ACR/ARHP 2011 Annual Scientific Meeting Overal Needs Assessment/Practice Gaps

The American College of Rheumatology and the Association of Rheumatology Health Professionals are committed to providing comprehensive education to improve the knowledge and performance of physicians, health professionals and scientists. Through evidence-based educational programs, the organization strives to enhance practice performance and improve the quality of care in those with or at risk for arthritis, rheumatic and musculoskeletal diseases. The 2011 annual meeting program has been developed independent of commercial influence. The following groups were involved in the planning process: the ACR Committee on Education; the ACR Annual Meeting Planning Committee; the ARHP Education Committee and the ARHP Annual Meeting Program Planning Committee.

The program is the result of a planning process that identified educational needs to change or enhance the knowledge, competence or performance of rheumatology professionals. The program's content was derived from both needs assessment and practice gap analysis based on professional activities, practice setting, ABIM recertification requirements and physician attributes.

PROGRAM HIGHLIGHTS

- Educational tracks to help attendees identify content targeted to them. Tracks include: business of rheumatology, clinical, clinical and research, clinical practice, educators, fellow-in-training, pediatrics, pediatrics and clinical, and research;
- Latest science and best-practices presented through peer-reviewed and selected clinical and scientific abstracts, and invited speakers providing clinical, evidence-based and quality focused content;
- Diverse formats of education delivery, including: didactic lectures, debates, and interactive sessions, such as poster tours, Meet the Professors and Workshop sessions;
- A larger forum for discussion of practical management issues such as the Curbside Consults – Ask the Professors session and Medical Aspects lectures;
- Extensive learning opportunities in the basic science of rheumatology, an area of the program developed by a subcommittee of US and internationally prominent basic scientists. Offerings include: Basic Science Symposia, State-of-the-Art Lectures, a series of Immunology Updates for the Clinicians, and a Basic Science pre-meeting course;
- Clinical management sessions, including the Thieves' Market, Curbside Consults – Ask the Professors, The Great Debate and the ACR Knowledge Bowl;
- A specific pediatric rheumatology track plus content integrated throughout the program designed to provide a high-level educational program to pediatric rheumatologists; and relevant updates to adult rheumatologists;
- Formal presentations of new practice guidelines provided to alert the membership and explain, in an open forum, the data supporting the guidelines and propose approaches for implementation;
- Over 40 workshops designed to provide hands-on skills training.

For additional details, refer to the session level learning objectives at www.rheumatology.org/annual.

About ACR/ARHP Education

The American College of Rheumatology and the Association of Rheumatology Health Professionals, a division of the ACR, are organizations of physicians, health professionals and scientists serving members through programs, including education and research. Through these programs, the ACR and the ARHP foster excellence in the care of people with rheumatic and musculoskeletal diseases. The 2011 ACR/ARHP Annual Scientific Meeting programs have been independently planned by the ACR Committee on Education, the ACR Annual Meeting Planning Committee, the ARHP Annual Meeting Program Committee, and the ARHP Clinical Focus Course Task Force.

This program is sponsored by the American College of Rheumatology for educational purposes only. The material presented is not intended to represent the only or the best methods appropriate for the medical conditions being discussed, but rather are intended to present the opinions of the authors/presenters, which may be helpful to other healthcare professionals. Attendees participating in this medical education program do so with the full knowledge that they waive any claim they may have against the ACR for reliance on any information presented during these educational activities. The ACR does not guarantee, warrant or endorse any commercial products or services.

PROGRAM OBJECTIVES

At the conclusion of the 2011 ACR/ARHP annual meeting, participants should be able to:

- identify recent developments in the diagnosis and management of patients with rheumatic diseases
- outline new technologies for the treatment of rheumatologic problems
- describe potential challenges in the delivery of care to patients with rheumatic diseases and to specify possible solutions
- utilize new research data to improve the quality of care of patients with rheumatic diseases
- summarize recent rheumatology research findings

Certificates of CME Credit or Participation

Accreditation Statement: *The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.*

Statement of Designation: *The ACR designates this live educational activity for a maximum of 47.25 AMA PRA Category 1 credits™. Physicians should claim only the credit commensurate with the extent of their participation in the activity.*

International Physicians: *International physicians who register as part of a group and require AMA PRA Category 1 Credit(s)™, must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers, and e-mail address. The information will be used to verify your meeting attendance.*

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting AMA PRA Category 1 Credit ™ to EACCME credit should contact the UEMS.

Health Professionals: *Participants may claim hours to receive a Certificate of Participation for an activity designated for AMA PRA Category 1 Credit(s)™. For non-CME sessions, attendees may also request a certificate of participation.*

Meeting Evaluations, CME Credit/ Certificates of Participation

Computers are available for you to complete your CME/Certificate of Participation application and meeting evaluation form online during the meeting. In addition, you can complete the evaluation and print your certificate after you return home.

If you are an international physician and require a Certificate of Attendance, this is enclosed in your meeting bag. If your country recognizes *AMA PRA Category 1 Credit(s)™* in accordance with *AMA PRA* requirements, please complete a meeting evaluation and CME application.

Your evaluation of the meeting is very important. The ACR/ ARHP annual meeting planning committees use feedback from attendees to assist in the development of future educational activities; therefore, we encourage you to complete your evaluation and CME/Certificate application online.

CONFLICT OF INTEREST/DISCLOSURE STATEMENTS

(See index for Authors Disclosures)

As an educational provider accredited by the Accreditation Council for Continuing Medical Education (ACCME), the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all speakers and moderators participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

None: Nothing to disclose

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part-time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Speakers, moderators and abstract authors submitted their disclosure online prior to publication. Disclosures for invited speakers are listed in the indices by presenters' last name.

Abstract author disclosures are published online and in a supplement to the October issue of *Arthritis & Rheumatism*. Disclosures for the Late-Breaking abstracts are published online and in the December issue of *Arthritis & Rheumatism*. Any individual who refuses to disclose relevant financial relationships will be disqualified from being a planning committee member, a presenter, an author of a CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

ACR DISCLOSURE POLICY

It is the policy of the American College of Rheumatology to ensure that its CME activities are independent and free of commercial bias.

To ensure content objectivity and balance, and guarantee that the content presented is in the best interest of its learners and the public, the ACR requires that everyone in a position to control content disclose all relevant financial relationships with any commercial interest if the relationship is financial and occurred within the past 12 months. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content.

COPYRIGHT MATERIALS POLICY

The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

The names, insignias, logos and acronyms of the ACR, the ARHP and the REF are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

EMBARGO POLICY

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special supplement of *Arthritis & Rheumatism*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract online.

However, the ACR continues to require that information that goes beyond that contained in the abstract, e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting, is under embargo until 5:00 PM Eastern Time on Saturday, November 5. Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate.

Authors are responsible for notifying financial and other sponsors about this policy.

ACR Poster Session A
Antiphospholipid Syndrome
Sunday, November 6, 2011, 9:00 AM–6:00 PM

1

Lupus Anticoagulant at a High-Risk Clinic: Results From a 5-Year Review of 2,169 Patients. Christine A. Clark, Karen A. Spitzer and Carl A. Laskin. University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON

Background/Purpose: The lupus anticoagulant (LAC) Is one of several antiphospholipid antibodies (aPL) that comprise laboratory criteria for the antiphospholipid syndrome (APS). From many studies of recurrent early pregnancy loss (RPL) in the context of aPL, there is a perception that LAC is prevalent in this population. We wanted to determine the distribution of LAC positivity at a large tertiary clinic that sees about 250 new patients with RPL annually in addition to those with SLE and/or APS. We also wanted to identify the most frequent clinical manifestations of APS associated with repeated LAC positivity and to establish any correlations with the number of positive LAC tests in a real world setting.

Methods: We included all patients tested in our laboratory for LAC and anticardiolipin antibodies (aCL IgG and IgM) from 2005 to 2010. We reviewed charts of patients with repeated prolonged LAC to ascertain diagnoses including histories of adverse obstetric and thrombotic events (TE). LAC were measured using a panel of 4 tests according not only to ISTH guidelines (DRVVT and PTT-LA) but also using dilute PT and KCT assays; aCL IgG and IgM were measured using INOVA kits.

Results: Over 5 years we measured 3,446 LAC for 2,169 patients (many had multiple tests). There were 370 (1.1%) positive LAC tests distributed among 138 patients; 31 were positive on only one occasion of many retests, 43 were positive with no subsequent tests, and 64 (3.2%) were positive on $\geq$ 2 occasions. Fifty-nine of 64 charts were available for review: 26 (44.1%) have APS; 19 (32.2%) have SLE/APS; 7 (11.9%) have SLE and 7 (11.9%) have other diagnoses. Twenty-two patients (37.3%) have a history of TE, 7 (11.8%) have had more than 1 TE; 13 patients (22.0%) have had a TE in the absence of a predisposing factor; 4 have had a post-partum TE (6.8%); 9 (15.2%) had a TE while on oral contraception. Twenty-four (40.7%) patients have had $\geq$ 1 stillbirth (SB); 9 (15.3%) have a history of IUGR; 6 (10.2%) had preeclampsia and/or HELLP during a pregnancy; and 3 (5.1%) have a history of early RPL only. Patients were evenly distributed among the number of positive tests in the 4-test LAC panel. There were no differences among distribution of SB, IUGR, preeclampsia or HELLP, early RPL, or live birth ever; however patients with 3 or 4 positive in the LAC panel were significantly more likely to have had a TE than those with 1 or 2 positive (54.8% *vs* 21.4% respectively, p = 0.017, 95% CI: 0.087–0.581). Neither mean values nor increased prevalence of > 40 GPL or MPL aCL IgG or IgM were significantly different among the LAC positive groups.

Conclusion: ISTH guidelines recommend using only 2-test LAC panel, but we found significantly more patients with TE were positive for $\geq$ 3 compared to one or two of the LAC panel. A history of SB was the most common clinical manifestation of repeatedly positive LAC, occurring twice as frequently as idiopathic TE. LAC was found in <3% of patients attending a tertiary clinic restricted to patients with SLE, APS and RPL, and in only 0.2% of patients referred with a history of exclusively early RPL. These findings reinforce the need to redefine APS and validate the proposition that early RPL should be excluded from the classification criteria.

2

Effect of Normal Pregnancy on the Lupus Anticoagulant: No Need to Establish Pregnancy-Specific Reference Ranges. Christine A. Clark, Karen A. Spitzer and Carl A. Laskin. University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON

Background/Purpose: The physiological basis for the hypercoagulability of pregnancy is well understood. Shortened clotting times, especially later in pregnancy, may be a result of increased Factor VIII and fibrinogen levels. Whether alterations in these coagulation and hemostatic mechanisms also result in a change in the normal ranges for the lupus anticoagulant (LAC) remains controversial. Some investigators have reported data indicating no change during pregnancy (Derksen *et al,* 1992) and yet recent ISTH guidelines suggest that specific pregnancy-related reference ranges be used when measuring the LAC during pregnancy (J Thromb Hemost 2009;7:1737–40). We wanted to determine if the LAC varies in healthy women between ante- and post-partum plasma samples.

Methods: We recruited 53 consecutive healthy pregnant women with no history of obstetric, hematologic, or autoimmune abnormalities as part of an ongoing study (PROMISSE). Non-study plasma samples were collected during pregnancy and post-partum and were analysed for the presence of LAC using a panel of 4 tests including dilute Russell's viper venom time (dRVVT), dilute prothrombin time (DPT), a lupus-anticoagulant sensitive PTT (PTT-LA), and kaolin clotting time (KCT). We compared values from samples collected between 20–27 weeks' gestation and again post partum and determined not only if there was a statistical difference between the 2 groups, but also if the values were outside previously established reference ranges from a general population sample.

Results: There was no significant difference between ante- and post-partum PTT-LA [median (range) 38.0 (29.0–56.5) vs. 39.7 (31.2–69.0 sec) respectively, p= 0.27], dRVVT [32.7 (23.3–50.0) vs. 30.8 (20.3–39.1); p = 0.07), or KCT [55.5 (35.0–90.7) vs. 54.4 (33.5–104.2); p = 0.81]. Results for dPT showed a significant decrease during pregnancy [39.0 (22.9–54.1)] compared to post-partum [44.1 (24.5 – 65.0); p < 0.001, (95% CI for the difference of means: 4.4–10.4)]. However, this pregnancy-related difference did not fall outside the non-pregnant reference range for dPT in our laboratory.

Conclusion: Normal pregnancy did not affect the dRVVT, PTT-LA or KCT. Only the dPT showed a pregnancy-related decrease, but although the difference between mean pregnant and non-pregnant clotting times was statistically significant, both pregnant and non-pregnant ranges were within the general population reference range for this assay. Our results support Derksen's earlier findings and we conclude that any changes in LAC levels in normal pregnancy, if present at all, are too small to necessitate the use of pregnancy-specific reference ranges, as suggested in the ISTH guidelines.

3

Association of IgG, IgM, and IgA Isotypes of Anticardiolipin Alone or In Combination In Prediction of Thrombosis In Systemic Lupus Erythematosus. Vinicius Domingues, Hong Fang and Michelle Petri, Johns Hopkins. University School of Medicine, Baltimore, MD

Background/Purpose: The Sydney APS Classification Criteria include medium to high titer anticardiolipin IgG or IgM. We explored the association of all anticardiolipin isotypes, singly or in combination, with thrombosis in SLE.

Methods: There were 1567 SLE patients (92% female, 55% Caucasian, 37% African-American, mean age at entry 39.6±12.9) who participated. There were 668 total thrombotic events (arteral: total 328, TIA 67, stroke 129, myocardial infarction 58, digital gangrene 31, other arterial 45; venous: total 340, DVT or PE 211, superficial 54, other venous 75). Anticardiolipin IgG, IgM, or IgA were assessed at each visit (Inova Diagnostics Inc, San Diego, CA), with cut-offs of 20 for medium positive and 40 for high positive.

Results:

Assay	OR	P-value
Venous Thrombosis		
IgG > 20 ever pos	2.26 (1.70,3.00)	<0.0001
IgG > 40 ever pos	2.34 (1.65,3.34)	<0.0001
IgM > 20 ever pos	1.32 (0.98,1.78)	0.0688
IgM > 40 ever pos	1.46 (1.01,2.11)	0.0432
IgA > 20 ever pos	2.17 (1.42,3.31)	0.0006
IgA > 40 ever pos	2.14 (1.18,3.87)	0.0176
IgG > 20 OR IgM > 20 ever pos	1.79 (1.38,2.32)	<0.0001
IgG > 40 OR IgM > 40 ever pos	1.81 (1.34,2.45)	0.0002
IgG > 20 OR IgA > 20 ever pos	2.06 (1.56,2.71)	<0.0001
IgG > 40 OR IgA > 40 ever pos	2.03 (1.44,2.87)	0.0001
Arterial Thrombosis		
IgG > 20 ever pos	1.95 (1.45,2.620	<0.0001
IgG > 40 ever pos	2.39 (1.67,3.43)	<0.0001
IgM > 20 ever pos	1.42 (1.05,1.93)	0.0264
IgM > 40 ever pos	1.68 (1.16,2.44)	0.0081
IgA > 20 ever pos	1.99 (1.28,3.09)	0.0036
IgA > 40 ever pos	2.75 (1.55,4.98)	0.0013
IgG > 20 OR IgM > 20 ever pos	1.70 (1.30,2.23)	0.0002
IgG > 40 OR IgM > 40 ever pos	1.96 (1.44,2.67)	<0.0001
IgG > 20 OR IgA > 20 ever pos	1.79 (1.34,2.39)	<0.0001
IgG > 40 OR IgA > 40 ever pos	2.49 (1.77,3.52)	<0.0001
Stroke		
IgG > 20 ever pos	1.74 (1.17,2.60)	0.0087
IgG > 40 ever pos	2.19 (1.37,3.51)	0.0025
IgM > 20 ever pos	1.34 (0.89,2.03)	0.1787
IgM > 40 ever pos	1.25 (0.74,2.11)	0.3910
IgA > 20 ever pos	1.54 (0.84,2.84)	0.1528
IgA > 40 ever pos	2.02 (0.93,4.37)	0.772
IgG > 20 OR IgM > 20 ever pos	1.53 (1.06,2.21)	0.0242
IgG > 40 OR IgM > 40 ever pos	1.70 (1.12,2.58)	0.0506
IgG > 20 OR IgA > 20 ever pos	1.51(1.02,2.24)	0.0506
IgG > 40 OR IgA > 40 ever pos	2.00 (1.26,3.17)	0.0045

Conclusion: Analysis of single isotypes found that IgG or IgA, > 20 or > 40 (but not IgM) were associated with venous thrombosis. For arterial thrombosis, all single isotypes were associated. For stroke, only IgG was

associated. Combinations of isotypes surprisingly did not add to the strength of the association nor to the statistical significance. We conclude that: 1) the association depends on whether it is venous thrombosis, arterial thrombosis, or stroke (which is important predictive information for clinicians); 2) IgA anticardiolipin should be added to the classification criteria for APS in SLE, as it performs better than IgM; and 3) combining different isotypes of anticardiolipin does not improve the association.

4

Anti-beta2 Glycoprotein I IgA in Systemic Lupus Erythematosus Versus Controls. Ana-Maria Orbai[1], Hong Fang[1], Joan T. Merrill[2], Graciela S. Alarcón[3], Caroline Gordon[4], Paul R. Fortin[5], Ian N. Bruce[6], David A. Isenberg[7], Daniel J. Wallace[8], Ola Nived[9], Gunnar K. Sturfelt[10], Rosalind Ramsey-Goldman[11], Sang-Cheol Bae[12], John G. Hanly[13], Jorge Sanchez-Guerrero[14], Ann E. Clarke[15], Cynthia Aranow[16], Susan Manzi[17], Murray B. Urowitz[18], Dafna D. Gladman[19], Kenneth C. Kalunian[20], Melissa I. Costner[21], Laurence S. Magder[22], Systemic Lupus International Collaborating Clinics (SLICC)[23] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Birmingham, Birmingham, United Kingdom, [5]Toronto Western Hospital, Toronto, ON, [6]A, Manchester, United Kingdom, [7]University College London, London WC1E 6JF, United Kingdom, [8]Cedars-Sinai/UCLA, Los Angeles, CA, [9]University Hospital, Lund, Sweden, [10]University Hospital Lund, Lund, Sweden, [11]Northwestern University Feinberg School of Medicine, Chicago, IL, [12]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [13]Dalhousie University, Halifax, NS, [14]University Health Network/Mount Sinai Hospital, Toronto, ON, [15]Research Institute of the McGill Univ. Health, Montreal, QC, [16]Feinstein Institute for Medical Research, Manhasset, NY, [17]Allegheny Singer Research Institute, Pittsburgh, PA, [18]Toronto Western Hospital and University of Toronto, Toronto, ON, [19]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [20]UCSD School of Medicine, La Jolla, CA, [21]North Dallas Dermatology Assoc, Dallas, TX, [22]University of Maryland, Baltimore, MD, [23]Chicago

Background/Purpose: Anti-beta2 glycoprotein I (GPI) is not part of the ACR classification criteria for SLE, and IgA isotypes are omitted from the classification criteria for APS. We studied the prevalence and associations of anti-beta2 glycoprotein I IgA in a large multi-center study.

Methods: The dataset consisted of 1384 patients with both anti-beta2-GPI IgA measured and a consensus physicians diagnosis (657 with SLE and 727 controls with other rheumatologic diseases). Of the 657 SLE patients, 599 (91%) were female, 394 (60%) were Caucasian, 134 (20%) were of African descent, and 76 (12%) were Asian. Their mean age (years) was 37.9±13.3. P-values were calculated based on the chi-square test (SAS Institute, Cary, NC, USA).

Results: The prevalence of anti-beta2-GPI IgA was 14% (94/657) in SLE patients and 7% (49/727) in controls (P-value<0.0001, OR=2.3 (95% CI: 1.6, 3.3)). Eleven percent (73/657) of SLE patients had anti-beta2-GPI IgA alone (no anti-beta2-GPI IgG or IgM).

Table 1. Percentage of SLE Patients with Anti-beta2-GPI IgA, by Demographic Variables

		Percentage with Anti-beta2-GPI IgA	P-value
Ethnicity	African Descent	21.6	0.019
	Caucasian	11.4	
	Asian	18.4	
	Other	11.3	
Gender	Female	14.2	0.78
	Male	15.5	
Age	≤30	20.3	0.0035
	>30	11.7	

Table 2. Percentage of SLE Patients with Various Clinical Conditions, by Anti-beta2-GPI IgA Status

ACR criteria	Anti-beta2-GPI IgA (%)	No Anti-beta2-GPI IgA (%)	P-value	Odds Ratio (95% CI)	Adjusted P-value for Race and Age
Malar Rash	52.1	43.5	0.12	1.4 (0.9, 2.2)	0.16
Discoid Rash	20.2	17.9	0.60	1.3 (0.7, 2.2)	0.42
Photosensitivity	48.9	51.0	0.71	1.0 (0.6, 1.5)	0.91
Oral Ulcers	38.3	41.6	0.55	0.9 (0.6, 1.4)	0.57
Arthritis	66.0	65.9	0.99	1.0 (0.6, 1.6)	0.93
Serositis	38.3	30.9	0.15	1.3 (0.8, 2.0)	0.33
Pleurisy	34.0	25.4	0.08	1.4 (0.9, 2.3)	0.16
Pericarditis	12.8	10.8	0.58	0.9 (0.5, 1.9)	0.86
Renal	39.4	31.1	0.11	1.1 (0.7, 1.8)	0.63
Proteinuria	37.2	30.0	0.16	1.1 (0.7, 1.8)	0.71
Urinary casts	9.6	7.1	0.40	1.1 (0.5, 2.5)	0.73
Neurologic	6.4	7.1	0.80	0.8 (0.3, 2.1)	0.72
Seizure	5.3	5.5	0.94	1.0 (0.4, 2.6)	0.92
Psychosis	3.2	2.0	0.44	1.5 (0.4, 5.8)	0.54
Hematologic lupus	61.7	49.7	0.032	1.5 (0.9, 2.4)	0.09
Leukopenia	35.1	28.4	0.19	1.2 (0.7, 1.9)	0.56
Lymphopenia	29.8	30.9	0.83	0.9 (0.6, 1.5)	0.72
Thrombocytopenia	18.1	14.0	0.30	1.2 (0.7, 2.3)	0.46
Anti-dsDNA	75.5	57.0	0.0007	2.4 (1.4, 4.1)	0.001
Anti-Smith	25.5	23.6	0.69	0.8 (0.5, 1.4)	0.51
Lupus anticoagulant	70.2	48.9	0.0001	2.4 (1.5, 3.9)	0.0003
Anticardiolipin IgG	40.4	16.2	<.0001	3.0 (1.9, 5.0)	<.0001
Anticardiolipin IgM	35.1	11.6	<.0001	4.0 (2.4, 6.7)	<.0001
Anticardiolipin IgA	8.5	0.9	<.0001	10.8 (3.2, 36.8)	0.0001
False positive RPR	9.6	3.4	0.032	3.3 (1.1, 10.1)	0.033

Table 3. Sensitivity and Specificity for SLE, based on Anti-beta2 Glycoprotein I IgA Positivity

	Sensitivity %	Specificity %
Anti-beta2-GPI IgA	14.3	93.3

Conclusion: Anti-beta2 glycoprotein I IgA was more prevalent in SLE patients (14%) than in patients with other rheumatologic diseases (7%) in this international multi-center study. It can occur as the sole isotype of anti-beta2-GPI in SLE. It was strongly associated with age, anti-dsDNA and other antiphospholipid antibodies and was highly specific for SLE. This was the rationale to include anti-beta2 glycoprotein I IgA in the new SLICC classification criteria for SLE.

5

Risk Factors for Rethrombosis In Patients with Primary Antiphospholipid Syndrome Regardless of Their Oral Anticoagulation Status. Gabriela Hernandez-Molina[1], Grissel Espericueta-Arriola[2] and Antonio R. Cabral[3]. [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico city, Mexico, [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico, Mexico

Background/Purpose: To ascertain the serological and non-serological factors for rethrombosis in patients with primary antiphospholipid syndrome (PAPS) regardless of their anticoagulation status.

Methods: We retrospectively studied patients with PAPS who had at least one thrombotic episode. Patients were excluded if they had a history of hereditary thrombophilia or SLE. We divided patients in 4 groups. **1:** Patients on oral anticoagulants (OA) that after discontinuation (self decision or medical contraindication) developed a new thrombotic event. **2:** Patients on OA that after discontinuation did not have a new thrombotic event. **3:** Patients on continuous OA that have remained thrombosis-free. **4:** Patients on OA who developed a new thrombotic event. We studied: age at time of thrombosis, time for rethrombosis, BMI, comorbidities (DM2, hypertension, dyslipidemia), pregnancies, bedridden, hormonal contraception, estrogen replacement, perioperative period, infections, tobacco use, prednisone, aspirin, immunosuppresors and INR during thrombosis. We also evaluated the frequency of aCL (IgG-IgM), anti-β_2GP-I (IgG-IgM), lupus anticoagulant (alone or combined) and persistently positive antibody titers. We used ANOVA, X^2, Student's t test and Odds Ratio (95% CI).

Results: We studied 95 patients (70 women, 74%): 32 (group 1), 25 (group 2), 29 (group 3) and 10 (group 4). Their overall mean age at time of study was 41.7 ± 14 years with a median follow-up of 4.5 years (0.3–26). Follow-up time was shorter for group 1 (2.8 years, p= 0.05) than the other groups. LA and triple markers (LA, aCL and anti-β_2GP-I) were more prevalent in group 1 than in group 2: 67 vs. 31%; OR= 4.5; 95% CI= 1.3–14.9; p= 0.01; and 57% vs. 27%; OR= 6.6; 1.7–25.2; p=0.03 respectively. These two variables remained associated with recurrence of thrombosis after comparing groups 1 & 4 with group 2: LA 62% vs. 31%, OR= 3.6; 95% CI= 1.1–11.2, p=0.03; triple marker 75% vs. 27%; OR= 8.0; 95% CI= 2.14–29.8; p= 0.04. Patients from group 2 were more frequently on aspirin than those from group 3 (62.4% vs. 31%; OR= 0.27; 95% CI= 0.08–0.84; p=0.02). We found no significant difference between the INR of our patients on oral anticoagulants (Group 3, INR= 2.7 vs. group 4= 2.3, p=0.2). Neither titers nor persistently positive antibody markers were associated with re-

thrombosis. Other studied clinical variables were not associated with recurrent thrombosis.

Conclusion: Our study showed that LA, alone or combined with aCL and anti-β_2GP-I, is a risk factor for recurrent thrombosis in patients with PAPS regardless of therapeutically effective oral anticoagulation.

6

Risk of Recurrent Stroke in Pregnancies of Patients with Antiphospholipid Syndrome and Previous Cerebral Ischemia. Rebecca Fischer-Betz, Christof Specker and Matthias Schneider. MNR-Klinik, Düsseldorf, Germany

Background/Purpose: Cerebral ischemia is one of the most prominent clinical manifestations of Antiphospholipid Syndrome (APS) and may be present with transient ischemic attacks (TIA) or stroke. There are only rare data on maternal and fetal outcome in pregnancies in women with previous cerebral ischemia.

Methods: We prospectively studied the outcome of 21 pregnancies in women with APS (10 primary and 11 secondary to SLE) and previous cerebral ischemia. 12 patients had previous transient ischemic attacks (TIAs) and 9 had stroke before pregnancy. The mean age at pregnancy was 30.5 years (± 5.08). The time between cerebral ischemia and pregnancy ranged from 14–182 months (median 70 months). All patients received treatment with aspirin 100 mg daily. 17 patients received low molecular weight heparin (LMWH). 4 patients were treated with warfarin before pregnancy and switched to therapeutic doses of LMWH.

Results: There were 18 live births (85.7 %) and 3 (14.3 %) pregnancy losses (1 at 10 weeks, 1 at 22 and 1 at 24 weeks). All together, 7/21 (33.3 %) women developed preeclampsia. 12/18 (66.6 %) deliveries were preterm (mean weeks of gestation 36.1 ± 2.27). 88.2 % underwent ceasarean section. The mean birth weight of the life born children was 2871 (± 563) g. One female child was born with a nasal hypoplasia. 1 patient who switched from warfarin to heparin presented with TIA during her 34th week of pregnancy, despite this, she had a normal pregnancy. 1 pregnancy was complicated by a further cerebral ischemic event at 3 weeks postpartum in a patient who unintentionally discontinued her aspirin medication while she was breast feeding. 1 woman developed a third ischemic event 1 year post partum despite continuous treatment.

Conclusion: Our data suggest that successful pregnancy and delivery is possible in APS patients with a history of cerebral ischemia. Despite the treatment with low-dose aspirin and anticoagulants there is a high risk for preterm deliveries and preeclampsia, but the risk for a recurrent cerebral event seems to be low. A previous episode of cerebral ischemia therefore may not be an absolute contraindication for an APS patient to become pregnant.

7

Utility of the Systemic Lupus International Collaborating Clinics (SLICC)/American College of Rheumatology (ACR) Damage Index for Antiphospholipid Antibody (aPL) Positive Patients. Medha Barbhaiya[1], Doruk Erkan[2], Esther Rodriguez-Almaraz[3], Glendalee Ramon[4], JoAnn Vega[4] and Michael D. Lockshin[4]. [1]Weill Cornell Medical Center, New York, NY, [2]Barbara Volcker Center for Women and Rheumatic Diseases, Hospital for Special Surgery, New York, NY, [3]Hospital "12 de Octubre", Madrid, Spain, [4]Barbara Volcker Center for Women and Rheumatic Diseases: Hospital for Special Surgery, New York, NY

Background/Purpose: SLICC/ACR Damage Index (DI) was designed and validated for systemic lupus erythematosus (SLE) patients to capture non-reversible organ damage, not related to active inflammation, lasting at least 6 months. Although aPL-positive patients with or without SLE develop aPL-related organ damage, no DI exists specific for these patients. The purpose of this pilot study was to assess the utility of SLICC/ACR DI in aPL-positive patients.

Methods: We identified two groups of persistently aPL-positive patients (positive LA test, aCL IgG/M/A ≥ 20U, and/or aβ_2GPI IgG/M/A ≥ 20U at least 12 weeks apart) from our aPL-registry: those without other systemic autoimmune diseases (SAIDx) and those only with SLE. All patients are assessed by SLICC/ACR DI and ACR SLE Classification Criteria (CC) at the registry entry. For the purpose of this study, we descriptively analyzed the limitations of SLICC/ACR DI use in aPL-positive patients. We grouped patients as (A) *aPL* only (no history of thrombosis, no SLE), (B) *aPL* with SLE-like Disease (ACR_SLE_CC=3/11), (C) *aPL* with SLE (ACR_SLE_CC>3/11), (D) *APS* (history of thrombosis, no SLE); (E) *APS* with SLE-like Disease, and (F) *APS* with SLE. We used One-Way ANOVA test with Games-Howell post hoc analysis to compare the mean SLICC/ACR DI scores between six groups.

Results: Of 51 patients (mean age at the time of the registry entry 39.5 ± 13.6), 73% were female and 86% were Caucasian. Top two limitations of SLICC/ACR DI use in aPL-positive patients were: a) not being able to record aPL-related "damage" (livedo reticularis/racemosa, adrenal infarcts requiring chronic treatment, diffuse pulmonary hemorrhage resulting in chronic symptoms, permanent inferior vena cava filter placement, multiple sclerosis-like disease, and/or white matter changes); and b) the definition of the two SLICC/ACR DI items ("venous thrombosis with swelling, ulceration, OR venous stasis for at least 6 months"; "skin ulceration [excluding thrombosis] for more than 6 months"). For the purpose of further analysis we created an experimental category for aPL-related damage assigning the above "damage" items one point each. We also scored all venous events and skin ulcers as one point. Table shows mean disease duration since the first positive aPL determination and SLICC/ACR DI using the original as well as the experimental criteria.

Patient Groups (n)**	Mean Disease Duration (y)	Mean SLICC/ACR Damage Index Score (Original)*	Mean SLICC/ACR Damage Index Score (Experimental)*
A. aPL with no SLE (7)	5.72 ± 8.00	1.29 ± 0.95	2.00 ± 1.16
B. aPL with SLE-like (5)	2.15 ± 2.18	1.80 ± 1.64	2.20 ± 2.38
C. aPL with SLE (4)	1.50 ± 0.82	1.00 ± 0.00	1.75 ± 0.96
D. APS with no SLE (19)	2.60 ± 2.81	2.32 ± 1.30	2.79 ± 1.55
E. APS with SLE-like (8)	5.57 ± 5.99	2.88 ± 2.41	3.13 ± 2.70
F. APS with SLE (8)	5.65 ± 3.50	5.50 ± 2.44	6.50 ± 2.93

* $p<0.0005$, One-Way ANOVA. ** $p<0.05$: A vs F, C vs D, C vs F for the original, and A vs F, C vs F, for the experimental SLICC/ACR DI

Conclusion: In persistently aPL-positive patients, the SLICC/ACR Damage Index: a) captures most, but not all, of aPL-related organ damage; and b) increases with additional aPL- and/or lupus-related damage. In persistently aPL-positive SLE patients, the SLICC/ACR Damage Index should be interpreted cautiously as it can overestimate lupus-related, and underestimate aPL-related damage. Our study provides a start point to modify and validate the SLICC/ACR Damage Index for aPL-positive patients.

8

Development and Initial Validation of a Chronic Damage Index in Patients with Antiphospholipid Syndrome. Mary-Carmen Amigo[1], Leonor A. Barile[2], Alberto Barragan[3], Gisela Espinosa-Cuervo[4], Mavis Goycochea[5], Laura Aline Martinez-Martinez[6], Gabriela Medina[7], Angelica Vargas[8] and Luis J. Jara-Quezada[9]. [1]ABC Medical Ctr, Mexico City, Mexico, [2]Hospital Especialidades CMN, Mexico City, Mexico, [3]México, Mexico, [4]Research Unit, Mexican College of Rheumatology, Mexico, Mexico, [5]Instituto Mexicano del Seguro Social and Research Unit, Mexican College of Rheumatology, Mexico City, Mexico, [6]Intituto Nacional de Cardiologia, Mexico, Mexico, [7]Seris/Zachila s/n La Raza, Mexico City, Mexico, [8]Instituto Nac de Cardiologia, Mexico City, Mexico, [9]Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico

Background/Purpose: The antiphospholipid syndrome (APS) is defined by the presence of venous or arterial thrombosis or recurrent pregnancy complications in association with antiphospholipid antibodies. Certain key manifestations are associated with a worse prognosis and permanent organ damage; but, at this time, there is not a comprehensive assessment of accumulative damage APS

Purpose: To describe the development and initial content, criterion and construct validity of a disease specific cumulative Damage Index in APS (DIAPS)

Methods: Phase 1 included generation for index content through an expert panel agreement, a list of items considered to reflect the damage in APS was generated in three rounds. An initial list of 60 manifestations linked with potential irreversible damage were identified by experts, then by an operative definition to report each manifestations was established; finally after independent revision by 3 clinicians experts in methodology and 3 APS experts a consensus round selected 47 items. A second phase was a cross-sectional study conducted in patients with APS diagnosis included in a multicentre electronic registry http://investigacion.colmexreuma.org.mx/saaf/index.html. The output rating was determined by the physician if each manifestation was absent (0), present but without sequel (1), or present with sequel (2). The final score was made adding the output rating reflecting the damage for domains and global index. Quality of life related to health status was evaluated with Euroqol for construct validation, considering that this analysis could reflect a good agreement among the physicians on the

assessment damage in the patients; α Cronbach and correlation with Euroqol scale were calculated with SPSS 18.0, ($p<0.05$)

Results: DIAPS was evaluated in 139 cases, female 76.4% (113), the mean of the age at diagnosis 35.5 ± 12.4 years; primary APS diagnosis in 72.6% (119), APS plus SLE in 22% (36) and APS plus Sjögren in 1.8% (3). The most common comorbidities were obesity 24.3% (36), depression 18.2% (27) and dyslipidemia 14.2% (21). The most frequent manifestations conditioning sequels were: deep venous thrombosis 26.6% (37) and ischemic stroke 11.5% (16). Blindness 5.8% (8); retinal occlusive vessel disease 4.3% (6); myocardial infarction 2.9% (4); Cardiac valve requiring replacement 1.4% (2); sequel of mesenteric thrombosis (including liver, spleen and intestine) 3.6% (5) and renal insufficiency 1.4% (2); The index has a high homogeneity (α Cronbach 0.954). Questionnaire DIAPS showed correlation with Euroqol as follow: pain (r 0.479, p 0.000), mobility (r 0.425, p 0.000), personal care (r 0.344, p 0.000), daily activities (r 0.329, p 0.000), current health status (r 0.249, p 0.003) and anxiety/depression (r 0.192, p 0.025).

Conclusion: The preliminary validation study demonstrated content, criterion and construct validity of a new physician-reported instrument of APS damage. DIAPS has a good correlation with Euroqol. Further studies have to be conducted to examine reliability and psychometric properties in extended populations. DIAPS could be a useful clinical tool and a good instrument in epidemiological and economic evaluations to measure the real impact of this severe disease.

Low Vitamin D Levels Are Common in Primary Antiphospholipid Syndrome: A Role in the Pathogenesis of the Disease? Laura Andreoli[1], Silvia Piantoni[1], Flavio Allegri[1], Pier Luigi Meroni[2] and Angela Tincani[1]. [1]Rheumatology Unit, University of Brescia, Brescia, Italy, [2]University of Milan, Milan, Italy

Background/Purpose: Low levels of vitamin D (vit.D) have been described in different systemic autoimmune diseases (SAD). *In vitro* studies and animal models have shown anti-inflammatory properties of vit.D. Therefore, hypovitaminosis D has been claimed to be involved in the pathogenesis of SAD. Primary Antiphospholipid Syndrome (PAPS) is characterized by thrombotic events and/or obstetric disease, whose pathogenesis is mediated by antiphospholipid antibodies. Differently from other SAD, PAPS patients (pts) do not usually have a full-blown disease that requires corticosteroids (and therefore the association of vit.D supplementation as osteoporosis prophylaxis), nor have particular limitations in sun exposure. These factors are relevant to vit.D levels. Thus, pts with PAPS appear to be a good model for studying hypovitaminosis D in SAD. Purpose:To assess the prevalence of hypovitaminosis D in a large cohort of PAPS (in comparison with normal population from the same geographical area) and investigate the association with clinical manifestations.

Methods: We enrolled 115 PAPS (19 m, 96 f, median age: 46 years) and 128 normal healthy donors (NHD) (55 m, 73 f, median age: 34). Vit.D levels were tested by the LIAISON® chemiluminescent immunoassay (DiaSorin, Italy), kindly provided by the manufacturer. The samples were grouped upon the season for statistical analysis.

Results: Vit.D deficiency (<10 ng/ml) was more prevalent in PAPS than NHD (17% *vs.* 5%). Seasonal variability was present in both groups (higher levels in the summer, lower levels during winter). However, median values were lower in PAPS than NHD at all time points, with the greatest difference during summertime (median: 28 vs. 40.1 ng/ml; $p<<0.01$), suggesting that PAPS pts may be somehow prevented from vit.D generation upon sun exposure. PAPS pts may receive specific instructions regarding the use of sunscreens in the presence of positive anti-nuclear antibodies (ANA). Comparing pts with positive (n=63) and negative ANA (n=40), we found comparable Vit.D levels during the summer (median: 27.7 *vs*. 28). PAPS were subdivided upon clinical features (thrombotic vs obstetric). Both groups had lower vit.D levels than NHD. Thrombotic PAPS had significantly lower levels than obstetric PAPS (median value: 20.8 *vs.* 33.3; $p<<0.01$).

Conclusion: Pts with PAPS displayed significantly lower levels of vit.D than NHD. Although these pts have limited inflammatory burden and organ involvement, rarely requiring immunosuppression, these epidemiological data make them similar to pts with SAD such as Systemic Lupus Erythematosus or Rheumatoid Arthritis. Using ANA positivity as a surrogate marker for sun exposure, we suggest that sun avoidance may not be the main reason for low vit.D levels. Hypovitaminosis D may be part of the mosaic of factors that determine autoimmunity, rather than a consequence of chronic disease and its treatment (factors that are poorly represented in PAPS). In particular, this hypothesis may be supported by the observation that pts with thrombotic PAPS, i.e. more aggressive disease, are more deficient than those with exclusive obstetric manifestations. This could fit well with a recent *in vitro* observation of anti-thrombotic properties of vit.D.

10

Thrombin Generation Indicates An Increased Risk for Thromboembolic Events in Lupus and Antiphospholipid Patients. A Prospective Cohort Study. Stephane Zuily[1], Veronique Regnault[2], Francis Guillemin[3], Pierre Kaminsky[4], Thomas Lecompte[5] and Denis Wahl[6]. [1]Vascular Medicine Unit, Vandoeuvre-Les-Nancy, France, [2]INSERM U961, Vandoeuvre, France, [3]Faculte de Medecin/BP 184, Vandoeuvre-les-Nancy, France, [4]Orphan disease Unit, Vandoeuvre, France, [5]Haematology, Vandoeuvre, [6]Nancy University Hospital and INSERM U961, Vandoeuvre-Les-Nancy, France

Background/Purpose: Predicting thrombosis in systemic lupus erythematosus (SLE) and/or antiphospholipid antibodies (aPL)-positive patients is an unsolved issue. Our objective was to perform a prospective cohort study to determine clinical and laboratory risk factors for thrombotic events including a novel thrombin generation (TG)-based activated protein C (APC) resistance assay in this population.

Methods: Ninety-two patients with SLE (n=30) and/or aPL (n=77) without anticoagulant treatment at inclusion were studied. Time to thrombotic event was determined according to clinical and laboratory variables (inherited thrombophilia, aPL profiles) and APCsr-aPL (TG-based APC sensitivity ratio: APCsr > 90th percentile of values from a control population, and persisting aPL positivity).

Results: Ninety two patients (74 women) (median age 40 years [interquartile range IQR: 29–58]) were followed-up during a median duration of 35 months (IQR: 26–62; 320 patient-years). Thrombosis during follow-up occurred in 18 patients: 4 arterial, 11 venous including 7 superficial venous thrombosis (SVT), 3 small vessel thromboses. In survival analyses, the presence of APCsr-aPL was associated with an increased risk of thrombotic events during follow-up (HR, 3.67 [95%CI, 1.31–10.31]) while the risk associated with patients positive for all aPL tests (triple positive) was not significant (HR, 2.32 [95%CI, 0.76–7.13]).

Conclusion: APC-resistance determined by thrombin generation predicts the risk for thromoembolic events in patients with antiphospholipid antibodies.

11

Myocardial Global Longitudinal Strain in Primary Antiphospholipid Syndrome. Gabriela Medina, Eduardo Gómez-Bañuelos, Erick Calderón-Aranda and Luis J. Jara. Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico

Background/Purpose: Measurement of myocardial deformation or Global longitudinal strain (GLS) by speckle tracking echocardiography (STE) is useful for detection of microvascular damage and myocardial contractility impairment in patients with diabetes mellitus and ischemic cardiopathy. Primary antiphospholipid syndrome (PAPS) is characterized by thrombosis, endothelial damage, and vascular dysfunction. GLS has not been studied in these patients.

Purpose: To evaluate the GLS from the left ventricle by STE in order to provide the early detection of myocardial dysfunction in patients with PAPS.

Methods: Patients with PAPS older than 16 years of age, without signs and symptoms of heart failure and angina were recruited and matched with healthy controls by age and gender. Patients with uncontrolled thyroid disease, poor echocardiographic window, or pregnancy were excluded. Demographic, clinical data, cardiovascular risk factors and lipid profile were recorded. Standard transthoracic evaluation was done and images from GLS 2, 3 and 4 chambers view were recorded and analyzed with STE and strain imaging. Segmental strain (in17 segments from the left ventricle), GLS2 chambers (represent the segments 4, 7, 10, 13, 15), GLS3 chambers (segments 2, 5, 8, 11, 13, 16), and GLS4 chambers (segments 3, 6, 9, 12, 14, 16), and average GLS were assessed. Mann Whitney U test was used to compare strain values.

Results: Thirty-eight patients and 21 controls were included. Average age was 46.7+/−10 and 42+/−7 years respectively. Only one patient had history of myocardial infarction and 13 had stroke. The prevalence of obesity (50% p=0.012) and dyslipidemia (44.73% p=0.001) was higher in PAPS group than the control. Only 4 patients had arterial hypertension under control. The frequency of other risk factors was similar between groups. Ventricular ejection fraction was normal. In the PAPS group, myocardial segmental strain was lower in apical segments (S13, S14, S16, S17), and in GLS2 (corresponding to inferior and anterior wall segments from the left ventricle)

($p<.0.03$). The average of GLS was significantly lower in comparison with controls ($p=0.01$).

Conclusion: Patients with PAPS without signs and symptoms of heart disease had lower values of myocardial GLS than controls probably due to coronary microcirculation abnormalities. Global longitudinal strain has a potential value in the assessment and treatment of myocardial dysfunction in PAPS patients.

12

C5 Inhibitor rEV576 Ameliorates *In Vivo* Effects of Antiphospholipid Antibodies. Ana Laura Carrera-Marin[1], Zurina Romay-Penabad[1], Samuel Machin[2], Hannah Cohen[2], Wynne Weston-Davies[3] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]University College London, LOndon, United Kingdom, [3]Varleigh Immuno Therapeutics, Ltd, London, United Kingdom

Background/Purpose: Murine models indicate involvement of the complement system in antiphospholipid (aPL)-mediated thrombosis. Complement split products (C5a and C3a) may enhance endothelial cell (EC) activation and pro-infflammatory/procoagulant states including tissue factor (TF) upregulation. rEV576 (coversin) is a recombinant salivary protein from the tick *Ornithodoros moubata* which protects it from attack by the host's complement system (Nunn M A et al., *J Immunol* **174** (4), 2084 (2005)). It is a small protein, which binds C5 inhibiting cleavage to C5a and C5b, the first component in the formation of MAC. Blockade of the complement cascade at the level of MAC generation is advantageous because it prevents the destructive effects of MAC while retaining the immunoprotective role of upstream complement components (e.g. C3b opsonization and phagocytosis).Here we examined the effects of coversin on aPL-mediated thrombosis and upregulation of TF in an *in vivo* murine model.

Methods: C57BL/6J mice were injected i.p. twice with 0.5 mg of IgG from a patient with Antiphospholipid Syndrome (APS) or with control IgG in normal human serum (NHS) preceded by i.p. injection of rEV576 0.2 mg, calculated to totally inhibit C5 cleavage, or phosphate buffer (PBS) control. The size of induced thrombus was measured 72 h after the first injection. TF activity was determined in carotid homogenates. Anticardiolipin (aCL) and anti- $\beta_2$glycoprotein I (anti-β_2GPI) antibodies were determined in the serum of the mice by ELISA.

Results: see table

Treatment	Thrombus size (μm^2)	TF carotid (pM/mg/ml)	aCL (GPL units)	anti-β_2GPI (SGU)
IgG-APS + PBS	2067 ± 693	602.8 ± 119.4	103.9 ± 26.4	96.5 ± 9.4
IgG-APS + rEV576	767 ± 179 (†)	176.7 ± 38.9 (†)	114.2 ± 15.7	104.6 ± 13.9
IgG-NHS + PBS	537 ± 118 (†)	187.1 ± 150.8 (†)	<10	<20
IgG-NHS + rEV576	481 ± 164	110.5 ± 20.3	<10	<20

(†) $p<0.001$ compared to IgG-APS + PBS

IgG-APS + PBS induced significantly larger thrombi and TF activity compared to other groups. Mice treated with rEV576 and APS IgG had significantly less thrombus and TF activity than those treated with PBS and APS IgG. Mice treated with IgG-APS had high titers of aCL and anti-β_2GPI at induction of thrombus.

Conclusion: The data confirm involvement of complement activation in aPL-mediated pathogenesis and suggest that complement inhibition might ameliorate APS clinical manifestations.

13

Pathogenic Effects of Antiphospholipid Antibodies Are Ameliorated In Tissue Deficient Mice. Zurina Romay-Penabad[1], Ana Laura Carrera-Marin[1], Nigel Mackman[2] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: Antiphospholipid (aPL) antibodies are associated with thrombosis in patients with the Antiphospholipid Syndrome (APS). APL antibodies are thrombogenic *in vivo* and have been shown to cause upregulation and expression of tissue factor (TF) on cultured endothelial cells and increased procoagulant activity in monocytes *in vitro*. Furthermore, monocytes from patients with aPL antibodies are known to have increased procoagulant activity. However, whether TF plays a role on aPL-mediated thrombosis *in vivo* is unknown. We addressed that question by measuring the thrombogenic potential of aPL antibodies in mice with greatly reduced levels of TF in all tissues (low TF mice, mTF−/−, hTF+), in an established mouse model of induced thrombosis.

Methods: mTF−/−, hTF+ and the corresponding control mTF+/−, hTF+ in groups 5 mice were injected intraperitoneally (i.p.) twice with either IgG from a patient with APS (IgG-APS) (500 μg) or with control IgG (IgG-NHS) (500 μg). Seventy-two hours after the first injection a surgical procedure was performed to study thrombus dynamics. The anticardiolipin (aCL) and anti-β_2 GPI titers in the serum of the mice were determined by ELISA.

Results: Thrombus sizes were significantly larger in mTF+/−, hTF+ mice injected with IgG-APS compared to these mice treated with IgG-NHS (1695 ± 382 μm^2 vs. 546 ± 48 μm^2; $p<.0001$). Importantly, the size of thrombus in mTF−/−, hTF+ mice injected with IgG-APS (712 ± 129 μm^2) was significantly smaller than the mean thrombus size in mTF+/−, hTF+ injected with IgG-APS (1695 ± 382; $p<.0001$). The mean aCL and anti-β_2 GPI titers in the serum of mTF +/−, hTF+ and mTF−/−, hTF+ mice injected with IgG-APS were: 55 ± 14 GPL and 22 ± 6 SGU and 53.3 ± 19.3 GPL and 51 ± 20 SGU at the time of surgery, respectively.

Conclusion: The data show that TF mediates aPL-induced thrombosis *in vivo*. Further studies will be performed to determine the cell types that express TF and are responsible for thrombosis in APS.

14

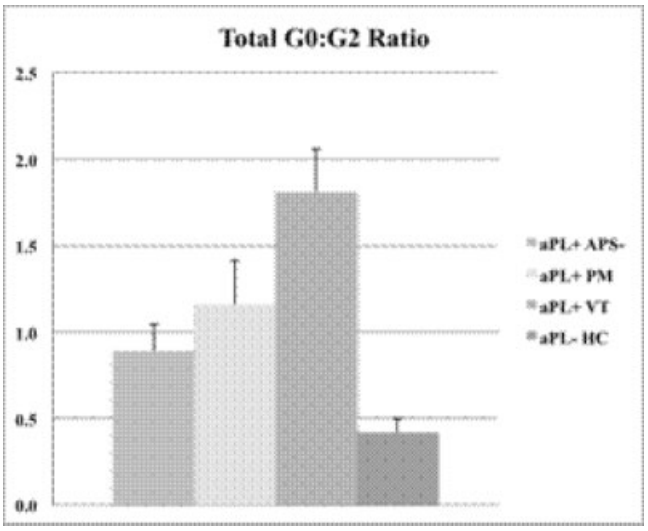
Patterns of Immunoglobulin-G Glycosylation Distinguish Different Clinical Phenotypes of Antiphospholipid Antibody Positivity. Edward Tarelli[1], John S. Axford[1], Ian Giles[2], Charis Pericleous[2], Silvia S. Pierangeli[3], Yiannis Ioannou[4], Anisur Rahman[2] and Azita Alavi[1]. [1]Sir Joseph Hotung centre for Musculoskeletal diseases, St George's University of London, London, United Kingdom, [2]Division of Medicine/Centre for Rheumatology Research, University College London, London, United Kingdom, [3]University of Texas Medical Branch, Galveston, TX, [4]University College London, London, United Kingdom

Background/Purpose: Polyclonal IgG and antiphospholipid (aPL) antibodies from patients with different clinical manifestations of the antiphospholipid syndrome (APS) have been shown to exert differential effects on signalling pathways and tissue factor activity in target cells. Interestingly, these biological effects were not distinguished by their degree of aPL binding which did not differ significantly between the different APS subgroups.

Given that glycosylation is known to influence the biological activity of IgG, and that changes in IgG glycosylation patterns have been shown to predict clinical manifestations for various autoimmune diseases, we examined whether differential glycosylation of IgG may be a factor in determining the observed differences in the mechanism of the effects of IgG from APS patients.

Methods: The glycosylation profile of IgG N-glycans, enzymatically released, from protein G purified IgG from four sets of 8 patients; APS with pregnancy morbidity (PM) alone (aPL+ PM), vascular thromboses (VT) alone (aPL+ VT), aPL+ve patients without APS (aPL+ APS-) and healthy controls (aPL- HC) was examined using Matrix Assisted Laser Desorption Ionisation Time-Of-Flight Mass Spectrometry (MALDI-TOF MS). IgG glycans were divided into three main groups based on the number of galactose residues: G0, G1 and G2. These biantennary complex glycans may be further modified by the presence/absence of fucose (F) and/bisecting N-acetylglucosamine (bis).

Results: There were no significant differences in aPL binding between the different APS and aPL+ groups. In contrast, the glycosylation profile of IgG was found to be significantly different in the 4 groups examined (Figure). IgG from the APS patients had significantly higher ratios of total G0:G2 compared with the aPL+ APS- patients ($p=0.038$) and those from aPL- HC ($p=0.002$). On further, more detailed, analysis, the IgG from patients with VT, which showed the most marked difference in total G0:G2 ratio, could be differentiated from the PM group based on significant differences in the levels of G1F, G2, G2F and G1Fbis ($p<0.05$).



Conclusion: Our findings show that IgG from patients with diverse clinical manifestations of APS and aPL positive healthy controls exhibit differential patterns of glycosylation that were not predicted by differences in aPL binding. Therefore, these glycosylation differences, which include the degree of galactosylation as well as fucosylation, could be used as a biomarker to discriminate between patients with VT and PM, and may provide a better insight into the different mechanistic action of IgG in these patients.

Role of Apolipoprotein B100 and Oxidized Low-Density Lipoprotein in Anti-beta2 Glycoprotein I Induced Tissue Factor Expression on Monocytes. Kotaro Otomo[1], Tatsuya Atsumi[1], Yuichiro Fujieda[1], Hisako Nakagawa[1], Masaru Kato[1], Olga Amengual[1], Tetsuya Horita[1], Shinsuke Yasuda[1], Masaki Matsumoto[2], Shigetsugu Hatakeyama[3] and Takao Koike[1]. [1]Department of Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Division of Proteomics, Kyusyu University Medical Institute of Bioregulation, Fukuoka, Japan, [3]Department of Biochemistry, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background/Purpose: To explore plasma molecule involvement in the tissue factor expression induced by beta2 glycoprotein I dependent anticardiolipin antibody (aCL/β2GPI) on monocytes.

Methods: Unknown beta2-glycoprotein I (β2GPI) binding molecules in plasma were screened by a proteomics technique using immunoaffinity chromatography and mass spectrometric analysis. To identify β2GPI binding proteins, FLAG-tagged human β2GPI was constructed. The expression vector encoding FLAG-β2GPI was transfected into HEK293T cells, and the expression of full length FLAG-β2GPI in the culture supernatant was confirmed by immunoblotting. Human serum sample with FLAG-β2GPI was incubated and applied for affinity chromatography with anti -FLAG antibody-conjugated Sepharose beads. The purified fraction was subjected to SDS-PAGE, followed by a silver staining. Immunopurified proteins were analyzed by an online-nanoLC-MS/MS. Obtained MS/MS data were searched against nrNCBI database MASCOT algorithm.

Results: Among many proteins detected in the spectrometry, ApoB100 was the only identified molecule as a candidate plasma protein. Since there was no significant binding between β2GPI and ApoB100 in ELISA, oxidized LDL, containing ApoB100 as well as ox-Lig1 (a known ligand of β2GPI) in its molecule, was considered as a β2GPI-binding molecule in plasma.

The involvement of oxidized LDL was further investigated in aCL/β2GPI induced tissue factor expression on monocytes. RAW264.7, a monocyte cell line, was incubated with a monoclonal aCL/β2GPI, WBCAL-1, in the presence/absence of oxidized LDL. Cells were lysed and TF mRNA was quantitated using Real Time PCR system. The presence of oxidized LDL (100μg/ml) and β2GPI markedly increased TF mRNA expression on RAW264.7 cells induced by WBCAL-1 (Fig). Oxidized LDL upregulated TF mRNA induction as well by purified IgG from APS patients with high titre of aCL/β2GPI.

Conclusion: Oxidized LDL was detected as a major β2GPI binding plasma molecule by proteomics analysis. The presence of oxidized LDL upregulated aCL/β2GPI induced TF expression on monocytes, suggesting the involvement of oxidized LDL in the pathophysiology of thrombosis in patients with APS.

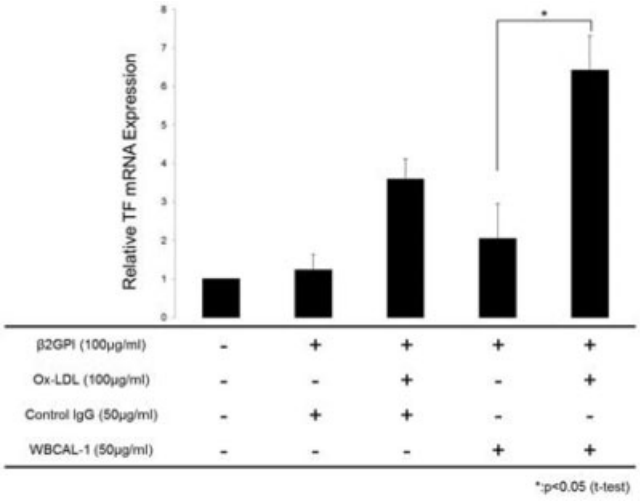

Figure. RAW264.7 cells were incubated with monoclonal aCL/β2GPI (WBCAL-1) in the presence of oxidized LDL. TF mRNA was quantitated by Real Time PCR.

Circulating B Cells Subpopulations in Patients with Antiphospholip Syndrome. Lorena Alvarez-Rodriguez[1], Marcos Lopez-Hoyos[1], Jaime Calvo-Alen[2], Rafael Barrio del[1], Orlando Pompei[1] and Victor M. Martinez-Taboada[3]. [1]Hospital Universitario Marques de Valdecilla. IFIMAV, Santander, Spain, [2]Hospital Sierrallana, Torrelavega, Spain, [3]Hospital Universitario Marques de Valdecilla-IFIMAV, Santander, Spain

Background/Purpose: Antiphospholipid syndrome (APS) is characterized by arterial and/or venous thrombosis and obstetrical complications together with the production of antiphospholipid autoantibodies. Its pathogenesis remains to be elucidated, but the production of autoantibodies suggests that B cells may have some role in APS. Our aim was to describe the peripheral blood frequency of B cells at different stages of maturation in APS.

Methods: Frequencies of B cells in peripheral blood of 25 APS patients and 11 SLE (without APS) were determined by flow cytometry. As controls, 12 age- and sex-matched healthy subjects (HC) were used. B cell subsets were identified with a combination of monoclonal antibodies (anti-CD5, -CD10, -CD19, -CD24, -CD27, -CD38, -CD138, -IgM and IgD) conjugated to different fluorochromes. Such a panel allowed us to identify the following B cell subsets: immature, naïve, double negative (DN), non-switched memory, switched memory and plasma cells.

