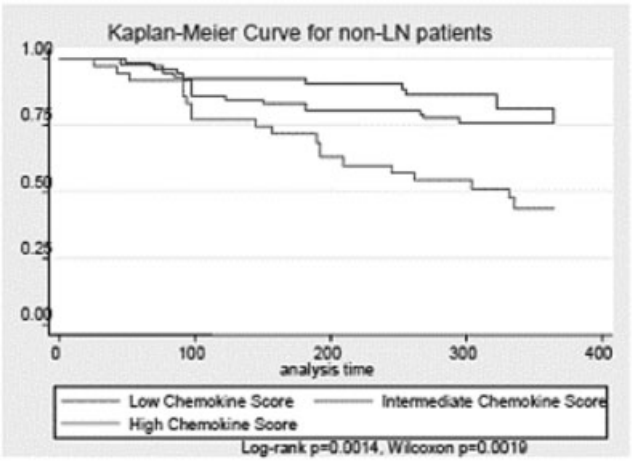
Association of Serum-Based IFN-Induced Chemokine Scores with Lupus Nephritis Disease Activity. Irene Blanco[1], Chaim Putterman[1], Michelle Petri[2] and Emily Baechler Gillespie[3]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]University of Minnesota, Minneapolis, MN

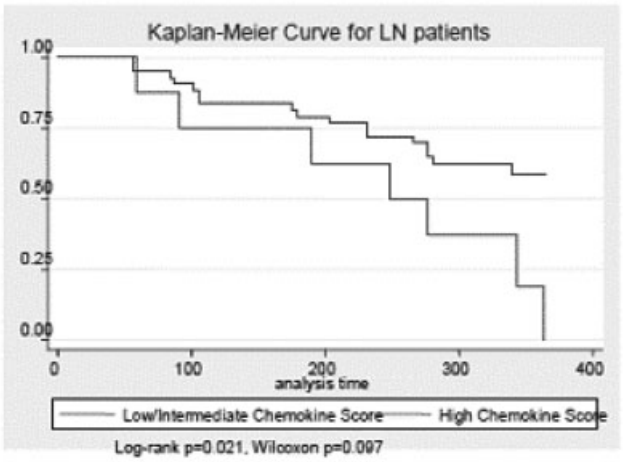
Background/Purpose: A serious complication of Systemic Lupus Erythematosus is lupus nephritis (LN). Despite treatment, many patients still develop renal failure. It has been previously shown that serum based IFN-induced chemokine scores are associated with overall lupus activity. However, it is unclear what the association of these scores are to disease activity in LN patients and how they compare to non-LN SLE patients.

Methods: 224 participants from the Autoimmune Biomarkers Collaborative Network (ABCoN), with IFN regulated serum chemokine (MCP-1, CXCL-10, and CCL-19) scores and longitudinal follow-up, were included in this study. MCP-1, CXCL-10 and CCL-19 were measured using chemiluminescence sandwich-based immunoassays. Individual chemokine scores were calculated and made into a composite score (CK Score). The composite CK score was evaluated in its ability to predict disease flare by survival analysis in LN and non-LN patients, by categorizing levels into: high (top quartile), intermediate (2nd and 3rd quartiles combines) and low (bottom quartile). We then performed a subset analysis of 62 patients at times of remission and flare to assess the score's relation to disease activity using the Wilcoxon matched-pairs signed-rank test. Flare was determined as a change in baseline SLEDAI≥3.

Results: Of the 224 participants included in this study, 54.7% were White, 37.5% Black and 7.4% were of other Races. 89.1% were female; the mean age was 43.2 ±11.9y. Median disease duration was 8y (IQR4–13); 52 participants have biopsy-proven LN.

Baseline CK scores were modestly correlated with disease activity as measured by SLEDAI (rho=0.198, p=0.0226). There was no difference at baseline in CK scores for non-LN and LN patients (31.3 v 31.5, p=0.87). Overall, higher CK scores were predictive of flare in non-LN patients (Log-rank p:0.0014, Wilcoxon p:0.0019). In those with LN however, only the highest quartile predicted a flare when compared to low and intermediate values. (Log-rank p=0.021)





Next, for patients in remission who then flared, non-LN patients had significantly higher serum CK scores at flare than at remission (40.21 v 31.66, p=0.01). In patients with LN and renal activity during the flare (renal SLEDAI≥4), flare CK scores were also significantly elevated compared to remission scores (43.47 v 33.66, p=0.047). However median levels for both LN and non-LN patients at flare fell into the range of the intermediate quartile (24.18–46.65) that was not predictive of flare in non-LN patients.

Conclusions: CK scores are correlated with SLEDAI scores, where the highest quartile of baseline score is predictive of increased disease activity in both non-LN and LN patients. Nevertheless at flare median levels are lower than the highest quartile. Therefore, further studies are needed to determine adequate cut-off points of the CK score to have the best sensitivity and specificity to predict flare.

Predictors of Renal Failure in Systemic Lupus Erythematosus. Michelle Petri[1], Hong Fang[1] and Laurence S. Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Renal failure remains a major issue in SLE, in spite of treatment with mycophenolate mofetil or cyclophosphamide. Although risk factors for lupus nephritis are well studied, fewer studies have investigated risk factors for renal failure because this requires a larger cohort. We investigated this in a large prospective cohort.

Methods: The cohort consists of patients with SLE who are followed quarterly. This analysis was based on the cohort experience of 1996 patients who did not have renal failure prior to cohort entry. The sample was 93% female, 57% Caucasian, 36% African American, with a mean age at entry of 37. We estimated the association between demographic and time-varying clinical variables and rates of renal failure, controlling for Cockcroft-Gault eGFR at cohort entry, using pooled logistic regression.

Results: 53 patients in our sample developed renal failure during cohort participation. Controlling for eGFR at cohort entry, the rate of renal failure was significantly elevated for those who were younger, African-American, had higher systolic blood pressure at entry, had anti-dsDNA or low C3 during follow-up (Table 1). Rates were significantly lower for those who were treated with hydroxychloroquine for more than 50% of their cohort follow-up (Rate Ratio=0.3, p=.0003). There was not a reduced rate among those treated with ACE inhibitors or ARB. The association between low C3 and failure rates diminished after controlling for other variables in a multivariable model, but the other associations persisted (Table 2).

Table 1. Association between predictors and kidney failure during cohort participation based on separate models for each variable, controlling for GFR at start of follow-up.

Variable		Rate Ratio (95% CI)	P-value
Gender	Male (vs. female)	1.9 (0.8, 4.5)	0.14
Age	30–39 (vs. < 30)	0.4 (0.2, 0.9)	0.018
	40+ (vs. < 30)	0.2 (0.1, 0.4)	<0.0001
Race	African-American (vs. Caucasian)	2.9 (1.6, 5.2)	0.0006
	Other (vs. Caucasian)	1.7 (0.5, 6.0)	0.38
Anti-dsDNA	Some but <50% of follow-up (vs. none)	1.6 (0.5, 4.4)	0.41
	>50% of follow-up (vs. none)	5.9 (2.5, 13.8)	<0.0001
Low Complement	Some but <50% of follow-up (vs. none)	1.7 (0.5, 6.3)	0.43
	>50%+ of follow-up (vs. none)	2.7 (1.3, 5.8)	0.011
Systolic Blood Pressure at start of follow-up	130+ mmHg (vs. <130)	2.0 (1.2, 3.5)	0.011
Hydroxychoroquine Use	Some, but <50% of time (vs. none)	0.4 (0.1, 1.3)	0.12
	>50% of follow-up (vs. none)	0.3 (0.1, 0.5)	0.0003
ACE or ARB[1]	Some, but <50% of time (vs. none)	2.0 (0.9, 4.7)	0.094
	>50% of follow-up (vs. none)	1.1 (0.5, 2.5)	0.87

[1] Controlling also for history of hypertension.

Table 2. Association between predictors and kidney failure during cohort participation based on a multivariable model.

Variable		Rate Ratio (95% CI)	P-value
Age	30–39 (vs. < 30)	0.4 (0.2, 0.9)	0.035
	40+ (vs. < 30)	0.2 (0.1, 0.5)	0.0005
Race	African-American (vs. Caucasian)	2.0 (1.0, 4.3)	0.066
	Other (vs. Caucasian)	0.6 (0.1, 3.1)	0.57
Anti-dsDNA	Some, but <50% of time (vs. none)	2.1 (0.6, 6.7)	0.22
	>50% of follow-up (vs. none)	6.4 (2.3, 17.8)	0.0004
Low Complement	Some, but <50% of time (vs. none)	1.2 (0.2, 5.5)	0.85
	>50% of follow-up (vs. none)	1.1 (0.5, 2.5)	0.87
Systolic Blood Pressure at start of follow-up	130+ mmHg (vs. <130)	2.4 (1.1, 4.9)	0.023
Hydroxychoroquine Use	Some, but <50% of time (vs. none)	0.4 (0.1, 1.4)	0.16
	>50% of follow-up (vs. none)	0.3, (0.2, 0.7)	0.0070

Conclusion: Anti-dsDNA was strongly associated with progression to renal failure in our SLE cohort. Thus, new biologic treatments which reduce anti-dsDNA early and effectively should be explored in trials of lupus nephritis. Our study also provides strong evidence that treatment with hydroxychoroquine reduces the risk of progression to renal failure. However, this protective effect requires that it be present for greater than 50% of followup time.

$CD4^+CD25^-Foxp3^+$ T Cells Are Indicative for Kidney Involvement in Systemic Lupus Erythematosus (SLE) Patients and Respond to Cyclophosphamide Therapy. Michael Bonelli[1], Lisa Goeschl[1], Anastasiya Hladik[1], Josef Smolen[2] and Clemens Scheinecker[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: $CD4^+CD25^-Foxp3^+$ T cells resemble regulatory T cells and are increased in SLE patients. Their precise role in SLE pathogenesis, however, has not been determined so far. We therefore analyzed $CD4^+CD25^-Foxp3^+$ T cells in SLE patients with different organ manifestations as compared to healthy controls (HC).

Methods: Proportions of $CD4^+CD25^-Foxp3^+$ T cells were determined by 6 color flow cytometry (FACS) within peripheral blood mononuclear cells (PBMC) in HC (n=21) and SLE patients (n=61) with different organ manifestations. In selected SLE patients with active glomerulonephritis, proportions of $CD4^+CD25^-Foxp3^+$ T cells were also determined in urine samples. $CD4^+CD25^-Foxp3^+$ T cells were analyzed for the expression of novel Treg markers Helios and Icos and proportions were correlated with clinical data, the immunosuppressive therapy and different disease activity indices. Finally time course analyses of proportions of $CD4^+CD25^-Foxp3^+$ T cells were performed in patients with active glomerulonephritis before and after treatment with cyclophosphamide and in patients with active skin involvement before and after cortisone treatment.

Results: Proportions of $CD4^+CD25^-Foxp3^+$ T cells were significantly increased in SLE patients as compared to HC and expressed Helios and Icos. We observed a significant correlation of % $CD4^+CD25^-Foxp3^+$ T cells with the SLEDAI, ECLAM and SIS disease activity score and with the daily cortisone dose. The analysis of patients with different organ manifestations revealed increased proportions of $CD4^+CD25^-Foxp3^+$ T cells in SLE patients with renal involvement. Moreover, $CD4^+CD25^-Foxp3^+$ T cells were also detected in urine samples of patients with active glomerulonephritis and proportions of $CD4^+CD25^-Foxp3^+$ T cells significantly correlated with the extent of proteinuria. Time course analysis revealed no influence of cortisone treatment on the percentage of $CD4^+CD25^-Foxp3^+$ T cells in patients with active skin involvement, whereas cyclophosphamide treatment of patients with active glomerulonephritis led to a decrease in $CD4^+CD25^-Foxp3^+$ T cells. Ongoing experiments have been designed to further reveal the origin of $CD4^+CD25^-Foxp3^+$ T cells. For this purpose $CD4^+CD25^-Foxp3^+$ T cells are analyzed for their cytokine profile and the expression of T cell lineage specific transcription factors.

Conclusion: The increase in proportions of $CD4^+CD25^-Foxp3^+$ T cells in patients with SLE who suffer from glomerulonephritis suggests their involvement in kidney pathology. In addition the analysis of $CD4^+CD25^-Foxp3^+$ T cells might allow to recognize and monitor patients with renal involvement.

Serum Cytokines in Lupus Nephritis, Levels of IL-17 and IL-23 in Association to Histopathology and Response to Treatment. Agneta Zickert[1], Petra Amoudruz[1], Johan Rönnelid[2], Vivianne Malmström[1] and Iva Gunnarsson[1]. [1]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [2]Uppsala University, Uppsala, Sweden

Background/Purpose: The pathogenesis for lupus nephritis (LN) is complex and involves many components of the immune system. Recent studies indicate an important role for the T-cell subset Th-17, and the associated cytokines IL-17 and IL-23, in LN. Increased knowledge of cytokines in LN, originating from both the innate and adaptive immune system, may contribute to further understanding of the pathogenesis, identification of new biomarkers and to development of new treatment strategies.

The aim of the study was to investigate cytokines, previously indicated in LN, in association to clinical and histopathological findings and response to therapy.

Methods: Fifty-two patients with active lupus nephritis were included. Renal biopsies were performed at baseline and after 6 months of standard induction treatment. Clinical and laboratory data were collected at baseline and at repeated biopsies and serum levels of TNFα, IFNγ, IL-2, IL-4, IL-6, IL-10, IL-6R, IL-17, IL-21, IL-23 and TGF-β were analyzed at both occasions. Biopsies were evaluated regarding WHO-classification and renal disease activity was estimated using the BILAG index. An improvement of at least 2 grades in renal BILAG was regarded complete response (CR), whereas 1 grade as partial response (PR). Serum samples from 13 healthy volunteers were used as controls.

Results: Baseline biopsies showed WHO-class III-IV (n=44) and V (n=8) and all patients had high renal disease activity (BILAG A/B). Follow-up biopsies showed WHO I-II (n= 19), III-IV (n=19) or V (n= 14). 22 patients were regarded CR, 20 PR and 10 non responders. At baseline, serum levels of IL-6, IL-10, IFNγ, IL-17-1L-23 and IL-6R were significantly higher in patients vs. controls and TGFβ was significantly lower ($p<0.05$ for all). Overall, the high cytokine levels except IFN γ decreased significantly after treatment.

Serum levels of IL-17 at baseline were significantly higher in patients with a persisting active nephritis at follow up (WHO III, IV or V) vs. those with a good histopathological response (WHO I or II) ($p<0.01$). The highest levels of IL-17 were found in class V. Overall, BILAG non-responders had significantly higher levels of IL-23 at follow up vs. CR and PR ($P<0.05$), most pronounced among non-responder patients with WHO class V at follow up ($p<0.02$).

Conclusion: Levels of IL-17 at baseline were significantly higher in patients not responding histopathologically to treatment, suggesting that patients with high levels of IL-17 may represent a subgroup of patients with more severe disease. Levels of IL-23 at follow up were significantly higher in BILAG non-responders than in responders, especially in LN class V. This study indicates a role for Th-17 (IL-17/IL-23) in LN regarding treatment response, especially in class V LN, and suggests that these cytokines may be used as biomarkers.

HMGB1 Is An Important Mediator in Cutaneous Inflammation in Systemic Lupus Erythematosus (SLE). Deena A. Abdulahad, Johanna Westra, Gerda Horst, Pieter C. Limburg, Cees GM Kallenberg and Marc Bijl. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: Systemic Lupus Erythematosus (SLE) is systemic autoimmune disease affecting many organs. Sunlight sensitivity is one of the characteristics of SLE, present in about one third to half of the patients. When exposed to physiological amounts of UVB these patients develop inflammatory skin lesions in the vicinity of apoptotic cells. High mobility group box 1 (HMGB1) is a DNA binding protein that is released from apoptotic cells and is secreted by activated cells. HMGB1 exerts its inflammatory actions through binding to several receptors such as RAGE (receptor for advanced glycation end products) and Toll-like receptors (TLRs) 2, 4, 7, and 9.

Objectives: To investigate whether HMGB1 release contributes to the development of inflammatory skin lesions in SLE patients after UVB exposure.

Methods: Eleven SLE patients and 10 healthy controls (HC) were exposed to a standard dose UVB. Biopsies were taken before and 1, 3, and 10 days after irradiation. Paraffin embedded sections were stained for HMGB1, CD3 and CD68, and frozen skin biopsies were analysed for mRNA expression of IL-8, HMGB1, RAGE, and TLRs (2, 4, 7 and 9) using RT-PCR. Primary keratinocytes were cultured and irradiated with UVB light for different timepoints. HMGB1 and IL-8 release were measured in supernatants by Western Blotting and mRNA expression of above mentioned markers were determined.

Results: A significant higher release of HMGB1 from the nucleus was seen in the un-irradiated skin of SLE patients compared to HC. Also after UVB irradiation, HMGB1 release was significantly higher in SLE patients compared to HC at all time points and HMGB1 release was correlated with presence of CD3 and CD68 positive cells. Only HMGB1 mRNA levels were increased in unirradiated skin of SLE patients compared to HC. After UVB mRNA levels of HMGB1, RAGE, TLR 2, 4, 7, and 9 all decreased and were lowest at day 3, whereas mRNA levels of IL-8 increased 24 hours after UVB irradiation without difference between patients and HC. Primary keratinocytes released HMGB1 and IL-8 into the supernatant starting from 24 hours after UVB irradiation.

Conclusion: HMGB1 protein release and mRNA expression are higher in the skin of SLE patients compared to HC. Upon UVB exposure release of HMGB1 in SLE further increases suggesting that SLE skin is more prone to release of HMGB1. As this release correlated with presence of macrophages and lymphocytes and as mRNA of the HMGB1 receptors before and after UV exposure are present in SLE patients our data suggest that HMGB1 release in SLE might be an important mediator of skin inflammation in SLE.

1660

Overexpression of Lupus-Susceptibility Gene HRES-1/Rab4 Causes Enhanced Microautophagy and Defective Mitochondrial Macroautophagy (Mitophagy) in Lupus T Cells. Tiffany Telarico[1], Edward Doherty[2], Brandon Clair[1], Walter Malorni[3] and Andras Perl[4]. [1]SUNY Upstate Medical University, Syracuse, NY, [2]SUNY Upstate, Syracuse, NY, [3]Istituto Superiore di Sanita, Rome, Italy, [4]Upstate Medical University, Syracuse, NY

Background/Purpose: T lymphocytes from systemic lupus erythematosus (SLE) patients show activation of the mammalian target of rapamycin (mTOR), that regulates autophagy. mTOR blockade by rapamycin is therapeutic in human and murine lupus. mTOR promotes expression of HRES-1/Rab4, an early endosomal trafficking protein that targets its cargo, including CD4 and CD3ζ, for lysosomal degradation. Despite increased protein degradation mediated by HRES-1/Rab4, mitochondrial mass is increased in SLE T cells. Mitochondrial mass depends on mitochondrial biogenesis, fusion and fission, the latter regulated by dynamin-related protein 1 (Drp1). Here, we examined the effect of HRES-1/Rab4 and mTOR blockade on microautophagy of proteins and macroautophagy of mitochondria (mitophagy).

Methods: Glutathione-S-transferase (GST) pull down assays were used to identify binding partners of HRES-1/Rab4, GDP-locked HRES-1/Rab4^{S27N}, GTP-locked HRES-1/Rab4^{Q72L} and phosphorylation-defective HRES-1/Rab4^{S204Q} in peripheral blood lymphocytes (PBL). Adeno-associated viruses (AAV) expressing HRES-1/Rab4 isoforms in pAAV-IRES-GFP were used to infect PBL. Jurkat cells expressing HRES-1/Rab4 or HRES-1/Rab4^{S27N} were also utilized. Macroautophagy of mitochondria was studied by flow cytometry and expression of Drp1 by western blot. Microautophagy was evaluated by expression of CD4 and CD3ζ. To determine whether autophagy is altered in lupus, expression of autophagy regulators Beclin-1, LC3, and Drp1 were measured in resting and CD3/CD28-stimulated PBL of SLE patients treated *in vivo* with and without rapamycin as well as of healthy controls matched for age, sex, and ethnicity. ANOVA and t-test were used for data analysis.

Results: HRES-1/Rab4 directly interacted with Drp1 and reduced its expression and phosphorylation in Jurkat cells (66% decrease, $p=0.01$) and PBL (62% decrease, $p=0.005$) that is consistent with formation of megamitochondria in lupus T cells. Along this line, expression of dominant-negative HRES-1/Rab4^{S27N} reduced mitochondrial mass in Jurkat cells (27% decrease, $p=0.005$) and in AAV-infected PBL (8% decrease in $CD4^+$ T cells, $p=0.025$; 19% decrease in $CD8^+$ T cells, $p=0.03$). In contrast, HRES-1/Rab4 overexpression in PBL diminished CD4 (26% decrease, $p=0.003$) and CD3ζ protein levels via lysosomal degradation (33% decrease, $p=0.049$) which are consistent with increased microautophagy. Expression of autophagy initiator protein Beclin-1 was reduced in lupus PBL in comparison to healthy controls (66% decrease, $p=0.0008$) and was normalized in SLE patients' T cells by *in vivo* rapamycin treatment ($p=0.036$, compared to SLE patients treated without rapamycin). CD3/CD28-stimulated PBL from rapamycin-treated SLE patients exhibited increased LC3II/LC3I ratio, indicative of restored autophagy via mTOR blockade ($p=0.01$). Drp1 expression was reduced in SLE PBL (48% decrease, $p=4 \times 10^{-5}$), but was not corrected in rapamycin-treated patients (50% decrease, $p=0.003$).

Conclusion: These results provide evidence for increased microautophagy and decreased mitophagy in lupus T cells which are mediated through the activation of the HRES-1/Rab4/mTOR axis.

1661

Rapamycin Treatment Normalizes CD3 and CD4 Recycling in Lupus T Lymphocytes. Tiffany Telarico[1], Brandon Clair[1] and Andras Perl[2]. [1]SUNY Upstate Medical University, Syracuse, NY, [2]Upstate Medical University, Syracuse, NY

Background/Purpose: Activation of the early endocytic pathway in T cells from systemic lupus erythematosus (SLE) patients is evidenced by increased expression of Rab5A and HRES-1/Rab4 mediate the increased internalization, recycling, and lysosomal degradation of signaling receptors, such CD3ζ and CD4. Diminished CD3ζ and CD4 and increased HRES-1/Rab4 expression inversely correlate in SLE T cells, which are targeted for lysosomal degradation by HRES-1/Rab4. SLE T cells exhibit increased recycling of CD3 and CD4 receptors. HRES-1/Rab4 directly interacts with CD3ζ and CD4, whose expression directly impacts T cell activation. Activity of the mammalian target of rapamycin (mTOR) is upstream of the endocytic pathway, as treatment with mTOR inhibitor rapamycin reduces HRES-1/Rab4 expression in SLE T cells. Here, we examined the effect of rapamycin treatment and HRES-1/Rab4 expression on CD3 and CD4 receptor recycling in SLE T cells.

Methods: SLE patients treated *in vivo* with and without rapamycin as well as healthy controls matched for age, sex, and ethnicity were studied. Flow cytometry was used to measure recycling of CD3, CD4, and CD8 surface receptors in untouched T cells prepared by negative isolation. To measure recycling, cells were stained with CD3, CD4, and CD8 antibodies in the presence of cycloheximide on ice, washed, and incubated at 37°C to induce receptor turnover. Samples were taken every 30 minutes for 2.5 hours and re-stained at the conclusion of the assay. T cell, $CD4^+$ T cell, $CD8^+$ T cell, $CD4^-CD8^-$ T cell, and B cell populations were compared among subjects by flow cytometry of freshly isolated peripheral blood lymphocytes (PBL). To determine whether enhanced recycling in SLE T lymphocytes is HRES-1/Rab4 dependent, PBL from healthy controls and SLE patients were infected with adeno-associated viruses (AAV) expressing HRES-1/Rab4 or a vector control (pAAV-IRES-GFP), and recycling was measured 48 hours post-infection. Two-way pair-wise repeated-measures analysis of variance (ANOVA) was used for statistical analysis.

Results: Treatment of SLE patients with rapamycin *in vivo* reversed the accelerated recycling of CD4 ($p=0.005$) and CD3 on $CD4^+$ T cells ($p=0.007$). Rapamycin also reduced the recycling of CD3 on $CD8^+$ T cells ($p=0.008$) and $CD4^-CD8^-$ T cells in comparison to SLE patients not treated with rapamycin ($p=0.0009$). PBL from rapamycin-treated SLE patients had a reduction in total B cell number, in comparison to SLE disease controls (30% decrease, $p=0.001$). Overexpression of HRES-1/Rab4 in SLE PBL promoted the recycling of CD3 ($p=0.02$) and CD8 ($p=0.005$), but reduced recycling of CD3 ($p<0.001$) and CD8 ($p=0.01$) in healthy controls.

Conclusion: The results suggest that HRES-1/Rab4 overexpression may be responsible for increased CD3 recycling in SLE T cells and rapamycin may normalize CD3 and CD4 recycling in SLE T cells through diminishing HRES-1/Rab4 activity.

1662

Lipid-Antigen Presentation by $CD1d^+$ B Cells Is Essential for the Maintenance of *I*nkt Cells: Aberrant B Cells From Patients with Systemic Lupus Erythematosus Impair *I*nkt Cell Homeostasis. Anneleen Bosma[1], Azza Abdel-Gadir[1], David A. Isenberg[2], Claudia Mauri[1] and E.C. Jury[1]. [1]University College London, London, United Kingdom, [2]University College London, London WC1E 6JF, United Kingdom

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by a profound breakdown in immune-regulatory mechanisms. Disease pathogenesis is complex but recent research has centred on the role of B cells secreting pathogenic auto-antibodies. However, B cells have other essential functions including CD1d-mediated lipid-antigen presentation to invariant natural killer T (iNKT) cells, a specialised T cell subset with regulatory function in both innate and adaptive immunity. Very few studies have examined the role of B cells on the maintenance of iNKT cells in the context of lupus. Profound reductions in iNKT cell frequency have been reported in SLE patients. To consider the *in vivo* role that B cells play in iNKT cell homeostasis and whether B cell dysfunction drives iNKT cell abnormality in lupus patients, we exploited B cell depletion therapy (rituximab) as an *in vivo* human model.

Methods: Peripheral blood mononuclear cells (PBMC) were collected from 250 patients with SLE and 90 healthy controls. Patients had active disease (BILAG>6) before rituximab treatment. Patients were considered B cell depleted (BCD) when B cell levels were below 5 cells/μl and in most cases their disease became inactive (BILAG <6). Responding patients remained in remission with inactive disease after B cell repopulation; non-responding patients developed active disease when B cells repopulated. B cell and iNKT cell phenotyping was determined by flow cytometry. To assess iNKT cell function PBMC were stimulated with a-galactocylceramide (aGC) for 7 days and iNKT cell proliferation and aGC driven cytokine profiles determined.

Results: SLE iNKT cells displayed an activated phenotype with clustered invariant (i)TCRs compared with dispersed iTCR distribution in iNKT cells from healthy individuals. In addition, compared to healthy, lupus iNKT cells expressed increased levels of CD69 paralleled by enhanced expression of surface Annexin V. Furthermore, we show that while healthy iNKT cells proliferate in response to *in vitro* a- aGC stimulation, SLE iNKT cells lack this capacity. When lupus patients were treated with rituximab, iNKT cell numbers remained low in the absence of B cells and in patients who had repopulated their B cell populations but did not respond clinically to treatment. However, iNKT cell numbers increased in patients with repopulated B cells responding to treatment, iNKT cells from these patients also regained their capacity to proliferate in response to aGC. We found that B cells from patients with SLE display significantly reduced levels of surface CD1d, compared to the levels expressed by healthy B cells. The expression of CD1d on B cells was exclusively recovered on B cell-repopulated patients responding to rituximab therapy and directly correlated with iNKT frequency.

Conclusion: These findings support our hypothesis that auto-reactive B cells in SLE patients impair iNKT cell-mediated responses and that B cell depletion therapy may restore this interaction by "resetting" the balance of B cell-iNKT cell homeostasis.

Altered Soluble Mediators of Inflammation At Baseline in Individuals Who Subsequently Transition to Systemic Lupus Erythematosus: Early Studies From the Lupus Autoimmunity in Relatives (LAUREL) Study. Melissa E. Munroe[1], Joel M. Guthridge[1], Diane L. Kamen[2], Jill M. Norris[3], Kathy L. Moser[1], Timothy B. Niewold[4], Gary S. Gilkeson[5], David R. Karp[6], Michael H. Weisman[7], Mariko L. Ishimori[8], Daniel J. Wallace[9], John B. Harley[10] and Judith A. James[11]. Background/Purpose: SLE is a multifaceted autoimmune disease marked by autoantibody production and immune dysregulation. Identification of at-risk populations is essential to curtail chronic inflammation and prevent end-organ damage. Healthy blood relatives of lupus patients are known to have a significantly increased risk of SLE development. Using a unique resource of family members with samples available before and after transition to SLE, this study seeks to identify early biomarkers of at-risk populations, as well as to understand roles of select inflammatory mediators in SLE development.

Methods: This study has re-enrolled 448 first-degree relatives (FDRs) of known SLE patients with samples available from previous genetic studies for follow-up evaluation. We have 19 previously unaffected FDRs who have now transitioned to SLE ($\geq$ 4 ACR criteria). Each individual provided detailed clinical (symptoms, medical history, medication usage, etc.) and demographic (age, race, etc.) information, and completed the Connective Tissue Disease Screening Questionnaire (CSQ) at baseline and follow-up. Where appropriate, medical records were obtained and reviewed for ACR classification criteria. Baseline and follow-up serum samples were tested for autoantibody production, including ANA, anti-dsDNA, aCLs and precipitating levels of Ro, La, Sm, nRNP, and ribosomal P autoantibodies. In addition, we assessed 52 soluble inflammatory mediators, including cytokines, chemokines, and soluble receptors, using either xMAP multiplex technology or sandwich ELISA (BLyS and APRIL). Samples from participants who transitioned to SLE were compared with two separate matched (age, race, gender) control groups, either ANA(−) or ANA(+).

Results: FDRs who transitioned to SLE had significantly higher BL CSQ scores than either ANA(−) or ANA(+) matched, unaffected FDRs ($p < 0.0001$). FDRs who transitioned to SLE had significant ($p \leq 0.01$) alterations in 34 (of 52) soluble mediators compared to ANA(−) and (+) matched FDRs. Compared to ANA(−) matched FDRs, FDRs with SLE had significantly lower ($p \leq 0.01$) levels of 29 analytes, including innate and adaptive mediators of inflammation and the cytokine APRIL; significant enhancement ($p \leq 0.01$) of 5 analytes, including BLyS, were also shown. Of particular interest were unaffected, ANA(+) matched FDRs, who showed no difference from FDRs with SLE with respect to BLyS, innate cytokines, sFasL, and sCD40L but showed significant differences compared to ANA(−) controls ($p < 0.05$). With respect to Th1, Th2, Th17, and regulatory-type cytokines, matched ANA(+) FDRs showed intermediate levels of analytes, significantly higher than FDRs with SLE, but significantly lower than matched ANA(−) FDRs ($p < 0.01$).

Conclusion: FDRs of known SLE patients who transition to clinical disease demonstrate significantly altered levels of soluble inflammatory mediators compared to matched FDRs who remain unaffected. That these alterations are present prior to the transition to active SLE suggests that multiple perturbations in immune-mediated inflammatory processes occur long before clinical classification and suggest that high-risk, pre-clinical individuals can be identified.

1664

Urinary Angiostatin As a Novel Biomarker in Lupus Nephritis. Tianfu Wu, Chun Xie, Jie Han and Chandra Mohan. University of Texas, Southwestern Medical Center at Dallas, Dallas, TX

Background/Purpose: Searching for biomarkers of immune-mediated nephritis, we previously conducted a 2D-gel based proteomic analysis of

urine from mice with anti-GBM disease, and identified urinary angiostatin as a marker of nephritis. In a more recent array-based screen of ~280 molecules using urine from patients with lupus nephritis, angiostatin again surfaced as a potential marker of nephritis. Angiostatin is a bioactive fragment of plasminogen, and has been known to have modulatory function in angiogenesis and inflammation. The goal of this study is to further investigate the potential of urinary angiostatin as a marker of lupus nephritis.

