Results: Microarray analysis revealed that *HLA-DRB5* was the only gene commonly up-regulated in patients with ILD compared to those without in both treatment groups. *HLA-DRB5* gene expression was significantly higher in PBMCs from SSc with ILD patients, than in those without ILD ($P = 0.007$). Although the frequencies of *HLA-DRB5* carriers were not significantly frequent in all SSc patients compared to controls, *HLA-DRB5* carriers were significantly more frequent in SSc patients with ILD (52.4 %) compared to those without ILD (25.0 % $P = 0.022$). Detailed genotyping of *HLA-DRB5* gene revealed that HLA-*DRB5*01:05* allele was significantly more frequent in SSc patients (22.9 %; $P < 0.001$), Especially *DRB5*01:05* allele was significantly more frequent in SSc patients with ILD (31.7 %, $P < 0.001$), compared to controls (5.4 %). (Table1)

Table 1. Frequencies (%) of *HLA-DRB5* alleles in patients with SSc with ILD, without ILD and in healthy controls

		SSc total N=70	ILD(+) N=41	ILD(−) N=29	Controls N=147	SSc vs controls	ILD(+) vs controls	ILD(−) vs controls
HLA-DRB5	**alleles**		(%)				OR (95% CI)	
*DRB5*01*	**01:01*	12.9	9.8	17.2	14.3	0.89 (0.38–2.05)	0.65 (0.21–2.01)	1.25 (0.43–3.64)
	**01:02*	18.6	22.0	10.3	14.9	1.30 (0.61–2.75)	1.83 (0.79–4.27)	0.66 (0.18–2.35)
	**01:05*	**22.9**	**31.7**	10.3	5.4	**5.15 (2.08–12.73)**	**8.07 (3.06–21.28)**	2.00 (0.50–8.06)
*DRB5*02*	**02:02*	4.29	4.88	–	2.0	2.15 (0.42–10.93)	2.46 (0.40–15.25)	

Numbers (%) Chi-square test or Fisher's exact test

Conclusion: *HLA-DRB5*01:05* allele is a risk factor for the development of ILD in patients with SSc.

***Transforming Growth Factor-β Receptor One* Variant Is Associated with Constitutively Decreased Transforming Growth Factor-β Signaling and Risk for Systemic Sclerosis.** Monique E. Hinchcliff[1], Michael Pennison[2], Jacquelyn Zimmerman[2], Naresh Bellam[2], Qinghua Zeng[2], Chiang-Ching Huang[1], Richard M. Pope[1], Maureen Sadim[1], Wendy Wolf[3], Jeffrey C. Edberg[4], Robert P. Kimberly[2], Kui Zhang[5], Jun Li[5], Nengjun Yi[5], Canadian Scleroderma Research Group (CSRG)[6], Scleroderma Registry Investigators[7], Maureen D. Mayes[7], John Varga[1] and Boris Pasche[2]. [1]Northwestern Univ Med School, Chicago, IL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Harvard Medical School, Boston, MA, [4]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, [5]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [6]SMBD Jewish General Hospital, Montreal, QC, [7]University of Texas Health Science Center at Houston, Houston, TX

Background/Purpose: The Transforming Growth Factor Beta (TGF-μ) signaling pathway plays a central role in the pathogenesis of systemic sclerosis/scleroderma (SSc) as a potent contributor to the fibrotic process. Only a few underpowered studies have investigated the association between genetic variants of TGF-β1 (*TGFB1*) and the risk for developing SSc, and the results have been inconsistent. Thus, there is no known association between naturally occurring variants of the TGF-β signaling superfamily and risk for SSc. We hypothesized that variants of the type I TGF-β receptor (*TGFBR1*) may be associated with risk for SSc given the central role of TGFBR1 as the initiator of SMAD- and non-SMAD-mediated signaling.

Methods: Using phase II HapMap data for the HapMap European (CEU) sample for *TGFBR1*, we selected 14 haplotype tagging single nucleotide polymorphisms (SNPs) in addition to *TGFBR1**6A, a functionally-relevant variant associated with cancer risk. Using a PCR-based protocol, we genotyped the 15 variants in 212 clinic-based patients with a diagnosis of SSc and 426 clinic-based individuals without a diagnosis of SSc or cancer who were well matched for age, sex, race, and smoking history. SNPs associated with risk for SSc were validated in 1373 patients and 744 control Caucasian, non-Hispanic subjects from the Scleroderma Registry and DNA Repository and from the University of Texas Medical School, Houston. The functional relevance of SNPs associated with risk for SSc in the combined analysis of both cohorts was assessed using lymphoblastoid cell lines from healthy individuals.

Results: The majority of the discovery cohort subjects were Caucasian (70.8% cases and 72.5% controls). One hundred and twenty (56.6%) and 84 (39.6%) had the diffuse and limited forms of SSc, respectively. Four hundred ninety-five (36.1%) and 789 (57.5%) patients in the validation cohort had diffuse and limited SSc respectively. One of the three *TGFBR1* SNPs associated with risk for SSc in the discovery cohort was also associated with risk for SSc in the validation cohort.

Combined logistic regression analyses of the two cohorts adjusted for race, gender, smoking and age shows OR 1.67, 95% CI 1.16–2.41 for rs2026811 and OR 0.62, 95% CI 0.45–0.86 for rs334348. Disease subset analysis shows that rs10733710 is associated with diffuse disease, rs2026811 is associated with limited disease, and rs334348 with both limited and diffuse disease. Functional analysis shows that lymphoblastoid cell lines that carry the two-SNP (rs2026811 x rs334348) *TGFBR1* haplotype associated with risk for SSc in the combined analysis have significantly reduced TGF-β signaling.

Conclusion: These findings provide the first evidence that the *TGFBR1* locus is associated with risk for SSc and suggest that constitutively altered TGFBR1 signaling contributes to the pathogenesis of this disease.

Anti-AT(1)R and Anti-ET(A)R Autoantibodies in Systemic Sclerosis: Indication of Possible Involvement in Disease Pathology. Angela Kill[1], Mike O. Becker[2], Jeannine Guenther[1], Harald Heidecke[3], Duska Dragun[2] and Gabriela Riemekasten[1]. [1]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany, [2]Charité University Hospital, Berlin, Germany, [3]CellTrend GmbH, Luckenwalde, Germany

Background/Purpose: Recently identified functional autoantibodies simultaneously targeting the angiotensin-II type-1 receptor (AT1R-Abs) and the endothelin-1 receptor type A (ETAR-Abs) were linked with vascular and fibrotic complications in patients with systemic sclerosis (SSc). Presence of both autoantibodies moreover predicted mortality due to cardiopulmonary complications implicating their contribution in SSc pathogenesis. Here, different autoantibody- and ligand-mediated effects and their blockade by receptor inhibitors were studied.

Methods: HMEC-1 were treated with IgG from SSc patients containing anti-AT(1)R and anti-ET(A)R autoantibodies, with IgG from healthy donors, and with the natural receptor ligands. In parallel, cells were pre-treated with various receptor antagonists alone and in combination. The effect on different cytokines, growth factors, cell signaling molecues, and cell viability was measured by e.g. toxicity test, qRT-PCR, and ELISA.

Results: Exposure of endothelial cells to SSc- IgG led to a strong upregulation of several mediators. In case of IL-8 mRNA and on protein expression levels, expression of mRNA was downregulated and partially reduced on the protein levels using pre-treatment with receptor inhibitors. There was a high variability in the response to the blockers exhibiting responders and non-responders. Interestingly, treatment with natural ligands did not result in IL-8 up-regulation.Treatment with SSc-IgG led also to a significantly reduced cell viability compared to N-IgG treatment. These effects were partially abolished by pre-treatment with AT(1)R- inhibitor, but completely abolished using by one but not by another ET – inhibitor. MCP-1 was also up-regulated by IgG from SSc patients but not from controls, but was not blockable using receptor inhibitors.

Conclusion: Our results suggest an autoantibody-driven cytotoxicity and inflammatory activation of endothelial cells by angiotensin/endothelin-receptors *in vitro*. The data also suggest a heterogeneity of the antibody-mediated effects, the role of other possible autoantibodies, and different responses to inhibitors and the natural ligands. Whether these *in vitro* data could be used to identify responders or non-responsers to therapy, remain to be studied. *In vivo* experiments are underway to give better insight into the complex nature of the SSc-antibody-mediated effects.

Identification of Major Histocompatibility Complex Class II Alleles Associated with Systemic Sclerosis Through Imputation Strategy. Jose Ezequiel Martin[1], International Scleroderma Group[2], Timothy RD Radstake[3], Filemon K. Tan[4], Frank C. Arnett[4], Maureen D. Mayes[4], Paul de Bakker[5], Bobby P.C. Koeleman[6] and Javier Martin[7]. [1]Instituto de Parasitología y Biomedicina López-Neyra, IPBLN-CSIC, Armilla (Granada), Spain, [2]Granada, Spain, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [4]University of Texas Health Science Center at Houston, Houston, TX, [5]Brigham and Women's Hospital, Boston, MA, [6]University Medical Center Utrecht, Utrecht, Netherlands, [7]Instituto de Parasitologia y Biomedicina Lopez-Neyra (CSIC), Granada, Spain

Background/Purpose: Different alleles of MHC class II molecules (namely, HLA-DRB1, DPB1 and DQB1) have been described to be associated either with risk to systemic sclerosis (SSc) or its subphenotypes. Due to the high cost of HLA typing, studies have been limited to small sample sizes, preventing definitive statements as to which HLA alleles are likely causal.

Methods: We have imputed the MHC class I and II alleles of 2,296 cases and 5,356 controls from the US, Spain, Germany and The Netherlands with a method previously developed, which uses genotype data from ~2000 SNPs in the MHC region and an independent reference panel of dense SNP and classical HLA typing data in >2700 unrelated Europeans. We obtained actual HLA typing data for both class I and II molecules for the Spanish and US cohorts, and compared the accuracy of the imputation. Besides classical HLA alleles, we also imputed amino acid changes encoded by genetic variants within the different MHC molecules. We compared the frequencies of the different alleles between cases and controls for SNPs, amino acids and classical HLA alleles.

Results: The accuracy of the imputations ranged from 90% to 98% depending on the alleles being imputed with an average of 93% for all alleles in both populations. We confirmed previous associations of HLA alleles with SSc or its auto-antibody positive subgroups (HLA-DRB1*0701, HLA-DPB1*1301, HLA-DRB1*1104, HLA-DQB1*0501). We define in deeper detail some of these associations down to the level of aminoacidic positions which affect epitope binding. Furthermore, we describe new associations of HLA alleles with auto-antibody positive subgroups, HLA-DRB1*0801, with the presence of anti-centromere auto-antibodies and HLA-DQB1*0301 with the presence of anti-topoisomerase I auto-antibodies. No associations in the MHC class I molecules was found.

Conclusion: Our data indicate that most associations of HLA alleles (and more precisely aminoacidic positions within them) are specific to the presence of auto-antibodies. Also, only MHC class II alleles are associated and not MHC class I.

FLOW Cytometric Analysis of Circulating Microparticles In Systemic Sclerosis. Line V. Iversen. Statens Serum Institut, Copenhagen S, Denmark

Background/Purpose: Microparticles (MPs) are small membranous vesicles released by apoptotic or activated cells. MPs exert regulatory functions in inflammation, thrombosis, vascular reactivity and angiogenesis. All these processes are involved in the disease manifestations of Systemic Sclerosis (SSc). SSc autoantigens have been identified in blebs released from cells undergoing apoptosis in vitro. This may link MPs to the development of systemic autoimmunity. Here, we characterize the circulating MPs a large group of clinically well-defined patients with SSc.

Methods: One hundred and twenty one (n = 121) unselected SSc patients, 49 sex- and age-matched healthy controls and 29 systemic lupus erythematosus (SLE) patients were included in the study. All samples were analyzed for MPs directly in citrated platelet poor plasma (PPP). A subset was also analyzed using washed MPs. MPs were characterized by a double labeling procedure using AnnexinV (AnxV) together with antibodies to platelet, leukocyte or endothelial cell surface markers. The reproducibility varied up to experiments and 12 % in day to day experiments.

Results: The total concentration of MPs and AnxV-binding MPs was significantly reduced in SSc and SLE patients compared to healthy controls. The concentration of MPs derived from platelets and leukocytes was reduced in patients while endothelial cell-derived MPs were not altered in SSc. The results from direct analysis in PPP and analysis of washed MPs from the same samples were significantly correlated with the exception of MPs derived from endothelial cells. No difference was found in the total MP concentration or cell-derived MP concentrations comparing diffuse and limited cutaneous systemic sclerosis.

Conclusion: The concentration of MPs was found to be reduced in patients with SSc and in patients with SLE compared to healthy controls. No differences in MP concentrations was found comparing limited and diffuse cutaneous systemic sclerosis.

A Peptide Derived From Endostatin Ameliorates Fibrosis Induced by TGF–β and Bleomycin in Multiple Pre-Clinical Models. Yukie Yamaguchi[1], Takahisa Takihara[2], Roger Chambers[2], Adriana T. Larregina[2] and Carol A. Feghali-Bostwick[2]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Systemic sclerosis (SSc) results in significant morbidity and mortality due to organ fibrosis characterized by increased deposition of extracellular matrix (ECM). There are currently no effective therapies for fibrosis. Endostatin, a 20-kDa internal fragment of the carboxy terminus of collagen XVIII, has anti-cancer properties due to its endogenous angiogenesis inhibitory effect. In this study, we evaluated the potential of endostatin and endostatin-derived peptides to ameliorate fibrosis in several pre-clinical models: *in vitro* using primary human fibroblasts, *ex vivo* using human skin, and *in vivo* in TGF-β and bleomycin-induced dermal and pulmonary fibrosis. We also identified the mechanisms mediating the anti-fibrotic effects of endostatin peptides.

Methods: Levels of ECM components in primary human fibroblasts stimulated with recombinant endostatin (rE) or synthetic peptides of human endostatin were evaluated by immunoblotting. The effects of endostatin-derived peptides were also assessed in TGF-β-induced dermal fibrosis *in vivo* in a mouse model, *ex vivo* in human skin, and in bleomycin-induced dermal and pulmonary fibrosis *in vivo*. Levels of lysyl oxidase (LOX) and matrix metalloprotease (MMP)-2 were evaluated using immunoblotting, immunohistochemistry, and zymography.

Results: rE suppressed production of fibronectin and type I collagen *in vitro* in primary human fibroblasts and reduced skin thickness induced by TGF-β *ex vivo* in human skin. A C-terminal endostatin peptide (E4) of rE, but not an amino-terminal domain (E1), prevented TGF-β- and bleomycin-induced fibrosis *in vitro*, *in vivo* in mouse skin and lung, and *ex vivo* in human skin. E4 exerted potent anti-fibrotic effects in all the pre-clinical models used. In addition to preventing fibrosis, E4 significantly reduced existing fibrosis when administered a few days following the fibrotic trigger. Furthermore, E4 exerted its anti-fibrotic effects via multiple mechanisms that included reducing LOX levels and activating MMP-2. A reduction in LOX results in reduced cross-linking of collagen, rendering the ECM more susceptible to degradation by activated MMPs.

Conclusion: A peptide corresponding to the C-terminal domain of endostatin displays anti-fibrotic activity and is a novel and effective therapeutic agent for organ fibrosis.

Thymic Stromal Lymphopoietin (TSLP) Is Overexpressed in Scleroderma Skin and It Is Induced by TLR3 Activation in Dermal Fibroblasts. Alicia Usategui, Manuel J. Del Rey, Elena Izquierdo, Patricia E. Carreira, Pablo Ortiz and Jose L. Pablos. Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain

Background/Purpose: Th2 responses are associated to the production of pro-fibrotic mediators such as IL-4 and IL-13. Contrarily, Th1 effectors such as IFN-gamma or TNF-α are anti-fibrotic. Thymic stromal lymphopoietin (TSLP) is a potent inducer of Th2 polarization in skin and lung allergic inflammation. TSLP is expressed by resident cells and can be regulated by activation of toll like receptors (TLR). Although T-cells participate in the pathogenesis of systemic sclerosis (SSc), the mechanisms of T-cell polarization and their relevance to fibrosis are unclear. The aim of this study was to analyze the expression and potential regulation of TSLP in human SSc and in the bleomycin model of scleroderma.

Methods: We analyzed by immunohistochemistry (IHC) the expression of TSLP in involved skin from 18 patients with diffuse SSc (mean disease duration 2.8±0.5 years), and in the bleomycin mouse model of scleroderma, compared to normal control tissues. Dermal fibrosis was induced in female C3H mice aged 6 wk by subcutaneous injections of bleomycin (1mg/ml) into the shaved back skin every day for 4 weeks. TSLP mRNA expression was analyzed by quantitative RT-PCR in bleomycin induced skin lesions and in cultured fibroblasts. Normal human and mouse dermal fibroblasts were cultured from healthy skin and treated with bleomycin or specific TLR-2, −3 and −4 agonists (LPS, Pam3Cys and poly(I:C) respectively). Data are

expressed as mean±SEM. Quantitative data were analysed by Mann-Whitney U-test and p-value<0.05 was considered significant.

Results: TSLP protein was detected by IHC in 14 of 18 (78%) human SSc skin sections whereas it was undetectable in normal skin from 3 healthy individuals. TSLP expression was observed in keratinocytes, mast cells and fibroblasts of involved SSc skin. In fibrotic lesions of bleomycin-injected mouse skin, we also observed an increase in TSLP expression in mast cells, keratinocytes and fibroblasts by IHC. We confirmed a 4.6±0.7 fold increase of the TSLP mRNA level in bleomycin-injected skin ($p<0.05$). In human fibroblasts, TLR-3 agonist induced a strong increase in TSLP mRNA expression (8.4±5.4, $p<0.05$), whereas TLR-2 and -4 agonists and bleomycin did not significantly modify TSLP mRNA expression. In mouse fibroblasts, all TLR-2, -3 and -4 agonists but not bleomycin induced TSLP mRNA expression. The strongest effect was observed for TLR-3 agonist (17.8±7.7, $p<0.05$).

Conclusion: We demonstrate overexpression of TSLP in resident cells of human SSc and mouse bleomycin-induced scleroderma. Among TLR agonists, TLR-3 was the most potent inducer of TSLP expression in human and mouse fibroblasts. These observations suggest that in scleroderma skin, Th2 differentiation may be induced by TSLP in response to TLR-3 activation in resident cells.

Oxidation of Protein Tyrosine Phosphatase-1B Leads to Pronounced PDGFR Activation in Scleroderma Fibroblasts. Pei-Suen Tsou[1], Adam J. Pinney[1], Nadin N. Talia[1], Sonsoles Piera-Velazquez[2], Sergio A. Jimenez[3], James R. Seibold[4], Kristine Phillips[1] and Alisa E. Koch[5]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]Thomas Jefferson University, Philadelphia, PA, [3]Jefferson Institute of Molecular Medicine, Thomas Jefferson University, Philadelphia, PA, [4]Scleroderma Research Consultants LLC, Avon, CT, [5]Department of Veteran's Affairs and University of Michigan, Ann Arbor, MI

Background/Purpose: Skin fibrosis is a main characteristic of systemic sclerosis (SSc). Platelet-derived growth factor (PDGF) and its receptor (PDGFR) have been shown to play key roles in promoting fibrosis in SSc. Upon PDGF stimulation, the PDGFR is phosphorylated (p-PDGFR), and its downstream signaling pathways, such as ERK1/2, are activated. The PDGFR is dephosphorylated by phosphatases, including protein tyrosine phosphatase 1B (PTP1B), and the signaling cascade is hence terminated. We previously following PDGF stimulation, ERK1/2 was phosphorylated (p-ERK1/2) to a greater extent in SSc dermal fibroblasts. Moreover, increased oxidative stress was observed in SSc cells compared to normal (NL) fibroblasts, and PTP1B was inactivated. In this study we hypothesize that the p-PDGFR profile in SSc fibroblasts is affected by the inactive PTP1B, and the mechanism of PTP1B inactivation is due to oxidation of its active site. The effect of the thiol antioxidant n-acetylcysteine (NAC) on p-PDGFR, p-ERK1/2, tyrosine-phosphorylated proteins, collagen I (Col I) production, and PTP1B mRNA expression was investigated.

Methods: SSc and NL dermal fibroblasts were isolated from skin biopsies. Cellular thiol content was measured by using 5,5'-dithiobis (2-nitrobenzoic acid). Tyrosine phosphorylated proteins were immunoprecipitated, and p-PDGFR was probed with rabbit anti-human PDGFR antibodies. Oxidized PTPs and p-ERK1/2 were measured by Western blotting. Col I was detected by immunofluorescence and quantitative PCR.

Results: Col I expression was significantly higher in SSc fibroblasts, accompanied by significantly lower amounts of free thiol compared to NL fibroblasts (464 ± 18 in NL vs. 344 ± 15 μM/mg protein in SSc cells, $n=3$, $p<0.01$). After PDGF stimulation, multiple proteins including the PDGFR, were phosphorylated to a greater extent in SSc fibroblasts. Moreover, the significantly lower PTP1B activity in SSc fibroblasts resulted from cysteine oxidation at its active site by higher levels of ROS, since oxidation of multiple PTPs, including PTP1B, was observed. NAC improved the profile of p-PDGFR and p-ERK1/2, decreased the number of tyrosine-phosphorylated proteins, and decreased both Col I protein and mRNA expression. The PTP1B mRNA level did not change in the presence of NAC in NL fibroblasts when stimulated with PDGF, but PTP1B mRNA significantly increased in SSc fibroblasts after 2 hr of PDGF stimulation (0.0023 ± 0.0005 vs. 0.0036 ± 0.0002 arbitrary unit in the absence or presence of NAC, $p<0.05$, $n\geq5$).

Conclusion: The inactivation of PTP1B was caused by oxidation of its active site due to the excess oxidative stress in SSc fibroblasts, as indicated by the lower cellular free thiol levels. This led to pronounced and prolonged activation of the PDGFR and ERK1/2 pathways and therefore the increase in Col I production. NAC treatment, by reducing oxidative stress and restoring the low PTP1B activity and expression, decreased Col I production in SSc dermal fibroblasts. We introduce a new mechanism by which ROS promote a profibrotic phenotype in SSc fibroblasts through oxidative inactivation of PTP1B leading to pronounced PDGFR activation and thus increased Col I production.

2318

The Expression and Activities of Protein Tyrosine Phosphatases in Scleroderma Dermal Fibroblasts: Impact of Oxidative Stress on DEP-1 and SHP-2. Pei-Suen Tsou[1], Adam J. Pinney[1], Ann Kendzucky[2], Sonsoles Piera-Velazquez[3], Sergio A. Jimenez[4], Kristine Phillips[1] and Alisa E. Koch[5]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]Grand Valley State University, MI, [3]Thomas Jefferson University, Philadelphia, PA, [4]Jefferson Institute of Molecular Medicine, Thomas Jefferson University, Philadelphia, PA, [5]Department of Veteran's Affairs and Unversity of Michigan, Ann Arbor, MI

Background/Purpose. We and others have shown that the platelet-derived growth factor receptor (PDGFR) is crucial for promoting fibrosis in systemic sclerosis (SSc). The PDGFR is activated via its ligand PDGF, and phosphorylation of the receptor occurs. Protein tyrosine phosphatases (PTP), such as PTP1B, SHP-2, and DEP-1, have been suggested to be able to dephosphorylate the PDGFR, and therefore terminate the initiation of the downstream signaling pathways. We previously showed that the increased oxidative stress in SSc dermal fibroblasts inactivates PTP1B, and that the ability to generate more PTP1B is hampered when cells are stimulated with PDGF. The loss of activity results from oxidation of its active site. Since PTP1B is not the only phosphatase that dephosphorylates the PDGFR, in this study we sought to determine the expression and activity of two other crucial phosphatases, namely SHP-2 and DEP-1, in SSc dermal fibroblasts. The impact of a thiol antioxidant, n-acetylcysteine (NAC), was also examined.

Methods: SSc and normal (NL) dermal fibroblasts were isolated from skin biopsies. Cells were stimulated with 30 ng/ml PDGF and the expression of DEP-1 and SHP-2 was determined by qPCR and Western blotting. Phosphate release assays were used to determine DEP-1 and SHP-2 activity.

Results: DEP-1 had higher protein expression in SSc dermal fibroblasts compared to NL ($p<0.05$, $n=7$), and NAC significantly increased DEP-1 expression in both NL and SSc cells. However, following PDGF stimulation DEP-1 mRNA decreased significantly in SSc cells compared to NL. There was no difference in DEP-1 activity in NL and SSc cells, but following NAC treatment the activity in SSc cells increased about 2 fold ($p<0.05$, $n=6$). On the other hand, the SHP-2 protein and mRNA levels in SSc fibroblasts were lower compared to NL. While NAC increased mRNA expression following PDGF stimulation, it had no significant effect on SHP-2 protein expression in SSc cells. The lower expression of SHP-2 in SSc dermal fibroblasts led to lower SHP-2 activity ($p<0.05$, $n=6$), while NAC had no effect on SHP-2 activity.

Conclusion: In SSc dermal fibroblasts, the pronounced and prolonged activation of the PDGFR pathway is likely due to the lower expression and activities of SHP-2 and PTP1B, which we showed previously. The increased DEP-1 expression might be a defense mechanism to overcome the lower expression of PTP1B and SHP-2. In addition, the susceptibility of these phosphatases to oxidative stress is different. While NAC restored PTP1B and DEP-1 activity in SSc cells, it had no effect on SHP-2 activity. Besides its thiol antioxidative effect, NAC also affects the expression of PTPs. This study suggests that the irregular expression and inactivated enzyme activity of PTPs in SSc dermal fibroblasts might contribute to the fibrotic phenotype seen in SSc patients.

Atorvastatin Attenuates Skin Fibrosis Through the PI3K Pathway. Yuko OTA, Yasushi Kawaguchi, Kae Takagi, Hisae Ichida, Takahisa Gono, Masanori Hanaoka and Hisashi Yamanaka. Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Atorvastatin, a member of the statin class of drugs, is an inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase. This drug offers several beneficial effects in treating conditions with vascular involvement, such as Raynaud's phenomenon and digital ulcers in patients with systemic sclerosis (SSc), by recruiting circulation endothelial progenitor cells. In addition to their well-known effects in down-regulation of serum cholesterol, statins induce pleiotropic effects at the cellular level, regulating intracellular signaling systems. Recently, it was reported that statins ameliorated liver and heart fibrosis. The aim of the present study was to investigate the antifibrotic effects of atorvastatin on skin fibroblasts from patients with SSc.

Methods: Skin fibroblasts from five patients with diffuse cutaneous SSc were cultured with increasing concentrations of atorvastatin for various times. The resulting supernatants were collected and stored at −80 °C. Procollagen type I C-peptide and IL-6 levels were then measured using commercial ELISA kits. In addition, mRNA levels of collagen 1α(II) and IL-6 were

estimated using real-time PCR. The phosphorylation of Akt (Thr308) was evaluated by Western blot analysis using specific monoclonal antibodies.

Results: In the supernatants of fibroblasts cultured with 10 μM of atorvastatin for 72 h, the levels of procollagen type I C-peptide and IL-6 were significantly suppressed ($p < 0.001$, Figure 1) as compared with those in supernatants obtained from cultures lacking atorvastatin. In skin fibroblasts cultured with LY294002 (PI3K inhibitor), procollagen type I C-peptide and IL-6 production were significantly suppressed ($p < 0.05$, and $p < 0.01$ respectively). IL-6 production was significantly suppressed ($p < 0.01$) upon the administration of Y27632 (Rho kinase inhibitor), although procollagen type I C-peptide levels were not suppressed. Treatment with U0126 (Erk1/2 inhibitor) did not affect the levels of collagen or IL-6. The results from Western blot analyses indicated that atorvastatin inhibited the phosphorylation of Akt (Thr308), which is regulated by the PI3K signaling pathway.

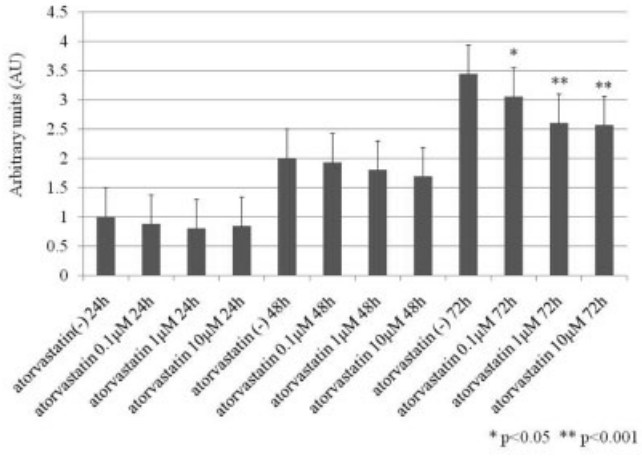

Figure 1. The effect of atorvastatin for collagen production on SSc fibroblasts.

Conclusion: Our results showed that atorvastatin attenuates, via the PI3K pathway, collagen and IL-6 production in skin fibroblasts from patients with SSc. Atorvastatin may represent a novel therapy not only for vasculopathy but also for fibrosis in patients with SSc.

2320

The Role of Adiponectin in the Pathogenesis of Dermal Fibrosis in Systemic Sclerosis. Yoshihide Asano, Yuri Masui, Takafumi Kadono and Shinichi Sato. The University of Tokyo, Tokyo, Japan

Background/Purpose: Adiponectin has been demonstrated to be one of anti-inflammatory and anti-fibrotic factors, suggesting the potential of this cytokine to be involved in the developmental process of systemic sclerosis (SSc). The purpose of this study is to investigate the clinical significance of serum adiponectin levels in patients with SSc and to examine if adiponectin affects the pro-fibrotic phenotype of SSc fibroblasts.

Methods: Serum adiponectin levels were determined by enzyme-linked immunosorbent assay in 32 patients with diffuse cutaneous SSc (dcSSc), 28 with limited cutaneous SSc (lcSSc), and 27 healthy controls. No significant difference between these groups existed in terms of sex, age, and body mass index. Normal and SSc fibroblasts were stimulated with adiponectin and mRNA levels of human α2(I) collagen and matrix metalloproteinase 1 genes were determined by real-time PCR. mRNA levels of adiponectin receptor 1 and adiponectin receptor 2 genes in those cells were also evaluated by real-time PCR.

Results: Serum adiponectin levels in dcSSc patients (4.93 ± 6.48 μg/ml) were significantly lower than those in lcSSc patients (9.69 ± 7.61 μg/ml, $P < 0.01$) and healthy controls (9.36 ± 5.57 μg/ml, $P < 0.01$). dcSSc patients with disease duration of ≤ 5 years had significantly decreased serum adiponectin levels (2.15 ± 1.69 μg/ml) than those with disease duration of > 5 years (13.29 ± 8.36 μg/ml, $P < 0.01$), lcSSc patients with disease duration of ≤ 5 years ($8.07 \pm 7.98$$\mu$g/ml, $P < 0.05$), lcSSc patients with disease duration of > 5 years (10.9 ± 7.34 μg/ml, $P < 0.01$), and healthy controls (9.36 ± 5.57 μg/ml, $P < 0.01$). Longitudinal studies in 5 patients with early dcSSc treated with oral prednisone demonstrated that serum adiponectin levels inversely correlate with the activity of progressive skin sclerosis in dcSSc patients. In normal fibroblasts, adiponectin stimulation decreased mRNA levels of human α2(I) collagen gene, while increasing mRNA levels of matrix metalloproteinase 1 gene. In SSc fibroblasts, mRNA levels of adiponectin receptor 1 and adiponectin receptor 2 genes were decreased compared with normal fibroblasts. Consistently, SSc fibroblasts were less sensitive to anti-fibrotic effect of adiponectin than normal fibroblasts.

Conclusion: Serum levels of adiponectin may serve as a useful marker to evaluate the activity of progressive skin sclerosis in dcSSc. As well as the decrease in serum levels of adiponectin, the decreased expression of adiponectin receptors contributes to the establishment of pro-fibrotic phenotype in SSc fibroblasts.

Platelet Derived Growth Factor Receptor Inhibitor ARRY-768 Prevents Experimental Dermal Fibrosis and Induces Regression of Pre-Established Dermal Fibrosis. Michal Tomcik[1], Nicole Reich[2], Katrin Palumbo[2], Pawel Zerr[2], Jérôme Avouac[3], Alfiya Akhmetshina[2], Clara Dees[2], Christian Beyer[4], Radim Becvar[1], Ladislav Senolt[5], Oliver Distler[6], Georg Schett[2] and Jorg HW Distler[2]. [1]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [4]University of Erlangen-Nuremberg, Erlangen, Germany, [5]Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [6]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Platelet derived growth factor (PDGF) is one of the key profibrotic cytokines in pathogenesis of systemic sclerosis. ARRY-768 is a highly selective, orally active, small molecule inhibitor of PDGF receptors, which targets PDGFR more potently than imatinib (IC_{50} of 3 vs. 69 nM, respectively). The aim of this study was to investigate the efficacy of ARRY-768 in prevention of dermal fibrosis and treatment of pre-established dermal fibrosis induced by bleomycin.

Methods: Design for prevention of dermal fibrosis (A) comprised 3 treatment groups injected with bleomycin s.c. for 3 weeks: group I was treated with ARRY-768 50mg/kg p.o., group II and III with imatinib mesylate 50 and 200mg/kg i.p., respectively, twice a day. Control groups, injected with NaCl (IV) and bleomycin (V) s.c., were treated p.o. with a vehicle (water). Design for the treatment of pre-established dermal fibrosis (B) consisted of 4 treatment groups injected with bleomycin s.c. for 6 weeks. During the last 3 weeks, groups I and II were treated with ARRY-768 30 and 100mg/kg p.o., whereas groups III and IV with imatinib mesylate 50 and 200mg/kg i.p., respectively, twice a day. Control groups, injected s.c. with NaCl (V) or bleomycin (VI) for 6 weeks or bleomycin for the first 3 and NaCl the last 3 weeks (VII), were treated p.o. with water for the last 3 weeks. A total of 40+56 (A+B) DBA/2 mice were examined weekly for weight, activity and the texture of the fur.

Results: In the standard model of bleomycin-induced dermal fibrosis (A), treatment with ARRY-768 50mg/kg (I) reduced dermal thickening by $67\pm2\%$ ($p<0.001$), hydroxyproline content by $23\pm6\%$ ($p=0.642$) and myofibroblast count by $47\pm5\%$ ($p<0.001$). Control treatment with imatinib (II, III) demonstrated comparable reduction of dermal fibrosis. Similarly in the model of bleomycin-induced pre-established dermal fibrosis (B), treatment with ARRY-768 30 (I) and 100mg/kg (II) decreased dermal thickening by $45\pm2\%$ ($p<0.01$) and $56\pm1\%$ ($p<0.01$), hydroxyproline content by $52\pm4\%$ ($p<0.001$) and $55\pm5\%$ ($p<0.001$), and myofibroblast count by $75\pm6\%$ ($p<0.001$) and $88\pm8\%$ ($p<0.001$), respectively. Control treatment with imatinib (III, IV) showed similar regression of pre-established dermal fibrosis. ARRY-768 demonstrated significant antifibrotic effects in both prevention and treatment of pre-established dermal fibrosis. The treatment with ARRY-768 was well tolerated for 3 weeks at all dosing regimens (30, 50 or 100mg/kg) and no signs of toxicity such as weight loss, decreased activity or changes in the texture of the fur were observed.

Conclusion: This is the first study on the anti-fibrotic effects of the selective PDFGR inhibitor ARRY-768. ARRY-768 did not only prevent experimental fibrosis, but also induced regression of pre-established bleomycin-induced fibrosis without toxic side effects. The efficacy of ARRY-768 was comparable to that of imatinib, suggesting that the effects of imatinib might be mediated primarily via inhibition of PDGFR, whereas inhibitory effects on c-abl, a downstream mediator of TGFβ, seem to be less relevant. These data highlight the importance of PDGF signaling in fibrotic diseases.

2322

Adenosine A_{2A}Receptor Activation Stimulates Collagen1 and Collagen3 by Different Signaling Pathways in Normal Human Dermal Fibroblasts (NHDF). Miguel Perez-Aso and Bruce N. Cronstein. New York Univ Medical Center, New York, NY

Background/Purpose: Prior studies have demonstrated that adenosine, acting at A_{2A} receptors, promotes wound healing and plays a role in dermal fibrosis, such as occurs in scleroderma, as well. The intracellular signaling pathways by which adenosine receptor activation stimulates collagen production have not previously been explored in dermal fibroblasts. We therefore examined the signaling mechanisms by which adenosine A_{2A} receptors, members of the $G_{\alpha S}$-linked family of receptors that generally signal via increased cAMP, promote collagen production in normal human dermal fibroblasts (NHDF).

Methods: Collagen1α1 (Col1α1) and Collagen3α1 (Col3α1) expression in Normal Human Dermal Fibroblasts (NHDF) was determined by Western blot for protein content.

Results: Stimulation of NHDF for 24h with the A_{2A}R agonist CGS21680 stimulated a biphasic increase in Col1α1 production (0.1μM: 160$\pm$11% of control, $p<0.05$; 1μM: 135$\pm$10% $p>0.05$; 10μM: 133$\pm$11% $p>0.05$ versus control, n=11), while the maximum increase of Col3α1 was at 1μM (0.1μM: 111$\pm$10% $p>0.05$; 1μM: 172$\pm$19% $p<0.05$; 10μM: 166$\pm$17% $p>0.05$ versus control, n=11). Interestingly, two different activators of Protein kinase A 8-Cl-cAMP and 6-Bnz-cAMP (0.1μM), both stimulated Col1α1 production, (8-Cl-cAMP, 280$\pm$74% of control, $p<0.01$; 6-Bnz-cAMP 157$\pm$6% of control, $p<0.01$, n=3). Stimulation with 8-Cl-cAMP did not affect Col3α1 production at 0.1μM, but decreased Col3α1 content at higher concentrations (1μM: 66$\pm$7% of control, $p>0.05$; 10μM: 32$\pm$11% of control, $p<0.01$; 100μM:48.2$\pm$24 $p<0.05$ versus control, n=4). Stimulation with the specific Epac activator 8-CPT-2'-O-Me-cAMP from 0.1 to 100μM did not affect Col1α1, but increased Col3α1 production in a dose-dependent fashion by as much as 260$\pm$70% (n=3, $p<0.05$). Blockade of Epac signaling by Brefeldin A (10μM) dramatically increased Col1α1 production (287$\pm$35% of control, $p<0.01$, n=3), but diminished Col3α1 to 32$\pm$15% of control ($p<0.01$, n=3). Inhibition of p38MAPK by SB203580 (1μM) abrogated the CGS21680 (1μM)-stimulated increase of Col3α1 from 170$\pm$21% to 73$\pm$9 of control ($p<0.05$, n=3).

Conclusion: These results demonstrate that adenosine A_{2A} receptor stimulation promotes collagen production by two different pathways. Adenosine A_{2A} receptors promote Col1α1 secretion via activation of a cAMP-PKA-dependent pathway whereas these receptors stimulate Col1α3 secretion via activation of a cAMP-Epac-p38Mapk pathway.

Adenosine-Mediated Dermal Fibrosis and Fli-1 Expression in CD39 and CD73 Knockout Mice. Edwin SL Chan[1], Gideon Smith[1], Patricia Fernandez[2], Hailing Liu[1], Andrew G. Franks[2], Maria Trojanowska[3] and Bruce N. Cronstein[4]. [1]New York University School of Medicine, New York, NY, [2]New York University, New York, NY, [3]Boston University, Boston, MA, [4]New York Univ Medical Center, New York, NY

Background/Purpose: Genetic deletion of CD39/73 results in vastly decreased adenosine in tissues, protecting against bleomycin-induced pulmonary fibrosis. To characterize the contribution of endogenous adenosine to fibrogenesis in the skin, we determined its impact on murine bleomycin-induced dermal fibrosis.

Methods: Male CD39/CD73-double deficient mice (CD39/73KO) were injected with bleomycin (0.1U sc qodx18d) and compared to wild-type littermates. Dermal morphometry was assessed on 6mm skin punch biopsies. Hydroxyproline levels were determined and adenosine levels assessed by HPLC. To further characterize the contribution of endogenous adenosine to skin fibrosis and the key parts of this pathway, we also looked at individual knockouts of CD39 and CD73.

Finally, we examined the expression of the transcription factor Fli1 (Friend leukemia integration-1), a repressor of key matrix-producing genes, in our mice. Deficiency of Fli1, downregulated in SSc fibroblasts, has been shown to reproduce the fibrotic changes of systemic sclerosis (SSc) in animals.

Results: CD39/CD73KO mice showed lower dermal thickness (0.29$\pm$0.05 vs. 0.36$\pm$0.10mm), skin-fold thickness (0.79$\pm$0.16 vs. 0.97$\pm$0.37mm), tensile strength (198.2$\pm$7.3 vs. 248.7$\pm$7.0g) and hydroxyproline content (21.7$\pm$1.2 vs. 26.5$\pm$1.1μg/mg tissue) (n=6, $p<0.01$ for each) compared to controls after bleomycin treatment; correlating with a decrease in adenosine levels, and associated with a mild increase in Fli-1 immunostaining.

CD73KO mice showed no statistically significant difference in dermal thickness (0.59$\pm$0.26 vs. 0.52$\pm$0.62mm), skin-fold thickness (1.08$\pm$0.06 vs. 1.07$\pm$0.09mm), or tensile strength (270.2$\pm$72.9 vs. 248.0$\pm$38.3g) (n=3, $p>0.05$ for each) compared to controls without bleomycin treatment, with no detectable changes in Fli-1 staining.

Conclusion: This work shows that extracellular adenosine, possibly acting in part through Fli-1, is necessary for the sclerosing effects of bleomycin. Blockade of adenosine or its receptors may be useful in the treatment of diseases such as scleroderma where dermal fibrosis is a prominent manifestation.

Enhanced IL-6 Trans-Signalling in Early dcSSc May Drive Fibrotic Response Via JAK2/STAT3 Signalling Pathways. Korsa Khan[1], Xu Shiwen[2], David J. Abraham[3], Christopher P. Denton[4] and Voon Ong[5]. [1]UCL medical School, London, United Kingdom, [2]Royal Free Hospital, London, United Kingdom, [3]Centre for Rheumatology and Connective Tissue Diseases, UCL Medical School, London, United Kingdom, [4]UCL Medical School, London, United Kingdom, [5]UCL Medical School, London, England

Background/Purpose: We have reported that a subgroup of diffuse cutaneous systemic sclerosis (dcSSc) with elevated serum IL-6 levels is associated with high modified Rodnan skin score (mRSS). In this study, we examine its potential profibrotic effects and downstream signalling pathways in patients with early dcSSc.

Methods: Using skin biopsies obtained from patients with early dcSSc (n=10, mean disease duration, Mean$\pm$SEM: 35$\pm$9.5 months) and healthy controls (n=5), colocalisation of IL-6 with aSMA and phospho-STAT3 were determined with immunohistochemical techniques. The effect of IL-6 trans-signalling on extracellular matrix(ECM) production was assessed on fibroblasts grown by explant culture from skin of SSc patients and healthy controls. Downstream signalling pathways regulated by IL-6 and soluble IL-6 receptor was examined using pharmacological inhibitors. These were stimulated overnight with IL-6 (0–50ng/ml) and sIL-6R (20ng/ml).

Results: There was greater dermal IL-6 expression in patients with early dcSSc compared to healthy controls. IL-6 accumulation was strongly associated with vascular structures and perivascular inflammatory infiltrate in 8/10 patients. Compared to controls, immunostaining for downstream IL-6 signaling molecules showed an increased expression of pSTAT3 in all cases with early dSSc particularly in the perivascular inflammatory foci and vascular structures. Similar co localisation of IL-6 and aSMA was observed in all skin sections with early dcSSc.

To explore the effect of IL-6 trans-signalling on ECM synthesis, incubation of dermal fibroblasts from healthy controls with either IL-6 alone (25–50 ng/ml) or sIL-6R (20ng/ml) alone had no effect on collagen, aSMA and CTGF production. However, there was upregulation of collagen synthesis in normal fibroblasts(34.3$\pm$2.45 vs 9.88$\pm$1.54 Densitometry Image Unit (DIU) controls, $p < 0.05$) in response to IL-6 (25ng/ml) and sIL-6R (20ng/ml). Similar induction of aSMA and CTGF by 12-fold and 15-fold ($p<0.01$) respectively were observed in normal fibroblasts incubated with a combination of IL-6 and sIL-6R. The IL-6 trans-signalling activation of collagen synthesis in normal fibroblasts was abrogated by AG490 (3.6-fold) and S3I-201 (3.5-fold, $p<0.02$), that targets JAK2 and STAT3 signalling pathways respectively.

Time-course analysis indicates that IL-6 trans-signalling induces maximal activation of pJAK2 and pSTAT3 at 45 min and this was diminished by 2 hours in normal fibroblasts. Constitutive activation of both JAK2 and STAT3 pathways was observed in SSc fibroblasts and further activation by the addition of IL-6 and sIL-6R occurred at 15 minutes and this was sustained at 1 hour.

Conclusion: Our results confirm overexpression of IL-6 in dcSSc and demonstrate a potent profibrotic effect of IL-6 trans-signalling via the JAK2/STAT3 pathways. The data also provide rationale that targeting the IL-6 trans-signalling as a potential fibrotic therapy in SSc.

Estimation of Cellular States From SSc Gene Expression Reveals Heterogeneity of Pathway Expression. J. Matthew Mahoney and Michael L. Whitfield. Dartmouth Medical School, Hanover, NH

Background/Purpose: Genome-scale gene expression profiles for SSc and healthy control skin biopsies have identified molecularly distinct subsets of SSc. These subsets have been linked to disease severity and may respond differently to therapy. It is less clear which biochemical pathways are dysregulated to produce the different disease states. Due to the cost and

complexity of perturbative experiments in disease models, bioinformatics approaches in SSc must use inference tools based on "static" gene expression profiles from patient skin biopsies to build hypotheses to test in models. Given the heterogeneity of scleroderma, we hypothesized that multiple canonical pathways would be dysregulated and that meaningful patterns of co-regulation could be statistically identified from gene expression in whole tissue.

Methods: We collected a database of canonical gene pathways comprised of KEGG, BioCarta, and Reactome annotated pathways and analyzed two independent gene expression datasets that analyzed SSc skin. To identify pathways that showed differential regulation, we employed a clustering method called "Pathway-based Clustering" on a publicly available SSc skin microarray data set (Milano et al. 2008 PLoS One) and a second, unpublished dataset. To infer the cellular state corresponding to the identified modes of regulation, we fit Gibbs distributions, which allow for the identification of gene-gene interactions and novel co-regulation, to the expression profiles of the clusters. Components of deregulated pathways in each subset are used to create a network diagram.

Results: Over 100 of the 880 pathways used in this study, including disease implicated pathways like TGFbeta, sphingolipid metabolism and IL10 showed significant differential regulation. Surprisingly, clustering often identified more than two modes of differential regulation. In the TGFb signaling pathway, for example, five distinct modes of regulation were found corresponding to differential regulation of different components of the canonical pathway. Thus, skin tissue in SSc patients shows that parts of canonical pathways are a regulated differently in separate subsets of patients. Furthermore, the fit Gibbs distributions identify putative co-regulation within pathways that is not annotated in the standard pathway diagrams.

Conclusion: Canonical gene pathways show complex modes of regulation in SSc skin tissue with different parts of the pathway regulated differently. The mechanisms behind this regulation are unknown, but the present study has established a framework for future pathway-based studies on gene expression in SSc.

2326

The Melanocortin System: A New and Important Actor on the Scene of Systemic Sclerosis. Grethe N. Andersen[1], Olga Nagaeva[2], Lucia Mincheva-Nilsson[3] and Jarl E.S. Wikberg[4]. [1]Hospital of Vendsyssel/Ålborg University, Hjørring, Denmark, [2]University of Umeå, Umeå, Sweden, [3]University of Umeå, Sweden, [4]Department of Pharmaceutical Pharmacology, Uppsala, Sweden

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrotic destruction of the skin, vascular tree and inner organs. In SSc, the leading edge of the skin lesion is infiltrated by mononuclear cells, causing cytokine network abnormalities with increased levels of tumor necrosis factor alpha (TNFa) and the main inducer of extracellular matrix (ECM) production: transforming growth factor beta (TGFb). Due to evidence of several abnormalities in TGFb signalling, the CAT-192 study, in which patients with diffuse (d)SSc of recent onset, were treated with recombinant antibodies against human TGFb1, was initiated. As the melanocortin system plays a significant role in the regulation of TGFb and TNFa synthesis, we examined the content of messenger (m)RNA for the melanocortin receptor subtypes: MC1, 2, 3 and 5 and for the precursor protein pro-opio-melanocortin (POMC) for their natural agonist ligands (the melanocyte stimulating hormones (MSHs) and adrenocorticotroin (ACTH) in skin biopsies from the leading edge of the skin lesion in a patient with dSSc, before and after treatment with recombinant human anti-TGFb monoclonal antibodies (mAbs) as well as in skin biopsies from 3 healthy controls.

Methods: Skin biopsies, 4 mm in diameter, were achieved from the upper arm and the leading edge of the skin lesion in a recent onset dSSc patient, who participated in the CAT-192 study, before and after treatment with recombinant human anti-TGFb1 mAbs and from 3 healthy controls. The biopsies were minced, RNA extracted and examined for content of TNFa-, TGFb-, MC1-, 2-, 3-, 5- and POMC mRNA by means of quantitative real-time reverse transcription polymerase chain reaction (qRT-PCR).

Results: In the biopsy taken from the leading edge of the skin lesion pre-treatment TNFa and TGFb levels were 4 times higher than in healthy controls, the POMC mRNA levels was similar to that found in controls. The MC1 mRNA level was slightly lower than in controls, while the MC2 and MC3 mRNA levels were immeasurable and the MC5 mRNA level low. In the biopsy taken post anti-TGFb mAbs treatment, TNFa and TGFb levels were normal. The most amazing finding was, however, an enormous rise in MC2 and MC3 mRNA levels, while MC5 mRNA increased 20-fold, POMC mRNA was considerably higher than in the pre-treatment biopsy.

Conclusion: Our results point at the suppression of the melanocortin system in the leading edge of the dSSc skin lesion, including suppressed expression of mRNA for the MC subtypes: 1, 2, 3 and 5 as well as of POMC mRNA. Treatment with anti-TGFb mAbs resulted in an exceptionally large increase in mRNAs for POMC, MC1, 2, 3, 5, probably a rebound effect, as TGFb is known to suppress POMC synthesis.

Melanocortin receptors are Gs-protein coupled and their activation results in a rise in intracellular cAMP, which in turn may inhibit the production of connective tissue growth factor (CTGF), a cytokine mandatory to TGFb stimulated ECM synthesis. Thus we hypothesize that the downregulation of the melanocortin system by TGFb, may further promote ECM synthesis in SSc and that the hyperpigmentation seen in SSc may be due to rebound effects in the melanocortin system in skin lesions of longer standing and decreasing TGFb concentrations.

2327

Identification of a Gene Expression Signature in Limited Cutaneous Systemic Sclerosis That Includes Several Vascular Genetic Factors. Cecilia B. Chighizola[1], Pia Moinzadeh[2], Korsa Khan[3], Tammara A. Wood[4], Pier Luigi Meroni[5], David J. Abraham[6], Michael L. Whitfield[4], Voon Ong[7] and Christopher P. Denton[3]. [1]University Of Milan, Milan, Italy, [2]Royal Free Hospital, Medical School, London, United Kingdom, [3]UCL Medical School, London, United Kingdom, [4]Dartmouth Medical School, Hanover, NH, [5]University of Milan, Milan, Italy, [6]Centre for Rheumatology and Connective Tissue Diseases, UCL Medical School, London, United Kingdom, [7]UCL Medical School, London, England

Background/Purpose: Systemic sclerosis (SSc, scleroderma) has a heterogeneous clinical presentation, unpredictable outcome and incompletely understood pathogenesis. Skin changes are the hallmark of SSc: vascular dysfunction, tissue fibrosis and immune dysregulation are key events.

Gene-expression profiling is a powerful tool not only to distinguish between scleroderma and normal skin, but also to detect different subsets. Moreover, analysis of genome wide mRNA signatures could provide further insights into pathogenesis and help identifying biomarkers to predict pattern of organ involvement and drug response. To complement several published studies have focused mainly on diffuse subset of SSc, we performed gene expression profiling in skin samples from patients with limited cutaneous SSc (lcSSc).

Methods: 4 mm skin punch biopsies were performed in 10 patients with lcSSc and 5 healthy controls. Total RNA was extracted from whole skin biopsy. Gene expression profiling was performed on a 44,000 element DNA oligonucleotide microarrays (Agilent Technologies). Each sample was analyzed in duplicates for a total of 30 microarray hybridizations. Probes missing more than 20% of data were excluded. Data were processed to display the changes in gene expression as the Lowess normalized $\log_2$ of the ratio of the intensity relative to its average. Spots with intensity 1.5 fold over background were selected. Each probe was centred on its median value across all arrays. 3578 genes whose expression varied from median value by 2-fold in at least two experiments were identified and analyzed by heuristic clustering. Wilcoxon test was used to select genes with a significant differential expression between lcSSc and control samples. Correction for multiple testing was applied. Our gene expression findings were validated by qRTPCR on 10 representative genes in independent biological replicate samples.

Results: All samples from affected individuals but one clustered onto one branch in the resulting dendogram. 469 probes with a false discovery rate $<$ 0.1% were selected. Among these, we identified potential pathogenic mediators whose relevance in SSc pathogenesis has already been investigated (Table 1).

In particular, a "vascular signature" emerged across lcSSc samples (in italics). This is consistent with both clinical manifestations and scientific reports, supporting a prominent vascular involvement in lcSSc. See **Table 1** for representative genes that were significantly differentially expressed.

Table 1.

Pathogenic Mediators Mean (SD) for scaled normalised expression of biological replicates with corrected p-value and mean fold change	p-value	Mean (SD) lcSSc (n=10)	Mean (SD) Control (n=5)	Mean fold change lcSSc/control
Pre-B-cell colony enhancing factor 1	0,0022	0,476 (0,809)	−0,982(0,438)	2.5
Cell adhesion molecule with homology to L1CAM	0,0022	0,255 (0,415)	−0,816 (0,369)	2.3
Periostin	0,0022	0,382 (0,570)	−1,448 (0,415)	2.3
Endothelin receptor type B	0,0033	0,136 (0,440)	−1,358 (0,469)	2.2
IL-8	0,012	0,151 (0,324)	−0,690 (0,558)	2.2
Interleukin 1 receptor, type I	0,01	0,273 (0,521)	−0,528 (0,438)	2.5
Intimal thickness-related receptor	0,0142	0,148 (0,506)	−0,754 (0,594)	2.2
Heat shock 105kDa/110kDa protein 1	0,0022	0,467 (0,528)	−0,502 (0,219)	2.9
Membrane metallo-endopeptidase CD10	0,0069	0,256 (0,400)	−0,608 (0,527)	2.3
Cadherin 19, type 2	0,0101	0,015 (0,603)	−1,290 (0,659)	2.0
Integrin, beta 8	0,0232	−0,059 (0,876)	−1,130 (0,873)	1.9
Intracellular signalling pathways				
Zinc finger protein 354A	0,0071	0,172 (0,361)	−0,620 (0,446)	2.3
PTEN	0,02	0,350 (0,516)	−0,456 (0,578)	2.8
Autoantigens				
Centromere protein F, 350/400ka (mitosin)	0,0143	0,344 (0,497)	−0,546 (0,424)	2.6
Sjogren syndrome antigen B (autoantigen La)	0,0197	−0,181 (0.702)	−1,372 (0,626)	1.9
Sjogren syndrome antigen A2 (60kDa)	0,0273	0,007 (0,572)	−0,642 (0,706)	2.0

Conclusion: Gene expression profiling of skin biopsies clearly differentiates lcSSc samples from healthy controls. Consistently with both clinical manifestations and previous scientific reports, we found a proangiogenic profile across lcSSc samples. These studies will inform biomarker discovery and studies of pathogenic mechanisms that may be especially relevant to vascular complications of SSc.

2328

A Novel Automated Longitudinal In Vivo Assessment of Bleomycin Induced Pulmonary Fibrosis in Mice Using In Vivo High Resolution Micro-Computed Tomography. Ellen De Langhe[1], Greetje Vande Velde[1], Jeroen Hostens[2], Frank P. Luyten[1], Ben Nemery[1], Uwe Himmelreich[1], Jeroen Vanoirbeek[1] and Rik Lories[1]. [1]KU Leuven, Leuven, Belgium, [2]Skyscan

Background/Purpose: In vivo high resolution μCT imaging in animal models of lung disease allows longitudinal observations of pathological processes and image-based measurements of functional parameters. Current μCT image based algorithms for fibrosis quantification are characterized by lower spatial resolutions, insufficient correlation to histopathological or physiological data, and are labor intensive.

Methods: Lung fibrosis was induced in 8-week old male C57/Bl6 mice, by intratracheal instillation of 0.05U bleomycin (BLM) or control phosphate buffered saline (PBS). Mice were treated daily with imatinib (50mg/kg/d via daily i.p. injection) or vehicle control (AD). A 'scanning only' group evaluated scan toxicity (all n=6). Freely breathing, isoflurane sedated mice were scanned weekly at 35 μm resolution (SkyScan® in-vivo μCT) with retrospective respiratory gating. 4 weeks after induction, invasive pulmonary function tests were performed (Flexivent® SCIREC). Tracheotomised mice were euthanized and lungs were scanned for pressure-volume loop construction, by externally applying decreasing pressures (30-0 cmH_2O). A fully automated algorithm calculated aerated lung volumes and densities. Lungs were collected for histopathological scoring (Ashcroft score). The hydroxyproline assay quantified total collagen content.

Results: Serial scanning caused no abnormalities. Imatinib attenuated fibrosis by 30%, based on Ashcroft score and lung compliance. Untreated BLM-challenged lungs had significantly lower aerated lung volumes, calculated upon μCT images, reflecting restrictive pulmonary disease. Imatinib-treated BLM-challenged animals had lung volumes intermediate between untreated BLM challenged and the control groups. Calculated lung volumes correlated to Ashcroft score and hydroxyproline content. Constructed pressure-volume loops agree with invasive pulmonary function tests. Plotted mean density histograms discriminate between our 5 experimental groups and show the dynamic progression of fibrosis in the longitudinal setup. The reconstructed 3- and 4D images provide critical information on topographical distribution of fibrosis.

Conclusion: We present a fully automated in vivo μCT fibrosis analysis protocol, resulting in quantitative measurement of pulmonary volumes in the bleomycin induced pulmonary fibrosis model. We show that the resulting volumes correlate with histopathological scores, total collagen contents and invasive pulmonary function tests. We demonstrate that this imaging technique and consecutive automated analysis is suitable for serial imaging of individual animals and is sensitive enough to detect modest treatment effects.

Gene-Gene Interactions In Interferon Pathway Gene-Mutations In European and American Scleroderma Cohorts. Pravitt R. Gourh[1], Filemon K. Tan[2], Blanca Rueda[3], Frank C. Arnett[2], Shervin Assassi[2], John D. Reveille[2], Timothy RD Radstake[4], Maureen D. Mayes[2], Javier Martin[5] and Sandeep K. Agarwal[2]. [1]UTHSC-Houston Medical School, Houston, TX, [2]University of Texas Health Science Center at Houston, Houston, TX, [3]Facultad de Ciencias de la Salud. Universidad de Granada, Granada, Spain, [4]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [5]Instituto de Parasitologia y Biomedicina Lopez-Neyra (CSIC), Granada, Spain

Background/Purpose: Tpe-I interferon(IFN), a central mediator of innate immunity, has been shown to be the hallmark peripheral blood gene expression pattern in lupus(SLE) and a similar type-I IFN signature has been noted in systemic sclerosis(SSc). Interferon regulatory factor 5 and 7(*IRF5/IRF7*) and tyrosine kinase 2(TYK2) are important genes involved in this signaling cascade. The purpose of this work was to investigate the association of *IRF5, IRF7, TYK2* polymorphisms with SSc.

Methods: We performed SNP genotyping for *IRF5(rs20024640), IRF7(*rs1061502*), TYK2*(rs2304256) genes using the Taqman Assay in 4 large cohorts comprising of North-American Caucasian, Dutch, Italian and Spanish samples totaling to 2,091 SSc patients and 1,434 race-matched controls. All SSc patients fulfilled ACR criteria or had at least 3 of the 5 CREST features. HWE testing, chi-square, logistic regression(LR) were used for statistical comparisons. Mesoscale assays were used for cytokine detection.

Results: After HWE verification, all 3 SNPs showed association with SSc in US Cohort with recessive pattern in IRF5 and a dominant pattern in IRF7 and TYK2. By LR analysis after controlling for gender and cohorts the association was confirmed in all cohorts{IRF5:P<0.0001,OR(CI)-0.68(0.6–0.8);IRF7:P=0.006,OR(CI)−0.80(0.7–0.9);TYK2: P=0.05,OR(CI)−0.85 (0.7–0.99)}. The association was stronger with anti-centromere subset{IRF5: P=0.0002,OR(CI)−0.59(0.5–0.8);IRF7:P=0.0008,OR(CI)−0.69(0.6–0.9); TYK2:P=0.04,OR(CI)−0.79(0.6–0.9)}.

The data was modeled based on mode of inheritance for the 3 SNPs and LR analysis performed controlling for gender and cohorts and revealed an extremely protective effect for the combination of mutations vs the wildtype{$IRF5^M$/$IRF7^M$,$TYK2^M$ vs $IRF5^{WT}$/$IRF7^{WT}$,$TYK2^{WT}$:P<0.0001; OR(CI)−0.39(0.3–0.6)}.

In the $IRF5^{WT}$/$IRF7^{WT}$,$TYK2^{WT}$group, the SSc patients had increased levels of TNF-α and IL-6 as compared to controls and there was no difference amongst the patients and controls in the $IRF5^M$/$IRF7^M$,$TYK2^M$ group.

Conclusion: Our data confirms the association of *IRF5* SNP with SSc and also demonstrates for the first time the association of IRF7 and TYK2 SNPs with SSc.

We demonstrate a gene-gene interaction in SSc between three non-linked loci- *IRF5, IRF7* and *TYK2*.

The 3 gene-SNPs have a protective effect in SSc patients and the presence of the 3 mutations simultaneously has the most protective effect. This effect is stronger in the anti-centromere subset of SSc patients.

Plasma TNF-α and IL-6 levels were increased in the SSc patients wildtype for the 3 SNPs vs controls, whereas there was no difference in TNF-α and IL-6 levels in the SSc patients having mutations for the 3 SNPs vs controls.

In summary, IRF5,IRF7,TYK2 SNPs have a protective effect in SSc which is stronger when there are polymorphisms on all of the genes as compared to each of them alone. The presence of these 3 polymorphisms simultaneously correspond to a lower level of proinflammatory cytokine production as compared to wildtype.

This suggests an important role of interferon pathway polymorphisms in susceptibility to SSc and the exact role of these interactions and their function in SSc susceptibility needs to be elucidated experimentally.

Human Leukocyte Antigen Alleles in Juvenile Onset Systemic Sclerosis. Anne M. Stevens[1], Maureen D. Mayes[2], John D. Reveille[2], Gretchen R. Henstorf[3] and J. Lee Nelson[4]. [1]University of Washington, Seattle, WA, [2]University of Texas Health Science Center at Houston, Houston, TX, [3]Seattle Children's Research Institute, Seattle, WA, [4]Fred Hutchinson Cancer Rsch, Seattle, WA

Background/Purpose: Systemic sclerosis (SSc) is rare in children and little is known about factors contributing to its pathogenesis in this population.

HLA class II allele associations have been reported for adult onset SSc. We evaluated HLA class II alleles in patients with juvenile onset SSc and families.

Methods: 50 children with juvenile onset systemic sclerosis were studied. HLA genotyping was conducted to high resolution for HLA-DRB1, DQA1 and DQB1. Demographic and clinical characteristics were summarized including race/ethnicity, sex, age at onset, whether disease was diffuse or limited and antibodies to topoisomerase 1 and centromere.

Results: Among the 50 children 41 were Caucasian, 4 African American, 1 Asian, 1 Native American, 2 other and 1 unknown. One child was a triplet. For analysis 40 singleton, Caucasian, juvenile SSc patients were compared to 109 similar healthy children. 85% of patients were female (34/40). The mean age of onset was 10.4 years (range 2.3–15.9). 23 patients had diffuse and 17 limited SSc. 32% had antibodies to topoisomerase 1 (13/40) and 10% to centromere (3/30 tested). HLA-DRB1*03 was present in 52% of diffuse SSc (12/23) compared to 20% of normals (22/109), odds ratio 4.3 p=0.003. DRB1*03 was not increased in limited SSc (29% 5/17). HLA-DRB1*11 was somewhat overrepresented in limited SSc (35% 6/17) compared to normals (19% 21/109), but this was not significant (not increased in diffuse SSc). There was no suggestion of increased HLA-DRB1 compatibility of children and their mothers (66% 23/35 were bi-directionally mismatched).

Conclusion: HLA-DRB1*03 was significantly increased in juvenile onset diffuse SSc in Caucasian patients compared to age similar healthy children. This result is dissimilar to adult Caucasian women where the primary association reported has been with HLA-DRB1*11. HLA-DRB1 sharing was not increased in mother-child pairs.

Methylprednisolone Modulates MicroRNA and Gene Expression in Human CD4$^+$ T Cells: A Novel Mechanism of Anti-Inflammatory Action. Trevor E. Davis[1], Katalin Kis-Toth[2], Attila Szanto[3], Laurie C. Miller[4] and George C. Tsokos[5]. [1]Floating Hospital for Children at Tufts Medical Center; Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center, Boston, MA, [3]Harvard Medical School; Massachusetts General Hospital, Boston, MA, [4]Tufts Medical Center, Boston, MA, [5]Beth Israel Deaconess Medical Center; Harvard Medical School, Boston, MA

Background/Purpose: MicroRNAs (miRNAs) are short RNA species (20–23 nt) that act post-transcriptionally to regulate messenger RNA (mRNA) translation or stability. They influence many biological processes such as immune system development and function. Abnormal levels of miRNAs have been implicated in cancers and autoimmune diseases such as rheumatoid arthritis and systemic lupus erythematosus. Steroids are "first line" anti-inflammatory medications that act through gene regulation both transcriptionally and post-transcriptionally. In many instances, steroids cause mRNA destabilization, indicating a potential role for miRNAs.

Methods: Naive CD4$^+$ T cells were isolated from peripheral blood of healthy donors using negative selection. Cells were activated by anti-CD3/anti-CD28 antibodies for 24h with or without 10^{-6} M methlyprednisolone treatment. Supernatants were collected for cytokine measurements by ELISA. A portion of cells was used for flow cytometric analysis and the remainder used for RNA or protein isolation. RNAs were simultaneously tested on miRNA and mRNA microarrays using the Wafergen system. Result ant Ct values were converted to relative copy numbers and normalized to housekeeping genes RNU44 (miRNAs) and B2M (mRNAs). These normalized values were compared between the untreated and treated groups. Genes with at least 2-fold expressional changes between groups were selected for further investigation. Potential targets for these selected miRNAs were obtained from the bioinformatic resource Targetscan. The potential targets were cross-referenced with the mRNAs selected from the mRNA array and subjected to further analysis. Individual qPCR assays were used to verify the treatment effects on selected miRNAs and mRNAs.

Results: We identified 12 miRNAs decreased by steroid treatment (miRNA 17, 25, 27b, 101, 133A, 155, 299-5P, 300, 496, 548K, 646, and 1244) with simultaneous increase of 52 predicted mRNA targets (e.g. APAF1, ARID4A, ATRX, BCL-2, BMPR2, BNIP3L, CCNG1 and 2, CD28, DUSP1, MNT, RB1CC1, SOCS1, TOB1). We identified 8 miRNAs increased by steroid treatment (miRNA 98, 181b-1, 514, 543, 590-5P, 758, 1207-5P, 1243) with simultaneous decrease of 20 predicted mRNA targets (e.g. ARHGAP31, BAG4, CASP-3, CCND2, FAS, IL-1A, SARM1, SMAD7, TNF, TNFRSF1B, UHRF1). Other notable mRNAs decreased by steroid treatment, although not targeted by identified miRNAs, were BCL2A1, CCND3, CCNE1, CDC6, CDK10, CDK4, IL12RB2, IL2, IL2RA, IRF1, LTA, MNAT1, NFKB2, RELA, TIRAP, TNFRSF1B, TRAF2, and TRAF4. Notable mRNAs that increased by steroid treatment, though not targeted by identified miRNAs, were ATM, CARD8, CASP-8, MAF, and SMAD3.

Conclusion: Using simultaneous high throughput analyses of both miRNA and mRNA combined with bioinformatic miRNA target prediction, we identified a group of miRNAs altered by methylprednisolone treatment in activated CD4$^+$ T cells with potential regulation of their target genes. These targets have been implicated in T cell activation, proliferation and homeostasis. Based on these findings, methylprednisolone may act via these miRNAs to regulate T cells, a novel mechanism to impart anti-inflammatory effects.

Deficient Thymic T Lymphopoeisis in Rheumatoid Arthritis Is Not Due to the Lack of CD34+ Lymphoid progenitors. Manuela Rossol[1], Anett Schulz[1], Annika Schatz[2], Undine Meusch[2], Dagmar Quandt[2], Christoph G. Baerwald[3] and Ulf Wagner[3]. [1]Translationszentrum für Regenerative Medizin (TRM), University of Leipzig, Leipzig, Germany, [2]University of Leipzig, Leipzig, Germany, [3]University Hospital, Leipzig, Germany

Background/Purpose: An important role for CD4+ T cells in the pathogenesis of rheumatoid arthritis (RA) is implicated by the HLA-DRB1*04 association of the disease, by the massive T cell infiltration in the rheumatoid synovium, and by the success of T cell directed therapies. Several lines of evidence show, that the T cell compartment of patients with RA is characterized by premature immunosenescence and a disturbed homeostasis. Aim of the study was to analyze if the reduced frequency of naïve CD4+ T cells in the peripheral blood of RA patients is due to a reduced bone marrow output of CD34+ haematopoietic stem cells and lymphoid progenitors.

Methods: Mononuclear cells of the peripheral blood of 28 RA patients (median age 63.1 years) and 28 age-matched healthy controls (median age 63.4 years) were analyzed by flow cytometry. RA patients were all ACPA+ and RF+, and 50% were SE-DR4+.

Results: The frequency of CD34+ haematopoietic stem cells as well as the frequency of lineage-negative CD34+ cells in the peripheral blood of RA patients is not different from healthy controls (0.09% vs. 0.08% and 0.007% vs. 0.006%).

The frequency of the pre-thymic lymphoid progenitor characterized by CD34+/Lin-/CD24-/CD10+ is increased in patients with RA compared to healthy controls (16 cells per 1E07 PBMC vs. 9 cells per 1E07 PBMC, p=0.01). However, the thymic output, characterized by the frequency of recent thymic emmigrants (CD4+/CD45Ra+/CD31+) is decreased in RA patients (32.0% vs. 43.9%, p=0.007).

Conclusion: The frequency of the CD34+/Lin-/CD24-/CD10+ lymphoid progenitor is increased in RA compared to healthy controls, while the thymic output of CD31+ recent thymic emigrants is reduced. We hypothesize, therefore, that insufficient thymic T cell genesis is the underlying cause of the disturbed T cell homeostasis in this disease, and might also contribute to the pathogenesis of the disease.

Synovial Fluid Vγ9Vδ2 T Cells Activated by Synovial Fibroblasts Induce Their Apoptosis. Anna Bendersky[1], Victoria Marcu[1], Yackov Berkun[2], Itamar Goldstein[1], Maya Gerstein[1], Shay Padeh[1] and Ilan Bank[1]. [1]Sheba Medical Center, Ramat Gan, Israel, [2]Hadassah Hebrew University Medical Center, Jerusalem, Israel

Background/Purpose: Recent data suggest that higher levels and proliferative responses of synovial fluid (SF) Vγ9+ T cells to a metabolite in the mevalonate pathway critical for survival of synovial fibroblasts (synfib), isopentenyl pyrophosphate (IPP), are positive prognostic indicators in juvenile idiopathic arthritis (JIA) (Berkun et al., J. Rheumatol 2011, 38:6, 1123). We designed experiments to define the functional role of SF Vγ9+ T cells in JIA.

Methods: Twenty JIA patients undergoing therapeutic arthrocentesis were studied. Mononuclear cells (MC) were isolated from the SF and PB by ficoll- hypaque density centrifugation. Plastic adherent cells from SF were cultured giving rise to CD90+CD14- synfib cell lines. MC were analyzed by flow cytometry after cell surface membrane staining with fluorescent dye

labeled specific monoclonal antibodies (mAb) to identify T cell subsets. Proliferation was assessed by flow cytometric analysis of 5,6-carboxyfluorescein diacetate succinimidyl ester (CFSE) labeled MC. Apoptosis was measured by annexin V staining of CFSE labeled fibroblasts after 48 hour culture alone, with IPP (2ug/ml) or with zoledronate (4uM). Cytokines were assayed by intracellular immuno-staining of freshly isolated or briefly cultured MC activated with phorbol myristate acetate (PMA) and ionomycin with or without added IPP, followed by flow cytometric analysis after staining of the cells with subset specific mAb.

Results: Equally high percentages (~35%) of PMA+ionomycin activated Vγ9+ T cells in SF and peripheral blood monuclear cells (PBMC) produced TNFα and IFNγ and a few (~1–3%) secreted IL-17. Stimulation with IPP, which is a potent auto-antigen for Vγ9J1.2+ T cells further equally amplified cytokine secretion among the SF and PBMC Vγ9+ T cells. However, only the SF Vγ9+ T cell subset expressed high levels of CD69 *in situ* suggesting its recent activation by synovial auto-antigens. Moreover, 24 hour co-culture of freshly isolated MC, with cultured synfib, but not with skin derived fibroblasts, enhanced CD69 on the SF but not the PB Vγ9+ T cells, which was further potentiated by zoledronate, a farnesyl pyrophosphate synthase inhibitor that increases endogeneous intracellular levels of IPP. Vγ9+ T cell proliferation in response to IPP, which was significantly lower in SF than PBMC cultures, was enhanced by depleting SF CD4+CD25+ FoxP3+ cells (Treg), but, importantly, both SF and PB Vγ9+ T cells proliferating in response to IPP induced apoptosis of co-cultured synfib in the presence of zoledronate or IPP, in a Vγ9+ T cell dose dependent manner.

Conclusion: Synfib induce activation of SF Vγ9+ T cells specifically and serve as auto-antigen (IPP)-presenting cells for cytokine secreting SF Vγ9+ T whose IPP driven proliferation is partly controlled by SF Treg. These activated Vγ9+ T cells induce apoptosis of synfib conditioned to express high levels of the IPP auto-antigen, suggesting they may play a critical role in controlling the proliferation of certain fibroblasts in the synovium.

Defining Pathogenicity of Human Th17 Cells in Rheumatoid Arthritis. Hiroshi Kato[1], Judith Endres[1] and David A. Fox[2]. [1]University of Michigan, Ann Arbor, MI, [2]Univ of Michigan Med Ctr, Ann Arbor, MI

Background/Purpose: Th17 cells, while crucial in host defense, may also play central causative roles in many autoimmune diseases including RA. Although our knowledge concerning murine Th17 cells, especially the mechanisms of their differentiation, has rapidly expanded, the pathogenic functions of human Th17 cells as well as immune-regulatory factors reversing such pathogenicity have not been fully defined. We assessed induction of cell-cell interaction molecules on fibroblast-like synoviocytes (FLS) by human CD4 T cell subsets as well as roles of IL-4 in regulating pathogenic features of human Th17 cells.

Methods: CD4 T cells isolated from healthy adult donors were cultured in RPMI culture media with 10%FCS, 1% Penicillin/Streptomycin, and 2% L-glutamine for 5 days either in the presence of plate bound anti-CD3, soluble anti-CD28, anti-IL-4, and IL-12 to induce Th1 cells, or autologous mature dendritic cells, soluble anti-CD3, anti-IFN-γ/IL-4/TGF-β, IL-1, IL-6, and IL-23 to induce Th17 cells. Th1 or Th17 cells were co-cultured with passage 4–8 FLS for 48 hours with/without neutralization of IFN-γ, IL-17, or both. Alternatively, FLS were treated only with IFN-γ or IL-17 for 48 hours. Expression of MHC-II, CD40, and CD54 on the FLS were assessed by surface staining followed by flow cytometry analysis. In a separate experiment, CD4 T cells were stimulated under Th17 polarizing conditions for 3 rounds interspersed with 2 days rest. After each round of stimulation, a part of Th17 cells was stimulated under Th2 polarizing conditions: plate bound anti-CD3, soluble anti-CD28, anti-IFN-γ, and IL-4. In all the experiments, T cell phenotypes were assessed by measurement of IFN-γ or IL-17 in culture supernatants by ELISA or intracellular staining of IL-17 versus IFN-γ/IL-4 followed by flow cytometry analysis.

Results: FLS significantly up-regulated MHC class II, CD40, and CD54 upon co-culture with Th1 or Th17 cells. Th1 cells, which secreted significantly higher amount of IFN-γ than Th17 cells, were more potent in up-regulating these molecules. During the co-culture of Th17 cells and FLS, neutralization of IFN-γ significantly abrogated FLS expression of MHC class II, CD40, and CD54 while neutralization of IL-17 did not inhibit and in some experiments augmented FLS expression of MHC class II, CD40, and CD54. Treatment with IFN-γ significantly up-regulated FLS expression of MHC class II, CD40, and CD54. Treatment with IL-17 at higher than 10ng/ml, which was comparable to what was secreted by Th17 cells, significantly decreased FLS expression of CD40 and CD54. *In vitro* induced human Th17 cells lost both IFN-γ and IL-17 expression upon exposure to IL-4, even after two rounds of Th17 polarization.

Conclusion: These data suggest that IFN-γ but not IL-17 is more contributory to human Th17 cell pathogenic function in the induction of relevant surface molecules on FLS, and that neutralization of IL-17 might be detrimental depending on the context. Given that IL-4 suppresses human Th17 cell differentiation as well as both IFN-γ and IL-17 synthesis by human Th17 cells, even after multiple rounds of Th17 polarization, IL-4 could serve as a potent immune-regulatory cytokine in Th17-driven autoimmune disease.

2335

T Cell Receptor Signal Strength Controls Onset and Severity of Arthritis in Antigen (Proteoglycan Epitope)-Specific T Cell Receptor Transgenic Mice. Katalin Olasz[1], Ferenc Boldizsar[1], Katalin Kis-Toth[2], Oktavia Tarjanyi[1], Akos Hegyi[3], Willem van Eden[4], Tibor A. Rauch[3], Katalin Mikecz[3] and Tibor T. Glant[3]. [1]Pecs, Hungary, [2]Boston, MA, [3]Rush University Medical Center, Chicago, IL, [4]Utrecht, Netherlands

Background/Purpose: T cell receptor transgenic (TCR-Tg) mice specific for the most arthritogenic 5/4E8 epitope of the G1 domain of cartilage proteoglycan (PG) were generated and backcrossed into arthritis-prone BALB/c background. Although over 90% of $CD4^+$T cells of all TCR-Tg lines "uniformly" expressed Vβ4 chain, some of the transgenic lines (e.g., TCR-Tg"A") proved to be highly sensitive to, and spontaneously developed, arthritis, while others were less susceptible (e.g., TCR-Tg"B"). The goal of this study was to understand how a single (monoclonal) TCR signaling can control the onset and severity of arthritis, and what level of T cell signaling is required for arthritis onset and severity.

Methods: TCR-TgA, TCR-TgB and wild-type (WT) BALB/c mice were immunized with recombinant human G1 domain on days 0, 21 and 42. Animals were sacrificed (i) before the immunization, (ii) 10 days after the 1st injection, (iii-iv) 4 days before the 2nd and 3rd, and (v-vi) 5 days after the 2nd and 3rd immunizations (n=4 in each group). Serum cytokines and auto-antibodies (Abs), antigen-specific *in vitro* T cell responses were measured. T and B cell markers (including activation, costimulatory, FoxP3, and apoptotic markers) and phosphorylation levels of ZAP-70, ERK1/2 and p38 in spleen and joint-draining lymph node (LN) cells were compared by flow cytometry. The cell surface expression and copy number of Vβ4 and Vα1.1 chains of 5/4E8 epitope-specific TCR were determined.

Results: TCR-TgA mice developed a more severe arthritis earlier than WT or TCR-TgB mice. AutoAbs to mouse G1 domain, APCAs or RFs were significantly higher (3–5-fold differences) in TCR-TgA than in TCR-TgB mice. This more pronounced Ab secretion in TCR-TgA mice was associated with a higher B cell percentage compared to that in TCR-TgB mice during the whole immunization period in the joint draining LNs or the spleen. Among the intracellular and cell surface markers, the $CD4^+$ $ICOS^{High}$ increased continuously in TCR-TgA (and arthritic) mice. However, the $CD4^+CD25^+FoxP3^+$ cell ratio was also significantly higher in TCR-TgA than either WT or TCR-TgB mice indicating that regulatory T cells (Tregs) play a dispensable role in regulating autoimmune processes in this model of RA. In contrast, $CD4^+$ T cells of TCR-TgB mice expressed twice as much TCR and CD3 molecules than the $CD4^+$ T cells in TCR-TgA line, and, upon stimulation, these T cells expressed significantly higher sensitivity to antigen-specific apoptosis. Indeed, when TCR-TgB $CD4^+$ T cells were engaged with the 5/4E8 peptide, significantly higher levels of phosphorylation of the key downstream signaling molecules were detected than in TCR-TgA T cells.

Conclusion: A strong arthritogenic (5/4E8) epitope-specific TCR-initiated signal in PG-TCR-TgA mice led to optimal T-cell activation and generated a "super-arthritic" phenotype. In contrast, an extremely "strong" TCR signal, likely due to higher TCR expression, led to *in vivo* T cell apoptosis and diminished arthritis in TCR-TgB mice. Theoretically, only the "optimal" T cell signaling (even triggered by multiple arthritogenic epitopes) can create the optimal milieu for autoimmunity and RA.

2336

Short Combination Therapy with Anti-CD3 and Anti-TNF Is Associated with Long Term Inhibition of Established Collagen-Induced Arthritis. Fabien Depis[1], Eric Hatterer[1], Céline Lamacchia[2], Cem Gabay[2], Jean-Marc Waldburger[2], Walter Reith[3], Marie Kosco-Vilbois[1] and Yann Dean[1]. [1]Nov Immune S.A., Plan-Les-Ouates, Geneva, Switzerland, [2]University Hospitals of Geneva, Geneva, Switzerland, [3]University of Geneva Medical School, Geneva, Switzerland

Background/Purpose: NovImmune has developed a fully human anti-CD3 monoclonal antibody (mAb), NI-0401, that is in clinical development and for which a subcutaneous formulation is available. In patients, NI-0401 modulates T cell responses and modifies T cell subsets. A plethora of data demonstrates that in addition to components of innate immunity, e.g. TNF, adaptive immunity involving T cells is implicated in the pathogenesis of autoimmune diseases such as rheumatoid arthritis (RA). In preclinical models of RA, as well as in RA patients, T cell infiltration and high levels of TNF are observed in affected joints. The objective of this study was to determine the effect of anti-CD3 therapy in mouse collagen induced arthritis (CIA), either alone or in combination, with a TNF neutralization strategy.

Methods: Anti-mouse mAbs V1q-Novi and 2C11-Novi were developed to act as surrogate reagents for their therapeutic counterparts Humira (anti-TNF) and NI-0401 (anti-CD3), respectively. CIA was induced in DBA/1 mice. The mAbs were administered intraperitoneally at onset of arthritis as follows: daily injections of 50 micrograms of 2C11-Novi for five consecutive days and a single administration of 100 micrograms of V1q-Novi.

Results: Targeting T cells with a short course of 2C11-Novi did not significantly modify disease severity in arthritic mice. In contrast, the single dose of the neutralizing anti-mouse TNF mAb (V1q-Novi) significantly inhibited disease progression only up to 10 days. Strikingly, the combination of the two mAbs demonstrated a potent synergy with increased duration of action, as assessed by clinical scores, up to 3 weeks beyond that observed with the anti-TNF therapy alone. The frequency and number of pathogenic and regulatory CD4+ T cell subsets in the draining lymph nodes were determined in order to investigate the cellular mechanisms of combination therapy. The results did not demonstrate any enhancement of CD25+Foxp3+ regulatory T cells but a significant reduction in pathogenic T effector cells (Th1 and Th17 specific for type II collagen).

Conclusion: Our data show that a short course therapy with anti-CD3 and anti-TNF antibodies inhibits the progression of established CIA by targeting collagen-specific Th1 and Th17 cells in relevant lymphoid tissues. This combination strategy could be employed in patients with RA using NI-0401 via a convenient subcutaneous administration.

Antigen-Specific Regulatory Tr1 Lymphocytes As New Cell-Therapy Approach for Immunotherapy in Arthritis. Delphine Martire[1], Julie Quentin[1], Anne-Laure Mausset-Bonnefont[1], Helène Asgnali[2], Nathalie Belmonte[2], Arnaud Foussat[2], Christian Jorgensen[3] and Pascale Louis-Plence[1]. [1]Inserm U844, Montpellier, France, [2]TxCell, Valbonne-Sophia Antipolis, France, [3]CHU Lapeyronie, Montpellier, France

Background/Purpose: Tr1 cells have been characterized as induced T regulatory lymphocytes (Treg) inhibiting inflammation in various chronic inflammatory models. Based on these data, a Phase I/II clinical trial is currently under investigation in Crohn's disease (TxCell). However, the therapeutic potential of these cells has not yet been evaluated in rheumatoid arthritis. In this study, we investigated the therapeutic potential of bovine type II collagen-(bCII) specific Tr1 cells, isolated from TBC mice, in the experimental model of collagen-induced arthritis (CIA).

Methods: Collagen type II specific Tr1 clones were obtained from TCR transgenic mice and expanded in vitro. Selected clones showed in vitro antigen specificity, Tr1 cytokine profile ($IL10^{high}/IL4^{neg}$) and IL10- and TGFb-dependent suppressive activity. Male DBA/1 mice were immunized with bovine type II collagen (bCII) and 10×10^6, 3×10^6, 1×10^6, $0.3\times10^6$of Tr1 cells were injected (i.v) 28 days post-immunization. Hind paws swelling and clinical signs of arthritis were scored, as well as biological parameters such as the level of anti-bCII antibodies in the sera of treated mice and the cytokine profile of bCII specific T cells.

Results: One single injection of 3×10^6 or $1\times10^6$of Tr1 cells at day 28, in ongoing arthritis, significantly inhibits the development of arthritic disease, shown by reduction of disease severity and incidence. In contrast the injection of 0.3×10^6 and 10M of Tr1 cells did not improve the clinical signs of arthritis. The analysis of the bCII specific T cell responses following euthanasia of the mice injected with $3\times10^6$and $1\times10^6$of Tr1 cells revealed a decrease of proliferation of bCII specific T cells and a slight increase of IL-10 secreted by activated splenocytes. The protection of the mice was associated with a decrease of anti bCII specific antibodies in the sera,.

Importantly, these preliminary data indicate that a single injection of Tr1 cells at disease onset could reduce disease severity and incidence in experimental arthritis.

Conclusion: Single dose 3×10^6, $1\times10^6$of Tr1 cell administration showed a reduction of disease incidence and severity in CIA demonstrating the therapeutic potential of Tr1 cells in arthritis. A phase I/II clinical trial is ongoing in Rheumatoid Arthritis patient in France (TxCELL, France).

Differences in Immune Cell Profile and Related Gene Expression Provide Clues to Susceptibility to Arthritis in Humanized Mice. David Luckey, Behrens Marshall and Veena Taneja. Mayo Clinic, Rochester, MN

Background/Purpose: Predisposition to develop Rheumatoid arthritis (RA) is associated with the presence of certain genetic factors. Genome wide association studies meta analysis has identified genes in the MHC region provide the strongest association. Pathways driven studies confirmed HLA mediated processes involved in susceptibility to RA. HLA-DQ8 haplotypes are associated with susceptibility while DQ6 haplotypes are associated with resistance to develop RA. We have characterized naïve DQ8 and DQ6 humanized mice for expression of various genes and T and B cell subsets. The purpose is a) to evaluate the immune cell profile associated with susceptibility, and b) to determine altered expression of genes of Th1/Th17 network in naïve mice to predict its association with susceptibility/protection.

Methods: We have generated HLA transgenic mice lacking all endogenous class II molecules (AEo) and expressing alleles known to be associated with susceptibility or resistance to arthritis. HLA-DQ8 renders susceptibility to develop collagen-induced arthritis (CIA) upon immunization with type II collagen while DQ6 mice are resistant to CIA. Arthritis in humanized mice mimics human disease in histopathology and antibody profile. Naïve mice were characterized for the presence of various T and B cell subsets by FACS analysis using conjugated antibodies. Further, naïve CD4+CD62L cells were cultured in vitro in various conditions to drive cytokine response to determine if they are programmed to produce proinflammatory cytokines. We next assessed the expression of genes related to Th1 and Th17 network in splenic cells isolated from naïve transgenic mice using quantitative RT-PCR technology

Results: Arthritis resistant and susceptible mice showed differences in presence of subsets of T and B cells. While overall T regulatory cells expressing FoxP3 were similar in both strains, CD8+FoxP3+ cells occurred with increased frequency with a concomitant decreased frequency of CD4+FoxP3+ cells in CIA-resistant mice compared to susceptible strain. Naïve CD4+CD25- CD62L+ cells isolated from DQ8 mice when cultured with various cytokines in vitro produced Th17 cytokines while DQ6 mice produced higher levels of IL-10. B cells expressing CD40 and CD80 were significantly lower in numbers in CIA-resistant compared to susceptible mice. PCR arrays to profile TH1/Th17 network showed that naïve CIA-susceptible mice express gene associated with production of proinflammatory cytokines and chemokines, IL-17, IL-23, IL-13, CCL2 and CCL20 while these genes are under expressed in CIA-resistant mice. Following immunization with type II collagen, CIA-resistant mice produced immune response to the antigen but do not produce proinflammatory cytokines.

Conclusion: The gene expression data in arthritis susceptible and resistant mice may provide an immune profile to predict susceptibility and hence may be useful to generate therapeutic targets for rheumatoid arthritis.

Investigation of Fibrinogen-Reactive T Cells in the Pathogenesis of Mouse Models of Rheumatoid Arthritis. Kristen N. Cordova[1], Rocky L. Baker[1], Gene Barbour[1], Kathryn Haskins[1] and V. Michael Holers[2]. [1]University of Colorado, AMC, Aurora, CO, [2]Univ of Colorado School of Med, Aurora, CO

Background/Purpose: Citrullinated proteins, derived from the conversion of peptidyl-arginine to peptidyl-citrulline, are present in the joints of rheumatoid arthritis (RA) patients, who also uniquely produce high levels of anti-citrullinated protein antibodies (ACPAs). Citrullinated fibrin(ogen) is abundant in rheumatoid synovial tissue, and ACPA-positive RA patients exhibit circulating immune complexes containing citrullinated fibrinogen,

suggesting that citrullinated fibrinogen is a major target of ACPAs in RA. ACPAs specific for citrullinated fibrinogen have also been shown to also enhance damage in animal models of autoimmune arthritis, and mice deficient in fibrinogen display reduced disease severity in the collagen induced arthritis (CIA) model of RA. Fibrin deposition in the joint is one of the most consistent features of both RA and animal models of RA, and several groups have demonstrated a role for fibrin in the pathogenesis of autoimmune arthritis by using thrombin inhibitors to hinder fibrin polymerization, resulting in disease suppression. T cells are believed to be involved in this process by initiating, controlling and driving antigen specific immune responses in RA.

Previously, we found that mice immunized with human fibrinogen (HF) or citrullinated human fibrinogen (HCF) develop a proliferative response to both HCF and HF present in lymph nodes and spleens. To determine if fibrinogen-reactive T cells are important in the pathogenesis in mouse models of autoimmune arthritis, we studied the phenotype of the T cells after immunization with HCF and isolated T cell lines reactive to HF or HCF.

Methods: DBA1/J mice were immunized with HCF, and then lymph nodes were taken at various time points and either evaluated directly *ex vivo* or cultured *in vitro*. *Ex vivo* T cells were evaluated for the presence of activation markers and cytokine production after antigen stimulation, while T cell lines were cultured long term *in vitro* with antigen and IL-2, and evaluated in the same manner. T cell lines were sorted and cultured based upon the vβ region of their T cell receptor (TCR) in order to obtain a uniform population of cells.

Results: We found by *ex vivo* analysis that, following two immunizations of HCF, mice develop higher levels of CD4 cells with an activated effector phenotype (CD44hi+CD62L-) than CFA-injected controls, and TNFα, IFNγ, and IL-17 are produced specifically by CD4 cells in response to challenge with HCF. Cultured T cell lines produce higher levels of TNFα and IL-17 as well as IL-6 when stimulated with HCF. One antigen-specific sorted line, HCF5 vβ5+, is highly reactive to citrullinated forms of both HF and mouse fibrinogen.

Conclusion: We conclude that fibrinogen-reactive CD4 T cell lines exhibit an inflammatory phenotype that may have an effect in inflammatory autoimmune arthritis. Currently, T cell lines are being evaluated *in vivo* to determine if they affect disease in CIA and in anti-collagen antibody-induced arthritis mouse models.

Lysophosphatidylcholine Enhances Suppressive Function of Human Naturally Occurring Regulatory T Cells Through TGF-Beta Production. Hitoshi Hasegawa, Jin Lei, Takuya Matsumoto, Sachiko Onishi, Koichiro Suemori and Masaki Yasukawa. Ehime University Graduate School of Medicine, Toon, Japan

Background/Purpose: Regulatory T cells (Treg) play a pivotal role in the maintenance of self-tolerance and immune homeostasis and are shown to exert therapeutic effects on autoimmune diseases. There are at least two subsets of Treg cells, naturally occurring Treg (nTreg) and peripheral induced Treg (iTreg) cells. The identification of molecules controlling Treg differentiation and function is important in understanding host immune responses and application to therapy. Previously, from screening of the libraries of lipids and nuclear receptor ligands, we isolated the fourteen bioactive molecules that enhanced Foxp3 expression and suppressive properties of human Treg cells and reported that peroxisome proliferator-activated receptor agonists together with TGF-beta converted human $CD4^+CD25^-$ T cells into functional $Foxp3^+$ regulatory T cells. In this study, of these, we demonstrated that lysophosphatidylcholine (LPC) enhanced Foxp3 expression and suppressive function of human nTreg cells, and analyzed this mechanism of LPC.

Methods: $CD4^+CD25^+CD127^{-/low}$ cells were isolated from human PBMC as nTreg cells, cultured for 72h in the presence of LPC, and then were examined the expression of Foxp3, suppressive function, and cytokine production. Furthermore, we analyzed the mechanism by which human nTreg cells were increased suppressive function through LPC.

Results: Foxp3 expression and suppressive properties of LPC-treated $CD4^+CD25^+CD127^{-/low}$ (nTreg) cells were increased significantly in comparison with those of the non-treated nTreg cells. This was due to TGF-beta1 production from nTreg cells treated with LPC. LPC enhanced the expression levels of mRNA and protein of latent TGF-beta1 in nTreg cells through its receptor, G2A. This was also confirmed with the human TGF-beta1 promoter assay. Moreover, LPC released and activated latent TGF-beta1 on nTreg cells. On the other hand, LPC did not induce the production of TGF-beta1 from $CD4^+CD25^-CD45RA^+$ T cells and $CD4^+CD25^-CD45RO^+$ T cells, although both cells expressed G2A. In addition, LPC-treated $CD4^+CD25^-CD45RA^+$ T cells did not convert to iTreg cells.

Conclusion: We demonstrated that LPC enhanced Foxp3 expression and suppressive function of human nTreg cells through TGF-beta production. TGF-beta and IL-2 are known to play an important role in the maintenance and function of human nTreg cells. LPC is a highly abundant bioactive lysolipid present at high concentrations in the circulation. Taken together, LPC may also contribute to the maintenance and function of human nTreg cells.

Multifunctional T Cell Reactivity to Native and Glycosylated Type-II Collagen in Rheumatoid Arthritis. Vivianne Malmström[1], Omri Snir[1], Johan Bäcklund[2], Lars Klareskog[1] and Rikard Holmdahl[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet, Stcokholm, Sweden

Background/Purpose: Type II collagen (CII) is a cartilage-specific protein to which a loss of immune tolerance may trigger autoimmune reactions and lead to arthritis. The major T cell epitope on CII, aa259–273, can be presented by several *HLA-DRB1*04* alleles both in its native and posttranslational-glycosylated forms. Here, we aimed to functionally explore and compare CII-autoreactive T cells isolated from blood and synovial fluid of patients with rheumatoid arthritis (RA).

Methods: Peripheral blood and synovial fluid mononuclear cells were obtained from 10 *HLA-DRB1*04* RA patients and stimulated *in vitro* with several variants of the $CII_{259–273}$epitope: *(a)* unmodified, or glycosylated on *(b)* lysine-264, *(c)* lysine-270, or *(d)* both lysine-264 and 270. Activation was assessed by determination of CD154 upregulation on responding T cells followed by intracellular staining for IL-17, IFNg and IL-2 by multicolor flow cytometry.

Results: Multifunctional T cell responses towards all examined variants of the $CII_{259–273}$ peptide could be detected. A comparison between blood and joint-derived T cell function revealed a significant increase of proinflammatory cytokines secreted by synovial T cells, in particular IFNg ($p=0.004$). Studies of longitudinal samples show that T cell responses were sustained over the course of disease, and even included epitope spreading.

Conclusion: Determination of CD154 upregulation in combination with intracellular cytokine staining provides a sensitive approach to study infrequent autoreactive T cells. Inflammatory T cell responses to both glycosylated and non-glycosylated variants of the major CII epitope in the same patients suggests that CII autoreactivity may be more common than previously appreciated.

Circulating CD4+CD161+ T Cells As Biomarker of Disease Activity in Recently Diagnosed, Non-Treated Rheumatoid Arthritis Patients. Paulina Chalan, Wayel H. Abdulahad, Minke G. Huitema, Bart-Jan Kroesen, Elisabeth Brouwer and Annemieke M.H. Boots. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: Ample evidence suggests a role for T lymphocytes in the pathogenesis of rheumatoid arthritis (RA). CD161 was shown to confer tissue migratory properties to T cells and may thus contribute to tissue pathology. The role of CD161+ T cells in recently diagnosed RA has not been investigated yet. Our first objective was to provide clues on T-cell subset(s) involved in RA by analyzing frequencies of naïve (T_{Naive}), central memory (T_{CM}), effector memory (T_{EM}), terminally differentiated (T_{TD}) T lymphocytes and by assessing CD161 expression in blood of newly-diagnosed RA patients and paired peripheral blood (PB)- synovial fluid (SF) samples of late-stage RA. Secondly, we assessed the cytokine profile of PB and SF- derived CD4+CD161+ T cells. Thirdly, we investigated in a longitudinal study, the influence of regular methotrexate (MTX) treatment on circulating CD4+CD161+ T cells

Methods: Blood from recently diagnosed, non-treated RA patients (n=30), age-/sex-matched healthy controls (HC, n=27) was stained with fluorochrome-conjugated anti-CD4, CD8, CD45RO, CCR7, CD161 antibodies and analyzed using flow cytometry. 21 patients had a second measurement 3 months after start of MTX treatment. DAS28, ESR, CRP were assessed at baseline and at 3 months (after treatment). T-cell subset composition was also analyzed in paired PB and SF samples from patients with an active disease (n=9). Cytokine (TNF-α, IFN-γ, IL-4, IL-17) and cytolytic granule (Perforin, Granzyme B) expression of PB- and SF- derived lymphocytes was assessed by intracellular staining and flow cytometric analysis

Results: The frequency of CD4+ T_{EM} was found to be significantly decreased while the frequency of CD4+ T_{Naive} was significantly increased in newly-diagnosed RA patients when compared to HC. Of note, the frequency

of CD4+CD161+ T cells, found to contain mostly effector memory cells, was significantly decreased in RA (p=0.04). The percentage and the absolute number of circulating CD4+CD161+ T cells correlated inversely with DAS28 (−0.41, p=0.028 and −0.42, p=0.023, respectively). We observed a significant enrichment of CD4+, but not CD8+ T cells expressing CD161 in SF when compared to PB (p=0.039). SF-derived CD4+CD161+ T cells showed enhanced IFN-γ and reduced IL-17 expression compared to their PB-derived counterparts. After 3 months of MTX treatment, a reduction in disease severity was associated with normalization of circulating CD4+CD161+ T lymphocytes

Conclusion: The frequency of CD4+ $T_{EM}$is significantly decreased while the frequency of CD4+ T_{Naive} is increased in PB of early RA. The decline of circulating CD4+CD161+ T lymphocytes correlated inversely with disease activity. The observed preponderance of CD4+CD161+ T cells in SF compared to PB suggests their influx in the joint. Increased IFN-γ production by SF CD4+CD161+ T cells may contribute to the disease process in RA. Furthermore, the normalisation of circulating CD4+CD161+ T cells following MTX treatment suggests that this subset might qualify as a biomarker of disease activity in RA.

2343

Circulating Human Collagen II-Reactive T Cell in Early Rheumatoid Arthritis Produce IL17. Anna Laura Fedele[1], Chiara Nicolò[2], Gabriele Di Sante[2], Barbara Tolusso[1], Silvia L. Bosello[1], Elisa Gremese[1], Francesco Ria[2] and Gianfranco Ferraccioli[1]. [1]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [2]Institute of General Pathology, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: Joint damage in Rheumatoid Arthritis is likely due to pro-inflammatory T cells specific for collagen and recruited into the synovium, where they are activated and promote acute presentation of the disease. We previously described the T cell repertoire specific for human Collagen II peptide 261–273 (huColl261) in HLA-DR4+ Early Rheumatoid Arthritis (ERA) patients, compared to that of DR4+ healthy subjects and followed it along disease course, showing that T cells specific for this epitope appear during flares of the disease but tend to disappear during remission (Ria et al., Art Res Ther, 2008). Here we report preliminary observations regarding the presence of specific clonotypes recognized by the ability of hColl-specific (HuColl2) T cells to respond to Collagen II peptide and we describe that they seem to secrete IL-17 more than IL-13.

Methods: PBMC obtained from 22 consecutive ERA patients were collected. All patients were typed for HLA-DRB1. 11 patients were DR 4+, 4 were DR1+ one was DR 4,1+. Patients were tested for the presence of HuColl2 peptide response by immunoscope. In 4 ERA patients synovial fluid cells were also examined. PBMC were also purified from 2 ERA patients and one RA patient at his first remission of disease, and stimulated in vitro with huColl261. Sixteen hours later, IL-17 and IL-13 secreting cells were enriched by MACS® secretion assay. The presence of huColl261-specific TCRs was assessed by immunoscope in samples enriched or depleted for each cytokine, and in samples allowed to proliferate for 3 days in response to the peptide antigen.

Results: We examined the usage of two TCR beta chains that we showed to be frequently used in DR4+ ERA patients. Collagen-specific T cells carrying BV11(139b) were used by 6/12 ERA DR4+ subjects, 2/4 DR1+ subjects(that were both also DR15+) and by 2/6 patients negative for both DR4 and DR1. Usage of BV13b (199) appears to be more specific for DR4+ subjects, since we found collagen specific T cells using this TCR-beta chain in 5/10 DR4+ ERA patients versus 1/10 DR4- ERA subjects. T cells obtained from 3 PB samples were tested for their capacity to secrete specific cytokines (IL17 or IL13) in response to stimulation with collagen II. T cells secreting any of the two cytokine represent only a part of the circulating T cell repertoire specific for huColl261, similar to the observation that a minority of the circulating repertoire is actually able to home to the synovium. IL17-secreting cells were detected in all 3 samples, but it appears that T cells from one patient in remission needed additional stimuli that include bacterial derived non antigenic moieties in order to produce IL-17. huColl261-specific IL-13 producing cells were detected only in one of the 2 ERA subjects.

Conclusion: By the immunoscope technique we could dissect the immune response against human collagen in ERA subjects. Results show that some rearrangements of the TCR-beta chain co-segregate with the collagen-specific response restricted by DR4 and/or DR1. The T cell precursors actually driving the proinflammatory response in the synovium by the production of IL-17 appears to represent a limited portion of the entire collagen specific repertoire.

A Novel Human Autoantigen Induces T and B Cell Responses in Patients with Antibiotic-Refractory Lyme Arthritis. Elise E. Drouin[1], Robert J. Seward[2], Chunxiang Yao[3], Kianoosh Katchar[1], Gail McHugh[1], Klemen Strle[1], Catherine E. Costello[3] and Allen C. Steere[1]. [1]Massachusetts General Hospital and Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Harvard Medical School and Boston University School of Medicine, Boston, MA, [3]Boston University School of Medicine, Boston, MA

Background/Purpose: Antibiotic-refractory Lyme arthritis (ARLA), defined as persistent synovitis lasting months to years after spirochetal killing with 2–3 months of oral and IV antibiotic therapy, is hypothesized to result from *B. burgdorferi*-induced autoimmunity in affected joints. Previous attempts to identify autoantigens based on sequence homology with borrelial proteins, proteome microarrays or recombinant antibody probes had been unrevealing. Therefore, we devised an innovative new approach that combines discovery-based proteomics with translational research for the identification of naturally processed, immunogenic HLA-DR-presented autoantigens in synovial tissue.

Methods: Naturally presented HLA-DR peptides were purified from the synovial tissue of individual patients, identified by tandem mass spectrometry, synthesized and tested for autoreactivity using the same patient's PBMC. Peptides shown to have autoreactivity were further evaluated for disease-associated T and B cell autoreactivity using PBMC and sera from a large cohort of patients with antibiotic-refractory Lyme arthritis and from individuals in comparison groups.

Results: Of the 120 non-redundant peptides identified from the synovial tissue of a single patient, only one peptide, which was derived from endothelial cell growth factor (ECGF), was recognized by his PBMC. Testing of PBMC from 44 additional patients with ARLA showed that 21 (48%) also had T cell autoreactivity with 1 or more of 7 T cell epitopes of ECGF, compared with 8 of 29 patients (28%) with antibiotic-responsive arthritis, 3 of 19 (16%) with erythema migrans (EM, an early disease manifestation), and 1 of 18 healthy control subjects (6%), as demonstrated by ELISPOT assay. In addition, as determined by ELISA and Western blotting, 49 of 112 patients (44%) with ARLA had IgG anti-ECGF autoantibodies with titers as high as 1:11,000; most patients with T cell responses also had B cell reactivity with this autoantigen, suggesting these responses were linked. In comparison with ARLA patients, antibody responses to ECGF were found in 11 of 32 patients (34%) with antibiotic-responsive arthritis (P=NS), 2 of 33 (6%) with EM (P<0.001), and 11 of 91 healthy subjects (12%) (P<0.001). ARLA patients with anti-ECGF-antibodies more often had HLA-DRB1*04 or 1501 alleles (alleles previously associated with chronic Lyme arthritis) compared with patients who lacked such autoantibodies. Finally, ECGF was found to be abundant in both synovial fluid and synovial tissue in ARLA patients, demonstrating the presence of the autoantigen at the site of inflammation.

Conclusion: About half of the patients with ARLA had T and B cell reactivity with the human protein ECGF. This is the first autoantigen identified that induces both T and B cell autoreactivity in ARLA patients. Clinical testing for anti-ECGF autoantibodies is a promising biomarker for diagnosis, and is likely to help in treatment decisions, including the use of DMARDs after antibiotic therapy. Furthermore, this innovative, cutting-edge methodology for identifying novel autoantigens is directly applicable to any of the chronic inflammatory arthritides, including rheumatoid arthritis.

IL-2/IL-2mAb Complex Induced Expansion of Treg Cells and Prolonged Suppression of Collagen Induced Arthritis in Mice by Fortifying IL-2 Signaling Pathways. seon Yeong Lee[1], Hye Jwa Oh[1], Joo-Yeon Jhun[1], Jun Geol Ryu[1], Mi La Cho[1], ji Hyeon Ju[1], Sang Heon Lee[2], Sung Hwan Park[1], Charles D. Surh[3] and Ho Youn Kim[1]. [1]Rhematism Research Center, Seoul, South Korea, [2]Division of Rheumatology, Seoul, South Korea, [3]Department of Immunology

Background/Purpose: To investigated the effect of IL-2/JES6-1(anti-IL-2 mAb) complex on in the control of collagen-induced arthritis (CIA) and to evaluate its impact on the induction/suppression of Treg and Th17.

Methods: Wild type and CIA DBA1/J mice were injected intraperitoneally (i.p.) with IL-2 or IL-2/JES6-1 three times with 2 day intervals. Surface markers of Tregs (CTLA4, GITR, ICAM, CD103, PD1, CD101, GARP and Foxp3) were analyzed by flow cytometry (FACs). After injection of IL-2 or IL-2/JES6-1, the time kinetics of IL-2 signaling

molecules (*phospho*(*p*)-STAT5, *p*-AKT and *p*-p38/MAPK) was examined by FACs and western blot. The concentration of IL-17 and IL-10 were measured by ELISA.

Results: Injection of IL-2/JES6-1 increased the proportion of $Foxp3^+$ Tregs in splenic $CD4^+$ T cells and reached the highest level on Day 4 after injection. Surface expression of CTLA4, GITR and GARP was simultaneously increased on the same day. Activation of *p*-STAT5 was apparent within 3 hours after injection. IL-2 signalings, including *p*-AKT and *p*-p38/MAPK, were also higher in the splenocytes treated with IL-2/JES6-1. The IL-2/JES6-1 suppressed the induction of CIA and the production of IL-17, while increasing the level of IL-10 in the spleen. Repeated injections of IL-2/JES6-1 complex, 3 weeks after primary immunization, prolonged the suppressive effect up two month after first the onset of arthritis.

Conclusion: Injection of IL-2/JES6-1 complex effectively suppressed the inflammatory response. The expansion of Treg (via STAT5) and concomitant increase of IL-2 signaling pathways by IL-2/JES6-1 postulates its potential usage as new therapeutic agent for arthritis

High Density Lipoproteins Stabilize Antigen Presenting Cell:T Cell Conjugates by Altering the T Cell Receptor Signalling Kinetics. A.L. Gomes[1], J. Delgado-Alves[1] and E.C. Jury[2]. [1]Faculdade de Ciências Médicas da Universidade Nova de Lisboa, Lisboa, Portugal, [2]University College London, London, United Kingdom

Background/Purpose: Epidemiologic studies in patients with autoimmune disease show a link between lipid metabolism and the immune system. In patients with systemic lupus erythematosus (SLE) a major cause of premature death is not the disease itself but events related to atherosclerosis associated with a shift in the serum cholesterol LDL:HDL ratio. In T lymphocytes, changes in plasma membrane lipid order have been correlated with altered T-cell antigen receptor (TCR) signalling resulting in differential patterns of proliferation and cytokine production. Interestingly, T cells from SLE patients are characterised by altered plasma membrane lipid microdomains and reduced lipid order. Here, we study the effects of HDL on the stability of plasma membrane lipid order and consequently on T lymphocyte signalling activation and proliferation.

Methods: CD4+ T lymphocytes were isolated from healthy donors by negative selection using magnetic beads. Cells were incubated with 350nM HDL for 2, 4, 24, 48 and 72 hours and assessed for plasma membrane lipid order, using the fluorescent probe di-4-ANEPPDHQ, and membrane cholesterol levels using filipin binding. For functional assays, cells were also stimulated with IL-2, anti-CD3 and anti-CD28 antibodies. The effect of HDL on T cell-antigen presenting cell (APC) interaction, TCR-associated intracellular signalling and cell cycling was assessed by flow cytometry using cell tracker markers, phosphoflow antibodies and DAPI, respectively. Cytokine production was assessed in supernatants using Cytokine Bead Array following the manufacturer's protocol.

Results: The results reveal that HDL reduces plasma membrane lipid order in $CD4^+$ T lymphocytes without altering total cholesterol levels. Culture with HDL did not alter the frequency of T cell-APC conjugate formation; however, HDL did increase the stability of T cell-APC conjugate interaction over a time course of 30 minutes. HDL also influenced the kinetics of proximal TCR-associated signalling events by prolonging TCR-zeta and ZAP-70 phosphorylation levels. Downstream signalling events were also affected demonstrated by delayed phosphorylation of ERK and increased NFKB phosphorylation compared to T cells not treated with HDL. The changes in T cell-APC interaction and TCR-mediated signalling were associated with altered T cell function in terms of proliferation shown by an increased frequency of cells in the G2/M phase of cell cycle, increased IL-6 production, and reduced IL-10 and TNF-alpha production compared to untreated control T cells. Thus the results suggest that differential levels of serum HDL could influence the response of T cells during immune activation.

Conclusion: In patients with SLE HDL levels can be severely affected. The consequences of altered serum cholesterol levels are typically associated with endothelial cell damage leading to cardiovascular disease. Here, we show that HDL directly affects TCR signalling and cytokine production in $CD4^+$ T lymphocytes, further supporting a tight link between the lipid metabolism and the immune system. This work was funded by Arthritis Research UK fellowship award (18106) to ECJ and by Fundação Amadeu Dias. ECJ and DAJ share senior authorship.

The Induction of c-Maf in Th17 Cells and Its Implications in the Development of Memory Th Cells. Kojiro Sato, Fumihiko Miyoshi and Toshihide Mimura. Saitama Medical University, Saitama, Japan

Background/Purpose: Th17 cells are a newly identified Th cell subset that mainly produces IL-17 (IL-17A). They are implicated in the pathogenesis of several inflammatory diseases, including RA. We previously reported that Th17 cells, but not Th1 or Th2 cells, promote the differentiation of osteoclasts, which are responsible for the bone resorption observed in the damaged joints of RA. Next, we wanted to identify the network of transcription factors at work in the course of Th17 differentiation.

Methods: We performed GeneChip transcriptome analysis using time-course mRNA samples from Th cells cultured under Th1, Th2 and Th17 conditions, respectively.

Results: Proto-oncogene Maf (encoding c-Maf) was significantly induced in Th17 cells. Th cells derived from c-Maf transgenic (Tg) mice produced significantly more IL-17 than wild type (WT) Th cells. Interestingly, most of the Tg Th cells had a memory phenotype ($CD62L^{lo}$/$CD44^{hi}$), suggesting that c-Maf might play important roles not only in Th17 differentiation, but also in the induction of memory Th cells. Consistent with this, much more Maf, Il23r and Il17a were expressed in WT memory-like Th cells generated by transferring Th cells into T-cell deficient Rag-2 knockout (KO) mice (utilizing homeostatic expansion) than in naïve Th cells. In order to perform loss-of-function analysis, we tried to generate bone marrow-chimeric mice (Rag-2KO mice with c-Maf deficient hematopoietic cells), as c-Maf knockout mice are embryonically lethal. As expected, when transferred into Rag-2 KO mice, c-Maf deficient Th cells produced less Il23r and Il17a compared with control Th cells, although there was no difference detected by flow cytometry in the expression levels of memory markers ($CD62L^{lo}$/$CD44^{hi}$). We next sorted human naïve, central memory and effector memory Th cells from the peripheral blood and performed transcriptome analysis again, and found that human effector memory Th cells also express Maf at a high level. In fact, it was the second most induced transcription factor in effector memory Th cells.

Conclusion: Although it seems that c-Maf is unnecessary for the expression of surface memory markers, it is indeed important for the expression of Il17a in memory Th cells. c-Maf is induced not only in mouse memory Th cells, but also in human memory Th cells, suggesting the importance of the transcription factor in the memory Th cell differentiation.

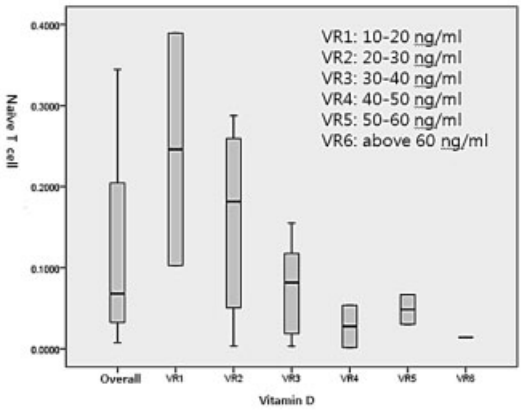
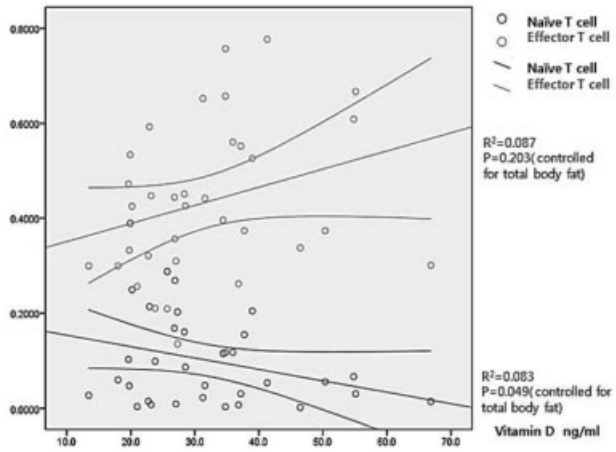
A Novel Role for Vitamin D in Immunosenescence: Is Enough Too Much for Naïve CD8 T Cells? Yong Gil Hwang[1], Fei Chu Lim[1], Qi Wu[1], PingAr Yang[1], Gordon Fisher[2], Gary Hunter[3], Hui-Chen Hsu[1] and John D. Mountz[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Department of Nutrition Sciences, University of Alabama at Birmingham, Birmingham, Alabama, USA, [3]Department of Human Studies, University of Alabama at Birmingham, Birmingham, Alabama, USA, [4]University of Albama at Birmingham/Birmingham VA Medical Center, Birmingham, AL

Background/Purpose: Intensive repletion of vitamin D (Vit D) has been advocated for patients with rheumatoid arthritis (RA) and systemic lupus erythematosis (SLE) who have high risk in cardiovascular disease (CVD). However, meta-analyses showed that calcium supplements with or without Vit D was associated with increased risk of CVD. Of note, CD8 T cells have the highest levels of Vit D receptor and senescent CD8 T cells are associated with increased prevalence of CVD and adverse outcomes. This study determined the relationship between Vit D levels and CD8 T-cell status.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from 34 healthy female subjects (all >60-yr-old). Naïve, effector, and senescent CD8 T cells were determined based on expression of CD28 and CD95 (Fas). PBMCs were stimulated with phytohemagglutinin (PHA) (10 μg/ml) and [3H]-thymidine incorporation was measured at days 3 (D3 PHA) and 7(D7 PHA). Anti-Fas antibody was added at days 2 and 4 (D7 PHA+anti-Fas) to induce apoptosis. Sera levels of 25-Hydroxy Vit D, IFNγ, IL-1, IL-6, IL-17, and IL-4 were determined by ELISA. Lipid profile and body composition data were measured. Bone density was determined by dual-energy X-ray absorptiometry.

Results: Overall, 19 (56%) participants had hypovitaminosis (equal or less than 30 ng/ml)(23.7± 4.8) and 15 (44%) subjects had higher than 30 ng/ml (42.2 ± 10.3). There was no difference in age(64±4), race, body fat, or lipid profile between the two groups. The low Vit D group had lower maximal oxygen consumption (p=0.019) and lower bone density only in L1 and L2 levels. There was a significantly higher percentage of naïve CD28+CD95- CD8 T cells (13.2% ±11.2, p=0.026) and a lower percentage of effector CD28+CD95+ CD8 T cells (37.8% ±13.5, p=0.018) in the low Vit D group. In contrast, high Vit D group had a lower percentage of naïve CD8s (6.2%± 6.1) but a higher percentage of effector CD8s (50.6% ±16.5). There was no significant difference in CD28-CD95+ senescent CD8 T cells and in D3 PHA and D7 PHA between the two groups. However, subtraction of D7 PHA+anti-Fas from D7 PHA was significantly higher in the low Vit D group (p=0.041). The low Vit D group had lower IL-4 and IL-17 as well as higher IL-1 and IL-6.





Conclusion: High levels of Vit D are correlated with decreased naïve and increased effector CD8 T cells, which are characteristic changes of CD8 compartment associated with ageing. These changes might be related with the anti-apoptotic effects of Vit D. The results indicate that while low levels of Vit D may predispose to development of autoimmune disease, high levels of Vit D may have a role in autoimmune disease progression and amplification, increased risk of CVD.

AKAP79 Expression Is Increased in Systemic Lupus Erythematosus T Cells and Reduces IL2 Production. Gabriel Criado, María Galindo, A. Javier García-González, Jose L. Pablos and María J. Pérez-Lorenzo. Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain

Background/Purpose: Reduced activation of Protein Kinase A (PKA) and IL2 production are characteristic of T cells from SLE patients. AKAP79 is a part of a heterogeneous group of proteins (A-kinase Anchoring Proteins) that associate to and regulate the activity of PKA. In addition to its association to PKA, AKAP79 interacts with Protein Kinase C (PKC) and Calcineurin, key regulators of IL2 production and T cell activation. Therefore, altered expression and/or function of AKAP79 can play a role in the deficient activation of PKA and IL2 production that characterise SLE T cells.

The aims of our work were to quantify the expression of AKAP79 in SLE T cells and analyse its role in T cell activation

Methods: T cells were isolated by negative selection from SLE patients (n= 21) and healthy controls (HC, n= 20). RNA was purified, retrotranscribed to cDNA and levels of AKAP79 and β-actin transcripts were quantified by quantitative real-time PCR using Sybr Green technology. Ten fold dilutions of Jurkat T cell line cDNA were included in each run and standard curves were generated by linear regression using log(Ct) versus log(cell number), and the cell equivalent (CE) number for the test samples was calculated. Data are expressed as the ratio between AKAP79 CE number and β-actin CE number, yielding the relative RNA expression units (REU). AKAP79 and β-actin protein expression was detected in T cell lysates by Western Blot, quantified with Quantity One Software and protein expression units (PEU) were calculated as the ratio between AKAP79 and β-Actin signal. Statistical differences between groups were analysed with non-parametric Mann-Whitney U test using GraphPad Prism software. For functional assays, Jurkat T cells were transduced with dual promoter pRRL-AKAP79/GFP- or control pRRL-GFP-expressing lentiviruses and stimulated with plate-bound anti-CD3 and soluble anti-CD28 antibodies, RNA was isolated and IL2 transcripts quantified by quantitative real-time PCR.

Results: T cells from SLE patients had significantly higher levels of AKAP79 mRNA compared to HC (3.70 +/− 0.77 REU in SLE vs 1.97 +/− 0.27 REU in HC, P= 0.008). Increased expression of AKAP79 in SLE T cells was confirmed at the protein level (0.68 +/− 0.18 PEU in SLE vs 0.37 +/− 0.05 PEU in HC, P= 0.04). Furthermore, levels of AKAP79 protein in SLE T cells positively correlated with SLEDAI (Pearson r=.64, P= 0.004). Analysis of AKAP79 function showed that overexpression of AKAP79 significantly reduced IL-2 expression upon TCR stimulation (20.64 +/− 0.19 REU in pRRL-AKAP79/GFP vs 6.02 +/− 0.06 in pRRL-GFP, P= 0.001).

Conclusion: AKAP79 is overexpressed by T cells in SLE patients and can contribute to the deficient IL2 production characteristic of these cells.

Oxidation Impairs PKCδ Signaling in Lupus. Gabriela Gorelik and Bruce C. Richardson. University of Michigan, Ann Arbor, MI

Background/Purpose: Defective T cell signaling combined with genetic and environmental factors is currently believed to play a key role in the development and establishment of autoimmunity.

Previous work demonstrated that decreased T cell ERK pathway signaling causes a lupus-like disease by decreasing DNA methyltransferase expression, causing hypomethylation and overexpression of methylation-sensitive genes resulting in autoimmunity. Similar results were found in CD4+ T cells from lupus patients. We recently demonstrated that a defective phosphorylation of PKCδ on T^{505} is responsible of the decreased ERK signaling in CD4+ T cells from lupus patients.

Recent reports have implicated oxidative stress in lupus pathogenesis with increased levels of reactive oxygen and nitrogen species. 3-NO2-Tyr proteins are increased in lupus and our preliminary evidence indicates that PKCδ is aberrantly nitrated in lupus T cells making it refractory to Thr phosphorylation and unable to activate the ERK pathway. Further, H_2O_2 is also increased in lupus.

The purpose of this research was to study the modification of PKCδ phosphorylation induced by H_2O_2 and its consequences on T cell ERK pathway signaling.

Methods: CD4+ T cells were purified from normal donors or active lupus patients by Ficol density gradient centrifugation and negative selection with magnetic beads. When indicated, cells were transfected using Amaxa nucleofection technology. The purified cells were treated with H_2O_2 and stimulated with 50 ng/ml phorbol 12-myristate 13-acetate (PMA) where indicated. Signaling protein expression and phosphorylation were quantitated in cellular lysates by immunoblotting.

Results: Purified T cells were incubated with increasing concentrations of H_2O_2 and then phosphorylation of kinases was analyzed by WB. H_2O_2 decreased the levels of p-Thr^{505} PKCδ following PMA stimulation as was observed previously in the presence of peroxynitrite and in lupus T cells. This effect was concentration and time-dependent (p-T^{505} PKCδ/PKCδ: mean ± SEM: 75.4 ± 6.9% decrease, p<0.03 treated vs non-treated, n=4, 5mM, 15 min). H2O2 affected only PKCδ, since PKCα and PKCθ were unaltered. Then, we studied if ERK signaling was impaired by H_2O_2 in T cells similar to lupus T cells where p-T^{505} PKCδ is decreased. Total and p-ERK were quantitated in H_2O_2 treated T cells. PMA stimulated ERK phosphorylation

was decreased after treatment ($p<0.02$). To investigate the mechanism by which H_2O_2 is affecting p-T^{505} PKCδ, T cells were incubated with L-NMMA, a NOS inhibitor, prior to H_2O_2 treatment. PKCδ phosphorylation was partially restored (p-T^{505} PKC δ/PKC δ: 39.5 ± 5.2% $p<0.05$, n=3 and 9.5 ± 1.2% $p<0.05$, n=3 inhibited vs non inhibited) after NOS inhibition. These results suggest that H_2O_2 may inactivate PKCδ through nitration similar to peroxynitrite. Both oxidants reproduced the PKCδ and ERK defect observed in lupus T cells.

Conclusion: These results demonstrate that H_2O_2 induces same modifications on PKCδ phosphorylation as those observed in the presence of peroxynitrite and in lupus T cells. Overall these results indicate that PKC δ may a the link between oxidative stress and the epigenetics modifications that drive to autoimmunity in lupus.

Linker for Activation of T Cells Is Displaced From the Immunological Synapse in Lupus T Cells After T Cell Activation. Nursamaa Abdoel[1], Carmen Bracho[2], Martin A. Rodriguez[1] and Ana M. Blasini[1]. [1]Hospital Universitario de Caracas, Caracas, Venezuela, [2]Instituto Venezolano de Investigaciones Científicas, Miranda, Venezuela

Background/Purpose: Several abnormalities in T cell receptor (TCR)-mediated signaling have been demonstrated in lupus T cells. LAT, a critical protein localized in lipid rafts and intracellular cytoplasmic vesicles, provides docking sites for the assembly of the calcium activation complex and other molecules needed for the coordinated activation of the MAPK signaling pathway. We have shown impaired ERK activation in lupus T cells activated via TCR/CD3 complex. Abnormal assembly of supramolecular activation complexes may impair downstream MAPK activation in lupus T cells. We have previously observed that activation via TCR/CD3 induces a significant decrease in the amount of LAT in total cell lysates from lupus T cells stimulated for 5 minutes compared with healthy control T cells (13.25 ± 2.65 vs. 21.58 ± 2.78; MFI ± SME, p= 0.038, n= 16). This finding was confirmed using confocal microscopy, a method that also revealed delocalization of LAT and GM1 at lipid rafts in SLE T cells stimulated for 5 min versus resting T cells (0.975 ± 0.002 vs. 0.978 ± 0.001; Pearson Rr ± SME, p= 0.008, n= 14). In order to test whether diminished LAT levels induced by activation of SLE T cells could affect the trafficking pattern in and out of the immunological synapse, we examined the behaviour of LAT and two key signaling molecules (PLCγ1 and adaptor Grb2) in artificially in vitro simulated T-cell synapses in SLE patients and healthy controls.

Methods: Highly enriched T cells were adhered to pLL coated slides and activated for 5 and 15 min at 37°C with 4.5 mm superparamagnetic polystyrene beads coated with antibodies against CD3ϵ and CD28. Cells were fixed, permeabilized and stained with antibodies recognizing LAT, Grb2 and PLCγ1. The cell-bead complexes were evaluated by confocal microscopy and densitometries were obtained using ImageJ, 1.44, National Institutes of Health, USA.

Results: Analysis revealed that activation via CD3/CD28 during 15 minutes induced a significant decrease in the amount of LAT at the synapse in lupus T cells in comparisson with resting T cells (24.95 ± 4.48 vs. 31.51 ± 8.68; MFI ± SME, p=0.020, n= 8), a difference not found in healthy control cells. LAT levels out of the synapse were also diminished after activation of lupus T cells (18.39 ± 4.05 vs. 19.25 ± 6.28; MFI ± SME, p=0.022, n=8). PLCγ1 and Grb2 recruited to the synapse remained unchanged upon activation in both SLE and healthy T cells.

Conclusion: We conclude that activation via CD3/CD28 negatively regulates LAT expression both in and out of the synapse in SLE T cells. The mechanistic cues for the downregulation of LAT in response to T cell activation in lupus T cells are currently unclear. The diminished expression of LAT after TCR-CD3 activation may potentially disrupt downstream signaling events and impair activation of the MAPK cascade in human lupus T cells. Effects of Direct Ras Inhibition on Lupus T Cell Cytokine Secretion. Ioana Moldovan, Leticia Ortloff, Adrian Costinescu, Keith K. Colburn and Lora Green. Loma Linda University, Loma Linda, CA

Background/Purpose: Direct ras inhibition by farnesylthiosalycilate (FTS), has been previously used in MRL/lpr mice, a known mouse model for lupus, and had beneficial effects in decreasing disease activity, suggesting that ras inhibition may represent a novel therapeutic approach for systemic lupus erythematosus. In previous experiments from our group, ras inactivation by FTS was able to markedly decrease the level of CD40Ligand (CD40L), a major player in the immune response, in lupus T cells and did not affect the level of CD40L in T cells from healthy controls, supporting the hypothesis that there is an intrinsic defect in the Ras signaling pathway in lupus.

The purpose of this study was to assess the effects of ras inhibition on cytokine secretion in lupus lymphocytes, in an attempt to further elucidate the molecular mechanisms by which ras blockade could influence lupus activity. We used TCR dependent and independent stimulation protocols and measured the levels of cytokines secreted by lupus lymphocytes versus controls subjected to Ras inhibition with FTS.

Methods: Blood from four healthy donors and five lupus patients was obtained. The lupus patients had moderately active disease (SLEDAI>3). T lymphocytes were separated by negative selection using an enrichment protocol. In each experiment, half of the samples were treated with 25 micromoles FTS for two hours. The samples where then divided equally and exposed for another two hours to a TCR (T cell receptor) independent stimulus (phorbol myristate plus ionomycin), TCR stimulation with anti CD3 plus anti CD28 antibodies, or left unstimulated in the control group. Both T helper (Th)-1 (IL-2, TNFα, and IFNγ) and Th-2 (IL-4, IL-10, IL-6, IL-13) cytokines were measured using a Luminex assay. Statistical differences were assessed using the t-test method.

Results: For T lymphocytes subjected to the TCR-dependent stimulation protocol, treatment with FTS significantly decreased the levels of both Th1 and Th2 related cytokines in lupus cells, and had no significant effects on cytokine secretion from normal subjects. The exception was IL-6, which levels increased, consistent with the cell stimulation. No significant differences between the normal and the lupus cytokine secretion were observed for both the TCR-independent protocol group and the unstimulated group.

Conclusion: Our study suggests that direct ras inhibition by FTS is a potent inhibitor of cytokine secretion in lupus T cells, possibly via TCR signal blockade, and does not affect normal T cells. The only cytokine secretion that was not affected was IL-6, likely controlled through a different signaling pathway. Both this present study and our previous studies on the effects of FTS on CD40L secretion in lupus T lymphocytes support the hypothesis that the ras signaling pathway plays a major role in lupus and that and that a possible abnormality is present in the ras pathway from lupus lymphocytes, which may account for the differences observed. The lack of effect on blood from normal subjects and the efficient decrease in the immune function of T cells further supports a potential therapeutic role of ras inhibition in treating lupus disease.

A Progesterone Receptor Regulates T Helper Cell Type 1 Functions and T Cell-Dependent Antibody Responses In Vivo. Alan Wong, Edward A. Clark and Grant C. Hughes. University of Washington, Seattle, WA

Background/Purpose: Progesterone (Pg) is a reproductive steroid that can suppress inflammation, cellular immunity and antibody production. Under physiologic conditions, Pg signals through two types of receptors: intracellular Pg receptors (iPRs) that are ligand-activated transcription factors, and membrane bound Pg receptors (mPRs) linked to inhibitory G proteins. However, the precise immunoregulatory functions of iPRs and mPRs in immune cells remain unknown. Determining these functions is critical for understanding links between female reproduction and autoimmunity, sexual immune dimorphisms, the immune requirements of pregnancy and the immunomodulatory effects of widely used synthetic forms of Pg. Here, we show that iPRs are natural regulators of T helper cell (Th) type 1 (Th1) functions and T cell-dependent (TD) antibody responses.

Methods: We measured primary TD IgG responses to alum-adsorbed DNP-KLH (or NP-OVA) and primary T cell-independent type 2 (TI-2) responses to DNP-Ficoll in iPR-deficient (iPRKO) and wild type (WT) mice. Spleen CD19+ B cells from naïve mice were compared for their ability to secrete IgG in vitro. Spleen CD4+ T cell (Th cells) were assessed for their ability to secrete Th1-related IFN-gamma or Th2-related IL-4 after CD3/CD28 stimulation, as well as their suppression by Pg. We used quantitative PCR to measure transcription in CD4+ T cells of IFN-gamma, T-bet and Pg receptor genes.

Results: iPRKO mice generated significantly more antigen-specific IgG1 and IgG2a than WT mice after TD immunization; in contrast, TI-2 IgG responses in iPRKO mice were deficient. Regulation of TD responses by iPR did not appear to involve B-cell intrinsic effects, since iPRKO B cells were deficient in their ability to secrete IgG in vitro in response to either T cell-associated signals (anti-CD40, IL-4) or T cell-independent signal (LPS). However, CD4+ T cells from iPRKO mice made significantly more IFN-gamma, but not IL-4, after CD3/CD28 stimulation in vitro compared to WT T cells, even in the absence of Pg. In the presence of Pg, IFN-gamma induction was significantly suppressed in CD4+ T cells in an iPR-dependent manner, as was transcriptional repression of

the IFN-gamma gene (ifng). Compared to WT, iPRKO CD4+ T cells made more IL-4, and showed more proliferation, but only in the presence of Pg.

Conclusion: iPR-mediated signals regulate Th1 functions and TD Ab responses in vivo. This appears to involve regulation of ifng by two mechanisms. First, iPR serves as a ligand-activated transcriptional repressor of activation-induced ifng transcription and IFN-gamma production in CD4+ T cells. Second, iPRKO CD4+ T cells, ex vivo or stimulated in vitro without Pg, showed enhanced levels of activation-induced ifng mRNA or IFN-gamma production, indicating iPR also regulates ifng locus structure. Interestingly, iPR may also be involved in suppressing other pathways of Pg signaling, since without iPR, CD4+ T cells became hypersensitive to proliferative effects of Pg. This latter effect may account for the increased levels of Th2-related IgG1 after TD immunization. The role of PR in other T cell-dependent immune responses is the focus of ongoing research. The Autoantibody-Inducing CD4 T Cell*ai*CD4 T cell) Which Induces Systemic Lupus Erytematosus (SLE) Belongs to CD45RB^{lo}122^{lo} Subpopulation. Yumi Miyazaki[1], Ken Tsumiyama[1] and Shunichi Shiozawa[2]. [1]Kobe University Graduate School of Health Science, Kobe, Japan, [2]Kobe University Graduate School of Health Science and Medicine/ The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

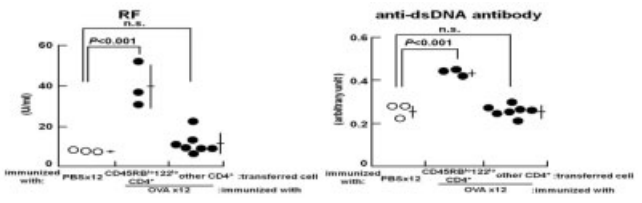
Background/Purpose: We have repeatedly immunized mice normally not prone to autoimmune disease with the same antigen and showed that repeated immunization reproducibly caused systemic autoimmunity, systemic lupus erytematosus (SLE). We show that a novel T cell type which we term an autoantibody-induing CD4 T cell (*ai*CD4 T cell) is generated *via de novo* T cell receptor (TCR) revision at periphery, in spleen. The *ai*CD4 T cell induced varieties of autoantibodies including rheumatoid factor (RF) and anti-Sm and anti-dsDNA antibodies, and also helped final differentiation of CD8 T cell into cytotoxic T lymphocyte (CTL) *via* antigen cross-presentation to induce lupus tissue injuries (Tsumiyama K. *et al.* PLoS ONE 4(12):e8382, 2009). We here tried to assign the CD number on *ai*CD4 T cell, and show that *ai*CD4 T cell belongs to CD45RB^{lo} 122^{lo} population.

Methods: BALB/c mice were repeatedly immunized with ovalbumin (OVA), keyhole limpet hemocyanin (KLH) or staphylococcal enterotoxin B (SEB). RF, anti-Sm and anti-dsDNA antibody were measured using ELISA. To assign CD number on the *ai*CD4 T cell, expression of effector / memory markers including CD45RB, CD27, CD122, PD-1, CD44, CD62L, CD127, CCR7 and Ly6C were studied using splenic CD4 T cell of repeatedly immunized mice. These splenic CD4 T cells were further isolated referring to CD45RB, CD27 and CD122 markers, and fractioned cells were adoptively transferred into naïve recipients. Autoantibodies were measured in sera of recipient mice 2 weeks after transfer.

Results: Upon repeated immunization >12x with OVA, KLH or SEB, varieties of autoantibodies including RF and anti-Sm and anti-dsDNA antibodies were increased ($P<0.01$). We also noted that CD45RB^{lo}, CD27^{lo} and CD122^{hi} CD4 T cells were significantly expanded as compared with control mice upon immunization with either OVA, KLH or SEB ($P<0.001$). We fractioned CD4 T cells by referring CD45RB, CD27 and CD122 markers. We adoptively transferred fractioned CD4 T cells into naïve recipients and tested if RF and anti-dsDNA antibody were increased. This transfer studies showed that RF and anti-dsDNA antibody were significantly increased by the transfer of either CD45RB^{lo} CD4 T cells or CD122^{lo} CD4 T cells. However, the transfer of CD27^{lo} CD4 T cell and CD27^{hi} CD4 T cell both induced the increase of RF and anti-dsDNA antibody. We then transferred CD45RB^{lo} 122^{lo} CD4 T cells into naïve mice to show that both RF and anti-dsDNA antibody were significantly increased ($P<0.001$).



Conclusion: The *ai*CD4 T cell that induces SLE belongs to CD45RB^{lo} 122^{lo} CD4 T subpopulation.

Sex-Specific Effects of Segmented Filamentous Bacteria In the Autoimmune-Prone NOD Mouse Strain—Segregation with Diabetes Protection In Females but Not Males. Martin A. Kriegel[1], Esen Sefik[2], Jonathan A. Hill[2], Hsin-Jung Wu[2], Christophe Benoist[2] and Diane Mathis[2]. [1]Brigham & Women's Hospital/Harvard Medical School, Boston, MA, [2]Harvard Medical School, Boston, MA

Background/Purpose: Segmented filamentous bacteria (SFB) are commensals capable of inducing a robust Th17 population in the small intestinal lamina propria (SI-LP) of the mouse gut. Consequently, SFB can promote IL-17-dependent autoimmune responses, including inflammatory polyarthritis in the K/BxN (KRN/NOD) mouse that resembles rheumatoid arthritis (Wu et al, Immunity 2010). Here, we exploit the incomplete penetrance of SFB colonization of NOD mice in our animal facility to explore its impact on autoimmune diabetes.

Methods: Fecal DNA was isolated from 4–6-wk old NOD mice using bead beating and phenol/chloroform. Realtime PCR was performed with SFB-specific 16S rDNA primers. Insulitis was assessed with H&E staining of pancreata. Lamina propria lymphocytes (LPL) were prepared and analysed using FACS. Intracellular cytokines were detected after ex vivo stimulation with PMA/ionomycin. RNA from sorted LPL was amplified, biotin labeled, purified and hybridized to an Affymetrix chip. Microarray data was analysed with the GenePattern suite.

Results: There was a strong co-segregation of SFB-positivity and diabetes protection in females, but not in males, which remained relatively disease-free regardless of the SFB status.

Cumulative Incidence of Autoimmune Diabetes

SFB Status	Males	Females
SFB-Positive	17.4%	15.8%
SFB-Negative	11.1%	91.3%
p-value	ns	<0.0001

In contrast, insulitis did not depend on SFB colonization suggesting that it may somehow modulate diabetes unfolding. SFB-positive, but not SFB-negative mice had a substantial population of Th17 cells in the SI-LP whereas Th1 and Treg populations were unaffected in the gut, pancreatic or systemic lymphoid tissues. Th17 signature transcripts dominated the very limited SFB-induced molecular changes detected in SI-LP CD4$^+$ T cells.

Conclusion: A single commensal bacterium, and the gut immune system alterations associated with it, can either promote or protect from autoimmunity (i.e. rheumatoid arthritis versus type 1 diabetes) in predisposed mouse models, likely reflecting their variable dependence on different Th subsets. Remarkably, the effects of SFB on autoimmunity in the NOD mouse were gender-specific, adding an entirely novel mechanism to help explain sex differences in autoimmune diseases. These findings should set the basis for a better understanding of strongly female-biased human autoimmune diseases like Sjogren's syndrome or SLE, both of which are also modelled in the autoimmune-prone NOD mouse strain.

Expansions of Interleukin-21-Secreting CD4 $^+$T Helper Cells in Inflammatory Arthritides. Pedro L. Vieira[1], Maria C. Lebre[2], Saïda Aarrass[2], Thomas Newsom-Davis[1], PP. Tak[2] and Gavin R. Screaton[1]. [1]Imperial College London, London, United Kingdom, [2]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease affecting synovial tissue in multiple joints. The inflammatory process in RA is regulated by several cytokines, especially TNF, which is produced not only by macrophages and DCs but also by activated antigen-specific CD4$^+$ T helper (Th) cells. IL-21 is a pleiotropic type 1 cytokine that shares the common cytokine receptor γ-chain, γ(c), with IL-2, IL-4, IL-7, IL-9, and IL-15. IL-21 is most homologous to IL-2. Whereas IL-2 promotes development of regulatory T cells and confers protection from autoimmune disease, IL-21 promotes differentiation of Th17 cells and is implicated in several autoimmune diseases, including type 1 diabetes, systemic lupus erythematosus and rheumatoid arthritis. IL-21, an inflammatory cytokine that belongs to the common γ-chain receptor binding family is secreted by several cell types including Th17 and T follicular helper cells (TFh). An increasing number of inflammatory molecules are being identified that may contribute to

RA pathology. Therefore we investigated the expression of interleukin-17A (IL-17A), IL-21 and IL-22 in RA, psoriatic arthritis (PsA) and undifferentiated arthritis (UA). In addition we dissected the in vitro requirements for the differentiation of human IL-21-secreting $CD4^+$ T helper (Th) cells.

Methods: Expression of surface markers and cytokine production at the single cell level in peripheral blood (PB) and matched synovial fluid (SF) from RA (n=8), PsA (n=4) and UA (n=5) patients, as compared to PB of healthy control subjects (n=25), was evaluated by flow cytometry following polyclonal stimulation ex-vivo. IL-21 concentrations were assessed by ELISA in cell-free SF samples of RA (n=15), PsA (n=14) and UA (n=9) patients and in 6 days supernatants of RA (n=6) and spondyloarthropathy (SpA, n=5) synovial biopsy cultures. Immunohistochemistry analysis were performed on synovial tissues (STs) of healthy donors (HD), RA, PsA, OA, and gout patients and sections were evaluated by digital image analysis.

Results: We observed significant expansions of IL-21-secreting cells, which represented up to 47% of total $CD4^+$ Th cells in SF. While the expression of IL-21 in STs and SF did not differ between the different arthritides, in ST IL-21 was significantly higher in inflammatory arthritis compared to HD. Interestingly, RA synovial biopsies released significantly higher levels of IL-21 compared to SpA. $CD4^+IL\text{-}21^+$ could be detected in RA ST that do not co-localized with IL-17 neither IL-22. Synovial IL-21-secreting cells did not phenotypically fit the TFh cell paradigm in that they did not express CXCR5. In humans, differentiation of naïve $CD4^+$ T cells into IL-21-secreting cells in vitro was preferentially driven by IL-21 and/or IL-6 in the additional presence of transforming growth factor-β.

Conclusion: IL-21 and IL-21 blocking therapy is now being tested in a number of diseases. The results of this study enhance the rationale for a trial of IL-21 blockade in RA where it may provide a useful adjunct in those patients refractory to or unable to tolerate anti-TNF therapy.