Results: A significant decrease of circulating immature ($p=0.006$) and naïve ($p=0.003$) cells in APS than in SLE patients was observed. However, non-switched ($p=0.001$) and switched memory ($p=0.038$) B cells from peripheral blood of APS patients were increased as compared with SLE. No differences in circulating DN and plasma cells were observed between both disorders. In addition, naïve B cells were higher in SLE patients than in HC whereas non-switched memory B cells were lower in SLE patients than in HC. No significant differences were found in B cells between HC and APS patients.

Conclusion: Circulating B cells at a more differentiated stage were higher in APS than in SLE, whereas immature B cells were higher in SLE than in APS. These data point for a higher ability of B cells from SLE to

mature in the periphery and to broad the spectrum of autoantigens they are reactive against. However, our data are only from the peripheral blood compartment and lack confirmation in bone marrow and germinal centres.

17

Circulating Cytokine Profile in Patients with Antiphospholipid Syndrome. Lorena Alvarez-Rodriguez[1], Marcos Lopez-Hoyos[1], Jaime Calvo-Alen[2], Rafael Barrio del[1], Orlando Pompei[1] and Victor M. Martinez-Taboada[3]. [1]Hospital Universitario Marques de Valdecilla. IFIMAV, Santander, Spain, [2]Hospital Sierrallana, Torrelavega, Spain, [3]Hospital Universitario Marques de Valdecilla-IFIMAV, Santander, Spain

Background/Purpose: Antiphospholipid syndrome (APS) is characterized by the combination of clinical manifestations (arterial and/or venous thrombosis, and obstetrical complications) and the presence of antiphospholipid antibodies. The role of cellular immunity in the pathogenesis of this syndrome remains unclear, although a shift to a Th1 response, and an increased production of TNFa has been described. The aim of the present study was to determine the peripheral blood cellular phenotype and the circulating cytokine profile in patients with APS.

Methods: Intracellular cytokine production was assessed in T cells (IFN-γ, IL-2, IL-4, IL-10, IL-17) and CD14+ cells (IL-1β, TNF-α, IL-6) by flow cytometry in 27 patients with APS. As control groups we included 17 age- and sex-matched healthy controls (HC) and 11 patients with systemic lupus erythematosus (SLE). Patients with SLE had to be with SLEDAI≤4 (only treatment with antimalarials and/or low-dose corticosteroids were allowed). Circulating cytokines were measured by Cytometric Bead Array (CBA) in 13 patients with APS and 26 HC.

Results: Compared to HC, APS patients were characterized by a decreased frequency of circulating CD3+IFNγ+ *ex vivo* (without stimulus). This decrease in circulating Th1 cells was accompanied by a significant decrease in serum IL-12p70. Although we did not find significant differences in the expression of intracellular proinflammatory cytokines between APS and HC, serum levels of IL-6 were significantly lower in APS patients. Compared to HC, SLE patients were characterized by a decreased frequency of circulating CD3+IL-2+ and CD3+IFNγ+ *ex vivo* (without stimulus). For circulating CD3+IL-2+, these differences were also significant compared to APS. Patients with SLE were characterized by a significant increased frequency of circulating Th17 (CD4+IL17+CCR6+ and CD4+IL17+IFNγ-) cells compared to HC and APS. Circulating CD4+IL17+IFNγ+ cells were also significantly higher in SLE compared to APS patients.

Conclusion: These preliminary results suggest that patients with APS show a distinct functional profile in the peripheral cell compartment. Despite clinical remission or low disease activity, circulating Th17 cells are increased in SLE patients but not APS patients.

The present work was supported by grants from Roche (Spain) and IFIMAV.

A Systematic Analysis Confirms the Importance of Toll-Like Receptor 4, p38 Mitogen Activated Protein Kinase and Nuclear Factor Kappa-B Activation by Antiphospholipid Antibodies in Multiple Different Cell Types. Katie Poulton, Anisur Rahman and Ian Giles. University College London, London, United Kingdom

Background/Purpose: Diverse experimental evidence exists implicating the activation of various different cell surface receptors and intracellular pathways by antiphospholipid antibodies (aPL). This evidence has been generated using a number of different cell types with varying numbers of aPL from different sources and disease sub-types. This experimental variability has led to uncertainty in their interpretation. Therefore we have undertaken a systematic analysis of this evidence implicating aPL mediated activation of intracellular signalling pathways to interpret their relevance to the pathogenesis of the antiphospholipid syndrome (APS).

Methods: A PubMed search was undertaken from 1966 up until May 2011 using combinations of key signalling pathway words. Each publication was systematically examined to note the following points; antibody type and patient population, outcome measures and use of receptor/signalling pathway inhibitors, and cell type and origin.

Results: We identified 24 original studies implicating the importance of aPL in activation of intracellular signalling pathways. The most convincing evidence from 21 *in vitro* and 3 *in vivo* studies in endothelial cells, monocytes, trophoblasts, platelets, and fibroblasts implicates toll like receptor 4 (TLR4), p38 mitogen activated protein kinases (p38 MAPK) and nuclear factor kappa B (NFkB) in mediating pathogenic intracellular effects of aPL. These consistent responses were confirmed in both thrombotic and obstetric relevant cell types using human monoclonal and polyclonal antibodies and measured by various different outcome measures.

Conclusion: The main finding of our systematic analysis is the striking degree of similarity between the conclusions of studies carried out by many different groups using different methods and cell types. A greater understanding of how aPL activate these intracellular pathways will potentially lead to the development of targeted agents to block these pathways, thus reducing our reliance on anticoagulation as the only current treatment of APS.

19

Anti-Phosphatidylserine/Prothrombin Antibody Titers Are Strongly Correlated with Lupus Anticoagulant Assays in Patients with Antiphospholipid Antibodies. Makoto Miyara[1], Laurent Arnaud[1], Laurent Dufat[1], Marie-Claude Diemert[1], Annick Ankri[1], Alexis Mathian[1], Julien Haroche[1], Du Boutin[1], Pascale Ghillani-Dalbin[1], Nathalie Costedoat-Chalumeau[1], Silvia Casas[2], Jean-Charles Piette[1], Lucile Musset[1] and Zahir Amoura[1]. [1]CHU Pitié-Salpêtrière, Paris, France, [2]Instrumentation Laboratory Werfen Group, Lexington, MA

Background/Purpose: Biological criteria for the antiphospholipid syndrome (APS) diagnosis are the detection of either anticardiolipin antibodies (aCL), antib2GPI antibodies (ab2GPI) or lupus anticoagulant (LA). LA is strongly associated with thrombotic events in APS. Detection of LA is complex as it requires several confirmatory steps, which may lead to delayed results. Anti-phosphatidylserine/prothrombin antibodies (aPS/PT) have been recently associated with the presence of LA. However, it is still unclear whether aPS/PT titers correlate with LA assays.

Methods: 504 sera from 101 patients with either definite APS syndrome (n=82) or stable antiphospholipid antibodies (APL, either aCL, ab2GPI or LA; ACL levels >80 UGPL) without clinical APS manifestations (n=19) primarily collected for aCL, b2gPI and/or LA detection, were tested on a aPS/PT (IgG+IgM) ELISA and on individual isotype aPS/PT IgG and aPS/PT IgM ELISA assays (INOVA Diagnostics, San Diego, CA). Correlations between titers of aPS/PT and those of aCL, ab2GPI, with Rosner index, dilute tissue thromboplastin inhibition ratio (dTTI) and dilute Russell's viper venom time ratio (dRVVT) were assessed using Spearman's non-parametric test. According to manufacturer instructions, aPS/PT titers were considered positive when >30 U/mL.

Results: aPS/PT were present in 12 of the 19 patients (63 %) with APL without thrombotic or obstetric events (4 with IgG isotype, 4 with IgM isotype and 4 with both) and in 69 of the 82 patients (84 %) with definite APS (19 with IgG, 11 with IgM and 39 with both isotypes).

Among the 81 patients with positive LA, 74 had aPS/PT (91 %) while 7 did not (9 %). Among the 20 patients without LA, 16 did not have aPS/PT (80 %) while 4 did (20 %). Presence of aPS/PT was significantly associated to the presence of LA ($p<0.0001$ using a chi-square test). 10 of 19 patients without APS had LA among whom 9 had aPS/PT (90%). Among the 9 other patients without LA, 3 had aPS/PT (33%). In the 82 patients with APS, 68 patients had LA, among whom 65 had aPS/PT (96%). Among the 14 other patients without LA, 4 had aPS/PT (28%).

aPS/PT titers strongly correlated with Rosner index ($r=0.72$, $p<0.0001$), dTTI ($r=0.801$, $p<0.0001$) and dRVVT ($r=0.67$, $p<0.0001$). The ROC Curve yielded an excellent sensitivity of 84%, specificity of 98%, and area under the ROC Curve of 0.92 for detecting the presence of LA using an aPS/PT cut-off titer of 53 U/mL.

Conclusion: We confirmed that the presence of aPS/PT antibodies (either IgG isotype, IgM isotype or both) is strongly correlated with the presence of LA. Furthermore, titers of aPS/PT were strongly correlated with Rosner index, dTTI and dRVVT. Our data suggest that aPS/PT (IgG+IgM) ELISA assay could be a good alternative test for the detection of LA.

Presence of Anti-Phosphatidylserine/Prothrombin Antibodies with Both IgG and IgM Isotypes May Be Associated with the Occurrence of Catastrophic Antiphospholipid Syndrome in Patients with Antiphospholipid Antibodies. Makoto Miyara[1], Laurent Arnaud[1], Laurent Dufat[1], Marie-Claude Diemert[1], Annick Ankri[1], Alexis Mathian[1], Julien Haroche[1], Du Boutin[1], Pascale Ghillani-Dalbin[1], Nathalie Costedoat-Chalumeau[1], Silvia Casas[2], Jean-Charles Piette[1], Lucile Musset[1] and Zahir Amoura[1]. [1]CHU Pitié-Salpêtrière, Paris, France, [2]Instrumentation Laboratory Werfen Group, Lexington, MA

Background/Purpose: Catastrophic antiphospholipid syndrome (cAPS) is a life threatening condition with simultaneous thrombosis in multiple organs that can occur in patients with antiphospholipid antibodies (APL). Predictive biological parameters for cAPS have not been defined yet. Anti-phosphatidylserine/prothrombin antibodies (aPS/PT) of either IgG or IgM isotypes or both have been recently associated with the presence of LA. It has not been determined whether aPS/PT isotypes are correlated to clinical features of antiphospholipid syndrome (APS).

Methods: 157 sera from patients with cAPS (n=29), 58 sera from patients with APS (n=29) and 31 sera from patients with stable antiphospholipid antibodies (APS, either aCL, ab2GPI or LA; ACL levels between 25 and 75 UGPL) without clinical APS manifestations (noAPS; n=19), primarily collected for aCL, b2gPI and/or LA detection, were tested on individual isotype aPS/PT IgG and aPS/PT IgM ELISA assays (INOVA Diagnostics, San Diego, CA). According to manufacturer instructions, aPS/PT titers were considered positive when >30 U/mL.

Results: In noAPS group, 8 patients had aPS/PT IgM (42%) while other patients did not have aPS/PT of IgG or IgM isotype (n=11, 58%). In patients with APS, 3 patients had aPS/PT IgG (10.3%), 6 had aPS/PT IgM (20.7%) and 3 patients had aPS/PT with both isotypes (10.3%) while 17 had no aPS/PT (58.6%). In cAPS group, 4 patients had no aPS/PT (13.8%), 4 patients had aPS/PT IgG (13.8%), 5 had IgM (17.2%) and 15 aPS/PT with both IgG and IgM (51.7%). Proportion of patients with aPS/PT with both isotype was significantly higher in patients with cAPS than in patients with APS without cAPS and patients with stable APL without clinical APS manifestations ($p=0.0014$ and $p<0.0001$ respectively using Fisher's exact test). No difference was observed in the proportion of isolated aPS/PT IgG or IgM between cAPS and APS patients or patients with patients with stable APL without clinical APS manifestations. The 3 patients with APS with aPS/PT with both isotypes developed adrenal insufficiency, cerebral venous thrombosis and Budd-Chiari syndrome.

Conclusion: Our data indicate that presence of aPS/PT of both IgG and IgM isotypes may be associated with severe features of APS, especially cAPS.

21

High Antiphospholipid Antibody Levels May Reflect Chronic Endothelial Damage in Non-Autoimmune-Associated Thrombosis. Anna R. Broder[1], Jonathan N. Tobin[2], Jacob H. Rand[3] and Chaim Putterman[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Albert Einstein College of Medicine/CDN Network, New York, NY, [3]Montefiore Medical Center, Bronx, NY

Background/Purpose: Persistently elevated antiphospholipid antibodies (aPL Ab) are associated with an increased risk of thrombosis, but factors that may affect aPL Ab levels are poorly understood. While statins have been shown to potentially decrease the risk of aPL Ab - associated thrombosis, the effect of statins on aPL Ab levels has not been studied. It is also not known if aPL Abs represent additional risk for thrombosis in people without autoimmune diseases, or if they reflect previous endothelial damage caused by traditional cardiovascular risk factors: high low-density lipoprotein (LDL), low high-density lipoprotein, hypertension, type 2 diabetes (T2DM), obesity, and smoking (Figure 1). We explored whether elevated aPL Abs were associated both with statin use and with the traditional risk factors in patients without autoimmune diseases hospitalized with a deep vein thrombosis (DVT), pulmonary embolism (PE), or stroke (CVA).

Methods: We included patients hospitalized in a large tertiary care center with a confirmed diagnosis of DVT, PE or CVA, who had lupus anticoagulant (LAC) and aPL Abs measured within 6 months from their index admission.

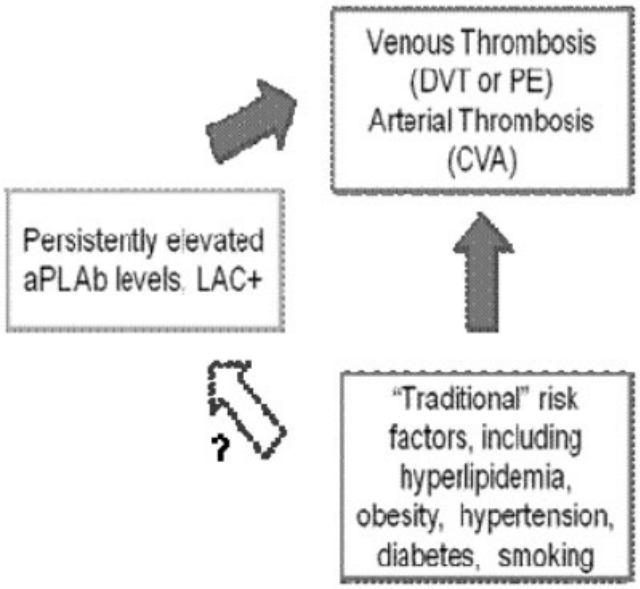

Figure 1. The proposed relationship between thrombosis, aPL Abs/Lac, and traditional cardiovascular risk factors

Results: Among 175 patients included, statin use at the time of aPL Ab measurement was associated with an OR of 7.1 (95% CI 1.1, 43.9, $p = 0.035$) of at least one aPL Ab $\geq$ 40 units, compared with no statin use in a multivariate model adjusted for age, race, gender, history of T2DM, hypertension, smoking and LDL. Furthermore, patients who had LDL < 130 mg/dl and were on statins were 14.5 times more likely to have at least one aPL Ab $\geq$ 40 units, (95% CI 1.1, 186.6, $p = 0.04$), compared with people with LDL < 130 mg/dl and not on statins, adjusted for age, gender, race, history of smoking and history of T2DM. LAC+ was not associated with stain use. None of the traditional risk factors at the time of DVT/PE/CVA was associated with aPL Ab levels $\geq$ 40/LAC+.

Conclusion: In patients without autoimmune diseases, we did not find an association between high aPL Ab levels and any of the traditional risk factors at the time of the thrombotic event. Thus, high aPL Ab levels did not confound the relationship between thrombosis and the traditional risk factors. Statins are associated with elevated aPL Ab levels. Alternatively, if statin therapy reflects the history of prior hyperlipidemia, high levels of aPL Abs may be a marker for prior endothelial damage caused by hyperlipidemia before statin therapy was initiated.

22

The Role of Fatty Acid Composition in Antiphospholipid Syndrome and Systemic Lupus Erythematosus. Amaris K. Balitsky[1], Ellie Aghdassi[2], David WL. Ma[3], Stacey Morrison[4], Jiandong Su[4] and Paul R. Fortin[4]. [1]The University of Toronto, Toronto, ON, [2]University Health Network, Toronto, ON, [3]University of Guelph, Guelph, ON, [4]Toronto Western Hospital, Toronto, ON

Background/Purpose: Despite similar traditional Framingham risk scores, systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) patients present with greater thrombovascular disease compared to the general population. APS can occur alone, as primary APS (PAPS), or be associated with SLE, referred to as secondary APS (SAPS). Dietary fat composition and metabolism play an important role in inflammatory reactions. For example, omega-3 polyunsaturated fatty acids (ω-3 PUFA), including alpha-linoleic acid (ALA) and its metabolites, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), have been shown to have anti-inflammatory and cardioprotective effects. On the other hand, arachidonic acid (AA, ω-6 PUFA), derived from linoleic acid (LA), leads to formation of inflammatory mediators. The purpose of this study was to determine and compare an association between the red blood cell (RBC) FA profile and: the presence of APS, TE and aPL.

Methods: Fifty-nine individuals were selected from the lupus and antiphospholipid outpatient specialty clinics and divided into 4 groups: 1) primary APS (PAPS, n=15) as defined by the revised Sydney criteria, 2) SAPS (n=14), 3) SLE with a previous TE (n=15), and 4) SLE without previous history of TE and no aPL (n=15). All SLE patients met at least four

of the American College of Rheumatology (ACR) classification criteria. Demographics, Framingham risk score and RBC profile including phospholipids, phosphatidylcholine (PC) and phosphatidylethanolamine (PE), and their respective FA compositions were reported. RBC FA compositions were determined using thin-layer and gas chromatography.

Results: The mean (±SD) age (years) of the 4 groups were similar (PAPS: 51.7 ± 16.8; SAPS: 53.0 ± 11.7; SLE+TE: 52.1 ± 10.5; SLE-TE: 53.5 ± 10.3, $p > 0.05$). Framingham risk scores were also similar across the four groups. The PAPS group had less arterial events (40.0%) compared to SAPS (71.4%) and SLE+TE (80.0%). RBC-PC and PE values were similar across PAPS, SAPS, SLE+TE, and SLE-TE. The PAPS group, compared to the three SLE groups, had a higher RBC-PE ALA:DHA+EPA ratio (PAPS: 0.06 ± 0.02; SLE: 0.04 ± 0.02, $p < 0.05$), indicating less efficient conversion of ALA to its anti-inflammatory metabolites, EPA and DHA. In patients with the history of TE, RBC-PE ω-6 PUFA (inflammatory) was higher than the levels of total ω-3 PUFA (anti-inflammatory) (TE: 36.40 ± 3.92; no TE: 34.98 ± 2.26, $p = 0.09$). The presence of aPL tended to be associated with a lower RBC-PC LA:AA ratio, indicating more efficient conversion of LA to its pro-inflammatory metabolite (aPL: 2.40 ± 0.65; no aPL: 2.79 ± 0.97, $p = 0.08$). Those taking ω-3 PUFA supplements had higher levels of RBC-PC EPA+DHA (ω-3: 4.1 ± 1.7 vs. no ω-3: 3.0 ± 1.1; $p = 0.08$).

Conclusion: In patients with APS and SLE, FA composition is in favour of an inflammatory process. Presence of TE, aPL and PAPS were associated with a less favourable FA composition, while those individuals who took ω-3 supplements were associated with a more favourable FA composition.

23

Profiling Sub-Types of Anti-β2 Glycoprotein I and Anti-Domain I Antibodies May Distinguish Between Different Clinical Phenotypes of the Antiphospholipid Syndrome. Charis Pericleous[1], Acely Garza-Garcia[2], Lucy Murfitt[2], Paul C. Driscoll[2], David A. Isenberg[1], Silvia S. Pierangeli[3], Ian Giles[1], Yiannis Ioannou[1] and Anisur Rahman[1]. [1]University College London, London, United Kingdom, [2]MRC National Institute of Medical Research, London, London, United Kingdom, [3]University of Texas Medical Branch, Galveston, TX

Background/Purpose: Laboratory classification criteria for the antiphospholipid syndrome (APS) include the quantification of IgG and IgM, but not IgA anticardiolipin (aCL) and anti-β2 glycoprotein I (aβ2GPI) antiphospholipid antibodies (aPL), though recent studies suggest a possible role for IgA. These assays do not reliably differentiate patients with a history of vascular thrombosis (VT) from those with pregnancy morbidity (PM). Of the five domains of β2GPI, pathogenic IgG aPL are considered to target Domain I (DI). We have developed a direct anti-DI ELISA using bacterially expressed DI. Here we investigate whether IgG, IgM and IgA anti-DI levels correlate with IgG, IgM and IgA anti-β2GPI and which of these tests correlate best with clinical phenotypes.

Methods: We used 9 different ELISAs (IgG/IgM/IgA for each of aCL, aβ2GPI and aDI) to test 158 serum samples - 46 from patients with APS (F:M 41:5, mean age 46.4±12.1); 77 with SLE but not APS (F:M 72:5, mean age 38.8±11.3); and 35 healthy controls (HC) (F:M 23:12, mean age 30.8±7.4). Of 46 APS subjects, 21 suffered VT only, 12 PM only, and 13 both. IgG/IgM aCL activity was defined as GPLU/MPLU respectively. For all remaining assays, results were expressed in units of activity by reference to an in-house standard. Univariate analysis was performed using one-way ANOVA to determine which assay(s) best differentiate APS from SLE and HC, and whether any were associated with the VT or PM phenotypes within APS.

Results: 7 of 9 assays gave significantly higher antibody titers in APS compared to SLE and HC ($p<0.0001$ in each case). The exceptions were IgM aCL (high in both APS and SLE) and IgA aDI (few positive samples). For 3 of these 7 assays, titers were raised in SLE compared to HC, thus only 4 assays (IgG/IgM/IgA aβ2GPI and IgG aDI) selectively recognized APS-derived sera. In the APS group, there was a strong correlation between aβ2GPI and aDI for IgG ($p=0.003$, $r=0.5858$) and IgA ($p<0.0001$, $r=0.8603$) but not IgM. In contrast, there were no correlations between aβ2GPI and aDI in the SLE group. Although none of the aβ2GPI assays nor IgG aDI could discriminate between patients with VT compared to PM, IgM aDI was found to be associated with PM ($p<0.0001$) and IgA aDI with VT ($p\leq0.01$).

Conclusion: To our knowledge, this is the first study to measure IgG/IgM/IgA aPL against CL, β2GPI and DI simultaneously. aβ2GPI of all isotypes and IgG aDI were found to be most specific for APS. The correlation between aβ2GPI and aDI in APS, but not non-APS subjects supports the idea that pathogenic aβ2GPI bind specifically to DI. The finding that IgA and IgM aDI show specific associations with VT and PM respectively is interesting but needs to be repeated in larger studies.

24

Prevalence of Antibodies to Prothrombin in Solid Phase (aPT) and to Phosphatidylserine/Prothrombin Complex (aPS/PT) in Patients with and without Lupus Anticoagulant (LA). Maria Laura Bertolaccini[1], Savino Sciascia[1], Veronica Murru[1], Giovanni Sanna[2] and Munther A. Khamashta[1]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]Louise Coote Lupus Unit, St. Thomas' Hospital, London, United Kingdom

Background/Purpose: Although aPS/PT has been reported to strongly correlate with the LA, both aPT and aPS/PT have been found in patients with LA. As their clinical diagnostic value and true relationship with the LA remains elusive, we designed this study to evaluate the prevalence and significance of aPT and aPS/PT in a large cohort of patients with and without LA.

Methods: Samples from 263 patients were included. aPT (in-house assay) and aPS/PT (INOVA Diagnostics) were tested by ELISA. LA was tested as per the current criteria from the ISTH Subcommittee on LA-Phospholipid-dependent antibodies.

Results:

	aPS/PT IgG/IgM	aPS/PT IgG	aPS/PT IgM	aPT IgG/IgM	aPT IgG	aPT IgM
LA+ve n/76 (%)	38 (50)	30 (39)	26 (34)	24 (32)	21 (28)	4 (5)
LA-ve samples n/187 (%)	43 (23)	38 (20)	17 (9)	54 (29)	46 (25)	11 (6)

Thrombosis, particularly venous thrombosis was associated with IgG aPT in the LA+ve group (OR7.1 [95% CI 2.2–22.7], $p=0.0006$). aPT was not associated with thrombosis in the LA-ve group. aPS/PT, either IgG/IgM, IgG and IgM were associated with thrombosis in general in the LA+group ($p=0.003$, $p<0.0001$ and $p=0.025$; respectively). After further analysis, this association was only retained for IgG aPS/PT and venous thrombosis (OR8.7 [95%CI 3.0–25.1], $p<0.0001$). In the LA-ve group, aPS/PT was associated with thrombosis ($p=0.026$), particularly, the IgM isotype (OR5.6 [95%CI 1.8–16.7], $p=0.0002$). Titers of IgG aPS/PT were not different between LA+ve and LA-ve (13U±29 vs. 7.5±22, $p=0.9$). Titers of IgM aPS/PT were higher in LA+ve than LA-ve (20.3±30 vs. 6.9±16, $p<0.0001$).

Conclusion: aPS/PT, but not aPT, are more frequently found in patients with LA. Although IgG aPS/PT does not seem to correlate with the LA, the correlation with the IgM isotype deserves further study.

25

Antibodies to Phosphatidylserine/Prothrombin (aPS/PT) Are An Independent Risk Factor for Thrombosis in Patients with Systemic Lupus Erythematosus (SLE). Maria Laura Bertolaccini[1], Savino Sciascia[1], Veronica Murru[1], Cesar Garcia-Fernandez[1], Giovanni Sanna[2] and Munther A. Khamashta[1]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]Louise Coote Lupus Unit, St. Thomas' Hospital, London, United Kingdom

Background/Purpose: aPS/PT have been reported to be closely associated with the presence of lupus anticoagulant (LA) in patients with antiphospholipid syndrome. Moreover, aPS/PT has been shown to have a similar diagnostic value to aCL in such patients. We designed this study in an attempt to clarify the role of aPS/PT as risk factors for thrombosis in patients with SLE.

Methods: IgG and IgM aCL, anti-b2GPI, aPT and aPS/PT were tested by ELISA. LA was tested following current criteria from the ISTH. All patients fulfilled at least 4 of the 1982 ACR criteria for SLE. APS patients fulfilled the 1999 Sapporo criteria.

Results: 226 SLE patients (214 female, mean age 42.6±12) were included. Of these, 57 had APS and 82 had a history of thrombosis (35 arterial, 28 venous and 19 both). Miscarriages were recorded in 39 women and fetal death in 36. Univariate analysis showed that aPS/PT were more frequently found in patients with thrombosis than in those without (OR7.0 [95%CI 3.7–13.2], $p=0.025$). IgG and IgM aPS/PT were more frequently found in patients with arterial and venous thrombosis than

in those without ($p<0.001$ for IgG, $p=0.001$ for IgM in arterial and $p<0.001$ for both IgG and IgM in venous thrombosis). aPS/PT were associated with pregnancy morbidity ($p<0.001$ for IgG and IgM), particularly with fetal death ($p<0.001$ for both isotypes) and miscarriages ($p<0.001$ for IgG only; IgM=ns).

Multivariate analysis (including aCL, LA, aPT and anti-b2GPI) confirmed that aPS/PT is an independent risk factor for thrombosis, particularly the IgG isotype that was independently associated with arterial and venous thrombosis ($p=0.002$ and $p=0.003$) and miscarriages ($p=0.03$). IgM aPS/PT was also found to be an independent risk factor for miscarriages ($p<0.001$).

Conclusion: aPS/PT is an independent risk factor for arterial and venous thrombosis and miscarriages in patients with SLE. IgM aPS/PT are also an independent risk factor for miscarriages. Testing for aPS/PT may be warranted in SLE patients.

26

The Value of Testing for Antibodies to Phosphatidylethanolamine (aPE) in Patients with Systemic Lupus Erythematosus (SLE). Maria Laura Bertolaccini[1], Veronica Murru[1], Savino Sciascia[1], Giovanni Sanna[2] and Munther A. Khamashta[1]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]Louise Coote Lupus Unit, St. Thomas' Hospital, London, United Kingdom

Background/Purpose: aPE have been reported to be an independent risk factor for idiopathic venous thrombosis and fetal death. However, these findings are the focus of constant debate. The purpose of the present study was to evaluate if testing for aPE has a diagnostic value in patients with SLE.

Methods: This study included 226 patients, all fulfilling the 1982 ACR criteria for SLE. Of these, 214 were women, with a mean age of 42.6 ± 12 and mean disease duration of 12.2 ± 8.8 years. 25% of the patients also fulfilled the 1999 criteria for the antiphospholipid syndrome. aCL, anti-b2GPI, aPT and aPS/PT were tested by in house ELISA. LA was tested according to the ISTH recommendations. aPE were also tested by an in-house ELISA using fetal calf serum. IgG and IgM aPE values were calculated from a sample showing a high binding used as a standard. The cut off value was established on 8U for IgG and 9U for IgM, by the 99th percentile of 140 healthy controls.

Results: aPE were found in 92 patients (41%). Of them, 68 were positive for IgG, 13 for IgM and 11 for both. aPE were more frequently found in patients with thrombosis, particularly the IgG isotype (OR2.0 [95%CI 1.1–3.5], $p=0.01$). When subdividing between venous and arterial thrombosis, only the association with venous thrombosis was retained (OR2.2 [95%CI 1.2–4.6], $p=0.009$). No associations were found between the presence of aPE and pregnancy morbidity in this cohort. The presence of aPE was highly correlated with that of aCL ($R^2=0.61$, $p=0.008$). There were no aPE in the absence of aCL. After multivariate analysis, including all other aPL as variables, clinical associations failed to retain significance.

Conclusion: aPE are frequently seen in SLE. aPE are not an independent risk factor for thrombosis or pregnancy morbidity and their presence is highly associated to that of aCL.

Steroid Receptor Coactivator-3 and Angiogenesis in Autoimmune Disease Associated Leg Ulcers. Victoria K. Shanmugam[1], Elena Tassi[2], Maram Al-Otaiby[2], Bhaskar Kallakury[1], Mihriye Mete[3], Christopher Attinger[4] and Anton Wellstein[2]. [1]Georgetown University Hospital, Washington, DC, [2]Georgetown University, [3]MedStar Health Research Institute, Hyattsville, MD, [4]Georgetown Universtiy Hosptial, Washington, DC

Background/Purpose: Delayed wound healing is a complication of several autoimmune diseases including scleroderma, rheumatoid arthritis and systemic lupus erythematosus (SLE). While the mechanisms of delayed healing in these patients are not known, we hypothesize that dysregulation of angiogenesis may play a role. Angiogenesis is critical in wound healing. Patients receiving bevacizumab and other vascular endothelial growth factor (VEGF) inhibitors exhibit impaired wound healing, and animal studies of angiogenesis in malignancy support this association.

The purpose of this study was to use immunohistochemistry (IHC) of formalin fixed paraffin embedded (FFPE) biopsy specimens from leg ulcers associated with autoimmune disease, diabetes and bevacizumab use to investigate the distribution of critical angiogenic markers. Steroid receptor coactivator-3 (SRC-3; also named Amplified in Breast Cancer-1) is a p160 steroid receptor coactivator that enhances NF-κB-mediated signaling in inflammatory disease, and modulates angiogenesis in malignancy. Fibroblast growth factor binding protein-1 (FGF-BP1) is another important molecule that is upregulated in wound healing, and acts as an angiogenic switch in malignancy.

Methods: FFPE samples were selected from the following groups: Diabetes Mellitus (n=3), Mixed Connective Tissue Disease (n=4), Systemic Lupus Erythematosus (n=5), Scleroderma (n=5) and bevacizumab use (n=2). The following stains were performed using standard IHC protocol: hematoxylin and eosin (H&E), steroid receptor coactivator-3 (SRC-3), fibroblast growth factor binding protein-1 (FGF-BP1), CD45, CD4, CD8, CD68 and CD34.

Blinded quantitative analysis at $\times200$ magnification using Image-J was used to quantify staining. Representative regions across each specimen were selected moving from intact to ulcerated tissue. Data was analyzed using Stata/IC 11.2 for Windows using linear regression and analysis of variance models to compare cell counts and ratio of blood vessel size between disease groups and across sampling fields.

Results: Total CD34 staining as a measure of blood vessel density was similar across the disease groups. However, the ratio of large to small vessels was significantly lower for autoimmune ulcers and VEGF inhibitor-associated wounds compared to the diabetics ($p=.005$). Pairwise comparisons with Bonferroni adjustment showed that the mean ratio of large to small vessels was significantly greater for diabetics compared to the other group means.

Regression analysis estimating the differences in staining pattern adjusting for location of the sampling field found that steroid receptor coactivator-3 was significantly higher in the SLE group compared to other diseases ($p< 0.001$). We did not find associations with FGF-BP1.

Conclusion: In autoimmune wounds, the ratio of large to small blood vessels was significantly reduced suggesting dysregulation of blood vessel structure or maturation. SRC-3 was significantly higher in SLE-associated ulcers. This study provides preliminary data to support the hypothesis that dysregulation of anigiogenesis and in particular SRC-3 may play a critical role in wound healing in autoimmune disease.

Differential Regulatory Functions of HIF-1α and HIF-2α During Angiogenesis of Human Microvascular Endothelial Cells (HMECs). Martin Hahne[1], Steffi Luetkecosmann[2], Cam Loan Tran[2], Cindy Strehl[2], Monique Fangradt[2], Manuela Jakstadt[2], Georg Duda[2], Paula Hoff[2], Timo Gaber[2], Gerd-Rüdiger Burmester[3] and Frank Buttgereit[2]. [1]Berlin Brandenburg School for Regenerative Therapies, Berlin, Germany, [2]Charité University Medicine, Berlin, Germany, [3]Charité University Hospital, Berlin, Germany

Background/Purpose: Hypoxia and angiogenesis are features of inflamed and injured tissues. The transcription factors Hypoxia inducible factor (HIF)-1a and (HIF)-2a control cellular metabolic response to decreased oxygen tension thereby promoting angiogenesis and having implications on the pathogenesis of RA. We focused on the effects of HIF-1α and HIF-2α on angiogenesis and developed a human microvascular endothelial cells (HMEC) lentiviral based knockdown system for both transcription factors allowing us to analyze angiogenesis of HMECs under hypoxia in the absence of HIF-1a or HIF-2α, respectively.

Methods: Specific knockdown of HIF-1a or HIF-2α was achieved using lentiviral-based shRNA technology. The reduction of HIF-1a or HIF-2α was confirmed on transcriptional and translational level by realtime RT-PCR and Western blot. Angiogenesis of transduced and non-tronsduced HMECs was studied by investigating both tubuli and node formation under hypoxia (<1% O_2). Expression of hypoxia driven genes *HIF1A*, *HIF2A*, *VEGFA* and *IL8* was quantified by realtime RT-PCR. Multiplex suspension array technology was used to measure the concentrations of secreted VEGF and IL8.

Results: The successful knockdown of HIF-1α and HIF-2α was confirmed by demonstrating considerably reduced gene expression levels of *HIF1A* and *HIF2A* by up to 71% ($p=0.0222$) under normoxic and hypoxic conditions. As a consequence, strongly reduced HIF-1α and HIF-2α protein levels were detected by Western blot. Targeting of HIF-1α led to a significantly decreased node formation (1.6-fold change under hypoxia, $p=0.0067$) with similar effects by trend on tubuli formation. The HIF-2α knockdown also led to a significantly decreased tubuli formation (1.7-fold change, $p=0.0444$) with similar effects by trend on node formation. Furthermore, HIF-1α targeted cells did not show any significant decrease in the gene

expressions of *VEGFA* and *IL8* but surprisingly raised cytokine levels of IL8 under hypoxia (1.4-fold change, p=0.021) compared to the control. In contrast, targeting of HIF-2α gave rise to reduced levels of secreted VEGF and IL8 with a significant suppression of *IL8* gene expression under normoxia (2.1-fold change, p=0.0101).

Conclusion: Our findings show essential and overlapping functions of HIF-1α and HIF-2α with regard to their regulatory potential of angiogenesis in HMECs. Both transcription factors have the same impact on VEGF but differ in their effects on IL8 expression. These findings provide new insights into basic principles of angiogenesis in inflamed tissues and are therefore considered to be of clinical importance.

Glucocorticoid-Induced Leucine Zipper Inhibits TNF-Induced Endothelial Cell NFκB Activation and Adhesive Function. Eric Morand, Michael Hickey and Qiang Cheng. Monash University, Melbourne, Australia

Background/Purpose: The protein glucocorticoid-induced leucine zipper (GILZ) was recently reported to be expressed in RA synovial tissue, and to exert anti-inflammatory effects in the CIA model of RA (Beaulieu et al, Arthritis Rheum 2010). Strong expression of GILZ was noted in RA synovial endothelial cells, but the function of GILZ in endothelium is unknown. Endothelial cell activation, which is required for leukocyte recruitment into inflamed tissue, is critically dependent upon NFkB and ERK MAP kinase pathways, both of which are reported intracellular targets of GILZ. We tested the hypothesis that GILZ has important regulatory effects on endothelial cell function.

Methods: Primary human umbilical vein endothelial cells (HUVEC) and a human microvascular endothelial cell line (HMEC) were stimulated with TNF. Adhesive function and adhesion molecule expression were examined using flow chamber and flow cytometry respectively.

Results: To determine the functional significance of GILZ in endothelium, we first examined whole blood leukocyte rolling and adhesion interactions with HUVEC. TNF-induced rolling and adhesion, and E-selectin and ICAM 1 expression, were inhibited by GILZ overexpression. No inhibition of HUVEC chemokine expression was observed, and of note, GILZ silencing did not abrogate glucocorticoid inhibition of TNF-induced rolling and adhesion on HUVEC. Overexpression of GILZ in HMEC inhibited TNF-induced NFkB luciferase activity equivalent to the effects of the specific NFkB inhibitor BAY-11–7082. Moreover, chemical NFkB inhibition did not further suppress NFkB activity in GILZ overexpressing cells, indicating that GILZ expression can maximally suppress this pathway. Unexpectedly, we were unable to demonstrate binding interactions of GILZ with NFkB p65, or inhibition of NFkB p65 nuclear translocation or ser-536 phosphorylation. In contrast, we observed that GILZ inhibited TNF-induced activation (phosphorylation) of p38, ERK, and JNK MAP kinases, associated with increased expression of the MAPK inhibitory phosphatase MKP1. TNF-induced NFkB activity was dependent on ERK, but not p38 or JNK, suggesting GILZ effects on NFkB may depend on ERK.

Conclusion: These data demonstrate that GILZ can exert inhibitory effects on endothelial cell function, adhesion molecule expression, NFkB and MAP kinase activation. GILZ inhibition of NFkB may depend on inhibition of ERK MAP kinase. Therapeutic modulation of GILZ may represent a means to modify inflammatory leukocyte recruitment.

Superoxide Anion Mediates the L-Selectin Down-Regulation Induced by Non-Steroidal Anti-Inflammatory Drugs In Human Neutrophils. M. Jesus Dominguez-Luis[1], Ada Herrera-Garcia[2], M.Teresa Arce-Franco[3], Susana Cardenas[4], Marta Rodriguez-Pardo[5], Manuel Feria[5], Francisco Sanchez-Madrid[4] and Federico Diaz-Gonzalez[3]. [1]Hospital Universitario de Canarias, La Laguna, Spain, [2]Hospital Universitario de Canarias, La Laguna. Tenerife, Spain, [3]Rheumatology Service, La Laguna, Spain, [4]Hospital Universitario La Princesa, Madrid, Spain, [5]University of La Laguna, La Laguna. Tenerife, Spain

Background/Purpose: A group of non-steroidal anti-inflammatory drugs (NSAIDs) are able to induce in neutrophils the shedding of L-selectin, a surface molecule that plays a critical step in the migration of leukocytes to site of inflammation, through a mechanism still not well-understood. The aim of this work was to study both the functional effect of NSAIDs on the neutrophils/endothelial cells dynamic interaction, and the potential implication of reactive oxygen species (ROS) production in the L-selectin down-regulation caused by NSAIDs

Methods: Human neutrophils were isolated from peripheral blood of healthy volunteers and patients with chronic granulomatous disease (CDG) ($p47^{phox}-/-$), a group of hereditary diseases in which cells of the immune system have difficulty forming superoxide radical. The dynamic interaction between neutrophils and activated endothelium was studied in a flow chamber. Surface expression of L-selectin and CD11b were assayed by flow cytometry. Neutrophil-free supernatant L-selectin concentration was determined by ELISA. Intracellular and mitochondrial ROS production was detected by flow cytometry using dihidroethidium (DHE) and MitoSOX Red, respectively. Wilcoxon signed-rank test ($p<0.05$) was used to evaluate the statistical significance.

Results: When human neutrophils were incubated with diclofenac but not with piroxicam, a significant reduction in the number of cells that rolled on activated endothelial cells was observed. Dithiol reducing agents such as, DL-Dithiothreitol (DTT) and 2,3-dimercapto-1-propane-sulfonic acid (DMPS) abrogated the down-regulatory effects of diclofenac, flufenamic acid and meclofenamic acid on neutrophils L-selectin basal expression. Several NSAIDs (n=10) caused variable increases in the mitochondrial and intracellular ROS concentration in neutrophils that were inversely proportional to the change they produced in L-selectin surface expression ($r=-0.8$, $p< 0.01$). The inhibition of NADPH oxidase activity with diphenyleneiodonium (DPI) prevented the down-regulation of L-selectin by diclofenac. The pre-incubation of neutrophils with superoxide dismutase but not with catalase showed both a significant protective effect on the L-selectin down-regulation induced by several NSAIDs and prevented diclofenac's effect on neutrophil rolling ($p<0.05$). Interestingly, neutrophils from CGD patients showed a significant less ability to release L-selectin from neutrophil surface than control in response to diclofenac.

Conclusion: All these data indicate that: 1) a group of NSAIDs is capable of interfering with the ability of neutrophils to interact with endothelial cells by means of the L-selectin-shedding and 2) the generation of superoxide anion by activation of NADPH oxidase at plasma membrane level seems to play a major role in the L-selectin shedding induced by NSAID in neutrophils, suggesting that ROS generation may assume a potentially novel function as regulators of inflammatory response

A Concerted Dynamic Real Time In Vivo and Static Ex Vivo Analysis of Granulomonocytic Cell Migration in the Collagen Induced Arthritis Model. Ruth Byrne[1], Eva Rath[1], Anastasiya Hladik[1], Birgit Niederreiter[1], Michael Bonelli[1], Sophie Frantal[1], Michael Klimas[1], Josef Smolen[2] and Clemens Scheinecker[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Granulomonocytic cells (GMC) drive the inflammatory process at the earliest stages of rheumatoid arthritis (RA). The migratory behavior and functional properties of GM cells within the synovial tissue are, however, only incompletely understood. This tempted us to study GMC in the murine collagen induced arthritis (CIA) model of RA with the help of multi-photon real time in vivo microscopy together with the subsequent and sequential ex vivo analysis of GMC on tissue sections.

Methods: CIA was induced in LysM-EGFP C57BL/6 transgenic animals that carry the EGFP fluorescence protein under the lysozyme promoter. Individual joints were prepared by surgical microscopy in healthy control and in CIA subjects and $EGFP^+$ GMC were analyzed by 2-photon laser microscopy over 2 hours. One group of animals received one single dose (0.25 mg) of prednisolone i.v. before in vivo imaging. Afterwards the animals were sacrificed and cryo-, and paraffin sections were prepared for immunofluorescence and histomorphological analysis, respectively.

Results: GMC were barely detectable in healthy animals but were abundant in the synovial tissue as soon as clinical arthritis was apparent. GMC were motile and migrated randomly through the synovial tissue with a reduced mean velocity (2.75 ± 1.17 mm/min) of as compared to healthy controls (3.11 ± 1.51 mm/min; $p<0.001$). In CIA subjects the frequent formation of dynamic cell clusters was observed that consisted of both $EGFP^{high}$ neutrophilic granulocytes and $EGFP^{low}$ monocytes. In addition $EGFPI^{ow}$ $F4/80^+$ $TRAP^+$ osteoclast precursor cells were occasionally observed at the synovial-bone junction and areas of bone erosions. Prednisolone treatment reduced the mean velocity of cell migration (2.19 ± 1.06 μm/min; $p<0.001$) and significantly diminished the immigration of GMC into the

synovial tissue, but did not affect GMC allocation within cell clusters or throughout the entire tissue.

Conclusion: The combined application of real time in vivo microscopy together with elaborate static post-mortem analysis of GMC enabled the description of dynamic migratory characteristics of GMC together with their precise allocation in a complex anatomical environment. Moreover this approach was found sensitive enough to detect subtle therapeutic effects within a very short period of time.

32

miRNA-126 Regulates Increased VCAM-1 Expression in Muscle Biopsies From Children with Untreated Juvenile Dermatomyositis of Short Disease Duration. Lauren M. Pachman[1], Erin Kim[2], Joan Cook-Mills[1], Gabrielle Morgan[2], Janice Caliendo[1] and Simone Treiger Sredni[1]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Children's Memorial Hospital, Chicago, IL

Background/Purpose: Juvenile dermatomyositis (JDM) is an autoimmune systemic vasculopathy, targeting small blood vessels in both the skin and muscle, in which untreated disease chronicity is accompanied by progressive vascular damage, phenotypic and genotypic alterations. Vascular adhesion molecule, VCAM-1, present on a range of cells, including endothelial cells, aids in the recruitment of leukocytes from the blood to the tissue, and acts as a gatekeeper for the inflammatory process. MicroRNAs are non-coding RNAs that regulate several messenger RNAs simultaneously by mechanisms such as translational repression or cleavage of target messages, potentially offering a new avenue of therapeutic intervention.

Objective: To evaluate the impact of the duration of untreated disease (DUD), disease chronicity, in children with JDM on: 1) expression of VCAM-1 and miRNA in diagnostic muscle biopsies (MBx), and, 2) serum levels of soluble VCAM-1 (sVCAM-1) and TNF-α at the diagnosis of JDM, compared with age-matched controls.

Patients and Methods: After obtaining informed consent, healthy pediatric controls (n=8) and children with definite/probable JDM (n=28) were enrolled. For JDM, short DUD (n=11) was defined as ≤2 months untreated symptoms before diagnostic MBx (mean=1.3±0.4mo); long DUD (n=17) as >2 months (mean=17.1±25.5mo). MBx sections were stained using triple immunoflorescence with antibodies to VCAM-1, α-smooth muscle actin (SMA) and von Willebrand factor (vWF). Total area (microns^2) and total intensity (pixels) of VCAM-1 expression was measured. sVCAM-1 and TNF-α levels (ELISA) were tested in sera from JDM with long (n=8) vs short DUD (n=6). MicroRNA from 6 untreated JDM (3 long DUD, 3 short DUD) was evaluated using Exiqon's miRCURY LNA microRNA Array, v.11.0.

Results: MBx of JDM with short DUD displayed a significantly higher total area and intensity/hpf of VCAM-1 expression than those with long DUD and controls ($p<0.05$). In addition, JDM children with short DUD had sVCAM-1 levels that were significantly higher compared to controls ($p=0.013$). Similar patterns were found in TNF-α levels ($p=0.048$). MicroRNA miR-126, which regulates VCAM-1 expression, was significantly downregulated (FC= −1.92, p-value=0.014) in muscle of untreated JDM with a short DUD.

Conclusion: VCAM-1 protein expression in JDM MBx, regulated by miR-126, is more prominent in JDM with a short DUD (≤2 months) versus long DUD (>2 months), suggesting that VCAM-1 may play a critical role *early* in JDM pathophysiology in response to miRNA-126 control.

Supported by the Wellesley City Scholars Program (EK), Cure-JM and the Macy's Miracle Foundation (LMP).

33

Angiogenic Factors in Early Inflammatory Arthritis. Luana Mancarella[1], Olga Addimanda[1], Lia Pulsatelli[1], Paolo Dolzani[1], Elisa Assirelli[1], Veronica Brusi[1], Stefano Galletti[1] and Riccardo Meliconi[2]. [1]Istituto Ortopedico Rizzoli, Bologna, Italy, [2]Istituto Ortopedico Rizzoli and University of Bologna, Bologna, Italy

Background/Purpose: Angiogenesis is an important event in rheumatoid synovitis, with an increase in immature and destabilized vessels. Fibroblast growth factor-2 (FGF2) and vascular endothelial growth factor (VEGF) play a major role in angiogenesis. PTX3 (long pentraxin-3) is an acute phase glycoprotein produced by several cell types in response to primary inflammatory signals (e.g. Toll-like receptor, TNF, IL-1 but not IL-6). It interacts directly with FGF2 and inhibits its angiogenic activity (1). PTX3 systemic levels have been shown to be elevated in patients with some vascular and inflammatory disorders and seem to correlate with clinical outcome and disease activity (2). The aim of our study was to evaluate the serum concentrations of some angiogenic factors and other biomarkers in patients with early inflammatory arthritis (IA) and their possible relationship with disease activity and ultrasound (US) features.

Methods: We analyzed 37 patients with early inflammatory arthritis (IA) with at least one swollen joint and who had had symptoms for less than one year (except for 4 patients who had had symptoms for more than one year); we compared this group with 24 age- and sex-matched healthy controls (HC). VEGF, vascular cell adhesion molecule-1 (VCAM-1), FGF2, IL-6, and soluble IL-6 receptor and PTX3 levels in peripheral blood samples were determined by ELISA. Demographic (gender, age), clinical (disease duration, tender and swollen joints count, Health Assessment Questionnaire score, 100 mm visual analogue scales for pain and global health status), laboratory (erythrocyte sedimentation rate, C reactive protein, presence or absence of rheumatoid factor and anti-CCP antibodies) data were collected. US scans with 7.5–15 MHz linear array (to assess synovial thickness, power Doppler signal – PDS, and erosions) were carried out and a Disease Activity Score for 28 joints (DAS28) was calculated. Data were analysed using analysis of variance (ANOVA) or the Mann-Whitney U Test (to compare variables not normally distributed). Fisher's exact test was used to compare categorical variables. Pearson's correlation coefficient (*r*) (for linear relationship), otherwise Spearman's rank correlation (*rho*) to assess correlations. The level of significance was $p<0.05$.

Results: A mean age of 57.2 ± 14.5 yrs was found, a disease duration of 32.4 ± 47.7 weeks and a moderate disease activity (DAS28 of 4.8 ± 1.2). 97% of patients had PDS positivity on US examination and 22% had erosive features. VCAM-1 were higher ($p=0.002$), and PTX3 lower ($p<0.0005$) in patients compared to HCs. We found a statistically significant positive correlation between VEGF and IL-6 levels and DAS28 ($r=0.374$, $p=0.03$ and rho= 0.45, $p=0.02$, respectively). At 3rd month of follow up, basal FGF levels had a positive trend with DAS28 ($p=0.08$); patients who continued to show PDS positivity, tended to have higher basal levels of IL-6 and VCAM-1 compared to PDS negative patients ($p=0.06$ and $p=0.07$, respectively).

Conclusion: Our preliminary results show increased VCAM-1 and decreased PTX3 (an anti-angiogenic factor) levels in early IA. Angiogenic factors and IL-6 show a positive trend with disease activity and its persistence.

34

Junctional Adhesion Molecule C Regulates the Transendothelial Migration of Murine Synovial Fibroblasts of Human TNFalpha Transgenic Mice. Marianne Heitzmann[1], Adelheid Korb-Pap[1], Christina Wunrau[1], George Kollias[2], Stefan Butz[3], Dietmar Vestweber[3], Hermann Pavenstädt[1] and Thomas Pap[1]. [1]University Hospital Muenster, Muenster, Germany, [2]Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece, [3]University Muenster, Muenster, Germany

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disorder that starts in few single joints and continuously spreads to unaffected ones. Recently, it was demonstrated that RA fibroblast-like synoviocytes (FLS) have the potential to migrate via the bloodstream and invade distant cartilage in the SCID mouse model of disease. The mechanisms of endothelial transmigration of RA-FLS are unknown. In this context, the junctional adhesion molecule C (Jam-C), the third member of Jam family is an interesting candidate molecule because it has been found on RA-FLS and implicated in the transendothelial migration of leukocytes. Here, we used the human TNFalpha transgenic (hTNFtg) mouse as a model for human RA and studied the role of Jam-C in the transmigration of FLS derived from these mice.

Methods: The expression of Jam-C on wildtype and hTNFtg FLS was investigated by Western-blot analysis and immunocytochemistry. The transmigratory capacity of these cells was studied in a transmigration assay using the murine endothelioma cell (bEnd.5) as an endothelial barrier. Murine cartilage tissue treated with IL-1alpha was used as chemoattractant stimulus for the transmigration assays. Functional analyses included the knock down of Jam-C expression by siRNA against murine Jam-C.

Results: We identified the expression of Jam-C on the surface of both wildtype FLS and FLS from hTNFtg mice and found it most prominently on sites of cell-cell interactions. While expression levels of Jam-C were low in wildtype cells, FLS from hTNFtg mice showed a significantly higher expression. Transmigration experiments demonstrated a significantly higher potential of hTNFtg FLS to migrate through the endothelial monolayer than FLS from wildtype mice (+40%, p≤0,05), and cartilage explants pre-treated with IL-1alpha enhanced the migratory capacity of hTNFtg FLS. Interest-

ingly, siRNA-mediated knock down of Jam-C expression reduced the number of transmigrating hTNFtg FLS by 40%.

Conclusion: Our data demonstrate that the inflammatory environment as found in the joints of hTNFtg mice results in an upregulation of Jam-C on FLS in a similar way as described for human RA-FLS. Moreover, they indicate that this environment facilitates the development of a phenotype of FLS that is capable of transmigrating through endothelial barriers. Jam-C appears to be involved functionally in the transmigration and, thus, in extravasation of FLS and, therefore targeting Jam-C may be a promising therapeutic strategy for RA.

35

Matrix Effects on Cellular Adhesion of Fibroblasts From Patients with Rheumatoid Arthritis, Osteoarthritis and Systemic Sclerosis. Stephanie Lefevre[1], Simone Benninghoff[1], Angela Lehr[2], Stefan Rehart[2], Henning Stürz[3], Jürgen Steinmeyer[4], Andreas Günther[5], Ulf Müller-Ladner[1] and Elena Neumann[1]. [1]Justus-Liebig-University of Gieβen, Bad Nauheim, Germany, [2]Markus-Hospital, Frankfurt, Germany, [3]University Hospital Gieβen and Marburg, Giessen, Germany, [4]University Hospital Gieβen and Marburg, Gieβen, Germany, [5]Justus-Liebig-University of Gieβen, Giessen, Germany

Background/Purpose: In rheumatoid arthritis (RA), aggressive synovial fibroblasts (SFs) play a central role in cartilage destruction and the spreading of the disease. We recently demonstrated the long-distance migratory potential of RASFs *in vivo* as well as the importance of extracellular matrix (ECM) regarding cellular adhesion with subsequent cartilage invasion. When cartilage was embedded into carrier matrices coated with growth factor-reduced Matrigel® (GFR MG) in the SCID mouse model of RA, a reduced RASF invasion compared to cartilage in Matrigel® (MG)-coated or non-coated carrier matrices was observed. Therefore, matrix-associated growth factors appear to influence migration and adhesion of RASFs. In this study, the effects of ECM-associated growth factors on the adhesion of fibroblasts from different rheumatic diseases as well as healthy individuals were analyzed.

Methods: Multi-well culture plates were coated with MG, GFR MG, or remained untreated, respectively. Cellular adhesion of RASFs (n=4), osteoarthritis (OA) SFs (n=3), RA dermal fibroblasts (n=5), systemic sclerosis (SSc) fibroblasts (n=7), synovial (n=1) and dermal fibroblasts of healthy individuals (n=6) was analyzed after 15 min. For this purpose, the fibroblasts were stained with Calcein-AM and adhesive fibroblasts were quantified using a fluorescence microscope.

Results: In general, an increased adhesion was observed after multi-well plate coating with GFR MG or MG. By using GFR MG, a reduction of cellular adhesion (1.4fold) of RASFs was observed compared to coating with MG. This behaviour was also visible when analyzing RA dermal fibroblasts (1.06 reduction of adhesion to GFR MG compared to MG). Fibroblasts of OA and SSc patients or healthy synovial or dermal fibroblasts showed the opposite reaction, an increased adhesion using GFR MG was observed compared to MG (OA: 1.6fold; SSc: 1.22fold; healthy SFs: 1.8fold; healthy dermal fibroblasts: 1.3fold).

Conclusion: The data show that ECM and its associated components, e.g. growth factors, play a critical role in RASF attraction and adhesion to cartilage. These factors are able to activate different adhesion molecules in RASFs, which are central features of this cell type, as RASFs are characterized by increased surface expression of adhesion molecules. Of note, dermal fibroblasts of RA patients show a similar behaviour but fibroblasts of other diseases or controls do not appear to be influenced by growth factors with respect to an increased expression of adhesion molecules. Therefore, the observed behaviour of RA dermal or synovial fibroblasts regarding adhesion to growth factor-containing matrix appears to be a disease-specific property.

A Disintegrin and Metalloprotease 10 (ADAM10) Is Overexpressed in Rheumatoid Arthritis Synovial Tissue and Mediates Angiogenesis. Takeo Isozaki[1], Bradley J. Rabquer[1], G. Kenneth Haines III[2] and Alisa E. Koch[3]. [1]University of Michigan, Ann Arbor, MI, [2]Yale University, New Harven, CT, [3]Veteran's Administration and Unversity of Michigan, Ann Arbor, MI

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammation and joint destruction. Angiogenesis is important in a variety of vasculoproliferatine states in RA. A disintegrin and metalloprotease (ADAM) are a family of proteases that are responsible for the liberation of a variety of types of cell surface expressed proteins. ADAM10 has been shown to cleave a number of inflammatory mediators from the cell surface including CX3CL1 and CXCL16. In this study, we examined the expression of ADAM10 in RA synovial tissue (ST) and the role it plays in angiogenesis.

Methods: ADAM10 expression was determined in ST samples from normal (NL) subjects, osteoarthritis (OA) patients and RA patients using immunohistological staining. To determine whether ADAM10 was expressed by human dermal microvascular endothelial cells (HMVECs) and whether it was regulated by interleukin-17 (IL-17), phorbol 12-myristate 13-acetate (PMA) or lipopolysaccharide (LPS), Western blots and real time polymerase chain reaction (RT-PCR) were performed. In order to confirm the role of ADAM10 in angiogenesis, we did Matrigel assays *in vitro*. To block the expression of ADAM10, HMVECs were transfected with siRNA against ADAM10. After treatment with ADAM10 siRNA, HMVECs were plated on Matrigel and were incubated with phosphate buffered saline (PBS) or basic fibroblast growth factor (bFGF) (positive control) (5nM). Chemotaxis assays were performed to determine the role of ADAM10 in endothelial cell (EC) migration.