Methods: Three sets of studies were carried out. First, we screened the urine of 5 patients with lupus nephritis (average age = 38.3, average SLEDAI = 19.4) and matched controls for the levels of ~280 molecules using an array-based proteomic platform. Next, to validate the array findings, we assayed the urine of 17 patients with active lupus nephritis (average SLEDAI = 14), 10 with inactive lupus nephritis (average SLEDAI= 2.4), and 10 healthy controls. Finally, we examined a cohort of 21 patients with ISN/RPS Class III/IV lupus nephritis where urine was collected at the time of renal biopsy, so that the urinary profiles can be related to concurrent pathology.

Results:

1. In the array-based screen, urinary angiostatin was significantly increased in SLE patients compared to healthy controls (10964 ± 7130 vs 944 ± 822 AU, $P < 0.05$).
2. In the ELISA-based validation assays, urinary angiostatin was significantly increased in active lupus nephritis patients compared to the inactive group (1672±372 vs 189±72 pg/mg urine creatinine, $P < 0.02$) and healthy controls (12±4 pg/mg urine creatinine, $P < 0.01$).
3. When concurrent urine-kidney paired samples from patients with lupus nephritis were examined, we found that urine angiostatin was strongly related to concurrent ISN/RPS Class IV GN ($r = 0.50$, $P < 0.011$), performing better than urine protein/creatinine ($r = 0.22$, $P = 0.17$). Urine angiostatin levels were correlated weakly with concurrent renal pathology activity index ($r = 0.27$, $P < 0.12$), but better with concurrent renal pathology chronicity index ($r = 0.44$, $P = 0.02$).

Conclusion: Thus, urinary angiostatin emerges as a novel biomarker of clinically active Class IV nephritis in SLE, and a marker of concurrent renal pathology activity and chronicity. Longitudinal studies are in progress to assess the predictive potential of this novel biomarker in comparison to currently used yardsticks. Mechanistic studies are also in progress to fathom how angiostatin functions within the kidneys.

Everyday Life and Rheumatoid Arthritis—Implications for Patient Education. Tine Mechlenborg Kristiansen[1], Jette Primdahl[1], Rasmus Antoft[2] and Kim Hørslev-Petersen[1]. [1]University of Southern Denmark, Graasten, Denmark, [2]Aalborg University, Aalborg, Denmark

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease affecting several aspects of everyday life. The purpose of patient education is to help people with RA to manage their chronic illness. There is no tradition in Denmark to engage people with RA in developing and implementing patient education. This study aims to explore how everyday life is affected by RA and to discuss the implications for patient education.

Methods: In total six focus groups were conducted including 19 women and 13 men with RA. The groups were selected according to purposeful sampling, aimng to span the greatest possible variation in age, educational background and illness duration. Three groups were made up of participants with newly diagnosed RA (max. 1,5 years of diagnosis) and three groups of participants with diagnosis more than 1,5 years. The interviews were transcribed verbatim and content analysis inspired by Coffey and Atkinson was used in managing and analyzing the data.

Results: The analysis resulted in four distinct categories that describe how everyday life was affected by RA. Self-identity and self-perception was affected, social relations within the family and friendships changed, work relations were challenged and new relations within health- and social systems were established that affected the individuals in both positive and negative ways. The most important for the participants was the wish to continue "normal life". The analysis showed that a few individuals were able to continue most daily activities as RA had only a minimal impact on normal life. This was due to receiving a fast diagnosis and effective medical treatment that kept symptoms under control.

Implications for future patient education—four interrelated areas of support:

(1) Support to manage the symptoms in everyday life including disease-specific knowledge about RA
(2) Support for areas of social interaction, as for instance work and support to understand how RA can affect one's social life
(3) Support to manage psychological and emotional reactions related to how RA affects conceptions of self and identity, especially in the early phases of RA
(4) Support to facilitate meeting others with RA

Conclusion: For the most people, living with RA affects almost every aspect of everyday life. This has important implications for patient education. To ensure that patient education is perceived as relevant and supportive, it should be inter-disciplinary and should incorporate not only disease-specific knowledge about RA and managing RA symptoms but also social and psychological dimensions related to everyday life, and it should facilitate meeting others with RA.

1666

One-Year Outcomes of Systemic Lupus Erythematosus (SLE) and/or Antiphospholipid Antibody (aPL) Positive Patients Enrolled in An Ongoing Cardiovascular Disease (CVD) Prevention Counseling Program (PCP). Aeshita Dwivedi[1], Virginia Haiduc[1], Monica C. Richey[1], Sotiria Everett[1], Lisa Konstantellis[1], Ann R. Garment[2], Hassan Ghomrawi[1] and Doruk Erkan[1]. [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medical Center, New York

Background/Purpose: SLE patients have high-risk CVD profiles as they have increased prevalence of traditional CVD- and lupus-related thrombosis risk factors. In addition, aPL-positive patients are at increased risk for thrombosis. We have developed a free-of-charge counseling program for SLE and/or aPL-positive patients that provides a basic assessment of and education about the CVD and thrombosis risk factors (Arthritis Rheum 2009;60;S743). We report one-year outcomes of patients enrolled in our ongoing CVD-PCP.

Methods: The *assessment* phase of CVD-PCP includes the evaluation of blood pressure (BP), blood glucose, cholesterol profile, waist circumference, body mass index (BMI), diet and exercise habits, smoking status, Framingham 10-year CVD risk calculation, aPL-profile, and medications. The *education* phase includes detailed discussion of the above risk factors as well as CVD and thrombosis prevention strategies. At the end of the counseling, patients: a) receive tailored lifestyle recommendations and a written report; and b) are referred to the Nutrition and Physical Therapy Departments as needed based on pre-set criteria. Patients are followed every 3–6 months based on their CVD risk-profiles, and their rheumatologists receive a report after each counseling. While analyzing one-year outcomes, in order to estimate change over time, we used repeated measures regression analysis with time as the predictor.

Results: Between March 2009 and December 2010, 100 patients were enrolled in the program (mean age: 41.7 ± 14.3y; female: 87%; SLE with/without aPL: 74%; and aPL-positive patients without SLE: 26%) with a total of 344 visits (mean: 3.4 ± 1.9; range: 1–7). *At baseline:* a) 83% and 65% of patients required further nutrition and exercise counseling, respectively; b) 62% of patients were overweight or obese with a mean BMI of 28.4 (16.5–49.9); and c) 47%, 5%, and 75% of patients required better BP, blood sugar, and cholesterol management, respectively in order to meet the guidelines (cholesterol profile was available in 70% at baseline). *Based on the analysis of 77 patients who completed at least one-year follow-up:* a) there was a significant improvement in diet and exercise habits (Table), however not in BMI; b) the percentage of patients requiring better BP, blood glucose, and cholesterol management did not differ significantly (cholesterol profile was available in 93% at one-year follow-up).

Variable	3 or 6m Visit OR (95%CI)	9 or 12m Visit OR (95%CI)
Increased Fruits & Vegetables in Diet	1.51 (0.76–2.99)	1.94 (0.94–3.97)
Increased Whole-Grain & High-fiber in Diet	1.67 (0.84–3.32)	2.04* (1.00–4.16)
Increased Fish in Diet	2.35* (1.16–4.74)	2.10* (1.01–4.34)
Increased Attention to Cholesterol Free Diet	2.14 (0.93–4.93)	1.11 (0.43–2.85)
The Need for Further Nutrition Counseling	0.36* (0.16–0.78)	0.51 (0.23–1.17)
Increased Exercise at Least 30 min/day	2.95* (1.38–6.33)	3.42* (1.57–7.47)
The Need for Further Exercise Counseling	0.27* (0.19–0.68)	0.14* (0.06–0.35)

* $p < 0.05$

Conclusion: The one-year preliminary analysis of our ongoing CVD Prevention Counseling Program demonstrates positive changes in diet and exercise habits of SLE and/or aPL-positive patients. However, the lifestyle changes have not yet translated into clinically meaningful outcomes at one-year follow-up. The three-year longitudinal analysis will determine the true effectiveness of the program whether it decreases the prevalence of CVD risk factors.

Designing a Community-Based Intervention to Improve the Health of Medically-Underserved Women with Systemic Lupus Erythematosus. Candace H. Feldman[1], Patricia A. Fraser[2], Bonnie L. Bermas[1], Melanie Zibit[1], Derrick J. Todd[1], Paul R. Fortin[3], Elena M. Massarotti[1] and Karen H. Costenbader[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Genzyme Corporation, Cambridge, MA, [3]Toronto Western Hospital, Toronto, ON

Background/Purpose: Medically-underserved women with systemic lupus erythematosus (SLE) have disproportionately high morbidity and mortality. We conducted focus groups to discuss 4 potential interventions to improve the health status of medically- underserved women with SLE.

Methods: From our Lupus Registry of 1,650 patients with SLE, defined according to the ACR Criteria, we identified 282 women, age 18 and older, residing in 11 urban, federally-defined medically-underserved area (MUA) zip codes. IRB-approved flyers were mailed to these women inviting them to participate. Additional flyers were distributed by the leaders of 2 predominantly African-American SLE support groups. In 90 minute focus groups, 3 trained moderators followed a detailed guide to present 4 potential interventions: 1) SLE-specific health navigators; 2) a peer support program; 3) a booklet of personal medical and SLE information ("Lupus Passport"); and 4) initiation of rheumatology specialty care at community health centers. The focus groups were tape-recorded, transcribed and coded, based on themes. Discussions concerning the interventions were analyzed in terms of perceived benefits, limitations, ideal target populations, and implementation questions.

Results: 29 women with SLE were divided randomly into 3 focus groups (n=9, n=9, n=11). 80% were African American, 10% Hispanic and 10% White. 83% were from urban MUAs. Mean age was 51 years (SD 18) and mean age at SLE diagnosis was 35 years (SD 15). Dominant themes included the desire for increased SLE education for patients and their families, the need for a patient navigator and advocate, the feeling of isolation at the time of SLE diagnosis, and the potential benefit of an assigned peer supporter. The Lupus Passport's explanations in plain English and inclusion of past and present medications interested many women. Several women felt that an assigned healthcare worker would be necessary to update the passport. The majority of participants already received their care at major academic medical centers and did not feel they would benefit from a rheumatologist at a community health center. Most women believed that any intervention, particularly a peer support program, should target newly diagnosed women. The women suggested quality of life and self-efficacy for disease control as potential measures of outcome.

Conclusion: Women with established SLE living in urban MUAs who participated in these focus groups were eager to partner with researchers to design interventions to improve their health and well-being. These women were enthusiastic about the development of a peer support program, and the utilization of a Lupus Passport, in particular for women with newly diagnosed SLE. Further collaboration with the community is needed to develop and test such interventions.

A Randomised Comparison of Interactive and Conventional Education to Increase Adherence with a Dutch Physical Therapy Practice Guideline for Hip and Knee Osteoarthritis. Wfh Peter[1], Ph van der Wees[2], J. Verhoef[3], Z. de Jong[1], L. Vos[1], Wkha Hilberdink[4], M. Fiocco[1] and Tpm VlietVlieland[1]. [1]Leids University Medical Center, Leiden, Netherlands, [2]The Royal Dutch Society of Physical Therapy (KNGF) Amsersfoort, CAPHRI Maastricht University, IQ Health Care, Nijmegen, Netherlands, [3]Hogeschool Leiden, Leiden, Netherlands, [4]Paramedical Center for Rheumatology and Rehabilitation, Groningen, Netherlands

Background/Purpose: There is insufficient use of physical therapy (PT) guidelines in the Netherlands. The literature (1) and daily practice indicate a need for interactive forms of education to enhance guideline usage, but the evidence on their effectiveness is lacking. The aim of this study was to compare the effectiveness of two educational courses (interactive (IT) and conventional (CT)) as a part of the implementation of the Dutch PT guideline for hip and knee osteoarthritis (HKOA) (www.kngfrichtlijnen.nl/654/KNGF Guidelines in English.htm).

Methods: In 3 regions in the Netherlands, all PTs who were a member of the KNGF and working in primary care were randomly offered one of two educational courses. IT comprised the presentation of 3 clinical cases with the cooperation of 3 patient partners and 3 expert PTs per region, executed according to the method of clinical reasoning. CT included a presentation by one expert PT about the guideline development process and the most important recommendations. Both courses were pilot-tested among 10 PTs and adapted according to the comments received. Assessments were done before the educational course, immediately afterwards and three months thereafter. Assessments consisted of a self-developed electronic questionnaire, 18 questions on the usage of the guideline (5-point Likert scale, total score range 18–90) and 19 questions on knowledge (mixed format of items; total score range 0–76) which was pilot-tested among 15 PTs. In addition, sociodemographic characteristics of the participants were recorded. Statistical analysis included comparisons of total mean scores between the IT and CT groups across 3 time points by using General Linear Model analyses.

Results: In total 2059 PTs were invited, of whom 203 (9.9%) were willing to take part in the study and randomized in IT (n=108) or CT (n=95). The baseline characteristics of the participants of the IT and CT groups were comparable concerning age, gender, work setting, years of experience, the number of patients treated in the past three months and advanced education in OAmanagement. The unadjusted statistic analyses showed a significant difference for the total mean change usage of the guideline over 3 time points between CT (73.87(6.97)–74.31(6.18)–75.31(6.79)) and IT (75.05(6.69)–76.91(5.83)–78.31(5.77)), p=0.008 in favour of IT. Concerning knowledge there was no significant difference between the total mean change over 3 time points of CT (54.95(12.07)–60.87(12.35)–57.96(12.27)) and IT (55.43(11.08)–62.54(10.12)–59.73(10.19)), p=0.19.

Conclusion: An interactive educational course was found to be more effective with respect to improvement of self-reported guideline usage than a conventional educational course, whereas knowledge increased in both groups but did not differ significantly. A further analysis of the effectiveness of both educational strategies will facilitate the optimization of comprehensive PT guideline implementation strategies.

Funding: This project was funded by the Royal Dutch Society of Physical Therapy and the Dutch Arthritis Association.

Development and Usability Testing of ANSWER: A Web-Based Methotrexate Decision Aid for Patients with Rheumatoid Arthritis. Linda C. Li[1], Paul M. Adam[2], Anne F. Townsend[3], Diane Lacaille[3], Charlene Yousefi[3], Shawn Turnau[1], Dawn Stacey[4], Jessie McGowan[5], Peter Tugwell[6], Catherine L. Backman[1] and ANSWER Team[7]. [1]University of British Columbia, Vancouver, BC, [2]Mary Pack Arthritis Centre, Vancouver, BC, [3]Arthritis Research Centre of Canada, Vancouver, BC, [4]University of Ottawa, Ottawa, ON, [5]Universtiy of Ottawa, Ottawa, ON, [6]Institute of Population Hlth, Ottawa, ON, [7]Vancouver & Ottawa

Background/Purpose: Decision aids are evidence-based tools designed to inform people of the potential benefits and harm of treatment options, clarify their preferences, and provide a structure for discussion at a clinic visit. For patients with rheumatoid arthritis (RA) who are considering methotrexate, we have developed an interactive web-based decision aid called the ANSWER. The current study aims to: 1) assess the usability of the ANSWER prototype; and 2) identify important components of usability testing from the patient's perspective.

Methods: Development of the ANSWER was consistent with the International Patient Decision Aid Standards.[1] This decision aid consists of: 1) six animated patient stories and narrated information on the evidence of methotrexate for RA; and 2) interactive questionnaires to clarify patients' treatment preferences. Eligible participants for the usability test were patients with RA who had used methotrexate. We used the concurrent think-aloud method, whereby participants were asked to verbalise their thoughts while using the ANSWER. Sessions were audiotaped and field notes taken. Participants completed the System Usability Scale (SUS) [2;3] to assess the overall usability of the decision aid (range=0–100; higher=more user friendly). We conducted content analysis to identify major themes to understand the user experience.

Results: 15 patients participated in the usability testing; the majority were age 50 or over and university/college graduates (n=8, 53.4%). The median disease duration was 5 years (IRQ=0.83–10). Participants took an average of 56.1 minutes (SD=34.8) to complete the program. The mean SUS score was 81.2 (SD=13.5), indicating high usability. Content analysis of audiotapes and field notes revealed three themes that participants focused on while testing the ANSWER: 1) user engagement (i.e., the relevance of the decision aid design and content to the user); 2) information quality (i.e., clarity and credibility of information); and 3) user-tool interaction (i.e., consistency of the design; ease of use). Across these themes, participants commented extensively on the overall integration of the content and navigation (e.g., challenges of moving from one task to the next). We made revisions to the prototype based on the findings.

Conclusion: Although the SUS score indicated high usability, findings from the think-aloud sessions highlighted additional areas where further modifications were needed for the online ANSWER decision aid. Our results highlight the importance of direct observation methods in usability testing. With an increasing number of online and mobile programs being developed to improve arthritis knowledge and care, further research to advance the methodology of usability testing is warranted.

The Impact of An Evidence-Based Community-Delivered Exercise Program on Arthritis Symptoms and Health-Related Quality of Life. Dina L. Jones, Jennifer L. Eicher, Matthew J. Gurka, Ruoxin Zhang, Melissa Himes, W. Lynn Harrington, Abhishek Vishnu and R. Turner Goins. West Virginia University, Morgantown, WV

Background/Purpose: Although the efficacy of exercise in people with arthritis has been established, there is less literature to support the effectiveness of these interventions when delivered in the community setting. The EnhanceFitness® program is an evidence-based, community-delivered intervention that is effective in older adults, however, its effectiveness in people with arthritis has not been studied. Thus, the purpose of this study was to determine if participation in 12 weeks of EnhanceFitness® resulted in arthritis-specific health benefits and improvement in health-related quality of life (HRQOL) for the participants.

Methods: One-hour exercise classes were offered three times per week for 12 weeks at 11 senior centers, three churches, one rehabilitation facility, and one recreational center in nine counties in West Virginia. Each class was limited to adults, aged 18 years and older, with self-reported physician-diagnosed arthritis who were sedentary or low active (reported ≤ 60 minutes per week of moderate-intensity activity). Participants were assigned to an immediate exercise group or a delayed-intervention group that began exercise 12 weeks later. The program consisted of low-impact aerobics, strength-training exercises, flexibility, and balance exercises. Data on demographics, arthritis symptoms, and HRQOL were collected at baseline (pre-exercise) and after the 12-week class (post-exercise). Arthritis pain, fatigue, and stiffness were assessed using 10-centimeter Visual Analogue Scales. The SF-12 Physical Component Summary (PCS) and Mental Component Summary (MCS) scores were used to measure HRQOL. Participants who attended at least 50% of classes and all data collection sessions were defined as study completers and included in the analysis. Within-group comparisons between baseline and 12 weeks were conducted using generalized linear mixed models and natural log transformations where appropriate.

Results: The 323 participants who enrolled in the study were primarily female (86%) and white (95%) with a mean age ± standard deviation of 68 ± 11 years old (range 27 to 95 years). The immediate exercise group contained 181 (56%) people and the delayed intervention group included 142 (44%) people. There were 175 (54%) study completers (Group 1, n = 108; Group 2, n = 67). Participants were more likely to withdraw if they were in the delayed-intervention group, younger, had lower physical and mental HRQOL, or more chronic health conditions. There was no significant difference in the SF-12 PCS ($p = 0.42$) or MCS ($p = 0.23$) scores from baseline to 12 weeks. There was, however, an improvement in pain, stiffness, and fatigue during the intervention ($p < 0.01$).

Conclusion: Participants who attended at least 50% of an evidence-based exercise program delivered in the community setting reported an improvement in arthritis pain, stiffness, and fatigue. Physical and mental HRQOL did not change perhaps due to the differential loss of participants with poorer health and lower HRQOL from the intervention. Overall, the EnhanceFitness® exercise program appeared to improve arthritis symptoms in inactive older adults with arthritis.

The TNFα Induced Microrna-17/92 Cluster Promotes Synovial Fibroblast Aggressiveness by Repressing Key Signaling Pathway Inhibitors. Michelle Trenkmann[1], Matthias Brock[1], Renate E. Gay[1], Christoph Kolling[2], Rudolf Speich[3], Beat A. Michel[1], Steffen Gay[1] and Lars C. Huber[3]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Clinic and Policlinic for Internal Medicine, University Hospital Zurich, Zurich, Switzerland

Background/Purpose: The miR-17/92 cluster encompasses six distinct microRNAs (i.e. miR-17, −18a, 19a, −19b, −20a and −92a) and has been associated with various (patho)physiological processes such as the maturation of the immune system or the development of malignant tumors. To elucidate the role of this microRNA cluster in the pathogenesis of rheumatoid arthritis (RA) we studied expression and function of the primary transcript C13orf25 and mature miRs derived from miR-17/92 in RA synovial fibroblasts (SF).

Methods: RASF (n=5) were stimulated with 10ng/ml TNFα for 1h, 2h, 4h, 8h, 16h and 24h. The C13orf25 mRNA and the mature miR-18a, −19a, −20a and −92a were measured by SYBR Green quantitative real time PCR (qPCR). RASF (n=5) were transfected with C13orf25 promoter constructs and reporter gene assay was performed after 8h of TNFα stimulation. RASF (n=5) were transfected with pre-miRs and then stimulated with TNFα for 24h. IL6 and MMP1 were measured by qPCR and ELISA. 3′UTRs of potential target genes were cloned into luciferase vectors and reportergene assays were carried out in pre-miR-18a transfected Hek293 cells (n=4).

Results: TNFα significantly induced the expression of both the C13orf25 transcripts and of the mature miRs-18a, −19a, and −20a in a time dependent manner with peak induction observed at 16h of stimulation. The activity of the C13orf25 promoter was significantly enhanced by TNFα as assessed by reporter gene assay; conversely, deletion of the NF-κB binding site within the promoter region abolished this induction (wt 1.47±0.23-fold, ΔNF-κB 1.17±0.15-fold; $p<0.05$). Transfection of pre-miRs and subsequent stimulation of SF with TNFα increased the mRNA expression levels of IL6 and MMP1 in miR-18a transfected cells. Thus, the expression of IL6 and MMP1 was upregulated by 2.4±1–fold and 4.9±4.9–fold ($p=0.046$ and $p=0.068$). Additionally, miR-18a transfection strongly enhanced the TNFα-induced expression of IL6 (190±58-fold) and MMP1 (1044±864-fold) to 418±139–fold and 2207±1479-fold, respectively ($p<0.05$). These data were confirmed on protein level by ELISA showing an increase of MMP1 by 5.9±5.1-fold (basal; $p=0.1$) and 1.13±0.09-fold (TNFα; $p=0.03$), and of IL6 by 1.85±0.79-fold (basal; $p=0.07$) and 1.63±0.43-fold (TNFα; $p=0.03$) Following a TargetScan database search, the MAP kinase phosphatase PTP4A3 and PIAS3, an inhibitor of Stat3 and NF-κB signaling, were studied as potential target genes of miR-18a. Reporter gene assays utilizing the respective 3′UTRs (wt or mutated miR-18 seed match) demonstrated that PIAS3 and PTP4A3 are direct miR-18a targets ($p<0.05$).

Conclusion: We show here for the first time that the miR-17/92 cluster is induced by TNFα in SF via the NF-κB pathway. We demonstrate that miR-18a targets inhibitors of major signaling pathways involved in the activation of RASF which, in turn, may result in the upregulation of inflammatory cytokines and matrix degrading enzymes. Our data thus provide first evidence that miR-18a might have a pivotal role in the regulation and integration of signal transduction pathways in RASF.

MiR-323, a Novel MicroRNA in Rheumatoid Arthritis, Promotes the Activated Phenotype of Synovial Fibroblasts. Mary Connolly[1], Michelle Trenkmann[1], Joanna Stanczyk[1], Emmanuel Karouzakis[1], Christoph Kolling[2], Beat A. Michel[1], Douglas J. Veale[3], Ursula Fearon[3], Renate E. Gay[1], Steffen Gay[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Dublin Academic Medical Centre, University College Dublin, Dublin, Ireland

Background/Purpose: MicroRNAs (miRNA) belong to a class of small, evolutionarily conserved noncoding RNAs that function as post-transcriptional repressors of gene expression. An accumulating body of evidence suggests that up to 50% of the human genome is regulated by miRNAs. The aim of this study was to examine expression of miRNA-323 in synovial fibroblasts from patients with rheumatoid and osteoarthritis (RA and OA) and to elucidate the role of miR-323 in the pathogenesis of arthritis.

Methods: Synovial fibroblasts (SF) were isolated from RA and OA patients undergoing joint replacement surgery. Total RNA was isolated using the mirVana™ miRNA isolation kit. MiR-323 levels were analyzed by real-time PCR and data was calculated by the dCt method using miR-let-7a as an endogenous control. The effect of pro-inflammatory stimuli and DNA methylation was examined by stimulation of SF with IL-1β (10ng/ml), TNFα (10ng/ml), poly(I:C) (10μg/ml) or 5-azaC (0.5μM). Overexpression/silencing of miR was analysed using a synthetic precursor of Pre or Anti-miR™-323 respectively. Cytokine and MMP levels were measured by PCR and ELISA. Cell migration, adhesion and proliferation were examined using scratch, fibronectin-based adhesion or MTT assays. Cytoskeletal rearrangement was examined by immunoflourescent staining of filamentous actin (F-actin). The 3′UTR of TIMP-3 was cloned into a luciferase vector and reporter gene assays were carried out in pre-miR-323 transfected Hek293 cells.

Results: Expression of miR-323 was significantly higher in RA (n=6) compared to OASF (n=4, $p<0.05$). Levels of miR-323 remained unchanged in RASF following treatment with IL-1β, TNF-α and TLR-3 ligand, poly(I:C). Incubation of OASFs with hypomethylating agent, 5-azaC, resulted in a 2.8 fold increase in miR-323 mRNA, suggesting that epigenetic mechanisms mediate regulation of miR-323 in synovial fibroblasts. Overexpression of miR by transfection with pre-miR-323 resulted in significant upregulation of IL-8, MMP-1 and MMP-3 in RASF (n=4, $p<0.05$), however no significant differences were observed in transcript levels of IL-6. Conversely, transfection of cells with anti-miR-323 resulted in marked downregulation of MMP-1,3 and IL-8. Similar results were observed with pre/anti miR when protein levels were examined (n=4). Overexpression of miR-323 accelerated RASF migration in a scratch assay and significantly increased cell adhesion and proliferation (n=3, $p<0.05$). Furthermore, pre-miR induced cytoskeletal disassembly in RASF, resulting in filopodia and microspike formation. Reporter gene assays confirmed TIMP-3 as a direct target of miR-323, since transfection of the 3′UTR of TIMP-3 sense construct with miR-323 resulted in lower relative luciferase activity as compared with mock transfected HEK cells.

Conclusion: Our data provides evidence that miR-323 is significantly increased in RA and thereby involved in the upregulation of proinflammatory cytokines and matrix metalloproteinases in RASF. miR-323 also potentiates cell migration, proliferation and adhesion, other key processes in the pathogenesis of RA. We conclude that miR-323 is involved in the development of the activated phenotype of RASF.

1673

The Role of Microrna-34 and Microrna-22 in Dendritic Cells and Monocyte Activation in Rheumatoid Arthritis. Stefano Alivernini[1], Derek S. Gilchrist[2], Lynn Crawford[2], Lucy Ballantine[2], John Hunter[3], Derek Baxter[2], Barbara Tolusso[4], Elisa Gremese[4], Gianfranco Ferraccioli[4], Iain B. McInnes[2] and Mariola Kurowska-Stolarska[2]. [1]University of Glasgow, Glasgow, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]Gartnavel General Hospital, Glasgow, United Kingdom, [4]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: MicroRNAs (miRs) are a novel class of post-transcriptional regulators that have been implicated in the pathogenesis of distinct human diseases, including Rheumatoid Arthritis (RA). We have previously shown that miR-34 family members and miR-22 are overexpressed in synovial fluid (SF) monocytes compared to matched peripheral blood (PB) monocytes in RA patients. The aim of this study was to investigate the functional role of miR-34 and miR-22 in the biology of monocytes and monocyte-derived DCs in the context of their abnormal activation in RA.

Methods: Expression of miR-34a and miR-22 in RA and osteoarthritis (OA) synovial tissues were evaluated by *in situ* hybridization. To characterize miR-34a positive cells, fluorescent *in situ* hybridization and immunostaining for CD68 were performed on RA tissues. Expression of miR-34a and miR-22 was evaluated by qPCR on DCs isolated by CD1c and CD304 specific microbeads from matched PB and SF of RA patients (n=3). Monocytes from PB of healthy donors (n=5) were isolated by CD14+ microbeads (AutoMACS) and transfected with miR-34a, miR-22 or control mimics. Cells were subsequently stimulated with LPS (10 ng/ml) or CL097 (1 mg/ml). DCs were generated from PB CD14+ cells stimulated with GM-CSF (100 ng/ml) and IL-4 (20 ng/ml) for 7 days. Once generated, CD14+ derived DCs (n=4) were transfected with miR mimics and stimulated as described above. After 18h of stimulation, supernatants were collected and evaluated for chemokine and cytokines levels (Luminex assay). To identify miR-34/22 targets HumanTargetScan cross-referenced with transcriptomic profile of SF CD14+ cells was employed. Identified targets were experimentally verified by miR luciferase assay and qPCR.

Results: miR-34a and miR-22 are overexpressed in SF DCs compared to matched PB DCs in RA patients. *In situ* hybridisation showed that miR-34a and miR-22 are widely expressed in RA synovium compared to OA. Double immunofluorescence staining revealed that miR-34a is present in RA synovial tissue myeloid cells. Enforced overexpression of miR-34a but not miR-22 in PB monocytes increased TLR7/8 triggered TNF-alpha production. Overexpression of miR-34a and miR-22 in monocytes-derived DCs increased spontaneous, TLR4 and TLR7/8 triggered TNF-alpha production. In addition, miR-22 but not miR-34a induced production of chemokines and interferon alpha by DCs. Computational target ranking system cross-referenced with transcriptomic profile of RA SF CD14+ cells identified Axl and Tyro3, receptor tyrosine kinases involved in negative feedback mechanism limiting TLRs-induced myeloid cells activation, as potential direct targets for miR-34a and miR-22. Experimental validation confirmed that miR-34a and miR-22 target 3′ UTR of Axl and Tyro3 mRNAs, respectively. Consistently, Axl and Tyro3 levels are downregulated in myeloid cells overexpressing miR-34a and miR-22, respectively.

Conclusion: This study indicates that overexpression of miR-34a and miR-22 in myeloid cells can lead to the disregulation of their self-regulatory mechanism. Thus, high levels of miR-34a and miR-22 in synovial myeloid cells of RA patients may be responsible for an excessive pro-inflammatory activation of these cells.

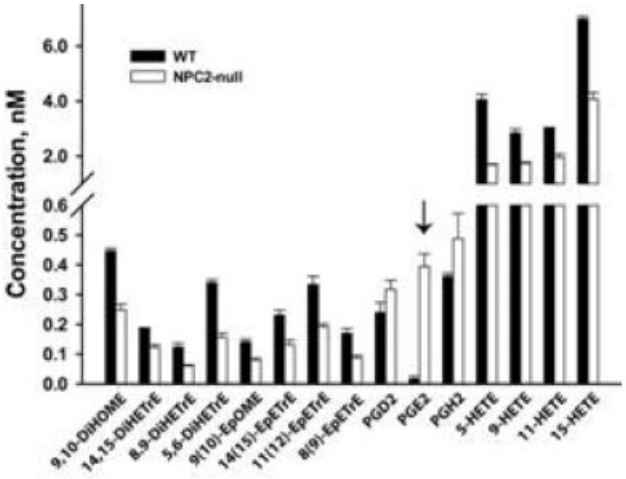
Niemann-Pick Type C2 Protein As a Negative Regulator of Innate Immunity: Inflammatory Cytokines and Eicosanoids. Andrey Frolov[1], Min Jiang[2], Hua Dong[3], Lihua Yang[1], Rahul Matnani[1], Bruce Hammock[3] and Leslie J. Crofford[1]. [1]University of Kentucky, Lexington, KY, [2]University of Cincinnati, Cincinnati, OH, [3]University of California Davis, Davis, CA

Background/Purpose: Synovial fibroblast (SF) activation has been proposed to be a central event in RA initiation. SF activation is characterized by upregulated production and secretion of inflammatory cytokines and eicosanoids. We have recently identified Niemann-Pick type C2 (NPC2) protein as a negative regulator of fibroblast activation and demonstrated that SF isolated from RA patients are NPC2-deficient (1). In the current study, we elucidated a molecular mechanism for NPC2-dependent suppression of inflammatory mediators in human fibroblasts.

Methods: NPC2-null human skin fibroblasts were derived from patients with NPC2 disease (1). DNA microarray and real-time RT-PCR analyses of NPC2-null cells were performed as described (1). Arachidonic acid (AA) metabolome profiling was performed by the liquid chromatography (LC) electrospray ionization tandem mass spectrometry (LC/MS/MS) (2). Suppression of cytosolic phospholipase A2 (cPLA2) activity and lysophosphatidic acid (LPA) signaling was achieved by using their respective specific inhibitors, Calbiochem 525543 and Ki 16245. All cell manipulations and measurements were performed under unstimulated conditions.