Th17 but Not Th22 Cells Display Pathological Behaviour in Rheumatoid Arthritis Synovial Inflammation. Jan Piet van Hamburg, Odilia B.J. Corneth, Sandra M.J. Paulissen, Nadine Davelaar, Patrick S. Asmawidjaja and Erik Lubberts. Erasmus MC, University Medical Center, Rotterdam, Netherlands

Background/Purpose: T cells and their cytokines play a central role in the processes underlying synovial inflammation in rheumatoid arthritis (RA). In particular the IL-17A and IL-22 producing Th17 cells have been shown to be critically involved in the induction and progression of arthritis. Recently a novel Th22 subset was discovered, which was characterized by the expression of IL-22 in the absence of IL-17. However, it remains unclear whether Th22 cells, like Th17 cells, directly contribute to RA synovial inflammation. In this study we examined the potency of Th22 cells to activate synovial fibroblasts. In addition, it was investigated whether IL-22 is critical in Th17-mediated experimental arthritis.

Methods: Th17 (CD4+CD25-CCR6+CCR4+CCR10-) and Th22 (CD4+CD25-CCR6+CCR4+CCR10-) cells were analyzed in peripheral blood of treatment-naïve RA patients in comparison to age and sex matched healthy controls by flow cytometry. Furthermore, synovial fluid of patients with established RA was analysed for the presence of Th17 and Th22 cells. To test the contribution of IL-22 or Th22 in synovial inflammation, co-culture experiments of RA synovial fibroblasts (RASF) with Th22 and Th17 cells were performed. The *in vivo* relevance of IL-22 in synovial inflammation was investigated in a T cell-mediated arthritis model using mice deficient for IL-22.

Results: Both the Th17 and Th22 cell populations were increased in peripheral blood of treatment naïve patients with early RA compared to age and sex matched healthy controls. In addition, Th17 and Th22 cells were present in synovial fluid of patients with early RA. When RASF were co-cultured with Th17 or Th22 cells, in both conditions the neutralisation of IL-22 resulted in an induction of the pro-inflammatory cytokine IL-6. In contrast, IL-22 activation with FICZ (6-formylindolo(3,2-b)carbazole) resulted in a reduction of IL-6. Comparing the RASF co-culture condition of Th17 with Th22, Th17 cells were markedly more potent than Th22 cells in the induction of IL-6, IL-8 and matrix metalloprotease (MMP)-1 and MMP-3. In line with this, mouse Th17 cells lacking IL-22 expression were able to induce IL-6 expression in mouse synovial fibroblasts similar as normal mouse Th17 cells. In addition, no difference in T cell-mediated experimental arthritis severity was found between IL-22 deficient mice compared to wild type mice.

Conclusion: These findings show that both Th17 and Th22 cells are present in patients with RA. However, in contrast to Th17 cells, Th22 cells are less potent activators of RASF activation and IL-22 even appear to have an inhibitory effect on IL-6 production. These data imply that treatment of T cell-mediated inflammatory arthritis should focus on targeting Th17 cells rather than Th22 cells.

HRES-1/Rab4 Lupus Susceptibility Gene Selectively Regulates Mammalian Target of Rapamycin Complexes 1 and 2 in T Lymphocytes. Tiffany Telarico[1], Gabriella Miklossy[2], David Sabatini[3], David Kwiatkowski[4], Nahum Sonenberg[5] and Andras Perl[2]. [1]SUNY Upstate Medical University, Syracuse, NY, [2]Upstate Medical University, Syracuse, NY, [3]Whitehead Institute for Biomedical Research, Cambridge, MA, [4]Brigham and Women's Hospital, Boston, MA, [5]Goodman Cancer Research Centre, McGill University, Montreal, QC

Background/Purpose: Activation of the mammalian target of rapamycin (mTOR) mediates abnormal activation of lupus T cells via HRES-1/Rab4-regulated endosomes. *In vivo* blockade of mTOR by rapamycin improves disease activity both in lupus-prone mice and patients with SLE. Importantly, mTOR is co-localized to recycling endosomes with HRES-1/Rab4 and Rab5A, small GTPases over-expressed in SLE T cells. Therefore, we examined the role of HRES-1/Rab4 in the activity of mTOR complexes 1 (mTORC1) and 2 (mTORC2) and feedback regulation of the endocytic pathway by mTOR.

Methods: Glutathione-S-transferase (GST) pull down assays were used to identify binding partners of HRES-1/Rab4, GDP-locked dominant-negative HRES-1/$Rab4^{S27N}$, GTP-locked HRES-1/$Rab4^{Q72L}$ and phosphorylation-defective HRES-1/$Rab4^{S204Q}$ in peripheral blood lymphocytes (PBL). Adeno-associated viruses (AAV) expressing HRES-1/Rab4 isoforms in pAAV-IRES-GFP were used to infect PBL. Jurkat cells expressing HRES-1/Rab4 or HRES-1/$Rab4^{S27N}$ were also utilized. Expression and phosphorylation of proteins were measured by western blotting. Regulation of the early endosome by mTOR was studied by Rab4A and Rab5A expression, which regulate endocytic recycling and receptor internalization, respectively, in mouse embryonic fibroblasts (MEFs) deficient in Rictor, mLST8 (a mTORC1 and mTORC2 component), TSC1 and TSC2 (negative regulators of mTORC1), and 4E-BP1 (a mTORC1 substrate). Student's t-test was used to evaluate gene expression changes by western blot.

Results: Using GST pull-down assay, HRES-1/Rab4 showed direct interaction with mLST8, a component shared by mTORC1 and 2. HRES-1/$Rab4^{S27N}$and HRES-1/$Rab4^{S204Q}$ were associated with Raptor (regulator of mTORC1) and Rictor (regulator of mTORC2), respectively. HRES-1/Rab4 over-expression in AAV-transduced PBL and Jurkat cells stimulated mTORC1, as indicated by phosphorylation of S6 kinase (2.0-fold increase in PBL, p=0.015, 1.5-fold increase in Jurkat cells, p=0.02) and 4E-BP1 (1.5-fold increase, p=0.0026 in PBL, 0.76-fold decrease in dominant negative HRES-1/$Rab4^{S27N}$Jurkat cells). HRES-1/Rab4 over-expression reduced Rictor (30% decrease, p=0.002) while HRES-1/$Rab4^{S27N}$ increased Ser473 phosphorylation of Akt, a downstream target of mTORC2 (4.2-fold increase, p=0.049), suggesting that HRES-1/Rab4 inhibits mTORC2 activity. Inactivation of TSC2, which negatively regulates mTORC1, increased Rab4A (1.8-fold increase, p=0.046) and Rab5A expression (2-fold increase, p=0.007). Inactivation of TSC1 increased Rab5A (3.1-fold increase, p=0.009), but had no effect on Rab4A expression. Absence of mTORC1 substrate 4E-BP1 reduced Rab5A expression (0.6-fold, p=0.002). Inactivation of Rictor increased expression of Rab4A (1.3-fold increase, p=0.01) and Rab5A (7.8-fold increase, p=0.03).

Conclusion: HRES-1/Rab4 selectively promotes mTORC1 and represses mTORC2 activity in lymphocytes. Increased mTORC1 activity enhances HRES-1/Rab4 and Rab5A expression, while mTORC2 exerts opposite effects. These results suggest that early endosome traffic regulators operate in a positive feedback cycle with mTORC1 and negative feedback cycle with mTORC2.

Abatacept (CTLA-4Ig) Treatment Reduces Activation Induced Cell Death (AICD) and Susceptibility of T Cells to Regulatory T Cell Suppression in Patients with Rheumatoid Arthritis (RA). Michael Bonelli[1], Lisa Goeschl[1], Stefan Blueml[1], Anastasiya Hladik[1], Emmi Puujalka[1], Carl-Walter Steiner[1], Josef Smolen[2] and Clemens Scheinecker[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Abatacept (CTLA-4Ig) inhibits the binding of CD28 to the B7 ligands CD80/CD86 on antigen presenting cells (APC) and thereby effector T cell activation. Besides APC, costimulatory molecules can also be expressed on T cells upon activation. Whether this allows CTLA-4Ig to directly affect distinct T cell subsets, exerting a positive or negative effect, remains unclear.

We therefore performed phenotypic and functional analysis of T cells in RA patients before and after the initiation of CTLA-4Ig therapy.

Methods: Peripheral blood mononuclear cells (PBMC) were collected from RA patients (n=15) before and 2 and 4 weeks after the initiation of CTLA-4Ig therapy. Proportions of naïve and memory $CD4^+$ T cells and $CD4^+CD25^+Foxp3^+$ regulatory T cells (Treg) were determined by flow cytometry (FACS). In addition T cells were analyzed for the expression of marker molecules characteristic for activated T cells and Treg. PBMCs from healthy controls (HC) were pre-incubated with different doses of CTLA-4Ig before T cell receptor (TCR) stimulation and analyzed by FACS. Moreover apoptosis was induced in CTLA-4Ig incubated cells by anti-Fas antibody and DNA fragmentation was measured by TUNEL staining. Finally $CD4^+CD25^+$ Treg were isolated from RA patients by cell sorting and analyzed for their functional capacity. In addition suppression assays were performed with Treg and responder T cells from HC after pre-incubation of individual cell populations with CTLA-4Ig.

Results: Proportions of $CD4^+$ T cells and Treg substantially increased 2 and 4 weeks after the initiation of CTLA-4Ig treatment. No differences were observed for the percentage of memory and naïve $CD4^+$ T cells. Phenotypic analyses revealed a downregulation of activation associated marker molecules and of CD95 on $CD4^+$ T cells and Treg. Likewise, pre-incubation of PBMCs from HC with CTLA-4Ig before stimulation led to a dose dependent downregulation of activation markers on $CD4^+$ cells and Treg. Moreover in vitro analyses of $CD4^+$ T cells and Treg from HC showed a dose dependent decrease in AICD after incubation with CTLA-4Ig. Functional analysis of isolated Treg from RA patients revealed a diminished suppressive capacity of Treg 4 weeks after treatment with CTLA-4Ig. However, only the pre-incuabtion of responder T cells, but not of Treg, from HC resulted in a decreased T cell suppression.

Conclusion: Within our study we were able to demonstrate for the first time a direct effect of CTLA-4Ig on T cells in RA patients, which results in increased proportions of $CD4^+$ and Treg, the downregulation of CD95 and a decrease in AICD. Blockade of costimulatory molecules on T cells by CTLA-4Ig leads to a diminished susceptibility of T cells for Treg suppression which might be counter balanced by increased Treg numbers.

Do Immune Complexes (ICs) Binding Low Affinity FcγRIIIA/B Bearing $CD4^+$T Cells Contribute to the Autoimmune Pathology? Anil K. Chauhan[1] and Terry L. Moore[2]. [1]Saint Louis University, St. Louis, MO, [2]Saint Louis University, Saint Louis, MO

Background/Purpose: Low affinity Fc receptor, FcγRIIIA/B has not been previously reported on $CD4^+$T cells. A key role for FcγRIIIA/B receptors in B cell responses and other leukocyte functions has been well established. We asked the question whether the ICs binding to $CD4^+$ T cells in SLE patients is mediated via FcγRIIIA/B expression on autoimmune $CD4^+$T cells.

Methods: $CD4^+$T cells from normal subjects and SLE patients were analyzed for ICs binding in flow cytometric analysis. To analyze the nature of the receptors on the T cells, ICs wer binding was investigated using anti-FcγRIIIA/B monoclonal antibody in competitive inhibition assay. The $CD4^+$ T cells directly from SLE patients and the cells from normal were expanded by activating with anti-CD3 and anti-CD28. These cells were then stained using anti-FcγRIIIA/B antibodies and examined by confocal microscopy. The total RNA purified from these cells were then analyzed for the presence of Fc receptor transcripts using two sets of gene specific primer with RT-PCR. The identity of these amplified transcripts were further re-confirmed by DNA sequencing.

Results: We observed that a small population of $CD4^+$T cells in normal population (1 to 4%) demonstrated IC binding. This population expanded to 5 to 12% in the SLE patients (n=17). The $CD4^+$ T cells activated using anti-CD3 and anti-CD28 also demonstrated expansion of the FcγRIIIA/B population. A 50% inhibition of labeled aggregated human gamma-globulin to these cells was observed with anti-FcγRIIIA/B monoclonal antibody. The immunoprecipitates prepared using anti-FcγRIIIA/B showed protein bands of expected molecular size 26 – 29 kDa for low affinity type III receptors. The RT-PCR from total RNA, amplified an appropriate size gene product using two set of different primers specific to *FcγRIIIA/B* gene. The PCR product on further DNA sequence analysis confirmed the expression of the *FcγRIIIA/B* gene in $CD4^+$T cells. These results confirm the presence and the expansion of FcγRIIIA/B^+CD4^+T cells in autoimmune pathology. The ICs show binding to these peripheral $CD4^+$cells expressing FcγRIIIA/B.

Conclusion: The presence of FcγRIIIA/B on $CD4^+$T cells implies a role for ICs in T cell mediated responses observed in SLE pathology. T cell receptor (TCR) complex that mediate downstream signaling during T cell activation, require phosphorylation of ζ-chain. The ζ-chain forms heterodimer with the FcRγ chain. The FcRγ chain is the signaling unit of FcγRIIIA that can replace ζ-chain function in T cells. This implies that the T cells can be activated by signaling proteins that are part of major B cell signaling pathway. Our results point sharing of this pathway by $CD4^+$ T cells during autoimmune pathology. Further investigation of the role for FcγRIIIA/B receptors and ICs in T cell physiology during the disease pathogenesis of SLE is required.

Leptin Modulates Apoptosis of Autoimmune T Cells in Systemic Lupus Erythematosus. Gil Amarilyo[1], Noriko Iikuni[2], Bevra H. Hahn[3] and Antonio La Cava[4]. [1]UCLA, Los Angeles, CA, [2]UCLA, CA, [3]UCLA David Geffen School of Medicine, Los Angeles, CA, [4]Univ of California Los Angeles, Los Angeles, CA

Background/Purpose: In systemic lupus erythematosus (SLE), the abnormal clearance of dead cells leads to the availability and accumulation of self-antigens that can facilitate the initiation and maintenance of T cell-driven autoimmune responses. Leptin is an adipokine that controls metabolism and pro-inflammatory immune responses, and is significantly increased in patients and mice with SLE. Purpose of this study was to study the influence of leptin on apoptosis in SLE.

Methods: Thymocytes from (NZB x NZW)F1 (BWF1) lupus-prone mice were incubated with dexamethasone (that promotes apoptosis) in the presence or not of leptin and compared with their parental strains (NZB and NZW mice) for the induction of apoptosis (measured by TUNEL assay). Additional controls included thymocytes from non autoimmune mice. The expression of the anti-apoptotic molecule bcl-2 in CD4 T cells was evaluated in parallel by flow cytometry. To study the effects of leptin on apoptosis in autoreactive CD4 T cells, ovalbumin (OVA) T-cell receptor transgenic DO11.10 mice were immunized with OVA and then divided into two groups: one receiving leptin and one serving as control (receiving vehicle). Peripheral OVA-specific autoreactive T cells sorted by tetramer staining were co-stained for BrDU, annexin V and bcl-2. Concomitantly, proliferation and apoptosis of peripheral autoreactive cells in BWF1 lupus mice immunized with two different anti-DNA Ig-derived epitopes and treated or not with leptin was investigated.

Results: Leptin inhibted T cell apoptosis in BWF1 lupus mice as compared to the parental NZB and NZW mice ($P<0.03$ for both) and to the non-autoimmune animals ($P<0.01$). This inhibition of apoptosis by leptin associated with the upregulation of the anti-apoptotic molecule bcl-2 ($P<0.009$), both in thymocytes and in peripheral T cells. Interestingly, administration of leptin facilitated the survival and proliferation of peripheral T cells autoreactive to anti-DNA Ig-derived epitopes in BWF1 lupus mice, as shown in flow cytometry and proliferation assays. Similarly, in OVA-transgenic DO11.10 mice, leptin treatment was associated with inhibition of apoptosis and the induction of bcl-2 in peripheral OVA-specific CD4 T cells, and also with an increased proliferation of the autoreactive T cells.

Conclusion: Leptin facilitates the survival and proliferation of autoreactive T-cells through a leptin-dependent upregulation of bcl-2. This newly described role of leptin in the facilitation of autoreactive T cell activity in SLE may have implications for new targeted therapeutic approaches in the disease.

Identification of a $CD62L^{hi}CD44^{low}$ T_{FH} Precursor Capable of Developing into An $IL21^{hi}$ $IL17^{hi}$ Mature T_{FH} in Autoimmune BXD2 Mice. Yanna Ding[1], Hui-Chen Hsu[1] and John D. Mountz[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham and Birmingham VAMC, Birmingham, AL

Background/Purpose: Follicular T helper (T_{FH}) cells have been found in some SLE patients and correlated with autoantibodies production and disease severity. We recently identified that autoimmune BXD2 mice demonstrated higher T_H-17 and GCs response and displayed 2.5-fold increased frequency of $CXCR5^+ICOS^+$ T_{FH} in the spleen compare to B6. T_{FH} is now considered as the key effector T cells for antibody formation. However, rational therapy to target T_{FH} by blocking its development is impeded by lack of identification of the phenotype of the T_{FH} precursor CD4 T cells. The aim of this study is to determine the T_{FH} precursor in BXD2 mice.

Methods: Single cell suspensions or isolated CD4 T cells prepared from mouse spleens were subjected to FACS staining with or without culture with IL-21/IL-17. CD4 T cells were used for RNA extraction and Real-time PCR analysis for mRNA levels of T_{FH}-related genes. Frozen spleen sections were subjected for confocal imaging analysis of CD62L, CD44, IL-21, IL-17 and CXCR5 in CD4 T cells.

Results: Compared to CD4 T cells from B6 mice, CD4 T cells in BXD2 mice displayed an expansion of the $CD62^{hi}CD44^{hi}$ effector and $CD62L^{-}CD44^{hi}$ memory phenotype with a concomitant reduction in $CD62L^{hi}CD44^{-}$ and $CD62L^{hi}CD44^{lo}$ naïve CD4 T cells. Interestingly, highest levels of IL-21 was observed in $CD62L^{hi}CD44^{lo}CD4$ T cells whereas highest levels of BCL6, IL-17, CXCR5, were observed in the $CD62^{int}CD44^{hi}$ effector CD4 T cells from BXD2 mice, suggesting that upregulation of IL-21 occurs prior to upregulation of IL-17. Consistent with this, compared to WT BXD2 mice, there was decreased frequency of $IL\text{-}17^{+}$ T_{FH} in BXD2-*Il21*$^{-/-}$ mice. In contrast, increased frequency of $IL\text{-}21^{+}$ T_{FH} was observed in BXD2-*Il17r*$^{-/-}$ mice.

In vitro IL-21 stimulation shifted $CD62L^{hi}CD44^{-}$ naïve CD4 into the $CD62L^{hi}CD44^{lo}$ phenotype and promoted BCL6 and IL17R expression in $CD62L^{hi}CD44^{lo}$ CD4 T cells of BXD2 and BXD2-*Il21*$^{-/-}$ mice. IL21 plus IL17 induced the highest levels of BCL6 in $ICOS^{+}CXCR5^{+}T_{FH}$. Real-time PCR confirmed that IL21 treatment increase mRNA levels of *Bcl6*, *Il21*, *Il17r* and *Il17*.

Confocal imaging analysis showed that $CD62L^{hi}CD44^{lo}$ CD4 located between naïve CD4 T area and GC while $CD62^{hi}CD44^{hi}$ subset located in LZ of a GC where $IL\text{-}17^{+}IL\text{-}21^{+}$ T_{FH} can also be visualized.

Conclusion: Our study suggests that the $CD62L^{hi}CD44^{lo}$ CD4 subset that produces IL-21 is a T_{FH} precursor, and that the $CD62^{hi}CD44^{hi}$ subset that produces CXCR5, IL-17, and IL-21 is the mature T_{FH}. Because the development of spontaneous GC was dramatically diminished in both BXD2-*Il21*$^{-/-}$ and BXD2-*Il17r*$^{-/-}$ mice despite the increased frequency of T_{FH} in BXD2-*Il17r*$^{-/-}$ mice, our results suggest that the formation of spontaneous GC in BXD2 mice requires both IL-17 and IL-21. IL-21 stimulates BCL6, IL-21 and IL-17. IL-17 provides an additional signal to stimulate BCL6 in T_{FH}.

Effects of Altering Fli1 Levels in Lupus T Cells on Disease Expression and T Cell Function in the MRL/Lpr Mouse Model. Fahmin Basher[1], Marlene Bunni[1], Zainab Amani[1], Xian Zhang[2] and Tamara K. Nowling[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina & Ralph H Johnson VA Medical Center, Charleston, SC

Background/Purpose: The Ets factor Fli1 is implicated as a key modulator of lupus disease expression. Over-expressing Fli1 in healthy mice, results in the development of an autoimmune kidney disease similar to that observed in lupus. Lowering the global levels of Fli1 in two lupus mouse models significantly improved disease and prolonged survival. Lowering the levels of Fli1 in hematopoietic cells in MRL/lpr lupus mice resulted in significantly improved kidney disease. The cell type mediating this protective effect is unknown. We have analyzed the effects of reducing Fli1 levels in lupus T cells on disease expression using an adoptive transfer model and on T cell function in kidney infiltration, proliferation and apoptosis assays.

Methods: T cells were isolated from spleens of MRL/lpr Fli1+/+ and Fli1+/− mice. Fli1+/+ T cells were transferred into MRL/lpr Fli1+/− mice and Fli1+/− T cells were transferred into Fli1+/+ mice. As a control, Fli1+/+ T cells and Fli1+/− T cells were also transferred into Fli1+/+ and Fli1+/− mice, respectively. All donors and recipients were 7 weeks old. Urine and blood were collected at 2, 4, 8 and 12 weeks after transfer. ELISAs were performed to measure proteinuria and serum anti-GBM, anti-dsDNA and Ig levels. Proliferation was measured by CFSE staining and apoptosis by AnnexinV staining following stimulation with PMA and ionomycin. T cell subsets infiltrating the kidney were analyzed by flow cytometry.

Results: Transferring Fli1+/+ T cells into Fli1+/− mice does not significantly increase the urine albumin levels of the Fli1+/− mice but transfer of Fli1+/− T cells into Fli1+/+ mice decreases the levels of urine albumin compared to controls. Similarly, Fli1+/+ mice that received Fli1+/− T cells had significantly decreased serum IgG levels ($p=0.026$) but Fli1+/− mice that received Fli1+/+ T cells did not have a significant increase in IgG levels compared to controls. Additionally, MRL/lpr Fli1+/− mice have significantly fewer numbers of total T cells infiltrating the kidney compared to MRL/lpr Fli1+/+ mice at 14 weeks of age ($p=0.017$). Specifically, MRL/lpr Fli1+/− had both decreased percentages and numbers of CD4+ T cells ($p<0.004$) and activated/memory CD3+ T cells ($p<0.02$). However, no significant differences were observed in proliferation or apoptosis between MRL/lpr Fli1+/+ and Fli1+/− T cells.

Conclusion: These results suggest that reducing Fli1 levels in T cells may have specific effects on autoantibody production. Because transferring Fli1+/− T cells into Fli1+/+ mice resulted in reduced urine albumin and serum IgG levels and transferring of Fli1+/+ into Fli1+/− mice did not significantly increase urine albumin and serum IgG levels, it suggests that T cells with reduced Fli1 levels may be playing a regulatory role to suppress Fli1+/+ pathogenic T cells. In addition, the results of the kidney infiltration analyses suggest Fli1 also may play a role in T cell migration, proliferation, apoptosis and/or differentiation. However, our results indicate Fli1 does not significantly affect proliferation or apoptosis of lupus T cells following mitogenic stimulation. The role of Fli1 on T cell differentiation and regulatory function are currently being explored.

DNA Methylation Regulates Gene Expression in CD4+CD28- T Cells Through Micrornas. Dipak R. Patel, Anura Hewagama, Gabriela Gorelik, Sushma Yarlagadda, Faith Strickland and Bruce C. Richardson. University of Michigan, Ann Arbor, MI

Background/Purpose: CD4+CD28- T cells are enriched in chronic inflammatory diseases like rheumatoid arthritis and lupus. They are cytotoxic and resistant to apoptosis. Disease severity and atherosclerosis correlate with increasing numbers of these cells.

Compared to CD28+ cells, CD28- CD4 T cells over-express killer immunoglobulin-like receptors (KIRs) and other molecules that may contribute to their pro-inflammatory phenotype. These genes are regulated by DNA methylation- CD4 T cells demethylated in vitro over-express KIRs and other immunostimulatory molecules. This is a result of decreased signaling through the ERK and JNK pathways, which consequently decreases activity of enzymes (DNMTs) responsible for DNA methylation. Changes in DNA methylation also affect microRNA (miRNA) expression, and the role of miRNAs in CD28- T cells is unknown. We studied differences in mi- and mRNAs in CD4+CD28+ and CD4+CD28- T cells. Protein phosphatase 5 (PP5), expressed in CD4+CD28- but not CD4+CD28+ T cells, inhibits both ERK and JNK signaling, so we also hypothesized that overexpressing PP5 in CD4 T cells will induce expression of methylation sensitive genes unique to CD28- T cells.

Methods: PBMCs from healthy donors were stimulated with phytohemagglutinin (PHA). CD4 T cells were then isolated by negative selection and cultured 3 days with IL-2. CD4+CD28+ and CD28- cells were separated by flow cytometry. Over 900 miRNAs were profiled with PCR arrays, and mRNAs analyzed with Affymetrix arrays. Micro- and mRNAs of interest were compared in CD4+CD28+ and CD4+CD28- T cells isolated from lupus patients. CD4 T cells stimulated with PHA from healthy donors were transfected with vectors encoding either GFP or GFP and PP5 (Amaxa). GFP+ cells were analyzed by flow cytometry 3 days after transfection.

Results: Twelve miRNAs were over- or underexpressed > 1.5-fold in CD4+CD28- T cells relative to CD4+CD28+ cells. MicroRNAs 362 and 500* were over-expressed in CD28- T cells generated in vitro and CD28- T cells isolated from SLE patients. These miRNAs were also overexpressed in CD4 T cells demethylated in vitro. CD20 and KIR mRNAs were over-expressed in CD28- T cells from both systems, and these mRNAs are predicted to be regulated by miRNAs that were underexpressed in CD28- T cells. CD20 mRNA was increased in patients with SLEDAI<4, compared to patients with more active disease. Surface expression of KIR protein was increased 4 fold ($p=0.045$) in CD4+ T cells transiently transfected with PP5, compared to cells transfected with a control vector.

Conclusion: MicroRNAs 362 and 500* are increased in CD4+CD28- T cells as well as CD4 T cells demethylated in vitro, indicating they are regulated by DNA methylation. These miRNAs are predicted to interact with proteins regulating DNA methylation (MBD1, DNMT3a) and apoptosis (Fas), and these interactions are being confirmed. CD20 and KIR mRNAs were also increased in CD4+CD28- T cells, and this could contribute to their phenotype. CD20+ CD4 T cells are present in RA, and they are eliminated by rituximab. Overexpressing PP5 increases KIR, supporting the hypothesis that PP5 blocks inhibitory signaling pathways upstream of KIR. PP5's effects on these pathways and other methylation sensitive genes are currently being studied.

CTLA-4 and TNF-á Promoter –308 A/G Polymorphisms and ANCA-Associated Vasculitis Susceptibility: A Meta-Analysis. Young Ho Lee, Sung Jae Choi, Jong Dae Ji and Gwan Gyu Song. Korea University Medical Center, Seoul, South Korea

Background/Purpose: The aim of this study was to explore whether the cytotoxic T lymphocyte associated antigen-4 (CTLA-4) or tumor necrosis factor-α (TNF-α) polymorphisms contribute to anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) susceptibility.

Methods: The authors conducted a meta-analysis on associations between polymorphisms of the 3′ untranslated region (UTR) microsatellite at exon 3, exon 4 CT60 (A/G), exon 1 +49 (A/G), and promoter −318 (C/T) of CTLA-4, and TNF-α promoter −308 (A/G) and AAV susceptibility as determined using; 1) allelic contrast and 2) homozygote contrast, 3) recessive, and 4) dominant models.

Results: A total of 11 comparisons were considered in this meta-analysis. These studies encompassed 7 CTLA-4 studies and 4 TNF-α studies in 10 European populations and 1 Asian population. The $(AT)_n$ repeat polymorphisms of CTLA-4 were found to be significantly associated with AAV in European populations (OR of 86 vs. xx allele = 0.402, 95% CI = 0.184–0.875, p = 0.022). The one study conducted on this polymorphism in Asians showed no significant association with AAV. Meta-analysis of the 86/86 (recessive effect), 86/86 and 86/xx (dominant effect), and 86/86 vs. xx/xx (homozygote contrast) of the $(AT)_n$ repeat revealed a significant association with AAV in Europeans. Both the *CTLA-4 CT60* and *+49* polymorphisms were found to be significantly associated with AAV in European populations, and allele and genotype-based analyses showed a significant association between the *CTLA-4 CT60* and *+49* polymorphisms with AAV in Europeans (OR of the A allele of CT60 = 0.769, 95% CI = 0.619–0.017, p = 0.035; OR of the T allele of +49 = 1.382, 95% CI = 1.147–1.664, p = 0.001, respectively). Meta-analysis of the *CTLA-4* -318 polymorphism failed to identify any association with AAV. Furthermore, meta-analysis of the AA genotype, the AA and AG genotypes, and the A allele of TNF-α failed to reveal any association with Wegener's granulomatosis (WG).

Conclusion: This meta-analysis demonstrates that the CTLA-4 polymorphisms confer susceptibility to AAV in Europeans. In contrast, no association was found between the TNF-α -308 polymorphism and susceptibility to WG in Europeans.

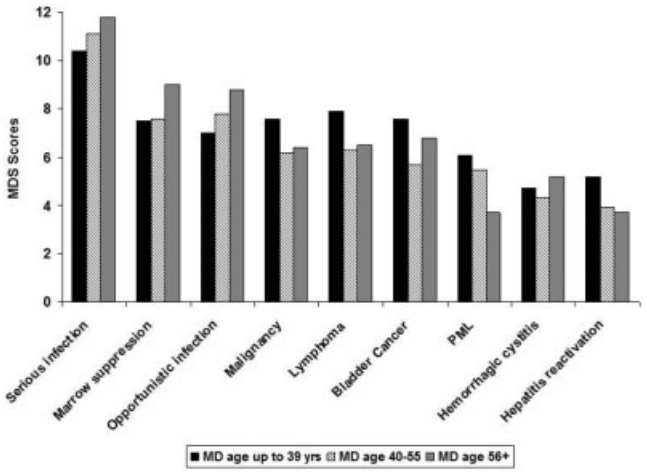
How Do Rheumatologists Choose Between Cyclophosphamide and Rituximab? Raluca Cozmuta[1], Peter A. Merkel[2] and Liana Fraenkel[3]. [1]St. Vincent Medical Center, Bridgeport, CT, [2]Boston University School of Medicine, Boston, MA, [3]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT

Background/Purpose: Recent randomized controlled trials have found that rituximab is as effective as cyclophosphamide at inducing remission in patients with ANCA-associated vasculitis (AAV). As a result, the treatment decisions depend substantially on how rheumatologists perceive differences in the risk profiles associated with both options. The objective of this study was to quantify the influence of specific adverse events (AEs) on rheumatologists' treatment decisions for patients with newly diagnosed AAV.

Methods: We administered a MaxDiff Scaling (MDS) survey to rheumatologists attending the 2010 American College of Rheumatology National Meeting. The survey included 23 AEs associated with either rituximab and/or cyclophosphamide. Participants were given the following instructions: *On the following pages you will be asked to consider (given your knowledge about the severity and probability of each of the adverse events) how much each adverse event influences your decision about which medication to prescribe for a 50 year old post-menopausal woman with newly diagnosed severe ANCA-associated vasculitis. Assume the patient is hospitalized with pulmonary and renal involvement.* The survey asked respondents to choose the most important item from a series of sets (determined by the MDS software) containing different combinations of 4 items from the master list of 23 AEs. We used Hierarchical Bayes modeling to generate the mean relative importance score for each adverse event. We subsequently examined the association between physician characteristics and ratings using multivariate linear regression models.

Results: 118 physicians completed the survey; mean age (SD) = 48 years (10); 68% male; 81% spend the majority of time in clinical practice; 39% work in an academic setting; 46% see between 1 and 5 patients with AAV per year; 22% see between 6 and 10 patients with AAV per year, and 25% see more than 10 patients with AAV per year. Although there was significant viability in rankings, physicians' treatment decisions were most strongly influenced by the risk of infection (see Figure). Older physicians were more strongly influenced by the risks of infection (standardized estimate= 0.29, p=0.004) and less strongly influenced by the risk of cancer (standardized estimate= − 0.25, p=0.02) compared to younger rheumatologists (after adjusting for gender, work setting, and number of patients with AAV seen per year).



Conclusion: Despite the lack of difference in the risks of serious infections in head-to-head clinical trials, risk of serious infection is the most important risk considered by rheumatologists in deciding which treatment to prescribe for AAV. Future studies generating precise risk estimates for both rituximab and cyclophosphamide-based remission-induction regimens will help inform and improve medical decision making for patients with AAV and prescribing physicians.

Treatment for ANCA-Associated Vasculitis: What Are the Experts Prescribing? Raluca Cozmuta[1], Peter A. Merkel[2] and Liana Fraenkel[3]. [1]St. Vincent Medical Center, Bridgeport, CT, [2]Boston University School of Medicine, Boston, MA, [3]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT

Background/Purpose: Data from randomized controlled trials suggest that cyclophosphamide (CTX) and rituximab (RTX) are equally effective at inducing remission in severe ANCA-associated vasculitis (AAV), and although the types of risks differ, the burden of adverse events appears to be comparable in the short-term. Therefore, until long-term studies are available, decision making depends primarily on expert opinion and/or extrapolation from use of these agents in other conditions. The objective of this study was to examine treatment choices among AAV experts.

Methods: We invited experts (defined as physicians whose practices focus on vasculitis and physicians engaged in research in vasculitis) to complete a web-based survey. Treatment choices were elicited for 3 scenarios [1) newly-diagnosed severe AAV in a treatment-naïve patient without co-morbidities, 2) recurrent severe AAV in a patient without co-morbidities previously treated with oral CTX, 3) recurrent severe AAV in a patient without co-morbidities previously treated with IV CTX] for 4 patient profiles [22 year-old woman, 62 year-old women, 22 year-old man, 62 year-old man]. Differences between groups were examined using multinomial generalized estimating equation analysis.

Results: The survey was successfully delivered to 145 experts; opened by 94 and completed by 50. 77% were male, 49% were rheumatologists, and 39% were nephrologists. 90% were attending physicians and 4% were trainees. 67% reported spending the majority of their time in clinical practice, 31% in clinical research and 2% in basic research. 71% worked in a university hospital setting. 24% were from the US and 61% were from Europe. Preferences for treatment of newly-diagnosed young women (52% with RTX) differed significantly (p<0.001) from those for older men (76% with CTX) and older women (74% with CTX) (see Table). Efficacy, toxicity and cost were all important reasons underling experts' choices for patients with newly diagnosed AAV. Uncertainty

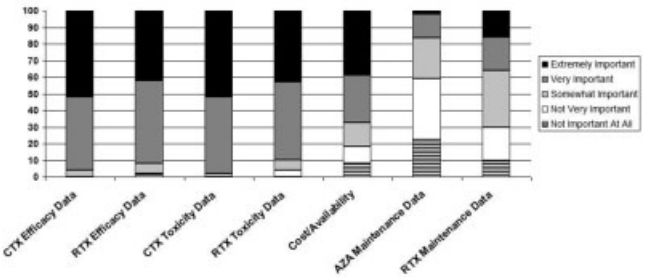
regarding the efficacy of azathioprine and RTX to maintain remission had much less influence (see Figure). 60% or more of respondents preferred RTX for recurrent disease regardless of patients' age or sex.

Table. Treatment Preferences for AAV

	Newly Diagnosed AAV: Treatment Naïve*				Recurrent AAV: Received PO CTX - on AZA			Recurrent AAV: Received IV CTX - on AZA		
	PO CTX	IV CTX	RTX	No Preference	CTX	RTX	No Preference	CTX	RTX	No Preference
Young Woman	2%	30%	56%	12%	2%	92%	6%	5.9%	88.2%	5.9%
Older Woman	10%	64%	10%	16%	17.6%	70.6%	11.8%	19.6%	60.8%	19.6%
Young Man	2%	48%	36%	14%	4%	84%	12%	10%	78%	12%
Older Man	12%	64%	10%	14%	16%	72%	12%	18.4%	61.2%	20.4%

* Treatment preferences for a young woman differ significantly from those of an older woman and older man.

Figure. Importance of Reasons Underlying Treatment Preference



Conclusion: Most vasculitis experts prefer to prescribe RTX for young women with newly-diagnosed AAV and for all patients with recurrent disease who have been previously treated with either oral or IV CTX. In contrast, IV CTX is the preferred treatment among most experts for older patients with new-onset disease. There appears to be less agreement regarding the preferred treatment for newly-diagnosed young men.

Are Patients with ANCA-Associated Vasculitis Entered In Clinical Trials Representative of Patients Followed In Observational Cohorts? Christian Pagnoux[1], Simon Carette[2], Nader A. Khalidi[3], David Cuthberston[4], Paul R. Fortin[5], Gary S. Hoffman[6], Carol A. Langford[7], Paul A. Monach[8], Luc Mouthon[9], Philip Seo[10], Ulrich Specks[11], Steven R. Ytterberg[11], Peter A. Merkel[12], Loic Guillevin[13], French Vasculitis Study Group (FVSG)[14] and The Vcrc[8]. [1]University Health Network, Toronto, Canada, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON, [3]McMaster University, Hamilton, ON, [4]University of South Florida, Tampa, FL, [5]Toronto Western Hospital and University of Toronto, Toronto, ON, [6]Cleveland Clinic Found A50, Cleveland, OH, [7]Cleveland Clinic, Cleveland, OH, [8]Boston University, Boston, MA, [9]Hopital Cochim, Paris, France, [10]Johns Hopkins Vasculitis Center, Baltimore, MD, [11]Mayo Clinic, Rochester, MN, [12]Boston University School of Medicine, Boston, MA, [13]Cochin University Hospital, Paris, France, [14]Paris, France

Background/Purpose: It is not clear whether patients with granulomatosis with polyangiitis (Wegener's; GPA) or microscopic polyangiitis (MPA) entered into therapeutic clinical trials are representative of those followed in observational cohorts.

Methods: We compared the clinical characteristics at diagnosis and subsequent death and/or relapse of patients with systemic/severe GPA or MPA with five-factor score (FFS) ≥1 enrolled in the WEG91 or WEGENT trials to those followed in the FVSG or VCRC observational cohorts (with the same GPA form or MPA severity at diagnosis, and never included in any other therapeutic trial). All patients fulfilled ACR and/or Chapel Hill classification criteria.

Results: Data from 423 patients enrolled in the observational cohorts (167 in the FVSG, 256 in the VCRC) and 220 patients enrolled in the trials (159 WEGENT, 61 WEG91) were available for analysis (Table). Compared to patients in the cohorts, patients in the trials were older, had more frequent and severe renal involvement, and more frequent lung and cardiovascular manifestations at diagnosis. Patients in the trials had a higher mortality, mainly during the first 2 years post-diagnosis, but a lower relapse rate (with a slightly shorter follow-up). We separately analyzed patients with GPA and found similar differences for characteristics at diagnosis, with higher mortality (24% vs 3%; $p<0.001$) and lower relapse rate (50.8% vs 61.5%; $p=0.02$) in the patients in the trials. However, relapse-free survival rates at 5 years post-diagnosis were eventually comparable (38.4% (95% CI, 29.0–47.6) in the FVSG cohort vs. 39.5% (95% CI, 32.5–46.4) in the patients in the trials).

Characteristics	Patients in Observational Cohorts n=423	Patients in Clinical Trials n=220	P value
Diagnosis—n (% of patients with available data)			
Microscopic polyangiitis (MPA)	26 (6.1)	41 (18.6)	***<0.001***
Granulomatosis with polyangiitis (Wegener's; GPA)	397 (93.9)	179 (81.4)	
Age at diagnosis (years ± SD)	46.5 ± 17.3	56.6 ± 13.9	***<0.001***
Sex ratio M/F (n)	218/205	110/110	0.67
Constitutional symptoms (n, (%))	375 (88.9)	194 (91.1)	0.40
Cutaneous manifestations	118 (28.0)	72 (33.8)	0.19
Eye involvement	94 (22.3)	61 (28.6)	0.08
ENT involvement	311 (73.9)	162 (75.0)	0.48
Lung involvement	275 (65.6)	169 (78.2)	***<0.001***

Cardiomyopathy	3 (0.7)	8 (3.8)	0.10
GI manifestations	28 (6.7)	26 (12.3)	***0.02***
Renal involvement	231 (53.7)	174 (80.9)	***<0.001***
Mean creatinine (μmol/l ± SD)	131.4 ± 142	196.0 ± 218	***<0.001***
Mean MDRD-GFR (ml/min/1.73 m^2)	74.4 ± 34.1	56.4 ± 34.3	***<0.001***
Mononeuritis multiplex	81 (19.1)	43 (20.2)	0.94
CNS involvement	14 (3.4)	14 (6.6)	0.11
ANCA status			
Anti-PR3 positive	248 (65.6)	110 (50.0)	0.09
Anti-MPO positive	58 (15.3)	51 (23.2)	***0.01***
Both anti-PR3 and anti-MPO	4 (1.0)	2 (0.9)	0.99
FFS (for patients with MPA only)			
1	24 (92.3)	17 (41.5)	0.23
≥2	2 (7.7)	24 (58.5)	
BVAS	16.7 ± 7.5	22.4 ± 7.5	***<0.001***
Mean follow-up since diagnosis (months ± SD)	72.5 ± 61.7	61.6 ± 44.3	***0.02***
Death	14 (3.3)	49 (22.3)	***<0.001***
Relapse	256 (60.5)	101 (45.9)	***0.01***

Conclusion: Patients enrolled in clinical trials of AAV may differ from those followed in observational cohorts in terms of disease manifestations at diagnosis and mortality and flare rates. These findings may have important implications for interpretation of study results and design of clinical trials.

2369

Optimal Definition for the Duration of Sustained Remission in ANCA-Associated Vasculitis. Gunnar Tomasson[1], Michael Walsh[2], Thomas F. Hiemstra[3], Maarten Boers[4], Peter A. Merkel[1] and EUVAS Investigators[5]. [1]Boston University School of Medicine, Boston, MA, [2]McMaster University, Hamilton, [3]Addenbrookexs Hospital University of Cambridge, Cambridge, United Kingdom, [4]VU University Medical Center, Amsterdam, Netherlands, [5]Cambridge, United Kingdom

Background/Purpose: Outcome measures and end-points in randomized clinical trials (RCTs) in ANCA-associated vasculitis (AAV) were developed by consensus panels of expert investigators. Most RCTs in AAV have been equivalency trials or negative with respect to declaring one treatment strategy significantly superior to the reference strategy. Therefore, outcome measures and end-points currently used remain to be validated with respect to their discriminatory capability between active treatment and placebo. In the IMPROVE trial, azathioprine (AZA) was found superior to mycophenolate mofetil (MMF) for remission maintenance in AAV. Therefore, data from IMPROVE provides an opportunity to explore which elements of currently-used outcome measures and trial end-points are able to discriminate active (effective) treatment from placebo (ineffective or less effective) treatment. *Sustained remission* has been used as end-point for RCTs in AAV and has been arbitrarily defined as a consecutive period of 6 months without evidence of active disease. The objective of this study was to arrive at a definition for *duration* of sustained remission in AAV that best discriminates between more effective treatments vs. less effective treatment in RCTs.

Methods: Subjects were participants in the IMPROVE clinical trial. Remission was defined as score of zero on the Birmingham Vasculitis Activity Score (BVAS). To determine the optimal duration of remission, 36 candidate periods (1 to 36 months long) were tested to arrive at the highest risk ratio (RR) of those subjects who achieved sustained remission between those randomized to AZA vs. MMF.

Results: In the IMPROVE trial, 156 subjects achieved remission and were randomized to AZA (n=76) or MMF (n=80). Median duration of follow-up after remission was achieved was 45.3 months (IQR: 39.1–47.1) and 88% of subjects were followed for at least 24 months. During follow-up, 72 subjects had disease relapse, 30 in the AZA-group and 42 in the MMF-group. The definition of

sustained remission of 6 months resulted in the highest RR (1.6) for achieving sustained remission between the AZA and MMF study groups, and any definition of sustained remission between 4 and 13 months discriminated much better between the two treatment regimens than sustained remission defined outside of this interval (Figure). Remission duration of 3 months or less did not discriminate between AZAand MMF.

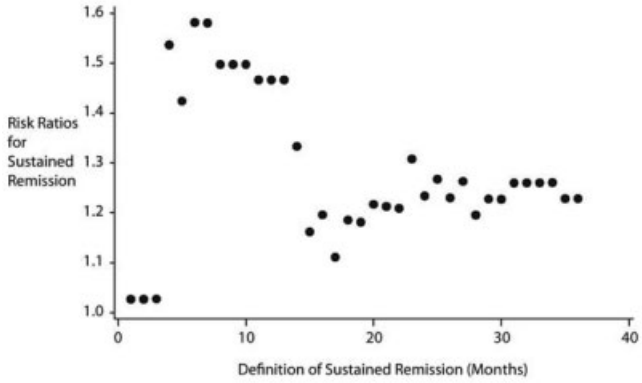

Figure. Risk ratios of achieving sustained remission among subjects randomized to azathioprine vs. mycophenolate mofetil at different definitions for sustained remission in months.

Conclusion: These results suggest that defining sustained remission as a consecutive period of 4 and 13 months is optimal to discriminate between effective treatment and less (non-) effective treatments in AAV. These findings have implications for the design of future trials in AAV.

2370

Neural Correlates of Chronic Fatigue in Granulomatosis with Polyangiitis (GPA; Wegener's)—A Functional Magnetic Resonance Imaging (fMRI) Study. Neil Basu[1], Gareth T. Jones[1], Raashid A. Luqmani[2], Alison D. Murray[1], David M. Reid[1], Gary J. Macfarlane[1] and Gordon D. Waiter[1]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]University of Oxford, Oxford, United Kingdom

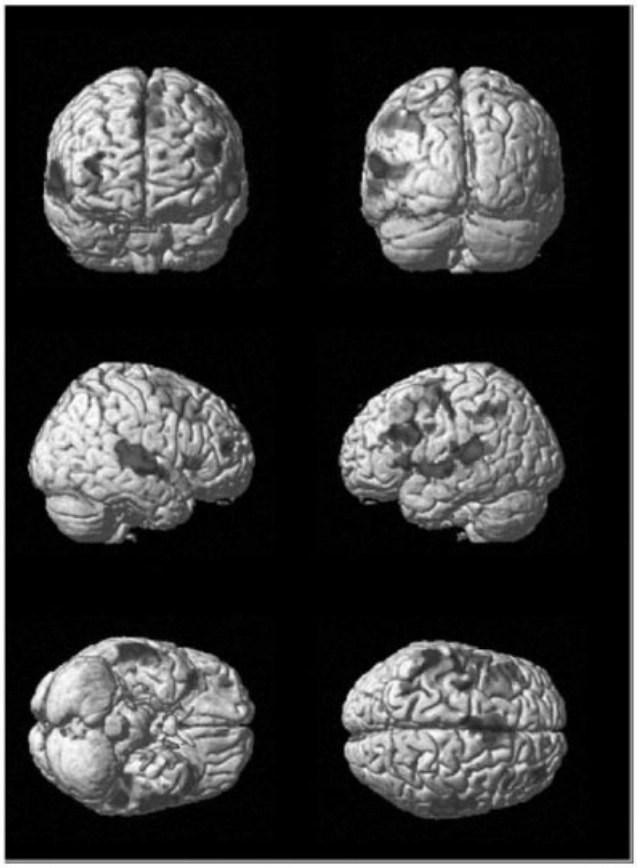
Background/Purpose: Chronic fatigue is a common disabling problem in patients with GPA, even for those in clinical remission. As with other populations, the mechanisms underlying fatigue are poorly understood. Current generic hypothetical models implicate frontostriatal structures of the brain. In order to better understand the mechanisms specific to GPA, we used fMRI to examine the neural correlates of fatigue in patients with clinically inactive disease.

Methods: GPA patients were recruited based on fatigue status; those reporting problems with fatigue for >3 months and scoring >3 on the Chalder Fatigue Scale (CFS) were defined as cases with fatigue (GPA-F), those without fatigue (<3 on the CFS) were defined as cases without fatigue (GPA-NF). All cases were in clinical remission, with a Birmingham Vasculitis Activity Score=0 for >3months. A control group with idiopathic chronic fatigue (CF) was also studied. Controls fulfilled the same fatigue criteria as GPA-F cases and, following medical assessment had no clear clinical explanation for their fatigue.

All subjects completed Hospital Anxiety and Depression Scales (HADS-A, HADS-D). During fMRI, they performed a modified paced auditory serial attention test, a cognitive task validated to induce fatigue.

Functional data was acquired with a 3 Tesla MRI scanner and analysis of the blood oxygen level dependant (BOLD) signal was performed using SPM8. A cluster threshold of $p<.05$, correcting for multiple comparisons was used.

Results: GPA-F (n=12), GPA-NF (n=14) and CF (n=13) groups were not significantly different in terms of age (mean: 58.5, 51.6, 52.2 respectively) and sex (males: 6, 6, 7). As expected, the CFS scores were higher in the fatigued groups (mean 8.5, 1.4, 7.7), but also HADS-A (5.5, 2.6, 4.3) and HADS-D (4.9, 0.9, 3.5). After adjusting for HADS-A and HADS-D, comparison of GPA-F with GPA-NF revealed statistically significantly greater BOLD activation in the left (L) paracentral lobule, L medial frontal gyrus, right (R) thalamus and R lentiform nucleus of the GPA-F group. GPA-F and CF shared many overlapping areas of activation, however, in addition the CF group showed significantly greater activation elsewhere, principally the L precentral gyrus, R superior frontal gyrus and R cingulate gyrus (Figure 1).



Conclusion: 1) Chronically fatigued patients with quiescent GPA activate the basal ganglia, thalamus and frontal lobes of the brain significantly more than a matched population of GPA patients without chronic fatigue. This supports current hypothetical neural models of fatigue processing.

2) FMRI activation patterns of fatigued GPA subjects overlap with those with similarly fatigued controls, however control subjects appear to recruit additional neural regions. This implies an element of condition specificity in neural fatigue processing, which may reflect a difference in the fatigue dimensions experienced by the 2 populations and/or differing aetiological mechanisms.

2371

Mental Health As a Predictor of Disease Flare in Granulomatosis with Polyangiitis (Wegener's Granulomatosis). Morgana L. Davids[1], Huong Do[1], Gunnar Tomasson[2], John C. Davis[3], Gary S. Hoffman[4], W. Joseph McCune[5], Ulrich Specks[6], E. William St Clair[7], John H. Stone[8], Peter A. Merkel[9] and Robert F. Spiera[1]. [1]Hospital for Special Surgery, New York, NY, [2]Boston University School of Medicine, Boston, MA, [3]Genentech Inc, South San Francisco, CA, [4]Cleveland Clinic, Cleveland, OH, [5]University of Michigan, Ann Arbor, MI, [6]Mayo Clinic, Rochester, MN, [7]Duke University Medical Center, Durham, NC, [8]Massachusetts General Hospital, Boston, MA, [9]Boston University, Boston, MA

Background/Purpose: Emotional stress has been anecdotally suspected to contribute to the development of autoimmune disease and trigger disease flares. While several recent reviews suggest that psychological stress plays a role in the pathogenesis of autoimmune disease, no studies have looked at mental health as a risk factor for the onset of flares in patients with granulomatosis with polyangiitis (GPA, Wegener's granulomatosis). The aim of the present study was to investigate the relationship between mental health and disease exacerbations in patients with GPA. The primary hypothesis was that worse mental health was associated with greater likelihood of flare at subsequent visits.

Methods: This was a retrospective analysis of participants in the Wegener's Granulomatosis Etanercept Trial (WGET) who achieved sustained remission (defined as 6 months of continuous remission) during the trial.

Self-reported health was assessed with the Short Form 36 Health Survey (SF-36) at each visit during the trial. The SF-36 includes physical and mental component summary scores (PCS and MCS) which are measured on a scale of 0 to 100, with 100 being the healthiest. Flare status was assessed with the Birmingham Vasculitis Activity Score for Wegener's Granulomatosis (BVAS/WG). Subjects were considered in remission when their BVAS score was equal to 0. Baseline MCS and PCS were compared for different patient disease stratifications using two-sample t-tests. Data from all visits subsequent to a period of sustained remission were analyzed to assess the relationship between current visit flare status and SF-36 MCS and PCS scores from the preceding visit.

Results: Data from 143 subjects who achieved sustained remission during the WGET were included in the analysis. Baseline MCS and PCS were not significantly different when stratifying patients by disease severity (severe vs. non-severe) or new-onset disease vs. relapsing disease. Baseline MCS and PCS were also similar among patients who remained in remission throughout the trial vs. patients who relapsed. In a multivariable model adjusting for time since enrollment and disease severity, a five-point lower MCS at the preceding visit was associated with a 19% increased likelihood of having a flare at the current visit (OR: 1.19, 95%CI: 1.06–1.33, $p < 0.01$), whereas a five-point lower PCS at a sustained remission visit was only associated with an 8% increased risk of having a flare at the following visit, and this was not significant (OR: 1.08, 95%CI: 0.96–1.21, $p = 0.19$). Analyses using MCS and PCS from two visits prior to the current visit showed no association with current flare status.

Conclusion: Among patients with GPA, a lower MCS at a time of sustained remission predicts an increased likelihood of a disease flare in the immediate future, independent of PCS, whereas a lower PCS at a time of sustained remission is not associated with a flare in the immediate future. This suggests that mental health may be an important independent factor affecting the likelihood of future disease flares in patients with GPA. This association merits further investigation.

2372

Patient-Driven On-Line Survey on Granulomatosis with Polyangiitis. Adam Hall[1], Marta Rode[2], Christian Pagnoux[3] and Elaine Yacyshyn[1]. [1]University of Alberta, Edmonton, AB, [2]None, Jasper, AB, [3]University of Toronto, Toronto, ON

Background/Purpose: Granulomatosis with polyangiitis (Wegener's; GPA) is a rare small-sized vessel vasculitis with a prevalence estimated at 24 to 157 cases/million. These low numbers make it difficult to recruit large numbers of patients for cross-sectional studies. In recent years, along with several patient registry initiatives, internet-based forums and weblogs (blogs) have emerged as a means for patients with rare diseases to connect and share experiences. Recently, one of our patients with GPA posted a link on her blog, requesting GPA patients worldwide to complete a SurveyMonkey® questionnaire on their disease.

Methods: The survey was entirely devised by our GPA patient (M.R.), who put it on-line in November 2010 on her blog (http://weggiesunite.blogspot.com/p/survey-inquiring-weggies-wanna-know.html). The survey targeted patients with GPA, as a self-reported diagnosis, and included 10 questions to anonymously assess country of residence, gender, age at diagnosis, selected comorbidities, presenting symptoms, specialty of the physician who eventually provided the diagnosis, diagnostic delay and initial treatments.

Results: Late June 2011 (after 7.5 months), 369 respondents had completed the survey. Six of them were excluded because of reported associated lupus, inflammatory bowel disease or rheumatoid arthritis. After reviewing the remaining forms for clinical manifestations at diagnosis and initial medications, 345 respondents with consistent evidence for GPA and who filled in >80% of the questionnaire were retained for this analysis. Among them, 61.9% were women and 62.3% were aged between 30 and 60 years at diagnosis. Of the 316 who answered the question where they were living at diagnosis, most of the patients were from North America (74.7%), 16.8% from Europe, and 8.5% from elsewhere (primarily India, New Zealand and Australia).

The main self-reported signs at diagnosis were fatigue (67.8%), sinus issues (67.2%), arthralgias (59.1%), night sweats (41.2%), earache (35.4%), weight loss (35.4%), coughing (32.8%), loss of appetite (31.9%), headaches (30.1%), cutaneous symptoms (30.1%), ocular manifestations (24.9%) or bloody sputum (24.3%). Prior history of allergy was reported by 30.5% of the patients. GPA diagnoses were mostly established by rheumatologists (for 40% of the respondents), but also ENT surgeons, respirologists or nephrologists (for 15.4, 13.0 and 12.2%, respectively). The delay between first symptoms attributed to GPA and diagnosis was 15.1 ± 26.0 months. Only 3 patients reported not having received corticosteroids as part of their initial treatment (cotrimoxazole instead), whereas 61.3% were given cyclophosphamide.

Conclusion: Patient-driven surveys and reported outcome studies represent novel and powerful methods to study rare diseases such as GPA. The high response rate to this original patient-driven online survey strongly supports such initiatives. Even though its design did not allow us to confirm GPA diagnosis, its findings are close to those previously reported on diagnostic delay and initial GPA manifestations.

2373

Rituximab in Relapsing Granulomatosis with Polyangiitis (Wegener's Granulomatosis): a Case Series. Pamela M.K Lutalo, Ian C. Scott, Shirish Sangle and David P. D'Cruz. Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom

Background/Purpose: The relapse rate in ANCA positive granulomatosis with polyangiitis (GPA) vasculitis remains high despite aggressive therapy such as Cyclophosphamide, Methotrexate and Mycophenolate. There is mounting evidence that B cell depletion therapy may have an edge over Cyclophosphamide in managing GPA relapses. We present an observational study in patients with GPA who received B cell depletion therapy.

Methods: 10 patients with severe relapsing ANCA-associated vasculitis were treated with intravenous Rituximab infusions 1 gram on day 1 and day 15 as per protocol between 2006–2010. All patients' disease duration, system involvement and previous immunosuppression was documented. Birmingham Vasculitis Activity Score (BVAS); laboratory markers of disease activity, lymphocyte subsets and ANCA titre were measured at baseline, 1 month, 6 month and 12 month intervals. SPSS-18 was used for statistical analysis.

Results: The mean age = 49 years (33–65 years) and mean disease duration= 9 years. All patients' BVAS scores improved post-Rituximab. Anti-PR3 titres dropped from a median pre-Rituximab PR3= 45 u/ml to a median post-Rituximab PR3= 1 u/ml ($p=0.008$). B-cell depletion was observed in all patients (B-cell count < 5 cells/μL) at 6 months. 2 patients relapsed after 18 months and received further immunosuppressant therapy. The longest documented relapse-free period was 57 months (Table 1).

Details are summarised in table 1.

PATIENT	AGE	GENDER	DISEASE TYPE	DISEASE DURATION (YEARS)	PREVIOUS TREATMENT FAILURES	FEATURES OF CURRENT FLARE	CLINICAL RESPONSE TO RITUXIMAB	ANTI-PR3 TITRES PRE- POST-RITUXIMAB	B CELL LEVELS PRE-/POST-RITUXIMAB	FOLLOW-UP (MONTHS)	NUMBER OF POST-RITUXIMAB RELAPSES
1	55	M	Systemic	10	MTX, AZA, CYC	Lung, sinus peripheral nerves	All features improved	192/1	–/2	4	0

3	53	M	Limited	21	MTX, AZA, MMF, CYC, IVIG	ENT	Improved	0/0	32/5	5	0
4	57	F	Systemic	3	MTX, AZA, MMF, CYC, IVIG	Destructive retro-orbital mass	Improved	6/0	–/1	57	0
5	55	M	Systemic	25	MTX, CYC	Restro-orbital mass with optic nerve compression	Resolution symptoms, reduction mass size	3/1	78/1	34	1
6	65	F	Systemic	6	MTX, AZA, CYC	Headache, retro-orbital mass	Improved	18/0	88/0	18	1
7	38	F	Systemic	5	MTX, AZA, CYC	Retro-orbital mass with optic nerve compression	Improved	46/1	336/1	30	0
8	35	F	Systemic	12	MTX, AZA, CYC	ENT, subglottal stenosis	Improved	43/2	–/1	35	0
9	51	F	Systemic	3	AZA, MMF, CYC	Extra-cranial mass, headache, papilloedema	Improved	5/2	85/0	8	0
10	48	F	Systemic	3	AZA, MMF, CYC	Pulmonary-renal syndrome	Resolution of lung lesions, normal renal function	26/2	39/2	5	0

AZA Azathioprine, CYC Cyclophosphamide, ENT ear, nose, throat GFR Glomerular filtration rate, IVIG intravenous Immunoglobulins, MMF Mycophenolate Mofetil, MTX methotrexate

Conclusion: Our data supports the use of Rituximab therapy in treating GPA relapses and it may provide longer remission in relapsing ANCA associated vasculitis.

2374

B Cell Depletion by Rituximab Severely Reduces Immunoglobulin Levels in Patients with ANCA-Associated Vasculitis Previously Treated with Cyclophosphamide. Jens Thiel, Nora M. Effelsberg, Hans-Hartmut Peter, Reinhard E. Voll, Klaus Warnatz and Nils Venhoff. Dpt. Rheumatology and Centre for Chronic Immunodeficiency, University Hospital Freiburg, Freiburg, Germany

Background/Purpose: In ANCA-associated vasculitides (AAVs) cyclophosphamide (CYC) is part of the standard therapy regimen for severe manifestations. Rituximab (RTX) is effective in the treatment of AAVs. No data on the cumulative effect of a sequential treatment with CYC and rituximab on immunoglobulin levels in AAV are available. Such data are of great interest since both therapies can induce hypogammaglobulinemia

leading to an increased risk of infections worsening the overall outcome. We report a retrospective analysis of the impact of immunosuppressive therapy with CYC and RTX on serum immunoglobulin (Ig) concentrations and peripheral B cells in patients with AAV.

Methods: Ig levels were analyzed in AAV patients either treated with CYC alone or treated with CYC and RTX. The effect of CYC on Ig levels was assessed in study group A (n=26), while the impact of RTX treatment alone was examined in study group B (n=29). In patients previously treated with CYC followed by RTX we compared changes in Ig concentrations prior to CYC to those after RTX treatment (group C; n=15). The median CYC doses were 8.05±0.56 g, 18.76±14.55 and 13.11±13.27 g in groups A, B and C and median RTX doses in group B and C were 1.8±0.8 g and 1.97±1.04 g respectively. The mean prednisone equivalent in patients treated with RTX was 12.35±7.52 mg/day. Statistics: Mann Whitney U Test, if not indicated otherwise.

Results: Mean Ig levels (mg/dL) prior to CYC therapy were normal. Means and standard deviations (SD) for group A are: IgG: 11.84±3.24, IgM: 1.31±0.94, IgA: 2.46±1.19. After CYC treatment IgG, IgM and IgA significantly decreased to 8.6±2.51 (p=<0.001; t-test), 0.88±0.53 (p=0.048), and 1.74±0.6 (p=0.021) respectively. In group B, median IgG levels prior to RTX were 9.74±3.49, IgM levels 0.81±0.45 and IgA levels 2.3±1.15. Over a period of 6 months after treatment, IgG significantly declined to 7.45±2.79 (p=0.001), IgM to 0.52±0.35 (p=0.003) and IgA to 1.69±0.81 (p=0.003). When assessing the effect of RTX therapy following CYC (group C) we observed the strongest decrease of all 3 isotypes: median IgG levels of 12.68±4.29mg/dL prior to CYC decreased to 6.59±1.98mg/dL (p=<0.001) after the dual treatment, IgM of 1.15±0.68 mg/dL to 0.52±0.42 mg/dL (p=0.002), and IgA of 2.65±1.25 mg/dL to 1.56±0.78 mg/dL (p=0.007). Follow-up measurements after RTX treatment did not show an increase in Ig levels within 24 months. RTX led to a complete depletion of B cells (</=2/μl) in all patients within the first 3 months after therapy. Interestingly, in all 7 patients that were available for analysis of peripheral B cell numbers 24 months after last RTX treatment, a persistent B lymphocytopenia with mean a B-cell count of 3.2/μl±1,7 was detected.

Conclusion: In patients with AAV, treatment with CYC leads to a decline in immunoglobulin levels, which is profoundly aggravated by subsequent RTX treatment. Data in our cohort furthermore indicates that B cell repopulation in AAV patients after RTX treatment might be delayed. Hence, Ig concentrations should be assessed after combined treatment with CYC and RTX.

2375

A Cost Effectiveness Analysis of Weekly Complete Blood Count Monitoring for Leukopenia In Patients with Granulomatosis with Polyangiitis (Wegner's) On Cyclophosphamide. Atul A. Khasnis[1], Richard Wilson[2], Gary S. Hoffman[1], Alexandra Villa-Forte[1] and Carol A. Langford[3]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Case Western Reserve University, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH

Background/Purpose: Daily cyclophosphamide (CYC) is used in the management of patients with severe granulomatosis with polyangiitis (Wegener's) (GPA). Leukopenia is a common toxicity of daily CYC which can be associated with infectious complications; however, no evidence based guidelines exist for white blood count monitoring in these patients. We assessed the cost-effectiveness of weekly compared to monthly complete blood count (CBC) monitoring in patients with severe GPA receiving oral CYC.

Methods: The two CBC monitoring approaches for surveillance of leukopenia and its consequences were compared using a decision analysis model created using TreeAge Pro 2009™. The parameters for prevalence of leukopenia, infections, and outcomes were obtained from an existing registry at the Cleveland Clinic (130 patients) and literature review of studies using daily CYC for management of severe GPA as well as the literature on outcomes in patients with sepsis. Only studies clearly documenting the frequencies of parameters required in the model and the relationship between severe leukopenia and severe infection were included. Parameter values that were unavailable from the published literature were entered by consensus and subjected to wide ranges for sensitivity analyses. Costs were in dollars (2010) and effectiveness as quality-adjusted life-years (QALYs) gained. Analysis was performed from a societal perspective. In addition to a baseline cost effectiveness analysis, we performed univariate sensitivity analyses and probabilistic sensitivity analysis (PSA) to check for robustness of the parameters included in the analysis. Although the base case patient was 45 years old, we analyzed the results over a wide range of patient ages (25–65 years).

Results: The expected utility of weekly CBC monitoring of these patients for leukopenia is 18.74 QALYs versus 18.52 QALYs with monthly CBC. The expected gain is 0.22 QALYs and incurs $489 lower cost per patient. The weekly CBC strategy dominated (was more effective and less expensive than) the monthly CBC strategy. In clinical scenarios generated by the univariate sensitivity analyses where the weekly strategy did not dominate the monthly strategy, it was still more effective but as or more expensive than the monthly CBC strategy. The results were not sensitive to changes in patient age. The acceptability curve generated by PSA also demonstrated dominance of the weekly CBC strategy.

Conclusion: Weekly CBC monitoring appears to be cost-effective for prevention of severe leukopenia and severe infections in patients on daily CYC for GPA. Further prospective studies with systematic data collection regarding frequencies of parameters in the model are required to confirm and validate our findings.

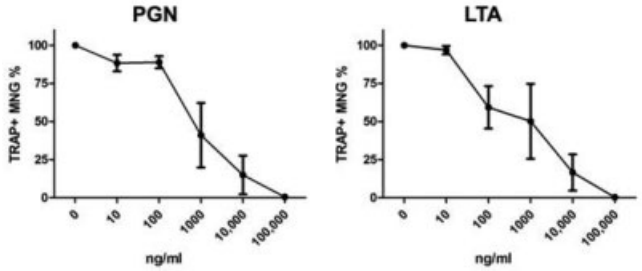
Gram-Positive Bacterial Wall Components Inhibit Formation of Osteoclast-Like Multinucleated Giant Cells: Possible Explanation for Their Scarcity in Sinonasal Inflammation of Granulomatosis with Polyangiitis. Jin Kyun Park. Johns Hopkins University, Baltimore, MD

Background/Purpose: One distinguishing feature of Granulomatosis with polyangiitis (GPA), previously known as Wegener's granulomatosis, is systemic granulomatous inflammation with multinucleated giant cells (MNG). The phenotype of those MNGs in sinonasal inflammation and their interactions with colonizing bacteria have not been studied to date.

Methods: MNG phenotype was examined by immunohistochemistry in serial paraffin sections of GPA sinus tissue (N=12) using antibodies recognizing the osteoclast (OC)-lineage markers CD68, cathepsin K and using tartrate-resistant-acid-phophatase (TRAP) assay. To examine the influence of the bacteria on MNG formation, monocytes were isolated from peripheral mononuclear cells of three GPA patients and were cultured in 96-well plates in the presence of RANKL, M-CSF and increasing concentrations of bacterial wall component peptidoglycan (PGN) and lipoteichoic acid (LTA). After 9 days, TRAP+ MNGs with 3 nuclei or more per well were counted. Fisher Exact test was performed and $p < 0.05$ was considered significant.

Results: MNGs in GPA sinonasal inflammatory infiltrates expressed TRAP and cathepsin K, specific enzymes of bone-resident osteoclasts. In addition, MNGs expressed CD68, indicating their monocytic lineage. Interestingly, MNGs were less frequently observed in GPA sinus tissues (where Gram-positive bacterial colonization is frequent) as compared to GPA lung tissues (23.1 % vs. 70 %, p=0.04). In the presence of RANKL and M-CSF, monocytes of GPA patients formed on average 229.3 TRAP+ MNG/well ± 74.4 (SEM). MNG formation was inhibited by PGN and LTA in a dose-dependent manner; approximately 50%, 75%, and 100% inhibition were achieved at 1 μg/ml, 10 μg/ml, and 100 μg/ml, respectively (Figure).



Conclusion: The relative rarity of MNG in the sinuses compared to the lungs of GPA patients is striking. The inhibition of MNG formation by Gram-positive bacterial cell wall components may occur preferentially in this sinonasal microenvironment known to be heavily colonized by Gram-positive bacteria in GPA.

2377

Perspective on Hypoxic Signalling in Granulomatosis with Polyangiitis (Wegener's)—Increased Expression of HIF-1α and Glut-1 in Granulomatous Lesions of the Nasal Cavity. Nina Kesel[1], Antje Müller[2], Dorothee Köhler[1], Martin Laudien[3], Elena Csernok[2], Udo Schumacher[1] and Sebastian Ullrich[1]. [1]University Medical Center Hamburg, Hamburg, Germany, [2]University of Lübeck, Bad Bramstedt, Germany, [3]Christian-Albrechts-University Kiel, Kiel, Germany

Background/Purpose: Hypoxia is a micro-environmental feature in the inflamed tissue. The expression of hypoxia inducible factor 1 α (HIF-1α) and

its major target gene glucose transporter-1 (Glut-1) are markers for hypoxia in human tissues. The aim of this study was to investigate if hypoxia occurs in inflamed nasal mucosa from patients with Granulomatosis with Polyangiitis (GPA) by examining HIF-1α and Glut-1 expression in nasal tissues from patients with GPA and sinusitis, as well as in nasal tissue transplants derived from an immunodeficient mouse model.

Methods: Tissue sections from GPA patients (n=10) with histologic (H&E) features of active inflammation and patients with sinusitis as control (n=10) as well as nasal tissue sections derived from an immunodeficient mouse model were stained immunohistochemically for HIF-1α and Glut-1.

Results: The number of HIF-1α^+ and Glut-1$^+$ cells was found to be significantly higher in GPA compared to sinusitis. The expression of HIF-1α and Glut-1 was in accordance with the severity of inflammation and GPA disease activity.

Conclusion: The localization of hypoxic areas in nasal mucosa from active GPA was identified and an up-regulated expression of two hypoxic signs (HIF-1α and Glut-1) was observed. In addition, HIF-1α and Glut-1 expression were evaluated in an immunodeficient mouse model. According to our data, hypoxia seems to be a prominent feature in granulomatous lesions. Further studies on the pathogenesis of the GPA granuloma need to consider the impact of HIF-1α- and Glut-1-mediated modulation on cell to cell signalling and recruitment of cells into inflamed tissue.

2378

CT Imaging Characteristics of the Sino-Nasal Tract and Orbits in Granulomatosis with Polyangiitis (Wegener's) and Churg–Strauss Syndrome. A Cross-Sectional Review. Khaldoun Chaabo[1], Shirish Sangle[2], Dhiren Shah[3], Hema Verma[4] and David P. D'Cruz[2]. [1]St Thomas' Hospital, London, SE1 7EH, United Kingdom, [2]Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom, [3]Guy's and St Thomas' Hospitals NHS Foundation Trust, London,SE1 9RT, United Kingdom, [4]Guy's and St Thomas' Hospitals NHS Foundation Trust, London, SE1 9RT, United Kingdom

Background/Purpose: The upper airways are commonly involved in granulomatosis Polyangiitis (GPA) and Churg–Strauss syndrome (CSS), two types of antineutrophil cytoplasmic auto antibodies (ANCA) associated vasculitis. Both disorders are associated with vasculitis and granulomatous formation in the sino-nasal tract leading to chronic rhino-sinusitis. Computed tomography (CT) has been widely accepted as the radiographic modality of choice in the evaluation of rhino-sinusitis especially in delineating the bony structures of the sino-nasal tract. The aim of this cross-sectional study was to evaluate the CT characteristics of the sino-nasal and orbital involvement occurring in GPA and CSS in comparison with the chronic non-vasculitic rhino-sinusitis (NVRS) patients.

Methods: A cross-sectional evaluation of the CT imaging of the sino-nasal tract and orbits was performed in 80 patients in 3 groups. 34 had GPA, 16 CSS, and 30 had NVRS. The scans were randomised and reviewed by one Radiologist blinded to the clinical diagnosis. Sinus mucosal and bony involvement, orbital and naso-septal changes were quantified using Lund-Mackay score (LMS). The results were statistically analyzed using independent binary and continuous statistical tests.

Results: The GPA group consisted of 18 women (53%) and 16 men (47%), the CSS 10 women (62.5%) and 6 men (37.5%) and in the NVRS group 17 women (57%) and 13 men (43%). The median age of the GPA patients was 47 years (28–83), 51 (39–73) for CSS, and 46.5 (27–77) years for NVRS. The mean duration between the time of diagnosis and the time of the CT scan was: 5.9 years in GPA and 2.1 years in CSS.

Twenty eight WG patient (83%) and 8 CSS patients (50%) were positive for ANCA antibodies.

The presence of sinus opacification was observed in 33 WG patients (97%), 15 CSS patients (94%) and all patients with NVRS. The prevalence and severity (LMS) of mucosal thickening was high in the three groups with a higher LMS in the control group (NVRS). The prevalence of sinus bony erosion was 14/34 (41%) in GPA, 1/16 (6%) in CSS and 4/30 (13%) in NVRS. Fisher's exact test revealed statistically significant difference between the prevalence of bony erosions in GPA and controls (P = 0.024), between GPA and CSS (P = 0.019), but not between the CSS and controls (P = 0.65). The prevalence of sinus neo-osteogenesis was 10/34 (29.5%) in GPA, 1/16 (6%) in CSS and 2/30 (6.6%) in NVRS. Fisher's exact test revealed an overall statistically significant difference between the prevalence of neo-osteogenesis in WG and controls (P = 0.026), but not between the GPA and CSS (P = NS), or between the CSS and NVRS (P = NS). Orbital changes involvement were only observed in WG (20.5%) but not in CSS or NVRS (p = 0.005). A naso-septal defect was observed only in WG (20.5%) but not in CSS or NVRS (p = 0.005).

Conclusion: GPA appears to have a distinct radiological phenotype with significant bony erosions, orbital involvement and nasal septal defects which may be used to distinguish GPA from CSS.

2379

Churg–Strauss Syndrome: Analysis of 58 patients' Relapses and Outcomes. Maxime Samson[1], Camillo Ribi[2], Pascal Cohen[3], Marc Stern[4], Christian Pagnoux[5], Jean-Francois Cordier[6], Luc Mouthon[7] and Loic Guillevin[8]. [1]Hôpital Cochin, University Paris Descartes, Paris, France, [2]Hôpital Universitaire Cantonal de Genève, Geneve, Switzerland, [3]Service de médecine interne, Centre de Références des Vascularites, Université Paris Descartes, APHP, Hôpital Cochin, 75005 Paris, France., Paris, France, [4]Hôpital Foch, Suresnes, France, [5]University of Toronto, Toronto, ON, [6]Division of Pneumology, Hôpital Louis-Pradel, Hospices Civils de Lyon, Lyon 1, Lyon, France, [7]Hopital Cochim, Paris, France, [8]Cochin University Hospital, Paris, France

Background/Purpose: Churg Strauss Syndrome (CSS) is a rare small-sized–vessel vasculitis. Its nonsevere manifestations, as defined by the Five-Factor Score (FFS), respond to corticosteroids (CS) alone. For more severe cases (FFS≥1), combined CS + cyclophosphamide (CYC) is mandatory for disease control, followed by azathioprine (AZA) or methotrexate for maintenance, but relapses remain frequent. This study aimed to describe clinical, biological and immunological characteristics, therapeutic responses and outcomes of CSS patients who suffered ≥1 relapses.

Methods: Relapses and failures occurring during follow-up of 115 CSS patients, stratified according to the 1996 FFS version and enrolled in 2 prospective trials[1,2] between 1995 and 2002, were analyzed. Patients with FFS≥1 (n=43) were assigned to receive 6 or 12 CYC pulses + CS while those with FFS=0 (n=72) received CS alone, with immunosuppressant (IS) adjunction when CS failed. Relapses were defined as the recurrence of ≥1 vasculitis manifestations but excluded an isolated eosinophil rise or asthma exacerbation without eosinophilia. We distinguished between major relapses requiring CS pulses with/without IS, and minor flares treated with dose-intensified CS alone. Failure was defined as the absence of clinical remission with the assigned treatment.

Results: Mean±SD overall follow-up was 69±27.6 months. Among the 115 patients, 58 (50.4%) suffered a relapse (n=51) or failure (n=7). At diagnosis, their mean age was 49.6±13.8 years, mean Birmingham Vasculitis Activity Score 2003 (BVAS) 22.6±7.43, eosinophil count 6.93±5.65 G/L; among the 25 (43.9%) ANCA-positive, 80% had myeloperoxidase specificity. After inclusion, 7 patients suffered primary failures at 3.3±2.1 months, with second-line therapy achieving remission for all, and relapses, minor for 29 (56.9%) patients and major for 22 (43.1%), occurred at 15.75±15.6 months. At relapse, 3 (5.9%) patients were taking CS+IS, 42 (82.4%) CS (mean dose 13.23±12.9 mg/d) alone, 32 (62.7%; CS <10 mg/d) and 9 (17.6%) were not treated; mean BVAS was 7±4.7; eosinophils rose (>0.5 G/L) in 41 (80.4%) and were normal (<0.5 G/L) in 7 (13.7%). CS were reintroduced or increased for 46 (90.2%) patients and IS were prescribed for 20 (39.2%): intravenous CYC for 8, oral CYC for 3 and AZA for 9; 45 (88.24%) achieved remission. Among the 58 patients, 16 (27.6%) entered long-term remission, 37 (63.8%) developed ≥1 new relapse(s) and 5 (8.6%) died. Among the 53 survivors at the last follow-up visit, 4 (7.5%) had stopped CS+IS, 47 (88.7%) were taking CS and 21 (39.6%) an IS: AZA for 16, oral CYC for 2, IVIg for 1 or mycophenolate mofetil for 2. The mean vasculitis damage index was 2.57±1.35, mostly reflecting chronic asthma and peripheral neuropathy.

Conclusion: About half of CSS patients relapse, most often when IS are stopped and CS are <10 mg/d. CS with/without IS were able to obtain second remissions. However, two-thirds of patients suffered further relapses. Five years after diagnosis, almost 90% of patients are still taking CS and about 40% are on IS.

IgG4 Immune Response in Churg-Strauss Syndrome. Augusto Vaglio[1], Johanna Strehl[2], Bernhard Manger[2], Federica Maritati[1], Federico Alberici[1], Christian Beyer[2], Juergen Rech[2], Jorg HW Distler[2], Georg Schett[2], Renato Sinico[3] and Jochen Zwerina[2]. [1]University of Parma, Parma, Italy, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Ospedale San Carlo Borromeo, Milano, Italy

Background/Purpose: Churg-Strauss Syndrome (CSS) is a systemic vasculitis usually occurring in individuals with a history of asthma. TH2 responses are common in allergic diseases and enhance the production of immunoglobulin (Ig)G4 antibodies. We therefore assessed IgG4 immune response in CSS patients.

Methods: We included consecutive patients with CSS (n=34, 22 with active and 12 with quiescent disease), granulomatosis with polyangiitis (GPA, n=18) and healthy controls (n=20). We defined the clinical phenotype of CSS patients and determined serum IgG, IgM, IgA and IgE levels. We further assessed IgG subclass distribution and stained tissue biopsies from CSS patients for local IgG4 production.

Results: Whereas active CSS and GPA patients both showed increased total IgG as compared to healthy controls, CSS (mean±SEM: 272±40 mg/dl) but not GPA (mean 90±17 mg/dl) patients showed significantly increased serum IgG4 levels as compared to healthy controls (mean 35±7 mg/dl; $p<0.001$). Serum IgG4 levels correlated with the number of organ manifestations ($p<0.05$) and with disease severity, as patients with a Five-Factor Score (FFS)≥1 had higher IgG4 levels than patients with a FFS=0 ($p<0.05$). IgG4 levels were normal in CSS patients in remission. Heart involvement and peripheral neuropathy were more frequent in IgG4-high (IgG4>135 mg/dL) CSS patients (p=0.13 and p=0.056, respectively). In three out of the nine available CSS tissue biopsies, intense IgG4-producing plasma cell infiltration were detected.

Conclusion: An increased IgG4 production is found in active CSS; IgG4 levels correlate with disease severity, and may differentiate CSS from other vasculitides such as GPA.

2381

Airway Inflammation and Systemic Inflammation During Churg-Strauss Syndrome Natural Course: A Multidisciplinary Monocentric Crosse-Sectional Study. Chiara Baldini[1], Sara Grossi[1], Manuela Latorre[2], Pasquale Pepe[1], Valeria Giorgerini[1], Alessandra Della Rossa[1], Federico Dente[2], Silvia Cianchetti[2], Pierluigi Paggiaro[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Pneumology Unit, Italy

Background/Purpose: Asthma is a key feature in Churg-Strauss syndrome (CSS). Nonetheless, the relationship between asthma clinical course and the natural history of the other CSS systemic clinical manifestations over the follow-up have been scarcely investigated. *Primary aim:* to compare asthma activity/severity and systemic disease activity/damage in consecutive patients with a diagnosis of CSS. S*econdary aims*: a) to compare sputum inflammatory markers with blood inflammatory disease biomarkers in order to evaluate the relationship between airway inflammation and systemic inflammation during CSS natural course; b) to compare asthma severity estimated according to clinical and functional findings and airway inflammation as assessed by induced sputum analysis.

Methods: Twenty consecutive patients with a diagnosis of CSS (ACR criteria) were enrolled in this cross-sectional study. Systemic disease manifestations, BVAS and VDI were recorded. All patients were assessed for lung function (Tiffeneau index, FEV1) and bronchial iperreactivity (methacholine challenge test). Asthma severity and control were established according to GINA guidelines and ACT questionnaire. Sputum eosinophil percentages and exhaled nitric oxide (eNO) were measured as markers of airway inflammation. Peripheral blood eosinophiloa, and serum anti-neutrophil cytoplasmic autoantibody (ANCA), eosinophil cationic protein (ECP), IgE, IL2, IL4 and IL5 were also assessed. Chi-square test, t-test and McNemar test were used to assess the primary aim. Pearson correlation coefficient and Welch-ANOVA were employed to investigate secondary aims.

Results: Patients demographic, clinical and laboratory features and data on asthma severity and sputum inflammatory markers are shown in Table 1. Overall, the study results demonstrated that despite the fact that the vast majority of the patients presented a complete systemic remission, the 80% of the patients still showed a moderate/severe persistent chronic asthma. No statistical correlation was found between peripheral eosinophil count and asthma severity. Furthermore, no statistical relationship was obtained between sputum inflammatory markers and blood inflammatory soluble mediators, including ECP. A significant correlation was detected between sputum eosinophil counts and ACT ($r = -0.64$, $P = .014$) and sputum eosinophil counts and GINA control score (p=0.008). No relationship was found between sputum inflammatory markers and FEV1 and FEV1/SVC..

Table 1

Patients n°	20 (9F 11M)		
Age yr (M±SD)	60±14		
Age at diagnosis (M±SD)	51.7±14.5		
Disease duration	8.9±7.7		
Latency asthma-vasculitis	7.3±12.7		
	onset	follow-up	p-value
Eosinophilic count	5004±4240	507±342	<0.0001
Constitutional (%)	90	20	<0.0001
ENT (%)	95	35	<0.0001
Lung Infiltrates (%)	55	5	0.001
Heart (%)	30	10	0.06
PNS (%)	40	40	n.s
Gastrointestinal (%)	15	0	<0.0001
Skin (%)	65	10	<0.0001
BVAS	14±5	3±2	<0.0001
VDI	0	1.6±1	<0.0001

FEV1% predicted (M±SD)(v.n.>80%)			81,45 ± 2.05
FEV1/SVC% (M±SD)(v.n.>88%)			79.2 ± 15.8
SPO2% (median (range))			97 (94-99)
Asthma control	ACT	Well controlled %	14
		Partially controlled %	38.1
		Poorly controlled%	38.1
	GINA guidelines	Well controlled%	19
		Partially controlled %	57.1
		Poorly controlled %	23.8
DLCO (ml/min/mmH) (M±SD)(v.n.>80)			91.48 ± 15
PD20 FEV1 mcg (geometric mean) (v.n.>1000)			341
eNO ppb (median (range)) (v.n.<25 ppb)			39 (8-160)
Sputum eosinophil% (median (range)) (v.n.<3%)			28.21 (0-91.35)

Conclusion: Chronic asthma negatively affects the natural history of CSS. Nonetheless airway inflammation seems to be not correlated to the systemic manifestations of the disease. Sputum inflammatory markers might represent a complementary tool in monitoring asthma in CSS patients as well as blood inflammatory disease biomarkers reflect CSS systemic activity.

2382

Cell Clonality in Churg-Strauss Syndrome: What Pathogenetic Role? Chiara Baldini[1], Sara Galimberti[2], Pasquale Pepe[1], Sara Grossi[1], Elisabetta Sordi[2], Valeria Giorgerini[1], Alessandra Della Rossa[1] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Hematology Unit, Pisa, Italy

Background/Purpose: A sustained and elevated blood eosinophilic count of unknown origin exceeding 1500 cells/ml and leading to organ infiltration characterises both Churg-Strauss syndrome (CSS) and idiopathic hypereosinophilic syndrome (lHES), leading to overlapping classifications, especially in ANCA negative patients. Important therapeutic implications may derive from the understanding of the pathogenetic pathways underlying these two conditions. This is a monocentric, cross sectional study aimed at assessing the prevalence of TCR g- and d-chain gene rearrangements in consecutive patients with a diagnosis of CSS. *Secondary aims:* a) to compare the prevalence of TCR g- and d-chain gene rearrangements in CSS vs lHES b) to explore any correlation between TCR rearrangements and clinical and laboratory features in patients with CSS and lHES

Methods: Consecutive patients with a diagnosis of CSS (ACR criteria) or lHES (Chusid criteria) were enrolled in the study from January 2010 to April 2011. Salient features prospectively collected in the study were 1) demographic data 2) clinical, immunologic and molecular features at the onset of the disease and 3) during disease evolution. Eosinophil cationic protein (ECP), IL2, IL4 and IL5 were measured as biomarkers of eosinophilic activation. TCR g- and d-chain gene rearrangements was evaluated by fluorescent PCR. Statistical analysis was performed by chi-square test, ANOVA and t-test

Results: Twenty-four patients with a diagnosis of CSS and 19 patients with a diagnosis of lHES were enrolled in the study. Table1 summarises patients demographic, clinical and laboratory data. Nine CSS patients out of 24 showed positive TCR g- and d-chain gene rearrangements with an overall prevalence of 37.5%. Out of them, 2 CSS patients had a confirmed positive serology for ANCA and 3 a histologically proven necrotizing vasculitis. No statistically significant difference was detected in the prevalence of TCR g- and d-chain gene rearrangements in CSS in comparison to lHES (37.5% CSS vs 57.8% lHES, p=0.22). In patients with mild to severe eosinophilia, TCR g- and d-chain gene rearrangements correlated only with the presence of constitutional symptoms.No correlation was found between TCR gene rearrangements and eosinophilic count, IL2, IL4 and IL5.

Table 1.

Clinical manifestations	CSS (24)	HES (19)	p-value
Male/Female	13/24	13/19	0.37
Age (mean ± SD)	58 ± 14	57 ± 16	0.64
Disease duration (mean ± SD)	6.7 ± 5.3	4.2 ± 4.2	0.09
Asthma	24	5	<0.0001
Age asthma at onset (mean ± SD)	41 ± 15	31 ± 20	0.32
Latency between asthma (mean ± SD)	9.7 ± 13	9.8 ± 9.7	0.99
Eosinophilia at onset (mean ± SD)	6060 ± 5110	6494 ± 7191	0.83
Constitutional symptoms	17/24	2/19	0.99
ENT involvement	18/24	6/24	0.005
Kidney involvement	1/24	1/19	0.99
Heart involvement	7/24	3/19	0.47
Purpura	11/24	0/9	0.03
Lung transient infiltrates	13/24	2/9	0.004
Peripheral nervous system	13/24	2/19	0.004
Abdominal pain	8/24	6/19	0.99
Splenomegaly	0/24	2/19	0.18
ANCA-MPO	9/24	0/19	0.01
Vasculitis	16/24	0/19	<0.0001
TCR clonality	9/24	11/19	0.22

Conclusion: This study demonstrated a comparable prevalence of TCR gene rearrangements in CSS and lHES.A cross-talk between eosinophils and clonal T-cells may play a potential role in the pathogenesis of both HES and CSS.

2383

Cocaine and ANCA Associated Vasculitis-Like Syndromes: A Single Centre Study. Khaldoun Chaabo[1], Shirish Sangle[2] and David P. D'Cruz[3]. [1]St Thomas' Hospital, London, SE1 7EH, United Kingdom, [2]Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom, [3]St Thomas' Hospital, London, United Kingdom

Background/Purpose: Cocaine is a potent vaso-constrictor leading to destructive inflammation and necrosis. We describe the clinical and serological manifestations mimicking ANCA associated vasculitis in chronic cocaine users.

Methods: We describe 6 patients with a history of chronic cocaine abuse, referred to our Vasculitis Clinic at St Thomas' Hospital for possible ANCA associated vasculitis. All patients presented with upper respiratory tract involvement with nasal septal defects and ongoing active sinusitis. Two patients presented as late onset asthma with significant eosinophilia (>10%), arthralgia, and peripheral neuropathy. One had cautaneous vasculitis and another presented with intestinal perforation and hematuria. All patients had imaging of chest and. Two patients had nasal mucosa biopsies. Their BVAS, VDI, inflammatory markers and treatment were documented. All patients received corticosteroids. One patient had intravenous cyclophosphamide and 2 others were maintained on azathioprine and methotrexate orally.

Results: Median age of the patients was 37.8 (28 – 42) years. There were 3 male patients. One woman was Far-Eastern in origin and all others were Caucasian. Median duration of cocaine abuse was 10 (6 –15) years. All had naso-septal defects. Four patients had a Wegener's Granulomatosis (WG) - like syndrome and two had Churg-Strauss syndrome (CSS). All were positive for ANCA antibodies. Two patients with a diagnosis of CSS had positive tests for P-ANCA but were negative for myeloperoxidase (MPO) antibodies. One had histopathological features suggestive of CSS in the nasal mucosal biopsy. All WG-like syndrome patients had positive C-ANCA with positive PR-3 antibodies on ELISA. Patients with WG had destructive changes in the sinuses on CT scans of the upper airways. A sino-nasal biopsy in one patient with WG-like syndrome revealed histopathological features suggestive of WG. None had systemic involvement. All were managed successfully with a combination of oral steroids, methotrexate and co-trimoxazole.

Conclusion: Chronic cocaine abuse may be associated with clinical, serological, histo-pathological and radiological manifestations identical to ANCA associated vasculitis. It may be difficult to distinguish cocaine induced midline granuloma from idiopathic ANCA associated vasculitis. The presence of nasal septal defect should raise the suspicion of cocaine use.

2384

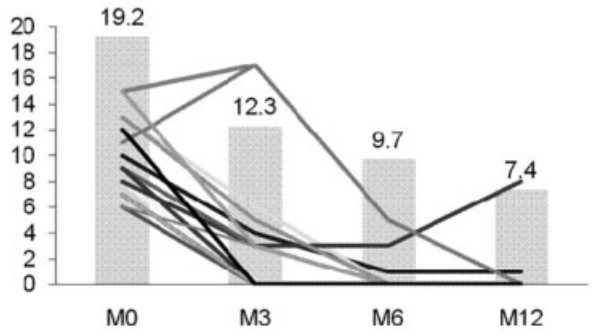
Rituximab Therapy for Systemic Vasculitis Associated with Rheumatoid Arthritis in the AutoImmunity and Rituximab Registry. Xavier Puéchal[1], Jacques-Eric Gottenberg[2], Jean-Marie Berthelot[3], Laure Gossec[4], Olivier Meyer[5], Jacques Morel[6], Daniel Wendling[7], Michel De Bandt[8], Eric Houvenagel[9], Bénédicte Jamard[10], Thierry Lequerré[11], Gauthier Morel[12], Pascal Richette[13], Jérémie Sellam[14], Loic Guillevin[4] and Xavier Mariette for the AutoImmunity and Rituximab Registry[15]. [1]Center for Rare Systemic Autoimmune Diseases, Le Mans General Hospital, Le Mans, France, [2]Strasbourg University Hospital, Strasbourg, France, [3]Nantes University Hospital, Nantes, France, [4]Cochin University Hospital, Paris, France, [5]Bichat University Hospital, Paris, France, [6]Montpellier University Hospital, Montpellier, France, [7]Minjoz University Hospital, Besancon, France, [8]R. Ballanger Hospital, Aulnay Sous Bois, France, [9]St Philibert Hospital, Lomme, France, [10]Toulouse University Hospital, Toulouse, France, [11]Rouen University Hospital, Rouen, France, [12]Valenciennes Hospital, Valenciennes, France, [13]Lariboisière University Hospital, Paris, France, [14]St Antoine University Hospital, Paris, France, [15]Bicêtre University Hospital, Le Kremlin Bicetre, France

Background/Purpose: Rituximab improves articular symptoms in rheumatoid arthritis (RA) and has been recently shown to be an effective induction therapy for ANCA-associated vasculitis. We assessed the efficacy and safety of rituximab in a real-life clinical setting among patients with systemic rheumatoid vasculitis (SRV).

Methods: We analyzed data from the AutoImmunity and Rituximab registry, which includes patients with autoimmune diseases treated with rituximab.

Results: Of the 1,994 RA patients enrolled in the registry, 17 were treated with rituximab for active SRV. At baseline, their mean BVAS/RA was 9.6 with a mean prednisone dosage of 19.2 mg/day. After 6 months of rituximab therapy, twelve (71%) patients achieved complete remission of their vasculitis, four had a partial response, and one died with uncontrolled vasculitis. Mean BVAS/RA was reduced to 0.6 and mean prednisone dosage to 9.7 mg/day. At 12 months, 14 (82%) patients were in sustained complete remission. Severe infection occurred in three patients, corresponding to a 6.4/100 patient-years rate. In the 6 patients who received further rituximab as maintenance therapy, no relapse of vasculitis was observed. However, among the 9 patients who did not, a relapse was observed in 3 patients who were treated with methotrexate alone. Remission was re-established by reintroducing rituximab in two cases.

Figure. Each line shows the progression of the individual BVAS/RA.
Bars show the mean daily dose of prednisone at the different end points of the study.



Conclusion: Complete remission of SRV was achieved in 3/4 of patients receiving rituximab in daily practice, with a significant decrease in prednisone dosage and an acceptable toxicity profile. Rituximab represents a suitable therapeutic option to induce remission in SRV but maintenance therapy seems to be necessary.

2385

Assessment of Disease Activity in Behcet Disease: Comparison of Behcet's Disease Current Activity Form (bdcaf), Behcet's Syndrome Activity Score (bsas) and Routine Assessment of Patient Index Data (rapid) 3 Scores. Sedat Yilmaz[1], Ismail Simsek[1], Muhammet Cinar[1], Hakan Erdem[1], Osman Kose[1], Yusuf Yazici[2] and Salih Pay[3]. [1]Division of Rheumatology, Gulhane School of Medicine, Ankara, Turkey, [2]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY, [3]GATA, Ankara, Turkey

Background/Purpose: Behcet's disease (BD) is a quite heterogeneous clinical syndrome that differs in organ involvement. Furhermore it has a

fluctuating course and there is no spesific laboratory markers in paralel with the disease course. Therefore, it remains to be an important problem for clinicians to define the disease activity in BD. The BDCAF is most commonly used index but a clinical assessor is needed to complete it. As an alternative to BDCAF, a patient-derived assessment tool, Behcet's syndrome activity score (BSAS) has been developed and found to be correlated with the BDCAF in a small number of patients with BD. BSAS consists of 10 questions, which consists of visual analog scales (VAS) for patient's level of discomfort with regards to oral ulcers, genital ulcers, skin lesions, current disease activity along with the number of oral ulcers, genital ulcers, and skin lesions present, and records symptoms attributable to the GIS, vascular, or eye involvement. Routine assessment of patient index data 3 (RAPID3) is a composite index based on 3 multi-dimensional health assessment questionnaire (MDHAQ) components, patient function, pain and patient global assessment. The objective of the present study was to evaluate the BSAS as a new tool for measuring disease activity, as compared to the already established BDCAF, and to use the RAPID3 form as a secondary exploratory index.

Methods: Patients seen consecutively at the Rheumatology Center between May 1 and June 25, 2011 were given the BSAS questionnaire and MDHAQ to complete, and all attending physicians filled the BDCAF. Descriptive statistics, and Pearson correlation coefficients were calculated for each measure.

Results: Fifty-two patients completed all three assessments. The BSAS (range 0–100) mean score was 16.9 (SD 10.7); BDCAF (range 0–12) mean score was 2.6 (SD 1.7); RAPID3 (range 0–30) mean score was 8.9 (SD 5.7), median was 12.5 (IQR 18.5); Physician Global (0–10) mean score was 3.6 (SD 2.1). The correlation between BSAS and BDCAF was moderate (r:0. 491, $p<0.0001$), while BSAS was strongly correlated with RAPID3 (r:0. 65, $p<0.0001$). The correlation between the RAPID3 and BDCAF was found to be poor (r:0.277, $p=0.047$).

Conclusion: We found that the BSAS questionnaire, composed of patient responses only, has a strong, positive correlation with the BDCAF, a questionnaire that is completed by a clinical assessor. An outcome score composed of only patient-derived observations may have the additional advantage of being easier to use in a routine care setting.

The Impact of Positive Pathergy Test on the Performance of Diagnostic Criteria in Behcet's Disease. Fereydoun Davatchi, Bahar Sadeghi Abdollahi, Cheyda Chams-Davatchi, Farhad Shahram, Zahra Ghodsi, Tahereh Faezi, Abdolhadi Nadji, Massoomeh Akhlaghi and Roghieh Larimi. Shariati Hospital-Tehran Univ, Tehran, Iran

Background/Purpose: No diagnostic test exists for Behcet's Disease (BD) except the pathergy test that reveals the pathergy phenomenon of the disease. Positive pathergy test (PPT) is an important criterion of many classification/diagnosis criteria. There are actually 16 sets of diagnosis/classification criteria for BD: Curth (1946), Hewitt (1969), Mason and Barnes (1969), Hewitt Revised (1971), Japan (1972), Hubault and Hamza (1974), O'Duffy (1974), Zhang (1980), Dilsen (1986), Japan Revised (1988), International Study Group (ISG) in 1990, Iran (1993), Classification Tree (1993), Dilsen revised (2000), Korea (2003), and the International Criteria for Behcet's Disease (ICBD) in 2006. The aim of this study was to find, how much PPT accounts in the overall performance of those diagnostic criteria that use PPT as a criterion. We selected 9 of the most renowned of them for this study.

Methods: Patients with BD (6607) were selected as consecutive patients from the Behcet's Disease registry, and 4292 control patients. The diagnosis of BD was made on "Expert Opinion" without taking into account any known criteria. Control patients were those sent to find if they had BD, and the expert opinion was against the diagnosis. The 9 criteria sets were tested in them, once taking into account the PPT, and then without it. The sensitivity, specificity, and accuracy (percent agreement) of them were calculated to find the impact of PPT.

Results: Without PPT, all tested criteria lost some of their sensitivity. The largest lost was for Dilsen, ISG, and revised Dilsen criteria (17.3%, 16.1%, 16.1%). The least was for ICBD, Japan revised, and Classification Tree criteria (6.5%, 7.6%, 7.6%). The largest gain on specificity was for ICBD (3.9%) and the least for Japan and Japan revised criteria (0.1%, 0.1%). The largest lost in accuracy was for ISG, Dilsen revised, and Dilsen criteria (9.5%, 9.5%, 8.6%) and the least for ICBD, Classification Tree, Japan, and Japan revised criteria (3.6%, 4.2%, 4.6%, 4.6%). The best overall accuracy (without PPT) was ICBD, the Classification Tree, and the Japan revised criteria (93.7%, 93%, 86.1%). Details for all tested criteria are shown in Table 1.

Table 1. Performance of different Criteria set with and without pathergy test

		SENSITIVITY			SPECIFICITY			ACCURACY		
	PPT	%	95%CI	Lost%	%	95%CI	Gained%	%	95%CI	Lost%
ISG	Yes	78.0	1.0	16.1	99.0	0.3	0.8	86.3	0.6	9.5
	No	61.9	1.2		99.8	0.1		76.8	0.8	
ICBD	Yes	98.3	0.3	6.6	95.9	0.6	3.9	97.3	0.3	3.6
	No	91.7	0.7		99.8	0.1		93.7	0.5

	No	64.7	1.2		99.7	0.2		78.4	0.8	
DILSEN_R	Yes	79.4	1.0	16.1	98.9	0.3	0.8	87.1	0.6	9.5
	No	63.3	1.2		99.7	0.2		77.6	0.8	
IRAN	Yes	90.7	0.7	13.5	97.0	0.5	0.8	93.2	0.5	7.9
	No	77.2	1.0		97.8	0.4		85.3	0.7	
TREE	Yes	97.2	0.4	7.6	97.3	0.5	0.8	97.2	0.3	4.2
	No	89.6	0.7		98.1	0.4		93.0	0.5	
KOREA	Yes	86.3	0.8	9.9	98.1	0.4	0.7	90.9	0.5	5.6
	No	76.4	1.0		98.8	0.3		85.3	0.7	

Conclusion: ICBD and Classification Tree criteria were the least dependent on PPT to classify patients as having BD. They have also the best sensitivity and the best accuracy without using the PPT, making them the best diagnostic instrument in countries where PPT is rarely encountered (countries far from the Silk Road). They are also the most performing Diagnosis/Classification criteria for countries inside the Silk Road.

2387

A Mucocutaneous Activity Index for Behcet's Disease. Gonca Mumcu[1], Nevsun Inanc[2], Haner Direskeneli[2] and Tülin Ergun[3]. [1]Marmara University-,Faculty of Health Sciences, Department of Health Informatics and Technologies, Istanbul, Turkey, [2]Marmara University School of Medicine, Istanbul, Turkey, [3]Department of Dermatology, Marmara University School of Medicine, Istanbul, Turkey

Background/Purpose: Evaluation of disease activity is fairly difficult in Behçet disease (BD) with different organ manifestations. A "Composite Index" (CI) was previously validated for oral ulcer activity in BD by our group (Mumcu 2009). Although other mucocutaneous symptoms are also common clinical symptoms, no standardized activity index is present to assess all of them together in BD. Therefore, the aim of this study was to develop a disease-specific muco-cutaneous activity index in Behcet's disease.

Methods: One hundred BD patients (F/M:62/38, mean age:37.7±10.8 years) were included in the study. Mucocutaneous index (MI) was composed of genital ulcer activity index (GI), erythema nodosum activity index (EI) and CI. It evaluated both pain scored by visual analogue scale (VAS-pain, 0–100 mm) and functional status coded by Likert-type scale of each involvement during the last month. Score of MI could be between 0 and 30 (0–10 points for each involvement). Internal reliability was evaluated by Cronbach-alpha coefficient in functional disability score, as the same scoring procedure was applied in this multi-item scale. The score was evaluated in patients with both active and inactive disease for content validity. Patients with any mucocutaneous symptom were categorised as active group (n=85), whereas the others were accepted inactive (n=15).

Results: Oral ulcer activity was present in 85% of the patients (n=85) in the study group. The ratios of genital ulcer and erythema nodosum activities were 15% for each involvement (n=15). MI score (5.8±4.8) was higher in active patients (n=85, 6.8±4.6) than inactive ones (n=15, 0±0)($p=0.000$). Similarly, scores of CI, GI and EI were also lower in inactives (0±0) compared to active ones (5.0±2.7, 5.5±3.3 and 5.2±2.3, respectively) for each involvement. Cronbach-alpha coefficients for functional status were 0.9109 for CI, 0.9387 for GI and 0.9572 for EI. Fifteen active patients were examined by both observer 1 (TE) (8.8±2.3) and observer 2 (HD) (9.1±1.3) to evaluate interobserver difference without a significant difference ($p>0.05$). Almost three quarters of active patients (n=74, 74%) were treated with colchicine in BD. The others were using ISs (n=26, 26%). MI score was lower in patients treated with immunosuppressives (3.9±4.9) than colchicine (6.3±4.8) ($p=0.03$).

Conclusion: The validated, new mucocutaneous activity index can be a valuable tool to assess mucocutaneous-specific clinical symptoms and the effects of treatment modalities in BD.

2388

Gender-Specific Differences in Adamantiades-Behçet's Disease Presentation and Their Relationship with *HLA-B5*: An Analysis of 731 Subjects From the German Registry for Adamantiades-Behçet's Disease. Nikolaos G. Bonitsis[1], Liem Binh Luong Nguyen[2], Nestor Papoutsis[1], Andreas Altenburg[1], Ina Kötter[3], Alfred Mahr[2] and Christos C. Zouboulis[1]. [1]Departments of Dermatology, Venereology, Allergology and Immunology, Dessau Medical Center, Dessau, Germany, [2]Department of Internal Medicine, Hospital Saint-Louis, Paris, France, [3]Department of Internal Medicine II, Rheumatology Division, University Hospital Tübingen, Tübingen, Germany

Background/Purpose: Adamantiades-Behçet's disease (ABD) is a multisystem disorder characterized by highly variable presentations. The factors driving the individual disease expressions are not well known. Gender-specific differences in clinical features, such as increased risk of eye involvement in males, have been proposed. The ABD susceptibility allele *HLA-B5* is tightly associated with male gender and ocular disease, and it could be hypothesized that the effect of gender on ABD expression is to some extent confounded by *HLA-B5* positivity. We undertook a study to investigate the effect of gender on the demographic and clinical features in ABD and to assess whether any differences may account for *HLA-B5* status.

Methods: This study was based on the German Registry of ABD, a national, multicenter registry prospectively collecting demographic, clinical and genetic information for ABD patients since 1990. Age at diagnosis and cumulative clinical variables (oral ulcers, genital ulcers, pathergy reaction and ocular, skin, joint, neurological, heart, pulmonary, and kidney involvement) were compared accordingly to gender and *HLA-B5* status. Statistical analyses used Pearson's chi^2 and Student's t tests.

Results: A total of 731 subjects were evaluated (mean age at diagnosis: 27.8 yr [SD 11.7], 58% males, 40% Germans, 44% Turks). The International Study Group classification criteria were satisfied by 629/728 (86%) subjects overall and by 375/423 (89%) males and 254/305 (83%) females ($P=0.04$). *HLA-B5* was found in 350/603 (58%) and was significantly higher in males (relative risk [RR]: 1.27, 95% CI: 1.09–1.48, $P=0.001$). The age at disease onset did not differ by gender ($P=0.22$). Male gender was associated with a significantly increased prevalence of ocular involvement (RR: 1.21, 95% CI: 1.06–1.38, $P=0.004$), skin involvement (RR: 1.11, 95% CI: 1.02–1.21, $P=0.01$), major vessel involvement (RR: 2.86, 95% CI: 1.89–4.43, $P<0.0001$) and heart involvement (RR: 9.98, 95% CI: 1.41–203.40, $P=0.006$) and a decreased prevalence of genital ulcers (RR: 0.<82, 95% CI: 0.74–0.92, $P<0.0001$) and joint involvement (RR: 0.84, 95% CI: 0.72–0.99, $P=0.03$). Analyses of the clinical characteristics by *HLA-B5* status showed that *HLA-B5* was positively associated with ocular disease (RR: 1.43, 95% CI: 1.22–1.67, $P<0.0001$) and skin involvement (RR: 1.14, 95% CI: 1.04–1.25, $P=0.004$) and negatively associated with gastrointestinal involvement (RR: 0.51, 95% CI: 0.30–0.86, $P=0.008$). The HLA status did not affect the links between male gender and eye and skin involvement, respectively, with RR of 1.10 (95% CI: 0.94–1.32, $P=0.24$) and 1.06 (95 %CI: 0.95–1.19, $P=0.34$) among *HLA-B5* positive patients and 1.15 (95% CI: 0.86–1.55, $P=0.35$) and 1.18 (95% CI: 1.00–1.39, $P=0.05$) among *HLA-B5* negative patients.

Conclusion: This study adds support to gender-specific differences in ABD clinical presentation and to the link between male gender and *HLA-B5* positivity. The fact that *HLA-B5* status did not affect the link between gender and clinical presentation suggests that gender and *HLA-B5* are independent ABD expression modifiers. These findings may provide further insight into the mechanisms underlying the physiopathology of ABD.

2389

Exploration of Male Gender in Heterogeneity of Association Between *HLA-B51/B5* and Behçet's Disease Using Mixture Models. Michael P. LaValley[1], Hailong Cheng[2], Mathilde de Menthon[3] and Alfred Mahr[3]. [1]Boston University School of Public Health, Boston, MA, [2]Sunovion Pharmaceuticals Inc., Marlborough, MA, [3]Hospital Saint-Louis, Paris, France

Background/Purpose: In a previous random effects meta-regression of association between the *HLA-B5* and *HLA-B51* (*HLA-B51/B5*) genotype and Behçet's disease (BD) in case-control studies we found stronger association in studies with greater percentages of male subjects (Male%), and this was the only study factor that explained excess variation (heterogeneity)in association (*Arthritis Rheum* 2009;61:1287–96). To corroborate this result, we use a different association measure and a mixture model analysis that addresses heterogeneity by dividing studies into a small number of fixed effects sub-distributions rather than by use of a non-specific random effect. Study factors are then linked to these sub-distributions.

Method: A systematic literature search and extraction of was conducted as described in previous reports. Unlike previous reports, the arcsine difference (ASD) was used as association measure for *HLA-B51/B5* and case status as it follows a normal distribution more closely than the log odds ratio and has stable variance with sparse data. ASD near 1 indicate much higher prevalence of *HLA-B51/B5* in cases than controls; ASD near 0 indicate equal prevalence. Study level factors were Male%, publication factors, study area, tested allele (*HLA-B5* or *HLA-B51*), classification criteria, clinical manifestations, and ethnic matching of cases and controls. We fit meta-analysis mixture models with 1 to 9 fixed-effects sub-distributions using Bayesian Markov-Chain Monte Carlo with non-informative prior distributions, with the deviance information criterion (DIC) used to choose the number of sub-distributions. Studies were classified to sub-distributions based on posterior probability of membership and study level factors compared between sub-distributions by univariate t- or chi-square tests. Funnel plots of study precision (1/SE^2) by ASD were used to display results.

Results: ASD were calculated for 80 studies with fixed effects combined ASD of 0.39 (95% CI 0.38–0.41) with 68% of the variability in ASD due to heterogeneity. The minimum DIC was obtained with 2 sub-distributions: A) mean ASD 0.32 (95% Posterior Interval 0.10–0.49) and 47% of the studies; B) mean ASD 0.50 (95% Posterior Interval 0.33–0.78). Studies with ASD < 0.41 (dashed line in figure) were assigned to the first sub-distribution. Mean Male% was 56% in sub-distribution 1 and 68% in 2 ($p=0.01$), no other study level factor was significant (all $p>0.1$). Studies with Male% over the median value of 60% (squares in figure) cluster in and near the second sub-distribution.

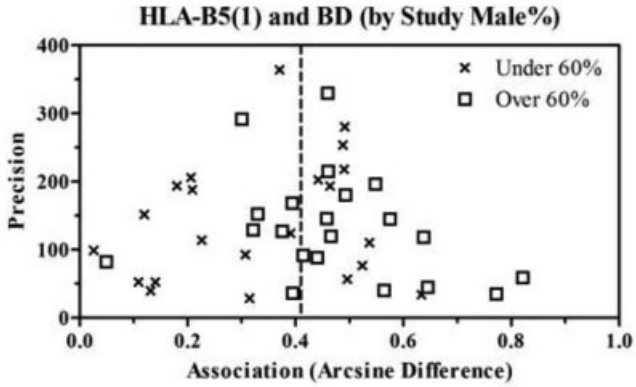

Figure 1. Funnel Plot by Study Male%

Conclusion: This analysis of study-clustering on the outcome corroborates the earlier finding of stronger association between *HLA-B51/B5* genotype and BD in studies with higher percentages of male subjects, providing further evidence of a sex-specific genetic effect in BD. The mechanism underlying the gender-differential effect of *HLA-B51/B5* on BD is unclear.

2390

CC Chemokine Receptor 5 Polymorphism in Behçet's Disease. Fabiola Atzeni[1], Luigi Boiardi[2], Bruno Casali[3], Enrico Farnetti[3], Piercarlo Sarzi-Puttini[1], Nicolo Pipitone[2], Ignazio Olivieri[4], Fabrizio Cantini[5], Fabrizio Salvi[6], Renato La Corte[7], Giovanni Triolo[8], Davide Filippini[9], Giuseppe Paolazzi[10] and Carlo Salvarani[2]. [1]Rheumatology Unit, L. Sacco University Hospital of Milan, Milan, Italy, [2]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [3]Molecular Biology Laboratory, Arcispedale S. Maria Nuova,, Reggio Emilia, Italy, [4]Rheumatology Department of Lucania, San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Potenza, Italy, [5]Stabilimento Ospedaliero Misericordia, Prato, Italy, [6]Dept. of Neurological Sciences, Ospedale Bellaria,, Bologna, Italy, [7]Chair of Rheumatology, University of Ferrara,, Ferrara, Italy, [8]Rheumatology Unit, University of Palermo, Palermo, Italy, [9]Rheumatology Unit, Ospedale Niguarda,, Milan, Italy, [10]Ospedale Santa Chiara, Trento

Background/Purpose: Behçet's disease (BD) is a primary systemic vasculitis characterised by oral and genital ulcerations associated with other clinical manifestations, such as skin lesions, uveitis and thrombosis. The aim of this study was to evaluate potential associations of CC chemokine receptor 5 (CCR5)Δ32 polymorphism with BD and disease expression.

Methods: One hundred and ninety-six consecutive Italian patients satisfying the International Study Group criteria for BD followed up for seven years and 180 healthy controls were genotyped for CCR5Δ32 polymorphism by molecular methods. The patients were grouped on the basis of the presence or absence of clinical manifestations. The diagnoses of deep venous thrombosis (DVT) and

superficial thrombophlebitis (ST) were initially made clinically, and then confirmed by means of ultrasonography or contrast venography.

Results: The distribution of the CCR5Δ32 genotype was not significantly different in the BD patients and healthy controls (p corr = 0.072), but the CCR5Δ32 allele was more frequent in BD than in controls (p corr = 0.004, odds ratio [OR] 3.1, 95% CI 1.5–6.7). Carriers of the CCR5Δ32 allele (Δ 32/ Δ 32 + CCR5/ΔC32] were significantly more frequent in BD patients than in controls (p corr = 0.024, OR 2.37, 95% CI 1.1–5.1).

The CCR5Δ32 polymorphism was found more frequently in the BD patients with ST than in the controls (25.0% vs 5.6%, P=0.009), whereas there was no significant difference between BD patients with and without ST (25.0% vs 10.8%, P=0.07). There was no other significant association between clinical manifestations (including DVT) and the CCR5Δ32 polymorphism in the BD patients.

Conclusion: The CCR5Δ32 polymorphism might be associated with an increased risk of developing BD. Chemokines may have a role in the pathophysiology of BD and in the development of ST.

2391

Genome-Wide Expression Profiling of CD14+ Monocytes in Behcet's Disease: An Upregulated TGF-b Signaling and N-Methyltransferase Activity. M. Dozmorov[1], F. Ozdemir[2], V. Yilmaz[3], E. Eksioglu-Demiralp[2], J. Wren[1], G. Saruhan-Direskeneli[3], A. Sawalha[1] and H. Direskeneli[4]. [1]Department of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Marmara University, School of Medicine, Department of Immunology, Istanbul, Turkey, [3]Istanbul University, Istanbul Faculty of Medicine, Department of Physiology, Istanbul, Turkey, [4]Marmara University, School of Medicine, Department of Rheumatology, Istanbul, Turkey

Background/Purpose: To obtain a global view of the gene expression profile in CD14+ monocytes of Behcet's Disease (BD), a systemic, inflammatory disorder with unknown etiology.

Methods: Patients with BD (n=3), compared to controls (n= 5) were investigated. Whole-genome microarray profiling was performed with human U133 (Plus 2.0) microarrays on an Affymetrix platform using isolated CD14+ monocyte subset from peripheral blood mononuclear cells. Differentially expressed genes were identified by associative analysis and assessed for gene ontology enrichment (DAVID), affected canonical pathways and networks (Ingenuity Pathway Analysis) and for transcription regulation of the promoters (PAINT).

Results: When genes with at least 3-fold expression difference were selected, 135 unique genes were upregulated, and 36 were downregulated in CD14+ cells in BD. One gene, EZH1, was uniquely overexpressed in BD, with no detectable expression in controls. Out of 135 upregulated genes 87 were phosphoproteins, indicating that proteins coded by those genes are post-translationally modified by the attachment of a phosphate group. Among the upregulated profile, genes related to intracellular organelle lumen (n=27), endocytosis (n=7), enzyme linked receptor protein signaling pathway (n=8) and N-methyltransferase activity (C1orf25, EZH1, MLL, PRDM2 and SETD2) were the most prominent. Canonical pathway analysis showed an upregulated TGF-β Signaling (ACVR1B, BMPR2, PIAS4, SMAD5, SMAD7, SOS1, SOS2 and TGFBR2). Upregulated genes formed a single network highlighting TNFa and interferon-g as major regulators and associated also with several adhesion-related molecules and signal transducer receptors including CD36, ITGB2 and DSC2. When downregulated genes were investigated, 24 molecules out of 36 shared "cell death" ontology, suggesting that CD14+ cells are in proliferation in BD. Some molecules associated with pattern recognition receptors of bacteria and viruses were also downregulated (C5AR1, CLEC7A, IL1B, NLRP3, RIPK2 and TLR4).

Conclusion: Both up- and downregulated genes highlight enhanced proliferation of CD14+ cells in BD. Common hub molecules, mainly interferon-g and TNFa, seem to be activated. Downregulation of molecules related to pattern recognition receptors point to a dysregulated anti-bacterial and viral immunity.

2392

Parvovirus B19 in Behçet's Disease. Zahra Habibagahi, Mojtaba Habibagahi and Said Mostafa Said Mardani. Shiraz University of Medical Sciences, Shiraz, Iran

Background/Purpose: Behcet is a systemic vasculitis known with repeated oral and genitalia aphthous, ophthalmology, and dermatology manifestations. The etiology of Behcet Disease (BD) is unknown.Viral infections are supposed to have a role in disease pathogenesis. Higher levels of antibodies to herpes simplex and varicella zoster virus antigens have been shown in patients with BD compared to controls. Herpes simplex DNA has been extracted from oral, genitalia and intestinal ulcers of BD patients.

There are varying results that show an association between parvovirus B19 and BD. The quantity of viral DNA in non ulcerated skin rashes was significantly higher than skin ulcers of healthy volunteers, although other investigators could not confirm this relationship. Signs of parvovirus B19 infection has been demonstrated in various autoimmune diseases like vasculitis, rheumatoid arthritis, systemic lupus erythematosus, and reactive arthritis.

The conflicting results of these studies cannot prove the role of parvovirus B19 in BD. Higher prevalence of antivirus antibodies may only be an incidental finding because of the high prevalence of viral infection in population. Persistent viral DNA also may be expected in patients with compromised immunity as a result of delayed in virus clearance.

We aimed to quantify parvovirus B19 DNA in BD patients in comparison to healthy controls by real time PCR and determine the relation of the level of virus DNA with disease severity.

Methods: Fifty five patients with BD (M/F; 0.67, mean age; 37.4 +/− 8.68 years, and mean disease duration of 7 years) were selected according to the International Study Group classification criteria to enroll in study after obtaining consents forms. The study was approved by the ethics committee of Shiraz University of Medical Sciences, Shiraz, Iran.

The patients were selected in a simple random manner and divided into mild, moderate, and severe groups according to disease severity score.

Parvovirus 19 specific quantitative real time PCR with TaqMan technology was used to assess the levels of viral DNA in patients' serum and age/sex matched controls. We also determined the relation between levels of virus DNA and disease severity indexes.

Data analysis was done by SPSS version 16 and using student T test.

Results: The disease was inactive in 8 patients (14.5%) while the disease severity in others was measured as mild in 18 (32.7%), moderate in 16 (29.2%), and severe in 13(23.6%) patients by behcet disease severity score. Among 55 selected patients, only 1 (1.8%) showed detectable virus in her serum. In the control group, 1volunteer (2.4%) had measurable serum B19 virus. No significant difference was found between patients and controls regarding to this finding. Also, the level of B19 DNA in serum was not correlated to the disease severity.

Conclusion: We could not find any relation between BD and parvovirus infection. Disease severity was not affected by the level of virus in patients' serum. Search for parvovirus DNA in tissue samples may be more helpful to show the role of virus infection in BD.

2393

Management and Prognosis of Non-Pulmonary Large Arterial Disease in Behcet's Syndrome: A Reappraisal of 25 Patients From a Single Center. Hasan Tuzun, Emire Seyahi, Caner Arslan, Vedat Hamuryudan, Kazim Besirli and Hasan Yazici. University of Istanbul, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background/Purpose: To assess management and prognosis in a cohort of 25 patients with non-pulmonary arterial aneurysms due to Behcet's (BS) syndrome by formally re-assessing their outcome at the present time.

Methods: We identified 25 (24 M/1F) BS patients with non-pulmonary aneurysms (n= 23) occlusions (n = 2) between 1996 and 2007. All patients fulfilled the International Study Group Criteria for BS. Aneurysms were demonstrated with CT or MRI after first line USG. Standard by-pass procedures were carried out in all patients except in 4 patients with small asymptomatic non-ruptured saccular aneurysms (2 aortic and 2 carotid arteries) which were treated with only medical therapy. For aneurysms located in the aortic bifurcation we preferred aortobiiliac bypasses. For the 6 extremity aneurysms we were able to ligate arteries. For the other 10 extremity aneurysms we used PTFE grafts for bypass procedures. All patients received immunosuppression with cylophosphamide and corticosteroids before the operation and continued in the postoperative period. All patients were examined between January and December 2010, paying special attention for new and anastomotic aneurysms and graft patency.

Results: There was one death and one lost to follow-up. The remaining 23 (92 %) patients were under follow-up after a mean of 7.4 ± 2.9 years following operation. Patients who had ligated arteries complained of mild to moderate claudication. Four (40 %) PTFE grafts occluded without severe complication. Three patients developed relapsing aneurysms elsewhere and 2 other had recurrence at the initial surgical site.

Conclusion: The surgical management of large non-pulmonary arterial complications of BS is quite satisfactory. The prognosis has significantly improved as compared to what we had previously reported, then a 33% mortality at 4 years, from the same center some years ago (1). When the false

aneurysm is in the infrarenal aorta, aortobiiliac bypass is the preferred surgical intervention. Extremity aneurysms can be treated with synthetic graft insertion, but occlusions can be seen. In selected cases ligation can give satisfactory results, however post-operative claudication is common. In some patients with small intact saccular aneurysm surgery may not be necessary. Patients must be prescribed to immunosuppressive therapy with cylophosphamide and corticosteroids before and after the surgical intervention in order to avoid BS activation.

Long-Term Outcome of Arterial Lesions in Behçet's Disease: A Series of 101 Patients. David Saadoun[1], B. Asli[2], Bertrand Wechsler[2], Habib Houman[3], Guillaume Geri[2], Jean-Charles Piette[2], Zahir Amoura[2], Mathieu Resche Rigon[1] and Patrice Cacoub[2]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]CHU Pitié-Salpêtrière, Paris, France, [3]department of internal medicine hôpital la rabta Tunis Tunisie, France

Background/Purpose: The vasculitis of Behçet's disease (BD) is distinctive because of involvement of both arteries and veins of all sizes. The concept of vasculo-Behçet has been adopted for cases in which vascular manifestations are present and often dominate the clinical features. While venous manifestations are frequent and have been reported in many publications, data regarding arterial lesions in BD are rare and often isolated.

Methods: We reported the main characteristics, treatment and long-term outcome of 101 (12.3%) patients with arterial lesions among a cohort of 820 BD patients. Factors that affect prognosis were assessed by multivariate analysis.

Results: There was 93 (91.2%) male with a median age at diagnosis of BD of 33 [27–41] years. Arterial lesions included aneurysms (47.3%), occlusions (36.5%), stenosis (13.5%) and aortitis (2.7%). Lesions mainly involved aorta (n=25), femoral (n=23) and pulmonary (n=21) arteries. Patients with arterial lesions were more frequently of male gender (91.2% versus 62.4%, respectively, p=0.017) and had higher rate of venous involvement (80.4% versus 29.8%, respectively, p<0.001) compared to those without arterial manifestations. Thirty nine (38.6%) patients achieved a complete remission. In multivariate analysis, the presence of venous involvement [odds ratio (95% CI), 0.29 (0.08–1.11)] and arterial occlusive lesions [0.13 (0.01–1.25)] were negatively associated with complete remission. The use of immunosuppressants [3.38 (0.87–13.23)] was associated with the occurrence of complete remission. The 20-years survival rate was signicantly lower in BD patients with arterial involvement compared to those without arterial lesions (73% vs 89%, p<0.0001, respectively).

Conclusion: In conclusion, the long-term outcome of arterial lesions in BD is poor, especially in case of occlusive lesions and associated venous involvement. The use of immunosuppressants improved the prognosis.

2395

Immunosuppressants Reduce Venous Thrombosis Relapses in Behçet's Disease. anne Claire Desbois[1], Bertrand Wechsler[2], Jean-Charles Piette[3], Du Boutin[1], Zahir Amoura[4], Fabien Koskas[1], Patrice Cacoub[4] and David Saadoun[5]. [1]Department of Internal Medicine and 2Laboratory I3 Immunology, Immunopathology, Immunotherapy, UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]Hopital de la Pitie, Paris, France, [3]Paris, [4]CHU Pitié-Salpêtrière, Paris, France, [5]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France

Background/Purpose: Venous disease is more common than arterial involvement and its prevalence may account 14% to 39% of patients with Behçet's disease (BD) according to studies. Venous thrombosis in BD is a severe disorder which may affect many differents sites including inferior vena cava, superior vena cava, pulmonary artery, supra-hepatic vessels and cardiac cavities. Treatment and outcome of venous thrombosis in BD is not well defined.

Methods: Among a cohort of 820 BD patients, 296 patients (36.7%) [73.6% of male and the median (Q1-Q3) age was 30 (24–36) years] fulfilling the international criteria of BD and with venous thrombosis were reported. Factors associated with relapses of thrombosis and mortality were assessed.

Results: There was a total of 582 venous thrombosis events including 555 deep and 27 superficial thrombosis. Main deep thrombosis localizations included limbs (n=323, 55.1%), cerebral veins (n=77, 13.1%), pulmonary embolism (n=57, 9.7%), vena cava (n=63, 10.7%), Budd Chiari syndrome (n=14, 2.4%) and cervical veins (n=13, 2.2%). The mortality rate was 6.4% (19/296) after a median (Q1-Q3) follow up of 4.75 [2–7] years. In univariate analysis, death was associated with male gender (p=0.0088), cardiac involvement (p=0.026) and Budd Chiari syndrome (p=0.004). In multivariate analysis, factors that prevent relapses of venous thrombosis were immunosuppressants [HR 0.27 (0.14–0.52), p<0.001] and corticosteroids [HR 0.62 (0.40–0.97), p= 0.058].

Conclusion: Budd Chiari syndrome is the more severe venous involvement in our series of BD. Immunosuppressants use reduce the relapses of venous thrombosis in BD.

2396

Difference of Manifestations and Treatment Among Behcet's Syndrome Patients in the United States and Japan. Yuri Ohara[1], Mitsumasa Kishimoto[1], Tatsuo Kobayashi[2], Christopher Swearingen[3], M.T. Filopoulos[4], Yasuharu Tokuda[5], Hideto Oshikawa[2], Kazuki Yoshida[2], Masako Utsunomiya[2], Makiko Kimura[2], Masato Okada[1], Kazuo Matsui[2] and Yusuf Yazici[6]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]Kameda Medical Center, Kamogawa City, Japan, [3]University of Arkansas for Medical Sciences, Little Rock, AR, [4]Hospital for Joint Diseases, New York, NY, [5]University of Tsukuba, Ibaraki, Japan, [6]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Several studies showed regional differences in Behcet's syndrome (BS) presentation. These differences may have consequences in treatment and prognosis. Purpose of our study is to compare BS cohorts from the U.S. and Japan for disease manifestations and treatment histories.

Methods: All BS patients seen in the NYU Hospital for Joint Diseases BS Center in the U.S., St. Luke's International Hospital and Kameda Medical Center in Japan between 2003–2010 were included in the analysis. The diagnosis of BS was made on clinical manifestation and expert opinion. Disease manifestations and treatment histories were reviewed at baseline visits and during follow up.

Results: We included a total 772 patients (the U.S. n=630 and Japanese n=142). Age at onset was significantly older in Japanese patients than the U.S. patients (average 46.85 vs 35.96). Japanese patients were significantly less likely to be female, have genital ulcers or arthritis, and more likely to have epididymitis, pulmonary disease, and HLAB51, B52, and A26 positivity. In addition, significantly more patients had been treated with sulfasalazine/mesalazine in Japan, while significantly more patients in the U.S. received NSAIDs, hydroxychloroquine, thalidomide, first-line immunosuppressants (azathioprine, methotrexate, cyclosporine, and mycophenolate mofetil) and TNF inhibitors (etanercept, infliximab and adalimumab).

Conclusion: There are differences in clinical manifestations in our study. It revealed that the U.S. patients receive more aggressive treatments than in Japanese patients. These regional differences need to be taken into considerations when designing trials, treating patients and developing diagnostic criteria.

Neuro-Behçet′s Disease in Brazil: Higher Incidence in Females and Atypical Manifestations. Livia A. Dutra[1], Celio R. Gonçalves[2], José L. Pedroso[1], Pedro Braga-Neto[1], Alberto A. Gabbai[1], Orlando G. P. Barsottini[1] and Alexandre W. S. de Souza[1]. [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: The type and frequency of systemic and neurologic manifestations of BD (Behçet′s disease) vary with ethnicity. In Brazil, BD occurs as sporadic cases. Here we describe clinical and radiological features of Brazilian patients of mixed ethnicity presenting neurologic manifestations of BD.

Methods: Medical records of 178 BD patients were reviewed from the two largest tertiary hospitals in the city of São Paulo, Brazil, between February 2009 and July 2010. Forty patients (22%) with neuro-Behçet's disease (NBD) were identified. Information about gender, clinical manifestations, cerebral spinal fluid analysis, electromyography, electroencephalogram and brain magnetic resonance imaging was collected.

Results: Among 40 NBD patients, 57.5% were female and parenchimal involvement was observed in 32 (80%). The brain stem was the most affected structure (42%). Neurological complaints were the first manifestations of BD in 7 (17.5%) patients. Other neurologic manifestation observed were: seizures

(27.5%), optic neuropathy (15.0%), isolated aseptic meningitis (15.0%), peripheral neuropathy (7.5%), cerebral venous thrombosis (7.5%) and spinal cord involvement (5.0%). Twenty two patients (55.0%) presented at lease one relapse and aseptic meningitis was the most common relapsing manifestation. No significant difference was found concerning the number of relapses between parenchymal and non-parenchymal groups. Cyclosporin use was not associated with a higher rate of NBD manifestations. A multivariate analysis that included disease duration, white cell count in spinal fluid, cyclosporine use, and immunosuppressive use at onset, age at NBD onset or optic neuritis did not reveal significant associations with relapses in NBD patients.

Conclusion: Brazilian patients with NBD present a different pattern of neurologic involvement when compared to other population groups with a higher prevalence of parenchymal involvement, aseptic meningitis, optic and peripheral neuropathy, and a higher rate of neurologic relapses. Furthermore, the frequency of cerebral venous thrombosis among Brazilian NBD patients is lower than the previously described.

2398

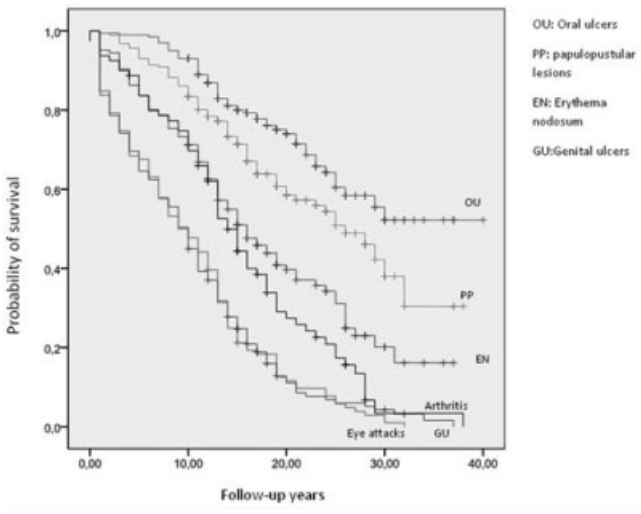
Some Manifestations Disappear Earlier Than Others in Behcet's Syndrome. F. Sevgi Sacli[1], Emire Seyahi[2], Serdal Ugurlu[3], Yilmaz Ozyazgan[2], Cem Mat[2] and Hasan Yazici[2]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]University of Istanbul, Cerrahpasa Medical Faculty, Istanbul, Turkey, [3]Rheumatology, Istanbul, Turkey

Background/Purpose: In a 20 year outcome study (1), we had observed that the frequency of all mucocutaneous lesions and arthritis decreased in frequency with the passage of time. In this study we investigated whether some manifestations disappeared before other lesions.

Methods: We studied consecutive BS patients who were seen in the dedicated BS outpatient clinic at Cerrahpaþa Medical Faculty in Istanbul between February 2009 and January 2011. Only BS patients whose disease duration and follow-up were 10 years or longer were included in the study. With the help of a questionnaire, patients were asked whether skin mucosa lesions, arthritis and uveitis attacks occurred for the preceding one year. If not, they were asked about the date when the manifestation occurred for the last time. Also a pathergy test was done to those who volunteered.

Results: We studied 202 (114 M, 88 F) patients. The mean age of the patients was 48 ± 8 and the mean disease duration 19 ± 6 years and the mean follow-up 17 ± 6 years. As seen in the Table, the frequency of those with any BS manifestation during the preceding one year including pathergy positivity was decreased significantly at the final visit compared to that found at the initial visit. Kaplan-Meier survival curve showed that, eye attacks were the first to cease followed by genital ulcers, arthritis and skin lesions. The most frequent lesion late during the disease course was oral ulcer, followed by the papulopustular lesions. The probability of continuing to appear still after 30 years of disease onset was 60 % for oral ulcers and 40 % for papulopustular lesions. Men and women showed a similar decreasing trend in all manifestations. A correlation matrix analysis done to see the associations between the last visit manifestations revealed that, the oral ulcers were associated with every lesions while arthritis with papulopustular lesions and eryhthema nodosum.

Figure. Kaplan Meier survival plot for duration of BS manifestations



Conclusion: In BS, some disease manifestations disappear earlier than others. These findings may have important pathogenetic and clinical implications. There has been debate whether the papulopustular skin lesions were, part of BS or whether they were non specific (2). However, the fact that papulopustular lesions continue to appear still late during the follow-up, show us that this lesion is in fact an inherent lesion of BS. Furthermore, the persistence of the well described papulopustular lesions - arthritis association (3), even late during the disease course, might also support the contention that these skin lesions are part of the syndrome rather than chance findings. Finally, since our survey was cross-sectional and retrospective, caution is required in interpretation.

Spectrum of Cardiac Lesions in Behçet's Disease. Guillaume Geri[1], Bertrand Wechsler[1], Du Le Thi Huong[1], Richard Isnard[2], Jean-Charles Piette[1], Zahir Amoura[1], Mathieu Resche Rigon[3], Patrice Cacoub[1] and David Saadoun[3]. [1]CHU Pitié-Salpêtrière, Paris, France, [2]Department of Cardiology, CHU Pitié-Salpêtrière, 47–83 Boulevard de l'hôpital, 75651 Paris Cedex 13, Paris, France, Paris, France, [3]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France

Background/Purpose: Behçet's disease (BD) is a multisystemic vasculitis of unknown etiology. Cardiac involvement is rare in BD. Data regarding clinical presentation and outcome of cardiac involvement.in BD are lacking. The aim of this study was to describe the spectrum of cardiac lesions in a large cohort of patients with BD.

Methods: We reported a series of 52 consecutive patients with cardiac involvement fulfilling the international criteria of BD. Multivariate analysis was performed to determine factors associated with complete remission of cardiac involvement in BD.

Results: Among a cohort 807 BD patients, 52 (6.4%) had a cardiac involvement. They were mostly of male gender (86.5%) Mean age at diagnosis was 33.5±16.5 years and cardiac involvement was the first feature of BD in 17 patients (32.7%). Main types of cardiac lesions included pericarditis (n=20; 38.5%), endocardium involvement [mostly aortic insufficiency] (n=14 26.9%), intracardiac thrombosis [right atrium or ventricule] (n=10; 19.2%), myocardial infarction (n=9; 17.3%), endomyocardic fibrosis (n=4, 7.7%) and myocardial aneurysm (n=2, 3.8%). BD patients with cardiac involvement had a higher mortality rate at 5 years compared to those without (16.5% vs 4.2%, p=0.03). Eight patients died after a mean follow up of 3.3±2.7 years [myocardial infarction (n=2), sepsis (n=2), bacterial endocarditis (n=1) and unknown (n=3)]. Large-vessel vasculitis and deep-vein thrombosis occurred more frequently in patients with cardiac involvement than in those without (42.3 vs. 11.1, p<0.0001 and 59.6 vs. 35.8; p<0.005, respectively). Factors associated with complete remission of cardiac involvement were the use of immunosuppressants and colchicin, and oral anticoagulation.

Conclusion: Cardiac lesions involved 6% of our BD patients and are associated with a poor outcome.

Is It Possible to Maintain Remission After Suspension of Infliximab for Sight- and Life-Threatening Involvement in Behcet's Disease? A Proposal of a Tapering Schedule. Rosaria Talarico, Anna d'Ascanio, Laura Bazzichi and Stefano Bombardieri. Rheumatology Unit, Pisa, Italy

Background/Purpose: Behcet's disease (BD) is a systemic vasculitis tipically characterized by recurrent oral and genital ulcers. Ocular and central nervous system (CNS) involvement are worrying complications of the disease and traditional therapies frequently fail to reduce its exacerbations, or to stop its progression. Literature data show growing data reporting effectiveness of TNF-alpha blockers in inducing remission for ocular and CNS involvement in BD. Poor data are available on maintaining remission after suspension of therapy.

The primary aim of this study was to assess the efficacy of Infliximab (IFX) in maintaining remission after suspension of therapy in a cohort of BD patients with severe ocular and CNS involvement. The secondary aim of the study was to quantify the mean number of infusions performed until suspension.

Methods: Among twenty-seven BD patients receiving IFX and prospectively studied, we selected 9 subjects (mean ± SD disease duration: 11±5 yrs) with a minimum period of 12 months of complete remission (defined as the absence of ocular or CNS relapses) according to medical decision. Outcome definition consisted of ophthalmological examination, visual field and/or fluorescein-angiography and/or optical coherence tomography for ocular involvement and neurological examination and magnetic resonance imaging for CNS involvement. After the first 8 infusions, the tapering schedule of suspension was characterized by an administration every 8 weeks for three infusions and then after 10 weeks.

Results: IFX was administered as an intravenous infusion of 5 mg/kg in 4 patients and 3 mg/kg in the others, at time 0, at week 2, 6 and then every 6 weeks; concomitant therapies were: methotrexate in 6 patients, none in 3 and in all low doses of steroids. Indications to start treatment were: ocular involvement in 6 patients (retinal vasculitis and posterior uveitis in all cases) and CNS involvement in 3 (ischemic pons-mesencephalon lesions in 2 subjects and one case of meningoencephalitis with brainstem involvement). At 24 months follow-up after IFX suspension complete disease remission was maintained in all but one cases; one patient who relapsed two months after autonomously withdrawal without any tapering, was successfully promptly retreated and he is still receiving IFX. The mean number of infusions before stopping IFX was 12±3 (min:9, max:15), with a mean period after remission of 14±3 months.

Conclusion: Although further long term follow-up controlled studies are needed to define a standardized duration of infusions, IFX seems to be effective for maintaining remission for ocular and CNS involvement due to BD also after suspension, particularly when gradually tapered. At the moment, we are prospectively validating this tapering schedule in further BD patients with ocular and CNS involvement.

2401

Neurological Involvement in Behcet's Disease: A Worrying Cause of Morbidity and Mortality. Rosaria Talarico, Claudia Ferrari, Anna d'Ascanio and Stefano Bombardieri. Rheumatology Unit, Pisa, Italy

Background/Purpose: Neurological involvement represents a worrying complication of Behcet's disease (BD), constituting an important cause of morbidity and mortality.

The primary aim of the study was to assess the prevalence of neurological involvement in a cohort of patients with BD, who have been followed in the last twenty years in our Institution. The second aim was to evaluate the time interval between BD onset and the onset of neurological involvement. The third aim was to compare the subset of patients with Neuro-BD with the other patients of the cohort.

Methods: One hundred and twenty patients were studied; the males/females, ratio was 1.6:1, with a mean disease duration of 11±5 yrs. Their mean age was 42±7 years (min:18, max:77), while the mean age at disease onset was 25±4 years (min:10, max:58). Prevalence of neurological findings demonstrated by MRI were retrospectively analysed in all patients (pts).

Results: Neurological involvement was observed in 34% (41 patients, 32 males and 9 females; mean age at the onset 25±4 years). The most common presenting symptoms among pts who experienced central nervous system involvement were headache (n=40), behavioural changes (35), hemiparesis (31); pyramidal signs occurred in 15 pts, while sphincter disturbances were observed in 12. The other neurological findings were represented by: meningeal signs (7), optic neuropathy (5), hearing loss (4), seizures (4) and sleepiness: (3). Organic brain involvement, demonstrated by MRI was due to ischemic pons-mesencephalon lesions in 19 pts and to meningoencephalitis with brainstem involvement in the others. Peripheral nervous system involvement was confirmed by electroneuromyographic study in 4 pts, and consisted of peripheral neuropathy prominent in the lower extremities in all cases; we have also observed only 2 cases of endocranial hypertension. Excluding peripheral neuropathy, the onset of CNS involvement was in 2 pts after 1 years of the onset of BD, in 4 cases after 3 years, in 24 after 5 years and in 7 after 10 years. Comparing Neuro-BD with other pts who didn't experience neurological involvement, the only statistical significant difference in the prevalence of the typical features of disease was in the frequency of ocular involvement, that resulted less frequent in BD patients with CNS involvement.

Conclusion: Neuro-BD is more frequent in young males and it never represents a presenting feature of disease. The most frequent time of onset of neurological involvement seems localized after the first 5 years of disease. Since neurological involvement may result in severe functional disability or be a life-threatening disease, a careful follow-up during the first decade after the onset is strongly recommended.

Consensus Statements for Management for Intestinal Behcet's Disease in Japan. Mitsuhiro Takeno[1], Reikou Watanabe[1], Hirotoshi Kikuchi[2], Masakazu Nagahori[3], Kazuyoshi Saito[4], Nagamu Inoue[5], Michiko Kurosawa[6], Yoshiaki Ishigatsubo[1] and Behcet's Disease Reserch Commitee of Japan[7]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Teikyo University, Tokyo, Japan, [3]Tokyo Medicai Dental University, Tokyo, Japan, [4]University of Occupational & Environmental Health, Japan, Kitakyushu, Japan, [5]Keio University, Tokyo, Japan, [6]Juntendo University, Tokyo, Japan, [7]Yokohama, Japan

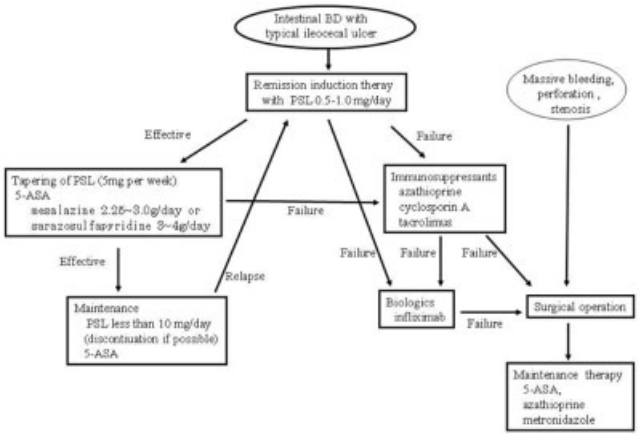
Background/Purpose: Intestinal lesions are found in 10 to 20 % of patients with Behcet's disease (BD) in Japan. It is sometimes hard to differentiate intestinal BD form inflammatory bowel diseases such as Crohn's disease. Moreover, the standard therapy has not been established. Therefore, it is necessary to establish clinical guideline from the diagnosis to the therapy.