Results: ECs within RA ST expressed high levels of ADAM10, while ECs within OA ST and NL ST expressed significantly less ADAM10 (mean ± SEM RA ST 46 ± 6.6% expression of total ECs, OA ST 9 ± 3.29% expression of total ECs and NL ST 0.91 ± 0.61% expression of total ECs). We found that ADAM10 was significantly elevated at the protein level in HMVECs stimulated with proinflammatory mediators such as IL-17, PMA or LPS compared with nonstimulated cells ($p<0.05$). The expression of ADAM10 messenger RNA (mRNA) was induced by stimulation with LPS after 1 hour. ADAM10 siRNA treated HMVECs had decreased EC tube formation compared with control siRNA treated HMVECs (3 ± 1.47 number of tubes formed and 37.3 ± 3.94 number of tubes formed, $p<0.05$). In addition, ADAM10 siRNA treated HMVECs had decreased migration compared with control siRNA treated HMVECs (14.7 ± 0.01 number of cells migrated and 20.5 ± 0.01 number of cells migrated, $p<0.05$).

Conclusion: These data show that ADAM10 is overexpressed in RA and suggest that ADAM10 may play a role in RA angiogenesis. ADAM10 may be a potential target in inflammatory disease like RA.

37

Regulation of Synoviocyte Migration by phosphoinositide 3 Kinase (PI3K) Delta. Beatrix Bartok[1], Deepa Hammaker[2], Christian Rommel[3] and Gary S. Firestein[4]. [1]UCSD, La Jolla, CA, [2]Univ of California San Diego, La Jolla, CA, [3]Intellikine, Inc., La Jolla, CA, [4]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Class I phosphoinositide 3 kinase (PI3K) mediate their biological activity through generation of phosphatidylinositol 3, 4, 5 –triphosphate (PIP3) at the cell membrane, which recruits downstream signaling molecules like Akt. One isoform, PI3Kdelta, was originally thought to be expressed mainly in leukocytes but was recently demonstrated in RA synovial tissue and cultured fibroblast–like synoviocytes (FLS). Using a novel selective PI3Kdelta inhibitor INK007, we showed that PI3Kdelta is a major regulator of synoviocytes growth and survival. The goal of current study was to assess role of PI3Kdelta in synoviocyte migration in response to PDGF, a known chemotactic factor for mesenchymal cells.

Methods: FLS were cultured in 6-well plates in presence of medium or PDGF-BB (10 nM) with or without PI3K inhibitors. The selective PI3Kdelta inhibitors INK007 was used for these studies, which has >20 fold selectivity over PI3Kgamma. The cells were wounded by clearing a region with a pipet tip, and the number of cells that migrate into the cleared area at 0 and 24 hour was determined by counting cells with light microscopy. For directed chemotaxis, 24-well modified Boyden transwell with 8.0 μ pore filters were used. Medium was added to the upper chamber and PDGF-BB (10nM) or media were added to the lower chamber. Cells were preincubated with PI3K inhibitors or vehicle for 1 hour prior to the assay and migrating cells were analyzed after 4 hrs. The filters were stained with 1% crystal violet and cells were counted by light microscopy.

Results: The effect of PI3K inhibition on undirected FLS motility in the presence of PDGF was studied using wound healing assay. There was a 2.6 fold increase in the number of migrating cells within the wounded area after 24 hrs in presence of PDGF compared with medium alone ($p<0.03$). The PI3Kdelta inhibitor INK007 significantly decreased number of migrating cells in a concentration dependent manner, with 50±5% inhibition at 1 uM, which is approximately the EC50 for this compound for other functional assays ($p< 0.04$). A pan PI3K inhibitor completely blocked cell migration in response to PDGF, suggesting that other PI3K isoforms also participate. A PI3Kalpha selective inhibitor decreased the number of migrating cells by 60±5% at 1 uM ($p<0.04$). We then studied

effect of PI3K inhibition on PDGF-mediated chemotaxis using a transwell chemotaxis assay. There was a 2.5-fold increase in the number of cells that migrated in response to PDGF compared with medium ($p<0.03$). Preincubation of FLS with PI3Kdelta, or panPI3K inhibitor decreased number of migrated cells by 50±3%. ($p<0.04$ for each).

Conclusion: PI3Kdelta regulates PDGF-mediated FLS migration in addition to its previously defined role in synoviocyte survival and growth. Our findings suggest that targeting PI3Kdelta could be beneficial in RA by modulating synoviocyte function and potentially suppressing joint damage.

38

Soluble Junctional Adhesion Molecule-B Inhibits Angiogenesis in Rheumatoid Arthritis. Bradley J. Rabquer[1], Beatrix Balogh[1], Jeffrey H. Ruth[1], Beat A. Imhof[2] and Alisa E. Koch[3]. [1]University of Michigan, Ann Arbor, MI, [2]University of Geneva, Switzerland, [3]Department of Veteran's Affairs and Unversity of Michigan, Ann Arbor, MI

Background/Purpose: Angiogenesis is a highly regulated process of new blood vessel formation that may occur from pre-existing blood vessels. Rheumatoid arthritis (RA) is characterized by synovial hyperplasia, inflammation, and neovascularization. In RA, angiogenesis is regulated by the expression of pro- and antiangiogenic growth factors, cytokines, and adhesion molecules. Junctional adhesion molecule-B (JAM-B) is a recently described adhesion molecule expressed by several cell types, including endothelial cells (ECs). The aim of this study was to determine if JAM-B is found in soluble form (sJAM-B) and if it mediates angiogenesis.

Methods: We designed and performed an ELISA to determine if sJAM-B was present in normal and RA serum, and RA synovial fluid (SF). To determine if sJAM-B mediates *in vivo* angiogenesis, we performed Matrigel plug angiogenesis assays. Matrigel was mixed with sJAM-B or controls and implanted subcutaneously into C57BL/6 mice. After 7 days, the plugs were removed and homogenized for hemoglobin determination, a correlate of vascularity. To determine if sJAM-B mediates *in vitro* angiogenesis, Matrigel EC tube formation assays were performed. Human microvascular endothelial cells (HMVECs) were stimulated with sJAM-B to determine which signaling pathways were activated.

Results: Our results indicate that JAM-B is present in soluble form and that sJAM-B inhibits angiogenesis. sJAM-B was detected in normal serum (n=the number of patients=9, 630 (mean) ± 30 (SEM) pg/ml) and was significantly elevated in RA serum (n=7, 820 ± 80 pg/ml) and RA SF (n=8, 1,090 ± 130 pg/ml) (all $p<0.05$). In an *in vivo* Matrigel plug angiogenesis assay, plugs containing basic fibroblast growth factor (bFGF) (n=the number of mice=7, 1234 (mean) ± 63 (SEM) (μg/ml)/g) had significantly more hemoglobin than those with PBS (n=7, 707 ± 96 (μg/ml)/g) ($p<0.05$), whereas plugs with sJAM-B (n=7, 469 ± 24 (μg/ml)/g) had significantly less hemoglobin than those with PBS ($p<0.05$). *In vitro*, Matrigel EC tube formation assays indicated that when alone sJAM-B (n=the number of experiments=4, 36 (mean) ± 3 (SEM) tubes) induced low levels of tube formation compared to PBS (n=4, 29 ± 2 tubes) ($p<0.05$), but that sJAM-B in combination with bFGF (n=2, 52 ± 2 tubes) resulted in lower levels of tube formation than bFGF alone (n=2, 61 ± 1) ($p<0.05$). Lastly, sJAM-B stimulated the phosphorylation of Erk1/2 and p38 kinases and induced the dephosphorylation of Src kinase in HMVECs.

Conclusion: Our results show that sJAM-B is upregulated in RA serum and SF compared to normal serum. In addition, we show that sJAM-B inhibits *in vivo* angiogenesis. These results suggest that modulation of sJAM-B may provide a novel route for controlling angiogenesis in RA.

39

FAAH Inhibition Reverses Glucocorticoid Effects in Synovial Fibroblasts of Patients with Osteoarthritis and Rheumatoid Arthritis. Torsten Lowin[1], Elena Neumann[2], Ulf Muller-Ladner[3] and Rainer H. Straub[1]. [1]University Hospital Regensburg, Regensburg, Germany, [2]Justus-Liebig-University of Gieβen, Bad Nauheim, Germany, [3]Justus-Liebig Universität Gieβen, Kerckhoff-Klinik GmbH, Bad Nauheim, Germany

Background/Purpose: In rheumatoid arthritis, glucocorticoid secretion in relation to inflammation is inadequate. Besides their direct effects on inflammation, GCs induce indirect effects by modulation of the endocannabinoid system, e.g., the production of anandamide after cortisol stimulation of neurons. We hypothesize that cortisol stimulation leads to the generation of endocannabinoids by synovial fibroblasts (SFs) with a distinct profile of action from cortisol. We used *fatty acid amide hydrolase* (FAAH) inhibition to unmask the endocannabinoid effects.

Methods: We performed immunofluorescence analysis and cell-based ELISAs to quantify cannabinoid receptor1 (CB1R) and FAAH levels. Adhesion and proliferation was assessed using the *Xcelligence* system by Roche. Flow cytometry was employed for the detection of integrin $\alpha5$.

Results: Cortisol increased the adhesion of synovial fibroblasts to fibronectin, reaching a maximum at 10^{-8}M. FAAH inhibition plus cortisol reversed cortisol only effects and inhibition of adhesion was maximal at 10^{-8}M cortisol. This effect was partially mediated by modulation of the fibronectin receptor integrin $\alpha5\beta1$. Proliferation of SFs was significantly reduced by cortisol and this effect was reversed when FAAH was blocked. Furthermore, cortisol downregulated levels of FAAH and CB1R but concomitant FAAH inhibition increased levels of both proteins.

Conclusion: FAAH inhibition reversed cortisol effects on adhesion, proliferation and FAAH and CB1r expression. As FAAH inhibition by itself had no influence on SFs it is likely that an endocannabinoid/eicosanoid is synthesized upon cortisol treatment which explains the observed effects.

Design of Peptides From CD2 to Modulate Protein-Protein Interactions and Immune Response. Ameya Gokhale[1], Veena Taneja[2] and Seetharama Satyanarayanajois[1]. [1]University of Louisiana at Monroe, Monroe, LA, [2]Mayo Clinic, Rochester, MN

Background/Purpose: Cell adhesion molecules play a central role at every step of the immune response. The function of the leukocyte can be regulated by modulating adhesion interactions between cell adhesion molecules to develop therapeutic agents against autoimmune diseases. CD2 and its ligand CD58 are two of the best-characterized adhesion molecules mediating the immune response. To modulate the protein-protein interaction and hence cell adhesion interaction, six peptides with conformational constraints were designed from the discontinuous epitopes of β-strand region of CD2 protein. The purpose is, a) to evaluate the cell adhesion inhibition activity of peptides using cell adhesion assay, b) to evaluate the peptides for immunomodulation in an in vitro assay, and c) to elucidate the three-dimensional structure of the peptides using Nuclear Magnetic Resonance (NMR) and Molecular Dynamics (MD).

Methods: The ability of the CD2-derived peptides to inhibit cell adhesion interaction was studied by E-rosetting assay and lymphocyte epithelial assay using T cells and Caco-2 cells that express CD2 and CD58 proteins respectively. The binding of Peptide 6 to CD58 protein was studied in a competitive binding assay using FITC-antiCD58 by flow-cytometry. Structure of the peptides was studied by NMR spectroscopy, Circular Dichroism Spectroscopy (CD) and MD simulation. In vitro effect of the CD2-derived peptides was done by inhibition of antigen-specific T cell proliferation using HLA-DQ8 (DQA1*0301/DQB1*0302) transgenic mice.

Results: Among the six peptides studied in this series, peptides **6** and **7** inhibit the cell adhesion activity with an IC_{50} value of 7 nM and 11 nM respectively, in lymphocyte-epithelial adhesion assay. These peptides were also able to suppress the antigen-specific T cell response in cells isolated from humanized mice known to be susceptible to inflammatory polyarthritis. The binding of Peptide 6 to CD58 protein was studied in a competitive binding assay using FITC-antiCD58 by flow-cytometry. Peptide 6 inhibited antibody binding to CD58 on Caco-2 and OVCAR cells expressing CD58. NMR and molecular modeling results indicated that peptides **6** and **7** exhibited β-turn structure with a β-hairpin structure in solution.

Conclusion: Peptides designed from the hot-spot region of CD2 protein may form the lead compounds to inhibit immune response and hence may be therapeutically useful for autoimmune diseases such as rheumatoid arthritis.

Toll-Like Receptor 2 Induced Cell Migration and Invasion Is Mediated Through β1-Integrin Signalling Pathways and Cytoskeletal Dynamics. Trudy McGarry[1], Mary Connolly[2], Jennifer McCormick[1], Douglas J. Veale[1] and Ursula Fearon[1]. [1]Dublin Academic Medical Centre, University College Dublin, Dublin, Ireland, [2]Center of Experimental Rheumatology, University Hospital Zürich, Zurich, Switzerland

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial inflammation and destruction of cartilage and bone. TLR-2 is implicated in the pathogenesis of RA. This study investigates if TLR-2 induced cell migration and invasion is mediated through **β1-integrin** signalling pathways and cytoskeletal dynamics.

Methods: IA patients (n=20) underwent clinical assessment, videoarthroscopy and synovial biopsy pre/post biologic therapy. Macroscopic

synovitis/vascularity was measured by visual analogue scale. Immunohistology/immunoflourescence examined β1 integrin and filamentous actin (F-actin) expression in synovial tissue (ST), primary RA synovial fibroblasts (RASFC) and microvascular endothelial cells (HDEC). Cytoskeletal rearrangement following Pam3CSK4 (1ug/ml)(TLR2-ligand) stimulation was examined by F-actin immunofluorescent staining. Pam3CSK4 induced adhesion, cell migration and invasion was assessed by FACS analysis, wound repair assays and transwell matrigel™ invasion chambers in the presence or absence of anti-β1 integrin (10ug/ml) or IgG control antibody (10ug/ml).

Results: β1 integrin was highly expressed in IA ST compared to osteoarthritis and control tissue. β1 integrin lining and sub-lining layer expression significantly correlated with macroscopic synovitis ($p<0.05$), vascularity ($p<0.05$), and was significantly reduced in biologic responders. β1-integrin and F-actin expression predominantly co-localized to synovial blood vessels and lining layer. Pam3CSK4 induced cell surface expression of ICAM ($p<0.05$). Using RASFC and HDEC, Pam3CSK4 induced cell migration and cytoskeletal disassembly, resulting in filopodia and microspike formation and significantly induced cell invasion through a matrigel ($p<0.05$). Finally, we demonstrated that Pam3CSK4 induced cell migration was inhibited in the presence of anti-β1 integrin, an effect that was also observed for PAM3CSK4 induced cellular invasion ($p<0.05$). No effect was observed for IgG matched control antibody.

Conclusion: b1-integrin is highly expressed in the inflamed joint and mediates cell TLR-2 induced migrational and invasive mechanisms, critical to the pathogenesis of IA.

Epigenetically Regulated MicroRNA-126 Influences Migratory Potential and Apoptosis of Synovial Fibroblasts in Rheumatoid Arthritis. Mojca Frank[1], Maria Filkova[1], Joanna Stanczyk[1], Mary Connolly[1], Christoph Kolling[2], Beat A. Michel[1], Blaz Rozman[3], Renate E. Gay[1], Steffen Gay[1] and Astrid Jungel[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]University Medical Centre, Ljubljana, Slovenia

Background/Purpose: Increased migration and decreased apoptosis are main characteristics of the aggressive behaviour of rheumatoid arthritis (RA) synovial fibroblasts (SF). Increased migration has been implicated in spreading RA from affected to unaffected joints, resulting in polyarticular disease. Dysregulation of several microRNAs (miRs) has been found to play a role in cell migration, apoptosis and inflammation.

Objectives: To analyse the expression of most relevant miRs in RA, their regulation by proinflammatory and epigenetic mechanisms in SF and their functional role in shaping the aggressive behaviour of RASF.

Methods: TaqMan Single Assays were used to analyse the expression of 260 miRs in human RASF and osteoarthritis (OA) SF (n=3 each). MiR-126 was further quantified in RASF (n=10), OASF (n=9), RA (n=10), OA (n=6) synovial tissue and RA (n=20) or healthy control sera (n=17) by Taqman Real Time PCR. Let-7a was used as an endogenous control. The regulation of miR-126 expression was investigated in RASF (n=5) treated with TNFα, IL-1β, IFN-β, Poly(I:C) or LPS and in RASF (n=6) exposed to hypoxia (24h, 1% O_2). Additionally, RASF and OASF were treated with 5'azacytidine (5'AZA, 0.1, 0.5 and 1mM, 5 days) or Trichostatin A (TSA, 1mM, 24h). The functional role of miR-126 (migration/scratch and Annexin-V apoptosis assays) was studied in SF following Lipofectamine transfection (48h) with pre-miR-126 (100nM), mature miR-126 (25, 50nM), anti-miR-126 (25, 50nM) or scrambled controls.

Results: MiR-126 was significantly upregulated in RASF (dCt± SE=7.93±2.43) vs. OASF (dCt=9.91±0.81, p=0.022) and in sera from RA patients (dCt=−1.79±1.01) compared to healthy controls (dCt=−1.26±0.61, p=0.031), while no significant difference was found between RA and OA synovial tissue. Proinflammatory cytokines, TLR ligands or hypoxia (1% O_2) had no effect on the expression of miR-126 in RASF. DNA demethylation of RASF (x-fold: 1.78±0.53, n=2) and OASF (1.58±0.21, n=4) with 5-AZA and treatment of OASF (1.50±0.34, n=6, p=0.031) and RASF (1.70±0.34, n=4) with TSA upregulated miR-126. Transfection with pre-miR-126 decreased the migration of SF in the scratch assay by 86±0.05% in all of OA and by 48±16% in 4 out of 6 RA patients. Anti-miR-126 had no significant effect on migration. Apoptosis significantly increased in SF (n=7) transfected with mature miR-126 (2.67±0.43; p=0.008) and anti-miR-126 (1.71± 0.25, p=0.031).

Conclusion: MiR-126 is epigenetically upregulated in synovial fibroblasts by acetylation and demethylation and significantly alters the migration and apoptotic ability of SF. Therefore it may serve as a potential new therapeutic target in RA possibly influencing the spread of RA to unaffected joints.

43

Mathematical Modeling of Interleukin-6 Signaling Inhibition: Comparative Efficiency of Different Intervention Strategies. Saroja Ramanujan[1], Daniel Young[1], Peter Maisonpierre[1], Stevan Shaw[2], Jason Chan[1] and Kosmas Kretsos[2]. [1]Entelos, Inc., Foster City, CA, [2]UCB, Slough, United Kingdom

Background/Purpose: A cascade of binding events between IL-6, IL-6R, and gp130 leads to formation of IL-6 signaling complexes in inflammatory conditions.[1] Tocilizumab (TCZ), an anti-IL-6R antibody (Ab), inhibits IL-6 signaling by preventing IL-6+IL-6R dimerization (axis 1 intervention).[2] Axis 1 intervention can also be achieved with anti-IL-6 Abs. Subsequent assembly steps present alternative strategies for IL-6 signal inhibition, including IL-6-targeted agents that prevent trimer formation (IL-6+IL-6R+gp130; axis 2 intervention) or the formation of the $(IL\text{-}6+IL\text{-}6R+gp130)_2$ signaling hexamer (axis 3 intervention).

Methods: We developed a dynamic, mathematical model of IL-6 signaling within a target compartment, with initial steady state IL-6, soluble (s) IL-6R, and sgp130 concentrations. The model encompassed IL-6 interaction with membrane-bound IL-6R (cis) or with both membrane-bound and sIL-6R (cis and trans signaling), including the impact of inhibiting membrane-bound and sgp130 by different targeted strategies. The validity of the model was confirmed by comparison to published PK/PD data for TCZ.[3] Four prototypical intervention strategies were modeled: anti-IL-6R, axis 1; anti-IL-6, axis 1; anti-IL-6, axis 2; and anti-IL-6, axis 3. Simulations compared the sensitivity of drug responses to parameter variations at multiple clinically relevant IL-6, sIL-6R, and sgp130 concentration scenarios. All simulated parameters for interactions and responses were based on a one-compartment linear PK model.

Results: Anti-IL-6 axis 3 intervention was predicted to be the most efficient inhibitor of combined cis + trans IL6 signaling. This advantage held true both when IL-6 concentration was limiting (approximate serum-like RA conditions; Figure 1A), and under conditions of equimolar IL-6 and IL6R (approximate synovial-like RA conditions; Figure 1B).[4] The advantage of anti-IL-6 axis 3 intervention over anti-IL-6R or anti-IL-6 approaches to axis 1 intervention was robust to changes in single parameters, and was lost only in large excess of IL-6 over IL-6R or when multiple conditions coincided, such as a combination of: excess IL-6; inefficient Ab binding to membrane-bound targets; increased IL-6 turnover or slower IL-6R turnover; slow IL-6+IL-6R dimerization kinetics; and low Ab dissociation constant.

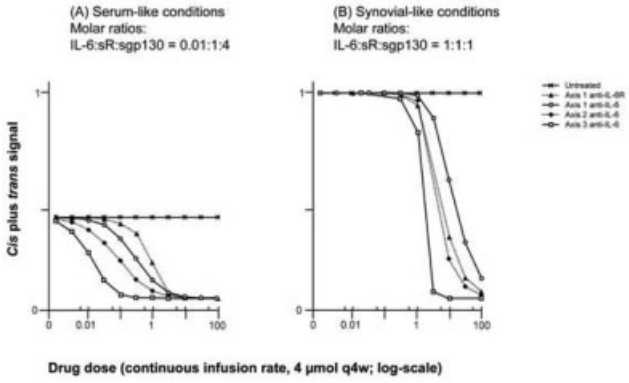

Figure 1. Modeling IL-6 signal inhibition by antibodies targeting different axes of intervention.

Conclusion: Anti-IL-6 intervention at axis 3 may be more efficient at inhibiting IL-6 signaling than axis 1 intervention with an anti-IL-6R Ab, in either serum- or synovial-like conditions. Multiple factors simulating sensitivity of drug responses were required to challenge the advantage of axis 3 intervention.

Abnormalities in a JAK-STAT Pathway Are Involved in the Aberrant Production of IL-6 by BAFF-Stimulated Peripheral Monocytes of Patients with Primary Sjögren's Syndrome. Keiko Yoshimoto[1], Maiko Tanaka[1], Masako Kojuma[1], Hideko Ogata[1], Hideto Kameda[1], Tohru Abe[2] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Saitama Medical School, Kawagoe-shi Saitama, Japan

Background/Purpose: It has been reported that B cell activating factor belonging to the TNF family (BAFF) and IL-6 are involved in the development of primary Sjögren's syndrome (pSS). BAFF is mainly expressed in monocytes and dendritic cells, and regulates proliferation, differentiation and survival of B cells, which play a pivotal role in the production of autoantibodies and hence in the development of autoimmune diseases. IL-6 is produced by many types of cells including monocytes, and promotes differentiation of B cells. In our previous study, we found that soluble BAFF (sBAFF) abnormally induced the production of IL-6 by peripheral pSS monocytes cultured in vitro.In the present study, we investigated a regulatory mechanism for the production of IL-6 by BAFF-stimulated monocytes and possible abnormalities of pSS monocytes.

Methods: Peripheral monocytes were prepared from pSS patients and age-matched normal individuals. The cells were stimulated in vitro with sBAFF in the presence or absence of inhibitors against several protein kinases, i.e., JAK2, JAK3, p38MAPK and JNK. The production of IL-6 by the cells was measured by ELISA. The expression levels of the kinases were analyzed by quantitative PCR.

Results: pSS monocytes produced substantial amount of IL-6 even in the absence of stimulation, while normal monocytes produced only marginal amount of IL-6. The production of IL-6 by the cells was increased when the cells were stimulated with sBAFF. The increase was especially remarkable for pSS monocytes as compared with normal monocytes. The elevated productions of IL-6 by the cells were significantly suppressed in a dose dependent manner by inhibitors against protein kinases, such as JAK2, JAK3, p38MAPK and JNK, thus far examined. Among the inhibitors, a JAK3 inhibitor showed the highest effect. Quantitative PCR analysis indicated that no significant difference was observed between normal and pSS monocytes in the expression level of JAK3. However, stimulation of pSS monocytes with sBAFF strongly induced the expression of JAK3 while normal monocytes did not significantly respond to the stimulation. Similarly, the expression levels of STAT3 and STAT4 in monocytes were increased upon stimulation with sBAFF, and the increase was higher in pSS monocytes than the control. The increase was remarkable for STAT4 as compared with STAT3.

Conclusion: Our data suggest that a JAK3-STAT4 pathway may be involved in the production of IL-6 by sBAFF-stimulated peripheral monocytes. In addition, abnormalities in the induction of JAK3 and STAT4 may be responsible for the abnormal responses of pSS monocytes to sBAFF. These abnormalities may be involved in the pathogenesis of pSS.

45

MiR-451 in Microparticles Derived From Monocytes Influences Gene Expression in Rheumatoid Arthritis Synovial Fibroblasts. Meike Dahlhaus[1], Joanna Stanczyk[1], Mojca Frank[1], Beat A. Michel[1], Christoph Kolling[2], David S. Pisetsky[3], Renate E. Gay[1], Steffen Gay[1], Astrid Jüngel[1] and Diego Kyburz[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Duke University Medical Center, Durham, NC

Background/Purpose: Microparticles (MPs) are small membrane-enclosed vesicles, produced by a variety of cells by budding of cell membranes. It was shown that MPs contain different levels of RNAs, including miRNAs. Here, we investigate the expression of miR-451 in monocyte-derived MPs and its influence on the expression of its target gene *Macrophage Migration Inhibitory Factor* (MIF) in rheumatoid arthritis synovial fibroblasts (RASF).

Methods: MPs were isolated from U937 cells after stimulation with TNFα (10ng/ml) for 16h by differential centrifugation. RASF were cocultured with MPs for 24h. As negative control, MPs were incubated with RNaseA and Triton-X 100 for 60min at 37°C to digest RNA before coculture. To generate miR-451 deficient MPs, U937 cells were transfected 24h before stimulation with an anti-miR451 oligonucleotide (Ambion) with Lipofectamine 2000 (Invitrogen). RNA from cells and MPs were isolated by miRNeasy Kit (Qiagen). Expression of miRNAs (miR-451, miR-144, let7a as endogenous control, cel-39 as spike-in control) and RNAs (MIF, 18S) were determined using semiquantitative Real-time PCR.

Results: MiR-451 is strongly enriched in MP derived from U937 cells without stimulation with TNFα compared to the parental cells (delta Ct: -12.7 (U937) and -6.99 (MPs), $p=0.0313$, $n=6$). After stimulation with TNFα (10ng/ml), miR-451 was strongly enriched in MPs as well (delta Ct: -13.7 (U937) and -8.14 (MPs), $p=0.0313$, $n=6$). MiR-144, located in the same cluster as miR-451, was not enriched in MPs. RASF cocultured with MPs for 24h show an 2-fold increase in miR-451 expression ($p = 0.0156$, $n=6$) and a 30 % decrease in the expression of its target MIF ($p = 0.0156$, $n=6$). Coculture of RASF with RNase A treated MP abolished this effect.

Conclusion: The process of miRNA-transfer by microparticles is a new mechanism of cell-to-cell communication. We show for the first time that miR-451 transferred via MPs influences the gene expression in RASF.

46

The Influence of Cigarette Smoke on Expression of Histone Deacetylases in Rheumatoid Arthritis. Anna Loeffler[1], Peter Kunzler[1], Fabienne Niederer[1], Astrid Jungel[1], Christoph Kolling[2], Giovanni Camici[3], Beat A. Michel[4], Renate E. Gay[1], Steffen Gay[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Institute of Physiology, University of Zurich, Switzerland, [4]University Hospital, Zurich, Switzerland

Background/Purpose: The superfamily of histone deacetylases comprises HDACs and sirtuins (SIRTs) that regulate many cellular processes by deacetylation of histone and non-histone proteins. Expression and activity of histone deacetylases is altered in rheumatoid arthritis (RA). Smoking is an environmental risk factor for RA. The aim of this study was to examine the influence of cigarette smoke on expression of HDACs and SIRTs in synovial fibroblasts and synovial tissues from RA patients and in joints of mice exposed to cigarette smoke.

Methods: Synovial tissues were obtained from smoking ($n=5$) and non smoking ($n=5$) RA patients undergoing joint replacement surgery. RA synovial fibroblasts (RASF) from non smokers ($n=6$–10) were stimulated with freshly prepared 5% cigarette smoke extract (CSE) for 24 hours. Mice were exposed to room air ($n=8$) or cigarette smoke ($n=6$) in a whole body exposure chamber for 3 weeks, sacrificed and joints were removed. Expression of HDACs and SIRTs was detected at the mRNA level by Real-time TaqMan and SYBR green PCR and at the protein level by immunoblot analysis.

Results: Stimulation of RASF with CSE significantly enhanced the expression of HDAC1 (x-fold: 2.0 ± 0.4; $p=0.04$), HDAC2 (1.9 ± 0.3; $p=0.02$) and HDAC3 (2.4 ± 0.4; $p=0.01$) at the mRNA level while the expression of HDAC 4–11 remained unchanged. However, the protein levels of HDAC1 and HDAC3 were not altered, whereas the expression of HDAC2 protein was decreased. Among all sirtuins examined the transcriptional level of SIRT4 was 4.3-fold ±1.0 ($p=0.01$) and SIRT6 mRNA was 2.7-fold±0.5 increased ($p=0.02$) in CSE stimulated RASF. The elevated expression of SIRT4 and SIRT6 was also detected at the protein level, confirming that stimulation with CSE affects the expression of these two sirtuins in vitro.

Also in joints of mice exposed to cigarette smoke the basal mRNA levels of SIRT4 and SIRT6 were 2.3-fold (DCT smoking 14.6 ± 0.6; DCT control $15.5\ \pm0.7$; $p=0.04$) and 1.8-fold (DCT smoking 13.6 ± 0.9; DCT control 14.7 ± 1.0; $p=0.04$) higher as compared to control mice. In human synovial tissue samples from RA patients, smokers had 3.1-fold (DCT smokers 2.12 ± 0.37; DCT non smokers 3.75 ± 0.48; $p=0.03$) higher mRNA levels of SIRT6 and 2.1-fold higher mRNA levels of HDAC2 (DCT smokers 2.00 ± 0.20; DCT non smokers 3.07 ± 0.34; $p=0.03$) as compared to non smokers.

Conclusion: In the current study we found that the expression of histone deacetylases, in particular SIRT4, SIRT6 and HDAC2 can be altered in

RASF, murine joints and human synovial tissue by environmental factors such as smoking. Since histone deacetylases play an important role in the epigenetic regulation of gene transcription, we suggest that smoking influences gene expression by modification of histone deacetylases.

A-SAA Induced Angiogenesis and Endothelial Cell Invasion Is Mediated Through NOTCH Signalling Pathways. Peter Rooney[1], Mary Connolly[2], Wei Gao[3], Douglas J. Veale[4] and Ursula Fearon[4]. [1]University College Dublin, Dublin, Ireland, [2]Center of Experimental Rheumatology, University Hospital Zürich, Zurich, Switzerland, [3]St. Vincent's University Hospital, Dublin, Ireland, [4]Dublin Academic Medical Centre, University College Dublin, Dublin, Ireland

Background/Purpose: Acute Serum Amyloid A (A-SAA) is strongly expressed in rheumatoid arthritis (RA) synovial tissue (ST) and is critically involved in regulating cell migration and angiogenesis. Cell migration and EC morphology is dependent on interactions which link NOTCH signalling pathways to cytoskeletal rearrangement and extracellular matrix.

Objectives: To examine if A-SAA induced angiogenesis, cell migration and invasion are mediated by the NOTCH signalling pathways.

Methods: RA whole tissue synovial explants (RAST) and human microvascular endothelial cells (HDEC) were stimulated with A-SAA (10 and 50μg/ml) or TNFα (10ng/ml) for (3–24 hours). NOTCH1 IC, its ligands DLL-4, JAGGED 1 and downstream signalling components HRT1, HRT2 were quantified by Real-time PCR. NOTCH1 IC, and growth factors (VEGF, Angiopoietin-2) were assessed by western blot and/or ELISA. A-SAA induced angiogenesis cell migration and invasion were assessed by Matrigel tube formation, scratch and invasion assay. A-SAA modulation of filamentous actin (F-actin) and focal adhesions (vinculin) was examined by dual immunofluorescence. A-SAA induced angiogenesis, invasion, altered cell shape and migration were performed in the presence or absence of siRNA against NOTCH 1. Pro-inflammatory chemokines IL-8 and Gro-Alpha levels in cultured supernatants were quantified by ELISA.

Results: A-SAA (10μg/ml) increased NOTCH1 IC and VEGF mRNA and protein expression ($p<0.05$). A-SAA induced HRT-1 and JAGGED 1 mRNA ($p<0.05$), with no effect on HRT-2 mRNA. In contrast, A-SAA inhibited DLL-4 mRNA ($p<0.05$), consistent with a negative feedback loop controlling interactions between NOTCH1 IC and DLL-4 in the regulation of EC tip vs. stalk cells development. Alterations in cytoskeletal dynamics in response to A-SAA were observed as early as 15 minutes with maximal effect at 24 hours, where F-actin disassembly and formation of filopodia and microspike protrusions was observed.Finally, A-SAA induced angiogenesis, cell migration and invasion were inhibited in the presence of NOTCH 1 siRNA ($p<0.05$). In contrast A-SAA induced IL-8 and Gro-alpha expression were not altered by NOTCH 1 siRNA.

Conclusion: A-SAA induces the NOTCH signalling pathway, VEGF and cytoskeletal rearrangement which allows temporal and spatial reorganization of cells during cell migratory events and EC morphology. Together these results suggest a critical role for A-SAA in driving cell shape, migration and invasion in the inflamed joint.

48

Age-Related Mitochondrial Dysfunction Sensitizes Human Synoviocytes to Inflammatory Response. M. Noa Valcárcel-Ares[1], Romina R. Riveiro-Naveira[1], Carlos Vaamonde-García[1], Laura Hermida-Carballo[1], Francisco J. Blanco[2] and Maria J. López-Armada[1]. [1]Aging and Inflammation Research Lab, INIBIC-CHU A Coruña, A Coruña, Spain, [2]Osteoarticular and Aging Research Lab, INIBIC-CHU A Coruña, A Coruña, Spain

Background/Purpose: Rheumatoid arthritis (RA) is an age-related disease characterized by a marked inflammatory profile. Mitochondrial dysfunction has been widely related with aging and age-related diseases. Evidences support that RA synoviocytes present an increased mitochondrial genome mutagenesis, leading to mitochondrial alterations. However, its role in the inflammatory response of synoviocytes has not been investigated. The purpose of our study was to investigate the role of age-induced dysfunctional mitochondria in the inflammatory response of normal human cultured synovial cells.

Methods: The mitochondrial respiratory chain inhibitor oligomycin (OLI) was used to simulate the aging process in which ROS production is increased and mitochondrial bioenergetics is altered. The cytokines IL-1β and TNFα were employed as they constitute the major pro-inflammatory mediators in the diseased joint. The inflammatory response was measured by cyclooxygenase-2 (COX-2) protein (flow cytometry) and mRNA expression (RT-PCR), and prostaglandin E_2 (PGE_2) and interleukin-8 (IL-8) levels (ELISA). To identify possible pathways NF-kappaB activation was determined by EMSA and BAY was used as an inhibitor of NF-kappaB; also, N-acetylcysteine (NAC) was used as ROS scavenger. Cells were preincubated with the natural antioxidant resveratrol (RSV) to investigate its effect in our mitochondrial dysfunction model.

Results: We found that oligomycin-induced mitochondrial dysfunction per se significantly stimulated the expression of slight levels of COX-2, PGE_2 and IL-8. Oligomicyn-induced mitochondrial dysfunction synergistically intensifies the inflammatory response induced by low concentrations of cytokines. Pre-treatment of synoviocytes with 10μg/ml OLI for 30 minutes significantly increases the IL-1β (0.1ng/ml)-induced COX-2 protein expression (32.5 ± 2.5 OLI+IL-1 vs. 6.5 ± 2.4 IL-1 and 4.5 ± 1.7 OLI, expressed as fluorescence intensity units, $n=3$, $p<0.001$) and COX-2 mRNA expression. Interestingly, the percentage of increase is higher with the lower dosage of cytokines (5ng/ml vs. 0.01ng/ml). When PGE2 production was assessed the synergistic effect was also found (277.0 ± 67.6 OLI+IL-1 vs. 15.4 ± 2.6 IL-1 and 97.5 ± 45.6 OLI, expressed as pg/50,000cells, $n=3$ duplicate, $p<0.005$). Similar results were obtained when IL-8 production was measured (2887 ± 272.6 OLI+IL-1 vs. 1313 ± 201.2 IL-1 and 62.36 ± 15.39 OLI expressed as pg/50,000cells, $n=4$ duplicate, $p<0.005$).

Finally, we demonstrated the involvement of NF-kB and ROS in this process since the inflammatory response was counteracted by the addition of BAY or NAC. NF-kB activation was also shown by EMSA assay. The natural antioxidant resveratrol also proved to significantly reduce inflammatory response.

Conclusion: The present study identifies for the first time mitochondria as organelles implicated in the proinflammatory response in human synoviocytes, since mitochondrial dysfunction sensitizes these cells amplifying the inflammatory response induced by cytokines. This effect is especially relevant in aging, in which a chronic low grade inflammatory state could act as a bridge between normal aging and age-related diseases.

49

Regulatory and Anti-Inflammatory Effects of MAP Kinase Phosphatase-1 in Inflammation and Arthritis. Riku Korhonen[1], Riina Nieminen[1], Tuija Turpeinen[1], Ville Taimi[1], Antonis Goulas[2], Andrew R. Clark[3] and Eeva Moilanen[1]. [1]University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland, [2]Aristotle University of Thessaloniki, Greece, [3]Imperial College London, London, United Kingdom

Background/Purpose: MAP kinase phosphatases (MKPs) are protein phosphatases that dephosphorylate and thereby down-regulate the activity of MAP kinases. In the present study, we investigated the effects of MKP-1 on the activation of MAP kinases, on the expression of inflammatory genes and the development of acute inflammatory response in mice.

Methods: The effect of MKP-1 on inflammatory gene expression was investigated by silencing MKP-1 with siRNA in macrophages and chondrocytes, or by using cells and tissues from MKP-1 deficient mice. Also, acute carrageenan-induced paw inflammation was investigated in wild-type and MKP-1 knock-out mice.

Results: MKP-1 deficiency enhanced phosphorylation of p38, but not JNK, and enhanced the expression of inflammation and arthritis associated genes COX-2, IL-6, MMP-3, TNF, and iNOS in macrophages and/or chondrocytes. Also, acute carrageenan-induced paw inflammation was increased in MKP-1 knock-out mice as compared to wild-type mice. The production of IFNγ and IL-2 was increased in splenocytes from MKP-1 knock-out mice. Interestingly, the anti-rheumatic drug aurothiomalate enhanced MKP-1 expression in chondrocytes and in human cartilage, reduced the phosphorylation of p38 MAP kinase, and inhibited the expression of IL6, COX2 and MMP3. Experiments with cartilage from MKP-1 knockout mice confirmed that aurothiomalate decreased inflammatory gene expression via the upregulation of MKP-1.

Conclusion: The data supports that MKP-1 is an endogenous factor that negatively regulates inflammatory gene expression. Compounds that upregulate MKP-1 expression or enhance its function have a promise as novel anti-inflammatory/antirheumatic drugs.

Critical Role for the IL-23/TNF Axis During TLR2/NOD2 Mediated Acute Joint Inflammation. Ferry Cornelissen[1], Odilia B.J. Corneth[2], Anne-Marie Mus[1], Patrick S. Asmawidjaja[1] and Erik Lubberts[1]. [1]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Erasmus MC, University Medical Center, Rotterdam, Rotterdam, Netherlands

Background/Purpose: IL-23 is essential in the development of chronic autoimmune diseases and supports the maturation of pathogenic Th17 cells. Although the role of IL-23 during adaptive immunity in arthritis has been studied extensively, the role of IL-23 during acute joint inflammation is unknown. Therefore, the purpose of this study is to investigate the role of IL-23 in the development of an acute, macrophage-mediated joint inflammation.

Methods: Peptidoglycan (PG) or streptococcal cell wall fragments (SCW) were intra-articularly injected into the knee joint of naïve wt or IL-23p19-deficient mice. Joint swelling was assessed by measuring joint thickness using a caliper. In addition, synovial expression of different cytokines was measured by specific ELISA and/or Q-PCR. Moreover, synovial explants of wt and IL-23p19-deficient mice were stimulated with SCW and cytokine levels were measured by ELISA.

Results: TLR2/NOD2-mediated streptococcal cell wall (SCW) and peptidoglycan (PG) induced acute joint inflammation in IL-23p19-deficient mice resulted in a profound reduction of local joint inflammation compared to control mice in both these models. Synovial IL-23p19 transcript was detected at 1.5 and 4 hours after arthritis induction and was further increased 1 day after PG injection with a peak at day 2. Interestingly, IL-23p19-deficient mice showed a significant reduction in synovial TNFalpha, but not IL-6 levels 4 hours after TLR2/NOD2-mediated arthritis induction in the knee joint. In line with this, reduced TNFalpha levels were detected in the culture supernatant of SCW-stimulated synovial explants from IL-23p19-deficient mice compared to control mice.

Conclusion: These data show a critical role for IL-23 in the development of a TLR2/NOD2-mediated acute joint inflammation and reveal a novel IL-23/TNFalpha axis in this process.

51

T-Cell-Related Cytokines Are Inhibited in Response to Tocilizumab in Patients with Rheumatoid Arthritis in Contrast with TNF-Inhibitor. Jiro Yamana[1], Mitsuyoshi Iwahashi[2], Motoaki Kim[1], Rie Sasaki[1], Keisuke Kobayashi[1], Seizo Yamana[1], Yusuke Sasaki[3], Yasushi Shimonaka[3] and Masahiko Mihara[4]. [1]Higashi-hiroshima memorial Hospital, Hiroshima, Japan, [2]Higashi-Hiroshima Memorial Hospital, Higashi-hiroshima, Japan, [3]Chugai Pharmaceutical Co., Ltd., Kamakura, Kanagawa, Japan, [4]Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan

Background/Purpose: Tocilizumab (TCZ), a humanized monoclonal antibody to the interleukin-6 (IL-6) receptor, inhibits the binding of IL-6 to its receptor, preventing IL-6 signaling. However, the correlation between cytokine profiles and disease activity after TCZ administration in rheumatoid arthritis (RA) has not been clarified. We measured serum concentrations of cytokines in patients received TCZ to identify the mechanisms and predictors of TCZ efficacy in comparison with tumor necrosis factor (TNF) inhibitor.

Methods: In 42 RA patients (27 in the TCZ group, 15 in the TNF-inhibitor group), serum concentrations of IL-1, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12(p70), IL-13, IL-17, granulocyte colony stimulating factor (G-CSF), granulocyte-macrophage (GM)-CSF, interferon (INF) g, monocyte chemotactic protein (MCP)-1, macrophage inflammatory protein (MIP)-1β, TNFα, chemokine (C-C motif) ligand (CCL)-20, IL-23 and TNF-like weak inducer of apoptosis (TWEAK) before treatment (M0) and after 6 months of treatment (M6) were measured by the multiplex method and ELISA. Clinical response was evaluated with disease activity score 28 using the C-reactive protein (DAS28-CRP) and European League against Rheumatism (EULAR) response criteria.

Results: DAS28-CRP was 4.7 $\pm$ 0.9 (mean $\pm$ SD) in the TCZ group and 5.1 $\pm$ 1.3 in the TNF-inhibitor group (p=0.16) at M0. The ratio of good responders / moderate responders / no responders at M6 was 16/9/2 in the TCZ group and 4/7/4 in the TNF-inhibitor group, respectively. Analysis of the cytokine profiles at M0 and M6 in good responders or moderate responders revealed that T-cell-related cytokines were inhibited mainly in the TCZ group, while chemokines were inhibited mainly in the TNF-inhibitor group (Table). When the cytokines that decreased to less than 40% at M6 were examined in good responders (TCZ group: 16, TNF-inhibitor group: 4), this trend was more pronounced in both groups (Table). Interestingly, the results of a univariate logistic regression analysis showed that M0 cytokines tended to be higher in good responders than in moderate responders.

Difference between TCZ and TNF inhibitor in inhibition of cytokines

	TCZ group	TNF-inhibitor group
Significant inhibition at M6	IL-2, IL-7, IL-8, IL-12, GM-CSF, TNF	IL-6, IL-8, MIP-1β, CCL-20
Among good responders, decrease to $\leq$40% at M6	IL-2, IL-7, IL-10, IL-12, GM-CSF, IFNγ	IL-6, IL-12, CCL-20

* IL-4, IL-5, IL-13, IL-17 and IL-23 were undetectable in more than 50% of RA patients at M0, so they were excluded from the analysis.

Conclusion: Whereas TNF-inhibitor inhibits chemokine type cytokines and might reduce infiltration of inflammatory cells, TCZ inhibits T-cell-related cytokines and might normalize the immunological abnormality. Therefore, it is possible that TCZ can induce a deeper remission than TNF-inhibitors. In patients with high T-cell-related cytokine values before treatment, good response can be expected with TCZ.

52

Increased Plasma Levels of IL17F in Rheumatoid Arthritis Patients Are Reduced by Methotrexate and Biologic Agents. Jeffrey D. Greenberg[1], Victoria Furer[1], John Todd[2], Quynh Ann Lu[2], Renita Ramirez[2], Michael Lock[2], Steven B. Abramson[1] and Mukundan Attur[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Singulex, Alameda, California, Alameda, CA

Background/Purpose: A pivotal role of Th17 cells and related cytokines have been recognized in RA. Multiple isoforms of IL17 have been discovered, including IL17A, IL17F and IL17AF, but have not been well characterized in RA patients (pts).

Methods: Using plasma samples from cohorts of RA pts (N= 149) and a knee osteoarthritis (OA) pts (N= 128) serving as controls, we assayed IL17A, IL17F, IL17A/F and a panel including IL1Ra, IL6, IL6R, TNF, sTNFRII, pro-MMP9, MMP9, VEGF, and CRP. The RA cohorts consisted of 78 RA pts off any DMARDs and 71 RA pts with pre/post samples including 33 anti-TNF starts, 27 abatacept starts and 11 methotrexate (MTX) starts.Assays were performed using a fluorescence based, highly sensitive Erenna Immunoassay system (Singulex, Inc). Clinical assessments included DAS28-ESR. Median values between RA vs OA patients were compared using the Wilcoxon rank sum test and adjusted comparisons for age and gender were made using multivariate linear models. Correlations of markers were assessed using Spearman rank correlations. The change in marker value with treatment was assessed by the ratio of the post-drug value to the pre-drug value. Marker and ratio values were log-transformed.

Results: ***RA vs OA (Control) Disease Comparisons:*** Plasma levels of IL17A, IL17A/F and IL17F were all significantly increased in RA vs OA patients, but the magnitude of differences varied. Median IL17F levels in RA (78.0 pg) were approximately 18-fold higher than OA patients (4.4 pg), $p<0.001$ in unadjusted comparisons, and remained significant ($p<0.001$) in adjusted comparisons. The difference between cohorts in IL17A and IL17AF was smaller in magnitude (0.3 vs 0.2 pg, $p<0.001$ and 2.6 vs 2.1 pg, $p=0.004$, respectively), although the latter difference was not significant in adjusted models. Within the RA cohort, correlation between DAS28 and IL17F was weak (rho = 0.32) and almost nonexistent between DAS28 and IL17A (rho = 0.11). RA pts also exhibited statistically significantly higher levels of the following proteins: IL1Ra, IL6, IL6R, pro-MMP9, VEGF, sTNFRII and CRP.

Pre and Post Drug Cohorts: Significant reductions were observed for multiple biomarkers across drug categories (Table), including a consistent reduction of IL17F across drug classes for abatacept ($p<0.001$), anti-TNFs ($p=0.02$) and MTX ($p=0.006$). Neither IL17A nor IL17AF was significant reduced with abatacept, anti-TNFs or MTX.

Table. Change in Plasma Biomarkers with DMARD Interventions

Biomarker	Abatacept (N=27)		Anti-TNF (N=33)		Methotrexate (N=11)	
	Post/Pre Treatment Ratio (Median)	p-value	Post/Pre Treatment Ratio (Median)	p-value	Post/Pre Treatment Ratio (Median)	p-value
CRP	0.88	NS	0.75	0.009	0.56	NS
VEGF	0.82	0.02	0.64	NS	1.05	NS
IL-17A	1.15	NS	0.86	NS	0.77	NS
IL-17F	0.69	<0.001	0.85	0.02	0.47	0.006
IL-17 A/F	0.97	NS	0.76	NS	0.77	NS
IL-6	0.92	NS	0.83	0.04	0.38	0.007
IL-6 R alpha	1.03	NS	0.98	NS	1.06	NS
Total MMP9	0.85	NS	0.70	NS	1.1	NS
pro MMP9	0.69	0.04	0.80	NS	1.22	NS
TNF-alpha	0.91	NS	1.96	<0.001	0.61	NS
sTNF RII	0.90	0.01	1.17	0.03	1.02	NS

Conclusion: 1. Although both IL17A and IL17F plasma levels are increased in RA patients, the magnitude of elevation for IL17F in RA patients was much higher than IL17A.

2. Plasma levels of IL17F but not IL17A were consistently reduced by 3 efficacious drug classes, suggesting that inhibiting IL17F, in addition to IL17A, may relate to RA drug efficacy. Further mechanistic studies are required.

53

Decrease of Serum IL-35 Predicts Clinical Improvement in Patients with Very Early RA. Ladislav Senolt[1], Mária Filková[1], Hana Hulejová[1], Lucie Andrés Cerezo[1], Ondrej Pecha[2], Lenka Plestilová[1], Katerina Jarosova[1], Karel Pavelka[1], Jiri Vencovsky[1] and Herman F. Mann[1]. [1]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Biophysics and Informatics, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic

Background/Purpose: Interleukin-35 (IL-35) is a member of the IL-12 cytokine family. Although IL-35 has been recently described as an anti-inflammatory cytokine in mice (1), recent studies have questioned this finding. We have previously found increased levels of IL-35 in synovial fluids of patients with rheumatoid arthritis (RA) and rather pro-inflammatory properties of IL-35 in humans (2). The aim of this study was to examine serum levels of IL-35 and to evaluate its response to treatment in patients with very early RA (VERA).

Methods: Patients with VERA fulfilling the ACR/EULAR 2010 classification criteria for RA with symptom duration of <6 months were studied. Disease activity was independently assessed using serum levels of CRP, DAS28-ESR and total swollen joint count (SJC) out of 66 joints prior to (n=54), 12 (n=54) and 24 (n=45) weeks after initiation of treatment. A majority of patients were initially given methotrexate and low dose glucocorticoids. Serum levels of IL-35 were measured by ELISA (USCN Life Science) in patients with VERA at baseline and at week 12 and cross-sectionally in 49 healthy controls. If the concentration of IL-35 was bellow detection limit, it was assessed as a minimal detection limit (0.70 pg/ml).

Results: Levels of serum IL-35 were significantly higher in patients with VERA compared with healthy individuals (median [max-min]: 41.51 [0.70–379.70] vs. 32.55 [0.70–238.10] pg/ml; p=0.015) and significantly decreased after the treatment (2.48 [0.70–258.90] pg/ml; p<0.001). The level of IL-35 was bellow detection limit in 9 healthy controls, in 9 patients with VERA at baseline and in 24 patients with VERA after the treatment. IL-35 significantly correlated with disease activity as assessed by CRP (r=0.410, p=0.002), DAS28 (r=0.388, p=0.004) and SJC (r=0.320, p=0.018) at baseline and changes in IL-35 correlated with clinical improvement as assessed by change in CRP (r=0.422, p=0.002), DAS28 (r=0.465, p=0.001) and SJC (r=0.354, p=0.029) after 12 weeks of the treatment. Furthermore, decrease in IL-35 from baseline to week 12 significantly predicted clinical improvement as assessed by change in CRP (r=0.521, p<0.001), DAS28 (r=0.371, p=0.012) and SJC (r=0.345, p=0.020) over 24 weeks. There was no correlation between IL-35 and RF or ACPA serum levels at any time points.

Conclusion: This is the first study to show elevated serum levels of IL-35 in patients with VERA. The decrease of IL-35 levels following treatment and correlation of IL-35 with various disease activity parameters indicate that IL-35 may be a good biomarker of disease activity and may even be considered for early prediction of treatment response in patients with RA.

Vitamin D Deficient Healthy Individuals Have Decreased Activated T Cells and Altered Lymphocyte Responses to Cytokine Stimulation. Lauren L. Ritterhouse[1], Holden T. Maecker[2], Hongwu Du[3], C. Garrison Fathman[4], Joel Guthridge[1] and Judith A. James[5]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University School of Medicine, Stanford, CA, [3]Stanford University School of Medicine, Stanford, CA, [4]Stanford Univ Medical Center, Stanford, CA, [5]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK

Background/Purpose: Vitamin D has been shown to possess many different immunomodulatory functions. Additionally, epidemiologic evidence has associated vitamin D deficiency with many autoimmune disorders as well as infectious diseases. The objective of this study was to examine the effects of vitamin D deficiency on the immune systems of healthy individuals.

Methods: A cohort of 774 healthy individuals were screened for 25(OH)D levels by ELISA. Twenty vitamin D deficient (25(OH)D < 10.5 ng/mL) and 20 matched vitamin D sufficient (25(OH)D > 30 ng/mL) individuals were selected for further analysis. Sera were measured for 52 cytokines using a multiplex bead-based assay and ELISAs. Immune cell phenotyping and phospho-flow cytometry was performed on peripheral blood mononuclear cells. Unpaired t-tests and Mann Whitney tests were used for statistical analyses.

Results: Vitamin D deficient individuals had significantly increased serum levels of hsCRP, leptin, and GM-CSF (p=0.005, p<0.001, p=0.003, respectively), although the associations with hsCRP and leptin were confounded by BMI. Vitamin D deficient individuals also had decreased percentages of activated CD4+ and CD8+ T cells (HLA-DR+CD38+) (p=0.021 and p=0.028). Vitamin D deficient individuals had decreased pSTAT1 in response to IL-2 and IL-10 stimulation in CD4+ T cells (p=0.007 and p=0.014), and increased pSTAT1 and pSTAT3 in response to IFNγ stimulation in CD4+ T cells (p=0.006 and p=0.033). Deficient individuals had decreased pSTAT1 responses to IL-2, IL-10, and IL-21 stimulation in CD8+ T cells (p=0.018, p=0.049, and p=0.032, respectively). Deficient individuals also had increased pSTAT3 in response to IFNα stimulation in B cells (p=0.043), while they had decreased pSTAT1 in response to IL-2, IL-6, IL-10, and IL-21 stimulation in B cells (p=0.005, p=0.016, p=0.003, and p=0.042, respectively).

Conclusion: The presence of decreased activated T cells in vitamin D deficient individuals as well as altered lymphocyte signaling responses to cytokine stimulation may contribute to systemic autoimmune rheumatic diseases, as well as other vitamin D deficient associated disease states.

55

Hypoxia and Inflammation Synergistically Promote Bone Destruction. Shankar Revu[1], Vivekananda Sunkari[2], Akilan Krishnamurthy[3], Ileana R. Botusan[2], Sergiu-Bogdan Catrina[2] and Anca Irinel Catrina[4]. [1]Rheumatology unit, Stockholm, Sweden, [2]Stockholm, Sweden, [3]Karolinska Institute, Karolinska University Hospital, Solna, Stockholm, Sweden, [4]D2:01, Stockholm, Sweden

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial inflammation and consecutive local hypoxia, leading to cartilage and bone destruction. Hypoxia promotes osteoclasts formation in vitro but its role in mediating bone destruction in the presence of chronic inflammation has not previously been investigated. We aimed to investigate the effect of hypoxia on the RANKL/OPG system and bone destruction in the presence of pro inflammatory stimuli

Methods: We investigated the in vitro effect of hypoxia on RANKL/OPG expression in osteoblast-like (Saos2) cells. Cells were cultured in normoxic (21% pO_2) or hypoxic (1% pO_2) conditions with or without TNFα. Expression of RANKL and OPG mRNA was detected by rtPCR. Cellular and soluble forms of RANKL and OPG proteins were determined by Western blot and ELISA respectively. Hypoxia effect on bone resorption was evaluated in a dentine pit formation assay using peripheral blood mononuclear cells from RA patients. Statistical analysis was performed using one-way ANOVA

Results: Exposure to hypoxia induced a significant increase in cellular RANKL mRNA and protein expression, with minimal changes of the cellular OPG. In contrast soluble OPG levels significantly decreased following hypoxia exposure with no changes in the soluble levels of RANKL. Small interfering RNA against HIF2alpha but not HIF1alpha was able to abolish hypoxia effect on cellular RANKL expression. Concomitant exposure to both hypoxia and TNFα had an additive effect resulting in a further increase of the

RANKL/OPG ratio. Hypoxia mimicking by prolyl hydroxylases inhibitors acted synergistically with TNF in inducing pit formation and resorption on synthetic osteologic bone discs

Conclusion: TNF and hypoxia act synergistically to promote bone destruction potentially through a HIF2alpha dependent mechanism. These findings add on the current understanding of bone destruction in the setting of chronic inflammation.

Anti-TNF Therapy Sensitizes Rheumatoid Arthritis Monocytes to TRAIL-Induced Apoptosis Via Inhibition of Pro-Survival Effects of Soluble TNF. Undine Meusch[1], Manuela Rossol[2], Dagmar Quandt[1], Christoph G. Baerwald[3] and Ulf Wagner[1]. [1]University of Leipzig, Leipzig, Germany, [2]Translationszentrum für Regenerative Medizin (TRM), University of Leipzig, Leipzig, Germany, [3]University Hospital, Leipzig, Germany

Background/Purpose: The autoimmune disease rheumatoid arthritis (RA) is characterized by the production of monocytic cytokines like TNF alpha and IL-1 beta. Both cytokines induce increased survival rates in monocytes. The role of TRAIL in RA has not been intensively studied. Induction of apoptosis by TRAIL is a classic functional consequence, but its effect on primary monocytes has not been investigated. Apoptosis is mediated by the activating TRAIL receptors 1 and 2 and inhibited by receptors 3 and 4. Aim of the study was to analyze TRAIL-induced apoptosis of monocytes from healthy donors and patients with rheumatoid arthritis (RA).

Methods: Monocytes isolated from the peripheral blood of healthy donors (HD) and of RA patients (without or with anti-TNF therapy) were incubated with 100 ng/ml TRAIL for 16h. Subsequently TRAIL induced apoptosis was measured via annexinV/PI staining. Production of different pro-inflammatory cytokines was analyzed by ELISA. Expression levels of all TRAIL receptors and membrane TRAIL (mTRAIL) were detected by flow cytometry. To analyse the influence of sTNF and IL-8 on TRAIL induced apoptosis and IL-8 production, HD monocytes were pre-incubated with 100 pg/ml TNF for 1h before stimulation with TRAIL. Subsequently apoptosis rate, expression of TRAIL receptors and TRAIL induced IL-8 production were analyzed.

Results: Monoctyes of RA patients show resistance to TRAIL-induced apoptosis while HD monocytes undergo apoptosis in response to TRAIL. Interestingly, RA monocytes show decreased expression levels of all TRAIL receptors and mTRAIL. However, TRAIL induces an increased IL-8 production in RA monocytes but not in HD monocytes. Production of IL-1beta, IL-6 and TNF remain unaffected by TRAIL in both analyzed groups. Analysis of TRAIL-induced apoptosis in HD monocytes shows that pre-incubation with soluble TNF or IL-8 has an inhibitory effect on TRAIL-induced apoptosis, pointing to a role of the pro-inflammatory cytokine milieu in influencing monocyte functions. sTNF pre-incubation also led to TRAIL-induced IL-8 production in HD monocytes and decreased expression of TRAIL R1, R2 and R4. Surprisingly, in monocytes from RA patients treated with anti-TNF reagents, TRAIL-induced apoptosis is comparable to HD monocyte apoptosis levels. Additionally, no TRAIL-induced IL-8 production was detectable.