Results: In order to elucidate a molecular mechanism responsible for the increased production of interleukins 1B (IL-1B) and 6 (IL-6) in NPC2-null cells (1), we probed the cPLA2 metabolic pathway. DNA microarray and real-time RT-PCR data demonstrated upregulation of cPLA2 (*PLA24GA*), phospholipase D3 (*PLD3*), prostaglandin-endoperoxide synthase 2 (*PTGS2*),

and prostaglandin E synthase (*PTGES*) mRNAs by respectively ~60-fold, 3-fold, 150-fold, and 10-fold. The LPA receptor EDG2 (*LPA1*) and the prostaglandin E2 receptor *EP4* were induced by ~2-fold and ~3-fold, respectively. Inhibition of cPLA2 led to suppression of *IL-1B* and *IL-6* mRNA levels by ~ 90%. Blocking EDG2 signaling resulted in ~75% suppression of *IL-1B* and *IL-6* mRNAs. Because LPA was implicated in the induction of a key RA inflammatory mediator, prostaglandin E2 (PGE2), we examined PGE2 production by NPC2-null fibroblasts using LC/MS/MS. The data showed more than 10-fold upregulation of PGE2 production and secretion by NPC2-null cells as compared to control. More importantly, AA metabolome profiling by LC/MS/MS revealed the very specific nature of PGE2 up-regulation as the other analyzed AA metabolites were mostly down-regulated (Fig. 1).



Conclusion: This work identifies NPC2 protein as an important negative regulator of the cPLA2 metabolic pathway which drives production of both the inflammatory cytokines and PGE2 in activated human fibroblasts. Given the crucial role of these mediators in RA, we envision NPC2 protein or its signaling pathway as a potentially novel and multifaceted therapeutic tool to target activated SF in RA.

A Novel CR3 Agonist Attenuates Pro-Inflammatory Signaling in Subjects with Common and Variant ITGAM Polymorphism, rs1143679.

Manish Jain[1], Michael Amato[1], Jill P. Buyon[1], Vineet Gupta[2] and Robert M. Clancy[1]. [1]New York University School of Medicine, New York, NY, [2]Division of Nephrology and Hypertension, Department of Medicine, University of Miami, Miami, FL 33136, U.S.A., Miami, FL

Background/Purpose: The mechanism underlying initiation and perpetuation of inflammation—with eventual end organ injury—in Systemic Lupus Erythematosus (SLE) is not yet defined. Equally unclear are mechanisms to attenuate such inflammation. An important candidate for initiation and perpetuation of the inflammatory response may be the chronic stimulation of resident leukocytes through toll like receptors (TLR). Complement Receptor 3 (CR3), a heterodimeric receptor on the surface of various types of leucocytes, is known to decrease pro-inflammatory signals by dendritic cells when ligated to iC3b. The goal of this study was to evaluate whether a TLR-mediated pro-inflammatory stimulus is attenuated by a novel iC3b mimetic specific for CR3—known as LA1—on other cells expressing CR3: macrophages and neutrophils. ITGAM polymorphism rs1143679, encoding for a non-conserved R77H substitution in the CD11b alpha chain of CR3, is known to be associated with SLE across various ethnic groups. While the polymorphism is theorized to affect ligand binding to CR3, its functional significance is unknown. A sub-goal was to evaluate if rs1143679 carrier status attenuated the effect of LA1.

Methods: The effect of LA1 on basal and stimulated responses by macrophages and neutrophils of human subjects (twenty healthy donors) was evaluated. Rs1143679 carrier status of subjects was determined by allelic discrimination. Macrophages derived from CD14+ monocytes of healthy human donors were treated with R848 (a specific TLR7 ligand, 1 uM), with and without LA1 (a recently described CR3 agonist, 15 uM). Quantification of TNF-α secretion, the readout of TLR7 activation, was assessed by ELISA. Neutrophils derived from healthy subjects were evaluated for superoxide anion production after stimulation with FMLP (.1 uM) in the absence and presence of LA1 (15 uM). Neutrophils were also evaluated for adhesion to a fibrinogen-coated surface in the presence of LA1.

Results: Treatment of macrophages with R848 significantly stimulated TNF-α release compared with macrophages alone (1265 $\pm$ 297 pg/ml versus 26 $\pm$ 30 pg/ml, respectively, $p = 0.006$, $n = 7$). Pre-exposure to LA1 followed by treatment with R848 impaired TNF-α secretion from macrophages (R848 + LA1: 700 $\pm$ 249 pg/ml, $p=0.015$). Exposure of macrophages to LA1 in absence of R848 had no effect on cellular morphology, and did not induce TNF-α over 24 hrs. The % inhibition by LA1 of TNF-α in rs1143679 non-carriers was 63% ($n=5$) vs. 17% ($n=2$) in rs1143679 carriers (heterozygous). The addition of LA1 to neutrophils 15 min before FMLP resulted in the inhibition of O° production (13 nmol O*/5 min vs 7 nmol O*/5 min). As expected, pretreatment with LA1 alone stimulated the adherence of neutrophils to fibrinogen-coated surface (8$\pm$10 PMNs baseline, 5,930 $\pm$ 250 PMNs, LAI, 15 uM).

Conclusion: As previously shown in dendritic cells, inflammatory responses in macrophages and neutrophils are able to be attenuated in a CR3-specific fashion—in this case, by novel agonist LA1. These results also suggest significant cross-talk between CR3 and other pro-inflammatory pathways, such as TLR7. A novel functional difference in immune response to iC3b mimetic LA1, based on carrier-status of the rs1143679 polymorphism, is suggested.

Musculoskeletal Inflammation and Estrogens: T-Cell Leukemia 1A (*TCL1A*) Gene-Dependent Regulation of Inflammatory Cytokines.

Mohan Liu[1], Liewei Wang[1], Tim Bongartz[1], John R. Hawse[1], Svetomir N. Markovic[1], Daniel J. Schaid[1], Paul E. Goss[2], James N. Ingle[1] and Richard M. Weinshilboum[1]. [1]Mayo Clinic, Rochester, MN, [2]Massachusetts General Hospital Cancer Center, Harvard University, Boston, MA

Background/Purpose: Arthralgia, myalgia and inflammatory arthritis occur in up to 50% of women who receive inhibitors of estrogen synthesis (aromatase inhibitors, AIs) for the treatment of breast cancer. In a recent genome-wide association study (GWAS), we identified 4 SNPs on chromosome 14, one of which created an estrogen response element, that were associated with musculoskeletal adverse events (MS-AEs) in women who participated in an adjuvant therapy trial (NCIC-CTG MA.27, Ingle et al. J Clin Oncol 2010;28:4674) using AIs to treat early breast cancer. Those SNPs mapped near the 3'-end of the T-Cell Leukemia 1A (*TCL1A*) gene. Therefore, we set out to study the possible role of TCL1A in mediating MS-AEs during AI therapy.

Methods: Functional genomic studies in pursuit of this GWAS SNP signal included characterization of TCL1A and inflammatory cytokine and cytokine receptor expression in response to estrogen using qRT-PCR in a sarcoma cell line (U2OS) stably transfected with ERα. We assayed cytokine expression changes after TCL1A knockdown and over-expression, as well as NF-kB transcriptional activity. In order to characterize the impact of the SNPs identified during the GWAS on NF-kB activity, we also used lymphoblastoid cell lines (LCLs) stably with known SNP genotypes transfected with ERα to perform selected experiments.

Results: We showed that TCL1A expression was increased by estradiol (E2) and that it significantly decreased expression of IL-17RA, increased IL-17, IL-12, IL-12RB2 and IL-1R2 expression as well as NF-kB transcriptional activity. Increased TCL1A expression was associated with variant SNP genotypes in E2-treated LCLs stably transfected with ERα. Finally, exposure of these LCLs to E2, followed by ERα blockade with ICI-182,780, resulted in greatly increased NF-kB transcriptional activity for variant SNP genotypes. These studies have linked variant SNP sequences near *TCL1A* to AI-dependent musculoskeletal pain, to enhanced E2-dependent TCL1A expression and to downstream alterations in cytokine and cytokine receptor expression.

Conclusion: Our recent case-control GWAS of DNA samples from a large AI clinical trial identified SNPs near the 3′-end of *TCL1A* that were associated with AI-dependent MS-AEs. In the present studies, we found that E2 induces TCL1A expression that, in turn, alters IL-17RA, IL-17, IL-12, IL-12RB2, and IL-1R2 expression as well as NF-kB transcriptional activity. These results provide a novel pharmacogenomic explanation for a clinically important adverse drug reaction, as well as insight into a novel estrogen-dependant mechanism for the regulation of cytokine and cytokine receptor expression.

An International Collaboration for the Genetic Fine Mapping of 8,000 Rheumatoid Arthritis Cases and 12,000 Controls Refines Associations to Known Loci, Indicates Multiple Independent Affects and Reveals Novel Associations. Stephen Eyre[1], John Bowes[2], Anne Barton[3], Soumya Raychaudhuri[4], Christopher Amos[5], Dorothee Diogo[4], Annette T. Lee[6], Lars Klareskog[7], Leonid Padyukov[8], Eli A. Stahl[4], Peter K. Gregersen[9], Robert M. Plenge[4] and Jane Worthington[1]. [1]University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [4]Brigham and Women's Hospital, Boston, MA, [5]Houston, TX, [6]Feinstein Institute Med Rsch, Manhasset, NY, [7]Karolinska Institutet, Stockholm, Sweden, [8]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [9]Feinstein Institute Medical Reschearch, Manhasset, NY

Background/Purpose: Genome wide association studies (GWAS) have been tremendously successful in identifying loci associated with a range of traits and disorders. Indeed, there are over 240 confirmed susceptibility loci reported for nine autoimmune diseases alone. One task now is to take these findings and translate them into clinical utility. The first step in this is to elucidate the genetic architecture of the loci in each disease with fine mapping experiments. These are expected to localise the association signal, indicate whether multiple, independent genetic affects are present and may point to the casual gene.

Methods: The aim of this study was to fine map loci significantly associated with autoimmune disease in a large cohort of 10,000 rheumatoid arthritis (RA) cases and 14,000 controls using the custom Illumina Immunochip. The Immunochip was designed by a consortium of researchers investigating 12 autoimmune diseases and represents all known genetic variation from dbSNP, 1kG and sequencing projects for approximately 200 validated loci.The genotyping for the RA samples was performed in multiple centres and therefore all raw genotyping data was collated centrally for combined clustering and analysis. The data was first re-clustered and after applying strict QC metrics (98% SNP and 98% sample) the samples were subjected to further pruning for relatedness and ancestral outliers.

Results: In the initial analysis we have examples of re-focusing of the strongest association signal (e.g. 2q11), evidence for multiple independent associations within a locus (e.g. *PADI4, PTPN22*) and associations to previously unconfirmed RA loci (e.g. *IRAK1, IRF8*).Within the 2q11 locus the peak of associations has moved 76kb to now lie within the *AFF3* gene. The *PADI4* gene has, for the first time, been robustly associated with RA in a Caucasian population ($p = 7\times10^{-8}$). There is also evidence for two independent affects in this region, one of which is correlated with the variant previously reported to be associated with RA in Japanese populations. In addition we have preliminary evidence that there may be 2 independent associations around the *PTPN22* locus. The second affect is centred on the RSBN1/PHTF1 genes, a region previously implicated with PsA. We also have preliminary evidence of genome-wide significant ($p<5\times10^{-8}$) associations to *IRF8*, a gene previously associated with Multiple Sclerosis, and to a region on ChrX incorporating *IRAK1*, a loci previously associated with systemic lupus erythematosus. This is the first evidence of a significant association with a locus on ChrX with RA.

Conclusion: Although GWAS studies have underpinned a dramatic advance in our understanding of the genetic architecture of rheumatoid arthritis it is clear that large scale fine mapping efforts, such as this, will be necessary to better interpret the complexity of the results and translate the findings into clinicsal utility.

Background/Purpose: Genetic risk factors for adult dermatomyositis (DM) and juvenile DM outside of the major histocompatibility complex (MHC) have been difficult to identify, although family studies have suggested that DM shares genetic risk factors with other autoimmune diseases.

Methods: We performed a genome-wide association study (GWAS) on adult DM and juvenile DM subjects of European ancestry meeting probable or definite Bohan and Peter criteria using the Illumina platform. DM cases (n=1178: 705 with adult DM and 473 with juvenile DM) were compared to geographically- and race-matched controls (n=4724). Ingenuity Systems Pathway Analyses were performed based on the genes identified by GWAS.

Results: As expected, we observed a strong signal in the MHC locus across the class II region (maximum $p=2.79\times10^{-29}$) but no other locus reached genome-wide significance in this dataset. To assess for possible shared genes with other autoimmune diseases, however, we examined the association signals in 140 non-MHC loci that have been associated with autoimmune diseases. Strikingly, seven SNPs from six genes had p values $\leq$ 0.01, thus substantially exceeding expectation. These included: B lymphocyte kinase (*BLK*: rs2736340, $p=6.53\times10^{-5}$); chemokine (C-C motif) ligand 21 (*CCL21*: rs2492358, $p=2.10\times10^{-4}$; and rs951005, $p=3.17\times10^{-5}$); protein tyrosine phosphatase non-receptor type 2 (*PTPN2*: rs1893217, p=0.0029); signal transducer and activator of transcription 4 (*STAT4*: rs7574865, p=0.0050); interleukin 2 receptor alpha (*IL2RA*: rs7072793, p=0.0073); and a gene encoding a 153–amino acid protein with four putative transmembrane domains (*ORMDL3:* rs2290400, p=0.0010). Based on the associated genes from the entire GWAS, canonical pathways that seemed particularly important in DM were those relating to antigen presentation ($p=9.49\times10^{-23}$), cytotoxic T cell-mediated apoptosis of target cells ($p=1.44\times10^{-17}$), allograft rejection signaling ($p=1.44\times10^{-17}$), the OX40 (CD134) signaling pathway ($p=5.9\times10^{-17}$) and autoimmune thyroid disease signaling ($p=5.0\times10^{-13}$).

Conclusion: Our findings indicate that DM shares many genetic features and canonical pathways with other autoimmune diseases. This first identification of these common autoimmune disease genetic predispositions that promote the development of DM suggests potential novel therapeutic approaches for this disorder.

1679

Genome Wide Association Study of Quantitative Anti-CCP Level in Rheumatoid Arthritis Identified New Risk Variants. Jing Cui[1], Kimberly E. Taylor[2], Henrik Kallberg[3], Michael E. Weinblatt[4], Lars Klareskog[3], Lindsey A. Criswell[5], Nancy A. Shadick[4], Robert M. Plenge[6] and Elizabeth W. Karlson[6]. [1]Brigham and Womens Hospital, Boston, MA, [2]University of California, San Francisco, San Francisco, CA, [3]Karolinska Institutet, Stockholm, Sweden, [4]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [5]University of California San Francisco, San Francisco, CA, [6]Brigham and Women's Hospital, Boston, MA

Background/Purpose: Anti-cyclic citrullinated peptide (anti-CCP) antibody is a proxy for disease activity of rheumatoid arthritis (RA). We conducted a study to test if anti-CCP level is a heritable trait. We then carried out a genome wide association study (GWAS) meta-analysis using more than 2 million SNPs in 2031 anti-CCP+ RA patients from 3 large cohorts of European American RA patients,

Brigham Rheumatoid Arthritis Sequential Study (BRASS), North American Rheumatoid Arthritis Consortium (NARAC), and Epidemiological Investigation of RA (EIRA) to identify SNPs that influence quantitative anti-CCP level in RA patients.

Methods: Anti-CCP was measured using the second generation ELISA assay for all 3 cohorts. Genotyping platforms Affymetrix 6.0, Illumina 550K and 317K were used for BRASS, NARAC and EIRA samples, respectively. Anti-CCP measures were normalized by taking the inverse normal of the rank. A mixed linear model analysis was used to estimate the proportion of variance that explained by genotyped SNPs from the whole genome, so called heritability. Association between SNPs and anti-CCP level was tested assuming a genetic additive model adjusting for the first three principal component values in each cohort. Inverse variance weighted meta-analysis was used to combine statistics from the 3 cohorts. Polygenic risk scores of additive, beta weighted risk allele counts at independent SNPs were conducted assuming thousands of genetic variants that have small impact on anti-CCP level.

Results: 483 BRASS, 868 NARAC and 680 EIRA samples that passed all quality control filters were included. Heritability analysis estimated that 38% of anti-CCP variation was attributable to all SNPs genome wide. Meta GWAS analysis showed the human leukocyte antigen (HLA) region was the top hit with p-value of 8.8E-12 for rs3117097 (near BTNL2 gene). There were 65 SNPs in this region that exceeded the genome-wide significance threshold of 5E-8. The SNPs were in linkage disequilibrium (LD) with the HLA-DR3 allele with LD r^2 in range of (0.25–0.89). Suggestive novel associations outside of HLA were also observed. The top SNP was rs8063248 with p-value of 6E-7. The top 10 findings are listed in the table. None of known RA risk alleles (~45 loci) were associated with anti-CCP level except for HLA. Using SNPs at p-value <0.05, polygenic analysis excluding the HLA region revealed that polygenic risk scores (N= 14498 SNPs) were associated with quantitative anti-CCP level and explained ~1.5% total variance.

Table. Top 10 SNPs associations with anti-CCP level outside HLA

Chr	rs	gene	Base pair	Allele A	Minor allele frequency	Meta Beta	Meta p value

Conclusion: We show that anti-CCP level is a heritable trait and genetic factors explain ~38% of the phenotypic variance. We confirmed that the HLA region is associated with anti-CCP level. There are suggestive genetic effects outside the HLA region that influence anti-CCP level. GWAS results explain a small percent of the variance and other techniques such as next generation sequencing should be pursued.

Genome-Wide Association Study of African Americans Implicates Multiple Lung and Inflammatory Disease-Associated Loci in Sarcoidosis Susceptibility. Indra Adrianto[1], Chee Paul Lin[1], Jessica J. Hale[1], Albert M. Levin[2], Indrani Datta[2], Ryan Parker[1], Adam Adler[1], Jennifer A. Kelly[1], Kenneth M. Kaufman[3], Christopher J. Lessard[1], Kathy L. Moser[4], Michael C. Iannuzzi[5], Benjamin A. Rybicki[2] and Courtney G. Montgomery[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Henry Ford Health System, Detroit, MI, [3]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation and US Department of Veterans Affairs Medical Center, Oklahoma City, OK, [4]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]SUNY Upstate Medical University, Syracuse, NY

Background/Purpose: Sarcoidosis is a systemic inflammatory disease, characterized by the formation of granulomas primarily in the lungs, but the disease can also affect other organ systems including the bones, joints, muscles, spleen, lymph, liver, glands, brain, skin, and heart. While the etiology of this disease remains elusive, the causal chain likely involves a dysregulated immune in response to an environmental agent in a genetically susceptible host. Despite its higher prevalence and morbidity in African Americans (AAs), to date, genome-wide association studies (GWASs) of this disease have focused only on non-African populations. We present here the first GWAS of sarcoidosis in a population of African origin.

Methods: We genotyped 1487 AA sarcoidosis cases and 1504 AA family members and independent controls using the Illumina HumanOmni1-Quad platform for 1.1 million single-nucleotide polymorphisms (SNPs) across the genome. After applying sample and SNP quality control, the final set comprised 2,918 samples (1,273 cases and 1,645 controls) including 180 HapMap YRI and ASW controls from the Illumina iControlDB and 887,296 SNPs. We assessed single SNP association to sarcoidosis using the Efficient Mixed-Model Association eXpedited (EMMAX) software that simultaneously controls for both pairwise genetic relatedness between individuals and population stratification under the additive model. Regions associated at a suggestive level of $p < 1 \times 10^{-4}$ were imputed using IMPUTE2 program and the 1000 Genomes Project haplotypes as reference panels.

Results: We identify two novel sarcoidosis effects reaching genome-wide significance ($p < 5 \times 10^{-8}$) at *NOTCH4* ($p = 4.30 \times 10^{-9}$) and *HLA-DQA1* ($p = 1.04 \times 10^{-11}$). We also replicated previous sarcoidosis Caucasian GWAS hits of *RAB23* ($p = 9.47 \times 10^{-5}$) and *BTNL2* ($p = 6.10 \times 10^{-6}$) and confirmed association in 12 regions shown to be involved in other lung or inflammatory diseases, including *TGM3* ($p = 5.60 \times 10^{-6}$) and *DMBT1* ($p = 8.70 \times 10^{-5}$), associated with celiac and Chrohn's disease, respectively. Pathway-based analyses suggested involvement of inflammation regulation and apoptosis ($p < 0.001$) pathways and an effect-specific heritability estimation analyses suggested the existence of rare genetic effects in sarcoidosis.

Conclusion: We completed the first GWAS for sarcoidosis in AAs. The novel, replication and confirmatory findings of this study highlight both the usefulness of and need for genetic studies of sarcoidosis in the understudied but greatly affected AA population. Future replication and sequencing studies are required to further elucidate the functional variants that may underlie these novel associations.

Vyse on behalf of SLEGEN[8], Patrick M. Gaffney on behalf of LLAS2[5], Carl D. Langefeld[9], John B. Harley[10], Changwon Kang[1], Robert P. Kimberly[2] and Sang-Cheol Bae on behalf of Korean Investigators[3]. [1]Korea Advanced Institute of Science and Technology, Daejeon, South Korea, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [4]Pfizer-University of Granada-Junta de Andalucía, Grranada, Spain, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK, [6]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [7]Sanatorio Parque, Rosario, Argentina, [8]King's College London, Guy's Hospital, London, United Kingdom, [9]Wake Forest School of Medicine, Winston-Salem, NC, [10]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH

Background/Purpose: Systemic lupus erythematosus (SLE, OMIM 152700) is a chronic autoimmune disease with etiology that includes genetic and environmental factors. *ITGAM*, integrin alpha M (complement component 3 receptor 3 subunit), a ligand for intracellular adhesion molecule (ICAM) proteins, is an established SLE susceptibility locus. However, the independent and joint effects of common variation in the genes that encode ITGAM and ICAM have not been previously evaluated.

Methods: We examined 12 directly typed and 58 imputed loci in the *ICAM1-ICAM4-ICAM5* locus spanning ~22 kb on chromosome 19p13, a single locus in *ITGAM* and 347 ancestry informative markers using customized arrays based on the Illumina iSelect platform in a total of 17,481 unrelated SLE affecteds and controls from four divergent ancestry backgrounds (European, African, Hispanic, Asian). All participants were of self-reported sex and race/ethnicity. Affecteds had a minimum of four of eleven 1997 American College of Rheumatology revised criteria for the classification of SLE. We estimated allele frequencies in SLE affecteds relative to controls using logistic regression based on additive models and adjusted for population substructure.

Results: The A-allele of *ICAM1-ICAM4-ICAM5* rs3093030, associated with elevated plasma levels of soluble ICAM-1, showed the strongest association with increased SLE susceptibility in each of the ancestry populations and the trans-ancestry meta-analysis (OR_{meta}=1.16, 95% CI 1.11–1.22; P=4.8×10^{-10}) as did the *ITGAM* rs11436679-A allele (OR_{meta}=1.67, 95% CI 1.55–1.79; P=3.32×10^{-46}). Carriers of both *ICAM* rs30930330-AA and *ITGAM* rs1143679-AA were significantly more likely to develop SLE compared to

carriers without at-risk alleles at both loci (OR=4.08, 95% CI 2.09–7.98; $P=3.91\times10^{-5}$), supporting a synergistic receptor-ligand interaction.

Conclusion: These findings are the first to provide evidence to support the contribution of the ICAM locus alone and an ICAM-integrin mediated pathway to SLE susceptibility.

Major Histocompatibility Complex Association to Rheumatoid Arthritis Is Explained by Polymorphic Amino Acids In the Binding Grooves of *HLA-DRB1*, *HLA-B*, and *HLA-DPB1*. Soumya Raychaudhuri[1], Eli A. Stahl[1], Xiaoming Jia[1], Lars Alfredsson[2], Leonid Padyukov[3], Katherine A. Siminovitch[4], Lars Klareskog[5], Jane Worthington[6], Robert M. Plenge[1], Peter K. Gregersen[7] and Paul de Bakker[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Institute of Environmental Medicine, Unit of Cardiovascular Epidemiology, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [4]Mount Sinai Hospital, Toronto, ON, [5]Karolinska Institutet, Stockholm, Sweden, [6]University of Manchester, Manchester, United Kingdom, [7]Feinstein Institute Medical Reschearch, Manhasset, NY

Background/Purpose: Rheumatoid arthritis (RA) is a common autoimmune disease that affects up to 1% of the general adult population worldwide. While the RA association at the major histocompatibility complex (MHC) has been noted for >20 years, there has been controversy about other associations outside DRB1, and the causal alleles within DRB1 itself.

Methods: In order to fine-map the MHC association, we used a strategy previously described (Pereyra *et al*., Science, 2010) to impute classical types and amino acid polymorphisms for the classical *HLA-A*, *HLA -B*, *HLA-C*, *DPA1*, *DPB1*, *DQA1*, *DQB1*, and *DRB1* loci along with 2,537 SNPs across the MHC in 5,018 anti-CCP+ cases and 14,974 controls from 6 GWAS data sets (Stahl *et al*., Nature Genetics, 2010). Using logistic regression across all 6 data sets jointly, we performed conditional analyses to identify independent variants, correcting for 5 principal components in each GWAS.

Results: We compared imputed classical alleles to *DRB1* 4-digit genotypes for 1150 overlapping individuals from two cohorts; the imputation was 96.5% and 85.4% accurate for 2-digit and 4-digit types, respectively. We also observed that classical *DRB1* associations were identical to previously reported effect sizes. The strongest signal mapped to the presence of a valine or leucine in position 11 of *DRB1* (OR=3.7, $p<10^{-500}$), accounting in itself for 9% of the phenotypic variance. With conditional haplotype analysis we found that most of the *DRB1* signal can be parsimoniously explained by 3 amino acid positions within DRB1 (11, 71, 74), refining the "shared epitope" hypothesis to include position 11, located at the floor of the binding groove, but to exclude positions 70, 72, and 73. We also confirmed an independent effect due to a single amino acid polymorphism in *HLA-B* (OR=2.1; $p=2\times10^{-38}$, Asp at position 9), corresponding to *HLA-B*08*, and identified a novel independent effect at *HLA-DPB1* (OR=1.3; $p=5\times10^{-22}$, Phe at position 9). Controlling for all of these variants leaves no additional significant associations within the MHC ($p>10^{-6}$).

Conclusion: In each case, the amino acid residues at these positions point into the binding groove of the HLA molecule, highlighting the importance of these residues in presenting auto-antigens to the immune system. In aggregate, these independent variants account for almost all of the known MHC signal in RA, and explain ~15% of the phenotypic variance, a significant increase relative to the most recent genome-wide meta-analysis in RA.

IL-10 Mainly Derived From Activated Hepatic T-Cells Suppresses Toll-Like Receptor 9-Mediated Macrophage Activation Syndrome Independent of Effects on the Pathogenic IL-12/Interferon-γ Axis. Scott W. Canna[1], Michele E. Paessler[1], Portia Kreiger[2], Katharine Slade[1], Sheila Rao[1] and Edward M. Behrens[1]. [1]Childrens Hospital of Philadelphia, Philadelphia, PA, [2]A.I. DuPont Hospital for Children, Wilmington, DE

Background/Purpose: Macrophage Activation Syndrome (MAS) is a potentially fatal cytokine storm syndrome that complicates multiple rheumatic illnesses. We have recently shown the critical role of IL-10 as a regulator of MAS in an infection-free murine model. The current study dissects the mechanisms by which IL-10 exerts this profound regulatory effect.

Methods: As previously described, the Toll-like Receptor 9 (TLR9) agonist CpG1826 was injected repeatedly to induce MAS. Cellular IL-10 production was assessed by means of both intracellular flow cytometry and a YFP reporter system. Signaling of IL-10 and IL-12 were inhibited by monoclonal antibodies to IL10R1 and IL-12 (1B1.3A & C17.8), respectively. Transgenic mice and dendritic cell (DC)-depleted mice were utilized as detailed.

Results: As shown previously, CpG given during IL-10R blockade resulted in fulminant MAS, complete with excess hemophagocytosis. Additionally, serum IFNγ, IL-10, IL-6 and IL-12 levels in IL-10R blocked mice were dramatically elevated compared to IL-10 sufficient mice. Investigating the source of this protective IL-10, we found that CpG resulted in induction of IL-10 by a variety of hematopoietic cells, particularly activated ($CD44^{hi}CD69^{hi}CD62L^{lo}$) hepatic T-cells. Both Rag−/− and DC-deficient mice developed enhanced MAS in response to CpG, correlating with reduced IL-10. These data are consistent with DC/T-cell interactions as a possible mechanism for IL-10 induction.

Earlier studies showed that IFNγ is critical for driving MAS, and thus we tested whether the fulminant MAS seen in IL-10R blocked mice was due to enhanced IFNγ production. CpG given to IFNγ−/− mice during IL-10R blockade resulted in fulminant MAS indistinguishable from WT mice. IL-12 was elevated above WT levels in IL-10R blocked IFNγ−/− mice, and thus we tested whether IL-12 might be driving an IFNγ independent mechanism. Interestingly, coadministration of an IL-12 blocking antibody with CpG prevented MAS in IL-10 sufficient mice, but still led to severe disease in IL10R blocked mice. IFNγ levels were depressed regardless of IL-10R blockade, suggesting IFNγ induction is IL-12 dependent.

Conclusion: While TLR9-induced MAS appears to be predominantly dependent on the IL-12/IFNγ axis in IL-10 sufficient mice, IL-10R blockade reveals other mechanisms by which TLR9 stimulation can cause severe MAS. Further studies will elucidate pathogenic mechanisms not reliant on IL-12 or IFNγ, specify the nature of DC/T-cell interactions in driving T-cell IL-10 production, clarify the function of these cells, and discern which cells and tissues must respond to IL-10 in order to prevent severe disease. These studies support the critical role of IL-10 in prevention of fulminant MAS, explicate an important pathogenic axis in this disease, and continue to identify targetable cell populations and pathways for treating MAS patients.

Reduction of Annexin A5 Anticoagulant Activity in Children with Systemic Lupus Erythematosus. Dawn M. Wahezi[1], Norman T. Ilowite[1], Xiao Xuan Wu[2], Bas de Laat[3], Jacob H. Rand[2] and the APPLE Investigators[4]. [1]Children's Hospital Montefiore, Bronx, NY, [2]Montefiore Medical Center, Bronx, NY, [3]Maastricht University Medical Center, The Netherlands, [4]Varies by Investigator

Background/Purpose: Children with systemic lupus erythematosus (SLE) have a high prevalence of antiphospholipid (aPL) antibodies and are at increased risk of aPL-related thrombosis. In adults, reports have implicated domain one (D1) of β2-glycoprotein I (β2GPI) as the major antigenic target for thrombogenic aPL antibodies. In addition, evidence has evolved suggesting that the antibody-mediated disruption of an annexin A5 anticoagulant shield may play a role in the pathogenesis of aPL-related thrombosis. We investigated the association between anti-D1 antibodies and annexin A5 anticoagulant activity in a cohort of children with SLE.

Methods: Using plasma samples collected during the Atherosclerosis Prevention in Pediatric Lupus Erythematosus (APPLE) trial, we evaluated 183 children with SLE (mean age: 15.6 years) for resistance to the anticoagulant effects of annexin A5, using the annexin A5 resistance (A5R) assay. This assay measures coagulation times in the presence and absence of annexin A5 and resistance is expressed as a reduction in this ratio. Mean A5R levels were compared with pediatric controls (mean age: 12.4 years) without known autoimmune or thrombophilic disorders. In children with SLE, plasma samples were additionally screened for the presence of anti-D1 antibodies and available data regarding lupus anticoagulant (LA) and anti-cardiolipin (aCL) antibodies were examined.

Results: Overall, children with SLE had significantly reduced mean A5R levels (i.e. greater resistance to annexin A5 anticoagulant activity) compared to healthy pediatric controls: mean A5R = 172 ± 30 % versus

243 ± 30 % ($p<0.0001$) (Figure 1). The association between mean A5R levels with LA (n=87) and aCL antibodies (n=19) are presented in Table 1. In children with SLE, 46 (25.1 %) patients had positive anti-D1 antibodies and significantly lower mean A5R levels as compared to the rest of the cohort: mean A5R = 155 ± 24 % versus 177 ± 30 % ($p<0.0001$).