Methods: We have previously developed consensus statements for the diagnosis and management of intestinal Behcet's disease using a modified Delphi approach in 2007.

The individual statements were re-evaluated by expert meeting members including 10 gastroenterogists, 4 rheumatologists, one general physician, and one pathologist, based on literatures, a nationwide epidemiological survey of infliximab (IFX) for intestinal BD patients, and individual clinical experience.

Results: The statements consist of diagnosis, assessment of clinical activity, treatment, and supplementary comments. Diagnosis of intestinal BD is made, when round or oval shaped deep ulcers are found in the ileocecal region by endoscopic or radiological examinations in patients who meet the 1987 Japan BD classification Criteria. Other types of intestinal lesions are distinguished from intestinal BD at the present. When patients have typical intestinal ulcer without extraintestinal lesions of BD, they should be carefully monitored. It is necessary to exclude infectious enteritis including tuberculosis, drug-induced enteritis as differential diagnosis. Clinical activity is comprehensively determined by systemic and local findings including endoscopic analysis, and laboratory data.

Recommended pharmacological therapies include corticosteroids, mesalasine, sulfasalazine surazosulfapyridine, and immunosuppressants such as azathioprine. Based on the favorable outcomes of the epidemiological survey, IFX is listed as an option in patients having refractory intestinal lesions to conventional therapies. Surgical operation is considered when massive bleeding, perforation, and stenosis occurred and when pharmacological therapies were insufficient. Algorithm of the therapies is summarized in the following figure.



Conclusions: The consensus statements provide helpful information for physicians who manage patients with intestinal BD.

2403

Measurement of Pain Perception in Children and Adolescents with Musculoskeletal Pain. Melissa Fraga[1], Claudio A. Len[1], Rafael Azevedo[1], Marcelo I. Yoguim[1], Maria Teresa Terreri[2] and Maria Odete E. Hilário[1]. [1]Universidade Federal de São Paulo/UNIFESP, São Paulo, Brazil, [2]Universidade Federal de São Paulo/UNIFESP, Sao Paulo, Brazil

Background/Purpose: The fact that musculoskeletal pain in childhood and adolescence is related to physical, emotional, familiar and cultural factors make both diagnosis and treatment real challenges in pediatric rheumatology. Therefore, the approach must be individual and based in the perception of each patient. Our aim was to measure the individual perception in hypothetical situations related to physical pain, emotional pain (deprivation of the company) and pain related to medical procedures.

Methods: We evaluated pain perception in 150 children and adolescents (8–18 years), that were included in 3 distinct groups: 50 with polyarticular juvenile idiopathic arthritis (JIA), 50 with idiopathic musculoskeletal pain (IMP) and 50 healthy children (without clinical history of chronic or recent acute pain). Pain perception was measured by 3 vignettes that illustrated life situations related to pain: physical trauma (bicycle fall), medical procedure (needle injection) and social isolation; the scores were measured by a 100 mm visual analogical scale (VAS). The evaluation also included 3 questionnaires: CHAQ, PedsQL 4.0) and the Pediatric Pain Coping Inventory (PPCI).

Results: JIA patients presented worse physical ability (measured by the CHAQ) when compared to IMP patients ($p<0{,}0001$). On the other hand, we observed lower scores in the IMP group in all aspects of health related quality of life ($p<0{,}0001$), including the physical domain. Concerning individual perception of pain, children and adolescents with IMP presented higher scores in the 3 pain situations ($p<0{,}0001$). With respect to pain coping, the 5-factor solution of the PPCI (cognitive self-instruction, seek social support, strive to rest and be alone, cognitive refocusing and problem-solving self-efficacy), children with IMP had worse scores in all of them, excluding cognitive self-instruction ($p<0{,}001$).

Conclusion: Our data reinforce the belief that the treatment of musculoskeletal pain should be performed by a multidisciplinary team, not just based on the use of analgesics. The perception has pain is personal and involves physical, emotional and social aspects. We also conclude that a focused education is required for pain coping, once the attitudes taken by children and adolescents in the presence of pain are not always for its control.

2404

Development of a Quality Patient-Health Care Provider Communication Scale Based On Patients' Perspective. Elizabeth G. Salt, Leslie J. Crofford, Jamie L. Studts, Robert W. Lightfoot and Lynne Hall. University of Kentucky, Lexington, KY

Background/Purpose: Effective patient-provider communication is an important component of quality health care for patients with rheumatoid arthritis (RA) (Lempp et al., 2006). Existing measures of patient-provider communication in samples of patients with RA have significant limitations (Berrios-Rivera et al., 2006; Smith et al., 2006). The aims of this study were to: devise a measure of the quality of patient-provider communication based on patients' perspectives; and evaluate the psychometric properties of this measure in a sample of patients with RA in a university clinic setting.

Methods: Items were developed from focus group sessions and individual interviews with 15 patients with RA. The participants described dimensions of quality patient-provider communication. The item pool generated was reviewed by experts in scale development and rheumatology. Final adjustments to the measure were made after six patients with RA provided feedback on item readability and ease of comprehension. A cross-sectional volunteer sample of 150 RA patients was recruited to evaluate the reliability and validity of the measure. A subset of 99 patients completed the measure again two weeks later to evaluate test-retest reliability.

Results: For the 21-item *Patient-Health Care Provider Communication Scale* (PHCPCS), the estimate of internal consistency was.89 using Cronbach's alpha, and the estimate of test-retest reliability over a 2-week time period was moderate ($r=0.52$, $p=0.01$, $n=99$). Two dimensions of the quality of patient-provider communication (*Quality Communication* and *Negative Patient-Health Care Provider Communication)* were identified using principal components analysis. The *Perceived Involvement in Care Scale* (Lerman et al., 1990) was moderately correlated with the PHCPCS ($r=0.34$, $p=0.01$) (Tables 1–2).

Table 1. Principal Components Analysis with Varimax Rotation of the Patient-Health Care Provider Communication Scale with Two Components Rotated ($N = 150$)

Items	I[δ]	II[δ]	Component[a]	
12.	Takes my health concerns seriously		.87	.03
10.	Pays attention to what I say about my health condition.		.85	.14
28.	Feel comfortable with the way my health care provider relays health information to me.‡		.83	.25
13.	Believes the symptoms that I report.‡		.82	−.02
23.	Treats me as she or he would want to be treated.		.81	.06
19.	Treats me with kindness.		.80	.12
24.	Approaches my treatment with a positive attitude.		.80	.15
22.	Explains my health condition in detail.		.77	.18
16.	Is patient.		.75	.17
3.	Answers my questions about my health.		.73	.01
11.	Tries to find the answers to my health problems.		.73	.08
7.	Understands my concerns about my health condition.		.72	.05
20.	Presents me with all of the treatment options.		.72	.13
21.	Is knowledgeable about my health condition.		.70	.05
14.	Is honest with me about my health.		.69	.02
8.	Is concerned about my understanding of my health.		.67	−.02
30.	Am able to make health-related decisions because of the information provided by my health care provider.		.60	−.07
27.	Feel comfortable telling my health care provider about my health concerns.		.59	.14
4.	Asks me questions so that he/she understands my health problems.		.54	.02
9.	Knows about my life outside of my health condition (stressors and joys).*		.45	−.15
25.	Is personable.*		.44	−.04
15.	Is decisive about their recommendations for my health condition.*		.43	.16
1.	Uses words I can understand to explain my health condition.*		.41	.10
2.	Uses written information, models, and pictures to help me understand my health condition.*		.35	−.14

[a] Component I= *Quality Communication*
* Component II= *Negative Patient-Health Care Provider Communication*
Items were deleted from the final scale because wording and lower component loadings.
‡ Items were deleted from the final scale because of inter-item correlations greater than.80.
[δ]↓lumns represent component loadings. Items with component loadings greater than.30 for Components I and II are underlined.

Table 2. Intercorrelations Among the Patient-HCP Communication Scale and Subscales and the Perceived Involvement in Care Scale (PICS) and Subscales[a].

Patient-HCP Communication Scale Total/Subscale	PICS Total Score	PICS Subscale Scores: Doctor Facilitation	Patient Information	Patient Decision-Making
Total Score	.19*	.34***	.08	−.04
Quality Communication	.27**	.38***	.15	.02
Negative Patient-Health Care Provider Communication	−.09	*.05*	−.10	−.14

[a] Sample size varies from 149 to 150 due to missing data.
* $p \leq .05$; ** $p \leq .001$; *** $p \leq .0001$

Conclusion: A measure of the quality of patient-provider communication was developed based on the patient perspective, and the measure demonstrated evidence of reliability and validity in a sample of patients with RA. This measure could assist health care providers in improving RA patient care by increasing our understanding of the effects of the interaction between patient and provider.

"It's Totally Turned Around the Way I Think": The Patient Perspective of Cognitive Behavioural Therapy for Fatigue In Rheumatoid Arthritis. Emma Dures[1], Karen Kitchen[2], Celia Almeida[1], Nicholas Ambler[3], Alena Cliss[1], Alison Hammond[4], Bev Knops[3], Marianne Morris[1], Annette Swinkels[1] and Sarah Hewlett[1]. [1]University of the West of England, Bristol, United Kingdom, [2]University of Bristol, Bristol, United Kingdom, [3]Frenchay Hospital, Bristol, United Kingdom, [4]University of Salford, Salford, United Kingdom

Background/Purpose: RA fatigue is a common, overwhelming symptom caused by interacting clinical and psychosocial factors. Cognitive

behavioural therapy (CBT) addresses links between thoughts, feelings and behaviours and uses cognitive restructuring to help patients make behaviour changes. In a randomised controlled trial, group CBT for RA fatigue reduced fatigue impact and severity and improved perceived coping, mood and quality of life.[1] A nested qualitative study explored the nature of the processes and outcomes of the programme from the patient perspective.

Methods: After the end of each programme, a focus group with participants was run by researchers not involved in programme delivery (10 groups, 38 patients). Transcripts were analysed using a hybrid (inductive & deductive) thematic approach. Initial codes were generated, depicting patterns across the datasets, and combined to form themes. Analysis was by an independent researcher with a subset analysed by a research team member and a patient partner.

Results: 3 overarching themes were identified

"They made us work it out ourselves" (how the programme facilitated change). Patients spontaneously highlighted key elements of CBT as critical, including guided discovery and personal goal-setting ("we own our own plans and they've not been foisted on us"), peer support ("I think we all learnt something from each other") and steering by tutors ("they had to throw the ball into the court for us to pick it and what they have also had to do is stop us going off at a tangent"). Metaphors were memorable ("the picture [assertiveness] sort of stuck in my mind of this little submissive guy in the middle which was me and I thought a lot about that and I'm not like that at all now"). Fatigue itself was a barrier for some ("it was very tiring").

"Taking a different route" (the nature of changes). Cognitive changes included accepting RA fatigue ("you're never going to get back to optimum health because optimum health is actually a myth"). Emotional changes included being less volatile ("I was quite fiery but I've calmed down") and less fearful ("I'm not so scared of it [fatigue] now"). Greater self-efficacy and enhanced problem solving ("you analyse these things and then you can turn them around and make them work differently") led to perceived behaviour change and success ("I am managing my fatigue rather than the fatigue managing my life").

"My life has changed so much it's unbelievable" (benefits beyond fatigue). Patients re-engaged in previously abandoned activities, ("I got my life back again, you know it's nice, I enjoy myself"), with greater social participation ("I have turned outwards rather than inwards"), improved relationships ("how I am with my family, that has brought us quite a lot closer together") and being more active ("I actually feel more confident to try more things now").

Conclusion: Patients highlighted that CBT elements were key to making behaviour change, suggesting information alone would have been insufficient. Despite the focus on fatigue, benefits extended into wider life issues. Further research should examine whether this is due to the far-reaching impact of fatigue on daily life or the application of CB approaches to those issues.

Factors Affecting Role Strain In Patients with Newly Diagnosed Rheumatoid Arthritis. Mary-Beth Coty[1], John A. Myers[1], Elizabeth G. Salt[2] and Said K. Abusalem[1]. [1]University of Louisville, Louisville, KY, [2]University of Kentucky, Lexington, KY

Background/Purpose: The purpose of the study was to examine the affect multiple roles, role stress, and key psychosocial variables (self-efficacy, social support) had on role strain in patients with rheumatoid arthritis (RA).

Methods: Eighty men and women newly diagnosed with RA (< 4 years) completed questionnaires that assessed roles stress (role conflict, role overload, and lack of role balance), social support, generalized self-efficacy, and role strain (psychological distress, absence of positive affect or life satisfaction). Descriptive statistics, correlation coefficients, and linear regression models were used during data analysis. Four linear regression models were used to determine if role conflict, role overload, and role balance independently predicted overall role strain, psychological distress, positive affect, and satisfaction with life. Self-efficacy and social support were then tested to determine whether they modified these relationships.

Results: This predominantly Caucasian female sample (73.8%) was educated (70.1% had at least some college), employed (58.8%), married or partnered (77.5%), and in their relationship for an extended time (24.42 years). The mean age and duration of disease was 54.2 years and 24.2 months, respectively. Role balance influenced each outcome ($p<0.001$). Role conflict only affected role strain ($p<0.001$) and no effect was found from role overload. Self-efficacy modified relationships with role strain ($p=0.002$) and life-satisfaction ($p=0.028$). Social support did not modify any relationships.

Conclusion: The findings from this study suggest that the degree of role strain is influenced by perceptions of role stress and feelings of being self-efficacious and less to do with support received from others. Few models exist describing the relationships among multiple role involvement and psychosocial variables that influence psychological well-being in patients with RA. This study makes significant progress towards our understanding of this important health topic

Acknowledgement: The study was funded by a New Investigator Award from the Arthritis Foundation.

Integrating An Acceptance-Oriented Cognitive-Behavioural Therapy within Multidisciplinary Rehabilitation for Highly Distressed Patients with Arthritis: A Proof-of-Concept study. Johanna E. Vriezekolk[1], Rinie Geenen[2], Agnes M.M. Eijsbouts[1], Frank H.J. van den Hoogen[1], Hanneke Beenackers[1], Helma Slot[1], Wim G.J.M. van Lankveld[1] and Cornelia H.M. van den Ende[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Utrecht University, Utrecht, Netherlands

Background/Purpose: Targeting psychological distress is not common practice in rehabilitation. This study investigates the potential effectiveness and feasibility of an acceptance-oriented cognitive-behavioural therapy embedded in a multidisciplinary rehabilitation programme for rheumatic patients with high levels of psychological distress and impaired daily functioning despite adequate medical treatment.

Methods: Highly distressed adult patients with inflammatory rheumatic diseases or osteoarthritis referred for multidisciplinary treatment were included in this observational study. High levels of psychological distress was based on established cut-off scores for (sub)clinical levels of depressed mood and anxiety (IRGL). Primary outcome was psychological distress (yes/no). Other outcomes were quality of life (SF-36), acceptance (ICQ), and coping flexibility (COFLEX). Repeated measurements were taken before and after treatment, and at 1 year follow-up. Effect sizes (ES) were calculated. Individual changes were evaluated by the reliable change index (RCI) and clinically significant change (CSC) methodology. Feasibility of the programme was examined through evaluation of screening and admission patterns, attrition rates and patient satisfaction.

Results: Of 141 referrals, 87 (64%) were highly distressed. Thirty-five patients were eligible for treatment and 25 patients (mean age 51 (7.1), 76% female, 48% osteoarthritis) were enrolled in the study. Three out of every four patients who were highly distressed before treatment were not longer distressed after treatment and at 1 year follow-up. Reliable improvement to a well-functioning level for rheumatic patients was observed for almost half of the highly distressed patients. The SF-36 health domains improved to levels showing trivial to small deviations from the norm for rheumatic patients after treatment (mean ES = −0.15) and follow-up (mean ES = −0.17). A large increase of acceptance was found (ES >= 1.41). Attendance rate (> 95%) and patient satisfaction (ranging from 6.8–8.0) were high.

Conclusion: Preliminary evidence for the effectiveness of an acceptance-oriented cognitive-behavioural therapy embedded in a multidisciplinary rehabilitation programme for highly distressed patients with rheumatic diseases was demonstrated.

Family Stress in Childhood of Patients with Fibromyalgia. Robert S. Katz[1], Sharon M. Ferbert[2], Ben J. Small[3] and Susan Shott[1]. [1]Rush University Medical Center, Chicago, IL, [2]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL, [3]Rush University Medical School, Chicago, IL

Background/Purpose: We explored the issue of childhood stress as a possible precipitating factor predisposing to FMS.

Methods: As a part of an Internet survey administered by the volunteer community fibromyalgia organization 763 female respondents with self-described FMS answered questions about various forms of childhood stress. The respondent selected one of the choices from 1 = not to 4 = often. Only women's responses were analyzed to eliminate confounding by gender. *To validate the Internet Survey, an identical rheumatology office questionnaire was administered to 115 FMS patients and 63 control patients with other rheumatic diseases*. The chi-square test of association was used to compare percentages and the Mann-Whitney test was done to compare FMS respondents and controls with respect to age and frequency ratings. A 0.05 significance level was used and all tests were two-sided.

Results: In the Internet survey the mean respondent age was 49.8 ± 11.4 years. FMS respondents had higher frequency ratings than controls for emotional trauma (2.6 ± 1.2 vs. 1.9 ± 1.2, $p < 0.001$), loud arguments between parents (2.3 ± 1.2 vs. 2.0 ± 1.1, $p = 0.005$), verbal abuse (2.3 ± 1.2 vs. 1.8 ± 1.1, $p < 0.001$), feeling neglected (2.2 ± 1.2 vs. 1.8 ± 1.1, $p < 0.001$),excessive parental drinking (2.0 ± 1.3 vs. 1.6 ± 1.0, $p = 0.017$)), physical trauma (2.0 ± 1.1 vs. 1.5 ± 1.0, $p < 0.001$),witnessing domestic violence (1.8 ± 1.1 vs. 1.5 ± 1.0, $p = 0.005$) and sexual abuse (1.6 ± 1.0 vs. 1.4 ± 0.9, $p = 0.040$)). FMS respondents had lower frequency ratings than controls for maternal affection (3.0 ± 1.0 vs. 3.3 ± 1.0, $p = 0.002$) and paternal affection (2.7 ± 1.1 vs. 3.1 ± 1.1, $p < 0.001$).

In the rheumatology office questionnaire the mean age was 48.1± 12.3 years for FMS patients and 50.7 ± 13.6 for control patients ($p = 0.092$). 81.7% of the FMS patients and 61.9% of the control patients were women ($p = 0.004$). FMS patients had worse frequency ratings than control patients for emotional trauma (2.2± 1.3 vs.1.5± 0.9, $p<0.001$), loud arguments between parents (2.2± 1.2 vs. 1.8± 1.0, $p = 0.031$), verbal abuse (1.9± 1.2 vs. 1.5± 0.9, $p = 0.008$), feeling neglected (1.7± 1.1 vs. 1.3± 0.8, $p = 0.013$), physical trauma (1.6± 1.0 vs. 1.3± 0.7, $p = 0.009$), sexual abuse (1.4± 0.9 vs. 1.1± 0.3, $p = 0.002$), and maternal affection (3.3± 0.9 vs. 3.6± 0.8, $p = 0.027$). There was no statistically significant difference between FMS and control patients with respect to witnessing domestic violence (FMS 1.5± 0.9 vs. control 1.4 ±0.8, $p = 1$), how often the mother was in the home (FMS 4.0 ±0.2 vs. controls 4.0 ±0.3, $p = 0.52$), how often the father was in the home (FMS 3.7 ± 0.8 vs. controls 3.8 ± 0.7, $p = 0.43$), paternal affection (3.0 ± 1.0 vs. 3.1 ± 1.0, $p = 0.69$), or excessive parental drinking (1.9± 1.2 vs. 1.7± 1.1, $p = 0.22$).

Conclusion: FMS patients experienced frequent stress during childhood, including more emotional and physical trauma, loud arguments between parents, verbal abuse, more feelings of neglect, more sexual abuse, and less maternal and paternal affection, compared to controls. Stress during childhood may be a major factor predisposing to FMS.

2409

Childhood Social Ostracism in Fibromyalgia. Afton L. Hassett[1], Sharon M. Ferbert[2], Susan Shott[3] and Robert S. Katz[3]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL, [3]Rush University Medical Center, Chicago, IL

Background/Purpose: Multiple investigations related to early life stress in fibromyalgia (FM) have reported high rates of physical, sexual, and emotional abuse**.** Other chronic stressors, however, have rarely been evaluated. Social ostracism during grade school years could produce emotional and physiological consequences. Herein, we present preliminary data that childhood social ostracism could be another early life stressor worth assessing in patients with FM.

Methods: 763 female respondents with self-described FM and 115 denying FM diagnosis (controls) completed an online survey in which questions related to childhood social interactions were queried. Only the women's responses were analyzed to eliminate confounding by gender. Respondents were allowed to endorse more than one option. The online questionnaire was developed by the volunteer organization Advocates for Fibromyalgia Funding, Treatment, Education and Research (AFFTER). Percentages were compared using the chi-square test of association with a 0.05 significance level.

Results: Participants were predominantly married (64.5%) or divorced (14.3%), with a mean age of 49.8 ± 11.4 years. When asked about their childhood, FM respondents were significantly more likely than controls to report having been a loner (31.6% vs. 12.2%, $p < 0.001$), having had no friends (7.1% vs. 0%, $p = 0.003$), having had difficulty making friends (34.7% vs. 17.4%, $p < 0.001$) and keeping friends (16.4% vs. 3.5%, $p < 0.001$). In contrast, 49.8% of FM respondents indicated that most of the children they knew liked them, which is not significantly different from the 47.8% rate for controls. Similarly, the difference between the 30.3% of FM respondents and 35.7% of controls who reported having had many friends was not significant.

Conclusion: A subgroup of FM patients (approximately one third) likely experienced social ostracism during their childhood years. The lack of social support, loneliness and even bullying associated with having few or no friends can have long-term emotional and physiological consequences that could play a role in the manifestation of FM. Approximately one half recalled good social adjustment in childhood and could represent a more resilient subgroup of individuals with FM.

The Role of Pain and Depression in Self-Reported Fatigue/Energy in Systemic Lupus Erythematosus. Feridey N. Carr[1], Perry M. Nicassio[2], Dilrukshie Cooray[3], Ioana Moldovan[4], Emmanuel P. Katsaros[5], Karina D. Torralba[6], Shuntaro Shinada[7], Meenakshi Jolly[8], Mariko L. Ishimori[9], Alisa L. Wilson[9], Daniel J. Wallace[10] and Michael H. Weisman[11]. [1]California School of Professional Psychology at Alliant International University—Los Angeles, Alhambra, CA, [2]UCLA, Los Angeles, CA, [3]Harbor UCLA Medical Center, Torrance, CA, [4]Loma Linda Univ Medical Center, Loma Linda, CA, [5]Loma Linda Univ, Loma Linda, CA, [6]University of Southern California-Los Angeles County Medical Center, Los Angeles, CA, [7]USC Keck School of Medicine, Los Angeles, CA, [8]Rush University Medical Center, Chicago, IL, [9]Cedars Sinai Medical Ctr, Los Angeles, CA, [10]Cedars-Sinai/UCLA, Los Angeles, CA, [11]Cedars Sinai Med Ctr, Los Angeles, CA

Background/Purpose: Fatigue is reported by 50 to 80% of patients (pts) with systemic lupus erythematosus (SLE)[1]. Pain is also a common problem. Studies have shown that levels of depression are higher in pts with SLE [2]. This study examined the contribution of pain and psychological distress to fatigue.

Methods: 125 Caucasian and Hispanic adult pts with SLE were recruited from 4 medical centers in Los Angeles. Demographic data along with measures of disease activity and psychological functioning were collected. The Systemic Lupus Activity Questionnaire (SLAQ) evaluated patient-reported disease activity, while the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) assessed lupus activity. Psychological functioning was evaluated using the Patient Health Questionnaire (PHQ-9) and the Helplessness and Internality Subscales of the Rheumatology Attitudes Index. A subscale of the SF-36, Vitality, measured energy. A visual analogue scale for fatigue (FVAS) and visual analogue scale measuring pain (PVAS) were also utilized.

Results: Two hierarchical regressions were conducted. Ethnicity, age, annual income, and education were also included as variables in the model.

In the first analysis where fatigue was the dependent variable, ethnicity was entered in the first step, followed by age, income and education on step 2, PVAS, SLAQ and SLEDAI at step 3, and psychological factors at step 4. At step 1, ethnicity was significant, R^2 change =.15, $F(1,123) = 21.63$, $p<.001$, be = -.39, $p <.001$, with Caucasians reporting more fatigue. At step 2, no demographic variables were significant. At step 3, PVAS, SLEDAI and SLAQ were significant when entered as a block, R^2 change =.56, $F(3,117) = 77.54$, $p<.001$. However, the contribution of pain independently explained a large amount of variance, be =.73, $p<.001$. At step 4, depression was significant, R^2 change =.03, $F(3,114) = 5.26$, $p<.01$, be =.25, $p<.001$.

In the second analysis, energy was the dependent variable and the sequence was repeated. At step 1, ethnicity was again significant, R^2 change =.14, $F(1,123) = 20.08$, $p<.001$, be =.38, $p<.001$, with Hispanics reporting more energy. At step 2, demographic variables were not significant when entered as a block, R^2 change =.04, $F(3,120) = 2.01$, $p=.117$. However, age was independently significant, be = -.20, $p<.05$. At step 3, PVAS, SLEDAI and SLAQ were significant when entered as a block, R^2 change =.23, $F(3,117) = 15.08$, $p<.001$. Of those variables, only pain uniquely predicted energy, be = -.4, $p<.001$. At step 4, depression was significant, R^2 change =.09, $F(3,114) = 6.72$, $p<.001$, be = -.33, $p<.001$.

Conclusion: Both pain and depression are strong predictors of fatigue. This was confirmed when pain and depression were negatively correlated with energy. As pain often interacts with psychological factors, these results support a need for clinical assessment of pain and depression among pts with SLE.

Piloting a Patient Health Questionnaire Depression Screening Tool in a Hospital-Based Multi-Disciplinary Lupus Clinic. Su Jin Kim[1], Pretima Persad[2], Monica C. Richey[2], Mavis Seehaus[1], Roberta Horton[1], Kyriakos A. Kirou[2], Doruk Erkan[2] and John Barnhill[3]. [1]Dept. of Social Work Programs - Hospital for Special Surgery, New York, NY, [2]Mary Kirkland Center for Lupus Care—Hospital for Special Surgery, New York, NY, [3]Division of Psychiatry—Hospital for Special Surgery, New York, NY

Background/Purpose: Studies have demonstrated that patients with Systemic Lupus Erythematosus (SLE) exhibit high levels of depression, which can adversely affect adherence to medical treatment and health outcomes. Due to increasing reports of depression from our patients, we

piloted the Patient Health Questionnaire (PHQ-9), a nine item depression screening inventory. Our goal was to more accurately assess depression among our Lupus Clinic population to provide appropriate interventions for mental health services.

Methods: Adult patients seen in our Lupus Clinic completed a self-administered PHQ-9 Depression Screening Tool provided by a Nurse Practitioner. Once scored, all patients were referred to the Social Work Manager (SWM) for an assessment and appropriate referrals. Patients scoring in the *minimal (score 1–9) or moderate (10–19) depression* ranges received a psychosocial assessment (psycho-educational counseling related to depression); they were also provided with a mental health resource sheet with referrals. If open to receiving a referral, patients were given specific mental health agency referrals through 1–800-LIFENET, a mental health referral line. Patients who requested a mental health referral were followed closely by the SWM by telephone to see if an appointment was received. Patients who scored in the *severe (20–27) depression* range and/or exhibited any active suicidal ideations were initially assessed by the SWM and then evaluated that same day by our Psychiatric Liaison.

Results: Fifty patients (mean age: 37 +/− 14 [18–74]) were screened (88% Female; 52% Caucasian, 38% African American, 10% Asian; 48% Hispanic). Forty-eight (96%) were English speakers; 40 (80%) were low income, with Medicaid as their primary insurance. The table shows the distribution and mean age of patients among the different levels of depression based on their PHQ-9 Scores. Twenty patients (40%) were provided with specific mental health referrals as per their requests; 18/20 (90%) that requested referrals reported initiating mental health services and actively attending psychotherapy and/or psychiatry.

Level of Depression	# of Patients (%)	Mean Age +/− SD	Mean PHQ-9 Score +/− SD
None (0)	3 (6)	51.3 +/− 4.6	0
Minimal (1–9)	24 (48)	34.2 +/− 14.8	5.3 +/− 2.2
Moderate (10–19)	19 (38)	36.7 +/− 13.7	13.8 +/− 2.7
Severe (20–27)	4 (8)	48.5 +/− 17.6	22.8 +/− 1.5

Conclusion: This pilot depression screening initiative indicates the potential effectiveness of a self-report screening tool (PHQ-9) in a population of chronically-ill patients with lupus. We found that depression is common in the lupus clinic population and that these patients will not only agree to seek psychiatric treatment but will generally be able to access it. Our results outline the increased need to regularly screen lupus patients for depression as it can impact on their overall disease and quality of life. The PHQ-9 screening tool as well as our triage system may serve as a useful model that can be incorporated into routine lupus patient assessments.

The Challenges of Being a Father with Systemic Sclerosis. Janet L. Poole[1], Donna Haygood[2] and Cindy F. Mendelson[1]. [1]University of New Mexico, Albuquerque, NM, [2]Bernalillo Public Schools, Bernalillo, NM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disease that affects multiple systems and results in thickening of the skin, vascular insufficiency and fibrotic changes in the muscles, joints and internal organs. SSc is a rare disease primarily affecting women. However, men also have SSc. The mean onset of SSc is between 30–50 years of age which are peak years when men are becoming or being fathers. The role of a father can be impacted in many ways by this chronic illness and its unpredictability. Despite the severity of SSc, little is known about the impact this illness has on parenting especially being a father. Therefore, the purpose of this qualitative study is to describe the impact of scleroderma on the role of a father.

Methods: Ten fathers with scleroderma that had children 18 years of age and younger living with them at least 50% of the time, participated in this study. The mean age of the fathers was 44.80 years; mean disease duration was 3.76 years. Ninety percent were married, 60% worked full time, and the mean number of children was two. Fathers completed demographic questionnaires and were interviewed over the telephone. The interviews consisted of questions regarding the aspects of SSc that interfered with their ability to parent, situations in which SSc interfered with their ability to parent, what would make parenting easier, advice for other fathers, and support that makes being a father easier. The interviews were tape-recorded and transcribed verbatim. Content analysis was used to determine the primary codes and a summary statement generated for each code. Working from the summary statements the data was aggregated into two key themes with a single overarching theme.

Results: The overarching theme, *I'm still Dad* described the feelings of the fathers that scleroderma does not negate the fact or importance of parenting. Daily tasks and daily routines change but the fathering role stays constant. The two key themes that emerged from the findings related to the *emotional impact of the illness* and the *day to day realities of the illness*. The unpredictability and rareness of the illness lead to ongoing feeling of isolation and the fear of the mortality of the illness. The daily activities fathers participated with their children changed related to fatigue, vascular and musculoskeletal physical changes. Even though the men had physical challenges, support systems in place helped them to complete day to day routines.

Conclusion: Being a father with scleroderma has positive and negative influences. The negative effects are the inability of the fathers to participate in all of the physically activities the children enjoyed such as outdoor sports and throwing a ball. Being able to take time to spend quality time with the child was a positive influence of the illness.

Development of a Care Pathway for Inflammatory Arthritis. Shona P. Lee[1] and David Kane[2]. [1]Adelaide and Meath Hospital Inc National Children's Hospital, Dublin 24, Ireland, [2]Adelaide, Meath hospital Dublin (incorporating the National Children's hospital), Dublin 24, Ireland

Background/Purpose: To develop a care pathway for patients with newly diagnosed inflammatory (IA) arthritis at a Dublin teaching hospital. Routine waiting lists and standard outpatient appointments do not serve the challenge of effective management of IA as per international guidelines.

Methods: A change management approach was adopted for implementation of this project. Following consultation with all of the multidisciplinary team, outpatient review appointments by medical doctors, clinical nurse specialist, physiotherapist and occupational therapist were arranged on a phased basis for the first year of treatment, for patients with a diagnosis of IA. Evidence based care informed the development of this pathway. Outpatient visits occurred monthly for the first 3 months and three monthly thereafter for first year. A health professional clinic was part of this pathway whereby all newly diagnosed patients were seen and assessed by allied health professionals at one visit. Outcome measures were agreed. A process for patient self referral back for triage/ urgent review via a telephone helpline was facilitated. Data was collected on an excel spreadsheet.

Results: The care pathway facilitates timely and appropriate assessment and treatment from all of the multidisciplinary team. Appointments are facilitated at an urgent review clinic when the patient needs it, as opposed to when the old system dictated.

Conclusion: Development of the care pathway facilitates holistic care where education, appropriate treatment, necessary medication changes, psychological support and measurement of outcomes can be made in line with international guidelines regarding optimal treatment of pts with newly diagnosed inflammatory arthritis.

Online Access for Patients to Their Electronic Medical Record: Advantages, Drawbacks and Preconditions According to Care Providers. Rosalie van der Vaart[1], Constance H.C. Drossaert[1], Erik Taal[1] and Mart AF van de Laar[2]. [1]University of Twente, Enschede, Netherlands, [2]Medisch Spectrum Twente & Twente University, Enschede, Netherlands

Background/Purpose: Technology currently makes it possible to provide patients access to their own electronic medical record (EMR) from the hospital. The purpose of the study was to see if professional practice is ready for this possibility, by mapping the vision of rheumatology care providers on (dis)advantages and preconditions of this service.

Methods: 18 semi-structured in-depth interviews with 9 nurses (and nurse practitioners) and 13 rheumatologists were conducted. The main aim of the dialogues was to get insight into the motives that care providers have for the acceptation of the possibility to give patients online access to their medical record. Questions were related to the advantages and disadvantages they perceived, the preconditions that they would set and the content that should (or should not) be available to their patients, according to them.

Results: Overall care providers show a very mixed opinion on this topic. Most did see advantages of giving patients access to their medical record. These include: (1) an increase in patients' knowledge, autonomy and

involvement in treatment, (2) improvements in communication, (3) opportunities for the patient to look back on medical data and to show it to relatives and their GP, (4) an increase in trust and service offered to the patient and (5) increased patient safety through check-ups of the record by the patients. Yet, most care providers also reported a number of disadvantages, including: (1) a risk of causing fear, turmoil or patients drawing wrong conclusions because of problems with interpretation of (lab)data and difficulties with jargon, (2) a higher workload, (3) an overflow of questions by patients about the EMR during consult, which causes time constraints or delay in consults, and (4) it would be unpleasant and undesirable if patients read their notes. Important preconditions of this service are therefore: good security of data, careful considerations on if, when and how data will be presented to patients and presumably a filter on parts of the EMR.

Conclusion: According to care providers, giving patients access to their medical record might be a valuable next step into patient empowerment and patient safety, provided that there is optimal security and careful consideration of the content and presentation of the data.

2415

Anti-Tumor Necrosis Factor Dose Escalation Among Biologic Naïve Rheumatoid Arthritis Patients in Commercial Managed Care Plans in the Two Years Following Therapy Initiation. Machaon Bonafede[1], Kathy M. Fox[2], Kathleen L. Wilson[1] and Shravanthi R. Gandra[3]. [1]Thomson Reuters Healthcare, Cambridge, MA, [2]Strategic Healthcare Solutions, LLC, Monkton, MD, [3]Amgen Inc, Thousand Oaks, CA

Background/Purpose: This study estimates dose escalation patterns over the first and second years of therapy among biologic naïve rheumatoid arthritis (RA) patients initiating tumor necrosis factor inhibitor (anti-TNF) therapy with etanercept (ETN), adalimumab (ADA), or infliximab (INF) using real-world managed care claims data.

Methods: Commercially insured non-elderly adult (age 18–65) RA patients initiating anti-TNF therapy between July 1, 2005 and April 30, 2009 were identified using the MarketScan Commercial Claims and Encounters Database. The new use of ETN, ADA, or INF was the index event. A six month pre-index period was used to describe baseline patient characteristics and to identify new anti-TNF use. Patients were excluded if they had a condition for which an anti-TNF therapy was indicated (other than RA) or contraindicated during the pre-index period, including but not limited to psoriasis, psoriatic arthritis, juvenile idiopathic arthritis, ankylosing spondylitis, HIV, multiple sclerosis, lupus, or cancer. Patients were included if they remained on therapy for 12 months, without switching or having a therapy gap of greater than 60 days. Dose escalation was evaluated in the subset of patients persistent on index therapy for 12 and 24 months. Doses for ETN, ADA, or INF were calculated based on an average weekly dose (AWD). Dose escalation was defined as having at least one average weekly dose (AWD) that was 15%, 30%, or 50% higher than the initial AWD. For INF, the initial dose was defined as the AWD for the fourth infusion. Differences were evaluated using chi-square tests for proportions.

Results: A total of 2,909 patients met the inclusion criteria (mean age 50 years [SD=10] and 74% female). The patients were geographically dispersed with more patients in the South (44%) than in the North Central (28%), West (17%) or East (11%) regions of the US. The majority of patients (79%) lived in an urban area. Nearly half of the patients (47%) initiated anti-TNF therapy with ETN, 33% initiated with ADA, and 20% initiated with INF. During the pre-index period, the three treatment cohorts had similar Deyo Charlson comorbidity index scores (1.07–1.12) and prevalence of methotrexate use (71%–75%), glucocorticosteroid (57%–61%) use or analgesic use (34%–37%). Patients took an average of 8.6 unique medications during the 6 months prior to initiating anti-TNF therapy. Initial AWD were 48mg for ETN, 21mg for ADA, and 52mg for INF. Dose escalation rates for ETN, ADA, and INF were consistent between treatments across years 1 and 2 (see table).

Table. Proportion and magnitude of dose escalation

	Dose escalation rates over a 12 month period			Dose escalation rates over a 24 month period		
Dose escalation Method	ETN (n = 1322)	ADA (n = 1010)	INF (n = 577)	ETN (n = 514)	ADA (n = 401)	INF (n = 265)
115% higher than initial average weekly dose	4%	13%*	44%*	5%	18%*	59%*
130% higher than initial average weekly dose	3%	12%*	32%*	4%	17%*	43%*
150% higher than initial average weekly dose	1%	11%*	18%*	1%	15%*	28%*

$p<0.001$ compared to ETN

Conclusion: RA patients newly initiating ETN had significantly lower rates of dose escalation compared to patients initiating ADA or INF. This finding was consistent across dose escalation measures in both the first and second year following therapy initiation.

2416

Comparing Costs of Tumor Necrosis Factor Blockers Per Treated Patient for Psoriatic Arthritis Using Real-World Data in US Managed Care. Vernon F. Schabert[1], Shravanthi R. Gandra[2], Crystal Watson[2], Seth Goodman[1], Kathy M. Fox[3], Jason Yeaw[1], Sandra Milev[4] and David J. Harrison[2]. [1]IMS Consulting Group, Alexandria, VA, [2]Amgen Inc, Thousand Oaks, CA, [3]Strategic Healthcare Solutions, LLC, Monkton, MD, [4]IMS Brogan, Ottawa, ON

Background/Purpose: Tumor necrosis factor (TNF)-blockers etanercept (ETN), adalimumab (ADA) and infliximab (INF) are FDA approved for the treatment of psoriatic arthritis (PsA). However, they differ in their method of administration, dosing ranges and dosing frequency. These differences can lead to cost fluctuations that can be captured as cost per treated patient using real world data. This study describes annual costs of ETN, ADA and INF per treated PsA patient using real world data.

Methods: IMS LifeLink™ Health Plan Claims database was used to identify adult patients (≥18y) with ≥1 claim for ETN, ADA or INF between 11/1/2005–3/31/2009 (first claim in study period is index claim); including patients new to TNF blocker treatment (i.e., with no claims for a TNF blocker during the 180 days prior to index claim) and those continuing TNF blocker treatment. Patients had to have ≥360 days continuous plan enrollment following index claim (follow-up) and ≥180 days prior to index claim.

In the 180 days prior to index claim, patients had to have a PsA diagnosis, but were excluded if they had a diagnosis of rheumatoid arthritis, psoriasis, ankylosing spondylitis, Crohn's disease, ulcerative colitis or juvenile idiopathic arthritis. Patients were followed until end of study period (3/31/2010) or plan disenrollment.

Mean monthly dose was computed for patients on therapy; wholesale acquisition costs were applied to mean monthly dose and Medicare Physician Fee Schedule was applied to related drug administrations. Costs from restarting index TNF blocker therapy after discontinuation and costs from switching to a different TNF blocker were attributed to patients' index TNF-blocker therapy.

Results: Overall, 3,738 patients with PsA (2,295 ETN, 864 ADA and 579 INF), were identified. Median age ranged from 46.6–48.2 years, with 42–50% female. The 1-year mean cost per treated patient for all patients was lowest for ETN-$14,163, followed by ADA-$18,418 and INF-$24,276. For biologic-naïve patients, mean cost per treated patient was $13,447 ETN, $17,614 ADA and $23,329 INF. For patients continuing biologic therapy, cost per treated patient was $14,476 ETA, $19,098 ADA and $24,806 for INF.

Conclusion: When comparing cost per treated patient across commonly used TNF blockers with different modes of administration and dosing frequencies, ETN has the lowest cost for PsA patients using actual utilization data from US commercially-insured population.

Measuring Fear of Progression in Patients with Systemic Sclerosis. Linda Kwakkenbos[1], Frank H.J. van den Hoogen[1], José Custers[2], Judith Prins[3], Madelon C. Vonk[4], Wim G.J.M. van Lankveld[1], Eni S. Becker[2] and Cornelia H.M. van den Ende[1]. [1]Department of Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [2]Behavioural Science Institute, Clinical Psychology, Radboud University, Nijmegen, Netherlands, [3]Department of Medical Psychology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [4]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Although concerns about the future are often expressed by patients with systemic sclerosis (SSc)(1), as yet no valid quantitative measure is available to assess the extent to which patients with SSc are troubled by those concerns. The purpose of the present study was to validate the Dutch translation of the Fear of Progression-Questionnaire Short

Form (FoP-Q-SF)(2) for patients with SSc. The FoP-Q-SF was originally developed for the assessment of FoP in breast cancer.

Methods: Measurement properties of the FoP-Q-SF were assessed using a cross-sectional design in which 215 patients with SSc were included. Patients completed the FoP-Q-SF as well as questionnaires on physical and psychological functioning.

Psychometric properties of the FoP-Q-SF were assessed using the COSMIN checklist (3).

Results: In total, 69 men and 146 women completed the questionnaires. Most patients (74.1%) were married or living as married. One-third of the patients were employed at time of the study, and 42 % received higher education. Mean time since onset of non-Raynaud symptoms was 9.2 years (SD=7.9). Mean FoP-Q-SF score in patients with SSc was 30.05 (SD= 8.97). There were no indications of floor- or ceiling effects. Confirmative factor analysis supported the single-factor structure of the questionnaire (χ^2 *(52)=96.84, p<.001, RMSEA =.064, CMIN/DF=1.86*). Cronbach's alpha was.86 for the questionnaire. Most of our a-priori determined hypotheses (13 out of 14, 92.8%, Table 1) were confirmed in the data, supporting the construct validity of the questionnaire.

Table 1. Hypotheses and correlations of variables with Fear of Progression Questionnaire-Short Form

HYPOTHESES	CORRELATION	P	CONFIRMED
Moderate to large positive correlation with:			
Anxiety (IRGL[a])	.59	<.001	Yes
Depressive symptoms (CES-D[b])	.58	<.001	Yes
Active problem-oriented coping (CISS[c])	−.01	.862	No
Moderate to large negative correlation with:			
Social functioning (subscale SF-36)	−.39	<.001	Yes
Role-emotional (subscale SF-36)	−.47	<.001	Yes
Mental health (subscale SF-36)	−.58	<.001	Yes
Small to moderate negative correlation with:			
Physical functioning (subscale SF-36)	−.25	<.001	Yes
Role-physical (subscale SF-36)	−.37	<.001	Yes
Bodily pain (subscale SF-36)	−.34	<.001	Yes
General health (subscale SF-36)	−.42	<.001	Yes
Vitality (subscale SF-36)	−.45	<.001	Yes
Age (years)	−.15	.031	Yes
Control variables (No or small correlation):			
Travel distance to hospital (kilometres)	.09	.185	Yes
Body height (centimetres)	−.15	.032	Yes

a.Impact of Rheumatic Diseases on General Health and Lifestyle
b. *Center for Epidemiologic Studies- Depression*
c.*Coping Inventory Stressful Situations*
a.*Medical Outcomes Trust Short Form–36*

Conclusion: Results of the present study demonstrate that the FoP-Q-SF is a useful and valid instrument for the measurement of fear of disease progression in patients with SSc. This is important since fear of progression is one of the most important stressors in these patients.

2418

Construct Validity of Three PROMIS Instruments in An Arthritis Sample. Kirsten A. Nyrop, Bryce B. Reeve, Robert F. DeVellis, Darren Dewalt, Rebecca J. Cleveland and Leigh F. Callahan. University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: This study assesses the construct validity of PROMIS® (Patient-Reported Outcomes Measurement Information System®) measures of Physical Function, Pain and Fatigue, using data from an effectiveness study of the *Walk With Ease (WWE)* program for adults with self-reported arthritis/joint pain. Our approach derives from the Multitrait-Multimethod Matrix (MTMM) developed by Campbell and Fiske (1959) -- the PROMIS measures must demonstrate both convergent (concepts that should be related theoretically are related in reality) and discriminant validity (concepts that should *not* be related theoretically are *not* related in reality).

Methods: At baseline, 415 *WWE* participants completed PROMIS measures via Computerized Adaptive Testing (CAT) -- Physical Function, Depression, Fatigue, Pain Impact, Sleep Disturbance, and Satisfaction with Social Role Participation. Participants also completed self-report measures routinely used to assess arthritis outcomes: Health Assessment Questionnaire (HAQ) and visual analogue scales (VAS) for Arthritis Symptoms (Pain, Fatigue and Stiffness). Physical performance was assessed by measures traditionally used in arthritis trials: chair stands, 360° turns, leg stands, walking speeds, and 2-minute step test. Spearman correlations were analyzed to identify associations among variables.

Results: As hypothesized, PROMIS Physical Function and HAQ were correlated(r=0.67, p<.001), and both instruments correlated moderately well (r≥ 0.30) with most physical performance measures. All other PROMIS measures were not as highly correlated with the physical performance measures, with the exception of PROMIS Pain Impact which also correlated with HAQ (r=0.61, p<.001) (Table 1). As hypothesized, the highest correlations for PROMIS Pain and PROMIS Fatigue were with their respective VAS measures (r =0.59 and 0.65). Other PROMIS measures were not as highly correlated with the VAS measures (Table 2).

Table 1. Spearman Correlations between PROMIS Measures, HAQ and Physical Performance Measures

	HAQ	Chair Std 1	Chair Std 3	Turn Right	Turn Left	Leg Std R	Leg Std L	Normal Walk	Fast Walk	2-min Step
PROMIS Pain	0.61	0.34	0.35	0.30	0.32	0.16	0.15	0.26	0.36	0.28
PROMIS Fatigue	0.48	0.24	0.26	0.15	0.15	0.09	0.08	0.18	0.19	0.17
PROMIS Depress.	0.35	0.15	0.12	0.10	0.10	0.00	0.01	0.14	0.13	0.10
PROMIS Sleep D.	0.21	0.17	0.10	0.02	0.01	0.01	0.05	0.01	0.01	0.06
PROMIS Social R.	0.43	0.25	0.24	0.13	0.12	0.11	0.10	0.18	0.18	0.23
PROMIS PhyFunc	**0.67**	**0.38**	**0.41**	**0.40**	**0.40**	**0.27**	**0.25**	**0.44**	**0.50**	**0.39**
HAQ	1.00	0.43	0.44	0.44	0.45	0.25	0.28	0.51	0.54	0.35

Table 2. Correlations between PROMIS Measures and Self-Reported Arthritis Symptoms (Visual Analogue Scales)

	Pain	Fatigue	Stiffness
PROMIS Pain	**0.59**	0.43	0.53
PROMIS Fatigue	0.37	**0.65**	0.44
PROMIS Depression	0.29	0.43	0.29
PROMIS Sleep Dist.	0.22	0.36	0.28
PROMIS Social Roles	0.30	0.39	0.31
PROMIS Phy. Func.	**0.37**	**0.37**	**0.35**

Conclusion: PROMIS Physical Function's construct validity is suggested by its convergence with HAQ and by comparable correlations with physical performance measures. PROMIS Pain and PROMIS Fatigue construct validity are suggested by correlations with VAS measures for pain and fatigue, respectively—higher than all other PROMIS measures. This evidence supports the use of PROMIS measures for Physical Function, Pain and Fatigue as measures of disability and symptoms in an arthritis sample.

2419

Validity of SenseWear Armband to Estimate Energy Expenditure During Activities of Daily Living In Rheumatoid Arthritis. Marie Tierney[1], Alexander D. Fraser[2] and Norelee M. Kennedy[1]. [1]University of Limerick, Limerick, Ireland, [2]Mid Western Regional Hospital, Limerick, Ireland

Background/Purpose: In Rheumatoid Arthritis (RA), it is thought that the level of physical activity may be reduced due to many factors linked with the disease course. However, there is a lack of quality research in the area to confirm this. One of the methodological flaws in the research conducted to date centres on the use of physical activity outcome measures which are not validated in the RA population. The aim of this study is to assess the accuracy of the SenseWear Armband (SWA) to estimate energy expenditure in people with RA during activities of daily living (ADLs).

Methods: 14 (8 male, 6 female) subjects participated in this study. All had a confirmed diagnosis of RA in conjunction with American College of Rheumatology (ACR) criteria, were on a stable steroidal and disease modifying anti-rheumatic drug regime in previous 3 months, were ambulatory independently or with assistance of one unilateral aid, were over 18 years of age and were not

pregnant. Patients were recruited from the rheumatology outpatients' clinic of the Mid-Western Regional Hospitals, Limerick, Ireland. Each subject wore a SWA on the right upper arm and was fitted with the Oxycon mobile indirect calormetry system with facemask which acted as the criterion measure. Subjects performed a 75 minute standardised routine consisting of lifestyle and housework activities of varying intensities. Statistical analyses was performed using PASW (formally SPSS) version 18.0 for Microsoft Windows. Intraclass correlation coefficient (ICC) 2,1 and Bland and Altman analyses were used to assess the level of agreement between the two measures.

Results: 14 (8 male, 6 female) subjects participated in this study. Mean age±standard deviation and BMI±standard deviation was 64.43±6.80 and 26.9±3.4 respectively. The mean length of disease duration±standard deviation was 12.4±13.2 years. SWA is highly accurate at predicting energy expenditure in subjects with RA (ICC=0.85). Bland and Altman analysis also verifies this finding with SWA having a relatively small mean difference (182.48kJ), a small standard error of the mean difference (41.95 kJ) and 95% confidence intervals which are tightly centred around the mean difference (−273.11→ −91.84) when compared to indirect calorimetry. When the activities were grouped based on their intensity, SWA still accurately estimated the energy expenditure levels at all intensities. Activities of 3–5 METS showed an ICC of 0.76, activities of 2–3 METS showed an ICC of 0.81, while activities of 1–2 METS showed an ICC of 0.73.

Conclusion: This is the first occasion this tool has been validated for use in the Rheumatoid Arthritis population. The accurate findings of this study indicate that SWA can accurately be used as a measure of energy expenditure in individuals with RA during activities of daily living.

2420

mtDNA Haplogroups and Serum Levels of SOD2, Catalase and Gelsolin In the Osteoarthritis Disease. Ignacio Rego-Pérez[1], Mercedes Fernández-Moreno[1], Sonia Pértega[2], Carlos Fernández-López[1], Natividad Oreiro[1] and Francisco J. Blanco[1]. [1]INIBIC-Complejo Hospitalario Universitario A Coruña (CHUAC), La Coruña, Spain, [2]Epidemiology Unit. INIBIC-Complejo Hosp. Univ. A Coruña, La Coruña, Spain

Background/Purpose: To measure the serum levels of Manganese Superoxide dismutase (SOD2), Catalase and Gelsolin in order to evaluate their possible application as hypothetical biomarkers in OA together with the mtDNA haplogroups.

Methods: Serum concentrations of SOD2, Catalase and Gelsolin were measured by enzyme-linked immunosorbent assays (ELISAs) in 150 samples from Hospital Universitario A Coruña (77 healthy controls and 73 OA patients). Knee and hip radiographs from the subjects were classified according to Kellgren and Lawrence (K/L) scoring from Grade 0 to Grade IV. Appropriated statistical approaches were carried out in order to assess the incidence of diagnosis and haplogroups, as well as other clinical variables, such as radiologic grade, gender, age and body mass index (BMI), on serum levels of the described enzymes.

Results: Serum levels of SOD2 were significantly increased in OA patients (36378.36 ± 11161.54) compared with healthy controls (20830.11 ± 30811.08), regardless of gender, age and BMI ($p<0.001$), and the higher the radologic grade, the higher the serum levels of SOD2 ($p<0.001$). Serum concentration of Catalase showed a non significant trend towards higher levels in OA patients (21.88 ± 40.94) compared to healthy controls (14.50 ± 27.68), as well as increased levels in carriers of mtDNA haplogroup J ($p=0.027$). Finally, serum levels of gelsolin, an actin-binding protein related to oxidative stress and inflammation, appeared significantly decreased in OA patients (500999 ± 43888.70) compared to healthy controls (511752.99 ± 49709.35) ($p=0.008$), and significantly increased in carriers of the haplogroup U (520178.68 ± 38409.87) ($p=0.015$).

Conclusion: The results obtained support that local inflammation and, specially, oxidative stress are key processes in the OA disease, and SOD2 appears as a candidate biomarker for prognosis of OA. The influence of the mtDNA haplogroups on serum levels of Catalase and Gelsolin could arise from the described different performance of the OXPHOS system among the mtDNA haplogroups.

2421

The Hospital Anxiety and Depression Scale (HADS) Positive Affect Subscale: A Preliminary Evaluation of Its Utility for the Assessment of Resilience in Fibromyalgia. Afton L. Hassett[1], Chad M. Brummett[2], Jenna Goesling[2], Kevin Rakovitis[2], Daniel J. Clauw[3] and David A. Williams[4]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan Health System, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]Univ of MI Hlth System-Lobby M, Ann Arbor, MI

Background/Purpose: Resilience factors like positive affect have been found to be even better predictors of outcome than negative factors like depression and anxiety in a number of medical populations. However, increasing interest in measuring positive affect in patients with chronic pain is often tempered by concerns about adding patient burden during assessment. Several widely used instruments commonly chosen to measure constructs like depression and anxiety also have positive affect scales, but few of these have been validated for pain states. The objective of this study was to assess the performance of a positive affect subscale contained within the Hospital Anxiety and Depression Scale (HADS) in a sample of patients with chronic pain.

Methods: 170 patients meeting ACR survey criteria for fibromyalgia (FM) completed the HADS, Positive and Negative Affect Scale (PANAS), Brief Pain Inventory (BPI), and the PROMIS Physical Function Short Form 1 (PROMIS SF1). The HADS is a 14-item self-report instrument with two 7-item subscales (anxiety and depression). The positive subscale consists of six items that assess positive emotions (e.g., I feel cheerful). The HADS positive affect subscale was analyzed for internal consistency with Cronbach's alpha. To evaluate convergent and discriminant validity, correlations between the HADS positive affect subscale score were calculated with similar and dissimilar constructs.

Results: Mean age for the participants was 46.3 (SD13.4) years. Most were female (63.5%). The HADS positive affect subscale had good internal consistency (0.79). Pearson correlations supported the validity of the HADS positive affect subscale as its score was significantly related to the PANAS positive affect scale ($r=0.62$, $p<.001$) and inversely related to the PANAS negative affect scale ($r=-0.52$, $p<.001$). Further, the relationships between the HADS positive affect subscale score and clinically relevant variables were significant including BPI pain severity, BPI pain interference and PROMIS SF1 (Table 1). Compared to the PANAS positive subscale and the HADS depression and anxiety subscales, the HADS positive affect subscale demonstrated similar or stronger relationships with clinically relevant measures (also in Table 1).

Table 1.

	HADS Positive	PANAS Positive	PANAS Negative	HADS Depression	HADS Anxiety
BPI Pain Intensity	−.329*	−.237*	.229*	.319*	.230*
BPI Pain Interference	−.460*	−.366*	.307*	.508*	.203*
PROMIS Physical Function	.476*	.358*	−.332*	−.551*	−.307*

*$p < 0.0001$

Conclusion: The HADS positive affect subscale is a promising measure of resilience in chronic pain patients like those with FM. In many instances, the HADS positive affect subscale had stronger associations with the clinical variables of interest than the other commonly used measures. In the case where the HADS is already in use, there will be no additional patient burden to calculate this measure.

A Bayesian Mixed Treatment Comparison Demonstrates Differences Between Anti-Tumour Necrosis Factor Agents in Rheumatoid Arthritis. Susanne Schmitz[1], Roisin C. Adams[2], Michael Barry[2], Cathal Walsh[3] and Oliver M. FitzGerald[4]. [1]Department of Statistics,Trinity College Dublin, Dublin, Ireland, [2]National Centre for Pharmacoeconomics, Dublin, Ireland, [3]Trinity College Dublin and National Centre for Pharmacoeconomics, Dublin, Ireland, [4]St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: A number of tumour necrosis factor alpha antagonists (anti-TNF-α) are available to treat rheumatoid arthritis. All of these have demonstrated considerable efficacy in placebo controlled trials, but few head-to-head comparisons exist to date. This work's objective is to estimate the relative efficacy among licensed anti-TNFs in patients who have had an inadequate response to methotrexate. Different outcome measures are used to highlight the advantages of continuous measures in such methodologies.

Methods: A systematic review indentified randomized controlled trials comparing the efficacy of licensed anti-TNF-a agents to placebo at 24 weeks in patients who have had an inadequate response to methotrexate. Relative efficacy was estimated using Bayesian mixed treatment comparison (MTC) models. Three different outcome measures were used; Risk ratios of achieving an ACR20 and ACR50 response and the percentage improvement in HAQ score. 80% credible intervals are presented for risk ratios and HAQ improvement.

Results: 16 published trials were included in the analysis. All anti-TNFs show considerably improved efficacy over placebo. The MTC results also provide evidence of some differences in efficacy of the

anti-TNF-α antagonists. Etanercept appears superior to infliximab and golimumab; certolizumab to infliximab and adalimumab. The ACR results find evidence of certolizumab being more effective than golimumab. For HAQ improvement all anti-TNFs appear superior to infliximab and etanercept shows improved efficacy to adalimumab.

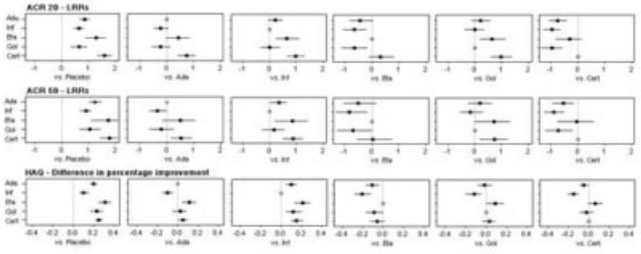

Figure 1. Graph for pair wise log risk ratios (LRRs) for ACR 20 and ACR 50 outcome and estimated HAQ improvement of anti-TNF against placebo and one another. Results are presented at 80% credible intervals.

Conclusion: There are differences in efficacy among the anti-TNF-α antagonists. In a MTC a continuous outcome measure has more strength to detect such differences than a binomial outcome measure, due to its enhanced sensitivity to change.

2423

Development of Quality Indicators for Physical Therapy in Hip and Knee Osteoarthritis. Wilfred FH Peter[1], Ph van der Wees[2], J. Verhoef[3], Z. de Jong[1], L. Vos[1], Wkha Hilberdink[4] and Tpm VlietVlieland[1]. [1]Leids University Medical Center, Leiden, Netherlands, [2]The Royal Dutch Society of Physical Therapy (KNGF) Amsersfoort, CAPHRI Maastricht University, IQ Healthcare, Nijmegen, Netherlands, [3]Hogeschool Leiden, Leiden, Netherlands, [4]Paramedical Center for Rheumatology and Rehabilitation, Groningen, Netherlands

Background/Purpose: In 2010 the revised version of the national Dutch physical therapy practice guideline for hip and knee osteoarthritis (OA) (www.kngfrichtlijnen.nl/654/KNGF_Guidelines_in_English.htm) was published. So far, little is known about its actual use in daily practice. The aim of this study was to develop quality indicators for physical therapy in hip and knee OA according to international criteria.

Methods: The use of quality indicators has been suggested as an appropriate method to estimate adherence to international guidelines (1). Guideline recommendations were rated for their relevance by an expert panel, transformed into indicators and incorporated in a questionnaire called Quality Indicators for Physical therapy in Hip and Knee OA (QIP-HKOA). After pilot testing among 15 PTs an adjusted version was administered to two groups of selected general PTs (n=134) en expert PTs (n=51) to test its discriminative power. In addition, the test-retest reliability of the questionnaire was evaluated in 118 PTs who subscribed to an educational course on the revised guideline who were asked to complete the questionnaire two times with a period of 7 days in between. Finally the internal consistency of the QIP-HKOA was calculated.

Results: The expert panel selected 19 recommendations, which were transformed into a questionnaire, which was slightly adjusted after pilot-testing. Thirteen items concerning treatment (12 items) and the diagnostic process (1 item) showed ceiling effects and/or did not discriminate between general and experts physical therapists and were excluded from the QIP-HKOA. For one of these items, concerning treatment (patient education), the proportion of physical therapists frequently following that item was $< 75\%$ in both groups. Therefore this item was included again. The final QIP-HKOA (containing 7 items) score (range 7–35)was significantly lower in 134 general physical therapists (23.06 SD 4.00) than in 51 expert physical therapists (27.04 SD 4.00) ($p< 0.000$). There was a high correlation (ICC 0.87) between the final QIP-HKOA scores of two time points of 46 physical therapists who completed the questionnaire twice. Cronbachs' alpha was 0.67.

Conclusion: The QIP-HKOA is feasible, valid, has a good test-retest reliability and discriminative power. Internal consistency was questionable. Its value in the measurement of the effectiveness of strategies to implement the guideline needs to be further determined.

Funding: This project is funded by the Royal Dutch Society of Physical Therapy and the Dutch Arthritis Association.

Patient Preference of Disability in Rheumatoid Arthritis. Li Alemo Munters[1], Nina Brodin[2], Elin Löfberg[2], Sara Stråt[2] and Helene Alexanderson[3]. [1]Rheumatology Unit,, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [2]Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Rheumatoid Arthritis (RA) affects the individual on many levels: impairment, activity limitation/ participation restriction and health related quality of life. Patient reported outcomes (PRO:s) have been recommended to be used in RA. The predefined PRO: s have not been as responsive or sensitive to pharmacological or exercise interventions as a patient preference outcome such as the McMaster Toronto Arthritis patient preference disability questionnaire (MACTAR). The aim was to investigate disabilities most important to improve in RA patients in Sweden by using the MACTAR and to compare the self selected disabilities to items in predefined measures for RA. Further aims were to categorize the identified disabilities using the International Classification of Functioning (ICF), to correlate the MACTAR to RA core set measures, and to evaluate test-retest reliability of the MACTAR over one week.

Methods: Forty-five RA patients attending rheumatologists at the Rheumatology Clinic, Danderyd Hospital, Stockholm, Sweden, during a 6 month period were included. They had a median (md) age of 59 years (Q1-Q3) 52–65 and diagnosis duration of md 10 years (4–21). They were assessed regarding disease activity (Disease Activity Score, DAS-28), lower and upper limb function (Timed Stands Test, TST, and Shoulder Function Assessment, SFA), pain (VAS), activity limitation (Health Assessment Questionnaire, HAQ) and Patient Global assessment of well-being (PGA) and patient preference (MACTAR), which was assessed twice within a week.

Results: The most important disabilities to improve were fatigue in relation to social life (n=26), walking (n=21) and sleep (n=19). Fourty-seven percent of the identified disablilities were represented in items of the Comprehensive ICF core-set for RA and 53% in the HAQ. All except one of the identified disabilities were categorized into the ICF activities and participation component. Correlations between the MACTAR were r_s −0.65 to the DAS 28, r_s −0.61 to pain, r_s −0.61 to the PGA, r_s −0.51 to the HAQ, r_s 0.38 to the SFA, and r_s −0.19 to the TST. Test-retest analysis with Weighted Kappa koefficient (K_w) and Intra class correlation coefficient were 0.59 and 0.82 respectively with no systematic differences (sign-test, p=0.22).

Conclusion: The MACTAR identified fatigue in relation to social activities, walking and sleep as the disabilities most important to improve for RA patients in Sweden. Moderate to low correlations were revealed between the MACTAR and RA core set measures. The MACTAR has very good test-retest reliability and could be considered as assessing disabilities important to the patient not covered by recommended RA outcomes.

2425

Sensitivity to Change of the Bristol Rheumatoid Arthritis Fatigue Scales. Sarah Hewlett[1], Emma Dures[1], John R. Kirwan[2], Fiona Cramp[1], Joanna Nicklin[3], Celia Almeida[1], Kathryn Mitchell[3] and Rosemary Greenwood[2]. [1]University of the West of England, Bristol, United Kingdom, [2]University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom, [3]University of Bristol, Bristol, United Kingdom

Background/Purpose: Fatigue in RA is a major problem and measurement is recommended in clinical trials. The Bristol RA Fatigue Multi-Dimensional Questionnaire (BRAF-MDQ) is a validated 20 item patient reported outcome measure (PROM) (global score 0–70) with 4 subscales: Physical (0–22), Living with fatigue (0–21); Cognitive (0–15) and Emotional (0–12). Three single item numerical rating scales (BRAF NRS) measure fatigue Severity and Effect (0–10) and Coping (10–0).[1,2] This study examined their sensitivity to change.

Methods: RA outpatients given a single high dose of i/m glucocorticoids for clinical reasons, completed PROMs at weeks 0 and 2: BRAF scales, comparator fatigue PROMs [Functional Assessment of Chronic Illness Therapy Fatigue Scale (FACIT-F), Multi-dimensional Assessment of Fatigue (MAF), Profile of Mood States (POMS), Short Form 36 Health Survey Vitality Subscale (SF-36 VT)], VAS pain and global opinion of disease, and Health Assessment Questionnaire (HAQ).

Results: 42 patients participated: 34 female, mean age 56.7yrs (30–76, SD 12.6yrs), disease duration 10.7yrs (0.05–43, SD 10.7yrs); HAQ 1.875, (0–3, SD 0.65), pain 70.83 (SD 19.9) and global opinion 58.24 (SD 24.93). 15% MAF not scored due to missing data (POMS 9%, SF36 2%, BRAFs 1%). Baseline BRAF fatigue was high: BRAF-MDQ global

43.00/70 (SD 14.51), BRAF-Physical 16.80/22 (3.42), BRAF-Living 11.45/21 (5.60), BRAF-Cognitive 7.90/15 (4.3) and BRAF-Emotion 6.24/12 (3.63); BRAF-NRS Severity 7.15/10 (1.67), Effect 7.04/10 (2.32) and Coping 5.56/10 (low bad) (2.25).

Mean change and effect sizes (change/SD at baseline) show all scales sensitive to change except BRAF-NRS coping (Table 1).

Table 1.

	Mean change	95% confidence interval	P value for paired t test	Effect size
BRAF Global	−7.74	(−12.11, −3.38)	0.001	0.56
BRAF Physical	−2.89	(−4.59, −1.2)	0.001	0.54
BRAF Living	−2.32	(−3.69, −0.95)	0.001	0.53
BRAF Cognition	−1.20	(−2.34, −0.05)	0.041	0.33
BRAF Emotion	−1.34	(−2.34, −0.34)	0.010	0.42
BRAF NRS Sev	−1.25	(−2.07, −0.43)	0.004	0.47
BRAF NRS Effect	−1.25	(−2.09, −0.41)	0.005	0.46
BRAF Cope (Rev)	−0.13	(−1.03, 0.77)	0.771	0.05
SF36 (Rev)	7.68	(0.48, 14.88)	0.037	0.34
FACIT (Rev)	5.57	(2.43, 8.71)	0.001	0.55
POMS	−3.46	(−5.59, −1.32)	0.002	0.53
MAF	−5.34	(−8.65, −2.04)	0.002	0.57
Pain	−20.43	(−27.89, −12.96)	0.001	0.87
Global opinion	−7.93	(−15.81, −0.05)	0.049	0.31

Using a fatigue transition question as an anchor, BRAF-MDQ Global mean change was +3.57 for worse fatigue (SD 5.77, n=7) −2.42 for no change (SD 8.3, n=13) and −15.81 for less fatigue (SD 14.3, n=20); BRAF-NRS Severity was +0.29 (SD 1.38), 0.75 (SD 1.3) and −3.30 (SD 2.27); NRS Effect was +0.71 (SD 1.25), +0.39 (SD 1.9) and −3.0 (SD 2.39).

Conclusion: The BRAF MDQ, NRS Severity and Effect are sensitive to change. The BRAF Coping NRS was not sensitive to change after a pharmacological intervention. Along with the differential effect sizes in the BRAF-MDQ subscales, this supports the theory that fatigue consequences and coping are distinct concepts that require separate PROMs and interventions.

Human Amniotic Membrane Stem Cells as an Alternative Cellular Therapy for Articular Cartilage Repair. Emma Muiños[1], Silvia Diaz-Prado[2], Tamara Hermida-Gómez[1], Esther Rendal[1], Isaac M. Fuentes[2], Francisco J. De Toro[1] and Francisco J. Blanco[1]. [1]INIBIC-CHUAC, La Coruña, Spain, [2]INIBIC-CHUAC/University of A Coruña, La Coruña, Spain

Background/Purpose: Amniotic mesenchymal stromal cells (hAMSC) and amniotic epithelial cells (hAEC) are progenitor cells that can be remove from the amniotic membrane. Human amniotic membrane (HAM) has an increasing interest for its use in the field of regenerative medicine. This is due to both cell types are capable to differentiate towards three germinal cell lines. It has large advantages over the others sources of progenitor cells: high availability, large size and no ethical problems regarding with its use. The aim of this study is to determine the useful of the hAMSC and the hAEC on regenerating human joint cartilage in an *in vitro* model.

Methods: HAM was used as support for the culture of hAMSCs or hAECs. Focal injuries in human joint cartilage biopsies were done. Later, a pellet of cells (hAMSCs or hAECs, depending on the repair model developed) was implanted into the focal defects of cartilage. HAM, with the cells grown on it, was placed in direct contact with the cartilage surface to be repaired. These implants were cultured in chondrogenic medium, for 8 weeks. The repair tissues were analyzed by histological and histochemistry techniques considering the *ICRS* macroscopic evaluation of cartilage repair.

Results: Both cell types had good appearance during their cultured on HAM and their transplant onto focal cartilage injuries. hAMSCs and hAECs penetrated into the nearby surface of the chondral defect. The Hematoxylin and Eosin staining displayed that hAMSC or hAECs pellet filled the chondral defect. There was a good integration between the repair tissue and native cartilage. Type II collagen and aggrecan stainings of repair tissue were slightly positive on the extracellular matrix, and positive inside the cytoplasm of the cells. The safranin O staining expressed the presence of proteoglycans. Finally, type I collagen stainings were weak or totally negative (Figure 1). We carried out an *ICRS* macroscopic evaluation of cartilage reparation to compare both kinds of progenitor cells in the *in vitro* model. hAMSCs displayed better degree of defect repair, greatest integration to border zone and, in general, higher repair assessment (Table 1).

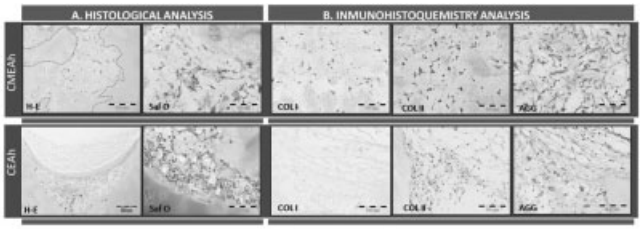

Figure 1: A) Histological and B) inmunohistoquemistry analysis. H-E (hematoxiline-Eosine), Saf O (Safranin O), COL I (Type I Collagen), COL II (Type II Collagen) and AGG (Aggrecan) staining methods.

Table 1. hAMSCs and hEACs means assessment considering the ***ICRS*** **histological visual scale.**

ICRS macroscopic evaluation of cartilage repair	hAMSCs mean	hEACs mean
Degree of defect repair	2.25 (±0.5)	1.5 (±0.58)
Integration to border zone	2.5 (±0.58)	1.75 (±0.96)
Macroscopic appearance	4	4
Overall repair assessment	8.5 (±0.58)	7 (±0.82)
	17.25 (±1.5)	14.25 (±2.06)

Conclusion: We get reduce the area of the defect with quality integration. The morphology of the repair tissue exhibited a fibrocartilaginous appearance and a high cellularity. hAMSCs showed better results *vs.* hAECs considering the *ICRS* macroscopic evaluation of cartilage repair. JAK2 Mediates the Stimulatory Effects of Transforming Growth Factor beta on Fibroblast Activation and Tissue Fibrosis. Clara Dees[1], Michal Tomcik[2], Katrin Palumbo[1], Alfiya Akhmetshina[3], Angelika Horn[1], Pawel Zerr[1], Oliver Distler[4], Georg Schett[1] and Jorg HW Distler[1]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [4]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Systemic sclerosis (SSc) is characterized by an uncontrolled activation of fibroblasts resulting in the release of excessive amounts of extracellular matrix components. Janus kinase 2 (JAK2) is a key-regulator of cytokine signaling and mutations in the JAK2 gene have been identified as key-event in the molecular pathogenesis of myeloproliferative diseases. In the present study, we evaluated the role of JAK2 in the pathogenesis of SSc and analyzed the potential of JAK2 inhibition as a novel anti-fibrotic approach.

Methods: Activation of JAK2 was determined by immunohistochemistry for pJAK2. Dermal fibroblasts were stimulated with TGFβ and incubated with the specific JAK2 inhibitor TG 101209 in different concentrations. Fibroblast activation was determined by staining for α-smooth muscle actin (αSMA) and stress fibers. Bleomycin-induced dermal fibrosis and tight-skin 1 (Tsk-1) mice were used to evaluate the anti-fibrotic potential of a specific JAK2 inhibition *in vivo*.

Results: Increased activation of JAK2 with prominent accumulation of pJAK2 particularly in fibroblasts was observed in skin of SSc patients. Of note, the activation of JAK2 persisted in cultured SSc fibroblasts. Inhibition of JAK2 by the selective JAK2 inhibitor TG 101209 or by

siRNA abrogated the activated phenotype of SSc fibroblasts by decreasing the formation of stress fibers by 41 ± 5 %, the expression of αSMA by 41 ± 6 % and the basal mRNA levels of col 1a1 and col 1a2 by 59 ± 4 % and 51 ± 3 % ($p < 0.05$ each). These inhibitory effects in the absence of exogenous stimulation were only observed in SSc fibroblasts, but not in resting healthy dermal fibroblasts. However, stimulation of healthy fibroblasts with TGFβ increased time-dependently the levels of pJAK2. Pre-incubation with TG 101209 abrogated the stimulatory effects of TGFβ on fibroblast activation with decreases in stress fiber formation by 74 ± 12 %, αSMA expression by 84 ± 11 % ($p < 0.05$) and reduced col 1a1 and col 1a2 mRNA levels by 90 ± 21 % and 92 ± 14 % ($p < 0.05$). In addition, the expression of the TGFβ target genes CTGF and PAI-1 was potently reduced. Consistently, inhibition of JAK2 exerted potent anti-fibrotic effects in experimental fibrosis. In the model of bleomycin-induced fibrosis, treatment with TG 101209 decreased dermal thickening by 95 ± 5 % ($p = 0.007$), hydroxyproline content by 76 ± 7 % ($p < 0.001$) and myofibroblast counts completely back to baseline levels ($p = 0.001$). Potent anti-fibrotic effects were also observed in the Tsk-1 model. Application of TG 101209 reduced hypodermal thickening, hydroxyproline content and myofibroblast counts by 82 ± 10 % ($p = 0.002$), 75 ± 25 % ($p = 0.03$) and 99 ± 13 % ($p = 0.01$).

Conclusion: We demonstrate that JAK2 is activated in SSc in a TGFβ-dependent manner and mediates the stimulatory effects of TGFβ on fibroblasts. Inhibition of JAK2 reduced collagen synthesis specifically in SSc fibroblasts, prevented fibroblast activation and exerted potent anti-fibrotic effects in experimental fibrosis. As inhibitors of JAK2 are currently evaluated in clinical trials for myeloproliferative disorders and are well tolerated, our findings might have direct translational implications and stimulate clinical trials with JAK2 inhibitors in SSc patients.

RNAi Mediated Silencing of the Autoantigen hnRNP-A2 Dcreases Inflammatory Arthritis by Inhibiting Activation of Cells of the Mononuclear Phagocytic System. Sonja Herman[1], Jessy Presumey[2], Juergen Pfatschbacher[1], Wim B. Vandenberg[3], Florence Apparailley[2] and Gunter Steiner[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Hôpital Saint Eloi, Montpellier, France, [3]Radboud University Nijmegen Med Center, Nijmegen, Netherlands

Background/Purpose: HnRNP-A2 belongs to a heterogenous family of nuclear proteins importantly involved in mRNA trafficking, transcriptional and translational processes. Recent evidence let suggest that hnRNPs post-transcriptionally modulate expression of inflammatory mediators such as COX-2, TNF-a, IL-1b and iNOS by affecting mRNA stability and translation. Strong upregulation of hnRNP-A2 at sites of inflammation and the generation of antibodies and autoreactive T-cells against hnRNP-A2 in patients with rheumatoid arthritis (RA) and various arthritis models points towards a potential involvement of this protein in the pathogenesis of inflammatory arthritis.

Methods: Expression of hnRNP-A2 in tissues and cells was analysed by flow cytometry and immunoblotting. In-vitro silencing of hnRNP-A2 was studied in J77.4 cells. Collagen-induced arthritis (CIA) in DBA1 mice and K/BxN serum transfer arthritis in BL/6 mice were used as arthritis models. For silencing of hnRNP-A2 expression, siRNA containing lipoplexes were used, which were injected intravenously once a week. Control animals were treated with unspecifc siRNA/lipoplexes or PBS. Silencing efficiency was analyzed by immunobloting and real-time PCR. Arthritis was measured by an established clinical scoring system, inflammation and bone erosions were analyzed by histomorphometry.

Results: HnRNP-A2 was highly expressed in lymphoid organs such as lymph-nodes, spleen and thymus. Among cells of the immune system monocytes/macrophages showed the strongest expression of hnRNP-A2. Silencing of hnRNP-A2 in a monocytic cell line diminished the proliferative capacity of transfected cells.

Silencing of hnRNP-A2 in vivo revealed a 60%–70% silencing efficiency in lymph nodes and spleen of injected mice. Remarkably, incidence of arthritis in those mice, which were injected with hnRNP-A2 specific siRNA-lipoplexes, was only 20% as compared to 70 and 80%, respectively, in the control groups. Moreover, arthritis scores and weight loss differed significantly from control animals. Histological analysis of paws confirmed that both inflammation and bone erosion were significantly reduced in animals treated with hnRNP-A2 specific siRNA. Serum levels of cytokines typically produced by cells of the mononuclear phagocytic system such as TNF-α, IL-23 and IL-1 were strongly reduced. The effects observed were similar in both arthritis models indicating that hnRNP-A2 is crucially involved in the effector arm of autoimmune arthritis.

Conclusion: In-vivo silencing of hnRNP-A2 largely prevents induction of arthritis development by inhibiting activation of the mononuclear phagocyte system thereby diminishing the inflammatory immune response.

2429

A Functional *IRF5 V*ariant Predicts Prognosis in Patients with Systemic Sclerosis. Roozbeh Sharif[1], Maureen D. Mayes[1], Filemon K. Tan[1], Olga Gorlova[2], Laura K. Hummers[3], Ami A. Shah[3], Daniel E. Furst[4], Dinesh Khanna[5], Javier Martin[6], Lara Bossini-Castillo[7], Emilio B. Gonzalez[8], Hilda T. Draeger[9], Jun Ying[10], Sandeep K. Agarwal[1], Frank C. Arnett[1], Fredrick M. Wigley[3] and Shervin Assassi[1]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]University of Texas M.D. Anderson Cancer Center, Houston, TX, [3]Johns Hopkins University, Baltimore, MD, [4]UCLA Medical School, Los Angeles, CA, [5]University of Michigan, Ann Arbor, MI, [6]Instituto de Parasitologia y Biomedicina Lopez-Neyra (CSIC), Granada, Spain, [7]Consejo Superior de Investigaciones Científicas (CSIC), Armilla (Granada), Spain, [8]University of Texas Medical Branch, Galveston, TX, [9]Univ of TX Health Sci Ctr, San Antonio, TX, [10]University of Texas M. D. Anderson Cancer Center, Houston, TX

Background/Purpose: The first genome-wide association study (GWAS) in systemic sclerosis (SSc) demonstrated three non-major histocompatibility complex (non-MHC) susceptibility loci in *IRF5*, *STAT4*, and *CD247* regions. Our goal was to investigate the impact of these gene variants on survival and severity of interstitial lung disease (ILD) in SSc. We also examined the effect of the *IRF5* SNPs on its transcript expression in monocytes.

Methods: We examined 1443 Caucasian patients with SSc, enrolled in the GENISOS and Scleroderma Family Registry (n=914 –discovery cohort) and The Johns Hopkins Scleroderma Cohort (n=529-replication cohort). Demographic, clinical, and serologic data were recorded. Forced vital capacity (FVC) % predicted was used as a surrogate for ILD severity. All patients were genotyped by the Illumina Human610-Quad BeadChip. Five SNPs, *IRF5* (rs10488631, rs12537284, rs4728142), *STAT4* (rs3821236), *CD247* (rs2056626) reached genome wide significance in the SSc-GWAS and were examined in the current study. The primary outcome was survival. Cox proportional hazards regression model was used for survival analysis. Then, the correlation of the investigated SNPs with FVC% predicted at enrollment was examined by linear regression. Next, we explored the effect of the three investigated *IRF5* SNPs on transcript expression using gene expression microarrays. The transcript levels of *IRF5* in monocytes were examined conditional on the *IRF5* SNPs in SSc patients and unaffected controls.

Results: Overall, 15.5% of the patients had died over the follow up time of 5.5 years. The *IRF5* rs4728142 minor allele was predictive of longer survival in the discovery cohort (HR: 0.76, 95%CI: 0.60–0.96, $P=0.021$) and in the independent replication cohort(HR: 0.73, 95%CI: 0.54–0.99, $P=0.047$). This SNP was also associated with better survival in the combined cohort (HR: 0.75, 95%CI: 0.62–0.90, p=0.002), which remained significant even after Bonferroni's correction ($p_{corr}=0.01$). Moreover, the impact of this SNP on survival remained significant even after adjustment for age at disease onset, disease type, and autoantibody profile ($p=0.043$). The minor allele frequency of *IRF5* rs4728142 in the combined sample was 49.4%.

Moreover, *IRF5* rs4728142 minor allele correlated with higher FVC% predicted at enrollment ((b: 2.64, CI: 0.43– 4.84, $P=0.019$)), adjusted for disease duration. The other two *IRF5* SNPs, as well as *STAT4* and *CD247* polymorphisms were associated neither with survival nor with ILD severity. Finally, the *IRF5* rs4728142 minor allele was associated with lower *IRF5* transcript expression in patients and controls (p=0.014 and p=0.034, respectively), suggesting that the *IRF5* rs4728142 SNP may be functionally relevant.

Conclusion: This is the first study, linking a non-MHC genetic locus to survival and/or severity of ILD in SSc. A functional SNP in the *IRF5* promoter region (rs4728142), associated with lower *IRF5* transcript levels, was predictive of longer survival and milder ILD in patients with SSc. This finding supports the pivotal role of *IRF5* and related type I interferon pathways in SSc which could lead to identification of novel therapeutic targets and development of prognostic biomarkers.

2430

Feasibility, Safety and Clinical Effects of a Single Intradermal Administration of Autologous Tolerising Dendritic Cells Exposed to Citrullinated Peptides in Patients with Rheumatoid Arthritis. Ranjeny Thomas, Shayna Street, Nishta Ramnoruth, Helen Pahau, Soi Law, Marion Brunck, Claire Hyde, Brendan O'Sullivan, Christelle Capini, Ai Tran, Jennifer Ng and Sanjoy Paul. Univ of Queensland, Brisbane, Australia

Background/Purpose: Bone marrow-derived dendritic cells modified with the irreversible NF-kappaB inhibitor, Bay11–7082 (Bay-DCs), exposed to arthritogenic antigen, transfer antigen-specific suppression of inflammatory arthritis in mice, through induction of regulatory T cells. We carried out a phase I clinical trial of autologous peripheral blood (PB) Bay-DCs exposed to citrullinated peptide antigens (known as Rheumavax) in HLA-DR shared epitope (SE)+ anti-citrullinated peptide antibody (ACPA)+ rheumatoid arthritis (RA) patients. The aims of this phase I first-in-man study were to demonstrate feasibility and safety of autologous peripheral blood (PB) DC immunotherapy, and to describe its clinical and immune effects.

Methods: Bay-DCs were generated from 250ml PB under good laboratory practice (GLP) conditions after purification of PB mononuclear cells by density sedimentation, and PB monocytes by elutriation, then culture in the presence of RPMI, 10% human serum, 400U/ml GM-CSF and 800U/ml IL-4 and 2.5 uM Bay11–7082 for 60h. During the final 18h, cells were pulsed with a mixture of four citrullinated peptide antigens (cit-vimentin 447–455, cit-fibrinogen beta chain 433–441, cit-fibrinogen alpha chain 717–725, cit-collagen type II 1237–1249). Rheumavax was administered intradermally once to each group of 9 RA patients on usual disease modifying drugs (DMARDs) in 2 progressive vaccine dose levels (total of 18 vaccinated subjects) in an escalating dose regimen. Group 1 received 1 million DCs and group 2 received 5 million DCs on day 1 of study. Open label control group of 11 patients received usual DMARDs. The primary outcomes were 1. clinical, and 2. laboratory measures of safety and 3. citrullinated peptide-specific tolerance; the secondary outcome was clinical response. Patients were evaluated at baseline, monthly for 3 months and finally at 6 months.

Results: We recruited 29 SE+ ACPA+ patients with RA, including 18 females, with mean age 56 (range 38–76), mean disease duration of 5.4 (range 1–10) years, and treated with at least 1 DMARD, to the study. All Bay-DC cultures were sterile. Rheumavax was well-tolerated at both doses and did not provoke local skin reactions, lymphadenopathy, allergic reactions, infections or immediate disease flares. Adverse events were all grade 1 (of 4) severity and included headache (2), and laboratory evidence of anemia (3), lymphopenia (3), leukopenia (3) and elevated alkaline phosphatase (2) or AST (1). DAS scores decreased below 2.5, sometimes for prolonged periods, in 7/9 Rheumavax recipients who commenced the trial with DAS4vCRP>2.5. DAS scores were stable in 7/9 Rheumavax patients who commenced the trial with DAS4vCRP<2.5. Systemic effects of Rheumavax were demonstrated by reductions in CRP, ESR and the homeostatic model of insulin resistance (HOMA-IR). Immune tolerance outcomes will be discussed.

Conclusion: These data demonstrate the feasibility and safety of a single intradermal administration of autologous tolerising dendritic cells exposed to citrullinated peptides in RA patients.

2431

Genome-Wide Analysis of Imputed Genotypes Identifies Chemokine Receptor-1 *CCR1*) As a Novel Candidate Risk Locus in Behçet's Disease. Yohei Kirino[1], George Bertsias[1], Michael J. Ombrello[1], Duran Ustek[2], Colleen Satorius[1], Julie Le[1], Nobuhisa Mizuki[3], Yoshiaki Ishigatsubo[3], Emire Seyahi[4], F. Sevgi Sacli[4], Ahmet Gul[5], Daniel L. Kastner[1] and Elaine Remmers[1]. [1]National Human Genome Research Institute, National Institute of Health, Bethesda, MD, [2]Istanbul University, Istanbul, Turkey, [3]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [4]University of Istanbul, Cerrahpasa Medical Faculty, Istanbul, Turkey, [5]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey

Background/Purpose: Behçet's disease (BD) is a genetically complex disease characterized by recurrent inflammatory attacks affecting the orogenital mucosa, eyes and skin. We have previously performed a genome-wide association study with 311,459 SNPs in 1,215 BD cases and 1,278 healthy controls from Turkey, and have identified independent associations with HLA-B*51, an additional MHC class I locus, *IL10*, and the *IL23R-IL12RB2* locus.

Methods: To identify additional BD susceptibility loci, we carried out whole-genome imputation using as a reference, 96 of the Turkish healthy controls genotyped on Illumina HumanOmni1M-Quad SNP chips. SNPs were excluded for deviation from HWE ($p<5\times10^{-4}$), low call rate (<95%), and low MAF (<5%). Imputation was conducted using MACH v1.0.15 providing 814,474 SNPs for analysis in the 1,215 BD cases and 1,278 healthy controls. Sequenom iPLEX assays were used to validate the imputation results and to fine map the associated region. Two independent replication sets were genotyped for the most significant SNP.

Results: Using a p-value cut-off of 1×10^{-5}, we identified 114 non-HLA gene SNPs suggestive of association with BD. One imputed SNP rs7616215 on chromosome 3, located ~38 kb from the 3' UTR of the chemokine receptor-1 gene (*CCR1*), (odds ratio [OR] 0.71, $p=1.9\times10^{-8}$) exceeded genome-wide significance ($P<5\times10^{-8}$). Fine mapping of the *CCR1* region confirmed the imputation results for rs7616215 and identified 2 additional SNPs in strong LD with rs7616215 that also exceeded genome-wide significance. The association of rs7616215 also replicated using additional Turkish and Japanese BD cases and controls (in a meta-analysis of 2,195 cases and 2,187 controls OR = 0.73, 95% CI 0.66–0.81, $p=1.8\times10^{-10}$). CCR1 belongs to the family of CC-motif chemokine receptors, is expressed on neutrophils, monocytes, and T lymphocytes and binds several chemokine ligands, including CCL5/RANTES, CCL3/MIP-1α, and CCL4/MIP-1β. A role for CCR1 has been characterized in several inflammatory conditions, such as rheumatoid arthritis, multiple sclerosis, and transplantation rejection. ENCODE data indicate that rs7616215 resides in a putative regulatory genomic domain, and analysis of *CCR1* transcripts from the HapMap European (CEU), Chinese (CHB) and Japanese (JPT) subjects showed that the protective minor allele (C) correlated with significantly increased *CCR1* expression ($p<0.03$).

Conclusion: We have identified *CCR1* as a novel risk gene locus in BD, with potential implications in regulation of inflammatory responses in the context of the disease.

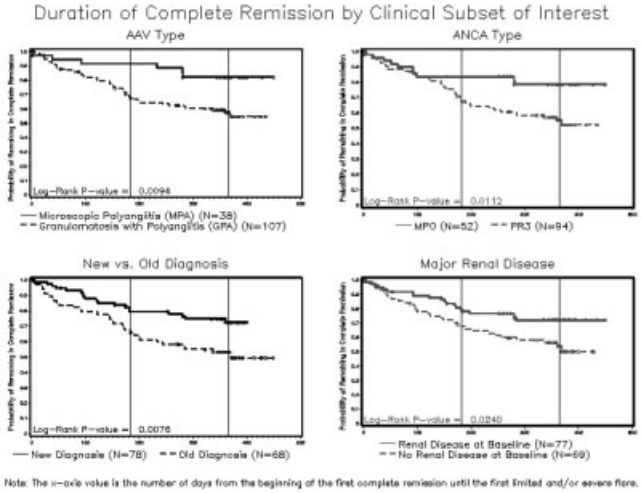
Phippard[9], Brett Jepson[14], Alice Lail[14], Adam Asare[9], Noha Lim[9], Mark Mueller[15], Paul Brunetta[16], Nancy B. Allen[17], Fernando Fervenza[13], Duvuru Geetha[18], Karina Keogh[13], Eugene Y. Kissin[19], Paul A. Monach[19], Tobias Peikert[13], Coen Stegeman[6], Steven R. Ytterberg[13], Ulrich Specks[13] and for the RAVE-ITN Research Group[20]. [1]Massachusetts General Hospital, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Johns Hopkins Vasculitis Center, Baltimore, MD, [4]Hospital for Special Surgery, New York, NY, [5]Cleveland Clinic, Cleveland, OH, [6]University Medical Center Groningen, Groningen, Netherlands, [7]Duke University Medical Center, Durham, [8]Univ of Alabama-Birmingham, Birmingham, AL, [9]Immune Tolerance Network, Bethesda, MD, [10]National Institute of Allergy and Infectious Diseases, [11]NIAID, Bethesda, MD, [12]Johns Hopkins University, Baltimore, MD, [13]Mayo Clinic, Rochester, MN, [14]Rho, Chapel Hill, NC, [15]Food & Drug Administration, Bethesda, MD, [16]Genentech, So San Francisco, CA, [17]Duke University Medical Center, Durham, NC, [18]Johns Hopkins University, York, PA, [19]Boston University, Boston, MA, [20]Bethesda

Background/Purpose: Rituximab (RTX) is non-inferior to cyclophosphamide (CYC) for remission-induction in severe ANCA-associated vasculitis (AAV) [microscopic polyangiitis (MPA), granulomatosis with polyangiitis (Wegener's, GPA)] and superior for patients with relapsing disease. Understanding longer-term outcomes, particularly in certain disease subsets, is essential for optimizing AAV treatment. We evaluated the efficacy of one course of RTX compared to CYC followed by AZA over 18 months (M), with assessments of outcomes according to original treatment assignment, ANCA type, AAV type, renal disease, and relapsing disease at baseline.

Methods: A randomized, double-blind, placebo-controlled trial tested the hypothesis that RTX (375 mg/m^2 iv weekly × 4) was not inferior to CYC (2 mg/kg/d po) for remission-induction at 6 months [*N Engl J Med* 2010]. CYC was replaced by AZA and RTX by placebo between 3–6M if remission was achieved. Patients were followed for a minimum of 18M. Remission was defined as a Birmingham Vasculitis Activity Score/Wegener's Granulomatosis (BVAS/WG) of 0, and complete remission by BVAS/WG=0 off prednisone. Remission rates were compared for the following subsets using log-rank tests: new diagnosis vs relapsing disease at baseline; MPO- vs

PR3-ANCA; MPA vs GPA; and presence vs absence of major renal disease at baseline.

Results: Nine centers enrolled 197 patients with severe GPA or MPA (3:1), all positive for either PR3-ANCA or MPO-ANCA (2:1). At entry, 49% of patients had new disease, 52% had major renal disease. Complete remission was achieved and sustained at 6, 12, and 18M by 64%, 47%, and 39% in the RTX arm, vs 53%, 39%, and 33% in the CYC/AZA arm, respectively (P=0.NS). Disease flares in the two treatment arms did not differ in number/severity. No unexpected safety issues were detected. The Figure shows Kaplan-Meier plots for duration of complete remission for pre-specified disease subsets.



Patients at highest risk for flare had relapsing disease at baseline, no major renal disease, PR3-ANCA positivity, or GPA. Relapsing disease and no major renal disease subsets were enriched with PR3-ANCA-positive patients, who overlapped substantially with a diagnosis of GPA. Among RTX-treated patients who achieved complete remission, flares occurred only after the return of detectable levels of B cells.

Conclusion: A single course of RTX is as effective as 18 months of standard therapy (CYC followed by AZA) for remission induction and maintenance in severe AAV. Patients at increased risk for flares are identifiable by ANCA type, AAV type, absence of major renal disease at baseline, and prior flare history. Additional mechanistic studies may define the immunological events surrounding relapses more precisely.

Compromised Expression of the Complement Membrane Inhibitor CD59a Propagates Age-Related Joint Degeneration in Mice. Vishal Paringe[1], Anja C. Bloom[1], Ernest Choy[1], Bryan P. Morgan[1] and Anwen S. Williams[2]. [1]Cardiff University, Cardiff, England, United Kingdom, [2]Cardiff University, Cardiff, United Kingdom

Background/Purpose: The influence of complement-mediated innate immune responses on cartilage and bone homeostasis in the ageing joint have not been studied. Inappropriate complement-mediated cell damage is prevented by membrane regulators such as CD59. Synovial tissue expression of CD59 is altered during inflammatory arthritis; elevated CD59 levels may be necessary to protect joint tissues. Roles of CD59 in maintaining tissue equilibrium and structural architecture within the synovial joint have not been described previously. Since CD59a is the primary regulator of membrane attack complex assembly in mice; we used CD59a-gene-deleted mice ($CD59a^{-/-}$) as tools to unravel the function of CD59a in modulating age-related joint degeneration.

Methods: Hind limbs were collected from C57BL/6J wild type (WT) and $CD59a^{-/-}$ mice at 8-, 20- and 50- weeks of age (6 to 10 mice/group). The Mankin score was used to classify the histopathological severity of osteoarthritic (OA) lesions. Three dimensional radiological image analysis provided objective markers of early degenerative changes at the patellofemoral joint and tibiofemoral joint (TFJ). Sulcus angle, coherence angle, TFJ medial and lateral joint space, femoral subchondral bone thickness, lateral femoral and tibial expansion and osteophytes were measured. Statistical analysis by one-way ANOVA unless specified otherwise. C57BL/6J wild type (WT) and $CD59a^{-/-}$ mice.

Results: Articular cartilage degeneration was detected earlier in $CD59a^{-/-}$ versus WT. In male mice the Mankin score was 0.1 ± 0.1, 4.2 ± 1.4 ($P=0.02$; Mann–Whitney U test) and 7.7 ± 1.8 in $CD59a^{-/-}$ compared with 0.2 ± 0.1, 0.9 ± 0.3 and 7.2 ± 1.6 in WT at 8-, 20- and 50- weeks (all mean±SEM). Lateral subluxation occurred earlier and was of significantly greater magnitude in $CD59a^{-/-}$ than WTs ($P=0.009$; two-way ANOVA). A significant ($P=0.03$) increase in sulcus angle was noted in $CD59a^{-/-}$ mice over time; no such difference was recorded in WTs. Mean coherence angle measured in $CD59a^{-/-}$ at 8-, 20- and 50- weeks was -6.5, $+15.5$ and $+25$ ($P=0.0008$) compared with -2, -7 and $+11$ ($P=0.01$) for WTs indicating significant lateral subluxation of patella with increased age in both strains. TFJ medial and lateral joint space and subchondral bone thickness measurements suggested that bone remodelling was higher in $CD59a^{-/-}$ versus WT at all ages. Osteophytes were clearly visible in $CD59a^{-/-}$ joint specimens across the timecourse but were only observed in WT at 50 weeks. In female mice we observed less articular cartilage pathology than in male mice. However, structural changes indicative of osteoarthritis were consistently more severe in $CD59a^{-/-}$ versus WT mice. Significant joint space narrowing was evident in the medial ($P=0.01$) and lateral ($P=0.01$) compartment of the TFJ in $CD59a^{-/-}$ versus WT (two-way ANOVA). Osteophytes were clearly visible in $CD59a^{-/-}$ joint specimens at 20 and 50 weeks but were only observed in WT mice at 50 weeks.

Conclusion: CD59a deficiency markedly accelerates the progression of age-related joint degeneration in mice. The identification of disease-modifying markers is necessary in order to improve the prediction of disease progression at the individual level and open exciting possibilities for novel treatment options for OA.

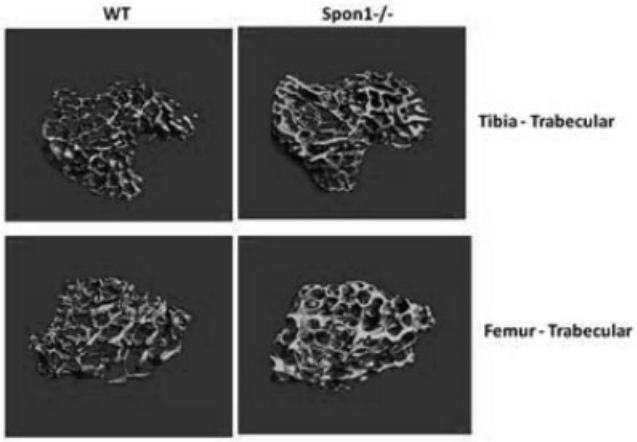
F-Spondin (spondin-1) Null Mice Exhibit Increased Bone Formation. Mukundan Attur[1], Glyn Palmer[1], James Liu[1], Yang Qing[2], Daniel Rifkin[2], Frank Beier[3] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]New York University School of Medicine, New York, NY, [3]Schulich School of Medicine and Dentistry, London, ON

Background/Purpose: We have previously reported that F-spondin (spondin-1), a neuroregulatory protein, is upregulated by chondrocytes in osteoarthritis. These studies showed that spondin-1, a member of the TSR (thrombospondin) type I class super family, activated latent TGF-b, which appeared to account for selected *in vitro* effects, including induction of the hypertrophic chondrocyte phenotype. In this study we generated Spon1 knockout mice to investigate in vivo the role of spondin-1 on skeletal maturation.

Methods: Total TGFβ-1 was detected using R &D ELISA kit. MicroCt was performed on the Scanco mCT 35 system on proximal tibia and femurs bone evaluation. Values represent the average of 4 WT and 5 KO mice.

Results: Spondin-1 knockout mice ($Spon1^{-/-}$) were generated by targeted deletion of exon 1 in C57BL/6 mice. Exon 1 deletion was confirmed using Southern blot analysis and PCR using probes specific for wild type (WT) and mutant loci. Spon1−/− null mice were viable and initial macroscopic observations revealed no overt differences in size and body weight compared with WT (mice up to 6 months). Since we previously reported spondin-1 to regulate TGF-b and MMP activities, we measured their levels in adult mutant mice. Relative to WT mice, Spon1 deletion reduced serum levels of total TGFβ-1 (82 ± 20 ng/ml vs. 30 ± 25.0 ng/ml; $p<0.002$) and increased serum total MMP activity (48 ± 15 RFU to 84 ± 18.0 RFU; $p<0.061$). Cultured chondrocytes isolated from the rib cages of 5 day old $Spon1^{-/-}$ mice also produced significantly less TGF-b (30%) compared to WT controls ($p<0.01$). To determine whether Spon1 deletion affected bone phenotype, we performed microCT of tibia and femurs in mutant and WT mice aged 1–6 months. Relative to WT mice, $Spon1^{-/-}$ exhibited increased bone formation at 6 months, evidenced by, a) increased trabecular and cortical bone volume fraction (Bone volume/Total volume: 0.27 ± 0.03 versus 0.15 ± 0.04, $p<0.005$; Fig 1), b) decreased trabecular spacing (0.14 ± 0.02 versus 0.2 ± 0.04, $p<0.03$); and c) increased trabecular number (7.8 ± 1.2, versus 5.0 ± 1.5, $p<0.014$). Interestingly, no significant changes were observed at 1 or 3 months, suggesting that spondin-1 effects are age-dependent.



Conclusion: Our studies indicate that F-spondin or spondin-1, a latent TGF-b activating ECM protein, over-expressed in OA bone and cartilage, regulates bone metabolism in aging male mice. Spon1 $^{-/-}$ male mice exhibit increased trabecular and cortical bone formation. Together these data suggest that a primary function of spondin-1 in skeletal tissue is the regulation of bone mass via latent TGF-b activation. Further studies are in progress regarding the potential of spondin-1 as a drugable target in future therapy of osteoporosis or osteoarthritis.

Synovial Wnt and Wnt-1-Induced Secreted Protein 1 Expression Induce Osteoarthritis-Like Cartilage Damage by Skewing of Transforming Growth Factor-Beta Signaling From Smad 2/3 towards Smad 1/5/8 Phosphorylation. Martijn H. van den Bosch, Arjen B. Blom, Peter L. van Lent, Henk M. van Beuningen, Fons A. van de Loo, Esmeralda N. Blaney Davidson, Peter M. van der Kraan and Wim B. van den Berg. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Although many osteoarthritis (OA) patients show significant synovial involvement, consequences are largely unknown. We found strong up-regulation of canonical Wnts 2b and 16 and Wnt-1-induced secreted protein 1 (WISP1), in knee joints in two experimental murine OA models. Wnt signaling has been implicated in OA incidence and modulation of the β-catenin pathway leads to OA-like changes in cartilage. In addition, TGF-β signaling is critical in cartilage maintenance. TGF-β signals via both ALK5 and ALK1 and downstream via Smad 2/3 and Smad 1/5/8 respectively. In the present study we investigated the potency of canonical Wnts, produced by synovial cells, to induce OA pathology and whether canonical Wnts skew TGF-β signaling from the protective Smad 2/3 pathway to the Smad 1/5/8 pathway, which can induce chondrocyte hypertrophy.

Methods: Western blot analysis was done to detect phosphorylation of Smad 2/3 and Smad 1/5/8. *In vivo* synovial overexpression of genes from the canonical Wnt signaling pathway was achieved by intra-articular injection of adenoviral vectors. Joint pathology was assessed by histology at several time points after injection. Gene expression was analyzed by qPCR after overexpression of Wnt genes in isolated human chondrocytes.

Results: To determine if synovial overexpression of canonical Wnts leads to cartilage damage, adenoviral vectors for Wnts 8a and 16, excluded from targeting chondrocytes because of their size, were injected in murine knee joints. At day 7 a highly significant induction of OA pathology was found at the medial margin of the medial tibial plateau. The incidence was 92% (n=12) for Wnt8a overexpression compared to 17% (N=12) for the control virus and 80% (N=5) for Wnt16 overexpression, but only 20% (N=5) for the control virus. In addition, overexpression of Wnt16 led to significantly increased synovial cellularity, mainly macrophages, and cartilage pathology on the lateral side of the femoral-tibial joint. Because of their relatively small size, Wnts and WISP1 proteins can migrate to the cartilage and possibly alter chondrocyte phenotype. Synovial Wnt8a and Wnt16 overexpression led to β-catenin accumulation in chondrocytes, a tell-tale sign of canonical Wnt signaling, indicating diffusion of Wnts to the cartilage. Moreover, overexpression of canonical Wnts and WISP1 in human chondrocytes led to a significant increase of collagen type I and a significant decrease in type II collagen expression, suggesting a loss of chondrocyte phenotype. Pre-incubation with Wnt3a or WISP alone or Wnt3a + WISP1 together resulted in decreased TGF-β-induced phosphorylation of Smad 2/3, whereas phosphorylation of Smad 1/5/8 was increased. This implies a shift towards dominant TGF-β signaling via the hypertrophy-inducing ALK1 pathway.

Conclusion: Canonical Wnts produced in the synovium may play an important role in OA pathology by inducing β-catenin signaling in the cartilage followed by cartilage damage. Synovial overexpression of canonical Wnts, as is found in experimental OA, may lead to chondrocyte phenotype changes, probably via modulation of the important TGF-β signaling pathway. This underlines that synovial Wnt/WISP1 expression may be a potential target for OA therapy.

2436

Inhibition of Osteoclast Formation by Adenosine A_{2A} Receptor Is Due to Inhibition of NFkB Nuclear Translocation by a PKA-Mediated Mechanism. Aranzazu Mediero[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]New York Univ Medical Center, New York, NY

Background/Purpose: Adenosine, a nucleoside released at sites of injury and hypoxia and which mediates the anti-inflammatory effects of methotrexate, mediates its effects via activation of G-protein-coupled receptors (A_1, A_{2A}, A_{2B}, A_3). Previously we reported that the $A_{2A}R$ agonist CGS21680 inhibited osteoclast differentiation in a dose–dependent manner. We therefore determined which intracellular pathways are involved in $A_{2A}R$-mediated regulation of osteoclast differentiation

Methods: Osteoclast differentiation was studied as the M-CSF/RANKL-stimulated formation of multinucleated TRAP-positive cells from primary murine (C57Bl/6) bone marrow-derived precursors in the presence or absence of CGS21680, ZM241385 (A_{2A} receptor antagonist), activators and inhibitors of PKA/EPAC pathways. Signaling events (PKA/EPAC, MAPK and NFATc1 activation) were studied by Western Blot. A_{2A} Receptor, Cathepsin K and NFATc1 expression were studied by real time RT-PCR. Cytokine expression was assayed by ELISA.

Results: During M-CSF/RANKL-stimulated osteoclast formation the expression of $A_{2A}R$ changed over time, increasing in control and ZM241385 pre-treated cells, an effect which was abrogated in CGS21680-treated cells. Cathepsin K is upregulated in control and ZM241385-treated cells (up to 80 fold, $p<0.001$) but CGS21680 reduces the increase. NFATC1 was upregulated during osteoclast differentiation under all conditions studied. CGS21680 decreased NFkB nuclear translocation in a time-dependent manner, an effect that was abrogated by ZM241385 (88±2% vs 176±12% of control, CGS21680 alone or with ZM241385, respectively, $p<0.001$, n=4), a finding confirmed by direct assay of NFkB transcriptional activity. Western Blot showed PKA activation increased over time in the presence of CGS21680 and this correlated with decreased EPAC activation over the same period of time. CGS21680 increased pERK after 5 and 15min, 1h and 12h (to as much as 119±0.6%, $p<0.001$, n=4), and pre-treatment with ZM241385 reversed this activation. CGS21680 also increased p38MAPK phosphorylation to as much as 110±1% of control, $p<0.5$, n=4), an effect which was abrogated by ZM241385. Finally, CGS21680 activated pJNK over time to as much as 181±2% of control, $p<0.001$, n=4) and ZM241385 partially reversed this effect. A PKA inhibitor (PKI) and/or EPAC activator (8-CPT-cAMP) reversed the effect of CGS21680 on osteoclast differentiation.

Conclusion: Adenosine, acting at $A_{2A}R$, inhibits osteoclast differentiation and regulates bone turnover mainly by the activation of PKA and MAPK, the inhibition of NFkB translocation to the nucleus and decreasing the expression of pro-inflammatory cytokines. Because adenosine mediates the anti-inflammatory effects of methotrexate we speculate that the capacity of methotrexate to inhibit bone erosion in Rheumatoid Arthritis may be mediated by increases in adenosine which inhibit osteoclast formation and function.

2437

MicroRNA-453 Modulates Sonic Hedgehog Gene Expression in Human Chondrocytes by Directly Targeting Its Open Reading Frame. Nahid Akhtar[1] and Tariq M. Haqqi[2]. [1]Case Western Reserve University/Metrohealth Medical Center, Cleveland, OH, [2]Metro Health Medical Center/Case Western Reserve University, Cleveland, OH

Background/Purpose: MicoRNAs (miRNAs) are small endogenous, non-coding RNAs that are important post-transcriptional regulators of gene expression. Sonic Hedgehog (SHH) morphogen is an essential signaling molecule required for numerous processes during development and has recently been implicated in OA pathogenesis. However, regulation of SHH expression in OA remains unclear. Here we studied (a) whether IL-1β-induce

the expression of SHH; and (b) whether miRNAs play a role in regulating expression of SHH in human chondrocytes.

Methods: Chondrocytes were derived by enzymatic digestion of human cartilage from OA patients (OA chondrocytes) undergoing total knee arthroplasty. Chondrocytes were stimulated with IL-1β (5ng/ml) *in vitro* and total RNA was prepared. Expression of SHH and its downstream targets PTCH-1, GLI-1, HHIP, ADAMTS-5 and MMP-13 was quantified by TaqMan Assays. miRGen Targets (http://diana.pcbi.upenn.edu/cgi-bin/miRGen/v3/Targets.cgi) was used to identify miRNAs that potentially target the SHH mRNA and the free energy scores of selected miRNA: mRNA hybrids were determined using RNAHybrid program (http://bibiserv.techfak.uni-bielefeld.de/rnahybrid). miRNAs were purified using the mirVANA system and single stranded cDNA was synthesized with the stem loop-specific primers and the expression of miRNAs was quantified using TaqMan Assays. HEK293 cells were co-transfected with pre-miRNAs, antagomirs and SHH expression plasmid and the protein expression was determined by Western Immunoblotting. Data was analyzed using Origin 6.1 software package and $p<0.05$ was considered significant.

Results: Our results showed that the expression of of SHH was higher in damaged cartilage (stained with India ink, slight or no loss of Safranin O staining) compared to smooth cartilage (no staining with India ink, little or no loss of Safranin O staining) obtained from OA patients at the time of knee arthrthroplasty. The expression of SHH signaling genes and their downstream targets (PTCH-1, GLI-1, and HHIP, MMP-13, ADAMTS-5, COL10A1 and RUNX-2) was also higher in damaged cartilage. A full length search of SHH transcript identified several miRNAs including Hsa-miR-453, Hsa-miR-602 and Hsa-miR-608 with seed matched sites within the coding sequence of SHH mRNA. IL-1β-stimulation (10 ng/ml) resulted in significant up-regulation of SHH mRNA (~11.3-fold at 6h; ~15.5-fold at 12 h) and protein levels in chondrocytes obtained from damaged cartilage. In addition, IL-1β-stimulation also down regulated the expression of Hsa-miR-453 (~4.6-fold at 6h; ~11.6-fold at 12 h), Hsa-miR-602 (~3.9-fold at 6h; ~2.9-fold at 12 h) and Hsa-miR-608 (~3.6-fold at 6h; ~7.5-fold at 12 h) in these chondrocytes. Co-transfection of HEK-293 cells with the SHH expression plasmid and the pre-miR-453 resulted in significant inhibition of SHH mRNA and protein expression, while the transfection of SHH expression plasmid with the antagomirs had no effect on the SHH mRNA and protein expression.

Conclusion: Our findings indicate that miR-453 regulates the expression of SHH in OA chondrocytes by directly targeting its coding sequence. This provides an important and novel perspective for developing therapeutic strategies to treat OA.

2438

The Unfolded Protein Response (UPR) Is Activated by Biomechanical Stress in Normal Cartilage Chondrocytes, but Priming of the UPR Prior to Mechanical Stress Results in Increased Cartilage Catabolism. Matthew R. Husa[1], Freyr Petturson[1], Ron June[1], Shawn Grogan[2], Darryl D'Lima[2], Martin K. Lotz[2], Ru Liu-Bryan[1] and Robert Terkeltaub[1]. [1]UCSD/VAMC, La Jolla, CA, [2]The Scripps Research Institute, La Jolla, CA

Background/Purpose: Mechanical stress can result in either catabolism or anabolism of cartilage matrix by chondrocytes. To investigate the role of mechanical stress in chondrocyte survival and matrix metabolism, we studied the UPR, a fundamental means by which cells successfully resolve stress by controlling protein translation and folding. Three UPR signaling/proteolytic cascades are triggered by dissociation of distinct ER membrane proteins from the chaperone GRP78, which normally dampens the UPR, limits apoptosis, and promotes autophagy. Generation of the UPR-specific transcription factor XBP1s (spliced XBP1) and terminal expression of CHOP are key events. Unsuccessful UPR resolution promotes oxidative stress, inflammation, and apoptosis. Sustained UPR activation (priming) results in increased sensitivity to cell stress. We tested the hypothesis that mechanical stress activates the UPR in chondrocytes, and priming the UPR prior to mechanical stress increases cartilage catabolism.

Methods: Normal bovine knee chondrocytes were placed into 3-D alginate matrix molds and subjected to cyclic compressive forces (maximum compression 22% height, 12% amplitude at 0.5Hz) in a unique biomechanical reactor. Cell death, GAG release and NO production (Griess assay) were measured, and various UPR mediators (GRP78, CHOP) were compared.

Results: Alginate-embedded chondrocytes stimulated with sub-lethal cyclic compressive stress demonstrated rapid increase (over 1–7 days post compression) in GRP78 and CHOP. High-level UPR activation via tunicamycin (UPR activator) prior to mechanical stress induced elevated GAG and NO release beyond that with compression alone ($p<0.05$), although tunicamycin (without injury) had no effect on matrix catabolism.

Conclusion: To our knowledge, this is the first demonstration of UPR activation by mechanical stress in chondrocytes. Moreover, sustained activation of the UPR prior to mechanical stress significantly promotes cartilage matrix catabolism, suggesting that cell stresses known to activate the UPR (inflammatory cytokines, reactive oxygen species, etc) act in concert with mechanical stress to promote catabolic activity in chondrocytes. Thus, UPR dysregulation (or prolonged activation) may be a key event promoting a catabolic phenotype in osteoarthritic chondrocytes. Taken together, these data provide new insights into the regulation of cartilage matrix catabolism, and indicate a primary role of the UPR in OA pathogenesis and chondrocyte mechanotransduction.

Giant Cell Arteritis Is Associated with Incident Coronary Heart Disease-A Population-Based Study. Gunnar Tomasson[1], Johannes Bjornsson[2], Michael P. LaValley[3], Yuqing Zhang[1], Vilmundur Gudnason[4] and Peter A. Merkel[1]. [1]Boston University School of Medicine, Boston, MA, [2]Landspitali University Hospital, Reykjavik, Iceland, [3]Boston University School of Public Health, Boston, MA, [4]The Icelandic Heart Association, Kopavogur

Background/Purpose: There are well-established associations between several systemic inflammatory diseases, including rheumatoid arthritis and systemic lupus erythematosus, with coronary heart disease (CHD). Few studies have described the association between giant cell arteritis (GCA) and CHD. The objective of this study was to determine the association of GCA with CHD in a well-defined population cohort with detailed information on cardiovascular risk factors regardless of exposure status.

Methods: Data from the Reykjavik Study (RS), a population-based prospective study with a primary focus on cardiovascular disease, were used. All persons born in 1907–1935 that were living in Reykjavik, Iceland or in adjacent communities on December 1st 1967 were invited to participate. Subjects came for a study visit in 1967–1996 and information on cardiovascular risk factors, including smoking, blood pressure, diabetes mellitus, body mass index, and serum cholesterol was obtained in a protocolled manner. Temporal artery biopsies (TAbx) were identified for all subjects in the RS in all three pathology laboratories in Iceland during the period 1961–2009. All TAbx were examined in a protocolled fashion by a single pathologist with expertise in vascular pathology. Subjects met exposure criteria for GCA at the date on which a TAbx diagnostic of GCA was obtained. In the RS, there was a continuous surveillance for CHD, defined as myocardial infarction, percutaneous coronary intervention, coronary artery bypass grafting, or sudden cardiac death, until December 31, 2006. Cox proportional hazards regression models were used with GCA status included as a time-varying predictor. Subjects with GCA were considered unexposed until the time they met exposure criteria. Adjustments were done for age, sex, and cardiovascular risk factors.

Results: 19,360 subjects participated in RS, of who 424 subjects were excluded for this study (412 subjects with CHD at baseline and 12 with a TAbx diagnostic of GCA prior to baseline). The 18,936 included subjects had a mean age of 53.5 years (standard deviation (sd): 9.7 years) and 52.2% of subjects were female. TAbx was performed in 678 (3.6%) prior to December 31, 2006 and was diagnostic for GCA in 185 subjects. The 185 subjects with GCA had a mean age at diagnosis of 73.0 years (sd: 6.8, range 55.3–90.0 years) and 129 (69.7%) were females. The median time from study visit to diagnosis of GCA was 18.0 years (inter-quartile range

(IQR): 10.4–24.9). Median follow-up time was 23.7 years (IQR: 15.7–31.3). During follow-up 5,192 (27.4%) of the 18,936 subjects had incident CHD, including 51 (27.6%) of 185 subjects with GCA. Subjects with GCA had increased risk of incident CHD after adjustment for age and sex with HR=1.57 (95% confidence interval (CI): 1.14–2.16). This effect estimate was only minimally attenuated after adjustment for cardiovascular risk factors: HR=1.49 (95% CI: 1.06–2.09).

Conclusion: Compared with the general population, patients with biopsy-proven GCA have an increased risk of incident CHD, even after adjustment for cardiovascular risk factors.

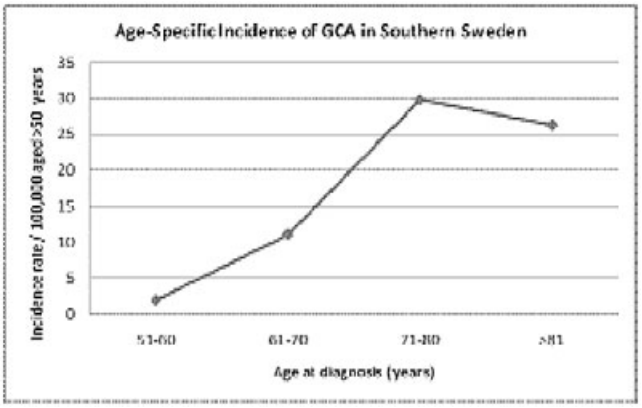
2440

Incidence, Prevalence, and Mortality Rates of Biopsy-Proven Giant Cell Arteritis in Southern Sweden. Aladdin Mohammad[1], Jabbar Mohammad[1], Jan-Åke Nilsson[2], Lennart TH Jacobsson[2], Peter A. Merkel[3] and Carl Turesson[2]. [1]Skåne University Hospital, Lund, Sweden, [2]Skåne University Hospital, Malmö, Sweden, [3]Boston University School of Medicine, Boston, MA

Background/Purpose: To study the epidemiology and survival rates in patients with biopsy-proven giant cell arteritis (GCA) in a well defined population in southern Sweden.

Methods: The study area was the County of Skåne with a total population of 1,243,000 as of December 2010 (36% aged ≥50 years). Patients who underwent temporal artery biopsy (TAB) between 1997 and 2010 and lived in Skåne at time of biopsy were identified using the database at the Departments of Pathology serving the County of Skåne. Only patients with TAB-positive GCA were included in the statistical analysis. Standardized mortality ratios (SMR) were calculated using age- and sex-specific mortality data for the Swedish population as the reference.

Results: A total of 3,510 TABs (2,420 women) were identified. There were 792 patients with TAB-positive GCA (23%). The median age at diagnosis was 76.0 years [Interquartile range (IQR) 69.8–81.1)] for all patients; 75.8 (IQR 69.2–81.2) for men and 76.0 (IQR 70.0–81.1) for women. The annual incidence rate per 100,000 inhabitants aged ≥50 years (total 454,356 inhabitants), was 13.3 (95% CI 12.3–14.2); 7.2 (6.2–8.2) for men and 18.5 (17.0–20.0) for women. The incidence rates increased with older age up to the age of 80, with estimates of 2.0, 11.1, and 29.8 per 100,000 in the age groups 51–60, 61–70, 71–80 years, respectively ($p<0.001$). There was no further increase in the group aged ≥81 years vs. the 71–80 years age group (26.3/100,000), Figure.



As of January, 1, 2011 there were 517 patients (387 women) alive and living within the County of Skåne with a previous TAB positive for GCA. The corresponding point prevalence per 100,000 inhabitants aged ≥50 years was 114 (95% CI 104–124); for men 61 (50–71) and for women 162 (145–178). The median time of follow-up for all patients from diagnosis to March 1, 2011, or death was 60.2 months (IQR 23.8–100.8). Two hundred and fifty-one patients (184 women) died during this follow-up period. For all patients, the absolute survival rate was 92 % at 1 year, 77 % at 5 years and 54 % at 10 years. Mortality during the first 5 years of follow-up was similar to the background population [SMR 1.03 (95 % CI 0.86–1.20)]. The estimated SMR was slightly higher for men: 1.14 (0.82–1.47) as compared to 0.98 (0.78–1.18) for women. With extended follow-up, overall mortality rates among GCA patients remained similar to the expected. In analyses stratified by age, those ≤70 years at diagnosis had a significantly increased mortality [SMR during the first 5 years of follow-up: 1.82 (1.04–2.95)].

Conclusion: The annual incidence rates of GCA in Southern Sweden were comparable with other studies of European populations and increased with age. The prevalence of GCA in Sweden is the highest prevalence for this disease ever reported. Overall, the survival of patients with TAB-positive GCA was similar to that of the general population, but patients diagnosed at age ≤70 years had a significantly increased mortality.

2441

Prevalence and Demographics of Systemic Lupus Erythematosus and Lupus Nephritis Among U.S. Adults with Medicaid Coverage, 2002–2004. Candace H. Feldman[1], Linda T. Hiraki[2], Daniel H. Solomon[1], Tamara Shaykevich[1], Michael A. Fischer[1], Wolfgang C. Winkelmayer[3] and Karen H. Costenbader[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital/ Harvard School of Public Health, Boston, MA, [3]Stanford University School of Medicine, Stanford, CA

Background/Purpose: Past estimates of the prevalence of systemic lupus erythematosus (SLE) in the general U.S. population have ranged from 40 to 150/100,000. Lupus nephritis (LN) occurs in 20–60% of adults with SLE. No information is available on the prevalence and sociodemographics of SLE and LN among adults with Medicaid, the joint federal-state program providing health insurance to low-income individuals. African Americans have higher rates of SLE and LN and are also disproportionately covered by Medicaid. We examined the nationwide prevalence and sociodemographics of SLE and LN among adult Medicaid beneficiaries.

Methods: Individuals aged 18 through 65 with SLE (≥ 2 visits with ICD-9 code 710.0) were identified from the Medicaid Analytic eXtract (MAX), which contains all inpatient and outpatient claims from 49 states and Washington, D.C., 2002–2004. LN was identified from billing codes for ≥ 2 ICD-9 codes for glomerulonephritis, proteinuria and renal failure (PPV 88%; Chibnik et al., 2009). The prevalence of SLE and LN among adults with Medicaid was calculated with 95% confidence intervals among different sociodemographic categories. Crude prevalence ratios were also calculated.

Results: From 18,646,925 adults who were Medicaid beneficiaries between January 1, 2002 and December 31, 2004, we identified 31,018 subjects with SLE (prevalence = 166/100,000). Of these, 93% were female; 38% White, 37% African American, and 12% Hispanic (**Table 1**). The prevalence of SLE was 6 times higher among women than men. African Americans and Native Americans were almost twice as likely to have SLE compared with Whites. The prevalence was highest in the U.S. South for Whites and African Americans, and highest in the U.S. West for Asians and Hispanics. A total of 6,285 (20%) had LN (prevalence = 34/100,000). Women had a 4 times higher prevalence of LN than men. The prevalence of LN was higher among African Americans, Hispanics, Asians and Native Americans than among Whites.

Table 1. Prevalence of SLE and Lupus Nephritis per 100,000 among U.S. Medicaid Beneficiaries aged 18–65 (2002–2004)

	SLE*	Prevalence Ratio	Lupus Nephritis*	Prevalence Ratio
Total	166 (165–168)	-	34 (33–35)	-
Men	37 (35–39)	Referent	11 (10–12)	Referent
Women	220 (218–223)	5.9	43 (42–44)	4.1
Non-Hispanic Whites	130 (127–132)	Referent	19 (18–19)	Referent
African Americans	256 (251–261)	2.0	65 (63–68)	3.5
Asians	107 (99–116)	0.8	33 (29–39)	1.8
Hispanics	134 (130–138)	1.0	29 (27–31)	1.6
Native Americans	239 (225–254)	1.8	56 (49–63)	3.0
Northeast	136 (132–139)	Referent	27 (25–28)	Referent
South	197 (194–201)	1.5	41 (40–43)	1.5
Midwest	155 (151–159)	1.1	34 (32–36)	1.3
West	167 (163–171)	1.2	31 (29–32)	1.1

* Prevalence per 100,000 (95% CI)

Conclusion: From 2002–2004, the prevalence of SLE in the U.S. Medicaid population was 166/100,000 and the prevalence of LN was 34/100,000. We identified considerable sociodemographic variation in the prevalence of SLE and LN. Our estimates are slightly higher than previously reported estimates that were not restricted to Medicaid beneficiaries. Additional studies are needed to determine whether SLE and LN are more common than previously estimated, or whether the low socioeconomic status populations served by Medicaid are at elevated risk.

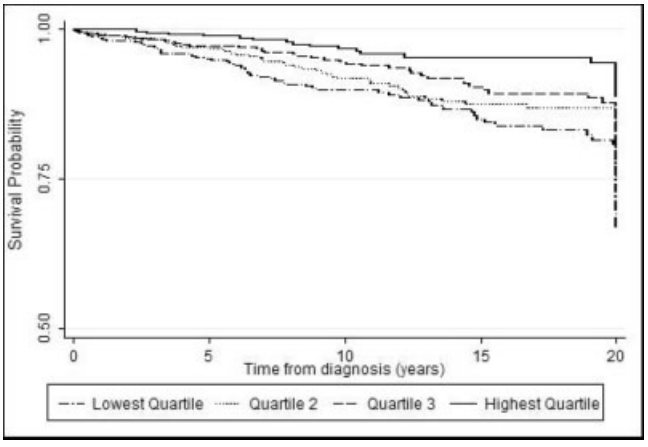
2442

Socioeconomic Status and Survival in Systemic Lupus Erythematosus: Results From the Michigan Lupus Epidemiology and Surveillance (MILES) Program. Sarah M. Barnhart[1], W. Joseph McCune[1], Wendy Marder[1], Patricia C. Cagnoli[1], Emily E. Lewis[1], Peter DeGuire[2], C. Gordon[3], Charles G. Helmick[4], J. Patricia Dhar[5], James C. Leisen[6], Emily C. Somers[1] and MILES Group[7]. [1]University of Michigan, Ann Arbor, MI, [2]MI Dept of Community Health, Lansing, MI, [3]University of Birmingham, Birmingham, United Kingdom, [4]Centers for Disease Control and Prevention, Atlanta, GA, [5]Wayne State University, Detroit, MI, [6]Henry Ford Hospital, Detroit, MI, [7]Ann Arbor, MI

Background/Purpose: Socioeconomic status (SES) has been demonstrated to impact survival among many chronic disease conditions. We performed this analysis to determine if area-based SES was independently associated with survival among systemic lupus erythematosus (SLE) patients from a diverse, population-based setting.

Methods: MILES is a population-based, active SLE surveillance program utilizing multiple sources of case-finding to identify prevalent SLE cases in Washtenaw & Wayne Counties, MI (2002–2005). Detailed record reviews are performed for potential cases meeting eligibility criteria. This analysis used a case definition based on the "gold standard" of rheumatologist investigator judgment ("definite SLE"). Each case was assigned a previously validated area-based SES index score based the sum of standardized scores of 7 census economic indicators (median household income, proportion with income $<$ 200% of fed poverty level, median house value, median monthly rent, mean education level, proportion of college graduates among ages $\geq$ 25 yrs, and proportion of employed persons with a professional occupation) linked to zip code of residence at baseline. Survival was determined by linkage to the MI Vital Statistics Database. Left-truncated Cox proportional hazards modeling was used to evaluate the association between survival and SES. Race, gender, smoking status, age of diagnosis, and number of ACR criteria were included as covariates relevant to survival.

Results: The 1945 cases (mean age at diagnosis 40.4 yrs; 62% African American, 34% White; 90% female) had a median follow-up time of 10.3 yrs since diagnosis. A total of 192 (10%) deaths occurred during follow-up. After adjustment for age at diagnosis, race, sex, smoking status, and total number of ACR criteria, SES was independently associated inversely with survival, both when SES was modeled continuously (HR 0.9, 95% CI 0.9–1.0; p=0.0486) or as quartiles (HRs vs quartile 1: Q2 0.8, Q3 0.7, Q4 0.6; test of trend p=0.0415). The following variables were also associated with reduced survival, after adjustment for all other covariates in the model: black race (white race referent: HR 2.7, 95% CI 1.8–4.2), male sex (HR 1.9, 95% CI 1.3–3.0), "ever" smoker status ("never" referent: HR 1.5, 95% CI 1.1–2.0), and increasing number of ACR criteria (HR=1.1, 95% CI: 1.0–1.2).



Kaplan-Meier survival estimates for SLE by quartile of SES index score

Conclusion: Area-based SES is independently associated inversely with survival in SLE patients from the general population; for each unit decrease in area-based SES score, survival was reduced by 10%. Black race, male sex, smoking, and an increasing number of ACR criteria were independently associated with the reduced survival. Similarly to other chronic disease outcomes, our results add to a growing body of evidence that low SES is associated with reduced survival among SLE patients.

The Natural History and Predictive Factors of Long Term Outcomes in Systemic Lupus Erythematosus. Penny Watson[1], Alan Brennan[1], Helen Birch[2], Hong Fang[3] and Michelle Petri[3]. [1]University of Sheffield, Sheffield, United Kingdom, [2]GlaxoSmithKline, Uxbridge, United Kingdom, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Statistical models are often used to extrapolate patient outcomes beyond the clinical trial period for cost-effectiveness analyses. The aim of this study was to develop and test a set of statistical models to describe the natural history of Systemic Lupus Erythematosus (SLE) that can be used in health economic evaluations.

Methods: Longitudinal data from a cohort of 1354 patients with median follow-up of 10 years were included in the analysis. At clinic visits that were scheduled every 3 months, data were collected on SLE Disease Activity Index (SLEDAI), treatment, Systemic Lupus International Collaborative Clinics/American College of Rheumatology Damage Index (SLICC/ACR DI) events, and laboratory tests. Independent statistical models were run to describe the disease. Change in SLEDAI score was estimated as a function of gender, ethnicity and binary variables to indicate renal involvement, increased DNA binding, low complement, haematological involvement or anaemia using a linear random effects model. Average prednisone dose was estimated as a function of SLEDAI score with random effects. Organ damage and mortality were estimated as a function of Adjusted Mean SLEDAI (AMS), cumulative average prednisone dose, indicator variables for organ system involvement, and other risk factors associated with long-term outcomes using parametric survival models. A simulation model combined the separate statistical models to reproduce the cohort to assess the validity of the natural history predictions.

Results: The disease activity model found that previous SLEDAI, age, ethnicity, increased DNA binding, low complement and organ involvement significantly affected future SLEDAI score. In the prednisone model a unit increase in average SLEDAI increased average prednisone dose increased by 0.77mg per day. Risk of mortality, cardiovascular, renal and peripheral vascular damage increased with higher AMS ($p<0.1$). Organ involvement predicted mortality, cardiovascular, renal, neuropsychiatric, pulmonary, gastrointestinal, ocular, and skin damage. Corticosteroids increased the risk of gonadal failure, diabetes, cardiovascular, musculoskeletal, neuropsychiatric, and gastrointestinal damage. The simulation reproduced the baseline characteristics and patient outcomes reported in the cohort. Figure 1 illustrates the proportion of patients who died or reported organ damage in the cohort and simulated cohort.

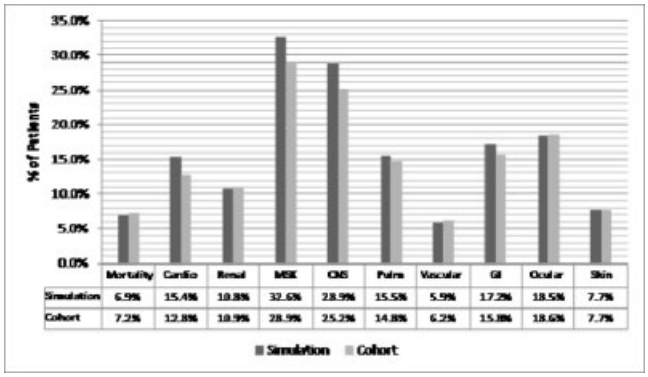

Figure. The proportion of patients who recorded mortality or organ damage at time of withdrawal from cohort or simulation.

Conclusion: The analysis generated a natural history model that could be used to extrapolate patient outcomes beyond a clinical trial and to estimate the long term benefits of reducing disease activity and steroid exposure. This can be used to estimate the effectiveness and cost-effectiveness of new treatments for SLE.

2444

The Georgia Lupus Registry: The Incidence and Prevalence of Systemic Lupus Erythematosus. S. Sam Lim[1], Rana Bayakly[2], C. Gordon[3], Charles G. Helmick[4], Kirk Easley[5], Gaobin Bao[1], Neeta Shenvi[5] and Cristina M. Drenkard[1]. [1]Emory University, Atlanta, GA, [2]Georgia Department of Public Health, Atlanta, GA, [3]University of Birmingham, Birmingham, United Kingdom, [4]Centers for Disease Control and Prevention, Atlanta, GA, [5]Emory University-Rollins School of Public Health, Atlanta, GA

Background/Purpose: US epidemiologic estimates of SLE are outdated and have varied widely due to the use of different case definitions, limited sources for case ascertainment, and small source populations. The Georgia Lupus Registry (GLR) is a population-based registry designed to more accurately estimate the incidence and prevalence of SLE for blacks and whites in the two counties (Fulton and DeKalb) that include Atlanta, Georgia.

Methods: The state HIPAA exemption for surveillance allowed health care providers and facilities to provide access to protected health information without written patient consent. Sources of cases included hospitals (20), rheumatologists (35), nephrologists (10), dermatologists (20), commercial labs, and population databases. Trained abstractors reviewed >8,000 medical records identified as possibly having SLE. Incidence rates (per 100,000 person years) were determined for years 2002–2004 and prevalence rates (per 100,000) for 2002. Definite cases had ≥4 ACR criteria; probable cases had 3 ACR criteria plus a final diagnosis of SLE by a rheumatologist. Rates were age adjusted using the 2000 projected US population. Age adjusted estimates and 95 % confidence intervals were calculated by the direct method using R (routine ageadjust.direct).

Results: Prevalence of SLE (2002)

		Definite		Definite + Probable	
Race/ Sex	Population[1]	Cases (n)	Adjusted Rate (95% CI)	Cases (n)	Adjusted Rate (95% CI)
Total	1552970	1153	72.8 (68.6, 77.3)	1345	85.8 (81.2, 90.5)
Black	765475	889	118.5 (129.4, 127)	1021	138 (129.4, 147.2)
female	408642	806	196.2 (182.6, 210.7)	922	226.6 (211.9, 242.3)
male	356833	83	23.7 (18.5, 31.3)	99	29.2 (23.3, 37.4)
White	720292	251	32.7 (28.8, 37.2)	311	40.7 (36.3, 45.7)
female	352914	222	59 (51.4, 67.5)	276	73.3 (64.9, 82.7)
male	367378	29	7.5 (5, 11.2)	35	9.4 (6.4, 13.5)

Average annual incidence of SLE (2002–2004)

		Definite		Definite + Probable	
Race/Sex	3 year Population[1]	Cases (n)	Adjusted Rate (95% CI)	Cases (n)	Adjusted Rate (95% CI)
Total	4742264	266	5.6 (4.9, 6.3)	332	6.9 (6.1, 7.7)
Black	2321302	196	8.6 (7.4, 9.8)	245	10.7 (9.3, 12)
female	1239819	168	13.4 (11.4, 15.7)	215	17 (14.7, 19.5)
male	1081483	28	3 (1.9, 5.2)	30	3.3 (2, 5.4)
White	2210389	62	2.7 (2, 3.5)	77	3.3 (2.6, 4.2)
female	1082131	53	4.7 (3.5, 6.2)	66	5.8 (4.5, 7.5)
male	1128258	9	0.7 (0.3, 1.5)	11	0.8 (0.4, 1.7)

[1] US Census Bureau 2000, Vintage 2009
13 validated prevalent and 10 incident cases from other racial/ethnic groups were excluded.

Conclusion: The GLR is one of the most comprehensive epidemiologic efforts in SLE in the US and provides updated and more accurate incidence and prevalence rates in a large white and black population. Black women have significantly higher incidence than previously reported. Overall prevalence is also higher and may indicate longer survival and/or more frequent diagnosis. SLE continues to afflict significant numbers of people with a disproportionate burden on black women.

Rilonacept (Interleukin-1 Trap) for Treatment of Colchicine Resistant Familial Mediterranean Fever: A Randomized, Multicenter Double-Blinded, Alternating Treatment Phase II Trial. Philip J. Hashkes[1], Steven J. Spalding[2], Edward H. Giannini[3], Bin Huang[4], Grace Park[5], Karyl S. Barron[6], Michael H. Weisman[7], Noune Pashinian[8], Andreas Reiff[9], Jonathan Samuels[10], Dowain A. Wright[11], Daniel L. Kastner[12] and Daniel J. Lovell[4]. [1]Cleveland Clinic/Shaare Zedek Medical Center, Jerusalem, Israel, [2]Cleveland Clinic, Cleveland, OH, [3]PRCSG-Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]National Institutes of Health/NHGRI, Bethesda, MD, [6]NIAID-NIH, Bethesda, MD, [7]Cedars Sinai Med Ctr, Los Angeles, CA, [8]Glendale, CA, [9]PRSCG, Los Angeles, CA, [10]NYU Hospital for Joint Diseases, New York, NY, [11]Childrens Hospital Central Cal, Madera, CA, [12]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD

Background/Purpose: There is no proven treatment alternative for pts with familial Mediterranean fever (FMF) whose disease is resistant to, or do not tolerate colchicine. Since pyrin has an important role in IL-1β regulation we hypothesized that IL-1 inhibition would decrease the number of FMF attacks in these pts. We aim to determine if rilonacept, a fusion protein that binds and neutralizes IL-1, decreases the number of FMF attacks compared to placebo.

Methods: FMF pts ≥4 years of age with at least 1 FMF attack per month despite adequate doses of, or intolerant to colchicine were recruited at 6 U.S. sites. Pts received two 3-month courses of rilonacept (Arm A) at 2.2 mg/kg (max 160 mg) by weekly SC injection and two 3-month courses of placebo (Arm B). Pts were randomized to 1of 4 treatment sequences (ABAB, BABA, ABBA, BAAB). Escape visits were allowed to switch arms (blinding was maintained) for pts with at least 2 attacks within a course. The primary outcome was the difference in the frequency of FMF attacks between rilonacept and placebo courses. Responders were defined as pts with a >40% difference. Data were analyzed by signed rank tests and Bayesian methods.

Result: Fourteen pts were randomized, 8 males and 6 females, mean (±SD) age 24.4±11.8 yrs (range 4.5–47.3; 4 pts <18 yrs), disease duration 17.5±12.6 yrs, with 3.1±2.0 attacks per month at baseline. Eleven pts completed 12 months and 3 discontinued early (1 each due to lack of efficacy, distance from study site and lost to follow-up). Among the 12 pts who completed at least 2 treatment courses, the mean number of attacks per month was 1.0±1.2 on rilonacept vs. 1.8±0.9 on placebo (P=0.027). The risk ratio for attacks (ArmA/ArmB) by Bayesian analysis (consistent for all prior assumptions) was 0.57±0.17 (2.5–97.5 percentile estimates of 0.31–0.98, significant lower rate in Arm A). There were 8 responders; all 4 non-responders were adults. Significant exploratory outcomes include the number of treatment courses without attacks (29% Arm A vs 0% Arm B, P=0.004), courses with >50% decrease in attacks compared to baseline (75% Arm A vs 35% Arm B, P=0.006), the proportion of time pts were treated with Arm A (57.5%) vs Arm B (42.5%, P=0.05) and fibrinogen levels (P=0.04). No significant differences were seen in the proportion of days in attack (Arm A 0.15±0.2 vs Arm B 0.22±0.23, P=0.08), number of escape courses (25% Arm A vs 46% Arm B, P=0.13), patient/parent (P=0.07) and physician global assessment (P=0.14), the modified Armenian Severity Score (P=0.1) and other acute phase reactants. There were significant differences in physical but not psychosocial aspects of quality of life between treatment arms (P=0.01 and 0.64, respectively). The median time to develop 2 attacks was >90 days (not reached by end of course) in Arm A vs 36 days in Arm B (p=0.009). There were 2 respiratory infection SAEs, 1 on rilonacept and 1 on placebo. Injection site reactions were significantly more frequent with rilonacept (P=0.04) but no differences were seen in other adverse events, including infections.

Conclusion: Rilonacept significantly reduces the number of FMF attacks and has an acceptable safety profile. IL-1 inhibition is a treatment option for most colchicine resistant FMF pts and especially children.

Interleukin-1 Beta It Is: High Efficacy of Canakinumab In Schnitzler Syndrome. Heleen D. de Koning, Joost Schalkwijk, Johanna van der Ven-Jongekrijg, Monique Stoffels, Jos W. M. van der Meer and Anna Simon. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Schnitzler syndrome is a chronic disabling auto-inflammatory disorder, characterized by chronic urticaria, paraproteinemia and systemic inflammation. The effectiveness of the interleukin-1 receptor antagonist (IL-1ra) anakinra in over 40 cases to date implies a crucial pathophysiological role of IL-1, but does not discriminate between IL-1a and IL-1β. The burden of painful daily injections raised the need for longer-acting agents, and in vitro findings hinted at IL-1β as the principal proinflammatory cytokine involved in the pathophysiology. Canakinumab is a monoclonal anti-IL-1β antibody which requires administration only once every 4 to 8 weeks. It is effective in Cryopyrin-Associated Periodic Syndrome (CAPS), a rare hereditary autoinflammatory disorder caused by increased IL-1β activation, which has phenotypical similarities to Schnitzler syndrome. We therefore initiated a trial of canakinumab in Schnitzler syndrome to determine long-term safety and efficacy.

Methods: Upon ethical approval and patients' informed consent, we started an open-label trial (ClinicalTrials.gov NCT01276522) with canakinumab (150 mg subcutaneously once every 4 weeks) in eight patients with Schnitzler syndrome, either classical or variant type, for 6 months. In order to enter the study, the patients would stop their treatment with anakinra and report to us at time of recurrence of symptoms.