Conclusion: A pro-inflammatory cytokine milieu induces resistance to TRAIL-induced apoptosis in RA monocytes. The treatment with anti-TNF reagents overrides this resistance and sensitizes RA monocytes to TRAIL-induced apoptosis.

57

Regulation of Suppressor of Cytokine Signaling-1, -2 and -3 Expression in Patients with Early Arthritis. Ricardo J. Villares[1], Amalia Lamana[2], Coloma Costas[1], Ana M. Ortiz[2], Mercedes López-Santalla[1], Mario Mellado[1] and Isidoro González-Alvaro[2]. [1]Centro Nacional de Biotecnología. CNIC, Madrid, Spain, [2]Hospital Universitario de La Princesa. IIS Princesa, Madrid, Spain

Background/Purpose: Most cytokines involved in the pathogenesis of Rheumatoid Arthritis (RA) act through receptors that trigger several signal transduction pathways that are initiated by JAK/STAT activation. The activation of this system triggers up-regulation of many genes, including those that encode suppressor of cytokine signaling proteins (SOCS). Mice lacking SOCS3 show severe joint inflammation as well as those lacking SOCS1 and IFN-γ. By contrast, SOCS3 overexpression affects T cell responses and prevents development of collagen-induced arthritis. Studies based on SOCS expression in RA patients are very limited and contradictory. Therefore, the objective of our work was to study the expression of SOCS1, SOCS2 and SOCS3 during the follow-up of patients with early arthritis (EA).

Methods: We have studied 144 patients from our EA register (82% female, median age 53 y-o). Demographic, disease related variables, as well as treatment prescribed were systematically recorded and blood samples were obtained at each visit (baseline, 6, 12, 24 and 60 months). The expression levels of SOCS1, SOCS2 and SOCS3 and β-actin as housekeeping was determined through real-time PCR in 223 mRNA samples obtained from the peripheral blood mononuclear cells. RT-PCR data were normalized against β-actin expression and ΔΔCt were determined against the mean expression of SOCS genes in 17 healthy volunteers (53% female, 42.5 y-o). In 45 cases there were two-three samples including the baseline visit (114 samples) allowing us to study the transcriptional regulation of these three genes. To determine the effect of independent variables on levels of SOCS expression, we fitted population-averaged models by generalized linear models, nested by patient and visit, using the *xtgee* command of Stata 10.1 for Windows (StataCorp LP, College Station, TX, USA).

Results: The baseline samples of patients showed significantly lower levels of SOCS1 (median ΔΔCt 0.7 [IQR: 0.365–1.375] vs 1.31 [0.96–1.64]; $p=0.02$) and SOCS3 (0.63 [0.29–1.54] vs 0.95 [0.77–1.97]; $p=0.03$) compared to controls. In addition, all three SOCS showed down-regulation of their levels during the follow-up. The decrease in SOCS expression reached statistical significance only when we compared samples from baseline and 12 months visit ($p=0.05$ for SOCS1 and $p=0.01$ for SOCS2). The decrease of SOCS3 expression did not reach statistical significance at any time. In addition, the multivariable analysis showed that the expression of all three SOCS significantly correlated with the swollen joint count at each visit, but not with tender joint counts, patient global disease assessment or C-reactive protein. In addition, elderly patients showed significantly lower SOCS3 expression.

Conclusion: The expression of SOCS in peripheral blood mononuclear cells from patients with early arthritis seem to be lower than that of healthy controls even at baseline when the expression of these molecules are up-regulated due to a higher disease activity (number of swollen joints).

Expression Levels of Interleukin-17A, Interleukin-17F and Their Receptors in Synovium of Patients with Rheumatoid Arthritis, Psoriatic Arthritis and Osteoarthritis: A Target Validation Study. Lisa G.M. van Baarsen, Maria C. Lebre, Dennis van der Coelen, Danielle M. Gerlag and PP. Tak. Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Accumulating evidence suggests an important role for interleukin (IL)-17 in the pathogenesis of several inflammatory diseases, including rheumatoid arthritis (RA). IL-17A has been well studied in models of arthritis, but little is known about the relative expression and cellular source(s) of IL-17A, IL-17F, and their receptors in human synovial tissue. The current study is aimed to determine the origin and expression of IL-17A, IL-17F and their receptors IL-17RA and IL-17RC in synovial tissues of patients with RA, psoriatic arthritis (PsA) and inflammatory osteoarthritis (OA).

Methods: Synovial biopsy specimens were obtained by arthroscopy from patients with RA ($n=13$), PsA ($n=15$) and inflammatory OA ($n=14$). For comparison synovial tissues from non-inflammatory controls ($n=7$) were included. Immunohistologic analysis was performed on frozen sections using monoclonal antibodies specific for IL-17A, IL-17F, IL-17RA and IL-17RC. Stained sections were evaluated by digital image analysis. Immunofluorescence analysis was performed using antibodies specific for T cells (CD4, CD8), neutrophils (CD15), macrophages (CD68, CD163), B cells (CD19), endothelial cells (CD31, Von Willebrand Factor, PNAd), lymphatics (Lyve-1) and mast cells (mast cell tryptase). Stained sections were evaluated by confocal microscopy.

Results: Levels of IL-17A, IL-17F, IL-17RA and IL-17RC were abundantly present in synovial tissues of all patient groups and highly variable between patients. Whereas IL-17RA was mostly present in the synovial sublining, IL-17RC was abundantly expressed in the intimal lining layer. Digital image analysis showed a significant increase of IL-17A but not of IL-17F, IL-17RA and IL-17RC in patients with arthritis compared to non-inflamed control tissues (Table 1), while the expression of IL-17A, IL-17F and IL-17RA was similar between the different patient groups. Expression of IL-17RC in the intimal lining layer was significantly increased in PsA compared to OA patients ($p<0.05$). IL-17A was found to be expressed by CD4 and CD8 positive cells, while CD15, CD19 and mast cell tryptase (MCT) positive cells were negative. IL-17F was not expressed by CD4, CD8,

CD15 and MCT positive cells in the synovial tissues of arthritic patients. Interestingly, IL-17A and IL-17F staining was also observed in some macrophages as well as in endothelial cells and lymphatics.

Table 1. IL-17 expression in synovial tissues as determined by immunohistochemistry

	Non-inflammatory controls (n=7)	Inflammatory arthritis (n=42)	p-value
IL-17A	351 (15–8,934)	6,827 (2,131–24,925)	*0.0089*
IL-17F	1,831 (303–4,120)	1,871 (445–4,519)	0.7642
IL-17RA	11,281 (2,564–39,076)	3,067 (332–57,222)	0.5580
IL-17RC in intimal lining layer	13,604 (8,441–63,165)	71,373 (1,292–417,194)	0.3494

Data given as median integrated optical density per mm2 (25th–75th percentile); p-value determined using the appropriate T test.

Conclusion: Increased expression of IL-17A is not restricted to synovial tissues of RA patients but also observed in other forms of inflammatory arthritis. In inflamed synovium various cell types contribute to the production of IL-17A and IL-17F. IL-17 blockade could provide a novel therapeutic approach in a variety of arthritides.

Type I Interferon and Clinical Phenotype in Idiopathic Inflammatory Myopathies. Louise Ekholm[1], Anna Tjärnlund[1], Clio P. Mavragani[2], Peter J. Charles[3], Leonid Padyukov[1], Mary K. Crow[4] and Ingrid E. Lundberg[5]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden, [2]Department of Experimental Physiology, School of Medicine, University of Athens, Athens, Greece, [3]Kennedy Institute of Rheumatology, Imperial College, London, United Kingdom, [4]Hospital for Special Surgery, New York, NY, [5]Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are rare autoimmune diseases characterized by proximal muscle weakness and muscle inflammation. Recent studies suggest a pathogenic role for type I interferon (IFN) in IIM patients, particularly within the subgroup dermatomyositis (DM). Expression of type I IFN and IFN-regulated genes, the IFN signature, in muscle tissue and skin biopsies from DM patients have been reported. Studies indicate that an IFN signature in peripheral blood cells of patients correlates to disease activity although results are contradictory. Autoantibodies are a characteristic feature of IIM, and immune complexes have been demonstrated to induce type I IFN expression in target cells. Its effect and correlation with clinical phenotype are, however, poorly understood.

The aim of this study was to examine if the type I IFN activity of sera from IIM patients correlates with disease activity, clinical manifestations, autoantibody profile, or HLA haplotype.

Methods: Clinical, serological, genetic and laboratory data were collected from a cohort of IIM patients with the diagnoses DM, polymyositis (PM), inclusion body myositis (IBM) and juvenile dermatomyositis (JDM). Patient sera were assessed for their type I IFN activity using an *in vitro* system with the WISH epithelial cell line. Expression of IFN-inducible genes, IFIT1, IFI44, and MX1, which are preferentially induced by IFN-alpha, were quantified using real time-PCR. Two groups of patients, IFN+ (N=13) and IFN- (n=119), were categorized based on IFN score, the sum of the individual gene expression scores. Differences between the two groups were assessed for clinical, serological and genetic variables, as well as correlation between IFN score and variables.

Results: The proportion of the IIM subgroups within the IFN+ and IFN- patient groups was equal. No correlation between the type I IFN activity in sera from IIM patients and disease activity was found for any of the IIM subgroups. No significant differences between the two patient categories for any of the assessed clinical or laboratory variables were found. Autoantibody analysis demonstrated that significantly more IFN+ patients were positive for anti-nuclear antibodies (ANA) compared to IFN- patients (p=0.001). HLA-DRB1 typing of patients revealed no differences between the two patients groups. Interestingly, the IFN- patients had a significantly higher prednisolone dose compared to the IFN+ patients (p=0.002). Moreover, a trend for higher self-perceived pain among the IFN+ patients was found.

Conclusion: Our findings show that type I IFN activity in patient sera can be found for all major subgroups of IIM and does not correlate with disease activity. Ability to induce expression of IFN-regulated genes was found to be associated with presence of ANA. This is in line with reports demonstrating nucleic acid containing immune complexes and their interaction with specific TLRs and induction of type I IFNs. In agreement with studies showing suppression of type I IFNs by glucocorticoids, the type I IFN activity in sera was lower for patients receiving higher dose of cortisone treatment.

Comparative Cytokine Analysis Across a Spectrum of Genetically and/or Clinically Defined Auto-Inflammatory Syndromes. Apostolos Kontzias[1], Yongqing Chen[1], Nicole Plass[1], Damaris Garcia[1], Elizabeth Joyal[1], Robert Wesley[2] and Raphaela T. Goldbach-Mansky[1]. [1]National Institutes of Health Clinical Center, Bethesda, MD, [2]National Insitutes of Health Clinical Center, Bethesda, MD

Background/Purpose: Auto-inflammatory diseases constitute a group of disorders that manifest systemic inflammation in the absence of infection, auto-antibodies or auto-reactive T cells. A specific genetic mutation is identified in some of them, such as in Neonatal Onset Multisystem Inflammatory Disease (NOMID) or Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated temperature (CANDLE) syndrome, while in others such as Chronic Recurrent Multifocal Osteomyelitis (CRMO), and Adult onset Still's Disease (AOSD) a specific cause is yet to be elucidated. The rapid response to targeted cytokine blocking therapies suggests that these disorders are mediated by specific cytokines. Herein we investigate whether each disease is characterized by a specific cytokine signature.

Methods: Serum samples, on visits when patients had clinically active disease, were collected and assayed by Luminex for the presence of 43 inflammatory cytokines at 9timepoints. Disease groups (mutation positive and negative NOMID; CANDLE syndrome; CRMO; adult and pediatric Still's disease; rheumatoid arthritis, including juvenile idiopathic arthritis were compared to normal controls whose assays were run at the same time. Ratios of patient values divided by the average of corresponding set of healthy control values were statistically tested for whether they significantly differed from 1 and also among the various disease groups.

Results: A distinct cytokine profile is found in different auto-inflammatory diseases. Specifically, AOSD is characterized by markedly increased levels of Interleukin-18 (p= 0.005, mean= 3.068) and IL-1a (p= 0.032, mean= 1.5687) compared to controls. NOMID mutation positive patients had increased levels of IL-1a (p= 0.00078, mean=1.7819), IL-6 (p 0.001, mean=1.5376) and IL-18 (p= 0.001, mean=1.4924) compared to controls and NOMID mutation negative patients. Il-18 levels in AOSR patients were actually significantly higher than in patients with mutation positive and negative NOMID. CANDLE patients have highly increased IFNg inducing protein 10 (IP-10) levels (p= 0.00053, mean=3.9872) compared to controls and the other autoinflammatory diseases. CRMO patients had low levels of IL-8 (p= 0.005, mean= 0.1697), GM-CSF (p= 0.00684, mean= 0.0969) and MCP-1 (p2=0.002,mean= 0.0687) compared to controls and other diseases. These differences in cytokine profiles disappeared when patients were on effective therapies.

Conclusion: During active disease specific cytokine profiles may allow us to detect dysregulated cytokine pathways that discriminate between clinically different autoinflammatory syndromes. A comprehensive approach of cytokine profiling may be useful to develop a therapeutic plan. Further studies are needed to determine it this approach can be used to monitor therapy and help in the definition of inflammatory disease remission in patients with a number of autoinflammatory disorders.

61

PGE2 and FGF-2 Upregulate Activities of the Human F-Spondin Promoter. Mukundan Attur[1], Yang Qing[2], Jinhua Wang[3], Kimberlee Mix[4], Glyn Palmer[1] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]New York University School of Medicine, New York, NY, [3]New York University Cancer Institute, New York, NY, [4]Loyola University New Orleans, New Orleans, LA

Background/Purpose: The extracellular matrix protein, F-spondin is a marker of both hypertrophic and osteoarthritic cartilage. Understanding the mechanisms that regulate its expression could therefore identify key pathways that regulate chondrocyte activity in development and disease. In this study we investigated transcriptional regulation of human F-spondin via the cloning and characterization of its 5' regulatory (promoter) region.

Methods: Genomic sequence containing the 5' regulatory region of F-spondin was obtained by PCR of human total genomic DNA (Clontech) using upstream primers designed from F-spondin genomic sequence available at the gene database www.ncbi.nlm.nih.gov, gene ID: 10418. PCR fragments

were cloned into pGL3 Luciferase Reporter Vectors (Promega) for functional analysis. Luciferase assays were performed 36 h after transfection in the human chondrosarcoma cell line, SW1353.

Results: An upstream 2.4 kb genomic sequence of human F-spondin was obtained by PCR, subcloned and sequenced bidirectionally. DNA sequence fidelity was confirmed using the NCBI blast alignment search tool. DNA sequence analysis revealed the presence of TATA box at position -74 and identification of transcription factor binding sites was performed using the JASPAR CORE database (http://jaspar.genereg.net/). High scoring putative binding sites within the 2.4 kb promoter region included NURR1 (NR4A2-nuclear receptor), NFAT, SOX-10 and CREB1. Functional promoter activity was assessed by transient transfection of pGL3 luciferase vectors encoding 2.4 kb (pFS-2.4Luc) and 0.5 kb (pFS-0.5Luc) of F-spondin upstream genomic sequence. In human chondrocytes, both pFS-2.4Luc and pFS-0.5Luc significantly increased luciferase activity above a pGL3 promoterless control vector, 20- and 70-fold, respectively. Since we have previously observed that F-spondin mRNA levels are induced by FGF-2 and PGE2 in OA chondrocytes, we examined their effects on promoter activity. PGE2 (10 uM) stimulated F-spondin luciferase activity 10–20-fold for both 2.4 and 0.5 kb promoter constructs ($p<0.001$) above unstimulated controls. Cotransfection of a cDNA encoding NURR1, a transcription factor induced by PGE2 in human chondrocytes, also increased luciferase activity (100-fold) irrespective of promoter length. This is consistent with the presence of multiple putative NURR1 binding sites (~16) throughout the 2.5 kb promoter region. Conversely, FGF-2 (25 ng/ml) significantly increased luciferase activity of pFS-0.5Luc (2-fold; $p<0.05$) but not pFS-2.4Luc. This finding suggests that regulation of F-spondin via FGF-2 occurs via regulatory regions within its proximal 0.5 kb region.

Conclusion: Our results indicate that both developmental (FGF-2) and proinflammatory (PGE2) factors induce F-spondin expression in chondrocytes via discrete regions in its promoter. Sequence analysis and transfection studies suggest that NURR1 may mediate PGE2 induction of F-spondin via multiple binding sites in the promoter region. The current findings are consistent with previous observations demonstrating overlapping pro-inflammatory/catabolic effects of PGE2, NURR1 and F-spondin in OA chondrocytes.

62

Correlation of Vascular Endothelial Growth Factor and Interleukin-6 Levels with Power Doppler Ultrasound of Synovial Joints in Early Inflammatory Arthritis. Joanne Kitchen[1] and David Kane[2]. [1]Adelaide and Meath Hospital, Dublin, Ireland, [2]Adelaide, Meath hospital Dublin (incorporating the National Children's hospital), Dublin 24, Ireland

Background/Purpose: To correlate Power Doppler ultrasound findings in peripheral joints of patients with early inflammatory arthritis with serum levels of IL-1α, IL-1β, IL-2, IL-4, IL6, IL-8, IL-10, VEGF, TNFα, and IFNγ

Methods: Fifty-five patients diagnosed with early inflammatory arthritis completed clinical and serological assessments (DAS 28 CRP, HAQ, EUROQOL, SF-36, ESR and CRP) at baseline (T0), 3 months (T3) and 6 months (T6), with 30 completing a 12 month assessment. Standard greyscale and power Doppler ultrasound examination of the DAS28 joint set plus ankles and metatarsophalangeal joints was performed by a single ultrasonographer (JK) in pre-selected imaging planes [EULAR standardised, MyLab70 XVG system (Esaote, Genoa, Italy)]. Serum samples were analysed for IL-1α, IL-1β, IL-2, IL-4, IL6, IL-8, IL-10, VEGF, TNFα, and IFNγ using the Evidence Investigator™ biochip array (Randox).

Results: There was a significant reduction in greyscale and power Doppler scores from T0 to all subsequent time-points. Both ESR and CRP correlated significantly with both GS and power Doppler scores at baseline ($p < 0.0005$ for all Spearman's rho) but this correlation was reduced following treatment (T3, T6, T12). DAS28 scores correlated significantly with both ultrasound scores but there was less consistent correlation of ultrasound scores with HAQ and SF36. Serum levels of IL-6 correlated significantly with total greyscale ultrasound scores at all time-points during the study. Levels of VEGF correlated significantly with total greyscale scores at T0, T6 and T12 but not at T3. Correlations between each cytokine and the corresponding power Doppler score were evaluated, including data from 26 normal control patients. This resulted in correlation of 198 data sets to determine the overall correlation between power Doppler and each cytokine. The strongest correlation was seen between power Doppler and IL-6 ($r = 0.427$, $p < 0.0005$) and there was a significant correlation between VEGF and power Doppler ($r = 0.203$, $p = 0.004$). Significant correlations were seen between power Doppler and IL-2 ($r = 0.280$, $p < 0.0005$), IL-10 ($r = 0.226$, $p = 0.001$), IL-1α ($r = 0.224$, $p = 0.002$), IL-1β ($r = 0.193$, $p = 0.006$) and MCP-1 ($r = 0.16$, $p = 0.024$).

Conclusion: Power Doppler and greyscale ultrasound correlate significantly with clinical parameters of inflammation and with serum levels of IL-6 and VEGF in patients with early inflammatory arthritis. IL-6 and VEGF are further implicated in the pathogenesis of the power Doppler signal from inflamed synovial joints.

63

Preferential Inhibition of IL-6 TRANS-Signaling Shows Potent Anti-Inflammatory Activity *In Vivo*: The Potential of NI-1201, a Novel Fully Human IL-6R Monoclonal Antibody. Florence Guilhot[1], Vanessa Buatois[1], Laurence Chatel[1], Laura Cons[1], Eric Hatterer[1], Greg Elson[1], Suzanne Herren[1], Giovanni Magistrelli[1], Pauline Malinge[1], Simon Jones[2], Manuela Gabler[3], Thomas Kamradt[3], Cristina de Min[1], Marie Kosco-Vilbois[1] and Walter Ferlin[1]. [1]NovImmune S.A., Plan-Les-Ouates, Geneva, Switzerland, [2]Cardiff University, Cardiff, United Kingdom, [3]Institute of Immunology, Jena University Hospital, Jena, Germany

Background/Purpose: Preclinical animal models and successful clinical studies have validated targeting the IL-6 pathway in chronic inflammatory diseases. IL-6 acts via binding to either membrane IL-6-Receptor (mIL-6R), termed CIS-signaling, or soluble IL-6R (sIL-6R) known as TRANS-signaling. TRANS-signaling is characteristically involved in endothelial cell activation and mononuclear cell recruitment, while CIS-signaling in mediating IL-6 effects on hepatocytes and activating naive T cells. With the objective of optimizing the efficacy/safety balance of IL-6 pathway targeting, we aimed to generate a fully human IL-6R monoclonal antibody (mAb) that more efficiently targets TRANS-signaling.

Methods: The fully human mAb, NI-1201, that targets an IL-6R epitope important for binding to the signal-transducing (gp130, CD130) receptor subunit was generated. NI-1201 was tested in synovial explant cultures obtained from RA patients and benchmarked to Tocilizumab. Furthermore, the corresponding mouse surrogate antibody was tested in murine models of inflammatory disease.

Results: Functional *in vitro* assays to measure IL-6 TRANS-signaling, using human-gp130-transfected BAFF-cell proliferation, NI-1201 demonstrated superior neutralization capability when compared to Tocilizumab. Biacore analysis showed high affinity of NI-1201 for soluble IL-6R and IL-6/IL-6R complex (IL-6Rc): 0.06nM and 5.64 nM, respectively. To study and compare the contribution of the different signaling mechanisms *in vivo*, we used the G6PI arthritis model of arthritis and representative anti-mouse mAbs. Administration of 1F7, the NI-1201 mouse surrogate mAb, demonstrated superior efficacy in terms of clinical manifestations as compared to the Tocilizumab-like mAb, 2B10 (area under the curve, for clinical score as measured by paw thickness in mm *versus* days post G6PI immunization, was calculated and demonstrated a significant difference ($p=0.0317$) between 1F7, 10 ± 6 mm.day, and 2B10, 74 ± 22 mm.day). 1F7 also demonstrated improved efficacy when administered therapeutically in the MOG-induced model of Multiple Sclerosis (MS). 1F7 controlled inflammation yet spared CIS-signaling mediated IL-6 effects, such as acute phase protein production by the liver (SAA induction).

Conclusion: NI-1201 is a fully human mAb with high affinity for IL-6R and sIL-6Rc, blocking the latter from binding to gp130. NI-1201 potently blocks IL-6 TRANS-signaling-dependent proliferation *in vitro*. Using the NI-1201-surrogate mAb 1F7 in animal models, we show superiority with improved efficacy in an arthritis and an MS model. Furthermore, while controlling inflammation, 1F7 preserved important physiological functions of IL-6 such as the liver acute phase response.

64

Interleukin-22 Promotes Osteoclastogenesis in Rheumatoid Arthritis Through Induction of Receptor Activator of Nuclear Factor-Kb Ligand From Synovial Fibroblasts. Sang-Heon Lee[1], Jung-Hwa Lee[1], Hae-Rim Kim[1] and Kyoung-Woon Kim[2]. [1]Konkuk University Medical Center, Seoul, South Korea, [2]Konkuk University, Institute of Biomedical Science and Technology, South Korea

Background/Purpose: This study aims to determine the regulatory role of interleukin(IL)-22 on the expression of receptor activator of NF-kB ligand(RANKL) and the induction of osteoclastogenesis in rheumatoid arthritis(RA).

Methods: The concentrations of IL-22 and RANKL in sera and synovial fluids(SF) of RA patients were measured using ELISA. After RA synovial

fibroblasts were treated with rhIL-22, the expression of RANKL mRNA and protein was determined using real-time PCR, western blot, and intracellular immunostaining. The IL-22-induced RANKL expression was determined after blockage of intracellular signal molecules. Human monocytes were co-cultured with IL-22-prestimulated RA synovial fibroblasts and monocyte-colony stimulating factor(M-CSF), and then osteoclastogenesis was determined by counting of TRAP-positive multinucleated cells.

Results: SF IL-22 concentration in RA patients was higher than that in osteoarthritis(OA) patients. Serum IL-22 concentration was also higher in RA than OA patients and healthy volunteers. Serum IL-22 concentration was correlated with serum rheumatoid factor titer, and SF IL-22 concentration was correlated with serum anti-cyclic citrullinated peptide antibody titer. When RA synovial fibroblasts were treated with rhIL-22, the expression of RANKL mRNA and protein was increased in a dose-dependent manner. The IL-22-induced RANKL expression was significantly down-regulated by inhibition of p38 MAPK/NF-kB and JAK-2/STAT3. When human monocytes were cultured with IL-22-prestimulated RA synovial fibroblasts in the absence of RANKL, the monocytes were differentiated into osteoclasts, but this osteoclastogenesis was decreased after the inhibition of p38 MAPK/NF-kB and JAK-2/STAT3.

Conclusion: Our results revealed that IL-22 up-regulated RANKL expression in synovial fibroblasts, which facilitated the induction of osteoclastogenesis from precursor cells in rheumatoid joint.

65

Leptin Promotes Th17 Responses. Yiyun Yu[1], Yaoyang Liu[1] and Antonio La Cava[2]. [1]UCLA, Los Angeles, [2]Univ of California Los Angeles, Los Angeles, CA

Background/Purpose: Leptin, an adipocyte-derived hormone encoded by the obese (ob) gene, can link nutritional status and immune responses by directly modulating the production of inflammatory mediators and the activation, proliferation and maturation of different immune cell subsets including T cells. The role of leptin in the differentiation and activity of Th17 cells has not been explored, yet this aspect is relevant because of the importance of this T cell population in the promotion of pro-inflammatory and autoimmune responses.

Methods: Th17 cells were compared in the peripheral blood, and IL-17 levels in the plasma, among wilt-type (WT) C57Bl/6J (B6), *ob/ob* leptin-deficient and *db/db* leptin receptor-deficient mice (also on the B6 background). The possibility of direct Th17 cell modulation in the peripheral blood was investigated by administering recombinant leptin to *ob/ob* mice, and the effects of scalar doses of leptin were evaluated on the transcription of the Th17 master regulator RORγt (detected as luciferase activity after retroviral transfection of cells with a reporter construct encoding RORγt). The results were compared to those obtained in (NZB × NZW)F1 (BWF1) lupus-prone mice treated or not with leptin.

Results: Fewer Th17 cells and reduced levels of plasma IL-17 were found in *ob/ob* mice and *db/db* mice as compared with WT mice. Leptin administration in *ob/ob* mice promoted Th17 cell differentiation both *in vivo* and *in vitro*. Leptin upregulated the surface expression of leptin receptor, through which it induced RORγt transcription in $CD4^+$ T cells. In BWF1 lupus mice, leptin facilitated Th17 cell differentiation and expansion, both in vivo and in vitro.

Conclusion: Leptin promotes Th17 response by enhancing RORγt transcription through leptin receptor-mediated signaling. These results suggest that leptin could be targeted for IL-17 modulation in states characterized by autoimmune responses such as in SLE.

Differential Regulation of Serum Cytokine Profiles In Patients with Rheumatoid Arthritis Treated with Tocilizumab: Possible Involvement of Macrophage Migration Inhibitory Factor. Tsuyoshi Kasama[1], Kuninobu Wakabayashi[1], Takeo Isozaki[2], Hidekazu Furuya[1], Ryo Yanai[1], Kumiko Ohtsuka[1], Michihito Sato[1] and Ryo Takahashi[1]. [1]Showa University School of Med, Shinagawa-ku Tokyo, Japan, [2]University of Michigan Medical School, Ann Arbor, MI

Background/Purpose: To examine the relationship between serum cytokine levels and clinical responsiveness to tocilizumab, a humanized monoclonal antibody specific for the IL-6 receptor, in patients with rheumatoid arthritis (RA) as well as the impact of tocilizumab administration on serum cytokine levels.

Methods: Serum levels of the cytokines TNF-alpha, IL-6, macrophage migration inhibitory factor (MIF), CCL2, CCL3, CXCL8, CXCL10 and CX3CL1 were quantified using double ligand enzyme-linked immunosorbent assays. Measurements were made prior to (i.e., baseline) and after 12 weeks of treatment with tocilizumab (8 mg/kg) in 21 RA patients. The disease status and serum cytokine levels at baseline and 12 weeks after tocilizumab treatment were assessed using the clinical disease activity index (CDAI). The moderate and major responses to tocilizumab were defined as an improvement of greater than 6 and 14 points, respectively, from the baseline CDAI, which is consistent with the improvement criteria proposed by Smolen et al.

Results: At the initiation of therapy, the mean age of patients was 56.1 yrs, mean disease duration was 11.8 yrs, and mean baseline CDAI was 22.4. After 12 weeks of tocilizumab administration, 15 patients achieved a major/moderate response, but there were no significant responses in 6 patients. Although there were no significant correlations between serum levels of any of the cytokines and disease activity (CDAI) at baseline, there was a significant correlation between serum MIF levels and either total tender joint counts or swollen joint counts. Furthermore, there was a significant reduction in MIF, but not other cytokines, in all 21 patients (1857.0 ± 1510.0 to 1401.1 ± 1315.5 pg/ml at week 12, $p = < 0.01$). Basal levels of MIF were significantly higher in the group that responded well to tocilizumab (2065.8 ± 1288.3 pg/ml, $p < 0.01$) than in the unresponsive group (1335.3 ± 818.1). A comparison of patients with lower (<1347 pg/ml; median of MIF levels) and higher (^{3}1347 pg/ml) basal MIF levels revealed no significant differences in CDAI, serum CRP levels or daily prednisolone dosages. However, the percentage of patients with a major/moderate response was statistically higher in patients with higher basal MIF levels compared to those with lower MIF levels. In addition, serum MIF levels were diminished (MIF declined from 2875.5 ± 1407.8 to 1189.7 ± 1070.0, $p < 0.05$) in patients with higher basal MIF levels in response to tocilizumab but not in those with lower basal levels.

Conclusion: Our results suggest that in patients with active RA, serum MIF may be sensitive to tocilizumab therapy and that regulation of MIF via the IL-6/IL-6 receptor plays a crucial role in the pathogenesis of RA.

67

Glucosamine Sulphate Reduces the Prostaglandin E_2 Production In Osteoarthritic Cartilage Through the Inhibition of Microsomal Prostaglandin E Synthase-1. Mohit Kapoor, Francois Mineau, Hassan Fahmi, Jean Pierre Pelletier and Johanne Martel-Pelletier. Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC

Background/Purpose: Among the prostaglandins of the E series, PGE_2 is one of the major inflammatory/catabolic mediators involved in cartilage degradation associated with osteoarthritis (OA). Moreover, several of the effects of the catabolic cytokine, IL-1β, are mediated through the stimulation of PGE_2 production. As glucosamine sulfate (GS) has been inferred to have a potential anti-inflammatory effect on OA symptoms, we explored its effect on PGE_2 in human OA chondrocytes and at which level in the PGE_2 pathway its effect takes place. This pathway includes the cyclooxygenases (COX)-1 and -2, the terminal enzyme responsible for PGE_2 synthesis, mPGES-1, as well as its co-factor glutathione and its transcriptional signalling pathway, the early growth response factor (Egr)-1. In addition, as PPAR-g activation inhibits IL-1β induced mPGES-1, we also examined the effect of GS on this factor.

Methods: The effect of GS treatment (0.2, 1, and 2 mM) on human OA chondrocytes ($n = 5–8$) was investigated in the absence or presence of IL-1β (100 pg/ml). The expression levels (real time PCR) and protein production/activity of PGE_2, COX-1, COX-2, mPGES-1, glutathione, Erg-1, and PPAR-g, using specific primers (expression), antibodies or assays (protein), were determined.

Results: Data showed that GS treatment at 1 and 2 mM significantly inhibited ($p \leq 0.03$) the basal endogenous and IL-1β-induced PGE_2 production. GS in both the absence and presence of IL-1β did not significantly modulate COX-1 protein production but, interestingly, GS at 1 and 2 mM demonstrated a decrease in COX-2 activity in that it reduced the molecular mass of COX-2 synthesis from 72–74 kDa to 66–70 kDa. Under IL-1β stimulation, GS significantly inhibited the mPGES-1 mRNA expression and synthesis at 1 and 2 mM ($p \leq 0.02$) as well as the activity of glutathione ($p \leq 0.03$) and the Erg-1 ($p \leq 0.05$) at 2 mM. Finally, data showed that in both the absence and presence of IL-1β, PPAR-g was significantly induced by GS at 2 mM ($p \leq 0.02$).

Conclusion: Our data further documents the potential mode of action of GS at reducing the catabolism of human OA cartilage. GS inhibits PGE_2 synthesis via a reduction in the activity of COX-2 and the production and activity of mPGES-1. These findings may help explain the mechanisms by which this drug exerts its positive effect on OA pathophysiology.

68

Role of Transcription Factor Fli-1 in Regulation of Dendritic Cell and Monocyte Development. Eiji Suzuki[1], Sarah Williams[2], Eva Karam[1], Gary S. Gilkeson[3] and Xian Zhang[3]. [1]Medical University of South Carolina, Charleston, SC, [2]Ralph H. Johnson VA Medical Center, Charleston, SC, [3]Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC

Background/Purpose: The Fli-1 gene is a member of the *ets* family of transcription factors that is expressed in hematopoietic cells, and has important roles in the immune system. Overexpression of Fli-1 protein in transgenic mice results in the development of a lupus-like disease. Expression of Fli-1 in systemic lupus erythematosus (SLE) patients and animal models of lupus is higher compared to normal controls. Dendritic cell and monocytes have a critical role in immunity and autoimmunity. The molecular mechanisms of Fli-1's role in lupus development are still unclear. In this report, we demonstrate Fli-1 plays an important role in regulating the development of monocytes and dendritic cells.

Methods: C57BL/6 (B6) mutant Fli-1 mice (Fli-$1^{\Delta CTA}$) express a truncated Fli-1 protein that lacks the C-terminal transactivation domain. Removal of this domain of Fli-1 reduces overall in vitro transcriptional activation activity by 40–50%. Fli-$1^{\Delta CTA}$ and wild-type B6 mice were sacrificed at the ages of 8–12 weeks. Bone marrow cells, spleen cells and peripheral blood mononuclear cells were prepared from each mouse and analyzed with Flow cytometery using specific antibodies.To further reveal the molecular mechanisms, Multipotent progenitors (MPP) were sorted from cultured bone marrow cells from both wild-type and Fli-$1^{\Delta CTA}$ mice. The expression of FMS-like tyrosine kinase 3 ligand (Flt3L) in MPP was measured by real-time PCR.

Results: Common dendritic cell precursors population in bone marrow from Fli-$1^{\Delta CTA}$ B6 mice was significantly higher than that from wild-type controls (Fli-$1^{\Delta CTA}$, 0.45±0.061% VS wild-type, 0.25±0.028%, $p<0.05$). The cell number of CD8+ and double negative conventional dendritic cells and macrophages in spleen from Fli-$1^{\Delta CTA}$ B6 mice were significantly higher compared to wild type littermates (for CD8+ dendritic cells, Fli-$1^{\Delta CTA}$, 1.10±0.183 $\times 10^6$ VS wild-type, 0.62±0.060 $\times 10^6$, $p<0.05$; for double negative conventional dendritic cells, Fli-$1^{\Delta CTA}$, 2.77±0.641 $\times 10^6$ VS wild-type, 1.19±0.053 $\times 10^6$, $p<0.05$; for macrophages, Fli-$1^{\Delta CTA}$, 4.60±0.131 $\times 10^6$ VS wild-type, 2.55±0.252 $\times 10^6$, $p<0.01$). Pre-conventional dendritic cells, plasmacytoid dendritic cells and monocytes in peripheral blood from Fli-$1^{\Delta CTA}$ B6 mice were significantly higher compared to wild-type littermates (for pre-conventional dendritic cells, Fli-$1^{\Delta CTA}$, 0.37±0.041% VS wild-type, 0.12±0.014%, $p<0.01$; for plasmacytoid dendritic cells, Fli-$1^{\Delta CTA}$, 0.48±0.044% VS wild-type, 0.27±0.052, $p<0.05$; for monocytes, Fli-$1^{\Delta CTA}$, 2.72±0.637% VS wild-type, 0.92±0.193%, $p<0.05$). The expression of Flt3L in MPP obtained from Fli-$1^{\Delta CTA}$ B6 mice was significantly increased compared to wild-type controls ($p<0.05$).

Conclusion: Our results demonstrate that Fli1 plays an important role in myeloid cell development and the CTA domain in Fli-1 protein negatively regulates the myeloid cell development. We also demonstrated that Fli-1 affects myeloid cell development by directly or indirectly regulating the expression of Flt3L, a key molecule during dendritic cell development.

Resveratrol Deacetylating Rela/p65 Contributes to Inhibit Transforming Growth Factor-Alpha Induced Inflammation Via a Sirt1 Dependent Manner. Xiaoxia Zhu[1], Meimei Wang[2], Jianhua Qiu[3] and Hejian Zou[1]. [1]Division of Rheumatology, Huashan Hospital, Fudan University, Shanghai, China, [2]Division of Rheumatology, Zhongda Hospital, Dongnan University, Nanjing, China, [3]Neuroscience Center, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Progressive inflammation is a main mechanism of autoimmune disorders, such as rheumatoid arthritis, systemic sclerosis. Suppression of inflammation is a key resolution to treat the diseases. Sirtuin1 (Sirt1), a NAD^+-dependent deacetylase, plays a role in regulation of inflammation by deacetylating NF-κB subunit RelA/p65. As a potent Sirt1 activator, resveratrol is a natural phytoalexin and has been shown to have anti-inflammation property. However, the mechanism is not fully understood.

Methods: NIH/3T3 cell line (mouse embryonic fibroblast) was treated by TNF-α to induce inflammation. Inflammatory factors and acetylated RelA/p65 were examined by gel zymography, quantitative real-time PCR or immunoblotting. To investigate the role of resveratrol in inflammation, resveratrol was used to treat the cells with TNF-α, inflammatory factors were then examined after treatment. To further explore whether Sirt1 is involved in the anti-inflammation mechanism, Sirt1 was knocked down by siRNA interference before resveratrol treatment.

Results: Upregulation of matrix metalloproteinases 9 (MMP9), interleukin-1beta (IL-1β), IL-6 and inducible nitric oxide synthase (iNOS) were observed in the 3T3 fibroblasts after being treated by TNF-α. Resveratrol suppressed the upregulation of inflammatory factors induced by TNF-α in a dose-dependent manner. However, inflammatory inhibition of resveratrol was largely dependent on Sirt1 expression. Knockdown of Sirt1 caused cell sensitizing to TNF-α stimulation and diminished the inflammatory inhibition of resveratrol. Furthermore, resveratrol inhibited TNF-α-induced RelA/p65 acetylation, which is notably Sirt1 dependent. Resveratrol also attenuated phosphorylation of both mTOR and S6 ribosomal protein while ameliorating inflammation.

Conclusion: Our data suggested that Sirt1 is an efficient target for suppression of inflammation and Sirt1 activator such as resveratrol may be used for anti-inflammatory therapy. This study provides a novel insight or treatment of inflammation-related autoimmune disorders.

70

Fasting Expands Regulatory T Cells in Lupus Mice. Yaoyang Liu[1], Yiyun Yu[1] and Antonio La Cava[2]. [1]UCLA, Los Angeles, [2]Univ of California Los Angeles, Los Angeles, CA

Background/Purpose: Caloric restriction has been found beneficial in the prevention and amelioration of the clinical manifestations of systemic lupus erythematosus (SLE), but the mechanisms responsible for these effects remain elusive. Fasting associates with significant changes in the immune response and with significantly reduced levels of circulating leptin. Since recent studies have shown that leptin influences the activity and proliferation of $CD4^+CD25^+Foxp3^+$ regulatory T cells (Tregs)—a subset of lymphocytes with a key role in the maintenance of immune tolerance—we studied whether fasting in (NZB × NZW)F1 (BWF1) lupus-prone mice could modulate Tregs activity in SLE through leptin.

Methods: Cohorts of C57BL6/J wild-type (WT), leptin-deficient ob/ob, leptin receptor-deficient db/db and BWF1 lupus mice were fasted 48 hours during which time they were treated with either leptin or vehicle (PBS). Additional control animals were fed ad libitum and treated with leptin or vehicle. Serum leptin was determined by ELISA and the percentage of Tregs from the periphery blood evaluated by flow cytometry. In vitro suppression assays using thymidine incorporation or CFSE staining in flow cytometry concomitantly addressed Tregs function.

Results: Fasting for 48 hours reduced the serum levels of leptin in all mice, as expected. In both WT and BWF1 lupus mice, 48hr acute starvation significantly expanded the number of functional peripheral Tregs (fasted & PBS vs. fed ad libitum WT mice: 9.80±0.42 vs. 6.32±0.46, $p<0.03$; in BWF1 lupus mice fasted vs fed: 7.69±0.33 vs. 3.85±0.40, $p<0.01$). Specificity of the findings was indicated by the fact that the administration of leptin during starvation reversed the expansion of the Tregs. In the leptin-deficient ob/ob mice, the number of peripheral Tregs was not affected by fasting (P ns vs ob/ob mice fed ad libitum) but significantly deceased when the animals received leptin (fasted & leptin vs. fasted & PBS: 8.64±0.98 vs. 14.50±0.81, $p<0.01$). In leptin receptor-deficient db/db mice, the reduction in serum leptin after starvation had no impact on the number and suppressive function of the Tregs (P ns vs db/db mice fed ad libitum).

Conclusion: This study shows that fasting associates with an expansion of functional Tregs through a reduction of leptin levels in BWF1 lupus mice. This finding advances the understanding of the mechanisms responsible for the beneficial effects of caloric deprivation in SLE. The observed expansion of Tregs that associates with fasting is reversed by the exogenous administration of leptin, suggesting that the link between the nutritional status and immune regulation might represent a new target for the modulation of Tregs activity in SLE.

71

Microarray Gene Expression Profiling of Articular Chondrocyte In Patients with Osteoarthritis. Ying-Juan Chen[1], Ci-Bo Huang[1], Su-Ping Niu[1], Ai-Hua Liu, Bei Lai and Chun-Mei Zhang. [1]Beijing Hospital, Beijing, China

Background/Purpose: Osteoarthritis (OA) is characterized by degeneration of articular cartilage which involves complicated multiple gene events. In this study, we used gene microarray technique to investigate the gene expression profiling of articular chondrocyte and the function and pathway of the differentially expressed genes in patients with OA.

Methods: Three patients with OA, three patients with rheumatoid arthritis (RA) and three traumatic controls without arthritis were selected which divided into OA versus RA and OA versus the traumatic control two groups, and their articular cartilage cells were cultivated. The gene expression profiling was performed through human genome oligonucleotide microarray technique. The differences of gene expression of the articular chondrocyte in OA versus RA group and OA versus the traumatic control group were compared respectively by using Significant Analysis of Microarray software. The function and pathway of these differentially expressed genes were analysed by using the biological information database of Molecule Annotation System.

Results: The number of differentially expressed genes was 145 when OA compared the traumatic control, in which 70 were up-regulated and 75 were down-regulated; and the number was 281 when OA compared RA, in which 94 were up-regulated and 187 were down-regulated. The Gene Ontology (GO) functions of differentially expressed genes of OA in each group were related to pathological and immune courses including cellular process, physiological process, cell part, biological regulation and cell signal transduction. The statistically significant pathways of these genes in each group included cell cycle regulation, apoptosis, inflammatory cell, cell signal transduction, cytokine and its receptor pathways ($p<0.05$). There displayed not only marked differences in GO function and gene pathway of differentially expressed genes between OA versus RA group and OA versus the traumatic control group, but also displayed significant overlaping differentially expressed genes and pathways between two groups.

Conclusion: The differentially expressed genes and pathways of articular chondrocyte involved apoptosis, extracellular matrix and cytokines in OA, which contribute to search the early warning genes of OA.

72

Progesterone Modulates Interferon-Alpha-Inducible Gene Expression in Human Leukocytes. Michael Cho[1], John Zheng[2] and Grant C. Hughes[2]. [1]Univ of Wash School of Medicine, Seattle, WA, [2]University of Washington, Seattle, WA

Background/Purpose: Interferon-alpha (IFN-a) is a central pathogenic cytokine in systemic lupus erythematosus (SLE). Exposure of leukocytes to IFN-a results in activation of the type 1 IFN receptor, transcription of IFN-a-inducible genes (IIGs) and subsequent leukocyte activation and differentiation. Female sex steroids like estrogen (Es) and progesterone (Pg) modulate SLE autoimmunity. Es is permissive, likely through direct effects on leukocyte activation, maturation and migration. Pg, on the other hand, appears to protect against SLE autoimmunity. Recent data from our lab shows that Pg may do this by suppressing IFN-a production. However, observational data from human tissues indicate transcription of genes involved in IFN-a signaling is under Pg's control—suggesting Pg may also protect against lupus by limiting the immunostimulatory effects of IFN-a. Thus, we hypothesize that Pg inhibits IFN-a signaling in human leukocytes.

Methods: To test our hypothesis, we assessed the effects of Pg treatment on a surrogate measure of IFN-a signaling: induction of IIG expression after IFN-a exposure. Briefly, we isolated peripheral blood mononuclear cells (PBMCs) from healthy donors. PBMCs were cultured in media, ethanol (vehicle), or physiologic concentrations Pg (100 nM), with or without IFN-a stimulation (50 – 100 IU/ml). After 20 h, total RNA was isolated, converted into cDNA, and expression of established IIGs (CXCL10, MX1, IFIT1) was measured by quantitative PCR and normalized to 18s. We recruited healthy donors of both sexes, since expression of Es and Pg receptors is not restricted to female PBMCs.

Results: In a series of 9 independent experiments (4 female, 5 male donors), Pg exposure resulted in variable effects on IIG induction. Pg inhibited to a small degree induction of IFIT1 and MX1, but not CXCL10. Pg alone did not affect IIG expression. Interestingly, Pg appeared to have different effects on IIG induction in female vs. male PBMCs. In female PBMCs, there was a trend toward increased expression of CXCL10 ($p = 0.09$), MX1 ($p = 0.26$) and IFIT1 ($p = 0.40$). In male PBMCs, Pg inhibited induction of MX1 ($p = 0.27$) and IFIT1 ($p = 0.40$), but had no discernable effects on CXCL10.

Conclusion: Pg may regulate IIG induction and IFN-a signaling in human leukocytes. Consistent with our hypothesis, Pg exposure inhibited IIG induction, but this effect was restricted to male PBMCs. In female PBMCs, Pg had the unexpected effect of increasing IIG induction. Thus, inhibition of IFN-a signaling by Pg in leukocytes is unlikely to be involved in protection of women against SLE. However, Pg may inhibit this pathway in men, highlighting a potentially important sexual dimorphism in immune functions related to SLE. This research is supported by NIH grants AR007108 and AI073739.

73

Temperature Sensitive Transient Receptor Potential Channels in Human Peripheral Blood Mononuclear Cells Enhance the LPS-Mediated Cytokine Response. Monique Stoffels, Lonneke M. Elders, Heleen D. de Koning, Jos W. M. van der Meer and Anna Simon. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Exposure to cold can induce an exaggerated inflammatory response in a number of disorders. One of these is the hereditary autoinflammatory syndrome cryopyrin-associated periodic syndrome (CAPS), in which NLRP3-mutations cause a very diverse clinical phenotype of inflammation. Particularly patients with the subtype familial cold induced autoinflammatory syndrome (FCAS) are uniquely sensitive to cold exposure. Cold triggers an urticarial rash, fever, joint pain and systemic inflammation. Another example is idiopathic cold urticaria. It is unknown how the inflammatory system senses cold. Neurons are known to sense temperature through certain transient receptor potential (TRP) channels. In the present study we aimed to explore how inflammatory cells sense cold.

Methods: Quantitative real-time polymerase chain reaction assays for mRNA analysis of three known TRP channels, and Western Blot for TRP protein levels were done in several human-derived cell lines and primary cells. Peripheral blood mononuclear cells (PBMCs) were incubated with LPS and menthol, a known stimulus of TRP melastatin subfamily member 8 (TRPM8). Cytokine concentrations in culture supernatants were detected by Enzyme-linked immunosorbent assay (ELISA).

Results: PBMCs express the 'cool' menthol receptor TRPM8 and the noxious cold receptor TRP subfamily A (ankyrin-like) member 1 (TRPA1), as well as the close relative 'hot' capsaicin receptor TRPV1 at the RNA level. TRPM8 protein was detected by western blot in fibroblast and Epstein-Barr virus transformed lymphoblast cell lines. PBMCs preincubated with menthol show increased interleukin-1 beta (IL-1β) secretion in response to LPS, compared to LPS stimulation only. Stimulation with menthol alone did not result in an inflammatory response.

Conclusion: Human PBMCs express the temperature sensitive TRP channels TRPA1, TRPV1 and TRPM8. *Ex vivo* stimulation of PBMCs with menthol results in an increased inflammatory response to LPS. We hypothesize that *in vivo* cold exposure results in a modulated inflammatory response, through activation of temperature sensitive ion channels. Our results suggest that temperature sensing is not only important in the nervous system, but also plays a direct role in innate immunity.

74

Synergy Between Adiponectin and Interleukin-1β on the Expression of Interleukin-6, Interleukin-8, and Cyclooxygenase-2 in Fibroblast-Like Synoviocytes. Yeon-Ah Lee[1], Sang-Hoon Lee[2], Hyung-In Yang[2], So Mi Kim[1], Seung-Jae Hong[1], Myung Chul Yoo[3] and Kyoung Soo Kim[1]. [1]Kyung Hee University, Seoul, South Korea, [2]Kyung Hee University Hospital at KANGDONG, Kyung Hee University, Seoul, South Korea, [3]Kyung Hee University Hospital at KANGDONG, Seoul, South Korea

Background/Purpose: To determine whether adiponectin may have synergistic effects in combination with the proinflammatory cytokine interleukin (IL)-1b regarding the production of proinflammatory mediators during arthritic joint inflammation.

Methods: Synovial cells from rheumatoid arthritis (RA) patients were treated with adiponectin, IL-1b, and their combination for 24 hours. Culture supernatant was collected and analyzed by enzyme-linked immunosorbent assay for levels of IL-6, IL-8, prostaglandin E_2 (PGE_2), vascular endothelial

growth factor (VEGF), and matrix metalloproteinases (MMPs). Adiponectin-mediated intracellular signaling pathways were investigated to elucidate the molecular mechanisms underlying their synergy. The association of proinflammatory mediators with adiponectin was investigated in the synovial fluid of arthritis patients.

Results: Adiponectin functioned synergistically with IL-1b to activate IL-6, IL-8, and PGE_2 expression in RA fibroblast-like synoviocytes; Levels of VEGF, MMP-1, and MMP-13 were not synergistically stimulated. Adiponectin appears to activate gene expression through the IkB signaling pathway. However, adiponectin and IL-1b did not synergistically support the degradation of IkB-a or the nuclear translocation of NF-kB. Synergistically increased gene expression was significantly inhibited by MG132, an NF-kB inhibitor. Supporting the in vitro results, IL-6 and IL-8 levels were positively associated with adiponectin in synovial joint fluid from patients with RA, but not osteoarthritis (OA)

Conclusion: Adiponectin and IL-1b may synergistically stimulate the production of proinflammatory mediators through unknown signaling pathways during arthritic joint inflammation. Adiponectin may be more important to the pathogenesis of RA than previously thought.

75

The Discordant Impact of IL-1 Signaling on Experimental Uveitis and Arthritis. Holly L. Rosenzweig[1], Stephen R. Planck[1], April L. Woods[1], Jenna S. Clowers[2], Martin J. Nicklin[3] and James T. Rosenbaum[1]. [1]Oregon Health & Science University, Portland, OR, [2]Veterans Affairs Medical Center, Portland, OR, [3]University of Sheffield, United Kingdom

Background/Purpose: Uveitis, or inflammatory eye disease, is an extra-articular manifestation of many systemic autoinflammatory diseases involving the joints. The importance of IL-1 in many arthritic diseases is apparent from the effectiveness of Anakinra (recombinant IL-1 receptor antagonist, IL-1RA) therapy. Yet, very little work has investigated the extent to which IL-1 signaling or IL-1RA influences the onset and/or severity of uveitis. The purpose of this study was to elucidate the impact of IL-1R1 and IL-1RA on murine uveitis.

Methods: The onset and severity of uveitis was monitored by histology and intravital videomicroscopy out to 20 weeks of age and compared to the progression of spontaneous arthritis within the ankles and knees of naïve IL-1RA deficient mice or in mice previously administered an intraperitoneal injection of 25 μg LPS at 8 weeks of age. Expression levels of IL-1R1 and its negative regulators (IL-1RA, IL-1RII, IL-1RAcP, SIGIRR) were analyzed in ocular compared to joint tissues. Differences in uveitis induced by intraocular injection of LPS in mice lacking IL-1R1 or IL-1RA were assessed.

Results: Deficiency in IL-1RA predisposes to arthritis, which is exacerbated by prior systemic LPS exposure. The mouse eye, however, remains unaffected by inflammatory disease despite the progressive arthritis or prior systemic LPS exposure. Tissue-specific expression patterns for IL-1RA and regulators of IL-1R1 were observed in the ankle, knee and eyes and these appear to predict relative disease susceptibility in each tissue in that ankles are most susceptible and eyes are least susceptible. Uveitis in mice does result from locally administered LPS. Interestingly, IL-1RA deficiency markedly exacerbates uveitis induced by locally admininstered LPS whereas IL-1R1 deficiency has no effect on the disease severity.

Conclusion: This study demonstrates discordance between the eyes and joints in the extent to which IL-1RA protects against spontaneous inflammation. Nonetheless, IL-1RA plays an important role in suppressing cellular inflammatory responses to intraocular LPS.

76

The Expression of the Receptor for Advanced Glycation End-products in Fibroblast Like synoviocytes From Rheumatoid Arthritis Patients Is Induced by Interleukin-17. Young Ok Jung[1], Mila Cho[2], Hae-Rim Kim[3], Sang-Heon Lee[4], Sung-Hwan Park[5], Hye-Jwa Oh[2] and Ho-Youn Kim[5]. [1]Seoul, South Korea, [2]Catholic Medical Univ, Seoul, South Korea, [3]Konkuk University Medical Center, Seoul, South Korea, [4]Konkuk University Hospital, Seoul, South Korea, [5]Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul, South Korea

Background/Purpose: Receptor for advanced glycation end-products (RAGE) has been implicated in the pathogenesis of arthritis. We conducted this study to determine the effect of interleukin (IL)-17 on the expression and production of RAGE in fibroblast-like synoviocytes (FLS) from patients with rheumatoid arthritis (RA). The role of nuclear factor-kB (NF-kB) activator 1 (Act1) in IL-17-induced RAGE expression in RA-FLS was also evaluated.

Methods: RAGE expression in synovial tissues was assessed by immunohistochemical staining. RAGE mRNA production was determined by the real-time polymerase chain reaction. Act-1 short hairpin RNA (shRNA) was produced and treated to evaluate the role of Act-1 on RAGE production.

Results: RAGE, IL-17, and Act-1 expression increased in RA synovium compared to osteoarthritis synovium. RAGE expression and production increased by IL-17 and IL-1b (*$P < 0.05$ vs. untreated cells) treatment but not by tumor necrosis factor (TNF)-a in RA-FLS. The combined stimuli of both IL-17 and IL-1b significantly increased RAGE production compared to a single stimulus with IL-17 or IL-1b alone ($P < 0.05$ vs. 10 ng/ml IL-17). Act-1 shRNA added to the RA-FLS culture supernatant completely suppressed the enhanced production of RAGE induced by IL-17.

Conclusion: RAGE was overexpressed in RA synovial tissues, and RAGE production was stimulated by IL-17 and IL-1b. Act-1 contributed to the stimulatory effect of IL-17 on RAGE production, suggesting a possible inhibitory target for RA treatment.

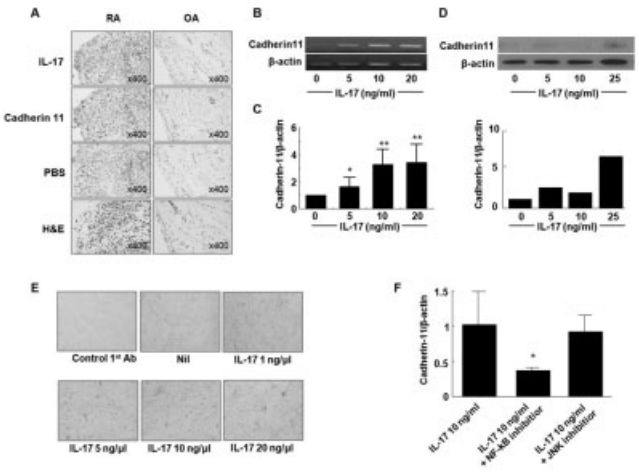
77

Interleukin 17 Increased Cadherin 11 Expression in rheumatoid Arthritis. Young Eun Park[1], Seong Hu Park[2], Seung Geun Lee[2], Seung Hoon Baek[3], Geun Tae Kim[4], Jun Hee Lee[5], Joung Wook Lee[6], Mi La Cho[7] and Sung Il Kim[1]. [1]Pusan National University Hospital, Busan, South Korea, [2]Pusan Nationl University Hospital, Busan, South Korea, [3]Pusan National University Yangsan Hospital, Yangsan, South Korea, [4]Kosin University Gopsel Hospital, Pusan, South Korea, [5]Ilsin Christian Hospital, Pusan, South Korea, [6]Busan st. Mary's Medical Center, Busan, South Korea, [7]The Rheumatism Research Center, Catholic Research Institute of Medical Science, The Catholic University of Korea, Seoul, South Korea

Background/Purpose: IL-17, produced from Th17 cells, plays important roles in synovial inflammation and joint destruction of autoimmune experimental arthritis model and rheumatoid arthritis (RA). Cadherin 11 is expressed primarily on synovial fibroblasts (FLS) in the synovium, and promotes invasive behavior of FLS in chronic synovitis and rheumatoid arthritis. Cadherin 11 expression is regulated by mediators of inflammation. The purpose of this study was to examine the effect of IL-17 on the expression of cadherin 11 in RA synovium.

Methods: Synovial tissue specimens were isolated from 4 RA and osteoarthritis (OA) patients who were undergoing total knee replacement surgery. IL-17 and Cadherin 11 expressions were examined in synovium of patients with RA and osteoarthritis (OA) by immunohistochemistry. The expression of cadherin 11 were also examined from IL-17 stimulated FLS of RA patients with or without cell signal pathway inhibitors such as parthenolide (NK-kB inhibitor) and SP600125 (JNK inhibitor).

Results: Cahderin 11 and IL-17 expressing cells were more abundantly distributed in RA synovim compared to OA synovium (A). In cultured RA FLS, the mRNA and protein levels of cadherin 11 were measured by RT-PCR (B), real-time PCR (C), western blot (D) and cell stain (E), and increased by IL-17 stimulation. The enhancement of IL-17 expression was blocked by NFkB inhibitor, but not JNK inhibitor (K).