Figure 1: Annexin A5 Resistance in Pediatric SLE Patients versus Controls

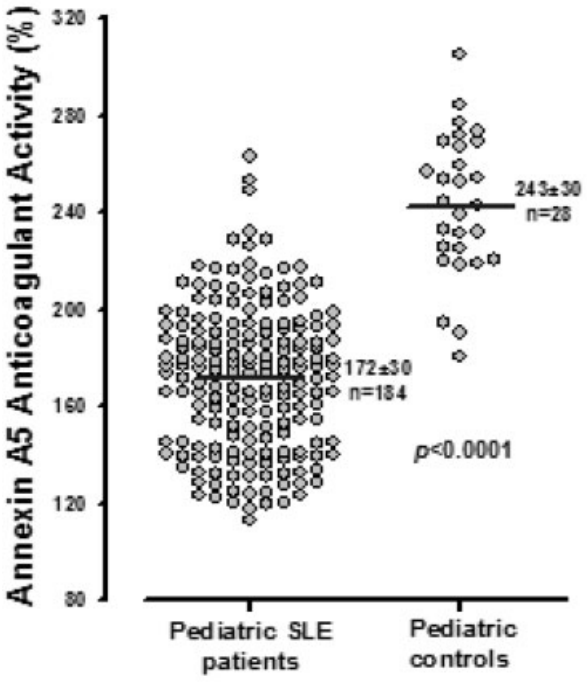

Table 1. Mean A5R (%) in relation to the presence aPL antibodies in a cohort of children with SLE (n=183)

	Positive	Borderline/Negative	p-value
Lupus anticoagulant (n=87)*	150 ± 24	169 ± 30	**0.021**
aCL antibodies (n=19)*	157 ± 25	179 ± 27	0.285
Anti-D1 antibodies (n=183)	155 ± 24	177 ± 30	**<0.0001**

* Data not available on the remainder of the cohort

Conclusion: Children with SLE have markedly reduced annexin A5 anticoagulant activity as compared to pediatric controls. Additionally, the presence of aPL antibodies, including anti-D1 antibodies, led to further reduction in A5R. Future examination of the clinical implications of annexin A5 resistance and antibody specificity for D1 in children with SLE is warranted.

1685

A Markedly Low-Level of Interferon-Induced Gene Expression Distinguishes Active Systemic Juvenile Idiopathic Arthritis Synovium From the Oligoarticular Subtype; A Difference That Cannot Be Attributed to Monocytic Hypo-Responsiveness to Interferon-γ. Keith A. Sikora, Ndate Fall, Sherry Thornton and Alexei A. Grom. Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is an autoinflammatory syndrome where IL-1β and IL-6 play a pivotal role. SJIA is strongly associated with the macrophage activation syndrome (MAS), a hemophagocytic syndrome where inflammatory macrophages are believed to be driven by interferon-γ (IFN-γ). However, recent gene expression studies have failed to demonstrate the presence of an IFN-induced signature in fresh peripheral blood mononuclear cells (PBMCs) from active SJIA/MAS patients, while the status of this signature has not been adequately studied within affected tissues. An altered responsiveness to IFN-γ, perhaps due to cross-talk between IL-1β and IFN-induced signaling pathways, has been suggested as a possible explanation. The main goals of this study were to determine the presence of an IFN-induced signature within affected synovial tissue and to gauge IFN-induced signaling pathways in freshly isolated monocytes from active SJIA patients by measuring STAT1 phosphorylation (STAT1-P), as well as IFN-induced gene expression, at baseline and upon stimulation with IFN-γ.

Methods: To detect a possible IFN-induced signature within affected synovium, total mRNA was extracted from frozen synovial biopsies from 12 active SJIA and 9 active oligoarticular JIA patients as a control. Real-time PCR was then used to quantify IP-10, MIG, and I-TAC mRNA levels. To determine potential IFN-responsiveness, fresh PBMCs were collected from 3 active SJIA patients and 3 healthy controls (HCs). CD14+ PBMCs were isolated and treated with and without 100 units IFN-γ for 1 hour. STAT1-P levels were then quantified via intracellular FACS. Finally, to gauge transcriptional responsiveness to IFN-γ, fresh CD14+ PBMCs from 4 active SJIA patients and 7 HCs were isolated and then incubated with and without 100 units IFN-g for 3 hours. Total mRNA was then extracted and real-time PCR was used to quantify IP-10, MIG, and STAT1 mRNA levels.

Results: We detected a markedly lower level of IFN-induced mRNA levels in SJIA synovium compared to oligoarticular JIA; on average, IP-10 levels were 4.5x lower, MIG levels were 15.8x lower, and I-TAC levels were 3.6x lower. In regards to STAT1-P, baseline STAT1-P levels in CD14+ PBMCs from SJIA patients were mildly increased over HCs. Upon stimulation with IFN-γ, the amount of STAT1-P in SJIA patients increased by a greater magnitude compared to HCs. Lastly, CD14+ PBMCs from active SJIA patients displayed a significantly lower baseline level of MIG and STAT1 mRNA, while baseline IP-10 was comparable to HCs. However, upon stimulation of these cells with IFN-γ, the increase in MIG mRNA was significantly greater than HCs and while not statistically significant, the increase in IP-10 and STAT1 mRNA levels trended towards being greater.

Conclusion: A markedly low-level of IFN-induced gene expression distinguishes active SJIA synovium from active oligoarticular JIA synovium. In CD14+ PBMCs, this signature appears altogether absent, but this is not likely due to a hypo-responsiveness to IFN-γ. In contrast, SJIA PBMCs appear to have an *increased* responsiveness compared to HC cells. The impact of this apparent difference on terminal macrophage differentiation in SJIA is an area that deserves much attention.

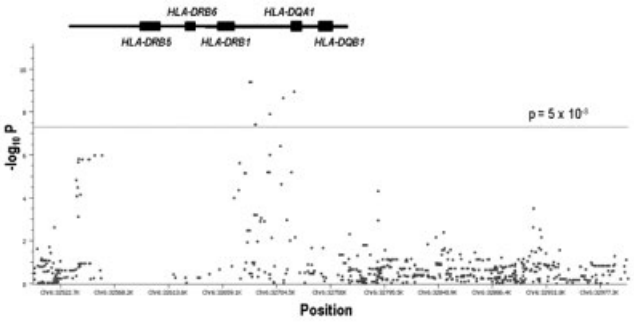
Major Histocompatibility Complex Class II Gene Cluster Harbors Systemic Juvenile Idiopathic Arthritis Susceptibility Locus. Michael J. Ombrello[1], Elaine Remmers[1], Alexei A. Grom[2], Wendy Thomson[3], Alberto Martini[4], Marco Gattorno[5], Seza Ozen[6], Ahmet Gul[7], John F. Bohnsack[8], Sampath Prahalad[9], Andrew S. Zeft[8], Elizabeth D. Mellins[10], Colleen Satorius[1], Jane L. Park[10], Carl D. Langefeld[11], Eleftheria Zeggini[12], David N. Glass[2], Susan D. Thompson[2], Daniel L. Kastner[1], Patricia Woo[13] and International Childhood Arthritis Genetics Consortium[14]. [1]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Manchester Medical School, Manchester, United Kingdom, [4]IRCCS G Gaslini, Pediatria II, Reumatologia, Genova, Italy, [5]Istituto di Ricovero e Cura a Carattere Scientifico G. Gaslini, Genova, Italy, [6]Hacettepe University Faculty of Medicine, Ankara, Turkey, [7]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [8]University of Utah, Salt Lake City, UT, [9]Emory Children's Center, Atlanta, GA, [10]Stanford University Medical Center, Stanford, CA, [11]Wake Forest School of Medicine, Winston-Salem, NC, [12]The Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [13]University College London Medical School, London, United Kingdom, [14]Manchester, United Kingdom

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a systemic inflammatory disease whose etiology remains unknown. The inflammatory features of sJIA clearly distinguish it from other subtypes of JIA, and immunologically, sJIA patients demonstrate innate immune activation not seen in other JIA subtypes. sJIA is a rare, complex genetic trait, and the discovery of sJIA susceptibility genes has been hindered by sampling bias, population stratification, and genetic heterogeneity. In this study, we used genome wide SNP genotyping to address these obstacles in a large patient collection as we sought to identify sJIA susceptibility loci.

Methods: We performed SNP genotyping on 576 children fulfilling ILAR criteria for sJIA and 366 healthy subjects with Illumina Omni1M Quad beadchips and an iScan platform. Samples (cases/controls) were obtained from Cincinnati Children's Hospital Medical Center (205/210), University of Manchester (188/0), Genoa University (56/60), Hacettepe University (54/0), University of Utah (42/0), Stanford University (34/0), and Istanbul University (0/96). Additionally, Omni1M Quad genotypes from 60 unrelated HapMap CEU individuals were obtained from the Illumina iControl database for use

in the genome-wide analysis. SNPs with call rates < 95 %, minor allele frequencies < 0.05, or Hardy-Weinberg Equilibrium p < 1E-5 were excluded. Using MaCH imputation software, we assembled a chromosome 6 SNP set that included 1594 additional controls from the 1958 U.K. Birth Cohort. We used principal components (PC) analysis to exclude genetically dissimilar individuals and to correct association testing. PC analysis, association testing, and logistic regression analysis were performed using SVS7, and haplotypes were analyzed using Haploview. Two-digit *HLA-DRB1* data were available for 231 cases and 1752 controls in our PC-matched collection.

Results: Genome-wide association testing revealed 12 SNPs within the MHC Class II region whose associations exceeded the threshold for genome-wide significance (p < 5E-8). Analysis of the MaCH-imputed chromosome 6 SNP set identified 7 additional SNPs with p < 5E-8, and logistic regression identified rs615672 as responsible for the regional association. Further, we identified a 203 Kb sJIA-associated SNP haplotype (p = 5.33E-12; OR = 2.184, 95 CI 1.74, 2.74) which included *HLA-DRB1, -DQA1,* and *-DQB1*. This extended haplotype had a greater effect size and a stronger association than any individual SNP. We also found that *HLA-DRB1*11* was associated with sJIA (p = 1.31E-6, OR = 2.09 [95% CI = 1.55–2.81]).



SNP Associations within the Major Histocompatibility Complex Class II Gene Cluster sJIA. Displayed is a plot of the PC-corrected $-\log_{10}$ p values of association for the MHC Class II cluster. The horizontal line at y=7.3 represents the genome-wide significance threshold of p < 5E-8.

Conclusion: We have identified an association of sJIA with genetic variants in the MHC Class II gene cluster, closest to *HLA-DRB1* and *HLA-DQA1*. This suggests that although innate immune activation has been reported in sJIA, adaptive immune mechanisms may also influence its pathogenesis.

1687

Serum Follistatin-Like Protein 1 Is Elevated in Systemic Juvenile Idiopathic Arthritis and Is a Biomarker for Macrophage Activation Syndrome. Mark Gorelik[1], Ndate Fall[2], Susan D. Thompson[2], Alexei A. Grom[2] and Raphael Hirsch[3]. [1]Univ of Pittsburgh Med Ctr Children's Hospital, Pittsburgh, PA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) can be complicated by macrophage activation syndrome (MAS), an often fatal disorder characterized by multisystem organ failure. IL-1b and IL-6 are key inflammatory mediators in SJIA and blockade of these cytokines can ameliorate disease activity in a subset of patients. We have recently demonstrated that follistatin-like protein 1 (FSTL-1) can increase secretion of IL-1b and IL-6 from monocytes and mesenchymal stromal cells (MSC). This study was performed to determine how FSTL-1 levels correlate with measures of clinical disease activity and development of MAS.

Methods: FSTL-1 serum levels were measured by ELISA in 27 patients with sJIA, including 6 patients who developed MAS, as well as in 15 normal controls. Levels were correlated with CD163 and sIL2Ra expression. Peripheral blood mononuclear cells (PBMC) were separated on Ficoll gradients, and RNA was analyzed to evaluate differential gene expression.

Results: FSTL-1 serum levels are elevated at the time of initial diagnosis of sJIA, as compared to controls (mean of 216.3 ng/ml vs. 156.1 ng/ml, p=0.01). FSTL-1 levels decreased during the course of treatment (mean of 132.5 ng/ml after 24 months, p = 0.001). Especially high levels of FSTL-1 were present in patients during acute MAS (mean of 231.5 ng/ml). In 3 patients for whom paired samples were available pre- and post-treatment for MAS, FSTL-1 levels changed from a mean of 289.5 ng/ml to a mean of 124.0 ng/ml, p=0.08. Patients with elevated FSTL-1 levels showed increased expression of markers previously associated with MAS, including CD163. PBMC from these patients also showed a 2-fold or greater increase in expression levels of IL-1 receptor, Lipocalin 2, MMP-8, MMP-9, IL-18, as well as other genes associated with TLR4/IL1R signaling (p <0.05).

Conclusion: Serum FSTL-1 is elevated in clinically active sJIA and may represent a biomarker for development of MAS. Patients with elevated levels of FSTL-1 had increased expression of Interleukin-1 and TLR4 related genes, and may represent a subgroup with more severe disease.

1688

Analysis of the Immunochip in a Large Cohort of Oligo- and Polyarthritis Juvenile Idiopathic Arthritis Cases Confirms Previous and Identifies Novel Associations. Joanna Cobb[1], Anne Hinks[1], John Bowes[1], Marc Sudman[2], Miranda C. Marion[3], Mehdi Keddache[4], Lucy R. Wedderburn[5], Johannes Peter Haas[6], David N. Glass[2], Carl D. Langefeld[3], Wendy Thomson[1] and Susan D. Thompson[2]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Wake Forest School of Medicine, Winston-Salem, NC, [4]Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]University College London (UCL), United Kingdom, [6]German Centre for Rheumatology in Children and Young People, Garmisch-Partenkirchen, Germany

Background/Purpose: Genome wide association studies (GWAS) have been hugely successful in the identification of susceptibility loci for autoimmune diseases. One interesting outcome of these studies is the observation that many of the loci are shared across these diseases. The regions identified now require more detailed fine-mapping to localize the association signal, identify potential pleiotropic effects and identify putative functional variants. To this end the Immunochip consortium was established to pool confirmed loci from 12 diseases to include on a custom genotyping chip. The Immunochip, based on the Illumina Infinium platform, investigates ~200 established autoimmune susceptibility loci. For each locus, all known genetic variation from dbSNP, 1000 Genome and other sequencing projects was included. Juvenile idiopathic arthritis (JIA) is the most common arthritic disease of childhood. Candidate gene and GWAS have identified a number of common autoimmune genes that confer susceptibility to JIA. However, JIA has been less well studied using GWAS approaches and thus genotyping using the Immunochip has the potential for not only fine-mapping previously associated regions but also to identify novel loci for JIA.

Methods: Genotyping was performed using the Immunochip, in a large cohort from the UK, US and Germany comprising 1749 JIA oligoarthritis and RF negative polyarthritis cases and 8854 controls. All raw genotyping data was combined for clustering and QC. SNPs failed QC based on a call rate <98% and/or cluster separation score <0.4. Samples failed QC based on a call rate <98%. Outliers of mean heterozygosity, related individuals and ancestral outliers were removed. Final sample size after QC was 1614 cases and 7153 controls. Analysis was performed using logistic regression adjusting for the top 5 principal components in PLINK vers1.07.

Results: Initial analysis has not only confirmed previously associated JIA loci (*PTPN22*, *IL2RA, IL2, STAT4, PTPN2* and *SH2B3/ATXN2)* but has strengthened their association, such that all now reach genome-wide significance. A number of novel loci have been identified, some of which showed weak evidence previously, such as *IL7R* and *IRF1,* and others which have never been associated with JIA to date, such as *REV3L* and *TYK2*. These will require validation in independent cohorts.

Conclusion: The Immunochip project enables cost-effective fine-mapping of autoimmune loci in diseases such as JIA. This preliminary analysis has confirmed and strengthened the association of a number of previously associated genes as well as the identification of novel susceptibility loci for JIA. Further analysis of this data will help characterise all associated variants and identify the likely causal variants for future functional studies.

Questionable Relevance of Subclinical Synovitis: First Degree Ultrasound Findings Are Not Associated with Pain, Swelling or Power Doppler Findings in Rheumatoid Arthritis (RA). Matthias Witt, Felix Mueller, Axel Nigg, Christiane Reindl, Nicola Stein, Stefan Mayer, Christina Gebhardt, Ariane Hammitzsch, Claudia Dechant, Hendrik Schulze-Koops and Mathias Grunke. University of Munich, Munich, Germany

Background/Purpose: Several ultrasound scores have been developed for the assessment of patients with RA. Most of these are using a semiquantitative grading system with scores between 0 and 3 for greyscale (GS) and power doppler (PD) scoring. Borderline results are often scored as grade 1 and are usually counted as synovitic joints. As treatment decisions are increasingly based on US findings, this work investigated the relevance of grade 1 GS findings in regard to their association with pain, swelling and PD findings.

Methods: The three small joint regions of metacarpophalangeal (MCP-), proximal interphalangeal (PIP-) and metatarsophalangeal (MTP-) joints of 63 patients with RA were assessed clinically for tenderness and swelling according to the EULAR examination technique. All joints were then independently evaluated by ultrasound GS and PD mode with an 18 MHz high resolution device for capsule swelling and synovial hyperperfusion. The MCP-, PIP- and MTP- joints of 20 healthy individuals were examined by ultrasound and served as controls. Joints with grade 1 GS findings were identified and evaluated for their association with swelling, pain and power Doppler findings.

Results: 633 MCP-, 641 PIP- and 628-MTP joints of 63 patients with rheumatoid arthritis were assessed. 160 (25,3%), 100 (20,5%) and 100 (18,3%) grade 1 GS findings were identified for all MCP-, PIP- and MTP-joints, respectively. With exception of MCP4 and MTP5 all joints were affected similarly on the single joint level. When compared to healthy controls, significantly more grade 1 GS findings were found in the RA group for the PIP- and MTP-joints but not for the MCP-joints. In the presence of grade 1 findings, no association with swelling, pain or PD findings was observed ("subclinical synovitis"). In contrast, in the presence of grade 2 or 3 GS findings, significant association of swelling, pain and PD findings was noted.

Conclusion: Grade 1 GS findings in joints of RA patients are a frequent finding in the individual RA joint and coined the term of "subclinical synovitis". In general, these findings show a homogenous distribution across the three joint regions examined in this study. Notably, there was no significant difference between RA patients and healthy controls in regard to grade 1 findings in the MCP joints. Together with the lack of association with swelling, pain and PD findings, this data suggests a questionable clinical relevance of grade 1 GS findings especially in regard to treatment decisions. Longitudinal observation of these joints is underway to clarify their susceptibility for inflammatory exacerbation and development of erosive disease.

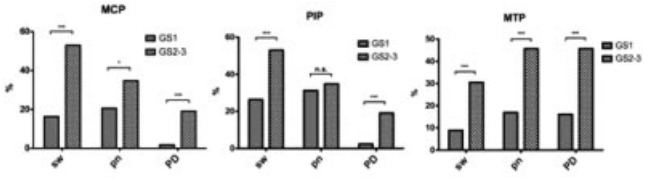

Figure 4. Significant associations of swelling, pain and PD findings in grade 2 or 3 GS findings versus grade 1 GS findings.

Patient Reported Outcome Measures: Its Impact on Disease Activity and Adherence to Therapy in Inflammatory Arthritis. Yasser M. El Miedany[1], Deborah Palmer[1] and Maha El Gaafary[2]. [1]Darent Valley Hospital, Dartford, United Kingdom, [2]Ain Shams University, Cairo, Egypt

Background/Purpose: To assess the impact of the patient reported outcome measures, recorded in the standard clinical practice, on the disease activity as well as the patients' adherence to anti-rheumatic drug therapy in patients with inflammatory arthritis.

Methods: This was a double-blind randomized controlled study. 127 patients diagnosed to have inflammatory arthritis according to the ACR criteria were included in this work. All patients received DMARDs / Biologic therapy and were monitored over the period of 1-year. Every patient completed a copy of the multidimensional patient reported outcome measures (PROMs) questionnaire. By the 6th month of treatment, the patients were randomly allocated to an active group (64 patients) who were able to view the scores recorded of their former self-reported outcome measures as well as discuss the changes in their reported disease activity parameters, functional disability and quality of life; and a control group (63 patients) who continued their treatment and management based on the view of their presentation and clinical assessment on that particular clinic visit. The patients were assessed at 3 monthly intervals for another 6 months. Before every assessment in the clinic every patient in both groups completed a copy of the PROMs questionnaire. Primary outcome was the patients' adherence to their medications; change in disease activity score (DAS-28) and PROMs disease activity parameters. Secondary outcome was the results of a survey completed by every patient in both the active group and control group (using VAS) by the end of 1-year of management, to rate the patient's perspective regarding their condition and treatment.

Results: Viewing of the PROMs scores before and after treatment led to a significant greater reduction of disease activity parameters, DAS-28 score, as well as improvement of the patients' adherence to anti-rheumatic therapy ($p<0.01$). Stopping the DMARDs therapy because of intolerance was significantly less in the active group ($p< 0.01$). The improvement of disease activity parameters was associated with improvement in functional disability and quality of life scores. Initially, the mean changes in disease activity parameters showed no significant differences at 3 and 6 months of therapy but differences were statistically significant at 12 months follow up ($p< 0.01$). Medication compliance was significantly correlated with changes in all measured disease activity parameters. Analysis of the patients' answers to the survey revealed that the active group were more likely to adhere to their medication, less likely to stop their medication because of intolerance, more able to cope with their activities of daily living, and have less concern about their future.

Conclusion: By monitoring PROMs and viewing these changes in the standard clinical practice, a new experience has been created. This has enabled the patients to see how they are doing regarding their disease activity and helped to optimize their adherence to their treatment. PROMs had a positive and significant impact on the disease activity control.

1691

Influence of Autonomic Nervous Modulation on Rheumatoid Arthritis. Olga Malysheva, Petra Baum, Anke Esber and Christoph G. Baerwald. University Hospital, Leipzig, Germany

Background/Purpose: Growing evidence supports the hypothesis that alteration of the interaction between the autonomic nervous system (ANS) and the immune system contributes to the pathogenesis of rheumatoid arthritis (RA). To further characterize neuroimmune interactions common variants of the beta2-adrenergic receptors (beta2R) and functional stress pattern responses were studied in RA patients and controls.

Methods: An allele-specific polymerase chain reaction was used to determine the common variants of the beta2R at position 16, 27, and 164 in patients with RA (n = 310) and ethnically matched healthy controls (n = 305). In a subgroup of RA patients (n = 100) the autonomic response upon various standardized stressors was performed by utilizing the heart rate variability (HRV) test (ProSciCard III, Version 2.2a, Medi-Syst GmbH, Germany) and compared to 40 age and sex matched osteoarthritis patients. HRV measures including frequency domain analysis (employing rapid processing of a 5 minute ECG rhythm strip) yielding measures of parasympathetic and sympathetic activity as well as the total power of ANS influence on various parameters: high frequency (HF), low frequency (LF), and very low frequency index of HRV and square root of the mean of the squares of successive R-R interval differences (RMSSD).

Results: There was a highly significant distortion in the distribution of beta2R polymorphisms at codon 16 between RA patients and controls. Arginine (Arg) at codon 16 was present in 278 RA patients (89.7 %) compared to 202 controls (66.2%; OR 4.43, 95 % CI 2.81 to 7.02, p = 0.00001). Interestingly, HRV at baseline in RA patients was characterized by reduced power of the ANS in general as well as a decreased parasympathetic activity compared to OA patients (HRV index: 7.81 ±

0.3 vs. 9.23 ± 0.6, p < 0.05; RMSSD: 25.46 ± 1.2 ms vs. 33.84 ± 3.2 ms, p < 0.03). Otherwise, sympathetic stress response was reduced under the mental stress test (MST) in RA patients compared to OA patients (LF HRV: 1.69 ± 0.21 Hz vs. 3.05 ± 1.0 Hz, and LF/HF HRV: 1.1 ± 0.09 vs. 1.34 ± 0.06, p < 0.05, respectively). Stratifying RA patients for the genetic at position 16 revealed a statistically significant decrease of parasympathetic activity, in particular for the deep breathing test, in patients with homozygosity for Glycine (Gly) 16 compared to RA patients with heterozygosity (Arg16Gly). However, RA patients with homozygosity for Glycine 16 showed a normalisation of the sympathetic reactivity upon MST. Interestingly, all patients exhibiting parasympathetic hyperactivity at baseline (RMSSD >50 ms) were in remission (DAS 1.4 ± 0.4).

Conclusion: Polymorphisms of the beta2AR contribute to the genetic background of RA and is associated with disturbed functional autonomic stress reactivity in RA patients. In particular parasympathetic reactivity might be used as an indicator of RA remission. Further studies are warranted to determine the role of the ANS in the disease process of RA.

1692

Low Persistence of Serotype Specific Antibodies 1.5 Years After Vaccination with 7-Valent Pneumococcal Conjugate Vaccine in Patients with Established Arthritis. Meliha C. Kapetanovic[1], Tore Saxne[2], Göran Jönsson[3], Lennart T. Truedsson[4] and Pierre Geborek[2]. [1]Dept of Clinical Sciences Lund, Lund, Sweden, [2]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden, [3]Dept of Clinical Sciences Lund, Section of Infectious Diseases, Lund, Sweden, [4]Dept of Clinical Sciences Lund, Section of Microbiology, Immunology and Glycobiology, Lund, Sweden

Background/Purpose: To study the persistence of antibodies 1.5 years after vaccination using 7-valent pneumococcal conjugate vaccine in patients with established rheumatoid arthritis (RA) and spondylarthropathy (SpA).

Methods: Of 505 patients initially recruited, data on current antirheumatic treatment and blood samples were obtained from 399 (79%) subjects after mean (SD) 1.4 (0.03) years. Antibody levels against pneumococcal serotypes 23F and 6B were analyzed by ELISA. Original treatment groups were RA on methotrexate (MTX), RA on anti-TNF as monotherapy, RA on anti-TNF+ MTX, SpA on anti-TNF as monotherapy, SpA on anti-TNF+MTX, and SpA on NSAID/analgesics (controls).

Results: At follow up 300 (75.2%) patients had unchanged medication. Geometric mean levels (GML; 95% CI) and proportion (%) of patients with putative protective antibody levels ≥1 mg/L for both serotypes calculated in different treatment groups were compared to results 4–6 weeks after vaccination (Table). GML for each serotype were significantly lower in all groups at 1.5 years follow up (p-value 0.035 to <0.001; paired sample T-test) as were proportion of patients with protective antibody levels for both serotypes (p<0.001; Chi2 test).

Table. GML (95%CI) in mg/L and percentage of patients with protective antibody levels for 23F and 6B in different treatment groups at 4–6 weeks and 1.5 years follow up

	RA on methotrexate	RA on anti-TNF as monotheraphy	RA on anti-TNF + MTX	SpA on anti-TNF as monotherapy	SpA on anti-TNF+MTX	SpA on NSAID/ analgesics
No of patients at vaccination	85	79	89	83	83	86
GML (95% CI) for 23F 4–6 weeks after vaccination	1.9 (1.3–2.6)	1.9 (1.3–2.7)	1.4 (1.1–1.9)	3.1 (2.2–4.5)	2.5 (1.8–3.5)	6.4 (4.5–9.1)
GML (95% CI) for 6B 4–6 weeks after vaccination	3.5 (2.5–4.9)	3.6 (2.5–5.3)	2.3 (1.7–3.2)	4.8 (3.3–6.9)	3.0 (22.1–4.4)	9.5 (6.7–13.6)
% of patients with protective antibody levels for both 23F and 6B 4–6 weeks after vaccination	**63.5%**	**59.5%**	**53.9%**	**77.1%**	**65.1%**	**84.9%**
No of patients (%) at 1.5 years	57 (67.1%)	50 (63.3%)	55 (61.8%)	47 (46.7%)	49 (59.0%)	42 (48.8%)
GML (95% CI) for 23F at 1.5 years	0.6 (0.4–0.8)	0.5 (0.4–0.8)	0.4 (0.3–0.5)	1.0 (0.6–1.6)	0.8 (0.5–1.3)	1.9 (1.2–3.0)
GML (95% CI) for 6B at 1.5 years	1.2 (0.7–1.9)	1.0 (0.6–1.7)	0.6 (0.4–1.0)	1.4 (0.9–2.1)	1.0 (0.6–1.6)	2.7 (1.6–4.4)
% of patients with protective antibody levels for both 23F and 6B at 1.5 years	**40.6%**	**32.0%**	**20.0%**	**59.6%**	**49.0%**	**69.0%**
Relative Ratio of protective antibody at 1.5 years compared to 4–6 weeks	**0.64**	**0.54**	**0.37**	**0.77**	**0.75**	**0.81**

Conclusion: Postvaccination antibody levels were significantly lower 1.5 years after pneumococcal vaccination compared to levels 4–6 weeks after vaccination. Persistence of protective immunity against the serotypes tested was shorter than reported in healthy individuals (Musher et al, JID, 2010). Revaccination earlier than recommended for healthy persons may be needed in patients with arthritis.

1693

Inverse Relationship Between 25-Hydroxyvitamin D and Parathyroid Hormone Observed in the General Population but Not Among Rheumatoid Arthritis Patients. Anna R. Broder[1], Amy Skversky[2], Michal L. Melamed[3], Jonathan N. Tobin[4], John A. Hardin[5] and Chaim Putterman[3]. [1]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, [2]Montefiore Medical Center, Bronx, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Albert Einstein College of Medicine/CDN Network, New York, NY, [5]Albert Einstein Coll of Med, Bronx, NY

Background/Purpose: Vitamin D deficiency and insufficiency are defined as 25-hydroxyvitamin D (25OHD) levels below 20 ng/ml and 30 ng/ml, respectively, based on data from the general population demonstrating that parathyroid hormone (PTH) levels normalize (below 65 pg/ml) at 25OHD concentrations above 30 ng/ml. Our hypothesis is that the relationship between 25OHD and PTH is altered in rheumatoid arthritis (RA) due to chronic inflammation and corticosteroid use. We studied the relationship between 25OHD and PTH using both the National Health and Nutrition Examination Surveys (NHANES) 2003–2006 and RA patients from a large tertiary care center.

Methods: For the NHANES cohort and for the tertiary care center cohort we included all adult participants with recorded values for 25OHD and PTH. Participants from both cohorts were excluded if their estimated glomerular filtration rate was < 50 ml/min/1.73 m2, because of the known altered relationship between 25OHD and PTH in chronic kidney disease. In the NHANES we compared participants with RA and participants without arthritis, based on self-report. Linear regression adjusted for age, gender, race/ethnicity and body mass index (BMI) was used for the NHANES cohort within each 25OHD interval (< 10, 10 to 20, 20 to 30, and >30 ng/ml). We constructed Kernel-weighted local polynomial smoothing curves for the RA cohort from our center.

Results: In the NHANES cohort, there were 363 participants with RA, and 5995 without arthritis. In the no-arthritis group the relationship between PTH and 25OHD within each stratum of 25OHD was similar to what was previously described in the general population. However, there was no statistically significant relationship between PTH and 25OHD in any of the strata among RA participants (Table 1). Similarly, among 47 RA patients from the tertiary care center who satisfied the inclusion criteria, PTH levels normalized at 25OHD levels slightly above 10 ng/ml and remained fairly constant at all 25OHD levels (Figure 1).

Table 1. Linear regression model showing the change in PTH (95% CI) per 1 ng/ml change in 25OHD within each 25OHD interval (ng/ml): < 10, 10 to 20, 20 to 30, and >30, adjusted for age, gender, race/ethnicity, and BMI

	RA (363 observations, subpopulation 4460045)	No arthritis (5995 observations, subpopulation size 91951415)
For 25OHD < 10 ng/ml, change in PTH, pg/ml (95% CI)	0.08 (−4.3, 4.4)	−2.9 (−5.1, −0.7)
p-value	0.969	0.011
For 25OHD ≥ 10 ng/ml and < 20 ng/ml, change in PTH, pg/ml (95% CI)	−1.2 (−3.0, −0.5)	−0.8 (−1.3, 0.3)
p-value	0.154	0.003
For 25OHD ≥ 20 ng/ml and < 30 ng/ml, change in PTH, pg/ml (95% CI)	−0.1 (−1.0, 0.77)	−0.1 (−0.5, 0.2)
p-value	0.796	0.5
For 25OHD ≥ 30 ng/ml, change in PTH, pg/ml (95% CI)	−0.3 (−0.9, 0.2)	−0.2 (−0.3, −0.1)
p-value	0.19	0.003

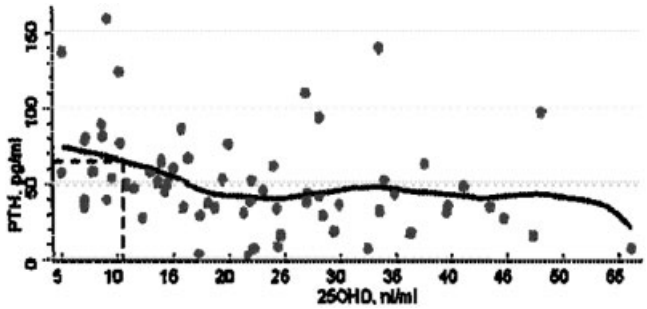

Figure 1. Polynomial curve for RA from a large tertiary care center (n=47)

Conclusion: The relationship between PTH and 25OHD is altered in RA compared with the general population. This finding has important implications for future clinical trials and for optimizing vitamin D replacement in RA.