Results: The 6 men and 2 women (age 59–75) that were included had suffered from Schnitzler syndrome for 5 to 25 years, and had been asymptomatic on daily anakinra injections for 4 months to 7 years. Within 36 to 96 hours after stopping anakinra, the patients gradually developed general malaise, non-pruritic to burning urticaria, fever and arthralgia, as before initiation of anakinra. Four to six days after discontinuing anakinra, they presented with disseminated urticaria, arthralgia (arthritis in some), strongly elevated serum C-reactive protein (CRP) concentrations and neutrophilic leukocytosis. Upon a single subcutaneous injection of 150 mg canakinumab, their symptoms started to abate within 6–16 hours, and all were asymptomatic after two to seven days. CRP concentration dropped dramatically within the first week and remained low or undetectable. After an initial complete response, one patient quit the study because symptoms returned within four weeks and he did not want an increased dose. The others are still in complete remission. No serious adverse events occurred. The final patient will complete the 6 months study in September 2011 so full data will be available at time of presentation.

Conclusion: Monthly injection with canakinumab is an effective long-acting treatment of Schnitzler syndrome. This observation singles out IL-1β as the key cytokine responsible for inflammation in Schnitzler syndrome, thereby providing a pivotal pathophysiological clue for this enigmatic disorder and corroborating the evidence for its autoinflammatory nature.

Proteasome Disability Syndrome: An Analysis of the Pathogenesis of a New Autoinflammatory Syndrome, Nakajo-Nishimura Syndrome. Hiroaki Ida[1], Kazuhiko Arima[2], Nobuo Kanazawa[3] and Koh-ichiro Yoshiura[2]. [1]Kurume University School of Medicine, Kurume, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Wakayama Medical University, Wakayama, Japan

Background/Purpose: Nakajo-Nishimura syndrome (NNS) (MIM 256040) is a new autoinflammatory disorder that segregates in an autosomal recessive fashion and shows inflammatory and wasting symptoms including periodic fever, skin rash, myositis, partial lipodystrophy, contracture of joints and calcification of basal ganglia. The purpose of this study is to detect the responsible gene and to analyze the molecular features in cells from patients with NNS.

Methods: 1) Genomic DNA samples were analyzed with the SNP microarray-based homozygosity mapping following to determine the affected gene by direct sequencing. 2) Proteins from immortalized NNS lymphoblastoid cell lines were separated into fractions by glycerol gradient. Each fraction was assayed for 3 different peptidase activities of the proteasome, chymotrypsin-like, trypsin-like, and caspase-like activities, using the fluorescent peptide substrates. 3) An amount of proteasome subunits and accumulation of ubiquitinated proteins were detected by Western blotting. 4) Immunological staining was performed on skin biopsy sections obtained from NNS patients. 5) Concentrations of 27 different cytokines were determined using a multiplex bead-based enzyme linked immunosorbent assay on a suspension array in serum samples obtained from healthy controls (HC), rheumatoid arthritis (RA) patients, and NNS patients. 6) We investigated activation of the various signal transduction pathways that could be responsible for inflammation using EMSA and Western blotting.

Results: 1) We detected a homozygous mutation in the human *PSMB8* gene that encodes immunoproteasome subunit β5i in patients with NNS. 2) The resultant amino acid substitution (G201V) abolished all three peptidase activities of proteasome and 3) disturbed maturation of the immunoproteasome complex. 4) Accumulation of ubiquitinated proteins was detected in the NNS lymphoblasts and infiltrating cells in the skin lesion of patients with NNS. 5) The productions of inflammatory cytokine (IL-6) and chemokine (IP-10) were seen in greater numbers in sera from NNS patients compared to HC and RA. 6) While no differences in the amount of the NF-kB p65/p50 heterodimer were observed in nuclear extracts from NNS and HC fibroblasts, the amounts of phosphorylated p38 (p-p38) in the nuclear extracts from NNS fibroblasts and peripheral blood leukocytes were seen in larger amounts, irrespective of TNF-α stimulation.

Conclusion: Our findings reveal that a decrease in proteasome activity, which is associated with a novel mutation of the β5i immunoproteasome subunit, causes definitive human autoinflammatory phenotypes in NNS. This fact suggests that the ubiquitin-proteasome pathway might play an important role for inflammation and provides a new insight into the pathogenesis of other persistent inflammatory diseases.

Progressive Multifocal Leukoencephalopathy Associated with Immunosuppressive Therapy in Rheumatic Diseases: Evolving Role of Biologic Therapies. Eamonn S. Molloy[1] and Leonard H. Calabrese[2]. [1]St Vincent's University Hospital, Dublin 4, Ireland, [2]Cleveland Clinic, Cleveland, OH

Background/Purpose: Progressive Multifocal Leukoencephalopathy (PML) is a rare and often fatal opportunistic infection recently associated with several biologic therapies. However, ascribing risk to individual therapies has been problematic. This study examined the aggregate experience of PML reported in association with autoimmune rheumatic diseases (ARD) in the FDA Adverse Event Reporting System (AERS) database.

Methods: A Freedom of Information Act request was submitted for all cases of PML and/or JC virus infection within the FDA AERS database, updated through March 31, 2010. MedWatch forms with identified ARD were selected for further analysis. PML was classified as confirmed or unconfirmed, based on results of cerebrospinal fluid analysis and/or brain biopsy. Relevant data collected included drug treatment and disease association cofactors of PML.

Results: 30 confirmed cases of PML in the setting of ARD were identified (16 SLE, 9 RA, 5 other). Of these, 15 were treated with biologic agents (14 rituximab (RTX), 6 anti-TNF therapy). RTX was the most recent biologic treatment for ARD in all 14 confirmed cases associated with its use; 5 patients were treated with anti-TNF therapy prior to RTX. PML developed after a median of 2 courses of RTX (range 1–4). The median interval between the first and last infusion of RTX and the development of PML was 12 months (range 1–59) and 5 months (range 0–29), respectively. Two RTX-treated patients were receiving no other immunosuppressive therapy at the apparent time of onset of PML; all other biologic-treated patients were also receiving one or more synthetic disease-modifying agents. Three biologic-treated patients (2 RTX, 1 infliximab) were concomitantly receiving CYC at the time of onset of PML; three additional RTX-treated patients had previously received CYC. Two RTX-treated patients had received chemotherapy for malignancy (1 oropharyngeal cancer, 1 MALT lymphoma). No confirmed cases of PML were reported in association with the use of other biologic agents such as tocilizumab, anakinra or abatacept. The remaining 15 confirmed cases of PML among ARD patients were treated with synthetic DMARDs only. 12 of these had received an alkylating agent (10 CYC, 2 chlorambucil), in 9 cases this was ongoing at the time of development of PML. Of the 30 confirmed cases of PML, 13 were treated with azathioprine and 7 with mycophenolate mofetil.

Conclusion: PML is a reported complication of various ARD and associated with both synthetic and biologic immunosuppressive therapies. Definitive attribution of causality is not possible given the small numbers of cases, potential for reporting bias and existence of confounders in many cases. However, the relative paucity of confirmed cases in patients recently treated with anti-TNF therapy, despite their widespread use, suggests that a causal relationship is unlikely. In contrast, there is an increasing, specific signal emerging regarding the association between RTX and the development of PML. Although this is a rare complication, continued vigilance is mandated by the devastating nature of PML, particularly in patients with current or prior exposure to an alkylating agent.

2449

Pulmonary and Extrapulmonary Recurrence of Sarcoidosis After Lung Transplantation. Fariha Kausar[1], Troy K. Takagishi[1], Rochella A. Ostrowski[2] and Rodney Tehrani[3]. [1]Loyola University Medical Center, Maywood, IL, [2]Loyola Univ Medical Ctr, Maywood, IL, [3]Loyola Univ Medical Center, Maywood, IL

Background/Purpose: Sarcoidosis accounts for 2.8% of lung transplants (LT) in the United States. It has been reported to be the most frequently recurring disease after LT. Although recurrence of pulmonary sarcoidosis has been estimated to be as high as 47% following LT, multiple studies have suggested that outcomes for sarcoidosis patients undergoing LT are equivalent to those of overall transplant patients. A review of literature revealed no studies documenting extra-pulmonary recurrence of sarcoidosis following LT. We predict that pulmonary and

extra-pulmonary recurrence of sarcoidosis after LT is frequent. We hypothesize that survival rates are similar in patients undergoing LT due to sarcoidosis (LT/sarcoidosis) compared to patients undergoing LT due to COPD (LT/COPD).

Methods: We performed an observational and retrospective chart review of all patients with LT/sarcoidosis at a large tertiary care medical center between 1992–2010. We searched for any histologic recurrence of pulmonary sarcoidosis on surveillance lung biopsies done after LT, as documented by the presence of non-caseating granulomas. We also searched for possible extra-pulmonary recurrence of sarcoidosis after LT, by doing extensive chart reviews of patients' follow up visits. We then plotted out survival outcomes of LT/sarcoidosis and compared them to survival outcomes of LT/COPD in the UNOS national registry from 1/1/91 to 12/31/09. COPD was chosen as the control group because it comprises the largest group of patients undergoing LT in the United States.

Results: From 1992–2010, 29 patients underwent LT at a large tertiary care medical center for end-stage pulmonary sarcoidosis. 6/29 (20.6%) patients had pulmonary recurrence of sarcoidosis, documented as non-caseating granulomas on surveillance lung biopsies. This equates to 1 episode of pulmonary recurrence/16.95 patient-years. 5/29 (17.2%) patients had possible extra-pulmonary recurrence of sarcoidosis. This equates to 1 episode of extra-pulmonary recurrence/20.34 patient-years. The Kaplan-Meier survival curves for LT/sarcoidosis and LT/COPD respectively at 30 days was 89.6% and 95.3%, at 1 yr was 89.6% and 83.1%, at 3 yrs was 74% and 65.3%, and at 5 years was 61.7% and 49.8%. Survival rates between the two groups were compared using the Chi-square test and found to be statistically insignificant.

Conclusion: To the best of our knowledge, there is no literature documenting extra-pulmonary recurrence of sarcoidosis after LT. Survival outcomes for LT/sarcoidosis patients have been shown to be equivalent to those of overall transplant patients. We found that both pulmonary and extra-pulmonary recurrence of sarcoidosis is frequent after LT. Pulmonary recurrence was histologic and not necessarily of clinical relevance. We found that survival rates did not differ significantly between the LT/sarcoidosis and LT/COPD groups. In LT/sarcoidosis patients, we found that early mortality is high, a finding also cited by other studies. Although recurrence is frequent, LT remains a feasible option for patients with end-stage pulmonary sarcoidosis.

2450

TNFRSF1A and MFEV Mutations in Idiopathic Recurrent Acute Pericarditis. Guillaume Geri[1], Pierre Hausfater[2], Catherine Dodé[3], Nathalie Costedoat-Chalumeau[1], Zahir Amoura[1], Jean-Charles Piette[1], Damien Sène[1], David Saadoun[4] and Patrice Cacoub[1]. [1]CHU Pitié-Salpêtrière, Paris, France, [2]Department of Emergency, CHU Pitié Salpetriere, 47–83 Boulevard de l'hôpital, 75651 Paris cedex 13 France, Paris, France, [3]Biochemistry and Molecular Genetic, CHU Cochin, rue du Faubourg Saint Jacques, 75014 Paris, France, Paris, France, [4]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France

Background/Purpose: Recurrent acute pericarditis (RAP) is the most common complication of acute pericarditis. The etiological search is often inconclusive and up to 85% of RAP are idiopathic. Serosal membrane inflammation is a common feature of hereditary periodic fever syndromes (HPFS) such as Familial Mediterranean Fever (FMF) and tumour necrosis factor receptor-1 associated periodic syndrome (TRAPS). Genetic biomarkers of HPFS are helpful, i.e. mutations of MFEV for FMF and TNFRSF1A for TRAPS. We aimed at assessing the prevalence of HPFS genetic markers in idiopathic RAP.

Methods: Consecutive patients with idiopathic RAP, defined as > 2 episodes of pericarditis and a negative check-up, from a French tertiary hospital were included. Mutations of MFEV and TNFRSF1A were searched for by amplifying (PCR) genomic DNA and direct sequencing. Epidemiological, clinical and biological features, and therapeutic response were compared in RAP patients presenting with and without HPFS mutations.

Results: 81 patients (mean age at first RAP diagnosis 41.6 ± 18 years; F/M sex ratio 0.44) were included, 45 (55.6%) patients were European and 6 (7.4%) North African. A familial history of pericarditis was noted in one case. The mean number of RAP episodes per patient was 4.0 ± 2.5. An increase of inflammation biomarkers was evidenced in 30/81 (37.0%) patients. RAP was associated with extra-cardiac symptoms in 30 (37.0%) patients, mainly pleural effusion (n=12) and joint involvement (n=8).

A MFEV mutation was evidenced in 6/39 (15.4%) patients, i.e. heterozygous M694V (n=2), heterozygous M694I (n=1) and heterozygous E148Q (n=3). A TNFRSF1A mutation was evidenced in 6/38 (15.8%) patients, i.e. heterozygous R92Q (n=4), heterozygous P46L (n=1) and homozygous R92Q (n=1). None patient had a mutation on both TNFRSF1A and MFEV.

Before colchicine treatment, patients with compared to those without HPFS mutations had a higher number of RAP episodes (4.8 ± 3.5 vs. 4.0 ± 1.7; $p=0.95$). After colchicine treatment, a PAR relapse was evidenced more frequently in patients with compared to those without HPFS mutation [5/12 (41.7%) vs. 4/27 (20%); $p=0.10$].

Conclusion: Patients with "idiopathic" recurrent acute pericarditis showed high prevalence of hereditary periodic fever syndrome genetic mutations. A higher frequency of pericarditis relapse seems to be associated with the presence of such mutations.

Predictors of Organ Damage Despite Serologic Remission in a Subset of Patients with Neonatal-Onset Multisystem Inflammatory Disease (NOMID). Cailin H. Sibley[1], Nicole Plass[1], Carmen Brewer[2], Kelly King[2], Christopher Zalewski[2], H. Jeffrey Kim[2], Rachel Bishop[3], Patrick Kicker[1], Zachary Phillips[1], Joseph G. Dolan[1], Deborah Stone[4], Dawn C. Chapelle Neal[1], Christopher Snyder[1], John Butman[5], Robert Wesley[5] and Raphaela T. Goldbach-Mansky[1]. [1]NIAMS/NIH, Bethesda, MD, [2]NIDCD/NIH, Bethesda, MD, [3]NEI/NIH, Bethesda, MD, [4]NHGRI/NIH, Bethesda, MD, [5]NIH, Bethesda, MD

Background/Purpose: NOMID, caused by mutations in *NLRP3*, results in organ-specific and systemic inflammation with elevated serum inflammatory markers. While patients universally respond to therapy with IL-1 blocking medications, organ damage progresses in a subset of patients.

Methods: 26 patients were treated with anakinra (IL-1 receptor antagonist) for a minimum of 36 months. Clinical and laboratory parameters were measured at scheduled intervals.

Results: Patients frequently relapsed and remitted from inflammatory control with serum remission (CRP$<$0.5 mg/dl) observed in 51.6% of the study visits. At 36 months, 11/25 patients had elevated leukocytes in the CSF ($>$ 5 cells/ml) obtained by lumbar puncture (LP). Of these patients, 7/11 (63.6%) had normal CRP values compared to 8/14 (57.1%) without CSF leukocytosis. Of the patients without leptomeningeal enhancement on MRI, CSF leukocytosis was seen in 12/15 (80%) at baseline and 6/19 (31.8%) at 36 months suggesting that imaging is not as sensitive as LP to detect aseptic meningitis in this cohort. The majority of patient ears (36/44, 81.8%) did not worsen by ASHA criteria over 36 months, while 8/44 ears (18.2%) from 7 patients showed worsening. Patients with worsened ears had a higher mean CRP over the first 36 months of the study at 1.68 compared to 0.89, $p=0.0172$ and inner ear inflammation as manifested by cochlear enhancement on gadolinium-enhanced MRIs was higher for ears that worsened compared to those that did not worsen (0.478 ± 0.104 vs. 1.229 ± 0.284, $p=0.0161$). The mean deviation on automated visual field testing across all patients was stable over the examination period except in two patients where their four eyes worsened by greater than 10% over the treatment period in the absence of clinically detectable intraocular inflammation. In both patients optic nerve thickness was severely decreased at baseline. Mean visual field deviation scores per eye at three years strongly correlated with optic nerve thickness (Pearson correlation = 0.59, $p=0.016$, n = 16).

Conclusion: Control of disease at the serum level is inadequate to prevent further organ damage in some patients with severe NOMID. Low grade CNS

inflammation and progressive hearing loss can occur in some patients even when serum markers are low. Inner ear MRIs are non-invasive tools to monitor cochlear inflammation. Our data suggest that monitoring of inflammatory organ manifestations is necessary to guide treatment decisions and prognostic estimates in NOMID. These data suggest that aggressive dose escalation of IL-1 blocking therapy to control systemic and organ specific inflammation is necessary to prevent progressive organ damage in patients with severe NOMID.

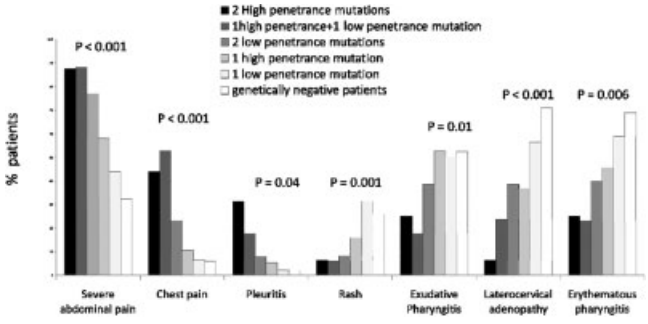
Impact of *MEFV* Mutations in Caucasian Children with Periodic Fevers: Clinical Evidence for a Gain of Function Effect. Silvia Federici[1], Giuseppina Calcagno[2], Martina Finetti[3], Romina Gallizzi[4], Antonella Meini[5], Agata Vitale[2], Francesco Caroli[1], Marco Cattalini[5], Roberta Caorsi[1], Francesco Zulian[6], Alberto Tommasini[7], Antonella Insalaco[8], Maria Pia Sormani[9], Maurizia Baldi[10], Isabella Ceccherini[1], Alberto Martini[3] and Marco Gattorno[1]. [1]G. Gaslini Institute, Genova, Italy, [2]Sezione di Reumatologia Pediatrica, Università di Messina, Messina, Italy, [3]IRCCS G Gaslini, Pediatria II, Reumatologia, Genova, Italy, [4]Sezione di Immunologia e Reumatologia Pediatrica, Università di Messina, Messina, Italy, [5]Dipartimento di Pediatria, University of Brescia, Brescia, Italy, [6]University of Padua, Padova, Italy, [7]Dipartimento di Pediatria, Univerity of Trieste, Trieste, Italy, [8]Divisione di Reumatologia, Ospedale Pediatrico Bambino Gesù, Roma, Italy, [9]Unità di Biostatistica, DISSAL, University of Genoa, Genova, Italy, [10]Ospedale Galliera, Genova, Italy

Background/Purpose: despite FMF is considered an autosomal recessive disease caused by mutations of *MEFV*, one third of patients carry one mutation only. Aim of the present study was to analyze the clinical manifestation associated with periodic fever in a set of Caucasian children with periodic fever to evaluate the actual impact of *MEFV* mutations on the phenotype.

Methods: 113 Caucasian patients carrying *MEFV* mutations (46 with mutations in two alleles, 67 heterozygous) and 205 genetically negative patients for MEFV, TNFSF1A and MEFV (70% with a PFAPA phenotype) were analyzed. The extracellular region of the p55 TNF receptor (from exon 1 to exon 6) of the TNFRSF1A gene, the 10 coding exons (from 2 to 11) of the MVK gene and exons 2, 3, 5 and 10 of the MEFV gene were analyzed by means of denaturing high-performance liquid chromatography (DHPLC) and DNA sequencing. For each patient detailed clinical information about family and personal history, prevalence and frequency (sometimes, often, always) of the clinical manifestations associated with fever episodes had been collected by means of a standardized questionnaire. The following groups were considered: patients with: i) 2 high penetrance mutations (M694V, M694I, M680I), ii) 1 high, 1 low penetrance mutation, iii) 2 low penetrance mutations, iv) 1 high penetrance mutation, v) one low penetrance mutation, vi) genetically negative.

Results: Patients with two *MEFV* mutations displayed higher prevalence of chest pain ($p = 0.001$, Fisher's Exact Test), pleurisy ($p = 0.003$) and severe abdominal pain ($p = 0.002$). In contrast, patients carrying one mutation displayed an higher prevalence of erythematous ($p = 0.01$) and exudative ($p = 0.009$) pharyngitis, enlarged cervical lymph nodes ($p = 0.002$) and skin rash ($p = 0.007$). Moreover, patients with 2 *MEFV* mutations displayed also a later disease onset (mean 47 ± 40 months) and a shorter duration of fever episodes (2.9 ± 1.6 days) in respect to heterozygous patients (mean 30 ± 36.9 months, $p = 0.02$; and 5.1 ± 6.9 days, $p = 0.03$, respectively).The frequency of "FMF-like symptoms" decreases from patients carrying two high penetrance mutations towards patients with a single low penetrance mutation with a opposite behavior for "PFAPA-like symptoms" (Figure).



Conclusion: the present study shows a dosage effect of MEFV mutations not consistent with a pure autosomal recessive disorder. A dominant negative or gain of function effects or variants of still unidentified modifier genes may influence the presence of a FMF phenotype in heterozygous patients.

Development of a Clinical Disease Activity Measure for Juvenile Localized Scleroderma. Suzanne C. Li[1], Kathryn S. Torok[2], Elena Pope[3], Katie G. Stewart[4], Gloria C. Higgins[5], Egla C. Rabinovich[6], Kathleen M. O'Neil[7], Ivan Foeldvari[8], Kathleen A. Haines[1], Heidi Jacobe[9], Marilynn G. Punaro[4], Ronald M. Laxer[10], Themba Nyirenda[1] and Knut M. Wittkowski[11]. [1]Hackensack University Medical Center, Hackensack, NJ, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]Hospital for Sick Children, Toronto, ON, [4]Texas Scottish Rite Hospital, Dallas, TX, [5]Nationwide Childrens Hosp, Columbus, OH, [6]Duke University Medical Center, Durham, NC, [7]Okla Univ Health Science Ctr, Oklahoma City, OK, [8]Hamburger Zentrum Kinder-und Jugendrheumatologie, Hamburg, Germany, [9]UT Southwestern Medical Center at Dallas, Dallas, TX, [10]The Hospital for Sick Children, Toronto, ON, [11]Rockefeller University, NY

Background/Purpose: Juvenile localized scleroderma (jLS), unlike adult disease, frequently involves deeper tissues and other organs. Children are at risk for major morbidity including limb length discrepancy, facial hemiatrophy, and arthropathy. There is a need for validated sensitive assessments to be able to conduct comparative effectiveness studies. We describe our efforts to develop a validated clinical jLS disease activity measure.

Methods: A prospective study of jLS patients was conducted, with active to inactive patients enrolled at 2:1 ratio. Each patient had one lesion (study lesion) examined at 3 study visits by same clinician. Assessed features included change in lesion size, erythema, violaceous color, skin thickness, warmth, distinct margin, skin texture, and atrophy. Lesion temperature was measured with a handheld infrared thermometer, and parents were asked for their global assessment (GA) of their child's disease activity and impact.

Physicians rated disease activity (DA) of study lesion and overall disease, and damage of study lesion and overall disease on visual analog scales (physician global assessment (PGA)). Spearman's rho was calculated between each assessed parameter and PGA using SAS version 9.2 (SAS Institute Inc., Cary, NC).

Results: 103 jLS patients were enrolled at 8 pediatric rheumatology centers from 2/2009 to 6/2010. Most patients were Caucasian, female, and had linear scleroderma, either alone or as part of mixed morphea (Table 1).

Table I. Demographics

	All Patients	Active Patients (71)	Inactive Patients (32)
Age (median) at study entry [range]	11.54 yrs [0.33–21.25 yr]	11.00 yrs [0.33–19.67]	12.04 yrs [5.25–21.25 yr]
Age (median) at disease onset [range]	8.0 yrs [0–15.33 yr]	8.0 yrs [0–15.33 yr]	7.0 yrs [2–14 yr]
Disease duration at study onset [range]	2.75 [0.08–15.75 yr]	2.17 [0.08–11.75 yr]	2.92 [1.42–15.75 yr]
Sex	76F: 24 M (76%)	53 F: 15 M (78%)	23 F: 9 M (72%)

Ethnicity/race	72 Caucasian 6 Hispanic 3 African Am 4 SE Asian 2 Asians 12 Mixed	51 Caucasian 5 Hispanic 2 African Am 3 SE Asian 2 Asians 5 Mixed	21 Caucasian 1 Hispanic 1 African Am 1 SE Asian 7 Mixed

Interim analysis of 59 patients who completed all 3 study visits showed different patterns of correlation with PGA of DA of study lesion for several parameters, most having fair to moderate level of correlation (Table 2). Some parameters correlated at all, others at only 1 or 2 visits, suggesting some may be time dependent. Dermal and subcutaneous atrophy, dyspigmentation, and stable lesion size correlated with PGA of damage.

Table 2. Correlation between clinical parameters and PGA of DA of study lesion

	Visit 1			Visit 2			Visit 3		
Parameter	Spearman's Rho	Confidence Interval	p value	Spearman's Rho	Confidence Interval	p value	Spearman's Rho	Confidence Interval	p value
Erythema	0.651	0.473, 0.777	<0.0001	0.477	0.215, 0.653	0.0001	0.624	0.438, 0.759	<0.0001
Larger lesion	0.283	0.028, 0.502	0.0298	0.326	0.077, 0.538	0.0112	0.441	0.209, 0.627	0.0004
Stable lesion size	−0.356	−0.561, −0.110	0.0053	−0.297	−0.514, −0.044	0.0219	−0.372	−0.573, −0.128	0.0035
Parental GA of DA	0.486	0.243, 0.671	0.0002	0.369	0.122, 0.573	0.0041	0.457	0.225, 0.640	0.0003
Skin thickness: border	0.301	0.049, 0.517	0.0201	0.297	0.042, 0.516	0.0232			NS
Skin thickness: center			NS	0.356	0.107, 0.562	0.0058	0.493	0.258, 0.666	<0.0001
Abnormal skin texture	0.361	0.115, 0.565	0.0047	0.329	0.080, 0.540	0.0105			NS
New non-study lesion	0.380	0.137, 0.580	0.0028			NS	0.262	0.007, 0.486	0.0444
Violaceous color	0.348	0.101, 0.555	0.0066			NS			NS
Distinct Margin	0.444	0.212, 0.629	0.0004			NS			NS
Lesion warmth			NS			NS	0.516	0.297, 0.683	<0.0001

Conclusion: This is the first multi-center prospective study to evaluate correlation between clinical features and DA in jLS. Interim analysis of 59 patients identified several clinical features correlated with PGA–DA at fair to substantial levels. We have now finished study data collection and will be carrying out multivariate analysis to determine relationships and level of correlation of parameters. We hope to generate a weighted clinical DA measure to enable rigorous evaluation of treatment efficacy. Identifying optimal therapy for jLS will reduce disease and medication-related morbidity, and thereby improve the long-term outcome for these patients.

Defining Clinical Remission and Inactive Disease in Juvenile Systemic Lupus Erythematosus. Rina Mina[1], Laura E. Schanberg[2], Marisa Klein-Gitelman[3], B. Anne Eberhard[4], Gloria Higgins[5], Karen Onel[6], Nora G. Singer[7], Kathleen M. O'Neil[8], Deborah M. Levy[9], Shannen L. Nelson[10], Wajeeha Yousaf[11], Rubén J. Cuttica[12], Lori B. Tucker[13], Michael W. Beresford[14], Graciela Espada[15], Angelo Ravelli[16], Alberto Martini[17], Edward H. Giannini[18] and Hermine Brunner[19]. [1]Cincinnati Children's Med Ctr, Cincinnati, OH, [2]Duke University Medical Center, Durham, NC, [3]Children's Memorial Hospital, Chicago, IL, [4]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [5]PRCSG, Columbus, OH, [6]University of Chicago, Chicago, IL, [7]MetroHealth Medical Center, Cleveland, OH, [8]Okla Univ Health Science Ctr, Oklahoma City, OK, [9]The Hospital for Sick Children, Toronto, ON, [10]Cincinnati Children's Hospital, Cincinnati, OH, [11]University of Cincinnati, [12]Hospital de Pediatría Pedro de Elizalde, Buenos Aires, Argentina, [13]BC Childrens Hospital, Vancouver, BC, [14]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [15]Childrens Hosp Ricardo Gutierrez, Buenos Aires, Argentina, [16]Istituto di Ricovero e Cura a Carattere Scientifico G. Gaslini, Genova, Italy, [17]IRCCS G Gaslini, Pediatria II, Reumatologia, Genova, Italy, [18]PRCSG-Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [19]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: An initial Delphi survey delineated key commonalities for a standard definition of clinical remission and inactive disease in jSLE. However, additional clarifications were required. The aim of this project is to develop a definition of and criteria for clinical remission and inactive disease in jSLE.

Methods: A second international Delphi survey was conducted among pediatric rheumatologists. Consensus was set at 75%. Data from a cohort of jSLE (n=36) patients considered to be in remission by their treating physician were compared to the results of the survey.

Results: There were 311 respondents (response rate: 52%). Consensus was achieved regarding the key definitions under consideration (Table 1). Respondents agreed that with clinical remission: a) there could be at most one mild, non-limiting symptom (i.e. fatigue, joint pains, headaches or myalgia) but no objective physical signs of disease activity; b) the ANA could be persistently abnormal but not the complete blood count, urine sediment, and complement C3; and c) there could be regular use of several systemic medications (Table 1). Majority of the respondents stated that regular use of non-steroidal anti-inflammatory drugs and hydroxychloroquine with clinical remission were permissible. Data from jSLE patients supported the results of the survey.

Table 1. Definition of Clinical Remission and Clinically Inactive Disease in JSLE

		Acceptable Use of Medications for Lupus				
Construct	**Time frame**	**Cortico steroids**	**Immuno suppressives**	**Preventive medications¶**	**Medications to treat SLE damage**	**Consensus**
Clinically Inactive Disease	Time-point	Yes	Yes	Yes	Yes	93% (227/244)
Clinical Remission on Medication	Time-period: ≥ 6 months	Yes	Yes	Yes	Yes	95% (231/244)
Clinical Remission on Preventive Medication	Time-period: ≥ 6 months	No	No	Yes	Yes	95% (224/237)
Clinical Remission Off Medication	Time-period: ≥ 12 months	No	No	No	Yes	83% (200/241)

Legend: Preventive medications include systemic medications that can be used to prevent disease and treat damage such as statins, aspirin, angiotensin converting enzyme (ACE) inhibitors, biphosphonates, vitamin D, and omega-3-fatty acids

Conclusion: Consensus has been reached on the definition of 'Clinical Remission' and 'Clinically Inactive Disease' in jSLE. The results of the Delphi process will be used to guide the data-driven development of provisional criteria of clinical remission and inactive disease in jSLE.

2455

Cancer Risk In Pediatric Systemic Lupus: Updated Analyses. Sasha Bernatsky[1], Rosalind Ramsey-Goldman[2], Earl D. Silverman[3], Ciaran M. Duffy[4], Kiem Oen[5], Alan M. Rosenberg[6], Laura E. Schanberg[7], Kathleen M. O'Neil[8], Emily von Scheven[9], Jeremy Labrecque[1], Elizabeth M. Turnbull[1] and Ann E. Clarke[1]. [1]Research Institute of the McGill Univ. Health Ctre, Montreal, QC, [2]Northwestern University, Chicago, IL, [3]Hospital for Sick Children, Toronto, ON, [4]Children's Hospital of Eastern Ontario, Ottawa, ON, [5]University of Manitoba, Winnipeg, MB, [6]Royal University Hospital, Saskatoon, SK, [7]Duke University Medical Center, Durham, NC, [8]Okla Univ Health Science Ctr, Oklahoma City, OK, [9]UC San Francisco, San Francisco, CA

Background/Purpose: There is increasing interest in the malignancy profile of patients with systemic lupus erythematosus, SLE. Compared to the wealth of data regarding cancer risk in adults with SLE, relatively little is known about cancer risk in pediatric-onset SLE. Our objective was to assess the observed cancer incidence in a large combined clinical cohort of individuals with pediatric-onset SLE, and compare this to the expected incidence, based on general population cancer incidence rates.

Methods: We ascertained cancer incidence within the SLE clinic registries maintained at six North American pediatric rheumatology centers (Duke University Medical Center N=79; University of California-San Francisco N=219; University of Oklahoma N=31; Sick Children's Hospital Toronto N=368; University of Manitoba, Winnipeg N=45; Royal University Hospital, Saskatoon, SK N=34; and Montreal Children's Hospital N=21).Subjects in each clinic registry were linked to regional tumor registries to determine cancer risk over theobservational interval, spanning the calendar years 1974–2009. In-situ cancers were excluded. The person-years of follow-up for each subject were calculated from the date first seen at the rheumatology clinic, and the first of three possible events: death, cancer, or the end of the study interval (December 31, 2009). Pooling the data, we determined the total number of observed cancers occurring over the total person-years of observation. Total number of cancers expected to occur over the observation interval was calculated by multiplying the person-years in the cohort by the geographically matched age, sex, and calendar year-specific cancer rates, and summing over all person-years. The ratio of observed to expected malignancies represents the standardized incidence ratio, SIR.

Results: The study sample was comprised of 797 patients. The proportion of females in the cohort was 79%, and the average age at cohort entry was 13.1 years (SD=3.8); these characteristics were consistent across all six cohorts. Subjects were observed for a total of 5649 patient-years, with an average follow-up of 7.1 years (SD=6.1). Within this observation interval, based on regional age- and sex-appropriate cancer rates, 2.1 invasive cancers would have been expected, however, 9 invasive cancers occurred, for an SIR of 4.29, 95% confidence interval, CI 1.96, 8.14. These events occurred an average of 13.5 years after SLE diagnosis (the most recent being within two months after SLE diagnosis, the latest event being 22.8 years after SLE diagnosis). The cancer cases included two non-Hodgkin lymphoma, NHL, and one leukemia, for a hematologic cancer SIR of 6.7 (95% CI 1.4, 19.5).

Conclusion: These data represent the most up-to-date results from our multi-centre initiative to clarify baseline cancer risk in pediatric-onset SLE. This suggests an increased risk in over-all cancer occurrence in pediatric onset SLE, which may be driven by hematologic cancer risk. Further work is in progress to further assess this issue.

Distinct Functional Activation and Connectivity Patterns for a Visuo-Constructional Task in Childhood-Onset Systemic Lupus Erythematosus and Matched Controls. Marisa Klein-Gitelman[1], Adlin Cedeno[1], Aimee Baker[2], Frank Zelko[1], Dean Beebe[2], Blair Dina[1], Anna Carmela P. Sagcal-Gironella[3], Darren Gitelman[4], Hermine Brunner[2], Mark Difrancesco[2] and Brian Zappia[2]. [1]Children's Memorial Hospital, Chicago, IL, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]Northwestern University, Chicago, IL

Background/Purpose: To use functional MRI (fMRI) to characterize brain activation and connectivity differences for a visuo-constructional (VC) task between cSLE patients and matched best-friend controls.

Methods: As part of a broader study protocol, 44 subjects (F:M=36:8; age 10–17 yrs; 59% African-American, 41% Caucasian; 11% Hispanic), 22 with cSLE and 22 controls matched for age, sex, and race performed a square completion task during fMRI. This task exercises visuo-constructional ability (VCA), a domain showing deficits by formal neuropsychological testing in cSLE.

Image data were pre-processed and analyzed for activation in SPM8 (www.fil.ion.ucl.ac.uk/spm) and for functional connectivity using CONN v.12.p (nitrc.org). Image data, acquired at 3 Tesla, consisted of T2*-weighted echo-planar images with TR=3s, 64×64 matrix, 256 mm FOV, and 44 axial 3 mm slices. A high resolution T1-weighted anatomic reference image was acquired for each subject. Average activation was calculated for the cSLE and control groups. Differences in connectivity strength to specific regions of interest between groups were assessed.

Results: Figure 1A shows activation and deactivation patterns for the control group when performing the square completion task. This is compared to the activation patterns for the cSLE group in Figure 1B. Qualitatively, the cSLE group activates more strongly in the ventral visual stream while the control group is stronger in frontal regions including the anterior cingulate (AC). More deactivation is observed in the posterior cingulate (PC) region for controls compared to cSLE.

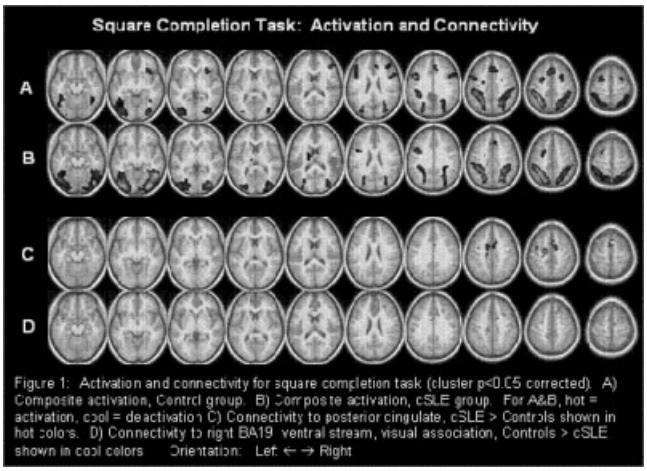

Figure 1: Activation and connectivity for square completion task (cluster p<0.05 corrected). A) Composite activation, Control group. B) Composite activation, cSLE group. For A&B, hot = activation, cool = deactivation C) Connectivity to posterior cingulate, cSLE > Controls shown in hot colors. D) Connectivity to right BA19 ventral stream, visual association, Controls > cSLE shown in cool colors Orientation: Left ← → Right

Led by these trends in activation, differences between subject groups were calculated with regard to voxel-wise functional connectivity to the PC region (Figure 1C) and to the right visual association (rVA) region (Figure 1D). During the square completion task, cSLE subjects maintained a stronger connection between the PC and frontal cortex, particularly the AC, while connectivity between the rVA and the ACC was stronger for the control group.

Conclusion: For a VC task, probing a domain known to show deficits for cSLE, these findings suggest that regions of the brain, such as the PC, that generally need to deactivate when engaged in a challenging task, are not suppressed as much in cSLE compared to controls and that stronger connectivity is maintained between these regions and the frontal lobe. A complementary finding is that connectivity between rVA, part of the ventral visual stream, and the frontal lobe is more robust for the control subjects while cSLE subjects need to activate the ventral stream more strongly to perform the task. Together, these results suggest an imbalance of task-negative and task-positive communication and function in networks pertaining to VCA in cSLE.

Patients with a Severe Clinical Disease Course Can Be Identified Using Cluster Analysis – Results From a Canadian National Early Arthritis Cohort. Ye Sun[1], Cindy Lim[2], Gilles Boire[3], Boulos Haraoui[4], Carol A. Hitchon[5], Edward C. Keystone[6], Janet E. Pope[7], J. Carter Thorne[8], Diane S. Ferland[9], Vivian P. Bykerk[10] and CATCH Investigators[11]. [1]Mount Sinai Hospital, Toronto, ON, [2]Mount Sinai Hospital, Toronto, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]Institut de Rhumatologie, Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]Rebecca MacDonald Centre for Arthritis and Autoimmune Disease, Mount Sinai Hospital, Toronto, ON, [7]St. Joseph's Health Care, University of Western Ontario, London, ON, [8]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [9]LaSalle, QC, [10]Brigham & Women's Hospital, Boston, MA, [11]Canada

Background/Purpose: In any patient (pt) with early RA there is significant variability of their disease course. In order to predict treatment response it is important to understand which patients (pts) will fit in any given disease trajectory (traj) based on that pts' baseline (BL) presentation. We aimed to determine if pts clinical disease course fit into distinct clusters as trajectories (trajs) and whether differences in clinical course could be attributed to specific baseline characteristics or to pts medication use.

Methods: We applied a group-based trajectory of modeling approach proposed by Nagin (1) to 185 early RA patients with 2 years of follow up, from a national early inflammatory arthritis observational cohort study, to test the hypothesis that clustering exists.

Results: 5 distinct trajs were identified within this sample of RA pts (Figure). BL variables age, employment status, RF and ESR were identified to be significantly different between the clusters (Table). Pts in traj 1 had low levels of disease activity (DA) and went into remission. In traj 5 pts had very high levels of DA (DAS28 > 7.0) at BL and remained in that state. In traj 2 pts had moderate levels of DA and remained in that state. Two groups of pts emerged presenting initially with high DA but diverged in their course. Although pts in traj 3 and traj 4 had the same DA at BL, pts in traj 3 showed marked improvement and went into remission whereas those in traj 4 had high moderate DA despite more intense treatment than those in traj 3. Overall, pts with a worse clinical disease course needed more intense therapy over time.

Baseline characteristics	1	2	3	4	5	p-value

Figure. Patient's clinical course over time clustered into trajectories based in clinical presentation.

Conclusion: Distinct differences in clinical course occurs over 2 years in pts with early RA that can be predictably clustered into a disease trajectory using the methodology of Nagin. This method could enhance predictive modeling of patient outcomes using BL clinical factors in studies of observational RA cohorts and allow better understanding of treatment responses.

Defining Erosive DISEASE Typical of RA In the LIGHT of the 2010 ACR/EULAR Criteria for Rheumatoid Arthritis–PHASE 1. R. Knevel[1], Désirée van der Heijde[1], Tom W.J. Huizinga[1], Cédric Lukas[2], Bernard G. Combe[2] and Annette H.M. van der Helm-van Mil[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Hopital Lapeyronie, Montpellier, France

Background/Purpose: Last year, the EULAR in collaboration with the ACR derived the 2010 classification criteria for Rheumatoid Arthritis (RA)1. According to these criteria, RA can be classified if patients fulfill 6 out of 10 points or if

patients have 'typical' erosive disease on radiographs. At the publication of the criteria it was agreed that the definition of significant erosive disease should be further investigated1. This study reports the first stage of the results of a EULAR taskforce that aimed to define RA-specific erosiveness.

Methods: Baseline radiographs of hands and feet of early arthritis patients included in the Leiden EAC between 1993 and 2006 (n=980) were studied. It was evaluated which number of erosive joint as well as which location of erosiveness could best identify patients with RA. In this study, RA was defined by the initiation of any DMARD-therapy during the first year of follow-up. MTX therapy was not commonly used before 2000, which makes it a less suitable outcome measure than any DMARD-therapy. Secondly, it was tested which degree of erosiveness could best identify persistent disease after 5-years follow-up. It was aimed to have a high specificity and a low false positive classification.

Results: Data on treatment in the first year and on disease persistency over 5-years was available for respectively 902 and 886 patients. 64% of the patients were female, 37% anti-CCP+ and 42% RF+. For all outcome measures the presence of more than 4 erosive joints resulted in the highest specificity (95–97%) and positive predictive value (94%) (Table I). No difference in joint location was observed for specific joints (MCP/PIP/MTP) or extremities (hands/feet).

Table 1. Test characteristics when the cut-off of erosiveness was set at different number of erosive joints.

			Leiden-EAC						
Outcome	**Erosion-group**	**N (%)***	**Sens**	**Spec**	**PPV**	**NPV**	**LR+**	**LR-**	**AUC**
DMARD	no erosions	395							
(N=902)	≥1 joint	507 (56)	0.72	0.75	0.85	0.57	2.90	0.37	0.74
	≥2 joints	387 (43)	0.57	0.86	0.89	0.50	4.03	0.50	0.72
	≥3 joints	307 (34)	0.46	0.89	0.89	0.45	4.09	0.61	0.67
	≥4 joints	227 (25)	0.35	0.93	0.91	0.42	5.21	0.70	0.64
	> 4 joints	179 (19)	0.28	0.97	0.94	0.40	8.51	0.74	0.62
PERSISTENCY	no erosions	395							
(N=886)	≥1 joint	473 (54)	0.12	0.97	0.93	0.28	4.61	0.90	0.55
	≥2 joints	358 (41)	0.47	0.80	0.89	0.30	2.41	0.65	0.64
	≥3 joints	283 (33)	0.38	0.85	0.90	0.28	2.63	0.72	0.62
	≥4 joints	209 (24)	0.29	0.92	0.92	0.27	3.45	0.78	0.60
	> 4 joints	169 (19)	0.24	0.95	0.94	0.26	4.55	0.81	0.59

Sens = sensitivity, Spec = specificity, PPV = positive predictive value, NPV = negative predictive value, LR+ = positive likelihood ratio, LR- = negative likelihood ratio
* number and percentage of patients positive in this analysis

Applying this erosion criterion in addition to the recently published ACR/EULAR 2010 criteria1 resulted in 14 patients that were additionally classified as RA compared to applying the ACR/EULAR 2010 criteria without assessing radiographic data. All of these 14 patients had persistent disease over 5 years.

Conclusions: These data indicate that the presence of >4 erosive joints is highly specific for RA. Comparable analyses in an independent cohort of early arthritis patients is required to define RA-specific erosiveness in the light of the 2010 ACR/EULAR criteria.

The New ACR/EULAR Definition of Remission in Rheumatoid Arthritis: A Comment on the Patient Global Assessment Criterion. Marloes Vermeer[1], Ina H. Kuper[1], Arie E. van der Bijl[2], Hetty Baan[3], Marcel D. Posthumus[4], Herman L.M. Brus[5], Piet L.C.M. van Riel[6] and Mart A.F.J. van de Laar[1]. [1]University of Twente & Medisch Spectrum Twente, Enschede, Netherlands, [2]Isala Klinieken, Zwolle, Netherlands, [3]Ziekenhuisgroep Twente, Almelo, Netherlands, [4]University Medical Center Groningen, Groningen, Netherlands, [5]TweeSteden Ziekenhuis, Tilburg, Netherlands, [6]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background/Purpose: Recently, new definitions of remission in rheumatoid arthritis (RA) for clinical trials have been proposed by the ACR/EULAR committee. According to the Boolean based definition, a patient is in remission when the scores on the following measures are all ≤1: 28 tender joint count (TJC28), 28 swollen joint count (SJC28), C-reactive protein (CRP, mg/dL) and patient global assessment (PGA, 0–10 scale). However, it remains debatable whether or not the PGA criterion represents remission. The hypothesis of this study is that patients in daily clinical practice will frequently score high on the PGA, despite low scores on objective clinical parameters that represent remission. The objective of the present study was to assess the prevalence of ACR/EULAR remission in a cohort of patients with very early RA in daily clinical practice, and to analyze cases in which all remission criteria except for the PGA criterion were fulfilled.

Methods: Data were used from the Dutch Rheumatoid Arthritis Monitoring (DREAM) remission induction cohort study. In this study, patients with very early RA (symptom duration ≤1 year) were treated according to a treat to target strategy aiming at remission (DAS28<2.6). PGA was assessed using a visual analogue scale (VAS) for arthritis specific global health. In observations where the TJC28, SJC28 and CRP criteria were met but not the PGA criterion, a higher PGA score could be explained by disease activity in joints not included in the 28 joint count (e.g. the feet). To take this into account, more comprehensive joint counts were used. We defined clinical remission as a TJC53≤1, SJC44≤1 and CRP≤1.

Results: This study analyzed 4866 observations of a total of 588 patients. ACR/EULAR remission for all 4 measures was observed in 17.9% (869/4866) of the observations. In 20.8% (1014/4866) of the observations, patients had a high PGA score (>1) despite low tender and swollen joint counts (TJC28≤1, SJC28≤1) and normal CRP (≤1). The distribution of the PGA showed wide ranges beyond the cut point for remission (median (IQR) of 2.5 (1.8–3.9)). When using more comprehensive joint counts, clinical remission (TJC53≤1, SJC44≤1 and CRP≤1) was observed in 1571 of 4866 observations. In half of these observations (787/1571), the new remission definition was not met due to high scores on the PGA.

Conclusion: In a considerable number of cases, high scores on the PGA (>1) were observed, despite a low number of tender and swollen joints and normal CRP. This might lead to misclassification of patients that are clinically in remission, but have high PGA scores due to other reasons. This finding was not explained by disease activity in joints not included in the 28 joint count. Apparently, other factors than these objective clinical parameters influence the PGA. Therefore, caution should be taken when using the new remission definition with regard to the PGA criterion.

2460

Performance of the New ACR/EULAR Remission Criteria Compared to DAS28 Remission in Unselected Real-Life Patients with Rheumatoid Arthritis. Dörte Huscher[1], Katja Thiele[2], Sascha Bischoff[2], Marina Backhaus[3], Martin Aringer[4], Ina Kötter[5] and Angela Zink[1]. [1]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Charité University Medicine, Berlin, Germany, [4]Uniklinikum TU Dresden, Dresden, Germany, [5]Department of Internal Medicine II, Rheumatology Division, Tübingen, Germany

Background/Purpose: The new ACR/EULAR remission criteria comprise two equally applicable definitions: either a boolean definition (number of swollen and tender joints each ≤1, CRP≤1 mg/dl, and patient global assessment ≤1 [NRS 0–10]), or a simplified disease activity index (SDAI) score of ≤ 3.3. Both definitions are more stringent than the established EULAR criterion based on a DAS28<2.6. Even though the criteria have been developed data-driven, it has to be further evaluated how these criteria perform in different cohorts of real-life patients.

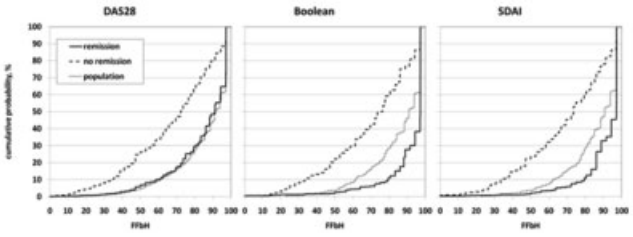
Methods: We used cross-sectional data of 6,864 RA patients, enrolled in the National Database of the German Collaborative Arthritis Centres between 2007 and 2009, for whom all 3 remission criteria could be calculated. Patients seen in more than one year were included only once. The functional status was measured by the Hannover Functional Status Questionnaire (FFbH) in percent of full function (0–100%)[1]. For patients in remission according to one ouf of the three criteria the functional status was compared to data from the age and sex matched general population.

Results: 75% of the patients were female, their mean age was 61.5 years, the median disease duration 9.1 years, and the mean DAS28 3.4. 1,931 patients (28%) were in DAS28 remission, 476 (7%) in boolean and 740 (11%) in SDAI remission.

If patients fulfilled the new, but not the DAS28 criterion, this was mainly due to high ESR (mean ESR 39.0 for patients in boolean but not DAS28 remission, and 39.1 for those in SDAI but not DAS28 remission). If patients fulfilled the DAS28 but not the new criteria, this was due to patient global assessments exceeding 1 (mean patient global for DAS28 remission but not boolean: 3.4, DAS28 remission but not SDAI: 3.6).

Compared to the DAS28 criterion, the new criteria select more stringently patients with low pain (mean 1.0 for boolean and 1.3 for SDAI compared to 2.8 for DAS28 remission), low fatigue (1.1, 1.3 and 2.6, respectively) and good function (92.4%, 91.8% and 84.3% of full function, respectively).

Compared to a population cohort (Fig.1), patients in remission according to the new criteria have a functional status that is even superior to their age and sex matched population counterparts.



Conclusion: The RA new remission criteria stringently select patients who have nearly no functional limitation, pain or fatigue. Since the functional status of these patients is better than expected from the age and sex matched population, a weakness of the new criteria could be that patients with disabling co-morbid conditions cannot reach remission even if their RA is entirely inactive. Other disabling conditions might influence the self-rating, even if patients are asked explicitely to refer to the RA only. More research is needed to better understand the influence of co-morbidity on patients' self assessments and the consequences for the definition of remission.

2461

RAPID3 Remission Vs New ACR Rheumatoid Arthritis Remission Criteria: RAPID3 Has Similar Utility and May Be Used in Everyday Clinical Care. Yusuf Yazici[1], Maria T. Filopoulos[2] and Christopher J. Swearingen[3]. [1]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY, [2]NYU Hospital for Joint Diseases, New York, NY, [3]University of Arkansas for Medical Sciences, Little Rock, AR

Background/Purpose: New remission criteria for RA have been introduced to be more stringent than currently available definitions of remission, by DAS28, CDAI or RAPID3. However there is very little information regarding the feasibility of the new remission criteria in routine clinical care and if it is better than RAPID3 definition of remission, a very simple, patient friendly tool and easily implemented in everyday patient care.

Methods: Arthritis Registry Monitoring Database (ARMD) has been collecting prospective patient data since 2005 in all patients seen in routine care at New York University. Each patient in this setting (with any diagnosis) completes a 2-sided, 1-page MDHAQ (multidimensional health assessment questionnaire) at every visit while waiting to see the physician in the infrastructure of clinical care. The MDHAQ includes scales for physical function, pain, patient global estimate (PATGL), fatigue, and a self-report RADAI painful joint count. Last visits of RA patients seen between between July 2005 and April 2011 were studied. Differences in self-report MDHAQ scores, RAPID3 (routine assessment of patient index data 3; an index of function, pain, and PATGL), and the new ACR remission criteria were analyzed.

Results: 704 RA patients were evaluated (mean age 53.9 (15.4), disease duration 5.5 (7.5) years, 80% female. 116 (16%) were in remission as defined by RAPID3 (≤ 3 of total 30 points) at last visit, while 61 (9%), 190 (27%), and 337 (48%) were in low, moderate and high disease activity respectively. Disease characteristics are given in Table 1, by RAPID3 scores. Similar classification percentage (17%) was seen by the new ACR criteria for remission. Percent agreement between remission by RAPID3 and new ACR criteria was 96% with a very strong agreement beyond chance (kappa = 0.86, $p < 0.001$).

	Remission	Mild	Moderate	Severe	Total
N	116	61	190	337	704
Age (Years)	52.7 (15.6)	53.0 (14.7)	51.8 (15.5)	55.6 (15.3)	53.9 (15.4)
Duration (Years)	4.8 (6.2)	4.7 (6.6)	5.3 (7.3)	6.1 (8.2)	5.5 (7.5)
Female (%)	88 (76%)	49 (80%)	151 (79%)	272 (81%)	560 (80%)
Function [0–10]	0.3 (0.5)	0.9 (0.9)	1.8 (1.3)	4.3 (1.9)	2.7 (2.2)
Pain [0–10]	0.6 (0.6)	1.9 (1.0)	3.7 (1.6)	7.4 (1.8)	4.8 (3.1)
Global [0–10]	0.4 (0.6)	1.8 (0.9)	3.5 (1.5)	7.0 (1.9)	4.5 (3.0)
MD Global [0–10]	1.0 (1.1)	1.7 (1.7)	2.0 (1.6)	3.0 (1.6)	2.3 (1.7)
Swollen [0–28]	0.1 (0.4)	0.5 (1.5)	1.2 (2.7)	2.7 (3.9)	1.7 (3.3)
Tender [0–28]	0.7 (2.0)	1.5 (3.5)	2.7 (3.5)	5.1 (4.9)	3.4 (4.4)
ESR (mm/hr)	17.5 (15.6)	20.9 (17.5)	24.5 (22.4)	31.4 (25.2)	25.3 (22.4)

Conclusion: Remission defined by RAPID3 (≤3/30) performs similarly to the new ACR remission criteria in this patient population and can likely be used in routine care as a target for disease control with similar benefits. The ease of use of RAPID3 compared to the new criteria may make it a good option for busy clinicians.

2462

American College of Rheumatology/European League Against Rheumatism Remission Criteria Achievement in Rheumatoid Arthritis: Data From 32 Countries. Nasim A. Khan[1], Tuulikki Sokka[2] and QUEST-RA[3]. [1]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [2]Jyvaskyla Central Hosp, Jyväskylä, Finland, [3]Jyväskylä

Background/Purpose: To a) assess the newly proposed American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) rheumatoid arthritis (RA) remission criteria prevalence in a multi-national cohort of RA patients and compare it to remission rates according to previous definitions and b) assess non-RA disease activity related factors that are independently associated with non-achievement of the ACR/EULAR remission.

Methods: This analysis is based upon 8488 patients in the Quantitative Standard Monitoring of Patients with RA (QUEST-RA) database who received usual care from rheumatologists in 32 countries. ACR/EULAR remission criteria was defined by fulfillment of all of the following: tender joint count (TJC) ≤ 1, swollen joint count (SJC) ≤ 1, patient's global assessment (PTGL) ≤ 1, and Erythrocyte Sedimentation Rate (ESR) < 30 mm/h for women or < 20 mm/h for men. ESR was used due to it's wider availability and measurement uniformity. Remission rates according to Disease Activity Score 28 (DAS28) and ACR, were available for 24 countries from the previous publication. We defined subset of patients in "near-remission" if they met any three of the four ACR/EULAR remission criteria. Multivariable logistic regression (MLR) model that included socio-demographic factors, RA characteristics, psychological distress measure, and comorbidity burden was performed to identify factors associated with non-achievement of the ACR/EULAR remission criteria.

Results: 550 (6.5%) patients met the ACR/EULAR remission criteria. ACR/EULAR definition leads lower remission rates than DAS28 but is quite similar to ACR definitions of remission (Table). 1052 (12.4%) patients met the near-remission criteria. The individual criteria (n, %) that excluded meeting of the ACR/EULAR remission in these patients were: PTGL (719, 68.3%), TJC (99, 9.4%), SJC (101, 9.6%), and ESR (133, 12.6%). DAS28 score [median (Q1-Q3)] for the remission and the near-remission groups were 1.75 (1.36–2.11) and 2.12 (1.71–2.58) respectively; while the corresponding Clinical Disease Activity Index (CDAI) score were 0.9 (0.4–1.8) and 4.10 (2.59–6.47) respectively. Residence in Low GDP country, low education level, longer RA duration, more comorbidites and psychological distress were associated with lower likelihood of achieving remission.

Table. Unadjusted rates of remission according to different remission definitions in the QUEST-RA study by country (DAS28 and ACR remissions from the reference)

	Definition of remission (percentage of patients)		
Country	ACR/EULAR	DAS28	ACR
Serbia*	0	0.0	0.0
Kosovo*	0	1.0	0.0
Egypt*	0.1		
Lithuania*	0.3	1.4	0.3
Russia*	0.6	4.5	2.8
Finland**	12.8	36.6	12.3
Netherlands**	13.6	40.8	16.3
Ireland**	14.2	22.4	14.0
USA**	14.2	36.1	13.8
Greece**	20.3	36.5	21.5
Total (for entire cohort)	6.5	19.6	8.6

*Countries with lowest ACR/EULAR remission rates; **Countries with highest ACR/EULAR remission rates

Conclusion: Prevalence of ACR/EULAR remission was low in this large multinational cohort of RA patients. Several non-disease activity related variables are associated with non-achievement of remission as per the stringent ACR/EULAR definition.

Immediate and Delayed Impact of Oral Glucocorticoid Therapy On Risk of Serious Infection In Patients with Rheumatoid Arthritis: A Nested Case-Control Analysis Using a Weighted Cumulative Dose Model. William G. Dixon[1], Michal Abrahamowicz[2], Marie-Eve Beauchamp[2], David W. Ray[3], Sasha Bernatsky[4], Samy Suissa[5] and Marie-Pierre Sylvestre[6]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]McGill University, Montreal, QC, [3]The University of Manchester, Manchester, United Kingdom, [4]McGill UHC/RVH, Montreal, QC, [5]Royal Victoria Hosp, McGill Un, Montreal, [6]University of Montreal, Montreal, QC

Background/Purpose: The association between glucocorticoid (GC) therapy and serious infection in patients with rheumatoid arthritis (RA) is uncertain. It is unclear which treatment regimes increase risk, what degree of risk is conferred, or what happens to risk on stopping therapy. Most published work uses crude models of exposure e.g. current use, ever use or cumulative dose. These ignore variations of dose with time and apply improbable weights to past therapy. The aim of this study was to explore the application of a novel weighted cumulative dose (WCD) model to examine the risk of serious infection in patients with RA treated with GC therapy compared to no GC therapy within a nested case-control analysis from a Canadian administrative database, and to compare the results with conventional approaches.

Methods: A case-control analysis matched 1,851 serious infection cases to up to five controls, selected from 16,207 elderly RA patients using disease modifying anti-rheumatic therapy between 1985–2003 in RAMQ, Quebec, Canada. Serious infections were identified as the first occurrence of a primary hospital discharge diagnosis of infection. Oral GC dosage was derived from dispensed pharmacy records. Ten conventional multivariable conditional logistic regression models, each representing GC exposure differently, were compared to a WCD model where GC exposure was represented as the weighted sum of past doses. Weights were estimated to reflect the relative importance of doses taken at different times in the past. Co-morbidity, disease severity and DMARDs were potential confounders and adjusted for in all analyses.

Results: All ten conventional models found a statistically significant association between GC exposure and risk of hospitalization for infection. However, the goodness of fit varied considerably depending on the way GC exposure was represented, the time window over which it was considered, and whether GC dose was taken into account. The WCD model predicted risks better than conventional models (>25 AIC units difference). Current and recent doses had the highest impact on current risk. However, doses taken up to 2.5 years ago were also associated with increased infection risk. Accepting some residual confounding by indication, a current GC user of 5mg prednisolone had a 33%, 53% or 105% increased risk of serious infection when used continuously for the last 3 months, 6 months or 3 years, respectively, compared to a non-user. The risk associated with 5mg prednisolone taken for the last 3 years was equivalent to that associated with 30mg taken for the last month. Discontinuing a two-year course of 10mg prednisolone six months ago halved the risk of infection compared to ongoing use.

Conclusion: GC therapy is associated with infection risk in older patients with RA. Current and recent doses have the greatest impact on infection risk but doses taken up to 2.5 years ago still affect the risk. Knowing how risk depends on past pattern of GC use can guide prescribing to minimize infection risk.

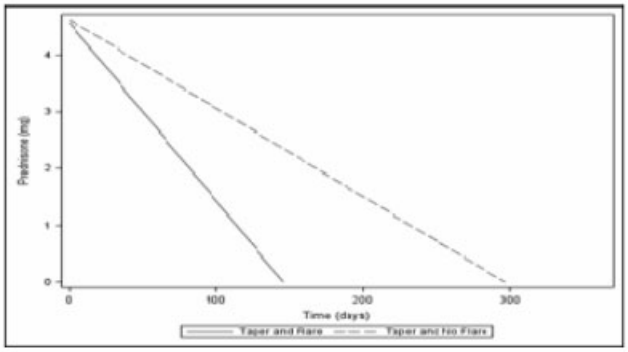
Successful Tapering of Glucocorticoids (GC) in Rheumatoid Arthritis Patients-Results From the Consortium of Rheumatology Researchers of North America Registry. Thasia G. Woodworth[1], Elizabeth Thomas[2], Jeffrey D. Greenberg[3] and Daniel E. Furst[4]. [1]Leading Edge Clinical Research, Stuart, FL, [2]Axio Research, LLC, Seattle, WA, [3]New York University School of Medicine, New York, NY, [4]UCLA, Los Angeles, CA

Background/Purpose: Rheumatoid arthritis (RA) treatment guidelines currently support short-term use of low dose glucocorticoids (GC) when methotrexate (MTX)/DMARDs treatment is initiated. Discontinuation when disease control is achieved is recommended to limit side effects of chronic use (fracture risk, cataracts, ASHD, diabetes). However, the most reliable approach to tapering and discontinuation is not well known. The purpose of this analysis was to identify factors, including RA flares that influence tapering of GC.

Methods: We identified RA patients who achieved stable disease control (CDAI) and stable GC dose over 2 visits (2–7 months apart), with at least 2 subsequent visits, during treatment with DMARDs and GC in the CORRONA RA database. Time to RA flare, operationally defined as an increase in CDAI by >= 1 category or need for additional GC (oral dose increase or intraarticular) from date of established stable disease, was examined in patients who tapered GC versus those who maintained stable doses. Patients who had less than 12 months of follow-up or/and did not flare were censored. Rate of tapering prednisone dose was compared among patients who tapered and experienced flare in the first year compared to those who tapered without flare. Baseline characteristics that might influence flare events and GC tapering were evaluated.

Results: 1076 patients met criteria for analysis, 284 (26.4%) tapering GC (tGC) in year 1 and 792 who remained on stable GC (sGC). CDAI remission/low disease activity was comparable for the tGC group (69.3%) and the sGC group (64.8%). More than half of patients in each group were receiving at least 5 mg/d prednisone, and ~70% were receiving MTX, with more than 60% receiving at least one additional DMARD or/and biologic. Compared to sGC patients, those in the tGC group had fewer flares over time: hazard ratio, 0.697 (95% CI 0.602–0.806, p=<0.001). Of 284 tGC patients, 145 did not flare in the first year. Patients without flare decreased dose at a significantly slower rate, 0.47 mg/month versus 0.95 mg/month (p<0.0001), as shown in graph. Baseline factors associated with successful tapering included use of a biologic (p=0.027) and/or MTX (p=0.042), and possibly baseline CDAI (p=0.061).



GC tapering rates in tGC patients not flaring (dotted line) vs flaring (solid line)

Conclusion: Successful tapering without flare was associated with incremental decreases in GC that were about half those associated with flare. Patients with good baseline disease control receiving MTX and/or a biologic appear less likely to flare. Stable GC did not appear to prevent flare.

Background/Purpose: Treatment of early rheumatoid arthritis (RA) with methotrexate (MTX) and etanercept (ETN) achieves high rates of remission.(1) Treating patients with inflammatory arthritis (IA) at an early stage

may provide a window of opportunity for further improvement. The objective of this study was to compare the efficacy of 12 months of methotrexate (MTX) monotherapy (mono) vs. MTX plus etanercept (ETN) combination (combo) therapy in achieving clinical remission defined as no tender or swollen joints (NTSJ), and DAS28(CRP) remission in patients with new IA.

Methods: 18 month study; inclusion criteria: DMARD-naïve, clinical synovitis in ≥1 joint, <3month duration, and positive for RF, ACPA or shared epitope. Patients were randomised to receive MTX up to 25mg/ wk plus placebo (PBO) or MTX (same titration) plus ETN 50mg/ wk for 12 months, followed by MTX monotherapy for both groups. If patients achieved sustained clinical remission(NTSJ [RAI+SJC=0] for >26 weeks), the ETN/PBO injections were stopped prior to 12 months. If patients had NTSJ >12 weeks after stopping ETN, MTX was weaned. Additional DMARDs were allowed after 12 months if there was ongoing disease activity. The primary outcome was NTSJ at week 52. Remission (NTSJ and DAS28(CRP) remission) and LDAS28 for the first 52 weeks are reported here. Pearson's chi-square was used to compare the groups. Holm-corrected threshold for 5% significance was set to $p<0.006$ for secondary outcomes.

Results: 110 patients were enrolled; 55 in each group. Mean age 48.6 years, 76% female, median symptom duration 7.0 months, mean baseline DAS28 4.22. 53% were RF+ve and 77% ACPA+ve. NTSJ at wk 2 was 11% vs. 2%, $p=0.051$ and at 26 weeks 16% vs. 24%, $p=0.340$ in the combo and the MTX mono groups respectively. NTSJ at wk 52 was achieved in 31% of the combo and 29% of the MTX mono group ($p=0.835$). At wk 2, the proportion of patients achieving DAS28 remission and LDAS28 was significantly greater in the combo than in the mono group (38% vs. 9%, $p<0.001$ and 53% vs. 26%, $p=0.003$). At wk 26 and wk 52 a high proportion of patients in both groups were in DAS28 remission and LDAS28 [wk 26 (DAS28 remission 67% vs. 49%, $p=0.053$; LDAS28 82% vs. 62%, $p=0.020$), wk 52 (DAS28 remission 67% vs. 64%, $p=0.688$; LDAS28 82% vs. 73%, $p=0.255$)]. Nine patients (8.2%) withdrew due to lack of efficacy and 5 (4.5%) due to toxicity.

Conclusion: In this group of patients with newly diagnosed inflammatory arthritis, rapid clinical responses were demonstrated with MTX+ETN combination therapy. High proportions achieved DAS 28 remission and low disease activity with approximately one third of patients demonstrating no clinical synovitis at one year. A particularly good response was also seen in this study with MTX monotherapy with similar results to the combination therapy group seen at one year. Predictors of response will be examined.

1. Emery P, Kvien TK, Combe B, Foehl J, Robertson D, Pedersen R, et al. Very early (< 4 months) treatment with combination etanercept (ETN) and methotrexate (MTX) produces significantly better remission rates: results from the COMET study. Ann Rheum Dis 2010;69(Suppl3):57.

Subsequent Therapy of Patients with Biologic Response Modifiers or Disease-Modifying Antirheumatic Drugs After Coccidioidomycosis.
Susan Knowles[1], Sara Taroumian[1], Jeffrey R. Lisse[1], James Yanes[1], Neil M. Ampel[2], Eric P. Gall[3], Rafael G. Grau[1], Barbara Y. Bode[2], Berchman A. Vaz[4], John Galgiani[5] and Susan E. Hoover[1]. [1]University of Arizona, Tucson, AZ, [2]Southern AZ VA Medical Center, Tucson, AZ, [3]Arizona Arthritis Center, Tucson, AZ, [4]Catalina Pointe Arthritis and Rheumatology, Tucson, AZ, [5]Valley Fever Center for Excellence, Tucson, AZ

Background/Purpose: Coccidioidomycosis (cocci, Valley fever) is a fungal infection endemic to the Southwestern United States, affecting approximately 150,000 people annually. While most are subclinical pulmonary infections, patients on biologic response modifiers (BRMs), including tumor necrosis factor (TNF) antagonists, are at higher risk of developing severe or disseminated disease. There are currently no guidelines regarding BRM or disease-modifying antirheumatic drug (DMARD) therapy or duration of antifungal therapy following cocci.

Methods: A retrospective chart review identified patients who developed cocci while on DMARDs or BRMs. Patients were seen at least once in a University-affiliated or Veterans Administration outpatient rheumatology clinic in Tucson, Arizona between 2007–2009. Charts were reviewed up to June 1, 2011. Review emphasized the mode of diagnosis, clinical manifestations, antifungal therapy and duration, and management of BRM/DMARDs after the diagnosis was made.

Results: We identified 44 patients with cocci during treatment with a BRM and/or DMARD. Rheumatologic treatment was BRM alone (11), DMARD alone (8), or combination therapy (25). Cocci manifestations were asymptomatic positive serologies (6), pulmonary cocci (29), or disseminated disease (9). After the diagnosis of cocci, patients had no change in immunosuppressive therapy (10), all BRM and DMARDs stopped (26), or BRM stopped but DMARD therapy continued (8). All but 3 patients had antifungal therapy initiated for 3 months or longer.

Follow-up data were available for 38 patients. BRM and/or DMARD therapy was continued or resumed in 33 and none have had dissemination or complications from cocci. Sixteen also continued on antifungal therapy. Four patients were not treated with BRM/DMARD due to remission of their rheumatic disease; 1 patient was not treated with BRM/DMARD due to dissemination. The most common reasons for continuing antifungal therapy were persistent positive serologies and disseminated cocci. The most common reason for stopping antifungal therapy was negative cocci serology. Follow-up for patients who stopped antifungals or were never treated is 3 to 96 months (median 30 mos).

Conclusion: Treating with a BRM and/or DMARD after cocci infection appears to be safe in some patients based on our small series. Several patients with negative serologies and resolution of infection resumed BRM/DMARD without concomitant antifungal therapy. Some patients with disseminated disease or persistently positive serologies continued on antifungal therapy when a BRM/DMARD was restarted. Larger studies with longer follow up are indicated to further characterize the relationship between BRM/DMARD therapy and this endemic fungal infection.

Red Blood Cell Folate Polyglutamates Are An Important Determinant of RA Disease Activity In Patients On Methotrexate – Implications for Folic Acid Supplementation.
Lisa K. Stamp[1], Peter T. Chapman[2], Murray Barclay[1], Joel M. Kremer[3] and Thierry Dervieux[4]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]Christchurch Hospital, Christchurch, New Zealand, [3]Albany Medical College and The Center for Rheumatology, Albany, NY, [4]3Exagen Diagnostics, Albuquerque, NM

Background/Purpose: Methotrexate (MTX) produces anti-arthritic effects at least in part through folate depletion. Patients receiving MTX are given supplemental folic acid which is thought to reduce MTX adverse effects with minimal effects on efficacy. There is conflicting evidence between United States (US) and New Zealand (NZ) cohorts as to whether elevated red blood cells (RBC) MTX polyglutamate (MTXGlu) concentrations are associated with lower disease activity in RA. However, data from both cohorts suggest that RBC folate polyglutamate (FPGs) may be an important determinant of disease activity. The aim of this study was determine the contribution of RBC $MTXGlu_n$ and RBC FPGs to disease activity in patients with RA from NZ and the USA.

Methods: Data from 428 patients receiving MTX monotherapy (256 patients from the US and 172 patients from NZ) were combined. Cohorts were compared and multivariate logistic regression analysis was undertaken to determine the relationships between RBC $MTXGlu_n$, RBC FPG and RA disease activity (DAS28>5.1).

Results: The mean age of the combined cohorts was 62.4years (18–90.8yrs), 73.6% were female, 61 (14%) were receiving weekly SC MTX and the remainder oral MTX. The majority of patients (386, 90%) were receiving supplemental folic acid (5mg/week in NZ and 1mg/day in US). In comparison to the US cohort, patients in the NZ cohort received higher MTX dose (15.8 vs. 14.0mg/wk; $p<0.001$) and fewer patients were receiving steroids (31.4% vs. 48%; $p<0.001$). DAS28 was significantly lower in the NZ cohort than the US cohort (2.97 vs. 3.8; $p<0.001$). This improved disease control was commensurate with higher long-chain RBC $MTXGlu_3$ (45 ± 1.6 vs. 40 ± 1.5; $p=0.02$) and lower RBC FPGs concentrations (518 ± 22 vs. 1111 ± 32 nmol/l; $p<0.001$) in the NZ cohort than the US cohort. Multivariate logistic regression analysis allowing for age, MTX dose, route of MTX administration, use of steroids, and country revealed that a DAS28>5.1 was associated with lower long-chain $MTXGlu_n$ concentrations ($MTXGlu_3$: $p=0.021$; $MTXGlu_{3-5}$ $p=0.02$) but higher RBC FPGs ($p=0.01$). There was a significant positive correlation between RBC FPGs and DAS28 ($r^2=0.1$, $p<0.001$). For patients with RBC folate ≥1000nmol/L significantly fewer patients had DAS28>5.1 when $MTXGlu_3$ concentrations were ≥20nmol/l compared to <20nmol/L ($p=0.04$) (Table 1).

Table 1. Number (%) of patients with DAS28>5.1 by long chain $MTXGlu_3$ and FPG concentrations

	RBC folate polyglutamates	
$MTXGlu_3$	Low (<1000nmol/l)	High (≥1000nmol/l)
Low (<20nmol/l)	3/44 (6.8%)	8/21 (38%)
High (≥20nmol/l)	10/172 (5.8%)	14/99 (14.4%)

Conclusion: In RA patients on methotrexate, disease activity is dependent on both long-chain MTXGlu and RBC folate concentrations. However, the RBC folate concentration appears to be the more important determinant. Because higher supplemental folic acid doses as well as dietary fortification in the US result in higher RBC folate concentrations in the US than in NZ, further studies will be important to determine the most appropriate regimen for folic acid supplementation in patients on MTX.

2468

Discontinuation of Adalimumab Without Functional and Structural Progress After Attaining Remission in Patients with Rheumatoid Arthritis. Yoshiya Tanaka[1], Shintaro Hirata[1], Shunsuke Fukuyo[1], Masao Nawata[2], Satoshi Kubo[1], Kunihiro Yamaoka[2] and Kazuyoshi Saito[1]. [1]University of Occupational & Environmental Health, Japan, Kitakyushu, Japan, [2]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background/Purpose: Biologics targeting TNF has revolutionized the treatment of RA, enabling high clinical remission rate and producing emerging endpoint of treatment, which has made us approach to biologic-free remission. Discontinuation of TNF inhibitors after acquisition of remission is an important issue from the viewpoints of safety and economy. However, reports on this topic are only from BeSt study and TNF20 study in early RA. We have reported that infliximab could be discontinued after attaining low disease activity by the RRR study. All of which were treated with infliximab. Recent finding in OPTIMA study using adalimumab is also done for early RA. The present study was undertaken to seek the possibility of discontinuing adalimumab therapy after acquiring clinical remission of RA and to evaluate progression of articular destruction during infliximab discontinuation.

Methods: The study included patients with any disease duration, but excluded patients who had received steroids at dosages greater than 5mg/day. After obtaining DAS28<2.6 for more than 24 weeks, adalimumab was discontinued. The primary endpoint was DAS28<3.2 at 6 months after the discontinuation. Modified total Sharp score (mTSS) was checked at registration and 1 year after the discontinuation. The second endpoint is DAS28, SDAI, mTSS and HAQ at 1 year after the discontinuation.

Results: Among 156 RA patients treated with adalimumab and MTX, 40 patients discontinued adalimumab because DAS28<2.6 was kept for more than 24 weeks. The average of age was 58, mean disease duration was 93 months and mean duration treated with adalimumab was 62 weeks. The disease duration was significantly shorter in patients who could discontinue adalimumab than those who kept the therapy. Thirty and 16 patients were estimated at 6 months and 1 year, respectively after the discontinuation of adalimumab. Twenty two cases (73%), 17 cases (57%) and 21 cases (79%) reached DAS28<3.2 low disease activity, DAS28<2.6 remission and SDAI<3.3 remission for 6 months after discontinuation of adalimumab, respectively, indicating the study is satisfied with the primary endpoint. DAS28 at study entry affected the primary endpoint and cut-off point affecting the study achievement was 1.9, suggesting "deep remission" is required for the discontinuation. Of 16 patients estimated at year 1 after the discontinuation, 10 (63%), 11 (69%) and 14 (88%) reached DAS remission, SDAI remission and HAQ remission, respectively. Radiographic estimation could be done in 17 patients. The ΔmTSS from the discontinuation to year 1 was −0.2 and 1.9, and the ratio of structural remission for 1 year was 100% and 71%, in 10 patients who kept remission for 1 year and 7 patients who flared within 1 year after the discontinuation, respectively.

Conclusion: Although it is a limited study, after reduction of disease activity to clinical remission in patients with RA by adalimumab, most patients, especially reaching "deep remission", could successfully remain clinical remission without adalimumab for 6 months or 1 year and without radiologic and functional progression of articular destruction. Thus, tight control targeting remission by ADA potentiates biologic-free remission without functional progress.

2469

Efficacy and Safety of Abatacept Over 12 Months in Patients with Lupus Nephritis: Results From a Multicenter, Randomized, Double-Blind, Placebo-Controlled Phase II/III Study. Richard Furie[1], Kathy Nicholls[2], Tien-Tsai Cheng[3], Frederic Houssiau[4], Ruben Burgos-Vargas[5], Shun-Le Chen[6], Richard Aranda[7], Stephanie Meadows-Shropshire[8], Michael Kinaszczuk[8] and Joan T. Merrill[9]. [1]North Shore-Long Island Jewish Health System, Lake Success, NY, [2]Royal Melbourne Hospital, Victoria, Australia, [3]Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan, [4]Cliniques Universitaires Saint-Luc, Brussels, Belgium, [5]Hospital General de Mexico, Mexico City, Mexico, [6]Joint Molecular Rheumatology Laboratory of Institute of Health Sciences and Shanghai Ren Ji Hospital, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences and Shanghai Jiao Tong University School of Medicine, Shanghai, China, [7]Bristol-Myers Squibb [at time of study], Princeton, NJ, [8]Bristol-Myers Squibb, Princeton, NJ, [9]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Abatacept (ABA), a selective T-cell costimulation modulator approved for rheumatoid arthritis, is being evaluated for lupus. Preclinical data in murine lupus and Phase II data in systemic lupus erythematosus (SLE) pts with arthritis, serositis or discoid lesions[1] supported the development of ABA in lupus nephritis (LN).

Methods: This was a 12-mth Phase II/III double-blind study in pts with active ISN/RPS Class III or IV LN, requiring: urinary protein/creatinine ratio (UPCR) ≥0.44 mg/mg (50 mg/mmoL); active urinary sediment (>5 red blood cells [RBC]/high power field [hpf] or >8 white blood cells/hpf or cylindruria); and renal biopsy within 3 mths (if biopsy 3–12 mths, abnormal C3, C4 or anti-dsDNA also required). All pts received mycophenolate mofetil (MMF; target dose 1.5–3.0 g/day dependent on race) and up to 60 mg/day prednisone or equivalent (with response-guided taper after 28 days). Pts were randomized to placebo (PBO) or IV ABA (either 3 mths of ABA 30 mg/kg followed by 9 mths of 10 mg/kg [30/10], or 12 mths of 10 mg/kg [10/10]). The primary efficacy endpoint was time to Complete Renal Response (CRR: GFR within 10% of pre-flare/screening value; UPCR <0.26 mg/mg [30 mg/mmol]; inactive urinary sediment) confirmed at 30 days after the first response, compared using a Cox proportional hazards model. Secondary endpoints included time to Renal Improvement (RI) and Mth 12 rates of CRR and RI (RI: ≥50% UPCR reduction, GFR ≥50% improved if screening 15–59, otherwise ≥90% of screening; no active sediment). Exploratory endpoints included 1) Patient Response (PR: UPCR <0.5 mg/mg [56.5 mg/mmol] or ≥50% UPCR improvement to <1.0 mg/mg [113 mg/mmol] if baseline ≤3.0 mg/mg [339 mg/mmol] or to 3.0 mg/mg if baseline >3.0; RBCs within reference range (<5–8/hpf) or ≥50% reduction; serum creatinine normal or ≤25% above baseline) and 2) Renal Response (RR: serum creatinine ≤25% above baseline; ≥50% UPCR improvement to <1.0 mg/mg if baseline ≤3.0 or to <3.0 mg/mg if baseline >3.0). Safety was assessed.

Results: Of 298 treated pts, 228 (76.5%) completed Mth 12 (78.0, 74.7, and 76.8% in PBO, ABA 10/10, and ABA 30/10). Time to CRR did not differ between groups (p=0.549 and 0.422) for ABA 10/10 and 30/10 vs PBO) nor did time to RI. Efficacy at Mth 12 is shown (Table). A subset analysis of 122 nephrotic pts (baseline UPCR >3.0 mg/mg) found ~20–30% greater reduction in UPCR in pts randomized to ABA vs PBO from Mth 6, maintained to Mth 12. Safety is reported (Table). Cause of death appeared to be underlying disease for 5 pts and infection for 7.

	Placebo N=100	10/10 N=99	30/10 N=99

Most common:*	3 (3.0)	4 (4.0)	4 (4.0)
Pneumonia	0	6 (6.1)	3 (3.0)
Herpes zoster	2 (2.0)	1 (1.0)	5 (5.1)
Gastroenteritis	2 (2.0)	2 (2.0)	0
Urinary tract infection			

*Reported in more than one pt in either abatacept group

Conclusion: ABA, MMF and steroids exhibited a safety profile similar to MMF and steroids in pts with LN. Pre-specified efficacy endpoints did not demonstrate a benefit at 12 mths for ABA vs PBO. Among nephrotic pts, an exploratory analysis showed improvement in proteinuria with ABA, suggesting that additional exploration may be warranted to investigate potential biologic activity in this subset.

Active Immunization Against IFNα with IFN-Kinoid in SLE Patients Is Safe, Immunogenic and Induces Down-Regulation of IFN-Mediated Genes. Frédéric. A. Houssiau[1], Raskov Rashkov[2], Eric Hachulla[3], Estibaliz Lazaro[4], Christian Jorgensen[5], François Spertini[6], Xavier Mariette[7], Géraldine Grouard-Vogel[8], Bernard Fanget[8], Olivier Dhellin[8], Bernard Lauwerys[1] and Pierre Vandepapelière[8]. [1]Université catholique de Louvain, Brussels, Belgium, [2]MHAT Sveti Ivan Rilski, Sofia, Bulgaria, [3]Internal Medicine, Lille CEDEX, France, [4]Hôpital Haut-Lévêque, Pessac, France, [5]Hospital Lapeyronie, Montpellier, France, [6]CHU Vaudois, Lausanne, Switzerland, [7]Université Paris-Sud, Le Kremlin Bicetre, France, [8]NEOVACS SA, Paris, France

Background/Purpose: Interferon alpha (IFNα) is associated with the severity and disease activity of SLE. Active immunization against IFNα induces polyclonal antibodies against all IFNα subtypes *in vivo* and prevents severe renal lupus disease in NZW/NZB SLE-prone mice. We evaluate IFNα-Kinoid in a first clinical study in SLE patients.

Methods: IFNα-Kinoid (IFNα-K, Neovacs SA, Paris, France) is an immunotherapeutic agent composed of recombinant human IFNα conjugated to KLH as a carrier protein, inactivated and adjuvanted with ISA-51 emulsion.

Twenty-eight patients with mild to moderate, seropositive lupus (SLEDAI 4–10) were enrolled in a double-blind, placebo-controlled, phase 1–2, dose escalation study to evaluate the safety and the immunogenicity of four doses of IFNα-K (30, 60, 120 or 240 mg) administered intramuscularly on Days 0, 7 and 28 with an optional fourth dose on Day 84. Safety evaluation included recording of adverse events and monitoring of haematological and biochemical parameters. Immune responses were measured through titration of anti-IFNα and anti-KLH antibodies, and cellular lymphoproliferation assays. Clinical response was assessed by evaluation of BILAG, SLEDAI, PGA, SRI and titration of serum auto-antibodies, and of IFNα regulated chemokines. PBMC were harvested at several time-points and transcriptomic studies were performed on total RNA using Genechip HGU133 Plus 2.0 arrays.

Results: The safety profile is very favourable. Few minor and transient local and systemic reactions have been observed following immunization. Only minor and transient infections were reported. Two lupus flares were reported as related serious adverse events, one in the active group in a patient who had spontaneously stopped glucocorticoid therapy after the first IFNα-K dose, the other in the placebo group. A dose-related anti-IFNα antibody response was measured in all immunized patients. Antibodies peak after the last dose and decline afterwards.

Transcriptomic studies performed on baseline PBMC samples indicated that the patients cluster into two groups, characterized by the presence or absence of an IFNa signature. Patients with a positive signature have significantly higher dsDNA Ab titers and significantly lower C3 and C4 levels. In the patients with a baseline IFN signature, follow-up transcriptomic studies, performed as early as 38 days after the first IFNα-K injection, showed a significant down-regulation of the expression of IFN-induced genes in the IFNα-K group as compared to the placebo recipients, and, more generally, of SLE over-expressed genes as a whole.

Conclusion: This is the first study to show positive immune and pharmacodynamic results with active immunotherapy against Interferon-α in the treatment of Systemic Lupus Erythematosus. These results are promising and further studies are planned in order to expand upon these observations.

2471

Omega-3 in Systemic Lupus Erythematosus: A Double-Blind, Placebo-Controlled Randomized Clinical Trial In Systemic Lupus Erythematosus. Kayode J. Bello[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Potential health benefits of Omega-3 fatty acids have been reported in cancer, depression, immune and inflammatory processes, and especially in the cardiovascular system (dyslipidemia and cardiac function). In a previous clinical trial, Omega-3 was reported to reduce disease activity in SLE. We performed a clinical trial to examine the effect of Omega-3 on disease activity, endothelial function, inflammatory markers and lipids in SLE patients.

Methods: A randomized, double-blind, placebo controlled clinical trial of Omega-3 polyunsaturated fatty acids was performed. 85 SLE patients (mean age 47.18, 55.29% Caucasian, 37.65% African-American, 94.11% female) were randomly assigned to two treatment groups of either 3 gram Omega 3 (Lovaza, GSK) or placebo for twelve weeks. Disease activity was measured using the physician global assessment (PGA) and SELENA-SLEDAI score. Endothelial function was measured using flow mediated dilation (FMD) calculated from high resolution B-mode ultrasound of brachial artery diameter in response to vasoactive stimuli. Blood samples were drawn for inflammatory markers (s-ICAM-1, s-VCAM-1, IL-6) and lipids profile at baseline and 12-week follow up visits.

Results: Omega 3 had no benefit for disease activity in SLE or for flow mediated dilation (FMD). There was no significant reduction in inflammatory markers. Total cholesterol and LDL cholesterol significantly increased in the Omega 3 group.

Table 1. Association between Omega 3 and various factors in patients with SLE

	Mean Change in Omega 3 Group (SD) (n=42)	Mean Change in Placebo Group (SD) (n=43)	P-value*
s-ICAM-1	−1.61 (40.27)	−5.56 (48.74)	0.2456
s-VCAM-1	−17.52 (101.65)	26.57 (135.98)	0.0918
IL-6	−1.95 (11.16)	−27.60 (186.37)	0.2447
Cholesterol	3.36 (27.24)	−6.48 (22.95)	0.0228
Triglycerides	−43.45 (71.71)	−29.48 (61.81)	0.7041
HDL	2.55 (8.49)	−2.21 (11.87)	0.0929
LDL	3.11 (21.99)	−1.87 (18.29)	0.0266
PGA	0.07 (0.54)	0.21 (0.44)	0.2914
SLEDAI	−0.17 (1.87)	0.51 (2.18)	0.1122

* Based on ANCOVA model using baseline values as a covariate

Table 2. Differences (post-treatment – pre-treatment) in mean percent diameter changes (SD) of flow-mediated dilation among those treated with Omega-3 or Placebo

Period	Variable	Omega-3	Placebo	P-value[1]
Post-Pre differences	Baseline	0.00 (0.04)	0.00 (0.05)	.99
	30 second % change	−0.60 (7.80)	−0.89 (0.83)	.87
	60 second % change	−2.36 (10.01)	−2.73 (8.72)	.86
	90 second % change	−3.96 (11.73)	−2.76 (9.68)	.62

[1] Based on a two-sample t-test.

Conclusion: In this trial, Omega 3 did not affect disease activity, improve endothelial function nor reduce inflammatory markers in SLE. Longer trials might be required if there are delayed clinical effects. However, there was evidence that Omega 3 may increase LDL cholesterol, which would reduce enthusiasm for its long term use in SLE.

2472

Effect of Belimumab Treatment on Renal Outcomes: Results From Phase 3 Belimumab Clinical Trials in Patients with Systemic Lupus Erythematosus. M.A. Dooley[1], F. Houssiau[2], C. Aranow[3], D.P. D'Cruz[4], Anca D. Askanase[5], D. Roth[6], Z.J. Zhong[7], W. Freimuth[7], E.M. Ginzler[8] and BLISS-52/-76 Study Groups[9]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Université catholique de Louvain, Brussels, Belgium, [3]Feinstein Institute for Medical Research, Manhasset, NY, [4]St. Thomas' Hospital, London, United Kingdom, [5]NYU School of Medicine, New York, NY, [6]GlaxoSmithKline, King of Prussia, PA, [7]Human Genome Sciences, Inc., Rockville, MD, [8]SUNY-Downstate Medical Center, Brooklyn, NY, [9]Multicenter

Background/Purpose: To evaluate the effect of belimumab on renal parameters in two phase 3 trials including patients with active systemic lupus erythematosus (SLE) without acute lupus nephritis.

Methods: Autoantibody-positive (antinuclear antibody ≥1:80 or anti-double-stranded DNA [anti-dsDNA] ≥30 IU/mL) SLE patients (N = 1684) with Safety of Estrogen in Lupus Erythematosus National

Assessment-SLE Disease Activity Index (SELENA-SLEDAI) score ≥6 were randomly assigned to belimumab 1 or 10 mg/kg, or placebo, plus standard therapy, for 52 wk (BLISS-52; NCT00424476) or 76 wk (BLISS-76; NCT00410384). The studies were not designed to assess treatment effects on renal outcomes, and patients with severe active lupus nephritis were excluded. Renal parameters collected included renal flares, renal remission, proteinuria, renal items from SELENA-SLEDAI and BILAG, as well as anti-dsDNA and complement (C3/C4) levels. Pooled data are reported through wk 52.

Results: At baseline, 16.4%, 16.1%, and 15.1% of patients treated with placebo, and belimumab 1 and 10 mg/kg, respectively, had renal involvement by SELENA-SLEDAI; 10.5%, 11.1%, and 10.3% had BILAG A or B renal domain scores; and 5.7%, 5.9%, and 6.0% had proteinuria ≥2 g/24 h. Over 52 wk, belimumab-treated patients had numerically lower rates of renal flare, higher rates of renal remission, and shorter time to 1st renal remission vs those treated with standard therapy alone (table). In patients with baseline proteinuria >0.5 g/24 h, the median % reduction in proteinuria at wk 52 was numerically greater in the belimumab groups. More belimumab plus standard therapy patients had renal improvement by both SELENA-SLEDAI and BILAG (10 mg/kg only) measures at wk 52 vs standard therapy alone. More patients receiving belimumab plus standard therapy converted from anti-dsDNA–positive at baseline to negative, and had normalized low baseline C3/C4 levels at wk 52 vs standard therapy alone. In patients with low C3/C4 and anti-dsDNA–positivity at baseline, the difference in wk-52 SELENA-SLEDAI renal improvement between belimumab plus standard therapy and standard therapy alone was more pronounced than in the overall population.

Renal Involvement at Baseline and Outcomes at Wk 52: Pooled Data	Standard Therapy Plus Placebo (n = 562)	Belimumab 1 mg/kg (n = 559)	Belimumab 10 mg/kg (n = 563)
SELENA-SLEDAI renal involvement at baseline (any of hematuria, proteinuria, pyuria, urinary casts), n (%)	92 (16.4)	90 (16.1)	85 (15.1)
BILAG renal domain A or B score at baseline, n (%)	59 (10.5)	62 (11.1)	58 (10.3)
Renal flare over 52 wk, n (%)[a]	16 (2.8)	14 (2.5)	8 (1.4)
Renal remission over 52 wk in patients with baseline proteinuria ≥1 g/24 h, (%)[b]	n = 44/75 58.7	n = 44/67 65.7	n = 55/78 70.5
Median time to first renal remission, d (min, max)	167 (27, 364)	139 (26, 343)	140 (26, 337)
Median % change in proteinuria from baseline at wk 52[c]	n = 116 −27.5	n = 110 −48.3	n = 112 −39.1
Any SELENA-SLEDAI renal improvement at wk 52, %[d,e]	n = 41/92 44.6	n = 46/90 51.1	n = 46/85 54.1
SELENA-SLEDAI proteinuria item improvement, %[f,g]	n = 33/79 41.8	n = 37/78 47.4	n = 31/69 44.9
Any SELENA-SLEDAI renal improvement in low C/anti-dsDNA+ subgroup at wk 52, %[e,h]	n = 21/62 33.9	n = 25/60 41.7	n = 30/60 50.0
Proteinuria item improvement in lowC/anti-dsDNA+ subgroup at wk 52, %[g,h]	n = 16/53 30.2	n = 21/54 38.9	n = 23/53 43.4
BILAG renal improvement at wk 52, %[e,i]	n = 11/22 50.0	n = 10/24 41.7	n = 14/22 63.6
Anti-dsDNA conversion from positive (≥30 IU/mL) at baseline to negative at wk 52, % [j]	n = 19/280 6.8	n = 47/314 15.0+	n = 50/313 16.0#
Low baseline C3 conversion to normal/high (≥90 mg/dL) level at wk 52, %[k]	n = 30/176 17.0	n = 51/193 26.4*	n = 77/202 38.1#
Low baseline C4 conversion to normal/high (≥16 mg/dL) level at wk 52, %[k]	n = 40/218 18.3	n = 86/246 35.0#	n = 115/259 44.4#

*p <0.05; +p <0.01; #p <0.001; otherwise, p = not significant.
[a] Renal flare defined as per Alarcón-Segovia D, Tumlin JA, Furie RA, et al. *Arthritis Rheum.* 48;442–54, 2003; [b]renal remission defined as erythrocyte count <10 cells/hpf, absence of cellular casts, and proteinuria <1 g/24 h equivalent without doubling serum creatinine level; [c]in patients with baseline proteinuria >0.5 g/24 h; [d] in patients with renal involvement at baseline; [e]p values not reported because studies were not designed to examine belimumab's treatment effect on individual organ domains and sample sizes are small; [f]in patients with renal item involvement at baseline; [g]proteinuria decrease of >0.5 g/24 h equivalent or decrease to ≤0.5 g/24 h equivalent; [h]in patients with positive anti-dsDNA (≥30 IU/mL), low C (C3 <90 mg/dL; C4 <16 mg/dL) and renal organ (or specific item) involvement at baseline; [i]in patients scored as having active renal disease at baseline by the principal investigator; improvement defined as step down from baseline BILAG A or B score to B, C, or D at wk 52; [j]in patients with positive anti-dsDNA at baseline; [k]in patients with low C at baseline. C, complement.

Conclusion: These data from a small subgroup of patients with renal involvement at baseline suggest that belimumab may have beneficial effects on renal outcomes in SLE and support initiation of a randomized trial to evaluate belimumab treatment for lupus nephritis.

2473

Allogeneic Mesenchymal Stem Cells Transplantation in Severe and Refractory Systemic Lupus Erythematosus-Four Years Follow up. Lingyun Sun, Dandan Wang, Huayong Zhang, Xia Li and Xuebing Feng. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background/Purpose: To assess the long-term efficacy and safety of allogenic bone marrow or umbilical cord derived mesenchymal stem cells transplantation (MSCT) for patients with severe and treatment-refractory systemic lupus erythematosus (SLE). ClinicalTrials.gov Identifier: NCT00698191.

Methods: A single-arm trial involved 87 SLE patients, aged from 12 to 56 years old, that were either refractory to standard treatment or with life-threatening visceral involvement. Disease duration was 37.5 months (range, 2 to 264 months). 51 of 87 patients were each given a total of 0.6~2.4gm of CYC intravenously. The other 36 patients received no CYC due to poor physical conditions at baseline. Twenty-three patients were infused once with bone marrow (BM) derived MSCs, 46 patients received once umbilical cord (UC) derived MSCs, while the other 18 patients were transplanted multiple MSCs, due to disease relapse or unsatisfactorily controlling. Allogeneic BM or UC MSCs were administered 1.0×10^6/kg of body weight intravenously once time. The clinical manifestations and laboratory parameters were compared pre- and post-MSCT, with a mean follow-up of 27 months (range, 12 to 48 months). Adverse event was monitored all the time during and post-MSCT.

Results: During the 4 years follow up, the overall rate of survival was 94% (82/87). Five patients died 5, 6, 6, 10 and 18 months post-MSCT respectively, due to uncontrolled infection or disease relapses. Disease-free survival (SLE Disease Activity Index, SLEDAI less than 3 and prednisone dose less than 10mg per day) was 28% at 1 year (23/83), 31% at 2 years (12/39), 42% at 3 years (5/12) and 50% at 4 years (3/6). Rates of relapse (SLEDAI increased at least by 3 and an increase in prednisone or immunosuppressive drug) were 12% (10/83) at 1 year, 18% (7/39) at 2 years, 17% (2/12) at 3 years and 17% (1/6) at 4 years. The overall rate of relapse was 23% (20/87). Significant improvements in SLEDAI score, serum albumin and complement C3 were examined at 1, 2, 3, and 4 years post transplantation. Renal function assessed by 24-hour proteinuria improved 1, 2, 3 and 4 years after MSCT. For those with abnormal levels of serum creatinine and urea nitrogen at baseline, these indexes improved significantly 1 and 2 years after MSCT. Glomerular filtration rate (GFR) was detected for 25 patients before MSCT and then yearly after transplantation, significant improvement was found for 11 patients (56.6 ± 22.8ml/min before MSCT, 78.0 ± 28.1ml/min at 1 year, 91.8 ± 21.3ml/min at 2 years, both $p<0.01$), no change in 12 patients (65.2 ± 27.7ml/min before MSCT, 63.5 ± 30.1ml/min at 1 year, 60.5 ± 32.6ml/min at 2 years), and deterioration in 2 patients (from 78.0 ± 8.5ml/min before MSCT to 30.0 ± 7.1 at 2 years), who also had disease relapses 28 and 24 months after MSCT respectively. During 4 years follow up, no transplantation-related adverse event was observed for all the patients. For 93% (76/82) patients, dose of glucocorticoid was tapered to less than 10mg per day, and dose of immunosuppressant was tapered to maintenance level for 60% (49/82) patients at the last follow up.

Conclusion: Allogeneic MSCs transplantation is a safe and effective therapeutic option for severe and refractory SLE patients.

2474

Abatacept for Lupus Nephritis: Alternative Outcome Measures Support Opposing Interpretations of Data From a Multicenter, Randomized, Double-Blind, Placebo-Controlled Phase II/III Study. David Wofsy[1], Stephanie Meadows Shropshire[2], Jan L. Hillson[3] and Betty Diamond[4]. [1]VA Medical Center, San Francisco, CA, [2]Bristol-Myers Squibb, Richmond, VA, [3]ZymoGenetics Inc., Seattle, WA, [4]Feinstein Institute Med Rsch, Manhasset, NY

Background/Purpose: Recent trials of novel therapies for lupus nephritis (LN) have used varying primary endpoints, but there is no consensus about which may be most sensitive to change or most representative of clinical status. We compared the performance of two different outcome measures when applied to the same data set from a double-blind, controlled phase II/III study of abatacept (ABA) in patients with LN (trial IM101075- efficacy and safety reported in a separate abstract).

Methods: In IM101075, 300 subjects were randomized 1:1:1 to one of: 3 mos ABA 30 mg/kg and 9 mos of 10 mg/kg [30/10]; 12 mos ABA10 mg/kg [10/10]; or placebo, administered IV in combination with MMF (target dose 1.5–3.0 gm/d) and corticosteroids (prednisone 60 mg/d or equivalent with response-guided taper.) We compared two outcome measures (OM) that have been accepted by

the FDA for use in trials of ABA for LN. OM1, from IM101075, is the proportion of subjects with complete response (CR) at Study Day 337 and 365, defined as eGFR within 10% of pre-treatment value, urine prot:creat ratio (UPCR) <30 mg/mmol, and normal urine sediment. In contrast, OM2 as defined in the ongoing ACCESS study (NCT00774852) is the proportion of subjects who reach CR,defined as serum creatinine either normal or ≤125% of baseline, UPCR <0.5 g/g, and prednisone dose ≤10 mg/d at Study Day 365; urine sediment is not a component of OM2. In 24 subjects from IM101075, renal disease was too mild at entry (UPCR <1 g/g) to apply the OM2 criteria; therefore, these subjects were excluded from the analysis of OM2.

Results: The analysis of OM1 in study IM101075 showed few CRs overall and no difference among the groups (Table). In contrast, OM2 yielded a much higher CR rate and significant differences among groups. The results with OM2 were most striking in patients who were nephrotic at baseline (UPCR >339 mg/mmol).

	Control	ABA 10/10	ABA 30/10
OM1 at Day 337 and 365 (all treated patients), n/N (%)	3/100 (3.0%)	3/99 (3.0%)	5/99 (5.1%) 2.4
Estimate of difference vs. Control (95% CI)		0.0 (−4.6, 4.7)	(−2.4, 7.2)
OM2 at Day 365 (patients with UPCR >1 at entry), n/N (%)	19/90	32/92 (34.8%)	27/92 (29.3%)
Estimate of difference vs. Control (95% CI)	(21.1%)	13.7 (0.6, 26.4)	8.2 (−4.4, 20.7)
OM2 at Day 365 (subjects nephrotic at baseline), n/N (%)	2/45 (4.4%)	9/38 (23.7%)	9/39 (23.1%)
Estimate of difference vs. Control (95% CI)		19.2 (4.4, 35.8)	18.6 (4.0, 35.0)

n=number of subjects with CR, N=number of subjects in the analysis

Conclusion: These findings demonstrate the importance of the choice of outcome measure for LN trials, and they strongly suggest that OM2 is more sensitive to differences between groups. The ability of either measure to predict long-term outcome remains to be determined. These findings have implications for the interpretation of the IM101075 study from which the data were drawn, supporting further evaluation of the efficacy ABA+MMF in patients with LN.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, heterogeneous autoimmune disorder characterized by inflammation, loss of tolerance to self-antigens, and dysregulated interferon responses. In this study, we sought to replicate loci with suggestive association with SLE from a previously published genome-wide association scan.

Methods: Genotyping was performed using Illumina iSelect technology. Stringent quality control measures were applied for Hardy- Weinberg proportions, missing genotypes, and excess missingness between cases and controls. In addition, genetic outliers were determined using principal component (PC) analysis. Only SNPs with minor allele frequencies >1% were considered. After quality control filtering, 3562 SLE cases and 3491 controls of European ancestry (EA), 1527 cases and 1811 controls of African-American (AA) descent, and 1265 cases and 1260 controls of Asian (AS) origin were included in the replication analysis. SNP-SLE association was tested using logistic regression under an additive genetic model in PLINK while adjusting for the first three PCs and gender. Meta-analysis was performed using METAL.

Results: Three regions exceeded genome-wide significance (GWS) after the trans-racial replication study. One region that replicated in EA, AA, and AS subjects was located at 11q24.1 outside the 3′UTR region of interferon regulatory factor 8 (*IRF8*; $P_{meta} = 2.34 \times 10E\text{-}9$). Approximately 300 additional SNPs were genotyped in the region of *IRF8*. Two risk haplotypes were observed within the EA subjects ($P = 3.85 \times 10E\text{-}7$ and $P = 7.99 \times 10E\text{-}10$). Logistic regression conditioning on the most significant SNP in each haplotype indicated that these effects were independent. The other two loci included a coding SNP in *TMEM39A* (transmembrane protein 39A; $P_{meta} = 8.62 \times 10E\text{-}9$), and an intra-genic SNP at 17q21 between the genes *IKZF3/ZBP2* in a shared promoter region ($P_{meta} = 3.48 \times 10E\text{-}9$). All three regions have been implicated in other autoimmune diseases. In addition, 13 other loci were replicated in EA but did not exceed GWS with $5 \times 10E\text{-}8 < P < 9.99 \times 10E\text{-}5$ (*CFHR1, CADM2, LOC730109/IL12a, LPP, LOC63920, SLU7, ADATMTSL1, C10orf64, SEN3, OR8D4, FAM19A2, STXBP6,* and *TMCO5*).

Conclusion: *IRF8* is a transcription factor involved in the regulation of the interferon pathway, which has been widely reported to be dysregulated in SLE and other autoimmune diseases. No biologically relevant data has been published for *TMEM39A*. Association with *IRF8* and *TMEM39A* has been previously reported with multiple sclerosis (MS). *IKZF3* is an important transcription factor regulating B lymphocyte proliferation and differentiation. Multiple other autoimmune diseases have identified association with this interval, including Crohn's disease, ulcerative colitis, primary biliary cirrhosis, and rheumatoid arthritis. Thus, this study identified 3 novel SLE risk loci exceeding GWS and replicated 13 additional loci suggestive of association.

Background/Purpose: Candidate gene and genome-wide association studies have identified several disease susceptibility loci in lupus patients.These studies have been largely performed in European-derived and Asian lupus patients. In this study, we examine if some of these same susceptibility loci increase lupus risk in African-American individuals.

Methods: Single nucleotide polymorphisms tagging 15 independent lupus susceptibility loci were genotyped in a set of 1,724 lupus patients and 2,024 normal healthy controls of African-American descent. The loci examined included: PTPN22, FCGR2A, TNFSF4, STAT4, CTLA4, PDCD1, PXK, BANK1, MSH5(HLA region) CFB (HLA region), C8orf13-BLK region, MBL2, KIAA1542, ITGAM, and MECP2/IRAK1.

Results: We provide the first evidence for genetic association between lupus and five lupus susceptibility loci in African-American lupus patients (C8orf13-BLK, BANK1,TNFSF4, KIAA1542 and CTLA4; P values= $8.0 \times 10–6$, $1.9 \times 10–5$, $5.7 \times 10–5$,0.00099, 0.0045, respectively). Further, we confirm the genetic association between lupus and five additional lupus susceptibility loci (ITGAM, MSH5, CFB, STAT4, and FCGR2A; P values= $7.5 \times 10–11$, $5.2 \times 10–8$, $8.7 \times 10–7$, 0.0058, and 0.0070, respectively), and provide evidence for a genome-wide significance for the association between ITGAM and MSH5 (HLA region) for the first time in African-American lupus patients.

Conclusion: These findings provide evidence for novel genetic susceptibility loci for lupus in African-Americans and demonstrate that the majority of lupus susceptibility loci examined confer lupus risk across multiple ethnicities.

Background/Purpose: Interleukin-10 (IL-10) is produced at high levels by B cells and monocytes of SLE patients and promotes B cell hyperactivity and autoantibody production in these individuals. In a trans-ancestral study, we assessed 16,003 case-control samples to fine map of the *IL10* locus and to evaluate SLE-associated SNPs for potential functions.

Methods: Eight tag SNPs selected from HapMap CEU dataset to cover the *IL10* locus and 347 ancestry informative markers (AIMs) were genotyped on a customized Illumina array. Samples used in association tests included European Americans (EA), African Americans and Gullahs (AA&Gullah), Asians (AS) and Hispanic and Native Americans (Hisp&NA). AIMs were used to estimate global ancestry for each subject and eliminate genetic outliers. We performed Chi-square test to compare the allelic difference between cases and controls, likelihood ratio test to distinguish independent signals from associated SNPs. K562 nuclear extracts were used in electrophoresis mobility shift assay (EMSA) to assess whether SLE-associated *IL10* SNPs might function in IL-10 regulation.

Results: In EA, six SNPs that defined a 6-kb haplotype block were significantly associated with SLE, exhibiting the strongest signal at rs3024505 ($P=2.25\times10^{-8}$, OR=1.29, 18.2% in 3980 cases vs. 14.7% in 3546 controls). Association signals of the other 5 SNPs were eliminated after conditioning on rs3024505, suggesting rs3024505 alone could explain the association of *IL10* with SLE in EA. In non-European ancestries, the SLE-associated allele of rs3024505 present at lower allele frequencies consistently exhibited higher frequencies in cases than controls (AA&Gullah: 4.5% in 1680 cases vs. 3.9% in 1935 controls, AS: 3.1% in 1272 cases vs. 2.7% in 1270 controls, Hisp&NA: 9.0% in 1580 cases vs. 8.3% in 812 controls) but was not significantly associated with SLE. rs3024505 located at 1kb down-stream of 3′UTR was in complete linkage disequilibrium (LD) with rs3122605 (10kb up-stream of 5′UTR), rs3024493 (intron 3) and rs3024495 (intron 4). EMSA results in Figure 1 revealed no binding activity to nuclear extracts using DNA fragments containing rs3024505 or rs3024493, but preferential binding activity in the risk allele of rs3122605 and rs3024495 compared to its respective non-risk allele. These results were consistent with bioinformatic predictions that the risk allele of rs3122605 and rs3024495 conferred differential binding to lymphoid transcription factors MZF1 and CP2/ZID, respectively.

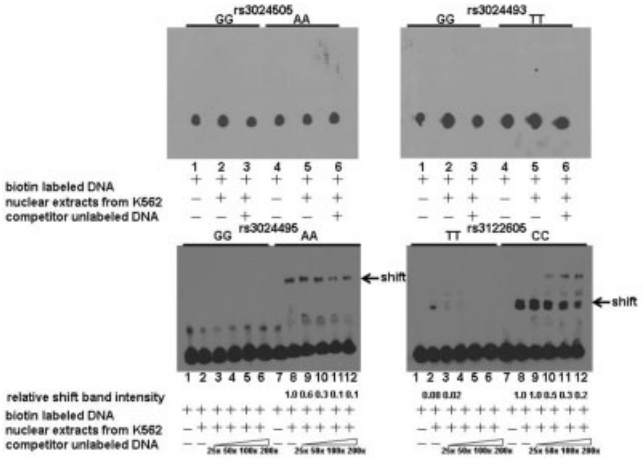

Figure 1. Transition of G to A at rs3024495 and T to C at rs3122605 alters specific binding to nuclear extracts. EMSA analysis of DNA fragment containing rs3024505, rs3024493, rs3024495 or rs3122605 was performed. Competition analysis using increasing concentration of unlabeled oligonucleotide competitor demonstrates the presence of the specific protein-DNA complexes in risk allele of rs3024495 and rs3122605, but not of rs3024505 or rs3024493. Results are one of the three experiments using three separate preparations of myeloblastoma K562 cell line extracts.

Conclusion: Our trans-ancestral mapping localized the association of *IL10* with SLE to rs3024505 in European ancestry, which was in complete LD with rs3122605 and rs3024495 located in the 5′ upstream region and intron 4, respectively. Preferential binding to transcription factors by the risk allele of rs3122605 and rs3024495 might regulate expression of *IL10* transcripts, predisposing to SLE.

2478

Determination of the Contribution of An *IRF5*-SLE Risk Haplotype to *IRF5* expression and Alternative Splicing Using Next-Generation Sequencing. Rivka Stone[1], Peicheng Du[2], Di Feng[1], Lars Ronnblom[3], Maija-Leena Eloranta[4], Robert Donnelly[1] and Betsy Barnes[1]. [1]University of Medicine and Dentistry of New Jersey, Newark, NJ, [2]New Jersey Medical School, Newark, NJ, [3]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden, [4]Section of Rheumatology, Uppsala University, Uppsala, Sweden

Background/Purpose: The transcription factor interferon regulatory factor 5 (*IRF5*) exists as multiple alternatively spliced 1.6-kb transcripts with unique cell type-specific expression. Polymorphisms in the *IRF5* gene have been shown to confer either risk for or protection from the development of systemic lupus erythematosus (SLE), possibly by contributing to aberrant alternative splicing and dysregulated IRF5 expression in patients with SLE. We have recently demonstrated that IRF5 expression and alternative splicing are significantly elevated in SLE patients and expression was associated with an *IRF5* SLE risk haplotype. The aim of this study was to unambiguously determine whether an *IRF5* SLE haplotype defines the profile of *IRF5* transcripts expressed, thus controlling the global function of IRF5 in SLE.

Methods: Standard molecular cloning techniques were used to isolate novel *IRF5* transcripts from purified peripheral blood mononuclear cells (PBMC) and monocytes of genotyped SLE patients and healthy donors. Next-generation sequencing technologies were used to construct comprehensive *IRF5* expression profiles in same samples. Using an array of open-source next-generation sequencing analysis software tools, *IRF5* transcripts were

quantified within and across samples and novel splice sites were identified by *de novo* junction discovery.

Results: Molecular cloning from purified PBMC and monocytes of genotyped SLE patients and healthy donors provided support that SLE patients have enhanced alternative splicing of *IRF5*. By this method, we identified 14 new differentially spliced *IRF5* transcripts in donor immune cells; 9 of which were specific to SLE. Using the ABI SOLiD 3 Plus system, we obtained at least 2×10^6 50-bp reads per sample, providing an unprecedented coverage depth of *IRF5* greater than 3,000-fold (equivalent to ~27,000 clones). Results from next-generation sequencing correlated well with results from cloning yielding identical abundance rankings for the variants. These data provide significant support that a distinct profile of *IRF5* transcripts is expressed in SLE patients as compared to healthy donors. Additionally, data support that the *IRF5* SLE haplotype defines *IRF5* transcript expression in SLE patients.

Conclusion: This study provides the first formal proof that an *IRF5*-SLE risk haplotype defines the profile of *IRF5* transcripts expressed in immune cells of SLE patients and healthy donors. We posit this newly defined workflow of next-generation sequencing as an alternative to traditional molecular cloning, whereby differentially spliced transcripts of a single gene can be rapidly enriched, identified, and quantified in donor RNA samples.

Lupus Nephritis Susceptibility Markers in *PDGRFA-GSX2, SLC5A11, ID4, and HAS2-SNTB1* Regions Identified From a Meta-Analysis of Genome Wide Association Studies of Women with Systemic Lupus Erythematosus. Yesim Demirci[12], Susan Manzi[13], Lindsey A. Criswell[1], Kathy L. Moser[14], Patrick M. Gaffney[14], Robert R. Graham[4] and Carl D. Langefeld[3]. [1]University of California, San Francisco, San Francisco, CA, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Wake Forest School of Medicine, Winston-Salem, NC, [4]Genentech, Inc., South San Francisco, CA, [5]King's College London, London, United Kingdom, [6]Feinstein Institute for Medical Research, Manhasset, NY, [7]University of Southern California, Los Angeles, CA, [8]Oklahoma Medical Research Foundation, Center for Genomics and Oncological Research Pfizer-University of Granada-Junta de Andalucia, Oklahoma City, OK, [9]University of California, Los Angeles, Los Angeles, CA, [10]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH, [11]Johns Hopkins University School of Medicine, Baltimore, MD, [12]University of Pittsburgh, Pittsburgh, PA, [13]Allegheny Singer Research Institute, Pittsburgh, PA, [14]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Lupus nephritis (LN) is a clinical manifestation of systemic lupus erythematosus (SLE) resulting from glomerular immune complex deposition and inflammation. LN demonstrates familial aggregation and accounts for significant morbidity and mortality. To facilitate the identification of SLE patients at highest risk for developing LN, we conducted a meta-analysis of three independent genome-wide association studies of SLE.

Methods: Through genotyping and imputation, over 2.5 million markers were assessed among 2,001 women with SLE of European descent. SLE cases were considered to have LN if they fulfilled the American College of Rheumatology renal criterion for SLE or had a renal biopsy consistent with LN. Logistic regression adjusting for admixture was computed to test for association between each genetic marker and LN (N=588 LN cases and N=1423 SLE cases without nephritis).

Results: The strongest evidence for association was observed outside the major histocompatibility complex (MHC) including markers localized to 4q11-q13 (*PDGFRA-GSX2*; OR 3.41; 95% CI 2.1–5.54; $P=2.7\times10^{-7}$), 16p12 (*SLC5A11*; OR 2.85; 95% CI 1.93–4.22; $P=3.0\times10^{-7}$), 6p22 (*ID4*; OR 0.57; 95% CI 0.46–0.7; $P=4.3\times10^{-7}$) and 8q24.12 (*HAS2-SNTB1;* OR 3.15; 95% CI 1.97–5.03*;* $P=6.2\times10^{-7}$). Both *HLA-DR2* and *HLA-DR3*, two well established SLE susceptibility loci, showed evidence of association with LN as assessed by their proxies rs9271366 (OR=1.37; 95% CI 1.09–1.71; P=0.037) and rs2187668 (OR 1.47; 95% CI 1.22–1.77; $P=6.0\times10^{-5}$), respectively. Within the MHC, a marker in the Class I region, rs9263871 (*C6orf15-HCG22*), had the strongest evidence of association with LN independent of *HLA-DR2* and *HLA-DR3* (OR 1.7; 95% CI 1.35–2.13; $P=5.0\times10^{-6}$).

Conclusion: This study is the first genome-wide investigation of LN, and provides promising evidence for non-MHC markers involved in the development of LN given SLE.

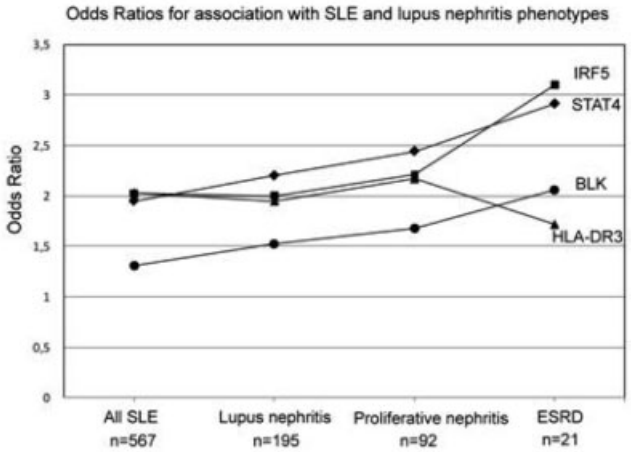
2480

Association of *STAT4, IRF5* and *BLK* Polymorphisms with Severity and Outcome in Lupus Nephritis. Karin G. Eriksson[1], Agneta Zickert[2], Johanna K. Sandling[3], Andreas Jönsen[4], Elisabet Svenungsson[2], Lars Rönnblom[1], Timothy W. Behrens[5], Robert R. Graham[5], Ward Ortmann[5], Ann-Christine Syvänen[3], Iva Gunnarsson[2] and Gunnel Nordmark[6]. [1]Section of Rheumatology, Uppsala University, Uppsala, Sweden, [2]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [3]Molecular Medicine, Uppsala University, Uppsala, Sweden, [4]Section of Rheumatology, Lund University, Lund, Sweden, [5]Genentech Inc, South San Francisco, CA, [6]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden

Background/Purpose: Lupus nephritis (LN) is a cause of significant morbidity and mortality and occurs in 15–50 % of patients with SLE. Proliferative nephritis is considered the most severe form. Approximately 10 % of LN patients develop end stage renal disease (ESRD). Several susceptibility genes for SLE have been identified where an association with LN has been shown for single nucleotide polymorphisms (SNPs) in *STAT4* and *ITGAM* (1–3). In a previous study, Swedish patients with SLE and controls were genotyped on a custom 12K SNP chip (Illumina Infinium II) (4). The aim of this investigation was to analyze the genetic data from our previous study (4) for association with LN, in particular proliferative nephritis and renal outcome.

Methods: A total of 567 Swedish Caucasian patients with SLE and 512 matched controls were included. All patients fulfilled the ACR criteria for SLE and 195 (34.4 %) had a history of LN. Renal biopsies were available from 153 patients where 92 (60.1 %) had a proliferative nephritis, WHO class III or IV. During follow-up (median 14 years, range 0–46), 11.1 % reached ESRD. Case-control analyses were performed for patients with LN, proliferative nephritis and ESRD, respectively. The allele frequencies in cases and controls were compared with Fisher's exact test and the results compared with analysis of all SLE patients versus controls.

Results: We detected strong signals of association between SNPs rs11889341 in *STAT4* (OR 2.2, 95% CI 1.7–2.8), rs2070197 in *IRF5* (OR 2.0, 95% CI 1.5–2.7) and rs3135394 as a marker for *HLA-DR3* (OR 1.95, 95% CI 1.4–2.6), in the analysis of LN patients versus controls (all $p < 0.0001$). In addition, six genes showed an association with LN with OR 1.5–2.2, $p < 0.001$ (*PMS2, TNIP1, CARD11, ITGAM, BLK* and *IRAK1*). When analyzing only the patients with proliferative nephritis versus controls the OR for association increased for *STAT4, IRF5* and *BLK* to 2.4, 2.2 and 1.7 respectively (all $p < 0.01$). For patients in ESRD the OR for *STAT4, IRF5* and *BLK* increased further to 2.9, 3.1 and 2.1 whereas the OR for association with the *HLA-DR3* marker was decreased to 1.7. The association between the risk alleles in *IRF5, STAT4* and *BLK* and LN phenotypes was stronger than the association to SLE per se.



Conclusion: Risk alleles in *STAT4, IRF5* and *BLK* are associated with an increased risk for LN. The association with the severe form, proliferative nephritis, was particularly strong and the risk of developing ESRD was even more striking. On the contrary, the *HLA-DR3* marker did not display a strong association with LN. We conclude that variations in genes in immunological pathways predispose to LN severity and renal outcome.

Effect of Warfarin On Survival In Scleroderma-Associated and Idiopathic Pulmonary Arterial Hypertension. A Bayesian Approach to Evaluating Treatment In Uncommon Disease. Sindhu R. Johnson[1], John T. Granton[2], George A. Tomlinson[2], Haddas Grosbein[3], Thaolan Le[4], Peter Lee[5], M. Elizabeth Seary[3], Gillian A. Hawker[6] and Brian M. Feldman[3]. [1]Toronto Western Hospital, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]The Hospital for Sick Children, Toronto, ON, [4]University Health Network Pulmonary Hypertension Programme, Toronto, ON, [5]Mt. Sinai Hospital, Toronto, ON, [6]Women's College Hospital, Toronto, ON

Background/Purpose: Warfarin is recommended in scleroderma-associated pulmonary arterial hypertension (SScPAH) and idiopathic PAH (IPAH) to improve survival. There is no evidence to support this recommendation in SScPAH and the evidence in IPAH is conflicting. We evaluated the ability of warfarin to improve survival using 2 large SScPAH and IPAH cohorts.

Methods: The effect of warfarin on all-cause mortality was evaluated. Bayesian propensity scores (PS) were used to adjust for baseline differences between patients exposed and not exposed to warfarin, and assemble a matched cohort. Bayesian Cox proportional hazards models were constructed using informative priors based on international PAH expert elicitation.

Results: Review of 1,138 charts identified 275 SScPAH (n=78 (28%) treated with warfarin), and 155 IPAH patients (n=91 (59%) treated with warfarin). Baseline differences in PAH severity and PAH medications between treated and untreated patients were resolved using PS matching. In the matched cohort of 98 SScPAH patients (n=49 treated with warfarin), the posterior median Hazard Ratio (HR) was 1.06 (95%CrI 0.70,1.63). In the matched cohort of 66 IPAH patients (n=33 treated with warfarin), the posterior median HR was 1.07 (95%CrI 0.57,1.98). The probability that warfarin improves median survival by 6-months or more is 23.5% in SScPAH and 27.7% in IPAH. Conversely, there is a greater than 70% probability that warfarin provides no significant benefit or is harmful.

Conclusion: There is a low probability that warfarin improves survival in SScPAH and IPAH. Given the availability of other PAH therapies with demonstrable benefits, there appears to be little role for warfarin in improving survival for these patients.

Diffusion of Carbon Monoxide Predicts Survival in Systemic Sclerosis Patients with Pulmonary Hypertension and Interstitial Lung Disease. Benjamin E. Schreiber[1], Chris Valerio[1], Greg Keir[2], Clive Handler[1], Athol U. Wells[2], Christopher P. Denton[3] and John G. Coghlan[1]. [1]Royal Free Hospital, London, London, United Kingdom, [2]Royal Brompton Hospital, United Kingdom, [3]UCL Medical School, London, United Kingdom

Background/Purpose: Predictors of survival in systemic sclerosis patients with concurrent interstitial lung disease and pulmonary hypertension are poorly understood.

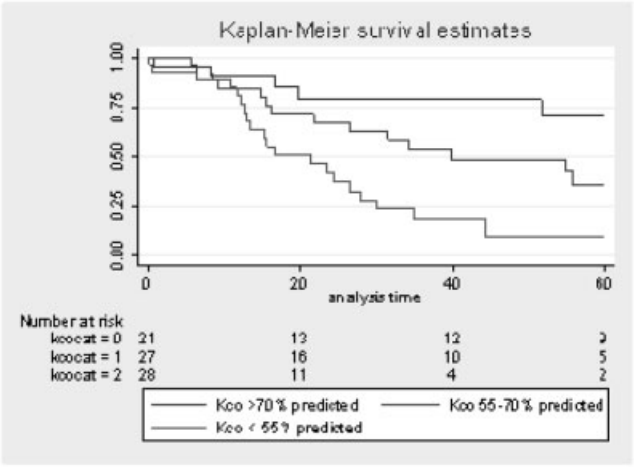
Methods: Retrospective analysis of a large regional single centre cohort of patients with systemic sclerosis associated pulmonary hypertension. Inclusion criteria were a diagnosis of systemic sclerosis, precapillary pulmonary hypertension as defined by mean pulmonary artery pressure (mPAP) >= 25 mmHg and pulmonary capillary wedge pressure (PCWP) <= 15 mmHg, and FVC < 70% predicted and presence of significant lung fibrosis on CT.

Results: 76 patients were identified. Mean age was 54.9 years. 51 (67%) female. 34 (44.7%) were classified to diffuse subset. Mean haemodynamics were: mPAP 37.3, PVR 554.6 dynes.s.cm-5. Mean survival was 34.3 months (95% CI 23.4–55.7).

The following variables did not predict survival on univariable analysis: age (p=0.09), gender (p=0.59), right atrial pressure (0.47). heart rate (0.36), cardiac output (0.29), cardiac index (0.76), mean pulmonary artery pressure (p=1.00), pulmonary vascular resistance (p=0.08), oxygen saturation (p=0.41), mixed venous saturation (p=0.23), systolic blood pressure (p=0.37), diastolic blood pressure (p=0.10), six minute walking distance (p=0.10, n=47), NTproBNP (p=0.98, n=27), FVC % predicted (p=0.72), anti-centromere antibody status (p=0.31), anti-topoisomerase-1 antibody status (p=0.12).

Significant variables on univariate analysis were functional class (p=0.007), Dlco % predicted (p=0.03), FVC/DLCO (p=0.006) and Kco % predicted (p<0.0005, n=76). On multiple variable Cox analysis with these four variables, Kco % predicted is the only significant predictor (p=0.017).

Kco % predicted has tertiles at 54.2 and 69.6. Kco % predicted was grouped into tertiles: <55%, 55–70%, >70%. The hazard ratio associated with dropping by one category is 2.4 (95% CI 1.5–3.7).



The survival differs in three groups (p=0.0002 by log-rank). 1, 3 and 5 year survival by group is given below:

	1 yr survival	3 yr survival	5 yr survival
Kco > 70% predicted	90.3% (67–98)	78.9% (53–92)	71.0% (43–87)
Kco 55–70% predicted	84.4% (63–94)	53.4% (32–71)	36.0% (16–57)
Kco < 55% predicted	80.4% (59–91)	18.5% (6–37)	9.2% (2–25)

Conclusion: Patients with systemic sclerosis, interstitial lung disease and pulmonary hypertension have a poor survival. We found that no demographic and haemodynamic variables predicted survival in this patient cohort.

On multiple variable models the only significant independent predictor of survival was Kco % predicted, which is the calculated diffusion of carbon monoxide adjusted for alveolar volume. KCO may reflect the extent of impairment of parenchymal dysfunction by combining both interstitial and vascular components of the disease process. Kco % predicted is a powerful predictor of outcome in this patient group.

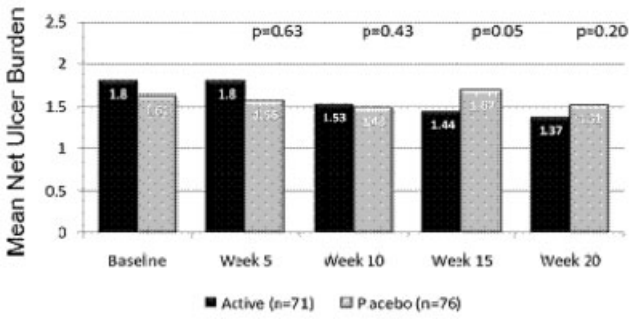
Background/Purpose: Prostacyclins are effective vasodilators for vascular features of systemic sclerosis (SSc, scleroderma) but systemic delivery requires the cumbersome logistics of intravenous infusion. Treprostinil diethanolamine (TDE) is an innovative salt form of the

prostacyclin analog treprostinil for oral delivery as a sustained-release (SR) osmotic tablet for twice-daily dosing. The objective of this study was to evaluate the safety and efficacy of TDE SR for digital ulcers (DU) in patients with SSc.

Methods: This was a randomized (1:1), placebo-controlled, parallel group, multicenter study of TDE in adult patients with SSc and presence of at least one DU meeting protocol definition as "active" at Baseline. Known PAH or bosentan therapy were excluded. Study drug was titrated to maximum-tolerated dose (up to 16 mg bid), with assessments at Weeks 5, 10, 15 and 20. The primary endpoint was change in net ulcer burden at Week 20. Secondary endpoints included patient DU pain, physician and patient global assessment and patient Raynaud symptoms by visual analogue scale (VAS), healing of cardinal ulcer, prevention of new ulcers, and measures of hand function and quality of life.

Results: 148 subjects (109 F/ 38M), mean age of 48.8 years and mean SSc disease duration of 10.5 years were enrolled in 27 centers. 64% of subjects had limited cutaneous SSc. Results for net ulcer burden were as follows:



Improvement ($p<0.05$) occurred in several secondary endpoints, including physician global DU VAS, SHAQ-DI (Scleroderma Health Assessment Questionnaire-Disability Index) components related to hand function, dyspnea VAS, and patient impression of change in overall ulcer status and of Raynaud symptoms. While there were no differences in outcome in subjects classified clinically as either limited or diffuse SSc, exploratory analyses of individuals who were anti-centromere antibody negative demonstrated a reduction in placebo-corrected mean net ulcer burden of −1.01 ($P=0.01$) at Week 20. Discontinuation due to adverse events occurred in 13% on TDE vs 8% on placebo with 82% and 86% completing the study, respectively.

Conclusion: Administration of TDE SR to patients with DU did not result in a statistically significant reduction in net ulcer burden compared to placebo. A variety of secondary endpoints suggested utility for Raynaud symptoms. Critical tissue ischemia in SSc may involve factors other than afferent vasomotor perfusion. Future studies of healing will benefit from refinements in both outcomes assessments and identification and stratification of subjects.

Microvascular Damage and Cardiac Fibrosis Detected by Heart MRI are a Hallmark of Systemic Sclerosis Heart Involvement. Tatiana Sofia Rodriguez-Reyna, Martha Morelos-Guzman, Pablo Hernandez-Reyes, Jaime Morales-Blanhir, Karla Montero-Duarte, Cynthia Martinez-Reyes, Carlos Reyes-Utrera and Jorge Vazquez-Lamadrid. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

Background/Purpose: Heart involvement has been described in 37–80% of systemic sclerosis (SSc) patients; prevalence rates vary depending on the diagnostic method and the type of patients included in the studies. Our aims were to determine the prevalence of heart involvement (fibrosis and microvascular damage) in a cohort of SSc patients without cardiovascular risk factors (diabetes, hypertension, dyslipidemia), to describe the patterns of heart involvement using cardiac MRI and coronary angiotomography, and to correlate these data with disease subsets, target organ involvement and laboratory parameters.

Methods: We included patients from our SSc cohort. They underwent clinical evaluation, EKG, CPK, CPK-MB, ultrasensitive-CRP, ESR, SSc-specific autoantibodies (anti-Topoisomerase I, anticentromere, anti-U1 RNP, anti-PMScl, anti-Pol III, anti-Ku), antiphospholipid antibodies (anticardiolipins, anti-β-2 glicoprotein 1, lupus anticoagulant), coronary angiotomography, and cardiac MRI (SSFP sequences to evaluate fibrosis, and adenosine challenge for semiquantitative perfusion analysis with signal intensity curves using echoplanar TIGRE images). Statistical analysis was performed using SSPS v.15; Chi^2 was used to analyze ordinal variables and Student′s t test to analyze numerical variables.

Results: We included 62 SSc patients (29 with diffuse cutaneous SSc (dcSSc): 47%, and 33 with limited cutaneous SSc (lcSSc): 53%); 60 of them were female; the mean time of evolution was 9.7 years; the mean LVEF was 59.4%; 79% showed subendocardic perfusion defects; 45% showed myocardial fibrosis (17.8% with patchy distribution, 35.7% in bands, 10.7% subendocardic, 28.5% with mixed patterns and 7.1% transmural), with higher prevalence in dcSSc than in lcSSc (58.6% vs 33.3%; $p=0.04$); the percentage of myocardium affected by fibrosis was significantly higher in dcSSc (6.7%) than in lcSSc (1.6%; $p=0.02$). Cardiac fibrosis was more prevalent in basal anteroseptal (27%) and inferoseptal (12.9%) segments, as well as in the middle segments of the anteroseptal wall (19.4% and 12.9% in segments 8 and 7, respectively). Ninety three percent of coronary angiotomographies were normal (mean Ca score 2.9); 28.8% of patients had abnormal EKGs (39.3% of dcSSc vs 19.3% of lcSSc, p=NS). Cardiac fibrosis was associated with lower LVEF (55.8 vs 66.5%, $p<0.0009$) and inversely associated with vascular involvement (86.7 vs 100%, $p=0.03$). Microvascular damage was associated with higher CRP (1.28 vs 0.22; $p=0.001$) and positive anti β2 glycoprotein 1 (aβ2GP) IgG antibody ($p=0.001$). There was no association of cardiac fibrosis or microvascular damage with abnormal calcium score nor atherosclerosis.

Conclusion: Patients with systemic sclerosis show preserved systolic function, high frequency of cardiac fibrosis and subendocardic concentric perfusion defects, related to microvascular damage. Cardiac fibrosis is more frequent in basal and middle segments of the left ventricle. These abnormalities are not caused by coronary artery disease. Cardiac MRI is a sensitive, noninvasive, useful method to detect heart involvement in SSc. Elevated CRP and positive anti-aβ2GP IgG antibodies may help to identify patients at risk for SSc heart involvement.

Development and Internal Validation of a Two-Year Mortality Risk Prediction Rule in Early Diffuse Systemic Sclerosis Patients. Robyn T. Domsic[1], Mary Lucas[1], Stephen R. Wisniewski[2], C. Kent Kwoh[3], Michael J. Fine[3] and Thomas A. Medsger[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA

Background/Purpose: Knowledge of mortality risk and associated predictors is important in SSc clinical trial design to risk stratify patients, but there is no validated short term mortality model in early diffuse cutaneous systemic sclerosis (dcSSc). The objective of this study was to derive and validate a two year mortality model in early dcSSc patients.

Methods: We used a large prospectively enrolled medical center SSc databank to identify an inception cohort of adult early dcSSc patients seen for an initial visit between 1980 and 2007. Patients were considered to have early dcSSc if their first visit occurred less than two years after the first symptom attributable to scleroderma, with skin thickening documented as proximal to the elbows or knees. Due to the small number of non-Caucasian patients, the analysis was limited to Caucasians. Vital status was determined using the Social Security Death Index. The population was randomly divided into derivation (two-thirds) and validation (one-third) cohorts. Predefined candidate predictor variables at the first visit (demographic, history, physical exam, lab values, organ system involvement and organ severity using the Medsger severity scale) were placed into a stepwise multivariable logistic regression model. Regression diagnostics were performed and area under the curve was calculated to assess discrimination in the derivation and validation cohorts.

Results: 791 early dcSSc patients were identified, of whom 424 had all objective testing required to assess severity of internal organ involvement at the first visit. The mean age was 50.3 ± 13.6 years and 75% female. The median duration of disease at first visit of 0.91 years (IQR 0.66, 1.33), and the mean modified Rodnan skin thickness score was 25.0 ± 11.7. There were no significant differences between the 424 and the 367 without the complete objective testing on these parameters. The final derivation cohort included 260, and the validation cohort 127 patients.

At two years, 74 of the 424 (19%) had died. Significant independent predictors of two-year mortality were older age, male gender, increased

skin thickness progression rate, severity of GI, cardiac and skeletal muscle disease, and degree of anemia (Table 1). The area under the curve (AUC) in the derivation cohort was 0.86 (95% CI 0.80–0.91), and when the model was applied to the validation cohort the AUC = 0.81 (95% CI 0.74–0.90).

Table 1. Multivariate model of two-year mortality in early diffuse systemic sclerosis patients

	Odds Ratio	95% Confidence Interval (CI)	p-value
Age at First Visit (years):			
<35	0.50	0.11–2.19	0.02
35–44	0.44	0.14–1.54	
45–54	1.00	–	
55–64	2.02	0.75–5.47	
>65	2.94	1.01–6.93	
Skin Thickness Progression Rate:			
Slow	–	–	0.04
Intermediate	1.04	0.38–2.80	
Rapid	2.74	1.08–6.93	
Medsger Gastrointestinal Severity:			
None	–	–	0.006
Mild	1.54		0.64–3.71
Moderate/severe	5.14	1.88–14.05	
Medsger Muscle Severity: None	–	–	0.006
Mild	1.56	0.65–3.73	
Moderate/severe	5.67	1.64–19.60	
Medsger Cardiac Severity: None	–	–	0.04
Mild	0.10	0.01–0.90	
Moderate	1.70	0.63–4.60	
Severe	2.15	0.56–8.27	
Hemoglobin level: >12 mg/dL	–	–	.005
10–12 mg/dL	4.41	1.79–10.87	
<10 mg/dL	2.55	0.90–7.15	

Conclusion: We have developed a multivariable model with high accuracy for identifying early dcSSc patients at risk for short term mortality. Based on the area under the receiver operating curve, we were able to internally validate this model in a randomly selected early dcSSc patient population. This model may be used to risk stratify patients for clinical trials and to provide prognostic information for patients and their treating physicians.

Race and Mortality Risk in Scleroderma. Allan C. Gelber, Rebecca L. Manno, Adrianne Woods, Ami A. Shah, Francesco Boin, Laura K. Hummers and Fredrick M. Wigley. Johns Hopkins University, Baltimore, MD

Background/Purpose: Experience suggests that African Americans express autoimmune disease differently than other racial groups. In the context of systemic sclerosis (scleroderma), we sought to determine whether race was related to mortality risk in a large observational cohort study.

Methods: Between January 1, 1990 and December 31, 2009, a total of 2394 patients with scleroderma were evaluated at a single university medical center. Among this group, 329 African American and 1415 Caucasian patients were prospectively followed. Cumulative incidence of mortality was estimated using Kaplan-Meier analysis. In addition, the independent risk of mortality associated with race was estimated using Cox proportional hazards analysis, with adjustment for age at disease onset, gender, scleroderma disease subtype and Scl-70 serologic status.

Results: Among the cohort of 1744 patients with follow-up visits to the scleroderma center, there were 1445 (83%) women and 299 (17%) men, among whom 1060 (61%) manifested the limited and 684 (39%) the diffuse cutaneous subtype of disease. Mean age (+SD) at disease onset was 46 (+14) years. During a median follow-up period of 4 years, 700 [159 African American; 541 Caucasian] patients died. Overall, cumulative mortality at 1, 3, 5 and 10 years of follow-up was 8, 22, 32 and 54%, respectively. At 5 years of follow-up, cumulative mortality was 35% among the African American compared to 31% among the Caucasian patients [logrank p = 0.0595). The relative risk of mortality, in unadjusted and adjusted analyses, associated with African American compared to Caucasian race, was as follows:

Model confidence interval	Relative Risk	95%
Unadjusted	1.2	1.0–1.4
Age-adjusted	1.4	1.2–1.7
Age, gender, disease subtype-adjusted	1.3	1.1–1.6
Age, gender, disease subtype, Scl-70-adjusted	1.6	1.2–2.1

Moreover, in stratified age-adjusted analyses, African Americans were at greater risk for mortality in both the Scl-70 seropositive [RR1.7; 95%CI 1.0 – 2.9] and seronegative [RR 1.6; 95%CI 1.2 – 2.2] strata.

Conclusion: In a large biracial cohort assembled over a 20 year period at a single referral center, overall mortality at 10 years of follow-up was approximately 54%. African Americans experienced a 60% increase in mortality relative to Caucasians, after taking age at disease onset, gender, cutaneous disease subtype and Scl-70 serologic status into account. These findings imply that race is modestly related to disease severity and mortality risk in scleroderma.

Efficacy and Safety of Adalimumab in Patients with Non-Radiographic Axial Spondyloarthritis – Results From a Phase 3 Study. Joachim Sieper[1], Désirée van der Heijde[2], Maxime Dougados[3], Philip J. Mease[4], L. Steven Brown[5] and Aileen Pangan[5]. [1]Charité Universitätsmedizin, Berlin, Germany, [2]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [3]Paris-Descartes University, Cochin Hospital, Paris, France, [4]Seattle Rheumatology Associate, Seattle, WA, [5]Abbott Laboratories, Abbott Park, IL

Background/Purpose: Adalimumab (ADA) is indicated for treatment of ankylosing spondylitis (AS) and was also effective in a pilot study of patients (pts) with non-radiographic axial spondyloarthritis (axSpA).1 ABILITY 1, the first pivotal trial to use the ASAS axSpA criteria, was designed to evaluate the efficacy and safety of ADA in axSpA pts without radiographic sacroiliitis.[2]

Methods: ABILITY 1 is an ongoing multi-country, phase 3 study. Eligible pts fulfilled the ASAS axSpA criteria but not modified NY criteria for AS, had BASDAI ≥ 4 cm, total back pain VAS ≥ 40 mm, and inadequate response/intolerance/contraindication for NSAIDs. Pts were randomized 1:1 to ADA (40 mg every other wk) or placebo (PBO) for 12 wks followed by a 92-wk open-label extension. Primary endpoint was ASAS40 response at wk 12. Subgroup analyses were performed to evaluate the impact of the following baseline conditions on the primary endpoint: sex, race, age, weight, CRP, HLA-B27, sacroiliitis by MRI, history of IBD or uveitis, and concomitant DMARD or NSAID use. Logistic model was performed to assess treatment and subgroup interaction, with significant interaction defined as Pvalue £0.10.

Results: Of the 192 randomized pts, 7 pts (4 ADA, 3 PBO) were excluded from efficacy analyses due to investigator noncompliance, leaving 91 randomized to ADA and 94 to PBO. Baseline demographics/disease characteristics were comparable between ADA and PBO groups (% or mean): females (52/57), age (38/38 yrs), symptom duration (10/10 yrs), duration since diagnosis (3/3 yrs), BASDAI (6.4/6.5), elevated CRP (32/39) and history of HLA-B27 positivity (79/71). Positive MRI fulfilling the imaging arm of the ASAS criteria was present in 51% of ADA and 46% of PBO pts. Baseline BASDAI was comparable regardless of which arm of the ASAS criteria pts fulfilled (MRI/HLA-B27): 6.4 (+/–), 6.2 (+/+) and 6.6 (–/+). A significantly higher percentage of ADA pts achieved the primary endpoint and other clinical and imaging outcomes compared to PBO (Table). The only significant interaction terms in the subgroup analyses for wk 12 ASAS40 were for the age and CRP subgroups (Table). Response rates were similar between MRI positive and negative pts. During the double-blind period, safety analyses for all 192 randomized pts revealed comparable results for ADA and PBO (%): AEs (57.9/58.8), serious AEs (3.2/1.0), and infectious AEs (29.5/28.9); there were no serious infections, TB, malignancies, or demyelinating disease.