Conclusion: IL-17 induced increases of synovial cadherin 11 expression might be involved in joint inflammation and destruction of RA.

78

Type-1 Interferon Does Not Directly Impair Endothelial Cell Function *in Vitro*: Implications for Cardiovascular Models of Systemic Lupus Erythematosus. John A. Reynolds[1], David W. Ray[1], Terence O'Neill[1], M. Yvonne Alexander[1] and Ian N. Bruce[2]. [1]The University of Manchester, Manchester, United Kingdom, [2]A, Manchester, United Kingdom

Background/Purpose: Systemic Lupus Erythematosus (SLE) is associated with a significantly increased risk of cardiovascular disease (CVD). Type-1 interferon (IFN) is the dominant inflammatory cytokine in SLE and IFN treatment can induce endothelial dysfunction in patients with viral hepatitis. Furthermore, IFN impairs the function of endothelial progenitor cells (EPCs) *in vitro*, replicating a phenotype similar to that seen in EPCs from lupus patients. The mechanism by which IFN impairs endothelial cell function is unknown. We aimed to determine the effect of IFN upon endothelial cells in order to establish an *in vitro* endothelial model relevant to SLE.

Methods: Human aortic endothelial cells (HAoECs) were cultured in standard conditions. For proliferation experiments, the effect of IFNα2b was studied either by counting cell nuclei in random fields or by MTT assay. An Affymetrix GeneChip Human Exon 1.0 ST Array was used to determine changes in gene expression at 6 hours following addition of IFNα2b. Nitric oxide bioavailability in the cell culture supernatant was measured using a Griess assay (total nitrate and nitrite) at 6 and 24 hours. The ability of HAoECs to form capillary networks in Matrigel at 18 hours and in type-1 rat tail collagen gels at up to 48 hours was studied in the presence or absence of IFNα2b.

Results: IFNα2b at concentrations of 0.1–100ng/ml had no effect on HAoEC proliferation measured by either cell count or MTT assay at up to 72 hours (n=3 for each). The expression of 164 genes was significantly changed (>2-fold change, q<0.2) by the addition of 10ng/ml IFNα2b at 6 hours. These genes were primarily those previously reported to be regulated by IFNα or those involved in cellular response to virus (e.g. IFIT1, IFI44L, MX1 and CXCL10).

Nitric oxide availability was not changed at up to 24 hours by the addition of IFNα2b (n=3). The formation of 2-dimensional capillary networks in Matrigel was variable and not consistently impaired by the addition of 10ng/ml IFN. Furthermore the development of 3-dimensional networks in collagen was not disrupted by the addition of IFNα2b to either the gel or the culture media.

Conclusion: Interferon-α2b did not affect the function of human aortic endothelial cells *in vitro*. Gene expression was not influenced beyond those genes involved in IFN signalling or in response to virus. We propose therefore, that the reported effects of IFN on EPC function do not extend to mature human endothelial cells. This has implications for the development of *in vitro* endothelial models relevant to SLE and further work should focus upon the role of IFN in EPC differentiation and function.

79

Polymyalgia Rheumatica Has a Nocturnal Rise in Serum Interleukin-6 Which Is Almost Completely Suppressed by Nighttime Prednisone. Samy Zakout and John R. Kirwan. University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom

Background/Purpose: Stiffness in polymyalgia rheumatica (PMR) follows a circadian rhythm. In rheumatoid arthritis (RA) morning stiffness is linked to a nocturnal rise in interleukin-6 (IL-6) and converting morning prednisone to a nighttime treatment (modified-release prednisone effective at 2am) led to a significant decrease in morning stiffness [1]. Previous studies of cytokines in PMR collected data only for one time of the day [2] and the possibility of a circadian pattern in IL-6 and the effects of glucocorticoids have not been investigated. The purpose of the study is to determine whether IL-6 follows a circadian rhythm in patients with newly diagnosed untreated PMR, and to compare the effects of morning and nighttime glucocorticoids on overnight IL-6 and morning stiffness.

Methods: 10 patients with newly diagnosed PMR were randomised to two treatment groups with either nighttime prednisone 7mg (Lodotra) or morning prednisolone 7mg. Hourly blood samples over 24-hours were taken before (Night A) and after (Night B) treatment to measure IL-6. Patients were then treated with morning prednisolone 15mg and after 2 weeks a single measurement of IL-6 was performed at 9am (Day C). Duration of morning stiffness was recorded on each occasion.

Results: IL-6 shows a circadian variation in PMR, with a rise during the early hours of the morning (Figure 1, IL-6 pre-treatment). Morning prednisolone 7mg partially suppresses IL-6 and morning symptoms, compared to subsequent treatment with 15mg. Nighttime prednisone 7mg almost completely suppresses IL-6 and morning stiffness (Figures 1 and 2).

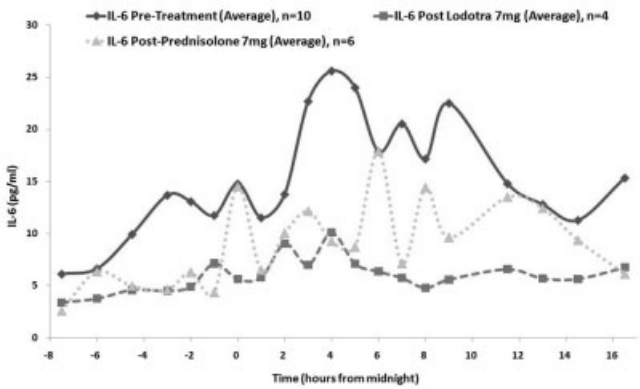


Figure 1

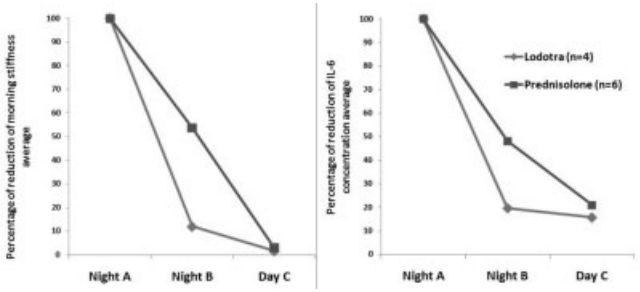

Figure 2

Conclusion: PMR, like RA, has a marked circadian variation in serum IL-6. IL-6 and symptoms of morning stiffness are both suppressed more by nighttime low dose glucocorticoids. This observation raises the possibility that PMR may be controlled by lower doses of glucocorticoids given at night compared to current conventional morning treatment.

Early Growth Response factor−1 Mediates the Suppressive Effect of Interleukin-1 on Peroxisome proliferator–activated Receptor Gamma Expression in Human Osteoarthritic Chondrocytes. Sarah S. Nebbaki[1], Fatima Ezzahra El Mansouri[2], Nadia Zayed[2], Mohamed Benderdour[3], Johanne M. Pelletier[2], Jean Pierre Pelletier[2] and Hassan Fahmi[2]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Center (CRCHUM), Notre-Dame Hospital, Montreal, QC, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [3]University of Montreal Hospital Research Centre, Sacré-Coeur Hospital, Montreal, QC

Background/Purpose: Peroxisome proliferator-activated receptor gamma (PPARg) gamma is a ligand activated transcription factor and member the nuclear hormone receptor superfamily. Several lines of evidence indicate that PPARg have protective effects in osteoarthritis (OA). Indeed, PPARg has been shown to down-regulate several inflammatory and catabolic responses in articular joint cells and to be protective in animal models of OA. We have previously shown that IL-1 down-regulated PPARg expression in OA chondrocytes. In the present study we will investigate the mechanisms underlying this effect of IL-1.

Methods: Chondrocytes were stimulated with IL-1, and the level of PPARg and Egr-1 protein and mRNA were evaluated using Western blotting

and real-time reverse-transcription polymerase chain reaction, respectively. The PPARg promoter activity was analyzed in transient transfection experiments. Egr-1 recruitment to the PPARg promoter was evaluated using chromatin immunoprecipitation (ChIP) assays. Small interfering RNA (siRNA) approaches were used to silence Egr-1 expression.

Results: We demonstrated that the suppressive effect of IL-1 on PPARg expression requires de novo protein synthesis and was concomitant with the induction of the transcription factor Egr-1. ChIP analyses revealed that IL-1 induced Egr-1 recruitment at the PPARg promoter. IL-1 inhibited the activity of PPARg promoter and overexpression of Egr-1 potentiated the inhibitory effect of IL-1, suggesting that Egr-1 may mediate the suppressive effect of IL-1. Finally, Egr-1 silencing with small interfering RNA blocked IL-1-mediated down-regulation of PPARg expression.

Conclusion: These results indicate that Egr-1 contributes to IL-1-mediated down-regulation of PPARg expression in OA chondrocytes and suggest that this pathway could be a potential target for pharmacologic intervention in the treatment of OA and possibly other arthritic diseases.

81

Circulating cytokines in Patients with Hidradenitis Suppurativa: is there a Clue for new Therapeutic Options? Orlando Pompei[1], Lorena Álvarez-Rodríguez[1], Ricardo Blanco[1], Ignacio Villa[2], Marcos López-Hoyos[1], Marcos González López[1], Hector Fernandez-Llaca[1], M. del Carmen Gonzalez Vela[1], Carmen Bejerano[1], Inés Pérez-Martín[1] and Victor M. Martinez-Taboada[1]. [1]Hospital Universitario Marqués de Valdecilla-IFIMAV, Santander, Spain, [2]Hospital Sierrallana, Torrelavega, Spain

Background/Purpose: Hidradenitis suppurativa (HS) is a debilitating chronic disease with a pathogenesis that remains largely unknown. Most treatments remain empiric, are usually supportive and do not prevent the progression of the disease. More recently, treatment with TNF antagonists has shown promising results, that should be confirmed in well-designed clinical trials. As new treatment options for inflammatory conditions are rapidly appearing, the aim of the present study was to determine the cellular phenotype and the circulating cytokine profile in patients with HS.

Methods: Intracellular cytokine production was assessed in T cells (IFN-g, IL-2, IL-4, IL-10, IL-17) and monocytes (IL-1b, TNF-a, IL-6) by flow cytometry in 22 patients with active HS and 18 age- and sex-matched healthy controls (controls). Circulating cytokines (IL-12p70, IL-10, IL-8, IL-1b, TNF-a, IL-6) were measured by Cytometric Bead Array (CBA) in 26 patients with HS and 37 controls. Four HS patients were also assessed after treatment with TNF antagonists.

Results: No significant differences between patients and controls were found for circulating levels of IL-12p70, IL-10, IL-8, IL-1b, and TNF-a. IL-6 was the only circulating cytokine significantly increased in patients with active disease ($p=0.001$). Using flow cytometry technology, we examined whether circulating monocytes were a major source of proinflammatory cytokines in patients with HS. The percentage of proinflammatory cytokine-producing cells *ex vivo* in patients with HS was similar to the percentage in controls. *In vitro* stimulation with LPS showed a clear response of circulating CD14+ cells, especially in controls. The percentage of IL-6, IL-1b and TNFa-producing cells after *in vitro* stimulation was significantly lower in patients with active HS. Compared to controls, HS patients were characterized by a decreased frequency of circulating CD3+IFNg+ *ex vivo* ($p=0.03$). Disease control with treatment was followed by a further decrease of circulating CD3+IFNg+ ($p=0.015$). Patients with active HS showed a non-significant increased frequency of circulating Th17 (CD4+IL17+CCR6+ and CD4+IL17+IFN-) cells compared to controls. Disease control with treatment was also followed by a tendency to decrease circulating Th17 cells ($p=0.06$).

Conclusion: To the best of our knowledge, this is the first report that demonstrate an increase in serum levels of IL6 in patients with HS. We hypothesize that the increased levels of IL6 found in patients with HS are not the result of IL6 production by circulating monocytes, and it is reasonable to assume that the major production of this proinflammatory cytokine is located at the site of the inflammatory process or in other cell types that predominantly produce IL6.

82

Differential Production of Angiopoietins-1 and -2 in Synovial Tissue of Rheumatoid Arthritis and Psoriatic Arthritis Patients Is Associated with Expression of Specific Putative Transcription Factors. M. Frleta, L.G.M. van Baarsen, A.M. Grabiec, D. de Launay, M. Garrelfs, D. Gerlag, PP. Tak and K.A. Reedquist. Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: The angiogenic factors angiopoietin (Ang)-1 and -2 are differentially expressed in the serum and synovial fluid of patients with different forms of arthritis. Ang-1 and -2 contribute to inflammation and joint destruction in rheumatoid arthritis (RA), but the underlying mechanisms for their differential expression and their consequences for synovial Tie2 activation are unknown. Here we conducted *in silico* studies to define transcription factors (TFs) potentially involved in the regulation of Ang-1/-2 expression, and investigated the expression of candidate TFs in correlation with Ang-1/-2 in RA and PsA synovial tissue.

Methods: *In silico* analysis was conducted to identify possible TF candidates in the Ang-1/-2 promoter region, using four different TF binding site prediction programs. RA synovial expression of TF and Ang-1/-2 was examined in publicly available gene expression data sets obtained from synovial tissue biopsies of 62 RA patients. Candidate TF and Ang-1/-2 expression was characterized by quantitative PCR arrays (qPCR) in synovial tissue samples obtained from 6 RA and 6 PsA patients.

Results: The *in silico* study identified 74 candidate TFs that might bind to Ang-1/-2 promoting regions. Analyzing correlations with Ang-1/-2 mRNA expression in publicly available gene expression data sets revealed 34 TFs potentially involved in Ang-1 expression and 22 TFs related to Ang-2 regulation. Further analysis by qPCR arrays identified 3 TFs significantly downregulated in PsA compared to RA (more than 2-fold), including ESR1 ($p=0.015$), SOX5 ($p=0.004$), and SOX9 ($p=0.014$). In RA synovial tissue, significant correlations were observed between expression of Ang-1 and 8 TFs: FOXJ2 ($r=0.94$, $p=0.017$), HLF ($r=0.94$, $p=0.017$), LMO2 ($r=1.0$, $p=0.0028$), NR3C1, TCF4, HOXA4, MEF2A and YY1 (all $r=0.94$, $p=0.017$). Ang-2 expression in RA correlated with HLF ($r=0.88$, $p=0.033$), TCF4 ($r=0.88$, $p=0.033$), ESR1 ($r=1.0$, $p=0.0028$), GATA2 ($r=0.88$, $p=0.033$), and JUN ($r=0.88$, $p=0.033$).

Conclusion: We have observed significant upregulation of a number of TFs involved in Ang-1/-2 regulation in RA compared to PsA synovial tissue. Further analyses of the cellular mechanisms driving expression and activation of these TFs in synovial tissue may provide a greater understanding of stimuli responsible for initiating angiogenesis in RA and PsA.

Development of a Collaborative Rheumatology and Orthopedic Musculoskeletal Ultrasound Training Program. Minna J. Kohler[1], John S. Reach[1], Janine Evans[1], Lawrence D. Weis[1], Joseph E. Craft[2] and Liana Fraenkel[1]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [2]Yale University School of Medicine, New Haven, CT

Background/Purpose: Interest in musculoskeletal ultrasound (MUS) training by rheumatologists has grown as a tool to facilitate personalized point-of-care diagnostic testing and treatment. Over the past decade, MUS training has been popular in Europe, and there is now increasing demand by American rheumatologists to obtain training. At this time, no formal training curriculum is required in U.S. rheumatology fellowship programs, and lack of MUS-trained rheumatology faculty often impedes the ability for fellows to become proficient in using MUS.

Methods: We describe the development and implementation of a novel, collaborative rheumatology/orthopedic MUS training program at a single academic medical center. The program was developed in conjunction with an orthopedist with advanced training in MUS, access to an ultrasound (US) machine, and clinics that provide care for patients with osteoarthritis and soft tissue rheumatism.

Results: The training program consists of 1) weekly, ½ to 1 day faculty-mentored MUS injection clinic, 2) instructional didactic sessions, 3) monthly hands-on didactic practice sessions, and 4) options to participate in a web-based fellows ultrasound training program (USSONAR) and the American College of Rheumatology MUS course for further training in rheumatology-focused MUS applications. In the MUS clinic, rheumatology fellows and orthopedic residents consecutively evaluate patients referred for musculoskeletal pain, willing to seek a corticosteroid injection if clinically indicated. All patients are evaluated by a fellow/resident under direct faculty supervision by our MUS expert. The clinic consists of half hour appointments in which the patient is clinically evaluated and diagnostic US or US-guided injection is performed. Instructional didactic sessions review basic physics

principles of US, function of basic controls on an US machine, and methods to optimize an US image. Monthly hands-on didactic training sessions review anatomy and ultrasound scanning protocols. Fellows/residents also practice US needle-guidance training with phantom models. The program additionally supports clinical research projects. To allow adequate mentored, hands-on ultrasound time, two fellows/residents per clinic can be trained over a year.

Conclusion: Development and implementation of a MUS clinic is feasible with an ultrasound expert, ultrasound machine, and patients who benefit from MUS point-of-care. The collaborative MUS program is beneficial to the education of both rheumatology fellows and orthopedic residents.

Educational Efficacy and Durability of Knowledge Gained From a Module on Gout. Bernadette C. Siaton[1], John S. Sundy[1], Sanjay Garg[2], Christopher G. Meyer[3] and Lisa G. Criscione-Schreiber[1]. [1]Duke University Medical Center, Durham, NC, [2]Center for Arthritis and Rheumatism, Fayetteville, NC, [3]Asheville Arthritis Ctr, Asheville, NC

Background/Purpose: With the projected shortage of rheumatologists, primary care providers will be expected to manage patients with common rheumatologic disorders. We aimed to create a validated educational product including a pre- and post-test about gout, assess the efficacy of this product in improving knowledge, and test the durability of acquired knowledge. We compared the efficacy of this educational product when delivered in live didactic sessions vs. on-line as a PowerPoint presentation. The test was designed to assess both knowledge gained and learners' confidence in their knowledge.

Methods: We obtained IRB exemption to perform this study that included Internal medicine (IM) and family medicine (FM) trainees at Duke University. We validated the pre- and post-test questions for relevance and clarity. Baseline knowledge was assessed via a pre-test on Blackboard, followed by the educational intervention, a module about gout. The module was either attended as a live lecture or the PowerPoint presentation was viewed online. The educational module included gout pathophysiology, clinical presentation, and therapeutic management. Immediate post-testing was performed. To assess knowledge durability, participants took the same post-test 6 months after the educational intervention. Six-month scores were compared to pre- and post-test scores. We also measured confidence in test answers at all time points. Data regarding method of didactic delivery (live vs. on-line), post-graduate year (PGY), and training program (IM vs. FM) was collected, and subgroup analyses were performed. The students' t-test was used to compare groups. ANOVA testing was used for PGY subgroup analysis; all other subgroup comparisons used Wilcoxon-Rank sum tests.

Results: Sixty-two learners completed paired pre- and post-tests for analysis. 28 learners completed the 6 month post-test. Test results from participants with incomplete data were eliminated from analysis. Post-test scores were significantly higher than pre-test scores (210.0 out of 260 possible points (pts) vs. 147.3 pts, $p<0.001$). The delivery method (live vs. on-line) did not affect scores. PGY3 had higher baseline knowledge and lower knowledge gains than PGY1 trainees ($p=0.02$). While IM trainees' baseline scores were higher than FM trainees' (151.4 pts vs. 119.7pts, $p<0.002$) both groups had similar score increases ($p=0.60$). Six-month test scores (177.3 pts) were lower than post-test scores ($p<0.001$), and higher than pre-test scores ($p<0.001$). Subgroup analysis showed higher knowledge retention for PGY3 trainees compared to PGY1 (-16.8 pts vs. -45.6 pts, $p=0.03$). IM and FM trainees demonstrated similar decreases in scores ($p=0.63$). Impact of didactic delivery on durability of knowledge was not analyzed. Attrition rate at 6 months was 55%.

Conclusion: Test scores significantly increased after the educational intervention, and increases persisted for 6 months with some decline. Higher PGY level was associated with higher knowledge retention. The mode of presentation did not appear to impact knowledge gained. We are enhancing the module for further on-line distribution. Testing how successful completion of this module informs clinical practice is a topic for future study.

85

Twitter and Rheumatology Based Medical Education – Analysis of the First 100 Followers. Christopher E. Collins. Washington Hospital Ctr, Washington, DC

Background/Purpose: Twitter is a social networking and microblogging service which enables its users to send and read messages called tweets (text-based posts of 140 characters or less). Users can "follow" a particular person or group and subscribe to their Twitter feed. Numerous groups utilize Twitter as a means of communicating with interested individuals and the emergence of Twitter in the world of healthcare is gaining popularity. Users range from professional medical organizations, healthcare advocacy groups, individual healthcare providers, medical trainees and patients. There are numerous Twitter accounts specific to the field of rheumatology as well as to medical education, however there are few profiles dedicated to both. @RheumPearls was created in March of 2011 to tweet rheumatology based medical "pearls of wisdom" geared towards medical trainees and physicians interested in rheumatology. In order to understand who was following @RheumPearls as well as ascertain if the target audience (medical trainees and physicians) was being reached, an analysis of the first 100 followers was conducted.

Methods: The first 100 followers of @RheumPearls was analyzed for the nature of the account (individual, patient, medical trainee, physician, medical organization, or healthcare advocacy group) and the geographic location of the user. Since one of the methods for attracting followers to a particular Twitter feed is through the phenomenon of "I follow you, you follow me", and given that several of the followers of @RheumPearls were likely obtained through this method, a second analysis was conducted just on the followers which discovered @RheumPearls through other means ($n=75$).

Results: The largest group of followers was physicians (23%) of whom 61% where rheumatologists. Patients with self identified rheumatic conditions were next representing 20% of the followers (lupus and rheumatoid arthritis being the most common diagnosis). Professional medical organizations accounted for 18% and self identified medical trainees (medical students and residents) 11%. The remaining identified groups were healthcare advocacy groups, individuals with interests in medical education and healthcare, and unknown individuals representing 9%, 7%, and 12% respectively. When looking just at followers who @RheumPearls did not follow first ($n=75$), the percentages of medical trainees, patients, and individuals all increased whereas physicians and medical organizations decreased. Geographically, followers from North American (predominately US) represented 65.5% of the cohort with Europe being the next most common (14.5%). Africa, South America, Australia, and Asia were also represented (3%, 1%, 3%, and 5.5% respectively).

Conclusion: @RheumPearls is a Twitter feed broadcasting rheumatology based medical education directed towards medical trainees and physicians, but available to everyone. An analysis of the first 100 followers suggests that with medical trainees and physicians representing 34% of the cohort, this goal is being achieved. The diversity of the followers as well as an extensive geographic distribution also suggests a wide appeal for rheumatology based education.

86

Arthrocentesis Training Using a Knee Simulation Model. Jordan E. Brodsky, Erin P. Patton and Harry D. Fischer. Albert Einstein College of Medicine at Beth Israel Medical Center, New York, NY

Background/Purpose: Arthrocentesis training is a necessary part of the skill set required for Internal Medicine residents. The American Board of Internal Medicine requires that all candidates demonstrate competency in the performance of this procedure. Unfortunately, residents may have limited exposure to patients requiring this procedure and alternative training methods may be needed. The ACGME supports the use of simulation models for the training of Internal Medicine residents. We studied the benefit of using a specialized knee mannequin for simulation training of arthrocentesis.

Methods: We developed a program for simulation training in arthrocentesis. The goal was to assess whether such a program is beneficial in acquiring the skills needed to perform the procedure. Internal Medicine residents were given a didactic lecture on the principles of joint aspiration. This was followed by hands on training by all participants using a simulated knee joint (Sawbones – Pacific Research Labs Inc, Vashon Island, WA). This knee model is equipped with an electric buzzer. When the procedure is correctly performed, the buzzer provides immediate feedback. All participants completed an anonymous questionnaire on arthrocentesis before and after the training session.

Results: 41 Internal Medicine residents, PGY1–13, PGY 2–10, PGY 3–8, PGY 4-1 as well as 9 medical students, participated. 64.4% were male and 36.4% were female. Only 9.8% of those surveyed felt that they were adequately trained in medical school in arthrocentesis. Preparedness to perform arthrocentesis was measured on a scale of 1, being the least prepared, to 10, being the most prepared. Preprogram preparedness averaged 3.36 and post program preparedness rose to 6.95 ($p<0.001$). Similarly, preprogram confidence in performing arthrocentesis measured 2.75 and post program confidence rose to 6.82 ($p<0.001$). Prior to simulation training, 56.1% felt

reluctant to perform a needed arthrocentesis, which decreased to 31.7% following the training (p-value=0.0124).

Conclusion: The use of a knee simulation model to train Medical Students and Internal Medical residents in the performance of arthrocentesis was studied. This training increased the participants' confidence, preparedness, and comfort in performing the procedure. When there are a limited number of patients requiring arthrocentesis available to train residents in this procedure, the use of a simulation knee model appears to be a valuble alternative.

87

Evaluation of a Novel Educational Method: The Rheumatology Toolbox. Richard Conway[1], John J. Carey[1], Ronan Kavanagh[2] and Robert J. Coughlan[1]. [1]Galway University Hospitals, Galway, Ireland, [2]Galway Clinic, Galway, Ireland

Background/Purpose: Management guidelines for many rheumatic diseases are published in specialty rheumatology literature but rarely in general medical journals. Musculoskeletal disorders comprise 14% of all consultations in primary care. Formal post-graduate training in rheumatology is limited or absent for many primary care practitioners. Demand for rheumatology care exceeds supply in many countries, a problem expected to increase in the coming decades. Primary care practitioners can be trained to effectively treat complex diseases and have expressed a preference for interactive educational courses.

Our aim was to evaluate a novel educational method for disseminating current knowledge on rheumatology disorders to primary care practitioners.

Methods: The Rheumatology Family Practice Toolbox is designed as an intensive 1/2 day course designed to offer up to date information to primary care practitioners on the latest diagnostic and treatment guidelines for common rheumatic diseases including early inflammatory arthritis, gout, ankylosing spondylitis, back pain, osteoporosis, fibromyalgia and osteoarthritis. The course structure involved a short lecture on each topic and 3 short practical workshops on arthrocentesis, joint injection and DXA interpretation. Participants evaluated their knowledge and educational experience before, during and after the course rating aspects on a 5-point Likert scale.

Results: 32 primary care practitioners attended, who had a mean of 15 years experience in their specialty. 66% completed all 3 course assessments. The mean number of educational symposia they attended in the previous 5 years was 15, with and average of <1 in rheumatology. 100% of respondents agreed believed course participation had significantly changed their practice. Participants stated the toolbox improved their knowledge of, and confidence in diagnosing and managing common rheumatologic disorders, and would improve the quality of their care and referrals, Table 1.

Table 1. Comparison of the pre and post course confidence of course participants for diagnosing and managing common rheumatic disorders.

Diagnosis			Management		
Condition	**Pre-course**	**Post-course**	**Condition**	**Pre-course**	**Post-course**
Osteoarthritis	80%	95%	Osteoarthritis	60%	95%
Fibromyalgia	20%	57%	Fibromyalgia	16%	52%
Gout	72%	95%	Gout	68%	100%
Inflammatory Arthritis	52%	86%	Inflammatory Arthritis	16%	76%
Osteoporosis	80%	95%	Osteoporosis	68%	86%
Back Pain	64%	90%	Back Pain	56%	86%
Ankylosing Spondylitis	12%	86%	Ankylosing Spondylitis	8%	67%

Conclusion: Post-graduate training in rheumatic diseases is uncommon in primary care. The Rheumatology Toolbox is an effective educational method for disseminating current knowledge in rheumatology to primary care physicians and improved participant's self-assessed competence in diagnosis and management of common rheumatic diseases. Further studies are needed to determine whether this improves the quality of patient care and rheumatology referrals.

88

The Gait, Arms, Legs & Spine Exam: An Effective Screening Tool for Rheumatoid Arthritis When Used by Family Physicians and Nurse Practitioners. Karen A. Beattie, Norma J. MacIntyre and Alfred A. Cividino. McMaster University, Hamilton, ON

Background/Purpose: Early referral to a rheumatologist for diagnosis of rheumatoid arthritis (RA) and initiation of appropriate treatment is critical. However, recognition of RA signs and symptoms in primary care remains a major challenge. The purpose of this study was to evaluate the sensitivity and specificity of the GALS (gait, arms, legs & spine) examination when used by family physicians and nurse practitioners to screen for signs and symptoms of RA.

Methods: Participating healthcare professionals (HCP), including 2 rheumatologists, 3 family doctors (FDs) and 3 nurse practitioners (NPs), were trained to perform the GALS exam and record their findings by viewing an instructional GALS DVD and attending a hands-on training workshop. One week after training, HCP performed the GALS on 41 study participants recruited through local rheumatology practices. Twenty participants had previously been diagnosed with RA while the remaining 21 participants had never been diagnosed with RA. Study participants were divided into two groups (A & B) such that approximately half of the participants in each group had RA. Those in Group A were assessed by 1 rheumatologist, 1 FD and 2 NPs while those in Group B were assessed by 1 rheumatologist, 2 FDs and 1 NP. HCPs recorded gait abnormalities, abnormalities of the movement or appearance of the arms, legs and spine and, ultimately, whether a diagnosis of RA was suspected. HCP were blinded to the medical history of the participants and were unaware that half of the study participants had previously been diagnosed with RA. Sensitivity and specificity were calculated for each HCP to determine the ability of the FDs and NPs to screen for RA signs and symptoms using the GALS when compared to the rheumatologists' screen on the study day.

Results: When compared to the rheumatologists' suspected diagnosis of RA based on the GALS examination findings on the study day, sensitivity for each of the 3 FDs was 60%, 80% and 100% while the specificity for each was 82%, 82% and 70%, respectively. Sensitivity for each of the 3 NPs was 60%, 80% and 90% while the specificity was 100%, 80% and 73%, respectively.

Conclusion: These results suggest that the GALS exam may be a useful screening tool for RA when used by FDs and NPs working in the primary care setting. Differences in level and type of clinical experience may contribute to the variations observed. The merits of introducing the GALS exam into primary care curricula should be explored.

89

Effects of Simulated Joint Aspiration Training on Self-Confidence. Jefferson R. Roberts[1], Jess D. Edison[2], Elizabeth A. Mewshaw[2] and Jeffrey Mikita[3]. [1]Walter Reed Army Medical Ctr, Chevy Chase, MD, [2]Walter Reed Army Medical Ctr, Washington, DC, [3]Senior Author, Washington, DC

Background/Purpose: Musculoskeletal problems encompass 23% of primary care visits and affects 43 million people in the United States. Arthrocentesis among medical providers is on the decline with 74% practicing this procedure in 1986 compared to 54% in 2006. Many medical training programs require three joint procedures for graduation, a requirement recently recommended by the American Board of Internal Medicine. In the setting of this requirement, only 15% of graduating trainees report confidence with arthrocentesis. Joint aspiration and injection are traditionally taught on an informal basis to medical providers during training. Our objective is to determine if the educational tool of joint simulation for needle aspiration improves self-confidence scores among medical providers.

Methods: A pre and post elective, anonymous survey was administered to medical providers who attended a one hour joint simulation workshop during a regional American College of Physicians annual scientific meeting. Knee and shoulder simulators were utilized as educational tools. Using a 10-point Likert type scale, respondents indicated their self-confidence in performing needle aspiration of the knee and shoulder. Medicine internists, subspecialists and trainees were surveyed. Data were compared using Wilcoxon rank sum test. The protocol for this study was approved by the department of clinical investigation at our institution.

Results: Twenty-five pre-joint simulation surveys and 23 post-joint simulation surveys were completed. Approximately half of the respondents were internal medicine staff and trainees and the other half encompassing various internal medicine subspecialists. Self-confidence in performing shoulder aspiration pre and post joint simulation improved significantly (mean scores 4.6+/−2.8 and 7.3+/−2.0 respectively; p<0.001). Self-confidence in performing knee aspiration pre and post joint simulation did not improve significantly (mean scores 6.5+/−3.0 and 8.0+/−1.6 respectively; p=0.14). The need for additional shoulder simulation training pre and post shoulder joint simulation improved significantly (mean scores 7.9+/−2.6 and 5.6+/−2.2 respectively; p<0.001). The need for additional knee simulation training pre and post knee joint simulation training did not improve significantly (mean scores 6.3+/−3.4 and 4.9+/−2.4 respectively; p=0.14). All

participants scored joint simulation as a useful teaching tool with a mean score of 9.0+/−.80.

Conclusion: Simulated arthrocentesis training improves procedural confidence and proves useful among internal medicine staff and trainees. Among participants of a one hour joint simulation workshop, shoulder training significantly improved self-confidence scores, where there was a trend towards improved self-confidence in knee arthrocentesis. Musculoskeletal simulation training proves useful as a teaching tool among internal medicine staff and trainees.

Increasing Rheumatology Exposure to Internal Medicine Residents in the Setting of Limited Resources: Evaluation of A Web-Based Image of the Month. Steven J. Katz. University of Alberta, Edmonton, AB

Background/Purpose: Previous studies have demonstrated poor musculoskeletal abilities of internal medicine residents when compared to other medical subspecialties. Further, a lack of rheumatology exposure is associated with this ability, with increased exposure being linked with improved ability. However, rheumatology manpower and resources remain limited to facilitate this.The internet may provide a solution to improve rheumatology exposure while using available resources efficiently.

Methods: An Image of the Month webpage was established in July 2010 on the www.EdmontonRheumatology.com website, a site representing rheumatologists in Edmonton, Alberta, Canada. Each month, a rheumatologist was responsible for posting a new image with a question which could be answered and submitted online by University of Alberta Internal Medicine residents. At the end of each month, a token book prize was awarded randomly to a correctly submitted respondent. One year data was analyzed to determine the change in rheumatology exposure for internal medicine residents and the resources required to implement this program.

Results: The Image of the Month webpage has posted images monthly for 12 months. There was no cost to implement the program as the website already existed and there was pre-existing funding for the book prize. The rheumatologist required no more than 15 minutes monthly to administer the contest. The webpage had over 700 unique visits. Out of 80 internal medicine residents, 46 participated at least once out of 12 possible images, with 34 having multiple entries. The average participation per resident was 3.6 times (range 1–11). 25 residents completed a rheumatology rotation over this time, of which 13 submitted an answer at least once. This means 33 residents received rheumatology exposure over the twelve months that may not have otherwise.

Conclusion: The Image of the Month webpage successfully improves rheumatology exposure with minimal resources required. Further study is necessary to determine the impact this exposure may have on MSK abilities of internal medicine residents.

91

Advocacy in Rheumatology: Implications for Medical Education Based on a Focused Literature Review. Jellena Wong and Mala Joneja. Queen's University, Kingston, ON

Background/Purpose: Advocacy in healthcare is a critical element of social accountability and a key competency in physician training as defined by the CanMEDS roles. Patient advocacy can be defined as the use of the physician's resources and expertise to enhance the patient's quality of life. Few models for teaching advocacy skills to physicians in training are available. The history and development of patient advocacy in rheumatic disease can serve as the basis for the development of a teaching model for residents and medical students. With this in mind, the purpose of this review was to: 1) Review the literature with respect to advocacy and rheumatic disease 2) Describe connections in the literature with respect to teaching advocacy in medical education 3) Based on our findings, propose a model for teaching advocacy skills to medical students and residents.

Methods: Two separate MESH keyword searches were conducted of Ovid Medline. The first search used "Patient advocacy" (MeSH) AND "Arthritis/Rheumatoid/or Arthritis, Psoriatic/ or Arthritis/ or Arthritis, Reaction" (MeSH) with no date restriction. The second Medline search used "Patient advocacy" (MeSH) AND "Education, Medical" (MeSH) with date restriction from 1996 to present. Further articles were obtained from the reference lists of these articles.

Results: Twenty-four relevant articles and one book were identified based on the two literature reviews. The review of literature on patient advocacy and rheumatic disease identified five broad themes including: 1) self-management, 2) the four psychosocial theories of chronic disease, 3) the advocacy group movement, 4) the Patient Education Model, and 5) specific areas unique to rheumatic disease. The review of the literature on advocacy and medical education identified three different themes including: 1) clinical bioethics and medical ethics, 2) social responsibility, and 3) communication. There is overlap in the literature emphasizing the importance of the role of the physician in educating patients in order to empower patients and promote the self-management of disease.

Conclusion: The literature addressing advocacy in rheumatic disease combined with the literature on advocacy in medical education supports a model of advocacy where the physician has a pivotal role in the education of patients about their condition and associated management strategies. Medical students and residents should be trained to speak to patients in non-medical language, facilitate patient education and provide a scaffolding for self-management strategies. Rheumatology, with its history of promoting self-management and the Patient Education Model, can be a leader in educating future physicians in advocacy in health care.

92

The Impact of An Intensive Rheumatology Teaching Programme on the Clinical and Diagnostic Skills of Intern House Officers. L.J Durcan[1] and Gaye Cunnane[2]. [1]St James's Hospital,, Dublin, Ireland, [2]St.James Hospital, Dublin, Ireland

Background/Purpose: It has been previously shown that junior doctors lack skill and confidence in rheumatological examination and diagnosis. This has consequences for patient care and for subsequent recruitment to rheumatology training programmes.

Methods: A dedicated 6 week rheumatology teaching programme for Interns was devised, focussing on clinical examination, recognition of common diseases and plain radiology. The effects on clinical skills were evaluated. Twenty interns were assessed by questionnaire before and after the teaching programme.

Results: Before the start of the programme, 70% of interns declared confidence in their clinical examination of the hand while only 10% were confident in foot examination. Thirty percent were confident in interpretation of hand radiology. The mean number of bones they could accurately name was 7.2 (SD 1.9) in the hand and 4.2 (SD 1.9) in the foot. Confidence in diagnosis of nerve entrapment syndrome was 40% for the ulnar nerve and 30% for the median nerve.

All (100%) felt they could diagnose rheumatoid arthritis, 90% acute gout, 40% psoriatic arthritis, 35% chronic gout, 15% scleroderma, while none knew how to diagnose dermatomyositis. However, when shown clinical pictures of these diseases, they reported in the correct diagnosis in 80% for RA, 50% for PsA, 75% for scleroderma, 75% for chronic ankylosing spondylitis and 70% for acute gout.

After the teaching programme, !00% were confident in the examination of the hand, 95% in the foot and 80% were confident in the interpretation of plain films of the hands. They could name a mean of 9 hand bones (SD.96) and 5.8 foot bones (SD.93). They felt 100% confident in the diagnosis of median, ulnar and radial nerve palsies. 95% felt confident in the diagnosis of PsA, 100% in RA, 100% in acute gout, 85% in chronic gout, 65% in dermatomyositis and 85% in scleroderma.

Conclusion: Interns lack confidence in clinical examination, plain film interpretation and diagnosis of common rheumatological conditions. A short training programme resulted in significant improvement in all modalities examined. It is essential to identify such deficiencies in order to develop clinical skills and encourage knowledge of basic rheumatologic competencies at an early stage in training.

93

Hospital for Special Surgery Rheumatology Academy of Medical Educators: Planning Retreat Demonstrates a High Degree of Faculty Interest in Teaching, a Teaching Career and Formalized Education to Increase Competency. Jessica Berman[1], Juliet Aizer[1], Anne R. Bass[1], William L. Cats-Baril[2], Mary K. Crow[3], Edward J. Parrish[1], Laura Robbins[3], Jane E. Salmon[1] and Stephen A. Paget[1]. [1]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [2]University of Vermont, Burlington, VT, [3]Hospital for Special Surgery, New York, NY

Background/Purpose: Academic rheumatologists are expected to teach although very little formal educational instruction is given to faculty and financial support and career advancement for time spent is often inadequate. The concept of the Academy, where intellectual and financial resources are made available to academic educators and their research, is not new, having

been successfully implemented at UCSF and several other institutions. At the Hospital for Special Surgery (HSS) an Education Retreat was recently convened to discuss the feasibility of, faculty interest in and institutional support for the formation of a Rheumatology Academy.

Methods: Faculty in the division of Rheumatology were surveyed pre- and post-retreat regarding their opinions about education in the division, interest in teaching, time and resources. The retreat was held for one day over 8 hours and was divided into 1) formalized didactics given by invited educators; 2) breakout groups assigned various topics for formalizing recommendations and prioritizing institutional goals; and 3) discussion regarding the feasibility of and financial resources necessary to establish an academy at HSS. Of the 41 individuals surveyed, 34 (83%) completed the survey pre- and 19 (46%) post-retreat. Responses ranged from 1=strongly disagree to 5=strongly agree and were anonymous.

Results: Prior to the retreat, the majority of faculty answered that they agreed strongly or very strongly to the following questions: "I have the interest to be a great teacher" (91%; 4.47) and "I have the commitment to be a great teacher" (94%; 4.47). Most were "satisfied with my performance as a teacher" (71%; 3.74). However there was less confidence that "I am an excellent teacher" (54%; 3.70), and fewer felt that they had an "understanding of the latest pedagogical techniques" (36%; 3.33), "the time to be a great teacher" (pre-retreat 39%; 3.15 and post-retreat 24%; 2.59) and "the resources and tools to teach well" (pre-retreat 32%; 3.00 and post 16%; 2.58). Few agreed that "I have the incentives to be a great teacher" (33%; 2.97), however a majority agreed that "if it did not negatively impact my income, I would like to teach more" (67%; 3.88). *A larger number than expected* agreed or strongly agreed that "I would like to be part of an Education Academy and move along a Clinician-Educator track" pre-retreat (42%; 3.29). Post-retreat interest in participation in the educational activities of an Academy rose further (68%; 3.79).

Conclusion: The HSS Rheumatology Academy aims to create a stimulating academic educational environment that enhances the quality of teaching and promotes teaching careers and education research. While the pre-retreat survey indicated a high degree of faculty interest in teaching and advancement on the Clinician-Scholar-Educator track, lack of formal education and support were reasons given for less participation. However, surveys highlight that enthusiasm is high regarding the ability of the Academy to provide faculty with resources. This emphasizes the clear advantages of such a formalized structure to achieve the rheumatology division's heightened educational goals and raise the importance and quality of teaching to equivalence with clinical care and research.

94

Attitudes of Pediatric Residents Regarding Musculoskeletal Evaluation and Complaints. Ricardo Guirola[1], Eyal Muscal[2] and Jennifer L. Arnold[2]. [1]Texas Children's Hospital, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Background/Purpose: Musculoskeletal (MSK) conditions may affect up to 30% of children and adolescents. Adult medicine trainees and general practitioners have expressed poor confidence in MSK knowledge and skills, confidence and comfort level. Similar domains have not been evaluated in US pediatric residency training programs.

The aim of this study was to evaluate attitudes regarding MSK skills and training of pediatric residents at a tertiary care residency program. We hypothesized that pediatric residents, like trainees in adult medicine, would: a) have low levels of comfort performing MSK exams and b) express low confidence in evaluating MSK complaints.

Methods: In January of 2011 pediatric residents at Texas Children's Hospital/ Baylor College of Medicine were sent a 16 question survey via a link in survey monkey. Survey results were compiled over a 5 month period. We analyzed relationships between survey responses and type of trainee (pediatric vs. medicine-pediatric), and post-graduate year (PGY level) using non-parametric tests of association for ordinal variables (Kendal tau-b coefficient, T).

Results: 101 out of 161 (62.7%) pediatric residents at our institution completed the survey. The responders included 31 (30.7%) PGY-1 residents, 36 (35.6 %) PGY-2 residents, 29 (28.7%) PGY-3 residents, and 5 (5.0%) PGY-4 residents (all medicine-pediatric). Fifteen of the survey respondents (14.8%) were medicine-pediatric residents. Eighty-two (82%) of responders believed that MSK medicine was important towards their future career. Medicine-pediatrics training was more strongly associated with this belief ($T = 0.208$, $p = 0.02$). Fifty-seven (56.4%) of the residents expressed discomfort in performing a MSK exam. Comfort levels increased after PGY-1 year and throughout training although these associations were not statistically significant ($T = 0.133$, $p = 0.12$). Seventy (69.3%) of the residents expressed a lack of confidence in making diagnoses for patients with MSK complaints. Confidence levels increased over time (maximum PGY-2 38.9 % [n=29] and PGY-4 80% [n=5]). Associations with PGY status was statistically significant ($T = 0.234$, $p < 0.01$). Higher comfort and confidence levels of medicine-pediatric residents were not statistically significant. Ninety-one residents (89.1%) believed that MSK training was not adequate and indeed only 48.5% stated previous formal MSK training. The acknowledgement of formal training increased throughout training (maximum % in PGY-3 and PGY-4 by 65.5% and 100% respectively, $T = 0.326$, $p = 0.01$). Medicine-pediatric residents (throughout all years of training) were not more likely to describe additional formal MSK training when compared to their categorical pediatric counterparts.

Conclusion: Pediatric trainees expressed low confidence, and discomfort with their MSK skills. Most residents expressed inadequacy of MSK medicine training. These negative perceptions were not ameliorated at the completion of training. Pediatric trainees at our institution were aware of the importance of MSK medicine and may be motivated to improve their skills. Evaluation of the effectiveness of standardized patients and web based modules to improve pediatric resident skills in MSK medicine is needed.

95

Anatomical Basis of Rheumatologic Examination: Upper Extremity and Cervical Region. Pablo Villaseñor-Ovies[1], Joseph Biundo[2], Juan J. Canoso[3], Simon Carette[4], Francisco J. de Toro-Santos[5], Cristina Hernández-Díaz[1], Robert A. Kalish[6], Dennis McGonagle[7], Miguel A. Saavedra-Salinas[8] and José E. Navarro-Zarza[9]. [1]Instituto Nacional de Rehabilitación, Mexico City, Mexico, [2]Luisiana State Univesity, USA, Metairie, LA, [3]ABC Medical Center and Tufts University, Mexico City, Mexico, [4]Toronto Western Hospital, Toronto, ON, [5]Complejo Hospitalario Universitario Juan Canalejo, Universidad de la Coruña, La Coruña, Spain, [6]Tufts Medical Center, Boston, MA, [7]University of Leeds and Leeds Teaching Hospitals, Leeds, United Kingdom, [8]Centro Médico Nacional, México, Mexico, [9]Mexican Taskforce for the Advancement of Clinical Anatomy, Mexico, Mexico

Background/Purpose: The rheumatologic examination, which is based on a sound internal medicine examination, focuses predominantly on the musculoskeletal system. However, seasoned rheumatologists recognize the importance of the neurologic and vascular examination as well. The current survey is a group effort at listing musculoskeletal, neural and vascular structures that may be most relevant to a successful training in, and practice of, rheumatology

Methods: The Mexican Task Force on Clinical Anatomy (GMAC) is an officially recognized group of the Mexican College of Rheumatology that is comprised of 6 rheumatologists (one off site, RAK) who have had extensive training in clinical anatomy, combined training sessions with the Mexican School of Ultrasonography and anatomists of the National University of Mexico (UNAM), as well as intragroup certification in clinical anatomy. Members of this group individually listed anatomical items felt to be relevant to the practice of rheumatology. A final items list was circulated to the GMAC members and 4 internationally recognized rheumatologists for a Delphi exercise. Items were rated as unimportant, fairly important, moderately important, important and very important. Consensus was reached when an item was rated important or very important by 8 or more of the 10 participants. The original list went through 2 Delphi rounds and consensus items were subsequently analyzed according to the structure involved, anatomical region and possibility of identification on physical examination.

Results: The initial list had 549 items including 381 (69.3%) musculoskeletal (bone, joint, ligament, tendon, enthesis, fascia, bursa), 75 (13.6%) neural, 14 (2.5%) vascular and 75 (13.6%) classified as other. At the 1st Delphi round consensus was reached in 129 items and at the 2nd round 92 consensus items were added reaching a total of 221 (40.2%) items. Of these 125 (56.5%) were musculoskeletal, predominantly muscles (47), joints (27), bones (23) and tendons (17). Of the items that reached consensus, 62 (28%) pertained to the hand, 53 (23.9%) to the shoulder, 45 (20.3%) to the cervical spine and 43 (19.4%) to the elbow. Finally, 103 (46.6%) items were considered identifiable on physical examination.

Conclusion: Given our interest in clinical anatomy our initial listing was, if anything, over-inclusive. However, most of the participants in this exercise are practicing rheumatologists and it was our hope that our collective experience would be reflected in the findings. While musculoskeletal items understandably prevailed a surprisingly high number of neural items were considered important. This should not be unexpected given the intricate anatomical and clinical relations between both systems.

96

Impact of Subspecialty Elective Exposures on Outcomes on the American Board of Internal Medicine Certification Examination. Katina C. Tsagaris[1], Amber Schilling[1], Hong Wang[2], Sameer Desale[2], Michael Adams[1] and Victoria K. Shanmugam[1]. [1]Georgetown University Hospital, Washington, DC, [2]MedStar Research Institute, Washington, DC

Background/Purpose: Medical knowledge is an Accreditation Council for Graduate Medical Education (ACGME) core competency, which can be measured by scores on the American Board of Internal Medicine Certification Examination (ABIM-CE). While formalized elective curricula are known to improve subspecialty scores on the ABIM-CE, no studies have evaluated the impact of individual subspecialty elective exposures on resident medical knowledge as measured by the ABIM-CE.This study was designed to evaluate whether exposures to particular subspecialty electives impact ABIM-CE scores.

Methods: This was a retrospective study of ABIM-CE scores and elective exposures from residents enrolled in the Georgetown University Hospital internal medicine residency program between 2002 and 2010. Total and subspecialty scores (percentage of items correct) on the ABIM-CE were compared to subspecialty elective exposures.

Results: For graduation years 2005 to 2013, 307 categorical residents were enrolled in the Georgetown Internal Medicine residency. Of these, 4 did not complete the residency, 29 were combined internal medicine-pediatrics residents, 144 did not have paired elective and ABIM-CE data and 18 withheld their ABIM-CE scores. Concurrent ABIM-CE scores and elective exposures were available for 111 residents. There were no significant differences in age, gender, or location of medical school between annual cohorts and none of these factors correlated with ABIM-CE scores. Rheumatology elective exposure was correlated with higher ABIM-CE score (77.79 +/− 0.76 compared to 79.96 +/− 0.78, $p=0.048$, table 1) whereas, none of the other subspecialty elective exposures had an association with ABIM-CE scores. There were no significant associations between elective exposures and total or subspecialty scores for any of the other subspecialties. ANOVA analysis comparing ABIM-CE scores in subjects with 0, 1 and more than 1 elective exposure in each subspecialty did not show a significant association between repeated elective exposures and improved performance on the ABIM-CE based either on the total percentage correct or the subspecialty percentage correct.

Table 1. ABIM-CE total and subspecialty scores based on percent correct based on elective exposure. (p values are based on unpaired t-test)

	TOTAL % CORRECT ON ABIM-CE (mean, SEM)			SUBSPECIALTY % CORRECT ON ABIM-CE (mean, SEM)		
	No Elective Exposure	Elective Exposure	*p* value	No Elective Exposure	Elective Exposure	*p* value
RHEUMATOLOGY	77.79+/−0.76 (n=57)	79.96+/−0.78 (n=54)	**0.048**	78.82+/−1.4 (n=57)	82.46+/−1.3 (n=54)	0.06
INFECTIOUS DISEASES	77.17+/−1.25 (n=23)	79.28+/−0.6 (n=88)	0.12	78.87+/−2.59 (n=23)	81.90+/−0.95 (n=88)	0.19
NEPHROLOGY	78.42+/−0.88 (n=45)	79/.14+/ −0.71 (n=66)	0.53	82.29+/−1.8 (n=45)	85.53+/−1.5 (n=66)	0.17
GASTROENTEROLOGY	78,7+/−0.79 (n=46)	78.95+/−0.76 (n=65)	0.82	77.41+/−1.59 (n=45)	79.48+/−1.28 (n=65)	0.31
PULMONARY	78.19+/−1.20 (n=31)	79.10+/−0.61 (n=80)	0.46	77.13+/−1.73 (n=31)	79.00+/−1.22 (n=80)	0.41
CARDIOLOGY	78.67+/−0.97 (n=36)	78.93+/−0.67 (n=75)	0.82	78.64+/−1.35 (n=36)	81.35+/−1.17 (n=75)	0.16
HEMATOLOGY	78.73+/−0.77 (n=60)	78.98+/−0.78 (n=51)	0.82	82.08+/−1.7 (n=60)	80.16+/−1.81 (n=51)	0.44
ENDOCRINOLOGY	78.97+/−0.76 (n=39)	78.78+/−0.75 (n=72)	0.86	77.62+/−1.8 (n=39)	79.07+/−1.3 (n=72)	0.51

Conclusion: This study identified a small but significant association between exposure to the rheumatology elective and score on the ABIM-CE. Repeated elective exposures in a single specialty were not associated with improved ABIM scores. Residents should consider these findings when they are making elective selections.

97

Availability of Pediatric Rheumatology Training within Pediatric Residency Programs in Canada. Roman Jurencak, Johannes Roth and Sarah Lawrence. University of Ottawa, Ottawa, ON

Background/Purpose: Musculoskeletal symptoms in children are very common, occurring in up to 30% of children at some point during childhood. However, a recent national survey from the United States found that only 18% of pediatricians believed they were adequately trained to diagnose and treat arthritis in children[1]. This may be at least partially attributable to lack of exposure to pediatric rheumatology during their training as only <60% of pediatric residency programs in the USA have an on-site rheumatologist[2]. The aim of this study was to survey all pediatric residency programs in Canada to determine the availability of pediatric rheumatology training.

Methods: Program directors of all 17 pediatric residencies in Canada were contacted and asked to fill out a questionnaire assessing formal pediatric rheumatology teaching in their program.

Results: Response was so far received from 11/17 programs (65%). There was no formal pediatric rheumatology teaching available on-site at 3 centers as there was no rheumatologist on staff. However, all 3 centers offered an off-site rotation at another university. Overall, 7 centers offered an elective rotation in pediatric rheumatology, while 4 centers had a mandatory rotation. The length of rotation at each centre was 4 weeks and was usually done in PGY 2 or PGY 3. When an elective rotation was available, it was chosen on average by <50% of residents. No university reported higher residents' demand than could be accommodated. Formal large group lectures on rheumatologic disorders were offered at all centers, on average 3 hours per year. Small group lectures (case based learning, problem assisted learning etc) we available at 7 centers, on average 3 hours per year. A formal lecture on MSK exam was a part of the postgraduate training at 9 centers.

Conclusion: There is excellent availability of pediatric rheumatology training for pediatric residents at the pediatric programs surveyed. However, at the majority of programs, rheumatology rotations are elective and are chosen by less than half of the residents in each program. Mandatory large and small group lectures on pediatric rheumatology topics combined account for only 5–6 hours of teaching per year. This indicates a clear need for development of strategies to ensure adequate training in pediatric rheumatology for pediatric residents.

Publication Outcomes of Abstracts Presented At the ACR/ARHP Annual Scientific Meeting. Gil Amarilyo, Jennifer MP Woo, Daniel E. Furst, Olivia I. Lund, Rotem Eyal, Cindy Piao, Miriam F. Parsa, Ornella J. Rullo, Alice DC Hoftman and Deborah K. McCurdy. University of California, Los Angeles, Los Angeles, CA

Background/Purpose: The American College of Rheumatology (ACR) and the Association of Rheumatology Health Professionals (ARHP) Annual Scientific Meeting (ASM) serves as the primary forum for introducing novel clinical and basic science research in the fields of rheumatology and immunology worldwide. However, unlike published studies in peer-reviewed journals, accepted abstracts are usually filtered by 2–4 reviewers who are exposed solely to the summary of the research study. Formal analyses of the scientific impact of ASM on abstract publication have not been performed to date. We therefore aimed to describe the probability of publication and impact factors of presentations and posters when presented at the ASM.

Methods: We identified all abstracts that were accepted for oral or poster presentation at the 2006 ASM. Using a defined search algorithm, which included first or last authors, we conducted a PubMed search for each accepted abstract. If more than one published article was identified, key terms from the abstract title were compared to titles of published articles. Journal name, journal impact factor and time to publication were analyzed for each published study.

Results: A total of 2161 abstracts were presented at 2006 ASM and analyzed. The publication rates are listed in Table 1. The average time from abstract to publication was 16.7 months, with 39.4% of published presentations being published within 12 months following the 2006 ASM. Overall, studies presented in oral format were significantly more likely to be published compared to poster presentations ($p<0.002$); however this association was seen only in clinical studies ($p<0.001$) and not in basic science studies. The average time to publication was significantly shorter for basic science studies compared to clinical research studies (14.66 vs. 17.89 months; $p<0.001$) in both presentation formats ($p<0.01$ for both). Presented studies were published in 144 individual journals. The five journals with the largest number of publications (incorporating 56.6% of all published abstracts) include *Arthritis and Rheumatism* (186), *Annals of Rheumatic Diseases* (99),

Journal of Rheumatology (86), *Rheumatology* (45), and *Clinical and Experimental Rheumatology* (29). Finally, the average journal impact factor of published studies presented in oral format was significantly higher than those presented as posters, irrespective of clinical or basic science research ($p < 0.002$ for clinical, basic, and overall).

Table 1. Publication Data: ACR/ARHP Annual Scientific Meeting, 2006.

Type (%)	Publication Ratio (%)	Time to Publication (months±SD)	Impact Factor of Journal (mean±SD)
Overall (100%)	36.4	16.7 ± 12.74	5.35 ± 3.35
Clinical (63%)	37.3	17.9 ± 12.41	5.2 ± 3.26
Poster sessions (83%)	35.3	17.4 ± 12.37	4.94 ± 3.11
Oral presentations (17%)	47	19.6 ± 12.61	6.17 ± 3.61
Basic Science (37%)	35	14.7 ± 13.07	5.59 ± 3.49
Poster sessions (82%)	34.7	14.7 ± 13.29	5.07 ± 2.55
Oral presentations (18%)	38.4	14.4 ± 12.27	7.64 ± 5.42

Conclusion: The ASM serves as an important forum for early dissemination of novel ideas. As comparable with other national specialty meetings, 36% of the abstracts are published. Abstracts selected for oral presentation represented studies that are more likely to be published in higher impact journals.

ACR Poster Session A
Epidemiology and Health Services Research I: Rheumatoid Arthritis
Sunday, November 6, 2011, 9:00 AM–6:00 PM

99

Risk Factors for Positive Rheumatoid Factor Among 31,207 People without Rheumatologic Disorders. Hiromichi Tamaki[1], Yuji Nishizaki[2], Ken-ichi Yamaguchi[3], Toshiko Kawakita[4], Mitsumasa Kishimoto[4] and Masato Okada[5]. [1]University of Hawaii, Honolulu, HI, [2]Juntendo University, Tokyo, Japan, [3]St. Luke's International Hospital, Tokyo, Japan, [4]St Luke's International Hospital, Tokyo, Japan, [5]St. Luke's International Hosptal, Tokyo, Japan

Background/Purpose: Rheumatoid factor is known to be associated with smoking, malignancy, hepatitis B or C as well as many rheumatologic disorders not limited to rheumatoid arthritis. However, there have been no large-scale studies to prove these relationships.

Methods: St. Luke's International Hospital Center for Preventive Medicine performs annual health examinations for more than 30,000 people each year, and rheumatoid factor is checked routinely during these examinations. The data in 2004 was obtained from the St. Luke's Center for Preventive Medicine, including rheumatoid factor, past medical history (hypertension, hyperlipidemia, diabetes, ischemic heart disease, malignancy, hepatitis B or C), pulmonary function test and BMI. The people with known rheumatologic disorders were excluded. This data were analyzed statistically.