1694

Do Rheumatoid Arthritis Patients Expect Less From Total Knee Arthroplasty? Hassan Ghomrawi[1], Lisa A. Mandl[2], Beverly Johnson[2], Michael Alexiades[2] and Susan M. Goodman[2]. [1]Weil-Cornell Medical College, NYC, NY, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: RA patients undergoing TKA often do not achieve the same functional results as osteoarthritis (OA) patients, yet are surprisingly satisfied. Satisfaction is determined not just by absolute improvements in pain and function, but also by fulfillment of pre-operative expectations. It is unknown if RA patients have different expectations compared to similar OA patients.

Methods: RA patients undergoing TKA were compared to OA patients matched for age, gender, and lower extremity activity (LEAS) score. All were drawn from a prospective institutional registry, patients with previous arthroplasties were excluded. Expectations were assessed using the validated Hospital for Special Surgery Expectations Survey (see Table 1). A composite score is calculated; range: 0–100; 100=highest expectations. Preoperative data collection also included level of education, living situation, WOMAC, VAS for pain, ED-5Q, SF-36. Wilcoxon Signed Ranks test with Bonferroni correction was used to compare individual expectation items and T-test for mean expectations score.

Table 1. Comparisons of Pre-operative Expectations in OA vs. RA

	OA Controls	Wilcoxon Signed Ranks Test
Knee Expectations Items		**P-value**
Relief of pain	Higher	0.127
Improve ability to walk short distance (indoors, 1 block)	Higher	0.036
Improve ability to walk medium distance (take a walk, < 1 mile)	Higher	0.097
Improve ability to walk long distance (> 1 mile)	Higher	0.254
Remove the need for a cane, crutch or walker	Higher	0.012
Make knee or leg straight	Higher	0.015
Improve ability to go up stairs	Higher	0.007
Improve ability to go down stairs	Higher	0.012
Improve ability to kneel	Higher	0.503
Improve ability to squat	Higher	0.083
Improve ability to use public transportation, drive	Higher	0.006
Be employed for monetary reimbursement	Higher	0.489
Improve ability to participate in recreation (e.g. dancing, pleasure travel)	Higher	0.071
Improve ability to perform daily activities (e.g., household chores, daily routine)	Higher	**<0.0026**
Improve ability to exercise or participate in sports	Higher	0.015
Improve ability to change position (e.g. go from sitting to standing or from standing to sitting)	Higher	0.003
Improve ability to interact with others (for example, take care of someone, play with children)	Higher	**<0.0026**
Improve sexual activity	Higher	0.036
Improve psychological well-being	Higher	0.003

Bonferroni corrected significant P-value <0.0026

Results: 62 RA patients were identified and matched to 124 OA controls. 87.1% were women, average age was 64.7±9.7 years, and average LEAS was 8.7±3.1 (range 2–17), which corresponds to being able to walk around the house and for several blocks without assistance. Other differences were statistically but unlikely clinically significant (see Table 2). There was no difference in living status or education. RA patients had a significantly lower expectations score than OA patients (mean 73.7 vs. 79.8 (p-value=0.03); a difference >6 is clinically meaningful. Scores on multiple individual expectations items were also lower for RA patients, but with a Bonferroni correction only statistically significant for two (see Table 2). In addition, RA patients had lower ED-5Q scale scores suggesting RA patients place a lower value on their current health state.

Table 2. Pre-Operative Data

Variable	RA Cases N=62	OA Controls N=124	P-value
Expectations score	73.7 ± 18.5	79.8 ± 17.1	0.030
WOMAC Pain	10.8 ± 2.8	9.8 ± 3.3	0.040
WOMAC Stiffness	5.1 ± 1.5	4.7 ± 1.6	0.188
WOMAC Function	38.6 ± 11.2	34.7 ± 11.9	0.048
SF-36 PCS	29.3 ± 7.7	32.5 ± 7.8	0.009
SF-36 MCS	45.4 ± 13.1	48.2 ± 13.1	0.190
EQ5D scale	62.9 ± 21.6	71.1 ± 20.4	0.017
EQ5D score	0.6 ± 0.2	0.6 ± 0.2	0.279

Conclusion: Compared to matched OA patients, RA patients had clinically meaningful differences in overall expectations prior to TKA. They also had lower expectations for multiple individual items, and also placed lower value on their pre-operative heath state. This may explain the discrepancy between higher satisfaction and lower functional outcomes in RA patients. In the anti-TNF era, RA patients may be inappropriately accepting poorer outcomes. This raises the possibility they may not be optimizing their post-surgical outcomes.

ACR Concurrent Abstract Session

Rheumatoid Arthritis Treatment - Small Molecules, Biologics, Therapy: Existing Disease-Modifying Antirheumatic Drugs - Tight Control, Induction and Drug Withdrawal Trials

Monday, November 7, 2011, 4:30 PM–6:00 PM

1695

Double-Blind Randomized CAMERA-II Trial: Better Control of Disease and Erosive Joint Damage with Inclusion of Low-Dose Prednisone Into a MTX-Based Tight Control Strategy for Early Rheumatoid Arthritis. Marije F. Bakker[1], Johannes W.G. Jacobs[1], Paco M.J. Welsing[1], Suzanne M.M. Verstappen[1], Janneke Tekstra[1], Evelien Ton[1], Monique A.W. Geurts[2], Jacobine H. van der Werf[3], G.A. van Albada-Kuipers[4], Z.N. Jahangier[5], Maaike J. van der Veen[6], C.M. Verhoef[7], Floris P.J.G. Lafeber[1] and Johannes W.J. Bijlsma[1]. [1]UMC Utrecht, Utrecht, Netherlands, [2]St. Antonius hospital, Nieuwegein, Netherlands, [3]Diakonessenhuis, Utrecht, Netherlands, [4]Meander Medical Center, Amersfoort, Netherlands, [5]Tergooi hospital, Hilversum, Netherlands, [6]St. Jansdal hospital, Harderwijk, Netherlands, [7]Flevohospital, Almere, Netherlands

Background/Purpose: Tight control treatment strategies for early rheumatoid arthritis (RA) are highly effective, but leave room for improvement. This study investigated whether including 10 mg/day prednisone from the start of treatment to a methotrexate (MTX) based tight control strategy for early RA is more effective than this strategy without prednisone, regarding disease activity and radiographic outcome, i.e. erosive joint damage.

Methods: Patients with early RA (<1 year) were enrolled in the two-year prospective randomized, placebo-controlled, double-blind, multi-centre MTX-based tight control step-up trial CAMERA-II (Computer Assisted Management in Early RA-II). Patients were randomized to a MTX-based tight control strategy with either prednisone (MTX-pred) or placebo (MTX-plac). MTX treatment was tailored to the individual patient at monthly visits, based on predefined response criteria, aiming for remission. If remission was not achieved at the maximum (tolerable) dose of MTX, a biological was added to the regimen. Primary endpoint was radiographic erosive joint damage after two years. Secondary endpoints included response criteria, remission, and the need of a biological during the trial.

Results: Respectively 117 and 119 patients were randomized to MTX-pred and MTX-plac. Erosive joint damage at the end of the trial was less in the MTX-pred than in the MTX-plac group (median (IQR); 0 (0–0) vs. 0

(0–2), p=0.04). The strategy with MTX-pred was also more effective in reducing disease activity and disability (p≤0.03). A higher proportion of patients in the MTX-pred group achieved sustained remission (72% vs. 61%, p=0.09) and a lower proportion needed biological treatment (14% vs. 36%, p<0.001), compared to the proportions in the MTX-plac group. In the MTX-pred group 29% of patients experienced adverse events compared to 35% in the MTX-plac group.

Conclusion: Inclusion of low-dose prednisone from the start into a two-year MTX-based tight control treatment strategy for early RA increases both effectiveness (i.e. disease activity variables) and outcome (i.e. erosive joint damage) without increasing toxicity. It also reduces the need for (early) treatment with biologicals.

1696

Validation of Methotrexate First Strategy in Early Rheumatoid Arthritis: A Randomized, Double-Blind, 2-Year Trial. James R. O'Dell[1], Jeffrey R. Curtis[2], Stacey Cofield[3], S. Louis Bridges Jr.[4], Ted R. Mikuls[5] and Larry W. Moreland[6]. [1]Univ of Nebraska Med Ctr, Omaha, NE, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]Univ of Alabama at Birmingham,, Birmingham, AL, [4]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [5]Omaha VA and University of Nebraska, Omaha, NE, [6]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: MTX is recommended by both ACR and EULAR guidelines as the initial DMARD for RA. However, there are no data from blinded randomized trials about this approach compared to initial combination therapy or importantly of the consequences of delaying combination therapy and giving it only to those who fail MTX.

Methods: The TEAR trial was an investigator initiated trial in early (mean duration 3.6 months) poor prognosis RA that randomized 755 patients to initial MTX (n=379) versus immediate combination therapy (MTX/etanercept or MTX/SSA/HCQ). MTX only patients stepped-up to combinations at 24 weeks if they failed to achieve low disease activity (DAS28 < 3.2). This design allows the unique opportunity to examine the strategy of using MTX monotherapy as the first intervention in RA.

Results: In the MTX only group, 28% achieved low disease activity and did not step-up to combination therapy. The mean DAS28 for patients remaining on MTX monotherapy at week 102 was 2.7± 1.1 indicating a durable response. This DAS28 was nominally lower than patients treated with immediate combinations (DAS28 3.0±1.4 [P=0.15] see Figure). Further, the MTX group had nominally less radiographic progression compared to immediate combination therapy (TSS 0.1±1.0 vs 1.1±6.; P=0.10). Patients who stepped-up had DAS28 similar DAS28 and radiographic progression to those on combo from the beginning by 12 weeks after step-up through 102 weeks. Results with both immediate combination approaches were similar.

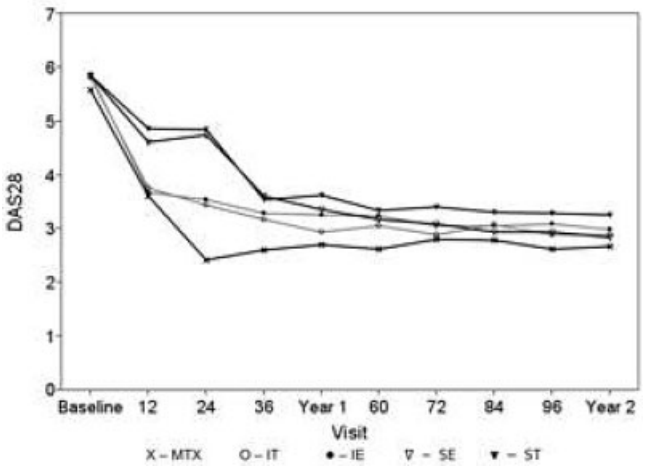

Figure. Observed DAS28 for MTX only, Immediate and Step-up Therapies

Conclusion: These data from a randomized blinded trial in patients with early, DMARD naïve, poor prognosis RA have for the first time validated the oft recommended strategy of starting with MTX mono-therapy. If this is done, approximately 30% of patients will not need combination therapy and the 70% who need add-on therapy will be clinically indistinguishable from those that received immediate combination therapy 3 months after step-up and importantly radiographically indistinguishable at 2 years.

1697

Efficacy of An Induction Therapy with Adalimumab Plus Methotrexate Versus Methotrexate Monotherapy in Recent Onset Rheumatoid Arthritis—An Investigator Initiated Randomized Controlled Trial. Jacqueline Detert[1], Hans Bastian[1], Joachim Listing[2], Anja Weiss[2], Siegfried Wassenberg[3], Anke Liebhaber[4], Karin Rockwitz[5], Rieke Alten[6], Klaus Krüger[7], Rolf Rau[8], Christina Simon[1], Eva Gremmelsbacher[1], Tanja Braun[1], Bettina Marsmann[2], Vera Höhne-Zimmer[1], Karl Egerer[1], Frank Buttgereit[1] and Gerd R. Burmester[1]. [1]Charité-Universitätsmedizin Berlin, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Evangelisches Fachkrankenhaus, Ratingen, Germany, [4]Rheumatologic Practice, Halle, Germany, [5]Rheumatologic Practice, Goslar, Germany, [6]Rheumatology Schlossparkklinik, Berlin, Germany, [7]Practice Center, München, Germany, [8]Düsseldorf, Germany

Background/Purpose: The effectiveness of an early induction therapy within the window of opportunity in patients with early rheumatoid arthritis (RA) is unclear. The present study (designated HIT HARD, funded by the German Ministry of Science) investigated whether disease activity of DMARD naïve patients with early RA benefits long term from induction therapy with adalimumab (ADA) plus methotrexate (MTX).

Methods: In a double-blinded, controlled multicenter trial, DMARD naïve RA patients (active disease ≥6 swollen, ≥6 tender joints, CRP≥10mg/l, disease duration of ≤12 months) were randomized into two groups. During the first 24 weeks (w), group A (n=87): MTX s.c. plus 40mg ADA eow; group B (n=85) 15 mg/w MTX s.c. plus placebo. After w24, both groups were treated only with MTX. Primary outcome was the DAS28 at w48. Secondary outcomes were the proportions of patients in remission (DAS28<2.6), ACR50 response, HAQ, and radiographic progression. Statistical analysis was based on the intention-to-treat population. To improve power, analysis of covariance (ANCOVA) with baseline status as covariable was applied to compare DAS28, HAQ scores between groups. Non-parametric ANCOVA was used to compare van der Heijde modified Sharp (Sharp vdH) scores. Multiple imputation method was used to replace missing data.

Results: Tables 1 and 2 show the baseline characteristics of patients, the outcome parameters at the end of the induction phase (w24) and at the end of follow-up (w48) in both treatment groups. 87% had disease duration of ≤3 months.

Table 1. Baseline characteristics

	ADA/MTX	Placebo/MTX
Age	47.2 ± 12.1	52.5 ± 14.3
Disease duration (months)	1.8 ± 2.1	1.6 ± 1.7
Rheumatoid factor positive	68 %	69 %
ACPA positive	54 %	52 %
DAS28	6.2 ± 0.8	6.3 ± 0.9
HAQ	1.4 ± 0.6	1.3 ± 0.6
Sharp vdH total score	2.3	4.6

Table 2. Outcome parameters at the end of the induction phase (w24) and at the end of follow-up (w48)

	w24 ADA/MTX	w24 Placebo/MTX	w24 p	w48 MTX mono (ADA-group)	w48 MTX mono (Placebo-group)	w48 p
DAS28	3.0 (1.2)	3.5 (1.4)	0.013	3.2 (1.4)	3.4 (1.6)	0.49
Remission (%)	47.0	30.6	0.035	43.8	36.8	0.42
ACR50 response (%)	65.5	49.4	0.033	54.0	48.2	0.45
ACR70 response (%)	47.1	35.3	0.007	41.4	35.3	0.41
HAQ	0.49 (0.6)	0.72 (0.6)	0.001	0.60 (0.6)	0.65 (0.6)	0.28
Sharp vdH total score				6.3 (5.0)	11.4 (14.8)	0.03

During the induction phase, combination therapy of ADA plus MTX reduced disease activity to a significantly greater extent than MTX plus placebo (tab. 2). After termination of ADA or placebo treatment and continuation with MTX alone, the differences between both groups in clinical outcome parameters (DAS28, remission, ACR50 response HAQ) decreased and did not reach statistical significance at w48. Nevertheless, combination therapy significantly reduced radiographic progression compared to MTX alone when analyzed after w48 (implying w24 after discontinuation) of ADA.

Conclusion: Combination therapy with ADA and MTX was significantly superior to MTX alone during the initial treatment phase of w24. A reduction of radiographic progression was observed at w48 indicating a sustained effect of combination treatment that was not found regarding for the primary endpoint, which was the reduction in disease activity. The numerical increase in the clinical outcome parameters of the ADA/MTX group from w40 onwards may reflect the loss of response after removal of ADA.

1698

Treating Rheumatoid Arthritis to Target: Outcomes and Predictors in Early Rheumatoid Arthritis Patients Treated with Adalimumab Plus Methotrexate, Methotrexate Alone, or Methotrexate Plus Subsequent Adalimumab. Josef Smolen[1], Roy M. Fleischmann[2], Paul Emery[3], Ronald F. van Vollenhoven[4], Benoit Guerette[5], Sourav Santra[6], Hartmut Kupper[7], Laura Redden[6], Benjamin Wolfe[6] and Arthur Kavanaugh[8]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]MCRC, University of Texas, Dallas, TX, [3]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [4]The Karolinska Institute, Stockholm, Sweden, [5]Abbott, Rungis, France, [6]Abbott, Abbott Park, IL, [7]Abbott GmbH & Co KG, Ludwigshafen, Germany, [8]University of California San Diego, San Diego, CA

Background/Purpose: The goals of these analyses were to evaluate 1) the optimal strategy for treating patients (pts) with early rheumatoid arthritis (RA) by comparing 78-wk outcomes in pts who continued methotrexate (MTX) or adalimumab (ADA)+MTX after reaching a stable target of DAS28 <3.2 (LDA) at wks 22 & 26 (responders, R), and 2) open-label (OL) ADA+MTX in MTX-pts who did not achieve the wk 22 & 26 target (inadequate responders, IR) in the OPTIMA trial.

Methods: MTX-naïve pts ≥18 years with RA <1 year, active disease [DAS28(CRP) >3.2, ESR ≥28 mm/hr or CRP ≥1.5 mg/dL], and either >1 erosion, RF+, or anti-CCP+ were randomized to ADA+MTX (n=515) or PBO+MTX (n=517) for 26 wks (Period 1, P1). Pts identified as R continued original treatment [ADA+MTX(R)→ADA+MTX and PBO+MTX(R)→PBO+MTX] for an additional 52 wks (P2) and were assessed for the primary composite outcome of DAS28 <3.2 and radiographic non-progression (ΔmTSS ≤0.5) at wk 78. PBO+MTX(IR) pts received OL ADA+MTX after wk 26 [PBO+MTX(IR)→ADA+MTX]. Responses after 26 wks of OL ADA+MTX were compared with those observed for ADA+MTX in P1. Regression analysis examined associations of variables at baseline (BL) and wk 12 with wk 26 rapid radiographic progression (RRP, ΔmTSS >1.5). Pts receiving ≥1 dose of ADA were monitored for adverse events (AEs).

Results: After 26 wks, significantly more ADA+MTX (44%) than PBO+MTX (24%, P <0.01) pts achieved the stable target. Although PBO+MTX(R)→PBO+MTX pts maintained robust clinical responses over 78 wks, significantly more ADA+MTX(R)→ADA+MTX pts achieved high levels of response (**Table**). Overall joint damage was persistently low (mean ΔmTSS: 0.4, PBO+MTX(R)→PBO+MTX; 0.1, ADA+MTX(R)→ADA+MTX); however, more PBO+MTX(R)→PBO+MTX pts had radiographic progression at wk 78 when compared with ADA+MTX(R)→ADA+MTX.

Table. Clinical, Functional, and Radiographic Outcomes at Wk 78

Treatment Group	DAS28 <3.2 and ΔmTSS ≤0.5[a], %	ACR 20/50/70, %	DAS28 <3.2, %	DAS28 <2.6, %	HAQ-DI <0.5, %	ΔmTSS ≤0.5[b], %
ADA+MTX(R)→ADA+MTX	70	95/89/77	91	86	67	89
PBO+MTX(R)→PBO+MTX	55	91/77/62	81	68	64	78
P value	.02	.23/.03/.01	.03	.002	.71	.02

All outcomes are LOCF, unless otherwise indicated.
[a]Primary endpoint of study; non-responder imputation.
[b]Multiple imputation.
Abbreviations: Wk, week; DAS28, 28-joint disease activity score; mTSS, modified total Sharp score; ACR, American College of Rheumatology; HAQ-DI, disability index of the health assessment questionnaire; ADA, adalimumab; MTX, methotrexate; R, responder; PBO, placebo.

PBO+MTX(IR)→OL ADA+MTX pts showed comparable clinical and functional responses with pts initiated on ADA+MTX in P1 but had more radiographic progression (mean ΔmTSS 1.2 vs. 0.15); importantly, OL ADA addition halted radiographic progression in P2. Regression analysis indicated that CRP, anti-CCP, and erosions at BL, and pt global at wk 12 were predictive of RRP at 26 wks (P <.001) among PBO+MTX(IR). AEs [n (%)] observed in 863 pts after any exposure to ADA included: serious AEs, 106 (12.3); serious infections, 35 (4.1); malignancies, 11 (1.3) including nonmelanoma skin cancer, 4 (0.5); opportunistic infections (excluding TB), 8 (0.9); confirmed TB, 4 (0.5); deaths, 9 (1.0).

Conclusion: Achieving a stable LDA target defined pts with good prognosis upon continuation of respective therapies. For PBO+MTX(IR), adding ADA after 26 wks halted radiographic progression and yielded outcomes comparable with naïve pts initiated on ADA+MTX, suggesting that rapid adjustment of therapy in early RA may be comparable with early initiation of ADA+MTX. However, pts with high levels of CRP, anti-CCP, and existing erosions at BL may benefit from earlier use of ADA+MTX.

1699

Withdrawal of Adalimumab in Early Rheumatoid Arthritis Patients Who Attained Stable Low Disease Activity with Adalimumab Plus Methotrexate: Results of a Phase 4, Double-Blind, Placebo-Controlled Trial. Arthur Kavanaugh[1], P. Emery[2], Roy Fleischmann[3], Ronald F. van Vollenhoven[4], Karel Pavelka[5], Patrick Durez[6], Benoit Guerette[7], Sourav Santra[8], Laura Redden[8], Hartmut Kupper[9], Theresa Peterson[8] and Josef Smolen[10]. [1]University of California San Diego, La Jolla, CA, [2]Leeds Teaching Hospital, Leeds, United Kingdom, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]The Karolinska Institute, Stockholm, Sweden, [5]1Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [6]Université Catholique de Louvain, Brussels, Belgium, [7]Abbott, Rungis, France, [8]Abbott, Abbott Park, IL, [9]Abbott, Ludwigshafen, Germany, [10]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: While treatment with adalimumab (ADA) plus methotrexate (MTX) has been shown to be effective in inducing low disease activity (LDA) or remission in early, active, MTX-naïve RA pts, it is not clear if subsequent withdrawal of ADA will allow maintenance of response. In this study, outcomes after 52 weeks of double-blind withdrawal or continuation of ADA were assessed in early RA pts who achieved a stable LDA target of DAS28 <3.2 at wks 22 & 26 with initial ADA+MTX.

Methods: MTX-naïve pts ≥18 years old with RA <1 year and active disease (DAS28[CRP] >3.2, ESR ≥28 mm/hr or CRP ≥1.5 mg/dL), and either >1 erosion, RF+, or anti-CCP+ were randomized to ADA+MTX (n=515) or PBO+MTX (n=517) for 26 wks (Period 1, P1). Pts who achieved the stable LDA target were re-randomized to continue ADA+MTX treatment [ADA+MTX(R)→ADA+MTX] or have ADA withdrawn [ADA+MTX(R)→PBO+MTX] for an additional 52 wks during P2. Clinical, radiographic, and functional outcomes were evaluated through P2. Logistic regression was used to determine study baseline (BL) predictors of stable composite outcomes (DAS28 <2.6 or SDAI ≤3.3, *and* HAQ <0.5, *and* ΔmTSS ≤0.5 from wks 52 to 78) in ADA+MTX(R)→PBO+MTX pts. Pts receiving ≥1 dose of ADA were monitored for adverse events (AEs).

Results: Of the 466 ADA+MTX pts completing P1, 207 pts (44%) achieved the stable LDA target and were re-randomized to ADA+MTX(R)→PBO+MTX (n=102) or ADA+MTX(R)→ADA+MTX (n=105). BL characteristics were similar, with a mean RA duration of 3.9 mos, mean DAS28 of 5.9/5.7, CRP of 28.4/23.5 mg/L, TJC68 of 25.5/23.3, SJC66 of 16.4/15.4, and mTSS of 12.2/10.8 for the two groups. Through wk 78, clinical, radiographic, and functional outcomes were generally comparable for both groups, although significantly more ADA+MTX(R)→ADA+MTX pts achieved higher measures of disease control (ACR70, DAS28 <3.2, and DAS28 <2.6), and numerically fewer pts exhibited radiographic progression at wk 78 (**Table**).

Table. Outcomes at Week 78 (LOCF unless otherwise specified)

Treatment group	ACR20/50/70, %	DAS28 <3.2, %	DAS28 <2.6, %	SDAI ≤ 11, %	SDAI ≤ 3.3, %	ΔmTSS ≤ 0.5, %*	mean ΔmTSS*	mean HAQ‡
ADA + MTX(R)→ PBO + MTX	94/80/65	81	66	84	51	89	0.3	0.35
ADA + MTX(R)→ ADA + MTX	95/89/77	91	86	92	62	81	0.1	0.33
P value	0.72/0.11/0.05	0.04	0.001	0.07	0.1	0.06	0.69	0.66

* multiple imputation; ‡ BL HAQ, ADA+MTX(R) → PBO+MTX: 1.62; ADA+MTX(R) → ADA+MTX: 1.39

Lower HAQ at BL predicted achieving stable composite outcomes from wks 52 to 78 (P <.01) in the ADA+MTX(R)→PBO+MTX group.

Other variables did not predict these outcomes. AEs [n (%)] observed in 863 pts after any ADA exposure included serious AEs, 106 (12.3); serious infections, 35 (4.1); malignancies, 11 (1.3) including nonmelanoma skin cancer, 4 (0.5); opportunistic infections (excluding TB), 8 (0.9); confirmed TB, 4 (0.5); deaths, 9 (1.0).

Conclusion: Most MTX-naïve pts with early, active RA who achieved a stable LDA after 26 wks of ADA+MTX treatment maintained good clinical, radiographic, and functional responses through wk 78 upon removal of ADA. Lower HAQ at BL predicted stable disease remission, normal function, and no radiographic progression. More pts who remained on ADA+MTX achieved higher levels of disease control compared with pts who had ADA removed, suggesting that certain pts may benefit from continued ADA+MTX therapy.

1700

Successful Dose De-Escalation of Infliximab in Rheumatoid Arthritis Patients with Stable Low Disease Activity and Treatment. Aatke van der Maas[1], Alfons den Broeder[1], Frank H.J. van den Hoogen[2], Piet Van Riel[3] and Bart J.F. van den Bemt[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Department of Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Optimal dosing of DMARDs and biologics in patients with rheumatoid arthritis (RA) requires maximum effect and minimum cost and side effects. Using step down strategies, frequent monitoring of disease activity, setting goals and adjusting therapy if the goal isn't reached are more effective than routine care, but can lead to overtreatment. This is also true for infliximab.

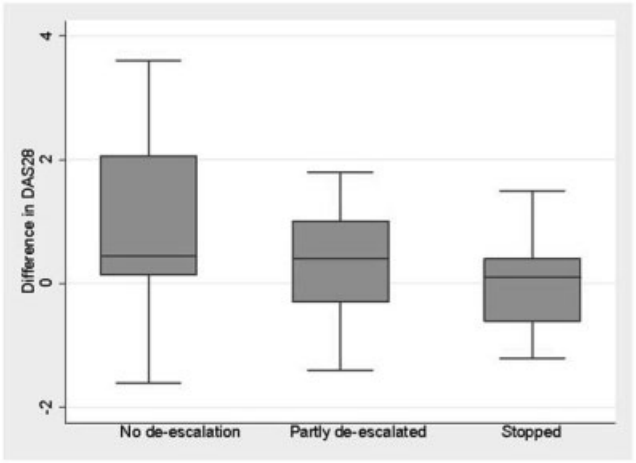
De-escalation or stopping infliximab in RA patients in remission has proven to be feasible in a part of the patients. Therefore our local treatment protocol includes tapering down infliximab dose until discontinuation in RA patients with stable low disease activity and treatment. The goal of this observational study is to describe the prevalence of successful de-escalation.

Methods: According to local treatment protocol infliximab dose was de-escalated with 25% of the original dose (3mg/kg) every 8–12 weeks without interval change in all RA patients with stable low DAS28 and treatment for at least 6 months. The dose was tapered until discontinuation or flare, defined as > 1.2 DAS28 increase, or >0.6 if DAS28 >3.2 on 2 subsequent visits. During 1 year DAS28 and medication changes were recorded. Descriptive statistics were used: percentage of patients de-escalated/stopped, infliximab dose and DAS28 difference before and after de-escalation with T-test and mean DAS28 difference with nonparametric tests.

Results: In 51 RA patients infliximab was de-escalated according to protocol (table 1). In 16% (95% confidence interval(CI) 6–26) and 45% (95%CI 31–59) respectively infliximab was stopped or de-escalated. In 39% (95%CI 26–53) no de-escalation was possible. Mean infliximab dose at start (224mg (95%CI 212–236mg) was significantly lower after 1 year (130 mg, 95%CI 105–154mg), which would imply a cost reduction of approximately € 645,-/infusion and yearly € 5.463/patient. Median DAS28 increased from 2.5 (p25–75=2.0–2.9) to 2.8 (2.2–3.6) after 1 year. This was most noticeable in patients in whom infliximab couldn't be de-escalated, however differences between groups (discontinued, de-escalated and not de-escalated) weren't significant (figure 1). During follow up extra corticosteroids were given in 6% of all 421 visits. DMARDs were seldom changed.

Table 1. Baseline characteristics

Number of patients	51
Age, years (sd*)	59 (11.2)
Female, N° (%)	29 (57)
Weight, kg (sd)	75 (13)
Disease duration in years, median [p25-p75]	12 [9-18]
RF positive, N° (%)	42 (82)
Anti-CCP positive, N° (%)	37 (73)
Erosive disease, N° (%)	39 (76)
DAS29 at inclusion (sd)	2.5 (0.8)
Duration of infliximab therapy, years (sd)	5.6 (2.6)
Interval duration at start, median [p25-p75]	8 [6-8]
Infliximab dose at start, mg (sd)	223 (41)
No of previous DMARDs, median [p25-p75]	3 [2-3]
Previous MTX, N° (%)	49 (96)
Previous anti-TNF-alpha therapy, N° (%)	5 (10)
Concomitant DMARD use, N° (%)	41 (80)
Concomitant MTX use, N° (%)	35 (68)
Concomitant corticosteroid use, N° (%)	2 (4)



Conclusion: In the majority of patients with stable low disease activity and treatment infliximab can be de-escalated or stopped. Mean DAS28 after 1 year is somewhat higher in patients who couldn't de-escalate, which might be partly explained by regression to the mean. Predictors for successful de-escalation are warranted however.

A Reverse Interferon-γ Signature Is Shared by CD103+CD4+ Dendritic Cells From HLA-B27 Transgenic Rat and Macrophages From Ankylosing Spondylitis Patients. Ingrid Fert[1], Nicolas Cagnard[1], Simon Glatigny[1], Franck Letourneur[1], Sebastien Jacques[1], Luiza Krause[1], Robert A. Colbert[2], Gilles Chiocchia[1] and Maxime A. Breban[3]. [1]Institut Cochin, 75014 Paris, France, [2]NIAMS NIH, Bethesda, MD, [3]Hopital Ambroise Pare, Boulogne, France

Background/Purpose: In HLA-B27/human β_2-microglobulin transgenic rat, the spontaneous development of an ankylosing spondylitis-like disease (AS) is strongly correlated with high levels of transgene expression and with abnormal function of dendritic cells (DCs). In this study, we investigated the factors implicated in HLA-B27 DC dysfunction by analysing their transcriptome. We further compared our results with those reported on monocyte-derived macrophages from AS patients (*Arthritis Rheum* 2008;58:1640).