Table. Week 12 Efficacy Outcomes*

	ADA N=91	PBO N=94	*P* value[a]
Primary endpoint:			
ASAS40, %	36.3	14.9	<0.001
Other efficacy endpoints:			
ASAS20, %	51.6	30.9	0.004
ASAS 5/6, %	30.8	6.4	<0.001
ASAS partial remission, %	16.5	5.3	0.014
BASDAI 50, %	35.2	14.9	0.001
ASDAS inactive disease state, %	24.2	4.3	< 0.001
Mean change in CRP, mg/L†	– 4.3	– 0.3	<0.001
Mean change in SI joint SPARCC score ‡	– 3.2	– 0.6	0.003
Mean change in spine SPARCC score ‡	– 1.8	– 0.2	0.001
ASAS40 response by subgroup: %	**ADA N=91**	**PBO N=94**	**Interaction *P* value[b]**
Sacroiliitis on baseline MRI			
Positive	34.8	16.3	0.649
Negative	37.8	13.7	
HLA-B27			
Positive	40.8	15.6	0.342
Negative	18.8	13.6	
Age,			
<40	46.4	13.5	0.051[c]
≥40	20.0	16.7	
CRP,			
Normal	27.4	17.5	0.027
Abnormal	55.2	10.8	

* non-responder imputation except where stated; † LOCF; ‡ Observed data (N ADA/PBO): SPARCC SI joint (84/84), SPARCC spine (85/83). [a]compares ADA to PBO, [b]logistic regression model interaction term, [c]age ≥40yrs combined for logistic regression analysis.

Conclusion: Adalimumab significantly improved the signs and symptoms of pts with active non-radiographic axSpA. Pts <40 yrs or with elevated baseline CRP were more likely to achieve ASAS40 with ADA, consistent with a previously published report.1 ABILITY 1 results suggest a favorable benefit-risk profile for ADA as treatment for non-radiographic axSpA pts.

Non-Steroidal Anti-Inflammatory Drugs Reduce Radiographic Spinal Progression in Patients with Ankylosing Spondylitis but Not in Non-Radiographic Axial Spondyloarthritis. Denis Poddubnyy[1], Hildrun Haibel[2], Joachim Listing[3], Elisabeth Märker-Hermann[4], Henning Zeidler[5], Jürgen Braun[6], Martin Rudwaleit[7] and Joachim Sieper[2]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Charité – Campus Benjamin Franklin, Berlin, Germany, [3]German Rheumatism Research Centre, Berlin, Germany, [4]Dr. Horst Schmidt Kliniken, Wiesbaden, Germany, [5]Medizinische Hochschule, Hannover, Germany, [6]Rheumazentrum Ruhrgebiet, Herne, Germany, [7]Ev. Krankenhaus Hagen-Haspe, Hagen, Germany

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are clinically effective and considered as a first line therapy in patients with axial spondyloarthritis (SpA) including ankylosing spondylitis (AS). At the same time NSAIDs might work not only as symptom-modifying drugs, but might also have disease-modifying activities retarding radiographic spinal progression and syndesmophyte growth in AS [1]. However, this earlier report [1] has not been confirmed until now. Furthermore, the influence of NSAIDs on radiographic progression has not been investigated so far in non-radiographic axial SpA (nrSpA). The objective of the study was to investigate the effect of NSAIDs intake on the radiographic spinal progression in patients with AS and nrSpA.

Methods: 164 patients with axial SpA (88 with AS and duration of symptoms <10 years; 76 with nrSpA and duration of symptoms <5 years) from the German Spondyloarthritis Inception Cohort (GESPIC) [2] have been selected for this analysis based on availability of spinal radiographs at baseline and after 2 years of follow-up and of the data on NSAIDs intake during this period of time. None of the patients included in this analysis received anti-TNF therapy. Radiographs of the cervical and lumbar spine were centrally collected, digitized, and subsequently scored according to the mSASSS independently by two trained readers, who were blinded for time point and all clinical data. Data on NSAIDs intake were collected at baseline and every 6 months thereafter during 2 years of follow-up. An index of the NSAIDs intake [3], as recommended by ASAS, counting both dose and duration of drug intake (range 0–100) was calculated. High NSAIDs intake was defined as a mean NSAID intake index over 2 years of ≥ 50, low NSAIDs intake—as a mean NSAID intake index <50.

Results: Patients with AS and high NSAIDs intake (n=24 or 27%), in comparison to patients with low NSAIDs intake (n=64 or 73%), had a significantly lower rate of radiographic spinal progression as assessed by the change of mSASSS score over 2 years (0.02±1.38 vs. 0.96±2.78 mSASSS units, respectively, p=0.039), and numerically lower rates of patients with progression by ≥ 2 mSASSS units (8.3% vs 21.9%) and with new syndesmophyte formation (4.2% vs 15.6%) over 2 years. After adjustment for other factors potentially associated with radiographic spinal progression in this cohort (baseline syndesmophyte, elevated acute phase reactants and smoking status) the high NSAIDs intake showed significant association with reduced radiographic spinal progression (OR=0.23, 95%CI 0.55–0.98 for the mSASSS progression by ≥ 2 units, p=0.047). In nrSpA, no significant differences regarding radiographic progression between subgroups with high (n=19 or 25%) and low NSAIDs intake (n= 57 or 75%) was found.

Conclusion: A high NSAIDs intake over 2 years is associated with lower radiographic progression in patients with AS. The lack of influence of NSAIDs intake on radiographic progression in nrSpA might be related to the relatively low baseline structural damage of the spine in this group.

Gender Related Differences in Severity of Psoriatic Arthritis. Lihi Eder[1], Arane Thavaneswaran[1], Vinod Chandran[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: It has been shown that males (M) with ankylosing spondylitis tend to suffer from more severe spinal disease while females (F) are more likely to have peripheral joint involvement. Gender related differences have not been thoroughly explored in Psoriatic Arthritis (PsA). We aimed to investigate whether there are gender differences in clinical and radiographic joint damage among patients with PsA.

Methods: A cross-sectional analysis was performed among patients who have been followed in a large PsA clinic from 2006 to 2011. Patients were followed according to a standard protocol. Demographic, clinical and radiographic data were retrieved from the clinic database. The number of clinically damaged joints (68 assessed joints) was defined as the presence of limitation of range of movement of >20% not related to the presence of joint effusion, presence of joint deformity, subluxation, loosening, or ankylosis. Axial involvement was defined by radiological evidence of either bilateral at least grade 2 sacroiliitis or unilateral grade 3 or 4 sacroiliitis. Radiographic damage to 42 joints was assessed according to a modification of the Steinbrocker method. Radiographic joint damage scores were grouped into four ordered categories: 0, 1–10, 11–30, >30. The association between gender and the following outcome variables: radiographic joint damage, clinical joint damage and axial involvement were assessed through multivariate regression analyses after adjustment for age, duration of PsA, smoking and level of education.

Results: 636 PsA patients were included in the study (F: 41.8%, M: 58.2%). There were no differences in the mean age (F: 52.2±13.9, M: 52.4±13 years) or age at diagnosis of PsA (F: 36.6±13.7, M: 37.3±12.6 years) across the genders. The age at diagnosis of psoriasis was lower in females (F: 26.5±15.2, M: 29.4±13.7years, p=0.01). While the frequency of HLA-B*27 was similar across genders (M: 16.7% F: 15.1%

p=0.61), males had more frequent axial involvement (M: 42.9% F: 31% p=0.0003). Active joint count was higher in females compared to males (F: 5.4±8.9 M: 3.9±7.2 p=0.03), however, swollen joint count was similar across the genders (F:0.6±1.5 M:0.6±1.9 p=0.76). In a multivariate negative binomial regression analysis male gender was associated with higher clinically damaged joint count (estimate 0.25 p=0.04). In addition, radiographic peripheral joint damage was worst among males. Although unadjusted modified Steinbrocker scores were similar in males and females (F: 21.2±35 M: 22.4±18.9 p=0.65), in multivariate analysis males were more likely to be in a higher radiographic damaged joint category than females (OR 1.56, 95% Confidence interval (CI) 1.1–2.1, p=0.006). Finally, multivariate logistic regression analysis showed that male gender was associated with axial involvement (OR 2.1, 95% CI 1.4–3.1, p=0.0002).

Conclusion: Among patients with PsA, men tend to accumulate more peripheral and axial joint damage compared to women. It is unclear whether these findings are secondary to differences in occupational physical activity, hormonal changes or other factors.

Interleukin-17A Blockade with Secukinumab Reduces Spinal Inflammation in Patients with Ankylosing Spondylitis As Early As Week 6, As Detected by Magnetic Resonance Imaging. Xenofon Baraliakos[1], J. Braun[1], D. D. Laurent[2], D. Baeten[3], D. van der Heijde[4], J. Sieper[5], P. Emery[6], I. McInnes[7], J. van Laar[8], R. Landewe[9], P. Wordsworth[10], J. Wollenhaupt[11], H. Kellner[12], A. M. Wright[13], S. Gsteiger[13] and W. Hueber[2]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Novartis Institutes for BioMedical Research, Basel, Switzerland, [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Charite Campus Benjamin Franklin, Berlin, Germany, [6]University of Leeds, Leeds, United Kingdom, [7]University of Glasgow, Glasgow, United Kingdom, [8]Newcastle University, Newcastle upon Tyne, United Kingdom, [9]Maastricht University Medical Center, Maastricht, Netherlands, [10]Nuffield Orthopaedic Centre, Oxford, United Kingdom, [11]Eilbeck Hospital, Hamburg, Germany, [12]Centre for Inflammatory Joint Diseases, Munich, Germany, [13]Novartis Pharma AG, Basel, Switzerland

Background/Purpose: Magnetic resonance imaging (MRI) is considered gold standard for assessment of spinal inflammation in ankylosing spondylitis (AS). So far, TNF blockers are the only treatment that demonstrated significant reductions of spinal inflammation in AS. In a recent trial, inhibition of IL-17A by secukinumab (AIN457) resulted in significant improvement of clinical signs and symptoms of AS[(1)]. We determined whether clinical effects observed after 2 infusions (10mg/kg i.v.) of secukinumab coincide with reductions of bone marrow edema seen on MRI.

Methods: Patients with active AS (n=30) who fulfilled the 1984 modified New York criteria were enrolled in a 28-week double blind, placebo controlled study. Patients were randomized 4:1 to receive secukinumab 2×10 mg/kg or placebo, given 3 weeks apart. The primary endpoint of the clinical trial was the proportion of patients achieving Assessment of SpondyloArthritis international Society (ASAS) 20 response at week 6. Sagittal MR images of the spine were performed including T1- and short tau inversion recovery (STIR) sequences at baseline, week 6 and week 28. Images were analyzed by an independent reader, who was blinded to treatment allocation and chronology of images, using the "Berlin modification" of the AS spinal MRI (ASspiMRI-a[(2)]) scoring system. Wilcoxon signed-rank test was used for the evaluation of changes between baseline and follow-up in each treatment arm.

Results: 27 patients (22 secukinumab; 5 on placebo) had evaluable MR images at baseline. Few patients (at week 6: 2 secukinumab; 3 placebo; at week 28: 6 secukinumab, 1 placebo) missed follow-up MRIs, mostly due to early discontinuation. MRI scores at baseline and changes at week 6 and week 28 are shown in Table 1. MRI score improvements were seen as early as week 6 and sustained up to week 28. Early improvements at week 6 were especially noted in patients with higher baseline scores (*Figure1, arrows*). Only minor changes were seen in patients on placebo (*Figure1, closed circles*).

Table 1. MRI scores at baseline, week 6 and week 28/end of study

	Secukinumab 2x10mg/kg			Placebo		
	Baseline	Week 6	Week 28*	Baseline	Week 6	Week 28
Number of patients	22	22	16	5	3	5
ASAS20 responders (n)	-	14	6	-	1	1
Mean Berlin score ± SD	9.2 ± 8.9	6.7 ± 6.6	5.7 ± 6.2	20.6 ± 20.2	21.0 ± 24.6	19.0 ± 19.3
P-value (vs. baseline)	-	0.10	0.16	-	0.50	0.25

* Data from 6 patients who discontinued prior to week 28 (lack of response) were not analyzed.

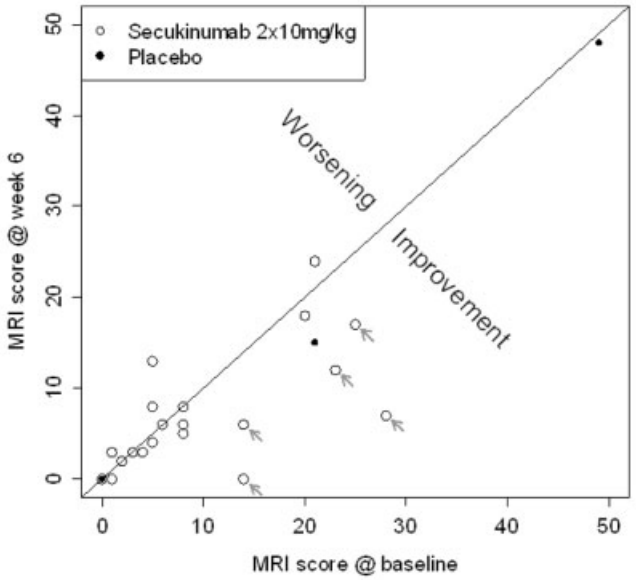

Figure 1. Changes of MRI scores from baseline to week 6

Conclusion: This exploratory study in patients with active AS suggests that after treatment with only 2 infusions of secukinumab substantial reductions of spinal inflammation as detected by MRI occurred. MRI changes were seen as early as 6 weeks after start of treatment, and were maintained up to week 28. Results are consonant with MRI findings obtained in previous AS trials with TNF blockers. Our results provide support that secukinumab may be a potential treatment for patients with active AS.

Radiographic Scoring Instruments Have High Specificity for Detecting Change in Axial Psoriatic Arthritis. Vinod Chandran[1], Ali Ibrahim[2], Arane Thavaneswaran[3], Lihi Eder[3], Philip Helliwell[4], Richard J. Cook[5] and Dafna D. Gladman[3]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Queen's University, Kingston, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON, [4]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [5]University of Waterloo, Waterloo, ON

Background/Purpose: Axial inflammatory arthritis is an important manifestation of psoriatic arthritis (PsA). Various instruments may be used to quantify radiographic spinal damage in axial PsA (AxPsA) including the Bath Ankylosing Spondylitis (AS) Radiology Index- spine (BASRI-spine), the modified Stoke AS spinal score (mSASSS), the Radiographic AS spinal score (RASSS) and the PsA Spondylitis Radiology Index (PASRI). We recently showed that these systems have good reliability in AxPsA. However, sensitivity to change is still not known. We aimed to determine the sensitivity to change of available scoring methods in AxPsA.

Methods: Spinal radiographs of 105 patients diagnosed with AxPsA (grade 2 or greater sacroiliitis and inflammatory back pain and/or restricted spinal mobility) were retrieved for 2 time points at least 2 years apart, and subsequently anonymized to name and order of examination. All radiographs were scored by three rheumatologists using a standard form, which allows calculation of BASRI-spine, mSASSS, RASSS and PASRI, along with features (such as osteoarthritis, DISH) that may be associated with PsA or complicate scoring. An independent expert reader determined whether there was radiographic progression from an overall impression after reading the radiographs with knowledge of chronologic order. This assessment was considered to represent 'true' change (gold standard). Descriptive statistics,

paired t-tests and logistic regression were used to determine whether the instruments accurately captured radiographic worsening.

Results: The 105 patients (71 males, mean age 52 years, mean PsA duration 16 years) had on average 8 actively inflamed joints, 1.6 swollen joints, 15 clinically damaged joints. The mean BASRI-spine, mSASSS, RASSS and PASRI scores at the time of first X-ray was were 3.4, 3.4, 3.6 and 8.5, respectively. The mean duration between the two sets of radiographs was 3.5 years. BASRI-spine (p= 0.02), mSASSS (p = 0.02) and PASRI (p= 0.01) showed statistically significant difference in mean scores between the two time points. The proportion of patients with worsening scores using the instruments was: PASRI 32%, BASRI-spine 29%, mSASSS 25%, RASSS 23%. 25 of the 105 (24%) patients showed progression as determined by the gold standard. The sensitivity (95% CI) and specificity (95% CI) for any increase in score to detect true change was as follows: BASRI-spine 0.48 (0.28,0.68), 0.78 (0.67,0.86); mSASSS 0.52 (0.32,0.72), 0.84 (0.73, 0.91); RASSS 0.44 (0.25,0.65), 0.84 (0.73,0.91); PASRI 0.52 (0.32, 0.72), 0.74 (0.63,0.83). Logistic regression analyses adjusted for age at first X-ray, presence of osteoarthritis and DISH showed that an increase in score was associated with the following odds ratios (95% CI) for 'true' change: BASRI-spine 3.0 (1.15,7.82), mSASSS 5.27 (1.92,14.48), RASSS 3.70 (1.32,10.36) and PASRI 3.06 (1.18,7.95).

Conclusion: 24% of patients with AxPsA show worsening of radiographic damage over 3.5 years. Available scoring systems for quantifying radiographic AxPsA have moderate sensitivity but high specificity to detect 'true' change. All measures performed equally well in detecting change.

Nail Disease in Psoriasis Is Associated with Sonographically Determined Systemic Subclinical Enthesopathy. Zoe R. Ash[1], Ilaria Tinazzi[2], Concepcion Castillo-Gallego[3], Chung Kwok[4], Caroline Wilson[5], Mark Goodfield[5], Paolo Gisondi[6], Ai Lyn Tan[1], Helena Marzo-Ortega[1], Richard J. Wakefield[7], Paul Emery[8], Sibel Aydin[9] and Dennis McGonagle[10]. [1]University of Leeds, Leeds, United Kingdom, [2]University of Verona, Verona, Italy, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Leeds Teaching Hospitals, Leeds, United Kingdom, [5]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [6]University of Veronia, Verona, Italy, [7]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals, Leeds, United Kingdom, [8]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [9]Goztepe Training and Research Hospital, Istanbul, Turkey, [10]University of Leeds and Leeds Teaching Hospitals, Leeds, United Kingdom

Background/Purpose: Psoriasis is associated with subclinical enthesopathy and psoriatic nail disease predicts psoriatic arthritis development. Based on previous observations that the nail is directly anchored in the entheses around the distal interphalangeal joint, this study tested the hypothesis that nail disease in psoriasis was more strongly associated with systemic subclinical enthesopathy than psoriasis without nail disease.

Methods: Forty six patients with psoriasis (without arthritis) were evaluated for the presence of nail disease. Thirty-one of the forty-six psoriasis cases had clinical nail disease. Twenty-one sex and age matched healthy controls (HC) were also recruited. A total of 804 entheses were scanned including the upper and lower limbs entheses by an ultrasonographer blinded to clinical details.

Results: Patients with psoriasis had higher enthesitis scores than HC [med (range): 21 (0–65) vs. 11 (3–39), p=0.005]. The enthesitis scores of psoriasis patients with nail disease [23 (0–65)] were higher than both patients without nail disease [15 (5–26), p=0.02] and HC [11 (3–39), p=0.003]. Sonographically determined inflammation scores of the entheses in patients with nail disease [13 (0–34)] were higher than in patients without nail disease [8 (2–15), p=0.02] and HC [5 (0–19), p<0.001]. Modified NAPSI (nail psoriasis severity index) scores on all nails were correlated to both inflammation (r^2 =0.45, p=0.005) and chronicity entheseal US scores (r^2 =0.35, p=0.04). The duration of psoriasis also tended to correlate with entheseal inflammation (r^2 =0.29; p=0.05) whereas no link between PASI and US scores was evident.

Conclusion: These findings confirm that systemic subclinical enthesopathy is common in psoriasis and shows a specific link with contemporaneous nail disease thus offering a novel microanatomical basis for the predictive value of nail psoriasis for PsA evolution.

2487

Determinants of Depressive Symptoms in Patients with Systemic Sclerosis, Including Fear of Progression and Appearance Self Esteem. Linda Kwakkenbos[1], Wim G.J.M. van Lankveld[1], Madelon C. Vonk[2], Eni S. Becker[3], Frank H.J. van den Hoogen[1] and Cornelia H.M. van den Ende[1]. [1]Department of Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [2]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Behavioural Science Institute, Clinical Psychology, Radboud University, Nijmegen, Netherlands

Background/Purpose: As a consequence of Systemic Sclerosis (SSc), patients report high levels of depressive symptoms. So far, potential determinants of these depressive symptoms are not comprehensively studied. Therefore, it is not clear which factors should be targeted in treating depressed SSc patients. This study was conducted to determine which disease-related and psychological factors, including fear of progression and appearance self esteem, are associated with depressive symptoms, independently of sociodemographic factors.

Methods: In total, 215 patients with SSc completed questionnaires on sociodemographics, physical functioning, pain, fatigue, psychosocial characteristics and depressive symptoms (CES-D). In addition, disease characteristics were collected by the attending rheumatologist. Hierarchical linear regression analysis was conducted to assess associations with depressive symptoms.

Results: Sample characteristics are displayed in Table 1. Mean CES-D score was 12.9 (SD 9.7) and the prevalence of patients scoring >= 16 in our sample was 32.1%. The prevalence of probable depression (CES-D>=19) was 25.1%. Besides pain and fatigue, neither sociodemographic factors, nor physician assessed disease characteristics and physical limitations were important determinants of depressive symptoms (Table 2). Significant determinants were mostly in the psychological domain, with lower satisfaction with social support, emotion-focused coping, helplessness, and higher fear of progression as independent determinants of depressive symptoms (total R^2=.65).

Table 1. Patient demographic and disease characteristics

Number of patients (% female)	215 (67.9%)
Mean age in years	56.4 (SD = 12.0, range 17.9–86.7)
Time since onset first Non-Raynaud symptom	9.2 (SD = 7.9, range 0.2–51.8)
Higher education (>12 yrs)	87 (41.2%)
Currently employed	70 (32.6%)
Married/ cohabitating	162 (75.4%)
Patients with limited SSc	158 (74.9%)
Mean mRSS	6.4 (SD = 5.9, range 0–37)
ANA positive	196 (91.2%)
ACA positive	54 (25.1%)
Anti-TOPO positive	57 (26.6%)
Anti-RNP positive	14 (6.5%)

mRSS, modified Rodnan Skin Score; ANA, antinuclear antibody; ACA, anticentromere antibody; anti-TOPO, antitopomerase antibody; anti-RNP, antiribonuclear protein antibodies

Table 2. Hierarchical regression analysis of demographics, disease status and psychological variables predicting depressive symptoms (CES-D, range 0–60).

	Variable	B[a]	[95% CI]	P	Beta[a]	Total R^2
1) Demographics	Age	−.04	[−.12, .05]	.371	−.05	
	Sex	−.86	[−3.00, 1.28]	.427	−.04	.03
2) Socioeconomic status	Higher education	−.37	[−2.42, 1.69]	.725	−.02	
	Married/Cohabitating	−2.0	[−4.41, .43]	.106	−.09	.07
3) Disease characteristics	Limited disease	−.04	[−2.38, 2.31]	.975	.00	
	Disease duration	.02	[-.10, .14]	.738	.02	
	mRSS	.08	[-.10, .26]	.409	.05	.09
4) Physical functioning	HAQ score	−1.16	[−2.95, .62]	.200	−.09	
	Pain	.05	[.00, .09]	.054	.11	
	Fatigue	.23	[.13, .33]	<.001	.31	.44
5) Psychosocial factors	Social support	−.03	[−.12, −.01]	.014	−.14	
	Helplessness	.39	[.04, .75]	.030	.17	
	Acceptance	.06	[−.26, .37]	.693	.03	
	Problem-focused coping	−.03	[−.12, .07]	.618	−.03	
	Emotion-focused coping	.18	[.08, .28]	<.001	.23	
	Avoidance coping	.06	[−.05, .16]	.298	.06	
	Appearance self esteem	−.23	[−.49, .03]	.083	−.10	
	Fear of progression	.20	[.05, .34]	.007	.18	.65

[a]Final model

Conclusion: A routine psychological assessment is recommended for patients with SSc, since assessment of physical functioning without systematically taking psychological factors into account might not be sufficient to identify patients at risk for depressive symptoms. For the development and trialling of psychological interventions, fear of progression could be an important target.

2488

Lifestyle Intervention for Health-Related Quality of Life in Overweight and Obese Patients with Systemic Lupus Erythematosus: A Pilot Study. Carol M. Greco[1], Amy D. Rickman[1], Nehal Shah[1], Anne E. Mishler[1], Nicole L. Wilson[2], John M. Jakicic[1], Susan Manzi[3] and Amy H. Kao[3]. [1]University of Pittsburgh, Pittsburgh, PA, [2]W Penn Allegheny Health System, Pittsburgh, PA, [3]Allegheny Singer Research Institute, Pittsburgh, PA

Background/Purpose: Many patients with systemic lupus erythematosus (SLE) are sedentary and have poor health-related quality of life (i.e. fatigue, pain, depressive symptoms). Few studies have evaluated the effects of a lifestyle intervention in patients with SLE. The purpose of this pilot study was to investigate the feasibility and effects of a 16-week lifestyle intervention on weight loss and health-related quality of life in SLE patients who are overweight or obese.

Methods: The lifestyle intervention program included a reduced calorie diet (1200/1500 kcal/d) and progressively increased physical activity from 100 to 300 min/wk by week 16. Participants met weekly as a group, completed food journals daily and engaged in a home exercise program. Measures included weight, Eating Behavior Inventory (EBI), Fatigue Severity scale (FSS), SF36 Health Survey v2, pain visual analog scale (VAS), and the Center for Epidemiologic Depression Scale (CES-D). Wilcoxon signed-rank tests were used to determine significant differences between baseline and 16 week self-report assessments.

Results: Participants were 15 women with SLE (mean age=39.7±10.4yrs, 53% Caucasian, mean body mass index =30.8±3.7 kg/m^2). Nine participants completed the study and provided baseline and 16-week assessments (60% completion rate). At baseline, 88% of study completers had clinically significant depressive symptoms as defined by CES-D >/=16, and the majority (67%) had significant fatigue as defined by FSS >/=36. Mean percentage weight change was −9.8±2.8% and mean weight lost was 8.2±2.0 kg. All 9 participants improved their healthy eating behavior assessed by EBI (change, +19, interquartile range [IQR]: 8 to 25, p=0.008). Significant improvements were seen in fatigue assessed by FSS (−7, IQR: −18 to 0, p=0.05) and SF36 Vitality Scale (+6.24, IQR: 3.1 to 18.6, p=0.009). Pain VAS improved (−11, IQR:−11 to −2, p=0.01) but not SF36 Bodily Pain scale (+4.2, IQR: 5.1 to 0, p=0.152). SF36 physical function improved as well (+4.2, IQR: 2.1 to 8.4, p=0.02). For mental health, depressive symptoms by CES-D (median: −4.5, IQR: −6.5 to −4, p=0.02), SF 36 Mental Health (+8.4, IQR: 2.8 to 14.1, p=0.008) and Role Emotional (+3.9, IQR: 0 to 3.9, p=0.03) all improved. Significant correlations were observed between changes in weight and fatigue (FSS: r=0.73, p=0.02; SF36 Vitality: r= 0.73, p= 0.03).

Conclusion: These results demonstrate that a lifestyle program focusing on weight loss and increased physical activity can lead to significant improvements in health-related quality of life, including mental health and fatigue in overweight/obese SLE patients. Research with a larger sample, a control group, a longer-term follow-up and strategies to improve retention will be important to determine how a lifestyle program may further impact the lives of SLE patients.

SF36v2 T-scores at Baseline and 16 weeks

Sexual Activity and Impairment Among Women with Systemic Sclerosis. Brooke Levis[1], Marie Hudson[1], Ruby Knafo[1], Murray Baron[2], Warren Nielson[3], Marilyn Hill[3] and Brett D. Thombs[1]. [1]McGill University, Montreal, QC, [2]Jewish General Hospital, Montreal, QC, [3]Univ of Western Ontario, London, ON

Background/Purpose: Systemic Sclerosis (SSc), or scleroderma, is a chronic, multi-system, connective tissue disorder with a number of physical and psychological consequences that might be expected to affect sexual functioning among women, including fatigue, depression, distressing changes in appearance, Raynaud's phenomenon, skin tightening and discomfort, vaginal tightness and dryness, thickening of the skin around the lips, finger ulcers and calcium deposits that are painful to the touch, gastrointestinal symptoms, joint pain and muscular weakness. Existing studies of sexual functioning among women with SSc have concluded that rates of sexual dysfunction are high, but have been limited by the use of single, unvalidated items to assess dysfunction and problems; by not explicitly distinguishing between sexual inactivity and sexual dysfunction; by small sample sizes; by investigating only a limited amount of etiological factors, or by not including multivariate assessments. The objectives of this study were to assess (1) the rates of sexual activity and impairment in a large sample of female SSc patients, (2) clinical correlates of sexual activity/impairment, and (3) common sources of pain during and after sex.

Methods: Cross-sectional, multi-center study of female SSc patients from the Canadian Scleroderma Research Group Registry. Patients underwent medical examinations and clinical histories and were asked whether they had engaged in sexual activities with their partner in the past 4 weeks. Sexually inactive patients indicated reasons for inactivity. Sexually active patients completed a 9-item version of the Female Sexual Function Index (FSFI) and items related to problems that may be linked to sexual dysfunction in SSc. Multivariate logistic regressions were done to assess independent predictors of activity/inactivity and sexual dysfunction.

Results: 238 of 559 patients (43%), including 226 of the 412 patients currently in relationships (55%), reported having engaged in sexual activities with a partner in the past 4 weeks. Independent predictors ($p<0.05$) of sexual activity were younger age, fewer GI symptoms and less severe Raynaud's symptoms. Among the 165 sexually active patients with complete data for all variables, 102 (62%) scored below the FSFI cut-off of 22.5, indicating impaired sexual function, which was independently associated with older age, higher skin scores and more severe breathing problems. Ratings of pain both during and after sex were substantially higher for all 10 variables reflecting potential sources of pain among those impaired in comparison to those not impaired. Both during and after sexual activity, women with sexual impairment were significantly more likely to report at least one source of pain ($p<0.001$). Among individual sources of pain, after controlling for multiple comparisons, they were significantly more likely to report vaginal pain ($p<0.001$).

Conclusion: Rates of sexual impairment are high among women with SSc compared to rates reported in the general population. Research is needed to develop interventions to address impaired sexual function in women with SSc.

The Relationship Between Cognitive Function and Physical Function in Persons with Rheumatoid Arthritis. So Young Shin, Laura J. Julian, Margaret I. Wallhagen and Patricia P. Katz. University of California San Francisco, San Francisco, CA

Background/Purpose: Population-based studies have found that cognitive impairment contributes to declines in daily function, yet no study has examined this relationship in persons with rheumatoid arthritis (RA). We addressed this gap by examining the association of cognitive impairment with functional limitations and disability in persons with RA.

Methods: Individuals with RA participating in a longitudinal cohort study who resided in the San Francisco Bay Area visited the clinical research center for a study visit that included a range of physical, psychosocial, and biological metrics. Cognitive function was assessed using a battery of 12 standardized neuropsychological measures yielding 16 indices covering a range of cognitive domains. On each test, subjects were classified as 'impaired' if they performed 1 *SD* below age-based population norms. The total cognitive impairment score was calculated by summing the transformed scores, ranging from 0 (no impairment) to 16 (worst impairment). Functional limitations were assessed with both performance-based (Short Physical Performance Battery [SPPB]; lower scores = worse function) and self-reported (Health Assessment Questionnaire [HAQ];

higher scores = worse function) measures. Disability was measured with the Valued Life Activities (VLA; higher scores = worse function) scale. Multiple regression analyses, controlling for gender, race, educational level, marital status, income, duration of RA, severity of RA, C-reactive protein (CRP), and depression were conducted to identify whether cognitive impairment independently predicted physical function difficulties.

Results: One hundred forty four subjects with a mean (±*SD*) age of 57.7 (±11.1) years were included. Sixty percent were female, 76% were white, and 10% had met criteria for major depressive disorder. Mean educational level was 15.1 (±2.3) years and duration of RA was 19.3 (±11.1) years. Mean total cognitive impairment score was 2.6 (±2.4), and ranged from 0–11. The proportion of persons who were classified as cognitively impaired on each test ranged from 9% (semantic fluency test) to 28% (non-verbal fluency test). The proportion of persons cognitively impaired on four or more tests was 29%. After controlling for gender, race, educational level, marital status, income, duration of RA, severity of RA, CRP, and depression, the total cognitive impairment score was significantly associated with greater functional limitations (SPPB: β = -.27, p =.008; HAQ: β =.27, p =.001) but not with disability (VLA: β =.12, p =.120).

Conclusion: Cognitive impairment was significantly associated with increased functional limitations in persons with RA. The findings of this study suggest that consideration of cognitive impairment may be warranted to improve functional status in persons with RA. None.

2491

Cognitive Impairment in Persons with Rheumatoid Arthritis. So Young Shin, Patricia P. Katz, Margaret I. Wallhagen and Laura J. Julian. University of California San Francisco, San Francisco, CA

Background/Purpose: For persons with chronic diseases such as rheumatoid arthritis (RA), intact cognitive function is crucial for performing main daily activities and adhering to self-management regimens. Persons with impaired cognitive function have decreased functional independence, reduced quality of life, and increased risk of mortality. Although several mechanisms may influence cognitive function in RA, it has not been well-studied in this population. This study explored the prevalence and possible predictors of cognitive impairment in persons with RA.

Methods: Individuals with RA participating in a longitudinal cohort study who resided in the San Francisco Bay Area visited the clinical research center for a study visit that included a range of physical, psychosocial, and biological metrics. Cognitive function was assessed using a battery of 12 standardized neuropsychological measures yielding 16 indices covering a range of cognitive domains. Subjects were classified as 'impaired' if they performed 1 *SD* below age-based population norms on at least 4 of 16 indices. Logistic regression analyses were conducted to identify which of the following were significant predictors of cognitive impairment: gender, race/ethnicity, income, education, disease duration, disease severity measured by the Rheumatoid Arthritis Disease Activity Index, C-reactive protein (CRP), steroid use, depression, and cardiovascular risk factors (self-reported presence of hypertension, diabetes, stroke, current smoking, or obesity [from body mass index]).

Results: One hundred subjects with a mean (±*SD*) age of 58.5 (±10.4) years were included. Eighty three percent were female, 83% were white, and 7% had met criteria for major depressive disorder. Mean educational level was 15.2 (±2.2) years and duration of RA was 21.1 (±11.6) years. The proportion of persons who were classified as cognitively impaired on each test ranged from 8% (visuo-spatial test) to 31% (non-verbal fluency test). Mean total cognitive impairment score was 2.5 (±2.2), and ranged from 0–10. The proportion of persons who were classified as cognitively impaired was 30%. Race, education, duration of RA, and cardiovascular risk factors independently predicted cognitive impairment controlling for income, severity of RA, CRP, steroid use, and depression. Individuals with cognitive impairment were more likely to be nonwhites (OR = 5.81, 95% CI: 1.16–29.05), and had less education (OR = 1.35, 95% CI: 1.05–1.75), lower disease duration (OR = 1.05, 95% CI: 1.01–1.10), and increased cardiovascular risk factors (OR = 3.36, 95% CI: 1.04–10.80).

Conclusion: About one third of RA patients were cognitively impaired. Nonwhites, persons with less education, shorter duration of RA, and one or more cardiovascular risk factors were more likely to have cognitive impairment in this cohort. These findings suggest that the burden of cognitive impairment in RA is significant, and future studies identifying specific etiological contributors to cognitive impairment are warranted.

Accounts of Chronic Pain and Emotional Distress in Children and Youth with Juvenile Idiopathic Arthritis or Chronic Pain: Qualitative Analysis of Interviews to Assess Content Validity of the Patient Reported Outcome Measurement Information System. C. Jeffrey Jacobson[1], Jennifer Farrell[2], Susmita Kashikar-Zuck[2], Emily Verkamp[2], Michael Seid[3] and Esi Morgan DeWitt[2]. [1]University of Cincinnati, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, Cincinnati

Background/Purpose: Chronic pain in children and adolescents is associated with functional impairment, increased distress, and reduced quality of life. Assessment of the pain experience is heavily dependent on child and youth self-reports of pain intensity, pain quality and emotional distress. However, knowledge about how children and adolescents understand and talk about their pain and distress and how this may vary across diagnosis, gender, or age or developmental stage is limited. Little research has examined the thematic, semantic and linguistic content of child accounts of pain and distress across these groups The objective of the current study was to qualitatively evaluate the content validity of the NIH Patient Reported Outcomes Measurement Information System (PROMIS, nihpromis.org) pediatric measures for self-reported health outcomes from the perspective of children and youth with juvenile idiopathic arthritis (JIA) or chronic pain syndromes. The eight PROMIS pediatric measures include a Pediatric Pain Interference Scale as well as emotional distress scales.

Methods: Trained interviewers conducted semi-structured individual interviews with children and youth ages 8 to 18 years old with either JIA or a non-inflammatory chronic pain syndrome). Each interview covered 2 to 4 of the health concepts underlying the 8 PROMIS pediatric domains: Anxiety, Anger, Depressive Symptoms, Fatigue, Pain Interference, Peer Relationships, Physical Function (Upper Extremity, and Mobility). For each domain, interviews elicited the subjective meaning of the construct and using both open-ended and structured probes. Participants also completed PROMIS Short Forms which were scored. Audio-recorded interviews were transcribed verbatim and entered into a qualitative text management software program (NVIVO8) to facilitate analysis. Transcript content was evaluated in relation to 1) the item-conceptual content of the 8 PROMIS domains 2) possible age-related differences in comprehension and reporting of the domains and 3) possible diagnosis-related differences in expression and reporting of the domains.

Results: 31 youth (16 JIA, 15 chronic pain) were interviewed, mean age 13.7 years (range 8–18), 80.6% female. We found age- and gender-related differences in child-reported understandings, expression, and articulation of the domains of anger, anxiety, depression and pain interference. Children younger than 14 years typically had difficulty defining one affective-distress domain without referring to another. Female participants were more verbally expressive than males. Differences based upon diagnosis were also explored to see whether there was any evidence of medical socialization in these illness groups.

Conclusion: These findings suggest need for a rigorous developmental approach to pediatric patient reported outcome measure development. Experience and expression of health constructs differed based upon developmental status, and possibly in part due to medical socialization.

Effective Anti-CD20 Therapy for Arthritis Is Associated with B-Cell Depletion in Efferent Lymph Nodes and Increased Lymph and Cellular Flow in Lymphatic Vessels From Arthritic Joints. Jie Li, Christopher T. Ritchlin, Ignacio Sanz, Andrea Bottaro, Ronald Wood, Lianping Xing and Edward M. Schwarz. University of Rochester School of Medicine and Dentistry, Rochester, NY

Background/Purpose: B cell depletion therapy (BCDT) is an effective intervention for some RA patients. However, the mechanisms that underlie the reduction of synovitis and decline in macrophage numbers remain unknown. Contrast enhanced (CE) MRI and near infrared (NIR) imaging of indocyanine green (ICG) of TNF-Tg mice has demonstrated that arthritic progression from the ankle to the knee is initially prevented by increased lymphatic drainage to "expanding" lymph nodes (LN), which significantly increase in size due to the accumulation of non-activated polyclonal CD23+/

CD21hi B cells (B-in). Subsequently, knee flare occurs following a sudden decrease in lymphatic flow, and LN collapse due to B-in translocation from the follicles into the sinus space, resulting in "clogging" of the lymphatic vessels. Here we tested the hypothesis that BCDT ameliorates TNF-induced knee arthritic flare by removal of B-in from the LN, which leads to increased flow and inflammatory cell egress through lymphatics in arthritic joints.

Methods: TNF-Tg mice with expanding or collapsed popliteal LN (PLN) were identified by CE-MRI and their knee synovial volume was quantified. Mice with collapsed PLN were treated with anti-CD20 (n=8; 16 knees) (10mg/kg/i.v. every 2 weeks) or placebo (n=4; 8 knees) for 6 weeks, with continuous CE-MRI every 2 weeks. Lymphatic flow was quantified by NIR-ICG. In vivo imaging of macrophages, B cells and T cells in lymphatic vessels draining the leg was performed by co-injection of fluorescently labeled dextran and antibodies against CD11b, IgM or CD3 into the footpad 2hr prior to direct immuno-fluorescent microscopy (IFM) of the surgically exposed vessels.

Results: NIR-ICG imaging demonstrated that collapsed PLN displayed decreased lymphatic draining vs. expanding in ICG clearance rate (43.8±17.6% vs.86.3±3.4%, p=0.018) and lymphatic pulsing frequency (0 vs. 1.4±0.03 pulse/minute). IFM showed a significant increase in the number of CD11b+ cells in lymphatic vessels afferent to collapsed vs. expanding PLN (No./mm vessel: 26.6±1.6 vs. 5.8±5.5, p=0.0007). Anti-CD20 treatment significantly decreased knee synovial volume (4.55±2.39mm^3 vs. 8.98±4.16mm^3 in placebo, p=0.02) at 6-weeks, and synovitis progression (p=0.0003) vs. the placebo group, which demonstrated a significant (p=0.0001) 0.81mm^3/week increase in synovitis. Anti-CD20 also increased ICG clearance rate vs. placebo (90.4±8.5% vs. 69.3±21.7%, p=0.03). The increased lymphatic flow was associated with a decrease in CD11b+ cells in lymphatic vessel (No./mm vessel: 1.8±0.4); a finding equivalent to that in vessels afferent to expanding PLN.

Conclusion: These results indicate that some arthritic flares are associated with B cell translocation into the lymphatic sinuses of LN, which "clogs" draining lymph from the joint. BCDT could clear these B-in cells and restore lymphatic draining function, leading to reduced tissue damage by removing CD11b+ inflammatory cells and other catalytic factors from affected joints. Thus restoration of lymphatic function is a novel mechanism of action for BCDT in treatment of RA.

A Whole-Blood Transcriptomic Signature Predicts Clinical Response to Rituximab in Rheumatoid Arthritis. Jeremie Sellam[1], Sandrine Marion-Thore[2], F. Dumont[2], Franck Letourneur[3], Stephanie Rouanet[4], Yassine Taoufik[5], Jean Sibilia[6], Jacques G. Tebib[7], Xavier Le Loët[8], Bernard G. Combe[9], Maxime Dougados[10], Xavier Mariette[11] and Gilles Chiocchia[3]. [1]Hopital Saint-Antoine, Pierre et Marie Curie University Paris 6, AP-HP, 75012, France, [2]INSERM U1016, Institut Cochin, Paris Descartes University, Paris, France, [3]Institut Cochin, 75014 Paris, France, [4]Roche, Neuilly sur Seine, France, [5]Hopital Bicetre, Université Paris Sud, AP-HP, France, [6]Service de rhumatologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France, Strasbourg, France, [7]Centre Hosp Lyon Sud, Pierre Benite, France, [8]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France, [9]Hopital Lapeyronie, Montpellier, France, [10]Paris-Descartes University, Paris, France, [11]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: The first aim of this study was to investigate transcriptomic profile of peripheral blood sample from rheumatoid arthritis (RA) patients before rituximab (RTX) to identify gene expression profile predictive of clinical response. The second aim was to analyze the transcriptomic profile of the same patients at week 24 (W24) after RTX.

Methods: 224 RA patients refractory or contra-indicated to anti-TNF were treated with RTX 1 g day 1 and 15 in an open label trial (SMART study) and clinical response was assessed at W24 using EULAR response. Two groups of patients were set up: non responders (NR, 29%) and responders (R, 71%), the later including both moderate (49%) and good responders (22%). This transcriptomic study involves 69 patients randomly selected among the 224 encompassing 24 NR and 45 R. RNA was extracted from peripheral blood sample and then amplified. Gene expression profiling was performed using Affymetrix Human gene 1ST array which covered the whole genome. Results were analyzed using both linear method LIMMA and ANOVA.

Results: Before RTX, differential gene expression between R versus NR at week 24 showed that 203 genes were significantly differentially deregulated. This set of genes allowed a good classification of 82% of the patients according to their response status. This first gene expression signature was then reduced to 62 genes by using Pearson correlation and allowed to correctly classify 90% of the patients into groups R and NR. The molecular signature consisted in genes regulating (a) inflammatory response including upregulation of interleukin 33 (IL-33), a member of the IL-1 family and of IRAK1, mediating the pleiotropic effect of IL-1 and downregulation of genes related to interferon (INF) response such as IFIH1, TRIM22, and DHX58, (b) cell to cell interaction: EMR4P and E-selectin playing a role in leukocyte trafficking were significantly higher in R and (c) cellular development including ZHX3, a transcriptional repressor downregulated in R. At W24 post-treatment, genes involved in B cell development and B cell functions were strongly down regulated in both groups, as expected after RTX. Differences in the regulation of B cell pathways were found between groups in term of quantity, and surprisingly, the NR group exhibited a larger number of down regulated B-cell related genes with more down-regulation of the immunoglobulin genes.

Conclusion: A pre-treatment molecular signature predicts the response to RTX in 90% of RA patients. This molecular signature involves upregulation of IL-33 and downregulation of IFN pathway. The comparison between pre and post-treatment signature revealed an unexpected stronger down-regulation of B cell genes in NR compared to R patients.

A Humanized Monoclonal Antibody Against a Surface Ligand of Mononuclear Cells Suppress Autoimmune Inflammatory Diseases by Upregulation of IL-10 Secretion. Yaakov Naparstek, Rina Ulmansky, Galia Katzavian, Ronit Meyuhas, Alon Hershko, Eli Moallem, Shira Yair and Dorit Landstein. Hadassah-Hebrew University Medical Center, Jerusalem, Israel

Background/Purpose: We have previously shown that resistance to Adjuvant Arthritis (AA) is due to the presence of anti-heat shock protein (HSP) antibodies, directed at peptide 6, a 16 amino-acid surface epitope, that cross reacts with a mononuclear cell surface ligand. In this work we have studied the effect of a humanized monoclonal antibody against peptide 6 on various models of autoimmune arthritis and colitis and the mechanism of their anti-inflammatory effect.

Methods: We have recently developed a humanized anti-peptide 6 antibody that cross reacts with a surface ligand of human mononuclear cells. Incubation of this antibody with murine and human mononuclear cells induced the secretion of IL-10.

Results: The antibodies bound to a cross reacting epitope of adenyl cyclase associated protein (CAP1) in human monocytes and induced upregulation of IL-10 mRNA, by upregulation of transcription factors that bind the IL-10 promoter, resulting in the induction of IL-10 secretion. Suppression of CAP1 expression by specific siRNA reduced the binding of the protective antibodies to the cells. Treatment of mice and rats with collagen induced arthritis, adjuvant arthritis and TNBS colitis with this antibody induced upregulation of serum IL-10 and suppression of disease. The level of anti peptide 6 antibodies in the serum of patients with rheumatoid arthritis was significantly lower than in healthy controls.

Conclusion: We conclude that HSP contains protective B-cell epitopes exposed on its surface, and that natural and acquired resistance to autoimmune arthritis is associated with the ability to develop an antibody response to these epitopes. These antibodies cross react with a monocyte surface receptor and modulate cytokine production. Lower levels of anti peptide 6 antibodies in patients with RA suggest that they play a role in protection against human autoimmune diseases as well. The monoclonal humanized anti-peptide 6 antibody may serve as a new therapeutic tool for suppression of human arthritis and inflammatory bowl diseases by skewing the immune system selectively towards an anti-inflammatory response.

B Cells Enhance the Type I Interferon Production by Plasmacytoid Dendritic Cells Via CD31. Lars Rönnblom[1], Olof Berggren[1], Gert Weber[2], Niklas Hagberg[1] and Maija-Leena Eloranta[1]. [1]Section of Rheumatology, Uppsala University, Uppsala, Sweden, [2]Structural Biochemistry, Free University of Berlin, Berlin, Germany

Background/Purpose: The type I interferon (IFN) system and B lymphocytes are activated in lupus and several other autoimmune rheumatic diseases. The main producer of IFN-α is the plasmacytoid dendritic cell (PDC), and the produced IFN can stimulate B cells and promote autoantibody production. However, the role of B cells on the PDC function has not been examined before. We therefore investigated the regulatory effect of B cells on the type I IFN response by PDC after stimulation with immune complexes (IC), virus and CpG-DNA. We further studied whether the PDC and B cell cross-talk was mediated by soluble factors or by cell-cell contact.

Methods: PDC and B cells were isolated from peripheral blood mononuclear cells from healthy blood donors. PDC alone or in co-cultures with B cells were stimulated with purified U1 snRNP and IgG from SLE patients (RNA-IC), herpes simplex virus (HSV) or the CpG containing oligonucleotide ODN2216. Supernatants from stimulated B cell cultures were collected after 20h and investigated for their stimulatory effect on the IFN-α production. The co-culture supernatants were analyzed for IFN-α, and several other cytokines. The cells were stained by monoclonal antibodies and analyzed by flow cytometry for intracellular IFN-α, as well as PDC and B cell associated cell surface molecules (BDCA-2, CD20, CD31 and CD38). Neutralizing antibodies to CD31 were used to investigate the PDC and B cell interactions.

Results: B cells enhanced the IFN-α production by PDC 3 to 15 fold (1000–8000 U IFN-α/ml) with all IFN inducers. B cells more strongly enhanced the PDC response when stimulated with HSV compared to RNA-IC and ODN2216 ($p=0.0001$ and $p=0.019$, respectively). PDC and B cells formed cell aggregates when IFN inducers were present in the co-cultures. Supernatants from ODN2216-stimulated B cells markedly promoted the IFN-α production by PDC, while supernatants from RNA-IC-stimulated B cells were poor IFN-α enhancers. Anti-CD31 antibody inhibited the IFN-α production induced by RNA-IC in co-cultures of PDC and B cells (~80% reduction), but not in co-cultures stimulated with ODN2216. Pre-incubation of PDC or B cells with anti-CD31 antibodies before co-culturing the cells with RNA-IC, reduced the IFN-α production to the same extent as when anti-CD31 antibodies were added directly to the co-cultures. PDC were responsible for the IFN-α production in the co-cultures. The PDC produced higher amounts of IFN-α per cell when stimulated by RNA-IC compared to ODN2216, while the latter induced higher frequency of IFN-α producing PDC. All IFN-α producing PDC showed high expression of CD31.

Conclusion: Our findings reveal an important interaction between the innate and adaptive immune system with B cells promoting the PDC function and increasing the type I IFN response to several different IFN-α inducers, including IC containing nucleic acids. B cells enhance the IFN-α production by PDC both via cell-cell contact and soluble factors depending on the stimuli. Since B cells are activated by type I IFN, this PDC-B-cell cross-talk may be of fundamental importance in the etiopathogenesis of SLE, and contribute to the observed IFN signature and chronic immune activation in SLE and other systemic rheumatic diseases.

The Critical Role of Protein Kinase C Beta in Lupus Development in Lupus Mice. Luojing Chen. University of Rochester, Rochester, NY

Background/Purpose: B cells play a central role in lupus and targeting B cells for the treatment of lupus is an area of great interest. Protein kinase C beta (PKCbeta) is important for mature B cell survival by mediating BCR and BAFF signaling. However, the function of PKCbeta in the survival of lupus B cells and the development of the disease has not been investigated.

Methods: Using congenic mouse models bearing the disease loci: Sle1 or Sle1Sle3, we generated PKCbeta deficient mice (Sle1.PKCbeta−/− and Sle1Sle3.PKCbeta−/− mice).

Results: the deficiency in PKCbeta abrogated all lupus associated phenotypes such as high levels of autoantibodies in serum and proteinuria and the appearance of Ig deposition in kidneys. Compared with Sle congenic lupus mice, PKCbeta deficient mice have a remarkable decrease in spleen size and greatly reduced activated CD4 T cells and B cells, CD4/CD8 T cell ratio, and CD138 plasma cells, of which are all typically high in lupus mice. In addition, PKCbeta deficient lupus mice showed a severe decrease in peritoneal B1 cells and have an impaired immune response to both T-cell dependent and independent antigens. Furthermore, we found that mouse lupus B cells, as well as a prototype of human autoreactive B cells (9G4+), display enhanced sensitivity to PKCbeta inhibition. The absence of PKCbeta impairs anti-IgM mediated proliferation and survival responses in lupus B cells, at least in part due to down-regulation of the NF-kB pathway. More importantly, the lack of detection of kidney lesions from the PKCbeta deficient lupus mice indicates the critical role of PKCbeta in lupus development.

Conclusion: Our results suggest that PKCbeta may represent a potentially specific therapeutic target for lupus treatment.

Effect of Intravenous Cyclophosphamide Treatment on B Cells in SLE Nephritis. Chungwen Wei[1], John Jung[1], Valentin Marian[1], Donna F. Hardwick[2], Gema Souto-Adeva[3], Youqun Huang[1], Bridget Neary[1], Gabor G. Illei[3] and Iñaki Sanz[1]. [1]University of Rochester, Rochester, NY, [2]NIH MSC 1616, Bethesda, MD, [3]NIDCR/ NIH #10 1N110, Bethesda, MD

Background/Purpose: Intravenous pulse cyclophosphamide (IVCY) has been shown to effectively induce remission and improve long-term outcome in patients with proliferative lupus nephritis. Despite its effectiveness, the mechanism of its efficacy is still not clear. Nonetheless, orally administered cyclophosphamide has been shown to suppress B cell proliferation and differentiation *in vitro*. However, the depth of IVCY-induced B cell depletion and its potentially differential impact on specific B cell subsets remains to be formally investigated. This study investigates the effects of IVCY on B cell profiles as a first step towards understanding its mechanism of action and identifying biomarkers of favorable response.

Methods: SLE patients treated with IVCY for active SLE were recruited either before initiation of treatment or during treatment (n=12). PBMCs were analyzed by two 12-color flow panels designed to recognize all major B cell subsets and to in-depth subset either memory or transitional B cell compartments. These panels share seven anchor markers (live/dead, CD3, CD19, IgD, CD27, CD38 and CD24) and include CD21, B220, CD95, CXCR3 in the memory panel and MTG, CD10, IgM, CD23 in the transitional panel. The resulting B cell profiles from the cross-sectional and longitudinal analyses of these patients were compared to those generated from a group of healthy subjects (n=9).

Results: In all, we analyzed 26 samples from 12 patients treated with IVCY. Of those, 22 represented longitudinal samples from 8 patients and 4 represented unique samples. Of which, 5 were baseline samples (pre-CY) and the other 21 were collected at different time points during the treatment (post-CY). The pre-CY group had a higher level of B cells than the healthy control group ($p<0.01$), while the post-CY group exhibited a severe B cell lymphopenia compared to both HC and pre-CY groups ($p<0.001$). Levels of $CD21^-$ and $CD95^+$ activated B cells in both IgD^-CD27^+ and IgD^-CD27^- switched memory subsets were elevated in the pre-CY group compared to the HC group ($p<0.01$). After treatment, there was a decrease in the IgD^+CD27^- population (which consists of both naïve and transitional B cells) and a concomitant increase in the switched memory cells. Despite the amelioration of clinical symptoms, the post-CY group still exhibited a memory dominant B cell profile. Of the 5 patients with a baseline, 4 responded well to the treatment. The mean SLEDAI went down from 18.5 to 4, and all achieved remission of proteinuria. Serum creatinine levels were also decreased by as much as 50%. Prior to IVCY treatment, the vast majority of B cells from these patients were bound *in vivo* by the VH4–34 encoded $9G4^+$ autoantibody. Strikingly, 9G4 painting was completely abolished from these responders after treatment.

Conclusion: In contrast with Rituximab, patients treated with IVCY with a favorable clinical response are characterized by the persistence of a dominant population of memory cells and lack of naïve/transitional dominance during reconstitution phases. Detailed B cell profiling in SLE patients treated with CY may provide significant insights into the pathogenic role of different B cell compartments and identify biomarkers of disease response and possibly of long-term remission.

IL-27 Receptor Signaling Is Critical for B Cell Differentiation in Collagen Induced Arthritis. Odilia B.J. Corneth[1], Anne-Marie Mus[2], Patrick S. Asmawidjaja[2], Rudi W. Hendriks[2] and Erik Lubberts[2]. [1]Erasmus MC, University Medical Center, Rotterdam, Rotterdam, Netherlands, [2]Erasmus MC, University Medical Center, Rotterdam, Netherlands

Background/Purpose: Th17 cells play a critical role in the autoimmune mouse model for rheumatoid arthritis, collagen induced arthritis (CIA). IL-27 receptor (IL-27R) signaling induces Th1 differentiation and IL-10 production and inhibits Th17 differentiation. In addition, IL-27R signaling is linked to B cell proliferation and IgG2a class switch recombination. In experimental autoimmune encephalomyelitis (EAE), an autoimmune mouse model for multiple sclerosis, IL-27R knock-out mice showed higher proliferation of draining lymph nodes with more production of IL-17, IL-6 and TNFα. We therefore hypothesized that CIA would be enhanced in IL-27R knock-out mice compared to wild type controls. The purpose of this study is to investigate the role of IL-27R signaling in CIA.

Methods: IL-27R knock-out mice and wild type controls were immunized with chicken collagen type II and complete Freunds Adjuvant (CFA), and boosted again 21 days later. Mice were euthanized 10, 36, 45 and 63 days

after immunization and B and T cell subsets in spleen, lymph nodes and joints were analyzed using flow cytometry. Furthermore, auto-antibodies were determined in serum using ELISA and immunohistochemic analysis of the spleen and histological analysis of the joints was performed. For antigen induced arthritis, mice were immunized with methylated bovine serum albumin (mBSA) in CFA and a local injection of mBSA in the knee joint was given one week later.

Results: Interestingly, both the incidence of CIA and the arthritis score were significantly lower in IL-27R knock-out mice compared to wild type controls. In addition, synovial inflammation was markedly decreased in IL-27R knock-out mice. Although the proportion of Th17 cells was increased in IL-27R knock-out mice, the total number of CD4+ T cells was significantly lower. To assess whether Th17 cells were pathogenic we made use of the Th17 mediated antigen induced arthritis (AIA) model. Inflammation of the knee joints in IL-27R knock-out mice in AIA was comparable to wild type controls, showing that the pathogenicity of these cells is normal. As B cells also play a significant role in CIA, we then analyzed B cells by flow cytometry. The total number of B cells was lower in IL-27R knock-out mice. Also, IL-27R knock-out mice hardly develop germinal center B cells, which we confirmed by immunohistochemistry. In line with this, we found that collagen specific IgG antibody levels were lower in these mice suggesting a critical role for IL-27R signaling in further differentiation of mature B cells.

Conclusion: Our data show a critical role of the IL-27 receptor signaling in the development of CIA. IL-27R deficient mice have a higher proportion of Th17 cells with normal pathogenic function but reduced numbers of CD4+ T cells en B cells. In addition, the development of germinal center B cells was significantly impaired. These data suggest that IL-27 receptor signaling is involved in both T en B cell development and function and that the lack of germinal center B cells in the IL-27R deficient mice is most critical for the reduced expression of CIA.

Interleukin-27 Receptor-Deficient Mice Develop Exacerbated Inflammatory Arthritis Associated with Heightened T- and B- Cell Responses. Gareth W. Jones[1], Anwen S. Williams[1], Mari A. Nowell[1], Brendan J. Jenkins[2] and Simon A. Jones[3]. [1]School of Medicine, Cardiff University, Cardiff, Wales, United Kingdom, [2]Monash Institute of Medical Research, Monash University, Melbourne, Australia, [3]Cardiff University, Cardiff, United Kingdom

Background/Purpose: Cytokine control of the adaptive immune response is a central process in the development of inflammatory diseases. T helper cells that produce interleukin-17 (IL-17; Th17 cells) have recently been identified as a distinct T cell subset implicated in a number of autoimmune diseases including rheumatoid arthritis (RA). As such, targeting of the inflammatory pathways that promote Th17 cell responses are currently of interest for developing new therapies to treat RA. The interleukin (IL)-6 family of cytokines share the ubiquitously expressed glycoprotein 130 (gp130) receptor for activation of intracellular signaling pathways and members of this family, most notably IL-6 and IL-27, have emerged as key regulators of the Th17 cell response. Through differential activation of signaling transducers and activators of transcription (STAT)1 and STAT3, IL-6 and IL-27 have opposing outcomes on the generation of Th17 cells. IL-6/STAT3 signaling promotes the differentiation of Th17 cells from naïve T helper cells while IL-27 *via* STAT1 counteracts this IL-6-driven process. Accordingly, IL-6 receptor-deficient (IL-6R$^{-/-}$) mice are protected from inflammatory arthritis, display no T cell infiltrates in the synovium and have an impaired Th17 cell response. Studies in IL-27R$^{-/-}$ mice have highlighted an anti-inflammatory role for IL-27 in inflammatory diseases. However, the mechanisms linking IL-27 to arthritis progression remain unclear.

Methods: Experimental inflammatory arthritis was induced in wild type (WT) mice and IL-27R$^{-/-}$ mice. Disease severity was assessed through measurement of joint swelling, histological analysis of joint sections and x-ray. Flow cytometry, immunohistochemical and immunological assays were used to monitor the peripheral immune response and the cellular response within the synovium. To support *in vivo* studies, *in vitro* approaches investigated T helper cell responses to IL-27.

Results: IL-27R$^{-/-}$ mice developed exacerbated inflammatory arthritis, displaying increased synovial infiltrates and bone erosions compared to WT mice. IL-27R$^{-/-}$ mice also displayed increased peripheral Th17 cell responses and higher serum IL-17 levels. Surprisingly, these mice also had heightened B cell responses associated with an increase in antigen specific serum IgG levels. Immunohistochemical analysis of synovial infiltrates revealed increased activation of STAT3 was associated with disease exacerbation, further confirming a damaging role for local STAT3 activation in arthritis progression.

Conclusion: Experimental inflammatory arthritis provides a valuable model for understanding the role of cytokines in inflammation-induced disease pathology. In this regard, IL-27R$^{-/-}$ mice develop exacerbated joint disease, demonstrating a protective role for IL-27 in inflammatory arthritis. This anti-inflammatory effect of IL-27 is attributed to regulation of T- and B-cell responses and modulation of STAT1/3 activation. Excessive activation of STAT3 within the joint contributes to inflammation-induced joint pathology and modulating the STAT1/3 axis may provide a potential therapeutic approach. In this regard, targeting of the IL-27 signaling pathway is currently being explored.

IL-22 Restrains the Progression to Severe Arthritis. Sujata Sarkar, Xiaoqun Zhou and Swaroopa Bommireddy. University of Arizona, Tucson, AZ

Background/Purpose: IL-22 belongs to the IL-10 family of cytokines and may be produced by T cells, NK cells or LTi cells. IL-22 is pathogenic in psoriasis and protective in inflammatory bowel disease and hepatitis. IL-22 knock-out mice have a reduced incidence of arthritis, however role of IL-22 during various phases of arthritis and its effector function in arthritis remains to be elucidated. This study was undertaken to evaluate the role of IL-22 and the underlying mechanism of action during effector phase of arthritis.

Methods: 8–10 week old DBA mice were immunized with collagen and CFA (complete Freund's adjuvant) to induce arthritis. Spleen, draining inguinal lymph nodes and paws were collected from naïve mice, mice 2 weeks following immunization and from mice with arthritis for analysis of expression of IL-22 and IL-22 receptor by real time PCR. To analyze the effector function of IL-22, splenocytes from various phases of arthritis or single cell suspension of arthritic paws were restimulated with collagen, anti-CD3 or H37Ra in the presence or absence of IL-22. IL-17, IFN-g, TNFa, IL-10, IL-1b, IL-1a and IL-6 were measured in culture supernatants by ELISA. For studies evaluating the in vivo function of IL-22, recombinant IL-22 or HBSS was administered, ip, every day, from days 23–35 following immunization with collagen and CFA (days 23–35 covers the period prior to the onset of arthritis and into the effector phase). Mice were scored for clinical arthritis every other day. At the conclusion of the exp around day 35, paws, spleen, draining lymph nodes, and serum were collected for various assays. Paws were analyzed for synovial inflammation, bone and cartilage damage by histopathology. Single cell suspension of spleen and draining inguinal lymph nodes were restimulated with collagen, anti-CD3 or H37Ra for analysis of IL-17, IFN-g, and IL-10 responses. For some experiments neutralizing anti-IL-10 antibody was administered in conjunction with recombinant IL-22.

Results: IL-22 is upregulated in lymphoid organs during arthritis and in arthritic paws. Further, IL-22 production could be induced in splenocytes from arthritic mice following re-stimulation in an antigen specific fashion with collagen. In-vitro studies showed that exogenous IL-22 induced IL-17, IL-6 and IL-10 in splenocytes during the effector phase of arthritis. Although IL-22 induced IL-17, IL-6 in vitro, in vivo administration of IL-22 was associated with a significant delay in progression of severity of arthritis. Splenocytes from mice receiving recombinant IL-22 showed an increased IL-10 production, without a significant increase in IL-17 or IFN-g. Administration of neutralizing anti IL-10 antibody in conjunction with recombinant IL-22 reversed the protective effect of IL-22 in arthritis.

Conclusion: While, IL-22 induces proinflammatory (IL-17, IL-6) as well as anti inflammatory cytokines (IL-10) in vitro, in vivo administration of IL-22 is associated with significant reduction in progression to severe arthritis in an IL-10 dependent manner. These findings are suggestive of a protective role of systemic IL-22 around the onset of arthritis.

Interferon-γ and Toll-Like Receptor 9 Collaborate to Cause Both Leukopenia and Anemia In a Murine Model of Macrophage Activation Syndrome by Two Distinct Mechanisms. Katharine Slade[1], Scott Canna[1], Portia Kreiger[2] and Edward M. Behrens[1]. [1]Childrens Hospital of Philadelphia, Philadelphia, PA, [2]A.I. DuPont Hospital for Children, Wilmington, DE

Background/Purpose: Macrophage Activation Syndrome (MAS) is a deadly complication of multiple pediatric rheumatologic conditions. One of the most striking features of MAS is the profound cytopenias that occur during the disease. Using our recently described murine model of Toll-like Receptor 9 (TLR9) induced MAS, we dissected the mechanisms by which Interferon-g (IFNγ) and TLR9 induce both leukopenia and anemia.

Methods: Mice were repeatedly injected i.p. with 50 μg of the TLR9 agonist CpG1826 as previously described to induce MAS. To explore the role of IFNγ, IFN$\gamma-/-$ mice were repeatedly injected with PBS, CpG, recombinant murine IFNγ (10 μg), or both CpG and IFNγ. To determine the cellular effectors of the IFNγ response we made use of mice deficient in the IFNγ receptor (IFNγR$-/-$). Bone marrow chimeric mice were made by exposing mice to sub-lethal gamma irradiation (900 rads) followed by bone marrow transplantation. Wild type mice were reconstituted with 1×10^6 cells from either wild type control mice or IFNγR$-/-$ mice. Chimeric experiments with the converse combinations were also performed.

Results: IFNγ and CpG were both required to induce leukopenia and anemia, injection of either of these stimuli singly did not induce a cytopenia. In contrast, IFNγ was necessary and sufficient to induce the MAS hepatitis, while CpG was not necessary for this feature of the disease. Wild type mice reconstituted with IFNγR$-/-$ marrow did not develop the CpG induced leukopenia compared to mice reconstituted with IFNγR$+/+$ marrow, suggesting the IFNγ responsive effectors cells mediating leukopenia are radiosensitive marrow cells. Interestingly, mice reconstituted with IFNγR$-/-$ marrow had as severe an anemia as mice with wild type marrow, suggesting a distinct IFNγ mediated mechanism for anemia that requires a radioresistant cell. As with leukopenia, IFNγ induced MAS hepatitis was at least partially mediated by a radiosensitive marrow cell. Hypercytokinemia was largely unaffected by the absence of IFNγR in the marrow in that serum IL-6, IL-10, and IL-12 levels remained similar between groups. IFNγ levels were higher in mice reconstituted with IFNγR$-/-$ marrow, likely due the the lack of negative feedback from the receptor.

Conclusion: In a murine model of TLR9 induced MAS, both IFNγ and TLR9 are required to induce leukopenia and anemia. This suggests that blockade of either of these pathways may be sufficient for treatment of MAS associated cytopenia in autoinflammatory settings. In contrast, IFNγ was more important for MAS induced hepatitis, and therefore is a more attractive target for this complication. Since different cellular effectors are responsible for these different mechanisms, cell targeted therapies would need to be chosen rationally based upon MAS symptomatology, as opposed to a "one size fits all" approach. Future studies are being directed at definitively identifying which cell types are involved in each of these processes.

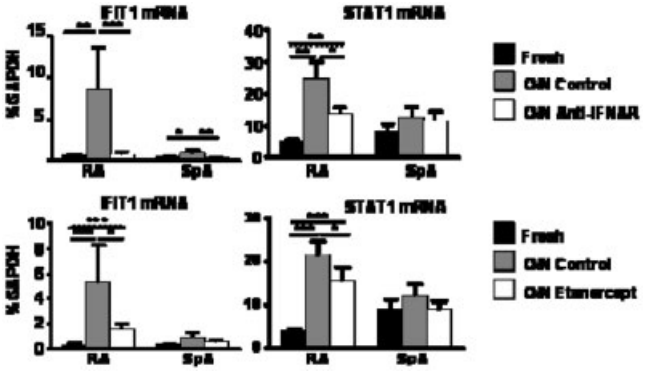
2503

Opposing Regulation of IFN Response Genes and *STAT1* in Rheumatoid Arthritis Synovial Fluid Macrophages by TNFá and the Synovial Fluid Microenvironment. Rachael A. Gordon, Galina Grigoriev, George D. Kalliolias and Lionel B. Ivashkiv. Hospital for Special Surgery, New York, NY

Background/Purpose: Increased expression of IFN-g-inducible genes in rheumatoid arthritis (RA) synovial tissues and macrophages (Mf) has been verified in several studies. IFN-g-inducible genes enhance antigen presentation and inflammatory cytokine production and thus a synovial IFN-g response likely contributes to RA pathogenesis. Most of these IFN-g-inducible genes are targets of the transcription factor STAT1. STAT1 is activated by, and mediates the effects of, several cytokines, particularly IFN-g, type I IFNs (IFNa/b), IL-6, IL-10 and IL-27. Because IFN-g is expressed at vanishingly low concentrations in RA synovium, and RA synovial Mf responses to IL-6, IL-10 and IL-27 are attenuated, type I IFNs emerge as potential activators of synovial STAT1 in RA. Recently we have shown that long term TNFa exposure initiates an IFNb-mediated autocrine loop in blood-derived Mf; here we test whether TNFa also could contribute to an IFN response in RA synovial Mf, and thus to the 'IFN signature' observed in RA.

Methods: Synovial fluid (SF) Mf obtained from 24 patients with RA and 18 patients with spondyloarthopathies (SpA) were cultured ex vivo for 12h in the presence or absence of IFNa/b blockade (anti-IFNAR) or etanercept. Expression of IFN-inducible genes was measured by qPCR. The Friedman test followed by post-hoc analysis with the Wilcoxon matched-pairs signed rank test was used for statistical analysis. (*=$p<0.05$, **=$p<0.01$, ***=$p<0.001$).

Results: Expression of IFN-inducible genes (*IFIT1*, *MX1, CXCL9, CXCL10* and *STAT1*) was increased on ex vivo culture of RA macrophages and was down-regulated by blockade of endogenous IFNa/b or TNFa (**Figure** and data not shown). Inclusion of SF in the cultures suppressed expression of these IFN response genes (not shown). RA SF inhibited also the induction of TNFa induced expression of *IFIT1* and *STAT1* by 91% and 82% respectively in blood-derived Mf from healthy donors (not shown, n=23, $p<0.0001$).



Conclusion: A STAT1/IFN-signature apparent in RA SF Mf increased on ex vivo culture and was dependent on autocrine TNFa, which activated type I IFN signaling. RA SFs suppressed the TNF-mediated IFN signature in RA synovial Mf, and also suppressed induction of IFN responses by exogenous TNFa in control Mf. Our findings implicate TNFa as a major inducer of the RA synovial IFN response and suggest that the expression of IFN response genes in RA synovium is regulated by interplay between TNFa and opposing homeostatic factors expressed in the synovial microenvironment.

Plasmacytoid Dendritic Cells in Human Lupus Bone Marrow Are Primed for Interferon Alpha Production. Sarah Nevarez, Arumugam Palanichamy, Alfred Rabinovich, Jennifer Barnard, Jamie Biear, Ben Panepento, Chungwen Wei, Christopher Ritchlin, James Kobie, Iñaki Sanz and Jennifer H. Anolik. University of Rochester, Rochester, NY

Background/Purpose: Inappropriate activation of type I interferon (IFN) plays a key role in the pathogenesis of systemic lupus erythematosus (SLE). We have previously reported an IFN signature in SLE bone marrow (BM). However, the etiology and impact of IFN activation in the BM remains unclear. Here we examined the homeostatic balance between immune cells in the BM microenvironment and the differential capacity of plasmacytoid dendritic cells to produce IFN.

Methods: BM aspirates were obtained from SLE patients and age matched healthy controls (HC) (n=10). B cell, T cell and dendritic cell (DC) subsets from BM and paired peripheral blood (PBL) were analyzed by multiparameter flow cytometry for defined subset and effector molecules (B cell markers: CD19, CD27, IgD, MTG, CD24, CD38, IgM, CD10, CD23, 9G4, CXCR3, B220, CD95, CD21, CD24; T cell: CD3, CD4, CD45RA (memory), CCR7 (central memory), CXCR5 and ICOS (T follicular helper), CXCR3 (Th1), CCR4 (Th2), CD25 and FoxP3 (Treg), HLADR4; DC: CD11c, CD123, CCR7, CD40, CXCR3, HLADR, CCR5. PBMCs were stimulated with CpG 2216 or CpG 2006 for 2h at 37C, followed by protein transport inhibition (Brefeldin A) for 2h and staining for surface Lin1, CD304, CD123 and intracellular IFNa.

Results: CpG induced type I IFN production in pDCs in a dose dependent fashion. A higher proportion of BM pDCs produced IFNa compared to paired PB (%pDCs + for IFN: 5.2+1.5 vs. 0.9+0.5, 5ug/mL CpG 2006). Notably, significantly more pDCs from lupus BM produced IFNa compared to normal BM (71.9% vs. 5.2%). This was despite the fact that DC fractions in SLE BM and PB were lower than age matched controls (mDC in BM: 7.3+1.6 vs. 15.2+2.4%, p=0.03; pDC in BM: 0.50+0.11 vs. 0.95+0.28%, p=0.19). Phenotypic differences were observed in SLE pDCs with higher CXCR3 expression (p=0.05). The differences between T cell subsets in PB vs. BM in both SLE and HC were striking with significantly lower fractions of CD4+ T cells (e.g. 30.6+4.9 vs. 10.7+5.4% in SLE), Th1 cells (e.g 58.4+2.7 vs. 12.4+6.5% of memory T cells in HC), and Tregs (e.g. 2.0+0.4 vs. 0.6+0.2 in SLE) in BM (p=0.009–0.05) and altered Treg phenotype (high HLADR, CCR4 in BM). There were significantly lower CD4+ T cells and higher Tregs in SLE BM and PB. As expected BM samples had higher fractions of precursor B cell populations compared to paired PB (p=0.0001 for CD10+ B cells). BM naïve and transitional B cells had much lower expression of CD23 compared to PB in both SLE and HC (p=0.02–0.006). Notably, mature B cells in SLE BM were very abnormal compared to HC with an expansion of CD27-IgD- memory (p=0.008) and activated, effector memory B cell populations (e.g on the switched memory for SLE vs. HC CD95+% 42.2+18.3 vs. 20.7+6.2, p=0.05 and CD21-% 30.5+13.6 vs. 10.9+2.5, p=0.008).

Conclusion: These results suggest that the bone marrow is an important but previously unrecognized target organ in SLE. Circulating immune complexes and apoptotic fragments in SLE BM may serve as ligands for toll like receptors on pDCs, and along with disturbances in the T cell and DC compartment, contribute to aberrant IFN production. IFN production in the BM impacts B cell development and may contribute to an activated B cell compartment.

Racial/Ethnic Differences in Physical Activity Among Participants in the Osteoarthritis Initiative (OAI). Jing Song[1], Marc Hochberg[2], Rowland W. Chang[3], Larry Manheim[1], Jungwha Lee[3], Pamela A. Semanik[4], Leena Sharma[3] and Dorothy D. Dunlop[1]. [1]Northwestern Univ Med School, Chicago, IL, [2]University of Maryland School of Medicine, Baltimore, MD, [3]Northwestern University, Chicago, IL, [4]Rehabilitation Institute of Chicago, Chicago, IL

Background/Purpose: Physical activity offers important health benefits to adults, including those with lower limb osteoarthritis (OA). This study examined whether there are racial/ethnic differences in objectively measured physical activity among people with or at risk for OA of the knee.

Methods: Physical activity was measured using accelerometers at the 48-month clinic visit in 1897 OAI participants (1085 with radiographic knee osteoarthritis (RKOA) in at least one knee and 812 participants without RKOA in both knees at baseline). Time spent in moderate-to-vigorous (MV) intensity activities was calculated to assess if participants met U.S. Department of Health and Human Services (DHHS) physical activity guidelines for arthritis populations (≥150 MV minutes/week in bouts lasting 10 or more minutes). Racial/ethnic differences in meeting guidelines were examined by bivariate and multivariate logistic regression models adjusting for socio-demographic factors (age, gender, income, education) and health factors (comorbidity, depressive symptoms, overweight/obesity, presence and severity of knee pain).

Results: Only 11.0% of these participants met the recommended physical activity guideline: 8.4% and 14.3% of the RKOA and the non-RKOA groups respectively. Overall African Americans compared to Whites were substantially less likely to meet the physical activity guidelines after adjusting for socio-demographics (odds ratio [OR] = 0.21, confidence interval [CI] = [0.08, 0.58]). After adjusting for health factors and presence of RKOA, racial/ethnic differences were attenuated but remained significant (OR=0.33, CI = [0.12, 0.87]). These differences held separately within the RKOA and no RKOA groups. After adjusting for all risk factors, racial/ethnic differences remained significant in the RKOA group (OR=0.30, CI = [0.10, 0.88]) and were substantial but not significant in the no RKOA group (OR = 0.34, CI = [0.09, 1.36]). Differences in overweight/obesity and pain were independent, strong, and significant contributors to the observed racial/ethnic differences in the combined sample and subgroups.

DHHS physical activity guideline attainment by race/ethnicity: percentages of adults with and without baseline radiographic knee OA (RKOA) after adjustment for age, gender, education, income*

Race/Ethnicity	Sample Size	Meeting DHHS Physical Activity Guidelines/ Active (≥150 MV bout mins/week)
Overall (n=1897)		
	n	% [95% CI]
African American	290	5.3 [1.9, 13.7]
White	1607	16.7 [11.8, 21.3]
Participants with Baseline RKOA (n=1085)		
	n	% [95% CI]
African American	166	3.1 [1.0, 9.0]
White	919	16.0 [11.8, 21.3]
Participants without Baseline RKOA (n=812)		
African American	124	8.1 [1.8, 29.4]
White	688	26.0 [19.2, 34.3]

* 4+ valid days of accelerometer monitoring; reference group are men aged 49–64 with 13+ education years and >$50k income.

Conclusion: Despite benefits from physical activity, attainment of physical activity guidelines among persons with or at risk of radiographic knee OA was low, especially for African Americans. Specific intervention in the African Americans community targeting overweight/obesity and pain may reduce future racial/ethnic differences in physical activity guideline attainment.

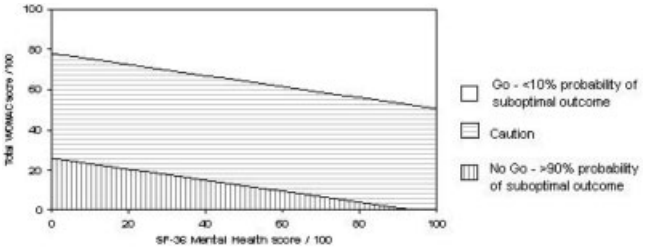
Tool for Patient Selection to Optimize Patient-Reported Outcomes Following Total Joint Arthroplasty. Gillian A. Hawker[1], Ruth Croxford[2], A. M. Davis[3], Sheila Dunn[1], Joy G. Elkayam[1], Melissa R. French[1], M. A. Gignac[4], Susan B. Jaglal[5] and Joanna Sale[5]. [1]Women's College Hospital, Toronto, ON, [2]Institute for Clinical and Evaluative Science, Toronto, [3]Health Care and Outcomes Research, Toronto Western Research Institute; Departments of Rehabilitation Science and Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, [4]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [5]University of Toronto, Toronto, ON

Background/Purpose: When medical management of hip or knee arthritis fails, total joint arthroplasty (TJA) is recommended. On average, TJA outcomes are good to excellent, but significant variability has been observed. We previously identified predictors of suboptimal TJA outcome, defined as insufficient improvement in arthritis pain and disability. The aim of this study was to use these data to develop a tool for use at point of care to help select patients for TJA.

Methods: The initial model was based on analyses of data from a population cohort with hip/knee arthritis in which annual interviews, from 1996 to 2008, were linked with health administrative databases to examine receipt of primary, elective TJA. Suboptimal outcome was defined as a pre-post change in WOMAC summary score < Minimal Important Difference (MID) proposed Wyrich et al (MID = 0.5 SD change of the mean difference in scores). Pre- and post-surgery WOMAC scores were those obtained at the interview prior to the index TJA date, and closest in date to the end of the post-operative period (i.e. 6 months post surgery), respectively. Predictors of suboptimal outcome were modeled using logistic regression; Akaike's Information Criterion was used to determine the size of the best predictive model, and then all possible subset regression was used to identify the final model of the selected size. Using the final multivariable model predicting suboptimal outcome, graphs were created to depict likelihood of suboptimal outcome based on the four final predictor variables: WOMAC summary score (higher scores worse); SF-36 mental health score (higher scores better); OA versus inflammatory arthritis (IA); and presence of other troublesome hips/knees.

Results: Of 166 cohort members who received a primary, elective TJA following their baseline interview and completed a post-TJA assessment, 48.7% met criterion for sub-optimal outcome (reduction in WOMAC score of < 9/100 points). Four graphs were created: OA *with* and *without* other troublesome hips/knees (78.9% and 13.9%, respectively) and IA *with* and *without* other troublesome hips/knees (6.0% and 1.2%, respectively). Figure 1 shows the results for the largest group, those with OA and at least one other troublesome hip/knee. For individuals with IA, the "go" region was smaller and the "no go" region was larger, while the reverse was true for those with no other troublesome hips/knees ("go" region larger and "no go" region smaller). Results using alternative definitions for suboptimal outcome were similar.



Conclusion: Individuals with little pain and disability pre-surgery are likely to experience a suboptimal outcome; conversely, individuals with extreme pain and disability are likely to obtain a meaningful improvement in pain and/or function. Between the two extremes, patient mental health contributes to pain and disability in predicting the likelihood of a suboptimal outcome.

The Association Between Lifelong Joint Force From Physical Activity, Local Joint Factors and Knee Osteoarthritis. Charles R. Ratzlaff[1], Mieke Koehoorn[1], Jolanda Cibere[2] and Jacek A. Kopec[3]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Ctr of CA, Vancouver, BC, [3]Arthritis Research Centre of Canada, Vancouver, BC

Background/Purpose: To examine the association between lifelong knee joint force, local joint factors and knee osteoarthritis (OA).

Methods: Design: Prevalence study, cross-sectional design; retrospective report of physical activity (PA)

Setting: Canada-wide population, Internet study

Source population: Canadian Association of Retired Persons

Outcome: Knee OA (self reported medically diagnosed PLUS pain, aching and stiffness most days)

Exposures

Lifetime Physical Activity: Data on sport, occupation and household activities from age 20–50 was self-reported via a validated online survey. For each specific activity type (e.g., each sport, occupation) detailed questions were asked regarding frequency, duration and intensity. Activities were further deconstructed by time spent in major body movement type (e.g., walk, run, squat).

Knee joint force from lifetime PA was estimated as the product of bodyweight (kg), typical knee force for specific activity type (% bodyweight) and time in specific activities (hours), and reported in kg-hours. Mean values for 5-year intervals over a person's lifetime, averaged over all subjects, were calculated. This variable was then categorized into quintiles based on the overall distribution in the sample.

Alignment. Self-reported standing presence of bow legs, knock-knees or neutral, using novel line diagrams.

Coordination. Coordination sub-scale of the Physical Self-Description Questionnaire (1), a self-administered validated, reliable instrument.

Joint hypermobility syndrome. The validated Hypermobility Questionnaire (2) was used to assess for the presence of joint hypermobility syndrome (JHS).

Other variables. Age, gender, BMI, previous knee joint injury

Analysis: Multiple logistic regression models were constructed separately for men and women to examine if levels of lifetime knee force were associated with a risk of knee OA, adjusting for age, injury, BMI, alignment, coordination and JHS.

Results: The 4,269 subjects had a mean age of 61.5 years, mean BMI of 27.5 and 63% were female. The highest quintile of mean lifetime knee force was a risk factor for development of knee OA in males (OR 2.03; 95% CI 1.08, 3.80) and females (1.67; 95% CI 1.11, 2.49). The highest levels of lifetime knee force from occupational activity in men and household activity in women were associated with a 2–3 fold increase in knee OA. In the final adjusted model, previous knee injury, obesity and malalignment (women) were also associated with prevalent knee OA. Higher coordination was protective. JHS was not a risk.

Conclusion: Lifelong knee force was generally safe for the knee, supporting the promotion of exercise as a major public health initiative. However, high levels of occupational force in men and household force in women were risk factors. This is the first report of a validated lifetime PA questionnaire that converted PA data to joint loading units, and used it to quantify the biomechanical effects and dose-response of PA on knee health, and the first report of an aspect of neuromuscular control (coordination) protecting against knee OA.

Incidence of Knee Symptoms and Radiographic and Symptomatic Knee Osteoarthritis in African Americans and Caucasians: The Johnston County Osteoarthritis Project. Barbara T. Do[1], Louise Murphy[1], Charles G. Helmick[1], Yiling J. Cheng[1], Kamil E. Barbour[1] and Joanne M. Jordan[2]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]UNC Thurston Arthritis Center, Chapel Hill, NC

Background/Purpose: Estimate the population-based incidence of 5 knee osteoarthritis (kOA)-related outcomes.

Methods: We analyzed baseline (1991–1997) and first follow up (1999–2005) data from Johnston County Osteoarthritis Project participants (n=1,590; aged > 45 years). The 5 outcomes were: 1) knee symptoms (pain, aching, and/or stiffness on most days); 2 & 3) radiographic and severe radiographic kOA (Kellgren-Lawrence [K-L] radiographic grades >2 and >3, respectively); 4) symptomatic kOA (K-L grade >2 and knee symptoms in radiographically affected knee); and 5) severe symptomatic kOA (K-L grade >2 and severe knee pain in radiographically affected knee). For each outcome, overall and stratified (age; sex; race; highest education attainment; body mass index [BMI] at age 18 and at baseline; and history of knee injury in affected knee) incidence rates were estimated among those who did not have the outcome at baseline.

Results: Overall incidence rates (people per 100 person-years) were 7.1 for knee symptoms, 3.1 for radiographic kOA, 2.6 for symptomatic kOA, 1.8 for severe radiographic kOA, and 0.5 for severe symptomatic kOA. In the stratified analyses, incidence of almost all outcomes rose with increasing age, clinically measured baseline BMI, self-reported BMI at age 18, and decreasing levels of education. The most consistent differences in absolute and relative incidence across all outcomes were for lowest and highest baseline BMI category (e.g., for symptomatic kOA, 1.6 among those with BMI < 25 (under/normal weight) and 4.5 among BMI ≥ 35 (obese class II). Last, for all outcomes, incidence was generally a quarter to a third higher among African Americans than Caucasians.

Conclusion: In this sample of ≥45 year olds, 0.5 to 7% developed at least one of the kOA-related outcomes each year. Age, BMI at both 18 and at baseline were the strongest predictors of symptomatic, severe symptomatic, and severe radiographic kOA incidence. More widespread intervention efforts (self-management education, physical activity, weight management, joint injury prevention) may reduce the onset and impact of these outcomes.

2509

Sick Leave and Disability Pension Among Patients with Knee Osteoarthritis. Jenny Hubertsson[1], Ingemar F. Petersson[1], Carina A. Thorstensson[2] and Martin Englund[3]. [1]Musculoskeletal Sciences, Dept of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [2]Spenshult Hospital for, Oskarstrom, Sweden, [3]Lund University, Lund, Sweden

Background/Purpose: To investigate the burden of sick leave and disability pension in patients with knee osteoarthritis (OA) and to compare these figures with the general population using prospectively ascertained cohort data.

Methods: Using the Skåne Health Care Register we identified all subjects seeking health care in primary, secondary, or in hospital care, registered with the diagnosis of OA of the knee (ICD-10 code M17) at least once during the period of 1998–2009, aged 16–64 years and resident in the Skåne County (population 1.2 million) during 2009. Using subjects' unique personal identification number, we then linked year 2009 social insurance data administered by the Swedish Social Insurance Agency. First, we calculated the share of knee OA patients who during 2009 had received either sickness benefit or disability pension payment and estimated the increase in risk compared to the general population in Skåne County aged 16 to 64 years (n=789 366) standardised for age. We also calculated the mean number of days with sickness benefit or disability pension. Second we estimated the proportion of the total number of sick leave and disability pension days attributable to knee OA or associated comorbidities in knee OA patients. To do this we calculated the total amount of days generated by knee OA patients and subtracted the total amount of days expected for this group (assuming the same rate as in the general population standardized for age and sex). We then divided the remaining share with the total amount of days for the county to calculate the proportion of days specific to knee OA patients.

Results: We identified 15 345 persons (49.6% women) who had been diagnosed with knee OA during the last 12 years and were at working age and resident in Skåne during 2009. They had a mean (SD) age of 55 (8.2) years for women and 53 (9.2) years for men. Compared to the general population the risk for having had one or more episodes of sick leave was 1.82 (95% CI 1.73–1.91) for women and 2.03 (95% CI 1.92–2.14) for men and the risk for disability pension was 1.54 (95% CI 1.48–1.60) for women and 1.36 (95% CI 1.28–1.43) for men. During 2009, the mean (SD) numbers of sick days (including days of sick leave and of disability pension) per knee OA patient and year was 114 (155) days for women and 63 (124) days for men. Of all sick leave and disability pension in the entire population, 2.0% of days were estimated to be attributable to knee OA or its associated comorbidity (3.1% for sick leave and 1.7% for disability pension).

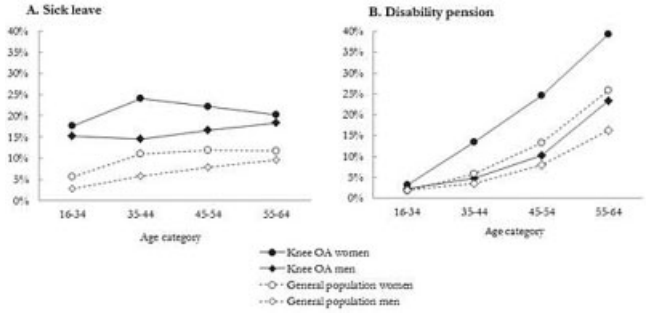

Figure 1. Proportion who had received sick leave or disability pension sometime during 2009.

Conclusion: Patients with knee OA have an almost two-fold increased risk for sick leave and about 40–50% increased risk for disability pension compared to the general population. Further, in the Swedish population about 2% of the total amount of sick days in the society is attributable to knee OA or associated comorbidity in knee OA patients.

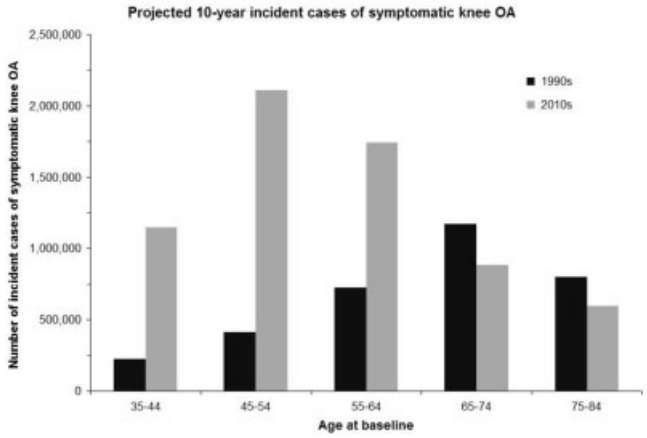
2510

Projecting the Future Public Health Impact of the Trend Toward Earlier Onset of Knee Osteoarthritis in the Past 20 Years. Sara A. Burbine, Alexander M. Weinstein, William M. Reichmann, Benjamin N. Rome, Jamie E. Collins, Jeffrey N. Katz and Elena Losina. Brigham and Women's Hospital, Boston, MA

Background/Purpose: Symptomatic knee osteoarthritis (OA) affects about 7% of Americans over the age of 45. Obesity and knee injuries have become more prevalent in recent years, which may contribute to increasing incidence of symptomatic knee OA, particularly in younger age groups. Temporal trends in the age of symptomatic knee OA onset and the resulting public health impact have yet to be studied.

Methods: We used the OAPol Model, a validated computer simulation model of the natural history of knee OA, to estimate the age-stratified 10-year incidence of symptomatic physician-diagnosed knee OA during two distinct time periods (the 1990s vs. the 2010s). Symptomatic knee OA incidence data for the 1990s were derived from published literature. Data for the 2010s were derived from the National Health Interview Survey 2007–08. We followed a simulated cohort from age 25 to death to track the onset of symptomatic knee OA. We coupled model output and CDC population estimates from each time period to project the number of incident cases of knee OA in the US population over each 10-year period. We compared ages of OA onset and 10-year cumulative incidence of knee OA for the two time periods.

Results: The mean age of physician-diagnosed knee OA onset fell from 72 ± 12 years (mean ± standard deviation) in the 1990s to 56 ± 18 years in the 2010s. Americans ages 35–84 in the early 2010s were expected to incur 6,475,642 incident cases of symptomatic knee OA over the next decade, with those ages 45–64 accounting for 59% of these cases (Figure). Among Americans who were ages 45–54 at the beginning of the 1990s, an estimated 412,214 incident cases of knee OA were expected over the subsequent 10 years, resulting in a 10-year cumulative incidence of 1.5%. Among people in the same baseline age group in the 2010s, 2,108,881 incident cases of symptomatic knee OA are expected over the next 10 years, a cumulative incidence of 4.8%. The projected number of 10-year incident cases among those ages 65–74 at baseline decreased slightly between the 1990s (1,169,615 cases) and the 2010s (882,997 cases).



Conclusion: Since the early 1990s, the age of onset of physician-diagnosed symptomatic knee OA has shifted dramatically, occurring on average 16 years earlier in life. This trend may reflect temporal changes in the prevalence of OA risk factors, as well as thresholds for patient care-seeking and physician diagnosis of OA. If the current OA incidence trend continues, nearly 6.5 million Americans between the ages of 35 and 84 will be diagnosed with symptomatic knee OA in the next 10 years, with those ages 45–64 accounting for more than half of these incident cases. A resulting spike in the utilization of healthcare, specifically total knee replacements, could have a dramatic economic impact and place additional burden on the healthcare system.

ACR Concurrent Abstract Session
Rheumatoid Arthritis Clinical Aspects: Predictors of Outcome
Tuesday, November 8, 2011, 4:30 PM–6:00 PM

2511

Clinical Disease Activity and Acute Phase Reactant (APR) Levels Are Discordant Among Patients with Active Rheumatoid Arthritis (RA) and Contribute Separately to Predicting Outcome At 1 Year. Jonathan Kay[1], Susan P. Messing[2], Joel M. Kremer[3], Jeffrey D. Greenberg[4] and Daniel E. Furst[5]. [1]University of Massachusetts Medical School, Worcester, MA, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY, [3]Albany Medical College and The Center for Rheumatology, Albany, NY, [4]New York University School of Medicine, New York, NY, [5]UCLA Medical School, Los Angeles, CA

Background/Purpose: Clinical trials of new treatments for RA typically require subjects to have an elevated APR, in addition to swollen and tender joints. However, many pts in clinical practice fail to meet these entry criteria. Despite having elevated individual components of the CDAI, such as tender and swollen joint counts and pt and MD global assessment, some pts with active RA may have normal ESR and/or CRP levels. Thus, clinical disease activity and APR levels can be discordant.

To address the **hypothesis** that clinical measures and APR each contribute separately to predicting the outcome of RA pts at 1 year, we assessed the relationship between CDAI and APR elevation in a large US registry of RA pts by comparing baseline characteristics and 1 year clinical outcomes of pts with active RA, grouped by baseline APR levels.

Methods: Using CORRONA data through 1/8/10, eligible pts had CDAI >2.8 (not in remission) and values for ESR and CRP. APR levels were considered elevated if ESR >28 mm/hr or CRP >1.5 mg/dL. Baseline was entry into the database, not necessarily a new drug start. The 1 year follow-up visit (365 ± 60 days) used was that with complete data available for mHAQ and components of CDAI. Comparisons were assessed subsequent to linear modeling using generalized estimating equations.

Results: Among 27,526 RA pts in the CORRONA database, 7804 with active RA (CDAI >2.8) met criteria for sample inclusion. Of these, 53% had neither elevated ESR nor CRP. Among the remaining pts, 16% had elevated ESR but not CRP, 15% had elevated CRP but not ESR, and 16% had elevated ESR and CRP levels. 1304 patients were evaluated at 1 year.

At baseline, pts with active RA but no elevation of either APR had significantly lower mHAQ and CDAI than pts in any other group ($p<0.006$). Also, pts with both APR elevated had higher mHAQ and CDAI than the other three groups ($p<0.003$). The groups with elevation of only one APR (ESR or CRP) were similar to each other, had higher mHAQ and CDAI then than those with no elevation of either APR ($p<0.006$) and had lower mHAQ and CDAI than those with both APRs elevated ($p<0.003$). Individual components of the CDAI followed the same trends (see Table).

Baseline characteristic	CDAI >2.8, ESR ≤28, CRP ≤1.5 (Group 1) (n=757)	CDAI >2.8, ESR >28, CRP ≤1.5 (Group 2) (n=195)	CDAI >2.8, ESR ≤28, CRP >1.5 (Group 3) (n=171)	CDAI >2.8, ESR >28, CRP >1.5 (Group 4) (n=181)
Age	59.28 ± 13.05	65.62 ± 12.83	59.35 ± 14.02	62.19 ± 13.80
Duration of RA (years)	11.49 ± 10.31	12.63 ± 9.70	12.59 ± 10.39	14.03 ± 11.85
1-year follow-up duration (days)	361.20 ± 32.19	358.44 ± 31.23	359.04 ± 32.66	361.13 ± 31.86
mHAQ	0.34 ± 0.39*	0.48 ± 0.49	0.45 ± 0.46	0.64 ± 0.58**
CDAI	13.40 ± 10.03*	16.77 ± 10.81	16.19 ± 12.54	20.84 ± 13.94**
Tender joints	3.69 ± 5.04*	5.07 ± 5.14	5.04 ± 6.40	6.33 ± 7.04†
Swollen joints	4.54 ± 5.12	5.29 ± 5.27	5.05 ± 5.54	6.73 ± 5.84†
Pt global assessment	34.15 ± 24.56*	38.32 ± 24.92	34.81 ± 25.01	44.85 ± 28.46†
MD global assessment	19.77 ± 15.83*	25.78 ± 18.08	26.26 ± 21.10	32.94 ± 21.17**

Values are mean ± SD. *$p<0.006$ for Group 1 vs. Groups 2, 3, & 4. ** $p<0.006$ or †$p<0.05$ for Group 4 vs. Groups 1, 2, & 3. Differences between Groups 2 & 3, other than age, were not statistically significant.

At the 1 year follow-up visit, mean mHAQ decreased by 0.10 ± 0.45 among the pts with elevation of both APR but increased by 0.05 ± 0.34, 0.06 ± 0.35, and 0.02 ± 0.32 in Groups 1, 2, & 3, respectively ($p<0.004$). The decrease in mean CDAI also was greatest among the pts with active RA and both APR elevated (−6.24 ± 15.04) and was significantly larger than in each of the other groups ($p<0.002$).

Conclusion: In a large US registry, over half of active RA pts do not have elevated ESR or CRP levels and APR levels are discordant in 31%. The magnitude of both clinical and functional improvement at 1 year correlates with the number of APR elevated at baseline.

2512

Discordance Between Patients and Physicians in Assessments of Global Disease Activity in Rheumatoid Arthritis: Agreeing to Disagree. Thomas V. Jones[1], Wenzhi Li[1], Andrew S. Koenig[1] and Michelle Stewart[2]. [1]Pfizer Inc., Collegeville, PA, [2]Pfizer Inc., Groton, CT

Background/Purpose: Physicians and patients often disagree when assessing disease severity.[1–4] Disagreements may indicate a focus on different aspects of the disease or differing perceptions of improvement. Understanding differing objectives for treatment may guide efforts to improve patient care. The purpose of this analysis is to examine differences between physicians' and patients' assessments of disease activity in RA and possible explanations for these differences.

Methods: Patients with moderate RA despite stable doses of oral MTX received open-label etanercept 50 mg weekly plus MTX for 36 weeks. Patients and physicians completed the global assessment of disease activity measure, a 0–10 fixed integer response visual analogue scale (VAS) rating patients' arthritis activity over the proceeding 2–3 days, with higher scores indicating more severe activity. The difference between each pair of patients' and physicians' scores were categorized as follows: positive discordance (patient global–physician global ≥2), negative discordance (physician global – patient global ≥2) or concordance (absolute difference between the 2 disease activity scores <2). The correlations (Pearson's r) with demographic characteristics and clinical variables were explored (concordance was combined with negative discordance for analysis). Stepwise logistic regression was used to determine significant predictors of discordance.

Results: Of the 834 RA patients (female 83%, Caucasian 74%, mean age 48y; disease duration 7y, mean baseline DAS28=4.4) the majority were concordant with physicians (72.7%) followed by positive discordance (24.7%) and negative discordance (2.6%) at week 36. Baseline morning stiffness, and week 36 HAQ, DAS28, morning stiffness, pain (BPI), and fatigue (FACIT-F), and change from baseline in CRP, ESR, HAQ, DAS28, BPI, and FACIT-F were significantly associated with discordance. At week 36, mean DAS28 for the positive discordant group was 2.8 (SD 1.1) compared to 3.1 (SD 1.3) for the negative discordant group and 2.2 (SD 0.9) for the concordant group (Table). Discordance was associated with patients' pain (OR 1.3, CI 1.14–1.56) and general health VAS (OR 1.1, CI 1.06–1.10). Among the 443 patients who achieved 0–1 SJC, 0–1 TJC, and CRP≤1 at week 36, positive discordance was still evident (20.8%) whereas negative discordance was lower (1.8%).

Table. Comparisons among concordant and discordant pairs based on patients' and physicians' global assessment of disease activity.

Variable	Concordant N=556	Positive Discordance N=189	Negative Discordance N=20	ANOVA F Statistic
Change in CRP	7.0 (17.0)	−3.4 (14.7)	0.9 (11.0)	0.006
Change in ESR	−11.1 (12.6)	−7.6 (11.2)	−3.6 (11.9)	0.0002
HAQ	0.5 (0.5)	0.9 (0.6)	0.7 (0.6)	<.0001
Change in HAQ	−0.7 (0.54)	−0.3 (0.6)	−0.5 (0.5)	<.0001
DAS28	2.2 (0.9)	2.8 (1.1)	3.1 (1.3)	<.0001
Change in DAS28	−2.2 (0.9)	−1.6 (1.0)	−1.4 (1.3)	<.0001
Patient General Health Assessment VAS	1.47 (1.16)	4.48 (1.79)	1.6 (1.27)	<.0001
Morning stiffness; min (SD)	38.6 (165.6)	77.9 (163.9)	62.7 (135.9)	0.0195
Morning stiffness, baseline; min (SD)	158.5 (313.5)	226.6 (383.6)	230.1 (445.2)	0.0485
BPI	1.07 (1.31)	3.21 (2.19)	1.89 (1.52)	<.0001
Change in BPI	−2.64 (2.05)	−1.46 (2.38)	−2.04 (2.4)	<.0001
FACIT-F	43.14 (7.99)	35.65 (9.47)	38.85 (9.38)	<.0001
Change in FACIT-F	9.42 (8.79)	4.9 (9.43)	9 (10.89)	<.0001

All values are mean values (SD) at week 36 unless otherwise indicated. "Change in" denotes change from baseline at week 36.

Conclusion: Over one quarter (27.3%) of patients were discordant with physicians (positively or negatively) regarding the rating of their disease activity. In most cases, discordance occurred due to higher severity ratings by patients (positive discordance). Substantial discordance remained when patients had minimal swollen and tender joint counts and a low CRP value. Further investigation may facilitate better alignment between outcome measures and treatment targets and aid efforts to improve disease management.

Development of a Matrix Risk Model to Predict Rapid Radiographic Progression in Early Rheumatoid Arthritis. Results From a Randomized Trial Population. Saedis Saevarsdottir[1], Kristina Forslind[2], Kristina Albertsson[1], Hamed Rezaei[1], Arvid Engström[1], Pierre Geborek[3], Ingemar F. Petersson[3], Sofia Ernestam[4], Johan Bratt[4] and Ronald F. van Vollenhoven[1]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Helsingborgs Lasarett and Lund University, Lund, Sweden, [3]Lund University, Lund, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden

Background/Purpose: Some patients with early rheumatoid arthritis (RA) show rapid radiographic progression (RRP). It has been suggested that a combination of baseline predictors could be used as a "matrix" to help clinicians identify subpopulations with increased risk of RRP[1–3], in order to choose initial therapy in a rational manner. The objective of this study was to validate previously published matrix models and develop an optimized matrix model for prediction of rapid radiographic progression (RRP) in patients with early RA.

Methods: Data from the SWEFOT-trial population were used[4]. In this trial, all patients were started on MTX 20 mg/week. Patients who achieved low disease activity after 3–4 months continued on MTX, while the other patients were randomized to add either sulfasalazine and hydroxychloroquine or infliximab. Hand and foot X-rays were obtained at baseline and after 1 and 2 years, and scored by the Sharp-van der Heijde (SvdH) method. RRP was defined as an increase in total SvdH of ≥5 after 1 year[1–3]. Potential baseline predictors of RRP were selected from multivariate analyses and previous studies, and combined in 3-parameter matrices, considering clinical feasibility and ease of use.

Results: Data where analyzed for 273 patients and this subgroup was representative of the study population. Of these, 65 patients had RRP. A matrix risk model including the following: C-reactive protein (CRP<10 vs. 10–35 vs. >35 mg/L), baseline erosions (yes/no) and current cigarette smoking (yes/no) differentiated best between RA patients with and without an increased risk of RRP. A step-up gradient was observed, where 63% of patients carrying all 3 predictors had RRP after 1 year vs. 12% with none (figure). The risk ratio for highest vs. lowest risk was 5.88 (95% CI 2.36–14.62). The previously published matrices[1–3] did not differentiate well between patients with and without RRP in this patient population.

Conclusion: This matrix, based on a trial that reflects standard care, identifies subpopulations of RA patients at high risk for RRP and, being based on easily accessible and objective variables, could be useful to clinicians for making appropriate treatment decisions. Validation of the matrix model in other populations is needed.

Derivation and Validation of An Infection Risk Score to Predict the Risk of Serious Infections for Rheumatoid Arthritis Patients. Jeffrey R. Curtis[1], Fenglong Xie[2], Paul M. Muntner[2], Lang Chen[2], Shuo Yang, Kenneth G. Saag[1] and Elizabeth S. Delzell[2]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

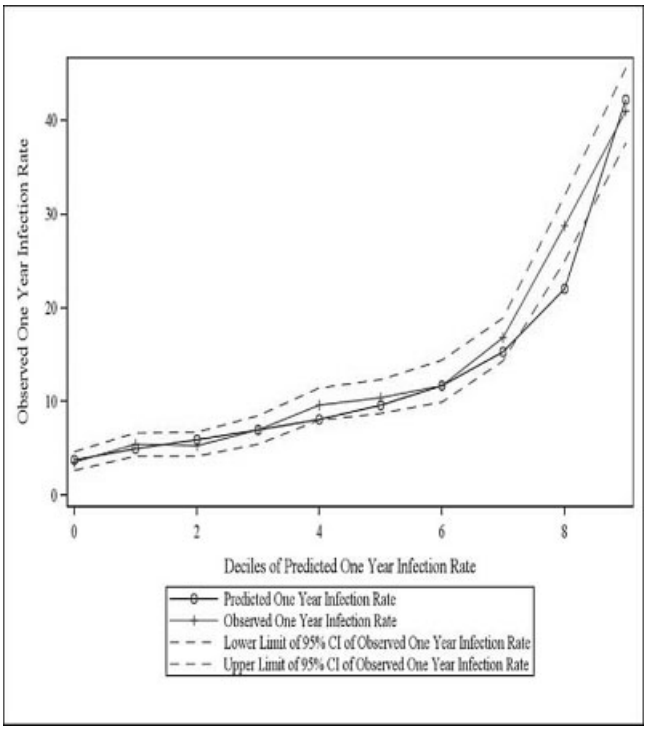
Background/Purpose: Infections remain important in characterizing the safety profile of therapies for rheumatoid arthritis (RA) therapies. There are currently no tools to predict the risk of infection for individual RA patients. Our objective was to derive and validate an infection risk score to predict the 1 year risk for serious infections among RA patients starting new biologics.

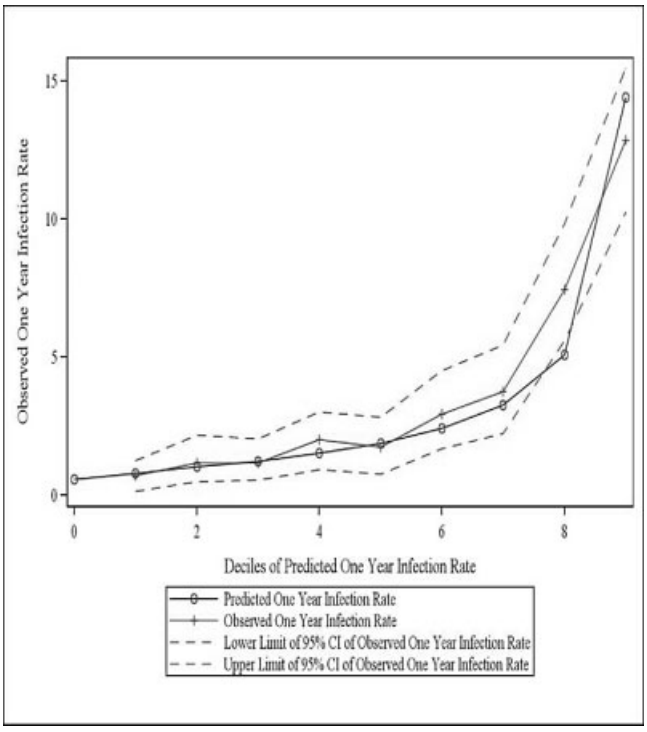
Methods: Using 2 administrative databases that included RA patients with commercial insurance or Medicare/Medicaid, we derived a dataset-specific infection score. The commercially insured database included individuals age < 65, and Medicare enrollees age >= 65. Observation time began when patients initiated methotrexate, leflunomide, or sulfasalazine/ hydroxychloroquine added to MTX. The outcome of the infection score was hospitalized infection in the subsequent one year, estimated using Cox models. We included in the score factors related to infection based upon content knowledge, prior literature, and strength of the association with the infection outcome.

Calibration and discrimination were assessed by plotting observed versus predicted risk in deciles. Validation was conducted by comparing predicted versus observed risk in 200 bootstrap samples, also used for 95% confidence intervals for observed risk. Dataset-specific weights for infection risk factors were computed and compared descriptively.

Results: Among 23594 (14702 Medicare/Medicaid, 8892 commercially-insured) new users of MTX, LEF, or SSZ/HCQ, we identified 1765 hospitalized

infections in the subsequent year. The infection score identified 25 and 13 factors significantly associated with serious infections in Medicare and commercially-insured RA patients; 10 of these factors were in-common. Weights for most risk factors in the two datasets differed modestly. Discrimination of the infection score was good (not shown); there was high agreement between predicted and observed infection risk (figure 1-Medicare, figure 2-commercially insured).





Conclusion: The one-year risk for serious infections can be accurately predicted at a patient level. This novel infection score can be used to control for infection-related confounding in future safety analyses where outcome data are sparse. It may also inform patient-physician communication, assist in risk stratification, and guide use of therapeutics for arthritis.

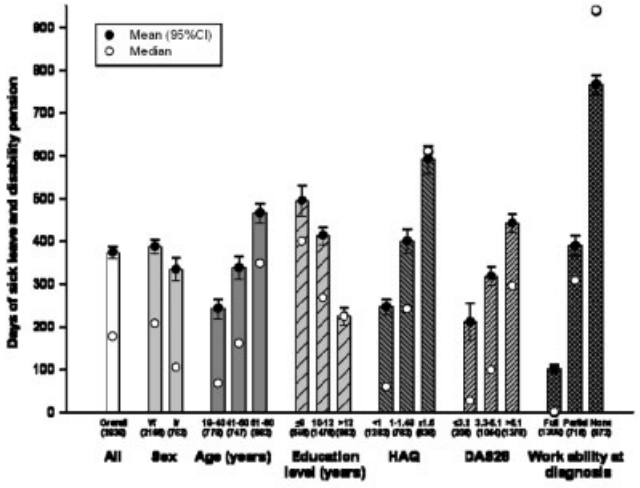
Predictors of Work Disability During the First 3 Years After Diagnosis in a National Rheumatoid Arthritis Inception Cohort. Tor Olofsson[1], Ingemar F. Petersson[2], Jonas Eriksson[3], Martin Englund[4], Julia F. Simard[3], Pierre Geborek[1], Lennart TH Jacobsson[5], Johan Askling[3] and Martin Neovius[3]. [1]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund University, Lund, Sweden, [2]Musculoskeletal Sciences, Dept of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [3]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden, [4]Lund University, Lund, Sweden, [5]Section of Rheumatology, Malmo, Sweden

Background/Purpose: To estimate predictors of sick leave and disability pension during the 3y period after diagnosis with early RA 1999–2007 in Sweden.

Methods: Individuals aged 19–59y diagnosed with early RA were identified in the Swedish Rheumatology Quality Register (1999–2007; n=3029; mean age 47y; 73% women). Baseline predictors of cumulative days of sick leave and disability pension during the 3y period after RA diagnosis were calculated using linear regression, retrieving days of sick leave and disability pension from the National Social Insurance Agency register covering all inhabitants in Sweden. Due to effect modification by baseline work ability, multivariable analyses were stratified into 3 categories: full=0 days of sick leave and disability pension the month before diagnosis; partial=1–29 days and none=30 days.

Results: In unadjusted analysis, there were large differences between categories of each predictor regarding cumulative days of sick leave and disability pension during the 3 years following RA diagnosis (Figure). In adjusted multivariable analysis, baseline levels of HAQ, DAS28, VAS global, VAS pain and tender joint count as well as age, education level and unemployment status were significant predictors of cumulative days during the 3y period, when stratifying for baseline work ability. Generally, the largest regression coefficients were seen for the subgroup with partial work ability at baseline and the smallest for the group with full work ability. A one-unit higher HAQ score was associated with 49 additional days off work ($p<0.001$) if having full work ability at baseline, 134 days ($p<0.001$) if having partial work ability and 112 days ($p<0.001$) if having no work ability. The corresponding coefficients for a one-unit higher DAS28 at baseline were 18 ($p<0.001$), 47 ($p<0.001$) and 30 days ($p=0.006$). A 10-year higher age at diagnosis was associated with 20 additional days off work ($p<0.001$) if having full work ability at baseline, 83 days ($p<0.001$) if having partial work ability and 77 days ($p<0.001$) if having no work ability. For education level (comparing ≤9 to >12 years) the corresponding coefficients were 79 ($p<0.001$), 159 ($p<0.001$) and 86 days ($p=0.03$).



Cumulative days of sick leave and disability pension during the first 3 years after RA diagnosis given as mean and as median and stratified for selected baseline variables (unadjusted).

Conclusion: The baseline level of work ability was strongly associated with total days of sick leave and disability pension during the 3y period after RA diagnosis. Taking this into account, modifiable disease variables such as HAQ and DAS28, as well as age and education level, were also significant predictors. The results indicate that interventions have the largest effect in the patient group with partial work ability at diagnosis.

Do Rheumatoid Arthritis Patients Meeting American College of Rheumatology/European League Against Rheumatism Remission Have Improved Functional Ability, Quality of Life and Work Productivity Compared to Those with Low Disease Activity? Aarat M. Patel[1], Christine L. Amity[2], Lynne M. Frydrych[2], Derek Sippel[2], Donald Jones[2], Danielle Goudeau[2], Heather Eng[3], David Kyle[3], Melissa Saul[3], Daniel Hal Solomon[4], Stephen R. Wisniewski[3], Larry W. Moreland[5] and Marc C. Levesque[2]. [1]Univ of Pittsburgh Med Ctr / Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]Univ of Pittsburgh, Pittsburgh, PA, [4]Brigham & Womens Hospital, Boston, MA, [5]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: RA patients meeting the new ACR/EULAR definition of remission should have better clinical outcomes than those with low disease activity. Therefore, we compared functional ability, HRQOL, work impairment and medication use between those meeting new ACR/EULAR remission and those in low disease activity or other defined states of remission.

Methods: Subjects were from the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry (n=721). We analyzed self-administered patient questionnaires (routine assessment of patient index-3 (RAPID3), short form-12 (SF12), work productivity and activity impairment (WPAI)), physician exam data (DAS28 and CDAI) from a single RACER visit. Subjects were grouped according to whether they met ACR/EULAR remission, DAS28 and CDAI remission, low, moderate and high disease activity. Demographics, questionnaire data and medication use were compared between those who did not fulfill the new remission criteria but did fulfill other remission and low disease activity states using Mann Whitney-U and Pearson Chi-Square tests.

Results: ACR/EULAR remission was achieved by 17.6% of the cohort. Age, sex, race and disease duration were similar between disease activity groups. The mean SF-12 physical and mental component scores (PCS / MCS) for subjects in ACR/EULAR remission were similar to healthy, comparably aged subjects. Subjects in CDAI remission (n=109) also met ACR/EULAR remission and had comparable SF-12, WPAI and RAPID3 scores (data not shown). In contrast, not all subjects in DAS28 remission (n=274) also met the ACR/EULAR definition of remission (n=127). Subjects in DAS28 remission but not ACR/EULAR remission (n=147) and subjects in DAS28 and CDAI low disease activity had worse SF12, WPAI and RAPID3 scores (**Table 1**). The use of DMARDs and/or biologics was similar between the remission and low disease activity groups. However, the ACR/EULAR and CDAI remission groups used significantly less narcotics and corticosteroids than subjects in DAS remission and all other disease activity groups ($p<0.0001$).

Table 1. Comparison of different remission and low disease activity definitions to the ACR/EULAR definition of remission and their effect on work productivity and health assessment (n = 721)

	ACR/EULAR Remission (n = 127)	DAS28 Remission (n = 147)	*P*	DAS28 Low Disease Activity (n = 125)	*P*	CDAI Low Disease Activity (n = 246)	*P*
SF12 PCS	45.8 ± 9.4	38.4 ± 9.1	<0.0001	34.4 ± 8.9	<0.0001	36.76 ± 9.3	<0.0001
MCS	52.4 ± 8.1	48.8 ± 10.0	0.005	47.0 ± 9.4	<0.0001	48.0 ± 9.9	<0.0001
WPAI (%) Activity Imp.	13.7 ± 20.7	29.4 ± 26.3	<0.0001	42.6 ± 24.2	<0.0001	35.1 ± 26.6	<0.0001
Time mixed	0.6 ± 3.2	9.6 ± 23.7	0.01	2.7 ± 11.4	0.143	5.9 ± 17.8	0.011
Imp. Working	9.4 ± 18.5	20.0 ± 21.9	<0.0001	29.3 ± 25.2	<0.0001	24.5 ± 22.8	<0.0001
Overall Imp.	10.1 ± 18.7	25.8 ± 29.4	<0.0001	31.5 ± 26.6	<0.0001	28.0 ± 26.8	<0.0001
RAPID5	1.0 ± 1.0	1.9 ± 1.7	<0.0001	3.4 ± 1.8	<0.0001	3.0 ± 1.8	<0.0001

* Remission definitions were individually applied to all subjects and those fulfilling ACR/EULAR remission are removed from other categories so some subjects are not represented in multiple groups. **Those in CDAI remission fulfilled ACR/EULAR remission so comparisons were not made.
RACER = Rheumatoid Arthritis Comparative Effectiveness Research ACR/EULAR = American College of Rheumatology/European League Against Rheumatism; DAS28 = disease activity score 28-joint count; CDAI = clinical disease activity index; SF12 = short form-12; PCS = physical component score; MCS = mental component score; WPAI = Work Productivity and Activity Impairment; RAPID3 = Routine Assessment of Patient Index Data-3

Conclusion: RA subjects in ACR/EULAR remission had a quality of life similar to healthy comparably aged subjects suggesting that the new ACR/EULAR remission criteria represent a true state of remission. The DAS28 definition of remission is not comparable since RA subjects in ACR/EULAR remission had better RAPID3, SF12 and WPAI scores. ACR/EULAR remission was associated with improved functional ability, HRQOL and work productivity compared to DAS28 and CDAI low disease activity. Medication data suggests that for subjects not in remission, achieving remission will require more optimal and/or greater use of combinations of immunosuppressive therapies. Our future goal is to determine the cost-effectiveness and the risk:benefit of more aggressive treatment approaches for patients not yet in remission and to study remission longitudinally.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Human Etiology and Pathogenesis II: Pathogenesis of Rheumatoid Arthritis—What's New?

Unique DNA Methylome Signature in Rheumatoid Arthritis (RA). Kazuhisa Nakano[1], John Whitaker[2], Wei Wang[3], David L. Boyle[2] and Gary S. Firestein[2]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]UCSD School of Medicine, La Jolla, CA, [3]UCSD, La Jolla, CA

Background/Purpose: Genome wide association studies have identified novel DNA polymorphisms associated with increased risk and severity of RA. However, even genetically identical twins have only a 12–15% concordance rate of RA. Epigenetics defines non-DNA encoding influences that could contribute to disease susceptibility and severity. DNA methylation of CpG motifs is one mechanism that can silence or activate genes. While the methylation of individual genes has been explored in RA, no systematic analyses have been performed. Therefore, we performed an unbiased genome-wide evaluation of DNA methylation loci in fibroblast-like synoviocytes (FLS) isolated from the site of disease in RA.

Methods: Genomic DNA was isolated from fifth passage 6 female RA and 5 female control (osteoarthritis) FLS lines and evaluated using the Illumina HumanMethylation450 chip. Cluster analysis of data was performed and corrected using Benjamini-Hochberg adjustment for multiple comparisons ($p<0.05$ considered significant). Pathway analysis was determined using the Kyoto Encyclopedia of Genes and Genomes (KEGG).

Results: 476,311 CpG loci out of 485,512 were technically adequate for analysis after excluding loci with high background or absent signal. Cluster analysis surprisingly showed that FLS completely segregated into RA and control based solely on DNA methylation patterns, with nearly 2000 loci from 1200 genes being differentially methylated in RA. Permutation analysis confirmed the specificity and statistical significance of clustering. Hypomethylated loci were identified in key genes and promoter regions relevant to RA, such as *CHI3L1* (gp39), *CASP1* (caspase 1), *STAT3, MAP3K5,* and *MEFV* (pyrin), and *WISP3*. Hypermethylation was observed in several loci related to RA, including *TGFBR2* and *FOXO1*. Hypomethylation was associated with increased gene expression with some genes, such as the joint specific antigen *CHI3L1*. In addition, grouped analysis of differentially methylated loci showed that over 200 genes have multiple CpGs that are significantly hyper or hypomethylated. For example, *COL1A1* (type I collagen) has 41 loci, of which 4 are signficantly hypomethylated in RA FLS with an enrichment of 79-fold compared to OA FLS ($P<10^{-6}$). Enrichment for MEFV (pyrin) hypomethylation is nearly 200-fold ($P<10^{-6}$). Of interest, 4 of 16 loci in the TNF promoter are hypermethylated in RA (relative enrichment=451; $P<10^{-9}$), suggesting that epigenetic control of TNF is aberrant in RA. Pathway analysis showed that hypomethylation was significantly increased in multiple pathways, including focal adhesion, cell adhesion, leukocyte transendothelial migration, adipokine signaling and extracellular matrix interactions.

Conclusion: The first genome wide unbiased evaluation of DNA methylation shows that RA FLS bear a striking pattern of DNA methylation distinct from control FLS that involves key genes involved in immune response, cell trafficking and inflammation. DNA methylation of critical genes and regulatory pathways in primary synoviocytes is a novel method to determine non-DNA encoding contributions to RA and identify new therapeutic targets.

A Distinctive Oral Microbiome Characterizes Periodontitis in Patients with Early Rheumatoid Arthritis. Jose U. Scher*[1], Carles Ubeda*[2], Walter Bretz[3], Michael H. Pillinger[1], Yvonne Buischi[3], Pamela B. Rosenthal[4], Soumya M. Reddy[1], Jonathan Samuels[1], Peter M. Izmirly[4], Gary E. Solomon[1], Mukundan Attur[1], Michele Equinda[2], Nicholas Socci[2], Agnes Viale[2], Gerald Weissmann[4], Dan R. Littman[4], Eric G. Pamer[2] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Memorial Sloan-Kettering Cancer Center, The Lucille Castori Center for Microbes, Inflammation and Cancer, New York, NY, [3]NYU College of Dentistry, New York, NY, [4]NYU School of Medicine, New York, NY

Background/Purpose: To profile the subgingival oral microbiota abundance and diversity in patients with new-onset, never-treated rheumatoid arthritis (NORA), in comparison with chronic-established RA (CERA), and healthy individuals.

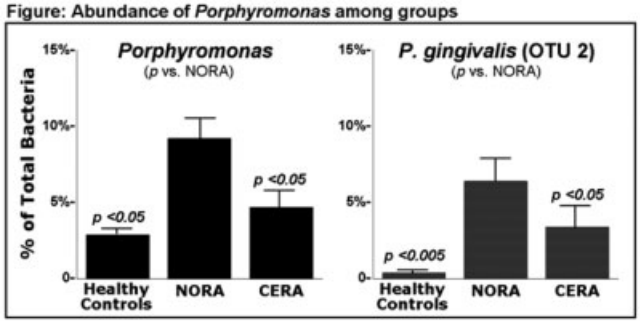
Methods: Periodontal status, clinical activity and sociodemographic factors were determined in patients with NORA (n=25), CERA (n=27), and healthy subjects (n=14). All RA patients enrolled in the study were ACPA positive. Dental examinations and biofilm acquisitions were performed by three calibrated and qualified periodontists in the NYU Rheumatoid Arthritis Periodontal Disease (RAPD) clinic. Massively parallel-454 pyrosequencing technologies were used to compare the composition of microbial communities in subgingival biofilms and establish correlations between presence/abundance of bacteria and disease phenotypes.

Results: The severe forms of periodontal disease were found in 75% percent of NORA patients, higher than that observed in CERA (57%), and healthy controls (8%) (p <0.01, all RA vs healthy controls; see Table). The oral microbiome of RA patients was equally dense and diverse compared to controls. However, the microbiome of patients with NORA was distinct, characterized by several bacterial families and genera that are more prevalent and abundant than observed in CERA), or healthy controls. Specifically, red-complex bacteria, the most virulent periodontopathic organisms, are overabundant in NORA, and decrease in better-controlled, treated RA (CERA). A single species-level operational taxonomic unit (OTU) belonging to the genus *Porphyromonas* and homologous to *P. gingivalis* is significantly more prevalent and abundant in NORA patients than in CERA or healthy subjects (p<0.05) (Figure).

Table. Prevalence and severity of periodontal disease in healthy individuals and patients with NORA or CERA

		Severity of Periodontal Disease			
Group	**Healthy Gums**	**Gingivitis**	**Slight**	**Moderate**	**Severe**
Healthy controls (n=14)	**62%**	15%	0	15%	8%
NORA (n=25)	0	4%	4%	17%	**75%**
CERA (n=27)	0	10%	10%	23%	**57%**
***p* value (ANOVA)**	$p<0.01$	NS	NS	NS	***p* <0.001**

Figure: Abundance of *Porphyromonas* among groups



Conclusion: Moderate to severe periodontal disease is present in over 90% of patients with new onset RA. Our data indicate that the oral microbiome of these drug-naïve, ACPA + NORA patients is distinct at disease onset, characterized by the overabundance of a single and virulent *Porphyromonas* species. These studies suggest that the further identification and characterization of a particular *Porphyromonas* species may explain the reported link between RA and periodontal disease.

MiR-196a Is An Important Regulator of Synovial Fibroblasts In the Pathogenesis of Rheumatoid Arthritis. Maria Filkova[1], Michelle Trenkmann[1], Joanna Stanczyk[1], Mojca Frank[1], Christoph Kolling[2], Lars C. Huber[3], Beat A. Michel[1], Renate E. Gay[1], Ladislav Senolt[4], Steffen Gay[1] and Astrid Jüngel[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Clinic and Policlinic for Internal Medicine, University Hospital Zurich, Switzerland, Zurich, Switzerland, [4]Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

Background/Purpose: Based on the comprehensive analysis of the expression of 260 miRs in RA synovial fibroblasts (SF) versus osteoarthritis (OA) SF, we found miR-196a to be one of the most downregulated miRs in RA. The dysregulation of miR-196a has been observed in disease conditions such as cancer showing oncogenic or tumor suppressive roles in a cell- or tissue specific fashion.

Objectives: To analyze the expression, regulation and the functional role of the miR-196a in RA as well as to investigate its contribution to the aggressive behavior of RASF.

Methods: TaqMan Low Density Array was performed to analyze the expression of 260 miRs in primary cell cultures of RASF and OASF (n=3 each). Expression of miR-196a was analyzed in additional RASF (n=10), OASF (n=9), RA (n=6) and OA (n=4) synovial tissues by TaqMan RealTime-PCR by single assays. Chromatin immunoprecipitation (ChIP) was used to analyze histone methylation (H3K4me3, H3K27me3) and acetylation (H3-Ac) within both promoters MIR-196A1 and MIR-196A2 in RASF (n=13) and OASF (n=11). Measurement of potential target genes by TaqMan RealTime-PCR and functional experiments (MTT, scratch assay, AnnexinV FACS) were performed following Lipofectamine transfection with pre-miR-196a (25nM) or miR-196a inhibitor (100nM) after 48h.

Results: Expression of miR-196a is significantly lower in RASF (dCt 6.94±1.78) than in OASF (dCt 3.89±0.21, p<0.0001) as well as in RA synovial tissues (dCt 8.42±0.9) compared with OA (dCt 5.14±0.71, p=0.01). Expression of miR-196a was not affected by proinflammatory cytokines (TNFα or IL-1β), TLR ligands (LPS), 1% hypoxia or 5'AZA mediated DNA demethylation. ChIP of MIR-196A2 promoter revealed significantly higher methylation of repressive H3K27me3 in RASF than in OASF (ratio to H3: 0.99±0.39 vs. 0.03±0.00, p=0.005), lower methylation of activating H3K4me3 (ratio to H3: 0.10±0.03 vs. 0.47±0.14, p=0.002) and hypoacetylation of H3 (ratio to H3: 0.18±0.06 vs. 0.63±0.15, p=0.008) in RASF compared to OASF. Expression of miR-196a (dCt) correlated significantly with these histone modifications (H3K27me3: r=0.93, p<0.0001, H3K4me3: r=−0.68, p=0.01, H3-Ac: r=−0.72, p=0.006). Predicted miR-196a targets HOXC8, HOXA9, RASSF3, HMGA2 and ANXA1 were down/upregulated after transfection with pre-miR/miR inhibitor (n=4). Pre-miR-196a reduced cell proliferation by 27.5% and migration by 41.5%, while miR-196a inhibitor enhanced both proliferation by 81.9% and migration by 231% (n=4). Apoptosis of RASF was induced by pre-miR-196a by 54.1% while it was reduced by miR-196a inhibitor by 52.3% (n=3).

Conclusion: The data demonstrate that low expression of miR-196a in both RA synovial tissue and in isolated synovial fibroblasts contributes to the aggressive and invasive phenotype of RASF. Moreover, functional assays confirmed that miR-196a contributes to the characteristic behavior of these cells by regulating proliferation, migration and apoptosis. Therefore, miR-196a epigenetically regulated by histone methylation and acetylation appears to function as an important contributor to the pathogenesis of RA.

Epigenome Analysis Reveals TBX-5 As a Novel Transcription Factor Involved in the Activation of Rheumatoid Arthritis Synovial Fibroblasts. Emmanuel Karouzakis[1], Michelle Trenkmann[1], Caroline Ospelt[1], Christoph Kolling[2], Renate E. Gay[1], Beat A. Michel[1], Steffen Gay[1] and Michel Neidhart[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland

Background/Purpose: Changes in DNA methylation and histone marks have been associated with diseases such as cancer, rheumatoid arthritis (RA) and systemic lupus erythematosus. Previously, we reported global genomic hypomethylation in RA synovial fibroblasts (RASF). Now, we searched for specific genes that are differentially methylated in RASF in comparison to osteoarthritis synovial fibroblasts (OASF).

Methods: Genomic DNA from OASF and RASF was isolated; 40 μg genomic DNA was used to perform seven methylation immunoprecipitation (MeDIP) reactions per patient; 1 μg of total input and methylated immunoprecipitated DNA was labelled with Cy3 /Cy5 dyes and hybridizised to a human promoter array (NimbleGen, Roche). Differentially methylated genes were confirmed with individual MeDIP reactions, combined bisulphite restriction digestion (COBRA) and bisulphite sequencing. The expression of related transcripts was determined by quantitative SYBR PCR and protein analysis was performed by Western blot and immunohistochemistry. Changes in histone marks, namely H3 K4 trimethylation and H3 K27 trimethylation were analysed by chromatin immunoprecipitation (ChIP).

Results: The promoter array analysis revealed 30 gene promoters which were hypomethylated in RASF. The TBX5 gene was significantly more methylated in the promoter and transcriptional initiation site of OASF than RASF, as shown by MeDIP assay (Promoter: OASF 16±4.5 and RASF 0.60±0.15 fold enrichment, p<0.03, n=4; transcriptional initiation site: OASF 17±2.9 and RASF 5±3.5 fold enrichment, p<0.04, n=6). The MeDiP results were confirmed by individual COBRA assays and bisulphite sequencing of the TBX5 promoter. TBX5 transcripts were significantly more expressed in RASF than OASF (RASF dCt: 16.0 ± 0.6; OASF dCt: 19±0.3, p<0.005, n=8). Overall, we found a 13-fold increase of TBX5 mRNA in

RASF compared to OASF. In addition, Western blot showed that the TBX5 protein was expressed in RASF, but not in OASF. Immunohistochemistry of synovial tissues confirmed that TXB5 is expressed in RA (n=6), but not in OA (n=6). The expression of TBX5 was nuclear and mostly localised in the synovial lining of RA tissues. Furthermore, in the TBX5 locus, ChIP revealed that RASF had more H3 K4 trimethylation– associated with an open chromatin -, than OASF (RASF H3 K4 trimethylation: 0.67±0.06 ratio to histone 3; OASF H3 K4 trimethylation: 0.02±0.005 ratio to histone 3, $p<0.01$ n = 4–5). On the other hand, OASF were found to have enrichment for H3 K27 trimethylation – associated with a closed chromatin -, when compared to RASF (OASF 0.25±0.09; RASF 0.02±0.001, $p<0.01$ n = 4–5). Previously, it was shown that TBX5 regulates genes such as cadherins, CDKN2A and gelsolin in the area of heart development and cancer.

Conclusion: Promoter specific DNA hypomethylation and an open chromatin are responsible for the intrinsically up-regulated TBX5 expression in RASF. TBX5 may be a novel regulator of cell junctions (cadherins), proliferation (CDKN2A) and extracellular matrix (gelsolin) and thereby associated with the chronically activated phenotype of RASF.

9G4 Expression on Antibodies to Citrullinated Residues in Patients with Early Inflammatory Arthritis and Established Rheumatoid Arthritis. Rita A. Moura[1], Inmaculada de la Torre[2], Maria J. Leandro[3], Jonathan CW Edwards[3] and Geraldine Cambridge[4]. [1]Rheumatology Research Unit, Instituto de Medicina Molecular, Lisbon, Portugal, Lisbon, Portugal, [2]Gregorio Marañón Hospital, Madrid, Spain, [3]UCL, London, United Kingdom, [4]University College London, London, United Kingdom

Background/Purpose: The rat monoclonal antibody 9G4 recognises immunoglobulin products of the human V4–34 germ-line heavy chain gene. Antibodies encoded by V4–34 are inherently autoreactive against red blood cells. 9G4+ autoantibodies to other targets (eg DNA) have also been described in autoimmune disease. In normal controls (NC), up to 10% of newly generated naïve B cells are 9G4+ but expression on circulating immunoglobulins is low. This is because although 9G4+B cells are present in lymphoid organs from NC they are excluded from germinal center (GC) reactions. Tonsils from patients with lupus, but not from patients with RA, however contain class switched 9G4+ memory B cells, suggesting a defect in pre-GC censoring in lupus, but not Rheumatoid arthritis (RA) patients. Preliminary studies in our laboratory showed increased numbers of circulating 9G4+ plasmablasts in patients with active RA. the aim of this study therefore was to determine whether these plasmablasts could be associated with any autoantibodiy species.

Methods: Patient groups were 27 patients with established RA and 46 with polyarthritis of less than 6 weeks duration of whom 23/46 were subsequently diagnosed with RA (ERA Group), and 23/46 with other arthridites (Early Non-RA group; ENRA). Serum was collected on first clinic visit. Total IgG and IgM anti-CCP2 antibodies and 9G4 expression on anti-CCP antibodies were measured by ELISA (Eurodiagnostica). Positive values in 9G4 analyses were defined as > than 3 SD above mean of 9G4 depleted serum controls. 9G4 was also measured on anti-tetanus toxoid (TT) and Pneumococcocal capsular polysaccharide (PCP) antibodies by ELISA (Binding Site, UK).

Results: 23/27 RA patients were positive for anti-CCP; 18 had both IgM and IgG CCP. 1 patient had only IgM- and 3, IgG-CCP only. Eight of the 27 patients (30%) with established RA had detectable 9G4+ anti-CCP and all were positive for both IgM and IgG anti-CCP. Levels of 9G4 expression correlated more closely with titer of IgM rather than IgG-CCP (Spearman; r2=0.65 cf 0.27). In the ERA group, 15/23 had anti-CCP, 10 had both IgM and IgG anti-CCP, 4 patients had only IgM and 1 only IgG anti-CCP. 4/23 patients (17%) with early RA had 9G4+anti-CCP. All 4 patients had both IgM and IgG anti-CCP. In ENRA patients, only 1 patient with polyarticular gout had 9G4+ anti-CCP antibodies, albeit at low titer and had only IgM anti-CCP. There was no expression of 9G4 on anti-TT or PCP antibodies.

Conclusion: This is the first description of the use of the V4–34 heavy chain gene by autoantibodies to citrullinated peptides. 9G4 expression was largely confined to CCP antibodies from patients with RA. Further, it was present on anti-CCP early after disease onset, and only very weakly expressed on 1 sample from a non-RA patient. Usage of V4–34 by anti-CCP antibodies also increased with increasing titer, particularly in IgM-CCP. It may therefore be possible that expansion of CCP-specific B cell clones may not be due to a breakdown in GC censoring but to a robust expansion of un-switched B cell clones, possibly including or analogous to those in the splenic marginal zone.

Heightened Immune Response to Autocitrullinated *Porphyromonas Gingivalis* Peptidylarginine Deiminase Is a Potential Mechanism for Breaching Immunologic Tolerance in Rheumatoid Arthritis. Anne-Marie Quirke[1], Natalia Wegner[1], Bart Hamilton[2], Peter J. Charles[3], Muslima Chowdhury[1], Elena B. Lugli[1], Jan Potempa[4], Geoffrey M. Thiele[5], Ted R. Mikuls[6] and Patrick Venables[7]. [1]Imperial College London, London, United Kingdom, [2]University of Nebraska Medical Centre and Omaha VA Medical Center, Omaha, [3]Charing Cross Hospital, London, United Kingdom, [4]Jagiellonian University, Krakow, Poland, [5]Univ of Nebraska Med Ctr, Omaha, NE, [6]Omaha VA and University of Nebraska, Omaha, NE, [7]Kennedy Institute, London, United Kingdom

Background/Purpose: *Porphyromonas gingivalis*, a major periodontal pathogen, has been implicated in the pathogenesis of rheumatoid arthritis (RA). It is the only known prokaryote to possess a bacterial peptidylarginine deiminase (PPAD), which in combination with *P.gingivalis* specific proteases, the arginine gingipains (Rgp), citrullinates peptides from both α-enolase and fibrinogen. Because both PPAD and Rgp are of potential importance in disease pathogenesis, we have examined the immune response to both bacterial enzymes in a cohort of patients with RA compared to normal controls, in addition to individuals with periodontitis as a positive control for active *P. gingivalis* infection.

Methods: We cloned GST-His tagged PPAD in a pET-49b(+) vector and expressed it in the protease-deficient BL21 strain of *Escherichia coli*. The enzyme activity was measured using a colorimetric PAD activity assay that detects formation of the ureido group of citrulline, using BAEE as synthetic substrate. Gingipain (RgpB-His) was cloned and expressed using previously published methods. ELISAs using PPAD and Rgp were developed and tested in serum from normal controls (n=80), PD (n=44) and RA (n=82). Reactivity of each serum was calculated as units per ml (AU/ml) using a standard curve on each ELISA plate. The Mann-Whitney U test was used to calculate p-values for mean differences between the sera groups for each peptide. To control for the specificity of the ELISA, 12 RA sera, 10 normal controls and 10 PD sera were examined by both immunoblotting and ELISA.

Results: Recombinant PPAD migrated as a full-length polypeptide with a molecular weight of approximately 68KD. It was a potent citrullinating enzyme using both the BAEE assay and when incubated with fibrinogen peptides as substrates. Immunoblotting with the anti-modified citrulline kit demonstrated that it was autocitrullinated. IgG anti-PPAD antibodies were significantly higher in the RA sera (mean 182.4 AU/ml), than what was found in both the PD sera (mean 96.4AU/ml; $p<0.01$) and the healthy control sera (mean 99.2AU/ml $p<0.05$). The anti-Rgp response was significantly higher in the PD sera (mean 533.8AU/ml) than what was found in both the RA sera (mean 257.6AU/ml, $p<0.001$) and the healthy control sera (mean 299.3AU/ml, $p<0.01$). The specificity of the anti-PPAD and anti-Rgp ELISAs was demonstrated by comparison of 10 healthy controls, 10 PD sera and 12 RA sera with immunoblotting. The results of immunoblotting correlated with those from ELISA both for PPAD ($p<0.05$) and for Rgp ($p<0.001$). In the healthy control sera, 6 patients reacted with PPAD and 4 also with Rgp, indicating that infection with *P. gingivalis* defined by immunoblotting is ubiquitous in the healthy population (~60%).

Conclusion: The anti-PPAD response was significantly elevated in RA patients compared to PD patients and controls, while the anti-Rgp response was higher in PD patients and in normal controls compared to those with RA. The anti-PPAD antibodies in RA could be part of a cross-reactive ACPA response, but more importantly, it could also indicate that PPAD itself could be a mechanism for breaching immunological tolerance to citrullinated antigens.

RA, Anti-TNF Therapy, and Risk of Malignant Melanoma-a Nationwide Population-Based Study From Sweden. Pauline Raaschou[1], Julia F. Simard[2], Martin Neovius[2], Marie Holmqvist[2], Jonas Eriksson[2], Johan Askling[2] and the ARTIS studygroup[3]. [1]Clinical Pharmacology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet

Background/Purpose: States of immune suppression, such as post-transplant therapy, have recently emerged as a possible risk factor not only for

non-melanoma skin cancer but also for malignant melanoma (Vajdic CM et al, JAMA 2006). An increased risk of melanoma associated with anti-TNF therapy has been reported (Wolfe F et al, Arthritis Rheum. 2007; Askling J. EULAR Conference Abstract 2009). We aimed to investigate the risk of malignant melanoma in patients with RA compared to the general population, and to investigate whether anti-TNF treatment influences melanoma risk in RA.

Methods: A nationwide and population-based cohort of patients with RA were identified using data from the Swedish outpatient register from 2001 through 2009 (n=56,336). Patients starting anti-TNF therapy were identified through linkage to the Swedish Biologics Register ARTIS and to the national Prescribed Drug Register (n=8,453) To each RA patient, 5 general population comparators were matched for sex, year of birth and county of residence. Occurrence of first-ever invasive malignant melanoma, as well as occurrence of first-ever cancer, irrespective of type (all-site), was assessed through linkage to the national Swedish Cancer Register. Relative risks (RRs) for malignant melanoma and all-site cancer were calculated using Cox regression with age as time-scale and anti-TNF therapy treated as a time-dependent variable, adjusted for selected co-morbidities. RRs were assessed overall and by time since start of anti-TNF therapy.

Results: Based on 135 incident melanomas during 253,572 person-years of follow-up among biologics-naïve patients with RA vs. 718 melanomas during 1,460,120 person-years of follow-up in the general population comparator, the RR for malignant melanoma in biologics-naïve patients with RA was 1.1 (95% CI 0.9–1.3). Based on 32 incident malignant melanomas during 44,858 person-years of follow-up from start of anti-TNF therapy, compared to biologics-naïve RA patients, the RR was 1.8 (95% CI 1.2–2.7). Based on 418 incident all site cancers during 42,418 person-years of follow-up among the anti-TNF exposed, the RR was 1.0 (0.9–1.1) compared to biologics-naïve RA patients (Table). Sensitivity analyses also including in situ melanomas resulted in a relative risk of 1.5 (95% CI 1.1–2.1).