Results: A total of 31,207 patients were evaluated. The mean age was 49.1 and men consists of 50.7% of the group and women 49.3%. 6.8% had positive rheumatoid factor. Rheumatoid factor was positive in 2.3% among people in their 20s, 4.3% in their 30s, 7.1% in their 40s, 7.8% in their 50s, 7.8% in their 60s, 8.9% in their 70s, and 14.9% in their 80s. Rheumatoid factor was positive in 9.8% of patients with cancer, 20.7% of patients with hepatitis B, 19.6% with hepatitis C. Among current smokers 7.3% people were rheumatoid factor positive and among remote smokers, 7.1%. Sex was not significantly associated with positive rheumatoid factor but age was. Multivariate logistic regression analysis with age and sex correction revealed smoking, diabetes mellitus, malignancy hepatitis B and hepatitis C were risk factors for positive rheumatoid factor. Each odds ratio was as below. Smoking 1.14 (95% confident interval (CI): 1.07 – 1.21, P value <0.0001), diabetes mellitus 2.14 (95% CI: 1.09 – 4.21, P value 0.0276), malignancy 1.26 (95%CI: 1.09 – 1.54, P value <0.0296), hepatitis B 3.605 (95% CI: 2.52 – 5.15, P value <0.0001), hepatitis C (95% CI: 1.99 – 4.17, P value <0.0001). Hypertension, hyperlipidemia, body mass index, ischemic heart disease, vital capacity as percent of predicted or forced expiratory volume in one second as percent of predicted were not associated with positive rheumatoid factor.

Conclusion: The relationship between positive rheumatoid factor and conventionally estimated risk factors such as smoking, malignancy, hepatitis B, and hepatitis C is confirmed. Diabetes Mellitus is also a risk factor for positive rheumatoid factor among non-rheumatologic patients.

100

The Association Between Rheumatoid Factor and Predisposing Factors for Atherogenesis in First-Degree Relatives without Rheumatoid Arthritis: *S*tudies of the *E*tiology of *R*heumatoid *A*rthritis. Jan M. Hughes-Austin[1], Kevin D. Deane[2], Lezlie A. Derber[3], Gary O. Zerbe[1], Dana M. Dabelea[1], Robert H. Eckel[4], Jeremy Sokolove[5], William H. Robinson[6], V. Michael Holers[7] and Jill M. Norris[1]. [1]Colorado School of Public Health/University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]University of Colorado AMC, Aurora, CO, [4]Aurora, CO, [5]Stanford University, Palo Alto, CA, [6]Stanford University, Stanford, CA, [7]Univ of Colorado School of Med, Aurora, CO

Background/Purpose: Systemic inflammation and immune dysregulation, which include presence of autoantibodies (Abs) and elevated inflammatory markers, characterize rheumatoid arthritis (RA) and precede the development of clinically-apparent RA by years. These two factors not only mark the future development of RA, but may also contribute to the pathogenesis of atherosclerosis and cardiovascular disease (CVD) in preclinical RA. We sought to investigate the relationships between RA-related Abs and atherogenic risk factors in first-degree relatives (FDRs) at risk for future RA, and whether systemic inflammation explains these relationships.

Methods: From the **SERA** project (a prospective study of preclinical RA), 113 FDRs who had been positive for any of 5 RA-related Abs: rheumatoid factor (RF), RF isotypes – IgM, IgG, IgA, or anti-cyclic citrullinated peptide (anti-CCP2) on at least one of their visits, and 100 FDRs who had never been Ab positive were selected. In samples obtained at 392 FDR visits, the following were measured: 1) lipids/lipoproteins: triglycerides, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol and apolipoprotein B (ApoB) (VAP-II); 2) endothelial activation/injury markers: soluble intracellular adhesion molecule-1, soluble vascular cell adhesion molecule-1 (VCAM-1) and E-selectin (ELISA); and 3) a panel of 25 cytokines/chemokines (bead-based assay) and high-sensitivity C-reactive protein (nephelometry). Cytokines/chemokines were standardized, weighted and summed for a Cytokine Score. Relationships between atherogenic risk factors and RA-related Abs, defined as RF and the high-risk profile (positive for anti-CCP2 and/or 2 RF isotypes), were calculated using a linear mixed model. All analyses were adjusted for age, sex, ethnicity, BMI, pack-years of smoking and statin use. Mediation analysis was performed using accelerated bootstrap confidence intervals to explore the effects of inflammation on the relationship between RA-related Abs and atherogenic risk factors.

Results: ApoB levels were lower by 4 mg/dL ($p=0.029$), and VCAM-1 levels were higher by 97 ng/mL ($p=0.0004$) in RF positive FDRs compared with RF negative FDRs. Inflammatory markers associated with both RF and VCAM-1 included IL-4, IL-6, IL-10, IL-12p70, GM-CSF, Eotaxin, IFN□, IP-10, MCP-1 and the Cytokine Score. When assessed for evidence of mediation, however, none of these inflammatory markers explained the relationship between RF and VCAM-1. No inflammatory markers were associated with both RF and ApoB. Therefore, mediation analysis for this association was not conducted. The high-risk profile was not associated with any of the measured atherogenic risk factors.

Conclusion: RF is associated with low ApoB and elevated VCAM-1 in a population without RA, but at increased risk for its future development. Systemic inflammation is associated with both RF and VCAM-1, but it does not explain the association, and suggests that RF affects VCAM-1 through either a different mechanism or another unmeasured marker of inflammation.As low ApoB and elevated VCAM-1 are predisposing factors for atherogenesis, these findings may indicate CVD development in preclinical RA.

101

Exposure to Ultraviolet Light and Risk of Developing Rheumatoid Arthritis Among Women in the Nurses' Health Study. Elizabeth V. Arkema[1], Kimberly Bertrand[1], Francine Laden[1], Abrar A. Qureshi[2], Elizabeth W. Karlson[2] and Karen H. Costenbader[2]. [1]Harvard School of Public Health, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

Background/Purpose: Previous studies have shown that people living in higher latitudes may be at a greater risk of RA. It has been hypothesized that the association between RA and latitude could be due to cutaneous exposure to ultraviolet (UV) light and production of vitamin D, a hormone with known immunomodulatory effects. We examined the relationship between cumulative average UV-B flux, based on residential location, and risk of RA among women followed in two large prospective cohort studies, the Nurses' Health Studies (NHS).

Methods: We examined the prospective association between cumulative

average UV-B flux exposure and RA risk among 222,792 women followed in the NHS 1976–2008 (born 1921–46, n=107,116) and NHSII 1989–2007 (born 1947–1964, n=115,676). Residential locations of NHS participants were available for 1976, 1986–2006 and for NHSII participants from 1989–2007. Incident RA cases diagnosed from 1976–2008 for NHS and 1989–2007 for NHSII were confirmed by medical record review. Average annual UV-B flux, a composite measure of mean UV-B radiation level based on latitude, altitude, and cloud cover, was estimated for all nurses according to state of residence during cohort follow-up. The relationship between tertile of cumulative average UV-B exposure and risk of RA was estimated using Cox proportional hazards models separately in each cohort, then combined using meta-analysis random effects models. Age- and multivariable-adjusted models, including age, parity, breast feeding, body mass index, pack-years smoking, physical activity, vitamin D intake, alcohol consumption, race, husband's education and oral contraceptive use, were used.

Results: We identified and confirmed 1146 incident RA cases. Although no significant heterogeneity between the two cohorts was found, the results were slightly different in the two cohorts. In the older women, NHS, there was a small but significant decrease in RA risk associated with increased UV-B exposure. In the cohort of younger women, however, this effect was not observed. When meta-analytically combined, cumulative UV-B flux exposure was not significantly associated with RA risk overall (**Table 1**).

Table 1. Cox proportional hazards model results estimating the effect of Cumulative Average UV-B on RA incidence

	RA Cases		Multivariable Cox Proportional Hazards Model*			
	NHS (N=875)	NHSII (N=271)	NHS	NHSII	Combined	p het**
Tertile cutpoints for Cumulative Average UV-B (R-B units***)						
≤109	348	73	1.00 (ref)	1.00 (ref)	1.00 (ref)	
109-≤117	318	79	0.87 (0.84, 1.01)	1.15 (0.84, 1.59)	0.96 (0.74, 1.26)	0.12
117	209	119	0.85 (0.72, 1.02)	1.14 (0.85, 1.53)	0.96 (0.73, 1.27)	0.10
p for trend			**0.05**	0.41	0.73	

* adjusted for age, parity, breast feeding, body mass index, pack-years smoking, physical activity, vitamin D intake, alcohol consumption, race, husband's education and oral contraceptive use
** p for heterogeneity between the two cohorts
*** Robertson-Berger UV-B flux units $\times 10^{-4}$

Conclusion: Results suggested an inverse association between UV-B exposure and incident RA in NHS, but there was no evidence of an association in NHSII or in combined analyses. Limitations include lack of data on time spent outside and sunscreen use, which could vary with nurse age. The overall results do not support an association between cumulative exposure to ambient UV-B light and RA risk; however, statistical power may have been limited to detect a modest association.

102

Is Sunlight Exposure and Vitamin D Intake Associated with Rheumatoid Arthritis? Nicole C. Wright[1], Brian T. Walitt[2], Jeffery R. Curtis[1], Mary Pettinger[3], Christine G. Parks[4], Anneclaire J. De Roos[3], Jean Wactawksi-Wende[5], Rachel Mackey[6], Rebecca D. Jackson[7], Michal L. Melamed[8] and Barbara V. Howard[9]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Washington Hospital Center, Washington, DC, [3]Fred Hutchinson Cancer Research Center, WA, [4]NIH/NIEHS, Research Triangle Park, NC, [5]University of Buffalo, Buffalo, NY, [6]University of Pittsburgh, Pittsburgh, PA, [7]Ohio State University, Columbus, OH, [8]Albert Einstein College of Medicine, Bronx, NY, [9]Medstar Research Institute, Washington, DC

Background/Purpose: Dietary vitamin D intake has been studied as a risk factor for incidence of RA in several longitudinal cohort studies; however, only few have evaluated sunlight exposure, the primary source of vitamin D, and the risk of RA.

Methods: Using the Women's Health Initiative Observational Study (WHI-OS), we examined the association between vitamin D exposure on the prevalence and incidence of rheumatoid arthritis (RA). Prevalent RA cases were identified using the combination of self-report and medications at baseline. Incident cases were ascertained using year three data, and the comparison group consisted of women who did not report RA at either time point. Vitamin D exposure was identified in three ways: 1) vitamin D intake from food frequency questionnaire and supplementation sources, 2) previous sunlight exposure, and 3) current sunlight exposure. Previous sunlight exposure was ascertained via questions regarding time spent outdoors during summer and non-summer months as a child, in their teens, and in their thirties. Respondents answering <30 minutes were given a score of 15; respondents answering 30 minutes to 2 hours were given a score of 75, and those responding ≥2 hours were given a score of 180. The scores at each period were summed to create cumulative minutes of previous sunlight exposure. Mean solar irradiance, calculated using the clinical center location and national weather data, was used to ascertain current sunlight exposure. The three exposure variables were categorized and after controlling for several variables, the association with prevalent RA was tested using logistic regression and the association with the incidence of RA was tested using Cox-proportional hazards models.

Results: The study population included 76,743 women without RA, 727 prevalent RA cases, and 190 incident RA cases. Women with RA were significantly older, heavier, and had a larger proportion of African Americans and current smokers than the comparison group. After adjustment, no association between vitamin D exposure and the prevalence of RA was found in the total population; however different trends were observed by race (Table). Though not statistically significant in either group, compared to the highest category of summer sunlight exposure (>500 minutes), White women with the lowest exposure (<300 minutes) were 15% less likely to have prevalent RA [OR (95% CI): 0.85 (0.65, 1.10)] whereas African American women in the lowest category were 17% more likely [1.17 (0.60, 2.28)]. Similar differences in racial trends were found in the other exposure variables. No significant association between vitamin D exposure and the incidence of RA was found.

Table. The Association between Vitamin D Intake, Sunlight Exposure and the Prevalence of Rheumatoid Arthritis by Race

	White		African American	
	N/# cases	OR (95% CI)*	N/# Cases	OR (95% CI)*
Vitamin D Intake (IU/day)				
≥600	13,674/114	1.00	358/4	1.00
<600–400	15,683/143	1.08 (0.85, 1.39)	849/16	1.64 (0.54, 4.96)
<400–200	10,527/76	0.85 (0.64, 1.14)	589/8	1.17 (0.35, 3.91)
<200	18,440/125	**0.75 (0.58, 0.97)**	2,084/35	1.32 (0.47, 3.75)
Sunlight Exposure—summer (mins)				
>500	15,028/126	1.00	1,073/17	1.00
500–400	17,574/143	0.95 (0.75, 1.21)	1,308/17	0.87 (0.44, 1.71)
400–300	12,100/91	0.89 (0.68, 1.17)	750/14	1.22 (0.59, 2.49)
<300	14,124/101	0.85 (0.65, 1.10)	1,030/18	1.17 (0.60, 2.28)
Sunlight Exposure—other seasons (mins)				
>400	15,722/149	1.00	1,471/23	1.00
400–300	8,112/58	0.78 (0.57, 1.05)	551/11	1.34 (0.65, 2.78)
300–200	20,941/151	0.81 (0.64, 1.01)	1,217/17	0.96 (0.51, 1.80)
<200	13,888/97	**0.76 (0.59, 0.99)**	884/14	1.01 (0.52, 1.97)
Solar Irradiance (g-cal/cm^2)				
500–475	11,771/85	1.00	404/10	1.00
430–400	9,550/80	1.18 (0.86, 1.62)	959/17	0.69 (0.31, 1.53)
380-375	6,745/50	1.05 (0.72, 1.52)	1,101/12	0.43 (0.18, 1.00)
350	12,743/77	0.80 (0.58, 1.10)	1,321/19	0.54 (0.25, 1.18)
325-300	18,935/175	1.28 (0.97, 1.68)	538/12	0.88 (0.38, 2.08)

* Adjusted for age, BMI, region at birth, education, smoking, alcohol, weight at birth wearing hat outdoors during thirties, and total recreational physical activity

Conclusion: Self-reported estimates of lifetime and current vitamin D exposure were not associated with incidence or prevalence of RA in the WHI-OS; however, results suggest that race may modify the association between vitamin D exposure and RA.

103

Prevalence and Incidence of Rheumatoid Arthritis in South Korea. Yoon-Kyoung Sung[1], Soo-Kyung Cho[1], Chan-Bum Choi[1], Jae Hoon Kim[2], Jin Ju Kim[2], Joo-Hyun Lee[2], Young Bin Joo[2] and Sang-Cheol Bae[1]. [1]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

Background/Purpose: Several studies of rheumatoid arthritis (RA) incidence and prevalence indicate that occurrence of the disease varies significantly among different populations. However, descriptive studies may be difficult to compare due to methodological differences in terms of case identification and ascertainment. We conducted this study to estimate the nationwide prevalence and incidence of RA with comparison of methodologies and results of other populations, and the prescription trend of disease-modifying anti-rheumatic drug (DMARD) use in South Korea.

Methods: Almost 100% of the population of South Korea is automatically registered as insured or qualified for Medicaid using an automated hospital billing system established throughout the country, since 2005. Hence we used Korean National Health Insurance (NHI) claims data to estimate the prevalence of RA from 2007 to 2009 and the incidence of RA in 2008. Changes in the use of DMARDs for RA during those three years were also documented.

Results: Using only the ICD-10 diagnostic code for RA, estimates for the prevalence of RA in 2007, 2008, and 2009 were 1.4%, 1.3%, and 1.2%, respectively. However, using our predefined operational definition of RA (a prescription for any DMARD or biologic drug with an RA diagnostic code in the same claim), the corresponding prevalence estimates were 0.26%, 0.27%, and 0.28%. The incidence of RA in 2008 was estimated at 42/100,000 in the general population of South Korea. The prevalence of biologic drug use for RA patients in 2007 was 0.84% and increased to 1.91% in 2009. During that period the prevalence of leflunomide use increased from 5.85% to 11.48%.

Conclusion: Use of data gathered nationwide through the NHI yielded estimates of RA prevalence and incidence in South Korea that are comparable to values for other countries in Asia. The use of leflunomide and anti-TNF agents is increasing in South Korea.

104

Postpartum and the Risk of Developing Rheumatoid Arthritis; Results From the Swedish EIRA Study. Camilla Bengtsson[1], Cecilia Orellana[1], Marie Holmqvist[2], Anita Berglund[1], Sara Wedrén[3], Lars Klareskog[3] and Lars Alfredsson[1]. [1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Clinical epidemiology unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: It has previously been described that the incidence of RA is reduced during pregnancy but increased after delivery. The increased risk has been observed during the first three months[1] up to two years after postpartum[2]. To our knowledge, no previous study has investigated the postpartum period and its effect on risk of the two subsets of RA, characterized by presence/absence of antibodies to citrullinated peptides (ACPA), separately.

Methods: Data from the Swedish population-based EIRA (Epidemiological Investigation of Rheumatoid Arthritis) case-control study encompassing women aged 18–50 years. In total, 547 incident cases and 658 randomly selected controls, matched on age, sex and residency, were analysed. Parous women were compared with nulliparous women according to the risk of developing RA overall, ACPA-positive and ACPA-negative disease, respectively. In a separate analysis, women with partum the year before symptom onset was analysed. Odds ratios (OR) with 95% confidence interval (CI) were calculated using unconditional logistic regression.

Results: In total, 360 (66%) of the cases and 431 (66%) of the controls were parous, meaning that there was no association between parity and the risk of RA overall. However, parity increased the risk of developing ACPA-negative RA (OR=1.5 (95% CI 1.0–2.3)). Women with partum the year before disease onset had more than a two-fold increased risk of ACPA-negative RA (OR=2.4 (95% CI 1.1–5.4)). There was no association between parity and the risk of ACPA-positive RA.

Conclusion: Our results indicate that the postpartum period increases the risk of ACPA-negative RA, but has no association with ACPA-positive RA. Why postpartum is associated only with an increased risk of ACPA-negative RA, and what biologic mechanisms are involved, remains to be elucidated. Finally, our results indicate that the higher RA incidence among women than among men, might to some extent be explained by hormonal/reproductive factors, such as the postpartum period.

105

Predictors for Remission in Rheumatoid Arthritis Are Affected by Remission Definition. Cheryl CM Barnabe[1], Joanne Homik[2], Susan G. Barr[1], Walter P. Maksymowych[2] and Liam Martin[1]. [1]University of Calgary, Calgary, AB, [2]University of Alberta, Edmonton, AB

Background/Purpose: The proportion of patients meeting remission criteria for rheumatoid arthritis varies by the definition used. We hypothesize that predictors for remission may thus also vary.

Methods: Our pharmacovigilance protocol captures clinical data on treatment efficacy and safety for patients treated with biologic therapies since July 2000. We calculated the proportion of patients achieving remission within the first year of initiating a new biologic agent, using the following definitions: i) 2011 ACR/EULAR Boolean (all of ≤1 tender joint, swollen joint, patient global and C-reactive protein (mg/dL)); ii) Simplified Disease Activity Index (SDAI) ≤3.3; iii) Clinical Disease Activity Index (CDAI) ≤ 2.8; iv) 1981 ACR Remission Definition; v) DAS28 ≤2.6. Predictors for remission were assessed first in univariate analysis for each remission definition. All significant predictors were then assessed in multivariate models.

Results: Our analysis includes 1,583 patients (70% female, mean disease duration 12 years, mean prior DMARDs=3) with a total of 4,532 visits during the first year of treatment. Remission was identified in 8.4% of the cohort using the 2011 ACR/EULAR Boolean definition, 14.6% using the SDAI score, 12.3% using the CDAI score, 5.2% using the 1981 ACR definition, and 34.5% using the DAS28 score. Correlation was good between SDAI and CDAI definitions (r=0.87), SDAI and new ACR/EULAR criteria (r=0.78) and CDAI and new ACR/EULAR criteria (r=0.76). Correlation values were less for DAS28 remission with SDAI (r=0.52), CDAI (r=0.50) and Boolean definitions (r=0.51), as well as between the 1981 ACR and 2011 ACR/EULAR definitions (r=0.55). In univariate analysis, male sex, seropositivity, and lower baseline values for DAS28 score, HAQ score and inflammatory markers predicted remission for all definitions. The number of prior DMARDs was significant predictor in all definitions except DAS28 remission. Short disease duration at inception was a predictor for remission in the DAS28 definition only. Obesity, smoking status and biologic naïve status did not predict remission by any definition. In multivariate models, a baseline DAS28 score <3.2 was a predictor for remission for all definitions (Table 1). A lower baseline HAQ score was a predictor for all definitions except DAS28 remission, and normal inflammatory markers at baseline was a predictor for remission using the 2011 ACR/EULAR Boolean, SDAI and DAS28 definitions. Additional variables in the multivariate model for DAS28 remission were male sex and seropositivity.

Table 1. Multivariate predictors for achieving remission in the first year of biologic therapy

	DEFINITION Odds Ratio (95% Confidence Interval), p value				
	2011 ACR/EULAR Boolean	SDAI	CDAI	1981 ACR	DAS28
Male sex	NS	NS	NS	NS	1.5 (1.2–1.9), p<0.001
Seropositive	NS	NS	NS	NS	2.2 (1.7–2.7), p<0.001
Baseline DAS > 3.2	0.87 (0.79–0.96), p=0.006	0.82 (0.74–0.91), p<0.001	0.78 (0.72–0.85), p<0.001	0.78 (0.69–0.88), p<0.001	0.56 (0.52–0.62), p<0.001
Baseline HAQ (per unit increase)	0.61 (0.49–0.77), p<0.001	0.60 (0.48–0.75), p<0.001	0.71 (0.59–0.85), p<0.001	0.71 (0.53–0.95), p=0.020	NS
ESR and CRP Normal at Baseline	3.0 (2.4–3.9), p<0.001	1.5 (1.1–1.9), p<0.001	NS	NS	1.9 (1.5–2.3), p<0.001

Legend: NS non-significant

Conclusion: In general, predictors for remission are constant across remission definitions. Additional predictors are identified in less stringent definitions. Similar analysis performed in additional cohorts will help clarify the effect of remission definition on the identification of predictors for remission.

106

Expectations of Treatment Goals and Goal-Setting Practices in People with Rheumatoid Arthritis. Vibeke Strand[1], Peter Taylor[2], Tom Sensky[3], Nik Harta[4] and Scott Fleming[5]. [1]Stanford University, Palo Alto, CA, [2]Kennedy Institute of Rheumatology, London, United Kingdom, [3]Imperial College, London, United Kingdom, [4]Opinion Matters, London, United Kingdom, [5]UCB, Slough, United Kingdom

Background/Purpose: A previous survey examining the impact of RA showed that the disease has a negative impact on employment, productivity, emotions, and intimate relationships, and causes women with RA to feel isolated.[1] This second survey was conducted to evaluate the expectations of men and women with RA regarding treatment and outcomes in care, particularly their awareness of targeted treatment and goal-setting practices.

Methods: People with RA from 6 countries (USA, UK, France, Germany, Italy, and Spain) were recruited by an online research panel to complete an Internet survey regarding how RA affects their lives. Eligible people were aged 25–65 years and were required to have a diagnosis of

RA ≥6 months. Respondents were queried on their perceptions of disease management, treatment expectations, as well as personal and health care provider (HCP) goal-setting (personal/social/treatment) for RA. Mean responses to each question were computed for the overall population of respondents.

Results: A total of 1829 people (1242 females and 587 males) were recruited from 6 countries (USA [n=303], UK [n=306], Germany [n=304], Spain [n=304], France [n=306], and Italy [n=306]). The majority of female participants (72%) were aged 25–34 years, whereas the majority of male participants (36%) were aged 55–65 years. When asked to describe the severity of their RA, 54%, 33%, and 13% of people responded with 'moderate,' 'mild,' and 'severe.' When asked about goal-setting practices when starting a new treatment, 81% set personal or social goals, and 91% set treatment goals. Most respondents (87%) agreed that establishing personal treatment targets would have a positive impact on disease management. A total of 63% of respondents agreed that a targeted approach to successful management was setting personal, lifestyle, and treatment goals and monitoring progress to achieve them. However, 61% reported that their HCP did not manage their RA with strict goals and timeframes in place and 73% reported that their HCP did not discuss treating RA with an approach that achieved personal or social targets. Regarding treatment perceptions, 81% of respondents wanted relief of signs and symptoms within 3 months of starting new therapy, yet only 75% expected to feel an improvement. However, 56% of respondents would wait 1 month or less to speak to their HCP if they felt a new treatment was not working. Furthermore, the majority of respondents (60%) shared decisions with their HCP regarding how best to manage their RA.

Conclusion: From the perspective of a person with RA, a targeted approach to successful disease management means setting personal, social, and treatment goals and monitoring progress to achieve these goals. People with RA want help from HCPs in determining and setting these goals to assess for themselves whether their treatment is working. As more treatments become available for RA, these expectations of people with RA are likely to increase.

Understanding What Motivates Patients with Rheumatoid Arthritis to Escalate Their Care. Liana Fraenkel[1], Meaghan Cunningham[2] and Paul Falzer[3]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [2]Yale University School of Medicine, New Haven, CT, [3]VA Connecticut Healthcare System, New Haven, CT

Background/Purpose: Current ACR guidelines advocate aggressive care with disease modifying anti-rheumatic agents (DMARDs) to achieve and maintain tight control. However, recent studies have found that patients are reluctant to escalate their treatment regardless of current disease activity and that patient reluctance to change treatment is a barrier towards implementing guideline recommendations. The purpose of this study was to examine the influence of specific factors, chosen by their known associations with patient decision making, on willingness to escalate care.

Methods: N=150 patients with RA, currently on at least one DMARD, reporting at least 3 on an 11-point pain scale, whose self-reported arthritis was either the same or worse compared to 2 months ago were interviewed. Predictors of willingness to change included: disease activity as measured by the RAPID-4, discrepancy between current and desired health state measured on a 1 (very close) to 10 (not very close) scale, the importance of improving pain relative to other DMARD-related benefits and risks (quantified using a conjoint analysis survey), worry about current DMARDs measured on a 1 (not at all) to 4 (a lot) scale, and attitude toward starting a new medication measured on a 7-point scale ranging from extremely worried to extremely hopeful. The dependent variable willingness to change was assessed by composite of three items on 1 to 10 scales a) add a DMARD, b) increase the dosage of the current DMARD, and c) switch to another DMARD. The importance of each predictor was assessed via MANOVA with F computed by Wilks' lambda.

Results: The mean age (SD) of the study sample was 58.8 (12.9); 85% were women; 82% Caucasian; 61% married; and 36% were college educated. In bivariate analyses, age (F=0.008, df=3/146, p=0.99) and the RAPID-4 (F=2.11, df=3/138, p=0.1) were not related to willingness to escalate care. Unadjusted and adjusted relationships between factors known to affect decision making and willingness to escalate care are provided in the table below.

Table. Factors influencing patients' willingness to change treatments

	Unadjusted			Adjusted*		
	F	DF	P	F	DF	P
Discrepancy	3.26	3/146	0.02	3.16	3/140	0.027
Importance of improving pain	4.12	3/146	0.008	3.07	3/140	0.030
Worry	2.34	9/351	0.014	2.02	9/341	0.036
Attitude toward new medication	4.45	3/145	0.005	3.27	3/140	0.023

* Containing all four predictors.

Conclusion: In contrast to the medical model, in which decision making is based on measures of disease activity (such as the RAPID-4), patients willingness to escalate care is explained by the discrepancy they perceive between their current and desired health state, the importance they place on pain reduction (relative to other DMARD-related benefits and risks) and emotions related to DMARDs. Addressing these factors may help improve the quality of decision making in clinical practice and consequently increase the number of patients willing to escalate care in order to improve long-term outcomes.

108

Factors Associated with Work Status and Missed Work Days in Patients with Rheumatoid Arthritis. Leslie R. Harrold[1], Mary A. Cifaldi[2], Ying Shan[1], George Reed[1], Katherine C. Saunders[3], Joel M. Kremer[4] and Jeffrey D. Greenberg[5]. [1]UMass Medical School, Worcester, MA, [2]Abbott Laboratories, Abbott Park, IL, [3]CORRONA, Inc., Southborough, MA, [4]Albany Medical College and The Center for Rheumatology, Albany, NY, [5]New York University School of Medicine, New York, NY

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk to be underemployed or not working due to the affects of their illness. Therefore we evaluated factors associated with reported work status and missed work days among RA patients who are participants of a multi-centered observational registry within the United States (the Consortium of Rheumatology Researchers of North America: CORRONA).

Methods: We identified RA patients enrolled between 3/1/06 to 4/30/11 and were aged 18 to 64 years. Outcomes of interest included working full-time or not (includes working part time, at home, student, disabled and retired) as well as missed work days in the prior 3 months due to RA in those working full-time. Covariates of interest included duration of RA (<1 year, 1 to 3 years, 4 to 10 years, and >10 years), education, living arrangement, measures of disease activity and severity, functional status as measured by the modified Health Assessment Questionnaire (mHAQ), receipt of joint surgery, and hospitalizations for RA. Descriptive statistics were conducted. Potential predictors of working full-time as well as missing work days were evaluated using logistic regression.

Results: There were 11,512 patients (44% with ≤ 3 years disease duration). Most were women (79%) and the mean age was 50.5 years. About half (54.5%) were working full time. Patients who were working full time were more likely to be younger (49.3 vs. 51.8 years; p<0.001), male (25.7% vs. 15.1%, p<0.001), have a college education (67.5% vs. 55.3%), be in remission based on the Clinical Disease Activity Index (CDAI) (24.6% vs. 14.7%; p<0.001), and have not needed joint surgeries (p<0.001 for comparisons of hip, knee, foot and hand surgeries) or a hospitalization for RA (1.7% vs. 4.0%, p<0.001). In regression models, increased disease duration (≥ 1year) and mHAQ as well as patient global assessment was associated with a reduced likelihood of working full-time (Table). Among those working full-time, in regression models increased disease duration(>3 years) was protective against missed worked days; in contrast tender joint count, patient global assessment, physician global assessment and mHAQ were all associated with a greater likelihood of missing work (Table).

	Adjusted Odds Ratios of Working Fulltime*	Adjusted Odds Ratios of Missing Work**
Disease duration		
<1	1	1
1–3	0.84 (0.73–0.96)	0.91 (0.72–1.15)
4–10	0.74 (0.64–0.85)	0.77 (0.60–0.98)
11+	0.69 (0.59–0.80)	0.76 (0.58–1.00)
Functional status		
mHAQ	0.45 (0.40–0.51)	2.19 (1.74–2.76)
Clinical Disease Activity Index (CDAI)		
Swollen joint count	0.99 (0.98–1.00)	0.98 (0.97–1.00)
Tender joint count	1.00 (0.99–1.01)	1.03 (1.01–1.05)
Patient global assessment	0.99 (0.99–1.00)	1.02 (1.01–1.02)
Physician global assessment	1.00 (1.00–1.00)	1.00 (1.01–1.01)

* adjusted for age, gender, education, living arrangement, hospitalizations for RA and prior joint surgery.
** adjusted for age, gender, education. living arrangement, hospitalizations for RA, prior joint surgery and erosive disease.

Conclusion: In this working age group of RA patients the likelihood of working full-time diminished early in the disease course. Among those working full time, increased disease activity and functional status were predictive of missed days from work. This suggests that rheumatologists should aggressively treat ongoing disease activity to prevent work loss.

109

Do Patients with Elderly-Onset Rheumatoid Arthritis Have Severe Functional Disability? Soo-Kyung Cho[1], Yoon-Kyoung Sung[1], So-Yeon Park[1], Jeeseon Shim[2], Chan-Bum Choi[3], Hoon-Suk Cha[4], Jung-Yoon Choe[5], Won-Tae Chung[6], Seung-Jae Hong[7], Jae Bum Jun[8], Tae-Hwan Kim[9], Tae-Jong Kim[10], Eun-Mi Koh[4], Jisoo Lee[11], Shin-Seok Lee[10], Sung Won Lee[6], Wan-sik Uhm[8], Dae-Hyun Yoo[9], Bo Young Yoon[12], Sang-Cheol Bae[1] and KORONA investigators[13]. [1]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [3]Hanyang University Hospital for Rheumatic Disease, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [5]Catholic university of Daegu, School of mediine, Daegu, South Korea, [6]Dong-A University Hospital, Busan, South Korea, [7]Kyung Hee University Hospital, Seoul, South Korea, [8]Hanyang University Hospital for Rheumatic Disease, Seoul, South Korea, [9]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [10]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [11]Ewha Womans University Mokdong Hospital, Seoul, South Korea, [12]Inje University Ilsan Paik Hospital, Goyang, South Korea, [13]Seoul

Background/Purpose: Elderly-onset rheumatoid arthritis (EORA) has been described as having a different clinical course and features in comparison with younger-onset RA. However, it has not been clearly established whether different outcomes can be expected for EORA patients. Recent studies have suggested that patients with EORA show worse disease-related outcomes than patients with YORA, while in earlier studies, EORA was associated with a more favorable or similar outcome to YORA. EORA patients may have greater disabilities than YORA patients, because of factors influencing disability such as the age-related increase in comorbidities and the increase in disease activity caused by less aggressive treatment. Therefore, it is important to determine whether elderly onset RA has a different disease outcome that YORA, with considering effects of current age and disease duration. Our aim in this study was to identify the clinical features of elderly onset rheumatoid arthritis (EORA) and their impact on disease outcome.

Methods: A total of 3,169 RA patients were recruited as part of the KORean Observational study Network for Arthritis (KORONA), a network of rheumatologists across South Korea. Patients were stratified according to age at disease onset: younger than 40 years (younger-onset RA, YORA), between the ages of 40 years and 60 years (middle aged-onset RA, MORA), older than 60 years (EORA). To evaluate the significance of differences in demographic and clinical features among these three groups, we performed analysis of variance (ANOVA) and the chi-square test. We used multivariable logistic regression analysis to examine the association of onset age with functional disability.

Results: Patients were divided into YORA (n=1,167), MORA (n=1,516) and EORA (n=486) groups. The Health Assessment Questionnaire (HAQ) score was significantly higher in patients in the EORA group than those in the YORA and MORA groups (p=<0.001). Multivariable analysis demonstrated that age (middle age: OR=1.55, CI 1.14~2.11, older age: OR=2.51, CI 1.82~3.45), female sex (OR=2.78, CI 2.01~3.83), high disease activity (OR=6.82, CI 5.38~8.64), disease duration ≥10 years (OR=1.77, CI 1.43~2.20), and cardiovascular disease comorbidity (OR=2.32, CI 1.51~3.57) affected disability, though EORA was not associated with high HAQ score (≥1). However, in a predefined subgroup analysis of patients with a disease duration of less than 10 years, elderly onset was an independent factor influencing the functional disability of RA patients (OR 3.04, CI 1.85~5.67: disease duration of < 5 years, OR 3.07, CI 1.64~5.74: disease duration of 5 to 10 years).

Conclusion: EORA is independently associated with functional disability in RA patients with a disease duration of less than 10 years. This finding suggests that an aggressive management approach is required to treat patients with EORA, as is currently the case for patients with YORA.

An Increase of Disease-Related Knowledge Improves Adherence to Tight Control. Sofie H.M. Manders[1], Laura T.C. van Hulst[1], Piet LCM Van Riel[1], Liana Fraenkel[2] and Wietske Kievit[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT

Background/Purpose: Rheumatoid arthritis (RA) patients with active disease are often reluctant to change their medications. Educating patients about the importance of tight control may help increase patient willingness to accept additional therapy. However, the relationship between patient knowledge and their beliefs about medicine and treatment preferences has not been clearly established. The objective of this study was to determine whether there is an association between 1) disease-related knowledge and 2) beliefs about medicine and patients' considerations in medication decisions.

Methods: We used a Maximum Difference Scaling (MDS) survey to determine the importance of 58 factors related to the decision to change medications for patients with active RA. Participants answered 24 choice tasks in which they chose the single most important item in their decision from five items. MDS generates a relative importance score for each factor. The factors were divided into eight categories (determined by consensus among three researchers). We also collected demographic characteristics as well as patients' beliefs about medicine and disease-related knowledge. We used multiple linear regression to analyze the relationship between disease-related knowledge and beliefs about medicines and the MDS importance scores of the following four categories: disease activity, risk of treatment, burden of treatment (e.g.: route of administration, frequency of drug administration, need for blood tests, number of medications) and disease progression/prognosis. A forward selection procedure was used to find and correct for confounding factors (age, gender, level of education, health literacy and disease duration). Interaction terms were added in the regression model to examine potential effect modification.

Results: 213 subjects completed the survey. The mean age was 60.0 years (SD=11.6), the median disease duration was 7.0 years (IQ range=12.5) and 69.5% of the participants were female.

After adjusting for patients' highest level of education, we found a negative relationship between disease-related knowledge and patients' ratings related to the burden of treatment (β=−0.348, p=0.008). In addition, data showed that this relationship was even stronger in patients with higher educational degrees (β=−0.246, p= 0.049). No relationships were found between disease-related knowledge and the importance of the remaining categories. In addition, no significant relationships were found between beliefs about medicine and any of the four categories.

Conclusion: Patients with greater disease-related knowledge are less likely to be influenced by the potential burden of treatment in the decision to escalate care. Therefore, educating patients seems to have a positive effect on the adherence to tight control. However further research is needed to determine if improving RA-related knowledge through targeted education programs will increase patient willingness to accept additional treatment.

111

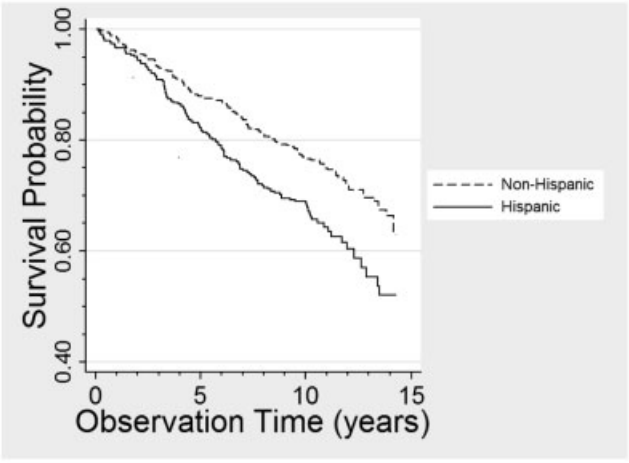
Does the Hispanic Paradox Apply to Mexican Americans With Rheumatoid Arthritis? Antonio E. Mancera[1], Inmaculada Del Rincon[2], Daniel F. Battafarano[3], Jose Felix Restrepo[4] and Agustin Escalante[5]. [1]Univ of Texas HSC San Antonio, San Antonio, TX, [2]UTHSCSA, San Antonio, TX, [3]Brooke Army Medical Ctr, San Antonio, TX, [4]University of Texas. Health Science Center, San Antonio, TX, [5]University of Texas Health Science Center, San Antonio, TX

Background/Purpose: Despite socioeconomic disadvantage and a higher disease burden, all-cause mortality in U.S. Hispanics is equal or lower than that of Non-Hispanic Americans. It is unclear if this "Hispanic Paradox" occurs in rheumatoid arthritis (RA). We compared clinical characteristics and survival between Hispanics and Non-Hispanics in a cohort of RA patients.

Methods: We recruited consecutive RA patients from private and public rheumatology clinics. After a comprehensive baseline evaluation of their clinical and sociodemographic characteristics, we invited them for annual follow-up evaluations. We followed patients until the censoring date of May 31, 2010, unless they died or were lost to follow-up. We learned about deaths from public databases, physicians, relatives, neighbors and obituaries, confirmed by death certificate. We used generalized estimating equations (GEE) to compare clinical characteristics between Hispanics and non-Hispanics, adjusting for confounders and accounting for repeated measures within patients. We used Cox proportional hazards regression to compare survival.

Results: The cohort included 779 patients, who participated in a total of 4,557 observations. Time from enrollment until last follow-up, death or the censoring date was 7,204 patient-years (a median of 10.3 years per patient). There were 434 Hispanic and 345 Non-Hispanic patients. At enrollment, Hispanics were younger on average (52 versus 59 years old) and more were women (74% versus 65%). After adjusting for age and sex, Hispanics had significantly more tender joints (GEE regression coefficient = 4.61, [95% CI = 3.04, 6.20]) more swollen joints (0.58 [0.08, 1.16]), more deformed joints (4.66, [2.97, 6.34]), a higher ESR (10.5 [7.4, 13.5]), and more joint damage, as measured by the modified Sharp score (13.4 [5.1, 21.8]). Hispanics were also significantly more likely to have rheumatoid factor (odds ratio = 1.51, [95% CI = 1.13, 2.03]). There was no significant difference in the frequency of nodules (OR = 1.16 [95 % CI 0.89, 1.52]), or the HLA-DRB1 shared epitope (0.90, [0.65, 1.24]).

237 deaths occurred, for a mortality rate of 3.3 per 100 patient-years [2.9, 3.7]. Among Hispanics, there were 115 deaths in 4,212 patient years for a rate of 2.7 deaths per 100 patient years [2.27, 3.8]. Non-Hispanics had 122 deaths per 2,991 patient years or 4.0 deaths per 100 patient years [95% CI 3.42, 4.88]. The unadjusted hazard ratio for mortality among Hispanics versus Non-Hispanics was 0.65 (0.50, 0.84]). However, after adjusting for age and sex, the difference in survival between Hispanics and Non-Hispanics was no longer significant (age- and sex-adjusted HR 1.07 [1.05, 1.08]).



Conclusion: These findings suggest that despite greater severity in most clinical manifestations among the Hispanics in this RA cohort, their mortality paradoxically was not increased. Further research is needed to understand the mechanisms underlying the Hispanic survival paradox

112

Subgroup Analyses of a Novel Baseline Biomarker of Acute-Phase Serum Amyloid A (A-SAA) and Serum Interleukin–2 Receptor Alpha (sIL-2Ra) That Predicted Long-Term (18 to 35 yrs) Mortality in a Cohort of Incident Rheumatoid Arthritis (RA) and Non-RA. Alfonse T. Masi[1], Jean C. Aldag[1] and Jean D. Sipe[2]. [1]University of Illinois College of Medicine at Peoria, Peoria, IL, [2]Boston University School of Medicine, Boston, MA

Background/Purpose: Research on biomarkers of mortality has high priority, especially for cardiovascular causes. A novel biomarker of either elevated serum A-SAA or sIL-2Ra levels predicted total mortality in decades-long follow-up of a prospective cohort (A&R 2010;62:S19). The biomarker is now analyzed for prediction of mortality in cohort subgroups.

Methods: Cohorts in this community-based (n = 21,061 adults) study of risk factors for RA enrolled in 1974. The pre-RA cases had clinical onset, 3 to 20 (mean 12) yrs, after entry (1977 – 1994). Controls (CN) were non-RA cohorts matched at entry (4CN: 1 pre-RA). Biomarker data were available on 192 (44 pre-RA, 148 CN) subjects, who were monitored for mortality, from 1992 thru 2009, excluding 12 pre- 1992 deaths. Baseline stored (−70°C) sera were assayed (ELISA) "blindly" for the combined biomarker. High sensitivity A-SAA was assayed (Hemagen kits) at Boston University (sensitivity 1 μg/ml). The sIL-2Ra was assayed (R & D Systems, high sensitivity kits) at Specialty Laboratories, Santa Monica, CA. Sex- and age - specific upper quartile (UQ) values of A-SAA *and* sIL-2Ra were determined to decrease such covariate confounding. Elevated baseline (1974) A-SAA (p = 0.048) and sIL-2Ra (CD 25), p = 0.036 separately predicted total mortality, from 1992 – 2009. The combined novel predictor is defined as an elevated UQ level of *either* biomarker. All cause, primary cardiovascular (CV) (ICD-9, 390–459 & ICD-10, 00–99), and all other combined mortality (non-CV) was monitored quarterly, from 1992 thru 2009. Subgroup analyses were performed for percentages of deaths, and hazard ratios (HR) of the novel biomarker by Cox regression models.

Results: All causes deaths occurred in 64 (33.3%) of 192 total subjects (biomarker HR = 2.37 (1.44 – 3.90), p = 0.001). Comparative death outcomes in cohort subgroups, percentile mortality, and biomarker predictions (HRs) by the Cox Model are shown in the Table. Mortality was greater in RA (50.0%) vs CN (28.4%), p = 0.017. The biomarker similarly predicted mortality outcomes for RA (HR = 2.50) and CN (HR = 2.32) subgroups. Mortality prediction was significant for females [HR = 3.33 (1.66 – 6.71), p = 0.001], but not for males [HR = 1.54 (0.77 – 3.10), p = 0.225]. Mortality prediction was significant for younger (< 47 yrs) subjects at entry [HR = 3.98 (1.76 – 9.00), p = 0.001], but not for older cohorts [HR = 1.62 (0.85 – 3.10), p = 0.145]. The biomarker strongly predicted CV mortality [HR = 6.38 (2.25 – 18.09), p < 0.001], but not the remainder of deaths [HR = 1.62 (0.90 – 2.94), p = 0.111], as shown in Table.

Cohort Subgroups, Mortality, and Cox Regression Models	Comparative Death Outcomes in Subgroups, and Biomarker Predictions by the Cox Model* Subgroup#1	Subgroup#2
RA (#1) vs CN (#2) Subgroups		
Mortality (%)	22 (50.0%) of 44	42 (28.4%) of 148
Cox Regression Model HR (95% CI) of Deaths:	2.50 (1.02–6.11)	2.32 (1.26–4.27)
p Values (for Biomarker)	p = 0.045	p = 0.007
Females (# 1) vs Males (# 2)		
Mortality (%)	32 (29.1%) of 110	32 (39.0%) of 82
Cox Regression Model HR (95% CI) of Deaths:	3.33 (1.66–6.71)	1.54 (0.77–3.10)
p Values (for Biomarker)	p = 0.001	p = 0.225
Younger (# 1) vs Older (# 2)		
Mortality (%)	26 (19.8%) of 131	38 (62.3%) of 61
Cox Regression Model HR (95% CI) of Deaths:	3.98 (1.76–9.00)	1.62 (0.85–3.10)
p Values (for Biomarker)	p = 0.001	p = 0.145
CV (# 1) vs Non-CV (# 2) Deaths		
Mortality (%)	18 (9.4%) of 192	46 (24.0%) of 192
Cox Regression Model HR (95% CI) of Deaths:	6.38 (2.25–18.09)	1.62 (0.90–2.94)
p Values (for Biomarker)	p < 0.001	p = 0.111

* Includes decades of age covariate

Conclusion: Baseline (1974) UQ levels of either serum A-SAA or sIL-2Ra predicted long-term (18 to 35 yrs) mortality, significantly for females (p = 0.001), younger cohorts (p = 0.001), and circulatory (p < 0.001) deaths. This novel biomarker deserves further testing as a long-term mortality predictor.

113

Risk of Cardiovascular Events in Rheumatoid Arthritis Patients Treated with Subsequent-Line Biologic Disease Modifying Antirheumatic Drugs After Switching From First-Line Anti-Tumor Necrosis Factor Agents.
Stephen Johnston[1], Adam Turpcu[2], Nianwen Shi[1], Dalia Moawad[2] and Kimberly Alexander[3]. [1]Thomson Reuters, Washington, DC, [2]Genentech, South San Francisco, CA, [3]Genentech, Inc., South San Francisco, CA

Background/Purpose: Rheumatoid arthritis (RA) patients frequently switch drug treatments. Little information exists on the risk of cardiovascular events among patients treated with subsequent-line (SL) biologic disease modifying antirheumatic drugs (BIO) after switch from first-line (FL) anti-tumor necrosis factor agents (aTNF). In addition, information is lacking on the relative risk of CV events in patients treated with SL aTNF agents or SL abatacept vs. SL rituximab.

Objectives: Compare the risk of cardiovascular events in RA patients treated with various SL BIO.

Methods: Retrospective analysis of Thomson Reuters MarketScan® Commercial and Medicare databases, a large U.S. administrative claims dataset. RA patients initiating FL anti-TNF therapy from 1/1/2004–3/31/2010 were identified and followed forward in time to capture all SL BIO episodes through 3/31/2010. SL episodes were constructed as time from initiation of a SL BIO until switch to another SL BIO, disenrollment, or 3/31/2010. SL episodes were classified into 1 of 5 SL BIOs: abatacept (ABA); adalimumab (ADA); etanercept (ETN); infliximab (INF); rituximab (RTX). Cardiovascular events, as identified by International Classification of Disease, ninth revision, clinical modification criteria, included the following: acute myocardial infarction, other acute and subacute forms of ischemic heart disease, ventricular arrhythmias, cardiac arrest, and atrial fibrillation/flutter. Multivariable Cox proportional hazards survival models compared the hazard of cardiovascular events across the SL BIOs with RTX as the reference group. The hazard models adjusted for important demographic and clinical confounders identified 12-months prior to initiation of SL BIO.

Results: A total of 4,332 SL episodes were identified: mean age 55 yrs; 80% female. Total person-years exposure by SL BIO were ABA 942, ADA 1,716, ETN 1,349, INF 777, 452 RTX. Average duration of follow-up was similar between SL BIOs (range: 1.1–1.3 yrs). Cardiovascular events occurred in 146 SL BIO episodes overall. The incidence rates of cardiovascular events per 100 person-years of observation were 2.1 INF, 2.4 RTX, 2.7 ADA, 3.0 ETN, 3.3 ABA. As compared to RTX, the adjusted hazard of cardiovascular events was not significantly higher for INF (HR 1.3 95% CI: 0.6–2.8), ABA (HR 1.6 95% CI: 0.8–3.2), ADA (HR 1.8 95% CI: 0.9–3.5), and ETN (HR 1.8 95% CI: 0.9–3.5).

Conclusion: The risk of cardiovascular events did not differ significantly between patients treated with SL aTNF agents or SL abatacept compared to patients treated with SL rituximab. As an observational study, results may be impacted by channeling or residual confounding. Findings are also limited by the infrequency of cardiovascular events.

114

Risk of Acute Myocardial Infarction Associated with Arthritis: A Systematic Review of Observational Studies.
Orit Schieir[1], Cedomir Tosevski[2] and E. M. Badley[3]. [1]University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, Toronto, ON, [3]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON

Background/Purpose: Various types of arthritis and rheumatoid arthritis in particular, have been associated with increased cardiovascular morbidity and mortality. However, the cumulative impact of arthritis on the risk of acute myocardial infarction (AMI), as well as potential differences across age groups, sex and between arthritis sub-populations remain unclear. The objective was to perform a systematic review of the risk for incident AMI associated with arthritis; and to compare the relative magnitude of AMI risk across age, gender and type of arthritis.

Methods: A systematic search was performed in MEDLINE, EMBASE and CINAHL databases for controlled population-based prospective/retrospective cohort or case-control studies examining the relationship between arthritis (any arthritis, ankylosing spondylitis (AS), gout, osteoarthritis (OA), psoriatic arthritis (PsA) or rheumatoid arthritis (RA)) and incident AMI (any AMI, fatal or nonfatal AMI) published between January 1980 and February 2011, and stratified or adjusted for at least age and sex. Study quality was assessed with a validated appraisal tool for observational studies; the Newcastle-Ottawa scale. Information on study design, country, funding source, duration of follow-up, crude and adjusted measures of association with 95% confidence intervals were abstracted for each study. All search screening, data abstraction and quality appraisal was performed by 2 independent reviewers.

Results: Nineteen studies met all eligibility criteria and were included in the present review (gout (6), RA (13)). Arthritis was a statistically significant independent risk factor for incident AMI in 17/19 studies. Gout was associated with a significant increased risk of incident AMI in 5/6 studies (Total AMI- RR range: 1.11–1.50; Fatal AMI- RR range; 0.96–1.35; Non-fatal AMI RR range: 1.11–1.59). RA was associated with a significant increased risk of incident AMI in 12/13 studies (Total AMI- RR range: 1.16–2.90; Fatal AMI- RR range; 1.10–2.24; Non-fatal AMI RR range: 1.25–2.17). Eight studies reported stratified estimates for sex and all suggested stronger risks for AMI in women than in men with arthritis, but confidence intervals between groups were wide and overlapped. Similarly, 3 studies included stratified estimates for age and all suggested stronger risks for incident AMI in younger vs. older arthritis populations but confidence intervals overlapped.

Conclusion: Gout and RA were independently associated with increased risks for incident AMI. Increased monitoring and/or enrollment in cardiovascular prevention programs are likely warranted in these patients. As no studies meeting inclusion criteria were identified for patients with AS, PsA and OA there was insufficient evidence to draw conclusions regarding independent risks of incident AMI in these populations. Future analysis including a quantitative synthesis with meta-analysis and meta-regression will help address limitations due to small cell sizes in individual studies and better understand factors contributing to heterogeneity in effect estimates between studies, respectively.

A Possible Source of Error in the Method of Cancer Risk Estimation in Patients with Rheumatoid Arthritis.
Hasan Yazici[1], Koray Tascilar[1], Yusuf Yazici[2], Gulay Kiroglu[3], Levent Duransoy[3] and Aydin Erar[3]. [1]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey, [2]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY, [3]Mimar Sinan University School of Science and Letters, Istanbul, Turkey

Background/Purpose: The magnitude of the association of cancer with rheumatoid arthritis, especially after anti-TNF use, remains in dispute. We recently proposed (1) an important selection bias was potentially inherent in the registry data especially when the comparator for the sought cancer incidence in RA was the cancer incidence in the "mother population", the population from which the registry is derived from. In a mother population within a given time there would be many patients with cancer who would not have the chance to develop RA since a. a sizeable fraction would die from their disease before having the chance to develop RA; b. The cancer treatment could potentially prevent the development of RA or finally, and particularly in the case of anti-TNF registries, c. If they remained alive and developed cancer the likelihood of them being included in such a registry would be small. All 3 factors could render the incidence ratio (incidence in the registry/ incidence in the mother population) less than unity even if biologically there are no real differences in the cancer frequencies between the 2 populations. Lastly this ratio would decrease in time as was observed in the Taiwan registry (1). We formally surveyed whether the same potential selection bias was present in other manuscripts reporting similar data.

Methods: We conducted a PubMed search with the search terms "registry" "cancer" and "rheumatoid arthritis" among 7 high-impact rheumatology journals between 2001 and May-2011 (inclusive). First, articles that reported cancer incidence in patients with RA were retrieved in full-text. Among these, those manuscripts which reported an incidence ratio at 2 or more time-points were included in this survey. We specifically sought a. whether the comparisons were made between the registry and a "mother population" and b. the changes in the above described ratio between the first and last time points.

Results: We retrieved 36 articles among 1274 search results. In 6/36 the incidence ratio comparisons were made between at least one RA registry and its mother population at more than 1 time point. The number of time-points ranged from 3 to 11. Sampling-period-length ranged from 8 to 40 years. In 5 of the 6 articles when a comparison was made with the mother population there was a reduction over time in the incidence ratio which ranged from 29 to 99%. In the remaining study there was no appreciable change in the incidence ratio.

Conclusion: There are many important methodological issues for a fair assessment of cancer incidence in RA especially with the use of anti-TNF agents (2) We propose that the selection bias we try to highlight here should be included in this list of issues especially when we compare the cancer in a RA cohort with that in the mother population.

Cancer Screening Rates in Patients with Rheumatoid Arthritis: No Different Than the General Population. Seo Young Kim[1], Sebastian Schneeweiss[2], Jessica E. Meyers[1], Jun Liu[1] and Daniel Hal Solomon[3]. [1]Brigham & Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham & Womens Hospital, Boston, MA

Background/Purpose: Both the U.S. Preventive Services Task Force and American Cancer Society recommend most adults be regularly screened for cervical, breast and colon cancer. Early detection of such cancers can decrease morbidity and mortality. Previous studies suggest that patients with chronic diseases, such as rheumatoid arthritis (RA), do not receive optimal preventive medical services including cancer screening tests, however few evaluated cancer screening in RA patients compared to non-RA.

Methods: Using data from a large US commercial insurance plan (1/2001–6/2008), we examined rates of screening tests for cervical, breast and colon cancer in patients with RA compared with non-RA. RA was defined as ≥ 2 diagnoses of RA and ≥ 1 prescription for a disease-modifying anti-rheumatic drug. Patients who never had an RA diagnosis were selected for the non-RA cohort. We required ≥ 1 year of follow-up. In sensitivity analysis, RA patients were compared to a subgroup of non-RA patients who have ≥ 2 diagnoses of hypertension (HTN), a chronic disease with similar health care utilization patterns.

Results: 13,314 RA patients and 131,989 non-RA patients were identified with a mean follow-up time of 2.38 years. Mean age was 52 for RA patients and 48 for non-RA. Unadjusted rates of cancer screening are shown in Table 1. Both RA and non-RA patients were screened, on average, once every 3 years for cervical cancer and once every two years for breast cancer. In the age-adjusted Cox regression model, women with RA were more likely to receive ≥ 1 Pap smear (HR 1.21, 95% CI 1.17–1.24), mammogram (HR 1.49, 95% CI 1.45–1.53), and colonoscopy (HR 1.69, 95% CI 1.61–1.77) compared to non-RA. Men with RA, compared to non-RA, were also more likely to receive a colonoscopy (HR 1.52, 95% CI 1.40–1.64). There was no significant difference in cancer screening rates between patients with RA and those with HTN (Table 2). These results were robust in multivariate analyses adjusted for age, number of physician visits, percent of visits made to primary care physicians and comorbidity index.

Table 1. Crude rates (95% confidence intervals) per 1,000 person-years for having at least one cancer screening test in RA and non-RA patients.

	RA	Non-RA
Papanicolaou smear	375.5 (365.7–385.5)	350.9 (347.7–354–1)
Mammogram	551.8 (537.7–566.2)	437.5 (433.0–442.0)
Colonoscopy	229.6 (221.9–237.6)	172.2 (169.7–174.8)

Table 2. Age-adjusted hazard ratios (95% confidence intervals) for having at least one cancer screening test in RA compared with a subgroup of non-RA patients with HTN.

	Women	Men
Papanicolaou smear	0.98 (0.95–1.01)	–
Mammogram	0.94 (0.92–0.97)	–
Colonoscopy	0.95 (0.90–1.00)	0.99 (0.91–1.07)

Conclusion: Individuals with RA did not appear to be at risk for receiving fewer cancer screening than either group of non-RA patients. Cancer screening rates in both RA and non-RA patients appeared to be in accordance with recommendations.

117

Biological Agents in Rheumatoid Arthritis and Risk of Malignancy—Results From the Nation-Wide Cohort Study in Japan. Masayoshi Harigai[1], Toshihiro Nanki[1], Ryuji Koike[1], Michi Tanaka[1], Kaori Watanabe[1], Yukiko Komano[1], Ryoko Sakai[1], Hayato Yamazaki[1], Takao Koike[2], Nobuyuki Miyasaka[1] and SECURE study investigators group. [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]Sapporo Medical Center NTT EC, Sapporo, Japan

Background/Purpose: Association of anti-tumor necrosis factor (TNF) therapy with development of malignancy has been addressed using meta-analytic and observational approach in Europe and the US. Risk for malignancy, however, varies widely among ethnics and geographical regions because of genetic predisposition and environmental factors. In this study, we investigate the risk for malignancy in Japanese patients with RA treated with biological agents including TNF inhibitors and tocilizumab.