Methods: RNA extraction and amplification was performed on $CD103^+CD4^+$DC samples purified from 3 groups of age-matched male rat spleens: 8 different pools of HLA-B27, 6 of HLA-B7 and 7 of nontransgenic rats, using magnetic cell sorting. Affymetrix Rat230_2 GeneChip (a genome-wide array with 31,100 probe sets) was used for the transcriptome assay. Gene expression levels were normalized using GC-RMA and flags were computed using MAS5. Quality assessment of the chips was performed with affyQCReport R package. Inter-group comparisons were done using Student's *t* test. We filtered the p-values at 5% and we only conserved expression fold changes ≥ 1.5. Data were submitted to Ingenuity Pathway Analysis to infer relevant biological pathways.

A meta-analysis was further performed, as previously described (*Immunity* 2010; 33(3): 375), between the rat data and published gene expression analysis performed on macrophages from 8 AS patients and 9 healthy controls: human data extraction, normalization and analysis were performed with the same method as for the rat study, in order to unveil possible correspondences between both species. The human and rat data were merged and submitted to hierarchical clustering.

Results: Rat microarray analysis revealed significant differential expression of 178 genes in HLA-B27 DCs, as compared with both HLA-B7 and nontransgenic DCs. Hierarchical clustering readily separated HLA-B27 from controls DCs. Among the differentially expressed genes, 45 (25.3%) were interferon-γ-regulated (IFNγ), among which 30 IFNγ–up-regulated described genes were underexpressed in HLA-B27 DCs, indicating a "reverse" IFNγ signature (fold

changes: 0.02–0.66). In contrast, several genes involved in antimicrobial peptides pathway were overexpressed in HLA-B27 DCs (fold changes: 7–209).

The combined rat/human hierarchical clustering, performed with 251 ortholog genes, strikingly separated all (n = 17) patient and HLA-B27 rat samples from most (n = 19/22) human and rat controls. The meta-analysis between rat and human data revealed 9 differentially expressed genes shared by AS patients and HLA-B27 rat, as compared to controls. Among these, 5 were indicative of a reverse IFNγ signature: IRF1, STAT1, CXCL9, CXCL10 and IFIT3.

Conclusion: This study reveals consistent differences in gene expression patterns between DCs from HLA-B27 rats vs. controls and AS patients vs. controls, with evidence for a "reverse" IFNγ signature shared with AS patients. Together with an overexpression of genes involved in antimicrobial peptides pathway, these results suggest that expression of HLA-B27 may lead to a defect in IFNγ signaling, with regulatory consequences and implications for disease pathogenesis.

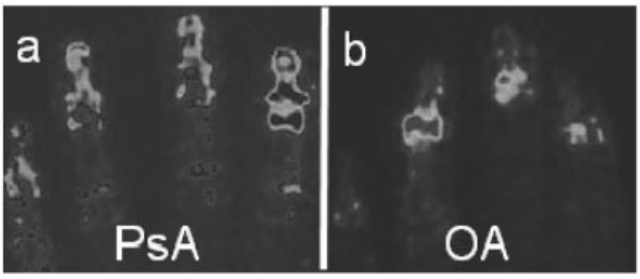
Regional Differences in Bone Metabolism in the DIP Joint in Psoriatic Arthritis Compared to Osteoarthritis Support the Concept of An Integrated Bone-Enthesis Nail Apparatus—A High-Resolution ^{18}F-fluoride Positron Emission Tomography Study. Ai Lyn Tan[1], Steven Tanner[2], Michael Waller[3], Elizabeth Hensor[4], Alison Burns[3], Alan Jeavons[2], Robert Bury[3], Paul Emery[5] and Dennis McGonagle[1]. [1]University of Leeds and Leeds Teaching Hospitals, Leeds, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]Leeds Teaching Hospitals, Leeds, United Kingdom, [4]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [5]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom

Background/Purpose: Bone involvement of the DIP joint including new bone formation and osteolysis are common in psoriatic arthritis (PsA) but are poorly understood in relationship to the nail. This study used high resolution positron emission tomography (hrPET) and ^{18}F-fluoride to explore bone metabolism in the DIP joints in PsA, osteoarthritis (OA) and in healthy controls (HC). The aim was to test the hypothesis that in PsA, the nail is functionally integrated with the bone.

Methods: 234 DIP joints were scanned in 30 subjects (10 PsA, 10 OA and 10 HC) using the QuadHIDAC nano PET scanner. ^{18}F-fluoride uptake intensity was normalised to a region in the mid shaft of a proximal phalanx in each hand. The images were assessed blinded to diagnosis and symptoms (VAS 0–10) for site and intensity (score 0–3) of increased isotope uptake.

Results: At the DIP joints, the uptake of ^{18}F-fluoride in the distal phalanx (DP) was strong relative to the intermediate phalanx in both PsA and OA. In PsA, uptake often occurred in a diffuse pattern involving most of the DP adjacent to the nail (43% of PsA joints, 19% of OA joints, p=0.01) (Fig a). There was also greater isotope uptake at the enthesis, the periosteum, and at the tufts of the DP of PsA compared to OA, which may explain the commonly seen bony phenotype of PsA ranging from periostitis (periosteal pattern of uptake) to end-stage osteolysis or whittling of DPs (diffuse and tuftal patterns of uptake). In contrast, in OA uptake was greatest in the peri-articular/sub-chondral region of the joint adjacent to known sites of osteophytosis and bone erosions (Fig b).



Of the 3 groups, the PsA joints showed an overall greater intensity of ^{18}F-fluoride uptake. Compared to the asymptomatic PsA DIP joints, there was greater intensity of isotope uptake in the symptomatic joints (median [range] intensity 2 [1–3] in symptomatic joints, 1 [0–2] in asymptomatic joints), and a greater proportion of symptomatic PsA DIP joints had DP isotope uptake at the subchondral bone and the periosteum, where there are large concentrations of enthesis attachments including attachments from the nail, suggesting that events taking place within bone may be major determinants of symptoms in PsA. The asymptomatic PsA joints had a greater degree of isotope uptake in the DPs compared to the HC asymptomatic joints (median [range] intensity in PsA 1 [0–2], normal 0 [0–1], p=0.001) supporting the established view of a large burden of asymptomatic subclinical disease in PsA.

Conclusion: This is the first reported study showing that hrPET can be used to study human arthritis and demonstrates diffuse increased bone metabolism involving the entire DP, periostium and entheses, especially in PsA. The subchondral bone and periosteum at the DP have large concentrations of enthesis attachments including attachments from the nail supporting the concept of an integrated nail and joint apparatus leading to a wide area of abnormal bone metabolism in PsA.

1703

Evidence That HLA-B27-Induced Endoplasmic Reticulum (ER) Stress Produces Pro- and Anti-Osteoclastogenic Cytokines in Rats with Spondyloarthritis-Like Disease. Gerlinde Layh-Schmitt, Eva Yang and Robert A. Colbert. NIAMS NIH, Bethesda, MD

Background/Purpose: Spondyloarthritis (SpA) is an immune-mediated inflammatory disease that can result in both systemic bone loss and aberrant bone formation. HLA-B27 (B27) is a major genetic risk factor, and in B27/human β_2m transgenic (B27-Tg) rats that develop SpA-like disease, B27 misfolding and generation of ER stress activates the unfolded protein response (UPR). This promotes IFN-β and IL-23 expression, and is associated with expansion and activation of CD4+ Th17 T cells, and IL-17 and TNF-α overexpression in the colon. IL-23 induction provides a plausible mechanism for the development of colitis, and suggests an 'upstream' role for B27 in promoting inflammation. Since HLA class I molecules are expressed in many different cell types, including those involved in bone homeostasis, we hypothesized that B27 may also have 'downstream' effects that alter cell behavior in response to pro-inflammatory cytokines. Thus, we examined whether B27 expression affects the development of osteoclasts from bone marrow (BM) precursors under the influence of TNF-α or RANKL.

Methods: BM monocytes (BMMo) were obtained from healthy wild type (WT) and B27-Tg rats, and treated for five days with M-CSF and either RANKL (10–100 ng/ml) or TNF-α (7.5–30 ng/ml) to induce osteoclast formation. Osteoclasts were quantified by counting TRAP (tartrate tesistant acid phosphatase)-positive cells with >3 nuclei. Expression levels of B27 and UPR-target genes (BiP and XBP1s) were examined by RT-PCR, western blot, and immunofluorescence. Neutralizing antibodies against IL-1α and IFN-β were used to block autocrine effects of these cytokines.

Results: BMMo from B27-Tg rats treated with TNF-α form 2–3-fold more osteoclasts than BMMos from wild type (WT) animals (n=6 experiments, 2.5-fold, 95% CI=2.16–2.94). In contrast, RANKL stimulated the formation of the same number of osteoclasts in B27-Tg and WT BMMos. TNF-α upregulated B27 expression, exacerbated misfolding, and activated the UPR in B27-Tg cells, but no UPR activation was seen in WT cells. In contrast, RANKL had no effect on B27 expression, and UPR activation was not seen in either B27-Tg or WT BMMos. Neutralization of IL-1α completely blocked the increase in osteoclast formation in B27-expressing BMMos, while IFN-β neutralization further promoted TNF-α-induced osteoclast formation in B27-Tg cells (2-fold). In WT cells neither antibody had a significant effect on osteoclast formation.

Conclusion: Our results indicate that osteoclast precursors from rats expressing HLA-B27 produce at least two activities in response to TNF-α most likely as a consequence of B27 misfolding and UPR activation; one activity (IL-1α) promotes osteoclastogenesis, while a second (IFN-β) inhibits osteoclastogenesis. Although the net result in this system is pro-osteoclastogenic and may contribute to the bone loss observed in these rats, other factors that further induce IFN-β could shift this balance towards a net anti-osteoclastognic effect. These results are of considerable interest given the bone phenotype of ankylosing spondylitis where aberrant bone formation is frequently juxtaposed with bone loss in the axial skeleton.

1704

Identification of a Unique Subset DC-STAMP+ (Dendritic Cell-Specific Transmembrane Protein) T Cells with a Th17 Signature in Psoriatic Arthritis (PsA) Patients. Yahui Grace Chiu, Edward M. Schwarz, Wojciech Wojciechowski, Ben Panepento, Igor Kuzin, Tim Bushnell, Sharon Moorehead, Rick Barrett and Christopher Ritchlin. University of Rochester, Rochester, NY

Background/Purpose: The contribution of Th17 cells to disease pathogenesis in psoriatic arthritis (PsA) is not well understood. We previously demonstrated that the expression of DC-STAMP (Dendritic Cell-Specific Transmembrane Protein), a 7-pass transmembrane protein required for monocyte fusion during osteoclast (OC) development, is increased in freshly isolated monocytes from PsA patients and may be a marker of osteoclast precursors. We also noted that a subset of CD3+/CD4+ T cells expressed DC-STAMP. Herein, we examined if DC-STAMP+/CD3+/CD4+ cells have a Th17 cell signature.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from PsA patients and healthy controls (HC), stained with an antibody cocktail composed of Th17-specific antibodies including IL-23R, CD161, CCR4, CCR6, and 1A2, a monoclonal antibody to DC-STAMP. The intracellular expression of IL-17, IFN-γ and IL-4 was also examined. A portion of PBMC was cultured in the presence of Th17-promoting cytokines and examined by the same antibody cocktail after 8 days in culture. IL-17 concentration in culture supernatants was evaluated by ELISA and the expression of Th17-specific genes was analyzed by real-time PCR (RT-PCR). Cellular localization of DC-STAMP on DC-STAMP+/CD3+/CD4+ T cells and DC-STAMP+/CD14+ monocytes was visualized and compared by Amnis ImageStream.

Results: Analysis of flow data from PsA patients (n=32) revealed a positive correlation between the percentage of DC-STAMP+ and DC-STAMP+/CD3+ cells (Pearson correlation=0.506, p=0.003). We identified a unique subset of CD3+/CD4+/DC-STAMP+ cells with a Th17 cell signature (CCR4+/CCR6+/IL23R+/IL17A+/CD161+). These cells expressed low levels of intracellular IL-4 and IFN-γ. Importantly, this subset was detected in PsA patients but not in HC. After 8-day culture in Th17-promoting conditions, the percentage of DC-STAMP+ cells was increased 2-fold and the Th17 phenotype was greatly enhanced. These cells secreted increased levels of IL-17 compared to unstimulated cells. RT-PCR analysis revealed an increase in CCR4, CCR6, IL23R and RORgammaT gene expression, which was associated with an elevated DC-STAMP signal after culture. DC-STAMP+/CD3+ cells from tonsil were distinct from those in PBMC and did not have Th17 signature. DC-STAMP was mainly expressed on the cell surface of DC-STAMP+/CD14+ monocytes but was found evenly distributed in the cytoplasm of DC-STAMP+/CD3+/CD4+ T cells.

Conclusion: A novel CD3+/CD4+/DC-STAMP+ cell population with a distinct Th17 cell signature was identified in a subset of PsA patients. This T cell phenotype was enhanced in the presence of Th17-promoting cytokines *in vitro* and was associated with increased secretion of IL-17. The intracellular localization of DC-STAMP on CD3+/CD4+ T cells suggests internalization of receptor/antibody complexes, a phenomenon commonly observed in chemokine receptors. Distinct cellular localization of DC-STAMP in CD14+ monocytes and CD3+/CD4+ T cells suggests divergent biological functions of DC-STAMP in these 2 cell lineages. Future studies on this unique DC-STAMP+ T cell subset may provide new insights into the mechanisms of inflammation and bone destruction regulated by T cells in PsA.

The Role of Gut Microflora and Autoreactive CD4+ T Cells in the Development of Spondyloarthritis and Inflammatory Bowel Disease in Beta-Glucan-Treated SKG Mice. Merja Ruutu[1], Jared Velasco[1], Daniel Aguirre[2], Helen Benham[1], Mark Morrison[2], Michael McGuckin[3] and Ranjeny Thomas[1]. [1]Univ of Queensland, Brisbane, Australia, [2]CSIRO, Brisbane, Australia, [3]Mater Medical Research Institute, Brisbane, Australia

Background/Purpose: Although spondyloarthritis and inflammatory bowel disease (IBD) co-exist in human spondyloarthropathies (SpA) the mechanism is unclear. Despite shared genetic associations, only a subset of patients develops spondyloarthritis and IBD, and either may present first. Autoimmune cross-reactivity towards joint and gut antigens may occur. Alternatively there may be coincident or sequential development of joint and gut autoreactivity driven by common innate mechanisms, potentially triggered by infection. The SKG ZAP-70^{W163C} mutation of the BALB/c strain reduces T cell receptor signaling, altering sensitivity of developing thymocytes to negative and positive selection, and enriching the peripheral repertoire with IL-17-skewed autoreactive T cells. When otherwise healthy SKG mice are housed in microbially clean (spf) conditions, systemic administration of 1,3-D beta-glucan (curdlan) triggers arthritis of wrists and ankles, spondylitis of tail and lumbar spine, Crohn's-like ileitis and unilateral anterior uveitis. To elucidate the mechanism underlying the involvement of multiple organs after a single trigger, we sought the contribution of the gut microflora, and of CD4+ autoreactive T cells to arthritis, spondylitis and ileitis in this model.

Methods: SKG mice housed in spf or rederived to germ free conditions were injected i.p. once with 3 ug curdlan. Arthritis, general appearance and weight loss were scored for 10 weeks. Organ pathology was determined by H&E staining of paraffin-embedded tissue sections at sacrifice between 1 and 10 weeks after injection of curdlan. Sera were analyzed for autoantibodies. $CD4^+$ T cells were transferred from lymph nodes and spleen of SKG mice treated 1 week previously with curdlan, to immunodeficient mice.

Results: Under spf conditions, histological analysis of tissues showed that arthritis and spondylitis developed simultaneously and progressively from 1 week after curdlan injection, associated with the development of anti-proteoglycan and anti-collagen type II autoantibodies. In contrast, there was no histological evidence of ileitis until 6–10 weeks after curdlan injection. All recipients of $CD4^+$ T cells from SKG mice treated 1 week previously with curdlan developed arthritis and spondylitis but not ileitis. However, immunodeficient recipients of $CD4^+$ T cells also developed colitis. Under germ free conditions, arthritis and spondylitis were markedly attenuated.

Conclusion: After systemic exposure to beta-glucan, SKG mice develop sequential features of SpA. Arthritis and spondylitis, transferable with CD4+ T cells and associated with autoimmunity to cartilage antigens, develops first, followed by ileitis. The failure of CD4+ T cells to transfer ileitis early in disease argues against T cell cross-reactivity towards joint and small intestinal autoantigens. The lack of arthritis in germ free conditions suggests, however, that gut microflora mediate systemic effects of curdlan, potentially through adjuvant effects on joint autoantigen presentation.

1706

Transcriptomic Analysis of Monocytes and Monocyte-Derived Dendritic Cells (MD-DCs) Reveals Several Genes Differentially Regulated Between Ankylosing Spondylitis (AS) Patients and Healthy Controls. Alice Talpin[1], Nelly Bonilla[1], Félicie Costantino[2], Franck Letourneur[1], Sebastien Jacques[1], Florent Dumont[1], Henri-Jean Garchon[2], Maxime A. Breban[3] and Gilles Chiocchia[1]. [1]Institut Cochin, 75014 Paris, France, [2]Institut Cochin, Paris, France, [3]Hopital Ambroise Pare, Boulogne, France

Background/Purpose: As originally shown in an HLA-B27 transgenic rat model, abnormal regulation of antigen-presenting cells is a characteristic feature of AS. Indeed, monocytes-derived DCs from AS patients exhibit a weaker stimulatory efficiency of CD4+ T cells than control DCs (*Arthritis Rheum.* 2009;60:1432). Consequently, it is of first importance to analyze the gene expression profile in DCs from AS patients.

Objectives: To identify genes differentially expressed in monocytes and MD-DCs from AS patients, as compared to healthy controls.

Methods: Monocytes were purified from 9 HLA-B27+ AS patients and 10 healthy controls PBMCs using anti-CD14-coupled immunomagnetic beads and either RNA directly extracted or cells were further cultured with IL-4 and GM-CSF for 7 days. MD-DCs were then stimulated with LPS for 6 and 24 hours. RNAs were extracted and copied into cRNA. Transcriptomic study was performed with Affymetrix HuGene 1.0 ST microarrays (23,021 genes) on monocytes and on unstimulated and stimulated MD-DCs. Data were analyzed with Bioconductor. Following normalization, gene expression levels in patients and in controls were compared using a multivariate design under a linear model (LIMMA). Bonferroni correction was applied. Analysis of signaling pathway-linked genes was done with Ingenuity Pathway Assist Software.

Results: Transcriptomic analysis identified 41 and 53 genes differentially expressed between AS and controls, in monocytes (0.18%) and in MD-DCs (0.23%), respectively. Highest statistical significance was observed for early growth response-2 (*EGR2*) and sphingomyelin synthase 2 (*SGMS2*) genes (Pcorr = 2.2×10^{-5} and 1.5×10^{-4}, respectively) in monocytes; and for metallopeptidase with thrombospondin type 1 motif 15 (*ADAMTS15*) and tumor necrosis factor superfamily, member 13B (*TNFSF13B/BAFF*) (Pcorr= 2×10^{-2} and 4×10^{-2}, respectively) in MD-DCs. IL-17 and IL-6 signaling canonical pathways were detected as

differentially regulated in monocytes between AS and controls. In MD-DCs, genes related to inducible T-cell co-stimulator (ICOS) signaling appeared differentially expressed. Validation by q-PCR of the most significant genes is underway.

Conclusion: This transcriptomic study reveals striking differences in the gene expression patterns of monocytes and MD-DCs between AS and controls. Several differentially expressed genes suggest interesting biological relevance, such as *EGR2* which is regulated by dectin and *BAFF* which may correlate with disease activity in psoriatic arthritis. Conversely, other genes, such as SGMS2, are unforeseen by previous works and may reveal new pathogenetic pathways.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects: General
Monday, November 7, 2011, 4:30 PM–6:00 PM

Favorable Prognosis in a Large, Prospective Multicenter Study of Lupus Pregnancies. Jill P. Buyon[1], Lamya Garabet[2], Mimi Kim[3], Emily R. Reeves[2], Marta M. Guerra[2], Michael D. Lockshin[4], Carl A. Laskin[5], Ware Branch[6], Lisa R. Sammaritano[2], Michelle Petri[7], Joan T. Merrill[8], Allen D. Sawitzke[9] and Jane E. Salmon[10]. [1]New York University School of Medicine, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Barbara Volcker Center for Women and Rheumatic Diseases: Hospital for Special Surgery, New York, NY, [5]University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON, [6]Univ of Utah, Salt Lake City, UT, [7]Johns Hopkins University School of Medicine, Baltimore, MD, [8]Oklahoma Medical Research Foundation, Oklahoma City, OK, [9]University of Utah Medical Ctr, Salt Lake City, UT, [10]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY

Background/Purpose: Accurate prediction of fetal and maternal outcomes of pregnancies complicated by lupus is required to plan treatment. The frequency of adverse outcomes and associated clinical and laboratory variables were evaluated in a large, prospective multicenter, multiethnic study.

Methods: The PROMISSE Study (**P**redictors of p**R**egnancy **O**utcome: Bio**M**arkers **I**n antiphospholipid antibody **S**yndrome and **S**ystemic Lupus **E**rythematosus) evaluated 333 pregnant women each month with ≥4 ACR SLE criteria enrolled in the first trimester. Exclusion criteria were multi-fetal pregnancy, prednisone >20mg/d, proteinuria >1gm/24hr, and/or creatinine >1.2 mg/dL. An adverse pregnancy outcome was at least one of the following: fetal/neonatal death, birth <36 weeks due to placental insufficiency, hypertension, or preeclampsia, and small for gestational age <5th percentile (SGA). Mild/moderate and severe flares were defined by SLEPDAI Index (**SL**E **P**regnancy **D**isease **A**ctivity **I**ndex), which excludes physiologic changes of pregnancy but incorporates the components of the SELENA-SLEDAI score as well as changes in clinical parameters and medications, and physician's global assessment (PGA). Subjects were: 56.8% Caucasian, 19.8% Black, 10.2% Asian, 13.2% mixed or other races; overall 16.0% Hispanic by ethnicity. Thirty-one percent had previous renal disease. At enrollment 38% were anti-dsDNA positive; 60% took HCQ, 41% prednisone, and 18% azathioprine. Mean SLEPDAI was 2.6 ± 2.8.

Results: Adverse pregnancy outcome occurred in 63 (19%) patients: 19 had fetal/neonatal death and 30 each had birth <36 weeks or SGA infants. The following baseline variables associated with poor outcome: SLEPDAI ≥4 (p=.02), high titer aPL (LAC + or IgG aCL > 40, p<.0001), higher median uric acid levels (3.4±1.4 vs. 3.0±2.2 mg/dL, p=.01), as was an increase over baseline in SLEPDAI ≥3 at 20 or 32 wks (p =.03) and an increase in PGA ≥0.3. None of the following influenced pregnancy outcomes: Hispanic ethnicity, prior renal disease or use of cylophosphamide, or at entry, proteinuria ≥2+ or 500–1000mg/d, positive anti-dsDNA, initial C3 or C4 level, HCQ, prednisone, or azathioprine. Ten percent of patients developed preeclampsia. Mild/moderate flares occurred in 10.2% at 20 wks and 7.8% at 32 weeks. Severe flares occurred in 2.1% at 20 wks and 2.4% at 32 weeks. Of the 15 patients with severe flares: 4 were renal, 5 pleuritis, 1 thrombocytopenia, 1 CNS, 2 arthritis, 1 myositis and 1 pericarditis. Neither the initial mean C3 or C4 nor presence of anti-dsDNA associated with flare.

Conclusion: Eighty percent of patients have a favorable pregnancy outcome. Adverse outcome was associated with an increase in lupus activity during pregnancy, high titer aPL antibody, and higher levels of uric acid at baseline. Mild/moderate and severe flares were infrequent in patients clinically stable at baseline despite anti-dsDNA antibodies or past history of renal disease. This large, prospective study provides reassurances for patients with stable lupus contemplating pregnancy and suggests parameters that merit caution for the minority at risk of adverse outcome.

Derivation and Validation of Systemic Lupus International Collaborating Clinics Classification Criteria for Systemic Lupus Erythematosus. Michelle Petri[1], Ana-Maria Orbai[1], Graciela S. Alarcón[2], Caroline Gordon[3], Joan T. Merrill[4], Paul R. Fortin[5], Ian N. Bruce[6], David A. Isenberg[7], Daniel J. Wallace[8], Ola Nived[9], Gunnar K. Sturfelt[10], Rosalind Ramsey-Goldman[11], Sang-Cheol Bae[12], John G. Hanly[13], Jorge Sanchez-Guerrero[14], Ann E. Clarke[15], Cynthia Aranow[16], Susan Manzi[17], Murray B. Urowitz[18], Dafna D. Gladman[19], Kenneth C. Kalunian[20], Melissa I. Costner[21], Hong Fang[1], Systemic Lupus International Collaborating Clinics (SLICC)[22] and Laurence S. Magder[23]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Birmingham, Birmingham, United Kingdom, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Toronto Western Hospital, Toronto, ON, [6]The University of Manchester, Manchester, United Kingdom, [7]University College London, London WC1E 6JF, United Kingdom, [8]Cedars-Sinai/UCLA, Los Angeles, CA, [9]University Hospital, Lund, Sweden, [10]University Hospital Lund, Lund, Sweden, [11]Northwestern University, Chicago, IL, [12]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [13]Nova Scotia Rehabilitation Center, Halifax, NS, [14]University Health Network/Mount Sinai Hospital, Toronto, ON, [15]Research Institute of the McGill Univ. Health, Montreal, QC, [16]Feinstein Institute for Medical Research, Manhasset, NY, [17]Allegheny Singer Research Institute, Pittsburgh, PA, [18]Toronto Western Hospital and University of Toronto, Toronto, ON, [19]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [20]UCSD School of Medicine, La Jolla, CA, [21]North Dallas Dermatology Assoc, Dallas, TX, [22]Chicago, [23]University of Maryland, Baltimore, MD

Background/Purpose: The Systemic Lupus International Collaborating Clinics (SLICC) revised the American College of Rheumatology (ACR) SLE classification criteria and then validated the new criteria in order to improve clinical relevance, meet more stringent methodology requirements and incorporate new knowledge in SLE immunology since 1982.

Methods: The new classification criteria were derived from a set of 702 expert-rated patient scenarios. Recursive partitioning and logistic regression were used to derive an initial rule that was simplified and refined based on SLICC physician consensus. The SLICC classification rule was validated in a new sample of 690 SLE patients and controls.

Results: The SLICC criteria rule for SLE classification requires: 1) Four criteria, with at least one clinical criterion AND one immunologic criterion OR 2) Lupus nephritis alone in the presence of ANA or anti-dsDNA antibodies. In the derivation set, the SLICC classification rule resulted in fewer misclassifications than the current ACR classification rule (49 compared to 70, p=0.0082), had greater sensitivity (94% versus 86%, p<0.0001) and equal specificity (92% versus 93%, p=0.39). In the validation set, the SLICC classification rule resulted in fewer misclassifications (66 compared to 74, p=0.43), had greater sensitivity (97% versus 83%, p<0.0001) but less specificity (84% versus 96%, p<0.0001).

Conclusion: The new SLICC classification criteria performed well on a large set of patient scenarios rated by experts. In particular, the new criteria provide updated and more inclusive definitions for each criterion.

Importantly, they require that at least one clinical criterion and one immunologic criterion be present to have a classification of SLE. Under the new SLICC classification lupus nephritis by biopsy (in the presence of SLE autoantibodies) is sufficient for classification.

Table. Clinical and Immunologic Criteria Used in the Classification Rule

Clinical Criteria

1. Acute cutaneous lupus
   including lupus malar rash (do not count if malar discoid)
   bullous lupus
   toxic epidermal necrolysis variant of SLE
   maculopapular lupus rash
   photosensitive lupus rash
   in the absence of dermatomyositis or subacute cutaneous lupus
   (nonindurated psoriaform and/or annular polycyclic lesions that resolve without scarring, although occasionally with postinflammatory dyspigmentation or telangiectasias).
2. Chronic cutaneous lupus
   including classical discoid rash
   localized (above the neck)
   generalized (above and below the neck)
   hypertrophic (verrucous) lupus
   lupus panniculitis (profundus)
   mucosal lupus
   lupus erythematosus tumidus
   chilblains lupus
   discoid lupus/lichen planus overlap
3. Oral ulcers: palate
   buccal
   tongue
   or nasal ulcers
   in the absence of other causes, such as vasculitis, Behcets, infection (herpes), inflammatory bowel disease, reactive arthritis, acidic foods
4. Nonscarring alopecia (diffuse thinning or hair fragility with visible broken hairs) *in the absence of other causes such as alopecia areata, drugs, iron deficiency and androgenic alopecia*
5. Synovitis involving two or more joints, characterized by swelling or effusion OR tenderness in 2 or more joints and thirty minutes or more of morning stiffness.
6. Serositis
   typical pleurisy for more than 1 day
   or pleural effusions
   or pleural rub
   typical pericardial pain (pain with recumbency improved by sitting forward) for more than 1 day
   or pericardial effusion
   or pericardial rub
   or pericarditis by EKG
   in the absence of other causes, such as infection, uremia, and Dressler's pericarditis
7. Renal
   Urine protein/creatinine (or 24 hr urine protein) representing 500 mg of protein/24 hr
   or
   Red blood cell casts
8. Neurologic
   seizures
   psychosis
   mononeuritis multiplex
   in the absence of other known causes such as primary vasculitis myelitis
   peripheral or cranial neuropathy
   in the absence of other known causes such as primary vasculitis, infection, and diabetes mellitus
   acute confusional state
   in the absence of other causes, including toxic-metabolic, uremia, drugs
9. Hemolytic anemia
10. Leukopenia (< 4000/mm^3 at least once)
    in the absence of other known causes such as Felty's, drugs, portal hypertension
    OR
    Lymphopenia (< 1000/mm^3 at least once)
    in the absence of other known causes such as corticosteroids, drugs and infection
11. Thrombocytopenia (<100,000/mm^3) at least once *in the absence of other known causes such as drugs, portal hypertension, TTP*

Immunological Criteria

1. ANA above laboratory reference range
2. Anti-dsDNA above laboratory reference range, except ELISA: twice above laboratory reference range
3. Anti-Sm
4. Antiphospholipid antibody: any of the following
   lupus anticoagulant
   false-positive RPR
   medium or high titer anticardiolipin
   anti-b2 glycoprotein I
5. Low complement
   low C3
   low C4
   low CH50
6. Direct Coombs test in the absence of hemolytic anemia

1709

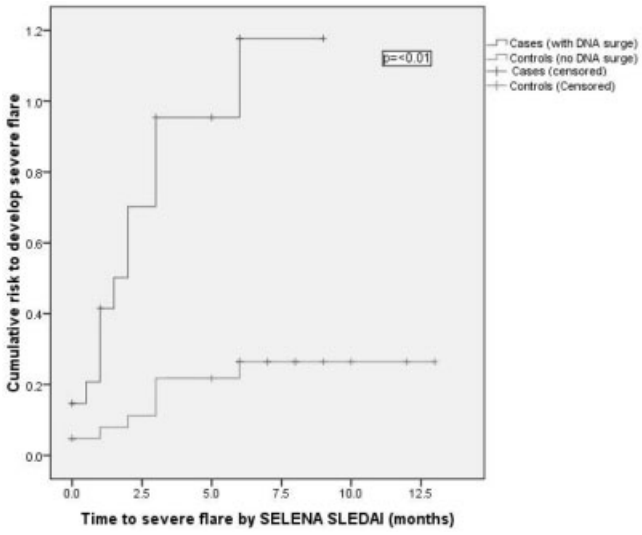
Rapid Surges of Anti-dsDNA Titers Predict Severe Clinical Flares in Systemic Lupus Erythematosus. Nancy Pan[1], Isabelle Amigues[2], Rolando Duculan[3], Faiza Aziz[4], Stephen L. Lyman[1], Mary K. Crow[1] and Kyriakos A. Kirou[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital Saint Joseph Saint Luc, Paris, France, [3]Mary Kirkland Center for Lupus Research-Hospital for Special Surgery, New York, NY, [4]Interfaith Medical Center, Brooklyn, NY

Background/Purpose: Autoantibodies to double stranded (ds) DNA (anti-DNA) are very specific for the diagnosis of systemic lupus erythematosus (SLE). Anti-DNA titers are used by 76% of US rheumatologists to monitor disease activity, though there are conflicting reports as to its utility. Studies have shown increased anti-DNA titers with no clinical activity, and conversely, increased disease activity with low or absent anti-DNA titers. We hypothesized that a rapid and dramatic increase in anti-DNA titers ("anti-DNA surge") may herald a severe SLE flare.