Table. Relative risks adjusted for age, sex and co-morbidities (95% confidence intervals) and number of cases among patients treated with anti-TNF, comparing Swedish patients with RA treated with anti-TNF (n=8,453) to biologics-naïve patients with RA (n=47,883).

	Anti-TNF-exposed vs. Biologics-naïve RA	Time since first anti-TNF treatment start		
	Overall	< 1 year	1–2 years	≥2 years
Melanoma				
Relative risk (95%CI), Cases	1.8 (1.2–2.7), 32	1.5 (0.6–4.1), 4	2.9 (1.4–5.9), 8	1.7 (1.0–2.7), 20
All-Site Cancer				
Relative risk (95%CI), Cases	1.0 (0.9–1.1), 418	1.0 (0.8–1.3), 74	0.9 (0.7–1.2), 63	1.1 (1.0–1.3), 281

Conclusion: In the absence of anti-TNF therapies, RA patients are not at elevated risk of malignant melanoma. Patients selected for and treated with anti-TNF have a higher risk of malignant melanoma than biologics-naïve RA patients.

2524

Opportunistic Infections in Patients Exposed to Anti-Tumour Necrosis Factor Therapy: Results From the British Society for Rheumatology Biologics Register. James B. Galloway[1], Audrey SL Low[1], Louise K. Mercer[1], William G. Dixon[1], Andrew Ustianowski[2], Mark Lunt[1], Kath D. Watson[1], British Society for Rheumatology Biologics Register (BSRBR) control centre consortium[3], Kimme L. Hyrich[1], Deborah PM Symmons[1] and. on behalf of the BSRBR[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]British Society for Rheumatology, London, United Kingdom

Background/Purpose: Anti TNF therapy is associated with an increase in the risk of infections. There are biological reasons to expect that certain infections might be disproportionately increased, especially those where the cellular immune system is crucial to defence. The British Society for Rheumatology Biologics Register (BSRBR) is an ideal setting to establish the risk and pattern of these opportunistic infections (OI).

Methods: The BSRBR was established in 2001 to evaluate the safety of anti-TNF therapies etanercept (ETN), infliximab (INF) and adalimumab (ADA) in people with RA. The anti-TNF treated cohort was recruited alongside a comparator group with active disease (DAS28 >4.2) treated with non-biologic disease modifying anti-rheumatic drugs (nbDMARD). Patients were recruited between 01/10/2001 and 30/06/2008 and followed up prospectively by consultant and patient questionnaires until first OI, 06/31/2010 or death, whichever came first. Tuberculosis was excluded from this analysis as we have reported on this previously. The BSBBR drew up a list of OI at its outset. Rates were compared using Cox proportional hazards. A propensity model was used to adjust for confounders.

Results: 11,864 anti-TNF and 3,666 nbDMARD patients were included (Table). The reported opportunistic infections are shown in the table. The absolute rates of infections were low in both cohorts (anti-TNF 0.8/1000 person years follow up (pyrs); DMARD 0.3/1000 pyrs). The fully adjusted hazard ratio for OI in the anti-TNF cohort was increased at 1.5 (0.3, 7.8). The highest frequency of OI was observed in the INF cohort (incidence: ETN 0.5/1000, INF 1.6/1000, ADA 0.7/1000). The hazard ratio for OI in the INF cohort was significantly higher when compared to either ETN or ADA.

Table. Baseline characteristics and incidence of infections.

	DMARD	All anti-TNF	ETN	INF	ADA
Subjects, n	3,666	11,864	4,136	3,472	4,256
Mean age, years (SD)	60 (12)	56 (12)	56 (12)	56 (12)	57 (12)
Female gender, (%)	2648 (72)	9038 (76)	3190 (77)	2624 (76)	3224 (76)
Disease Duration: years, median (IQR)	6 (1–15)	11 (6–19)	12 (6–19)	12 (6–19)	10 (5–18)
Baseline steroid use: n (%)	834 (23)	5243 (44)	1977 (48)	1609 (46)	1657 (39)
DAS28, mean (SD)	5.1 (1.3)	6.6 (1.0)	6.6 (1.0)	6.6 (1.0)	6.5 (1.0)
Exposure (pyrs)	12,592	45700	23026	13476	17211

			Ref	4.51 (1.86, 10.94)	1.68 (0.65, 4.32)
			0.60 (0.23, 1.53)	2.69 (1.11, 6.54)	Ref
Invasive fungal infection: n	1	3	0	3	0
Legionellosis: n	0	6	0	2	4
Listeriosis: n	1	8	2	4	2
Multidermatomal shingles: n	0	8	3	3	2
Pneumocystis pneumonia: n	1	6	1	3	2
Invasive salmonellosis: n	1	6	3	3	0

*Adjusted for baseline confounders: age, gender, disability, disease activity score, disease duration, steroid use, smoking, chronic lung disease, diabetes and year of entry into the study.

Conclusion: The absolute rate of OI was non-significantly higher in anti-TNF exposed patients. The INF cohort accounted for 44% these cases. Although we have attempted to address the issue of confounding by indication with our propensity model, unmeasured confounding may still exist. While there are limitations to the methodology, this pattern of risk has also been reported by other registries. The replication of this finding in the UK cohort adds weight to the evidence that INF may carry a greater risk of opportunistic infection than other ETN or ADA. It is important to acknowledge that the absolute risk of opportunistic infection was very low.

2525

The Risk of Solid Cancer in Patients Receiving Anti-Tumour Necrosis Factor Therapy for Rheumatoid Arthritis for up to 5 Years: Results From the British Society for Rheumatology Biologics Register. Louise K. Mercer[1], James B. Galloway[1], Audrey SL Low[1], Kath D. Watson[1], Mark Lunt[1], William G. Dixon[1], British Society for Rheumatology Biologics Register (BSRBR) control centre consortium[1], Deborah PM Symmons[1], Kimme L. Hyrich[1] and On behalf of the BSRBR[2]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]British Society for Rheumatology, London, United Kingdom

Background/Purpose: The use of TNF inhibitors in the management of rheumatoid arthritis (RA) has been coupled with concerns about tumorigenesis. Meta-analysis of patient-level data from randomised controlled trials (RCT) has not found an increased risk of solid cancer. The short duration and strict exclusion criteria of RCTs means latent events such as cancer may be missed. The aim of this study was to determine whether anti-TNF influences the risk of cancer when used in routine UK clinical practice.

Methods: The analysis was conducted in the British Society for Rheumatology Biologics Register (BSRBR), a national cohort study. Patients with RA starting treatment with the TNF inhibitors etanercept (ETA), infliximab (INF) or adalimumab (ADA) and a biologic-naïve comparison cohort exposed to non-biologic therapy (DMARD) were recruited between 2001–2009. The first six months of follow up for each subject was excluded from the analysis. Subjects were followed for 5 years, until 31/12/2009 or death, whichever came first. Subjects with a history of solid cancer prior to registration identified by record linkage with the UK cancer registry (NHS-IC) were excluded. Incident cancers were identified in 3 ways; lifelong flagging with NHS-IC; 6 monthly patient and physician questionnaires for 3 years and annual physician questionnaires thereafter. Only the

first solid cancer per subject (excluding non-melanoma skin cancer), confirmed by histology or NHS-IC, was analysed. Cancers occurring after stopping anti-TNF were attributed to the most recent anti-TNF. The rates of solid cancer in the anti-TNF and DMARD cohorts were compared using multivariate Cox proportional hazards models adjusted using inverse probability of treatment weighting (IPTW) for age, gender, comorbidity, disease duration, use of NSAIDs, smoking and registration year. Site specific analyses were performed for sites with ≥10 cancers in each cohort: colorectal, lung/bronchus and female breast.

Results: 386 solid cancers were confirmed: 91 in 3543 DMARD patients and 295 in 11719 anti-TNF patients (84 v 63 per 10000 patient-years (pyrs)) (Table). After adjusting for IPTW there was no difference in risk of solid cancer between the 2 cohorts (hazard ratio (HR) for anti-TNF 0.88 (0.65, 1.17)). The IPTW adjusted HR for ETA was 0.94 (0.68, 1.29), INF 0.87 (0.61, 1.25) and ADA 0.81 (0.57, 1.14). There was no significant difference in risk of colorectal, lung/bronchus or female breast cancer for anti-TNF compared to DMARD. The risk did not vary with duration of follow up.

Table.

	DMARD N=3543	Anti-TNF N=11719	Etanercept N=4072	Infliximab N=3429	Adalimumab N=4218

Female breast: N	14	58			
Female breast: Rate per 10000 pyrs	7 (3, 11)	6 (4, 7)			
Female breast: IPTW adjusted HR	Referent	0.99 (0.51, 1.92)			

Conclusion: In patients without prior solid cancer no increase in solid cancer risk was seen in this UK national cohort of RA patients treated with TNF inhibitors when followed for up to 5 years. Further follow up is warranted to further assess site specific risk and allow for longer latency.

2526

Safety of Infliximab Therapy in Rheumatoid Arthritis Patients with Pre-Existing Hepatitis B Virus Infection. Xuewu Zhang[1], Xia Liu[2], Yuan An[1], Ying Ning[1] and Zhanguo Li[1]. [1]Peking University People's Hospital, Beijing, China, [2]China-Japan Friendship Hospital, Beijing, China

Background/Purpose: To evaluate the safety of treatment with tumor necrosis factor-α (TNF-α) monoclonal antibody (Infliximab) in patients with rheumatoid arthritis(RA) who had normal liver function and pre-existent HBV infection.

Methods: In this multicenter study, all 41 cases met the ACR 1987 revised criteria for RA, including 7 men and 34 women, with average age of 46.2±2.72 years old and average disease course of 11.40±5.72 years. Upon enrollment, patients were assessed for HBsAg, anti-HBC, anti-HbsAb, anti-HBeAb. All patients were HBsAg(−); four of them were only anti-HBC (+); fifteen were anti-HBsAb (+), anti-HBeAb (+) and anti-HBc (+); six were anti-HBsAb (+) and anti-HBeAb (+); forteen were anti-HBsAb(+) and anti-HBc(+), two were anti-HBeAb (+) and anti-HBc (+). 40 patients had normal ALT and AST, and one patient with positive anti-HBc showed elevated ALT before administration of infliximab (60U/L). All patients received intravenous Infliximab therapy with dose of 3 mg/kg at week 0, 2, 6, 14 and 22 respectively after testing liver enzyme, Creatinine, T-bilirubin, leukocyte and platelet. All the above five parameters and HBsAg were reexamined at week 26.

Results: 40 out of 41 patients have their ALT, AST, T-bilirubin, Creatinine, leukocyte and platelet within normal range, with no significant difference between HBV positive and HBV negative groups. As for the patients with elevated ALT and AST levels after infliximab infusion, there was no statistically significant difference between previously HBV infected patients and patients without history of HBV infection. All patients reexamined for HBsAg at week 26 showed negative results.

Conclusion: In RA patients with pre-existing HBV infections, liver function abnormality were not observed during the Infliximab administration, as long as HBsAg was negative with normal liver function at baseline.

2527

Functional MRI (FMRI) Is Much Faster In Detecting Rapid Symptom Control by Certolizumab-Pegol In Patients with Rheumatoid Arthritis Than the Conventional MRI. Juergen Rech[1], Stephanie Finzel[1], Silke Kreitz[1], Matthias Englbrecht[1], Arnd Doerfler[1], Marc Saake[1], Andreas Hess[1] and Georg Schett[2]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: To define rapid effects of tumor necrosis factor (TNF) blockade in the central nervous system (CNS) of patients with rheumatoid arthritis (RA) and to compare that with peripheral effects. We hypothesized that CNS effects precede the clinical response much earlier in patients with RA and therefore performed non-invasive functional Magnetic Resonance Imaging (fMRI) to detect changes of neuronal activity by Blood-oxygen-Level Dependent (BOLD) in the brain (1).

Methods: Ten RA patients with a DAS28 score over 3.2 failing on at least one conventional DMARD were included. All patients started with 400 mg certolizumab treatment at 400mg on days 0, 14 and 28. DAS28 and HAQ scores were performed on days 0, 3, 7 and 28 as well as fMRI scans of the brain using a 3 Tesla scanner (Siemens) with a 8 channel phased array head coil. fMRI signals were retrieved during standardized compression of MCP joints and during finger tapping (control procedure). Also MRI scan of the index hand was performed on day 0 and 28 in five of these patients.

Results: BOLD signal volume and intensitiy in the CNS elicited by joint compression significantly decreased by 38% as early as 3 days after exposure to TNF blockade. This affected the thalamic and somatosensory cortical brain regions involved in nociception as well as the limbic system. No decrease in the clinical parameters (baseline-DAS28 5.4±0,86, baseline-HAQ 1,0±1,32; day 3-DAS28: 4,99±0,63 day 3-HAQ: 0,97±1,6) were observed at this early time point. In contrast, neuronal activity elicited by finger tapping did not decrease after 3 days. BOLD signal volume and intensitiy elicited by joint compression further decreased 28 days after initiation of TNF- blockade when clinical improvement was seen (DAS28 4.3 ± 1.78), but still detectable synovitis was present in 4 out of 5 patients.

Conclusion: TNF blockade elicits a change in neuronal activity in the CNS within days preceding its anti-inflammatory effect. These findings substantiate anecdotal clinical observations of immediate subjective improvement of the patients' condition after exposure to TNF blockade and suggest that immediate changes in neuronal activity precede the resolution of inflammation in arthritis much earlier than peripheral response.

2528

Etanercept Induces a Decrease in Left Ventricular Mass in Patients with Rheumatoid Arthritis. Claire Daien[1], Pierre Fesler[1], Vincent Daien[2], Guilhem du Cailar[1], Anne-Marie Dupuy[1], Jean-Paul Cristol[1], Jean Ribstein[1], Bernard G. Combe[1] and Jacques Morel[1]. [1]Hopital Lapeyronie, Montpellier, France, [2]Hopital Gui de Chauliac, Montpellier, France

Background/Purpose: Mortality in patients with rheumatoid arthritis (RA) is higher than in the general population, which is mainly due to premature cardiovascular disease. RA is associated with increased cardiac mass (left ventricular [LV] hypertrophy) which is a strong marker of cardiovascular morbidity and mortality. Experimental studies suggest that tumour-necrosis factor alpha (TNFa) may induce LV hypertrophy. Vessels abnormalities has also been identified in RA. Aim: To assess the influence of TNF inhibitors or synthetic drug-modifying anti-rheumatic drugs (sDMARD) on LV morphology, macrocirculation (arterial stiffness) and microcirculation (retinal arterial diameter) in RA patients.

Methods: Thirty-eight female patients with active RA were included and allocated to sDMARD (n=17; methotrexate, sulfasalazine, leflunomide) or etanercept (ETN) (n=21), according to current guidelines. Exclusion criteria were diabetes, obesity, previous cardiovascular events, cardiopathy, uncontrolled hypertension, alcohol abuse and renal disease. Clinical and biological monitoring, echocardiography, pulse wave velocity and retinal arterial caliber were performed at inclusion, after 3 and 6 months of etanercept or sDMARD therapy. All cardiovascular determinations of LV mass were performed on an offline station by the same operator who was blind of treatment assigment. Linear regression analysis and paired t test were used.

Results: (mean ± SEM) In sDMARD allocated subjects, age was 50 ± 4 yrs and RA duration was 1.7 ± 0.5 yrs. At baseline, DAS28 was 4.2 ± 0.3, LV mass index was 84 ± 7 g/m2 and LV hypertrophy (LV mass>110 g/m2) was present in 20% of subjects. In ETN allocated subjects, age was 56 ± 3 yrs and RA duration was 9.5 ± 2 yrs. At baseline, DAS28 was 4.8 ± 1.1, LV mass index was

96 ± 4 g/m^2 and LV hypertrophy was present in 25% of subjects. In group of patients on sDMARD, change in LV mass index was not significant after 3 months or 6 months (−1.4 ± 3.4 g/m^2; p=0.70 and −2.68 ± 3.23; p=0.43 respectively); whereas in patients on ETN, LV mass index decreased by −5.31 ± 1.7 g at 3 months (p=0.007) and by −13.99 ± 2.23 g/m^2 at 6 months (p<0.001). At 6 months, LV hypertrophy was present in 18% of patients on sDMARD (mean LV mass index: 88 ± 8 g/m^2) whereas in the ETN group, all patients had normal LV mass (mean LV mass index: 82 ± 3 g/m^2). Pulse wave velocity and retinal arterial diameter were not modified in either group.

Conclusion: In this longitudinal prospective comparative study conducted in RA, etanercept induced a significant decrease of LV mass whereas sDMARD did not influence cardiac remodeling. Macro and microcirculation was not modified by treatment. Those results suggest that TNF may be a main factor of LV hypertrophy. This could partly explain the previously reported benefit of TNFi on cardiovascular morbi-mortality in RA.

ACR Concurrent Abstract Session
Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment III
Tuesday, November 8, 2011, 4:30 PM–6:00 PM

Autoantibodies Against CD74 and Class II-Associated Invariant Chain Peptide (CLIP) in Spondyloarthritis. Niklas T. Baerlecken[1], Georg H. Stummvoll[2], Reinhold E. Schmidt[3] and Torsten Witte[4]. [1]MD, Hannover, Germany, [2]Medical University of Vienna, Vienna, Austria, [3]Hannover Medical School, Hannover, Germany, [4]Hannover Medical School, Hanover, Germany

Background/Purpose: Spondyloarthritis (SpA) is a relatively common inflammatory disorder with a frequency of 1–2% in the European population. Establishing the diagnosis however may be difficult, since abnormalities in conventional X-ray develop with a latency of several years and so far only HLA-B27 has been established as a laboratory marker of the disorders.

The goal of our study therefore was to identify new autoantibodies as markers of SpA.

Methods: As a screening procedure, we used protein array technology for detection of possible new autoantigens in ankylosing spondylitis (AS). Sera of patients with AS without peripheral manifestation (n = 5) and other diseases (n = 45), were studied. In the second step, the results of the protein macroarray were confirmed by ELISA using commercially available recombinant antigens (Abnova, Taiwan and abcam, United Kingdom) and new synthetic derived peptides (Biomatik, Canada). The sera for the ELISA were obtained from SpA patients visiting the rheumatological outpatients and inpatients clinics of the Medical Universities in Hannover and in Vienna, from 40 patients with rheumatoid arthritis (RA) and 40 with psoriatic arthritis (PsA) without peripheral involvement and from 100 blood donors.

All donors provided informed consent for the study which was approved by our local ethical committee (project number 4928).

We correlated the presence of autoantibodies with the disease duration, HLA-B27, BASDAI and therapy in a subset of the spondyloarthritis patients.

Results: Using the protein array, we detected IgG antibodies against CD74 in 4/5 SpA sera, but only in 1/45 controls. In order to develop an ELISA, we used a peptide which includes the MHC class II-associated invariant chain peptide (CLIP) within the CD74. We could detect IgG- and/or IgA-antibodies against CLIP in 59/128 (46%) of all the sera obtained from patients (treated and untreated patients combined) with SpA. The presence of IgG antibodies against CLIP was 45% and of IgA antibodies against CLIP was 25%. In the subset of patients with AS, 22/31 (73%) had IgG and 11/31 (35%) had IgA autoantibodies and 25/31 (81%) had IgG and/or IgA autoantibodies.

The prevalence of IgG antibodies against CLIP was 9/11 (82%) in SpA patients whose sera were obtained within 1 year after the diagnosis was established, In addition, 8/9 (88%) SpA patients with an active MRI proven sacroiliitis had IgG autoantibodies against CLIP.

In the further control groups, the prevalence of IgG autoantibodies against CLIP was 5/40 (12,5%) in PsA (without axial manifestation), 8/40 (20%) in RA and 3/50 (6%) in *blood donors* and of IgA autoantibodies 3/40 (7,5%) in PsA and 5/40 (12,5%) in RA and 2/50 (4%) in *blood donors* and of IgA and/or IgG autoantibodies 5/40 (12,5%) in PsA and 9/40 (22,5%) in RA and 5/50 (10%) in *blood donors*.

Conclusion: Antibodies against CD74 and CLIP are biomarkers associated with SpA. Considering their specifity and sensitivity of up to 88 % in active SpA, they may be an useful addition to our diagnostic tools for SpA in the future, in particular in the early disease stage.

2530

Incidence of Spondyloarthropathy In Patients with Crohn's Disease: A Population-Based Study. Raina Shivashankar, Edward V. Loftus Jr., William J. Tremaine, Tim Bongartz, W. Scott Harmsen, Alan R. Zinsmeister and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Spondyloarthropathy (SpA) is an important extraintestinal manifestation of inflammatory bowel disease (IBD), although the frequency is uncertain. We aimed to assess the cumulative incidence and clinical spectrum of SpA in patients with Crohn's disease (CD) in a population-based study.

Methods: The medical records of a population-based cohort of Olmsted County, MN residents diagnosed with CD from 1970 through 2004 were reviewed. Patients were followed longitudinally until moving from Olmsted County, death, or December 31, 2010. We recorded data on musculoskeletal symptoms and disease, and we used the European Spondyloarthropathy Study Group and New York criteria to identify patients with SpA. The cumulative incidence of SpA subsequent to CD diagnosis was estimated using the Kaplan-Meier method.

Results: The cohort included 309 patients with CD, of which 50.2% were women, and the median age at diagnosis of CD was 30.1 years (range 8–91). Prior to CD diagnosis, the prevalence of spondyloarthropathy was 1.3% (95% confidence interval [CI], 0.4%–3.3%). The cumulative incidence of a diagnosis of spondyloarthropathy after an established diagnosis of CD was 2.6% (95% CI, 0.7%–4.5%) at 10 years, 6.2% (2.5%–9.9%) at 20 years, and 10% (3.3%–16.2%) at 30 years. The 10-year cumulative incidence of ankylosing spondylitis was 0 while both the 20-year and 30-year cumulative incidences were 1.4% (95% CI, 0–3.3%). Sacroiliitis, oligoarthritis and polyarthritis were observed in 1.6%, 2.9% and 1.9% of patients in the post-CD diagnosis period, respectively.

Conclusion: We have for the first time defined the actual cumulative incidence of SpA in CD using complete medical record information in a population-based cohort. The cumulative incidence of all forms of SpA increased to about one in 10 patients by 30 years from CD diagnosis, and features of SpA generally occurred within the first 10 years after CD diagnosis. Our results emphasize the importance of maintaining a high level of suspicion for SpA when following patients with Crohn's disease.

2531

How Does Disease Duration Modify the Association of Radiographic Damage with Ankylosing Spondylitis Metrology? Roozbeh Sharif[1], Pooja N. Patel[2], Shervin Assassi[3], Lianne S. Gensler[4], Laura A. Diekman[5], Thomas J. Learch[6], Michael H. Weisman[7], Michael M. Ward[8] and John D. Reveille[1]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]University of Texas, Houston, Houston, TX, [3]Univ of Texas Health Science, Houston, TX, [4]UCSF, San Francisco, CA, [5]UT Health Science Center, Houston, TX, [6]Cedars-Sinai, Los Angeles, CA, [7]Cedars Sinai Med Ctr, Los Angeles, CA, [8]NIAMS/NIH, Bethesda, MD

Background/Purpose: Previous studies have indicated that radiographic damage is associated with measurements of spinal mobility in patients with ankylosing spondylitis (AS). In the current study, we investigated the correlation of radiographic damage with spinal mobility and examined the impact of gender, disease duration, and anti-tumor necrosis factor (TNF) treatment on this association.

Methods: Study population were participants in the **P**rospective **S**tudy of **O**utcomes in **A**nkylosing **S**pondylitis (PSOAS), a multi-ethnic, multi-center cohort of AS patients in the United States. The study investigators performed the following measurements (AS-Metrology): cervical rotation and flexion, occiput to wall distance, chest expansion, modified Schober, lateral spinal flexion, and hip internal/external rotation. One radiologist (TJL) read all cervical, pelvic, and spinal radiographs. Bath AS Radiologic Index-spinal (BASRI-s) was calculated. We used linear regression to examine the association of AS-Metrology and BASRI-s. We considered the possibility that certain factors might modify this association and examined the interaction term of disease duration, gender, and anti-TNF treatment with BASRI-s in regard to its association with AS-Metrology.

Results: We included 436 patients in the analysis: 70% male, 77% Caucasian, and 85% HLA-B27 positive. Median age and disease duration was 42.3 and 16.3 years, respectively. The BASRI score was associated with all AS-Metrology components ($p<0.001$) except hip external rotation ($p=0.223$). The analysis of potential effect modifier indicated presence of a significant interaction between disease duration and BASRI in regard to its association with AS Metrology ($p<0.05$), while gender and anti-TNF treatment were not effect modifiers. Therefore, we categorized the patient into three groups based on disease duration at enrollment: less than 10, 10 to 20; and more than 20 years and conducted

subgroup analysis. Patients with 10 to 20 years of symptoms demonstrated the highest correlation coefficient between BASRI and AS-Metrology (Table-1). Some of AS-Metrology variables were not normally distributed. Although, analysis of log transformed variable did not make any difference in outcome.

Table 1. Subgroup analysis of correlation between BASRI and AS metrology according to disease duration

	BASRI-s*					
Clinical measurements	**Disease duration** ≤ 10 years (n=126)**		**Disease duration 10–20 years (n=95)**		**Disease duration ≥ 20 years (n=114)**	
	***R*†**	***p-value***	***R***	***p-value***	***R***	***p-value***
Cervical rotation	−0.35	**<0.001**	−0.66	**<0.001**	−0.44	**<0.001**
Cervical flexion	−0.22	**0.011**	−0.68	**<0.001**	−0.58	**<0.001**
Occiput to wall	0.55	**<0.001**	0.70	**<0.001**	0.52	**<0.001**
Chest expansion	−0.30	**0.001**	−0.45	**<0.001**	−0.36	**<0.001**
modified Schober	−0.46	**<0.001**	−0.69	**<0.001**	−0.47	**<0.001**
Lateral spinal flexion	−0.48	**<0.001**	−0.72	**<0.001**	−0.43	**<0.001**
Hip external rotation	0.14	0.113	−0.23	**0.011**	−0.13	0.175
Hip internal rotation	0.05	0.577	−0.30	**0.003**	−0.14	0.128

** BASRI-s: Bath Ankylosing Spondylitis Radiology Index-spinal;*
*** Disease duration calculated from the onset of symptom until enrollment in PSOAS cohort; †R: Correlation coefficient.*

Conclusion: AS-Metrology is associated with BASRI. This correlation peaks 10 to 20 years after the onset of symptoms and is weaker in earlier and later stages of disease.

2532

Selection of Patients with Ankylosing Spondylitis for TNF-Inhibitor Therapy: Comparing Responses in Patients Selected by BASDAI & ASDAS. Karen Minde Fagerli[1], Elisabeth Lie[2], D.M.F.M. van der Heijde[3], Marte S. Heiberg[1], Synnøve Kalstad[4], Erik Rødevand[5], Cecillie Kaufmann[6], Knut Mikkelsen[7] and Tore K. Kvien[2]. [1]Diakonhjemmet hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Leiden University Medical Center, Leiden, Netherlands, [4]University Hospital in Northern Norway, Tromsø, Norway, [5]St. Olavs Hospital, Trondheim, Norway, [6]Vestre Viken, Drammen, Norway, [7]Lillehammer Hosp for Rheumatic Diseases, Lillehammer, Norway

Background/Purpose: BASDAI is the most commonly used measure to assess disease activity in ankylosing spondylitis (AS), and has been widely used as cut-off for eligibility for TNF-inhibitor (TNFi) therapy. ASDAS has been developed as a composite disease activity score for AS, and cut-off values for disease activity states have been published (Inactive disease <1.3, moderate disease activity 1.3–2.1, high disease activity 2.1–3.5 and very high disease activity > 3.5). High disease activity has been suggested as a suitable cut-off for eligibility for TNFi therapy, but whether this is a better cut-off than BASDAI ≥ 4 has not been widely explored.

Objectives: Compare 3-month responses to TNFi in patients selected by BASDAI or ASDAS alone, both or by neither measure.

Methods: The data is from the NOR-DMARD register where adult patients with inflammatory arthropathies starting a new DMARD treatment are included and followed longitudinally. For these analyses we included all patients with AS who had attended their 3 month follow-up after starting a TNFi, and had complete baseline data for calculating BASDAI and ASDAS. Response measures selected were ASDAS responses, BASDAI50 and ASAS responses, change in BASFI and % of patients with ASDAS inactive disease.

Results: 465 patients were included. The majority of patients were eligible both by ASDAS and BASDAI cut-offs (N=342). 47 patients were not eligible by either. Very few patients were eligible by BASDAI only (N=6), but 70 patients were eligible by ASDAS only. Baseline characteristics are shown in table 1.

Table 1.

		BASDAI < 4 (n=117)		BASDAI ≥ 4 (n=348)	
	Overall N=465	**ASDAS < 2.1 N=47**	**ASDAS ≥ 2.1 N=70**	**ASDAS < 2.1 N=6**	**ASDAS ≥ 2.1 N=342**
Age	43.1 (11.3)	41.3 (10.5)	42.6 (10.9)	47.6 (12.2)	43.3 (11.4)
Sex (% male)	68.1	74.5	81.4	83.3	64.2
Disease duration	11.8 (11.2)	11.2 (10.1)	12.8 (11.9)	13.0 (13.9)	11.6 (11.2)
HLA B27 pos. (%)	89.9	94.4	96.7	83.3	88.1
CRP(median (IQR))	8 (5–20)	3 (1–5)	17 (6–26)	1 (1–2)	9 (5–20.25)
ASDAS	3.48 (1.03)	1.59 (0.40)	2.84 (0.51)	1.94 (0.12)	3.77 (0.83)
ASDAS I.D.* (%)	1.7	17.0	NA	0	NA
BASDAI	3.34 (2.35)	2.12 (1.00)	3.07 (0.77)	4.75 (0.51)	6.44 (1.33)
BASFI	4.44 (2.31)	2.05 (1.92)	2.98 (19.2)	3.96 (2.51)	5.08 (2.07)

*ASDAS inactive disease

Percentages of responses in each group are shown in table 2. Patients who were eligible by both measures had the greatest response by all criteria, except achieving ASDAS inactive disease which is expected due to the higher baseline ASDAS. Patients eligible only by ASDAS have comparable ASDAS clinically important improvement and BASDAI 50 responses to those who are eligible by both measures, and had reasonable responses also using other outcome measures. The group fulfilling only BASDAI criteria is too small to make general assumptions, but responses are poor. Responses are also poor in patients fulfilling neither criteria.

Table 2.

		BASDAI < 4		BASDAI ≥ 4	
	Overall N=394–453	**ASDAS < 2.1 N=44**	**ASDAS ≥ 2.1 N=63–68**	**ASDAS < 2.1 N=5**	**ASDAS ≥ 2.1 N=285–334**
ASDAS M.I*	26.7	0	14.3	0	34
ASDAS C.I.I**	52.4	6.8	58.7	0	58.9
BASDAI 50	42.2	29.5	42.6	40	43.8
ASDAS I.D.***	25.9	50	38.1	0	20
ASAS 20	50.6	11.4	45.6	0	57.5
ASAS 40	36.1	2.3	27.9	0	42.8
Δ BASFI (SD)	−1.40 (1.92)	−0.15 (1.19)	−0.76 (1.22)	−0.81 (1.40)	−1.72 (2.03)

*ASDAS major improvement **ASDAS clinically important improvement ***ASDAS inactive disease

Conclusion: Very few patients who were eligible for TNFi therapy by BASDAI criteria were not also selected by ASDAS criteria. Using ASDAS increased the number of patients eligible for TNFi therapy. Patients who fulfill both BASDAI and ASDAS criteria had the best responses using a set of response measures, but additional patients identified by ASDAS had reasonable responses to TNFi.

2533

Obesity and the Risk of Psoriatic Arthritis in the General Population. Yanyan Zhu[1], Hyon K. Choi[1], Yuqing Zhang[1], Lindsay Wall-Burns[2], Alexis Ogdie[3], Joel Gelfand[4] and Thorvardur Love[5]. [1]Boston University School of Medicine, Boston, MA, [2]Arthritis Research Centre of Canada, Vancouver, BC, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania., Philadelphia, PA, [5]Landspitali University Hospital, Reykjavík, Iceland

Background/Purpose: Psoriatic arthritis (PsA) is a progressive and often destructive joint disease associated with psoriasis (Ps). Although PsA represents a lifelong burden for affected patients, its risk factors are poorly understood. Excess weight has been shown to increase the risk of Ps; however, its impact on the risk of PsA remains unclear. To address this issue, we examined the association between adiposity and the risk of incident PsA among Ps patients from the general population.

Methods: We conducted a cohort study using data from The Health Improvement Network (THIN), an electronic medical records database of the UK general population, collected between 1995 and 2010. Our primary study population consisted of individuals with physician-diagnosed Ps who were aged ≥20 years, had ≥2 years of enrollment in the general practice before entering the study cohort, and did not have a history of PsA. (Validity of the THIN code for Ps has been documented with a positive predictive value (PPV) of 90%.) Our end-points were incident cases of physician-diagnosed PsA. Our exposure of interest was the first body mass index (BMI) measured after Ps diagnosis, which we categorized into 4 levels: <25, 25–29.9, 30–34.9 and ≥35 kg/m^2. Individuals were followed from the time of first BMI measurement after Ps diagnosis until PsA incidence, death, discontinuation of enrollment, or the end of study period, whichever came first. We used Cox proportional hazard model to estimate the hazard ratios (HRs) of PsA after adjusting for potential confounders (i.e. age, sex, and histories of trauma, smoking, and alcohol consumption prior to BMI measurement). In our secondary analysis, we investigated the same association in the entire population, regardless of Ps status.

Results: Among 75,395 individuals with Ps (43% male, mean follow-up of 5 years, and mean age of 52 years), 976 developed PsA. The overall PsA incidence rate was 26.5 cases per 10,000 person-years. The PsA incidence rates increased with increasing BMIs. Compared to individuals with BMIs <25 kg/m^2, the adjusted hazard ratios (HR) were 1.09, 1.22, and 1.48 for BMIs of 25–29.9, 30–34.9, and ≥35 kg/m^2, respectively (p for trend <0.001, **Table**). In our secondary analysis among all individuals, regardless of psoriasis (~2 million), the corresponding multivariate HRs tended to be stronger (1.0, 1.17, 1.58, 1.97; p for trend <0.001); further adjustment of the history of psoriasis in this secondary analysis modestly attenuated the association (1.0, 1.12, 1.46, 1.75; p for trend <0.001).

BMI and the Risk of Incident PsA Among Ps Patents

BMI (kg/m^2)	Number of Incident PsA	Incidence Rate (cases/10,000 person-years)	Adjusted HR (95% CI)
<25	**300**	**23.09**	**1.0 (Reference)**
25–29.9	**341**	**25.37**	1.09 (0.93, 1.28)
30–34.9	**197**	**29.33**	**1.22 (1.02, 1.47)**
≥35	**138**	**38.04**	**1.48 (1.21, 1.82)**
P for Trend	**–**	**<0.001**	**<0.001**

Conclusion: This general population study provides the first large-scale epidemiologic evidence that higher obesity among Ps patients contributes to an increased risk of incident PsA. These findings add substantially to the importance of weight reduction among Ps patients, who often suffer from the metabolic syndrome and obesity.

2534

Frequency and Duration of Drug-Free Remission After One Year of Treatment with Etanercept Vs. Sulfasalazine in Early Axial Spondyloarthritis – 2 Year Data of the ESTHER Trial. In-Ho Song[1], Kay-Geert Hermann[2], Hildrun Haibel[1], Christian Althoff[2], Denis Poddubnyy[1], Joachim Listing[3], Anja Weiβ[3], Bruce Freundlich[4], Martin Rudwaleit[5] and Joachim Sieper[1]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Charite Medical School, Berlin, Germany, [3]German Rheumatism Research Centre, Berlin, Germany, [4]University of Pennsylvania, Philadelphia, PA, [5]Ev. Krankenhaus Hagen-Haspe, Hagen, Germany

Background/Purpose: In patients with early axial spondyloarthritis (SpA) with a disease duration of < 5 years and with active inflammation on magnetic resonance imaging (MRI) in the spine and/or sacroiliac joints (SIJ) on baseline who were treated with etanercept (ETA, n= 40) vs. sulfasalazine (SSZ, n= 36) for 48 weeks [1] to assess: a) the frequency and duration of drug-free remission and b) the efficacy of ETA after flare, and c) long-term response of ETA during year 2 in already ETA-treated patients (ETA treatment in year 1 and year 2).

Methods: At week 48, patients who reached study remission (defined as reaching ASAS remission and being free of active inflammation on whole-body-MRI in the spine and sacroiliac joints) were followed every 6 weeks without active treatment. In case of a flare (defined as a BASDAI increase of 2 points compared to week 48) all patients were (re-)treated with ETA for another year up to week 108. Patients who were in study remission at week 48 and who did not flare were excluded from the study at the end of year 2 (permanent drug-free remission). All patients who were not in study remission at week 48 were treated with ETA in year 2.

Results: Study remission at week 48 was reached significantly more often by ETA- compared to SSZ-treated patients (13/40= 33% vs. 4/36= 11%, p= 0.03). Among patients reaching study remission (n= 17) 70% belonged to the non-radiographic axial SpA group and 30% to the AS group. 23% (9/40) of the ETA-group flared after a mean of 24.4 weeks and 8% (3/36) of the SSZ-group flared after 39.6 weeks (no significant difference for time to flare between both groups).Thus, 8% (3/40) of ETA-treated patients vs. 3% (1/36) of SSZ-treated patients reached drug-free remission. After initiation of ETA during year 2, flare-patients (n= 9) showed a significant (p< 0.001) response to ETA-treatment (table 1): 56% of flare-patients reached ASAS remission and 44% study remission as well as ASDAS inactive disease at week 108.

Formerly ETA-treated patients (n= 22) who did not reach study remission at week 48 showed a good sustained clinical and MRI response at week 108 (50% ASAS remission; 5 additional patients reached ASAS remission at week 108 who were not in remission at week 48; table 1).

Table 1.

Parameter (mean and standard deviation)	Study time point	Remission-Flare Group ETA year 1-ETA year 2 (n= 9)	Remission-Flare Group SSZ year 1-ETA year 2 (n= 3)	Non-Remission-Group ETA year 1-ETA year 2 (n= 22)	Non-Remission-Group SSZ year 1-ETA year 2 (n= 26)
BASDAI	Baseline	5.7 (1.8)	5.9 (1.6)	5.4 (1.1)	5.9 (1.2)
BASDAI	Week 48	1.1 (0.6)	2.0 (1.0)	2.6 (1.7)	4.7 (2.3)
BASDAI	Flare time point	5.0 (1.5)	4.5 (0.4)	Not applicable	Not applicable
BASDAI	Week 108	1.5 (1.4)	1.7 (1.6)	2.7 (2.3)	3.2 (2.6)
MRI SIJ	Baseline	12.0 (6.4)	3.2 (3.9)	8.6 (7.3)	6.5 (5.8)
MRI SIJ	Week 48	1.1 (1.4)	0 (0)	2.4 (3.3)	2.7 (3.2)
MRI SIJ	Week 108	0.4 (0.5)	0 (0)	2.9 (3.7)	1.6 (2.0)
MRI Spine	Baseline	0.2 (0.7)	0.7 (1.2)	3.4 (5.6)	1.3 (2.5)
MRI Spine	Week 48	0 (0)	0 (0)	1.3 (1.9)	1.0 (1.9)
MRI Spine	Week 108	0 (0)	0.3 (0.6)	1.0 (1.7)	0.7 (1.6)
ASAS remission, % (n)	Week 108	56% (5/9)	67% (2/3)	50% (11/22)	23.1% (6/26)
MRI remission, % (n)	Week 108	56% (5/9)	67% (2/3)	13.6% (3/22)	26.1% (6/23)
Study remission, % (n)	Week 108	44% (4/9)	33% (1/3)	14% (3/22)	8% (2/26)
ASDAS inactive disease (<1.3)	Week 108	44% (4/9)	66.7% (2/3)	38.1% (8/21)	28.0% (7/25)

Conclusion: After one year of treatment with ETA 33% of patients with early axial SpA reached study remission, however 23% flared within 24 weeks while only 8% stayed in drug-free remission. Patients treated with ETA for 2 years showed continuously low disease activity with further improvement in a subgroup of patients.

Transforming Growth Factor Beta Mediated Activation of Canonical Wnt Signaling Is Crucial for the Development of Fibrosis In Systemic Sclerosis. Alfiya Akhmetshina[1], Katrin Palumbo[2], Christina Bergmann[2], Paulius Venalis[2], Clara Dees[2], Pawel Zerr[2], Angelika Horn[2], Christian Beyer[3], Jochen Zwerina[2], Ormond A. MacDougald[4], Oliver Distler[5], Georg Schett[2] and Jorg HW Distler[2]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Department of Pediatrics, University of Erlangen-Nuremberg, Erlangen, Germany, [5]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Wnt signaling profoundly affects developmental processes and plays an important role for tissue homeostasis. Aberrant activation of the canonical Wnt pathway has been implicated in a variety of different diseases. To avoid uncontrolled activation, Wnt signaling is tightly controlled by negative regulators such as dickkopf-1 (Dkk-1). Here, we investigated the interaction between TGFβ dependent pathways and canonical Wnt signaling as a novel molecular mechanism in SSc.

Methods: Canonical Wnt signaling was modulated in vivo using Wnt10b- and Dickkopf (Dkk)-1 transgenic mice. The role of Wnt signaling was investigated in the mouse model of bleomycin-induced dermal fibrosis, in tight-skin-1 (Tsk-1) mice and in mice overexpressing constitutively active TGFβ receptor type I.

Results: Canonical Wnt signaling is activated in SSc and in experimental fibrosis with nuclear accumulation of β-catenin and increased expression of the target gene axin-2. We demonstrate that the activation of canonical Wnt signaling in SSc is mediated by TGFβ. TGFβ decreases the mRNA and protein levels of Dkk-1, a potent inhibitor of Wnt signaling, in a p38 dependent, Smad-independent manner by more than 80%. Indeed, the expression of Dkk-1 is almost undetectable in the skin of SSc patients and in different models of experimental models of fibrosis. Stimulation with TGF-β or overexpression of constitutively active TGFβ receptor type I potently activated canonical Wnt signaling in vitro and in vivo with nuclear accumulation of β-catenin, increased TOP-reporter activity and induction of axin-2. In contrast, inhibition of TGFβ-signaling in experimental models of fibrosis by SD-208, a selective inhibitor of TGFβ receptor kinase activity, almost completely prevented the activation of canonical Wnt-signaling, highlighting the key-role of TGFβ for the activation of Wnt signaling in fibrosis. We also show that the activation of Wnt signaling directly contributes to the profibrotic effects of TGFβ. Canonical Wnt signaling stimulates the release of collagen in vitro and induces massive fibrosis in vivo. Recombinant Dkk-1 strongly reduced the stimulatory effects of TGFβ on cultured fibroblasts and decreased the TGFβ-induced upregulation of collagen, αSMA and stress fibers by up to 75%. Moreover, transgenic overexpression of Dkk-1 amelio-

rates fibrosis in mice induced by adenoviral transfection of constitutively active TGF receptor type I with reduction of dermal thickening, myofibroblast counts and hydroxyproline content by 75 ± 7%, 85 ± 5% and 80 ± 11% respectively ($p < 0.02$ for all). Overexpression of Dkk-1 also exerted potent anti-fibrotic effects in bleomycin induced dermal fibrosis and in Tsk-1 mice.

Conclusion: Canonical Wnt pathway is activated in SSc and potently stimulates fibroblast activation and tissue fibrosis. TGFβ activates canonical Wnt signaling in SSc by decreasing the expression of the Wnt inhibitor Dkk-1. Overexpression of Dkk-1 potently reduces the pro-fibrotic effects of TGFβ and prevents fibrosis in different experimental models, demonstrating that the interaction of the canonical Wnt pathway and TGF-β plays a key role in the pathogenesis of fibrotic diseases.

Anti-Fibrotic Effects of Microrna-145 in Systemic Sclerosis Via a Multi-Step Regulation of TGF-Beta/CTGF Signaling. Serena Vettori[1], Matthias Brock[1], Naoki Iwamoto[1], Britta Maurer[1], Astrid Jungel[1], Renate E. Gay[1], Maurizio Calcagni[2], Gabriele Valentini[3], Jorg HW Distler[4], Steffen Gay[1] and Oliver Distler[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Division of Plastic Surgery and Hand Surgery, Zurich University Hospital, Zurich, Switzerland, [3]Rheumatology Unit, Second University of Napoli, Napoli, Italy, [4]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Since hyperactivity of TGF-β/CTGF signaling is a leading cause of tissue fibrosis, we explored the expression and function of microRNAs (miR) regulating the TGF-β/CTGF pathway in systemic sclerosis (SSc).

Methods: Pooled SSc and healthy control (HC) fibroblasts (n=3) were used to screen the expression of 377 miRs by low-density array. Basal miR-145 and pri-miR-145 expression was analyzed in individual SSc ($n = 12$) and HC ($n = 6$) dermis and fibroblasts. Expression of miR-145 targets, COL1A1 and COL3A1 was analyzed under over-expression or silencing of miR-145 by pre/anti-miR-145 in SSc and HC fibroblasts, respectively, at both RNA and protein level by Real time PCR and Western blotting. A luciferase-based reporter gene system (pmirGLO vector) containing the 3′UTR of TGFBR2, was used to examine the direct interaction with miR-145.

Results: The low-density array displayed 26 down-regulated and 5 up-regulated miRs in SSc fibroblasts. Among these, miR-145 was analyzed further and confirmed to be down-regulated in both SSc dermis and fibroblasts by 45 and 51% respectively ($p < 0.001$). Similar results were obtained for the non-functional primary transcript, pri-miR-145, suggesting a regulation on the transcriptional level rather than post-transcriptional modifications. No significant difference in the expression of miR-145 was found between SSc fibroblasts and untreated controls exposed to hypoxia or pro-fibrotic cytokines (TGF-β, PDGF-B, and VEGF-A). However, down-regulation of miR-145 in SSc was mediated by epigenetic modifications, as inhibition of DNA methyltransferases by 5aza-C increased miR-145 levels by 25% in SSc fibroblasts. In silico analysis predicted multiple molecules of the TGF-β pathway as miR-145 targets including TGFB2, TGFB3, TGFBR2, SMAD3 as well as CTGF. Transfection of SSc fibroblasts with pre-miR-145 confirmed this analysis by decreasing TGFBR2 ($p < 0.001$), SMAD3 ($p < 0.01$) and CTGF ($p < 0.001$) mRNA by 53 to 66%. COL1A1 and COL3A1 mRNA were also reduced to a similar extent ($p < 0.01$). Consistent results were obtained at the protein level for TGF-βRII, Smad3 and collagen types I and III ($p < 0.05$). In addition, active Smad3 (P-Smad3) was also reduced ($p < 0.001$). Transfection of HC fibroblasts with anti-miR-145 further confirmed these findings by mimicking the SSc expression profile with increased expression of TGF-β signalling molecules at the mRNA level. Co-transfection of HEK293 cells with pmirGLO-TGFBR2 3′UTR construct and pre-miR145 reduced the luciferase gene activity by 34% ($p < 0.05$) suggesting a direct regulation by miR-145.

Conclusion: Our findings provide the first evidence for anti-fibrotic effects of miR-145 via direct post-transcriptional repression of TGF-β signaling (TGFBR2 and SMAD3) and CTGF. Our data indicate that the down-regulation of miR-145 in SSc appears independent from major pro-fibrotic stimuli, and thus targeting these stimuli in therapeutic approaches would not correct the effects of miR-145. Because miR-145 was consistently down-regulated in SSc, elevation of miR-145 could be an appropriate approach to treat SSc.

TLR4 Activation Enhances Fibrotic Responses Induced by TGF-β: A Mechanism for Maintaining and Amplifying Fibrosis in Scleroderma. Swati Bhattacharyya[1], Kathleen Kelly[2], Denisa S. Melichian[2], Kohtaro Ooka[3], Carol A. Feghali-Bostwick[4], Robert A. Lafyatis[5], Timothy RD Radstake[6] and John Varga[1]. [1]Northwestern Univ Med School, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Northwestern University, [4]University of Pittsburgh, Pittsburgh, PA, [5]E5 Arthritis Ctr-BUSM, Boston, MA, [6]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Fibrosis in scleroderma involves early inflammation and TGF-β production production, followed by sustained fibroblast activation and myofibroblast differentiation. Recent studies indicate a potential role for TLR4-mediated innate immune signaling, triggered by endogenous damage associated molecular patterns generated through tissue injury, in fibroblast activation. We sought to investigate the role and mechanism of TLR4-mediated fibroblast activation in fibrosis.

Methods: The expression of TLR4 and endogenous TLR4 ligands were investigated in scleroderma biopsies, and in a mouse model of fibrosis. The profibrotic effects of the TLR4 ligand LPS and constitutively active TLR4 were examined in skin fibroblasts. The role of TLR4 in fibrosis in vivo was investigated using C3H/HeJ mice with mutated TLR4.

Results: TLR4 was significantly elevated in scleroderma skin and lung biopsies. TLR4 expression was also markedly up-regulated in a bleomycin-induced mouse model of scleroderma. Overexpression of constitutively active TLR4 in fibroblasts dramatically enhanced sensitivity to TGF-β-induced collagen stimulation and myofibroblast differentiation. Similar effects were triggered by the TLR4 ligand LPS. These stimulatory responses were abrogated by specific pharmacological inhibitors of intracellular and extracellular domain of TLR4. Moreover, TLR4-null mouse skin fibroblasts were resistant to TLR4 ligand-mediated synergistic induction of TGF-β responses. TLR4 stimulation resulted in activation of canonical Smad signaling with increased cellular pSmad2/3 level and Smad-dependent transcriptional activity. The levels of the TGF-β pseudoreceptor BAMBI were significantly down-regulated by LPS via a TLR4-mediated pathway. Moreover, all the isotypes of the anti-fibrotic microRNA 29 were suppressed in a time-dependent (or dose dependent) manner with LPS treatment. In this model of scleroderma, TLR4 mutant C3H/HeJ mice showed increased early inflammation, but attenuation of skin and lung fibrosis.

Conclusion: Activation of the TLR4 signaling pathway induces profibrotic responses in normal fibroblasts, and sensitizes these cells to TGF-β. TLR4 signaling appears to be implicated in skin and lung fibrosis in scleroderma. These results lead us to propose a novel model for fibrogenesis in which TLR4 activation by damage-associated endogeous TLR4 ligands contributes to the progression of fibrosis.

Tribbles Homolog 3 Mediates Transforming Growth Factor Beta Driven Dermal Fibrosis In Systemic Sclerosis. Michal Tomcik[1], Katrin Palumbo[2], Jérôme Avouac[3], Angelika Horn[2], Aisa Khodzhigorova[2], Pawel Zerr[2], Clara Dees[2], Alfiya Akhmetshina[4], Christian Beyer[5], Radim Becvar[1], Ladislav Senolt[6], Oliver Distler[7], Georg Schett[2] and Jorg HW Distler[2]. [1]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [4]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [5]University of Erlangen-Nuremberg, Erlangen, Germany, [6]Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [7]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Tribbles Homolog 3 (TRB-3), is a member of a family of pseudokinases called Tribbles which regulate activation of a number of intracellular signaling pathways with roles extending from mitosis and cell activation to apoptosis and modulation of gene expression. The aim of this study was to investigate the role of TRB-3 in the pathologic activation of fibroblasts in systemic sclerosis (SSc).

Methods: Activation of TRB-3 in the skin and dermal fibroblasts was determined by real-time PCR, immunohistochemistry and immunofluores-

cence. Collagen synthesis of human dermal fibroblasts was quantified by real-time PCR and SirCol collagen assay. The expression of TRB3 was inhibited in cultured fibroblasts and in murine models of fibrosis with siRNA. The mouse models of bleomycin-induced dermal fibrosis and dermal fibrosis induced by attenuated adenovirus overexpressing a constitutively active TGF-β receptor I were used to investigate the role of TRB3 in fibrosis.

Results: Increased expression of TRB-3 was detected in the upper layer of the dermis of SSc patients. The overexpression of TRB-3 persisted in cultured SSc fibroblasts (4.1$\pm$0.4-fold increase, $p<0.001$). A similar increase in TRB-3 expression was observed in the skin samples from both murine models of experimental dermal fibrosis, both on mRNA and protein level. The upregulation of TRB3 was mediated by TGF-β. Stimulation of cultured fibroblasts with TGF-β increased expression of TRB-3 protein by 4.5$\pm$0.2-fold ($p<0.001$). Knockdown of TRB-3 by siRNA abrogated the stimulatory effects of TGF-β on fibroblasts and completely prevented the stimulatory effects of TGF-β on the release of collagen and the formation of stress fibers. Moreover, mice lacking TRB-3 were protected from experimental fibrosis. In the model of bleomycin-induced dermal fibrosis, siRNA mediated knockdown of TRB-3 decreased dermal thickening by 50$\pm$1% ($p<0.05$), the hydroxyproline content by 76$\pm$5% ($p<0.01$) and the myofibroblast counts by 86$\pm$10% ($p<0.05$). In the model of dermal fibrosis induced by adenoviral overexpression of constitutively active TGF-β receptor I, knockdown of TRB-3 decreased dermal thickening by 91$\pm$6% ($p<0.05$), completely prevented the accumulation of hydroxyproline ($p<0.01$) and decreased the myofibroblast counts by 82$\pm$7% ($p<0.05$). Consistent with the crucial role of TRB-3 for TGF-β signaling in vitro, knockdown of TRB-3 abrogated the nuclear accumulation of phosphorylated Smad-3 and prevented the induction of TGF-β target genes such as Smad-7 and CTGF in both mouse models.

Conclusion: We demonstrate for the first time a key-role of TRB-3 in fibroblast activation and tissue fibrosis in SSc. TRB-3 is upregulated in SSc and in experimental fibrosis in a TGF-β dependent manner. TRB-3 is essential for the pro-fibrotic effects of TGF-β and targeting of TRB-3 completely prevents the stimulatory effect of TGF-β on cultured fibroblasts. Moreover, knockdown of TRB-3 protected from experimental dermal fibrosis in different mouse models. Considering the potent anti-fibrotic effects observed in this study, TRB-3 might be a promising candidate for molecular targeted therapies of SSc.

Inhibition of Glycogen Synthase Kinase 3β Induces Dermal Fibrosis by Activation of the Canonical Wnt Pathway. Christina Bergmann[1], Alfiya Akhmetshina[2], Clara Dees[1], Katrin Palumbo[1], Pawel Zerr[1], Christian Beyer[3], Jochen Zwerina[1], Oliver Distler[4], Georg Schett[1] and Jorg HW Distler[1]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Wnt signaling plays a critical role in embryogenesis and in adult tissue homeostasis. The abnormal activation of Wnt signaling is associated with a wide range of diseases and might also play a role in SSc. Glykogen Synthase Kinase 3β (GSK-3) is a crucial regulator of the canonical Wnt signaling. In the absence of Wnt proteins, GSK-3 promotes the phosphorylation and subsequent degradation of β-catenin. Thus, the aberrant activation of the canonical Wnt pathway is prevented. However, in the presence of Wnt, GSK-3 becomes inactive and β-catenin is not degraded but stimulates the transcription of Wnt target genes. The aim of the present study was to define the role of GSK-3 as a central regulator of canonical Wnt signaling for fibroblast activation and in experimental models of SSc.

Methods: We used siRNA and two specific inhibitors, SB216763 and AR-A014418, to inhibit GSK-3 in cultured fibroblasts and in mice. The activation of the canonical Wnt signaling was analyzed by determining the levels of nuclear β-catenin and by measuring the mRNA levels of the Wnt target gene Axin2. The effects of GSK-3 on the release of collagen were evaluated in human dermal fibroblasts, in the mouse model of bleomycin induced dermal fibrosis and in the tight-skin-1 (tsk-1) mice. To investigate whether inhibition of GSK-3 alone is sufficient to induce fibrosis, SB216763 was applied to mice without additional profibrotic stimuli.

Results: Targeting GSK-3 potently activated the canonical Wnt pathway in fibroblasts *in vitro* and *in vivo* with a prominent accumulation of nuclear β-catenin and induction of Axin2. Incubation with inhibitors of GSK-3 dose-dependently upregulated the expression of col1a1 from cultured fibroblasts by up to 2.6 fold ($p<0.05$) and increased the release of collagen protein. Similar results were also obtained upon knockdown of GSK-3 with siRNA. The increased release of collagen was completely abolished by siRNA mediated knockdown of β-catenin suggesting that the pro-fibrotic effects of inhibition of GSK-3 are mediated by the canonical Wnt pathway. In vivo, inactivation of GSK-3 exacerbated bleomycin induced dermal fibrosis with increased dermal thickening by 84$\pm$15%($p<0.05$) compared to bleomycin treatment alone. Inactivation of GSK-3 also aggravated the tsk-1 phenotype. Moreover, inhibition of GSK-3 was sufficient to induce progressive dermal fibrosis in mice with increases in dermal thickening by up to 65$\pm$9% within 8 weeks ($p<0.05$).

Conclusion: We demonstrated that GSK-3 is a crucial regulator of the canonical Wnt pathway in dermal fibroblasts. Inhibition of GSK-3 stimulates the release of collagen from dermal fibroblasts in a β-catenin dependant manner and aggravates experimental fibrosis in different mouse models. Of note, inhibition of GSK-3 alone was sufficient to induce dermal fibrosis. These results highlight the key-role of canonical Wnt signaling in fibrosis and underline the importance of proper control of the canonical Wnt pathway.

The Nuclear Receptor CAR Mediates the Pro-Fibrotic Effects of TGF-β and Contributes to the Development of Experimental Dermal Fibrosis. Jerome Avouac[1], Michal Tomcik[2], Katrin Palumbo[1], Pawel Zerr[1], Clara Dees[1], Alfiya Akhmetshina[1], Christian Beyer[1], Oliver Distler[3], Georg Schett[1], Yannick Allanore[4] and Jorg HW Distler[1]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [3]University Hospital Zurich, Zurich, Switzerland, [4]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France

Background/Purpose: Tissue fibrosis caused by pathological activation of fibroblasts is a major hallmark of systemic sclerosis (SSc). The constitutive androstane receptor (CAR), a member of the nuclear receptor superfamily, is involved in shear and xenobiotic stress. CAR regulates target genes involved in drug metabolism, such as cytochrome P450 family members. CAR activation has also recently been shown to exacerbate hepatic fibrosis. We aim in the present study to investigate whether CAR might contribute to the pathologic activation of fibroblasts in SSc and to the development of experimental dermal fibrosis.

Methods: Expression of CAR was determined in human skin by immunohistochemistry and in fibroblasts by real time PCR and western blots. SSc and healthy dermal fibroblasts were stimulated with TGFβ and incubated with CITCO, a potent and selective agonist for the human CAR. Collagen release from fibroblasts was evaluated by mRNA levels of col1a1 and col1a2 and by the SirCol collagen assay. Col1a2 transcriptional activity was assessed by transfection assays performed with a luciferase reporter construct under control of the -772-bp to +58-bp col1a2 promoter. The synthetic agonist of mouse CAR TCPOBOP was used to evaluate the profibrotic potential of CAR *in vivo* in the mouse model of bleomycin induced dermal fibrosis or in the model of dermal fibrosis induced by local injections of replication deficient adenoviruses overexpressing a constitutively active TGF-β receptor I.

Results: Upregulation of CAR was detected in the skin and dermal fibroblasts of SSc patients. Stimulation of healthy fibroblasts with TGFβ increased the expression of CAR mRNA by 93$\pm$11% and protein by 81$\pm$14% ($p<0.05$ for both). Treatment of healthy or SSc fibroblasts with CITCO significantly increased the stimulatory effects of TGF-β on collagen synthesis. CITCO also amplified the stimulatory effects of TGF-β on col1a2 transcriptional activity by up to 41$\pm$5% ($p=0.03$). Consistently, activation of CAR with TCPOBOP exerted potent profibrotic effects in different models of experimental fibrosis. In the mouse model of bleomycin-induced fibrosis, activation of CAR increased dermal thickening by 35$\pm$1% ($p<0.05$). In addition, the collagen content and the number of myofibroblasts were significantly increased (respectively 42$\pm$3% and 69$\pm$11%, $p<0.05$). In the TGFβRI model, activation of CAR also exerted potent profibrotic effects and increased dermal thickening, collagen content and myofibroblast counts by 51$\pm$5%, 46$\pm$7% and 42$\pm$3%, respectively ($p<0.05$).

Conclusion: We demonstrate that CAR is activated in a TGFβ dependent manner in SSc and mediates the effects of TGF-β on collagen synthesis. In addition, activation of CAR contributed to the development of dermal fibrosis in different mouse models of SSc. Thus, CAR might be a promising new molecular target for the treatment of SSc and other fibrotic processes.

Does Medication Adherence Itself Confer Fracture Protection? An Investigation of the Healthy Adherer Effect In Observational Data. Jeffery R. Curtis[1], Jeff Lange[2], Huifeng Yun[1] and Elizabeth S. Delzell[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Proctor and Gambel

Background/Purpose: Prior studies have shown a relationship between bisphosphonate (BP) adherence and reduced fractures. One potential concern about the interpretation of this association is the healthy adherer effect, a phenomenon whereby patients who adhere to medications are systematically different than those who do not. The extent to which fracture-adherence analyses might be confounded by the healthy adherer effect in real-world settings is unclear.

Objectives: To quantify the association between high adherence with different medications and fracture risk.

Methods: Using MedstatMarketScan from 2000 to 2008, we identified 125,000 women with a new clinical fracture at the hip, spine, humerus, or wrist. We defined three mutually-exclusive cohorts of patients who initiated within 6 months post-fracture: 1) oral BPs; 2) selective serotonin reuptake inhibitors (SSRI), or 3) ace inhibitor, angiotensin receptor blocker, or calcium channel blocker (ACE/ARB/CCB). These medications were chosen for their expected favorable, unfavorable, and neutral effect on fracture risk. Adherence (medication possession ratio [MPR]) was assessed after 1 year of new use, updated every 90 days. Follow-up time for new fractures began after the MPR measurement and extended up to 4 years. Patients were categorized as highly adherent (MPR>=80%) vs. less adherent (MPR<50%). Cox proportional hazards models evaluated the association between high (vs. low) adherence within each medication group and fracture.

Results: We identified a BP cohort (11,712 patients, mean age=75), SSRI cohort (5,570 patients, mean age=76), and ACE/ARB/CCB cohort (5,731 patients, mean age=77) who initiated these therapies <=6 months after fracture. For these 3 cohorts, 46%, 43%, and 53%, respectively, had MPR >=80% at 12 months.

Crude hazard ratios for hip and non-vertebral fractures (Table) showed that high adherence (vs. lower adherence) with BPs decreased fracture risk; high adherence with SSRIs increased hip fracture risk, and high adherence with ACE/ARB/CCBs was neutral toward fracture risk.

Table. Relationship between High (vs. Lower) Adherence to Bisphosphonates, SSRIs, and ACEI/ARB/CCBs

	Bisphosphonates		SSRIs		ACEI/ARB/CCB	
Fracture Type	N, rate per 100py	HR (95% CI)	N, rate per 100py	HR (95% CI)	N, rate per 100py	HR (95% CI)
Hip, adherent	48, 0.5	0.56	47, 1.4	1.42	288, 1.2	1.15
Hip, non-adherent	84, 1.0	0.39–0.80	40, 1.0	0.93–2.17	187, 1.0	0.74–1.77
Nonvertebral, adherent	495, 5.6	0.76	226, 6.7	1.01	54, 6.3	1.05
Nonvertebral, non-adherent	635, 7.3	0.68–0.86	271, 6.6	0.85–1.20	32, 6.0	0.87–1.26

Conclusion: In this observational analysis of women enrolled in a commercial health plan, we did not find evidence of a healthy adherer effect that suggested that medication adherence itself conferred fracture benefit. Based upon this result, observational analyses evaluating the association between osteoporosis medication adherence and fracture risk appear to not be meaningfully confounded by the healthy adherer effect.

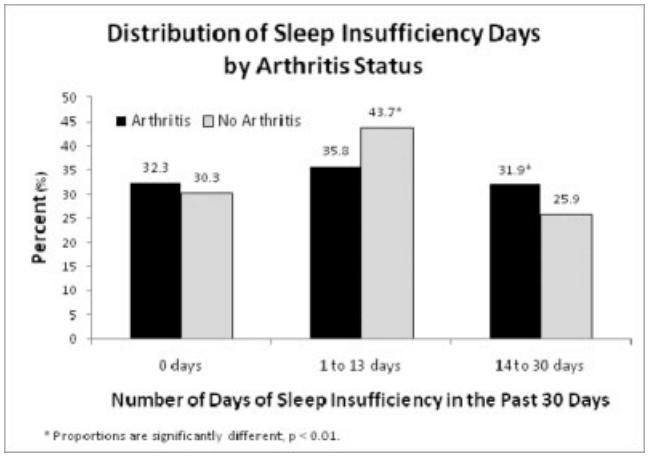
2542

Physical Activity and Frequent Sleep Insufficiency Among US Adults with Arthritis. Jennifer M. Hootman[1], Dianna Carroll[2], Lela McKnight-Eily[2] and Kelli D. Allen[3]. [1]Centers for Disease Control and Prevention, Kennesaw, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]Duke and Durham VA Medical Center, Durham, NC

Background/Purpose: Sleep problems occur in 30–80% of adults with arthritis. Physical activity may be a non-pharmaceutical approach to improving sleep. The purpose of this study was to assess the prevalence of sleep insufficiency and its association with physical activity (PA) level among adults with self-reported doctor-diagnosed arthritis (ARTH).

Methods: Using the 2009 Behavioral Risk Factor Surveillance System (BRFSS, n=424,592; n=153,914 with ARTH) we calculated moderate-intensity-equivalent minutes/week (2*vigorous min/wk + moderate min/wk) of self-reported PA for each respondent. Three PA levels were defined as: Active (ACT) (≥150 min/wk), insufficiently active (INSUF) (>10 – 149 min/wk), and inactive (INACT) (no PA for at least 10 min/wk). Frequent sleep insufficiency (FSI) was defined as reporting not getting enough sleep or rest for 14 or more days in the past 30. Weighted prevalence estimates (%) and 95% confidence intervals (CI) were calculated accounting for the complex sample design. Multivariable logistic regression models (adjusted odds ratios, AOR) were used to assess the association between PA level (INACT = referent) and FSI among adults with ARTH.

Results: Among adults with arthritis, 32% reported 0 days, 36% 1–13 days, and 32% 14+ days (adults without arthritis 30%, 44%, and 26% respectively). [FIGURE] The prevalence of FSI was significantly higher (p<0.0001) among adults with ARTH (31.9%, CI 31.5–32.4) compared to adults without ARTH (25.9%, CI 25.6–26.3). Among adults with arthritis, FSI prevalence decreased as PA level increased (39.4% INACT, 31.1% INSUF, 29.9% ACT, p<0.0001). Compared to INACT, INSUF (crude OR=0.71, CI 0.67–0.75) and ACT (crude OR=0.75, CI 0.71–0.80) PA levels were associated with lower odds of FSI. These adjusted associations remained statistically significant (INSUF AOR=0.89, CI 0.84–0.95; ACT AOR=0.83, CI 0.77–0.89) after adjustment for demographic variables (age, sex, race/ethnicity, education), health status variables (body mass index, self-rated health, arthritis-attributable activity limitation, joint pain) and co-morbid conditions (diabetes, hypertension, heart disease, asthma, frequent mental distress).



Conclusion: 1 in 3 adults with ARTH report FSI. Adults with ARTH meeting ACT levels of PA were 17% less likely to report FSI than INACT, suggesting physical activity may be a promising strategy to decrease FSI in this population. These findings need to be verified in prospective studies.

2543

Severe Foot Pain, but Not Milder Foot Pain, Is Linked to Falls in Older Men and Women: The Framingham Study. Alyssa B. Dufour[1], Virginia A. Casey[2], Thomas J. Hagedorn[2], Jody L. Riskowski[2] and Marian T. Hannan[3]. [1]Hebrew SeniorLife & Boston Univ, Boston, MA, [2]Hebrew SeniorLife, Boston, MA, [3]Hebrew SeniorLife & Harvard Med Sch, Boston, MA

Background/Purpose: Studies suggest that chronic pain is a risk factor for falls, but less is known about the effects of site-specific pain on the risk of falls. As foot pain is common and potentially affects physical function, the purpose of this study was to examine the association between severity of foot pain and falls in older adults.

Methods: Between 2002 and 2008, a validated examination was used to collect information on foot pain in Framingham Study Offspring cohort and Original cohort members. 2372 subjects who had information on foot pain and falls were included in this analysis. Foot pain (y/n) was queried: "on most days, do you have pain, aching or stiffness in either foot?" Foot pain severity was recorded as: no foot pain (referent), mild pain, moderate pain or severe pain. Subjects were asked if they had accidentally fallen

and hit the floor or ground in the past year (y/n). If a fall had occurred, the number of times they had fallen in the past year was queried. If 2 or more falls were reported, the participant was categorized as a recurrent faller (y/n). Information on falls was obtained from the Framingham exam within 1 year of the foot examination. For those missing falls information within 1 year, data from the most recent, previous or subsequent exam was used. Age (years) and body mass index (BMI, kg/m^2; categorized <25, 25–30, 30–35, 35+) were also collected. Logistic regression was used to calculate odds ratios and 95% confidence intervals for the association between falls (y/n) or recurrent falls (y/n) and foot pain (y/n or severity), adjusting for age, BMI categories, and cohort origin (Framingham offspring and original cohort).

Results: In the 2372 participants (1042 men; 1330 women), mean age was 68 yrs (± SD of 11) and mean BMI was 28 kg/m^2 (± SD of 5). Of the 522 participants reporting foot pain, 16% reported severe pain, 44% reported moderate pain and 40% reported mild pain. 20% of subjects reported falling in the past year, with 6% of fallers reporting recurrent falls. Foot pain (yes/no) was not associated with falls (y/n) or with recurrent falls, but foot pain severity revealed significant associations (Table). Severe foot pain vs. no pain was associated with a 2-fold increased risk of falls (p=.02) and 3-fold increased risk of recurrent falls (p=.001), even after adjustment for covariates. Moderate vs. no foot pain showed an increased risk of both falls and recurrent falls, although not statistically significant, with odds ratios of 1.3 (p=.18) and 1.5 (p=.14), respectively. Subjects reporting mild foot pain had no reported difference in falls from those with no foot pain.

Table. Odds ratios and 95% confidence intervals for the association between foot pain and falls, adjusting for age, BMI and cohort.

	n (%)	Fallen in past year	Recurrent faller (2+)
Foot pain (y/n)	522 (22)	1.11 (0.87, 1.42)	1.42 (0.97, 2.10)
Severity			
No foot pain	1850 (78)	1.0	1.0
Mild foot pain	208 (9)	0.88 (0.60, 1.30)	0.81 (0.40, 1.63)
Moderate foot pain	234 (10)	1.25 (0.90, 1.74)	1.48 (0.88, 2.47)
Severe foot pain	80 (3)	1.78 (1.09, 2.93)	2.94 (1.53, 5.68)

Conclusion: Foot pain alone does not contribute to falls in older people, but severe foot pain increases the odds of falling. Older men and women with foot pain should seek medical treatment early on, in order to prevent the foot pain from progressing and potentially to prevent a fall. Future work will examine foot pain and interventions upon new occurrence of falls.

2544

A Prospective Study of Alcohol Consumption and Risk of Rheumatoid Arthritis. Bing LU[1], Daniel H. Solomon[1], Karen H. Costenbader[2] and Elizabeth W. Karlson[2]. [1]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Background/Purpose: Several case-control studies suggested that moderate alcohol consumption may reduce risk for RA. However, early symptoms of RA may change alcohol intake and assessing alcohol after RA onset may thus over-estimate the effect of alcohol exposure. No published studies have assessed the association between repeated assessment of alcohol consumption over many years and future RA risk in the setting of a large prospective cohort study.

Methods: The Nurses' Health Study (NHS) was started in 1976, enrolled 121,700 registered female nurses aged 30–55 years from 11 US states, Lifestyle and environmental exposures and outcomes are collected through biennial questionnaires. Alcohol consumption was assessed on the food frequency questionnaire (FFQ) that was completed every 4 years, from 1980 through 2006. Among the 95,516 women who completed the FFQ at baseline, women who reported prevalent RA or other connective tissue disease were excluded and the diagnosis of incident RA through 2006 was confirmed using the connective tissue disease screening questionnaire and medical record review for the American College of Rheumatology criteria. We assessed the exposure variable using cumulative average alcohol consumption. We excluded the most recent record of alcohol intake and calculated the cumulative average alcohol including all other alcohol measures prior to RA onset. We categorized alcohol consumption into 5 groups (none, <5g/d, 5–9 g/d, 10–19 g/d, ≥20g/d). The estimated alcohol content of each alcohol beverage was 13.2 g per bottle or can of beer, 10.8 g per glass of wine, and 15.1 g per standard drink of liquor. Multivariable Cox proportional hazards models were used to estimate hazard ratios (HR), after adjusting for age, smoking, body mass index, menopausal status, hormone use, parity and breastfeeding.

Results: 718 incident cases of RA developed during 2,340,730 person-years of follow-up. The incidence rates of RA were 31, 30, 26, 33 and 34 /100,000 person-years across increasing levels of cumulative alcohol consumption (Table). After adjusting for other potential confounding factors, women who drank <5 grams alcohol per day had a 20% reduced risk of developing RA compared to women who did not drink any (P=0.022) (Table). Among women who drank 5–10 grams alcohol per day, the risk was reduced by 37% (p=0.001). Higher levels of alcohol consumption (≥20 grams per day) were not protective against the development of RA.

Table. Alcohol consumption and risk of RA

Alcohol (gram/day)	No. Cases/ Person-Yrs	Crude Incidence*	HR (95% CI)†	P
None	152/484365	31	1.00	
<5	323/1064692	**30**	0.80(0.66,0.97)	**0.022**
5–9	86/324905	**26**	0.63(0.48,0.83)	**0.001**
10–19	98/293966	33	0.89(0.68,1.15)	0.360
≥20	59/172802	34	0.85(0.62,1.15)	0.288

* Per 100,000 person-years.
† Adjusted for age, smoking, BMI, menopausal status, hormone use, parity and breastfeeding.

Conclusion: In this long-term prospective cohort study of women, with alcohol intake data collected many years prior to the onset of RA, evidence of a protective association between low levels (1–9 grams per day) of alcohol intake and risk of developing RA was found. Higher levels of alcohol intake were not protective. Future studies are needed to confirm and investigate the mechanism of this effect.

Baseline Co-Morbidities Predict Risk of Infection in An Inception Cohort of Rheumatoid Arthritis Patients Receiving Anti-Tumor Necrosis Factor Therapy. Joanne Homik[1], Nguen Xuan Thanh[2], Arto Ohinmaa[1], Cheryl CM Barnabe[3], Liam Martin[3], Susan G. Barr[3] and Walter P. Maksymowych[1]. [1]University of Alberta, Edmonton, AB, [2]Institute of Health Economics, Edmonton, AB, [3]University of Calgary, Calgary, AB

Background/Purpose: To evaluate the frequency of serious infections in Rheumatoid Arthritis (RA) patients treated with anti-Tumor Necrosis Factor (anti-TNF) therapy, associated costs and predictors of developing a serious infection

Methods: RA patients treated with anti-TNF therapy between January 2004 and March 2009 were followed prospectively in our biologics program to assess treatment efficacy and adverse events. Clinical and self-reported data were linked with provincial health care administrative databases. Infections were identified by using ICD 9 and 10 diagnosis codes and categorized as serious if there was an associated hospitalization. We used multivariate Cox-regression to assess independent predictors of the risk of infection and multivariate linear regression to assess independent predictors of infection-related costs.

Results: The cohort consists of 1,086 patients (70% female, mean age of 54 years) with a mean follow-up time of 2.3 years. Seventy percent of patients (n=764) reported an infection during follow-up, while 4% (n=42) suffered a serious infection, for an incidence density rate of 1.67 per 100 patient years of follow up. The most common infections in decreasing order of frequency were bronchitis, cellulitis, sinusitis, cystitis and upper respiratory infections. Compared to patients who remained on their first anti-TNF agent(n=731), patients who switched to another anti-TNF (n=212), patients on DMARD alone (n=75), and patients switched from DMARD to anti-TNF therapy (n=68) had similar Hazard Ratios (HR) (p>0.05) for both any and serious infections. In the cohort of patients on their first anti-TNF agent, the specific agent used did not predict risk of infection. Pre-existing lung disease (HR=1.99, p=0.001), underlying anemia (HR=3.31, p=0.030) and diabetes (HR=1.57, p=0.034) were associated with increased infection risk, while male sex was protective (HR 0.81, p=0.039). There was a trend for greater risk of infection in those patients with a higher

baseline DAS score (HR=3.89, p=0.072), and reduced risk in patients with university level education (HR=0.36, p=0.066).In linear regression, costs were significantly associated with higher baseline HAQ score (p<0.001), longer disease duration (p=0.005) and for those patients who required a switch between anti-TNF agents for inefficacy or adverse events (p=0.043).

Conclusion: Certain pre-existing co-morbidities, such as lung disease, diabetes, and underlying anemia significantly increased the risk of infection. The incidence density rate of serious infections was low (1.67 serious infections per 100 patient years), especially in patients who remained on their first anti-TNF agent (1.35 per 100 patient years) and is lower than reported in other cohorts. The risk of any or serious infection did not differ significantly between specific anti-TNF agents. Healthcare costs due to infections were associated with higher baseline HAQ score, longer disease duration at baseline and switching between anti-TNF agents.

Giant Cell Arteritis Is Associated with An Increase in Both All-Cause and Cardiovascular Mortality. Gunnar Tomasson[1], Johannes Bjornsson[2], Michael P. LaValley[3], Yuqing Zhang[1], Vilmundur Gudnason[4] and Peter A. Merkel[1]. [1]Boston University School of Medicine, Boston, MA, [2]Landspitali University Hospital, Reykjavik, Iceland, [3]Boston University School of Public Health, Boston, MA, [4]The Icelandic Heart Association, Kopavogur

Background/Purpose: Although patients with giant cell arteritis (GCA) have a well-documented risk of involvement of vital arteries and exposure to high doses of glucocorticoids, most epidemiologic studies have found no association of GCA with increased mortality. The objective of this study was to determine the association of GCA with all-cause mortality and cardiovascular mortality (CVM) in a well-defined population cohort with detailed information on cardiovascular risk factors.

Methods: Data from the Reykjavik Study (RS), a population-based, prospective cohort study with a primary focus on cardiovascular disease, were used. All persons born in 1907–1935 that were living in Reykjavik, Iceland or in adjacent communities on December 1, 1967 were invited to participate. Subjects came for a study visit in 1967–1996 and information on cardiovascular risk factors: smoking habits, blood pressure, diabetes, body mass index, and serum cholesterol was obtained in a protocolled manner. Temporal artery biopsies (TAbx) were identified for all subjects in the RS in all three pathology laboratories in Iceland during the period 1961–2009. All TAbx were re-examined in a protocolled and blinded fashion by a single pathologist with expertise in vascular pathology. Subjects met exposure criteria for GCA at the date on which a TAbx diagnostic of GCA was obtained. In the RS, there was continuous surveillance for vital status and CVM, defined as death from cardiovascular disease according to death certificates, until December 31, 2008. Cox proportional hazards regression models with GCA status included as a time-varying predictor were used; subjects with GCA were considered unexposed until the time they met exposure criteria. Adjustments were done for age and sex with additional adjustment for cardiovascular risk factors in the analysis of CVM.

Results: 19,360 subjects participated in RS, of whom TAbx was performed in 731 subjects (3.8%) prior to December 31, 2008. TAbx was diagnostic for GCA in 206 subjects. The 12 subjects who had a TAbx diagnostic of GCA prior to their RS study visit were excluded from this analysis. Therefore, 19,348 subjects were included: mean age 53.5 years (sd): 9.7); 51.9% female. The 194 subjects with GCA had a mean age at diagnosis of 73.2 years (sd: 6.9, range 55.3–90.0) and 70.7% were female. The median time from study visit to diagnosis of GCA was 19.0 years (inter-quartile range (IQR): 13.3–24.1). Median follow-up time was 26.1 years (IQR: 18.4–33.6). During the follow-up time, 11,392 of 19,348(58.9%) subjects died, including 111 out of 194 (57.2%) with GCA. Subjects with GCA had an increased risk of mortality after adjustment for age and sex with HR = 1.46 (95% CI: 1.21–1.74). During the follow-up time, 5,000 of 19,348(25.8%) subjects died from cardiovascular disease, including 54 of 194 (27.8%) with GCA. Subjects with GCA had an increased risk of CVM, HR=1.59 (95% CI: 1.22–2.08). This effect estimate was not attenuated after adjustment for cardiovascular risk factors: HR=1.55 (95% CI: 1.18–2.04).

Conclusion: Compared with the general population, patients with biopsy-proven GCA have a shortened life span, and increased mortality from cardiovascular disease after adjustment for traditional cardiovascular risk factors.

Type I Interferons Modulate Vascular Function and Repair, Thrombosis and Plaque Progression In Murine Models of Lupus and Atherosclerosis. Mariana J. Kaplan. University of Michigan Rheumatology, Ann Arbor, MI

Background/Purpose: SLE patients develop premature atherosclerosis not explained by the Framingham paradigm. Subclinical cardiovascular disease (CVD) in SLE is characterized by endothelial dysfunction, an imbalance of vascular damage and endothelial repair, a prothrombotic milieu and atherosclerotic plaque. Evidence from in vitro studies indicates that type I Interferons (IFNs) play a prominent role in increased CV risk in SLE. We now examined in vivo evidence for a role of type I IFNs in endothelial dysfunction, aberrant vascular repair, thrombosis and atherosclerosis in murine models of lupus and atherosclerosis.

Methods: Lupus prone NZM2328 mice (NZM) and atherosclerosis-prone ApoE knockout mice (ApoE−/−) were compared to mice lacking type I IFN receptor (INZM and ApoEIFNR−/−, respectively) in their endothelial vasodilatory function, neoangiogenesis on a matrigel assay, time to clot after carotid photochemical injury and atherosclerotic plaque development. Similar experiments were performed when NZM and ApoE−/− received an IFN-α-containing adenovirus (IFN-AD) or control-AD. Lipids and proinflammatory HDL (piHDL) were quantified.

Results: Loss of type I IFN signaling improves aortic endothelial-dependent vasorelaxation, leads to increases in endothelial progenitor cell (EPC) numbers and function and improves in vivo neoangiogenesis in lupus-prone mice, independent of disease activity. Further, acute exposure to IFN-α decreases endothelial function and repair in lupus-prone and non-lupus prone mice. ApoEIFNR−/− display decreased atherosclerotic burden, while acute administration of IFN-α to ApoE$^{-/-}$ and NZM mice promotes a prothrombotic milieu. Furthermore, Type I IFNs alter lipid levels and piHDL, promoting a proatherogenic environment.

Conclusion: Type I IFNs play a key role in endothelial dysfunction, impaired vascular repair, atherothrombosis and aberrant lipid profiles in murine SLE. These results support a prominent role for type I IFN responses in accelerated atherosclerotic disease and acute coronary events in SLE patients and, potentially, in the general population.

TLR7 Overexpression Drives Autoantigen-Mediated Expansion of Transitional and Follicular B Cells Independently of Type I IFN Signals. Natalia V. Giltiay. Department of Immunology, University of Washington, Seattle, WA

Background/Purpose: Loss of B cell tolerance plays a key role in the development of systemic lupus erythematosus (SLE). Toll-like receptor 7 (TLR7) is an intracellular TLR, specialized in the recognition of ssRNA and is highly expressed by plasmacytoid dendritic cells (pDC) and by B cells. Recent studies suggest that dual engagement of the B-cell receptor (BCR) and TLR7 by endogenous RNA and/or RNA-associated proteins promotes the activation of autoreactive B cells and drives the production of pathogenic anti-RNA Abs. Mice that overexpress TLR7 (TLR7Tg mice) develop SLE-like disease, characterized by increased numbers of myeloid cells and B cells, production of anti-nuclear autoantibodies and increased type I interferon (IFN). The main goal of our study was to define how TLR7 expression affected peripheral B cell development and to reveal the sites were self-reactive B cells are activated by RNA-associated antigens.

Methods: TLR7.1Tg mice were crossed to IRFNaRI-KO or to RNaseTg mice. Analysis of splenic B cell subsets was performed by multicolor flow cytometry. Cell proliferation was quantified by intracellular BrdU staining. Cell apoptosis was measured by Annexin V staining. Mixed bone marrow chimeras (BMC) were generated using allotype marked bone marrow cells.

Results: Young (8–10 week-old) TLR7Tg mice demonstrated significant abnormalities in B cell maturation: both transitional T1 and T2 B cells were increased by 1.5–2 fold; follicular (Fo) B cells by 3–4 fold, whereas the numbers of MZ B cells decreased with age. In vivo BrdU

labeling revealed that 15.4±8 % of the TLR7.Tg transitional B cells (compared to 1.2 ±0.8 in WT) were actively proliferating. TLR7 Tg mice also had increased numbers of apoptotic transitional B cells compared to WT mice suggesting both increased activation as well as negative selection at this B cell checkpoint. In BMC experiments, the persistent activation in T1 cells and their maturation towards Fo B cells in TLR7 Tg but not WT derived B cells indicated that B cell abnormalities were cell intrinsic. When TLR7Tg were crossed to RNaseTg mice, the number of T1 B cells was reduced 2-fold suggesting that RNA-associated antigens drive the expansion of these cells. TLR7 Tg mice that could not respond to type 1 IFN, demonstrated a partial reversion of the splenomegaly and myeloid cell expansion, but no significant effect on the expansion of T1, Fo or CD138+ B cells. In contrast, IFNaRI deficiency resulted in restoration of the MZ B cell population in TLR7Tg mice.

Conclusion: Increased expression of TLR7 causes proliferation and death of early transitional B cells with the net consequence of a B cell intrinsic, type 1 IFN independent, expansion of the transitional and follicular populations. Type 1 IFN does however regulate the MZ B cell population either by promoting egress of this B cell subset into the follicles or by influencing survival. Since overexpression of RNase significantly reduced the numbers of T1 B cells in TLR7Tg mice, it appears that RNA-associated antigens drive their expansion. These results therefore help to define the maturational stages at which activation of TLR7 in peripheral B cells impact B cell fate and also the role of autoantigen and IFN in this process.

Dual Regulation of IRF4 Function in T- and B-Cells Is Required for the Coordination of T-B Interactions and the Prevention of Systemic Autoimmunity. Alessandra Pernis. Hospital for Special Surgery, New York, NY

Background/Purpose: Effective humoral responses to protein antigens require the precise execution of carefully timed differentiation programs in both T and B cell compartments. Disturbances in this process underlie the pathogenesis of many autoimmune disorders including Systemic Lupus Erythematosus (SLE). Interferon Regulatory Factor 4 (IRF4) is induced upon the activation of T and B cells and serves critical functions in both T and B cells. In $CD4^+$ T helper cells, IRF4 plays an essential role in the regulation of IL-21 production while in B cells it controls class switch recombination and plasma cell differentiation. IRF4 function in T helper cells can be restricted by its interaction with a negative regulator termed Def6, a molecule that shares a high degree of homology with only one other protein, SWAP-70. While naïve T helper cells only express Def6, B cells express both Def6 and SWAP-70. Here we investigated the effects of the lack of both Def6 and SWAP-70 on immune responses.

Methods: Mice deficient in Def6 (on a C57/BL6 background) were crossed with mice deficient in SWAP-70 (also on a C57/BL6 background) to generate mice doubly deficient in Def6 and SWAP-70 (DKO mice). An extensive analysis of young and aged DKO mice was then performed. This analysis included an evaluation of the composition of lymphoid organs by flow cytometry and immunohistochemistry, an assessment of the ability of DKO mice to respond to T-dependent antigens and a thorough investigation of the presence of autoimmune features including the production of autoantibodies and the development of glomerulonephritis.

Results: We found that, on a C57BL/6 background, the absence of both DEF6 and SWAP-70 leads to the spontaneous development of age-related lymphoproliferation, autoantibody production, and glomerulonephritis. Similarly to human SLE, the disease preferentially affected the female gender. The lupus-like disease observed in the DKO mice is marked by the simultaneous deregulation of IL-21 production by T helper cells and increased IL-21 responsiveness by B cells. In the presence of aberrant IL-21 production by DEF6-deficient T cells, the absence of both DEF6 and SWAP-70 in B cells results in exaggerated AID expression, GC formation, and plasma cell differentiation. The B cell abnormalities in these mice are associated with an enhanced ability of IRF4 to access the regulatory regions controlling the expression of AID and Blimp-1. Interestingly, we show that DEF6 and SWAP-70 are differentially employed at distinct stages of B cell differentiation to selectively control the ability of IRF4 to drive the expression of specific target genes.

Conclusion: These studies suggest that DEF6 and SWAP-70 are two structurally and functionally related components of a complex molecular network aimed at ensuring the proper coordination of T and B cell interactions and at preventing the development of systemic autoimmunity.

BAFF/APRIL Inhibition Induces Negative Selection of Naïve Autoreactive B Cells but Does Not Prevent Positive Selection of Autoreactive B Cells in the Germinal Center. Anne Davidson. Feinstein Institute for Medical Research, Manhasset, NY

Background/Purpose: Our goal was to use the anti-DNA heavy chain site directed transgenic glD42 model to analyze the checkpoints for autoreactive B cell selection in autoimmune NZB/W mice. Regulation of transgenic B cells in non-autoimmune glD42 mice is achieved by clonal deletion at the pre-B to immature B cell stage, clonal anergy and receptor editing. Autoreactive hybridomas obtained following LPS stimulation of spleen cells from these mice use a diverse light chain repertoire and have a low affinity for DNA. When the same transgene is introduced into NZB/W mice, tolerance to DNA is broken and high affinity IgG anti-DNA antibodies appear in the serum with age. Whereas the naïve repertoire in NZB/W glD42 heavy chain mice is heavily skewed towards expression of glD42/Vk4–55, a combination that confers only low affinity autoreactivity, nearly all spontaneous IgG anti-DNA antibody producing hybridomas from use the original D42 light chain Vk16–104 (VkRF) that confers high affinity anti-DNA activity.

Methods: B cell subsets from transgenic mice were characterized by flow cytometry and the Vk repertoire of each subset was analyzed by single cell PCR. Expression of the glD42 heavy chain and the VkRF light chain was quantified in B cell subset cell pellets using real-time PCR. Light chains of interest were cotransfected with the glD42 heavy chain into 293 cells and the autospecificity of the resultant antibody determined by ELISA.

Results: Using single cell PCR we first showed that the generation of glD42/Vk4–55 and glD42/VkRF/Jk5 expressing B cells occurs in the bone marrow. There was positive selection of cells expressing light chains that conferred low affinity autoreactivity (including Vk4–55) into the naïve repertoire and counter-selection of these light chains in the germinal centers. In contrast, despite robust negative selection of glD42/VkRF/Jk5 expressing B cells in the bone marrow and transitional B cell stages, positive selection and expansion of rare autoreactive B cells expressing glD42/VkRF/Jk5 occurred in the germinal centers. Several other light chains with high affinity autoreactivity were also selected into the germinal centers. We then determined the effect of limiting BAFF using a 50:50 bone marrow chimera system in which competition from non-autoreactive B cells was provided. Competition significantly inhibited selection of glD42 expressing B cells into the naïve B cell repertoire such that only 4% of follicular B cells used the transgene; selection of naïve transgenic B cells was further inhibited by BAFF/APRIL blockade using TACI-Ig. TACI-Ig did not however inhibit selection of high affinity autoreactive B cells into the class switched repertoire which was still dominated by glD42/VkRF/Jk5 and the mice developed high serum titers of autoantibodies with only a 2 week delay.

Conclusion: These findings in sum show that despite a significant effect of BAFF inhibition on the survival of naïve autoreactive B cells, a major breach in B cell tolerance in NZB/W mice is at the germinal center checkpoint and this is not altered by BAFF/APRIL inhibition. These findings help explain why BAFF inhibition only modestly decreases titers of IgG autoantibodies in lupus mice or SLE patients.

CD4+ Cells Generated with TGF-β and All-Trans Retinoic Acid From Naïve CD4+ Cells Isolated From Lupus Mice Suppress Lupus in Mice. Song G. Zheng. USC Keck School of Medicine, Los Angeles, CA

Background/Purpose: Substantial evidence exists that TGF-β can convert conventional T cells isolated from normal mouse T cells to become Foxp3+ regulatory T cells. However, it is unclear whether TGF-β also converts T cells from lupus-prone mice to become Treg cells once these mice have developed lupus. Recent studies have demonstrated that all-trans retinoic acid (atRA), an active Vitamin A derivative can promote Tregs and inhibit Th17 cell production. We hypothesize that atRA will enhance the development of TGF-β induced Foxp3+ CD4regs

in mice with fully established lupus and enable them to have protective effects *in vivo.*

Methods: Naïve CD4+ cells isolated from NZB/W F1 young mice (<8 weeks) that typically expressed proteinuria (>24 weeks) were stimulated with anti-CD3/CD28 beads and IL-2 (control cells), + TGF-β (Treg cells), + atRA and TGF-β (atRA+TGF-β induced Treg) for 4–5 days. Surface and intracellular staining for CTLA-4, CD62L, CD103, CD122, GITR, TGF-β, CCR9 and $\alpha_4\beta_7$ was examined by flow cytometry. Suppressive activity *in vitro* was examined by adding various ratios of iTreg subsets to responder T cells labeled with CFSE and/or B cells from young or old mice. The cells were stimulated with anti-CD3 antibody in the presence of antigen-presenting cells (APC) isolated from young or old mice. The T cell proliferation was judged by the dilution of CFSE and antibody production by ELISA. *In vivo* protective activity was tested by transferring 5×10^6 various conditioned iTregs to young (8 week-old) or old (24 week-old) NZB/W F1 mice. IgG and anti-DNA in sera was analyzed with ELISA. Proteinuria and survival were monitored. Renal histopathology and IgG deposition were also assessed with H&E and immunoflorence staining.

Results: We found that TGF-β induced >50% naïve CD4+ cells from young mice to become CD25+ Foxp3+ cells that developed strong suppressive activity *in vitro* and *in vivo*. Although these effects were significantly diminished in old mice, the addition of atRA to TGF-β restored Foxp3 expression by CD4+ cells and suppression of T cell proliferation and antibody production that comparable of young mice. These cells also suppressed the expression of CD69, CD80 and CD86, and the IgG production of B cells *in vitro*. These cells suppressed T and B cell responses from young and old mice equivalently. Unlike Tcon, or Tregs induced with TGF-β, a single transfer of 5×10^6 atRA+TGF-β induced Tregs from old mice to young or old B/W F1 mice markedly prevented increased IgG production, decreased anti-dsDNA autoantibodies, suppressed proteinuria and prolonged survival of these mice.

Conclusion: The combination of atRA and TGF-β is able to induce naïve CD4+ cells from mice with lupus nephritis to become CD4+Foxp3+ Treg cells that can prevent the onset of lupus and ameliorate established lupus. Thus, although endogenous Tregs in mice with active lupus fail to prevent progression of disease, syngeneic Tregs induced ex-vivo with the appropriate epigenetic agent have the potential to be used as an adoptive immunotherapy to control autoimmunity.

The Constant Region Contributes to the Antigenic Specificity and Potential Pathogenicity of Anti-DNA Antibodies. Chaim Putterman. Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: Anti-double stranded (ds) DNA antibodies play a key role in the pathogenesis of lupus nephritis. High affinity for DNA and cross-reactivity with particular renal antigens are among the factors associated with enhanced renal pathogenicity. In addition, certain IgG subclasses are particularly enriched in immunoglobulin eluates from kidneys with active lupus nephritis, suggesting that antibody isotype is another important feature determining the outcome of antibody binding to renal antigens. Although classically the variable region was believed to be the sole determinant of antigenic specificity, more recent studies have shown that isotype switching leads to altered binding of a protective antibody. Our hypothesis was that antibody isotype may affect the renal pathogenicity of anti-DNA antibodies, by influencing antigen binding.

Methods: The parent PL9–11 clone is an IgG3 anti-DNA antibody isolated from a MRL/+ mouse (1). To obtain IgG1, IgG2b and IgG2a forms of the original PL9–11 antibody that would share identical variable regions, the PL9–11 (IgG3) hybridoma clone was isotype switched in vitro by stimulation with IL-4 and TGF-β for 7 days, followed by soft-agar cloning and sib selection. The PL9–11 (IgM) variant was generated by cloning the PL9–11 variable region into an IgM expression vector, followed by transfection of the construct into a mutant cell line expressing only the light chain of the original PL9–11 hybridoma. The affinity and specificity of the PL9–11 antibody panel (IgM, IgG3, IgG1, IgG2a, IgG2b) were analyzed using ELISA, surface plasmon resonance (SPR), and cross-inhibition studies. Specificity for renal antigens was studied by binding to mesangial cells, isolated glomeruli, and glomerular proteome arrays. Finally, renal deposition and pathogenicity was assayed by analyzing kidneys of SCID mice injected intraperitoneally with each member of the PL9–11 antibody panel. Antibody concentrations were carefully normalized by ELISA and Western blotting.

Results: By ELISA, we found that PL9–11 and its isotype switched variants had differential binding to single stranded (ss)DNA, dsDNA, chromatin and mesangial cells in order of IgG3>IgG2a>IgG1>IgG2b>IgM. This order of relative affinities of the different IgG isotypes for dsDNA was confirmed in a competition ELISA. In contrast, in binding to Matrigel, laminin, and collagen IV the IgG2a isotype actually had the highest affinity, followed by IgG3>IgG1>IgG2b>IgM. In concert with ELISA assays, assessing antibody specificity in glomerular proteome arrays also revealed significant differences between the members of the PL9–11 panel in binding to multiple antigens. Analysis of SPR and renal histopathology following injection is pending.

Conclusion: Our data suggest that the constant region plays an important role in the affinity and specificity of anti-dsDNA antibodies, and that IgG2a and IgG3 isotypes may be more nephritogenic due to higher potential for binding to multiple glomerular and nuclear antigens.

Developmental Trajectories of WOMAC Knee Pain and Their Predictors Over 3 Years Among Subjects of Osteoarthritis Initiative. Bin Zhang[1], Uyen Sa D. Nguyen[2], Jingbo Niu[2] and Yuqing Zhang[2]. [1]Boston Univ School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA

Background/Purpose: Pain from knee osteoarthritis (OA) is one of the most common reasons for seeking medical care. Little is known, however, about patterns of change in knee pain over time or the predictors of these pain trajectories. Identifying clusters of individuals with similar pain trajectories over time and the predictors associated with these trajectories will improve our understanding of the etiology of pain so that we can target appropriate intervention to specific groups of subjects whose knee pain are likely to worsen.

Methods: Knee pain severity was assessed at baseline and annually over three years using WOMAC pain questionnaires (0–20 scale) among the participants of the Osteoarthritis Initiative. We used group-based trajectory models, an application of the finite mixture modeling for time-based data, to identify distinctive trajectories of knees that follow similar patterns of pain over time. SAS macro *Proc Traj* was used to carry out the analyses and Bayes information criterion (BIC) was used to select the best model to balance model fitting and complexities. We then compared the baseline risk profiles among different trajectory groups using either $\chi 2$ test or one way ANOVA.

Results: Among 8802 subjects included in this analysis (58% women, mean age: 62, 17% of African Americas, mean BMI: 28.6 kg/m^2, mean WOAMC pain score: 2.3), we identified 8 distinctive trajectories of knee pain severity over 3 years (Figure, Table 1) based on BIC. Overall, the majority (89.5%, Groups 1, 2, 3, 6 and 8) of the individuals' knee pain did not change significantly over 3 years. About 3.3% of knees' pain severity (Groups 4 and 7) improved by > 90%, whereas 7.3% of knees' pain severity worsened (Group 5) by about 15% over 3-year period. Risk profiles were significantly different among the 8 groups. Compared with those who had higher baseline WOMAC pain score (Groups 4–8) subjects with lower scores (Groups 1–3) had fewer women and African Americans, lower prevalence of obesity, depression, and less moderate to severe ROA (Table 1). Of the three groups that had similar baseline WOMAC pain scores but had distinctive WOMAC trajectories (Groups 4, 6, 7), subjects in Group 6 had more African Americans, higher prevalence of obesity, major depressive symptom, and moderate and severe ROA(KL≥3) at baseline. Furthermore, fewer subjects in Group 6 had TKR than those in Group 4 and 7.

Fig. 1: Total WOMAC Knee Pain Trajectory Over Time

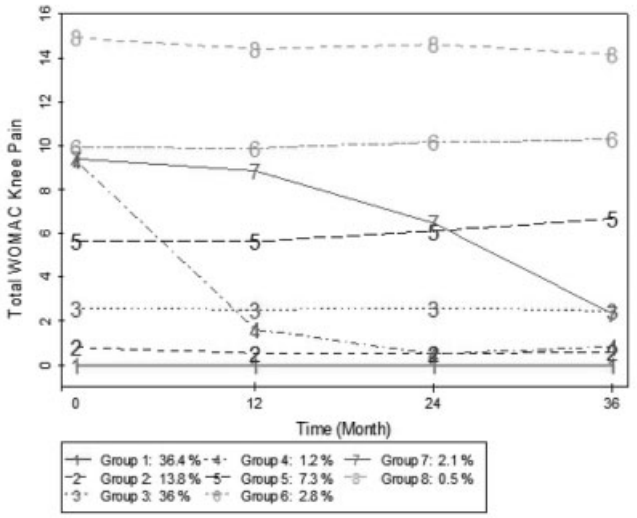

Table 1: Baseline Characteristics of Patient by WOMAC pain trajectory group

Baseline Variables	Group Membership							
	Low Baseline Pain			High Baseline Pain				
	1	2	3	4	5	6	7	8
N	2155	2541	2730	90	864	280	108	34
WOMAC Pain	0	1.0	2.7	10.2	5.9	10.1	10.2	15.3
Age	62	61	61	62	61	59	62	55
Female(%)	52	58	59	60	65	69	71	76
Race(AA %)	9	12	17	34	28	53	40	68
BMI≥30 (%)	26	32	40	48	51	61	55	62
Major Depression Symptom(%CES-D >21)	1.4	2.9	3.6	6.7	7.5	16.5	7.7	40
TKR (%)	0.6	1.1	2.4	6.7	5.0	4.3	18	0
K/L≥3 (%)	14	25	41	40	49	57	53	33

Conclusion: Our study demonstrated the different trajectory patterns of WOAMC pain among subjects with knee OA or at high risk of getting knee OA. The risk profiles for these distinctive trajectories are also different. Future studies should assess whether intervening on modifiable risk factors may change the trajectory of pain severity.

Proteomic Identification of A Panel of Novel Osteoarthritis Biomarkers In Serum and Cartilage. Patricia Fernández-Puente[1], Jesús Mateos[1], Carolina Fernández-Costa[1], Valentina Calamia[1], Cristina Ruiz-Romero[1], Carlos Fernández-López[2], Natividad Oreiro[2] and Francisco J. Blanco[3]. [1]Osteoarticular and Aging Res. Lab. Proteomic Unit-Associated Node to Proteored. INIBIC-CHUAC, La Coruña, Spain, [2]Osteoarticular and Aging Res. Lab. Rheumatology INIBIC-CHUAC, La Coruña, Spain, [3]Osteoarticular and Aging Res. Lab. Proteomic Unit-Associated Node to Proteored/ Lab. Rheumatology Division INIBIC-CHUAC, La Coruña, Spain

Background/Purpose: Osteoarthritis (OA) is a degenerative joint disease that is characterized by cartilage destruction and bone changes, occasionally accompanied by synovial inflammation. A major objective for OA research is the conceptualization and development of early diagnostic strategies. The discovery of protein biomarker panels for early diagnosis, therapeutic purposes and management of several diseases is an area of interest in medicine. In the present work, we have quantitatively screened differential proteins in sera and cartilage from patients suffering OA at diverse stages. To attain this objective, a quantitative proteomics approach has been followed, which is based on peptide differential labelling with iTRAQ reagents and subsequent multidimensional LC-MS/MS analysis.

Methods: 150 serum samples were obtained from OA patients at different stages of the disease (grade II, grade IV and control donors). Cartilage samples were obtained from OA patients undergoing joint replacement and normal donors without history of joint disease. Proteins were extracted with Urea 6M, 2% SDS using a mixer mill. Proteins were quantified, digested with trypsin and differentially labelled with iTRAQ isobaric tags. The peptide mixture was separated by two-dimensional LC coupled to MALDI-TOF/TOF mass spectrometry. Identification and relative quantification of the proteins were performed using ProteinPilot 3.0 software.

Results: The proteomic approach enabled the identification of 349 different proteins in serum. 171 of them could be quantified by the calculation of their iTRAQ ratios, and three sets of proteins were found to be altered with statistical significance ($p<0.05$) in OA samples when compared to healthy controls: a group of 7 proteins were altered (either increased or decreased) specifically in early OA, whereas 14 were modulated only in advanced OA and 7 were modified in both stages. Although some of these proteins, such Cartilage Oligomeric Matrix Protein (COMP), have a previously reported putative biomarker value for OA, most of them are novel biomarker candidates of the disease. 263 proteins were identified in cartilage samples and 59 of them were differential in OA patients compared to control with a significative p-value. Identification and quantification of some of these proteins both in serum and cartilage from OA patients indicate their potential biomarker value for the pathology. The alteration of some proteins was detected in both types of samples. This was the case of cartilage oligomeric matrix protein, lumican, complement factor D or thrombospondin-1, which were all found to be increased in OA, whereas the cytoplasmic actin was decreased. Finally, a number of other proteins were identified as altered either in cartilage (thus increasing our knowledge of OA pathogenesis) or in serum (which have also potential biomarker value).

Conclusion: In summary, we have identified for the first time a panel of novel OA protein biomarkers present in serum and cartilage from human patients by a proteomic approach. The specificity and selectivity of these candidates should be verified in order to develop new molecular diagnosis or prognosis tests for OA.

Development of the United Kingdom Evaluation of Daily Activities Questionnaire in Rheumatoid Arthritis using Rasch Analysis. Alison Hammond[1], Alan Tennant[2], Sarah Tyson[1], Ulla Nordenskiold[3] and Rachel Gill[1]. [1]University of Salford, Manchester, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]Sahlgrenska Univ Hospital, Goteborg, Sweden

Background/Purpose: The Evaluation of Daily Activity Questionnaire (EDAQ) is a patient reported measure of activity/activity limitations in Rheumatoid Arthritis (RA) (Nordenskiold et al 1996). The UK version includes 138 items in 14 activity of daily living and participation domains (Eating/Drinking; Personal Care; Dressing; Bathing; Cooking; Moving Indoors; House Cleaning; Laundry; Moving and Transfers; Communication; Moving Outdoors; Gardening/Household Maintenance; Caring; and Hobbies/ Leisure/ Social Activities). Each domain is split into two sections: one (A) which scores without aids, alternate methods or help; and another (B) which scores items with aids or alternate methods. All items are scored on a 0–3 scale (no difficulty to unable to do). Our aim was to identify if the UK-EDAQ fits the Rasch model in an RA cohort.

Methods: Participants were recruited from Rheumatology clinics. Data from each domain were assessed for initial unidimensionality by a Confirmatory Factor Analysis (CFA). Each domain was analysed separately for sections A and B (where section B overrides section A when applicable). A Root Mean Square Error of Approximation (RMSEA) of 0.10 and below (mediocre fit) was considered adequate as prepepartion for Rasch analysis. Rasch analysis involved testing stochastic ordering (fit); local independence (response dependency and unidimensionality) and properties of invariance across groups (gender, age and employment status: differential item functioning (DIF). RUMM2030 software was used.

Results: 383 people with RA participated: 286 women and 97 men; average age 60.38 (SD 11.18) years; RA duration 13.2 years SD 10.72; 118 (31%) were employed. Average pain (10 point VAS) = 4.99 (SD 2.59) and fatigue 5.61 (SD 2.53). CFA of the 14 domain sections (A&B) indicated unidimensionality after adjustment for local dependency (correlated errors) within each domain. All domains achieved RMSEA < 0.10. All domains satisfied Rasch model expectations after adjustments (by the use of testlets) for local dependency (Chi-square $p>0.05$). Virtually all items had ordered thresholds, and where this was not the case, the disordering was often marginal. Differential Item Functioning (DIF) by age, gender and employment status was also largely absent, with a few notable exceptions. For example, in the domain 'gardening and household maintenance' the item 'climbing ladders' showed significant DIF by age, with older people showing greater problems with this at any given level of the trait (ANOVA $p<0.05$).

Most domains showed a Person Separation Index reliability (PSI) consistent with individual use, even after adjustment for local dependency (PSI range 0.75–0.94). Where values were lower, this was largely a consequence of skewed data and the presence of a substantive floor effect which affects the PSI; whereas classical alpha values remained high. All domains supported strict unidimensionality.

Conclusion: Analysis of the UK- EDAQ support a 14 domain, two component structure (self care and mobility) where each domain, and both components, (independently for sections A and B) satisfy Rasch model requirements after adjustment for local dependency.

Internet Versus Mailed Administration of the Health Assessment Questionnaire Disability Index. Bonnie Bruce[1] and James F. Fries[2]. [1]Stanford Dept of Medicine, Palo Alto, CA, [2]Stanford Univ Medical Center, Palo Alto, CA

Background/Purpose: The Health Assessment Questionnaire Disability Index (HAQ) is a validated paper/pencil patient reported outcome (PRO) instrument for assessing physical function in rheumatology using conventional administration modes. However, it is unknown whether internet administration would be equivalent to paper/pencil administration. We conducted a cross sectional study to compare the HAQ's response rates, item completion rates, and instrument scores between mailed and internet administration.

Methods: Participants with rheumatoid arthritis (RA) and osteoarthritis (OA) were drawn from four longitudinal cohorts. They were classified as Internet-Adept or Not-Adept based on internet experience and comfort. We allocated participants to three study arms (n=126 each) controlling for diagnosis and cohort membership: Adept participants were randomly assigned to complete the HAQ online (Arm 1) or by mail (Arm 2). Not-Adept participants completed the HAQ by mail (Arm 3). Both instruments were similarly formatted, contained a one-week timeframe, the same 20 items, four response options, and were scored 0–100 (100=worst functioning). Data were analyzed using chi-square tests of proportions, means±standard deviation, analysis of variance, and regression analyses controlling for age, gender, and education.

Results: Participants were White (94%), female (65%), had 16 education years ($p>0.05$), and averaged 72 years old. The Not-Adept participants (Arm 3) were older than their Adept (Arms 1 and 2) counterparts ($p<0.001$). There were no differences in response rates (>90%, all study arms) or number of missing items by administration mode ($p>0.05$). Unadjusted HAQ scores were statistically different among study arms ($p<0.001$), increasing with age. Age-adjusted scores were similar among modes and study arms ($p>0.05$).

Conclusion: The HAQ may be administered to RA and OA participants over the internet or by mail with confidence of equivalent results after consideration of age effects. These data provide reassurance that mail, internet, or mixed modes for PROs may each provide valid data after adjustment when necessary. Use of mixed modes with data pooling is likely to be used increasingly in the future, as they can increase study efficiency. These data suggest that valid data pools may result. We suggest, however, that studies report separate analyses by mode to control for inadvertent bias.

2557

Using A Novel Approach to Estimate Effects of Depression On Changes In Knee Pain Severity In Osteoarthritis Initiative. Ke Wang[1], Bin Zhang[2], David T. Felson[3] and Yuqing Zhang[3]. [1]Boston University, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA, [3]Boston University School of Medicine, Boston, MA

Background/Purpose: In rheumatic studies some outcomes (eg. knee pain severity) are repeatedly measured in multiple joints using an ordinal scale. Since these outcomes can fluctuate over time, it is of great interest to identify risk factors that contribute to their fluctuations. Commonly used logistic or linear regressions which can analyze unidirectional change cannot work on this type of outcomes. Other methods such as multistate transition models extended from the Cox proportional hazard model require relatively precise time-to-event measurements, and thus are not suitable for large prospective community-based studies (such as OAI) with small numbers of visits over lengthy time intervals (eg. annual visits). Moreover, since outcomes are joint-specific, within-person correlations need to be accounted for.

We propose a multistate transition model that can appropriately estimate effects of risk factors on changes in an ordinal outcome during infrequent visits, accounting for within-person correlations. We apply the method to investigate depression's effect on fluctuation of knee pain severity.

Methods: Knee pain data are from OAI's four annual visits. The outcome is the time-varying knee-specific WOMAC pain score categorized into 3 levels: no pain (all grades=0), mild (max grade=1 or 2), and severe (max grade=3 or 4). A multistate Markov-chain transition model was used to estimate effects of covariates on transitions (change in levels) of the outcome. A first-order Markov property is assumed for the yearly-spaced observations. A transition happens if pain status changes over two consecutive visits. The predictor is depression status (CES-D score ≥ 16 vs. < 16) at each previous visit. Effect estimates are obtained for all possible transitions accounting for between-knee correlations using the robust covariance estimator and adjusting for age, sex, BMI, and race. Simulations were also carried out to compare results with and without accounting for correlations (results not shown).

Results: 9592 knees are included (mean age 61±9, BMI 29±5, 58% female, 18% black). As shown in Table, subjects with depression are more likely to have knee pain worsening, especially for a rapid progression from no pain to severe pain within one year: The odd is 1.4 times higher for progression from no pain to mild pain, 1.4 times higher for progression from mild to severe pain, and 3.3 times higher for progression from no pain to severe pain than those without depression. On the other hand, subjects with depression are less likely to have knee pain improvement, especially from severe pain to no pain.

Table: Effect of depression (CES-D ≥ 16) on changes in WOMAC pain:

	Previous \ Current	OR [95% CI]		
		No Pain	Mild	Severe
WOMAC Pain	No Pain	1.0 [Reference][1]	1.4 [1.1, 1.7]	3.3 [2.1, 5.1]
	Mild	0.7 [0.6, 0.9]	1.0 [Reference]	1.4 [1.1, 1.8]
	Severe	0.4 [0.2, 0.7]	0.6 [0.5, 0.9]	1.0 [Reference]

[1]A knee is in the reference group at a visit if pain severity does not change compared to the previous visit

Conclusion: We show that our multistate Markov-chain transition model is an appropriate method to analyze changes in a correlated longitudinal ordinal outcome. Results indicate persons with depression are more likely to have knee pain worsening and less likely to have pain improvement than those without depression.

Relationship Between Accelerometer-Based Measures of Physical Activity and the Yale Physical Activity Survey in Adults with Arthritis. Pamela A. Semanik[1], Jungwha Lee[2], Larry Manheim[3], Loretta DiPietro[4], Dorothy D. Dunlop[3] and Rowland W. Chang[2]. [1]Rehabilitation Institute Chicago, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Northwestern Univ Med School, Chicago, IL, [4]George Washington University School of Public Health and Health Services, Washington, DC

Background/Purpose: A reliable, valid self-report measure of physical activity that has clinical applicability would be a valuable addition to providers' resources. This study evaluated the correlation between the Yale Physical Activity Survey (YPAS) indices scores and objective accelerometer measures of time spent in light, moderate-to-vigorous intensity physical activities (MVPA), and MVPA in bouts lasting at least 10 minutes.

Methods: This cross-sectional study analyzed baseline data from 171 persons with rheumatoid arthritis (RA) and 139 persons with osteoarthritis (OA) enrolled in a randomized clinical trial of a physical activity promotion intervention. Persons fulfilling the 1988 ACR criteria for RA and persons with symptomatic, radiologic knee OA (Kellgren-Lawrence Class > 2) wore an accelerometer for 7 days, then responded to the YPAS questionnaire, and questions regarding demographics (age, gender, and race) and health factors [BMI, disease status (HAQ/WOMAC), comorbidities, pain and function]. Spearman Correlation coefficients were estimated between each YPAS index score [Total Time Index (TTI), Energy Expenditure Index (EEI) and Activity Dimensions Summary Index (ADSI)] and accelerometer measures.

Results: Participants were primarily female (RA: 82%, OA: 58%), White (RA: 76%, OA: 58%), older (mean for RA: 55 years, OA: 63 years), and overweight (mean BMI RA: 28, OA: 31); some participants reported

co-morbidities that may have affected mobility (RA: 28%, OA: 24%), pain (mean HAQ pain for RA: 3.4 out of 0[best]-10[worst], mean WOMAC pain for OA: 5.6 out of 0[best]-20[worst]) and functional limitations (mean HAQ function for RA: 0.7 out of 0[best]-3[worst], WOMAC function for OA: 17.5 out of 0[best]-88[worst]). Mean disease duration was 13.5 years (SD= 10) for RA, and 11 years (SD=11) for OA. In the RA participants, the YPAS summary index having the strongest correlation with objective accelerometer measures was the ADSI, which was significantly correlated with Average Daily Minutes of Bouted Moderate/Vigorous Activity ($r = 0.51$), Average Daily Accelerometer Counts ($r = 0.45$), and Average Daily Minutes of Moderate/Vigorous Activity ($r = 0.43$). In OA participants, the YPAS ADSI was also significantly correlated with Average Daily Minutes of Bouted Moderate/Vigorous Activity ($r = 0.36$), Average Daily Minutes of Moderate/Vigorous Activity ($r = 0.31$), and Average Daily Counts ($r = 0.24$).

Conclusion: For both RA and OA groups, the YPAS ADSI, which is fast to both administer and score, had the strongest significant correlations with objectively measured physical activity, which supports the ADSI's use as a tool for clinical applications and in rheumatology research.

Sexual Problems and Sexual Perception in Patients with Ankylosing Spondylitis. Anne Proven[1], Kari H. Berg[2], Elsa Almas[3], Espen E. Benestad[4] and Glenn Haugeberg[5]. [1]MD, Baerum, Norway, [2]MA, Kristiansand.S, Norway, [3]MA, Kristiansand, Norway, [4]MD, Kristiansand, Norway, [5]MD, PhD, Kristiansand.S, Norway

Background/Purpose: Ankylosing spondylitis (AS) is a chronic, systemic inflammatory rheumatic disease which most frequently affects the axial skeleton, but may also affect peripheral joints, tendons and internal organs. This disease which begins in the second or third decade may give rise to significant loss of function and impaired quality of life. Despite the importance of sexuality as part of quality of life, only a few studies have explored this important issue in AS patients. We therefore wanted to explore sexuality in patients with AS in regard to how satisfied they are with their sexual life and whether the patients think their sexuality is influenced by the disease.

Methods: This is a prospective, cross sectional study were patients with established AS seen in the outpatient clinic in three hospitals in the southern and eastern part of Norway, were asked to participate. A broad specter of demographic, clinical data, quality of life data, also including a general questionnaire on sexuality, was collected.

Results: At the end of 2008 105 patients had been included. The patient cohort contained of 66.7% men and 96.1% were HLA-B27 positive. The mean (SD) values for age was 46.2 (14.9) years and disease duration 15.5 (10.6) years. 23.8% patients were current users of biologics and 42.9% were current users of NSAIDs. Mean (SD) values was 3.3 (2.0) for BASDAI, 2.9 (2.2) for BASFI, 3.8 (2.4) for BAS-G, 2.6 (2.0) for BASMI and 0.58 (0.50) for HAQ. For ESR and CRP the mean values were 14.1 (14.5) mm/hr and 9.0 (11.2) mg/l, respectively.

On the sexuality scores 60.4% patients reported sex and sexuality important/very important to be satisfied with their daily life. 31.7% reported sexuality less important and only 7.6% thought sexuality was not important. 48.5% were satisfied/very satisfied with their sexual life while 29.3% were neither satisfied nor dissatisfied and 22.3% were dissatisfied. 49.5% reported to have had problems with their sexuality, however only 13% of the 105 patients had been seeking help to solve the problems. 32.4% of the patients thought their sexual problems were related to their disease, 11.4% in very high degree and 21% in some degree. The main causes of sexual problems from the disease were tiredness in 31.4%, stiffness in 30.5% and pain in 31.4%.

Conclusion: In this study of 105 patients with AS, as many as 49,5% reported to have had sexual problems, and 32,4% thought their sexual problems were related to their AS. The main causes of sexual problems were tiredness, stiffness and pain. We think the number of patients reporting sexual problems was high in this group since disease activity scores and health activity scores in this group was only modest high. More studies are needed to illuminate how sexual life is influenced by AS.

2559A

The Effect of Physician Communication on Treatment Adherence in Patients with Rheumatoid Arthritis. Maria F. Marengo[1], Richard L. Street Jr.[2], Sofia De Achaval[3], Hong Zhang[1], Marsha Richardson[4] and Maria E. Suarez-Almazor[5]. [1]UT MD Anderson Cancer Center, Houston, TX, [2]Texas A&M University, College Station, TX, [3]U.T. MD Anderson Cancer Center, Houston, TX, [4]UT MD Anderson, Houston, TX, [5]University of Texas. M.D Anderson Cancer Center, Houston, TX

Background/Purpose: Treatment adherence could be influenced by many factors. The physician-patient relationship is crucial in medical care. The objective of our study was to evaluate the effect of physician communication on treatment adherence in patients with Rheumatoid arthritis (RA).

Methods: This study was part of a 2– year prospective cohort of 201 patients with RA from 2 publicly-funded county hospitals. Patients' visits were audio typed at baseline and at 3 months. Information included: review of discussions on prescribed drugs, who initiated discussions (physician or patients), and physicians 'affective tone as determined by independent raters, who were graduate students in communication sciences, and followed structured protocol while listening to the audios. Affective tone was rated in the following categories: 'irritated', 'anxious', 'dominant', 'interested', 'friendly 'and 'empathetic'. Each category was scored from 1 to 5, were 1 was the absence of the tone quality, and 5 the highest possible value. The Compliance Questionnaire Rheumatology (CQR) was used to assess patients' adherence to prescribed drugs (score 0–100, where 100 is the most compliance).

Results: 74.6% were female, 52.7% Hispanic, 25% White and 21.4% African-American; mean age was 51y (±11.4), disease duration 7.5y (±5), CQR 70.3(±10.3). On baseline visit the scores of affective tone of interaction were ≤2 for irritated and anxious in 90%, 73%, respectively; and ≥4 for dominant, interested, friendliness or empathetic in 72%, 76%, 69%, and 54%, respectively. Discussions about drugs compliance was initiated by the doctor in 88% of cases. At 3 months there was a significant relationship between increased adherence to prescribed drugs and baseline physician empathetic tone ($r=0.3$, $p=<0.01$). An increased in irritated and anxious tone had association with decreased adherence at 3 months ($r=-0.17$, $p=0.05$ and $r=-0.19$, $p=0.02$). No association was observed with dominant ($r= 0.13$, $p=0.12$), interested ($r=0.12$, $p=0.17$), or friendly ($r=0.11$, $p=0.19$) affective tones.

Conclusion: Physician's communication style had an effect on subsequent patient adherence to prescribed drugs. Empathy and less irritated and anxious tone were associated with adherence in patients with RA.

2559B

Supervised Physical Exercise Improves Endothelial Function and Endothelial Progenitor Cells in Patients with Systemic Lupus Erythematosus. Edgard T. Reis Neto[1], Aline E. Silva[1], Carlos M. C. Monteiro[2], Erika L. Naka[2], Patricia Semedo[2], Neusa P. Silva[1] and Emilia I. Sato[1]. [1]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Escola Paulista de Medicina - Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: Cardiovascular disease (CVD) is an important cause of morbidity and mortality in systemic lupus erythematosus (SLE) and disturbances in endothelial function (EF) are implicated in its pathogenesis. EF also depends on endothelial progenitor cells (EPCs) that enhance angiogenesis, promote vascular repair and have potential as a marker of CVD. SLE patients have endothelial dysfunction and fewer EPCs than healthy controls. A previous study from our group demonstrated that supervised physical exercise (SPE) improved EF in SLE patients. Objective: To evaluate the effect of SPE in EPCs and in vascular endothelial growth factor (VEGF) in SLE patients.

Methods: Prospective, controlled, nonrandomized study in which women with SLE (18–45 years-old) were allocated according to availability to participate in the exercise group (EG) or control group (CG). Intervention: SPE was performed three times a week for 16 consecutive weeks and consisted of 10 minutes of initial warm-up/stretching, 40 minutes of walking at heart rate corresponding to the ventilatory anaerobic threshold, and 10 minutes of cooling down. Patients were evaluated at baseline (T0) and after 16 weeks (T16): high-resolution ultrasound of brachial artery in resting conditions, after reactive hyperaemia (flow-mediated dilation-FMD) and after oral glyceryl trinitrate (GTMD) was performed to assess endothelial function; EPCs were evaluated by flow cytometry using anti-CD34 (FITC), anti-CD133 (PE) and anti-KDR (APC); and VEGF was assessed by ELISA (R&D Systems, Minneapolis, USA).

Results: Four hundred and nine SLE patients were invited to participate, 186 manifested interest, but 110 were excluded due to exclusion criteria, 53 patients dropped out due to personal reasons and 21 were included. Nineteen patients completed the evaluations (mean age 33.4±8.7 years and mean disease duration of 102.6±80.7 months). Twelve patients were assigned in the EG and seven in the CG. Both groups were comparable and homogeneous regarding demographic variables and cardiovascular traditional risk factors. In the EG, we observed a significant increase in FMD (8.3±7.2% *vs* 16.4±8.9%, $p=0.011$) without changes in the CG (3.7±4.5% *vs* 5.6±4.6%, $p=0.526$). In the EG, we also found a significant improvement in exercise tolerance (11.8±2.1min *vs* 13.3±2.1min, $p=0.02$), maximum speed (7.5±1km/h *vs* 8.3±1.1km/h, $p=0.049$) and threshold speed (5.5±0.6km/h *vs* 5.9±0.6km/h, $p=0.011$). EPCs were analyzed in 10 patients of the EG and in seven of the CG. After 16 weeks we observed a significant increase in the number of CD34/CD133/KDR positive cells in the EG (0.38±0.37 vs. 1.57±1.38, $p=0.005$) without difference in the CG (0.62±0.83 vs. 0.82±0.58, $p=0.176$). There was no significant difference in VEGF levels in both groups comparing T0 and T16.

Conclusion: Despite the small number of patients, this is the first study demonstrating that physical exercise can improve endothelial function and EPCs number in SLE patients. The increment in the EPCs may be one of the mechanisms associated with endothelial function improvement after an exercise program. Physical exercise can be a useful strategy to prevent CVD morbidity and mortality in SLE patients.

2559C

Sexual Problems and Sexual Perception in Patients with Ankylosing Spondylitis. Anne Proven[1], Kari H. Berg[2], Elsa Almas[3], Espen E. Benestad[4] and Glenn Haugeberg[5]. [1]MD, Baerum, Norway, [2]MA, Kristiansand.S, Norway, [3]MA, Kristiansand, Norway, [4]MD, Kristiansand, Norway, [5]MD, PhD, Kristiansand.S, Norway

Background/Purpose: Ankylosing spondylitis (AS) is a chronic, systemic inflammatory rheumatic disease which most frequently affects the axial skeleton, but may also affect peripheral joints, tendons and internal organs. This disease which begins in the second or third decade may give rise to significant loss of function and impaired quality of life. Despite the importance of sexuality as part of quality of life, only a few studies have explored this important issue in AS patients. We therefore wanted to explore sexuality in patients with AS in regard to how satisfied they are with their sexual life and whether the patients think their sexuality is influenced by the disease.

Methods: This is a prospective, cross sectional study were patients with established AS seen in the outpatient clinic in three hospitals in the southern and eastern part of Norway, were asked to participate. A broad specter of demographic, clinical data, quality of life data, also including a general questionnaire on sexuality, was collected.

Results: At the end of 2008 105 patients had been included. The patient cohort contained of 66.7% men and 96.1% were HLA-B27 positive. The mean (SD) values for age was 46.2 (14.9) years and disease duration 15.5 (10.6) years. 23.8% patients were current users of biologics and 42.9% were current users of NSAIDs. Mean (SD) values was 3.3 (2.0) for BASDAI, 2.9 (2.2) for BASFI, 3.8 (2.4) for BAS-G, 2.6 (2.0) for BASMI and 0.58 (0.50) for HAQ. For ESR and CRP the mean values were 14.1 (14.5) mm/hr and 9.0 (11.2) mg/l, respectively.

On the sexuality scores 60.4% patients reported sex and sexuality important/very important to be satisfied with their daily life. 31.7% reported sexuality less important and only 7.6% thought sexuality was not important. 48.5% were satisfied/very satisfied with their sexual life while 29.3% were neither satisfied nor dissatisfied and 22.3% were dissatisfied. 49.5% reported to have had problems with their sexuality, however only 13% of the 105 patients had been seeking help to solve the problems. 32.4% of the patients thought their sexual problems were related to their disease, 11.4% in very high degree and 21% in some degree. The main causes of sexual problems from the disease were tiredness in 31.4%, stiffness in 30.5% and pain in 31.4%.

Conclusion: In this study of 105 patients with AS, as many as 49,5% reported to have had sexual problems, and 32,4% thought their sexual problems were related to their AS. The main causes of sexual problems were tiredness, stiffness and pain. We think the number of patients reporting sexual problems was high in this group since disease activity scores and health activity scores in this group was only modest high. More studies are needed to illuminate how sexual life is influenced by AS.

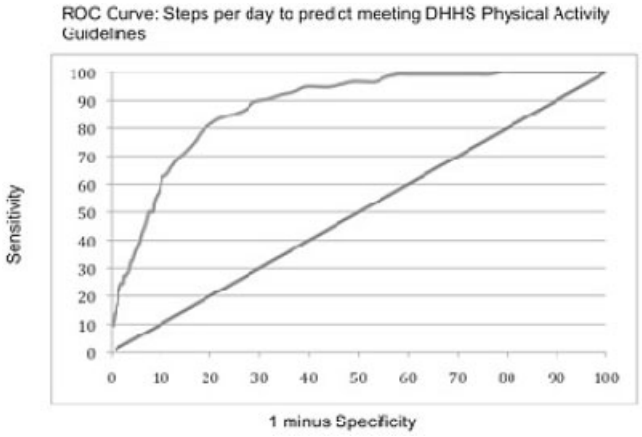
Is 10,000 Steps Enough to Meet Physical Activity Guidelines?: The Multicenter Osteoarthritis Study. Daniel K. White[1], David T. Felson[1], Yuqing Zhang[2], K. Douglas Gross[3], Jingbo Niu[1], Zhaolong Shen[4], Michael C. Nevitt[5], C.E. Lewis[6], James Torner[7] and Tuhina Neogi[4]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University Clinical Edpidemiology Reserach and Training Unit, Boston, MA, [3]MGH Institute of Health Professions, Boston, MA, [4]Boston University, Boston, MA, [5]University of California-San Francisco, San Francisco, CA, [6]University of Alabama, Birmingham City, AL, [7]University of Iowa, Iowa City, Iowa City, IA

Background/Purpose: The Department of Health and Human Services (DHHS) recommends all adults perform 150 minutes of moderate intensity exercise per week in 10 continuous minute bouts in order to achieve Physical Activity Guidelines. Given the popularity of using pedometers to quantify physical activity, a goal of taking at least 10,000 steps per day is frequently set as a benchmark for an 'active' level of activity. However, it is not known if taking 10,000 steps can act as a reasonable goal to approximate meeting Physical Activity Guidelines. Understanding this association is relevant for people with knee osteoarthritis (OA) who are often sedentary but benefit from supervised walking programs to reduce knee pain and improve function. Thus, we examined the ability of the 10,000 steps per day goal to predict meeting the DHHS Physical Activity Guidelines within the Multicenter Osteoarthritis Study (MOST).

Methods: MOST is an NIH funded longitudinal study of people who have or are at high risk for knee OA. Subjects at the 60 month visit wore an accelerometer-enabled pedometer (Stepwatch) to record steps taken over 7 days. Using Stepwatch data, we defined meeting the DHHS Physical Activity Guidelines as walking 150 minutes at a moderate intensity (i.e. a step frequency of at least 100 steps per minute) in at least 10 continuous minute bouts. We also calculated the proportion of subjects who had at least 10,000 steps per day, inclusive of all intensities. We calculated the sensitivity, specificity, and positive predictive value (PPV) of using the 10,000 steps per day goal to identify those who met Physical Activity Guidelines. We also generated a receiver operating characteristic (ROC) curve to determine how well step counts per day in general discriminated meeting Physical Activity Guidelines.

Results: Of the 1380 subjects who had 7 days of monitoring (Age 67 $\pm$ 8 yrs, BMI 31 $\pm$ 6 kg/m^2, female 60%, 9130 $\pm$ 3451 steps/day) 36% walked at least 10,000 steps per day, while only 6% met Physical Activity Guidelines. The sensitivity and specificity of the 10,000 steps per day goal to identify those meeting Physical Activity Guidelines was 88% and 72%, respectively. Of those walking at least 10,000 steps, 15.5% met Physical Activity Guidelines (PPV =15.5%). Overall the area under the curve from the ROC curve was 0.87 which suggests a moderate ability of steps per day to distinguish those meeting Physical Activity Guidelines. See Figure.



Conclusion: The 10,000 steps per day goal did not have sufficient predictive ability due to the low prevalence of meeting Physical Activity Guidelines within this study population. From a broader perspective, further research is needed to understand if health outcomes are optimized from steps per day irrespective of intensity, or solely by intensity of activity.

ARHP Concurrent Abstract Session
ARHP Clinical Practice/Patient Care II
Wednesday, November 9, 2011, 7:30 AM–8:30 AM

Does Informing Patients about the Link Between Dental Hygiene and Rheumatoid Arthritis Encourage Better Dental Care? Patricia J. Cornell[1], Selwyn Richards[2] and Sarah Westlake[2]. [1]Poole Hospital, Poole Dorset, United Kingdom, [2]Poole Hospital NHS Foundation Trust, Poole, United Kingdom

Background/Purpose: Recent evidence has shown that people with rheumatoid arthritis (RA) have a higher incidence of periodontal disease and that the extent and severity of both the periodontal disease and RA are linked. Furthermore periodontal therapy has been shown to have a beneficial effect on the severity of the RA. Moderate to severe periodontitis may also be a risk factor in the development of RA in non-smokers. One of the most important factors in oral care is access to dental health practitioners. In the UK it is well reported in the media about lack of

access to dental care. We decided to audit the access to dental care in a sample of our patient cohort with inflammatory arthritis. A patient dental care leaflet was produced highlighting the importance of dental care which was distributed to all our inflammatory arthritis patients. We then re-audited a sample of patients to determine if there had been any change in behaviour or access to dental care.

Methods: The first audit took place in 2009. All adult patients attending for rheumatology follow-up during a one month period were given an approved questionnaire to complete. Questionnaires were anonymous and included questions on access to both NHS and Private dental care. During 2010 a Trust approved patient leaflet about the importance of dental care was devised and given to all patients with inflammatory arthritis who attended the hospital rheumatology department. Six months later a second questionnaire was given to all adult patients attending for rheumatology follow-up during a one month period. This second questionnaire included questions on the dental care leaflet along with access to dental care.

Results: Demographics for both audits were similar. In the second audit 139 (95%) patients admitted to receiving the leaflet on dental care. All patients agreed or strongly agreed that the leaflet was easy to understand. Only 10 patients thought the leaflet contained no new information. 74 patients thought the leaflet applied to them and 125 patients thought the leaflet was helpful. Despite this very little change in behaviour was seen although 8 patients admitted that hey could not afford the dentist.

Results from audits of dental health questionnaire

	2009 n = 158			2010 n = 146		
	Yes	No	No anser	Yes	No	No answer
Annual review with dentist	126 (80%)	19 (12%)	13	123 (84%)	18 (12%)	5
Annual review with hygienist	55 (35%)	103 (65%)	0	59 (40%)	87 (60%)	0
NHS dentist	81 (51%)	52 (32%)	25	95 (65%)	34 (23%)	17
Admitted to smoking	19 (12%)	139 (88%)	0	19 (13%)	127 (87%)	0
Offered help to stop smoking	19	NA	NA	19	NA	NA
Have a dry mouth	44 (28%)	109 (69%)	5	43 (29%)	102 (70%)	1
Practitioner aware of dry mouth	14 (31%)	28 (64%)	2	16 (37%)	24 (55%)	3
Use an electric toothbrush	64 (40%)	89 (56%)	5	63 (43%)	83 (57%)	0

Conclusion: Dental care has become increasingly important in the light of new evidence linking severity of RA disease with both smoking and poor periodontal health. In our department a patient education leaflet led to minimal change in behaviour, with a slight increase in the amount of people accessing dental care and a moderate increase in access to NHS instead of private dentistry but no increase in the use of electric toothbrushes. Increasing the awareness of the potential link between poor oral hygiene and RA may have a useful impact on disease severity, however future studies need to concentrate on barriers to changing behaviour which may be due to cost or fear of dentists.

The Clinical Utility of Using Both the WOMAC and the MDHAQ Questionnaires in An Outpatient Osteoarthritis Clinic. Caroline Jones[1], Laurence A. Rubin[2] and Lesley Bainbridge[3]. [1]St Michael's Hospital, Toronto, ON, [2]St. Michael Hospital, Toronto, ON, [3]University of British Columbia, Vancouver, BC

Background/Purpose: A multidisciplinary osteoarthritis clinic (OA clinic) was established at St. Michael's Hospital to address the needs of an aging population with significant arthritis but not yet ready for joint replacement surgery. The goals of the clinic are to facilitate patient care that allows the patient to decrease pain, improve function and enhance quality of life. In order to objectively measure the patients' pain and function the use of a validated health questionnaire is necessary. Currently, the clinic utilizes two patient questionnaires: the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and the Multidimensional Health Assessment Questionnaire (MDHAQ).

Objectives: The purpose of this study was to examine the clinical utility of adopting both questionnaires into this clinical setting. The research question is what is the correlation between the MDHAQ and the WOMAC in an osteoarthritis patient population?

Methods: Retrospective chart review was conducted of patients who attended the OA clinic between August 2009 and January 2010. There were a total of 73 patients included in this study. The results of the MDHAQ and the WOMAC were correlated and the Pearson correlation coefficient was obtained.

Results: The following table depicts the results of the data collection depicting the maximum, minimum and average score.

Average Score on each measure

Variable	N	Mean	Std Dev	Sum	Minimum	Maximum
WOMAC	73	47.76	20.42	3487	9	88
MDHAQ-P	73	6.15	2.78	449	0.5	10
MDHAQ-FN	73	0.88	0.48	64.6	0	1.9
MDHAQ-S	73	13.40	26.82	978	0	180
MDHAQ-G	73	5.18	2.82	378.4	0	10
MDHAQ-FT	73	5.22	3.23	381	0	10

The WOMAC scores were correlated with each of the MDHAQ scores using the SASS system. The results are:

The WOMAC and the MDHAQ pain correlation was O.71

The WOMAC and the MDHAQ function correlation was 0.707

The WOMAC and the MDHAQ global health correlation was 0.68

The WOMAC and the MDHAQ fatigue correlation was 0.711.

The stiffness score did not correlate to the WOMAC score.

Conclusion: The MDHAQ and the WOMAC have a positive correlation. The WOMAC provided a single score with no maximum or minimal values but it is only applicable to patients with hip and knee arthritis. The MDHAQ provides separate scores and is applicable to patients with all types of arthritis but it did demonstrate maximum and minimum values in a number of areas. The questionnaires are easy to complete and score making the information available for use at the time of the patients' appointment. The results of this pilot study support the use of both questionnaires in an outpatient osteoarthritis clinic.

2563

Work Disability Is Related to the Presence of Arthritis, Not to a Specific Diagnosis. Hernan Maldonado Ficco[1], Rodolfo Perez Alamino[1], Fernando Dal Pra[1], Veronica Lencina[1], Luciana Casalla[2], Mariana Benegas[2], Oscar Rillo[2], Alberto Berman[3], Ana Lucía Barbaglia[3], Veronica Bellomio[4], Francisco Caeiro[5], Josefina Marcos[6], Juan Carlos Marcos[6], Antonio Catalan Pellet[7], Rodrigo Garcia Salinas[7], Sergio Paira[8], Federico Ceccato[8], Enrique Soriano[9], Zaida Bendran[9], Gabriela Salvatierra[10] and Gustavo Citera[1]. [1]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Hospital Tornu, Buenos Aires, Argentina, [3]Hospital Padilla, Tucuman, Argentina, [4]Consultorio, Tucuman, Argentina, [5]Hospital Privado de Cordoba, Cordoba, Argentina, [6]Hospital San Martin, La Plata, Argentina, [7]Hospital Rivadiavia, Buenos Aires, Argentina, [8]Hospital Jose Maria Cullen, Santa Fe, Argentina, [9]Hospital Italiano, Buenos Aires, Argentina, [10]Centro de enfermedades Reumaticas, Santiago Del Estero, Argentina

Background/Purpose: to evaluate work disability and its main associated factors in patients with early arthritis.

Methods: CONAART (Argentine Consortium for Early Arthritis) is the first early arthritis cohort in Argentina. Patients with at least one or more swollen joints and less than 2 years of symptoms duration were followed up prospectively in 13 rheumatology centers. Social, demographic, familiar, clinical and laboratory data were recollected. At first year and every year X-rays of hands and feet were performed and working status and pharmaco-economic data were evaluated. Work status (employed, unemployed, retired) and type of work were assessed by direct interview using a predesigned questionnaire. Patients retired due to age were excluded from final analysis. Categorical variables were compared using chi square and Fisher test and continue variables using student T test and ANOVA. Variables associated to work disability were analyzed by multiple logistic regression analysis.

Results: 848 patients were included, RA (ACR 87′ Criteria) = 483 (57%), UA= 365 (43%), 694 (81.8%) were women, median age was 46 years (IQR:35–55.7) and median symptoms duration 7 months (IQR:3–12). Demographic data and disease duration were comparable between both groups. Patients with RA had significantly higher disease activity,

worse functional capacity and quality of life, and more severe radiological damage (SENS score) compared to UA patients. Rheumatoid factor positivity was higher in RA vs UA (84.6% vs 34.1% p=0,001). However work disability (unemployed patients) was comparable between groups (RA=21% vs UA=18.6% p=NS). In both groups unemployed patients had higher DAS28, worse HAQ values and less years of formal education (p value <0,005 in all comparisons). Radiological damage was greater in unemployed patients but this difference did not reach statistical significance. In multivariate analysis, disease activity was the main variable associated with unemployment in both groups. No association was found with type of job or physical demand required for it.

Conclusion: Disease activity, but not radiological damage was the main cause of work disability in this cohort of patients with early arthritis, independently of the final diagnosis.

2564

Psychiatric Disorders in Fibromyalgia Patients, Results Patient Survey. Robert S. Katz[1], Sharon M. Ferbert[2], Alexandra Small[3], Susan Shott[1] and Patricia Kuenzi[1]. [1]Rush University Medical Center, Chicago, IL, [2]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL, [3]University of Illinois Medical School

Background/Purpose: We investigated the extent to which people with fibromyalgia (FMS) have also been diagnosed with psychiatric disorders.

Methods: 115 FMS patients and 63 control patients with other rheumatic diseases answered a rheumatology office questionnaire that contained questions about psychiatric disorders, including anxiety, depression, bipolar disorder, post-traumatic stress disorder, obsessive-compulsive disorder, attention deficit disorder, and alcoholism. The chi-square test of association and Fisher's exact test were used to compare percentages, and the Mann-Whitney test was done to compare FMS and control patients with respect to age. A 0.05 significance level was used and all tests were two-sided.

Results: 81.7% of the FMS patients and 61.9% of the control patients were women ($p = 0.004$). The mean age was 48.1 ± 12.3 years for FMS patients and 50.7 ± 13.6 for control patients ($p = 0.092$). FMS patients were significantly more likely than the control group to report a diagnosis or symptoms of anxiety (66.4% vs. 27.0%, $p < 0.001$), depression (64.2% vs. 28.6%, $p < 0.001$), bipolar disorder (10.4% vs. 0%, $p = 0.006$), post-traumatic stress disorder (15.6% vs. 4.8%, $p = 0.034$), obsessive-compulsive disorder (19.4% vs. 7.9%, $p = 0.045$), and attention deficit disorder (38.1% vs. 6.3%, $p < 0.001$). There was no statistically significant difference between FMS and control patients with respect to the percentage reporting a diagnosis or symptoms of alcoholism (1.9% vs. 3.2%, $p = 0.64$).

Conclusion: These results indicate that FMS patients report concomitant psychiatric diagnoses more frequently than controls, including anxiety, depression, post-traumatic stress disorder, obsessive-compulsive disorder, and attention deficit disorder. The presence of these psychiatric conditions can add to the difficulty of treating FMS.

Evaluation of ^{13}c-Acetate Plus Lactulose Breath Test, a New Examination to Measure Intestinal Absorption in Patients with Systemic Sclerosis. Tatsuhiro Yamamoto, Yoshihisa Urita, Kaichi Kaneko, Nahoko Tanaka, Yoshie Kusunoki, Kenji Takagi, Shinichi Kawai and Hirahito Endo. Toho University School of Medicine, Tokyo, Japan

Background/Purpose: To determine the quantitative analysis of the severity of the gastrointestinal (GI) involvements and GI predictive score in patients with systemic sclerosis(SSc), we measured the ^{13}C-fatty acid absorption-breath test and lactulose pulse ^{13}C-acetate breath test. Breath tests using fatty acids and acetate with a stable isotope (^{13}C) were carried out on patients with SSc in order to detect malabsorption, hypoperistalsis and bacterial overgrowth. We compared the outcome and a predictive score calculated by the absorption data and analyzed the therapeutic approach.