Methods: Japanese RA patients treated with biological agents have been registered from hospitals participating in SECURE (Safety of Biologics in Clinical Use in Japanese Patients with Rheumatoid Arthritis in Long-Term) study, which is a nation-wide cohort study implemented by Japan College of Rheumatology. All data were collected annually using electronic case report form from registration (year 0) to year 5. Data from the start of the first biological agent to year 0 of each patient were collected retrospectively and data after year 0 were collected prospectively. Demographic data, use of biological agents, occurrence of malignancy, and life prognosis were recorded. As of March 2011, data of 11,697 patients from 332 institutions were obtained. Age standardized incidence rate (ASR) and standardized incidence ratios (SIRs) of newly diagnosed malignancy were calculated as measures of relative risk using estimates from Japanese general population as a reference.

Results: Characteristics of the 11,697 patients were as follows: female, 81.1%; mean age at the start of their 1st biological agents, 56.6 y/o; accumulated number of patients who received each biological agent, 5,823 for infliximab, 6,418 for etanercept, 1,547 for adalimumab, and 1,607 for tocilizumab. In total, 207 cases of malignancy were reported; 44 hematopoietic and 163 non-hematopoietic. Hematopoietic malignancy included 41 cases of malignant lymphoma, 2 leukemia, and 1 multiple myeloma while non-hematological malignancy included 29 cases of gastric cancer, 24 colon cancer, 27 lung cancer, 20 breast cancer, and 63 others. ASR (95% confidence intervals [95%CI]) (/100,000 patient-year) of total malignancy were 302 (228–393) for female and 387 (280–522) for male patients, which were significantly lower than the incidence of total malignancy in Japanese general population (female 405, male 577). SIRs (95% CIs) of total malignancy and total non-hematopoietic malignancy were also significantly lower than Japanese general population in both female and male patients. None of SIRs of each site-specific non-hematopoietic malignancy was significantly elevated compared to Japanese general population. SIRs (95% CIs) of malignant lymphoma were 5.08 (3.33–6.98) in female and 3.93 (1.75–6.55) in male patients, but were numerically lower than those of a previous report from a large-scale Japanese cohort study of RA patients (Rheumatol Int 2010, doi 10.1007/s00296-010-1524-0) (6.00 for female and 6.22 for male patients), in which 97.6% of the patients were biologic naïve.

Conclusion: Risk for malignancy was not elevated in Japanese RA patients who received biological agents including TNF inhibitors and tocilizumab.

118

Prophylactic Therapy for Latent Tuberculosis Prior to Anti-Tumor Necrosis Factor Therapy in Patients with Rheumatoid Arthritis: A Decision Analysis. Glen S. Hazlewood[1], David Naimark[1], Michael Gardam[1], Vivian Bykerk[2] and Claire Bombardier[3]. [1]University of Toronto, Toronto, ON, [2]Brigham & Women's Hospital, Boston, MA, [3]Institute for Work & Health, Toronto, ON

Background/Purpose: Screening for latent tuberculosis infection (LTBI) prior to anti-TNF therapy is recommended, with patients offered prophylactic therapy if they screen positive. The utility of this in low-risk populations is uncertain, given a low absolute risk of TB reactivation in patients who screen positive and risks associated with prophylaxis. The objective was to determine if prophylactic therapy for LTBI should be initiated in patients with rheumatoid arthritis (RA) who screen positive prior to starting anti-TNF therapy.

Methods: A Markov model with a lifetime horizon and monthly cycles was developed to model the decision of whether to initiate prophylaxis with isoniazid (INH) for 6–9 months prior to starting anti-TNF therapy in a

hypothetical cohort of patients with RA who screen positive for LTBI. The base case was a 50-year old patient, born in a country with a low TB prevalence with a positive tuberculin skin test of 5–10 mm, who had not been vaccinated with BCG and had no other risk factors for TB reactivation outside of RA and anti-TNF therapy. All model inputs were based on literature reviews. The outcome was quality-adjusted life years, which were discounted at 3%/year. Sensitivity analyses were performed across all variables and for several model assumptions.

Results: No prophylaxis was the favoured approach with a gain of 8.1 quality-adjusted life-days. The decision was robust to the range of plausible values of relative risk (RR) of TB reactivation associated with anti-TNF therapy (RR: 1.3–15.5). Prophylaxis was favoured if the RR of TB reactivation associated with RA alone was > 3.2 or if the utility associated with INH prophylaxis was > 0.98. For any given baseline probability of TB reactivation, as age increased, prophylaxis was less favoured (Fig. 1). This occurred because the risk of hepatotoxicity is accrued initially and increases with age, and because older patients have less lifetime risk of TB reactivation and therefore less potential to benefit from prophylaxis. Prior BCG vaccine or the use of 4 months of rifampin instead of INH did not change the favoured decision.

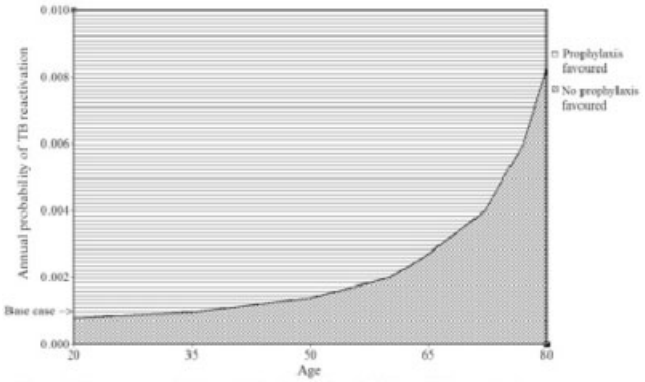

Figure 1: Two-way sensitivity analysis of annual probability of TB reactivation versus age. Prophylaxis is favoured for any patient in the area shaded with horizontal lines.

Conclusion: For RA patients with a low-positive LTBI screen, who are otherwise at low risk of TB reactivation, holding prophylaxis prior to anti-TNF therapy is appropriate. The decision to initiate prophylaxis should be tailored to a patient's age, baseline annual risk of TB reactivation and patient preference for a 9-month course of isoniazid.

119

Primary Care Physicians' Attitudes towards Managing Rheumatoid Arthritis: Room for Improvement. Daniel H. Solomon[1], Katie Garneau[1] and Maura D. Iversen[2]. [1]Brigham & Womens Hospital, Boston, MA, [2]Northeastern University, Department of Physical Therapy and Brigham & Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Many people with rheumatoid arthritis (RA) do not receive care from a rheumatologist. We surveyed primary care physicians (PCPs) to better understand their attitudes, knowledge, and practices regarding the optimal treatment of RA.

Methods: Randomly selected PCPs practicing in the US with valid e-mail addresses were surveyed, using a list supplied by the American Medical Association. The survey encompassed their experience with RA, use of disease modifying anti-rheumatic drugs (DMARDs), and experience with rheumatology referrals. Logistic regression analyses described the responses and examined the correlation between physician variables and use of DMARDs.

Results: E-mail invitations were opened by 1,103 PCPs and completed by 267 (25%). Most respondents were men (68%) in practice for over 10 years (64%) who reported 6 or more RA patients under their care in the last year (71%). The majority (59%) reported some RA training after medical school (such as grand rounds or journals), but only 1/3 felt very confident managing this condition. Most (81%) reported prescribing DMARDs, but 37% do not initiate them, with only 9% reporting being very confident starting a DMARD. 35% believe that DMARDs should only be used after a trial of NSAIDs or steroids. A variety of reasons were given for not considering patients appropriate DMARD candidates (see Table). Reasons commonly mentioned include: quiescent disease, too sick to take a DMARD, side effects of DMARDs too great, drug interactions, and monitoring and cost too burdensome. We examined whether PCP characteristics were associated with prescribing DMARDs, but none were significant correlates. Almost half (44%) of PCPs noted that patients report difficulty getting appointments with rheumatologists.

Table Attitudes of 266* PCPs regarding DMARD prescribing for RA

	DMARD Prescribers N = 217	DMARD Non-Prescribers N = 49
Factors that make patients inappropriate candidates for DMARDs		
No need (well controlled without DMARD)	110 (51%)	21 (43%)
Too sick to take a DMARD	78 (36%)	14 (29%)
Side effects of DMARDs too problematic	128 (59%)	20 (41%)
Drug interactions	74 (34%)	9 (18%)
Drug cost and monitoring are too high	115 (53%)	27 (55%)
Cannot get laboratory monitoring	17 (8%)	3 (6%)
Best time to initiate DMARDs		
After a trial of NSAIDs or steroids	75 (35%)	17 (35%)
Within the first 6 months of dx	132 (61%)	27 (55%)
At least 6 months after diagnosis	9 (4%)	4 (8%)
Comfort level starting a DMARD†		
Very comfortable	23 (11%)	0 (0%)
Somewhat comfortable	73 (34%)	6 (12%)
Somewhat uncomfortable	89 (41%)	23 (47%)
Very uncomfortable	30 (14%)	20 (41%)
Comfort level continuing a DMARD§		
Very comfortable	71 (33%)	4 (8%)
Somewhat comfortable	107 (50%)	23 (47%)
Somewhat uncomfortable	37 (17%)	17 (35%)
Very Uncomfortable	1 (0%)	5 (10%)

† 3 missing responses, § 2 missing responses

Conclusion: We found many PCPs are uncomfortable managing RA but perceive poor rheumatology access. Lack of accessibility to rheumatologists and discomfort in prescribing DMARDs for patients with RA are potential barriers to optimal treatment.

120

Nudging Patients with Rheumatoid Arthritis towards Accepting ACR Recommendations. Liana Fraenkel[1], Ellen Peters[2] and Valerie Reyna[3]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [2]Ohio State University, Columbus, OH, [3]Cornell University, Ithica, NY

Background/Purpose: Current American College of Rheumatology (ACR) guidelines "strongly recommend" aggressive care with disease modifying anti-rheumatic drugs (DMARDs) in order to achieve and maintain tight control in rheumatoid arthritis (RA). Despite the widespread endorsement of this approach, data suggest that many RA patients are not effectively treated with DMARDs. There are currently no proven mechanisms in place to effectively inform RA patients and enable them to process the complex information involving decisions related to escalating care. The objective of this study is to develop a decision tool, based on Fuzzy Trace theory, to effectively inform patients and to "nudge" RA patients with ongoing active disease, despite use of traditional DMARDs, to consider biologic therapy.

Methods: We first performed a systematic review to generate the outcome data and risk estimates required for the tool. To ensure equal emphasis on both adverse events (AEs) and benefits, we included the same number of benefits as risks. A Delphi panel of experts was used to determine which AEs should be represented to all subjects to ensure informed consent. Additional information can be accessed through links for those desiring additional information. Probabilistic information was presented using theoretically motivated manipulations: e.g.: bar graphs to emphasize relative benefits and pie charts were used for AEs to emphasize the denominator. Subjects are provided an opportunity to perform a value clarification exercise at the end of the tool. We conducted a pre-post test pilot study to assess the feasibility, acceptability, and preliminary evidence of the tool's efficacy in improving informed choice.

Results: We interviewed104 subjects; mean age (SD) = 62 (12); 84% female, 86% White; median duration of RA =13 years (range 1–61); 72% reported currently using a traditional DMARD and 39% a biologic. Knowledge (as measured by the sum of correct responses to 20 questions) and willingness to take a biologic (as measured on an 11-point numeric rating scale) significantly improved after viewing the tool (mean differences 3.1 and 1.4 respectively, both

$p < 0.0001$). Decisional conflict (informed and value subscales) also significantly decreased (mean differences 20.4 and 20.7, both $p<0.001$). Increased willingness to take a biologic was greater among younger adults and those with a college education. Improvement in knowledge was seen across varying ages and educational backgrounds. Over 90% of participants ratings; related to the quality and quantity of information were very good or excellent. 89% found the tool to be very helpful and all would recommend it for patients with RA.

Conclusion: A tool designed based on the principles of Fuzzy Trace theory to nudge patients towards accepting "strong recommendations" increased knowledge, decreased decisional conflict, and increased patient willingness to escalate care in a pre-post test setting.

121

An Analysis of the Use of Lipid Lowering Agents in Rheumatoid Arthritis: A Population Based Cohort Study. Bharath Manu Akkara Veetil, Eric L. Matteson, Sherine E. Gabriel and Cynthia S. Crowson. Mayo Clinic, Rochester, MN

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of cardiovascular disease and mortality. Lipid lowering therapy to reduce risk for major coronary events and coronary death is reportedly underused in patients with RA, but it is unknown whetheruse of lipid lowering medications in patients with RA differs from the general population.

Methods: A population-based inception cohort of patients who fulfilled 1987 American College of Rheumatology criteria for RA in 1988–2007 and a cohort of non-RA subjects from the same population base were assembled and followed until death, migration, or 12/31/2008. Cardiovascular risk factors, lipid measures and use of lipid-lowering agents were ascertained by review of the medical record. The national cholesterol education program (NCEP) adult treatment panel III (ATP III) guidelines were assessed at the time of each lipid measure throughout follow-up. Time from the first measurement of lipids meeting guidelines for initiation of lipid-lowering agents to initiation of lipid-lowering agents was assessed using Kaplan-Meier methods. Log rank tests were used to compare RA and non-RA cohorts.

Results: The study population included 412 RA and 438 non-RA patients with at least one lipid measure during follow-up and no prior use of lipid-lowering agents (mean age 60 years; 71% female in each cohort). No difference between RA and non-RA cohorts was found in the time from index date to the first lipid measure ($p=0.68$). The rates of lipid testing were lower among patients with RA compared to non-RA subjects, with 2209 lipid tests during 4454 person-years (0.50 per patient per year; 95% CI: 0.48, 0.52) in the patients with RA and 2780 lipid tests during 5119 person-years (0.54 per patient per year; 95% CI: 0.52, 0.56) in the non-RA subjects ($p<0.001$). Overall, patients with RA were less likely to receive lipid-lowering agents than non-RA subjects with 21% of RA and 28% of non RA subjects initiating lipid lowering therapy by 10 years($p=0.02$). The NCEP ATP III cardiovascular disease risk categories were similar in both cohorts ($p=0.48$). Among patients who met NCEP ATP III criteria for lipid lowering therapy during follow-up ($n=106$ RA and $n=120$ non-RA), there was no difference between patients with RA and non-RA in initiation of lipid lowering therapy (27% in RA vs 26% in non-RA, $p=0.36$). In the subset of subjects with LDL$\geq$160 mg/dl, there was no difference between RA and non-RA in initiation of lipid lowering therapy, with 24% of RA and 26% of non-RA patients initiating lipid-lowering agents within 2 years ($p=0.77$).

Conclusion: Patients with RA were less likely to receive lipid-lowering agents than non-RA subjects overall. However, among those who met NCEP ATP III criteria recommending initiation of lipid-lowering agents, the percentage of RA and non-RA patients who initiated lipid-lowering agents was similar. Substantial undertreatment occurred in both the RA and non-RA cohorts.

122

Quality of Care for Rheumatoid Arthritis and Osteoporosis: Results From the U.S. Medicare Physician Quality Reporting Program. Jeffrey R. Curtis[1], Pradeep Sharma[2], Tarun Arora[3], Aseem Bharat[3], Michael Morrisey, Kenneth G. Saag[3], Itara Barnes[5] and Elizabeth S. Delzell[3]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Atlanta, GA

Background/Purpose: Quality of care and pay for performance are an increasingly visible facet of medical care. In 2006, Medicare enacted the Physician Quality Reporting Initiative (PQRI) program that allowed physicians to report performance measures for osteoporosis; rheumatoid arthritis (RA) was added in 2008. The objective of this analysis was to describe the number of rheumatologists and other physician specialties participating in the PQRI program and to understand physician-reported reasons why recommended care for individual osteoporosis and RA patients was not provided.

Methods: Using the national random 5% sample of Medicare fee-for-service beneficiaries from 2007–2009, we identified all healthcare providers reporting on 1) PQRI Measure 41: percentage of patients with a physician diagnosis of osteoporosis who were prescribed an osteoporosis medication within 12 months (CPTII 4005F); and/or 2) Measure 108: percentage of RA patients prescribed a biologic or non-biologic DMARD (CPTII 4187F). Modifiers allowed physicians to report on circumstances where there were medical, patient-related, or other reasons why the recommended medications were not prescribed; multiple reasons were allowable.

Results: During 2007–2009, 1–3% of internal medicine and family physicians reported on prescription medication use for approximately 6,000 unique osteoporosis patients (measure 41); 10–12% of rheumatologists reported on this measure. For patients for whom their physicians reported the measure in 2009 ($n=5348$), 7.3% did not receive osteoporosis medication for medical reasons, 4.3% did not receive osteoporosis medication for patient reasons (e.g. refusal), and 15.4% of patients did not receive it for other reasons (e.g. cost). In total, 26% of osteoporosis patients who had their physician report measure 41 did not receive prescription medications due to a reason provided by the physician.

In 2008, a total of 177 (5.7%) out of 3078 rheumatologists reported on DMARD use for RA patients; the proportion of rheumatologists reporting on this measure increased in 2009 to 10.2%. Among unique RA patients in 2009 ($n=1765$), 13.3% of patients had their physician report a medical (6.9%) or other (6.7%) reason why they had not been prescribed a DMARD.

Conclusion: Through 2009, approximately 10% of U.S. rheumatologists were reporting on the quality of care for their rheumatoid arthritis and osteoporosis patients enrolled in Medicare. A substantial fraction of these patients had physician-documented reasons for why recommended care had not been provided. Health plans that report on quality of care that fail to provide a mechanism to allow physicians to provide reasons why care was not provided may misclassify up to 25% of patients for whom care is medically inappropriate, refused, or otherwise not feasible.

123

DMARD Underuse in the Medicare Current Beneficiary Survey: Evidence for Socioeconomic Disparities. Daniel H. Solomon[1], John Z. Ayanian[2], Bing Lu[3], M. Alan Brookhart[4], Sebastian Schneeweiss[5], Tamara Shaykevich[1] and Jeffrey N. Katz[1]. [1]Brigham & Womens Hospital, Boston, MA, [2]Brigham and Women's Hospital, [3]Brigham and Women's Hospital, Boston, MA, [4]University of North Carolina, [5]Harvard University, Boston, MA

Background/Purpose: There has been an increased appreciation for the importance of DMARDs for virtually all patients with RA. However, numerous studies have documented that many patients with RA do not appear to receive DMARDs. Our prior work has documented that there racial disparities in who receives DMARDs, but these studies have not examined the role of insurance, income, and education as possible correlates of racial disparities. The goal of these analyses was to determine if racial disparities in DMARD prescribing can be explained by insurance, income, and/or educational differences.

Methods: We examined DMARD use in the Medicare Current Beneficiary Survey (MCBS), a four-year longitudinal US national survey of randomly selected Medicare beneficiaries. This study included data from years 2001–2006. Participants in MCBS with at least one Medicare claim for RA plus a self-report of RA were included in the analyses. DMARD use was based on an in-home assessment of all medications. Variables considered as potential correlates of DMARD use in regression models included race/ethnicity, insurance, income, education, rheumatology visit, region, age, gender, comorbidity index, and calendar year. Because of the repeated measures of DMARD use, each year of follow-up was considered as a separate observation with adjustment for within subject correlation using generalized linear model applying a Generalized Estimating Equation approach.

Results: The cohort consisted of 513 MCBS participants with a mean age of 70 years, of which 72% were female. During follow-up, 42% received a DMARD. In fully adjusted analyses among the whole cohort, the strongest predictor of DMARD use was seeing a rheumatologist (see **Table**). In the total cohort, lower annual income was associated with a reduced probability of DMARD use. This was not observed in the cohort seen by rheumatologists. Among individual not seen by rheumatologists, Black non-Hispanics were much less likely to receive a DMARD (OR 0.16, 95% CI 0.03–0.98)

compared to white, non-Hispanics; this was not the case when these individuals were seen by rheumatologists (OR 0.89, 95% CI 0.12–6.62). Older age was associated with a reduced probability of DMARD use, especially in the cohort not seen by rheumatologists.

Table. Regression models predicting DMARD use in MCBS

Variables	Total Cohort	Among Subjects Without Rheumatology Visits	Among Subjects With Rheumatology Visits
	Odds Ratio (95% confidence interval)		
Age, years			
< 75	1.00	1.00	1.00

Rheumatology care	**7.74 (5.37–11.1)**	NA	NA

Notes: Bolded findings are statistically significant.NA, not applicable; Models adjusted for variables in the table plus education, region of residence (South, Midwest, Northeast, and West), insurance status (private, HMO, and drug insurance), comorbidity index, as well as year of observation.

Conclusion: We found that less than half of participants diagnosed with RA in MCBS used DMARDs. Among individuals not seeing rheumatologists, Black non-Hispanic ethnicity appears associated with a reduced probability of DMARD use, independent of income, insurance, and education. As has been the results of several other cohort studies, seeing a rheumatologist is the strongest predictor of DMARD use.

124

Patients Whose Global Estimates Are Higher Than Their Physician's Global Estimates Are More Likely to Be Female, Have Fewer Years of Formal Education, and Higher RAPID3 (Routine Assessment of Patient Index Data) Scores. Isabel Castrejón[1], Yusuf Yazici[2], Jonathan Samuels[1] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: To analyze levels of agreement of physician global estimates (DOCGL) with patient global estimates (PATGL), and characteristics of patients whose global estimates were higher than versus similar to versus lower than their physicians' global estimates, in patients with different rheumatic diseases, including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and osteoarthritis (OA), seen in usual care.

Methods: A database is maintained on all patients seen at an academic rheumatology clinical setting, which includes demographic, patient self-report MDHAQ (multidimensional health assessment questionnaire), medication, and laboratory data. Each patient completes an MDHAQ at each visit, to score physical function, pain, patient global estimate (PATGL), fatigue, anxiety, depression and quality of sleep. The MDHAQ also queries demographic data including gender, age and formal education level. RAPID3 (routine assessment of patient index data) is a composite index of physical function, pain and PATGL. A physician global estimate (DOCGL) is scored for each patient at each visit by the rheumatologist. One random visit of each patient between July 2005 and April 2011 was selected for analyses of the degree of possible agreement or discordance between PATGL (0–10 scale) and DOCGL (also 0–10). Mean DOCGL levels were classified into 3 groups: "PATGL>DOCGL" (PATGL 2 or more units greater than DOCGL); "PATGL=DOCGL" (differing by <2 units); and "DOCGL>PATGL" (DOCGL 2 or more units greater than PATGL). Analysis of variance (ANOVA) was used to compare differences in MHDAQ measures among the 3 groups.

Results: Overall, 980 patients were studied, including 145 with RA, 57 SLE, 173 OA and 605 with other rheumatic disease; 509 patients (52%) had PATGL=DOCGL (within 2 units on a 0–10 scale), 371 (38%) had PATGL>DOCGL (by 2 units or more), and 100 (10%) had DOCGL>PATGL (by 2 units or more). Patients with PATGL>DOCGL were significantly more likely to be female, have fewer years of formal education, and have higher scores for PATGL, MDHAQ-function, pain, fatigue, RAPID3, sleep, anxiety, depression, and RADAI. Similar, but not identical, patterns were seen in patients with RA, comparable to a published report [Barton JL et al, Arthritis Care Res 2010;62: 857–64].

Table 1. Mean of measures according to comparison of estimate of global status by the physician (DOCGL) and patient (PATGL).

	All Patients N=980	DOCGL>PATGL N=100	PATGL=DOCGL N=509	PATGL>DOCGL N=371	*p*
Age, mean (years)	50.2	51.7	49.3	51.3	0.10
Gender (% female)	68%	64%	64%	74%	0.001
Education (years)	15.5	16.3	15.7	15.0	0.002
DOCGL (0–10)	2.6	4.0	2.5	2.5	<0.001
PATGL (0–10)	4.1	1.2	2.7	6.8	<0.001
MDHAQ-function (0–10)	1.8	1.0	1.3	2.6	<0.001
MDHAQ-pain (0–10)	4.4	3.1	3.3	6.4	<0.001
MDHAQ-fatigue (0–10)	4.0	1.7	3.0	6.0	<0.001
RAPID3 (0–30)	10.3	5.2	7.4	15.7	<0.001
Get a good sleep (0–3)	0.94	0.59	0.80	1.24	<0.001
Anxiety (0–3)	0.58	0.34	0.49	0.76	<0.001
Depression (0–3)	0.48	0.30	0.37	0.70	<0.001
RADAI (0–48)	7.5	4.2	5.7	11.2	<0.001

Conclusion: Among 980 patients, 38% scored global estimates of at least 2 units higher than their physicians' global estimates. These patients were more likely to be female and have higher scores for all MDHAQ components, including depression and anxiety, and a lower formal education level, compared with patients whose physicians estimated global status similarly or worse than the patients' global estimates.

What Factors Affect Discordance Between Physicians and Patients in Assessments of Global Health in Rheumatoid Arthritis? Soo-Kyung Cho[1], Yoon-Kyoung Sung[1], So-Yeon Park[1], Jeeseon Shim[2], Chan-Bum Choi[3], Hoon-Suk Cha[4], Jung-Yoon Choe[5], Won-Tae Chung[6], Jae Bum Jun[7], Tae-Hwan Kim[8], Tae-Jong Kim[9], Eun-Mi Koh[4], Jisoo Lee[10], Shin-Seok Lee[9], Sung Hoon Park[5], Wan-sik Uhm[7], Dae-Hyun Yoo[8], Bo Young Yoon[11], Sang-Cheol Bae[1] and KORONA investigators[12]. [1]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [3]Hanyang University Hospital for Rheumatic Disease, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [5]Catholic University of Daegu School of Medicine, Daegu, South Korea, [6]Dong-A University, Busan, South Korea, [7]Hanyang University Hospital for Rheumatic Disease, Seoul, South Korea, [8]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [9]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [10]Ewha Womans University Mokdong Hospital, Seoul, South Korea, [11]Inje University Ilsan Paik Hospital, Goyang, South Korea, [12]Seoul, South Korea

Background/Purpose: The agreement of global health (GH) status between patient's reports and physician's assessments is essential to the safe and effective management of rheumatoid arthritis (RA) and improves outcomes. Our study aimed to identify the agreement between patient and physician in assessment of GH and explore influencing factors of discordance between them.

Methods: Total of 3,169 patients with RA were recruited from KORean Observational study Network for Arthritis (KORONA), a database generated by rheumatologist investigators across the Korea. Patients were divided into three subgroups according to their agreement between physician visual analogue scale (VAS) and patients VAS. We defined three groups as positive discordance (≥25mm), concordance (< 25 mm), negative discordance (≤−25) according to difference between patient VAS and physician VAS. The means ± SD of its difference were 43.26 ± 13.69, 1.44 ± 12.26 and −37.11 ± 11.08 in each group. Among them, 2,523 patients were enrolled to evaluate factors influencing on positive discordance. On univariate analysis, we identified association factors for positive discordance group. Then multivariable logistic regression analysis was used to identify predictors of positive discordance.

Results: Of the subjects, 1,901 patients (60.0%) were concordance group

and 225 patients (7.1%), 1,036 patients (32.7%) were negative discordance, positive discordance, respectively. Factors associated with positive discordance were female gender, disease activity, disease duration, comorbid with hypertension (HTN) and gastrointestinal (GI) disease, visual analogue scale (VAS) of fatigue and sleep disturbance in univariate analysis. Multivariable analysis demonstrated comobidity with HTN (OR=1.25, CI 1.01~1.55), comorbidity with GI disease (OR=1.54, CI 1.25~1.89), higher disease activity (OR=2.38, CI 1.75~3.24), higher fatigue VAS (OR=2.41, CI 1.99~2.92), and sleep disturbance VAS (OR=1.56, CI 1.26~1.92) affected on positive discordance. Patients were stratified according to disease activity. In patients with remission or low disease activity, age ≥60 was a protective factor on positive discordance. In moderate or high disease activity group, comorbid with HTN or GI dz. and disease duration of ≥10 were factors influencing on positive discordance.

Conclusion: About 32.7% patients thought their disease more severe than their doctors. Higher disease activity, comorbid with HTN and GI disease, fatigue and sleep disturbance were important factors on discordance between patient and physician.

Relative Effectiveness of Rituximab and An Alternative TNF Inhibitor in Patients with Rheumatoid Arthritis and An Inadequate Response to a Single Previous TNF Inhibitor: Interim Results From Switch-Rheumatoid Arthritis a Global Comparative-Effectiveness Observational Study. Paul Emery[1], Piercarlo Sarzi-Puttini[2], Robert J. Moots[3], Alexandros A. Andrianakos[4], Thomas P. Sheeran[5], Denis Choquette[6], Axel Finckh[7], Marie-Laetitia Desjuzeur[8], Eric Gemmen[9], Chiedzo Mpofu[8] and Jacques-Eric Gottenberg[10]. [1]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [2]L Sacco University Hospital, Milano, Italy, [3]University of Liverpool, Liverpool, United Kingdom, [4]Hellenic Foundation for Rheumatological Research, Athens, Greece, [5]Cannock Chase Hospital, Cannock, United Kingdom, [6]University of Montreal, Notre-dame Hospital, Montreal, QC, [7]University Hospital of Geneva, Geneva, Switzerland, [8]F. Hoffman-La Roche Ltd, Basel, Switzerland, [9]Quintiles Inc, Rockville, MD, [10]CHU Strasbourg, Strasbourg, France

Background/Purpose: A recent longitudinal cohort study suggested that after an inadequate response to a tumor necrosis factor inhibitor (TNFi), switching to rituximab (RTX) may be more effective than switching to an alternative TNFi.[1] The current study prospectively evaluated the relative effectiveness of RTX vs an alternative TNFi in rheumatoid arthritis (RA) patients with an insufficient response or intolerance to a single previous TNFi in routine clinical practice.

Methods: This is an interim analysis on an ongoing global, multicenter, prospective, observational study in patients with RA who were prescribed RTX or an alternative TNFi following the first TNFi failure. Propensity scores were generated for each patient to reflect the conditional probability of receiving treatment with RTX vs an alternative TNFi. 6-month changes in clinical variables (DAS28-ESR and ESR) following the initiation of the new therapy were compared in the two treatment groups using analysis of covariance; these analyses controlled for baseline value, propensity score, and other covariates found to be statistically different between the two groups at baseline.

Results: Data are presented for 1082 patients enrolled and 660 patients completing 6 months as of Feb 2011 in 9 countries. The 592 RTX and the 490 alternative TNFi patients had a mean (SD) age of 56.4 (12.46) and 54.4 (13.70) yrs, respectively; mean (SD) disease duration 8.9 (7.87) and 7.8 (6.60) yrs; female 77.4% and 80.6%; mean (SD) duration of all previous TNFi therapy 25.2 (25.4) and 25.4 (26.7) months. At the start of the new therapy, mean (SD) DAS28-ESR was significantly higher ($p<0.0001$) in the RTX group (5.57 [1.33]; n=385) vs the alternative TNFi group (4.97 [1.38]; n=272). At 6 months, there was a significantly greater decrease in DAS28-ESR in RTX patients (n=277) than in alternative TNFi patients (n=203): mean improvement at 6 months −1.6 vs −1.2; p=0.047. In addition, there was a significantly greater decrease in ESR (−15.4 vs −9.7; p=0.0219) in the RTX group vs the alternative TNFi group and numerically better results for the other DAS28 components (joint counts, global disease activity assessment).

Conclusion: Following discontinuation of a first TNFi, patients starting treatment with RTX achieved significantly better efficacy at 6 months as measured by DAS28-ESR compared with patients switching to an alternative TNFi.

Direct and Indirect Effects of Disease Activity on Functional disability in Rheumatoid Arthritis Patients Over Time and the Effect of Increasing Intensive Treatments: Results From Early Utrecht Rheumatoid Arthritis Cohort Study Group. Sandhya C. Nair, P.M.J. Welsing, F.P.J.G. Lafeber and J.W.J. Bijlsma. University Medical Center Utrecht, Utrecht, Netherlands

Background/Purpose: Disease activity influences functional disability in Rheumatiod Arthritis (RA). This influence theoretically constitutes a direct effect (due to current disease activity) and an indirect effect through the effect on joint damage of disease activity over time. It has been found that the direct relation between disease activity and functional disability becomes weaker with higher disease duration, but it has been questioned whether this still is the case with current intensive treatment (1,2). The indirect effect of disease activity on functional disability has not been studied extensively. It is important to understand the relations between these important outcomes and the effect of treatment strategy for the interpretation of disease activity in current tight control treatment strategies. Also with simulation of the progression of the disease in modeling studies as often performed within increasingly performed health-economic studies these relations should be taken into account. The objective of this study was to explore the relation of disease activity with functional disability over time considering indirect and direct associations and also the influence of treatment strategy on these relations.

Methods: Data from consecutive randomized clinical trials and their extension phases performed within the Early Utrecht Rheumatoid Arthritis Cohort study group studying increasing intensive treatment strategies were used. Functional capacity was measured using the HAQ and disease activity with the Disease Activity Score 28 (DAS28) every 12 months. Linear mixed models were used to model the longitudinal relation of DAS28 (current and lagged DAS28) and other variables on functional disability of patients over time. To investigate if the influence of variables changed over time interaction terms were tested in the model. Effect modification by treatment strategy was also studied in the model and in subgroup analyses.

Results: Current DAS28 was as expected positively longitudinally associated with HAQ. Lagged DAS28 was independently associated with HAQ. The longitudinal relation of DAS28 with HAQ decreased over disease duration. Remarkably the longitudinal relation of lagged DAS28 with HAQ increased over disease duration. Both were independent of treatment strategy. Although similar relationships between disease activity and functional disability was observed, HAQ progression was lowest in the high intensity treatment group as compared to low intensity treatment group ($\beta=-0.12$, $p=0.002$).

Conclusion: More intensive combination treatment strategies improve the long-term progression of functional disability. Although the longitudinal relation of disease activity with functional disability decreases the influence of lagged disease activity with functional disability increases with disease duration. This further underpins the importance of disease activity as a treatment target for RA early as well as later in the disease course. These results should be confirmed and be taken into account in studies modeling the progression of RA.

Rheumatoid Arthritis Continues to Improve in the New Millennium Whilst Use of Medication Change. Findings From a Representative Rheumatoid Arthritis Register Over 15 Years. Cathrine Austad, Tore K. Kvien and Till Uhlig. Diakonhjemmet Hospital, Oslo, Norway

Background/Purpose: During recent years and especially in the new millennium disease severity in patients with rheumatoid arthritis (RA) has been reported improved. It is important to retrieve such information from population based studies and to identify trends over time for this improvement. Purpose: To explore whether observed improved RA severity as measured by patient reported outcomes (PROs) improves over a perspective of 15 years and in the most recent years after introduction of biologic therapies.

Methods: In a population based registry of RA, 868 patients aged 20–79 years (mean (SD) age 59.9 (12.3) years, disease duration 13.0 (10.8) years, 77.1% females, 57.0 % RF+ or CCP+) responded in 2009 to a mailed questionnaire (response rate 60.6%). The PROs included pain, fatigue and patient global assessment of disease impact on 100 mm visual analogue scales, modified HAQ, SF-36 (with calculation of physical (PCS) and mental component summary (MCS) (low scores=poor health),

and SF-6D derived utility). Patients reported use of medications including disease modifying anti-rheumatic drugs (DMARDs).

Results are given with means and 95% confidence intervals (CI), and were compared with outcomes from previous cross-sectional health status surveys using the same instruments in 1994, 1996, 2001, and 2004. Comparisons across these cross-sectional data collections can be performed since the respondents are considered representative for the entire RA population in the geographic area [1]. Non-overlapping CI of a PRO at different time points was considered to represent a true difference. Subanalyses were performed to investigate differences in gender, disease duration ≤ or > 10 years and current use/non-use of DMARDs.

Results: Age, gender and disease duration were similar at all examination points. Use of DMARDs increased from 36.4% in 1994 to 59.6% in 2009, both overall and for genders separately. DMARD users were statistically significant younger than non-users, data not included, with gender distribution equal that of the registry. In 2009 20% of patients used a biological DMARD. A consistent improvement in health status was observed from 1994 to 2009, except for mental health (see table). MHAQ and SF-36 PCS demonstrated a clear improvement from 2004 to 2009. Mean improvements from 1994 to 2009 were in the magnitude of what is considered as minimum clinically important.

Fatigue (0–100)	50.0 (48.2; 51.8)	44.1 (42.3; 45.9)*	46.9 (44.9; 48.9)	46.1 (44.2; 48.1)	44.7 (42.8; 46.6)

* non-overlapping 95% CI with ≥1 other measure

Conclusion: The improvement in physical health and utility observed in 1994–2004 continued until 2009. Improvements were seen in both genders, with short and long disease duration, and independently of DMARD use. RA patients during the last 15 years had consistently reduced disability and better overall health and utility score, indicating that recent investments in health care for patients with RA are justified.

Perceived Benefits of Intravenous Biologic Therapy Among Patients with Rheumatoid Arthritis. Susan Bolge, Julie Vanderpoel, Helen Eldridge, Samir Mody and Mike Ingham. Janssen Services, LLC, Horsham, PA

Background/Purpose: Currently two modes of administration are available for biologic therapies used to treat rheumatoid arthritis (RA): intravenous infusion (IV) and subcutaneous injection (SQ). Patient preference for mode of administration may be one of many factors influencing choice of biologic therapy. The purpose of the study was to identify perceived benefits of IV biologic therapy among patients with RA who are currently treated with an IV biologic medication.

Methods: In August to September 2010, 209 patients self-reporting a diagnosis of RA and currently receiving IV biologic therapy participated in semi-structured telephone interviews about their experience with IV therapy. Study protocol and questionnaire were approved by an independent institutional review board (IRB). Patients rated their level of satisfaction with their current IV medication on a 7-point Likert scale, where 1=not at all satisfied and 7=very satisfied. Patients were asked to allocate $100 (U.S.) across six features of IV administration and services. Patients also discussed reasons for IV preference.

Results: Mean satisfaction was 6.2 out of 7, and 79% rated satisfaction as a 6 or 7. A mean of $31 out of $100 was allocated to the value of receiving treatment in a healthcare facility where healthcare professionals can assess and monitor the patient. Also highly valued were having a healthcare professional administer medication ($24) and infrequent dosing ($21). Of current IV users, most (83%, n=174) prefer an IV medication to a SQ. The most common reasons for IV preference are not wanting to give self-injections or not liking needles (41%), less frequent dosing (35%), and preference for healthcare professional administration (26%). Additional sub-analyses demonstrated that these results varied by demographics and factors related to treatment.

Conclusion: Patients with RA currently using IV biologic therapy are highly satisfied with their medication. Patients perceive the additional opportunity for healthcare provider interaction at infusion facilities as a benefit of this mode of administration. These results support the need for continued patient access to IV therapeutic options and shared decision-making between patients and physicians when selecting biologic treatment.

The Effect of Arthritis Self Management Program on Outcome in African-Americans with Rheumatoid Arthritis Served by a Public Hospital. Athan N. Tiliakos[1], Yi Pan[2], Kirk Easley[3], Steven D. Culler[2] and Doyt L. Conn[1]. [1]Emory Univ School of Medicine, Atlanta, GA, [2]Emory University-Rollins School of Public Health, [3]Emory University-Rollins School of Public Health, Atlanta, GA

Background/Purpose: Rheumatoid Arthritis (RA) affects poor people and minority patients more adversely than those who are more economically advantaged and Caucasians. Economically disadvantaged patients have more active disease, more disability, and lower functional status at the presentation of RA. The Arthritis Self Management Program (ASMP) is recognized as an important tool in the management of RA. The purpose of this study was to determine the effect of ASMP on a cohort of RA patients (mostly African-American) served by Grady Memorial Hospital.

Methods: 104 patients with definite RA (based on the 1987 ACR Criteria,) recruited from the rheumatology clinic of Grady Memorial Hospital, were randomized to participate in ASMP versus usual care alone, and were followed for 18 months. The 2 groups were compared with regard to disease activity, functional status, and utilization of health resources. This information was collected at baseline, and at 6, 12, and 18 months. The primary endpoint was clinical improvement, as indicated by the ACR 20.

Results: The percentage of patients achieving ACR 20 was similar in the ASMP (14% at 18 months) and usual care (17% at 18 months) groups (p=0.3.) However, 28% of the 25 ASMP patients who attended at least 4 classes, achieved ACR 20, whereas 5% of the 27 ASMP patients who attended fewer than 4 classes, were able to achieve ACR 20 (p=0.02.) There was a reduction in the total number of tender and swollen joints in both groups throughout the duration of the study, particularly in patient over 60 years of age. At each visit, one third of the patients were not taking their prescribed medications. Influencing adherence was poverty and lack of insurance. There was no difference in healthcare utilization between the two groups.

Conclusion: Although all patients had improvement in the total number of painful and swollen joints, those who attended at least 4 ASMP classes were more likely to achieve ACR 20. ASMP may provide clinical benefit in RA patients served by a Public Hospital. Adherence may be limited by economic and social factors

131

Effort-Reward Imbalance in Patients with Rheumatoid Arthritis? Jutta G. Richter, Thomas Muth, Birthe Koerbl, Nicole Hoffmann, Tobias Koch, Johannes Siegrist and Matthias Schneider. Heinrich-Heine-University, Duesseldorf, Germany

Background/Purpose: Working life factors influence patients' (life) satisfaction and their well being. Effort at work is spent as part of a 'social contract' that reciprocates effort by adequate reward. Components of work-related rewards have been shown to matter for health. Research on effort-reward imbalance (ERI) might contribute to the understanding of social and psychological factors related to the well-being of patients (pts) with rheumatoid arthritis (RA). We studied psychosocial stress levels at work measured by the ERI model.

Methods: Within a cross sectional nationwide study a set of standardized self-administered questionnaires was applied to RA pts. The ERI questionnaire assessed the effort-reward imbalance in RA pts capable for work. Effort-reward ratio (ERR) scores > 1 and the upper tertile scores of overcommitment (OCS) reflect relevant values. Data were analyzed in comparison to controls (c) not suffering from a rheumatic disease and recruited by the pts. Ethics committee approval had been obtained.

Results: 275 pts (85.1% female (f)) and 178 c (90.8%f) answered the questionnaire. Pts' mean age was 47.5±10.1 (c 42.8±9.8) years, mean disease duration (dd) 9.1±8.1 years, 83.6% self-reported at least one comorbidity (range 0–8). 74.5% received at least one disease modifying medication (DMARD, range 0–6). 44.0% were on steroids ≤7.5mg, 8.7% on steroids >7.5mg. 60.7% took NSAIDS. Occupational status and self-categorized occupation groups (scog) did not significantly differ between pts and c.

74.5% of the pts (C 5.4%;$p<0.01$) showed an ERR>1, this was consistent in f and male (m) pts ($p>0.05$), see table 1. Age, dd, functional capacity (fc), number of DMARDs, steroid dosages, education, marital status and scog did not significantly differ to those with ERR≤1. In contrast to fulltime (82.1%) or sporadically employed (81.8%), part time employees had significantly less ERR>1 (63.1%,$p<0.05$).

Table 1. Effort&reward and overcommitment scores, ERR>1 and OCS upper tertile in pts and c

	Effort mean±SD	Reward mean±SD	ERR>1 %	Overcommittment mean±SD	OCS upper tertile %
Pts	15.8±5.3	23.5±11.1	74.5	13.9±3.9	33.7
F pts	15.8±5.4	23.7±11.3	74.4	13.9±3.9	34.5
M pts	15.7±4.5	22.1±9.5	75.0	13.7±3.7	29.3
Controls	14.2±4.1	46.8±6.6	5.4	12.8±3.9	25.2
F c	14.0±4.0	47.0±6.5	4.1	12.6±3.8	23.2
M c	16.9±3.9	43.8±7.4	18.8	14.3±4.1	43.8

OCS showed relevant values in 33.7% pts (f 34.5%,m 29.3%; c 25.2% (both $p>0.05$). Age, dd, number of DMARDs, steroid dosages, education, marital status, and scog were not significantly different to those with OCS in lower tertiles. Fc was significantly lower in pts with relevant overcommitment.

Conclusion: This is the first study investigating the ERI in RA pts. Compared to controls a significantly higher proportion of pts reported a relevant ERI. Analysis on direct and indirect mechanisms potentially involved in the relation between psychosocial work characteristics and RA need further evaluations. However, although no cause and effect relationship can be established a reduction of stressful experiences in the framework of the worksites for RA pts seems reasonable.

Who Are the Patients with Early Arthritis Who Score States "worse Than death" on the EQ-5D? Results From the ESPOIR Cohort. Cécile Gaujoux-Viala[1], Bruno Fautrel[2], Francis Guillemin[3], René-Marc Flipo[4], Patrice Fardellone[5], Pierre Bourgeois[2] and Anne-Christine Rat[3]. [1]1 Nancy-University, Paul Verlaine Metz University, Paris Descartes University, EA 4360 Apemac, Nancy, France, 2 Paris 6 – Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France, [2]Université Pierre et Marie Curie - Paris 6 - Pitie Salpetriere University Hospital, Paris, France, [3]Nancy-University, Paul Verlaine Metz University, Paris Descartes University, EA 4360 Apemac CHU Nancy, Epidémiologie et Evaluation Cliniques, Nancy, France, [4]Rheumatology Department, Lille University Hospital, Lille, France, [5]C.H.U. D'Amiens, Amiens, France

Background/Purpose: Indirect utility measures are increasingly used to assess health benefits in RCTs and to estimate Quality-adjusted life-years (QALYs) gain in cost-effectiveness models. The EQ-5D is a 5-dimensional multi-attribute questionnaire widely used to calculate QALY. It allows negative utility values which theoretically correspond to health state "worse than death".

Objectives: To analyse the patients with EQ-5D <0 ie in states worse than death and to investigate their health status in a large multicenter prospective cohort of patients with EA.

Methods: EQ-5D measures were longitudinally assessed in 813 patients with EA. Clinical outcomes and laboratory measures were also recorded. The characteristics and health status of patients with an EQ-5D<0 were analyzed. Multivariate logistic regression was used to determine which specific aspects of early arthritis were independently associated with states worse than death.

Results: At baseline, 90 (11%) patients were in states worse than death. Mean EQ-5D values were −0.095±0.106 (range −0.594 to −0.003). Patients occupied 16 of the possible 84 health profiles with negative scores, with extreme pain/discomfort being the common characteristic of all these states. Concerning other domains, 40% of patients reporting severe anxiety/depression, 19% severe problems in usual activities, 8% severe problems in self-care, and 3% severe problems in mobility. All patients had at least moderate problems in anxiety/depression domain. Patients with negative EQ-5D scores had higher disease activity, higher HAQ score, more pain, more fatigue, lower mental component of the SF-36 and higher CRP than patients with EQ-5D>=0 (all $p<0.0001$). In the logistic regression model, increasing HAQ score and decreasing mental component of the SF-36 were associated with negative EQ-5D scores (Table). Results were similar at 6 and 12 months with 26 and 24 patients in states worse than death respectively.

Table. Determinants of being in state worse than death

Baseline Variable	EQ5D<0 N=90 (mean± SD)	EQ5D>0 N=723 (mean± SD)	OR [95%CI]
HAQ	1.98 ± 0.44	0.81 ± 0.60	21.3 [10.1;45.1]
Mental component of the SF36	28.2 ± 8.4	39.9 ± 10.6	0.92 [0.89;0.95]
Fatigue	68.3 ± 19.9	45.0 ± 28.0	1.01 [0.99;1.03]
DAS28	6.3 ± 1.2	4.9 ± 1.2	1.15 [0.86;1.54]
Pain	51.1 ± 28.9	35.4 ± 26.9	0.99 [0.98;1.01]

Conclusion: Pain/discomfort was the key domain leading to a state worse than death, scored at the most extreme level in every worse than death EQ-5D profile occupied by the early arthritis patients. In multivariate analysis HAQ and mental component of the SF36 were always associated with state worse than death. Early arthritis patients have specific needs necessitating better management of pain and anxiety.

An Overview of Health Technology Assessments for Rheumatoid Arthritis Biologics. Floortje Van Nooten[1], Kavita Gajria[2] and Karin Coyne[3]. [1]United Bioscience Corporation, London, United Kingdom, [2]MedImmune LLC, Gaithersburg, MD, [3]United Bioscience Corporation, Bethesda, MD

Background/Purpose: Health Technology Assessments (HTAs) often form the basis for reimbursement decisions and can include medical, economic, social, and ethical implications. The objective of this study was to establish the information assessed, reasons for rejection or restriction, and critiques provided by HTA agencies.

Methods: HTAs for rheumatoid arthritis biologics were searched in Australia, Canada, Germany, Italy, France, the Netherlands, Sweden, the United Kingdom, and the United States. Assessments were included if they contained clinical and health economic information.

Results: Of the 70 HTAs found, 31 were included in this assessment. Twenty-six were single technology assessments (STAs) and 5 were multiple technology assessments (MTAs). No assessments were found for Italy, Germany, France, or the United States. Clinical endpoints included in the STAs were American College of Rheumatology (ACR) scores, Disease Activity Score (DAS)-28, Health Assessment Questionnaire-Disability Index (HAQ-DI), Short Form-36, Sharp score, tender joint count, swollen joint count, proportion of European League Against Rheumatism (EULAR) responders, and Functional Assessment of Chronic Illness Therapy-Fatigue. Comparators were usually other biologics. Economic models included patient level simulation, cost minimization, stepwise, and Markov models. MTAs and STAs were similar in terms of clinical endpoints, models, and comparators. Economic analyses were usually based on cost per quality-adjusted life-years (QALY), with the exception of a Canadian HTA that included cost per ACR-50 response. Decisions for reimbursement varied depending on country-specific requirements. The most common reason for rejection was lack of optimal clinical effectiveness evidence. Additionally, a lack of evidence describing the relative benefit of a new agent against an established standard of care in the standard target population was noted. Criticisms identified by HTA agencies were a need for strong evidentiary support in indirect comparisons, target population not represented in the trial data submitted, preference for country-specific utilities over mapping utilities with HAQ-DI or DAS-28, and cost-effectiveness models not reflective of current medical practice.

Conclusion: Future HTA submissions need to provide clear evidence of clinical effectiveness in the appropriate target population and against established standards of care. Economic models that are reflective of current medical practice, including the use of appropriate comparators, consideration of direct measurement of utilities with an evaluation of time horizon that is 5 years and beyond, and measurement of outcomes using cost-per-QALY approaches, may be more successful with HTA agencies.

Validation of Diagnostic and Procedural Codes for Identification of Incident Cardiovascular Disease in Subjects with Rheumatoid Arthritis.

Lisa A. Davis[1], Grant W. Cannon[2], Andreas M. Reimold[3], Gail S. Kerr[4], Ted R. Mikuls[5] and Liron Caplan[6]. [1]Univ of Colorado School of Med, Aurora, CO, [2]Salt Lake City VA and University of Utah, Salt Lake City, UT, [3]Dallas VA and University of Texas Southwestern, Dallas, TX, [4]Washington DC VA and Georgetown University, Washington, DC, [5]Omaha VA and University of Nebraska, Omaha, NE, [6]Denver VA and University of Colorado, Aurora, CO

Background/Purpose: The use of International Classification of Diseases, Clinical Modification, Ninth Revision (ICD-9-CM) and Current Procedural Terminology (CPT) codes can be helpful in performing health services research, implementing clinical guidelines, and monitoring health care utilization. However, the accuracy of cardiovascular (CV) event-relevant codes has not been adequately validated for the purpose of identifying incident rather than prevalent CV disease. We examined a population at risk for CV disease (elderly subjects with rheumatoid arthritis) in order to assess the validity of these codes.

Methods: Subjects who are enrolled in the Veterans Affairs Rheumatoid Arthritis (VARA) prospective registry were included if their records in either the inpatient or outpatient treatment administrative databases contained a "primary/reason for visit" ICD-9-CM diagnosis code, ICD-9-procedure code, or CPT code relating to myocardial infarction (MI), stroke, coronary artery bypass graft (CABG) surgery, or percutaneous coronary intervention (PCI). For convenience, we limited this study to the Dallas, Omaha, and Denver VA sites. This coding was compared with a gold standard case definition for CV events, determined by medical record review using a structured chart abstraction instrument for incident MI, stroke, PCI, and CABG within a 3 month window of the code being assessed. The positive predictive value (PPV) was calculated for each of the included codes, and any individual diagnostic or procedural code with a PPV >60% was included in a composite coding algorithm for each clinical condition.

Results: We evaluated 158 instances of 21 codes. PPV for the codes for incident disease/procedures varied between 0–100% (see Table). Composite coding algorithms resulted in PPV values ranging from 72–100%. No false positive cases were identified for any of the CABG and PCI procedure codes (33 instances examined).

Table. Positive predictive values for incident cardiovascular event codes

Event	Code	TP (n)	FP (n)	PPV	95% CI	
Acute MI ICD-9-CM						
	410.x	12	3	0.80	0.52	0.96
	411.x	3	4	0.43	0.10	0.82
	412.x	1	8	0.11	0.00	0.48
	413.x	6	4	0.60	0.26	0.88
	414.x	3	19	0.14	0.03	0.35
	429.2	0	4	0.00	0.00	0.60
	v45.81	0	10	0.00	0.00	0.31
Composite MI (410.x, 413.x)		18	7	0.72	0.51	0.88
Stroke ICD-9-CM						
	433.11	1	1	0.50	0.01	0.99
	433.91	0	1	0.00	0.00	0.98
	434.91	9	0	1.00	0.66	1.00
	435.x	5	5	0.50	0.19	0.81
	436.x	3	11	0.21	0.05	0.51
	437.9x	0	2	0.00	0.00	0.84
	438.x	5	5	0.50	0.19	0.81
Composite Stroke(434.91)		9	0	1.00	0.66	1.00
CABG ICD-9-CM procedure						
	36.1x	10	0	1.00	0.69	1.00
PCI						
ICD-9-CM procedure		**20**	**0**	1.00	0.83	1.00
	36.06	1	0	1.00	0.25	1.00
	36.07	10	0	1.00	0.69	1.00
	0.66	9	0	1.00	0.66	1.00
CPT		**3**	**0**	1.00	0.29	1.00
	929.73	1	0	1.00	0.25	1.00
	929.8	1	0	1.00	0.25	1.00
	929.95	1	0	1.00	0.25	1.00
Composite PCI (all codes)		23	0	1.00	0.85	1.00

Key: TP= true positives; FP=false positives; PPV=positive predictive values; 95% CI=95% confidence interval; Acute MI=acute myocardial infarction; CABG=coronary artery bypass graft; PCI=percutaneous coronary intervention; CPT= Current Procedural Terminology; ICD-9-CM International Classification of Diseases, Clinical Modification, Ninth Revision

Conclusion: Validation of diagnostic and procedural codes allows for identification of incident rather than prevalent CV disease in RA patients. Proposed composite algorithms demonstrate improvements over prior attempts to validate diagnostic and procedural codes for this purpose and will lead to the improved detection of incident CV events in RA patients. The ability to detect incident CV events using trustworthy codes may further efforts in health services research, guideline implementation, and health care utilization.

The 2010 Rheumatoid Arthritis Criteria Versus the 1987 Rheumatoid Arthritis Criteria: Will the Real Criteria Please Stand up!

Aarat M. Patel[1], Christine L. Amity[2], Lynne M. Frydrych[2], Derek Sippel[2], Donald Jones[2], Danielle Goudeau[2], Heather Eng[3], David Kyle[3], Melissa Saul[3], Daniel Hal Solomon[4], Stephen R. Wisniewski[3], Larry W. Moreland[5] and Marc C. Levesque[2]. [1]Univ of Pittsburgh Med Ctr/Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]Univ of Pittsburgh, Pittsburgh, PA, [4]Brigham & Womens Hospital, Boston, MA, [5]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: The 1987 American College of Rheumatology (ACR) classification criteria for Rheumatoid Arthritis (RA) was revised in 2010 by the ACR/European League Against Rheumatism (EULAR) to identify patients with earlier disease and to incorporate anti-cyclic citrullinated peptide (anti-CCP) results. Our aim was to evaluate the usefulness of the 2010 ACR/EULAR RA classification criteria for identification of RA in a large cross-sectional cohort and to determine the characteristics of those that do not fulfill the new criteria.

Methods: We conducted an analysis of the Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry (N=606) to determine whether subjects met the 1987 and/or 2010 RA classification criteria. Subjects enrolled in RACER have RA based on the judgment of a treating physician and a second reviewer. Clinical data from the registry including age, sex, race, disease duration, disease activity score-28 joint count (DAS28), clinical disease activity index (CDAI), and laboratory measures (C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), rheumatoid factor (RF), and anti-CCP) were compared between groups. All variables of each criterion were compared for differences between groups. Statistical analysis was performed with Kruskal-Wallis and Pearson Chi-Square tests.

Results: The majority of RACER subjects met both classification criteria (88.3%) (see Table). The rest met either "1987 only" (4.6%), "2010 only" (4.5%), or neither criteria (1.8%). There were no significant differences between groups in demographics, disease activity (DAS28 and CDAI) and CRP but there were marked differences in disease duration, ESR, RF, and anti-CCP. There were significant differences between the "1987 only" and "2010 only" groups in morning stiffness (85% vs 7%; p=0.0120), having >10 joints affected (0% vs 52%; p<0.0001) and anti-CCP positivity (9% vs 58%; p<0.0001).

Table 1. Group Comparison of Each Domain of the 1987 and 2010 Rheumatoid Arthritis Criteria in RACER subjects (n=606)

	Patients meeting 1987 and 2010 criteria (n=535)	Patients meeting 1987 criteria only (n=33)	Patients meeting 2010 criteria only (n=27)	Patients meeting Neither criteria (n=11)	*P* value
RF, Positive	92%	25%	15%	36%	<0.0001
Mean ±SD	285.1 ± 663.4	13.54 ± 13.2	13.0 ± 13.2	23.3 ± 31.3	<0.0001
Median	84	5	5	5	
CCP, Positive	83%	9%	58%	27%	<0.0001
Mean ±SD	235.9 ± 382.2	3.6 ± 4.8	110.2 ± 218.4	27.7 ± 74.1	<0.0001
Median	100	2	13.5	2	
ESR, Abnormal	59%	32%	39%	20%	0.003
Mean ±SD	38.7 ± 29.8	24.3 ± 26.5	27.8 ± 32.8	23.8 ± 32.6	0.002
Median	33	16	11	12	
CRP, Abnormal	55%	48%	48%	45%	0.73
Mean ±SD	2.56 ± 4.71	1.23 ± 1.8	1.32 ± 2.09	1.24 ± 1.58	0.04
Median	0.90	0.64	0.45	0.70	
2010,1 large joint	64%	64%	59%	64%	0.978
2–10 large joints	59%	61%	52%	73%	0.691
1–3 small joints	100%	100%	93%	73%	<0.0001
4–10 small joints	85%	85%	74%	45%	0.003
>10 joints	38%	0%	52%	0%	<0.0001
≥6 weeks	99%	100%	100%	91%	0.154
1987,≥3 joints	99%	100%	89%	82%	<0.0001
Hand arthritis	99%	97%	89%	55%	<0.0001
Symmetric	98%	100%	85%	73%	<0.0001
Morn.stiffness	37%	85%	7%	27%	0.012
Nodules	14%	0%	0%	0%	<0.0001
Rad. changes	38%	27%	4%	0%	<0.0001

RACER: Rheumatoid Arthritis Comparative Effectiveness Research; SD: standard deviation; RF: rheumatoid factor (IU/ml); CCP: Anti-cyclic citrullinated protein antibody (EU); ESR: erythrocyte sedimentation rate (mm/hr); CRP: C-reactive protein (mg/dL)

Conclusion: Our patients represent a "real world" RA cohort with a wide-range of disease duration and variable disease activity. Patients not fulfilling the 2010 criteria tended to have a low number of joints affected and seronegative disease. The differences between groups are due to the individual features of each

criterion as some domains (morning stiffness, markers of longer disease duration (nodules and x-ray changes)) are not captured in the 2010 criteria and likewise some features are not captured in the 1987 criteria (anti-CCP). Our results support the idea that studies should consider using both criteria since a subset of patients with what would be defined as RA using the 1987 criteria would be missed if the 2010 criteria were used exclusively.