Methods: A matched case-control study was conducted to assess the association between a preceding anti-DNA surge and a subsequent clinical flare in patients with SLE. The study protocol was approved by the institutional review board. All patients were identified from the Hospital for Special Surgery (HSS) SLE Registry and met the American College of Rheumatology 1982 revised classification criteria for SLE. Cases had to have a surge of anti-DNA, defined as an increase of anti-DNA titer by the *Crithidia luciliae* assay from 0 to 3+/4+, or from 1+ to 4+, within a period of less than 12 months. The date of the anti-DNA surge was defined as Day 0. Two control SLE patients were identified through the HSS registry for each case and were matched for age, sex and race, and Day 0 (visit date closest to corresponding date for case), but without an anti-DNA surge.

The primary outcome was Severe Flare by SELENA SLEDAI within 6 months of an anti-DNA surge. Secondary outcomes were a Renal Flare (by BILAG Renal A or B) within 6 months, occurrence of a Mild/Moderate Clinical Flare (by SELENA SLEDAI), and mild, moderate or severe flare by the mSFI (Modified SELENA Flare Index) within 6 months. Chi square analysis and logistic regression were used to detect associations of anti-DNA surges with clinical SLE flares, age, sex, race, and complement levels.

Results: Twenty-three cases and 45 controls were identified. A higher proportion of cases, compared to controls, experienced a Severe Flare within 6 months of Day 0 (OR 6.3, p=0.02, CI 2–19). The cumulative risk of having a severe flare was significantly higher in cases (see figure). Anti-DNA surges also were associated with an increased risk for a severe or moderate flare by mSFI (OR 3.3, p=0.03, CI 1.1–9.5). An anti-DNA surge was not predictive of a Renal flare. Race, Hispanic ethnicity, and sex were not predictive of a severe SELENA flare. More dramatic anti-DNA surges (increase of titers from 0–4+) had a higher risk for a severe SELENA flare (OR 7.9, p=0.002) than less dramatic anti-DNA increases (OR 4.475, p=0.1).



Conclusion: A rapid, dramatic rise in anti-DNA titer was strongly associated with the development of a severe clinical SLE flare by SELENA SLEDAI within 6 months. We believe that clinicians should intensify follow-up for such patients and treat aggressively as soon as a clinical flare occurs.

The Resting State and Task Based Functional Magnetic Resonance Imaging Study in Non-Neuropsychiatric Systemic Lupus Erythematosus. Yongfei Fang and Qinghua Zou. Chongqing Southwest Hospital, Shapingba, China

Background/Purpose: To find evidence for occult cerebral functional damage resides prior to clinical symptoms by using resting state and task based functional magnetic resonance imaging(fMRI) in systemic lupus erythematosus (SLE) patients without neuropsychological symptoms.

Methods: 41 non-neuropsychiatric systemic lupus erythematosus (non-NPSLE) patients and 28 similar control participants were enrolled, performed paced visual serial addition test (PVSAT), and performed both resting state and PVSAT task based fMRI scanning. Data were processed and analysed by SPM8 software package, resting state data were post processed with method called regional homogeneity (ReHo). Difference of ReHo values between patients and controls were compared by independent t test. The activated brain areas of PVASAT tasks were compared in SPM8, and functional connectivity of these areas were tested in resting state data.

Results: During resting state, compared to the controls, non-NPSLE subjects displayed significantly decreased ReHo values in multiple areas including the bilateral posterior lobes of the cerebellum (predominantly in crus I and II of the neocerebellum), the vermis, left inferior frontal gyrus, left precuneus, right limbic lobe and cingulate gyrus; ReHo was increased in bilateral cuneus and in the calcarine gyrus. Both groups had no significant difference in PVSAT test. In PVSAT task based fMRI, in control subjects, the activations were situated in left superior and inferior parietal lobe, and left inferior frontal gyrus. While for non-NPSLE patients, significantly extended activations were found in left hemisphere in superior and inferior parietal lobe, superior, middle and inferior frontal gyrus. Brain areas activated in healthy controls were selected as regions of interest (ROIs) to test for the functional connectivity strength between patients and controls. Compared with controls, non-NPSLE patients exhibited a significantly higher magnitude of connectivity strength between areas activated during working memory task.

Conclusion: During resting state, non-NPSLE patients exhibited alteration of major areas of default mode network; while significantly expanded areas of activation in task based fMRI, both resutls demonstrated that cerebral damage existed prior to the presentation of any neuropsychological symptoms.

The Intrathecal Production of IL-6, IL-8, IP-10, MCP-1 and G-CSF Increases More Highly Than the Serum Production in Patients with Central Neuropsychiatric Lupus Erythematosus. Taku Yoshio[1], Hiroshi Okamoto[2], Kazuhiro Kurasawa[3], Yoshiaki Dei[4], Shunsei Hirohata[5] and Seiji Minota[6]. [1]Jichi Medical University, School of Medicine, Shimotsuke-shi, Tochigi-ken, Japan, [2]Minami-Otsuka Clinic, Tokyo, Japan, [3]Dokkyo Medical University, Mibu-machi, Tochigi-ken, Japan, [4]Saiseikai Utsunomiya Hospital, Utsunomiya-shi, Tochigi-ken, Japan, [5]Kitasato University School of Medicine, Sagamihara, Japan, [6]Jichi Medical University, Tochigi, Japan

Background/Purpose: To determine whether the intrathecal concentrations of cytokines/chemokines are associated with, or influenced by serum concentrations in patients with central neuropsychiatric SLE (NPSLE), and whether the increased production of cytokines/chemokines intrathecally relative to serum levels is associated with the presence of central NPSLE.

Methods: Fifty-two SLE patients, of whom the CSF and serum samples were obtained at the same time, were enrolled. Of the 52 SLE patients enrolled, 30 exhibited central NPSLE while the reminding 22 were non-NPSLE. The concentrations of IL-6, IL-8, TNF-α, IP-10, MCP-1, IFN-γ, IL-1β, IL-1ra, IL-2, IL-4, IL-5, IL-7, IL-9, IL-10, IL-12 (p70), IL-13, IL-15, IL-17, Eotaxin, FGF basic, G-CSF, GM-CSF, MIP-1α, MIP-1β, PDGF, RANTES and VEGF in the CSF and serum samples were measured by Bio-Plex Pro Assays. IFN-α in the CSF and serum samples were measured by ELISA.

Results: No significant positive correlation was observed between CSF concentration and serum concentration of each cytokine/chemokine in the 52 SLE patients. For each of the 30 NPSLE patients, the mean concentration of IL-6, IL-8, IP-10, MCP-1 and G-CSF was higher in the CSF than in the sera, (Table 1). Especially, the mean concentration of MCP-1 in the CSF was significantly higher than in the sera. The prevalence of higher IL-6, IP-10, and G-CSF concentrations in the CSF than in the sera were significantly greater in the 30 patients with NPSLE than in the 22 with non-NPSLE ($p = 0.00015$, $p = 0.036$ and $p = 0.0077$, Fisher's 2 tailed exact test, respectively). Furthermore, the concentrations of IL-6, IL-8, IP-10, MCP-1 and G-CSF in the CSF of the 30 patients with NPSLE were significantly higher than in the 22 patients with non-NPSLE, respectively (Table 2). Importantly, the largest differences occurred in CSF IL-6 concentrations. In each patient cohort, the mean concentration of RANTES 1 and IFN-α in the CSF was lower than those in the sera, respectively (Table 1).

Table 1. Comparison of cytokine/chemokine concentrations in the CSF and the sera of 30 patients with central NPSLE.

	Central NPSLE positive patients (n = 30)		
	CSF	Sera	P
IL-6 (pg/ml)	490.0 ± 1144.0	98.5 ± 133.5	0.668
IL-8 (pg/ml)	1993.0 ± 8665.4	62.0 ± 60.9	0.129
IP-10 (pg/ml)	9256.8 ± 15484.3	6259.3 ± 3884.9	0.211
MCP-1 (pg/ml)	2036.9 ± 7957.0	225.3 ± 511.8	0.00019
G-CSF (pg/ml)	176.8 ± 683.5	75.6 ± 53.7	0.00019
RANTES 1 (pg/ml)	15.4 ± 20.9	3978.6 ± 1729.1	2.87×10^{-11}
IFN-α (pg/ml)	13.1 ± 57.9	17.8 ± 32.7	0.0022

Table 2. Comparison of cytokine/chemokine concentrations in the CSF of 30 patients with central NPSLE and 22 patients with non-NPSLE.

	Central NPSLE		
	Positive (n = 30)	Negative (n = 22)	P
CSF IL-6 (pg/ml)	490.0 ± 1144.0	5.72 ± 5.63	6.82×10^{-5}
CSF IL-8 (pg/ml)	1993.0 ± 8665.4	31.6 ± 27.7	0.00037
CSF IP-10 (pg/ml)	9256.8 ± 15484.3	2096.4 ± 3390.3	0.0028
CSF MCP-1 (pg/ml)	2036.9 ± 7957.0	250.7 ± 163.5	0.00065
CSF G-CSF (pg/ml)	176.8 ± 683.5	5.70 ± 8.71	0.00010

Conclusion: In central NPSLE, the intrathecal concentrations of cytokines/chemokines are not influenced by the serum concentrations, indicating that the production of IL-6, IL-8, IP-10, MCP-1 and G-CSF might take place in CNS. These increased CSF cytokines/chemokines might be associated with the pathogenesis and appearance of central NPSLE. The measurement of these cytokines/chemokines, especially IL-6 might be useful for the diagnosis of central NPSLE.

1712

Systemic Lupus Erythematosus Disease Activity During a 12-Month Period and Risk of New Onset Organ System Damage and/or Death: Observations in a Single US Academic Medical Center. Deanna Hill[1], Peter Egger[2], Qinggong Fu[1], Hong Fang[3] and Michelle Petri[3]. [1]GlaxoSmithKline, Collegeville, PA, [2]GlaxoSmithKline, Stockley Park, United Kingdom, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: The association between disease activity over a short period and subsequent risk of new onset organ system damage or death has not been well-studied. Our objective was to investigate whether the pattern of SLE disease activity during a 12-month period (i.e. observation period; OP) was predictive of new onset organ system damage accrual or death in the subsequent follow-up period (FP) for patients with mild-to-moderate disease activity at cohort entry.

Methods: A prospective cohort of 1168 adult SLE patients were seen quarterly, or more often if clinically indicated, during 1987–2010. Individuals with a SLICC/ACR Damage Index (SDI) score ≥3, ESRD, history of organ transplant or malignant neoplasm at cohort entry were excluded from the analysis. The standardized protocol included measurement of disease activity using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) at every visit and organ system damage (SDI)

annually. To describe disease activity over time, adjusted mean SLEDAI (AMS) was the main exposure variable and the index date was 12 months after cohort entry. New onset damage was defined as ≥1-unit increase in SDI score between the OP and last recorded FP visit. Cox proportional hazard ratio (HR) models estimated the risk of new onset damage and death adjusted for age, gender, race, SLE duration, overall SDI score at start of the FP and ever prescribed oral prednisone dosage >7.5 mg/day during the OP.

Results: Women comprised 93% of the cohort. At cohort entry median age was 36 years, disease duration was 6 years, and SLEDAI score was 2. During the 12-month OP, 80% of patients had clinical manifestations in ≥1 organ system and median SDI score of 1. Fifty-percent of patients were prescribed oral prednisone in the OP and 60% of exposed patients were prescribed >7.5 mg/day. During the FP, 92 cohort patients died (8%). After restricting the analysis to patients without recorded damage at the start of the FP in the organ system of interest, 40% of patients had new onset damage in any organ system, 7% cardiovascular and 3% renal system damage (SDI≥1). In adjusted models, AMS and plaquenil use in the OP were significant predictors of death (HR=1.23, 95% CI: 1.14, 1.33; HR=0.46, 95% CI: 0.30, 0.73, respectively) and new onset renal damage (HR=1.24, 95% CI: 1.08, 1.42; HR=0.30, 95% CI: 0.13, 0.68, respectively). AMS and NSAID use in the OP were associated with increased risk of new onset cardiovascular damage (HR=1.18, 95% CI: 1.08, 1.30; HR=1.66, 95% CI: 1.04, 2.63, respectively) in the adjusted model. AMS in the OP was not a significant predictor of new onset overall damage (HR=1.05, 95% CI: 1.00, 1.11), after adjustment for other covariates.

Conclusion: A one-unit increase in AMS during a 12 month-period was significantly associated with a 23% increased risk of death and 18 to 24% increased risk of new onset cardiovascular and renal damage accrual in the FP, respectively, after adjustment for other covariates. Plaquenil use in OP was associated with a 54 to 70% reduction in risk of death and renal damage in the FP, respectively, while NSAID use in OP increased the risk of cardiovascular damage by 66% in patients with mild-to-moderate SLE at cohort entry. A Clinicopathologic Study of Retroperitoneal Fibrosis and Its Association with Immunoglobulin G4-Related Disease. Arezou Khosroshahi, Robert P. Hasserjian, Nisha I. Sainani, Vikram Deshpande and John H. Stone. Massachusetts General Hospital, Boston, MA

Background/Purpose: Retroperitoneal fibrosis (RPF) can be divided into idiopathic and secondary cases. Small studies have suggested that idiopathic RPF can be classified into cases that are associated with histopathologic features of IgG4-related disease (IgG4-RD) and those that are not. We analyzed 23 previously unclassified cases of RPF to evaluate clinicopathological differences between those associated with pathological features of IgG4-RD and those not associated with such features.

Methods: We searched our pathology service database to identify all patients with RPF diagnosed since 1990. Pathology blocks were available for immunohistochemical analysis on 23 patients. We subclassified RPF cases following chart review into either the idiopathic or secondary categories on the basis of clinical features, and performed immunohistochemical analysis for IgG4 and IgG. RPF cases were classified as IgG4-related if they had IgG4/IgG-positive plasma cell ratios >30%. Histologic features, age, sex, clinical symptoms, location of the fibrosis, and presence or absence of fibrosing lesions at other locations were compared between patients with IgG4-related and non-IgG4-related RPF. The statistical analysis was performed using Fisher's exact test. A probability of $P<0.05$ was considered statistically significant.

Results: Nineteen cases were categorized as idiopathic, and four as secondary. Twelve of 19 (63%) idiopathic cases were classified as IgG4-related and 7 (36%) as non-IgG4-related. The clinicopathologic features of these cases are summarized in Table 1. Compared with non-IgG4-related RPF, IgG4-related RPF was more likely to show periaortic involvement and more frequently showed storiform-type fibrosis and eosinophil infiltration. In the IgG4-related cases, the overall mean number of IgG4-positive plasma cells per high-power field (hpf) was 13, a figure much lower than that generally observed in other organs involved with IgG4-RD. The mean IgG4/IgG ratio, however, was 78%.

Table 1. Clinicopathologic features of IgG4-related with non-IgG4-related idiopathic RPF

	IgG4-related (n=12)	Non-IgG4-related (n=7)	Statistical comparison
Gender (M:F)	10:2	4:3	NS
Age, median (range)	58 y (38–71)	64 y (37–72)	NS
Periaortic involvement	10/12 (83%)	2/7 (28%)	p=0.02
Hydronephrosis	5/12 (41%)	5/7 (71%)	NS
Aortitis	2/12 (17%)	1/7 (14%)	NS
Storiform-type fibrosis	10/12 (83%)	2/7 (28%)	p=0.02
Eosinophils >5/hpf	10/12 (83%)	0/7 (0%)	p<0.001

Conclusion: IgG4-RD accounts for a sizeable subset of patients with RPF. Both histological features and IgG4 immunostaining are critical to the diagnosis of IgG4-RD. Findings of plasma cell infiltration, tissue eosinophilia, and storiform fibrosis should lead pathologists to perform IgG4 immunostains. The IgG4/IgG ratio may be more important in diagnosis than the absolute number of IgG4-positive plasma cells/HPF, particularly when extensive fibrosis is the paramount finding.

Developing a Disease Activity and Therapeutic Response Index in Connective Tissue Disease Related Interstitial Lung Disease: Initial Results of a Delphi Exercise. Lesley Ann Saketkoo[1], Doerte Huscher[2], Dinesh Khanna[3], Paul F. Dellaripa[4], Kevin Flaherty[3], Eric L. Matteson[5], Chester V. Oddis[6], Kristine Phillips[7], Athol U. Wells[8], Christopher P. Denton[9], Oliver Distler[10], Otylia M. Kowal-Bielecka[11], David Pittrow[12], Romy Christmann[13], Nora Sandorfi[14], Vibeke Strand[15], Kevin K. Brown[16] and James R. Seibold[17]. [1]LSU Health Science Center, New Orleans, LA, [2]Charité Universitaetsmedizin, Dept of Rheumatology and Clinical Immunology and The German Rheumatism Research Centre, Berlin, Germany, [3]University of Michigan, Ann Arbor, MI, [4]Brigham & Womens Hospital, Boston, MA, [5]Mayo Clinic, Rochester, MN, [6]University of Pittsburgh, Pittsburgh, PA, [7]University of Michigan Medical School, Ann Arbor, MI, [8]Royal Brompton Hospital, United Kingdom, [9]UCL Medical School, London, United Kingdom, [10]University Hospital Zurich, Zurich, Switzerland, [11]Medical Univ in Bialystok, Bialystok, Poland, [12]Institute of Clinical Pharmacology - University of Dresden, Dresden, Germany, [13]Boston University, Boston, MA, [14]Thomas Jefferson Univ Med Coll, Philadelphia, PA, [15]Stanford University, Palo Alto, CA, [16]National Jewish Hospital, Denver, CO, [17]Scleroderma Research Consultants LLC, Avon, CT

Background/Purpose: The lack of accepted and validated measures of disease activity and clinical response in patients with connective tissue disease (CTD)-related interstitial lung disease (ILD) makes clinical trial design difficult. We report a multi-tiered investigation to develop consensus on provisional criteria for disease activity and therapeutic responses in both CTD-ILD and Idiopathic Pulmonary Fibrosis (IPF). Within the OMERACT framework, 270 experts identified 23 "domains" and 616 "instruments" preparatory for a 3-tiered Delphi exercise. We report the results of Tier 1 expert voting.

Methods: Using a custom-designed secure web-site, participants in Tier 1 rated 23 domains and 616 instruments for IPF and CTD-ILD (1278 combined ratings) anchored in degree of usefulness of instruments on a 9-point Likert scale with "insufficiently familiar" as an additional voting option. A cut-off median <4 was applied to the results. Final review demanded 100% consensus agreement for item dismissal based on: 1. Lack of face validity, 2. Content validity more suited to diagnostic, demographic, or inclusion criteria and 3. Lack of feasibility.

Results: 90% of invited experts participated including 137 pulmonary, 102 rheumatology and 4 cardiology specialists from 32 countries/6 continents. 74% and 69% of participants considered 'ILD' and 'rheumatologic lung disease' respectively as a primary field of research or clinical interest. After statistical analysis, 20 domains and 96 instruments "survived" for inclusion in Tier 2.

Table 1. Results of Tier 1 Analysis

COUGH	**PHYSICIAN GLOBAL ASSESSMENT - DISEASE ACTIVITY**
Cough Severity by Visual Analogue Scale is the only surviving item	Only Visual Analogue Scale survives
DYSPNEA	**EXTRA-PULMONARY CTD FEATURES**
9 Instruments survive that measure dyspnea	5 Instruments survive
HEALTH RELATED QUALITY of LIFE (HRQoL)	**GASTRO ESOPHAGEAL REFLUX (GERD)**
3 Generic HRQoL instruments survive 2 Respiratory disease specific instruments survive	2 Instruments survive that measure GERD
	MEDICATIONS
FATIGUE	2 Items that measure medication use survive
6 Instruments survive that measure fatigue	
	BIOMARKERS
SLEEP	6 Serologic markers survive
4 Instruments survive that measure sleep quality	
	LUNG IMAGING
MENTAL HEALTH	6 Instruments related to HRCT survive
5 Items survive that measure anxiety & depression	
	LUNG PHYSIOLOGY / FUNCTION
PATIENT GLOBAL ASSESSMENT OF DISEASE ACTIVITY	7 Instruments related to 6MWT survive
Only Visual Analogue Scale survives	5 Items survive related to quantifying oxygenation
	4 Instruments survive related to spirometry
PHYSICAL FUNCTION	**COMPOSITE SCORES**
5 Items survive measuring physical function & ability	Only Composite Physiologic Index (CPI) survives
PARTICIPATION and PRODUCTIVITY	
No single item survived to measure participation; However; 'multi-dimensional' functioning is captured in generic HRQoL instruments	**LUNG VASCULAR** 2 instruments remain; both use RHC
	CARDIAC FUNCITON
2 Instruments survive that measure productivity (remunerative work, imminent job loss due to illness & work in the home)	2 Instruments survive measuring cardiac function
	SURVIVAL
	11 Items remain for survival or its surrogates

Conclusion: Development of clinically meaningful outcome measures that assess disease progression and therapeutic response is essential for performing clinical trials in CTD-ILD. This is the first comprehensive, multi-disciplinary and international effort to assess domains and instruments in the study of ILD. Experts identified a group of core set measures focused on radiographic, physiologic and patient-reported outcomes, culled from a large number of candidate instruments. A research agenda focused on candidate biomarkers will be developed. The high degree of participation in this Delphi process from a multidisciplinary ILD research community reflects the perceived need in this area.

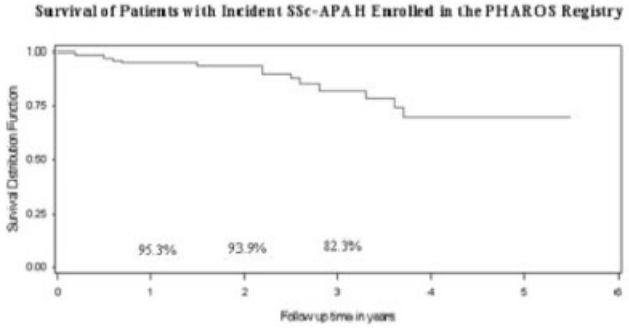
Better Survival in Systemic Sclerosis-Associated Pulmonary Arterial Hypertension Patients Enrolled in the Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma Registry. Lorinda Chung[1], Robyn T. Domsic[2], Bharathi Lingala[3], Virginia D. Steen[4] and PHAROS Investigators[5]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Stanford, [4]Georgetown Univ Medical Center, Washington, DC, [5]Washington, DC

Background/Purpose: Patients with systemic sclerosis-associated pulmonary arterial hypertension (SSc-APAH) experience poorer outcomes than patients with idiopathic PAH and other forms of connective tissue disease-APAH. We sought to assess cumulative survival rates and identify independent predictors of 1-year mortality in patients with incident SSc-APAH from the PHAROS registry.

Methods: Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) is a multi-center prospective registry of SSc patients at high risk for PAH or with definite PH diagnosed by right heart catheterization (RHC) within 6 months of enrollment. Only patients with World Health Organization Group I PAH (mean pulmonary artery pressure (mPAP)≥25 mmHg and pulmonary capillary wedge pressure≤15 mmHg without significant interstitial lung disease) were included in these analyses. Kaplan-Meier curves were estimated for survival from the time of the diagnostic RHC. Differences in outcomes between subgroups were assessed by the log-rank test. Univariate and multivariate Cox regression models were used to identify significant predictors of 1-year mortality. Backward selection was used to determine the final model retaining only variables with $p<0.05$.

Results: 125 patients with incident PAH had a mean age of 60.4±10.5 years and disease duration from first non-Raynaud symptom of 10.2±9.4 years. 85% were female, 82% Caucasian, 70% had limited cutaneous disease, and 34% were anti-centromere antibody positive. Mean 6 minute walk distance (6MWD) was 337±131 m, diffusing capacity of carbon monoxide 42±16% predicted, mPAP 36.7±10.3, pulmonary vascular resistance (PVR) 5.5±3.1 WU, and creatinine 1.0±0.6. 34% had a pericardial effusion; 57% were functional class (FC) I or II; and 5.6% were FC IV. Only 14 (11%) patients died over a mean follow-up of 1.8±1.3 years. 1-, 2-, and 3-year survival was 95.3%, 93.9%, and 82.4% in the overall cohort. The following variables were significant predictors of 1-year mortality in univariate analyses: FC IV (HR 5.8, 95% CI 1.3–27.2), 6MWD<165 m (HR 3.4, 95%CI 1.0–11.5), and PVR>4.6 WU (HR 5.8, 95% CI 1.3–25.6). Age>60, presence of a pericardial effusion, DLCO<32% predicted, mPAP>35 mmHg, and creatinine did not predict death. On multivariate analysis (N=77), FC IV (HR 7.9, 95% CI 1.5–41.3, p=0.01) remained the only significant predictor of mortality.



Conclusion: The 82.4% 3-year survival of SSc patients with incident PAH followed at scleroderma centers involved in the PHAROS registry was higher than other recently described cohorts. Not unexpectedly, those who are FC IV at the time of diagnosis have a high risk for death at 1 year.

1716

Clinical and Hemodynamic Features of Scleroderma Patients with Pulmonary Venous Hypertension Versus Pulmonary Arterial Hypertension. Jessica K. Gordon[1], Kamini Doobay[2], Evelyn Horn[3], Marcy B. Bolster[4], Lee S. Shapiro[5], Dinesh Khanna[6], Tracy M. Frech[7], Kara Fields[2], Chris T. Derk[8], Laura K. Hummers[9], Maureen D. Mayes[10], Virginia D. Steen[11] and PHAROS Investigators[12]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Weill-Cornell Medical College, New York, NY, [4]Medical Univ of South Carolina, Charleston, SC, [5]Albany, NY, [6]University of Michigan, Ann Arbor, MI, [7]University of Utah School of Medicine, SLC, UT, [8]Jefferson Medical College, Philadelphia, PA, [9]Johns Hopkins University, Baltimore, MD, [10]University of Texas Health Science Center at Houston, Houston, TX, [11]Georgetown Univ Medical Center, Washington, DC, [12]Washington

Background/Purpose: Pulmonary hypertension (PH) is a leading cause of death in patients (pts) with Systemic Sclerosis (SSc). The World Health Organization (WHO) classifies PH into groups: PAH (WHO group 1), most common in SSc, is characterized by a mean pulmonary artery pressure (mPAP)≥25 mmHg and a pulmonary capillary wedge pressure (PCWP) <15 mmHg. WHO Group 2 is PH secondary to left heart dysfunction or pulmonary venous hypertension (PVH.) WHO Group 3 is PH secondary to pulmonary disease. Here we describe the differences between SSc pts with PAH versus PVH as well as the overlap between the groups.

Methods: Pts in the PHAROS database with PH were categorized by WHO criteria. A PCWP<15 mmHg on initial right heart catheterization (RHC) differentiated Group 1 and 2 pts. Pts with ILD as defined by a forced vital capacity (FVC) <65% predicted and/or significant fibrosis on chest CT with a normal PCWP were included in group 3, and are not included in this analysis. Univariate analysis with Mann-Whitney and Fischer-Exact tests was performed.

Results: There are 197 pts with PH in the PHAROS database: PAH-127, PVH–32, and PH-ILD–38. Pts with PVH were more likely to be African-

American, younger, male, and have diffuse cutaneous (dc)SSc. 20% of PVH pts were anti-Scl70 positive vs 6.7% of PAH pts, (p=0.036). There was no difference with respect to disease duration based on time since first non-Raynaud's symptom. Although the systolic PAP was lower in PVH patients on echo, the mPAP on RHC was not significantly different. The pulmonary vascular resistance (PVR) was significantly lower in the PVH pts. The BNP and NT-BNP were increased in both groups but not significantly different. On PFTs, there was more restrictive disease with a lower FVC in PVH patients, but there was no difference in the DLCO, with both groups very low. The FVC to DLCO ratio was significantly higher in the PAH group.

Some PAH pts had evidence of PVH on either exercise RHC or on repeat RHC. An increased PCWP on repeat RHC was seen in 8.7% of PAH pts, and in 8 of 22 PAH pts undergoing exercise RHC (36.4%) the PCWP was ≥18. Unlike most other pts with PVH, the left atrial diameter (LAD) was not always increased, and in 39.3% of PAH pts, the LAD was > 4.0 cm on echo. There was no correlation between the LAD and PCWP or PCWP and BNP.

	PAH (n= 127)	PVH (n=32)	P-Value
Age (median, range)	61.00 (34, 84)	55.50 (35, 78)	0.015
Disease Duration (median, range)	7.32 (0.02, 43.2)	6.9 (0.2, 19.2)	0.47
Gender (% female)	84%	70%	0.045
Ethnicity (%)	83% Caucasian	60% Caucasian	0.019
Ethnicity (%)	9% Black	27% Black	
Ethnicity (%)	8% Other	13% Other	
SSc Subtype (%)	72% Limited	41% Limited	0.003
SSc Subtype (%)	24% Diffuse	50% Diffuse	
ECHO DATA			
Systolic PAP - mmHg	60 (31, 46)	49 (17, 38)	0.005
Ejection Fraction-%	60 (45, 82)	60 (25, 77)	0.49
Left Atrial Diameter–cm	3.7 (2.4, 6.3)	4.1 (2.1, 5.2)	0.50
PFT DATA			
Forced Vital Capacity-% pred, median (range)	81.7 (43, 123)	65.4 (27, 99)	<0.001
Diffusion Capacity-% pred, median (range)	38.9 (14, 98)	36.5 (13, 97)	0.40
FVC/DLCO Ratio	2.02 (0.95, 6.08)	1.69 (0.46, 2.96)	0.03
RHC DATA			
Pulmonary Artery Systolic Pressure–mmHg	55 (30, 119)	46 (36, 87)	0.004
Mean PAP–mmHg	35 (25, 75)	32.5 (26, 60)	0.11
PCWP–mmHg	10 (2, 17)	21 (16, 35)	<0.0001
PVR–dyn·s·cm^{-5}	368 (106, 999)	189.3 (56, 828)	<0.0001

Conclusion: In SSc, an increased PAP is not always PAH. PVH pts differ from PAH pts in several ways. They are more likely to be African American, younger, male, have dcSSc, and be anti-Scl70 positive. The RHC is critical in making this diagnosis since the echo can not determine the PCWP. The PVR is useful in distinguishing the groups. An exercise or fluid challenge may be helpful in determining a propensity for an increased PCWP under a stressor. Furthermore, in SSc there is evidence for some degree of PVH in a significant percentage of pts with PAH. How these categorizations affect the prognosis of PH pts will be further studied in the long-term follow-up of the PHAROS cohort.

1717

Validation of Potential Classification Criteria for Systemic Sclerosis. Sindhu R. Johnson[1], Jaap Fransen[2], Dinesh Khanna[3], Thomas A. Medsger[4], Christine A. Peschken[5], Patricia Carreira[6], Gabriela Riemekasten[7], Alan G. Tyndall[8], Marco Matucci-Cerinic[9], Murray Baron[10], Frank Van den Hoogen[11] and Janet E. Pope[12]. [1]Toronto Western and Mt. Sinai Hospitals, University of Toronto, Toronto, ON, [2]The Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]University of Michigan, Ann Arbor, MI, [4]Univ of Pittsburgh, Pittsburgh, PA, [5]University of Manitoba, Winnipeg, MB, [6]Hospital Universitario 12 de Octubre, Madrid, Spain, [7]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany, [8]University of Basel, Basel, Switzerland, [9]University of Florence, Firenze, Italy, [10]Jewish General Hospital, Montreal, QC, [11]Nijmegen, Netherlands, [12]St. Joseph's Health Care, University of Western Ontario, London, ON

Background/Purpose: Classification criteria for systemic sclerosis (SSc) are being updated jointly by EULAR and ACR. Potential items for classification were reduced to 23 using Delphi and Nominal Group Techniques. We evaluated the face, discriminant and construct validity of the items to be further studied as potential criteria.

Methods: Face validity was evaluated using the frequency of items in patients sampled from the Canadian Scleroderma Research Group, 1000 Faces of Lupus, the Pittsburgh, Toronto, Madrid and Berlin CTD databases. SSc (n=783) were compared to 1071 patients with diseases similar to SSc (mimickers): SLE (n=499), myositis (n=171), Sjögren syndrome (n=95), Raynaud's syndrome (n=228), MCTD (n=29), and idiopathic PAH (n=49). Discriminant validity was evaluated using odds ratios (OR). For construct validity, empiric ranking was compared to expert ranking.