Methods: ^{13}C-labeled fatty acid absorption breath test and ^{13}C-acetate plus lactulose test were measured in 35 patients with SSc and 20 healthy subjects. ^{13}C-labeled mixed fatty acids 200mg or ^{13}C-acetate 100mg plus lactulose 12g were given orally. $^{13}CO_2$ and H_2 contents in the expired air were analyzed by a mass spectrometer and by a breath analyzer, respectively. Using breath test data, fatty acid absorption were calculated by cumulative ^{13}C excretion for 8 hours and ^{13}C-acetate 100mg plus lactulose breath test were calculated by 3 hours. We measured the therapeutic effects using these breath tests quantitatively in GI involvements of SSc. Intestinal predictive score calculated by each data of ^{13}C-acetate absorption 3h cumulative recovery rate, ^{13}C-labeled fatty acid absorption 8hours cumulative rate, bacterial overgrowth rate and clinical bowel symptom score.

Results: ^{13}C-labeled fatty acid absorption breath test: ^{13}C cumulative excretion for 8 hours in patients with SSc was significantly lower than that of normal subjects. (32 SSc: 12±6%, 20 normal:21±4%, $P<0.05$). ^{13}C cumulative excretion rate in 4 SSc patients with parenteral hyperalimentation showed markedly low data (mean 3.4±2.6%). Lactulose plus ^{13}C-acetate breath test: ^{13}C cumulative excretion rate of 3 hours of ^{13}C-acetate absorption of SSc patients were lower than control. AUC-Cmax, ^{13}C-acetate absorption index of SSc patients were significantly lower than that of normal control (21 SSc 4.8±2.3%, 20 normal 5.4±1.8 %, $P<0.05$). Tmax as the time of peak $^{13}CO_2$ excretion of SSc patients was delayed than control (SSc 55.5±16.6, Control 43.9±10.4 min). After treatment by prokinetic drugs and antibiotics ^{13}C cumulative excretion rate increased 2.88% from 1.88% in a SSc patient with severe GI involvements Breath hydrogen (H_2) levels reflects intestinal bacterial overgrowth. H_2 excretion continued over 20ppm for 120 min after lactulose administration by small intestine bacterial overgrowth. After antibiotics administration H_2 concentration decreased. Predictive score correlated with seriousness of GI involvements. We can suppose connection with treatment plan determination and outcome of GI involvements with SSc.

Conclusion: Severe intestinal involvements loss quality of life in patients with SSc. ^{13}C-fatty acid and lactulose plus ^{13}C-acetate breath test is a simple and non invasive intestinal absorption examination and a use tool for the quantitative evaluation of GI involvements in patients with SSc. GI predictive score calculated by these examinations might be tool for determination of therapeutic approach to severe GI involvements of patients with SSc.

2566

The Association Between Cardio-Respiratory Fitness and Traditional Cardiovascular Risk Factors in Rheumatoid Arthritis Patients. Jennifer K. Cooney[1], Yasmeen Ahmad[2], Jonathan Moore[1], Andrew Lemmey[1], Jeremy Jones[1], Peter Maddison[1] and Jeanette Thom[1]. [1]School of Sport, Health and Exercise Sciences, Bangor University, George Building, Bangor, Gwynedd, LL57 2PZ, UK., Bangor, United Kingdom, [2]The Department of Rheumatology, Betsi Cadwaladr University Health Board (West), Llandudno, LL30 1LB, UK, Bangor, United Kingdom

Background/Purpose: RA is associated with increased mortality from cardiovascular disease (CVD). Traditional CVD risk factors do not fully explain this increased incidence. RA patients are typically known to have poor cardio-respiratory fitness (CRF), a known CVD risk factor. However their CVD risk factor profile needs further investigation. Thus the aim was to assess RA patients' CRF using a simple tool and to determine whether poor CRF correlated with traditional CVD risk factors.

Methods: 100 RA patients (69 female, 31 male) attending rheumatology clinics were recruited. CRF was measured using the Siconolfi Step Test. Patients were allocated into three groups based on their performance in the step test (i.e. unable to do the test, 'poor' fitness and 'better' fitness). RA activity/severity, traditional CVD risk factors, Framingham 10 year CVD risk and anthropometric characteristics were assessed.

Results: RA patients had well controlled disease (table 1). Some CVD risk factors were mildly elevated but 32% and 28% of patients were taking medication for hypertension and hyperlipidemia respectively. Their Framingham Risk Score was moderate at 16%. Because patients' range of CRF was poor, expected correlations with CVD risk factors were not observed. Despite no difference in disease duration 'unable' patients rated their arthritis as worse, more painful and disabling. Their Framingham Risk was also significantly higher than 'better fitness' patients. 'Unable' patients were also fatter, had bigger waists and were classed as obese (BMI >30).

Table 1. RA characteristics, P<0.05; # 1 vs 2; * 1 vs 3; ^ 2 vs 3

RA factors	Total Group	1. Unable (n=35)	2. Poor (n = 33)	3. Better (n = 32)
Age	59.6 ± 10.2	62.2 ± 8.4*	64.2 ± 7.2^	52.0 ± 10.6
Disease duration	10.4 ± 9.1	11.0 ± 10.5	11.4 ± 9.3	8.7 ± 7.2
DAS28 CRP	2.8 ± 1.4	3.0 ± 1.1	2.6 ± 1.1	2.6 ± 1.2
Global health (0–100)	32 ± 24	46 ± 24#*	23 ± 21	25 ± 19

Conclusion: The step test has emerged as a very useful tool, highlighting that RA patients have poor CRF and identifying those at greatest risk of developing CVD in the future. 'Unable' patients and those who perform poorly require medical intervention. This investigation has shown that screening for traditional risk factors may not be enough as the extent of their CVD risk is somewhat masked. Early detection of CVD risk using a tool like the step test could significantly reduce the CVD mortality in RA.

Immune Suppression and Injury Tolerance in Fibrotic Liver Are Mediated by Induced Regulatory T Cells Which Safeguard Fibroplasias From Clearance. Ming Feng[1], Yuan-Ping Han[1] and Song G. Zheng[2]. [1]University of Southern California, Los Angeles, CA, [2]USC Keck School of Medicine, Los Angeles, CA

Background/Purpose: Upon acute injury, hepatic stellate cells (HSCs) are mobilized to lead wound healing through a chain of reactions, from expression of matrix metalloproteinases (MMPs), to activation of latent transforming growth factor-beta (TGF-β), and releasing of active retinoic acids (atRA). On the other hand, TGF-β and atRA together can generate and promote Foxp3+ regulatory T cells (Tregs) from naïve T cells. In chronic injury or infection, HSCs are transformed into myofibroblasts and the liver becomes immune suppression and injury tolerance. In a recent report we showed that many MMP genes in myofibroblatic HSCs are permanently silenced through epigenetic suppression to favor ECM accumulation. Here, we uncover that the fibrotic liver maintains in immune suppression and injury tolerance, as marked by impaired inflammation, accumulation of regulatory T cells (Tregs), which protect fibroplasias from clearance.

Methods: Male mice (C57/BL6) mice with 8–10 weeks old were used. Hepatic fibrosis was induced by intraperitoneal injection with Thioacetamide (TAA) at 160mg/kg body weight for 8 weeks or saline as control. The frequency of hepatic Tregs was examined by flow cytomety and immunofluorescence. Tregs were depleted by the administration of anti-CD25 antibody (PC61) i.p. at 3 days before TAA challenge. 100 ml liposome-encapsulated clodronate (Cl2MDP) was injected intravenously at 24 hours before TAA challenge to deplete kupffer cells. 3 days after TAA challenge, mice were sacrificed and MMPs in liver tissues were tested by Zympgraph. Fibrolysis was evaluated by sirusis staining. The data are expressed as means ± SD. Values were regarded as statistic difference for P<0.05.

Results: We found that CD4+Foxp3+ regulatory T cells accumulated in fibrotic liver and suppressed inflammatory responses evoked by hepatic toxin. The depletion of Tregs by anti-CD25 antibody restored immune response and MMP expression in the fibrotic liver, and promoted fibrosis resolution. However, if depletion of kupffer cells at the same time, hepatic MMPs were reduced and clearance of fibroplasias was inhibited. Co-staining MMPs, F4/480 and desmin for immunofluorescence indicated that in fibrotic liver MMPs were produced by kupffer cells, while in normal liver hepatic stellate cells (HSCs) were the main source of MMPs. Liver fibrosis still can be developed in NOD/SCID mice where adaptive immunity is absent in chronic liver injury, but the fibrosis is resolved promptly. Transfusion of injury-type Tregs into NOD/SCID mice was unable to induce fibrosis, but instead, generated immune suppression and impaired fibrosis resolution.

Conclusion: The immune suppression and injury tolerance in fibrotic liver are mainly mediated by peripheral induced Tregs that safeguard fibroplasias from clearance. It is, therefore, that the control of induced Tregs development and function could be preventive and therapeutic in liver fibrosis in the chronic stage of liver injury and inflammation.

Activation of c-Jun N-Terminal Kinase and Extracellular Signal-Regulated Kinase Predicts Damage in Systemic Lupus Erythematosus. Mirit Amit-Vazina[1], Yair Molad[2], Eliyahu Yona[3], Lily Amram[3], Olga Bloch[4] and Micha J. Rapoport[4]. [1]Rheumatology Service, Assaf Harofeh Medical Center and Sackler School of Medicine, Tel-Aviv University, Israel, Zerifin, Israel, [2]Rheumatology Unit, Beilinson Hospital, Rabin Medical Center, and Sackler Faculty of Medicine, Tel Aviv University, Petah Tikva, Israel, [3]Internal Medicine Division, Day Care Unit, Assaf Harofeh Medical Center and Sackler School of Medicine, Tel-Aviv University, Israel, Zerifin, Israel, [4]Diabetes and Immunology Research Laboratory, Assaf Harofeh Medical Center and Sackler School of Medicine, Tel-Aviv University, Israel, Zerifin, Israel

Background/Purpose: Aberrant signaling along the p21ras/MAP kinase pathway has been demonstrated in systemic lupus erythematosus (SLE). We have previously reported that the activity of c-Jun N-terminal Kinase (JNK) and Extracellular Signal-Regulated Kinase (ERK) is associated with disease activity in SLE patients. The objective of the present study is to determine whether JNK and ERK activation predicts subsequent permanent end organ damage in a cohort of SLE patients.

Methods: Blood samples of 42 SLE patients were prospectively collected during four consecutive visits. Expression of total ERK and JNK kinases and their active forms (pERK and pJNK) was determined by western blot in whole protein lysates of peripheral blood mononuclear cells. Four years later the permanent damage attributed to SLE was assessed using the SLICC-ACR damage index (SLICC-DI). Correlations between SLICC-DI scores and mean and maximal expression of total ERK and JNK kinases and of pERK and pJNK were assessed by Spearman correlation test. Stepwise regression analysis was used to assess the most significant contributions to SLICC-DI.

Results: Demographic and clinical data of 36 SLE patients who were available for long term follow-up and determination of SLICC-ACR are demonstrated in the table. During follow-up period one female patient died of congestive heart failure complicated by sepsis at the age of 51 after 19 years of disease.

	Mean ± SD	Median
Age (years)	48.25 ± 11.8	49.5
Females (%)	32 (89)	
Disease Duration (years)	16.9 ± 4.3	16
Follow-up Duration Since Last Visit (years)	4.02 ± 0.68	4.25
SLICC-DI	1.9 ± 1.8	2

Mean values of JNK, pJNK and pERK but not ERK obtained during the initial follow-up period correlated positively with SLICC-DI values obtained after long term follow-up (r =0.32, 0.35 and 0.38 respectively, p<0.05 for all). Maximal values of JNK, pJNK and pERK also correlated with SLICC-DI (r=0.45, 0.35 and 0.36 respectively, p<0.01 for JNK and p<0.05 for pJNK and pERK).

On stepwise regression analysis using square root transformation of SLICC-DI values and excluding SLE disease activity index (SLEDAI) maximal value of JNK and mean value of pERK were most significantly associated with SLICC-DI.

	Max JNK	R	RSQ
Step 1	Mean pERK	0.51	0.28
Step 2	0.62	0.38	

Conclusion: The results of this long-term follow-up study indicate that increased expression of JNK as well as activated forms of JNK and ERK is associated with permanent end-organ damage and can serve as predictors of damage in SLE patients.

2569

Novel Regulation of TNF-α-Induced-IL-18 Bioactivity in Rheumatoid Arthritis Synovial Fibroblasts by Reducing Caspase-1 Via JAK2 Inhibition. Hubert Marotte[1], Tatiana Fedorova[1], Adam J. Pinney[1], Benjamin Lewis[1] and Alisa E. Koch[2]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]Veteran's Administration and Unversity of Michigan, Ann Arbor, MI

Background/Purpose: Rheumatoid arthritis (RA) is the most common inflammatory chronic joint disorder. Interleukin-1 (IL-1) family members play a key part in the pathogenesis of RA. Among the IL-1 cytokine family members, IL-18 is a proinflammatory cytokine, which modulates Th1 development and induces angiogenesis. We previously described regulation of TNF-α-induced-IL-18 bioactivity by blocking the ERK pathway. Here, we focused on modulation of TNF-α-induced-IL-18 bioactivity by reduction of caspase-1 expression.

Methods: Caspase-1 expression in RA synovial fibroblasts treated with TNF-α was assessed by qRT-PCR and Western blot. The critical pathways for TNF-α-induced caspase-1 expression were determined by using chemical inhibitors: pyrrolidine dithiocarbamate (PDTC; a nuclear factor kappa-light-chain-enhancer of activated B cells [NFκB] inhibitor; 200μM), MAPK inhibitors (ERK1/2, PD98059; p38, SB202190; or JNK2, SP600125; 10μM), or AG-490 (a Jak2 inhibitor; 10 μM) followed by TNF-α stimulation. Caspase-1 expression was determined by qRT-PCR and Western blot. Immunofluorescence (IF) staining was performed to check IL-18 production induced by TNF-α with or without preinhibition of ERK1/2 or JAK2 by using antibody recognized immature and mature IL-18. IL-18 functional activity was assessed using an IL-18 bioactivity assay using KG-1 cells and culture supernatants.

Results: TNF-α induced RA synovial fibroblast caspase-1 expression at the mRNA and protein levels in a time-dependant manner ($P < 0.05$; $n \geq 6$ patients). Blocking the Jak2 pathway reduced TNF-α-induced-caspase-1 expression at the transcriptional and protein level by approximately 60% and 40%, respectively ($P < 0.05$; $n \geq 4$). Blocking NFκB, ERK1/2, JNK or p38 pathways had no effect on TNF-α-induced-caspase-1 mRNA expression. We then confirmed by IF that TNF-α-induced IL-18 and investigated roles of ERK1/2 and JAK2 pathways. Blocking the ERK1/2 pathway dramatically decreased IL-18 expression induced by TNF-α. However, when blocking the JAK2 pathway, TNF-α induced intracytoplasmic granular IL-18 expression, suggesting a defect of caspase-1. Finally, blocking the Jak2 pathway, we observed a reduction of IL-18 bioactivity by 52% in RA synovial fibroblasts.

Conclusion: These results show a unique way to block TNF-α-induced-IL-18 bioactivity by blocking capase-1. These data provide a novel role for the Jak2 pathway in RA patients and emphasize the use of Jak inhibitors as a new therapeutic option in the management of RA.

STAT3 Phosphorylation of Circulating Leukocytes Correlates with Disease Activity in Early Untreated Rheumatoid Arthritis. Krista Kuuliala[1], Antti Kuuliala[1], Saara Aittomäki[1], Suvi Oksanen[1], Sanna Siitonen[2], Hannu Kautiainen[3], Marjatta Leirisalo-Repo[2] and Heikki Repo[1]. [1]Haartman Institute, Helsinki, Finland, [2]Helsinki University Central Hospital, Helsinki, Finland, [3]Central Finland Central Hospital, Jyväskylä, Finland

Background/Purpose: Signal transducer and activator of transcription (STAT) 3 is an important transcription factor in the regulation of inflammation. Experimental models suggest a role for STAT3 in the pathogenesis of RA [1, 2]. We aimed to evaluate STAT3 activation in peripheral blood leukocytes in early untreated RA in relation to disease activity.

Methods: Blood samples were obtained from 31 patients diagnosed with early RA who had not received prior DMARDs or corticosteroids. The mean age of the patients was 47 years (SD 14), median duration of symptoms 8 months (interquartile range 3–24 months), 81% were women, 81% rheumatoid factor positive, and 84% anti-CCP positive. Disease activity was evaluated by calculating the DAS28 score (available in 29 patients). The levels of activated STAT3 in leukocyte subsets (CD14+, CD3+CD4+, CD3+CD8+, CD19+) were determined by flow cytometry following lysis of erythrocytes, fixation and permeabilization of leukocytes, and incubation with phospho-specific (pY705) anti-STAT3 monoclonal antibody (as described in [3]). The proportion of pSTAT3 positive cells was determined using an electronic gate set to include <5% of positively fluorescing cells from a healthy control subject. Correlation coefficients were calculated by Spearman method.

Results: The proportion of pSTAT3 positive CD4+ cells was increased compared to controls in 18/31 patients (58%), CD8+ in 12/31 (39%), CD19+ in 8/31 (26%), and CD14+ in 17/31 (55%). DAS28 correlated with the proportion of pSTAT3+ CD4+ cells (Table), as well as the ratio of CD4+/CD14+ cells and CD4+/CD19+ cells (Table, Figure).

Table. Correlation of DAS28 with the proportion of pSTAT3 positive leukocyte subsets.

Cells	r	p
CD3+CD4+	0.37	0.047
CD14+	−0.06	0.74
CD19+	−0.30	0.11
CD3+CD4+ toCD14+	0.41	0.028
CD+CD4+to CD19+	0.44	0.017
CD14+ to CD19+	0.08	0.69

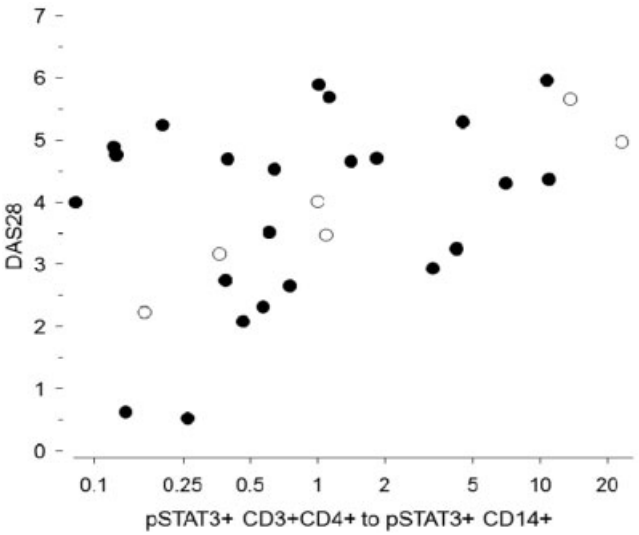

Figure. Correlation of DAS28 with the proportion of pSTAT3+ CD3+CD4+ to pSTAT3+ CD14+ cells. Filled in symbols denote anti-CCP positive and blank symbols denote anti-CCP negative patients.

Conclusion: STAT3 is constitutively activated in circulating leukocytes in early RA. The proportion of pSTAT3+ CD4+ cells correlates with disease activity evaluated by DAS28. Circulating lymphocyte STAT3 activation is not a unique feature of RA since it has also been reported in primary Sjögren's syndrome [4] as well as in acute pancreatitis with severe systemic inflammation [3]. Our results emphasize the heterogeneous involvement of immune inflammatory cells and may provide a novel strategy for personalized medicine in the treatment of early RA.

What Keeps An Autoantibody-Positive Healthy Individual Healthy? Lauren L. Ritterhouse[1], Holden T. Maecker[2], Hongwu Du[3], C. Garrison Fathman[4], Joan T. Merrill[1], Joel Guthridge[1] and Judith A. James[5]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University School of Medicine, Stanford, CA, [3]Stanford University School of Medicine, Stanford, CA, [4]Stanford Univ Medical Center, Stanford, CA, [5]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK

Background/Purpose: Antinuclear antibodies can be detected in up to 25% of the population, however only 5–7% of the United States is affected by an autoimmune disease. Therefore, a significant number of individuals are capable of mitigating the presence of autoantibodies and avoiding the development of clinical disease. The objective of this study was to investigate features of autoantibody-positive (aAb+) healthy individuals' immune systems and to examine the role that cytokines might play in maintaining immune equilibrium in ANA-positive individuals without autoimmune disease.

Methods: A cohort of 790 individuals was screened by multiplex, bead based assays for autoantibodies against: dsDNA, Chromatin, Ribosomal P, SS-A/Ro, SS-B/La, Sm, Sm/RNP, RNP, SCL-70, Jo-1, and Centromere B. The levels of 52 cytokines were measured in the sera from aAb+ individuals, as well as from matched aAb- controls and SLE patients, using multiplex bead-based assays and ELISAs. Hierarchical clustering was performed with the cytokine data on all individuals and Kruskal-Wallis tests with Dunn's multiple comparisons were used to compare cytokine levels as well as a false discovery rate. Immune cell phenotyping and phospho-flow cytometry was performed on peripheral blood mononuclear cells from a subset of aAb+ and aAb- healthy individuals. Unpaired t-tests and Mann Whitney tests were performed as appropriate.

Results: Of the screened individuals, 57 individuals were positive for at least one autoantibody specificity (7.2%), with 33.3% being Native American, 57.9% European American, 8.8% African American, and 89.5% female. European American aAb+ healthy individuals (n=31) and matched aAb- healthy controls and SLE patients were selected for further analysis. While aAb+ healthy individuals displayed some similar cytokine patterns to SLE patients, they also displayed a suppressed cytokine profile that included decreased T-cell cytokines [IFNγ ($p<0.05$), IL-5 ($p<0.05$), IL-17F ($p<0.01$)], decreased B lymphocyte stimulator levels ($p<0.05$), and increased interleukin-1 receptor antagonist levels ($p<0.001$). An increased percentage of IgD+CD27+ B cells was also found in aAb+ healthy individuals ($p=0.005$). While B cells from aAb+ healthy individuals showed significantly increased pSTAT1 and pSTAT5 in response to IFNγ stimulation ($p=0.004$ and $p=0.005$), decreased pSTAT1 was seen in B cells in response to IL-2, IL-6, IL-7, IL-10, and IL-21 stimulation ($p=0.011$, $p=0.009$, $p=0.005$, $p=0.036$, and $p=0.019$, respectively). CD4+ T cells from aAb+ healthy individuals showed dramatically decreased pSTAT1 and pSTAT3 in response to IL-2 stimulation ($p=0.004$ and $p<0.001$). IFNα stimulation significantly increased pSTAT1 and pSTAT3 in monocytes from aAb+ healthy individuals ($p=0.023$ and $p=0.016$), while IFNγ stimulation significantly increased pSTAT3 ($p=0.005$).

Conclusion: Although aAb+ healthy individuals exhibit features of inflammation and loss of immune tolerance, they are capable of suppressing these responses by regulatory mechanisms likely no longer functional in patients with autoimmune disease.

Aminopeptidase N/CD13 Localization and Chemotaxis in Rheumatoid Arthritis *In Vivo* and *In Vitro*. Rachel Morgan[1], Nilofar Behbahani-Nejad[1], Judith Endres[1] and David A. Fox[2]. [1]University of Michigan, Ann Arbor, MI, [2]Univ of Michigan Med Ctr, Ann Arbor, MI

Background/Purpose: Aminopeptidase N (CD13, EC 3.4.11.2) is a metalloproteinase expressed on the cell surface of fibroblast like synoviocytes (FLS) that has also been found in soluble form in serum and synovial fluid. We have shown that CD13 is higher in amount and activity in RA synovial fluids compared to OA. It has been suggested but not proven that CD13 can act as a chemokine for T cells in RA. The goal of this study was to determine whether FLS contribute to the CD13 in synovial fluid, and if CD13 could play a role in bringing T cells to the RA joint.

Methods: FLS were cultured in serum free media (Peprogrow) either alone, with cytokines, or with protease inhibitors. Cytokine activated T cells (Tck) were generated using IL-6, TNFα, and IL-2. The antibody 591.1D7.34, developed by our laboratory and another anti-CD13 mAb, WM15, were used to create a novel sandwich ELISA for CD13. CD13 enzymatic activity was measured in parallel by cleavage of L-leucine-7-amido-4-methyl coumarin hydrochloride (L-leu-AMC) to release the fluorescent molecule AMC. T cell chemotaxis was measured using an under agarose system. MMP14 or control siRNA was transfected into FLS and the FLS were grown up in 20% serum media and switched to serum free conditions for 6 hours prior to harvesting. GFP siRNA was used to determine success of transfection. Exosomes were isolated by centrifugation at 110,000 xg from synovial fluid, RA FLS culture supernatant or serum. Following centrifugation over an Optiprep density gradient, exosomes were obtained at 1.110–1.163 gm/ml density.

Results: Recombinant human CD13 was strongly chemotactic for cytokine activated T cells (Tck) over a range of concentrations with peak effect at 200ng/ml CD13 (3.85 chemotactic index, $p=0.0031$). Soluble CD13 was found in supernatants of FLS by ELISA (45.72±10.28 ng/ml) and enzymatic assay (497.96±167.27 nmoles of substrate cleaved per hour per ml). Among various protease inhibitors added to FLS cultures only GM6001 (a metalloprotease inhibitor) prevented release of CD13 into culture supernatants. Knockdown of MMP14 decreased FLS shedding of CD13 protein into the supernatant, as measured both by ELISA and enzymatic assay. We also found CD13 on exosomes in serum (19.16±0.64ng/ml), synovial fluid (66.55±4.68 ng/ml), and FLS culture supernatants (44.28±2.54ng/ml). In addition, the proinflammatory cytokines IFNγ, TNFα, and IL-17 all upregulated expression of CD13 mRNA by FLS, but with distinct kinetics of protein upregulation and compartmentalization induced by each cytokine.

Conclusion: CD13 is shed from the cell surface of FLS into culture supernatants and is found in synovial fluid. This process is mediated by one or more metalloproteases, including MMP14. CD13 is upregulated by proinflammatory cytokines that are commonly found in the RA joint. The combination of upregulation and shedding from FLS contributes to the high levels of CD13 in RA synovial fluid. CD13 induces chemotaxis of Tck, T cells that are similar to those found in the RA joint, at concentrations of CD13 detected *in vivo* in humans. Together this data demonstrates that CD13 could play an important role as a T cell chemoattractant, in a positive feedback loop that contributes to RA synovitis.

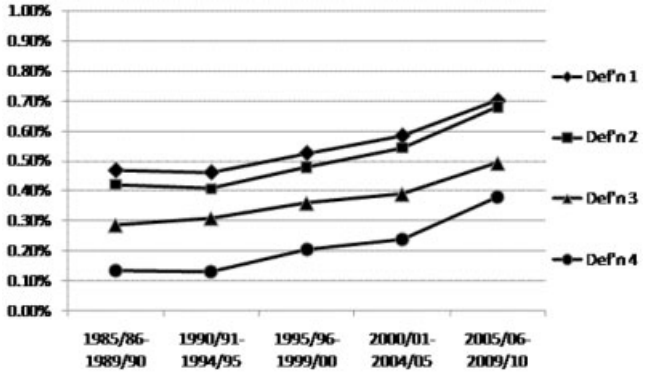
2573

Administrative Definitions of Rheumatoid Arthritis: Rising Prevalence Regardless of Definition Used. Christine A. Peschken[1], Carol A. Hitchon[2], Hui Chen[2], Allan Garland[2], Hani S. El-Gabalawy[2], Charles N. Bernstein[2] and Ruth Ann Marrie[2]. [1]Univ of Manitoba, Winnipeg, MB, [2]University of Manitoba, Winnipeg, MB

Background/Purpose: Recent studies suggest temporal changes in the incidence and prevalence of rheumatoid arthritis (RA), but are inconclusive. Administrative healthcare databases provide large comprehensive longitudinal datasets, but their accuracy for identifying RA must be established, given their use for billing purposes and the diagnostic uncertainty inherent in the disease.

Methods: In a stable population of over 900,000 adults, we used hospital and physician claims from a large administrative database to compare the effect of different case definitions on the 5-year period prevalence of RA from 1985 to 2010. For each 5 year interval, the mid-year population was used as the denominator. For physician claims, we identified RA using The 'International classification of diseases' (ICD)-9 code 714. For hospital claims we identified RA using the ICD-9 code 714 from 1985 to 2004, and the ICD-10 codes M05 & M06 from 2004 onward. Four case definitions were used: 1. ≥2 RA claims ≥2 months apart from any physician; 2. ≥2 RA claims ≥2 months apart from any physician, but excluded if there was a subsequent claim for another inflammatory arthritis or if not confirmed when seen by a rheumatologist; 3. ≥5 claims ever for RA by any physician or hospitalization if registered in the database at least 2 years; or ≥3 claims if registered in the database for < 2 years; 4. ≥2 RA claims ≥2 months apart from a rheumatologist.

Results: The prevalence rate for RA ranged from 0.14% to 0.47% in 1985–1990, and rose steadily to .38%-.70% in 2005–2010, depending on the case definition of RA (Figure 1).



Conclusion: Irrespective of the definition used, we found a steady rise in the prevalence of RA over the 25 year period, similar to the rise in prevalence recently described in Olmsted County. This may reflect true increased incidence, or improved ascertainment due to increasing awareness of RA among physicians, particularly with respect to early diagnosis of RA. Improved ascertainment is supported by the slightly steeper increase in the rate of patients followed by rheumatologists (definition 4) as rheumatology manpower in the region doubled

between 2000 and 2010. This study also demonstrates that only a small proportion of RA patients are followed by rheumatologists (Def'n 4), with most receiving no or episodic rheumatology care. Further attempts at determining diagnostic accuracy and disease outcomes in this 'gap' population using linkages with clinical and prescription databases are underway.

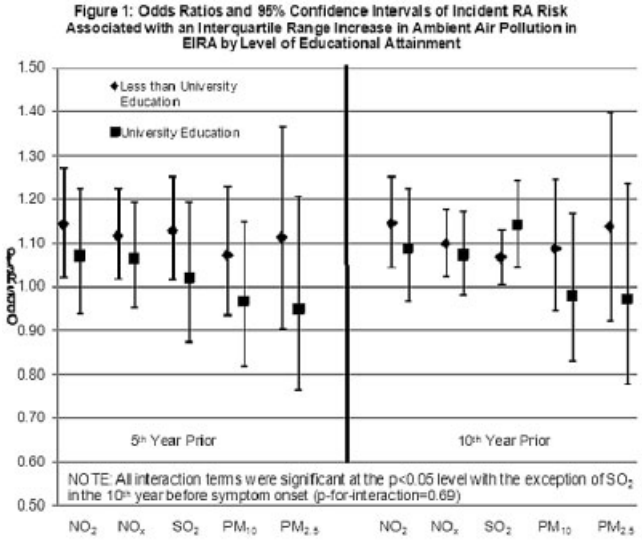
2574

The Association of Ambient Air Pollution Exposures and Risk of Rheumatoid Arthritis: Results From the Swedish EIRA Case-Control Study and the US Nurses' Health Prospective Cohort Study. Jaime E. Hart[1], Henrik Källberg[2], Francine Laden[3], Karen H. Costenbader[1], Marie Holmqvist[2], Lars Klareskog[2], Lars Alfredsson[4] and Elizabeth W. Karlson[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Karolinska Institutet, Stockholm, Sweden, [3]Harvard School of Public Health, Boston, MA, [4]Institute of Environmental Medicine, Unit of Cardiovascular Epidemiology, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Environmental factors play an important role in the development of rheumatoid arthritis (RA), and airway exposures to environmental agents are postulated to be of special importance. We examined whether long-term exposures to ambient air pollution were associated with risk of RA in the Swedish Epidemiological Investigation of Rheumatoid Arthritis (EIRA) Study and in the US Nurses' Health Study (NHS).

Methods: We studied 1,330 incident RA cases and 2,235 controls from EIRA and 91,203 members of the NHS, among whom 762 had developed RA. Exposures to particulate matter (PM_{10}, $PM_{2.5}$) and gaseous pollutants (SO_2, NO_2, and NO_x, in EIRA only) were predicted for all residential addresses. We examined the association of an interquartile range increase in each air pollutant with the risk of RA, and risks of seropositive (rheumatoid factor (RF) and anti-citrullinated protein antibody (ACPA)) RA phenotypes, using multivariable logistic regression for EIRA and Cox proportional hazards models for NHS. Models in EIRA were adjusted for age, gender, smoking status, and educational attainment. Models in NHS were adjusted for age, race, reproductive factors, hormone use, physical activity, body mass index, smoking status and pack-years, and individual and area level measures of socioeconomic status. As the relevant etiological time period of exposure is unknown, we examined pollution in various years before RA onset.

Results: In both studies there was no evidence for an increased risk of RA with PM_{10} or $PM_{2.5}$ in any exposure window or with any pollutant in the year of onset, and in some cases modest inverse associations were observed. In EIRA, elevated risks with increases in SO_2, NO_2, and NO_x in the 10^{th} and 20^{th} years prior to RA symptom onset were observed, particularly in models restricted to RF+ and ACPA+ phenotypes. For each interquartile range increase (2 $\mu g/m^3$ for SO_2, 7 $\mu g/m^3$ for NO_2, and 8 $\mu g/m^3$ for NO_x) in exposure in the 10^{th} year prior to onset, the fully-adjusted odds ratios for ACPA+ RA (95% confidence intervals (CI)) were 1.07 (1.01–1.13), 1.11 (1.01–1.21) and 1.07 (1.00–1.14) for SO_2, NO_2, and NO_x respectively. Results were strongest in individuals with less than a university education (Figure 1). In the NHS, only exposures to SO_2 were associated with modest increases in total RA risk (fully adjusted hazard ratio (95%CI) for an interquartile range (16 $\mu g/m^3$) increase in SO_2 10 years prior to onset 1.05 (0.92–1.19)).



Conclusion: In EIRA, we observed elevations in the odds of developing RA and seropositive RA in individuals with higher levels of gaseous air pollution exposures, particularly SO_2. These risks were strongest in those with less than a university education. In NHS, we observed modest elevations only with increasing exposures to SO_2. To the best of our knowledge, this is the first study to examine the effects of air pollution on risk of RA.

2575

The Performance of Matrix-Based Risk Models for Rapid Radiographic Progression in An Observational Cohort of Established Rheumatoid Arthritis Patients. Siri Lillegraven[1], Femke H.M. Prince[2], Nancy A. Shadick[2], Espen A. Haavardsholm[3], Michelle A. Frits[2], Christine K. Iannaccone[2], Tore K. Kvien[3], Michael E. Weinblatt[2] and Daniel H. Solomon[2]. [1]Brigham and Women's Hospital/Diakonhjemmet Hospital, Boston/Oslo, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Diakonhjemmet Hospital, Oslo, Norway

Background/Purpose: Matrix-based clinical risk prediction models have been proposed as a tool to forecast rapid radiographic progression (RRP, defined as ≥ 5 units change in Sharp score/year) in rheumatoid arthritis (RA). The three current models are based on data from clinical trials in early RA, and each model includes 4 of the following variables: treatment, joint erosions, serological status, swollen joint count, CRP and smoking. These models allow calculation of the predicted probabilities for RRP, similar to the use of the Framingham risk score. We tested the performance of the three risk models in an observational cohort with established RA.

Methods: Subjects in BRASS, an observational RA cohort with treatment according to clinical practice, were analyzed. 478 individuals had hand radiographs scored by the Sharp method at baseline and 2 years. All received disease modifying anti-rheumatic drugs (DMARDs) according to typical clinical practice. The three matrix-based risk models assessed were: A) the ASPIRE model[1], B) the BeSt model[2] and C) a model from the second year of the SWEFOT trial[3]. As the models suggest, we calculated separate risk scores for patients using synthetic DMARDs vs. biologics. Patients were classified as having RRP (cases) or not (non-cases) and allocated to the correct matrix cell for each model, with a corresponding predicted risk of RRP. The mean predicted probability for cases and non-cases, the net reclassification improvement (NRI) with continuous outcome, integrated discrimination improvement (IDI) and area under the receiver operating curve (AUC) were calculated for each model.

Results: The median (IQR) age for the 478 patients was 59 (50, 66) years, disease duration 12 (4, 23) years, swollen joint count 6 (2, 13) and tender joint count 7 (1, 4). 84% were female and 86% had presence of erosions at baseline. The percentage of patients with RRP was 12% (32 of 271) in the synthetic DMARD group and 10% (21 of 207) in the biologic DMARD group (either as monotherapy or in combination with synthetic DMARDs). Model statistics summarized in the table indicated that Model B fit our data best, but none of the models separated cases and non-cases well in this cohort.

	Discrimination				*Classification*	
	Model A	Model B	Model C		*Model A vs. model B*	Model B vs. Model C
Mean predicted probability cases/non-cases	9.8/9.1	29.6/20.2	22.3/20.2	**IDI * ‡**	8.7	−7.3
AUC	0.631	0.716	0.617	**NRI with continuous outcome * #**	42	−32.8

* For both NRI and IDI a positive number indicates better performance of the comparator model (mentioned last in the column heading)
‡ IDI compares the difference in mean predicted probability between cases and non-cases for two models
# NRI compares the ability of two models to correctly classify cases and non-cases

Conclusion: Matrix risk models developed in randomized clinical trials of patients with early RA had limited value in this observational cohort of RA patients with established disease. Limitations of this study include lack of feet radiographs, which might have led to fewer patients being classified as RRP, and potential confounding by treatment indication. The value of matrix risk models for RRP might be greater in early RA; larger cohorts may allow for better development and testing of such models. Furthermore, it may be necessary to develop separate risk models for RRP in established disease.

Are Biologics Cost-Effective? Analysis Based on Real-Life Rheumatoid Arthritis Patients. Hawre Jalal[1], Kaleb Michaud[2], Hyon K. Choi[3], Young Hee Rho[3] and Karen Kuntz[1]. [1]University of Minnesota, Minneapolis, MN, [2]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE, [3]Boston University School of Medicine, Boston, MA

Background/Purpose: Previous cost-effectiveness analyses (CEAs) of biologics for rheumatoid arthritis (RA) based on randomized controlled trials (RCTs) have been limited by short time horizon, failure to properly incorporate adverse events (AE) and discontinuation rates, and poor generalizability to real-world effectiveness. The cost-effectiveness of biologics in real-life RA patients has not been adequately explored. Our objective was to conduct CEAs of several commonly adopted treatment strategies involving sequential use of biologics based on an observational study.

Methods: We developed a Markov simulation model to estimate quality-adjusted life years (QALYs) and costs associated with several treatment strategies for RA patients over the lifespan. We evaluated strategies based on different sequences of 5 biologics (etanercept, infliximab, adalimumab, abatacept, and rituximab) compared to conventional non-biologic DMARDs. We modeled the discontinuation rate of each biologic as well as the reason (i.e. serious AE, cost of medication, or ineffectiveness). Those who discontinued because of ineffectiveness were allowed to transition to the next biologic in the sequence based on the probability of switching biologics in an observational study (the National Data Bank [NDB]). Those who discontinued because of the other reasons switched to nonbiologics. Markov health states were defined by Health Assessment Questionnaire (HAQ) scores and the types of medication the patients received. Transition probabilities, effectiveness measures (i.e., HAQ score improvements), AE rates, quality of life weights, and discontinuation rates were estimated from the NDB. Direct and indirect costs (2009 US dollars) were obtained from the literature. Both costs and effectiveness are discounted by 3% annually.

Results: Biologics were generally more effective than nonbiologics. The most cost-effective sequence of biologics was Etanercept -> Infliximab -> Adalimumab (EIA), with an incremental lifetime effectiveness of 0.1 QALYs compared to nonbiologics. The EIA strategy had an incremental lifetime cost of about $150,000 yielding an incremental cost-effectiveness ratio (ICER) >$1M/QALY, which is well above willingness to pay (WTP) thresholds considered acceptable. In a sensitivity analysis, we increased the HAQ improvement from rates reported in the NDB to those typically reported in trials (Table). Biologic strategies became cost-effective at WTP thresholds of $200K/QALY. However, this ICER is still higher than those reported in RCT-based CEAs.

Table. Cost-Effectiveness of Sequential Biologic Use (EIA) According to Assumptions

Sensitivity Analysis Assumptions	Cost ($)	Incremental Cost ($)	Effectiveness (QALY)	Incremental Effectiveness (QALY)	ICER ($/QALY)
Primary Model	192,905	149,421	13.53	0.10	1,485,800
A	169,738	126,017	14.29	0.75	166,600
A + B	169,183	125,656	14.03	0.57	216,900
A + C	162,520	119,448	13.85	0.74	160,100
A + D	149,189	108,050	12.74	0.54	199,600

A = HAQ progression rates are equivalent to those in RCTs of biologics.
B = There is additional mortality due to serious adverse events.
C = Study population's HAQ ranges between 1.1 and 2.0.
D = Study population's HAQ ranges between 2.1 and 3.0.

Conclusion: We used real-life observational data to model sequences of biologic use, discontinuation rates, and AEs. Using these observational data, we were unable to observe the cost-effectiveness reported by RCT-based CEA. The primary reasons for this discrepancy relate to a lower incremental effectiveness of biologics in real-life compared to RCTs.

2577

Statins and Risk of Acute Myocardial Infarction in Patients with RheumatoidArthritis: A Population-Based Study. Mary De Vera[1], Diane Lacaille[1], Michal Abrahamowicz[2], Jacek A. Kopec[1] and Hyon K. Choi[3]. [1]Arthritis Research Centre of Canada, Vancouver, BC, [2]McGill UHC/RVH, Montreal, QC, [3]Boston University School of Medicine, Boston, MA

Background/Purpose: Given their lipid lowering and anti-inflammatory properties, statins are postulated to have dual cardioprotective and anti-inflammatory benefits in rheumatoid arthritis (RA), a chronic arthritis associated with systemic inflammation and significant cardiovascular disease comorbidity. Our objective was to quantify the impact of statin initiation on risk of acute myocardial infarction (AMI) in a population-based cohort of RA patients.

Methods: We conducted a longitudinal study of statin initiators and non-initiators in a population-based cohort of RA patients followed from May 1996 to March 2006 using data from the British Columbia Ministry of Health. Utilization data for all provincially funded health services, including physician visits and hospitalizations, were obtained for all cohort members. We also obtained complete information on all prescription medications dispensed by pharmacists from January 1996 onwards, as well as mortality data from vital statistics, including date and cause of death. Non-fatal and fatal AMI outcomes were ascertained using hospitalization and Vital Statistics data. We applied propensity score methods to adjust for differences between statin initiators and non-initiators, and used Cox's proportional hazards models to evaluate the association between statin initiation and risk of AMI.

Results: During 15,271 person-years of follow-up in the propensity-score matched cohort of 3,104 statin initiators and 3,104 non-initiators, we identified 261 AMI events (incidence rates, 1.5 and 2.1 per 100 person-years in initiators and non-initiators, respectively). After adjusting for confounding by indication, the hazard ratio (HR) for AMI for statin initiators compared to non-initiators was 0.69 (95% CI, 0.54–0.90). Additional adjustments including the propensity score (HR, 0.68; 95% CI, 0.53–0.88) or unbalanced covariates (HR, 0.68; 95% CI, 0.52–0.88) did not materially change results.

Conclusion: These population-based data indicate that statin use among RA patients is associated with a 31% lower risk of AMI. Findings provide evidence for a postulated cardioprotective role of statins in patients with RA.

Quality of Care for Common Comorbidities Among Patients with Rheumatoid Arthritis: An Analysis of HEDIS Data. Gabriela Schmajuk[1], Laura Trupin[2], Chris Tonner[3], Amal N. Trivedi[4], Edward Yelin[3] and Jinoos Yazdany[5]. [1]University of California - San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA, [3]UCSF, San Francisco, CA, [4]Brown University, Providence, RI, [5]University of California San Francisco, San Francisco, CA

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk for cardiovascular disease and osteoporosis compared to the general population. We compared the performance on HEDIS (Health Plan Employer Data and Information Set) quality measures assessing care for comorbidities common in RA (hypertension, diabetes, hypercholesterolemia, and osteoporosis) among individuals with RA compared to the general (non-RA) population.

Methods: We analyzed individual-level HEDIS data for 8,946,881 persons at least 65 years old enrolled in Medicare managed care plans during 2009. Demographic and socioeconomic characteristics were identified through the Medicare beneficiary summary file; ZIP-code-based socioeconomic status was calculated using the Agency for Healthcare Research and Quality's socioeconomic status (SES) index score. Based on the HEDIS RA measure denominator, we identified patients who carried a diagnosis of RA. We calculated performance on 4 HEDIS measures in eligible patients from the RA and non-RA subsets. We used multiple logistic regression to estimate the effect of having RA on measure performance after adjusting for sociodemographic characteristics (sex, age, race, personal income, and ZIP-code-based SES). As a sensitivity analysis, we restricted the RA subset to patients who received a DMARD in order to increase the specificity of RA diagnoses.

Results: The non-RA population (n = 8,867,530) was 58% female, 82% white, and had a mean age of 75.0 years (SD 7.3). Patients in the RA subset (n = 79,351) were 76% female, 82% white, and had a mean age of 75.2 years (SD 6.7). Seventy two percent of RA patients received a DMARD in 2009. Performance on 4 HEDIS measures ranged from 33 to 62% in RA patients and 21–59% in non-RA patients (see Table). With and without adjustment, RA patients were at least as likely to fulfill each measure compared with non-RA patients. A sensitivity analysis comparing HEDIS performance for RA patients who received DMARDs to non-RA patients yielded similar results (data not shown).

HEDIS measure*	Non-RA population Eligible N	Non-RA population Measure performance (%)	RA population Eligible N	RA population Measure performance (%)	Unadjusted OR (RA vs. non-RA)	Adjusted OR† (RA vs. non-RA)
Blood pressure < 140/90 mm Hg in enrollees with hypertension	141,969	59.4	1,598	61.6	1.08 (0.97, 1.19)	1.12 (1.01, 1.24)
Hemoglobin A1C < 8% for enrollees with diabetes	251,344	40.3	2,305	40.9	1.02 (0.94, 1.11)	1.03 (0.95, 1.12)
LDL-C level less than 100 mg/dL for enrollees after a coronary event	162,519	44.5	1,820	43.7	0.97 (0.88, 1.06)	1.04 (0.95, 1.15)
BMD testing and osteoporosis treatment for female enrollees after fracture	109,010	21.3	1,924	33.1	1.82 (1.65, 2.00)	1.76 (1.60, 1.94)

* Technical specifications provided by National Committee for Quality Assurance
† Compared to non-RA performance, adjusted for age, sex, race, personal income, and ZIP-code-based SES.

Conclusion: In this national sample of patients with RA in Medicare managed care plans, management of common comorbid conditions needs improvement. With the exception of osteoporosis testing and treatment, clinical performance on chronic disease quality measures was similar for patients with and without RA.

Starting Dose, but Not Maximum Maintenance Dose, Is a Risk Factor for Allopurinol Hypersensitivity Syndrome: A Proposed Nomogram for Safe *Starting* Dosing of Allopurinol. Lisa K. Stamp[1], William Taylor[2], Peter B. B. Jones[3], Jo L. Dockerty[4], Jill Drake[5], Christopher Frampton[1] and Nicola Dalbeth[6]. [1]University of Otago, Christchurch, New Zealand, [2]University of Otago, Wellington, New Zealand, [3]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand, [4]Dunedin Hospital, Dunedin, New Zealand, [5]Christchurch Hospital, Christchurch, New Zealand, [6]University of Auckland, Auckland, New Zealand

Background/Purpose: Allopurinol is the most commonly used urate lowering therapy in gout. Allopurinol hypersensitivity syndrome (AHS) is a rare but potentially fatal adverse event. Risk factors include female sex, age, renal impairment, diuretic use, recent commencement of allopurinol therapy and in some ethnic groups HLA-B*5801. The relationship between allopurinol dose and AHS is controversial. Dosing guidelines based on CrCL have been proposed based on the recognition that doses ≥300mg/d may be associated with AHS, particularly in patients with renal impairment. However, the relationship between allopurinol starting dose and AHS is unknown. The aim of this study was to determine the relationship between allopurinol dosing and AHS.

Methods: A retrospective case-control study of gout patients who developed AHS between January 1998 and September 2010 was undertaken. For each case three controls with gout receiving allopurinol who did not develop AHS were identified. Controls were matched on gender, diuretic use at the time of commencing allopurinol, age ± 10 years, and eGFR. Analysis compared starting dose and maximally achieved dose between cases and controls.

Results: Fifty-four AHS cases and 157 controls were identified. Multivariate analysis allowing for matching between cases and controls, showed that the presence of tophi was associated with a reduced risk of AHS (OR=0.29, 95%CI 0.01 – 0.83; p<0.021). Compared with New Zealand Europeans there was a decreased risk of AHS in patients of Maori and Pacific Island descent (OR=0.24, p=0.02) and an increased risk of AHS in those of Chinese descent (OR=70.8, p=0.005). There was an increase in risk of AHS as the starting dose of allopurinol corrected for CrCL increased. For the highest quintile of starting dose/CrCL, the odds ratio was 23.2 (p<0.01) (Figure 1a). There was no significant difference in the means of the maximum doses of allopurinol ever achieved between cases and controls (Figure 1b). No risk relationship was observed between AHS and maximum dose. Using ROC analysis, starting allopurinol at a dose ≥1.5mg allopurinol/CrCL (mg/ml/min) was associated with 90% sensitivity and 37.5% specificity for AHS.

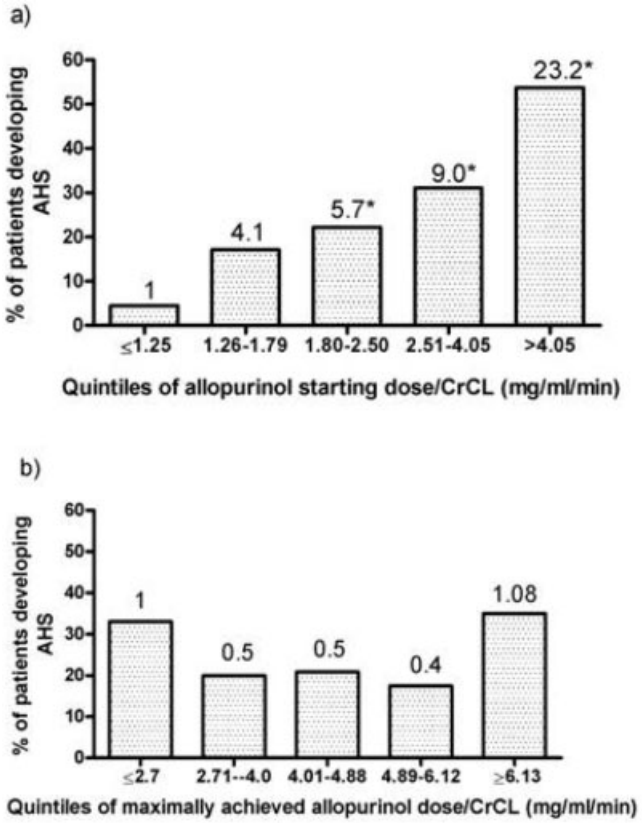

Figure 1. a) The percentage of patients developing AHS in each quintile of starting allopurinol dose/CrCL and the odds ratio for each quintile (*p<0.05). b) The percentage of patients developing AHS in each quintile of maximally achieved allopurinol dose/CrCL and the odds ratio for each quintile.

Conclusion: Starting allopurinol at a dose of 1.5mg/CrCL may greatly reduce the risk of AHS. These data provide information required for a new dosing nomogram, based on a starting dose of 1.5mg/CrCL. Progressive up-titration of dose to achieve the target serum urate is not associated with an increased risk of AHS. Further large prospective clinical trials of such a dosing strategy are required.

Severe Cutaneous Reactions Requiring Hospitalization in Allopurinol Initiators. Seo Young Kim[1], Craig Newcomb[2], David Margolis[2], Jason Roy[2] and Sean Hennessy[2]. [1]Brigham & Women's Hospital, Boston, MA, [2]University of Pennsylvania, Philadelphia, PA

Background/Purpose: Allopurinol, an effective urate-lowering drug, is primarily prescribed for patients with gout. Although rare but potentially life-threatening cutaneous adverse reactions such as Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) have been associated with use of allopurinol, population-based data on incidence and mortality of such reactions is scarce.

Methods: We conducted a large-scale cohort study using the Medicaid claims data (1999–2005) from 5 states with Medicare claims for dual-eligibles. Adults who had at least 180 days of Medicaid eligibility and at least one medical claim present before the first prescription of allopurinol were identified. Subjects with malignancy were excluded. Primary outcome was hospitalization for severe cutaneous reactions identified by the principal discharge diagnosis code 695.1 for erythema multiforme and related conditions, such as SJS and TEN, after initiation of allopurinol. Cumulative incidence rate (IR) and in-hospital mortality was estimated among new users of allopurinol. Age-standardized IR among non-allopurinol users was also estimated for a comparison. Multivariable Cox regression model was used to

compare the risk between the high-dose (≥ 300mg/day) and low-dose allopurinol group after adjustment for potential confounders.

Results: There were a total of 90,358 allopurinol initiators with a mean age of 65.5 (SD 15.6) years. During a follow-up period of 65,625 person-years, 45 were hospitalized with severe cutaneous reactions. Crude IR was 0.69 (95 %CI 0.50–0.92) per 1,000 person-years. All 45 cases occurred within the first 365 days and 41 (91.1%) within the first 180 days (Table 1). Twelve (26.7%) patients died during the hospitalization. Age-standardized IR in non-allopurinol users was 0.03 (95% CI 0.02–0.04) per 1,000 person-years. Age-adjusted rate ratio was 22.98 (95% CI 16.76–30.77) in allopurinol initiators. In our multivariable analysis adjusting for age, comorbidities and recent use of any diuretic, HR was 1.57 (95% CI 0.87–2.84) for the high-dose allopurinol users.

Table 1. Incidence rates (IR) of hospitalization for severe cutaneous reactions in allopurinol initiators

	Number of events	IR (95% CI) per 1,000 person-years
First 365 days	45	0.69 (0.50–0.92)
First 180 days	41	1.51 (1.08–2.05)
First 30 days	20	2.77 (1.69–4.28)

Conclusion: Severe cutaneous reactions in allopurinol initiators were found to be rare but often fatal and occurred mostly in the first 180 days of treatment. Compared to non-allopurinol users, risk of severe cutaneous reactions was 23 times greater in allopurinol initiators. Despite our large study size, we had little precision in estimating the risk relative to different dosage of allopurinol and various exposures to other drugs including specific diuretics.

2581

Colchicine Dosing Guidelines for Gout Patients with Varying Degrees of Renal Impairment Based on Pharmacokinetic Data. Suman Wason, Robert D. Faulkner and Matthew W. Davis. URL Pharma, Philadelphia, PA

Background/Purpose: Dosing of colchicine (Col) in gout patients with renal impairment is currently based on empirical data. This study obtained single-dose pharmacokinetic (PK) data in healthy subjects and subjects with varying degrees of renal impairment to allow predictions of Col steady state concentrations following 1.2mg/day Col given as 0.6 mg twice daily (the currently recommended dose of colchicine for gout flare prophylaxis). Based on these findings, dosing recommendations are made for renally impaired patients who require gout flare prophylaxis to achieve desired Col concentrations (i.e. ~2 ng/mL).

Methods: In this open-label, parallel-group study, 8 subjects in each group were randomized, based on Creatinine Clearance (CrCl), to receive a single dose of oral Col 0.6 mg as follows:

Healthy normal (CrCl> 90 mL/min), mild decrease renal function (CrCl >50 – 90 mL/min), moderate decrease renal function (CrCl >30 – 50 mL/min), severe decrease renal function (CrCl >15 – 30 mL/min), and end-stage renal disease (ESRD) (on and off dialysis, separated by 14 days) CrCl not determined.

Results: Col PK parameters were similar for subjects with normal renal function, subjects with mild renal impairment, and ESRD patients on and off dialysis. However, in subjects with moderate and severe renal impairment, Col clearance was reduced, resulting in higher AUC (approximately 2-fold increase) and Cmax (up to 1.5-fold increase). The single-dose data were then used to predict steady state (10 days) concentrations of Col following the recommended colchicine 0.6 mg twice daily regimen. With twice-daily dosing to steady state, Col concentrations in normal subjects, those with mild decrease, and those in ESRD averaged ~2 ng/mL. These concentrations were greatly exceeded in patients with moderate and severe renal impairment (Col concentrations ~5–6 ng/mL), suggesting that these groups require dosage adjustment.

Metabolites

Despite the reduced clearance of Col in renally impaired subjects, there was no difference in accumulation of metabolites in patients with moderate and severe renal impairment compared to the other groups.

ESRD and dialysis

On the day of dialysis, subjects were given Col 0.6 mg and dialyzed for 3–4 hrs beginning at one-hour post-dose. While on dialysis, the concentrations were generally lower by approximately 0.5 ng/mL.

Conclusion: Based on these data, for the prophylaxis of gout flares, no dosing adjustments are needed for patients with normal renal function or mild impairment (CrCl >50 mL/min) or ESRD on or off hemodialysis. For patients with moderate and severe renal failure (CrCl <50 mL/min), it is recommended that Col dose be reduced 50% (i.e. for those patients requiring 0.6 mg twice daily, the dose should be decreased to 0.6 mg once a day, and for those requiring 0.6 mg once a day, the dose should be decreased to 0.3 mg per day).

2582

Characterization and Management of Infusion Reactions in Refractory Chronic Gout (RCG) Treated with Pegloticase (PGL). Herbert Baraf[1], Robert A. Yood[2], John S. Sundy[3], Faith D. Ottery[4], Zeb D. Horowitz[5] and Michael A. Becker[6]. [1]Arthritis & Rheumatism Assoc, Wheaton, MD, [2]Fallon Clinic, Worcester, MA, [3]Duke University Medical Center, Durham, NC, [4]Savient, East Brunswick, NJ, [5]Celgene Corporation, Basking Ridge, NJ, [6]University of Chicago Medical Center, Chicago, IL

Background/Purpose: PGL is a pegylated mammalian recombinant uricase approved for treatment of pts with RCG, defined by hyperuricemia, progressive gout with signs/ symptoms reflecting inadequate urate control and refractoriness or contraindication to xanthine oxidase inhibitors.

Methods: 212 pts with RCG were treated with PGL 8 mg (q2wks or q4wks) or placebo (PBO) in 2 replicate 6-month blinded randomized controlled trials (RCTs). IR was defined as an adverse event (AE) occurring during or within 2 hrs of infusion. Safety was assessed by AE reports and lab tests. Pts received IR prophylaxis (fexofenadine 60 mg the night before infusion and again with acetaminophen1000 mg in AM, with hydrocortisone 200 mg i.v. just before each infusion). Flare prophylaxis (colchicine, NSAIDs or both) was used throughout the trial. Analysis of IRs by serum urate (SUA) is based on a post hoc analysis, increased risk of IR if SUA levels returned to >6 mg/dL after initial reduction. RCT completers could enroll in an open label extension (OLE) trial with PGL treatment for up to an additional 2.5 years.

Results: Of 212 pts enrolled, 157 completed the RCTs and 151/157 entered the OLE (149 on PGL, 2 observed). The most common AEs reported were gout flares and IRs. Flares were common at baseline, with initial increase and then decrease (Months 4–6) in pts with SUA <6 mg/dL and continued decrease in the OLE. The 169 pts randomized to PGL had 115 IRs in 3391 infusions (RCT+OLE). For the 43 PBO pts, 39 entered the OLE and had 85 IRs (4 on PBO, 81 on PGL) in 1296 infusions. Most IRs occurred after loss of PGL response (SUA >6 mg/dL): 105/115 IRs (91%) in the RCTs and 232/265 IRs (88%) in the OLE. The most common symptoms reported during IRs included chest pain or discomfort, back pain, flushing, nausea ± vomiting, erythema, muscle spasms, abdominal complaints, dyspnea, headache, hyperhidrosis, blood pressure changes (increase or decrease), urticaria, and pruritus; intensity varied from mild to severe. All IRs resolved with supportive measures that included slowing or stopping the infusion and/or 1 or more interventions that included: antihistamines, fluids, corticosteroids, analgesics. One pt received epinephrine for wheezing. No patient required intubation and no deaths resulted from an IR.

Conclusion: These findings suggest that the occurrence of infusion reactions during pegloticase therapy can be significantly abated by routine pre-infusion serum urate measurement and discontinuation of pegloticase therapy with loss of response, i.e., return of SUA to >6 mg/dL after initial reduction. This combination of loss of efficacy and increased risk of IRs adversely alters the benefit/risk ratio of pegloticase therapy and mandates that treatment should be discontinued, particularly if 2 consecutive pre-infusion urate values >6 mg/dL are observed.

IR rates per 100 infusions

	SUA < 6mg/dL	SUA >6mg/dL
RCT	0.5	4.8
OLE	0.8	5.5

2583

Economc Burden of Gout Patients Treated with Urate Lowering Therapy. Anna Forsythe[1] and Hyon K. Choi[2]. [1]Savient Pharmaceuticals, Inc., East Brunswick, NJ, [2]Boston University School of Medicine, Boston, MA

Background/Purpose: Gout is an inflammatory arthritis associated with substantial morbidity by causing tremendous pain and suffering. While gout could lead to increased resource utilization and associated medical costs[1], the

relevant data are limited. We evaluated the burden of illness, resource utilization and costs among adult gout patients treated with a xanthine oxidase inhibitors (XOI, allopurinol or febuxostat) in US managed care health plans.

Methods: We estimated the annual resource utilization and direct costs using IMS LifeLink™ Health Plan Claims Database. The study population consisted of individuals aged ≥18 years with a gout diagnosis (ICD-9-CM: 274.xx) and a XOI claim from 10/1/2008 to 9/30/2009 with the date of the first therapy as the index date. Subjects also needed to continue health plan enrollment for ≥6 months prior to and ≥12 months after the index date and to be covered by Medicare Risk if aged ≥65 years. We defined a gout flare as a gout diagnosis code followed by a claim for NSAIDs, colchicines, corticosteroids, ACTH, or intra-articular aspiration or injection within 7 days, or a diagnosis for joint pain (ICD-9-CM: 719.4) followed by a claim for colchicine within 7 days. Using Chi square tests, we compared patients: (1) with tophi and ≥3 flares vs. without tophi or flares (=controls); (2) with tophi and ≥6 flares vs. controls; and (3) with febuxostat use vs. with allopurinol use. The health plan's allowed amount was used as a proxy for medical costs.

Results: We identified 24,503 XOI-treated gout patients (mean age = 54 years old and 87% male). Comorbidities were similar between those with tophi and ≥3 flares (N=116) and controls (N=15,165). Those with tophi and ≥6 flares (N=21) had a higher rate of hypertension and dyslipidemia than controls ($p<0.05$). Febuxostat users (N=354) had a higher rate of pre-index chronic kidney disease than allopurinol pts (N=24,149, $p<0.001$). Patients with tophi and ≥3 flares had significantly more physician office visits (mean: 17.8 vs. 9.0), laboratory services (mean: 23.6 vs. 12.3), and ancillary services (mean: 23.8 vs. 12.2) than controls (all *p-values* <0.001). Febuxostat patients had more physician office visits (mean: 11.8 vs. 9.7 $p<0.001$) and laboratory services (mean: 16.6 vs. 13.2, $p<0.001$) vs. allopurinol patients. Febuxostat patients used colchicines (53.1%) more often than allopurinol patients (32.2%, $p<0.001$). Total 12-month post-index costs averaged $21,059 among patientswith tophi and ≥3 flares vs. $10,657 ($p<0.001$) in controls. Patients with tophi and and ≥6 flares (N=21) had even higher resource utilization and total healthcare costs of $32,178 (p<0.01) than controls. Febuxostat patients incurred $3,471 higher total outpatient and inpatient medical costs vs. patients on allopurinol.

Conclusion: Our findings indicate that annual resource utilization and costs are substantial among those with tophi and frequent flares. As anticipated, patients with tophi and flares incurred considerably greater costs than those without these features. The economic burden associated with these features should be considered in determining cost-effectiveness of gout management.

Arhalofenate, a Potential Novel Treatment for Hyperuricemia, with or without Metabolic Co-Morbidities, in Patients with Gout: Meta-Analysis of Urate Lowering in Four Phase 2 Studies in Type 2 Diabetes. Gopal C. Saha, David B. Karpf, Yun-Jung Choi and Brian K. Roberts. Metabolex, Inc., Hayward, CA

Background/Purpose: Hyperuricemia, the cardinal underlying feature of gout, is attributable to under-excretion of uric acid by the kidneys in about 90% of patients. In addition, the majority of gout patients have metabolic co-morbidities such as insulin resistance (pre-diabetes or type 2 diabetes) and hypertriglyceridemia. Many gout patients also have impairment in renal function. Arhalofenate is a novel oral agent that has completed a total of eight phase 1 and four phase 2 studies in healthy volunteers and patients with type 2 diabetes. In phase 1, oral once daily dosing of arhalofenate up to 1000 mg for 10 days demonstrated excellent PK with a half-life of approximately 60 hours. Recent *in vitro* studies have demonstrated that arhalofenate is a uricosuric agent that inhibits the URAT-1 transporter. This abstract reports the effect of arhalofenate on serum urate, as well as glucose and triglyceride levels, from the phase 2 clinical studies conducted to date.

Methods: During development as an insulin sensitizer for type 2 diabetes, a total of four global, randomized, double-blind, controlled phase 2 studies (totaling 955 patients) were conducted to evaluate the safety, PK, and efficacy of once daily oral administration of arhalofenate. Serum urate was measured prospectively, in blinded fashion, using a standard uricase method. A meta-analysis of serum urate results for all compliant patients (detectable study drug in serum) in the phase 2 studies was completed.

Results: In phase 2 studies, administration of arhalofenate at doses of 200, 400, and 600 mg for as long as 24 weeks resulted in significant reductions in fasting glucose (5–20%), HbA1c (0.2–0.6%), and triglycerides (5–20%). Additionally, arhalofenate demonstrated clinically meaningful and statistically significant dose-dependent reductions from baseline in serum urate (mean baseline ~5.0 mg/dL) of 13%, 22%, and 29% for the arhalofenate 200 mg (n=125), 400 mg (n=174), and 600 mg (n=159) groups, respectively, compared to placebo (n=252; p<0.0001 for all dose groups). Patients with mild to moderate renal impairment and those taking aspirin or diuretics experienced comparable reductions in serum urate. Of those patients with a baseline serum urate ≥6.0 mg/dL (mean 6.8–7.1 mg/dL), arhalofenate at doses of 200 mg (n=29), 400 mg (n=37), and 600 mg (n=35) resulted in 48%, 78%, and 83% of patients achieving a serum urate target of <6.0 mg/dL at the end of the study compared to 25% in the placebo group (n=61). Overall, daily treatment with arhalofenate for up to 24 weeks was found to be safe and well tolerated, with no effects on urine pH and no cases of urolithiasis.

Conclusion: Arhalofenate is a novel, oral uricosuric agent which has shown significant and dose-dependent reductions in serum urate and other metabolic parameters in several studies conducted to date in healthy volunteers and patients with type 2 diabetes. Arhalofenate is a potential therapy for treatment of chronic hyperuricemia, with or without metabolic co-morbidities, in patients with gout. Phase 2 proof-of-concept studies in monotherapy, and as add-on to XO-inhibitors, have been initiated in the target population of gout patients with hyperuricemia.

ACR Concurrent Abstract Session
Rheumatoid Arthritis Clinical Aspects: Risk of Cardiovascular Disease
Wednesday, November 9, 2011, 9:00 AM–10:30 AM

2585

Risk of Cardiovascular Disease in Rheumatoid Arthritis Is Independent of Disease Duration and the Level of Disease Activity. Elke.E.A. Arts[1], Jaap Fransen[1], Alfons den Broeder[2], Calin Popa[1] and Piet L.C.M. Van Riel[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands

Background/Purpose: Chronic inflammation may act as an independent risk factor for cardiovascular disease (CVD) in rheumatoid arthritis (RA). However, the level of inflammation apparently does not contribute to the risk of CVD in RA patients. Probably, disease duration is more important than the level of inflammation. Indeed, EULAR recommendations for cardiovascular risk management in RA do identify RA disease duration of >10 years as CV risk factor. Hence the objective of this study was to investigate the relationship between duration of inflammation and risk of CVD in RA patients, corrected for the level of inflammation.

Methods: All RA patients with a follow-up time of ≥ 6 months in the Nijmegen early RA cohort without a cardiovascular history were included in this study. The time-averaged DAS28 was calculated for each patient. The effect of disease duration on the risk of developing the first cardiovascular event was estimated by means of Kaplan-Meier survival analysis and Cox proportional hazards regression, including time-averaged DAS28, age and gender as covariates. The incidence of CVD within the first 10 years of the disease was compared with the incidence thereafter, using Kaplan-Meier survival curves and Log-rank testing.

Results: There were 855 patients with 6388 patient years included. Their mean age was 54 years, 66% was female and 76% RF positive, mean baseline DAS28 was 5.0. Ninety-one CV events, including myocardial infarction (MI), cerebrovascular accident (CVA) and heart failure were recorded during follow up. The course of hazards over time (not shown) did not indicate a change in the risk of CVD over disease duration (exposition time), which is also reflected by the absence of a deflection in the survival curves (fig.1a). The CV risk is significantly lower, only in the group of patients with very low DAS28 (<2.9) over time, versus the other groups ($p=0.038$). The survival distributions did not differ between a disease duration of <10 years or >10 years (Log-rank test: $p=0.365$) (fig. 1b).

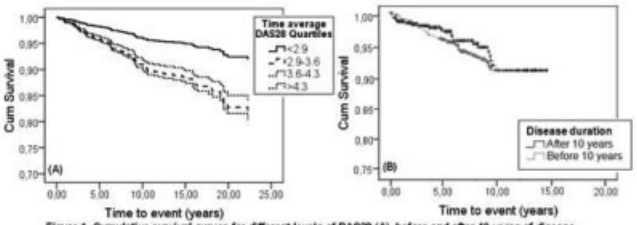

Figure 1. Cumulative survival curves for different levels of DAS28 (A), before and after 10 years of disease duration (B).

Conclusion: The duration of RA, i.e. the length of time a patient is exposed to inflammation, does not appear to further aggravate the risk of CVD over time. Particularly, the risk of CVD in RA patients was not increased after 10 years of disease duration compared to the first 10 years. The level of disease activity did not influence the risk of CVD, unless disease activity was kept at a very low level.

2586

The Effect of Body Mass Index On the Outcomes of Rheumatoid Arthritis. Frederick Wolfe[1] and Kaleb Michaud[2]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]National Data Bank for Rheumatic Diseases and University of Nebraska, Omaha, NE

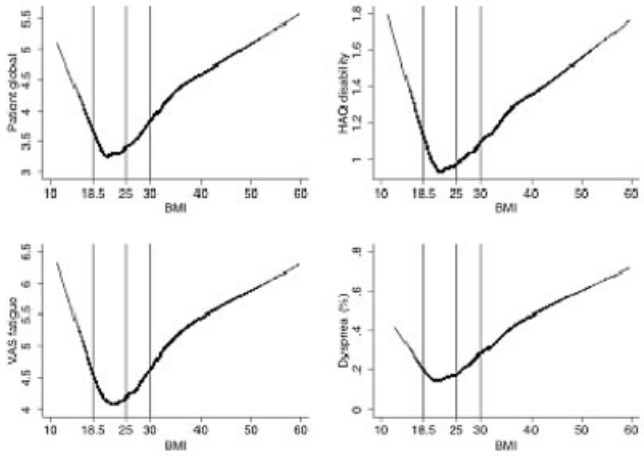
Background/Purpose: Body Mass Index (BMI) has a seemingly paradoxical effect on mortality in rheumatoid arthritis (RA), with the highest risk occurring in those with are underweight UW) (BMI 18.5 kg/m2) and a decreased risk in those who are overweight (OV) (BMI 25.0–29.9 kg/m2) or obese (OB) (BMI ≥30.0 kg/m2) compared with those with normal BMI (NW) (BMI 18.5–24.9 kg/m2). We explored the mechanism for this paradox and the role BMI plays in comorbidity and functional and quality of life outcomes.

Methods: We assessed 24, 549 RA patients for up to 12 years using a semiannual questionnaire. Mortality data were obtained from the U.S. National Death Index. Hazard ratios were estimated with time varying Cox regression.

Results: At a mean age of 61.8 years (71.8% female), 65% were OW or OB. The overall hazard ratio for mortality indicated an increased mortality risk in UW and a protective effect for OW and OB (Table 1). BMI had a U shaped relation to age, with BMI increasing through age 50 and falling thereafter. We identified an interaction between age and BMI on the risk of mortality: under age 50, OB increased mortality risk by 61%, but over age 50 mortality in OW and OB was reduced by 29–37% (Table 1). Regardless of BMI category, a 5-unit increase in BMI was associated with 26.2% (22.7, 29.8) increase in diabetes and a 34.7% (32.3, 37.3) increase in hypertension.

There was a U-shaped relation between all patient-reported clinical outcomes and BMI category. Four representative variables are shown in Figure 1. The "best" BMI for clinical outcomes, regardless of gender was 22–23. Compared with NW, the increase in annual total medical costs was UW $1151, OW $752, OB $3380.

	%	H.R. (95% CI)	H.R. (95% CI)	H.R. (95% CI)
Age Group	All	All	[2]50Years	>50Years
Underweight	2.1	2.13 (1.87, 2.44)	2.62 (1.11, 6.21)	2.46 (2.15, 2.81)
Normal weight	32.9	1.0	1.0	1.0
Overweight	32.1	0.81 (0.75, 0.88)	0.97 (0.60, 1.57)	0.71 (0.66, 0.77)
Obese	33.0	0.94 (0.86, 1.02)	1.61 (1.06, 2.44)	0.63 (0.58, 0.69)



Conclusion: Increased BMI leads to diabetes and hypertension, which are important predictors of mortality in RA. However, increased BMI itself is protective for mortality, except in patients less than 50 years of age. Overweight is not a direct risk factor for mortality, but influences clinical status and overall health. UW, OW and OB contribute to the severity of clinical measures and to increased costs.

2587

Inflammatory Burden Predicts Plaque Formation of Carotid Artery in Rheumatoid Arthritis. Churl Hyun Im, Na Ri Kim, Jong Wan Kang, Ji Hun Kim, Gi Bum Bae, Eon Jeong Nam and Young Mo Kang. Kyungpook National University Hospital, Daegu, South Korea

Background/Purpose: Rheumatoid arthritis (RA) patients have an increased risk of atherosclerosis and cardiovascular (CV) diseases compared with normal population. The chronic exposure to inflammatory mediators has been thought to underlie accelerated atherosclerosis in RA, as well as traditional CV risk factors. The aim of this study was to evaluate the role of inflammatory burden in the formation of carotid plaques in RA patients.

Methods: We performed carotid artery ultrasound to measure the carotid intima-media thickness (IMT) and plaques in 407 consecutive patients with RA and 209 age and sex matched controls. Clinical and laboratory variables relevant to RA activity were obtained. To assess inflammatory burden during the course of disease, the area under curve (AUC) of ESR over time was calculated in 194 female patients with regular follow up for longer than 5 years.

Results: The study population included 329 females and 78 males RA patients. Frequency of carotid plaque and mean IMT were significantly increased in RA group compared with normal controls (plaque 36.1% vs. 24.9%, $P = 0.005$; mean IMT 0.80 ± 0.17 vs. 0.72 ± 0.14 mm, $P < 0.001$). The frequency of CV diseases in RA patients was 5.7% (14 coronary heart diseases and 10 cerebrovascular diseases). Presence of CV diseases in RA patients was associated with carotid plaque ($P = 0.001$), but not with mean IMT. Among the traditional cardiovascular risk factors and RA related variables, fasting blood sugar (FBS), fibrinogen, Korean version of modified Health Assessment Questionnaire, tender and swollen joint counts (TJC and SJC), DAS28, ESR, CRP, and rheumatoid factor (RF) seropositivity were significantly associated with the presence of plaque after the adjustment with age and gender. After multivariate analysis, the factors found to be significantly associated with plaque were older age ($P < 0.001$), male ($P = 0.001$), FBS ($P = 0.033$), TJC ($P = 0.001$), ESR ($P = 0.002$), and RF positivity ($P = 0.008$). In the second step analysis of 194 patients with ESR-AUC calculation, factors significantly associated with the presence of plaque were older age ($P < 0.001$), higher blood pressure ($P = 0.038$), TJC ($P = 0.028$), and ESR-AUC ($P = 0.024$) in multiple logistic regression analysis. ESR-AUC was significantly correlated with plaque number ($r = 0.203$, $P = 0.002$), but not with mean IMT ($r = 0.057$, $P = 0.216$).

Conclusion: Our findings indicate that inflammatory burden increases the risk of carotid plaque formation in RA.

2588

NT-Pro-BNP Levels Are Associated with Increased All Cause and Cardiovascular Mortality in Early Inflammatory Polyarthritis Independent of Disease Severity and Autoantibody Status—Results From the Norfolk Arthritis Register (NOAR). Hoda Mirjafari[1], Suzanne Verstappen[1], Manjari Lahiri[1], Paul Welsh[2], Diane K. Bunn[3], Tarnya Marshall[3], Mark Lunt[1], Naveed Sattar[2], Deborah P. M. Symmons[1] and Ian N. Bruce[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]Norfolk and Norwich University Hospitals Trust, Norwich, United Kingdom

Background/Purpose: Patients with inflammatory polyarthritis (IP) experience excess cardiovascular disease (CVD) morbidity and mortality. NT-pro-BNP is a marker for left ventricular stress and is associated with incident CVD in the general population. The purpose of this study was to examine the relationship between NT-pro-BNP and all cause and CVD mortality in patients with early IP and to examine whether any association found was independent of IP disease parameters.

Methods: Patients with early IP (≥2 joints swollen for ≥4 weeks) over 16 years old were recruited to the Norfolk Arthritis Register (NOAR) from January 2000 to Jan 2009. Only subjects with ≤24 months symptom duration were included in this study. Patients completed a Health Assessment Questionnaire (HAQ) and were examined. A blood sample was taken at recruit-

ment to evaluate their C-reactive protein for IP disease activity score ($DAS28_{CRP}$), NT-pro-BNP, rheumatoid factor (RF) and anti-citrullinated peptide antibody (ACPA) status. Patients were considered seropositive if they had either RF or ACPA. Patients were followed up until March 2010. For patients who died, the cause and date of death was provided by the Office for National Statistics. Cox proportional hazards regression models were used to assess the association of NT-pro-BNP with the risk of death from all causes and from CVD. The analysis was adjusted for age, gender, DAS28 and HAQ. We carried out further analysis restricted to subjects with i) seronegative IP and ii) no prior CVD.

Results: Of 961 IP subjects in whom NT-pro-BNP levels were available 617 (64%) were female. 211 (22%) smoked and 163 (17%) had prior CVD. Patients had a median (IQR) follow up of 5.5 (3.7–7.7) years. Median (IQR) NT-pro-BNP and symptom duration at recruitment was 74 (38–153) pg/ml and 5.9 (3.2–10.5) months respectively. After 5526 patient years (pyrs) follow up 93 IP subjects died and in 32 the underlying cause of death was CVD. The mortality rate for CVD was 5.8 per 1000 pyrs (95% CI 5.6–5.9). Each 100 pg/ml increase in NT-pro-BNP level was associated with a 10% increased overall mortality risk and an 11% increased risk of CVD mortality after age and gender adjustment (HR (95% CI); 1.10 (1.06, 1.14) and 1.11 (1.05, 1.17)). These associations remained after adjustment for DAS28 and HAQ score (HR (95% CI); 1.13 (1.05, 2.98), 1.12 (1.04, 1.20)). Restriction of the analysis to subjects with seronegative IP and no prior CVD did not alter the association found (HR (95% CI); 1.08 (1.01, 1.15) and 1.10 (1.00, 1.21)).

Conclusion: Higher NT-pro-BNP levels were associated with death from all causes and from CVD in IP patients, independently of disease activity, prior CVD and autoantibody status. This raises the possibility of utilizing NT-pro-BNP as part of a screening strategy to identify IP patients at increased CVD risk. Studies are needed to investigate why these patients have apparently increased cardiac stress.

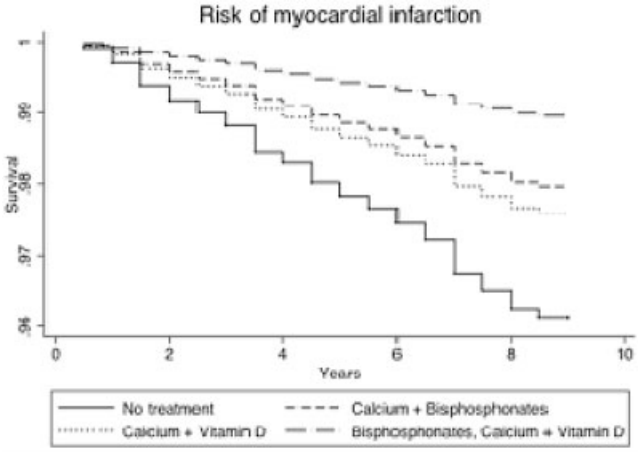
2589

Reduction in the Risk of Myocardial Infarction in Bisphosphonate and Calcium/Vitamin D Treated Rheumatoid Arthritis and Lupus Patients: A Longitudinal Cohort Study. Frederick Wolfe[1], Marcy B. Bolster[2], Cathleen Colon-Emeric[3], Christopher M. O'Connor[4], Kaleb Michaud[5] and Kenneth W. Lyles[4]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Medical Univ of South Carolina, Charleston, SC, [3]Duke University Medical Center and the Durham VA GRECC, Durham, NC, [4]Duke University School of Medicine, Durham, NC, [5]National Data Bank for Rheumatic Diseases, University of Nebraska, Omaha, NE

Background/Purpose: Recent studies have shown a reduction in mortality among patients treated with bisphosphonates. It has been suggested this may be the result of reduction in cardiovascular deaths. In addition, calcium therapy has been linked to cardiovascular risk. Bisphosphonates, calcium and Vitamin D are commonly used in rheumatic disorders such as rheumatoid arthritis and lupus for prevention and treatment of osteoporosis. As the risk of myocardial infarction is increased in rheumatoid arthritis and lupus patients, we evaluated a cohort of these rheumatic disease patients to assess the risk of osteoporosis treatment, including bisphosphonates, on myocardial infarction.

Methods: We studied 155,750 semiannual observations from 23,228 rheumatic disease patients from 2002 through 2010 (93% rheumatoid arthritis, 7% lupus) to determine the effect of bisphosphonate therapy on the risk of myocardial infarction. We used longitudinal population averaged logistic models and Cox regression analyses adjusted for demographic, economic, and cardiovascular risk factors.

Results: Over the course of the study, 26.4% of patients used bisphosphonates (alendronate 16.3%, risedronate 6.8%, ibandronate 3.1%, other bisphosphonates <0.2%). Age, sex, education, smoking, diabetes, hypertension, prednisone, and the use of statins predicted myocardial infarction, statins because of confounding by indication. Patients using bisphosphonates had more severe rheumatoid arthritis and lupus, with reduced functional status and increased prednisone and opioid use, among other measures. Bisphosphonate use was protective for myocardial infarction, odds ratio 0.75 (95% CI 0.58, 0.98), as was calcium and vitamin D (OR 0.57 (95% CI 0.42, 0.77). When calcium/vitamin D and bisphosphonates were analyzed as a group, the 3-drug combination resulted in an OR of 0.38 (95% CI 0.22, 0.66). Calcium and vitamin D alone was also associated with protective effect (OR 0.61 (95% CI 0.43, 0.87)). We also evaluated the effect of bisphosphonate use separately in patients just beginning bisphosphonate therapy, considering observations on therapy compared with those off therapy (Figure 1). The hazard ratio for the 3-drug use was 0.26 (95% CI 0.14, 0.51) in newly beginning patients. Calcium and bisphosphonates without vitamin D was also a significant predictor.



Conclusion: Myocardial infarction was reduced among rheumatic disease patients using bisphosphonate therapy after adjustment for known cardiovascular risk factors and for risk of prescription. Concomitant vitamin D use is associated with a further reduction in myocardial infarction. The data are consistent with studies that have shown reduced mortality risk in bisphosphonate users, and suggest that a randomized clinical trial may be indicated.

2590

Getting to the Heart of the Matter: The Need for More Aggressive Management of Cardiovascular Risk Factors in Rheumatoid Arthritis. Shailey S. Desai[1], James D. Myles[2] and Mariana J. Kaplan[1]. [1]University of Michigan Rheumatology, Ann Arbor, MI, [2]Michigan Institute for Clinical and Health Research, University of Michigan, Ann Arbor, MI

Background/Purpose: In patients with rheumatoid arthritis (RA), the leading cause of mortality is accelerated cardiovascular (CV) disease with a risk similar to that of type 2 diabetes mellitus (DM). Increased CV risk in RA patients is considered secondary to RA-specific mechanisms and to traditional cardiovascular risk factors (CRFs), i.e. smoking, obesity, BP, HDL, LDL, triglycerides, and fasting blood glucose. We hypothesize that CRFs are not as frequently managed in patients with RA as compared to DM or to the general population (GP). The aims of this study were to determine how often CRFs are identified and managed by: 1) rheumatologists and primary care physicians (PCPs) in RA patients; 2) PCPs in patients with RA as compared to DM and the GP.

Methods: We conducted a retrospective cohort study comparing age/gender/ethnicity-matched patients from three groups: RA, DM, and GP (without RA or DM). Patients were seen by a PCP and RA patients were also seen by a rheumatologist at a tertiary care referral center between June 2007-April 2011. Electronic patient records were reviewed during a continuous 12-month period to assess if CRFs were identified and managed. Identification was defined as documenting the CRF at any visit. Management was defined as documenting a plan to address the CRF. Kruskal-Walis test was used for continuous and chi-square test was used for categorical outcomes without accounting for matching. Subgroup analysis assessed how frequently CRF management occurred in patients with abnormal values.

Results: Each group had 251 patients with a mean age of 49 ± 10 years (81% females; 81% Caucasian). BMI and systolic BP were significantly higher in the DM as compared to RA and GP groups. LDL was significantly lower in the DM (99.5 ± 37.1 mg/dl; $p<0.001$) as compared to RA and GP groups (113.7 ± 32.4 mg/dl, 111.4 ± 29.1 mg/dl respectively). PCPs identified and managed CRF significantly more often than rheumatologists in RA patients (Table). Among PCPs, CRFs were identified and managed significantly more often in DM than in RA patients. Also among PCPs, CRF were independently more often managed in the GP than in RA, despite similar baseline clinical characteristics between the two groups. Subgroup analysis revealed that DM patients with abnormal CRF values had significantly increased management of these factors than in RA. Of patients with elevated LDL, PCPs managed 75% of the DM group, 60% of the GP, and 36% of the RA group ($p<0.0001$ for all groups, $p=0.01$ between RA and GP groups).

Number of patients whose CRFs were identified and managed by a rheumatologist and/or a PCP in RA, DM, and GP patients

CRF		Group A (RA) *Rheumatologist*	Group A (RA) *PCP*	Group B (DM) *PCP*	Group C (GP) *PCP*	p-all 3 *PCP*	p-A vs. C *PCP*
Smoking	Identified	52 (20.7%)	167 (66.5%)	161 (64.1%)	188 (74.9%)	0.02	0.0496
	Managed	32 (12.8%)	25 (10.0%)	28 (11.2%)	39 (15.5%)	0.1	0.08
Weight Management	Identified	67 (26.7%)	111 (44.2%)	191 (76.1%)	136 (54.2%)	<0.0001	0.03
	Managed	15 (6.0%)	72 (28.7%)	159 (63.4%)	99 (39.4%)	<0.0001	0.01
BP	Identified	233 (92.8%)	243 (96.8%)	250 (99.6%)	250 (99.6%)		0.04
	Managed	14 (5.6%)	53 (21.1%)	169 (67.3%)	80 (31.9%)	<0.0001	0.008
HDL	Identified	13 (5.2%)	109 (43.4%)	190 (75.7%)	144 (57.4%)	<0.0001	0.002
	Managed	5 (2.0%)	34 (13.5%)	137 (54.6%)	70 (27.9%)	<0.0001	0.0001
LDL	Identified	14 (5.6%)	110 (43.8%)	197 (78.5%)	146 (58.2%)	<0.0001	0.004
	Managed	4 (1.6%)	38 (15.1%)	160 (63.8%)	78 (31.1%)	<0.0001	<0.0001
Triglycerides	Identified	14 (5.6%)	109 (43.4%)	190 (75.7%)	141 (56.2%)	<0.0001	0.006
	Managed	5 (2.0%)	36 (14.3%)	142 (56.6%)	70 (27.9%)	<0.0001	0.0003
Fasting glucose	Identified	3 (1.2%)	58 (23.1%)	237 (94.4%)	68 (27.1%)	<0.0001	0.4
	Managed	0 (0%)	7 (2.8%)	232 (92.4%)	19 (7.6%)	<0.0001	0.03

Conclusion: Despite rheumatologists' awareness of increased CV risk in RA patients, they are significantly less likely to identify and manage CRFs than PCPs. Attempts at managing CRFs by PCPs are suboptimal in RA patients when compared to the GP and even more so to DM patients. Given the well-established increased CV risk associated with RA, physicians need to more aggressively identify and manage CRFs in these patients.

Rheumatoid Arthritis Treatment - Small Molecules, Biologics, Therapy: Novel Compounds I
Wednesday, November 9, 2011, 9:00 AM–10:30 AM

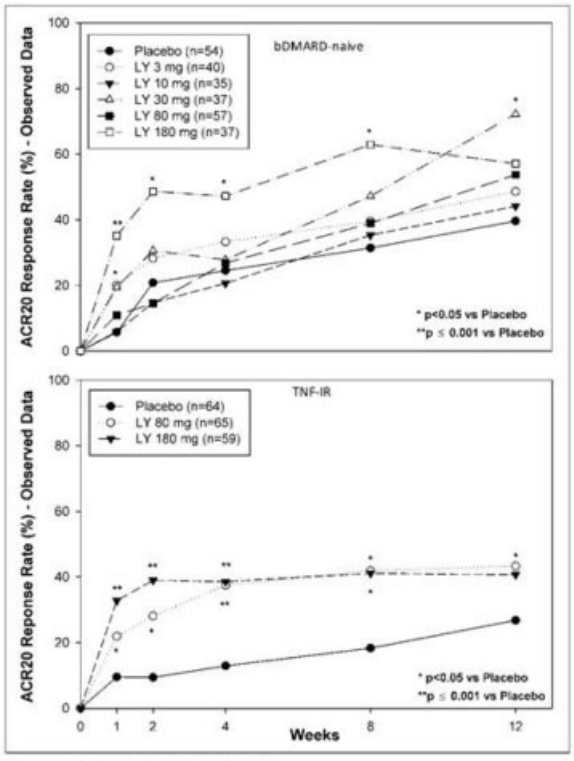
2591

A Phase 2 Study of Multiple Subcutaneous Doses of LY2439821, An Anti-IL-17 Monoclonal Antibody, in Patients with Rheumatoid Arthritis in Two Populations: Naïve to Biologic Therapy or Inadequate Responders to Tumor Necrosis Factor Alpha Inhibitors. Mark C. Genovese[1], Maria W. Greenwald[2], Chul Soo Cho[3], Alberto Berman[4], Ling Jin[5], Gregory Cameron[6], Li Xie[5], Daniel Braun[5], Subhashis Banerjee[5] and Laura Warner[7]. [1]Stanford University, Palo Alto, CA, [2]Desert Medical Advances, Palm Desert, CA, [3]St Marys Hospital, Seoul, [4]Hospital Padilla, Tucuman, Argentina, [5]Eli Lilly and Company, Indianapolis, IN, [6]Eli Lily and Company, Indianapolis, IN, [7]i3 Statprobe, Indianapolis, IN

Background/Purpose: To evaluate LY2439821 (LY), a humanized monoclonal antibody that neutralizes IL-17A, for the improvement of signs and symptoms of rheumatoid arthritis (RA) in 2 populations of patients (pts): (a) naïve to biologic therapy (bDMARD naïve) or (b) inadequate responders to tumor necrosis factor inhibitors (TNF-IR).

Methods: In this randomized, double-blind study, placebo (PB) or LY (3, 10, 30, 80, or 180 mg) was administered subcutaneously to 260 bDMARD naïve pts and 188 TNF-IR pts (LY 80 or 180 mg) at Weeks 0, 1, 2, 4, 6, 8, and 10 with concomitant conventional DMARD therapy. The primary objective was to determine the dose-response relationship of LY in bDMARD naïve pts at Week 12 based on logistic regression of the ACR20 response rate. Secondary objectives included additional safety and efficacy evaluations in the two populations at Week 12.

Results: There was a significant dose response relationship in bDMARD naive pts at Week 12 (p=0.031). Meaningful differences vs. PB were seen at Week 12 for ACR20 in bDMARD naïve pts receiving LY 30, 80 and 180 mg and in TNF-IR pts receiving LY 80 and 180 mg. (Figure, Table). There was a rapid onset of efficacy within 1 week after the first dose. CRP values showed a rapid drop with nadir values at 1 week after the first injection. Significant differences vs PB were observed for other clinical measures in both populations at Week 12. The frequency of TEAEs through Week 12 was similar across treatment arms in both populations (range: 45–64%). Infections were more frequent in LY arms compared to PB in bDMARD naïve (25 vs 19%) and TNF-IR pts (27 vs 23%). In bDMARD naive pts, SAEs occurred in 1 (1.9%) PB and 7 (3.4%) LY pts (6 were treatment emergent) with 1 serious infection-related event in a pt receiving LY 80 mg. In the TNF-IR population, SAEs occurred in 1 (1.6%) PB pt and 12 (9.7%) LY pts (10 were treatment emergent), and serious infections occurred in 4 (3.2%) pts in LY arms. There were no mycobacterial or systemic fungal infections observed in either population.



Non-responder Imputation at Week 12 in Table

Parameters at Week 12	bDMARD naïve						TNF-IR		
	PB n=54	LY 3 mg n=40	LY 10 mg n=35	LY 30 mg n=37	LY 80 mg n=57	LY 180 mg n=37	PB n=64	LY 80 mg n=65	LY 180 mg n=59

NRI=non-responder imputation.* — 1-sided Fisher's Exact test vs PB; # Last Observation Carried Forward 1-sided ANCOVA; ^ Last Observation Carried Forward 2-sided ANCOVA;

Conclusion: LY significantly improved signs and symptoms of RA compared to PB with a rapid onset of action and a safety profile comparable to other biologic therapies with no unexpected safety concerns.

2592

Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor, in Combination with Methotrexate Reduced the Progression of Structural Damage in Patients with Rheumatoid Arthritis: a 24-Month Phase 3 Study. Désirée van der Heijde[1], Y. Tanaka[2], Roy Fleischmann[3], Edward C. Keystone[4], J. M. Kremer[5], C A. F. Zerbini[6], M. Cardiel[7], S. B. Cohen[8], P. T. Nash[9], Yeong Wook Song[10], D. Tegzova[11], B. Wyman[12], D. Gruben[12], B. Benda[13], G. Wallenstein[12], S. H. Zwillich[12], J. D. Bradley[12], C. A. Connell[12] and the ORAL Scan investigators[14]. [1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]Rebecca MacDonald Centre for Arthritis and Autoimmune Disease, Mount Sinai Hospital, Toronto, ON, [5]Albany Medical College and The Center for Rheumatology, Albany, NY, [6]Centro Paulista de Investigação Clinica, Sao Paulo, Brazil, [7]Institute of Rheumatology, Prague, Czech Republic, [8]Metroplex Clinical Research Centre, Dallas, TX, [9]University of Queensland, Brisbane, Australia, [10]Seoul National University Hospital, Seoul, South Korea, [11]Institute Of Rheumatology, Prague, Czech Republic, [12]Pfizer Inc., Groton, CT, [13]Pfizer Inc., Collegeville, PA, [14]Groton

Background/Purpose: Tofacitinib (CP-690,550) is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator in

rheumatoid arthtitis (RA). This 24-mo study compared efficacy, including reduction of structural damage progression, and safety of tofacitinib vs placebo (PBO) in pts with active RA with inadequate response to methotrexate (MTX).

Methods: Pts on stable dose MTX were randomized 4:4:1:1 to 1 of 4 sequences in this Phase 3 study (NCT00847613): tofacitinib 5 mg twice daily (BID); 10 mg BID; PBO advanced to 5 mg BID; PBO to 10 mg BID. Pts on PBO advanced at Mo 6, or at Mo 3 if non-responsive (<20% reduction from baseline [BL] in swollen/tender joint counts). Reported data are from planned 12-mo analyses, which combined PBO into 1 group.

Results: 797 pts were randomized and treated. Pt groups were comparable for HAQ-DI, DAS28-4(ESR), disease duration, estimated structural progression, erosion score (ES), and positive RF/anti-CCP at BL. Tofacitinib 10 mg BID was efficacious compared with PBO in structure preservation measured by mean change from BL in modified Total Sharp Score (mTSS) at Mo 6 and demonstrated superior differences vs PBO for all 4 primary efficacy endpoints (Table). The 5 mg BID dose was superior to PBO for ACR20 response rates at Mo 6 but not for mTSS. Due to a step-down statistical procedure, significance was not declared for HAQ-DI and DAS28-4(ESR) <2.6 for 5 mg BID. Secondary analyses showed that the proportion of pts with no radiographic progression (mTTS change from BL ≤0.5) or no new erosions (ES change from BL ≤0.5) was superior to PBO for both doses, and evaluation of subgroups with predictors of poor prognosis showed a consistent pattern of structure preservation. Adverse events (AEs), serious AEs and serious infection events (SIEs) were distributed across groups (Table). Most frequently-reported AEs in the tofacitinib groups were infections; most were mild with similar incidence in both groups. There were 6 deaths (5 mg BID, 4; 10 mg BID, 1; PBO, 1). Decreases in neutrophils, increases in LDL and HDL, and small increases in serum creatinine were seen with tofacitinib.

Table. Primary and selected secondary efficacy endpoints and safety data

Efficacy	Tofacitinib 5 mg BID (n=321)	Tofacitinib 10 mg BID (n=316)	PBO (n=160)
ACR20[a] (%) Mo 6[e]	51.5***	61.8***	25.3
Mean change in mTSS[g] Mo 6[e]	0.12	0.06*	0.47
Mean change in ES[g] Mo 6	0.06	0.02	0.15
Mean change in JSN[g] Mo 6	0.06	0.04	0.31
Mean change in HAQ-DI[g] Mo 3[e]	-0.40[f]	-0.54***	-0.15
DAS28-4(ESR)<2.6 (%)[a] Mo 6[e]	7.2[f]	18.3***	1.6

Safety	Tofacitinib 5 mg BID (n=321)	Tofacitinib 10 mg BID (n=316)	PBO (n=160)[h]	PBO to 5 mg BID (n=81)[h]	PBO to 10 mg BID (n=79)[h]
Mo 0-3					
AEs	157 (48.9)	171 (54.1)	73 (45.6)	NA	NA
SAEs	12 (3.7)	10 (3.2)	5 (3.1)		
SIEs	5 (1.6)	3 (0.9)	0		
Mo 3-6					
AEs	145 (45.2)	111 (35.1)	21 (25.9)	18 (42.9)	15 (40.5)
SAEs	17 (5.3)	7 (2.2)	5 (6.2)	1 (2.4)	1 (2.7)
SIEs	8 (2.5)	2 (0.6)	2 (2.5)	0	0
Mo 6-12					
AEs	166 (51.7)	174 (55.1)	NA	34 (42.0)	35 (44.3)
SAEs	13 (4.0)	9 (2.8)		1 (1.2)	4 (5.1)
SIEs	3 (0.9)	2 (0.6)		0	2 (2.5)

Primary endpoints were tested by a step-down procedure; [f] p-values for HAQ-DI and DAS28-4(ESR)<2.6 for tofacitinib 5 mg BID are not significant since mTSS was not significant for 5 mg BID in the step-down procedure; *p<0.05 vs PBO, ***p<0.0001 vs PBO
[a]Primary endpoints; [e]non-responder imputation; [g]imputation using linear extrapolation then applying ANOVA; [g]mixed-effect longitudinal linear model; [h]n=81 (PBO), 42 (PBO to 5 mg BID), and 37 (PBO to 10 mg BID) at Mo 3-6; JSN, Joint Space Narrowing; NA, not applicable

Conclusion: In this P3 study, tofacitinib significantly reduced progression of structural damage vs PBO in pts with active RA on MTX. Consistent with other studies, tofacitinib demonstrated significant and clinically meaningful reductions in signs and symptoms of RA and physical function. No new safety signals were detected.

2593

The Oral S1P Lyase Inhibitor LX3305 (LX2931) Demonstrates Favorable Safety and Potential Clinical Benefit at 12-Weeks in a Phase 2 Proof-of-Concept Trial in Patients with Active Rheumatoid Arthritis on Stable Methotrexate Therapy. Roy M. Fleischmann[1], Jeffrey E. Poiley[2], Rumen Stoilov[3], Vibeke Strand[4], Joel Freiman[5], Tamas Oravecz[5], Arthur Sands[5], Brian Zambrowicz[5] and Lexicon Pharmaceuticals RA Clinical Development[6]. [1]University of Texas Southwestern Medical Center and Metroplex Clinical Research Center, Dallas, TX, [2]Arthritis Associates, Orlando, FL, [3]University Multiprofile Hospital for Active Treatment (UMHAT) St. Ivan Rilski EAD, Sofia, Bulgaria, [4]Stanford University, Palo Alto, CA, [5]Lexicon Pharmaceuticals, Inc., The Woodlands, TX, [6]The Woodlands, TX

Background/Purpose: Sphingosine-1-phosphate (S1P) is a lipid metabolite affecting lymphocyte trafficking and signal transduction pathways. S1P lyase (S1PL) catalyzed the irreversible degradation of S1P. Preclinical studies support that reduced S1PL activity reduces the inflammatory response in models of rheumatoid arthritis (RA). LX3305 (a.k.a. LX2931), a small molecule inhibitor of S1PL, is being developed as a novel, oral, disease-modifying antirheumatic drug (DMARD).

Methods: The safety, tolerability, and efficacy of LX3305 were evaluated in a multicenter, multinational, randomized, double-blind, placebo-controlled phase 2 trial in patients with active RA and an inadequate response to stable doses of methotrexate (MTX). Patients (N=208) with active RA (≥6 swollen/tender joints, C-reactive protein [CRP] >upper limits of normal [ULN]) on stable MTX therapy (10–25 mg/week) were randomly assigned with equal probability among treatments consisting of LX3305 taken orally (po) once daily (70 mg [n=55], 110 mg [n=54], 150 mg [n=50]) or placebo (n=49) in addition to their standard MTX regimen for 12 weeks. The study enrolled 177 patients in Eastern Europe and 31 patients in the United States. The primary measure of efficacy was the proportion of patients achieving an ACR20 response at Week 12. Other assessments included ACR50/70 response rates, DAS28-4, the hybrid ACR measure, individual components of the ACR and DAS28 response criteria, blood lymphocyte counts, and biomarkers of bone and cartilage turnover.

Results: ACR20 response at Week 12, the primary endpoint, was achieved by 60% of patients assigned to the 150 mg LX3305 group compared to 49% receiving placebo (not significant). The upper bound of the 95% CI computed on this difference was 29% and was consistent with a positive treatment effect. Sensitivity analyses showed that the middle and low LX3305 groups did not differ from placebo. In a post-hoc analysis, results from these groups were combined with placebo and compared against the 150 mg group in order to maximize statistical test efficiency. Sixty percent of the 150 mg LX3305 patients achieved an ACR20 response compared to 44.3% of all other patients [p = 0.038]. Overall, LX3305 was well tolerated over the 12 weeks of dosing, and adverse events were generally mild to moderate in intensity and comparable between placebo and LX3305 treatment groups. Only 2 serious adverse events were reported and these events were assessed by the Investigators as not related to study treatment.

Conclusion: LX3305, at 150 mg po QD for 12 weeks, produced a favorable safety profile and a potential clinical benefit in patients with active RA despite stable-dose MTX therapy. These results suggest that inhibition of S1PL by LX3305 represents a new mechanism for immune modulation, and supports further clinical development of LX3305 as a small molecule therapy for RA.

2594

Longer-Term Safety of Fostamatinib (R788) in Patients with Rheumatoid Arthritis—Analysis of Clinical Trial Data From up to 2 Years of Exposure. Arthur Kavanaugh[1], Michael E. Weinblatt[2], Mark C. Genovese[3], Theresa K. Musser[4], Elliott B. Grossbard[4], Daniel B. Magilavy[4], Sally Hollis[5], Eveline Wesby van-Sway[5] and David Millson[5]. [1]University of California San Diego, San Diego, CA, [2]Brigham and Women's Hospital, Boston, MA, [3]Stanford University, Palo Alto, CA, [4]Rigel Pharmaceuticals, South San Francisco, CA, [5]AstraZeneca, Macclesfield, United Kingdom

Background/Purpose: Fostamatinib, an investigational oral inhibitor of spleen tyrosine kinase has demonstrated significant outcomes in patients (pts) with rheumatoid arthritis in short-term phase II trials.[1,2] Presented here are longer-term safety and tolerability data for fostamatinib.

Methods: Data are from randomized, placebo (pbo)-controlled, fostamatinib phase II trials (TASKi1,[1] 2,[2] and 3[3]), the TASKi1 extension study and an ongoing open-label study (C-935788-012). TASKi1&2 pts were inadequate responders to methotrexate (MTX) on background MTX, and TASKi3 pts were inadequate responders to biologics on background disease-modifying antirheumatic drug (DMARD) combinations. Pts initially randomized to pbo received 100 mg bid or 150 mg qd fostamatinib in the extension study. Summaries are presented based on initial dose: fostamatinib 150 mg qd, 100 mg bid, all fostamatinib and pbo. Adverse events (AEs), serious AEs (SAEs), serious infection events (SIE), and fatal outcomes occurring from the initial treatment dose to 28 days after the last dose are presented for up to 24-mo exposure. Incidence rates (IRs) per 100 patient-years (PY) were calculated for each group.

Results: This analysis included 803 pts with 1,038 PYs of fostamatinib exposure (mean exposure 1.3 years) of which 265 PYs were contributed by 211 ex-pbo pts. Pts were well balanced across dose groups for age, gender, and ethnicity. Key findings are presented in the table. Fostamatinib IRs for SAEs, SIEs, treatment discontinuations, and dose reductions were higher in the TASKi3 (biologic refractory) group vs all other groups. The most common AEs were diarrhea (27.4%), hypertension (22.5%), and urinary tract infections (UTIs, 12.7%). Most common SAEs (IR per 100 PYs) were infective events (3.4) and gastrointestinal events (1.8). Most common SIEs (IR per 100 PYs) were pneumonia (1.0), UTIs (0.4), and cellulitis (0.3). The discontinuation rate on fostamatinib treatment was highest in the first 6 mo. Primary reasons for treatment discontinuations were lack of efficacy in TASKi3 and AEs (most commonly diarrhea, neutropenia, or increased transaminases). IRs (per 100 PYs) for blood pressure $\geq$ 160/100 mmHg and $\geq$ 180/110 mmHg for pts on fostamatinib vs pbo were (22.9 vs 24.8) and (4.9 vs 2.8), respectively. IRs (per 100 PYs) for neutrophil counts $<$ 1,500 mm^3 and $<$ 1,000 mm^3 for pts on fostamatinib vs pbo were (9.9 vs 3.7) and (2.2 vs 0), respectively.

	Inadequate responders to MTX		Inadequate responders to biologics	Inadequate response to MTX or biologics	
Dosing groups	150 mg qd + MTX	100 mg bid + MTX	100 mg bid + DMARDs	All fostamatinib* + DMARDs	Pbo** + DMARDs
	(TASKi2)	(TASKi1&2)	(TASKi3)		
	(N=218)	(N=282)	(N=204)	(N=803)	(N=273)
PY exposure	324	397	222	1038	109
Time	**Premature discontinuation rates (%)**				
6 months	13.8	15.3	34.6	20.2	26.6
24 months	35.6	35.1	59.2	42.2	–
	Incidence rates per 100 PYs (n)‡				
Any SAE	7.7 (25)	9.3 (37)	17.5 (39)	10.6 (110)	6.4 (7)
Any SIE†	3.1 (10)	3.0 (12)	6.3 (14)	3.8 (39)	4.6 (5)
Deaths††	0.6 (2)	0.5 (2)	0.4 (1)	0.5 (5)	0.9 (1)

* Includes 99 patients on other doses, mainly 50 or 150 mg fostamatinib bid in TASKi1.
** Combined pbo groups from randomized controlled trial studies. Pbo-controlled duration is 3 months for TASKi1 6 months for TASKi2.
‡ Presented for up to 24-months' exposure to a cut-off date of 7 December 2010 and excludes SAEs, SIEs, and reported fatal outcomes occurring greater than 28 days after last dose.
† There were no reported cases of tuberculosis or fungal infections.
†† A total of six deaths were reported; four occurred due to cardio- or cerebrovascular events (three were previously reported[2]) and two were due to infections (one occurred in the pbo group and was previously reported[3]).
MTX, methotrexate; DMARDs, disease-modifying antirheumatic drugs; pbo, placebo; PY, patient year; SAE, serious adverse event; SIE, serious infection event.

Conclusion: No new significant safety signals were identified with longer-term dosing of fostamatinib. Biologic refractory pts on a background of mixed DMARDs had a higher incidence rate of AEs, SAEs, and SIEs compared to MTX inadequate responders on background MTX; further confounding factors may play a role.[3] This will be explored in ongoing phase III studies.

Comparative Effectiveness of Abatacept Versus Subsequent Anti-TNF Agents Among Rheumatoid Arthritis Patients with Previous Anti-TNF Exposure. Leslie R. Harrold[1], George Reed[1], Jeffrey R. Curtis[2], Daniel H. Solomon[3], Marc Hochberg[4], Alina U. Onofrei[1], Joel M. Kremer[5] and Jeffrey D. Greenberg[6]. [1]UMass Medical School, Worcester, MA, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]Brigham & Womens Hospital, Boston, MA, [4]University of Maryland School of Medicine, Baltimore, MD, [5]Albany Medical College and The Center for Rheumatology, Albany, NY, [6]New York University School of Medicine, New York, NY

Background/Purpose: There are limited data to guide a rheumatologist's selection of a biologic agent among rheumatoid arthritis (RA) patients who have failed one or more anti-TNFs. We compared the effectiveness of abatacept (ABA) versus a subsequent anti-TNF agent among RA patients with previous anti-TNF exposure using data from a multi-center observational registry within the United States (the Consortium of Rheumatology Researchers of North America: CORRONA).

Methods: We identified RA patients between 2/1/02 through 12/14/09 who had discontinued at least 1 anti-TNF and initiated either ABA or a subsequent anti-TNF, were not in remission based on the Clinical Disease Activity Index (CDAI) at the time of initiation, and had follow-up at 6 months (n=1,061) and/or 12 months (n=780). Propensity score (PS) matching (n:1 match) based on age, duration of RA, swollen joint count, patient global assessment, physician global assessment and insurance type was used to control for imbalances between treatment groups. Treatment response was measured at 6 months and 1 year after initiation based on mean change in CDAI from baseline and achievement of an American College of Rheumatology (ACR) 20 and 50 response. Last observation carried forward (LOCF) was applied to patients who discontinued treatment. Regression models accounted for PS matching, clustering by physician, as well as residual differences in baseline characteristics. As a sensitivity analysis, 1:1 PS matching was used to generate the study cohort and the analyses were repeated.

Results: Most patients were female (77–81%) with a mean age of 56 to 57 years, mean disease duration of 12–14 years and mean CDAI of 21–23. Among patients with a visit at 6 months, there were small baseline imbalances between treatment groups: ABA users had more active disease based on the patient global assessment (51 vs. 47), self-reported pain (52 vs. 48) and modified Health Assessment Questionnaire (0.66 vs. 0.58). There were no significant baseline differences between the 2 treatment groups included in the 12 month follow-up analysis. The weighted mean change in CDAI at 6 and 12 months in ABA initiators as compared to anti-TNF initiators was not significantly different in unadjusted or adjusted analyses (Table). ACR20 and ACR50 response rates were similar at 6 months and 12 (Table). Results were similar in the 1:1 PS matched analyses.

	6 months		12 months	
	335 ABA	546 anti-TNF	241 ABA	399 anti-TNF
Change in CDAI				
Weighted mean improvement	6.6	6.0	7.9	8.2
Unadjusted difference (95% CI)	0.7 (−2.1 to 3.4)		−0.5 (−3.6 to 2.6)	
Adjusted difference (95% CI)	0.3 (−1.6 to 2.3)		−0.7 (−3.0 to 1.5)	
ACR20				
Weighted response rates	29%	30%	35%	35%
Unadjusted odds ratio (95% CI)	0.97 (0.71–4.28)		1.04 (0.64–1.69)	
Adjusted odds ratio (95% CI)	0.91 (0.63–1.30)		1.01 (0.61–1.71)	
ACR50				
Weighted response rates	18%	15%	19%	19%
Unadjusted odds ratio (95% CI)	1.32 (0.93–1.86)		0.92 (0.57–1.47)	
Adjusted odds ratio (95% CI)	1.24 (0.89–1.74)		0.89 (0.54–1.47)	

Conclusion: We were unable to detect any differences in effectiveness in this US cohort over a period of 12 months after switching from a prior anti-TNF to either ABA or another anti-TNF. Analyses of adverse events and longer term outcomes will be needed in order to determine best strategies in TNF failure pts with RA in the US. Both treatments appear reasonable to use in this population.

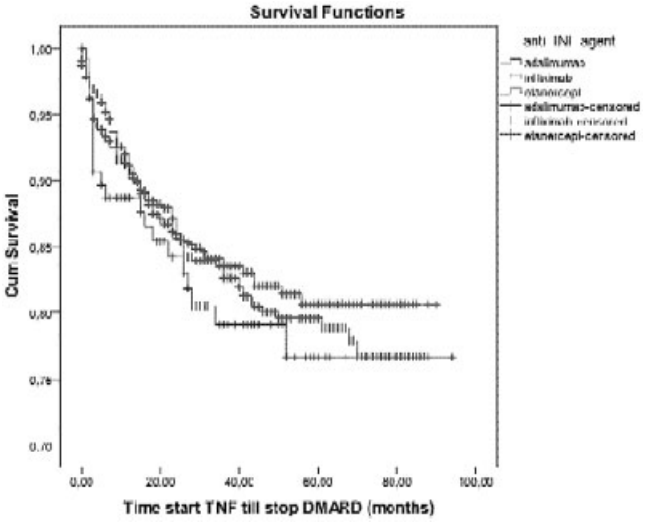
2596

Discontinuation of DMARDs in Patients With Rheumatoid Arthritis Treated With Tumor Necrosis Factor Blocking Agents: An Analysis in the Dutch Rheumatoid Arthritis Monitoring (DREAM) Registry. Sanne van Dartel[1], Jaap Fransen[1], Wietske Kievit[1], Alfons den Broeder[2], Henk Visser[3], Andre Hartkamp[4], Mart AF van de Laar[5] and Piet Van Riel[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands, [3]Alysis Care Group, Arnhem, Netherlands, [4]Jeroen Bosch Hospital, 's-Hertogenbosch, Netherlands, [5]Medisch Spectrum Twente & Twente University, Enschede, Netherlands

Background/Purpose: The majority of rheumatoid arthritis (RA) patients currently treated with biologics combine this therapy with a disease-modifying anti-rheumatic drug (DMARD), usually methotrexate (MTX). However, DMARDS can cause considerable toxicity. Patients might prefer discontinue a DMARD when disease activity becomes low after the initiation of TNF blocking agents. Objective of the study was to analyze whether it is possible to discontinue a DMARD and especially MTX during TNF blocking therapy and keep disease activity low.

Methods: Data from the Dutch Rheumatoid Arthritis Monitoring (DREAM) Biologic registry of 1553 RA patients using TNF blocking therapy with a DMARD as co-medication were used for the analyses. Since February 2003 the large majority of RA patients who started on one of the biologic agents for the first time in one of 13 centers in the Netherlands have been included in the DREAM register. In all analyses discontinuation of the DMARD was defined as an event on the condition that no other anti-rheumatic drugs were added within 3 months of discontinuation. Baseline differences were compared between patients in which MTX or a DMARD was discontinued and those in which MTX or a DMARD was not discontinued. The mean difference in DAS28 over 6 months after the moment of DMARD discontinuation was tested on a statistically significant difference from 0.3 (inferiority margin) by a one-sample t-test.

Results: 85% of RA patients treated with TNF inhibitors in daily clinical practice used at least one DMARD as co-medication, in 83% of the patients using a DMARD as co-medication this was MTX. Concomitant DMARDs were discontinued in only 15% of the patients (12,5% MTX). Most DMARDs were discontinued within the first three years after start of anti-TNF (13,6%), without notable differences between type of anti-TNF (p=0.71) (figure). There were no difference in characteristics between patients who discontinued a DMARD and patients who did not discontinue a concomitant DMARD. The mean (SD) DAS28 at start of the anti-TNF was 5.1 (1.1), the mean (±SD) DAS28 at discontinuation of a DMARD was 3.5 (1.4). In the patients in whom a DMARD was discontinued, there was no increase of disease activity the 6 months thereafter, (decrease −0.25 DAS28 point), significantly different from +0.3 (p=0.00).



Conclusion: Concomitant DMARDs are infrequently stopped, but in patients who stopped the disease activity did not increase.

Funding for the data collection for the DREAM cohort was obtained from the Dutch affiliations of Wyeth Pharmaceuticals, Abbott Pharmaceuticals, Schering-Plough Corporation, Roche pharmaceuticals, UCB pharma and Bristol-Myers Squibb. Funding for performing these analyses in particular was obtained from the Dutch affiliation of Wyeth Pharmaceuticals. No others than the authors were involved in the analyses, interpretation of results and writing the abstract.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects: Translational Studies

Members of the Receptor for Advanced Glycation Endproducts Axis Associate with Systemic Lupus Erythematosus, and May Serve As a Brake to Disease Activity. Manish Jain, Michael Amato, Robert M. Clancy, Peter M. Izmirly and Jill P. Buyon. New York University School of Medicine, New York, NY

Background/Purpose: The Receptor for Advanced Glycation Endproducts (RAGE) is a transmembrane cell-surface receptor found on a variety of immune and endothelial cells, which is upregulated in stress situations and mediates a pro-inflammatory response. RAGE has been implicated in the pathogenesis of diverse disease states characterized by vascular insult. Soluble forms of RAGE exist, with the total circulating pool of soluble RAGE (sRAGE) including both membrane-cleaved RAGE, as well as an alternative mRNA spliced form—endogenous soluble RAGE (esRAGE)—both with common ligand affinity. Isoforms of soluble RAGE may be protective by serving as decoy receptors. Simultaneous measurement of sRAGE and esRAGE, with attention to relative proportion, may be informative. Accordingly, RAGE axis markers in an SLE cohort with characterization of disease activity and subclinical atherosclerosis was assessed to provide insight into pathogenesis of SLE.

Methods: sRAGE and esRAGE were measured by ELISA in a cross sectional study of 99 SLE patients and 40 healthy controls in whom carotid ultrasonography was performed to evaluate for carotid plaque. SLEDAI for SLE patients was also calculated at the same visit.

Results: Median esRAGE level was higher in patients (288±262 pg/mL) than controls (171±162 pg/mL) (p=.0031), as was percent esRAGE/sRAGE (25.4±17.7 in SLE vs.14.9±11.6 in controls, p<.0001). In contrast, sRAGE levels did not differ between SLE patients and controls. A negative correlation was observed between SLEDAI score and esRAGE (rho=-.197, p=.049), and sRAGE (rho=-.303, p=.0014). SLE patients with high disease activity defined as SLEDAI >4 (23% of cohort) had lower median esRAGE levels (153±216) than patients with SLEDAI≤4 (295±269) (p=.029), with a trend for lower percent esRAGE/sRAGE in the high disease group as well (22.3±13.7 in high group vs. 27.5±18.2 in low group, p=.071). While median esRAGE in the low disease activity group was significantly different from controls (p=.0016), no significant difference in median esRAGE existed between patients with high disease activity and controls. When serologic factors (C3, C4, dsDNA) were excluded from disease activity, C3 and C4 had the strongest negative correlation with non-serologic disease activity (rho=-.294 and -.291, p=.0087 and p=.0097, respectively), followed by percent esRAGE/sRAGE (rho=-.235, p=.0438), followed by anti-dsDNA (rho=.150, p=.195). No association was noted between RAGE axis levels and the individual ACR criteria or medications. In both SLE patients and controls, no association with carotid plaque was noted with RAGE axis levels.

Conclusion: This study highlights the potential role of the RAGE axis in pathogenesis of SLE. The elevation of both esRAGE and percent esRAGE/sRAGE in SLE patients compared to controls may represent a compensatory attempt at protection. However, among SLE patients, the RAGE axis may serve as a brake to disease activity, reflected in part by inverse correlations of RAGE isoforms to disease activity, and lower esRAGE levels and percent esRAGE/sRAGE in high disease activity patients on cross-sectional analysis. Thus soluble forms of RAGE may have therapeutic value warranting further study.

Regulatory Role of Umbilical Cord Mesenchymal Stem Cells on Treg and Th17 Cells in Patients with Systemic Lupus Erythematosus. Dandan Wang, Huiqing Liu, Xia Li and Lingyun Sun. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background/Purpose: Mesenchymal stem cells (MSC) demonstrated multiple modulations on immune cell responses, such as effective T cells, B cells, NK cells, and dendritic cells. But its role on regulatory T cells and Th17 cells in patients with systemic lupus erythematosus (SLE) has not been well characterized. The aim of this study is to investigate the regulatory effect of umbilical cord MSC (UC-MSC) on Treg and Th17 cells in SLE patients.

Methods: Human UC-MSC were isolated, expanded and infused into 15 refractory SLE patients (ClinicalTrials.gov Identifier: NCT00698191, phase II). Clinical changes were evaluated pre and post-transplantation by SLE Disease Activity Index (SLEDAI), 24-hour urine protein, serum albumin and complement C3. The percentages of $CD4^+CD25^+Foxp3^+T$ cells and $CD3^+CD8^-IL17A^+T$ cells in peripheral blood were detected by flow cytometry. Concentrations of plasma TNF-α, TGF-β1, IL-6 and IL-17A were determined by ELISA. Gene expressions of Foxp3, RORγt, IL-6, TGF-β1 and IL23R were analyzed by real time PCR. Peripheral blood mononuclear cells (PBMC) from 11 active SLE were co-cultured with UC-MSC at different ratios (MSC: PBMC=0:1, 1:1, 1:10, 1:100) to examine the changes of $CD4^+CD25^+Foxp3^+T$ cells and $CD3^+CD8^-IL17A^+T$ cells and supernatant TNF-α, TGF-β1, IL-6 and IL-17A.

Results: SLEDAI scores decreased significantly at 3 months (7.8±1.2) and 6 months (6.9±0.9) after UC-MSC transplantation ($p<0.05$ *vs* pre-transplantation level 10.4 ± 0.9). Twenty-four-hour proteinuria decreased significantly 6 months

after MSC infusion (1489 ± 260mg vs 2454 ± 322mg, $p<0.05$). Meanwhile, serum albumin and complement C3 levels increased significantly from 1 month after transplantation ($p<0.05$). Peripheral blood $CD4^+CD25^+Foxp3^+$T cells percentage showed obvious increase at 1 week (2.32%±1.40%), 1 month (2.03%±1.30%), 3 months (2.41%±2.06%) and 6 months (2.81%±0.69%) visit (all $p<0.05$ *vs* pre-MSCT 1.58%±1.02%), in parallel with significant decline of $CD3^+CD8^-IL17A^+$T cells percentage after MSCT (1.30%±1.02% at 1 week, 0.73%±0.60% at 1 month, 0.56%±0.60% at 3 months, 0.52%±0.40% at 6 months, all $p<0.05$ *vs* pre-MSCT 1.69%±1.13%). Real time PCR showed that gene expression for RORγt decreased, while TGF-β1 increased significantly after transplantation, with no statistical change in IL-6, Foxp3 and IL23R. Plasma concentration of TNF-α decreased significantly at 1 week, 1, 3, 6 and 12 months after transplantation, with increased TGF-β1 at 1 week, 3 and 12 months ($p<0.05$ *vs* before MSCT). Plasma IL17A decreased obviously 1 month after transplantation, but no change in plasma IL-6 was found. The co-culture of UC-MSC with PBMC from active SLE patients resulted in a statistical increase of $CD4^+CD25^+Foxp3^+$T cells and reduce of $CD3^+CD8^-IL17A^+$T cells percentage in PBMC (all $p<0.05$ at UC-MSC: PBMC 1:1, 1:10, 1:100 ratio), but without a dose dependent manner. Supernatant TGF-β1 and IL-6 increased but TNF-α decreased significantly in the co-culture system. No change in IL-17A was observed.

Conclusion: UC-MSC transplantation markedly regulated Treg and Th17 cells in SLE patients, which may be one of the mechanisms for its therapeutic potential in refractory SLE.

N-Acetylcysteine Improves Disease Activity by Blocking the Mammalian Target of Rapamycin in T Cells of Lupus Patients. Zhiwei Lai[1], Robert Hanczko[1], Eduardo Bonilla[1], Adam Bartos[1], Tiffany Telarico[2], Gabriella Miklossy[3], Brandon Clair[2], John Jimah[3], Edward Doherty[4], Lisa Francis[1], Hajra I. Tily[5], Ricardo Garcia[1], Maha M. Dawood[4], Jianghong Yu[1], Irene Ramos[1], Travis Boevin[1], Stephen Faraone[1], Paul E. Phillips[6] and Andras Perl[3]. [1]SUNY, Syracuse, NY, [2]SUNY Upstate Medical University, Syracuse, NY, [3]Upstate Medical University, Syracuse, NY, [4]SUNY Upstate, Syracuse, NY, [5]SUNY, NY, [6]SUNY-Upstate Medical Univ, Syracuse, NY

Background/Purpose: Systemic lupus erythematosus (SLE) patients exhibit T-cell dysfunction which is regulated through the mitochondrial transmembrane potential ($\Delta\Psi_m$) and mammalian target of rapamycin (mTOR) by glutathione. Therefore, the safety, tolerance, and efficacy of glutathione-precursor N-acetylcysteine (NAC) were examined in this double-blind placebo-controlled study (FDA approval, IND No: 101,320; clinicaltrials.gov identifier, NCT00775476).

Methods: 36 SLE patients with clinically stable disease were randomized to receive daily placebo or 1.2 g, 2.4 g or 4.8 g of NAC. Disease activity was monthly evaluated by BILAG, SLEDAI and fatigue assessment scale (FAS) before and during 3-month treatment and after 1-month washout. $\Delta\Psi_m$ and mTOR were assessed by flow cytometry. Glutathione was measured by HPLC. 42 healthy subjects matched for patients' age, gender, and ethnicity were studied as controls.

Results: NAC was tolerated by all patients up to 2.4 g/day while 33% of those receiving 4.8 g/day had reversible nausea. Initial mean disease activity scores, as measured by SLEDAI (5.5), BILAG (26.1), and FAS (28.5), were similar in patients randomized into the placebo arm or any of the 3 NAC arms. Placebo or 1.2 g/day NAC did not influence any disease activity measure. Considered together, in patients receiving daily 2.4 g and 4.8 g of NAC, 1) SLEDAI was improved from 5.8 at baseline on all follow-up visits (after 1 month: SLEDAI: 3.6, $p = 0.0007$; after 2 months: SLEDAI: 4.0, $p=0.0009$; after 3 months: SLEDAI: 4.9, $p = 0.0030$; after 4 months/1-month washout: SLEDAI: 4.4; $p = 0.0046$); BILAG was reduced from 28.0 at baseline to 24.2 after 1 month ($p = 0.029$) and to 21.8 after 3 months ($p = 0.0009$); FAS was reduced from 30.2 at baseline to 25.4 after 2 month ($p = 0.002$) and to 24.5 after 3 months ($p = 0.004$); anti-DNA was reduced from 78.9 ± 45.2 IU/ml at baseline to 19.5 ± 6.0 IU/ml ($p=0.049$) after 1 month. Glutathione was reduced in PBL, but not in whole blood, suggesting that the metabolic dysfunction in lupus is confined to the immune system. 2.4 g/day and 4.8 g/day NAC increased glutathione in lupus PBL. While NAC increased $)R_m$ ($p=0.0001$) in all T cells, it prominently reduced mTOR activity ($p=0.0001$), enhanced apoptosis ($p=0.0004$) and reversed expansion of CD4-/CD8- T cells (1.35±0.12-fold; $p=0.008$), and stimulated Foxp3 expression in $CD4^+/CD25^+$ T cells ($p=0.045$). NAC did not influence $\Delta\Psi_m$ and mTOR in B cells.

Conclusion: This dose, tolerance, and mechanism-finding double-blind placebo controlled phase I/II study provides clear evidence that NAC improves disease activity in patients with SLE primarily by uncoupling $\Delta\Psi_m$ from activation of mTOR in all T cells and promoting the apoptosis of CD4-/CD8- T cells and the expansion of $CD4^+/CD25^+/Foxp3^+$ T cells. The selectivity of NAC for mTOR activation in T cells provides a safe, inexpensive, alternative, and potentially synergistic approach to B-cell blockade in SLE. Large-scale phase II/III studies are clearly warranted to determine long-term efficacy and whether NAC could also benefit patients with unstable disease.

This work was supported by grant AT 4332 from the National Institutes of Health and the Alliance for Lupus Research.

Circulating Mitochondrial DNA Copy Numbers As a Highly Sensitive Diagnostic Marker of Systemic Lupus Erythematosus and An Independent Predictor of SLE Activity. Nils Venhoff[1], Jens Thiel[1], Dirk Lebrecht[1], Chingching Foocharoen[2], Nora M. Effelsberg[1], Marten Trendelenburg[3], Paul Hasler[4], Reinhard E. Voll[1] and Ulrich A. Walker[2]. [1]Dept. of Rheumatology and Centre of Chronic Immunodeficiency, University of Freiburg, Freiburg, Germany, [2]Dept. of Rheumatology at Basel University, Felix-Platter Spital, Basel, Switzerland, [3]Dept. of Internal Medicine, University Hospital Basel, Basel, Switzerland, [4]Dept. of Rheumatology, Kantonsspital Aarau, Aarau, Switzerland

Background/Purpose: Toll-like receptor (TLR) 9 signaling is important in the pathogenesis of systemic lupus erythematosus (SLE) and its type I interferon signature. TLR9 recognizes dsDNA which may be released by neutrophil extracellular traps (NETs) upon stimulation by tissue injury. This study examines if the quantitative analysis of two dsDNA species, namely circulating mitochondrial DNA (mtDNA) or nuclear DNA (nDNA) may contribute to the understanding of SLE, be useful in the clinical diagnosis of SLE and the monitoring of its disease activity.

Methods: 77 SLE patients (mean age 46.2 years, 65 females, median disease duration 6.1 years, 43% with a history of lupus nephritis) and 40 controls (healthy volunteers, or persons hospitalized for osteoarthritis or herniated intervertebral disks, mean age 44.2 years, range 20–95 years, 23 females) from two tertiary care centers were included in this cross-sectional study. MtDNA and nDNA copy numbers in plasma were quantified by PCR. SLE activity was determined by means of the SLEDAI. C-reactive protein (CRP), C3, C4 and C3d-levels, as well as autoantibody titers against dsDNA, phospholipids, SSA, SSB, and proteinuria were quantified at the time of blood collection.

Results: Circulating mtDNA copy numbers in the plasma of SLE patients were increased by a factor of 82 (median 1,356,667/mL; interquartile range (IQR) 844,667–2,346,667) compared to controls (median 16,500/mL; IQR 11,275–33,816) ($p<0.001$). None of the SLE patients had mtDNA copies below the highest control value (113,667/mL). Circulating mtDNA-levels were not dependent on age or gender, but correlated with anti-dsDNA titers ($R^2=0.17$, $p<0.001$), C3d ($R^2=0.21$, $p<0.001$), C4 levels ($R^2=0.06$, $p=0.05$), CRP ($R^2=0.06$, $p=0.03$), and SLEDAI ($R^2=0.31$, $p<0.001$) on univariate analysis. In multivariate analysis, only C3d ($p=0.04$), and SLEDAI ($p=0.03$) remained predictive for the mtDNA-levels.

Conversely SLEDAI was predicted on multivariate analysis by mtDNA-levels ($p=0.001$), anti-dsDNA-antibodies ($p=0.03$), and CRP ($p<0.001$). Circulating nDNA copy numbers were low in both controls (7170/mL, IQR 3203.5–18170) and SLE patients (13,607/mL, IQR 4,567–33,933, $p=0.07$) and did not correlate with any covariate in SLE.

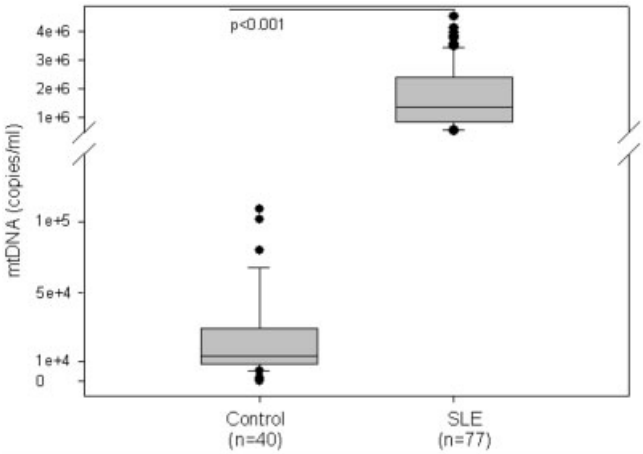

Figure 1. Circulating mtDNA copy numbers in plasma of SLE patients and control persons. Error bars represent IQR, individual points represent outliers.

Conclusion: Circulating mtDNA, unlike nDNA molecules, are markedly increased in SLE plasma. Regardless of disease activity circulating mtDNA-levels distinguish SLE patients from non-inflammatory controls with high sensitivity. In addition, circulating mtDNA copies represent an independent marker of SLE disease activity.

Interferon-Alpha Activity Levels Increase Immediately Preceding Clinical Classification of Systemic Lupus. Julie M. Robertson[1], Latisha Heinlen[2], Jourdan Anderson[1], Timothy B. Niewold[3], Michael P. Keith[4], John B. Harley[5] and Judith A. James[6]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]OUHSC, Oklahoma City, OK, [3]University of Chicago, Chicago, IL, [4]National Naval Medical Center, Bethesda, MD, [5]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH, [6]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK

Background/Purpose: Systemic lupus erythematosus (SLE) is a clinically variable disease with a complex etiology. Many lupus patients have increased interferon-inducible gene expression and elevated levels of interferon-a (IFNa) which correlate with increased disease activity. IFNa is released by plasmacytoid dendritic cells after stimulation through TLR binding by autoantigen/autoantibody complexes. However, the exact role of interferon in disease pathogenesis is still not understood. This study seeks to evaluate the temporal relationship between IFNa production and the onset of SLE characteristics.

Methods: Patient sera from 20 SLE cases with samples spanning from no ACR criteria to SLE classification were obtained from the Department of Defense Serum Repository (DODSR). Serial samples were tested for antibody isotype specificity against common lupus autoantigens (Ro, La, nRNP, Sm, Ribosomal P, dsDNA, and ANA) by ELISA and immunofluorescence. IFNa levels were examined utilizing a cell reporter assay measuring upregulation of interferon inducible genes (MX1, PKR, and IFIT1) by serum. Two sets of matched controls were also tested and results were reported as elevation of IFN levels above controls.

Results: Autoantibodies are common before diagnosis in SLE patient samples. As a patient moved toward SLE diagnosis the number of autoantibodies increased to include specificity toward multiple lupus autoantigens. Isotype class switching from IgM to IgG_1 was observed in the anti-Ro specificity. In examining dominant antibody isotypes for each lupus antigen we observed the IgG_1 isotype as dominant in nRNP, while Ro, Sm, and Ribo P had an IgG_2 isotype dominance before and at lupus classification. Interestingly, anti-La, anti-Sm, and anti-nRNP antibodies specificities showed detectable amounts of IgA and IgE antibody isotypes. Examination of IFNa levels indicated a statistically significant trend of increasing IFN levels leading up to SLE diagnosis ($p=0.0279$). There was a significant difference in IFN levels between samples prior to first criteria and at SLE diagnosis ($p<0.05$). Four individuals are shown to have autoantibody present in sera samples before the detection of serologic interferon activity.

Conclusion: Our results show IgG_2 is the dominant autoantibody specificity, class switching between IgM and IgG_1 for anti-Ro antibodies occurs leading up to diagnosis, and IFNa levels increase as the number of autoantigen specific antibodies increase leading up to SLE classification. Thus, the increase in IFN levels is more closely linked to disease onset as opposed to autoantibody production.

Vascular Biomarkers and Risk of Treatment Failure in the Maintenance Phase of a Randomized Multicenter Trial Comparing Mycophenalate Mofetil and Azathioprine for Lupus Nephritis. Robert M. Clancy[1], Peter M. Izmirly[1], E.M. Ginzler[2] and On Behalf of the Investigators in the MMF/AZA Lupus Nephritis Main Trial[1]. [1]New York University School of Medicine, New York, NY, [2]SUNY-Downstate Medical Center, Brooklyn, NY

Background/Purpose: The contribution of the vascular endothelium to the pathogenesis of lupus nephritis (LN) is of central importance given the role of renal endothelial activation and recruitment of inflammatory cells, including monocytes. Biomarker studies corroborating the involvement of the endothelium in LN have included the following cytokines/cofactors: adiponectin (ADPN), endothelial protein C receptor (EPCR), monocyte chemotactic protein-1 (MCP-1), Interleukin-18 (IL-18), nitric oxide (NO) and neutrophil gelatinase-associated lipocalin (NGAL). Data regarding the utility of these biomarkers to predict stability and/or relapse in patients with LN achieving initial response to induction therapy is limited. Accordingly, samples from the maintenance phase of the Aspreva Lupus Management Study were evaluated to identify predictors of outcome following treatment with mycophenolate mofetil (MMF) or azathioprine (AZA).

Methods: The study included 52 patients in whom LN was considered responsive following 6 months of induction therapy with either cyclophosphamide or MMF. At initiation of maintenance, patients were randomized to therapy with MMF (27 pts) or AZA (25 pts). The study outcome, treatment failure during maintenance phase, was defined as death, end-stage renal disease, sustained doubling of serum creatinine, and/or renal flare (proteinuric or nephritic). This endpoint occurred in 12 pts (23%). Plasma (p) and urine (u) were analyzed using validated protocols. Measurements were done at entry and at designated study intervals until treatment failure or the end of the maintenance study after 3 years. Analyses of the urine were normalized to u-creatinine. Median values were compared using the Mann Whitney U test.

Results: At entry into the maintenance phase there were no statistical differences between patients who were treatment failures compared to responders in mean baseline glomerular filtration rates and protein/creatinine ratios. Patients considered to have failed therapy had higher median levels of the following analytes compared to those who remained responders: u-ADPN (5.9 ug/mg vs 0.1 ug/mg, $p=0.0002$), p-MCP1 (552 ng/ml vs 150 ng/ml, $p = 0.0075$), u-MCP-1 levels (64 ng/mg vs 26 ng/mg, $p=0.014$), and p-NO levels (23 uM vs 16 uM, $p=0.039$). There were no significant differences in the levels of p-ADPN, u-NO, p/u-IL-18, or p/u-NGAL between failures or sustained responders. Consistent with our previously reported observation that increased mEPCR expression in PTCs may represent a novel marker for poor response to therapy for LN, the values of EPCR rose significantly by the last visit in those who failed compared to those whose LN remained in remission (166% vs 102%, $p=0.03$). u-ADPN also increased over time in patients whose LN flared vs those who remained in remission (254 vs 122, $p=0.03$). There was no association between response and change in levels of p/u-MCP-1 and p-NO.

Conclusion: This study supports the notion that evaluation of markers reflective of endothelial activation and inflammatory cell recruitment provides important adjunct information in subsetting initial responders with regard to greater risk of relapse following induction therapy.

Intermittent Systemic VEGF Inhibition Induces Pulmonary Arterial Hypertension In a Transgenic Mouse Model of Scleroderma. Emma Derrett-Smith[1], Audrey Dooley[1], Reshma Baliga[2], Adrian Hobbs[2], David J. Abraham[3] and Christopher P. Denton[1]. [1]UCL Medical School, London, United Kingdom, [2]Centre for Cardiovascular Pharmacology, University College London, London, United Kingdom, [3]Centre for Rheumatology and Connective Tissue Diseases, UCL Medical School, London, United Kingdom

Background/Purpose: Pulmonary arterial hypertension (PAH) is a major complication in ~15% of SSc cases and occurs throughout the disease suggesting that a second vascular event occurring in the context of a systemic disease may be responsible. We have previously shown that a transgenic mouse model develops many features of SSc including susceptibility to systemic vasculopathy and lung fibrosis. A role for altered VEGF signaling in PAH-SSc is supported by data that correlate circulating VEGF with mPAP at diagnosis. High circulating VEGF levels may be a marker of repair in response to vascular injury. VEGF signaling is upregulated in the TβRIIΔk-fib mouse model of SSc, which has evidence of a constitutive pulmonary vasculopathy. We have inhibited VEGF signaling using SU5416 to induce endothelial apoptosis in this model.

Methods: The transgenic mouse strain TβRIIΔk-fib expresses a kinase-deficient type II TGFβ receptor driven by a fibroblast-specific promoter leading to balanced ligand-dependent upregulation of TGFβ signalling. The constitutive pulmonary vasculopathy was confirmed by histological assessment of vessel architecture, isolated organ bath and *in vivo* haemodynamic studies. Biochemical analysis of the VEGF signaling axis by quantitative PCR and Western blotting was performed using cultured pulmonary artery smooth muscle cells, and by immunostaining of tissue sections. In vivo SU5416

administration to transgenic and wildtype animals was compared to vehicle administration alone (n=6 each group). Post mortem RV mass index measurements were taken, and histological and immunohistochemical stains (H&E, SR, CD31) were performed.

Results: Within the transgenic pulmonary arterial circulation, hypertrophy of the smooth muscle layer was increased (mean wildtype vessel thickness:circumference ratio 0.66±0.02, mean transgenic 0.88±0.04, $p<0.05$). Pulmonary arterial ring responses to direct and receptor-mediated contractile stimuli were reduced in the transgenic animals (in response to endothelin contraction at 10^{-5}M wildtype 1.10mN±0.02, transgenic 0.62±0.12, $p<0.05$) and right ventricular pressures were elevated in transgenic animals (wildtype mean 29mmHg±4 transgenic mean 37mmHg±3, $p<0.05$). Explanted transgenic PASMC showed upregulation of VEGF and VEGFR1. RV mass index in transgenic animals was increased after treatment with SU5416 (transgenic, vehicle only 0.19±0.01, SU5416 treated 0.29±0.03, $p<0.05$). Histological and immunohistochemical analysis revealed evidence of obliterative endothelial proliferation in transgenic SU5416 treated animals similar to human plexiform lesions which was not seen in any other group.

Conclusion: Treatment with SU5416 exacerbates the underlying constitutive pulmonary vascular defect of this transgenic mouse model and replicates the key histological and patho-physiological features seen in human PAH-SSc. These findings support a role for perturbed TGFβ and VEGF activity in the pulmonary circulation in SSc, supporting the concept of a second pulmonary endothelial injury leading to PAH in SSc. This model may provide a valuable platform for future therapeutic studies in vivo as well as providing insight into pathogenic mechanisms.

Overexpression of $VEGF_{165}b$, An Inhibitory Splice Variant of Vascular Endothelial Growth Factor, Leads to Insufficient Angiogenesis In Patients with Systemic Sclerosis. Mirko Manetti, Serena Guiducci, Eloisa Romano, Claudia Ceccarelli, Silvia Bellando-Randone, Maria Letizia Conforti, Lidia Ibba-Manneschi and Marco Matucci-Cerinic. University of Florence, Florence, Italy

Background/Purpose: Systemic sclerosis (SSc) is a chronic connective tissue disorder characterized by widespread microangiopathy, fibrosis, and autoimmunity that affects the skin and internal organs. Although in SSc there is a lack of sufficient angiogenic response to chronic tissue ischemia culminating in the loss of capillary vessels, the expression of vascular endothelial growth factor-A (VEGF) has paradoxically been shown to be upregulated in SSc skin and circulation. However, previous studies in the field did not distinguish between the proangiogenic $VEGF_{165}$ and antiangiogenic $VEGF_{165}b$ isoforms that are generated by alternative splicing in the terminal exon of VEGF pre-RNA. In the present study, we investigated whether VEGF isoform expression could be altered in skin and circulation of SSc patients.

Methods: The expression of $VEGF_{165}b$, pan-VEGF, VEGF receptor-2 (VEGFR-2), transforming growth factor-b1 (TGF-b1) and serine/arginine protein 55 (SRp55) splicing factor were investigated in skin biopsies from patients with SSc (n=35) and healthy subjects (n=23) using RT-PCR, quantitative real-time PCR, Western blotting, immunohistochemistry and confocal microscopy. Circulating levels of $VEGF_{165}b$ and pan-VEGF were measured by ELISA in plasma samples from SSc patients (n=61) and healthy controls (n=30). VEGFR-2 phosphorylation, intracellular signaling and capillary morphogenesis on Matrigel were studied in microvascular endothelial cells (MVECs) isolated from SSc (n=6) and healthy control (n=6) skin.