Results: Compared to mimickers, SSc are more likely to have skin thickening (OR 427), telangiectasias (OR 91), anti-RNA polymerase III antibody (OR 75), puffy fingers (OR 35), finger flexion contractures (OR 29), tendon/bursal friction rubs (OR 27), anti-topoisomerase-I antibody (OR 25), Raynaud's phenomenon (OR 24), finger tip ulcers/pitting scars (OR 19), anti-centromere antibody(OR 14), abnormal nailfold capillaries (OR 10), GERD symptoms (OR 8), and ANA, calcinosis, dysphagia, esophageal dilation (all OR=6), interstitial lung disease/pulmonary fibrosis (OR 5), PM-Scl antibody (OR 2), reduced DLCO (OR 1.5), PAH (OR 1.2), and reduced FVC (OR 0.9). Renal crisis and digital pulp loss/acro-osteolysis did not occur in SSc mimickers (OR not estimated). Empiric and expert ranking were correlated (Spearman rho 0.53, p=0.01).

Conclusion: The candidate items have good face, discriminant and construct validity. Further item reduction will be evaluated in prospective SSc and mimicker cases.

Ultrasonographic Hand Features in Systemic Sclerosis and Correlates with Clinical, Biological and Radiographic Findings. Muriel Elhai[1], Henri Guerini[2], Ramin Bazeli[2], Jerome Avouac[1], Veronique Freire[2], Jean-Luc Drape[3], Andre Kahan[1] and Yannick Allanore[1]. [1]Rheumatology A, Paris Descartes University, Cochin Hospital, APHP, Paris, France, Paris, France, [2]Radiology B, Paris Descartes University, Cochin Hospital, APHP, Paris, France, Paris, France, [3]Paris Descartes University, Radiology B Department, Cochin Hospital, Paris, France

Background/Purpose: Articular involvement is a common feature of systemic sclerosis (SSc) with major impact on quality of life. However assessment is frequently difficult, as clinical assessment is limited by concomitant skin involvement and X-ray cannot capture tendon damages. Therefore, the prevalence and characteristics of joint involvement are imperfectly known. Ultrasonography (US) has demonstrated its major input in other rheumatic conditions but only scarce data are available in SSc. Therefore, we set out to investigate ultrasonographic hand and wrists features in consecutive SSc patients and their relationships with clinical examination, biological and radiographic data.

Methods: 52 consecutive SSc were included in a cross-sectional observational study and in addition 24 patients with rheumatoid arthritis were enrolled as controls. All the patients underwent clinical examination. Global disability was assessed using the Health Assessment Questionnaire and the Duruoz Hand Index. US was performed on joints of both hands, both wrists and fingers. The following predefined features were searched for: synovitis, tenosynovitis, acro-osteolysis, calcinosis, power Doppler in the nail bed and in the pulp. Radiographies of the hands and wrists were also performed. Data were statistically analyzed using chi-square tests and the Student's t-test. A multivariate stepwise logistic regression analysis was also performed for all variables identified with $p \leq 0.10$. $P < 0.05$ was considered statistically significant.

Results: The characteristics of SSc-patients were: mean age: 56.3 (± 14.1) years, 75% were women, mean disease duration: 8.6 (± 8.6) years, 40% fulfilled diffuse cutaneous subtype. Prevalences of US abnormalities in SSc-patients were as follow: synovitis in 46%, tenosynovitis in 27%, calcifications in 40%, acroosteolysis in 19% and impairment in the distal microvascularisation in 44%. Synovitis were in 57% of cases mildly inflammatory (Doppler grade 1), whereas tenosynovitis showed a mixed pattern associating both inflammatory and fibrotic changes. As compared to RA patients, US hand features specific to SSc were "sclerosing" tenosynovitis (p<0.01), soft-tissue calcifications (p=0.01) and impairment in the distal microvascularisation (p<0.01). US detected 31% and 21% more patients with synovitis and tenosynovitis, respectively, than clinical examination. In multivariate analysis, a CRP level superior to 10mg/L was associated with inflammatory activity at power Doppler assessment (p=0.03). Disability did not correlate with synovitis or tenosynovitis. However, patients with at least 4 synovitis and/or tenosynovitis had a higher Duruoz Hand index than patients with less than 4 US abnormalities (p=0.006).

Conclusion: Our study confirms that articular involvement in SSc is frequent. It is associated with disability in cases of polyarticular disease and under-estimated by clinical examination. It is characterized by mild inflammatory damages associated with biological inflammatory syndrome and with US sclerosing findings for tenosynovitis. Further prospective studies are warranted to evaluate the predictive value of these findings.

1719

Effectiveness of Facet Joint Infiltration in Low Back Pain. Luiza H. C. Ribeiro, Rita V. Furtado, Monique Konai, Andre Rosenfeld, Ana B. Andreo and Jamil Natour. Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Background/Purpose: Lumbar facet joints are a well recognized source of low back pain. Studies have shown the prevalence of lumbar facet joint pain in 30% to 40% of the patients with chronic low back pain. Facet joint interventions, including intra-articular injections, medial branch nerve blocks, and neurotomy by radiofrequency are used to manage chronic facet-mediated spinal pain. Several studies have been evaluated the effectiveness of these interventions. Results of facet joint infiltration, however, are conflicting.The aim of this study is to evaluate the effectiveness of facet joint infiltration with corticosteroids in patients with facet joint syndrome.

Methods: Sixty subjects with diagnostic of facet joint syndrome were enrolled in the study. They were randomized into experimental and control groups. The experimental group was submitted to intra-articular infiltration of six facet joints (L3/L4;L4/L5;L5/S1 bilaterally) with triamcinolone hexacetonide. The control group was submitted to triamcinolone acetonide intramuscular injection of six lumbar paravertebral points. After the randomization, all subjects were assessed by an investigator blinded to the groups. The assessment were taken just before the interventions (T0) and them 7, 30, 90 and 180 days after the interventions. The following assessment instruments were used: pain visual analogical scale (VAS) (0–10cm), pain visual analogical scale during extension of the spine (VAS E) (0–10cm), Likert scale for improving (0–5), percentage scale of subjective improving perception(0–100%), Rolland-Morris questionnaire (0–24), short health survey questionnaire (SF36), accountability of medications taken for back pain: analgesics and non-steroidal antiinflamatories (NSAIDs). Statistical analysis: the homogeneity of the sample was tested using Student's T, Pearson's Chi- Square and Mann-Whitney tests. ANOVA with repeated measures was performed to evaluate inter- and intra-group differences. A 5% significance level was used for all variables and tests.

Results: There were no significant differences in the baseline characteristics between the two groups. The experimental group showed a significant improvement in the physical aspects domain, assessed by SF-36. At visit 7 the experimental group showed a better response of improving (much better) assessed by the Likert scale. However in the following visits both groups had similar results. The consumption of NSAIDs were significantly lower in the experimental group at the last visit (T180).

Conclusion: Facet joint infiltration had a weak effectiveness. The improvement was observed in few aspects of quality of life and self-assessment of improving. However it provided a reduction in NSAIDs intake.

1720

Health Outcomes From a Residential Multidisciplinary Rehabilitation Program for Musculoskeletal Conditions: A Ten Year Observational Study. Peter B. B. Jones[1] and Peter Sharplin[2]. [1]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand, [2]QE Health, Rotorua, New Zealand

Background/Purpose: In an era of increasingly technological approaches to arthritis care, intensive rehabilation has a lower priority for provision. There is a relative lack of outcomes data for such treatment. QE Health has an established intensive rehabilitation program for people disabled by chronic musculoskeletal conditions including inflammatory arthritis, degenerative conditions, and pain syndromes. The aim was to evaluate change in health outcome in these groups over a ten year period.

Methods: Patients accessed the program on referral from a specialist or general practitioner and were diagnosed with a musculoskeletal condition. Medical therapy was optimised prior to entry into the program. Govenrment funding was provided by third party purchasers. Demographic and disease data were gathered at admission, together with the following outcome measures at admission and on discharge: McGill Pain Questionnaire (MPQ); Wellness 10cm Visual Analog Scale (WVAS); EQ-5D; Stanford Health Assessment Disability Questionnaire (HAQ); 6-minute walk test (6MW). In addition a validated measure of holistic health status, the QE Health Scale (QEHS) was applied. The intervention was a 3 week residential program comprising medical, physiotherapy, occupational therapy, nursing and counselling interventions. Assistive devices, splints or orthoses were dispensed as required. Data was analysed for patients admitted between January 2001 and December 2010. Multivariate analysis was used using linear models to test for confounding effects from the following variables: age, gender, occupation, diagnosis, race, baseline values.

Results: There were 3214 admissions in the period comprising 2624 patients; recidivism was 16%. Mean age 59, mode 74; 26% employed, 38% retired. Chronic spinal pain (25%), osteoarthritis (21%), rheumatoid arthritis (15%) and fibromyalgia (13%) dominated the diagnostic categories. 83% were of NZ European ethnicity and 13% were Maori (indigenous); 72% were female. Complete data were available for 89.7% of care episodes. Overall, 82.9% of patients recorded improvements that exceeded the minimal clinically important difference in two or more measures. For each measure, significant and clinically meaningful improvements were observed (baseline, change, $p<0.0001$ for all): MPQ (22.6, −6.4); WVAS (4.9, 2.2); EQ5D (47.7, 25.4); HAQ (1.41,-0.32); 6MW (364.9, 62.2); QEHS (96.1, 19.5). Those with poorer baseline health status and Maori patients showed greater improvements. Age and gender showed significant but inconsistent effects.

Conclusion: In a large patient database, consistent, clinically meaningful and significant improvements in health status were observed during an intensive residential multidisciplinary rehabilitation program regardless of gender, race or diagnosis. Those with the lowest baseline scores showed the greatest improvements. Intensive multidisciplinary rehabilitation offers meaningful health change for people living with chronic disabling musculoskeletal conditions.

Risk Factors for Restricting Back Pain in Community-Living Older Persons. Una E. Makris[1], Liana Fraenkel[2], Ling Han[3], Linda Leo-Summers[3] and Thomas M. Gill[4]. [1]Yale, New Haven, CT, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [3]Yale University School of Medicine, New Haven, CT, [4]Yale University School of Medicine, New Haven

Background/Purpose: Back pain is a common and costly condition among older persons. We recently demonstrated that back pain, severe enough to restrict activity (hereafter referred to as restricting back pain), is often recurrent. Few longitudinal studies have evaluated the risk factors for restricting back pain. Our objective was to identify risk factors for restricting back pain in community-living older persons.

Methods: We evaluated the 733 participants (mean age 78.4 years, 65% women) of the Precipitating Events Project, a longitudinal study of community-living persons, aged 70+ years, who completed monthly telephone assessments of restricting back pain, defined as staying in bed for at least half a day and/or cutting down on one's usual activities due to back pain, for over 10 years. Candidate risk factors were measured from five domains (demographic, cognitive-psychosocial, health related, habitual, physical capacity) during comprehensive home-based assessments that were completed every 18 months for up to 108 months. Restricting back pain was assessed monthly for up to 126 months. In participants who did not report restricting back pain at the start of an 18-month interval, incident episodes of two distinct restricting back pain outcomes were determined during the subsequent 18-months: (1) short-term (one episode lasting one month) and (2) persistent (one episode lasting two or more months) or recurrent (two or more episodes of any duration). The cumulative incidence proportions of these two restricting back pain outcomes were estimated during the total follow-up period using a Generalized Estimation Equation binomial model. A multivariate Cox model was used to evaluate the adjusted associations between each candidate risk factor (eligible to enter the final model) and the two outcomes of interest.

Results: The cumulative incidence was 17.8% (95% CI: 16.5, 19.3) for the short-term outcome and 17.9% (16.1, 19.9) for the persistent or recurrent outcome. Table 1 shows the multivariate results; factors from each domain were independently associated with a higher risk of developing persistent or recurrent restricting back pain. Female sex (26% increased risk) and poor grip strength (33%) were the only factors associated with an increased likelihood of short-term restricting back pain. In contrast, female sex (47%), depressive symptoms (82%), BMI ≥25 (33%), arthritis (63%), greater than two chronic conditions (29%), and poor grip strength (33%) conferred a higher risk of persistent or recurrent restricting back pain.

Table 1. Factors Associated in Multivariable Analysis with Short-Term and Persistent/Recurrent Restricting Back Pain in 733 Community-Living Older Persons

Factor	Hazard Ratio (95% Confidence Interval) Short-Term	P-value	Persistent or Recurrent	P-value
Demographic				
Aged ≥ 85	1.04 (0.84–1.29)	0.69	0.81 (0.63–1.04)	0.09
Female	1.26 (1.03–1.54)	0.02	1.47 (1.11–1.95)	0.008
Not currently married	0.99 (0.82–1.19)	0.90	1.10 (0.85–1.42)	0.47
Cognitive-Psychosocial				
High depressive symptoms	1.21 (0.98–1.50)	0.07	1.82 (1.42–2.32)	<0.001
Low social support	0.95 (0.76–1.18)	0.63	0.92 (0.71–1.21)	0.57
Health Related				
No. chronic conditions (≥2)	1.16 (0.96–1.39)	0.13	1.29 (1.00–1.67)	0.05
Arthritis	1.08 (0.90–1.29)	0.43	1.63 (1.29–2.05)	<0.001
Weight loss ≥ 10 pounds in past year	1.08 (0.88–1.33)	0.46	1.02 (0.80–1.31)	0.87
Habitual				
Overweight (Body Mass Index: ˜25)	1.06 (0.88–1.28)	0.55	1.33 (1.05–1.70)	0.02
Physical Capacity				
Short Physical Performance Battery (per each point)	1.03 (0.82–1.29)	0.81	1.15 (0.87–1.52)	0.33
Poor grip strength	1.33 (1.09–1.62)	0.006	1.33 (1.02–1.75)	0.038
Hip weakness	1.19 (0.96–1.48)	0.11	1.20 (0.92–1.55)	0.175

Conclusion: In this longitudinal study, several factors were independently associated with clinically significant restricting back pain, including three (depressive symptoms, BMI ≥25, poor grip strength) that may be amenable to interventions designed to prevent the occurrence, persistence or recurrence of this common disorder in older persons.

1722

The Effectiveness of Exercise with and without Manual Therapy for Hip Osteoarthritis: A Multi-Centre Randomised Controlled Trial. Helen P. French[1], Tara Cusack[2], Aisling Brennan[3], Aoife Caffrey[4], Vanessa Cuddy[5], Martina Fitzpatrick[4], Oliver M. FitzGerald[6], Clare Gilsenan[5], David Kane[3], Paul G. O'Connell[5], Breon White[7] and G M. McCarthy[7]. [1]Royal College of Surgeons in Ireland, Dublin 2, Ireland, [2]University College Dublin, Dublin, Ireland, [3]Adelaide, Meath hospital Dublin (incorporating the National Children's hospital), Dublin 24, Ireland, [4]St. Vincent's University Hospital, Dublin 4, Ireland, [5]Beaumont Hospital, Dublin 9, Ireland, [6]St. Vincent's University Hospital, Dublin, Ireland, [7]Mater Misericordiae University Hospital, Dublin 7, Ireland

Background/Purpose: Although exercise therapy (ET) is recommended in the management of hip OA, research to date shows small effects for reduction in pain and improvement of physical function. Manual therapy (MT), which comprises joint mobilisations and other hands-on techniques is commonly used by physiotherapists as an adjunct to ET for hip OA but lacks evidence of efficacy. This RCT was undertaken to primarily determine the clinical effectiveness of physiotherapy-based ET with and without MT for hip OA. A secondary aim was to ascertain the impact of an 8-week waiting period for physiotherapy on clinical outcomes.

Methods: 131 people with hip OA recruited from four hospitals were initially randomised to one of three groups: ET (n=45), ET+MT (n=43) and wait-list control (n=43). Both intervention groups received treatment for 8 weeks, control group participants remained on the waiting list (8 weeks) and were subsequently randomised into the ET or ET+MT group. Their data were pooled with original treatment group data: ET (n=66) and ET+MT (n=65). All participants were assessed post-treatment (9 weeks) and at 18 weeks. The primary outcome was the WOMAC physical function (PF) subscale and secondary outcomes included physical performance tests, pain severity, hip range of motion (HROM), anxiety/depression, quality of life, pain medication usage, patient-perceived change and patient satisfaction. Ethical approval was obtained at all sites. Intention-to-treat analyses were used to determine between–group differences for the three groups at baseline and 9 weeks (prior to re-randomisation), and the two treatment groups (including re-randomised control group) at baseline, 9 and 18 weeks.

Results: There was no significant difference in WOMAC PF between ET and ET+MT groups at 9 weeks (mean diff −0.91; 95%CI −6.28, 4.44) or 18 weeks (mean diff −1.41; 95%CI −7.12, 4.29). 'Patient satisfaction with outcome' was greater for ET+MT group (p=0.02). There was no significant difference between groups in other outcomes. Results for the three groups (secondary aim) showed significant improvement in WOMAC PF in the ET (mean change from baseline 4.60 (SD=8.76)) and ET+MT (mean change from baseline 4.68 (SD= 15.31)) groups compared to the control group (mean change from baseline −3.82 (SD=8.97)). Similar trends were observed in HROM, pain severity and patient-perceived change. There was no significant difference between the three groups in remaining outcomes.

Conclusion: ET demonstrated improvements in self-report function, pain, HROM and patient-perceived change for hip OA. MT had no further benefit as an adjunct to ET, although patients who received additional MT reported greater satisfaction with outcome. Patients deteriorated in pain, function and HROM measures while waiting for physiotherapy. These findings have implications for clinicians who can use treatment time more efficiently and enhance self-management principles for those with hip OA, and for those managing waiting lists to develop initiatives to minimise waiting times for physiotherapy.

1723

Exercise Training Reverts Chronotropic Incompetence and Improves Heart Rate Recovery After Exercise in Women with Systemic Lupus Erythematosus. Danilo M. L. Prado[1], Renata Miossi[2], Thalita Dassouki[1], Luiz A. Perandini[1], Fernanda R. Lima[1], Bruno Gualano[3], Ana Lucia S. Pinto[1], Eloisa Bonfa[4] and Hamilton Roschel[3]. [1]University of Sao Paulo, Rheumatology Division, LACRE, Sao Paulo, Brazil, [2]University of Sao Paulo, Rheumatology Division, Sao Paulo, Brazil, [3]University of Sao Paulo, School of Physical Education and Sport, Sao Paulo, Brazil, [4]Faculdade de Medicina da Universidade de São Paulo (FMUSP), Sao Paulo, Brazil

Background/Purpose: We recently observed that patients with systemic lupus erythematosus (SLE) may present chronotropic incompetence and lower heart rate recovery (HRR) after maximal graded exercise, both suggesting autonomic dysfunction. Previous studies have shown in several diseases that aerobic exercise training attenuates autonomic dysfunction by increasing vagal tone and decreasing sympathetic activity. However, whether exercise training ameliorates chronotropic reserve and HRR after graded exercise in SLE remains unclear. Our purpose was to evaluate the effect of an exercise training program on chronotropic reserve and HRR in SLE woman.

Methods: Eighteen consecutive SLE women (age: 31.0 ± 1.3 years; BMI = 23.4 ± 0.7 kg/m^2; SLEDAI score = 1.0 ± 2.3) without cardiopulmonary involvement were divided into two groups: exercise training (n=10) and control group (n=8). A treadmill cardiorespiratory test was performed and heart rate response during exercise was evaluated. HRR at both one minute (ΔHRR1) and two minutes (ΔHRR2) were defined as the difference between heart rate at peak of exercise and at 1 and 2 minutes post-exercise, respectively. The supervised exercise program consisted of combined resistance and aerobic training exercises at moderate intensity, 60 min per session, twice-a-week, throughout 12 weeks.

Results: Exercise training resulted in significant improvements in chronotropic reserve and heart rate recovery (Table 1). Body weight, BMI and maximal oxygen consumption (VO_{2max}) were unchanged. Importantly, chronotropic incompetence was completely reversed.

	Exercise training		Control	
	pre	*post*	*pre*	*post*
CR	69.9 ± 5.0	101.1 ± 2.5*†	76.3 ± 5.2	77.0 ± 7.7
ΔHRR1	20.9 ± 3.0	39.4 ± 2.5*†	23.6 ± 3.0	22.8 ± 2.2
ΔHRR2	36.9 ± 4.0	57.0 ± 3.1*†	38.6 ± 3.5	38.3 ± 5.4

* p< 0.05 vs. pre; † p<0.05 vs. control. Repeated measures two-way ANOVA.

Conclusion: These findings indicate improvement in both chronotropic reserve and heart rate recovery in woman with SLE following a supervised exercise training program. Altogether, these data reinforce the compelling therapeutic relevance of exercise training in attenuating autonomic dysfunction in SLE.

1724

Is Knee Pain Relevant for Meeting Physical Activity Guidelines Among People with Knee Osteoarthritis Who Can Walk Already Walk At a Moderate Intensity? the Multicenter Osteoarthritis Study. Daniel K. White[1], David T. Felson[1], Yuqing Zhang[1], K. Douglas Gross[2], Jingbo Niu[1], Michael C. Nevitt[3], C.E. Lewis[4], James Torner[5] and Tuhina Neogi[6]. [1]Boston University School of Medicine, Boston, MA, [2]MGH Institute of Health Professions, Boston, MA, [3]University of California-San Francisco, San Francisco, CA, [4]University of Alabama, Birmingham City, AL, [5]University of Iowa, Iowa City, Iowa City, IA, [6]Boston University, Boston, MA

Background/Purpose: Knee pain precludes the ability to walk at a moderate intensity in knee osteoarthritis (OA), which is necessary to meet the Department

of Health and Human Services (DHHS) Physical Activity Guidelines. However, it is not known if knee pain is still relevant for meeting Physical Activity Guidelines among those who can already walk at a moderate intensity. Furthermore, it is not known if other modifiable factors, such as strength, walking speed, BMI, or depressive symptoms are relevant as well. Thus, we evaluated the association of knee pain along with other modifiable factors with meeting Physical Activity Guidelines among people with or at high risk of knee OA who could already walk at a moderate intensity.

Methods: MOST is an NIH funded study of people who have or are at high risk for knee OA. We selected subjects who were able to walk at a moderate intensity, defined as walking at a step frequency of at least 100 steps per minute during a 20-meter walk. Subjects wore an accelerometer-enabled pedometer (Stepwatch) to record steps taken over 7 days. Using Stepwatch data, we defined meeting Physical Activity Guidelines as walking 150 minutes at a moderate intensity (step frequency of at least 100 steps per minute) in at least 10 continuous minute bouts. We defined knee pain as pain on average in the last 30 days using a 0–100 visual analogue scale. We examined the association of knee pain along with isokinetic knee extensor strength, walking at a community speed (≥ 1.22 m/s), BMI, and depressive symptoms with meeting Physical Activity Guidelines adjusted for potential confounders using logistic regression.

		% (n/N) or Mean (sd)	Mutually adjusted* OR [95% CI]
Knee Pain [10 unit increments on 0-100 VAS scale]		1.5 (2.0)	1.0 [0.8, 1.1]
Strength [Tertiles]			
	Weakest	2 (7/303)	1.0 Reference
		5 (19/369)	1.6 [0.6, 4.3]
	Strongest	13 (50/379)	2.8 [1.3, 5.8]
Pedestrian Walk Speed [m/s]			
	<1.2	3 (17/543)	1.0 Reference
	>1.2	9 (64/714)	2.8 [1.3, 5.8]
BMI [kg/m^2]			
<25 'healthy weight'	<25	14 (29/201)	6.8 [1.5, 30.8]
25-30 'overweight'	25-30	7 (34/472)	4.2 [1.0, 18.6]
30-35 'obese class I'	30-35	4 (15/364)	2.6 [0.6, 12.1]
>35 'obese class II - III'	>35	1 (3/220)	1.0 Reference
Depressive Symptoms [CES-D > 16]			
	Absent	7 (77/1173)	1.0 Reference
	Present	5 (4/83)	0.9 [0.2, 3.0]

* Adjusted for age, sex, comorbidity, race, living situation, education, and study site. Higher OR indicates higher odds of meeting Physical Activity Guidelines.

Results: Of the 1380 subjects who had 7 days of monitoring (Age 67 ± 8 yrs, BMI 31 ± 6 kg/m^2, female 60%) 91% (1257/1380) were able to walk at a moderate intensity. Among these subjects, 6.4% (81/1257) met Physical Activity Guidelines. Greater knee pain severity was not associated with meeting Physical Activity Guidelines (OR = 1.0, 95% CI [0.8, 1.1]). In contrast, subjects with a BMI of 25 or less had 6.8 times the odds of meeting guidelines compared with those with a BMI 35 or greater (OR = 6.8 95%CI [1.5, 30.8]). Subjects walking at least a community speed (1.22 m/s) had 2.8 times the odds of meeting guidelines compared with those not walking a community speed (2.8 [1.3, 5.8]). Lastly, those in the highest strength tertile were 2.9 times as likely to meet guidelines compared with those in the lowest strength tertile (2.9 [1.1, 7.6]). Depressive symptoms were not associated with meeting guidelines.

Conclusion: We found BMI, walking speed, and knee strength but not knee pain or depressive symptoms to be associated with meeting guidelines among people who have the ability to walk at a moderate intensity. Targeting strength, walking speed, and BMI may be more promising than treating pain to increase physical activity among people who already have the ability to walk at a moderate intensity assessed in the clinic.

In Vivo Effect of Bone-Specific EphB4 Overexpression In Mice On Subchondral Bone and Cartilage During Osteoarthritis. Johanne M. Pelletier. Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC

Background/Purpose: In humans, evidence suggests the subchondral bone to be an active component of the osteoarthritis (OA) process. Some members of the ephrin system, including the receptor EphB4 and its specific ligand, ephrin-B2, were found to be involved in bone biology. Recently, our group showed that *in vitro* ephrin-B2 activation of the EphB4 receptor inhibits the resorptive activity of human OA subchondral bone osteoblasts. We further investigated, in mice, the *in vivo* effect of bone-specific EphB4 overexpression on OA development.

Methods: Morphological evaluations were performed on postnatal day 5 (P5) mouse skeletons with alizarin red/alcian blue staining and on 10-week-old adult mice radiographically. On the induced OA knee, histology (OARSI grading), cartilage collagen meshwork disorganization grading (sirius red staining), and micro-computed tomography scans (microCT) were performed on the medial compartment.

Results: Homozygous conditional type I collagen EphB4 overexpressing mice and wild type (WT) were used. Morphometric analysis and skeletal staining at P5 showed no obvious phenotypic difference in bone development between EphB4 and WT mice. Although 10-week-old WT and EphB4 mice had similar body size and bone length, EphB4 mice demonstrated increased bone density. OA was induced, using the partial medial meniscectomy (DMM) model, in the 10-week-old mice. Eight and 12 weeks after surgery, histology revealed that EphB4 mice had significantly less articular alterations than the WT in both medial condyle and tibia at 8 (4.9 ± 0.1 vs. 3.1 ± 0.4, $p<0.008$; 3.4 ± 0.3 vs. 2.1 ± 0.3, $p<0.0009$, respectively) and 12 weeks (3.4 ± 0.3 vs. 2.4 ± 0.30, $p<0.04$; 4.5 ± 0.3 vs. 3.3 ± 0.4, $p<0.04$) post-surgery. Evaluation of collagen fibril revealed significantly higher levels of disorganization in the WT mice compared with the EphB4 mice in the tibia at 8 (2.4 ± 0.4 vs. 1.1 ± 0.2, $p<0.0007$) and 12 weeks (2.3 ± 0.2 vs. 1.1 ± 0.1, $p<0.0003$) post-surgery. In addition, microCT of the medial tibia performed 12 weeks after surgery demonstrated a significant reduction in sclerotic subchondral bone volume as well as the trabecular thickness ($p\leq0.04$) in the EphB4 mice compared to the WT.

Conclusion: This study is the first to provide *in vivo* evidence that bone-specific EphB4 receptor overexpression exerts a protective effect on structural changes that occur in OA articular cartilage and subchondral bone. These data also support the notion that this system could be targeted as a specific therapeutic approach for OA.

Lysyl Hydroxylase 2b Is Strongly Induced During Experimental Osteoarthritis and the Potential Cause of Persistent Synovial Fibrosis. Dennis F.G. Remst, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Fibrosis contributes to stiffness in osteoarthritis (OA) and is associated with joint pain. Lysyl hydroxylase 2b (LH2b) increases pyridinoline cross-links during collagen synthesis, which are harder to degrade than "normal" cross-links and are increased in fibrosis. In previous studies we found a relationship between LH2b and irreversible fibrosis after TGF-β exposure in murine synovium. TGF-β induced LH2b expression in human synovial OA fibroblasts (hSF). In this study we examined whether LH2b is actually induced in experimental OA. Thereafter we investigated which TGF-β signaling route is involved in up regulation of LH2b expression and whether gene expression also translates into LH2 protein production by TGF-β in hSF.

Methods: We induced OA by i.a. injection of collagenase into the right knee joint of C57BL/6 mice. The mice were sacrificed after 7, 21 and 42 days. mRNA was isolated from the synovium for Q-PCR. Human synovium fibroblast were isolated from knee joints of OA patients undergoing arthroplasties. The hSF were transduced with Ad-TGF-β, Ad-CTGF or Ad-Luc to determine whether LH2b induction is TGF-β specific. Thereafter, hSF were stimulated with TGF-β with and without ALK5 or ALK1 kinase inhibitor, SB-505124 (SB) or dorsomorphin (DM) respectively. In addition, hSF were transduced with constitutive active ALK1 or ALK5 to determine whether LH2b expression is ALK1 or ALK5 specific. mRNA was isolated and the gene expression for LH1, 2 and −3, lysyl oxidase (LOX), collagen type 1A1 (COL 1A1), and CTGF were analyzed with RT-PCR. LH2 protein level was determined with Western Blot analysis.

Results: In murine experimental OA there was a significant and long-lasting increase of LH2b gene expression in the synovium on day 7, 21 and 42 compared to the control knee joints. In hSF Ad-TGF-β induced LH2b gene expression whereas Ad-CTGF did not, comparable to our observations in murine synovium. TGF-β stimulation induced LH2b, CTGF, COL1A1 and LOX gene expression as well as LH2 protein. No major changes in LH1 and LH3 gene expression were found. Ad-caALK5 but not Ad-caALK1 significantly induced LH2b. This was confirmed by SB completely blocking TGF-β induced LH2b, while DM only

slightly decreased LH2b. Identical results were observed for all five primary fibroblast cell cultures.

Conclusion: In this study we have shown that LH2b is strongly induced in an experimental OA model that is accompanied by synovial fibrosis. Furthermore, we showed that both LH2b gene expression and LH2 protein are induced by TGF-β in hSF. Overexpressing caALK5, the canonical TGF-β type I receptor, induced LH2b, whereas blocking ALK5 kinase activity prevented TGF-β induced LH2b. The overexpression of caALK1 did not alter LH2b gene expression, indicating TGF-β-induced LH2b relies on ALK5 signaling alone. During OA, TGF-β is elevated causing enhanced LH2b expression. LH2b increases pyridinoline cross-links in collagen. We therefore propose that LH2b will be responsible for the persistence of fibrosis during OA. Selective blocking of LH2b in OA may prevent the formation of the pyridinoline cross-links, and therefore the formation of persistent fibrosis. Thus LH2b is a highly interesting new target to treat OA-related fibrosis.

Background/Purpose: The substantial burden of arthritis has resulted in significant gaps in care such that there is a need to optimize access to and care for people with arthritis. The benefits of early diagnosis and treatment of inflammatory arthritis, wait times for joint replacement and limited health human resources have resulted in the development of alternative models of care delivery to address these care gaps. This study identified models of arthritis care and determined how care was organized within the models.

Methods: One-on-one interviews were conducted with program managers and care providers in British Columbia (BC), Alberta (AB) and Ontario (ON), Canada to determine how care was organized for people with arthritis. We also asked about the profession, role and skill set of those providing care. Interviews were transcribed verbatim and analyzed thematically using content analysis.

Results: 53 interviews were conducted, 17 in BC, 11 in AB and 25 in ON. Five overarching models were identified: 1) a community-based model that usually includes a single health professional or multiple health professions working independently with patients; 2) a traditional model where primary care physicians refer to specialists; 3) a multi-professional model; 4) an inter-professional model; and, 5) an inter-professional model where care is provided both by individuals and in a group format. Multi-professional models and inter-professional models were developed in the context of specialist care and rarely were situated in primary care. Rarely were models developed and implemented for people with arthritis in general. Additionally, some models had formalized linkages with community providers, particularly related to chronic disease management including exercise programs. None of the models addressed the entire continuum of care.

Some models include health professionals working in alternative ways, e.g. enhancement with extended roles or substitution where roles are delegated. Processes to enhance access for specific subgroups of people with arthritis including triage processes for people with suspected inflammatory arthritis for rheumatology consultation and for people who were likely candidates for joint replacement were most common.