Results: $VEGF_{165}b$ splice variant was selectively overexpressed at both the mRNA and protein levels in SSc skin. Elevated $VEGF_{165}b$ expression correlated with increased expression of profibrotic TGF-b1 cytokine and SRp55 splicing factor in keratinocytes, fibroblasts, endothelial cells, and perivascular inflammatory cells. Circulating levels of $VEGF_{165}b$ were significantly higher in SSc patients than in control subjects. MVECs isolated from SSc skin (SSc-MVECs) expressed and released higher levels of $VEGF_{165}b$ than healthy MVECs (H-MVECs). TGF-b1 upregulated the expression of $VEGF_{165}b$ and SRp55 in both SSc- and H-MVECs. In SSc-MVECs, VEGFR-2 was overexpressed, but its phosphorylation and ERK1/2 downstream signaling were impaired. Recombinant human $VEGF_{165}b$ and SSc-MVEC–conditioned medium inhibited $VEGF_{165}$-mediated VEGFR-2 phosphorylation, ERK1/2 activation and capillary morphogenesis in H-MVECs. The addition of anti-$VEGF_{165}b$ blocking antibodies abrogated the antiangiogenic effect of SSc-MVEC–conditioned medium. Capillary morphogenesis was severely impaired in SSc-MVECs and could be ameliorated by treatment with recombinant $VEGF_{165}$ and anti-$VEGF_{165}b$ blocking antibodies.

Conclusion: In SSc, a switch from proangiogenic to antiangiogenic VEGF isoforms may have a crucial role in the insufficient angiogenic response to chronic ischemia. The combination of proangiogenic $VEGF_{165}$ administration and $VEGF_{165}b$ neutralization might represent a potential therapeutic strategy to promote effective angiogenesis and capillary regeneration in SSc.

2605

Downregulation of Mir-193b in Systemic Sclerosis Regulates the Proliferative Vasculopathy by Urokinase-Type Plasminogen Activator Expression. Naoki Iwamoto[1], Serena Vettori[1], Britta Maurer[1], Matthias Brock[1], Maurizio Calcagni[2], Renate E. Gay[1], Steffen Gay[1] and Oliver Distler[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Division of Plastic Surgery and Hand Surgery, University Hospital Zurich, Zurich, Switzerland

Background/Purpose: We were interested in micro RNA (miR)-193b, because in silico analysis suggested that miR-193b might regulate the expression of urokinase-type plasminogen activator (uPA). uPA is a multifunctional protein that in addition to its fibrinolytic and matrix degradation capabilities also affects cytokine modulation, cell migration and proliferation. Since an association of the uPA-mediated plasminogen activation system and the pathogenesis of systemic sclerosis (SSc) have been reported, the aim of our study was to explore the expression of miR-193b in SSc and the regulation of uPA, and to investigate the functional role of uPA in SSc.

Methods: To investigate differentially expressed miRs in SSc and normal healthy (NH) skin fibroblasts, we performed micro RNA array analysis using RNA from pooled SSc and NH fibroblasts. Expression of miR-193b in SSc skin fibroblasts and paraffin embedded skin sections from SSc patients were analyzed by Real-time polymerase chain reaction (PCR). To explore factors that potentially down regulate miR-193b in SSc, skin fibroblasts were stimulated with TGF-β, PDGF-B and IL-1 β. Next, skin fibroblasts were transfected with synthetic precursor miRNA (pre-miR) / inhibitors of miRNA (anti-miR) of miR-193b using Lipofectamine and then the expression of uPA protein and mRNA were analyzed by Western blot and Real-time PCR. Basal expression of uPA in SSc and NH fibroblasts were also examined by Real-time PCR and Western blot. Furthermore, human pulmonary artery smooth muscle cells (HPASMC) were treated with human uPA and cell proliferation assay was performed using the methylthiazolyldiphenyl-tetrazolium bromide (MTT) assay.

Results: The array analysis revealed a specific expression profile of differentially expressed miRs in SSc fibroblasts. 6 miRs could be confirmed by Real-time PCR to be differentially expressed between cultured SSc and NH fibroblasts. Among them, miR-193b was further characterized, because of its consistent differential expression and its target identification by in silico analysis, which included uPA. MiR-193b was significantly down regulated in SSc fibroblasts (n=7) as compared with NH controls (n=7) (16.34 ± 10.05%, $p<0.0001$). In addition, miR-193b was also reduced in SSc skin sections (n=5) as compared with NH controls (n=5) (54.31± 16.39%, $p<0.005$). Stimulation of TGF-β, PDGF-B and IL-1β did not affect the expression of miR-193b. Induction of miR-193b in SSc and normal fibroblasts suppressed the production of uPA protein and the expression of uPA mRNA. Conversely, the knockdown of miR-193b increased the level of uPA expression. The basal expression of uPA in SSc fibroblasts was up regulated both on the protein (19.3% vs 39.6%, $p=0.29$) and mRNA levels (x-fold induction: 3.58, $p=0.43$) as compared with NH controls. Interestingly, uPA induced cell proliferation in HPASMC (121%).

Conclusion: Our results suggest that in SSc, miR-193b is down regulated independently from important cytokines. Thereby the down regulation of miR-193b induces the expression of uPA, which leads to proliferation of vascular smooth muscle cells and thereby contributes to the proliferative vasculopathy characteristic for SSc.

Heart Involvement in Patients with Systemic Sclerosis Is Mimicked by Fra-2 Transgenic Mice. Paulius Venalis[1], Laszlo Cziriak[2], Alfiya Akhmetshina[3], Clara Dees[3], Pawel Zerr[3], Zygmunt Mackevic[4], Ingrid E. Lundberg[1], Oliver Distler[5], Georg Schett[3] and Jorg HW Distler[3]. [1]Karolinska Institutet, Stockholm, Sweden, [2]University of Pécs, Budapest, Hungary, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, [5]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Systemic sclerosis (SSc) is a systemic autoimmune disease with vascular and fibrotic components. SSc-related cardio-

myopathy is increasingly recognized as a major cause of death. However, the pathogenesis of SSc-related cardiomyopathy is poorly understood. New therapies as well as platforms for testing are needed. Here, we aimed to characterize different murine models of SSc and identify the best animal model for SSc-related cardiomyopathy.

Methods: Six patients with definite systemic sclerosis were enrolled in the project. Age- and sex- matched patients autopsies served as controls. Patients with a medical record for cardiovascular disease were excluded from the study. We have chosen three systemic disease models of scleroderma: Fra-2 transgenic mice model (Fra-2), sclerodermatous chronic *Graft versus Host* disease (cGvHD) model and tight skin 1 mutation model (Tsk-1).Formalin fixed and paraffin embedded heart sections used for IHC. Heart sections from SSc patients, controls and mouse models of SSc were stained for α-SMA, CD31 and active caspase3 as well as with picrosirius and hematoxylin eosin.

Results: Significant fibrotic changes with accumulation of collagen were observed in hearts of SSc patients. The fibrotic area was increased in 8.8 ± 2.3 folds compared to controls ($P<0.001$). Same pattern was found in Fra-2 mice with 8.9 ± 2.8 fold increase ($P=0.0002$). In contrast, no significant increases in fibrotic area were observed in cGvHD mice and in Tsk-1 mice. To detect differentiation towards myofibroblasts we stained for the α-SMA. SSc samples presented with increased numbers of myofibroblasts 2.5 ± 0.6 vs. 0.5 ± 0.8 ($P=0.01$) per high power field (HPF) in controls. As expected same pattern found in all mice models of SSc, though highest mimicry to SSc hearts observed in Fra-2 model (3.0 ± 1.1 vs. 0.5 ± 0.6 $P=0.0005$). Slight increases in the numbers of myofibroblasts were also obtained in the cGvHD and in the Tsk-1 model. CD31 stainings revealed significant loss of capillaries in SSc hearts (2.16 ± 0.17 fold change vs. controls $P < 0.0001$). A prominent capillary loss was also observed in Fra-2 tg and in cGvHD models (2.0 ± 0.2 $P < 0.0001$ and 2.1 ± 0.3 $P<0.0001$ fold change, respectively). No changes were observed in Tsk-1 mice. Apoptosis of endothelial cells was increased in Fra-2 tg mice vs. controls (2.5 ± 0.9 vs. 0.17 ± 0.43 $P = 0.0001$). Apoptosis was observed in cGvHD mice though it was also elevated in controls (2.6 ± 0.7 vs. 1.2 ± 0.5 $P = 0003$). No apoptosis was detected in capillaries of Tsk-1 mice. Endothelial cell apoptosis was also elevated in SSc hearts with 1.2 ± 0.4 vs. 0.2 ± 0.4 ($P = 0.0018$) in controls. Detected higher numbers of perivascular leukocytes in SSc patients (5.8 ± 1.8 fold change, $P = 0.0001$), strengthened the hypothesis of vascular damage.

Conclusion: We demonstrate that the typical features of cardiac disease in SSc –loss of capillaries due to apoptosis of endothelial cell and fibrosis- are closely mimicked by Fra-2 tg mice. In contrast, the changes in the hearts of mice with sclerodermatous cGvHD and in Tsk-1 mice were less representative. Thus, Fra-2 tg mice are a promising preclinical model to study the mechanisms and therapeutic approaches of heart involvement in systemic sclerosis.

In Vivo Delivery of Alternatively Spliced Interleukin-4 Mimics Scleroderma Lung Disease. Sergei P. Atamas and Irina G. Luzina. University of Maryland School of Medicine, Baltimore, MD

Background/Purpose: Our previous studies and works of others have suggested that scleroderma lung disease (SLD) is driven by interleukin (IL)-4 and other type 2 cytokines. However, this notion does not explain the previously reported by us predominance of CD8+ cells in the lungs of patients with SLD. It is also contradicted by the absence of the typical type 2 phenotype in SLD, e.g., by the lack of overt eosinophilia and goblet cell hyperplasia seen in such prototypic IL-4-driven disease as asthma. Based on our previous discovery of a natural splice variant of IL-4, which omits exon 2-encoded region and is called IL-4δ2, and also based on our previous observation of elevated IL-4δ2 mRNA in patients with SLD, we hypothesized that SLD may be driven mostly by IL-4δ2 rather than by IL-4. Since the *in vivo* effects of IL-4δ2 are unknown, we tested whether the effects of the *in vivo* IL-4δ2 gene delivery will differ from those of IL-4 and will mimic SLD phenotype.

Methods: Replication-deficient adenoviral constructs were created, validated, and used to deliver IL-4δ2 or IL-4 to mouse lungs *in vivo*. The effects of such gene delivery on the lungs were investigated, compared to each other and to a non-coding NULL adenoviral vehicle control.

Results: Delivery of IL-4δ2 ($2{,}150 \pm 470$ pg/ml) and IL-4 ($2{,}230 \pm 530$ pg/ml) was confirmed by ELISA assays of lung homogenates. Based on immunohistochemical analyses of lung tissue and flow cytometric analyses of BAL samples, delivery of either IL-4δ2 or IL-4 caused similar pulmonary infiltration by T and B lymphocytes; ~30 % of BAL cells were lymphocytes in either case, whereas only ~3% of lymphocytes were observed in BAL samples of NULL-challenged mice. Delivery of IL-4δ2 attracted three fold more CD8+ cells than did delivery IL-4 (15.5 ± 2.9 % *vs* 5.5 ± 1.7 % of BAL lymphocytes, respectively). Delivery of IL-4 induced eosinophilia (29 ± 8 % of total BAl cells) and goblet cell hyperplasia (25 ± 9 cells/field), whereas delivery of IL-4δ2 did not have such effects ($\sim 2 \pm 2$ % eosinophils in BAL and 4 ± 2 goblet cells/field histologically). Both variants stimulated proinflammatory cytokines; IL-4δ2 induced higher levels of TNF-α and IFN-γ, whereas IL-4 induced higher eotaxin, IL-17, and MCP-1 in the lungs. Differential effects of IL-4δ2 and IL-4 on global gene expression were observed by microarray analyses of lung tissue. Expression of 84 genes was similarly affected by either IL-4δ2 or IL-4, including genes for CTLA4, MHC II, C1q, and several chemokines. Expression of 38 genes was uniquely affected by IL-4δ2, including genes for Cyr61, CD48, Egr2, Lck, lysyl oxidase, and CXCL13. Total pulmonary hydroxyproline assays revealed that both IL-4δ2 and IL-4 tended to increase accumulation of collagen in the lungs.

Conclusion: Both complete (IL-4) and alternatively spliced (IL-4δ2) isoforms induce immune inflammation in the lungs. However, the differences in eosinophil accumulation, goblet cell hyperplasia, and relative accumulation of CD8+ cells caused by IL-4 versus IL-4δ2 resemble the differences between patients with asthma and patients with SLD, respectively. Combined with our previous observation of elevated IL-4δ2 mRNA, these findings suggest that new therapies for SLD need to focus on targeting IL-4δ2 rather than IL-4.

2608

Functional Inhibition of the TRPV2 Non-Selective Calcium Channel Causes a Potent Stimulation of Genes Encoding Types I and III Collagens and α-Smooth Muscle Actin in Normal Dermal Fibroblasts: A Potential Mechanism of Myofibroblast Induction in SSc. Peter J. Wermuth[1], Sankar Addya[2] and Sergio A. Jimenez[1]. [1]Jefferson Institute of Molecular Medicine, Thomas Jefferson University, Philadelphia, PA, [2]Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background/Purpose: Transient receptor potential cation channel, subfamily V (TRPV) members are sensitive to a range of environmental stimuli, including heat, osmosensitivity and stress. Although originally described in sensory neurons, the ubiquitous expression of these non-selective calcium channels suggests a role in both sensory and nonsensory transduction. Systemic sclerosis (SSc) is a systemic disease characterized by fibrotic changes in skin and various internal organs. A comparison of global gene expression in early passage cultured dermal SSc fibroblasts to that in fibroblasts isolated from normal individuals identified the TRPV2 gene as one of the most downregulated genes in SSc versus normal dermal human fibroblasts. The role of TRPV1 and TRPV2 in regulating the expression of extracellular matrix (ECM) components was examined in this study.

Methods: Total RNA was isolated from early passage (<6) dermal fibroblasts of Caucasian subjects (3 normal, 3 diffuse SSc). RNA was labeled and hybridized to Affymetrix human U133 2.0 Plus microarrays. Volcano plots were used to identify differentially expressed genes employing the parametric testing assuming equal variances (based on the results of a Student's two-sample t-test for two groups). Comparisons were made between each normal and each SSc sample. Differential gene expression was confirmed by real-time PCR on the same RNA samples employed for the microarrays. The effect of agonists and antagonists of TRPV1 and TRPV2 on expression levels of extracellular matrix components and α-smooth muscle actin in normal human dermal fibroblasts was monitored by real-time PCR and accumulation of type I collagen in culture medium was assessed by Western blot.

Results: Microarray analyses showed that the expression of TRPV2 was downregulated 21 fold in SSc fibroblasts compared to the levels measured in normal human dermal fibroblasts whereas expression of the TRPV1 gene was unchanged. Real time-PCR analysis confirmed the dramatic decrease in TRPV2 expression. Normal dermal human fibroblasts exposed to Tranilast, a TRPV2-selective antagonist demonstrated a remarkable increase in the expression of numerous fibrosis related genes, including a 3.3-fold increase in type I collagen, a 2.8-fold increase in type III collagen and an 11.8-fold increase in α-smooth muscle actin. In contrast, the TRPV1 antagonist capsazepine, the TRPV1 agonist capsaicin, and the TRPV2 agonist probenecid did not affect the expression levels of any of these genes.

Conclusion: Expression of the TRPV2 gene was profoundly downregulated in SSc dermal fibroblasts compared to normal dermal fibroblasts by

global gene expression microarray and real time-PCR analysis. Exposure of normal human dermal fibroblasts to the TRPV2 inhibitor tranilast dramatically increased the expression of several genes encoding important ECM components and induced the expression of α-smooth muscle actin. These results suggest that downregulation of the TRPV2 receptor in SSc dermal fibroblasts may be important in the conversion of fibroblasts into activated myofibroblasts and, thus, may be involved in the dysregulated production of ECM proteins in SSc.

A Study to Investigate the Clinical Effectiveness of a Prefabricated Foot Orthosis in Patients with Early Rheumatoid Arthritis. Vicki Cameron-Fiddes. Stirling University, Scotland, UK, Stirling, Scotland

Background/Purpose: Rheumatoid Arthritis (RA) affects the foot in up to 90% of cases (Bouysset et al. 2006). Evidence indicates that joint damage occurs early (Devlin et al. 1997) and so suggests a relatively small window of opportunity for early Podiatry intervention. Foot orthoses (FO) can be used optimally early in the disease process (Helliwell et al. 2007). There are two main approaches to supplying FO; customised foot orthoses (CFO) and prefabricated foot orthoses (PFO). CFO are made to a cast of the patient's feet while PFO are mass produced to fit a generic foot shape (Redmond et al. 2009). The effectiveness of CFO in RA is well documented (Hawke et al. 2009) however fabrication of these devices is a lengthy process, which may result in a delay of treatment for the patient (Bennett et al. 1996). Alternatively, PFO can be dispensed at the chairside on the day of diagnosis; however no evidence exists to support their use. The aim of this study was to investigate any potential effects on the foot of one commonly prescribed PFO in patients with early RA.

Methods: Ethical approval was obtained from Fife, Scotland in 2006. A total of 35 patients diagnosed with RA within the past two years were recruited from Fife. Patients were excluded if they had concomitant musculoskeletal disease, central or peripheral nervous system disease, Diabetes, a history of foot fracture, or if they were already wearing FO. The study used a repeated measures design with data collected at baseline, three months and six months. At each time point patients were randomly assessed walking barefoot, shod (with standardised footwear), and with FO. The PFO was Algeos Slimflex™ Plastic (SP) which has been shown to be the most commonly used PFO by Rheumatology Podiatrists in Scotland (Cameron et al. 2009). The SP were individually customised for each individual to reflect current clinical practice. The Foot Impact Scale (FIS) was used to investigate foot health related quality of life (QoL), and the Tekscan walkway and in-shoe systems were used to investigate pressure time integral at the forefoot (PTIft), and walking speed (WS).

Results: The SP significantly decreased the FIS between baseline and three months, and baseline and six months ($p<0.05$). The SP significantly decreased PTIft at baseline, three months and six months between barefoot and shod, barefoot and FO, and shod and FO ($p<0.05$). WS significantly increased at baseline, three months and six months between barefoot and shod, barefoot and FO, and shod and FO ($p<0.05$).

Conclusion: SP may improve foot health related QoL in patients with early RA, and an improvement may be seen by three months. PTIft and WS may be significantly improved as soon as the SP is worn in the shoe. These findings suggest that the SP is effective in the management of the foot in early RA, according to the measured variables in the study. A RCT to directly compare CFO and PFO would be a logical extension to this study.

2610

Fatigue in Rheumatoid Arthritis: What Is the Role of Lower Extremity Muscle Weakness? Patricia P. Katz[1], Mary E. Margaretten[2], Marissa San Pedro[2] and Vladimir Chernitskiy[1]. [1]University of California San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA

Background/Purpose: Fatigue is widely recognized as a problem in rheumatoid arthritis (RA), to the extent that it is now recommended as an outcome measure for clinical trials of RA treatments by both the ACR and EULAR. However, sources of RA-related fatigue are not well understood. One potential etiology is muscle weakness. Cachexia and physical inactivity, both of which are often present in RA, are each associated with muscle weakness. Yet, the role of muscle weakness in RA fatigue has received little research attention, and is the focus of this analysis.

Methods: Subjects are participants in an on-going cross-sectional study of RA fatigue. Home visits are made to individuals with documented RA to collect measurements of a number of factors, including the outcome variable, fatigue (0–10 numeric rating scale of fatigue severity in the past week), lower extremity muscle strength (knee extension, hip flexor) measured by hand-held dynamometer, and a chair stand task (time to complete 5 chair stands), which is a measure of lower extremity functional strength. Because knee extension and hip flexor strength were correlated ($r=0.6$), we also added the values of the two to create a combined lower extremity strength variable. Subjects also completed questionnaires to measure RA disease activity (RA Disease Activity Index [RADAI]), sleep quality (Pittsburgh Sleep Quality Index [PSQI]), and depression (PHQ-8), and we measured height and weight to calculate body mass index (BMI). For these analyses, we defined severe fatigue as a rating of 7 or greater. Multiple regression analyses were used to identify predictors of severe fatigue. Analyses included measured hip, knee, or combined lower extremity strength and/or score on the chair stand task, in addition to covariates (age, PSQI score, PHQ-8 score, obesity defined by BMI, and RADAI score).

Results: Data have been collected for 68 subjects. 91% are female and 74% white non-Hispanic, with mean age 59 ($\pm$11) years. 27% of respondents reported severe fatigue. In multivariate analysis, poorer performance on the chair stand was associated with greater fatigue (see Table 1); dynamometer-measured muscle weakness was associated with severe fatigue, but the confidence intervals did not exclude 1. In follow-up analyses to determine if limited functional strength (chair stand) mediated the relationship between muscle strength and fatigue, both hip flexor and knee extensor strength were significantly associated with chair stand performance ($p<.01$).

Table 1. Odds of severe fatigue conferred by measures of lower extremity strength

	Multivariate models of individual strength measures	Multivariate models of chair stand score + measured strength variable		
Strength measure	OR (95% CI)	R (95% CI)	OR (95% CI)	OR (95% CI)
Chair stand score	0.28 (0.10, 0.76)	0.32 (0.11, 0.95)	0.32 (0.12, 0.90)	0.34 (0.12, 0.99)
Knee strength (ft-lbs)	0.96 (0.96, 1.01)	0.98 (0.93, 1.04)		
Hip strength (ft-lbs)	0.89 (0.79, 1.01)		0.95 (0.84, 1.07)	
Combined lower extremity strength (ft-lbs)	0.96 (0.92, 1.01)			0.98 (0.94, 1.03)

All models included covariates: age, PSQI score, PHQ-8 score, obesity defined by BMI, and RADAI score

Conclusion: Lower extremity muscle weakness was associated with functional limitations, which were, in turn, associated with severe fatigue. Results suggest that interventions to improve muscular strength may yield improvements in severe RA fatigue.

2611

Muscle Quality Contributes More to Postural Balance Than Muscle Atrophy in People with Rheumatoid Arthritis. Samannaaz S. Khoja, Bret H. Goodpaster and Sara R. Piva. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Patients with rheumatoid arthritis (RA) experience muscle atrophy and decreased muscle quality, meaning, low lean muscle mass with increased muscle fat mass and consequent muscle weakness. Patients with RA also experience impaired balance and increased incidence of falls, putting them at risk of further disability and morbidity. While weakness of the quadriceps muscles have been related to impaired balance, evidence to support a direct relationship between muscle atrophy or muscle quality and balance in RA is limited. Determining such relationship would be important to refine the interventions to improve balance in RA. The aim of this study was to determine the association between quadriceps muscle atrophy and quality (proportion of lean and fat skeletal tissue) and postural balance in subjects with RA.

Methods: Data of 21 subjects with RA (age 60.3 $\pm$ 10.1 yrs; RA duration 15.8 $\pm$ 10.8 yrs; BMI 31.8 $\pm$ 8.1 kg/m^2; 16 female) were used for this cross-sectional study. Postural balance was assessed by single leg balance test, representing the time the subject could balance on a single leg up to 30 seconds. Subjects were asked to do three trials for each leg

and we calculated the average of the three trials. Mid-thigh cross-sectional area (CSA) for each leg was measured by computed tomography (CT). The quadriceps muscles were outlined and assessed using Slice-O-Matic software. Muscle quality was defined by Muscle Attenuation (MA) coefficient, a measure of tissue density. MA ranging from 35–100 Hounsfield units represents normal density or lean muscle (NDM), whereas 0–35 HU represent low density or fatty muscle (LDM). We calculated total muscle CSA and then divided to total muscle area into NDM CSA and LDM CSA. To account for body size, CSAs of NDM and LDM were treated as % of total muscle CSA. Bivariate correlations were calculated between single leg balance time and CSA of total muscle and % of NDM and LDM of each leg. We used Pearson's or Spearman's correlation coefficients depending on data distribution. Alpha level of significance was set at 0.05.

Results: The association between %NDM and %LDM and single let balance were higher than the associations between total muscle CSA and single leg balance test. Both %NDM and %LDM showed significant moderate associations with single leg balance time albeit in opposite directions; %NDM had a positive correlation and %LDM negative. These findings indicate that subjects with higher proportion of lean tissue within skeletal muscle could balance longer time in single leg, and consequently those with higher proportion of fat in muscle had reduced balance. Descriptives and correlation coefficients are depicted in the table.

Table. Descriptives and Correlations of Muscle Characteristics with Single Leg Balance Time

Variables	Median (IQ:25-75)		Correlation with Single Leg Balance	
	Right side	Left side	Right Side	Left Side
Total Quadriceps CSA (sq cm)	45.2 (38.4–60.8)	47.8 (41.5–51.1)	0.33‡	0.38‡
NDM CSA (sq cm)	34.6 (28.3–46.9)	38.6 (31.9–52.2)		
% NDM	82.0 (68.0–86.0)	84.6 (71.0–87.6)	0.51*†	0.43†
LDM CSA (sq cm)	8.6 (6.6–13.6)	9.0 (6.9–12.7)		
% LDM	18.0 (14.0–32.0)	15.4 (12.4–29.0)	−0.51*†	−0.43†
Single Leg Balance (sec)	15.2 (1.8–24.7)	5 (2.1–25.3)		

* $p < 0.05$
% NDM or %LDM = (NDM or LDM area/Total muscle area) *100
‡ Partial correlation controlling for BMI
† Spearman rho

Conclusion: Muscle quality seems to play a larger role in postural balance than simply total muscle quantity. Future longitudinal studies should investigate if changes in muscle quality improve balance to a larger degree than changes in muscle bulk.

2612

Improvement 3 to 12 Months Post Hip and Knee Replacement: Implications for Rehabilitation. A. M. Davis[1], A. V. Perruccio[2], S. Ibrahim[3], S. Hogg-Johnson[4], R. Wong[5], E. Schemitsch[6], N. N. Mahomed[7], J. Flannery[8] and E. M. Badley[9]. [1]Health Care and Outcomes Research, Toronto Western Research Institute; Departments of Rehabilitation Science and Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, [2]Department of Orthopedic Surgery and The Arthritis Program, Toronto Western Hospital, Toronto, ON, [3]Institute for Work and Health, Toronto, ON, [4]Institute for Work and Health, and Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [5]Health Care and Outcomes Research, Toronto Western Research Institute, Toronto, ON, [6]Division of Orthopaedics, University of Toronto and St. Michael's, Toronto, ON, [7]Division of Orthopaedics, University of Toronto and The Arthritis Program, Toronto Western Hospital, Toronto, ON, [8]Department of Physiatry, University of Toronto and Toronto Rehabilitation Institute, Toronto, ON, [9]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON

Background/Purpose: Rehabilitation following primary hip (THR) and knee (TKR) replacement typically occurs based on care plans addressing the first 3 months following surgery. While this is the period where most recovery occurs following surgery, it is also accepted that further improvement occurs through one-year post surgery. This work evaluates the change in pain, activities of daily living (ADL) and participation in instrumental ADL (IADL) and leisure activities that occurs between 3 and 12 months post-surgery.

Methods: Participants (hip: n=437; knee: 494) completed measures pre-surgery and at 3, 6 and 12 months post-surgery. These included HOOS/KOOS pain; HOOS/KOOS activities of daily living (ADL); and, participation using the Late Life Disability Index (LLDI) limitation and frequency subscales. All measures were scored 0–10 with lower scores indicating less problems. RANOVA was used to evaluate recovery adjusting for age, sex, obesity, THR/TKR, low back pain and mood. Additionally, proportion of total change was calculated to 3 months and between 3 and 12 months post-surgery.

Results: THR: age 31–86 years with 55% female; TKR: age 35–88 years with 65% female. Significant improvements were observed for all measures over time. On average, for THR and TKR respectively from pre-surgery to 1year, pain improved 4.0 and 3.5 points; ADL improved 3.8 and 2.8 points; and, LLDI limitations improved 2.4 and 2.0 points and LLDI frequency improved 1.0 and 0.8 points. As noted in Table 1, while most change occurred up to 3 months, a large proportion of total change occurred between 3 and 12 months post surgery; 20% for pain for those with TKR and 13 and 14% for ADL for THR and TKR. For LLDI limitations in social/leisure activities, the percent of total change was 17 and 30% for those with THR and TKR respectively. Of note, frequency in IADL and social/leisure activities as measured by the LLDI while demonstrating a large proportion of change from 3 to 12 months, overall demonstrated minimal, although significant, absolute change over time.

Table 1. Proportion of total change by time interval

	Pre-surgery to 3 months post-surgery		3 to 12 months post-surgery	
	mean change	% total change	mean change	% total change
THR				
Pain	3.8	95	0.2	5
ADL	3.3	87	0.5	13
LLDI frequency	0.6	60	0.4	40
LLDI limitations	2.0	83	0.4	17
TKR				
Pain	2.8	80	0.7	20
ADL	2.4	86	0.4	14
LLDI frequency	0.4	50	0.4	50
LLDI limitations	1.4	70	0.6	30

Conclusion: A large proportion of recovery following THR and TKR occurs between 3 and 12 months post-surgery. Rehabilitation care pathways that include follow-up rehabilitation consultation during this period may improve the time to recovery and overall outcomes for people with THR and TKR, particularly related to participation in IADL and social and leisure activities.

Physical Activity, Body Functions, Activity and General Health Perception in Rheumatoid Arthritis. Birgitta Nordgren[1], Patrick Bergman[2], Christina H. Opava[1], Cecilia Fridén[1] and PARA 2010 Study group[3]. [1]Karolinska Institutet, SE 14183 Huddinge, Sweden, [2]University of Gothenburg, Sahlgrenska Academy, Gothenburg, Sweden, [3]Boden, Danderyd, Eskilstuna, Linköping, Stockholm, Östersund

Background/Purpose: Reduced physical activity, substantial disability and poor general health perception have previously been described in people with rheumatoid arthritis (RA). Most studies including description of body functions in large samples were however performed more than ten years ago, before biological treatment was introduced. Therefore, the aim of our study was to describe physical activity, body functions, activity and general health perception in a sample of patients with RA.

Methods: Two hundred and forty-three patients with RA (81% female, mean age 59 years, SD 9) from six rheumatology clinics in Sweden consented to be included in a physical activity intervention and constitute our sample. Self-reported physical activity was assessed with the International Physical Activity Questionnaire (IPAQ), aerobic capacity with the Åstrand sub maximal cycle ergometer test, lower limb function with the Timed-Stands Test (TST) and grip strength with the Grippit device. Pain, fatigue and general health perception were rated on visual analog scales (VAS, 0–100) and activity limitation was assessed with the Stanford Health Assessment Questionnaire, disability index (HAQ, 0–3).

Results: Fifty seven percent (58% females and 48% males) of the sample reportedly adhered to recommendations on health-enhancing physical activity. Four percent of the total sample were classified as having low aerobic fitness, 13% as fair, 35% as average, 17% as good and 11% as high, while results could not be calculated for 20%, mainly because of use of beta-blockers. Compared to norm values 44% of our sample had reduced lower-limb muscle function and a majority had decreased (77%) grip strength compared to norm values. Median values

(ranges) for pain, fatigue and general health perception were 21 (0–88), 35 (0–93) and 25 (0–92) respectively, while median (range) for activity limitation was 0.37 (0–2.25).

Conclusion: Despite the introduction of biological treatments resulting in reduced disease activity and less symptoms on a group level, a substantial part of patients with RA still accumulate too little physical activity and have significantly reduced body functions. We suggest that these individuals should be identified and at target for appropriate rehabilitation and life style interventions.

Erratic Control of Breathing During Exercise in Patients with Systemic Lupus Erythematosus. Renata Miossi[1], Danilo M. L. Prado[2], Luiz A. Perandini[2], Thalita Dassouki[2], Bruno Gualano[3], Hamilton Roschel[4], Fernanda R. Lima[2], Eduardo F. Borba[5], Eloisa Bonfa[6] and Ana Lucia S. Pinto[7]. [1]University of Sao Paulo, Rheumatology Division, Sao Paulo, Brazil, [2]University of Sao Paulo, Rheumatology Division, LACRE, Sao Paulo, Brazil, [3]University of Sao Paulo,School of Physical Education and Sport, Sao Paulo, Brazil, [4]University of Sao Paulo, School of Physical Education and Sport, Sao Paulo, Brazil, [5]University of Sao Paulo, Sao Paulo, Brazil, [6]Faculdade de Medicina da Universidade de São Paulo (FMUSP), Sao Paulo, Brazil, [7]University of Sao Paulo, School of Medicine, Rheumatology Division, LACRE, Sao Paulo, Brazil

Background/Purpose: The aim of this study was to provide a comprehensive evaluation of the pattern and timing of breathing during incremental exercise in patients with systemic lupus erythematosus (SLE).

Methods: In this cross-sectional study, 20 women with SLE without pulmonary involvement were compared with 20 gender-, BMI-, and age-matched healthy individuals. By using a cardiopulmonary incremental exercise test, the following parameters were assessed: tidal volume (VT); breathing frequency (BF); total respiratory time (TOT); inspiratory time (TI); expiratory time (TE); inspiratory time to total time (TI/TOT); mean inspiratory flow (VT/TI); ventilatory equivalent for carbon dioxide (VE/VCO_2) and end-tidal carbon dioxide pressure ($PETCO_2$).

Results: BF and BF/VT were significantly higher in patients with SLE *versus* controls, whereas VT, TE, TI and TOT were significantly lower in the former group ($p < 0.05$). Additionally, patients with SLE presented higher VE/VCO_2 and lower $PETCO_2$ than controls ($p < 0.05$), suggesting a ventilatory inefficiency.

Conclusion: We reported compelling evidence of abnormal pattern and timing of breathing during incremental exercise in SLE. Considering that an erratic control of breathing may play an important role in exercise intolerance and fatigue, respiratory exercises emerges as a potential treatment for these symptoms in patients with SLE.

Nafamostat Mesylate, a Serine Protease Inhibitor, Demonstrates Novel Antimicrobial Properties and Anti-inflammatory Effects in Chlamydia-Induced Arthritis. Robert D. Inman[1] and Basil Chiu[2]. [1]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON

Background/Purpose: Effective treatment of reactive arthritis would ideally achieve both control of inflammation and eradication of persisting arthritogenic pathogens. We use a model of experimental Chlamydia-induced arthritis (CtIA) to evaluate the effectiveness of nafamostat mesylate (NM), a serine protease inhibitor with complement-modifying effects and anticoagulant properties. To date clinical use of NM has largely been in Asia and has been primarily confined to inflammatory states such as pancreatitis.

Methods: In vitro studies examined inhibition of Chlamydia proliferation using fibroblast cell lines as targets and phase contrast microscopy. In vivo studies used an established protocol, experimental CtIA, induced in LEW rats by injection of synoviocyte-packaged *C. trachomatis*. NM was dissolved in water and administered by daily ip injection at a dose of 10 mg/kg beginning the day prior to the administration of Chlamydia. Readouts in vivo included (i) joint swelling, (ii) histopathology scoring of severity of arthritis, (iii) host clearance of the pathogen (by ELISA, the IDEIA *PCE* Chlamydia).

Results: NM exerted a dose-dependent inhibition of chlamydial proliferation in vitro (Fig 1). Without NM, the mean number of inclusion bodies (IB) per well was 17886 (± 1415). At 5 μg/ mL NM, there were 8490 (± 756) IB, at 25 μg/mL NM 35 IB and at 50 μg/mL NM no IB was detectable. Chlamydial antigens in each well along the concentration gradient were assayed by ELISA, demonstrating that at 25 μg/mL NM inhibition of Chlamydia was almost complete. In the experimental arthritis model, joint swelling was significantly reduced with NM treatment: average joint width for the NM-treated animals was 8.55 mm (s.d. ± 0.6578, n=10) *vs* 11.18 mm (s.d. ± 0.5672, n=10) in controls ($p = 7.9 \times 10^{-23}$). Histopathology scoring indicated that NM resulted in a marked attenuation of the inflammatory infiltration and joint damage: mean pathology score in NM-treated animals was 10.9 (± 2.45, n = 11) *vs* 15.9 (± 1.45, n = 10) in controls ($p = 9.8 \times 10^{-6}$). With respect to persistence of chlamydia within the synovial tissues, NM treatment was accompanied by a reduction in the microbial load in the joint: mean OD for ELISA with NM treatment was 0.05 (± 0.02, n=4) *vs* 0.18 (± 0.05, n=4) in controls ($p = 0.0027$).

Conclusion: NM is a protease inhibitor not previously recognized to possess antimicrobial properties. The present study demonstrates for the first time that NM exerts significant impact on experimental Chlamydia trachomatis-induced arthritis and suggests that such approaches may prove clinically useful in chronic reactive arthritis.

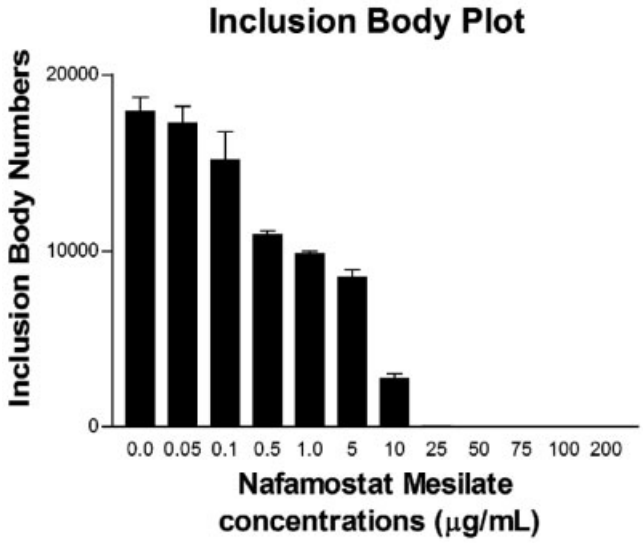

Fig 1. Number of Chlamydia inclusion bodies with increasing NM concentrations.

Macrophage Polarization Plays the Defining Role in Intracellular Persistence and Clearance of *Chlamydia*. Eric Gracey[1], Basil Chiu[1] and Robert D. Inman[2]. [1]Toronto Western Hospital, Toronto, ON, [2]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON

Background/Purpose: The obligate intracellular pathogen, *Chlamydia*, is the commonest cause of reactive arthritis (ReA), where it can exist in the joint in a distinctive persistent phenotype. The macrophage is a central component of the innate immune response and may be important in the early host response to *Chlamydia*. The phenomenon of macrophage polarization occurs upon exposure to a Th1 or Th2 environment, resulting in the generation of inflammatory (M1) and anti-inflammatory (M2) macrophages respectively. Aberrant macrophage polarization occurs in a number of the rheumatic diseases, and in particular an excessive M2 polarization phenotype has been reported in ReA. The role of macrophage polarization in *Chlamydia* infection has not yet been defined.

Methods: Experiments were performed with bone marrow-derived macrophages (BMDM) harvested from BALB/c mice. Macrophages were untreated

(M0), or were polarized by 24 hr treatment with IFNγ 20ng/ml and LPS 100ng/ml (M1) or with IL-4 20ng/ml (M2). Polarized BMDM were subsequently infected with *Chlamydia muridarum* 1 MOI for 6–72 hr. Analyses included (i) direct immunostaining of BMDM for *Chlamydia*, (ii) enumeration of *Chlamydia* by re-infection of McCoy B fibroblasts, (iii) qPCR for bacterial and host genes.

Results: All macrophage phenotypes displayed similar rates of infection with *C. muridarum* when directly stained. Enumeration showed M0 and M2 macrophages to be permissive for *C. muridarum* proliferation (Fig 1), while M1 macrophages controlled the organism (M0: 1.9×10^6 IFU: M2: 3.4×10^6 IFU vs M1: 3.4×10^3 IFU). Further analysis by qPCR showed up to 100-fold decrease in expression of *16sRNA* in M1 macrophages indicative of effective bactericidal mechanisms in these cells. Notably, a *Chlamydia* gene expression profile characteristic of persistence was seen only in M1 macrophages, whereby *Euo* and *IncA* were up-regulated (7.6 and 6.2 fold respectively) and *Omp1* and *Tal* were down-regulated (3.6 and 5.3 fold respectively). Analysis of host gene expression by qPCR demonstrated that *C. muridarum* down-regulates the expression of *IL12B*, *NOS2* and *TLR2* in the permissive M0 and M2 macrophages up to 12 hr post infection. These altered profiles may contribute to subversion of host response by limiting ability to detect *Chlamydia* by host TLR, and by preventing an appropriate inflammatory response by iNOS and IL12p40.

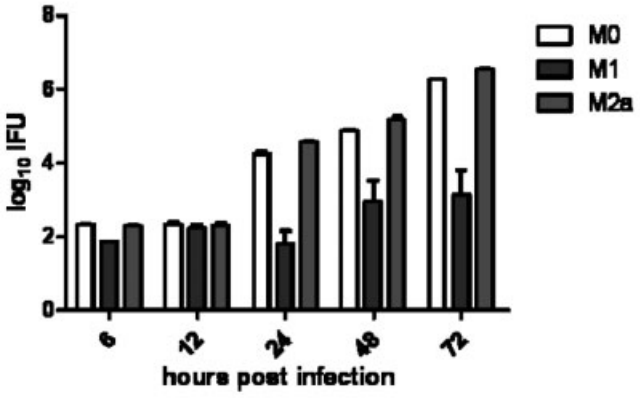

Fig 1. M0 and M2 are permissive to *Chlamydia muridarum* growth whilst M1 are controlling. Bacterial load assessed by serial dilution of infected BMDM lysate and re-infection of fibroblast monlayers.

Conclusion: These data suggest that macrophage polarization is critical in the control of *Chlamydia* infection and in the induction of persistence. These studies provide insight into the biological consequences of an M2 macrophage profile in ReA and highlight the mechanisms of ineffective host clearance of *Chlamydia.*

Reduction in *Chlamydia Trachomatis*-Associated Murine Reactive Arthritis by Novel Peptide Vaccine Candidates. Ilyes Benchaala[1], Indrajit Sinha[1], Mirabela Hali[1], Balaji S. Bharatwaj[2], Herve C. Gerard[1], Alan P. Hudson[1], Sandro R.P. da Rocha[2] and Judith A. Whittum-Hudson[1]. [1]Wayne State Univ Schl of Med, Detroit, MI, [2]Wayne State University Coll of Engineering, Detroit, MI

Background/Purpose: Chlamydia-associated reactive arthritis (ReA) develops in mice after genital or ocular infection with human biovars of *Chlamydia trachomatis* because organism disseminates to joints. A genus-wide vaccine against Chlamydiae which reduces or prevents ReA would be of value. We previously showed that an anti-chlamydial vaccine could reduce pathology and chlamydial load in murine ReA. We now report on unique panel of second generation peptide vaccine candidates.

Methods: The panel of peptides was obtained by phage display with a monoclonal antibody to a chlamydial antigen (Ag; GLXA). The peptides are mimotopes of the chlamydial Ag, and represent conformational epitopes on the carbohydrate of GLXA. The peptides are unique with no homology to human, mouse or chlamydial amino acid sequences. We tested whether vaccination with several peptides in either soluble or encapsulated Peptide 4 (Pep4) would alter microbiologic, immunologic and histopathologic features of genital infection with a human biovar of *C trachomatis* (K serovar; 2000TCID50) and the subsequent ReA which develops in this model. Female BALB/c mice received three immunizations at 3 wk intervals of Pep4 (AFPQFRSATLLL) either in polylactide microparticles (MP) or in alumina as adjuvant. We tested several peptide-MP concentrations (10–40 μg) and 100 μg soluble peptide. Serologic responses were determined with sera obtained from pre-bleeds and before each boost or challenge.

Results: The peptides tested to date are immunogenic and induce immunity to whole organism as well as to the specific peptides. Both IgG1 and IgG2 responses were detected, indicating both Th1 and Th2 responses to Pep4. Antibodies recognized *C trachomatis* and *C pneumonia* organism in infected cells supporting genus-specificity. Vaginal swabs were used to monitor shedding. By day 14 post-challenge, all concentrations of Pep4-MP induced significant reductions in chlamydial shedding. Knee and paw pathology was scored on a 0–4+ scale. Pep4-MP reduced knee and paw pathology compared to unimmunized controls and the 20μg dose of Pep-MP reduced inflammation best. qPCR showed that all peptide presentations reduced chlamydial load significantly compared to unimmunized controls. In recent experiments we have shown that Pep4 induces peptide-specific spleen cell proliferation *in vitro*.

Conclusion: Our results strongly support the efficacy of at least one novel peptide as a genus-wide anti-chlamydial vaccine. The peptides alone or in combination, or in cocktails with other potential vaccine candidates, pose promising advances in anti-chlamydial vaccinology to reduce both acute infection and the damaging pro-inflammatory sequelae such as ReA.

2618

Bacterial Peptidylarginine Deiminase (PAD)-Dependent Enhancement of Collagen-Induced Arthritis in DBA/1 Mice by Radiographic and QoL Results at Week 24 *Porphyromonas Gingivalis.* Katarzyna Maresz[1], Aneta Sroka[1], Joanna Koziel[1], Sviatlana Shashkova[1], Katarzyna Marcinska[2], Marian Szczepanik[2], Piotr Mydel[3] and Jan Potempa[1]. [1]Jagiellonian University, Krakow, Poland, [2]Medical Collage of Jagiellonian University, Krakow, Poland, [3]Institute of Medicine, The Sahlgrenska Academy Gothenburg, Gothenburg, Sweden

Background/Purpose: Rheumatoid arthritis (RA) is a prevalent autoimmune disease characterized by synovial inflammation. Although, a mechanism is yet not known, periodontitis (PD) has been implicated as a risk factor for rheumatoid arthritis (RA). *Porphyromonas gingivalis* (*Pg*) is the major pathogen in periodontitis and the only prokaryote producing peptidylarginine deiminase (PAD), which catalyzes the conversion of arginine to citrulline (Cit) in proteins. Recent data has identified posttranslationally modified proteins containing Cit as specific targets of autoantibody in RA patients.

Methods: To reveal if *Pg* infection might affect collagen-induced arthritis (CIA) in DBA/1 mice, a chamber model was employed. Subcutaneously implanted titanium chambers were inoculated with *Pg* (W83) and after 2 weeks following the infection, CIA was induced.

Results: It was found that mice inoculated with *Pg* into chamber developed the onset of CIA a few days earlier than control animals inoculated with broth only. Furthermore, the disease symptoms were more severe in the *Pg* infected group. Finally, we found that only live bacteria were able to enhance arthritic symptoms in mice. This suggests enzymatic activity of live *Pg* as a trigger factor, which may contribute to the breakdown of immunotolerance.

Methods: To elucidate how PAD influence *Pg* virulence we have compared the pathogenic outcome of chamber inoculation with the wild type W83 strain and PAD-deficient *Pg* mutant in DBA/1 mice.

Results: We found that *Pg*, which produced PAD, was more immunogenic than the PAD mutant. In comparison to mice inoculated with the PPAD mutant, animals injected with the wild-type strain suffered significantly increased mortality and morbidity. The PAD mutant strain was eliminated from the chamber much faster than the parental strain. It also generated less inflammatory mediators than the wild type strain in infected animals. *In vitro* data showed that PAD mutant was engulfed and killed by macrophages as well as neutrophils more efficiently than W83. This finding correlates well with *in vivo* results.

Conclusion: To summarize, the results of our *in vivo* and *in vitro* investigation revealed that *Pg* is able to enhance CIA in DBA/1 mice, and PAD is an important virulence factor of this bacterium.

Influenza A H1N1/2009 Vaccine in Rheumatic Disease Patients Under Anti-TNF Therapy: Safety and Response. Ivan L.A. França[1], Ana C. M. Ribeiro[1], Nadia E. Aikawa[1], Carla G.S. Saad[1], Ana L. G. Calich[1], Julio C. B. Moraes[1], Ieda Laurindo[1], Joao Miraglia[2], Maria A. Ishida[3], Eloisa Bonfa[1] and Clovis Silva[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Fundação Butantan, São Paulo, Brazil, [3]Adolfo Lutz Institute, Sao Paulo, Brazil

Background/Purpose: Immunogenicity and safety of a non-adjuvanted anti-influenza A H1N1/2009 vaccine were recently reported by our group in a large population of autoimmune rheumatic diseases (ARD) (Ann Rheum Dis 2011). There are, however, few data regarding the effect of anti-TNF therapy in antibody response to such vaccine. Therefore, the objective of this study was to evaluate immunogenicity and short-term safety of anti-influenza A H1N1/2009 vaccine in rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients under anti-TNF therapy.

Methods: One hundred thirty-four adult patients [RA (n=45), AS (n=61), PsA (n=28)] under anti-TNF agents (62 infliximab, 43 adalimumab and 29 etanercept) regularly followed in our Rheumatology Division and 125 age-matched healthy controls were vaccinated with a non-adjuvanted preparation of influenza A/California/7/2009 (H1N1) virus-like vaccine. All participants were evaluated pre- and 21 days post-vaccination and serology for anti-H1N1 was performed by hemagglutination inhibition (HI) assay. Seroprotection (HI antibody titer≥1:40), seroconversion (percentage of subjects with either a pre-vaccination HI titer < 1:10 and a post vaccination HI titer ≥ 1:40 or a pre-vaccination HI titer > 1:10 and a minimum four-fold rise in post-vaccination HI antibody titer) rates, geometric mean titres (GMTs) and factor increase (FI) in GMT (ratio of the GMT after vaccination to the GMT before vaccination) were calculated. The effect of concomitant drugs on vaccine response was assessed and adverse events were also evaluated.

Results: Patients and controls had comparable mean current age (43.8±13.1 vs. 45.7±12.2 years, p=0.233). Three weeks after immunization, seroconversion (61.2% vs. 70.4%, p=0.119) and seroprotection rates (64.9% vs. 75.2%, p=0.072) were similar in both groups, whereas the FI in GMT was significantly lower (7.29 vs. 11.54; p=0.0089) in patients *versus* controls. The assessment of the influence of concomitant use of other drugs in patients under anti-TNF showed a trend of a higher frequency of seroconversion rate in patients under diphosphate chloroquine compared to those without it (90.9% vs. 58.5%, p=0.05), but association with other drugs, such as prednisone, methotrexate and leflunomide did not interfere in the response (p>0.05). Local and systemic vaccine adverse events were mild and with similar frequencies in patients under anti-TNF and controls (p>0.05).

Conclusion: The overall immune response to influenza A H1N1/2009 in rheumatic disease patients under TNF blockage therapy is adequate with an excellent safety profile. (ClinicalTrials.gov, #NCT01151644)

Serum Vitamin D Status and Polymorphisms in Vitamin D Metabolism-Related Genes in Chronic Hepatitis C Virus Infection with Extra-Hepatic Manifestations. Benjamin Terrier[1], Frédéric Jehan[2], Mona Monteanu[3], Guillaume Geri[4], David Saadoun[5], Damien Sène[4], Thierry Poynard[3], Jean-Claude Souberbielle[6] and Patrice Cacoub[4]. [1]Pitié-Salpêtrière Hospital, Paris, France, [2]INSERM U561, Paris, France, [3]Hepatology, Pitié-Salpétrière, Paris, France, [4]CHU Pitié-Salpêtrière, Paris, France, [5]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [6]Laboratoire d'Explorations Fonctionnelles, Necker, Paris, France

Background/Purpose: The critical role of vitamin D in the regulation of the immune system has been suggested, in promoting the development of regulatory T cells and decreasing pro-inflammatory cytokines and B cell differentiation. The beneficial role of vitamin D administration was also suggested in chronic HCV infection. Objective: To evaluate the association between serum 25-hydroxyvitamin D [25-OH D] levels, polymorphisms in vitamin D metabolism-related genes and the presence of HCV extra-hepatic manifestations.

Methods: 94 HCV+ untreated patients [including 48 with mixed cryoglobulinemia (MC)-vasculitis] were assessed for serum 25-OH D levels and compared for clinico-biological characteristics according to vitamin D status. We analyzed the 25-hydroxyvitamin D 1α-hydroxylase (CYP27B1) promoter region polymorphism (rs10877012 G/T) and the haplotype structure of the human vitamin D receptor (VDR) promoter region (GATA-binding site SNP rs4516035 G/A and cdx2-binding site SNP rs11568820 G/A) in 220 HCV-RNA+ patients, including 100 with chronic HCV infection without mixed cryoglobulinemia (MC), 96 with MC vasculitis and 24 with asymptomatic MC.

Results: Patients with vitamin D deficiency vs. insufficiency vs. sufficiency had more frequently vasculitis (P=0.002), neuropathy (P=0.048), purpura (P=0.004), type II MC (P=0.002) and low C4 serum levels (P<0.0001). Serum levels of 25-OH D was correlated with cryoglobulin and C4 levels, and marginal zone B cells and regulatory T cells. In multivariate analysis, type II MC and the presence of vasculitis were independently associated with low 25-OH D levels.

The CYP27B1 promoter polymorphism had an impact on the presence of MC-related systemic vasculitis (73, 38 and 44% for rs10877012 TT, GT, and GG, respectively, P=0.04). HCV-infected patients with systemic vasculitis were less frequently G allele carriers than those without systemic vasculitis (88 vs. 97%%; P=0.03).

In contrast, the analysis of the haplotype structure of the VDR promoter region revealed that the presence of Hap1 (Hap1+) was significantly associated with the presence of mixed cryoglobulinemia [62% in Hap1+ vs. 47% in Hap1- patients; OR 1.36 (1.04–1.80), P=0.03]. The absence of Hap3 (Hap3-) tended to be associated with the presence of mixed cryoglobulinemia [60% in Hap3- vs. 48% in Hap3+ patients; OR 1.28 (0.96–1.69), P=0.10].

Conclusion: In chronic HCV infection, low 25-OH D levels correlate with extra-hepatic manifestations. The CYP27B1 promoter polymorphism is associated with MC systemic vasculitis. In contrast, the Hap1 haplotype of the VDR promoter is associated with the presence of mixed cryoglobulinemia. Interestingly, previous studies have showed that the VDR promoter activity is decreased in Hap1+ patients, suggesting that the over-expressed VDR Hap1 haplotype could be considered a risk allele for mixed cryoglobulinemia in HCV-infected patients.

Tocilizumab Is Efficacious in Patients with Systemic Juvenile Idiopathic Arthritis Across Baseline Demographic and Disease Characteristics and Prior/Baseline Treatments: 52-Week Data From a Phase 3 Clinical Trial. Fabrizio De Benedetti[1], Hermine Brunner[2], Roger Allen[3], Diane Brown[2], Jeffrey Chaitow[3], Manuela Pardeo[3], Graciela Espada[3], Berit Flatø[3], Gerd Horneff[3], Clare Devlin[4], Andrew Kenwright[4], Rayfel Schneider[2], Patricia Woo[5], Alberto Martini[3], Daniel Lovell[2] and Nicola Ruperto[3]. [1]Ospedale Pediatrico Bambino Gesù, Rome, Italy, [2]Pediatric Rheumatology Collaborative Study Group [PRCSG], Cincinnati, OH, [3]Paediatric Rheumatology International Trials Organisation—IRCCS [PRINTO], Genova, Italy, [4]Roche, Welwyn, United Kingdom, [5]University College London Medical School, London, United Kingdom

Background/Purpose: A placebo-controlled phase 3 trial (TENDER) demonstrated that the interleukin-6 (IL-6) receptor inhibitor tocilizumab (TCZ) is effective in the treatment of patients with systemic juvenile idiopathic arthritis (sJIA). The aim of this analysis was to examine whether baseline characteristics of patients with sJIA were associated with the long-term response to TCZ during the open-label (OL) extension of the TENDER trial.

Methods: Patients aged 2–17 years with active sJIA (≥6 months; inadequate response to prior nonsteroidal anti-inflammatory drugs [NSAIDs] and oral corticosteroids [CS]) who received TCZ or placebo every 2 weeks for 12 weeks in the placebo-controlled portion of the study (part 1) went on to receive OL TCZ in part 2 (extension) of the study. Stable doses of NSAIDs and methotrexate (MTX) were continued, with oral CS tapering permitted according to predefined criteria based on JIA ACR response, absence of fever, and erythrocyte sedimentation rate in part 1 and part 2. In part 1, patients qualifying for rescue therapy received standard of care and were offered OL TCZ. This post hoc analysis examines the proportion of patients with JIA ACR30 response plus absence of fever and JIA ACR70 response at week 52 by baseline demographic and disease characteristics and prior/baseline treat-

ments. Baseline for analyses was first dose of TCZ. Patients who withdrew due to insufficient therapeutic response (n=2) before week 52 were included and considered nonresponders, and patients who withdrew for non–efficacy-related reasons (safety, n=4; other, n=2) before week 52 were excluded.

Results: The intent-to-treat (ITT) population consisted of 112 patients (37 randomized to placebo and 75 randomized to TCZ in part 1). At the longer-term extension data cut, 103 patients had reached week 52 or previously withdrew due to insufficient therapeutic response. In each of the evaluated subgroups, the majority of patients achieved JIA ACR30 response plus absence of fever and/or JIA ACR70 response at week 52 (Table). No substantial differences in response were observed in patients grouped by baseline characteristics, including age, region, disease duration, number of active joints, fever status, C-reactive protein (CRP) level, oral CS dose, MTX use, and previous biologic treatment (IL-1 or TNF-α inhibitor).

Table. Efficacy End Points with TCZ Treatment at Week 52 by Selected Baseline Characteristics (ITT Population)

[a] Fever present, defined as any temperature ≥37.5°C in the 7 days preceding the week 52 visit.
[b] Fever present, defined as a temperature of ≥37.5°C in the 14 days preceding the baseline visit.
[c] Prednisone equivalent.
r/n=no. of responders/no. of patients reaching week 52 visit + no. of patients who previously withdrew due to insufficient therapeutic response.

Conclusion: TCZ was effective and provided a sustained response in patients with sJIA at 52 weeks across multiple baseline characteristics, including longer disease duration, highly active and severe disease, and previous treatment with biologic therapy.

2622

Phase III Study Results on the Efficacy and Safety of Canakinumab, a Long-Acting, Fully Human Anti-Interleukin-1β Antibody, in Systemic Juvenile Idiopathic Arthritis with Active Systemic Features. Hermine Brunner[1], Nicolino Ruperto[2], Gerd Horneff[2], Pierre Quartier[2], Tamás Constantin[2], Yackov Berkun[2], Tilmann Kallinich[2], Riva Brik[2], Manuel A. Ferrandiz[2], Karine Lheritier[3], Ralph Preiss[4], Lillian Tseng[4], Daniel J. Lovell[1], Alberto Martini[2], Paediatric Rheumatology International Trials Organisation[5] and Pediatric Rheumatology Collaborative Study Group [PRCSG][6]. [1]PRCSG, Cincinnati, OH, [2]PRINTO-IRCCS, Genova, Italy, [3]Novartis Pharma AG, Basel, Switzerland, [4]Novartis Pharmaceuticals Corporation, NJ, [5]Genova, Italy, [6]Cincinnati, OH

Background/Purpose: The study objective was to assess the efficacy and safety of canakinumab in systemic juvenile idiopathic arthritis (sJIA) with active systemic features at enrollment.

Methods: In this 4-week randomized, controlled, double-blind study, patients with sJIA received a single subcutaneous dose of canakinumab 4 mg/kg (maximum 300 mg) or placebo at Day 1. The primary objective was to show superior efficacy of canakinumab vs placebo in achieving an adapted ACR Ped30 (ACR criteria plus absence of fever) treatment response at Day 15.

Results: In total, 84 patients (age 2–19 yrs) received treatment (canakinumab, n=43; placebo, n=41). Baseline demographics and characteristics were comparable between groups, with the exception of age. The overall group means were: disease duration 3.4 yrs; CRP 200.6 mg/L (normal range 0–10 mg/L); number of active joints 14.1; and prednisone equivalent therapy 0.6 mg/kg/day. At Day 15, canakinumab was superior to placebo for the primary and secondary endpoints: ACR Ped30, 83.7 vs 9.8%; ACR Ped50, 67.4 vs 4.9%; ACR Ped100, 32.6% vs 0, respectively (all $p<0.0001$). ACR Ped30/50 responses with canakinumab remained significantly higher than with placebo at Day 29 (both $p<0.0001$). Six patients on canakinumab and 37 patients on placebo discontinued due to unsatisfactory therapeutic effects. Adverse events (AEs) occurred in 55.8% of canakinumab and 39.0% of placebo-treated patients. No discontinuations occurred due to AEs. Two non-fatal serious AEs were reported in each group.

Conclusion: Canakinumab has superior efficacy to placebo in patients with sJIA, providing rapid onset of action and robust response (at least ACR Ped50 with fever disappearance) in the majority of patients.

Double Blind, Placebo-Controlled Trial with Adalimumab for Treatment of Juvenile Ankylosing Spondylitis (JAS). Gerd Horneff[1], Sigrid Fitter[1], Hans-Iko Huppertz[2], Ivan Foeldvari[3], Jasmin B. Kuemmerle-Deschner[4], Rolf M. Kuester[5], Nikolay Tzaribachev[6], Angelika Thon[7], Michael Borte[8], Gerd Ganser[9], Ralf Trauzeddel[10] and Kirsten Minden[11]. [1]Asklepios Clinic Sankt Augustin, Sankt Augustin, Germany, [2]Krinikum Bremen-Mitte, Bremen, Germany, [3]Hamburger Zentrum Kinder-und Jugendrheumatologie, Hamburg, Germany, [4]University Hospital Tuebingen, Tuebingen, Germany, [5]Rheumaklinik Bad Bramstedt, Bad Bramstedt, Germany, [6]Center for Rheumatic Diseases, Bad Bramstedt, Germany, [7]Kinderklinik der Medizinischen Hochschule Hannover, Hannover, Germany, [8]Sankt Georg Clinics, Leeipzig, Germany, [9]Sankt Josef Stift, Sendenhorst, Germany, [10]Helios Clinics, Berlin, Germany, [11]Charite, Berlin, Germany

Background/Purpose: While adalimumab is licensed for adult AS, open uncontrolled studies suggest therapeutic efficacy of TNF-inhibitors in jAS.

Methods: This study is to determine efficacy of adalimumab in patients with juvenile AS in a 12 weeks double blind placebo controlled trial with a 12 weeks open label extension. In total 32 subjects aged 12 to 17 years suffering from severe, active, refractory jAS were enrolled into the trial HUM06–037. All subjects were randomized and included in the Intention -to-treat (ITT) analysis, among them 2 subjects who terminated the treatment prematurely after the 3rd injection due to insufficient efficacy.

Results: 17 patients were randomized to receive adalimumab 40mg/2 weeks and 15 patients received placebo. Stable doses of NSAIDs and low dose of corticosteroids (£10 mg per day) were permitted. Two patients (one of each group) discontinued prematurely due to insufficient efficacy and were label as non-responders.

In the adalimumab group a decrease of all disease activity parameters was noted at week 12 which was even more pronounced at week 24 while in the placebo group some changes were noted at week 12 but patients significantly improved at week 24 after switching to ADA at week 12 (table).

	PLC wk 0	PLC wk 12	PLC/ADA wk 24	ADA wk 0	ADA wk 12	ADA/ADA wk 24
active joints	2.9+/−5.0	1.6+/−2.0	0.8+/−1.1***	2.2+/−2.6	1.1+/−2.1	0.2+/−0.6**
LOM	4.7+/−5.9	2.7+/−2.6	1.1+/−1.3***	2.2+/−2.6	1.4+/−2.0	0.8+/−0.8*
spinal inflammation	*5.2+/−2.3*	*3.8+/−3.0*	*2.3+/−2.9*	4.3+/−2.0	1.5+/−1.7***	1.4+/−1.3***

ASAS 40		5 (33%)	9 (60%)		9 (53%)	12 (71%)

* $p<0.05$, ** $p<0.01$, *** $p<0.001$ (t-test compared to baseline)

ASAS 40 response rates after 4, 8 and 12 weeks were higher in the adalimumab group (41%/53%/53%) than in the placebo (20%/20%/33%) group while significant ($p<0.05$) differences were found at week 8. Per protocol analysis excluding 3 patients with violations of the inclusion criteria at baseline (who were met at screening) also reveals significantly higher ASAS20 ($p=0.03$) and higher ASAS40 ($p=0.06$) response to adalimumab after 8 weeks. At week 24, ASAS40 was reached by 12 (71%) in the group receiving adalimumab from the beginning and 9 (60%) in the group initially treated with PLC and at wk 12 switching to adalimumab.

In the total 24 weeks 97 adverse events (AE) have been noted in 23 patients., 8 SAEs occurred in 7 patients, 7 on adalimumab (one appendicitis and one pyelonephritis leading to hospital admission). During the 12 weeks controlled phase 28 AEs occurred in 10 patients with placebo compared to 26 AEs in 11 patients on ADA. Injection site reactions were the most common adverse event. There were 17 various infections occurring in the 12 week double blind phase, 8 on placebo, 9 on adalimumab and further 19 in the 12 week open label period.

Conclusion: Adalimumab shows superiority over placebo in a double blind randomized trial in patients with juvenile ankylosing spondylitis. Treatment effects rapidly occurred and persisted at least for 24 weeks on treatment. There was no unexpected intolerance.

Developing Consensus Treatment Plans for Proliferative Nephritis in Juvenile Systemic Lupus Erythematosus: Maintenance Therapy. Rina Mina[1], Hermine Brunner[2], B. Anne Eberhard[3], Marilynn G. Punaro[4], Stacy P. Ardoin[5], Marisa Klein-Gitelman[6], Lakshmi N. Moorthy[7], Suhas M. Radhakrishna[8], Mindy S. Lo[9], Matthew C. Hollander[10], Eyal Muscal[11], Joyce J. Hsu[12], Linda Wagner-Weiner[13], Deborah M. Levy[14], Carol Wallace[15], Norman T. Ilowite[16] and Emily von Scheven[17]. [1]Cincinnati Children's Med Ctr, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [4]Texas Scottish Rite Hospital, Dallas, TX, [5]Ohio State University, Columbus, OH, [6]Children's Memorial Hospital, Chicago, IL, [7]Robert Wood Johnson Medical School-UMDNJ, New Brunswick, NJ, [8]Children's Hosp Los Angeles, Los Angeles, CA, [9]Children's Hospital Boston, Boston, MA, [10]Seattle Children's Hospital, Seattle, WA, [11]Baylor College of Medicine, Houston, TX, [12]Stanford University, Palo Alto, CA, [13]University of Chicago Hospital, Chicago, IL, [14]The Hospital for Sick Children, Toronto, ON, [15]Childrens Hosp & Regional Med, Seattle, WA, [16]Children's Hospital Montefiore, Bronx, NY, [17]UC San Francisco, San Francisco, CA

Background/Purpose: The Childhood Arthritis and Rheumatology Research Alliance Lupus (CARRA)-Systemic Lupus Erythematosus (SLE) Committee is developing consensus treatment plans (CTPs) for proliferative lupus nephritis (LN) in juvenile SLE (jSLE) to guide therapy and to serve as the basis for future comparative effectiveness studies. The purpose of this phase of the project was to formulate CTPs for the maintenance phase (M-Rx) of proliferative LN based on medical evidence and consistent with current clinical practice.

Methods: Based on extensive literature review, an online Delphi survey addressing various aspects of M-Rx for proliferative LN was sent to 57 members of the CARRA-SLE Committee. A subsequent consensus conference held on June 1, 2011 was attended by 36 CARRA voting members who are experienced in the care of jSLE. The consensus level was set at 80%.

Results: The response rate to the Delphi survey was 86%. Consensus was reached that the duration of the CPTs for proliferative LN should be 36 months post-kidney biopsy at which time their effectiveness can be assessed (Figure 1). There was consensus that for a patient with substantial response to induction therapy (I-Rx): 1). mycophenolic acid (MMF) or cyclophosphamide (CYC) are the immunosuppressive medications to be used during M-Rx; 2). MMF and CYC dosing should be the same as specified for I-Rx; 3). MMF will be initiated within 2 weeks of the last CYC infusion given for I-Rx; 4). CYC administration, started 3 months after the last infusion of I-Rx will be continued every 3 months; and, 5). combination immunosuppressive therapy will not be used. Concerns about non-adherence, pregnancy, worsening of LN, and drug intolerance may warrant change of the immunosuppressive agent initially chosen for M-Rx; azathioprine use may be considered in these settings. There was consensus to utilize a uniform corticosteroid tapering regimen during M-Rx. Resolution of proteinuria, presence of avascular necrosis, and normalization of complement C3 and C4 levels all influence the decision to discontinue corticosteroid during M-Rx.

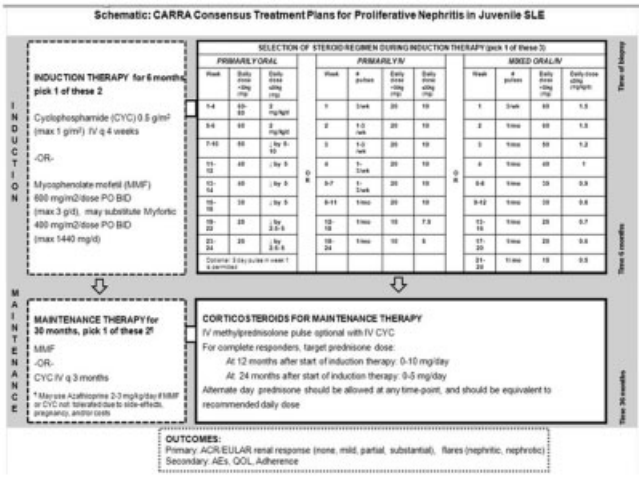

Figure 1. Consensus Treatment Plans for Proliferative LN in jSLE

Conclusion: Consensus was reached about key features of CTPs that are part of the M-Rx of proliferative LN in jSLE. Further efforts are in progress to address issues of partial response and renal flares during M-Rx for proliferative LN.

2625

Radiological Evaluation of Systemic Juvenile Idiopathic Arthritis Treated with Tocilizumab, An Anti-IL6 Receptor Monoclonal Antibody. Chie Aoki[1], Yutaka Inaba[1], Tomoyuki Imagawa[2], Takako Miyamae[2], Masaaki Mori[2], Tomoyuki Saito[2] and Shumpei Yokota[2]. [1]Yokohama City Unversity, Yokohama, Japan, [2]Yokohama City University, Yokohama, Japan

Background/Purpose: Recently tocilizumab (an anti-IL6 receptor monoclonal antibody) has shown clinical benefits in the treatment of systemic juvenile idiopathic arthritis (sJIA) patients. We radiologically evaluated the effects of tocilizumab on the joints by using the carpometacarpal ratio (Poznanski score) and Larsen score of sJIA patients.

Methods: Forty sJIA patients treated with 8mg/kg of tocilizumab every two weeks were enrolled in this study. We examined bilateral hand radiographs in 32 cases to assess the Poznanski score, and radiographs of the large joints, such as the shoulders, elbows, hips, knees and ankles, to assess the Larsen score in 40 cases before and during treatment. Their clinical response was assessed by active joint count and laboratory data.

Results: The mean age at the start of tocilizumab administration was 9.2 years (range: 2.0~18.6 years), and the mean follow-up period was 3.8 years (range: 0.9~8.8 years). The mean active joint count, and WBC, CRP, ESR and MMP-3 values improved significantly from 4.9 to 0.7 joints, from 15400 to 7200/μl, from 5.7 to 0mg/dl, from 40 to 2mm/h, and from 380 to 172ng/ml, respectively. The Poznanski score improved from −0.9 before tocilizumab treatment to −0.6 at the final follow-up; however, the total Larsen score increased from 10.5 to 11.7 during treatment. The Poznanski score improved in 19 cases (48%), but worsened in 12 cases (30%). The total Larsen score improved in 13 cases (33%: improved group), but worsened in 19 cases (48%: worsened group). There was a significant difference between the two groups in MMP-3 levels (53 in the improved group and 226 in the worsened group) at the final follow-up ($P<0.05$). The Larsen score in weight-bearing joints, especially the hips, increased more than in other joints in the worsened group.

Fig. 1 Improvement in damaged hip joints

Fig. 2 Progression in hip joints

Before tocilizumab 4 years After tocilizumab

Conclusion: We evaluated radiographs of patients treated with tocilizumab and observed an improvement in Poznanski score; however, the total Larsen score worsened in patients who had high MMP-3 levels.

Efficacy of Rituximab Retreatment in Refractory Systemic Juvenile Idiopathic Arthritis. Ekaterina Alexeeva, Saniya Valieva, Tatyana Bzarova, Rina Denisova, Kseniya Isayeva, Tatyana Sleptsova and Elena Mitenko. Scientific Center of Children's Health, Moscow, Russia

Background/Purpose: Chimeric monoclonal anti-CD20 B-cell antibody (rituximab) is promising drug for the treatment of JIA refractory to immunosuppressive drugs and TNF-α-blockers. To evaluate clinical efficacy of rituximab retreatment in patients with severe systemic juvenile idiopathic arthritis (JIA).

Methods: 75 patients were enrolled in the study, 36 boys and 39 girs with JIA. Range of age was from 2,3 to 17 years; mean disease duration was 5,32 (0.6; 7,0) years. Rituximab was administered at a mean dose of 375 mg/m^2/ administration according to the following regimen: 1 dose once a week for 4 consecutive weeks every 24 weeks. The next course of Rituximab was administrated if patients had systemic manifestations, active joints, increasing level of CRP and ESR in 24 weeks after Rituximab treatment. 75 patients have received one treatment course (24 weeks), 72 children have received 2 courses (48 weeks), 55 children have received 3 courses (72 weeks), 38–4 courses (96 weeks), 23–5 courses (120 weeks)

Results: The number of systemic manifestations was significantly reduced from 4,5±1,3 to 2,8±1,4, 1,6±0,9, 0,5±0,4, 0,7±0,5 and 0,5±0,3 at Week 24, 48, 72, 96 and 120, respectively. The ACR Pedi 30, 50, 70 were achieved by 85%,45%, 40% of patients at Week 24, and by 90%, 75%, 70% of patients at Week 48, respectively. At week 72 ACR pedi 50 and 70 were achieved by 75% and 70% of patients. The remission was achieved by 25% of patients at Week 24, by 48% of patients at Week 48, by 65% of patients at Week 72 and by 80% and 90% of patients at Week 96 and 120.

Conclusion: Rituximab is effective drug of treatment in patients with severe juvenile idiopathic arthritis. The remission was achieved by 90% of patients at Week 120.

Tofacitinib (CP-690,550) in Combination with Traditional Disease-Modifying Anti-Rheumatic Drugs: Phase 3 Study Patient-Reported Outcomes in Patients with Active Rheumatoid Arthritis and An Inadequate Response to Disease-Modifying Anti-Rheumatic Drugs. V. Strand[1], J. M. Kremer[2], Z. G. Li[3], S. Hall[4], Roy M. Fleischmann[5], M. C. Genovese[6], E. Martin-Mola[7], J. Isaacs[8], D. Gruben[9], G. Wallenstein[9], S. Krishnaswami[9], S. H. Zwillich[9], T. Koncz[10], R. Riese[9], J. D. Bradley[9] and the ORAL Sync investigators[11]. [1]Stanford University, Palo Alto, CA, [2]Albany Medical College and The Center for Rheumatology, Albany, NY, [3]Peking University People's Hospital, Peking, China, [4]Melbourne Rheumatology, Melbourne, Australia, [5]MCRC, University of Texas, Dallas, TX, [6]Stanford University Medical Center, Palo Alto, CA, [7]Hospital Universitario La Paz, Madrid, Spain, [8]University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom, [9]Pfizer Inc., Groton, CT, [10]Pfizer Inc., New York, NY, [11]Groton

Background/Purpose: Tofacitinib (CP-690,550) is a novel, oral Janus kinase (JAK) inhibitor investigated as a targeted immunomodulator for treatment of rheumatoid arthritis (RA). The efficacy and safety of tofacitinib vs placebo (PBO) were evaluated in pts with active RA with an inadequate response to ≥1 DMARD (traditional or biologic). Primary efficacy analyses have previously been reported. Here we report patient-reported outcomes (PRO).

Methods: In this 12-month (Mo) study (NCT00856544), pts receiving traditional background DMARDs were randomized (4:4:1:1) to: tofacitinib 5 mg twice daily (BID); 10 mg BID; PBO advanced to 5 mg BID; and PBO advanced to 10 mg BID. At Mo 3 all 'non-responder' PBO pts (<20% reduction from baseline in swollen/tender joint counts) were advanced to tofacitinib 5 or 10 mg BID. At Mo 6 all remaining PBO pts were advanced to tofacitinib. Most PROs were secondary endpoints and included: patient global assessment of disease activity (PtGA), pain, physical function (HAQ-DI); health-related quality of life (Medical Outcomes Survey [MOS] Short Form 36 [SF-36]), fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F]), and sleep (MOS Sleep Scale).

Results: 792 pts were treated; mean disease duration 8.1 – 10.2 years (y); mean age 50.8–53.3 y. At Mo 3 improvements from baseline in all PROs were statistically significantly greater in tofacitinib 5 and 10 mg BID groups than PBO (Table). Based on pts reporting improvements ≥ minimally clinically important differences [MCID], numbers needed to treat (NNTs) at Mo 3 for tofacitinib 5 and 10 mg BID, respectively, ranged from 4.6 – 6.0 and 3.7–8.3, respectively (full analysis set [FAS], no imputation).

Table. Patient-reported outcomes at Mo 3 (FAS, longitudinal model)

Patient-reported outcomes [MCID values]	Placebo n=159	Tofacitinib 5 mg BID n=315	Tofacitinib 10 mg BID n=318
PtGA [-10]	-12.54	-24.82*** (-16.39, -8.17)	-28.19*** (-19.76, -11.53)
NNT		5.2	4.3
Pain (VAS) [-10]	-11.38	-24.18*** (-16.90, -8.69)	-26.78*** (-19.50, -11.28)
NNT		4.6	4.2
HAQ-DI [-0.22]	-0.21	-0.46*** (-0.35, -0.16)	-0.56*** (-0.44, -0.26)
NNT		4.7	4.0
SF-36 Physical component score [-2.5]	2.40	5.92*** (2.15, 4.88)	7.54*** (3.77, 6.50)
NNT		5.8	3.7
SF-36 Mental component score [-2.5]	1.63	4.39* (1.05, 4.47)	4.40* (1.06, 4.49)
NNT		6.0	8.3
Fatigue (FACIT-F)	2.05	5.81*** (2.25, 5.28)	6.85*** (3.29, 6.33)
MOS sleep summary	-1.57	-6.19** (-7.33, -1.91)	-7.43*** (-8.58, -3.15)

*p<0.05; **p<0.001; ***p<0.0001 vs PBO

Conclusion: In this Phase 3 study of tofacitinib in combination with traditional DMARDs, treatment with 5 and 10 mg BID resulted in consistent statistically significant and clinically meaningful improvements in multiple PROs vs PBO at Mo 3.

2628

Double-Blind Study of Tocilizumab Plus Methotrexate Vs Tocilizumab Plus Placebo in Patients with Active Rheumatoid Arthritis Despite Prior Methotrexate: Progression of Structural Damage, Quality of Life, and Physical Function At 24 Weeks. Maxime Dougados[1], Karsten Kissel[2], Howard Amital[3], Philip G. Conaghan[4], Emilio Martin-Mola[5], Evgeny L. Nasonov[6], Georg Schett[7], Orrin M. Troum[8], Tiina Veldi[9], Corrado Bernasconi[10] and T.W.J. Huizinga[11]. [1]Paris-Descartes University, Cochin Hospital, Paris, France, [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [3]Sheba Medical Center, Tel-hashomer, Israel, [4]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [5]Hospital Universitario La Paz, Madrid, Spain, [6]Institute of Rheumatology, Moscow, Russia, [7]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [8]USC Keck School of Medicine, Santa Monica, CA, [9]East-Tallinn Central Hospital, Tallinn, Estonia, [10]Roche, Basel, Switzerland, [11]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: To evaluate clinical efficacy (including progression of structural damage, quality of life (QoL), and physical function) and safety of adding tocilizumab (TCZ) to methotrexate (MTX) vs switching to TCZ alone in patients (pts) with moderate to severe active rheumatoid arthritis (RA) despite MTX treatment.

Methods: In the double-blind, 2-year study ACT-RAY (NCT00810199,

EudraCT No. 2008-001847-20) patients on stable doses of oral weekly MTX were randomized to continued MTX with addition of TCZ 8 mg/kg every 4 wks or oral PBO+TCZ. The study was powered to assess the primary endpoint (DAS28 remission rate [RR] at 24 wks) for superiority of the combination arm based on a 12.5% difference between groups: 42.5% on TCZ+MTX vs 30% on TCZ+PBO. Baseline and wk-24 hand and feet radiographs were scored by independent readers blinded to treatment allocation, clinical response, and sequence of X-rays.

Results: Of 556 pts randomized (TCZ+MTX=279; TCZ+PBO=277) 92% (n=512; TCZ+MTX=260; TCZ+PBO=252) completed 24 wks. Mean baseline characteristics were similar for both groups (female, 80.3%; age, 53.3 yrs; RA duration, 8.2 yrs; DAS28, 6.35) except for radiographic scores (Table). DAS28 RR was 40.4% and 34.8% in TCZ+MTX and TCZ+PBO groups, respectively (difference between groups 5.65% [95% CI: –2.41, 13.71]; P=0.19; not significant). ACR20/50/70/90 response rates were 72%/45%/25%/6% (TCZ+MTX) and 71%/41%/26%/5% (TCZ+PBO) (all P=NS). Progression of structural damage was low, as shown by change in GSS (Table) and proportion of pts showing no progression (change ≤ 0). In analyses of covariance models, taking baseline values into account, there were no significant differences between groups. HAQ-DI and RAQoL improved significantly from baseline, with no differences between groups (Table). Rates per 100 patient-yrs of SAEs and serious infections were 21 and 6 for TCZ+MTX and 18 and 6 for TCZ+PBO, respectively; infections were the most frequent AEs and SAEs. AE-related discontinuations and dose modifications occurred in 3.9% and 27.4% of TCZ+MTX and 2.9% and 18.5% of TCZ+PBO pts, respectively. ALT elevations >60 U/L were observed in 16% and 6% of TCZ+MTX and TCZ+PBO pts, respectively.

Radiographic and QoL Results at Week 24

Genant-modified Sharp Score (GSS), Mean (SD)	TCZ + MTX N = 277	TCZ + PBO N = 276	Between-group Difference (95% CI)
Total GSS	30.4 (31.8)	37.1 (40.5)	
Baseline	3.71	4.47	
Baseline annualized progression rate	0.08 (1.88)	0.22 (1.11)	−0.13 (−0.39, 0.13)
Change from baseline (wk 24)			P=0.3304*
JSN Score	14.7 (17.3)	17.7 (21.7)	
Baseline	0.08 (1.49)	0.11 (0.70)	−0.02 (−0.22, 0.17)
Change from baseline (wk 24)			P=0.8235*
Erosion Score	15.7 (15.4)	19.4 (19.8)	
Baseline	−0.01 (0.79)	0.11 (0.63)	−0.11 (−0.23, 0.02)
Change from baseline (wk 24)			P=0.0871*
No Progression in GSS (Patients with Changes ≤0), n (%)			
Total GSS	181 (65.3)	162 (58.7)	P=0.0871†
JSN Score	218 (78.7)	203 (73.6)	P=0.1319†
Erosion Score	190 (68.6)	179 (64.9)	P=0.3317†
QoL Data Change From Baseline, Mean (SD)			
HAQ-DI	−0.56 (0.67)	–0.55 (0.53)	P=0.9323‡
RAQoL	−5.97 (7.95)	–5.19 (7.06)	P=0.3080‡

* P-values are for between-group differences in adjusted means (change from baseline to wk 24) from the analysis of covariance
† P-values are for between-group differences from a two-sided Cochran-Mantel-Haenszel test stratified for region and baseline DAS28
‡ P-values are for between-group differences from a 2-sided Wilcoxon rank-sum test of no difference between the 2 treatment groups in change from baseline

Conclusion: The study did not demonstrate clinical superiority of TCZ+MTX combination therapy over TCZ monotherapy at wk 24, based on DAS28 remission rates and other efficacy endpoints. This was confirmed by near complete arrest of progression of structural damage, with no significant differences between groups, leading to significant improvement in QoL with both treatments. The safety data confirmed previous findings. TCZ combined with MTX was associated more commonly with transaminase increases. These results show that clinically meaningful responses can be obtained with TCZ monotherapy and therefore MTX may not be a required concomitant treatment with TCZ.

Postmarketing Surveillance of Tocilizumab for Rheumatoid Arthritis In Japan—Full Analysis Report of 7,901 Patients. Hisashi Yamanaka[1], Masayoshi Harigai[2], Shigeko Inokuma[3], Naoki Ishiguro[4], Junnosuke Ryu[5], Syuji Takei[6], Tsutomu Takeuchi[7], Yoshiya Tanaka[8], Youko Sano[9] and Takao Koike[10]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Medical and Dental Univ, Tokyo, Japan, [3]Japanese Red Cross Medical Center, Tokyo, Japan, [4]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [5]Nihon University School of Medicine, Tokyo, Japan, [6]Kagoshima University, Kagoshima City, Japan, [7]Keio University School of Medicine, Tokyo, Japan, [8]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [9]Chugai Pharmaceutical Co. Ltd., Tokyo, Japan, [10]Sapporo Medical Center NTT EC, Sapporo, Japan

Background/Purpose: A postmarketing surveillance (PMS) was performed for all patients with rheumatoid arthritis (RA) who were treated with tocilizumab (TCZ) in Japan to investigate the safety and effectiveness in the daily clinical setting.

Methods: This full analysis report includes 7,901 patients. They received 8 mg/kg of TCZ every 4 weeks, and were observed for 28 weeks. Baseline characteristics, effectiveness as measured by 28-joint disease activity score (DAS28-ESR) and Boolean remission criteria (tender joint count ≤ 1, swollen joint count ≤ 1, patient global assessment [on 0–10 scale] ≤ 1, and serum concentration of C-reactive protein [mg/dL] ≤ 1), and all adverse events (AEs) were assessed.

Results: Baseline patient characteristics were as follows: mean age of 58.7 years (≥70 years of age in 20.7% of patients); mean disease duration of RA of 10.4 years (≥10 years in 37.8%); respiratory comorbidities in 17.0% and cardiac comorbidities in 5.1%; previous TNF inhibitor use in 62.8%; and concomitant methotrexate (MTX) use in 55.8% and concomitant glucocorticoid use in 74.0%. Mean baseline DAS28-ESR was 5.5, which declined to 2.9 at week 28 (LOCF method); 47.6% of patients achieved DAS28 remission (DAS28-ESR < 2.6), and 15.1% of patients achieved Boolean remission. The incidences of DAS28 remission and Boolean remission in patients with disease duration <2 years were significantly better than those in patients with ≥10 years' disease duration ($p < 0.001$, χ^2 test). TNF inhibitor naïve patients showed significantly better response than the patients with prior anti-TNF use ($p < 0.001$, χ^2 test) (Table).

		Disease duration (years)			Anti-TNF naïve		Anti-TNF used	
Incidence	total	<2	2≤>10	10≤	MTX+	MTX−	MTX+	MTX−
DAS28 remission	47.6	56.1*	50.1	42.4	60.5†¶	50.6¶	45.6†	39.1
Boolean remission	15.1	22.3*	16.4	10.7	22.1¶	20.2¶	12.0	11.7
AEs	43.9	43.8	43.4	46.3	42.0	43.0	45.4	43.5
SAEs	9.6	8.5*	8.3	12.0	8.7†	10.8	8.1†	11.8
Infections	11.1	8.9*	9.4	14.0	10.0§	12.0	10.5	12.0
Serious infections	3.8	2.6*	3.3	4.9	3.6‡	4.5	3.1	4.4

* ;p<0.001 between <2years and ≤10 years, †;p<0.001, ‡;p<0.01, §;p<0.05 between MTX+ and MTX-, ¶;p<0.001 between anti-TNF naïve and anti-TNF used

The incidences of total and serious AEs (SAEs) were 43.9% and 9.6%, respectively. The incidence of SAEs was higher in the patients whose disease duration was ≥10 years ($p < 0.001$, χ^2test, vs. <10 years) or who did not use MTX concomitantly ($p < 0.001$, χ^2test, vs. concomitant MTX use) (Table). Infections and infestations were the most frequent AEs (11.1%) and the most frequent SAEs (3.8%). Although malignancies were reported as AEs in 39 patients (0.5%), no specific patterns were observed. Gastrointestinal disorders were reported in 373 patients (4.7%) including 13 (0.16%) gastrointestinal tract perforations. Thirty-five patients died within 28 weeks, and the standardized mortality ratio, with the Japanese general population in 2008 as a control, was 1.15 (95%CI: 0.83–1.61), which was numerically lower than the previous report (1.66; 95%CI: 1.12–2.46 from the interim analysis reports of 3,818 patients) and similar to the results reported in the Japanese cohort study of RA patients (Nakajima A, et al. Scand J Rheumatol. 2010; 39: 360–7)

Conclusion: The results from this study revealed that TCZ was effective and well-tolerated in Japanese RA patients in the daily clinical setting.

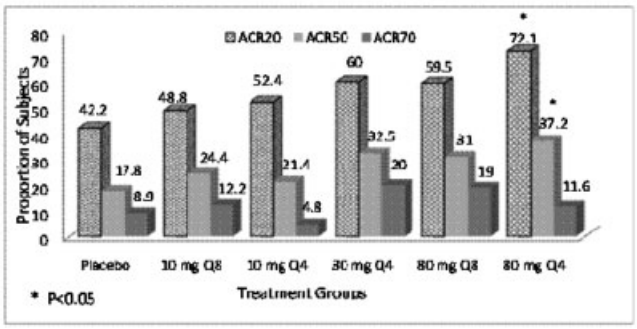
2630

A Multiple Ascending Dose/Proof of Concept Study of ATN-103 (ozoralizumab) in Rheumatoid Arthritis Subjects on a Background of Methotrexate. Roy Fleischmann[1], Savithree Nayiager[2], Ingrid Louw[3], Bernadette Rojkovich[4], Caifeng Fu[5], Chandrasekhar Udata[6], Parvin Fardipour[7], Bonnie Marshall[7], Michelle Hinz[7], Amarnath Sharma[7], Kathy Shields[7] and Gail Comer[7]. [1]Metroplex Clinical Research Center, Dallas, TX, [2]St. Augustine Hospital, Berea, KwaZulu-Natal, South Africa, [3]Panorama Medical Centre, Panorama, Western Cape, South Africa, [4]Polyclinic of the Hospitaller Brothers of St John of God, Budapest, Hungary, [5]Pfizer, Cambridge, MA, [6]Pfizer, La Jolla, CA, [7]Pfizer, Collegeville, PA

Background/Purpose: Inhibition of tumor necrosis factor (TNF) has been shown to be an effective treatment of Rheumatoid Arthritis (RA). ATN-103 (ozoralizumab), a novel TNF inhibitor, is a humanized, trivalent, bispecific Nanobody that contains 2 human TNF-binding domains linked to a human serum albumin-binding domain. ATN-103 was evaluated in a double-blind, seamless adaptive phase 1/2, Multiple Ascending Dose (MAD)/Proof of Concept (POC) study that assessed the safety and efficacy in subjects with active RA compared to placebo (PBO).

Methods: The study started as a randomized, sequential dose escalating study, stratified by prior TNFi use, and converted to a parallel enrolling study once multiple doses of all doses levels had been evaluated to be safe by a Data Monitoring Committee. Subjects (253) received subcutaneous injections of PBO or ATN-103 doses of 10 mg, 30 mg, or 80 mg administered every 4 weeks (Q4) or 10 mg or 80 mg every 8 weeks (Q8). The primary endpoint (ACR20 at week 16) was analyzed by the Cochran-Mantel-Haenszel test stratified by prior TNFi use status using a last observation carried forward (LOCF) for the modified intent-to-treat (mITT) population (all randomized subjects receiving at least 1 dose of study drug).

Results: Statistical significance (p= 0.006) compared to PBO for the primary endpoint was achieved by the 80 mg Q4 dose regimen only. The ACR 20/50/70 response at week 16 is shown below.



Statistically significant improvements over PBO in secondary endpoints were achieved for 80 mg Q4 dose regimen in DAS28, ACR50, HAQ-DI, tender and swollen joint counts, pain and general health visual analog scales, physician and patient global assessments, CRP and EULAR response.

Exposure to ATN-103 increased in an approximately dose-proportional manner with increasing dose. The mean terminal half-life ranged from 9.5 to 13.5 days, mean apparent clearance was 0.3 to 0.5 L/day, and the area under the plasma concentration-versus-time curve ranged from 22 to 247 μg.day/mL.

ATN-103 was generally safe and well tolerated with adverse events (AEs) similar to those reported for other TNFi agents. Thirteen (5.1%) serious adverse events (SAEs) were reported with no dose-dependent increase and no dose limiting toxicity identified. No SAE was reported in more than one subject and no SAEs were reported in the 80 mg Q4 group. The most common treatment-emergent AEs were upper respiratory infections and urinary tract infections. Injection site reactions were observed in 3 subjects.

Conclusion: The 80 mg Q4wk group was significantly better than PBO at week 16 in ACR20, ACR50, DAS28, HAQ-DI and other secondary endpoints. There was no dose dependent increase in either AEs or SAEs or dose limiting toxicities. Exposure to ATN-103 increased in a dose-proportional manner.

2631

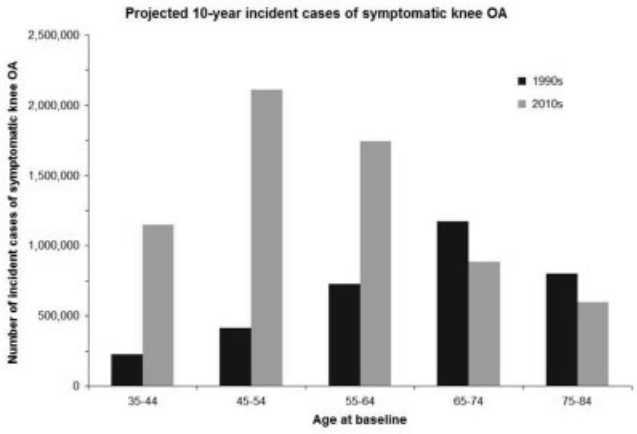
Results From a 2-Part, Proof-of-Concept, Dose-Ranging, Randomized, Double-Blind, Placebo-Controlled, Phase 2 Study of Sirukumab, a Human Anti-Interleukin-6 Monoclonal Antibody, in Active Rheumatoid Arthritis Patients Despite Methotrexate Therapy. Benjamin Hsu[1], Shihong Sheng[2], Josef Smolen[3] and Michael Weinblatt[4]. [1]Centocor R&D, a division of J&J Pharmaceutical R& D, LLC/Univ. of Pennsylvania, Malvern/Philadelphia, PA, [2]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [4]Brigham & Women's Hospital, Boston, MA

Background/Purpose: IL-6 overproduction is believed to be involved in RA pathogenesis. Sirukumab(formerly CNTO 136) is a human mAb that binds with high affinity to cytokine IL-6. In the proof of concept part (Part A) of a multicenter, randomized, double blind, pbo controlled, ph 2 study, 100mg sirukumab SC q2w were generally well tolerated & efficacious compared with pbo in pts with active RA despite MTX.

Methods: The ph2 dose ranging Part B was initiated to determine efficacious & safe sirukumab dose regimens and to describe SC sirukumab PK and PD in active RA pts. In Part B, pts with active RA despite MTX were randomized equally to: (1)pbo q2w at wks 0–10, then sirukumab 100mg q2w at wks12–24; (2)sirukumab 100mg q2w at wks 0–24; (3)sirukumab 100mg q4w at wks0–24; (4)sirukumab 50mg q4w at wks0–24;or (5)sirukumab 25mg q4w at wks0–24. Primary endpoint was ACR50 response at wk12, compared between each active grp vs pbo. Key secondary endpoints were change from baseline(bsl) in DAS28(CRP) at wk12, serum sirukumab PK and % change from bsl in serum CRP at wk2.

Results: In Part B, 151pts were randomized & treated(table). 85% pts were female, 60% Caucasian, 21% Japanese. At bsl, mean age: 53±11yrs, mean weight: 69±15kg, mean DAS28(CRP): 5.9±0.9, and median serum CRP: 1.7mg/dL. 26(87%) pbo pts crossed over to sirukumab 100mg q2w at wk12. At wk12, sirukumab significantly improved ACR50 response (overall p=0.010) and significantly reduced DAS28 scores (p<0.001, table). Sirukumab PK were linear over the SC dose range of 25–100mg. PK parameters were generally consistent between Caucasians& Japanese. Mean serum CRP levels decreased >80% from bsl with sirukumab at wk2 and remained suppressed thru wk24 (table). Thru wk38, AEs occurred more often with sirukumab than pbo (81 vs 67%), including mostly minor infections/infestations (31 vs 13%), GI disorders (19 vs 10%), and injection site reactions (16 vs 3%). AEs of leukopenia (9,13% [1 NCI Grade 3]), neutropenia (5,3% [3 Gr 3]), thrombocytopenia (3,2% [1 Gr 3, 1 Gr 4]), and lymphopenia (2,1%, [1 Gr 3, 1 Gr 4]) were reported with sirukumab. ALT(8 Gr 3, 7%) and AST(1 Gr 3, 1%) elevations not associated with increased bilirubin; and sustained increases from bsl starting at wk2 in total cholesterol (mean sirukumab vs pbo: 19% ± 17% vs −5% ± 12%) and LDL (20% ± 20% vs −4% ± 22%) were seen with sirukumab. These lab abnormalities occurred without dose relationship or short term clinical sequelae. SAEs were more common with pbo(4, 13%) than sirukumab(13, 9%); the majority were infections. 1 pt died of unrelated brain aneurysm. 4/136 (3%; 2 100mg q4w, 2 pbo→100mg q2w) evaluable pts had antibodies to sirukumab thru wk38; 3 of these pts were ACR50 responders at wk24, 0 had injection site reactions.

Sirukumab was efficacious & generally well tolerated in pts wi expected to incur 6,475,642 incident cases of symptomatic knee OA over the next decade, with those ages 45–64 accounting for 59% of these cases (Figure). Among Americans who were ages 45–54 at the beginning of the 1990s, an estimated 412,214 incident cases of knee OA were expected over the subsequent 10 years, resulting in a 10-year cumulative incidence of 1.5%. Among people in the same baseline age group in the 2010s, 2,108,881 incident cases of symptomatic knee OA are expected over the next 10 years, a cumulative incidence of 4.8%. The projected number of 10-year incident cases among those ages 65–74 at baseline decreased slightly between the 1990s (1,169,615 cases) and the 2010s (882,997 cases).



Conclusion: Since the early 1990s, the age of onset of physician-diagnosed symptomatic knee OA has shifted dramatically, occurring on average 16 years earlier in life. This trend may reflect temporal changes in the prevalence of OA risk factors, as well as thresholds for patient care-seeking and physician diagnosis of OA. If the current OA incidence trend continues, nearly 6.5 million Americans between the ages of 35 and 84 will be diagnosed with symptomatic knee OA in the next 10 years, with those ages 45–64 accounting for more than half of these incident cases. A resulting spike in the utilization of healthcare, specifically total knee replacements, could have a dramatic economic impact and place additional burden on the healthcare system.

2632

Results From a Multicenter, International, Randomized, Double-Blind, Placebo-Controlled, Phase 2 Study of Sirukumab, a Human Anti-IL-6 Monoclonal Antibody, in Patients with Active Rheumatoid Arthritis Despite Methotrexate Therapy. Benjamin Hsu. Centocor R&D, a division of J&J Pharmaceutical R& D, LLC/Univ. of Pennsylvania, Malvern/ Philadelphia, PA, Shihong Sheng, Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, Michael E. Weinblatt, Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA and Josef Smolen, Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: To assess remission rates from a phase 2 study of sirukumab, a human monoclonal antibody against the cytokine interleukin-6 (formerly named CNTO 136), using the new provisional 2011 ACR/EULAR rheumatoid arthritis (RA) remission criteria.

Methods: In the dose-ranging part of a 2-part, multicenter, randomized, double blind, placebo controlled, phase 2 study, pts with active RA despite methotrexate (MTX) therapy were randomized equally to receive SC injections of placebo q2w at wks 0–10 and sirukumab 100 mg q2w at wks 12–24 (n=30), sirukumab 100 mg q2w at wks 0–24 (n=30), sirukumab 100 mg q4w at wks 0–24 (n=30), sirukumab 50 mg q4w at wks 0–24 (n=30), or sirukumab 25 mg q4w at wks 0–24 (n=31). RA remission rates were prospectively assessed using the DAS28 (CRP) remission criteria and retrospectively assessed using the 2011 ACR/EULAR remission criteria (Boolean- and SDAI-based) at wks 12, 24, and 38. The 2011 ACR/EULAR remission criteria used in this study were: Boolean-based (68-joint TJC ≤1, 66-joint SJC ≤1, CRP ≤1 mg/dL, PGA ≤1 on a 1–10 cm VAS), index-based (SDAI score [ie, 28-joint TJC + 28-joint SJC + PGA + physician's global assessment + CRP mg/dL] ≤3.3).

Results: At wk 12 (pre-crossover), more pts were in remission with sirukumab than with placebo according to both Boolean- and SDAI-based ACR/EULAR criteria (2% vs 0% and 6% vs 3%, Table). The percentage of pts in remission according to all 3 criteria increased to a peak at wk 24 in the sirukumab 100 mg q2w and q4w treatment groups and remained higher than wk-12 rates at wk 38, 14 wks after the last dose of sirukumab. Pts who received sirukumab 100 mg q2w throughout the study achieved the highest remission rates according to all 3 remission criteria at all time points, including a statistically significant difference compared with placebo according to DAS28 remission criteria at wk 12 (20% vs 0%, p=0.024) and Boolean-based ACR/EULAR remission in 4/30 (13%) pts and SDAI-based ACR/EULAR remission in 7/30 (23%) pts at both wk 24 and wk 38. As expected, the more stringent 2011 ACR/EULAR remission criteria resulted in generally lower remission rates than the DAS28 remission criteria at all time points. Lower remission rates were seen for all groups at all time points with the Boolean-based vs the SDAI-based definition.

Table. Patients in remission according to the 2011 ACR/EULAR RA remission criteria and the DAS28 (CRP) remission criteria at weeks 12, 24, and 38

		Placebo*	Sirukumab				
			100 mg q2w	100 mg q4w	50 mg q4w	25 mg q4w	Combined
N		30	30	30	30	31	121
Wk 12	ACR/EULAR remission: Boolean-based	0	1 (3%)	0	0	1 (3%)	2 (2%)
	ACR/EULAR remission: SDAI-based	1 (3%)	3 (10%)	1 (3%)	2 (7%)	1 (3%)	7 (6%)
	DAS28 (CRP) remission	0	6 (20%)	1 (3%)	4 (13%)	3 (10%)	14 (12%)
Wk 24	ACR/EULAR remission: Boolean-based	1 (3%)	4 (13%)	1 (3%)	0	1 (3%)	6 (5%)
	ACR/EULAR remission: SDAI-based	3 (10%)	7 (23%)	5 (17%)	1 (3%)	2 (7%)	15 (12%)
	DAS28 (CRP) remission	6 (20%)	12 (40%)	8 (27%)	4 (13%)	7 (23%)	31 (26%)
Wk 38	ACR/EULAR remission: Boolean-based	4 (13%)	4 (13%)	1 (3%)	1 (3%)	1 (3%)	7 (6%)
	ACR/EULAR remission: SDAI-based	5 (17%)	7 (23%)	2 (7%)	2 (7%)	0	11 (9%)
	DAS28 (CRP) remission	9 (30%)	11 (37%)	5 (17%)	7 (23%)	2 (7%)	25 (21%)

* Twenty-six of 30 patients in the placebo group crossed over to sirukumab 100 mg q2w at week 12.

Conclusion: Higher remission rates according to both the 2011 ACR/EULAR and the DAS28 (CRP) criteria were achieved with sirukumab at SC dose regimens ranging from 25–100 mg q2w-q4w compared with placebo. After placebo crossover to sirukumab, all groups achieved increasing remission rates over time with continued sirukumab treatment. The highest sirukumab dose regimen (100 mg q2w) achieved the highest remission rates throughout the study. The 2011 ACR/EULAR criteria were more stringent than the DAS28 (CRP) criteria; and the Boolean-based definition was more stringent than the SDAI-based definition.

2633

Anterior Chest Wall Inflammation by Whole Body MRI in Patients with Spondyloarthritis: Lack of Association Between Clinical and Imaging Findings. Ulrich Weber[1], Robert GW Lambert[1], Kaspar Rufibach[2], Walter P. Maksymowych[1], Juerg Hodler[3], Anna Zejden[4], Stefan Duewell[5], Rudolf O. Kissling[6], Paul L. Filipow[1] and Anne G. Jurik[4]. [1]University of Alberta, Edmonton, AB, [2]University of Zurich, Zurich, Switzerland, [3]University Hospital Zurich, Zurich, Switzerland, [4]University Hospital Aarhus, Aarhus, Denmark, [5]Hospital Thurgau AG, Frauenfeld, Frauenfeld, Switzerland, [6]Balgrist University Hospital, Zurich, Switzerland

Background/Purpose: Inflammatory involvement of the anterior chest wall (ACW) impacts the quality of life in patients with spondyloarthritis (SpA). However, ACW involvement is often neglected in clinical routine and data on ACW inflammation by clinical examination and by various imaging modalities are controversial. Whole body (WB) MRI is a promising imaging method to assess also the ACW without additional inconvenience for the patients.

Objectives: To describe the frequency and distribution of ACW inflammation by WB MRI in SpA patients; to assess the association between imaging and clinical findings; to evaluate the performance of a WB MRI scoring system for the ACW.

Methods: The ACW of 122 consecutive SpA patients (95 with ankylosing spondylitis (AS) and 27 with inflammatory back pain (IBP)) and 75 healthy controls was scanned by sagittal and coronal WB MRI. The MR images were scored independently in random order by 7 readers blinded to patient identifiers. Active and structural inflammatory lesions of the ACW were recorded on a web-based scoring form. ACW pain by patient self-report, ACW tenderness on physical examination according to the Maastricht ankylosing spondylitis enthesitis score (MASES) and MRI lesions were analyzed descriptively. Kappa statistics served to assess inter-observer reliability and the agreement between clinical and imaging findings.

Results: ACW pain or tenderness was present in 26% with little difference between AS and IBP patients. Bone marrow edema (BME), erosion and fat infiltration were recorded in 49.5%, 36.8% and 33.7% of the AS patients, in 25.9%, 25.9% and 3.7% of the IBP patients, and in 9.3%, 12.0% and 5.3% of the controls, respectively. The most frequently affected joint by MRI lesions was the manubriosternal joint. The inter-reader agreement by kappa values for 7 observers and for the 3 MRI lesions BME, erosion and fat infiltration was 0.52, 0.48 and 0.46, respectively, being highest (0.65) for BME of the manubriosternal joint. The agreement between patient self-reports of pain and ACW tenderness upon clinical examination was moderate with a kappa value of 0.5. The kappa values between clinical assessment according to MASES and MRI inflammation ranged from −0.18 to only 0.25 for all SpA patients.

Conclusion: Clinical and WB MRI signs of ACW inflammation were found in 26% and up to 44% of SpA patients, respectively. There was no agreement between clinical ACW involvement according to MASES and inflammatory MRI findings. Possible explanations are subclinical ACW inflammation captured by MRI and/or a limited construct validity of the MASES ACW section.

2634

Higher Frequency of Metabolic Syndrome In Psoriatic Arthritis Compared with Rheumatoid Arthritis May Be Explained by High Triglycerides and Increased Rates of Obesity and Diabetes. Asena Bahce-Altuntas[1], Julie S. Schwartzman-Morris[1], Nicole Jordan[1], Jeffrey D. Greenberg[2], Chaim Putterman[1], George Reed[3] and Anna R. Broder[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]NYU Hospital for Joint Diseases, New York, NY, [3]UMass Medical School, Worcester, MA

Background/Purpose: Our understanding of cardiovascular (CV) disease in Psoriatic Arthritis (PsA) is often extrapolated from Rheumatoid Arthritis (RA). Since PsA is characterized by inflammation of both skin and joints, we may be underestimating this CV risk in PsA. The prevalence of

Metabolic Syndrome (MetS), a clustering of classical cardiovascular risk factors, in PsA has not been well studied. Furthermore, since MetS have been shown to be highly prevalent in RA and Psoriasis (PsO) patients, we hypothesized that the prevalence of MetS and its components in PsA patients are higher than those with RA.

Methods: We conducted a cross-sectional study to compare the prevalence of MetS and its components in PsA and RA participants in the Consortium of Rheumatology Researchers of North America (CORRONA) registry. Based on the International Diabetes Federation criteria, MetS was defined as: body mass index, BMI>30 kg/m^2, and any of the two: (1) diagnosis of diabetes, (2) diagnosis of hypertension, (3) high Triglycerides, TG>150 mg/dL (1.69 mmol/L), or (4) low High Density Lipid, HDL<40 mg/dL (1.03 mmol/L) in males, HDL<50 mg/dL (1.29 mmol/L) in females.

Results: Of the 25,976 RA and 4,015 PsA, 1956 CORRONA participants (1162 RA and 294 PsA) had all components of MetS available. The overall prevalence of MetS in PsA vs. RA patients was: 27% vs. 19%, p=0.004, with an unadjusted OR 1.5 (1.14–2.05). PsA were younger compared with RA patients, 55.7 ± 11.9 vs. 61.6 ± 12.2 years, respectively, p<0.001, and PsA patients had more men (54% vs. 23%, p<0.001) and RA patients had a higher percentage of minorities. After adjusting for age, sex, race/ethnicity in our multivariate model, the OR of MetS in PsA vs. RA decreases slightly, but remains statistically significant: OR 1.4 (1.05–1.96), p=0.02. Disease duration, history of previous cardiovascular events, and use of statins were statistically similar among the two groups. In regards to the individual components of the MetS definition, TG>150 was the only statistically significant component with a frequency of 38% in PsA compared to 28% in RA patients, p<0.001 and an unadjusted OR 1.58 (1.22–2.05). No statistically differences were observed between the two groups in frequency of low HDL and hypertension, but the difference between the two groups in prevalence of obese BMI and diabetes was nearly statistically significant (45% vs. 39%, p=0.06 and 15% vs. 11%, p=0.06, respectively). Since BMI>30 kg/m^2 was a necessary condition for MetS, we analyzed the subgroup of 133 PsA and 654 RA with obese BMI (BMI>30 kg/m^2) and found an unadjusted OR of MetS for PsA vs. RA to be 1.5 (1.04, 2.22), p=0.04. TG>150 again was more prevalent in the obese PsA group than the obese RA group (51% vs. 39%, p=0.01).

Conclusion: MetS is highly prevalent in both PsA and RA, and overall significantly higher in PsA compared to RA. Triglycerides appear to drive the estimated increase in risk of MetS in PsA vs. RA, but there is also a trend to association with obese BMI and diabetes. Thus, the difference in rates of MetS is mainly explained by potentially modifiable risk factors. More studies are needed to see if targeting these risk factors may improve cardiovascular disease related morbidity and mortality in PsA.

2635

The Prevalence and Risk Factors of Atlantoaxial Subluxation in Ankylosing Spondylitis. Ji-Seon Lee, Jae Hoon Kim, Jinju Kim, Joo-Hyun Lee and Tae-Hwan Kim. Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

Background/Purpose: Ankylosing spondylitis (AS) is a chronic rheumatic disorder characterized primarily by inflammation of the sacroiliac joint and spine. Cervical spine is also vulnerable the disease process, but atlantoaxial subluxation (AAS) have been considered as uncommon feature of AS, despite of several case reports, while frequent and important complication in rheumatoid arthritis (RA). This study aims at assessing the prevalence and risk factors of AAS developing in AS patients.

Methods: Total 819 patients, who fulfilled the modified New York criteria and examined with full-flexion lateral view of cervical spine x-ray, were enrolled from the outpatient clinic of Hanyang University Hospital for Rheumatic Diseases in Korea. The patients were retrospectively reviewed medical records and investigated distance between posterior aspect of atlas and anterior aspect of dens process of axis in lateral flexion view of C-spine x-ray by single subspecialty-trained radiologist with musculoskeletal experiences. In this study, we defined the AAS as an anterior atlanto-dental interval (AADI) of greater than 3 mm, and the significant progression as a progression rate of greater than 0.5mm/yr.

Results: C-spine x-ray was followed at with symptoms or routinely, a mean of 2.1 times. The AAS was revealed in 17.3% (142/819 patients) and diagnosed at mean 4.4 (± 0.4) years after diagnosis of AS, but already existed in 30.9% (44/142 patients) at diagnosis of AS. The AADI was on significant progression in 4.4% (13/297 patients) of negative AAS and in 22.1% (23/104 patients) of positive AAS (p-value=0.000), and one patient underwent operation for management of c-spinal instability with neurologic problems. As multiple logistic regression analysis, the AAS was significantly associated with AS duration (OR 1.081, 95% CI 1.036–1.128), peripheral arthritis (OR 2.030, 95% CI 1.338–3.081), uveitis (OR 1.514, 95% CI 1.022–2.394), and the usage of TNF-a antagonists (OR 2.195, 95% CI 1.447–3.330). The earlier development of AAS was associated with the younger age of diagnosis of AS (OR 1.054, 95% CI 1.005–1.106), but AS than JAS (OR 6.137, 95% CI 2.391–15.754).

Table 1. Prevalence of atlantoaxial subluxation (AAS) according to disease duration of AS

Disease duration (year)	no AAS (%)	AAS (%)
At diagnosis of AS	775 (94.6)	44 (5.4)
0–4.9*	465 (83.0)	95 (17.0)
5–9.9	133 (86.4)	21 (13.6)
10–14.9	61 (80.3)	15 (19.7)
15–19.9	16 (64.0)	9 (36.0)
>20	2 (50.0)	2 (50.0)
Total	677 (82.7)	142 (17.3)

* includng the patients with AAS at diagnosis of AS

Conclusion: AAS is more frequently complicated than we have thought during clinical course in AS. And the risk factors were revealed as the younger age at diagnosis, longer disease duration, presence of extra-axial symptoms, such as peripheral arthritis and uveitis, and severe disease activity, suggested the usage of TNF-a antagonists. So the clinician should consider the AAS during the course of AS, especially in case of having risk factors.

2636

Influence of Immunogenicity on the Efficacy of Long-term Treatment with Infliximab in Spondyloarthritis. Chamaida Plasencia[1], Dora Pascual-Salcedo[1], Maria Gema Bonilla[1], Laura Nuño[1], Ainhoa Ruiz[2], Emilio Martin-Mola[1] and Alejandro Balsa[1]. [1]La Paz University Hospital, Madrid, Spain, [2]PROTEOMIKA RESEARCH, Bilbao, Spain

Background/Purpose: Infliximab (IFX) is a quimeric monoclonal antibody against tumour necrosis factor (TNF) which has been shown to be very effective in the treatment of patients with Spondyloarthritis (SpA). Several studies have observed that some initially responder patients lose responsiveness or develop infusion reactions which might be related to the presence of antibodies against the drug. Our aim was to investigate the clinical relevance of the formation of anti-infliximab antibodies (anti-IFX Abs) in patients with SpA undergoing IFX treatment over a prolonged period of time

Methods: We studied 94 patients with SpA (50 Ankylosing Spondylitis, 12 Undifferenciated SpA, 22 Psoriatic Arthritis and 10 SpA associated with inflammatory bowel disease) treated with IFX from 1999–2010. Clinical characteristics, serum trough IFX levels and the presence of anti-IFX Abs were evaluated for a median of 4.45 (interval 0.4–10.2) years. Clinical activity was measured by Ankylosing Spondylitis Disease Activity Score (ASDAS) criteria: inactive <1,3; moderate ≥1,3-<2,1; high ≥2,1-≤3,5 and very high >3,5 at 3 time points (6 months, 12 months and > 4 years). We considered a clinically important improvement when ΔASDAS≥1.1.The levels of IFX and anti-IFX Abs were measured by ELISA. The survival of treatment was evaluated in relation to the presence or absence of anti-IFX Abs.

Results: Antibodies against IFX were detected in 24 (25.5%) patients. Patients with anti-IFX Abs had lower clinical improvement measured by ASDAS (0.48 ± 0.73 vs 1.4 ± 1.6 p=0.029 at 6 months; 0.81 ± 1.2 vs 1.56 ± 1.6 p=0.1 at 1 year; 0.45 ± 0.82 vs 1.43 ± 1.25 p=0.022 at > 4 years). Most patients with anti IFX Abs had high or very high activity (83% vs 30.8%; p=0.001 at 6 months, 50% vs 20%; p=0.091 at 1 year and 82% vs 24.4%; p=0.001 at > 4 years). Eleven patients (12%) developed infusion related reactions, in 8 (73%) anti-IFX Abs were present. Patients with infusion related reactions had higher titers of anti-IFX Ab (Mdn 12931, IQR 853–82437 vs Mdn 2454, IQR 449–7718 p=0,028). Patients with anti-IFX Ab had shorter survival on IFX treatment (4.25 years vs. 8.19 years, p<0.001). In 27 patients, IFX treatment was discontinued and anti-IFX Abs were present in most patients [18 (67%) vs 9 (33%), p=0.001]. In 19 patients the IFX dosing interval was reduced due to insufficient efficacy, 9/ 24 (37.5%) had anti-IFX Abs vs 10/70 (14.3%) without anti-IFX Abs, p=0.019.

Conclusion: In patients with SpA treated with IFX, the formation of anti-IFX Abs is associated with a poor clinical response, the appearance of infusion reactions and with the discontinuation of treatment. Anti-IFX Abs monitoring is useful in the assessment of the ongoing efficacy of the therapy.

The Effect of DMARD Co-Therapy on Anti-TNF Drug Retention in 1630 Spondyloarthritis Patients. Michael J. Nissen[1], Adrian Ciurea[2], Burkhard Moller[3], Juerg Bernhard[4], Ruediger Mueller[5], Bettina Weiss[6], Giorgio Tamborrini[7], Almut Scherer[8], Cem Gabay[1] and Axel Finckh[1]. [1]Geneva University Hospital, Geneva, Switzerland, [2]Department of Rheumatology, University Hospital, Zurich, Switzerland, [3]Inselspital University Hospital, Bern, Switzerland, [4]Buergerspital, Solothurn, Switzerland, [5]Cantonal Hospital, St. Gallen, Switzerland, [6]Balgrist University Hospital, Zurich, Switzerland, [7]University Hospital, Zurich, Switzerland, [8]SCQM Foundation, Zurich, Switzerland

Background/Purpose: Current recommendations suggest little role for DMARDs as co-therapy with anti-TNF (aTNF) agents in patients with spondyloarthritis (SpA), although many physicians prescribe this combination. The benefit of co-therapy in SpA patients, related to the disease manifestations and type of aTNF is unclear. Our aim was to investigate the impact of concomitant therapy with DMARDs on aTNF drug retention (DR) in 3 prospective SpA registries.

Methods: All patients in the 'Swiss Clinical Quality Management' (SCQM) registries with suspected axial spondyloarthritis (aSpA), psoriatic arthritis (PsA) or undifferentiated SpA (uSpA) as diagnosed by board-certified Rheumatologists were included, provided that they had been treated with ≥ 1 aTNF. Sensitivity analyses with the different classification criteria were performed. Anti-TNF DR was analyzed using Cox proportional hazard regression with adjustments for potential confounders (age, sex, disease duration, education level, disease activity and concomitant medications). Andersen-Gill Cox models were utilized to account for multiple aTNF discontinuations in the same patient.

Results: 1630 patients (1060 aSpA, 535 PsA and 35 uSpA) with a mean age of 44 years (+/− 12.1) and a median follow-up of 3.2 years [IQR 1.7–4.5] were included, with a total of 2158 aTNF treatment courses. 68.9% were treated with aTNF monotherapy and 31.1% with co-therapy. 58% of patients with suspected aSpA satisfied either the "modified New York" or "ASAS axial" criteria. Adalimumab (ADA), etanercept (ETN) and infliximab (IFX) were prescribed in 37.3%, 33.7% and 29.1% of patients respectively. The DMARDs utilized were methotrexate in 72.0%, sulfasalazine in 20.9% and leflunomide in 14.0%. Co-therapy patients were older and less likely to be HLA-B27 positive or to exhibit pure axial manifestations (see table). In unadjusted analyses of the first aTNF, the median DR was 2.8 years [IQR 0.9–8.4], with no significant differences between the aTNF monotherapy group and the co-therapy group (hazard ratio (HR) 1.04, 95% CI: 0.87–1.24). Similarly, in multivariate adjusted analyses, no benefit of DMARD co-therapy on aTNF DR was demonstrated (HR 1.06, 95% CI: 0.90–1.24). Predictors for longer DR were male sex (0.79, p=0.003) and longer disease duration (0.98, p<0.001), and for shorter DR, lower BASDAI at baseline (1.20, p<0.001) and prior aTNF use (1.60, p<0.001). There was no effect modification by type of aTNF (ADA vs. ETN vs. IFX) or by clinical manifestations (axial vs. peripheral vs. mixed involvement).

Baseline characteristics	Monotherapy (n=1123)	Co-therapy (n=507)	p-value
Age (years)	43.2 (42.5-44.0)	45.9 (44.9-46.9)	<0.0001
Sex (%, male)	59.8	56.0	0.15
Weight (kg)	74.6 (73.7-75.5)	75.0 (73.5-76.4)	0.31
Disease duration (median, years) [p25, p75]	8.4 [3.5-17.0]	8.3 [3.2-14.4]	0.16
HLA-B27 (% positive)	65.9	52.4	<0.0001
University level education (%)	31.3	32.1	0.75
BASDAI	4.9 (1.9-4.8)	4.8 (1.5-4.7)	0.41
BASFI	3.7 (3.6-3.8)	3.8 (3.7-4.0)	0.17
Pure axial disease (%)	57.3	40.2	<0.0001
Pure peripheral disease (%)	5.3	12.6	<0.0001
Mixed axial and peripheral disease (%)	26.4	24.5	0.42
Axial Spondyloarthritis (%)	73.7	45.8	<0.0001
Psoriatic Arthritis (%)	24.9	50.3	<0.0001
Undifferentiated Spondyloarthritis (%)	1.4	3.9	0.001
Infliximab (%)	26.7	34.5	0.001
Adalimumab (%)	37.4	37.1	0.90
Etanercept (%)	36.1	28.4	0.002

Conclusion: This study supports current recommendations that co-therapy with DMARDs is of no additional benefit compared with aTNF monotherapy in SpA patients. Higher rates of aTNF DR were seen in males and in patients with longer disease duration and lower baseline disease activity. There were no significant differences in aTNF survival between the different aTNF agents.

2638

Association Between Axial Pain Site and Site of MRI Inflammatory Lesions or Structural Change in Patients with Early Inflammatory Back Pain: The DESIR Cohort Study. Bertrand Coutanceau[1], Florence canoui-Poitrine[1], Maxime Dougados[2], Martin Blachier[1], Sylvie bastuji-Garin[1], Alain Saraux[3] and Pascal Claudepierre[4]. [1]Université Paris Est, Laboratoire d'Investigation Clinique (LIC) EA 4393, AP-HP, Hôpital Henri-Mondor, Service de Santé Publique, Créteil, France, [2]Paris-Descartes University, Medicine Faculty; UPRES EA-4058; APHP, Cochin Hospital, Paris, France, [3]CHU de la Cavale Blanche, Brest Cedex, France, [4]Université Paris Est, Laboratoire d'Investigation Clinique (LIC) EA 4393, AP-HP, Hôpital Henri-Mondor, Rheumatology department, Creteil, France

Background/Purpose: Although the role of axial MRI has appeared as major in the diagnosis of recent axial spondyloarthritis, it is still unknown which MRI view (spine or sacro-iliac joints (SIJ)) is the most informative and whether it can be guided by the site of the symptoms. The objective was to assess whether site of pain (dorsal, lumbar or buttock) is associated with inflammatory or structural lesions at MRI in patients with recent inflammatory back pain (IBP).

Methods: We conducted a cross sectional analysis among patients included in the DESIR cohort study (n=708), with baseline data. Inclusion criteria were age under 50 years old and IBP for more than 3 months and less than 3 years. For each axial level (e.g. buttock, lumbar, dorsal) the following data were collected: a) pain (past or current) and site (dorsal, lumbar and/or buttock) b) any sign of damage on SIJ or lumbar X-rays ("lumbar" mSASSS>1) c) MRI structural lesions defined by at least one syndesmophyte on one disco vertebral unit at the spine level, d) MRI inflammatory lesion (scored as normal, doubtful and abnormal; doubtful being pooled with abnormal). The endpoints were presence of inflammatory lesions or structural changes at the dorsal, lumbar or SIJ MRI. For each level, an association between site of pain and the endpoints were analyzed using univariate and multivariate logistic regressions, separately in the patients with and without structural damage at X-rays (at any site). Odds Ratios (OR) were adjusted for sites of pain and significantly associated mediating or confounding factors among baseline characteristics (age, sex, HLA B27 status, hs-CRP).

Results: At baseline, among 635 patients with complete data, mean age was 34 (±9) years, 52.6% were women, 60% were B27 positive, 62.3% had dorsal pain, 91.8% lumbar pain, and 79.6% buttock pain (82% had at least two sites of pain). Among patients with SIJ or lumbar X-rays lesions (n=341, 53.7%), 26.3%, 27.6% and 64.2% had MRI inflammatory lesions located respectively in dorsal, lumbar and SIJ sites. For each level, pain was associated with inflammatory lesions only at the corresponding site (Dorsal site: adjusted Odds ratios (aOR) $_{\text{dorsal pain}}$= 2.23; 95% CI: 1.26–3.93; lumbar site: (aOR) $_{\text{lumbar pain}}$= 2.59; 95% CI:0.85–7.86; p = 0.09; SIJ site: (aOR) $_{\text{buttock pain}}$= 3.58; 95% CI:1.89–6.76; p<0.001) after full adjustment. Among patients without lesions at SIJ and lumbar X-rays (n=294; 46.3%), 11.3%, 14.6% and 25.8% had MRI inflammatory lesions located respectively in dorsal, lumbar and SI joints. No significant association was found between pain at any site and MRI inflammatory lesions. For all patients, 9%, 8% and 33% had MRI structural changes located respectively at dorsal, lumbar and SIJ sites. No association was found between axial pain and MRI structural change at any level in the entire population except between buttock pain and SIJ lesions (OR)$_{\text{buttock pain}}$= 1.89; 95% CI:1.22–2.90; p=0.004).

Conclusion: These results suggest that site of pain (dorsal, lumbar or buttock) is associated with MRI inflammatory lesion at the same level, only in patients with already X-rays structural change.

Is Dietary Intake of Patients with Systemic Lupus Erythematosus Adequate? Ellie Aghdassi[1], Ladan Yeganeh[1], Amaris K. Balitsky[2], Stacey Morrison[3], Michael Frattasi[3], Jiandong Su[3], David WL. Ma[4] and Paul R. Fortin[5]. [1]University Health Network, Toronto, ON, [2]The University of Toronto, Toronto, ON, [3]The Toronto Western Hospital, Toronto, ON, [4]University Of Guelph, Guelph, ON, [5]Toronto Western Hospital, Toronto, ON

Background/Purpose: To compare the dietary intake of women with systemic lupus erythematosus (SLE) to the Dietary Reference Intake (DRI) established for North American women by the World Health Organization (WHO). DRI has 4 sets of nutrient standards: 1. Estimated Average Requirements (EAR) are average nutrients requirement for a population group, 2. Recommended Dietary Allowance (RDA) is based on EAR + 2 SD that would meet the needs of 97% of people in a particular population, 3. Adequate Intake (AI) is based on information about average intake of the nutrient by a healthy group of people when there is not enough information available to estimate RDA and, 4. Tolerable Upper Intake Level is the highest intake of a nutrient that does not pose a threat to health for most people. EAR is particularly appropriate for planning and assessing intakes for groups of persons while RDA and AI are both used to plan healthful diets for individuals.

Methods: Women (n=147) meeting the ACR classification criteria for SLE who attend the University of Toronto Lupus Clinic were enrolled in this study. Demographics, anthropometric measurements, SLE duration, SLE-Disease Activity Index-2000 (SLEDAI) and SLICC (Systemic Lupus International Collaboration Clinic)-Damage Index (SDI) were documented. We used a 24-hour diet recall to assess the dietary intake. Diet composition was determined using ESHA nutrient analysis software program. The adequacy of nutrients intake were determined using the EAR which is the estimated median requirement of the healthy individuals in a particular life stage and gender group.

Results: Demographic, anthropometric and disease related data for the study subjects were as following (mean (SD)): age: 47.5 (13.1) years, BMI: 25.6 (6.9) kg/m^2, waist circumference: 81.7 (14.8) cm, disease duration: 19.1 (12.0) years, SLEDAI: 2.8 (3.6), SDI: 1.9 (1.9), 55.1% were Caucasian, 32% had some post-secondary education, 60.5% were postmenopausal and 10.9% were smokers. The mean (SD) daily energy intake was 1658 (691) kcal and 10.9% of the patients had energy intake above the recommended level of 2403 kcal/day for women age 19–70 years of age. Percentage of energy from fat, saturated fat, protein and carbohydrate were 34.1% (27.0), 9.5% (7.3), 17.3% (6.1), and 54.2% (28.0), respectively. Although these mean values were close to the recommendations, 57.5% and 32.3% had fat and saturated fat intake exceeding the recommended levels (< 30% and <10% of caloric intake), 21.8% had protein intake below the EAR of 0.66 g/kg; and 32.5% of subjects had cholesterol intake more than the recommended 300 mg/d. More than 40% of the subjects had suboptimal intake of vitamins B1, B2, B3, B6, B12, C and selenium. Intakes of omega-3 fatty acids, calcium, magnesium, vitamins E and D were inadequate in more than 80% of the patients. Calcium, vitamin D, multivitamin and omega-3 supplements were used only by 68.7%, 85.7%, 42.9% and 21.8%, respectively.

Conclusion: Despite having a normal/high BMI, women with SLE do not meet the recommended levels of intake for protein and many of the micronutrients. Vitamin/mineral supplementation may be required for all SLE patients in order to meet the daily nutritional requirements of this patient population.

Physical Activity, Body Composition, and Cognitive Impairment Among Women with Systemic Lupus Erythematosus. Patricia P. Katz[1], Laura J. Julian[1], Jinoos Yazdany[1], Holly Wing[2], Sandi Kaplan[2], Laura Trupin[3], Lindsey A. Criswell[1] and Edward Yelin[1]. [1]University of California San Francisco, San Francisco, CA, [2]University of California, San Francisco, CA, [3]UC San Francisco, San Francisco, CA

Background/Purpose: Cognitive dysfunction is frequently present in SLE. There is growing attention to the role of both obesity and physical inactivity in cognitive impairment and decline in the general population. While obesity and physical inactivity are common in SLE, neither of these factors has been examined in relation to cognitive impairment in SLE. This analysis examined the relationship of obesity and physical activity to cognitive impairment in women with SLE.

Methods: Data were collected from an in-person visit conducted at the Clinical and Translational Science Institute's Clinical Research Center (CRC). Subjects (n=138 women) were drawn from participants in the longitudinal Lupus Outcomes Study, who lived in proximity to the clinical site. Body composition was measured with dual-energy x-ray absorptiometry (DXA). Obesity was defined by DXA % body fat based on age, sex, and race criteria. Physical activity was ascertained by self-report using the International Physical Activity Questionnaire (IPAQ); inactivity was defined as expenditure of ≤600 metabolic equivalent (MET)/minutes per week. Cognitive function was measured with a 12-index neuropsychological battery modified from the ACR recommended one-hour battery for cognitive assessment in SLE. Impairment was defined as age-adjusted z-scores ≤1.5 standard deviations below mean on 1/3 of tests completed. Scores were obtained for the total battery and for memory and executive function components. Multivariate analyses examined the relationship of obesity and physical activity, individually and combined, with cognitive impairment, controlling for education, race/ethnicity, disease activity, and depression.

Results: 50% of women were obese, 28% were inactive, and 14% of subjects were cognitively impaired on the total battery. Memory impairment was present in 28%; impairment in executive function was present in 10%. Women who were cognitively impaired on the total battery were more likely to be obese (79.0% vs. 45% of not impaired, p=.01) and inactive (47 % vs. 25%, p=.05). Considering the executive function portion of the cognitive battery, differences between impaired and non-impaired women in the prevalence of obesity (92% vs. 46%, p=.002) and inactivity (69 % vs. 24%, p=.001) were greater. Memory impairment was not associated with obesity or inactivity. Controlling for covariates, both inactivity and DXA-defined obesity were significantly associated with impairment on executive function battery (Inactivity: OR=7.0 [1.5, 34.1]; Obesity: 12.6 [1.4, 115.7]).

Conclusion: Both obesity and inactivity were significantly associated with impairment in cognitive function. If longitudinal studies show that physical inactivity and obesity are precursors to cognitive impairment, these may offer potent targets for intervention.

This research was supported by NIH/NIAMS grant P60 AR053308 and by NIH/NCRR UCSF-CTSI Grant Number UL1 RR024131.

Objective Measurement of Levels of Physical Activity in Rheumatoid Arthritis. Marie Tierney[1], Alexander D. Fraser[2] and Norelee M. Kennedy[1]. [1]University of Limerick, Limerick, Ireland, [2]Mid Western Regional Hospital, Co. Limerick, Ireland

Background/Purpose: Regular physical activity is encouraged to allow for improvements in various dimensions of health. However, in order to assess if physical activity has positive health benefits, it is necessary to measure the quantity of physical activity occurring. To date, it has been difficult to accurately ascertain the physical activity levels of individuals with Rheumatoid Arthritis (RA) due to the use of subjective measures and measures that were not validated for the population in previously conducted studies. Sensewear Armband (SWA) is an objective outcome measure of physical activity which has been validated for use to measure energy expenditure in the RA population. The aim of this study is to assess the level of physical activity in the RA population over a one week period.

Methods: All subjects recruited had a confirmed diagnosis of RA in conjunction with American College of Rheumatology (ACR) criteria, were ambulatory independently or with assistance of one unilateral aid, were over 18 years of age and were not pregnant. Patients were recruited from the rheumatology outpatients' clinic of the Mid-Western Regional Hospitals, Limerick, Ireland. Each subject provided written informed consent and was provided with a SWA which was worn on the right upper arm for 1 week. Descriptive statistics were used to analyse the results.

Results: 29 subjects (16 female, 13 male) were included in this study. All results are defined as mean±standard deviation. The age of the recruited subjects was 59.61±9.4 years while self reported disease duration was 8.72±8.45 years.

Outcome	Energy Expenditure kJ ± SD
Average weekly energy expenditure	65098.86 ± 12095.94
Average daily energy expenditure	9301.03 ± 1727.99
Average weekday (Monday-Friday) energy expenditure	9384.71 ± 1832.59
Average weekend (Saturday and Sunday) energy expenditure	9087.65 ± 1602.47
Average male weekly energy expenditure	69027.63 ± 12907.64
Average female weekly energy expenditure	61902.28 ± 10748.70
Average weekly energy expenditure (65 years) (n = 8)	61044.56 ± 6292.74
Average weekly energy expenditure (55-65 years) (n = 13)	66002.60 ± 14556.14
Average weekly energy expenditure (<55 years) (n = 8)	67676.20 ± 12426.48
Average weekly energy expenditure (employed) (n = 7)	67454.45 ± 12459.95
Average weekly energy expenditure (not employed) (n = 22)	64345.74 ± 12175.44

Conclusion: This is the first study to assess the level of physical activity of the RA population with regard to energy expenditure using a validated objective tool. This study highlights some interesting differences between varying demographic characteristics of the RA population and provides a method by which accurate comparison between the RA and non-RA population could be applied.

Influence of Lifecourse Social Position on Rheumatoid Arthritis Disease Severity in African Americans. Rebecca J. Cleveland[1], Todd A. Schwartz[1], Beth L. Jonas[1], Graciela S. Alarcon[2], Richard Brasington[3], Doyt L. Conn[4], Edwin A. Smith[5], George Howard[2], Larry W. Moreland[6], S. Louis Bridges Jr.[7] and Leigh F. Callahan[1]. [1]University of North Carolina, Chapel Hill, NC, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Washington Univ School of Med, St. Louis, MO, [4]Emory Univ School of Medicine, Atlanta, GA, [5]Med Univ of South Carolina, Charleston, SC, [6]University of Pittsburgh, Pittsburgh, PA, [7]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Current social position (SP), defined as individual level socioeconomic status, has been shown to be associated with poorer rheumatoid arthritis (RA) outcomes in whites, although it is less established in African Americans (AA). Associations between childhood SP and health have often been independent of adult SP, however this has not been evaluated for RA outcomes in whites or AA. We examined whether there are independent associations between SP over the lifecourse (current adult and childhood SP) with RA severity and patient reported outcomes (PROs).

Methods: We conducted a cross-sectional analysis of 371 AA individuals with RA who were part of a consortium of 5 medical centers in the southeastern US. Childhood SP was defined as the SP of their caregivers. Participants reported on their own and their childhood caregivers' SP, including educational attainment (≤ high school [HS] diploma, or >HS), occupation (OCC) (professional or non), and homeownership (yes or no). Outcomes included joint severity (tenderness, swelling and malalignment); radiographs (erosion, JSN score); laboratory measures (C-reactive protein [CRP] levels, rheumatoid factor [RF] isotype IgM [RFIgM] or RFIgA, and anti-cyclic citrullinated protein antibodies [anti-CCP]); and PROs (HAQ, pain and fatigue visual analog scales [VAS], helplessness Rheumatology Attitudes Index [RAI], and counts of poor physical, poor mental, and limited activity days). Covariates included gender, age, RA disease duration, clinical comorbidity index, current Methotrexate/Leflunomide and biologic agent use. Adjusted bivariate analyses were performed to examine mean values of RA severity markers and PROs according to measures of adult and childhood SP. Adjusted regression models were conducted on all SP measures to determine associations with RA severity and PROs.

Results: Participants' mean age was 56 years, RA duration was 137 months, and they generally had higher SP measures as adults than during childhood, where 53% of participants had >HS compared to only 16% of caregivers ($P<0.001$), and 49% had a professional OCC compared to 15% of caregivers ($P<0.01$). However, more participants' caregivers were homeowners than participants (57% vs. 46%, $P<0.05$). 11.9% had high lifecourse SP (both adult and childhood), 37.5% had current high/childhood low SP, 6.7% had childhood high/current low SP and 43.9% had low lifecourse SP. Mean fatigue VAS was significantly higher for participants' whose caregivers were non-homeowners or had ≤HS, as was physically unhealthy days. In regression models mutually adjusting for adult and childhood SP, significant associations were observed for low childhood SP for fatigue VAS (β=-1.0; 95% CI=−1.9, −0.1); however low adult SP appeared to have stronger independent associations with most measures of radiographs, lab values, HAQ, RAI and pain VAS. When compared to subjects with high lifecourse SP, those with low adult SP generally had poorer RA outcomes, regardless of childhood SP.

Conclusion: Although low childhood SP was associated with poorer values for some RA outcomes, low current adult SP appears to be a stronger independent predictor for most RA disease severity measures and PROs.

2643

Hypothyroidism and Risk of Adhesive Capsulitis in the General Population. Uyen Sa D. Nguyen[1], Hyon K. Choi[1], Christine Peloquin[1], Young Hee Rho[2], Yanyan Zhu[1], Daniel K. White[1], Jingbo Niu[1] and Yuqing Zhang[1]. [1]Boston University School of Medicine, Boston, MA, [2]Vanderbilt Medical Center, Nashville, TN

Background/Purpose: Adhesive capsulitis (AC) is a chronic shoulder condition that commonly causes pain and loss of range of motion, and can interfere with activities of daily living. Hypothyroidism is thought to be associated with AC. However, such an assumption was mainly based on case reports. One case-control study of treated hypothyroidism and idiopathic frozen shoulder had small sample size (n=224) and did not control for major potential confounders such as diabetes or cardiovascular diseases (OR=0.7 (95% CI: 0.1 to 10.1) in men; OR=1.9 (95% CI: 0.9 to 4.3) in women). We examined the association between hypothyroidism and incident AC in the general population, adjusting for key confounders.

Methods: We performed a matched case-control study nested within the Health Improvement Network (a UK general population database), an electronic medical record database of 7.3 million participants from 1990 to 2010 at 477 general practices in the UK. We defined an incident case as a person >40 years of age with first diagnosis of AC after at least one year of enrollment into the THIN database. We paired each case with a control that did not have AC at the time of the case diagnosis (i.e., index date), matching on sex, age, and year of enrollment. Hypothyroidism was present if there was a diagnosis by the general practitioner and at least one prescription for thyroid drugs prior to the index date. We used conditional logistic regression to adjust for potential confounders including diabetes, hypertension, myocardial infarction and cardiovascular disease assessed prior to hypothyroidism. We also conducted stratified analyses by sex and by age (< 65 vs. ≥ 65) to determine whether the relation between hypothyroidism and incident AC vary by these factors.

Results: There were 47,793 incident AC cases (58% women, mean age: 62 years). We found that 2.5% of cases and 2.0% of controls had hypothyroidism (crude OR=1.24, 95% CI: 1.13 to 1.35). After adjusting for potential confounders, participants with hypothyroidism had a 21% higher risk of developing incident AC than those without hypothyroidism (OR=1.21, 95% CI: 1.11 to 1.32). The magnitude of association tended to be larger among adults < 65 years old (OR=1.31, 95%CI: 1.16, 1.48) than among adults ≥ 65 years old (OR=1.11, 95%CI: 0.98 to 1.26) (p for interaction, 0.05). However, the association did not differ by gender (p for interaction, 0.66).

Conclusion: This general population study provides the first large-scale epidemiologic evidence that hypothyroidism is independently associated with the risk of incident AC. The impact may be more prominent among younger adults. Future studies should examine possible mechanisms in which hypothyroidism increased the risk for AC.

Humerus Fractures In the United States: Nationwide Emergency Department Sample, 2008. Sunny Kim[1], Robert Szabo[2] and Richard A. Marder[3]. [1]University of California Davis, Sacramento, CA, [2]University of California-Davis, Sacramento, CA, [3]University of California, Davis, CA

Background/Purpose: The objective of this study was to evaluate the epidemiology of emergency department (ED) visits due to humerus fractures in the United States (U.S.). Furthermore, we provided perspectives on future demands of ED care for humerus fractures relevant to aging baby boomers. To date, there have been no published studies on humerus fractures based on a representative sample in the U.S.

Methods: We analyzed the 2008 Nationwide Emergency Department Sample, which contained approximately 28 million ED records. We identified the cases of proximal, shaft, and distal humerus fractures.

Results: In 2008, approximately 370,000 ED visits in the U.S. were due to humerus fractures. Of those, proximal humerus fractures were the most common, accounting for 50% of humerus fractures (Figure 1). The rate of proximal humerus fractures (per 100,000 people) followed the shape of an exponential function in the ages 40–84 for women (R^2=97.9%) and 60–89 for men (R^2=98.2%) (Figure 2). After the exponential increase in these age

intervals, the growth rate of proximal humerus fractures slowed and eventually decreased (Figure 2). The number of ED visits for proximal humerus fractures in women and men aged 70 years and older were 425 and 150 (per 100,000), respectively. The next most common site of fracture was the distal humerus. The peak incidence of distal humerus fractures was in children aged 5 to 9 years (Figure 1). Although distal humerus fractures were relatively uncommon among adults, elderly women were at an elevated risk (Figure 2). The risk of shaft fractures was also increasing as people got older (Figure 2). As the baby boomer generation ages, more than 477,000 ED visits are expected due to humerus fractures in 2030 when the youngest of the baby boomers turn 65 years old.

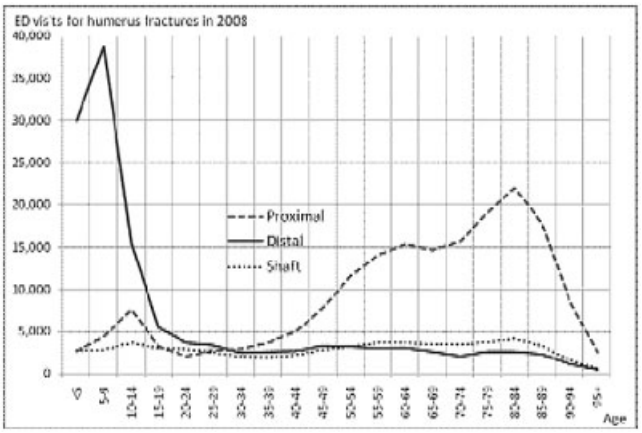

Figure 1. Number of emergency department visits due to humerus fractures in the United States.

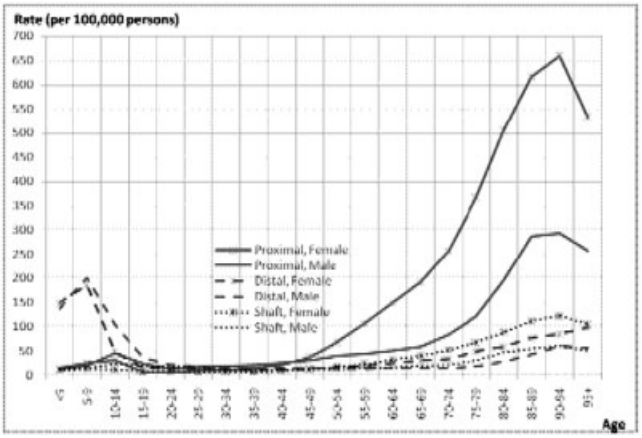

Figure 2. Rates of emergency department visits with humerus factures for every 100,000 people in each respective demographic group in the United States.

Conclusion: Compared to epidemiologic studies in other countries, the rates of proximal, distal, and shaft humerus fractures are substantially higher in the U.S. It is not clear whether Americans live in a more hazardous environment with respect to falling, or if Americans have an elevated level of osteoporosis. A recent study reported a rapid increase in total shoulder arthroplasty in the U.S. The high rate of humerus fractures in the expanding elderly population is likely to increase the demand for total shoulder arthroplasties. Rigorous safety measures to reduce falls and improved preventive treatments of osteoporosis are needed.