136

Sensitivity and Specificity of the American College of Rheumatology and Europe League Against Rheumatism Response Criteria in Rheumatoid Arthritis for Changes Important to Patients: Is An ACR20 Meaningful?

Maria I. Alba[1], Lori C. Guthrie[1] and Michael M. Ward[2]. [1]NIH, NIAMS, Bethesda, MD, [2]NIAMS/NIH, Bethesda, MD

Background/Purpose: ACR and EULAR response criteria are widely accepted outcomes in rheumatoid arthritis (RA) clinical trials, but many question whether ACR20 responses represent important improvement in RA status, and emphasize ACR50 and ACR70 responses. It is not known how well response criteria correspond to changes that are clinically meaningful to patients. We investigated the sensitivity and specificity of ACR and EULAR responses to reflect patients' subjective assessment of improvement in RA activity.

Methods: In this prospective longitudinal study, we enrolled adults with RA who had active arthritis (evidenced by six or more tender joints and physician judgment) and were either starting a new medication or undergoing a dose escalation of their anti-rheumatic medication. Participants were examined twice, at baseline and at 1 month (for those treated with prednisone) or 4 months later (all others). At each visit we performed joint counts, physician global assessment, ESR, CRP, patient global assessment, HAQ disability index and pain scales. At the follow up visit, we asked patients to report if their overall arthritis status was improved, unchanged or worse, and computed ACR and EULAR responses. We used patient-rated global improvement as the standard.

Results: We enrolled 214 patients (75% women, median duration of RA 6.5 years, mean age 52 years). At entry, the mean swollen joint count was 16, tender joint count 24, CRP 1.9, ESR 39, and DAS28 6.09. 136 (64%) patients reported improvement, 56 (26%) reported no change, and 22 (10%) said they were worse at the follow up visit. ACR20 responses were present in 41%, but only 8% had ACR70 responses (table). Specificity was high for each response criteria, but sensitivity was no higher than 0.55 (table).

	Prevalence	Sensitivity	Specificity	Kappa
ACR 20	41%	.55 (.46, .64)	.83 (.75, .92)	.34 (.22, .46)
ACR 50	16%	.24 (.17, .32)	.97 (.93, 1.0)	.17 (.10, .24)
ACR 70	8%	.11 (.06, .18)	.99 (.96, 1.0)	.08 (.03, .13)
EULAR Moderate	42%	.55 (.46, .64)	.81 (.71, .91)	.31 (.19, .43)
EULAR Good	9%	.11 (.05, .17)	.94 (.88, 1.0)	.04 (0, .10)

Sensitivity and specificity of the ACR20 was similar in subgroups by age, gender, and ethnicity, but sensitivity (0.64) and specificity (0.60) was lower in those with RA of 2 years or less. Many patients who reported improvement but failed to meet ACR20 criteria did so because they lacked 20% improvement in both tender and swollen joint counts.

Conclusion: An ACR20 response has a high specificity to detect changes in RA status rated as important by patients, suggesting that improvements of this degree capture changes that are meaningful to patients. EULAR responses were comparable to ACR responses.

137

Can American College of Rheumatology Criteria for Rheumatoid Arthritis Be Assessed Using Self-Report Data?—Comparison of Self-Reported Data with Chart Review.

Jack Chang[1], Pam Rogers[1] and Diane Lacaille[2]. [1]Arthritis Research Centre, Vancouver, BC, [2]Arthritis Research Centre; University of British Columbia, Vancouver, BC

Background/Purpose: To measure the agreement between self-report data and chart review to evaluate ACR diagnostic criteria for RA.

Methods: Participants were recruited from a longitudinal study of care for RA. Cases initially identified using administrative data, had agreed to participate in yearly surveys about RA. Complete medical records were obtained from their rheumatologist (rheum.), internist or family physician (FP) (for cases not followed by rheum.) and participants were mailed a self-administered survey designed to elicit specific ACR criteria for RA (presence (ever, for $>$ 6 weeks) of AM stiffness $>$1 hr, specific joint involvement (swelling) on a homunculus, presence of rheumatoid nodules, and RF results). We evaluated whether cases met 1987 ACR criteria for RA, using traditional (4/7 criteria) and "classification tree" schema. Medical records were reviewed by a rheumatologist to determine RA status based on the same criteria. Sensitivity, specificity, positive predictive value (PPV) of self-report compared to chart review (gold standard) were calculated, as well as agreement between self-report and chart review using kappa statistic and percent agreement.

Results: Of the 409 participants in the longitudinal study, permission to access their medical records was granted in 330 (81%), records were successfully obtained in 307 (75%) (165 from rheumatologists, 121 FPs, 21 internists). Response rate to the self-administered questionnaire was 74% (N=302). 216 with both medical records and questionnaire data are included in the analysis (69.8% female; mean (SD) age 65.5 (38); 82% had RA diagnosis according to impression of rheumatologist reviewing the chart). Using ACR criteria from chart review as the "gold standard", ACR criteria from self-reported data had a sensitivity of 68%, PPV of 70%, specificity of 48%, based on traditional ACR criteria. Using the "classification tree" schema, sensitivity improved to 76%, PPV 79%, with specificity of 44%. Agreement in RA diagnosis between self-reported and chart review data was fair using tree criteria (κ=0.238 [95% CI] [0.100–0.375]; 68% perfect agreement), and slight using traditional criteria (κ=0.115 [−0.020–0.25]; 60% agreement). Particularly problematic using self-reported data was eliciting rheumatoid factor (RF) status as 48% reported not knowing the result of their test. A limitation of our study was the large number of cases with records obtained from FPs, who may not routinely record information required to fulfill ACR RA criteria. Thus, we repeated the analysis, using only charts from rheumatologists. For traditional (4/7) criteria, sensitivity improved to 73%, but specificity was lower at 30%, with perfect agreement in 65% and κ=0.025 [−0.14–0.19]. For tree criteria, sensitivity was 81%, specificity 41%, with perfect agreement in 75% and κ=0.18 [0.001–0.37].

Conclusion: Overall, assessing ACR diagnostic criteria for RA using self-report data does not yield similar results to using chart review. Using the "classification tree" version of the criteria, and rheumatologist charts as gold standard, provided the best diagnostic accuracy results and best

138

Comparison of the 1987 American College of Rheumatology Criteria and the 2010 American College of Rheumatology/European League Against Rheumatism Criteria in Patients with Established Rheumatoid Arthritis.

Iman Hemmati[1], Maria Victoria Goycochea-Robbles[2], Eric C. Sayre[3] and Diane Lacaille[4]. [1]University of British Columbia, Vancouver, BC, [2]Regional Hospital No 1 IMSS, Mexico City, Mexico, [3]Arthritis Research Centre, Vancouver, BC, [4]Arthritis Research Centre; University of British Columbia, Vancouver, BC

Background/Purpose: The new 2010 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria were developed to improve the ability to classify people with early rheumatoid arthritis (RA). However, the ability of these criteria to classify patients with established RA has not been evaluated widely. If the 2010 criteria are to replace the 1987 criteria in epidemiological studies of RA with mostly prevalent RA cases, it is important to ensure that they accurately classify patients with established as well as early disease. In this study we evaluated the sensitivity and specificity of the 2010 criteria and the agreement between the 1987 and 2010 criteria in a cohort of patients with established RA.

Methods: Participants were recruited from a longitudinal study of care for RA. Prevalent RA cases initially identified using administrative data, had agreed to participate in yearly surveys about RA. Complete medical records were obtained from their rheumatologist, internist or family physician (if not followed by a rheumatologist). Medical records were reviewed by a rheumatologist (MVG) who evaluated whether cases met 1987 ACR criteria for RA, using traditional (4/7 criteria) and "classification tree" schema, and 2010 ACR/EULAR criteria for RA and also recorded her clinical impression from reviewing the chart. Sensitivity, specificity, positive predictive value (PPV) of both criteria compared to study rheumatologist's impression (gold standard) were calculated. Agreement between RA diagnosis using 1987 and 2010 criteria was calculated using kappa statistic (and 95% CI) and percent perfect agreement.

Results: Of the 409 participants in the longitudinal study, 330 gave permission to access their medical records, 307 records were successfully

obtained, but only 203 had adequate information to assess criteria and were included in the analysis (143 from rheumatologists; 54 family physicians; 4 internists and 1 ortho). The sample included 69.8% female; mean (SD) age: 65.5 (9.38) years); mean RA duration: 11 years. Using study rheumatologist impression as the "gold standard", RA diagnosis according to 1987 criteria (either the traditional or tree criteria) had a sensitivity of 83.6%, PPV of 95.9%, and specificity of 92.1%. Using the 2010 criteria, sensitivity was 86.3%, PPV 87.7% and specificity 81.0%. Agreement in RA diagnosis between the 2010 criteria and 1987 criteria was high with 86% perfect agreement and kappa = 0.70 (95% CI: 0.60–0.80).

Conclusion: Our study revealed that the 2010 ACR/EULAR criteria for diagnosis of RA can be used in assessing patients with established RA with sensitivities and PPV comparable to the 1987 criteria.

Association of Funding Source with Characteristics of Clinical Trials of Rheumatoid Arthritis. Nasim A. Khan[1], Manisha Singh[1], Horace Spencer[2] and Karina D. Torralba[3]. [1]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [2]University of Arkansas for Medical Sciences, Little Rock, AR, [3]University of Southern California-Los Angeles County Medical Center, Los Angeles, CA

Background/Purpose: A dramatic increase in pharmaceutical industry funding/support for clinical trials (CTs) has occurred in recent decades. The U.S. National Library of Medicine established ClinicalTrials.gov (CTG) registry in 2000 as an Internet-based publicly accessible registry. Funding information is a mandatory data needed for CTG registration. Our aim was a) to determine funding sources of CTs of rheumatoid arthritis (RA), and b) whether funding source is association with characteristics of RA CTs.

Methods: The CTG registry was queried on June 12, 2011 using "Search Term" field for "Rheumatoid Arthritis". CTs with only RA as study condition were eligible. Information on the study title, sponsor, dates (start, registration, completion), type, design, phase, endpoint(s), intervention(s), subject enrollment (planned or completed) and outcome were obtained. Lead sponsors were classified as industry (manufacturer of experimental intervention drug or device) or non-profit (governmental organizations, universities, foundations etc). 47 (6%) studies had both industry and non-profit funding, but for the purpose of analysis we have used lead sponsor as designated by study investigators/sponsors at CTG. Experimental study interventions were categorized as traditional disease modifying anti-rheumatic drugs (DMARD), biologic (alone or in combination with DMARD), small molecule (alone or in combination with DMARD) and others. Chi-square, Fisher's exact, Likelihood ratio test or Mann-Whitney U test were used to analyze results.

Results: Of 1210 CTs, 783 (64.7%) CTs were eligible. Lead sponsorship was by industry in 590 (75.3%) CTs, and 193 (24.7%) by a non-profit source. Industry-funded studies were mostly interventional, with safety and/or efficacy cited as their purpose, and have larger number of study subjects. Among interventional studies, industry funded CTs were more likely to be Phase 1–3, use a biologic or small molecule as the experimental intervention compared to non-profit source studies (Table). A similar proportion of interventional trials had random assignment of subjects, but industry-funded CTs were more likely to be double-blinded. Non-profit funded interventional studies were of significantly longer duration.

Table. Funding source and characteristics of RA clinical trials.

	Lead Study Sponsor		P**

Observational	32 (15–58.5)	25 (12–70)	0.569

* n (%) unless stated otherwise; ** Using Chi-square test, Fisher's exact test, Likelihood ratio test, or Mann-Whitney U test as appropriate ***For interventional studies only; **** For randomized clinical trials only; *****For studies with "complete" status only.

Conclusion: Funding source was associated with significant differences in study design, duration, subject enrollment and experimental intervention. The balance of funding of clinical trials (industry versus non-profit) has important implications for generation of evidence to guide clinical care.

140

Achieving Sustained Remission in Rheumatoid Arthritis Results in Reduced Long-Term Health Care Costs. Cheryl CM Barnabe[1], Nguyen Xuan Thanh[2], Arto Ohinmaa[3], Joanne Homik[3], Susan G. Barr[1], Liam Martin[1] and Walter P. Maksymowych[3]. [1]University of Calgary, Calgary, AB, [2]Institute of Health Economics, Edmonton, AB, [3]University of Alberta, Edmonton, AB

Background/Purpose: Remission status is of functional benefit to individual rheumatoid arthritis (RA) patients. Achieving remission may require a considerable initial investment when considering costs associated with more frequent physician visits, medication titration and ancillary tests. This investment however could result in long-term cost reduction due to decreased RA morbidity over time. We have linked administrative data with a clinical dataset to examine healthcare system costs of achieving various disease remission states.

Methods: We linked data on healthcare utilization (physician visits, outpatient department visits, and hospitalizations) from a provincial administrative database (years 2004–2009) with clinical data from a prospective cohort of biologic treated patients (n=1,086, mean age 54 years). Remission status was classified according to the DAS28 score by the following categories: i) sustained remission (DAS28 score ≤2.6 for >6 months; ii) sustained low disease activity (DAS28 score >2.6 but ≤3.2 for >6 months); iii) brief remission (DAS28 score ≤2.6 for ≤6 months); and iv) never achieving remission (DAS28 ≥2.6). We examined both total healthcare costs and costs directly attributable to RA for each category of clinical response, standardized to 2008 Canadian dollars. A propensity score model and quantile regression was used to account for confounding by individual variables affecting healthcare utilization, including specific therapy received, baseline function, smoking, age, sex, disease duration and medical comorbidities.

Results: Median cost differences between patients in sustained remission, sustained low disease activity, and a brief period of remission were not significantly different over the five year study period (Table 1). Patients in sustained remission had significantly reduced total and RA-attributable healthcare costs relative to those patients never achieving a remission period over the five years, with a savings of $616 (95%CI 90–1141; p<0.001) per patient. Costs directly attributable to RA were constant in all remission categories at approximately 25%.

Table 1. Median Study Period Healthcare Costs per Individual, by Remission Status

	Median Total Cost, 2008 Canadian $	**% of Costs Directly Attributable to RA**
Sustained Remission (n=271)	2575	26.4
Sustained Low Disease Activity (n=87)	2832	25.9
Brief Remission (n=222)	2712	24.3
No Remission (n=470)	3191	25.7

Conclusion: Healthcare system savings are observed in RA patients achieving remission or a low disease activity state. RA-attributable costs are constant across response categories. Ongoing observation of biologic treated patients longitudinally may identify more significant cost savings associated with a reduction in long-term severe morbidity.

141

Responsiveness of Health-Related Quality-of-Life Measures in Rheumatoid Arthritis Randomized Controlled Trials. Vibeke Strand[1], Kavita Gajria[2], Paul Williams[3], Amy Barrett[3], Ancilla Fernandes[2] and Fabio Magrini[4]. [1]Stanford University, Portola Valley, CA, [2]MedImmune LLC, Gaithersburg, MD, [3]RTI Health Solutions, Research Triangle Park, NC, [4]MedImmune Ltd, Cambridge, United Kingdom

Background/Purpose: As the number of available rheumatoid arthritis (RA) treatments increases, endpoints that can sufficiently discriminate between active treatments become valuable. Standard disease activity measures, such as the American College of Rheumatology (ACR) criteria, may not be sensitive enough to discriminate between active treatments in comparative randomized controlled trials (RCTs). Therefore, in addition to disease activity measures, health-related quality-of-life (HRQL) measures could be used to discriminate between treatments. We evaluated the responsiveness of HRQL measures in RA RCTs to find those most likely to discriminate between treatments.

Methods: A total of 150 randomized, placebo-controlled trials published between 2000–2010 were identified for potential inclusion. As general health status (measured by Short Form-36 [SF-36]) and fatigue (measured mostly by the Functional Assessment of Chronic Illness Therapy [FACIT-Fatigue] or Fatigue Visual Analog Scale [VAS]) were commonly evaluated in RA clinical trials, responsiveness of these endpoints was assessed by calculating effect size (ES). To allow between-study comparisons, relative responsiveness (RR) for SF-36 Physical Component Summary (PCS) and Mental Component Summary (MCS) was calculated as a ratio of their ES to that of the Health Assessment Questionnaire (HAQ). Similarly, RR for 8 SF-36 domains was assessed using the SF-36 mental health (MH) domain as a reference. For evaluating RR of fatigue scales, the SF-36 Vitality (VT) scale was used as a reference. Endpoint RR was further compared among 3 subpopulations: disease-modifying antirheumatic drug (DMARD)–naive, DMARD inadequate responders (IR), and anti–tumor necrosis factor (TNF) failures.

Results: For PCS, 40 ESs were calculated from 21 RCTs; median ES was 0.81. PCS ES was greater than HAQ ES in 14 of 25 (56%) comparisons; median RR was 1.06. For MCS, 31 ESs were calculated from 16 RCTs; median ES was 0.27. MCS ES was less than HAQ ES in all 16 comparisons; median RR was 0.18. For each of the 8 SF-36 domains, 20 ESs were calculated from 10 trials. Notably, Bodily Pain (BP; median ES, 1.0) and Role Physical (RP; median ES, 0.76) were most responsive to treatment (RR, >2 compared with MH). VT (median ES, 0.66) and Physical Function (median ES, 0.56) were of intermediate responsiveness (RR, 1.5–2). For Fatigue VAS, 10 ESs were calculated from 6 trials; median ES was 0.68 and median RR was 1.07. For FACIT-Fatigue, 7 ESs were calculated from 6 trials; median ES was 0.64 and median RR was 1.15. RR of all endpoints was comparable across the 3 subpopulations with the exception of MCS, where responsiveness was higher in anti-TNF failure trials but still less than HAQ.

Conclusion: Study results showed that MCS was less responsive, and PCS was generally more responsive, than HAQ. Of the 8 SF-36 domains, BP and RP were the most responsive. Fatigue had comparable responsiveness to SF-36 Vitality. With the exception of MCS, the findings did not appreciably change across DMARD naive, DMARD IR, and anti-TNF failure populations. Future studies should consider SF-36 PCS, BP, RP and fatigue as potential tools for discriminating between active treatments in RCTs.

142

A Comparison of RAPID3 Response Criteria and EULAR-DAS28 Response Criteria in the DANCER and REFLEX Rituximab Clinical Trials. Martin J. Bergman[1], Adam Turpcu[2], Pamela Wong[2], Carol Chung[2] and William Reiss[2]. [1]Taylor Hospital, Ridley Park, PA, [2]Genentech, South San Francisco, CA

Background/Purpose: In an effort to improve patient outcomes, an increasing number of physicians are treating Rheumatoid Arthritis (RA) patients to a disease activity target. Targets are typically based on composite indices of core data set measures such as the DAS28 (which is comprised of the TJC, SJC, ESR/CRP, and patient global) and the RAPID3 (which is comprised of the patient pain, patient global, and HAQ). However, there is no consensus as to which index should be used. It is important to understand how different targets compare.

Objectives: To compare EULAR response criteria with proposed RAPID3 response criteria in the REFLEX[1] and DANCER[2] clinical trials.

Methods: Patients treated with rituximab (1000mg) were classified as having EULAR good, moderate or no responses at the time of primary endpoint analysis (week24) in both trials. EULAR response categories[3] are defined in terms of reduction in DAS28-ESR and final DAS28-ESR attained as follows:

Good = decrease >1.2 units AND final <3.2;

Moderate = decrease >1.2 AND final ≥3.2, OR decrease of 0.6–1.2 AND final ≤5.1;

No response = decrease <0.6, OR decrease of 0.6–1.2 AND final >5.1.

Proposed RAPID3 response categories are defined as follows:

Good = decrease >3.6 units AND final <6;

Moderate = decrease >3.6 AND final ≥6, OR decrease of 1.8–3.6 AND final ≤12;

Poor = decrease <1.8, OR decrease of 1.8–3.6 AND final >12.

Responses were pooled across both trials. Comparisons involved cross-tabulations and weighted kappa statistics.

Results: Moderate agreement[4] was observed between the EULAR-DAS28 response criteria and the proposed RAPID3 response criteria (weighted Kappa = 0.50). A greater proportion of patients achieved a good response on the RAPID3 (30.3%) relative to the DAS28 (19.9%) with roughly half (49.6%) of the good RAPID3 responders being defined as moderate responders by the DAS28. A similar proportion of patients were classified as being poor responders by both the DAS28 and the RAPID3.

Table. EULAR Response Criteria vs RAPID3 Response Criteria in the DANCER and REFLEX clinical trials at 24 weeks.

		RAPID3 Good Response	RAPID3 Moderate Response	RAPID3 Poor Response	DAS28 Totals by Response Category
DAS28	Good Response	67 (14.8%)	18 (4.0%)	5 (1.1%)	**90 (19.9%)**
	Moderate Response	68 (15.0%)	117 (25.9%)	47 (10.4%)	**232 (51.3%)**
	No Response	2 (0.4%)	34 (7.5%)	94 (20.8%)	**130 (28.8%)**
RAPID3 Totals by Response Category		**137 (30.3%)**	**169 (37.4%)**	**146 (32.3%)**	**452 (100%)**

Each box displays the number of patients meeting RAPID3 response criteria and the corresponding EULAR-DAS28 response criteria. For example, the top-left box illustrates that 67 patients were classified as good responders by both RAPID3 and EULAR-DAS28 criteria.

Conclusion: Our findings suggest that patients are more likely to be classified as good responders under proposed RAPID3 response criteria relative to the EULAR response criteria. Substantive differences may exist between targets derived from different indices. To enable accurate between-patient and within-patient comparisons, it is important that practices maintain consistent targets where possible.

Patients' Ratings of Clinically Important Improvement in Pain, Global Assessment, and Physical Function in Rheumatoid Arthritis. Michael M. Ward, Lori C. Guthrie and Maria I. Alba. NIH, NIAMS, Bethesda, MD

Background/Purpose: Criteria for improvement in rheumatoid arthritis (RA) have not emphasized patients' perspectives. We sought to identify the amount of change in measures of pain, global arthritis assessment, and physical functioning that patients with RA consider an important change.

Methods: We enrolled adults with active RA (6 or more tender joints and physician judgment of activity) who were either starting a new anti-rheumatic medication or who were having escalation of their current medication regimen. Patients had physical examinations and completed a pain visual analog scale (0 – 100), global visual analog scale (0 – 100) and the Health Assessment Questionnaire Disability Index (HAQ; 0 – 3). They were reassessed after either 1 month (for those started on prednisone) or 4 months (all others). At the followup visit, patients were asked to report if they had improvement or worsening in each symptom. These judgments were related to measured changes in pain, patient global assessment, and HAQ.

Results: We studied 215 patients (mean age 52; 75% women; median duration of RA 7 years; 74% seropositive). At entry, they had a mean pain score of 59 ± 25, mean global assessment of 55 ± 25, and a mean HAQ score of 1.3 ± 0.7. Fifty-one patients were treated with prednisone, 64 patients were treated with a new disease-modifying medication, and 100 patients had dose escalation of current medications.

At follow-up, 61% reported improvement in pain, 63% reported improvement in global arthritis status, and 56% reported improvement in function. Changes in measured pain scores, global scores, and HAQ differed among patients who reported improvement, no change, or worsening in each aspect of health status.

	Mean (SD) Change in Pain	Mean (SD) Change in Global Assessment	Mean (SD) Change in HAQ
Improved	−26.6 (31.1)	−22.3 (25.4)	−.53 (.59)
No Change	−8.0 (20.6)	−7.0 (20.6)	−.08 (.42)
Worsened	3.5 (22.7)	0.8 (22.7)	.05 (.35)
p	<.0001	<.0001	<.0001

Of those with improvement, 89% rated the improvement as at least "moderately important" for each measure. Areas under receiver operating characteristic curves distinguishing improvement from no change/worsening were.74 for pain,.72 for global assessment, and.75 for HAQ. If the criterion for improvement were required to have a specificity of at least 0.75, an absolute decrease in pain score of 16, an absolute decrease in patient global assessment of 13, and an absolute decrease in HAQ of 0.375 were the cutpoints with maximum sensitivity (0.62, 0.62, and 0.59, respectively).

Conclusion: Patient ratings can accurately distinguish improvement in pain, global assessment, and functioning from no change or worsening. In this sample, decreases in pain score of 16 or more, decrease in global assessment of 13 or more, and decreases in HAQ of 0.375 or more, were specifically associated with clinically important improvement.

144

Employability-Adjusted-Life-Years in Patients with Rheumatoid Arthritis Treated with Golimumab Plus Methotrexate or Methotrexate Alone. Chenglong Han[1], Tim Gathany[2], Neeta Tandon[3] and Elizabeth C. Hsia[4]. [1]Johnson & Johnson Pharmaceutical Services, LLC, Malvern, PA, [2]Johnson & Johnson Pharmaceutical Services, LLC, Horsham, PA, [3]Johnson & Johnson North America Pharmaceuticals, Horsham, [4]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC/Univ. of Pennsylvania School of Medicine, Malvern, PA

Background/Purpose: Work disability is a major economic consequence among patients with rheumatoid arthritis (RA). Treatments that inhibit disease progression may delay the time when patients exit from the labor force due to disability. The purpose of this study was to estimate and compare employability-adjusted-life-years (EALYs) over time for RA patients in the GO-FORWARD clinical trial who were treated with GLM + methotrexate (MTX) vs. MTX alone.

Methods: GO-FORWARD was a double-blind, placebo controlled study of adult patients with active RA (>4 tender joints and 4 swollen joints) and inadequate response to MTX. In this analysis, we included patients aged less than 65 years and who received placebo + MTX (MTX Grp) or golimumab (50- or 100mg) q4 wks + MTX (GLM Grp). Self reported employment status and physical function measured by Health Assessment Questionnaire (HAQ) were collected from baseline over 3 years. Employability status was defined as 'unemployable' if a patient was unemployed and felt unable to work even if a job was available or 'employable' if patients were employed or felt well enough to work if a job was available. Long-term employability was estimated using a logistic regression model based on age, gender and HAQ score. HAQ was derived by a progression rate of 0.045 /per year for a person being treated with MTX and by 0 (base case) to 0.025 per year (sensitivity analysis) for a patient on biologics (GLM).[1]

Results: At baseline, the mean (SD) HAQ score was 1.36 (0.67); 61.9% of patients under age 65 were employable, and 44.8% of patients were actually employed. At week 24, the average HAQ score was 1.08 in MTX group and 0.92 in GLM group; 33% of patient unemployable at baseline became employable at week 24 in GLM group compared to 15% in the MTX group (p=0.04). GLM group maintained the HAQ improvement from 0.92 at week 24 to 0.88 at week 160. In the logistic regression model by using the derived HAQ score, age, and gender, in the base case scenarios, over 10 years period for a RA patient cohort with an average of 50 years of age, GLM-treated patients had expected employability adjusted life years of 5.92 for females and 7.15 for males, compared to 4.96 for females and 6.28 for males in MTX-treated patients, an increase of 0.96 years (19.2%) in females and 0.87 years (13.8%) in males. Sensitivity analysis demonstrated an improvement of 0.81 employability adjusted life years in males (16.4%) and 0.74 years (11.8%) in females in GLM-treated patients vs. in MTX-treated patients.

Conclusion: Results of analysis on the employability-adjusted-life-years showed that patients treated with GLM+MTX can realize improvement in employability over time.

Single Item Literacy Screening Questions Are Strongly Associated with Functional Status Among Rheumatoid Arthritis Patients. Liron Caplan[1], Kaleb D. Michaud[2], Frederick Wolfe[3] and Joel M. Hirsh[4]. [1]Denver VA and University of Colorado, Aurora, CO, [2]Univ of Nebraska Med Ctr & National Data Bank for Rheumatic Diseases, Omaha, NE, [3]National Data Bank for Rheumatic Diseases, Wichita, KS, [4]Denver Health Med Ctr, Denver, CO

Background/Purpose: Health Literacy (HL) has been associated with outcomes for a number of conditions and pilot data has linked HL to rheumatoid arthritis (RA) functional status. However, these studies have not adequately accounted for the large number of potential covariates that can influence rheumatoid arthritis outcomes. We examined the association of health literacy with functional status in 5,300 subjects participating in a prospective observational study, controlling for numerous important covariates.

Methods: Using linear regression, we analyzed the cross-sectional association of HL, as measured by two different validated single-item literacy-screening questions (SILS-instruction and SILS-confident), and functional status, assessed by the Health Assessment Questionnaire Disability Index (HAQ). Subjects reported demographics, comorbidities, validated estimates of social support, educational attainment, visual problems, memory problems, as well as prednisone, disease modifying antirheumatic drug, and biologic usage. A stable statistical model was constructed through the use of a backwards stepwise selection procedure with $p<0.25$ required for variable inclusion. The final model retained only those variables with $p<0.05$ and each SILS measure, as the variables of interest, were forced into the final model.

Results: Lower HL was present in 6.3% and 3.9% of subjects (per SILS-instruction and SILS-confident). Results (Table 1) were virtually identical for the two SILS instruments, when entered separately into the final model. When controlling for all covariates, lower HL was associated with a 0.369 greater HAQ score, compared to subjects with adequate HL ($p<0.001$, 95% CI 0.292–0.446). This relationship persisted, even after modeling educational attainment. Visual and memory problems were also associated with more disability, though social support demonstrated no association, after accounting for marital status.

Table 1. Multivariate regression demonstrating variables associated with Health Assessment Questionnaire

	Initial Model				Final Model

SILS-confident ****	0.359	<0.001	0.227	0.491	0.312	<0.001	0.217	0.406

SIMSS=single item measure of social support
DMARD=disease modifying antirheumatic drug
* refers to the number of different medications exposed to from the described class(es)
** Patients who report taking compliance of between 80–120% of their rheumatoid arthritis medication during last month according to the medication adherence self-report inventory (MASRI)visual analogue scale
*** Patients who responded with "often" or "always" to the question: How often do you need to have someone help you when you read instructions, pamphlets, or other written material from your doctor or pharmacy?
**** Patients who responded with "a little bit" or "not at all" to the question: How confident are you filling out medical forms by yourself?

Conclusion: Health literacy was more strongly associated with functional status than prednisone use, smoking history, and biologic use, and this effect was independent of educational attainment. Health literacy may play an important role in understanding functional status in RA patients. Single-item questions amenable to use in the clinical setting may identify subjects with lower HL, who are at risk for poor RA outcomes.

146

National and Regional Dosing Patterns of Tumor Necrosis Factor Blocker Therapy in Biologic-Naïve Rheumatoid Arthritis Patients in US Health Plans. Amie T. Joyce[1], Shravanthi R. Gandra[2], Kathy M. Fox[3], Timothy W. Smith[1] and Michael Pill[4]. [1]IMS Health, Watertown, MA, [2]Amgen Inc, Thousand Oaks, CA, [3]Strategic Healthcare Solutions, LLC, Monkton, MD, [4]Gemini HealthCare, Westbrook, CT

Background/Purpose: Although research using 2002–2005 data has shown higher rates of dose increases in some TNF blockers than others, the impact of more intensive cost management efforts in recent years on dosing patterns is not clear. This study examined the rates and magnitude of dose increases nationally and regionally among rheumatoid arthritis (RA) patients treated with TNF blockers between 2005–2010, when health plans began to more actively manage this class of drugs.

Methods: Based on a claims database covering approximately 78 million lives, a retrospective cohort study was conducted with commercially-insured adult RA patients who initiated treatment with a TNF blocker (adalimumab [ADA], etanercept [ETN], infliximab [INF]) between 2005–2009. Patients were excluded if they had a diagnosis for other conditions treated with TNF-blockers. Biologic-naïve patients continuously enrolled in the plan for at least 6 months before (baseline) and at least 12 months after start of anti-TNF therapy were followed for 12 months. For ETN and ADA, the maintenance (MTN) dose was the dose of the initial prescription. For INF, the MTN dose was based on the first stable dose (4th dose). Dose increases were assessed among patients using 3 methods 1) Average weekly dose: Dose increase was defined as an average weekly dose (total dispensed quantities in the study period/total days supply) that is ≥ label dose, 2) Average ending dispensing dose: Dose increase was defined as the average ending dispensing dose that is greater than the MTN dose and 3) Average dose after MTN dose: Dose increase was defined as an average dose after the MTN dose that is greater than the MTN dose. The percentages of patients with dose increases were quantified using above 3 definitions. Magnitude of dose escalation was examined by comparing the MTN and ending doses for each patient. Annual cost per patient to the health plan was computed. Statistical testing was performed using Chi-square tests.

Results: Overall, 1,420 ETN, 874 ADA, and 454 INF RA patients were included. Patients initiating ETN therapy had a significantly lower rate of dose escalation using the average weekly dose (3.9% vs. 21.4% ADA and 69.6% INF; $p<0.0001$), average ending dispensing dose method (1.1% vs. 10.6% ADA and 63.0% INF; $p<0.0001$), and average dose after MTN dose (2.8% vs. 15.7% ADA and 69.6% INF; $p<0.0001$). The rates and magnitude of dose escalation were similar for each product among the 4 US census regions. ETN had the lowest cost per treated RA patient ($18,590) compared to ADA ($23,032) and INF ($23,350).

Table 1. Proportion and amplitude of dose escalation overall and by region

	Etanercept (%) n = 1,420			Adalimumab (%) n = 874			Infliximab (%) n = 454		
Geography	Weekly dose	Avg ending	Avg after MTN	Weekly dose	Avg ending	Avg after MTN	Weekly dose	Avg ending	Avg after MTN
Nation (All Pts) (dose escalation rates)	3.9%	1.1%	2.8%	21.4%*	10.6%*	15.7%*	69.6%*	63.0%*	69.6%*
MTN Dose (mg)		50	50		20	20		55	56
Ending Dose (mg)		93	58		40	29		94	80
Magnitude of dose escalation among proportion of patient experiencing dose escalation		86.7%	15.5%		100%	44.9%		75.1%	44.9%
Northeast (dose escalation rates)	1.6%	0.3%	1.3%	20.6%*	12.5%*	15.6%*	69.2%*	65.9%*	69.2%*
MTN Dose (mg)		50	50	20	20	20		53	53
Ending Dose (mg)		100	63	40	40	32		94	80
Magnitude of dose escalation among proportion of patient experiencing dose escalation		100%	25.9%		100%	62.0%		81.7%	52.1%
Midwest (dose escalation rates)	3.2%	0.9%	2.5%	20.6%*	9.3%*	14.8%*	71.0%*	66.5%*	71.0%*
MTN Dose (mg)		50	50		20	20		57	57
Ending Dose (mg)		90	59		40	28		93	82
Magnitude of dose escalation among proportion of patient experiencing dose escalation		80.0%	18.4%		100%	38.2%		65.9%	43.4%
South (dose escalation rates)	5.3%	1.5%	3.5%	24.1%*	12.2%*	18.2%*	67.5%*	55.2%*	67.5%*
MTN Dose (mg)		50	50		20	20		54	55
Ending Dose (mg)		100	59		40	29		97	77
Magnitude of dose escalation among proportion of patients experiencing dose escalation		100%	17.2%		100%	43.8%		85.7%	42.6%
West (dose escalation rates)	6.7%	1.9%	4.8%	15.2%*	6.1%*	9.1%*	72.2%*	70.4%*	72.2%*
MTN Dose (mg)		50	50		20	20		56	57
Ending Dose (mg)		88	53		40	28		89	78
Magnitude of dose escalation among proportion of patient experiencing dose escalation		75.0%	5.4%		100%	41.0%		66.2%	43.3%
Mean annual cost per treated patient		$18,590			$23,032			$23,350	

* $p<0.0001$ compared to ETM, MTN = Maintenance Dose

Conclusion: Similar to previous published results, rates and magnitudes of dose increase differed by anti-TNF therapy. ETN patients had the lowest rates and magnitudes of dose increase across all dose increase calculation methods as compared to ADA and INF patients overall and regionally. Mean annual cost was lowest for patients treated with ETN.

147

Patients with Rheumatoid Arthritis Who Are in Remission According to the New ACR/EULAR Criteria Have a Very High Functional Capacity Which Is Comparable to Healthy Subjects. Joachim Listing[1], Anja Strangfeld[1], Joern Kekow[2], Siegfried Wassenberg[3], Thilo Klopsch[4], Thomas Kohlmann[5] and Angela Zink[6]. [1]Deutsches Rheumaforschungszentrum, Berlin, Germany, [2]Univ of Magdeburg, Vogelsang-Gommern, Germany, [3]Evangelisches Fachkrankenhaus, Ratingen, Germany, [4]Rheumatologist, Neubrandenburg, Germany, [5]University Greifswald, Greifswald, Germany, [6]Deutsches Rheumaforschungszentrum and Charité University Medicine, Berlin, Germany

Background/Purpose: New definitions for remission in patients with rheumatoid arthritis (RA) were developed by the ACR and EULAR. The new criteria identify patients with little, if any, disease activity, who should have a good prognosis for their functional outcome. We compared the functional status of RA patients fulfilling those criteria with subjects randomly selected from the normal population.

Methods: Data from two sources were used for the analysis: 4,459 RA patients enrolled in the German biologics register RABBIT at start of therapy with a biologic agent (67%) or with a non-biologic DMARD after at least one DMARD failure (33%) and data from a population based cross-sectional survey of 9,263 subjects [1]. Both sources provide data on functional capacity measured by the Hannover functional status questionnaire (FFbH) which is comparable to the health assessment questionnaire (HAQ). 12 months follow-up data were used for the comparisons. We considered 3 definitions of remission: the new boolean definition (≤1 number of swollen joint, ≤1 tender joint, ≤1 mg/dl CRP, ≤1 patient global assessment (0–10 scale)), the SDAI definition (simplified disease activity index (SDAI) ≤ 3.3) and the DAS28 definition(DAS28 < 2.6).

Results: Mean age of the RA patients was 55 (SD 12) years, the median disease duration 8 years, and the mean DAS28 at start of treatment 5.5 (1.3). After 12 months the stringent new Boolean definition of remission was fulfilled in n=72 (4.9%) of the DMARD treated and n=107 (4.0%) of the biologics treated patients. The remission rates were higher (7.8%, 6.8%) when the SDAI definition or when the "old" DAS28 definition (21.8%, 19.2%) were applied.

RA patients who fulfilled the Boolean or SDAI criterion had a high functional capacity which was fully comparable to age and sex matched subjects from the normal population (tab 1). The functional capacity of DMARD treated patients in remission was even higher. They had shorter disease duration, less joint damage und less treatment failures than patients treated with biologics.

Table 1. Age and sex adjusted mean functional capacity and percentage of patients with almost no limitations in activities of daily living (FFbH >90).

		Mean FFbH	FFbH >= 90 (in % of pts.)
Subjects from normal population		86.6 [86–87]	57.4 [56–59]
RA pts. treated with	RA pts. fulfilling		
DMARDs	Boolean crit. (n=84)	92.1 [88–96]*	66.6 [55–77]
Biologics	Boolean crit. (n=131)	88.8 [86–92]	59.1 [49–68]
DMARDs	SDAI crit. (n=133)	90.6 [88–93]	59.9 [50–69]
Biologics	SDAI crit. (n=212)	85.9 [83–88]	55.2 [48–63]
DMARDs	DAS28 crit. (n=352)	85.7 [84–87]	45.7 [40–51]*
Biologics	DAS28 crit. (n=581)	79.2 [78–81]*	33.8 [30–38]*

Each subgroup: mean age 55 years, (75% female), 95% confidence limits are given in parentheses; * significantly different ($p < 0.05$) from the normal population

62% of the patients in remission according to the new Boolean definition had almost no limitations in activities of daily living defined by a functional capacity > 90% of full function (FFbH >90 or a HAQ score< 0.25). This proportion was again comparable to subjects from the normal population. In contrast, patients in DAS28 remission were more limited in activities of daily living.

Conclusion: In patients with long-standing disease, the new ACR/EULAR remission criteria identify those with a high functional capac ity, comparable to age and sex matched subjects from the general population.

148

The Identification of Rheumatoid Arthritis Patients for Comparative Effectiveness Research Using An Electronic Health Record and Mathematical Modeling. Aarat M. Patel[1], Larry W. Moreland[2], Melissa Saul[3], Stephen R. Wisniewski[3] and Marc C. Levesque[4]. [1]Univ of Pittsburgh Med Ctr / Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Univ of Pittsburgh, Pittsburgh, PA, [4]Univ of Pittsburgh Med Ctr, Pittsburgh, PA

Background/Purpose: To develop an electronic search algorithm with a high specificity and sensitivity to accurately identify rheumatoid arthritis (RA) patients in a large health care system linked by an electronic health record (EHR) system.

Methods: Records from the Medical Archival Retrieval System (MARS) at the University of Pittsburgh Medical Center (UPMC) were used to identify potential RA patients. We searched the UPMC MARS system for subjects with a 714.0 International Classification of Diseases, 9th revision (ICD-9) code and used a recursive partitioning method to develop a search algorithm with a high specificity and sensitivity for the identification of RA patients; the recursive partitioning method used the 714.0 ICD-9 code and tested 35 additional variables (serology, inflammatory markers, medications, specific words in physician notes, etc). During the development and validation of the algorithm, patients were classified into those likely or unlikely to have RA and representative sets of these patient records were reviewed to determine if subjects met the 1987 and/or 2010 RA diagnostic criteria.

Results: We initially analyzed records from 2009 to study the effect of clinical setting (inpatient vs. outpatient rheumatology clinic) on the identification of RA patients. For inpatients, there was a low PPV of a 714.0 (39.0%) whereas for outpatient-rheumatology subjects there was a high PPV of a 714.0 for the identification of RA patients (87.3%), (n=95, $p<0.0001$; Fisher's exact test). When the records of subjects with and without a 714.0 ICD-9 code were analyzed (n=400), the sensitivity, specificity, PPV and NPV of a 714.0 among outpatient-rheumatology patients was 98%, 88%, 87% and 98%, respectively. We next used recursive partitioning to test whether other variables besides a 714.0 could be used to create a more specific algorithm for identifying RA patients among outpatient rheumatology patients seen in 2009. We found that a search algorithm with 3 variables 1.) 714.0 ICD-9 code, 2.) ratio of "rheumatoid arthritis" in a physician note per rheumatology visit and 3.) ratio of "RA" in a physician note per rheumatology visit improved the specificity for identifying RA patients. The sensitivity, specificity, PPV and NPV of the algorithm was 93%, 95%, 94%, 95% (n=400). Validation of this algorithm with analysis of an additional 400 subjects produced similar results (95%, 96%, 96%, 95%, respectively). We used this algorithm to analyze records from outpatient-rheumatology patients evaluated in 2010 (n=17,571) to identify 2,610 patients with RA.

Conclusion: The ICD-9 code for RA (714.0) alone was not reliable for identifying RA patients in the inpatient setting and had suboptimal specificity in the outpatient rheumatology setting. We developed and validated a simple algorithm using recursive partitioning that used 3 variables to identify RA patients with a high specificity, sensitivity, PPV and NPV. This simple algorithm represents a substantial improvement in terms of sensitivity and specificity over existing published algorithms. Using an EHR and this electronic search algorithm will enable large-scale comparative effectiveness studies on the treatment and management of RA in "real-world" clinical settings.

Personal Health Records in Rheumatoid Arthritis: Quality and Adhesion Factors. Sophie Trijau[1], Herve Servy[2], Adam M. Selamnia[2], Vincent Pradel[1], Pierre Lafforgue[1] and Thao Pham[1]. [1]Sainte Marguerite Hospital, Marseille, France, [2]SANOIA, Marseille, France

Background/Purpose: Personal Health Records (PHRs) are patient-controlled repositories, capturing health data entered by individuals and providing information related to the care of those individuals. PHRs include tools to help individuals take a more active role in their own health, and include decision-support capabilities that can assist physician in managing chronic conditions such as rheumatoid arthritis (RA). However, barriers to PHRs adoption exist, including economic and legal concerns. Especially, patients must understand and accept their role and responsibilities related to their own health care. *Objective*: To assess how support measures improve PHRs adoption and to determine factors that influence quality of self recorded data and tool adhesion of RA patients.

Methods: *Design*: controlled randomized study. *PHRs tool*: SANOIA developed PHRs web tool integrated with electronic health records (EHRs). SANOIA tool is a full privacy protection based on innovative anonymization techniques. *Patients:* RA patients fulfilling ACR 1987 criteria, with web access, randomized in 3 groups: Group 1 patients were given a written information about how to create and manage a PHR; Group 2 patients received the written information and a nurse support phone-call 48 hours after inclusion as an PHR filling assistance; Group 3 patients filled PHR with their rheumatologist during the consultation. *Data collected*: demographic data, amount and quality of self recorded data, DAS 28, RAPID 3, ongoing treatment, at baseline and 2 months after. Information quality was compared to rheumatologist medical records (gold standard) and 0–10 scored. Good quality score was defined as >9. Patients were considered as tool adherent if they connected at least twice and as non adherent if they connected once or never. *Statistical analysis*: Khi-2, Mann-Whitney tests.

Results: We included 56 RA patients (20, 19 and 17 in group 1, 2, 3 respectively), 73% female, 57.1 years mean age, 3.04 mean DAS 28 and 2.93 mean RAPID 3. Self reported data quality was significantly higher in group 2 (73.7%) and 3 (82.4%) than in group 1 (45.0%), ($p=0.04$). Moreover, a patient reported tuberculosis history and another neoplasia history that were not reported in the physician medical record. Patient adhesion was higher in group 2 (73.7%) compared to group 1 (55.0%) and 3 (58.8%) ($p=0.45$). Quality was correlated to adhesion ($p<0.0001$). Gender, age, disease duration and activity (DAS 28, RAPID 3) and treatments including biologics and steroids were not correlated to data quality or patient adhesion.

Conclusion: Information quality collected with PHRs was relevant and better when patients were initially assisted either by their physician or by a non-medical phone support. We observed a trend for a better adhesion when using phone call support at 2 months. A follow-up at month 6 is scheduled to confirm these results.

Background/Purpose: Several confirmed genetic susceptibility loci for lupus have been described. To date, no clear evidence for genetic epistasis is established in lupus. We test for gene-gene interactions in a number of known lupus susceptibility loci.

Methods: Eighteen SNPs tagging independent and confirmed lupus susceptibility loci were genotyped in a set of 4,250 lupus patients and 3,818 normal healthy controls of European descent. Epistasis was tested using a 2-step approach utilizing both a parametric and non-parametric (multifactor dimensionality reduction) methods. False discovery rate (FDR) was used to correct for multiple testing.

Results: We detected and confirmed gene-gene interactions between *HLA* and *CTLA4*, *HLA* and *IRF5*, *HLA* and *ITGAM*, and *PDCD1* and *IL21* in lupus patients. The most significant interaction detected by parametric analysis was between rs3131379 in the *HLA* region and rs231775 in *CTLA4* ($P = 7.73\times10^{-5}$ (FDR≤0.05), $P_{MDR} = 2.82\times10^{-47}$).

Conclusion: We provide a strong evidence for gene-gene epistasis in systemic lupus erythematosus. These findings support a role for genetic interaction upon the complexity of lupus heritability.

A Large-Scale Association Study Identified Multiple HLA-DRB1 Alleles Associated with Anti-Citrullinated Peptide Antibody Negative Rheumatoid Arthritis in Japanese. Chikashi Terao[1], Koichiro Ohmura[2], Yuta Kochi[3], Katsunori Ikari[4], Etsuko Maruya[5], Masaki Katayama[2], Kota Shimada[6], Akira Murasawa[7], Shigeru Honjo[8], Kiyoshi Takasugi[9], Keitaro Matsuo[10], Kazuo Tajima[10], Akari Suzuki[5], Kazuhiko Yamamoto[11], Shigeki Momohara[4], Hisashi Yamanaka[4], Ryo Yamada[1], Hiroo Saji[5], Fumihiko Matsuda[1] and Tsuneyo Mimori[2]. [1]Kyoto University, Kyoto, Japan, [2]Kyoto Univ Grad School of Med, Kyoto, Japan, [3]RIKEN, Yokohama, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]HLA Laboratory, Kyoto, Japan, [6]Sagamihara, Japan, [7]Niigata, Japan, [8]Honjo Rheumatism Clinic, Kanzaki, Japan, [9]Dohgo Spa Hospital, Matsuyama, Japan, [10]Nagoya, Japan, [11]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan

Background/Purpose: HLA-DRB1 is associated with rheumatoid arthritis (RA). However, it has recently been suggested that HLA-DRB1 is only associated with RA patients with anti-citrullinated peptide/protein antibody (ACPA), an antibody specific to RA. We intended to elucidate whether specific HLA-DR alleles are associated with ACPA-negative RA development.

Methods: HLA-DRB1 typing was carried out in 368 Japanese ACPA-negative RA patients and 1,508 healthy volunteers as the first set, followed by HLA-DRB1 typing of 501 cases and 500 controls as the second set. The HLA-DRB1 allele frequency and diplotype frequency were compared in each group, and the results of the two studies were combined to detect HLA-DRB1 alleles or diplotypes associated with ACPA-negative RA.

Results: HLA-DRB1*12:01 was identified as a novel susceptibility allele for ACPA-negative RA (p=0.000088, OR 1.72, 95%CI: 1.31–2.26). HLA-DRB1*04:05 and *14:03 showed moderate associations with ACPA-negative RA (p=0.0063, OR 1.26, 95%CI: 1.07–1.49 and p=0.0043, OR 1.81, 95%CI: 1.20–2.73, respectively). The shared epitope, including HLA-DRB1*04:05 was weakly associated with ACPA-negative RA, but no dosage effect was detected (p=0.016, OR 1.17, 95%CI: 1.03–1.34). A combination of HLA-DRB1*12:01 and DRB1*09:01 showed a strong association with susceptibility to ACPA-negative RA (p=0.00013, OR 3.62, 95%CI: 1.79–7.30). Homozygosity for HLA-DR8 was significantly associated with ACPA-negative RA (p=0.0070, OR 2.16, 95%CI: 1.22–3.82). We also found that HLA-DRB1*15:02 and 13:02 were protective against ACPA-negative RA (p=0.00010, OR 0.68, 95%CI: 0.56–0.83 and p=0.00059, OR 0.66, 95%CI: 0.52–0.84, respectively).

Conclusion: In our large-scale association study, we found multiple alleles and diplotypes associated with susceptibility to or protection against ACPA-negative RA.

152

Polymorphisms in the CCL2 Distal Regulatory Region Are Associated with Rheumatoid Arthritis in a North American Native Population with a High Disease Prevalence. Hani S. El-Gabalawy[1], Konstantin Jilkine[1], David B. Robinson[1], Irene Smolik[2], Donna M. Hart[3], Carol A. Hitchon[1], Christine A. Peschken[1], Charles N. Bernstein[1], Kiem Oen[1], Ye Sun[4] and Katherine A. Siminovitch[4]. [1]University of Manitoba, Winnipeg, MB, [2]University of Manitoba, Winnipeg, [3]Health Sciences Centre, Winnipeg, MB, [4]Mount Sinai Hospital, Toronto, ON

Background/Purpose: North American Native (NAN) populations exhibit a high prevalence of RA and frequent multi-case families, suggesting a strong genetic component to the disease. We have studied the Cree-Ojibway population in Central Canada and have previously shown that the genetic risk is imparted by a high frequency of shared epitope (SE) encoding alleles, with further contributions from TRAF1/C5 and TNFRSF14, the latter demonstrating an interaction with SE in disease risk (PMID:21614018). In addition to RA, this population also has a high burden of atherosclerosis and other chronic inflammatory diseases. MCP-1 plays a key role in the pathogenesis of chronic inflammation, and polymorphisms in the CCL2 locus, which encodes for MCP-1 protein, have been shown in other populations to be associated with increased serum levels of MCP-1 and with an increased risk of several chronic inflammatory diseases, including RA and atherosclerosis. We therefore sought to determine whether the CCL2 polymorphisms are associated with RA disease risk and serum levels of MCP-1 in the NAN population.

Methods: NAN RA patients (n=458), their disease-free FDR (n=300), and unrelated controls (C), (n=715) were recruited from several urban and rural locations in Central Canada. The gender distribution (% females) was RA=82%, FDR=70%, C=59%. All study subjects were genotyped for 3 CCL2 associated SNPs: RS1024610A/T (SNP1), RS1024611C/T (SNP2), RS2857654A/C (SNP3) by sequencing using the Sequenom Mass Array iPLEX platform. MCP-1 levels were tested in a subset of the RA (n=94), FDR (n=249), and C (n=186) by ELISA. Differences between groups were tested using genotypic, allelic, dominant, and recessive models.

Results: Minor allele frequency (MAF) for the CCL2 SNPs in the entire study population was SNP1=0.05, SNP2=0.21, SNP3=0.21, and all were in Hardy-Weinberg equilibrium. SNP2 and SNP3 are known to be in a high degree of linkage disequilibrium. The genotypic analysis indicated that there were significant differences between RA and C for SNP2 (18/168/261 vs. 33/214/457, p=0.04) and SNP3 (18/171/258 vs. 34/218/453, p=0.04). Further analysis indicated a significant difference using a dominant model: SNP2 and SNP3 OR=1.32, p=0.03, while there was no association with SNP1. There were no significant differences in the SNP allele distributions between FDR and C using any of the models. Serum MCP-1 levels for the 3 groups were RA=584±505, FDR=535±436, C=219±108 pg/ml (RA vs. FDR, p=NS; FDR vs. C, p=0.000). Analysis of the allele distribution of the SNPs relative to the serum levels of MCP-1 indicated that there was no clear association between the genotypes and the serum protein level in this population.

Conclusion: In a NAN population that has a high burden of RA, cardiovascular disease, and other chronic inflammatory diseases, there was a significant, albeit weak association of RA with SNPs in the regulatory region

of the CCL2 gene. Despite this, there was no clear association between these SNPs and serum levels of MCP-1. The surprisingly large differences in serum levels of MCP-1 between the disease-free FDR of RA patients and population controls cannot be explained on a genetic basis, and may relate to heretofore unidentified epigenetic effects.

153

Is There a Higher Genetic Load of Susceptibility Loci in Familial Ankylosing Spondylitis? Reeti K. Joshi[1], John D. Reveille[2], Matthew A. Brown[3], Michael H. Weisman[4], Michael M. Ward[5], Lianne S. Gensler[6], B. Paul Wordsworth[7], David M. Evans[8] and Shervin Assassi[9]. [1]Washington University in St. Louis, Saint Louis, MO, [2]University of Texas Health Science Center at Houston, Houston, TX, [3]Wellcome Trust Centre, Headington, United Kingdom, [4]Cedars Sinai Med Ctr, Los Angeles, CA, [5]NIH/NIAMS/IRP, Bethesda, MD, [6]UCSF, San Francisco, CA, [7]Bichester, Oxon, United Kingdom, [8]Chesterfield, MO, [9]Univ of Texas Health Science, Houston, TX

Background/Purpose: Several genes have been recently confirmed as genetic susceptibility loci for Ankylosing Spondylitis (AS) in genome wide association studies. The goal of this study is to examine whether the familial AS cases have a higher genetic load of these susceptibility loci.

Methods: Overall, 502 patients with AS were examined, consisting of 312 who had first-degree relatives (FDR) with AS (familial) and 190 who had no FDR with AS or spondyloarthritis (sporadic). All patients and affected FDRs fulfilled the modified New York Criteria for AS. The patients were recruited from North American Spondylitis Consortium (NASC), Prospective Study of Outcomes in Ankylosing Spondylitis (PSOAS) and United Kingdom- Oxford (UK-Oxford) cohorts.Only one AS case per family was included in the analysis. The frequency of AS susceptibility loci in *IL23R*, *IL1R2, ANTRX2, ERAP1*, two intergenic regions on chromosomes 2 and 21, as well as, a HLA B27 tag single nucleotide polymorphism (SNP), rs4349859 was compared between the familial and sporadic AS patients. Association between SNPs and multiplex status was assessed by logistic regression controlling for sibship size and Eigenstrat derived principal components from a previous genome-wide association study of AS.

Results: The UK –Oxford cohort included 160 familial AS cases with mean age of 47.9 years at enrollment, 60% being male. US cohort included 152 familial AS patients from NASC study with mean age of enrollment 44.4 years, 58% being male. PSOAS group included 190 sporadic AS cases with mean age 47.1 years, 76% being male. The risk allele in HLA-B27 tag SNP, rs4349859 was significantly more prevalent in familial cases ($p=0.002$, OR: 3.69, CI: (1.61, 8.46)). The frequency of AS susceptibility loci in the *ERAP1, IL23R*, *IL1R2*, *ANTXR2* genes in addition to two gene desert regions on 2p15 and 21q22 did not differ significantly between the familial and sporadic cases. However, the susceptibility locus on 21q22 showed a trend toward association ($p=0.054$) with the protective minor allele being less frequent in the familial cases. Further details of the results are shown in Table 1.

Table 1. Comparison of AS susceptibility loci between familial and sporadic AS cases after adjustment for sibship size

SNP	Candidate Gene	Minor Allele	Odds ratio (95% C.I.)	P-value
rs11209026	*IL23R*	A(P†)	0.55 (0.22, 1.36)	0.193
rs10865331	2p15*	A(R‡)	0.85 (0.61, 1.2)	0.365
rs2310173	*IL1R2*	A(R)	1.34 (0.94, 1.9)	0.105
rs4333130	*ANTXR2*	G(P)	0.9 (0.61, 1.32)	0.577
rs27434	*ERAP1*	A(R)	0.96 (0.64, 1.45)	0.855
rs2242944	21q22*	A(P)	0.68 (0.46, 1.01)	0.054
rs4349859	HLA B27 tag SNP	A(R)	3.69 (1.61, 8.46)	0.002

* These SNPs are located in gene deserts
† P: Protective Allele against AS
‡ R: Risk Allele for AS

We also repeated the analysis after restricting the sample to the US cases. The investigation of only US familial and sporadic AS cases showed similar results.

Conclusion: HLA tag SNP, rs4349859 which tracks closely with HLA-B27 is a susceptibility locus for familial AS. This finding confirms higher heritability in HLA-B27 positive subtype of AS. The frequency of the recently described non-MHC susceptibility loci is not markedly different between the sporadic and familial cases of AS.

154

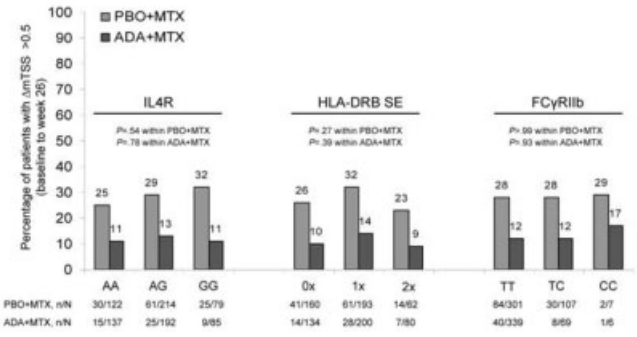
Analysis of Genetic Influence of HLA-DRB1, IL4R, and FcγRIIb on Radiographic Responses to Methotrexate Monotherapy or Adalimumab Plus Methotrexate Through 26 Weeks in Patients with Early Rheumatoid Arthritis. Alla Skapenko[1], Josef Smolen[2], Arthur Kavanaugh[3], Sourav Santra[4], Hartmut Kupper[5], Theresa Peterson[4] and Hendrik Schulze-Koops[1]. [1]University of Munich, Munich, Germany, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [3]University of California San Diego, La Jolla, CA, [4]Abbott, Abbott Park, IL, [5]Abbott, Ludwigshafen, Germany

Background/Purpose: Genetic factors may influence the susceptibility, severity, and radiographic progression of rheumatoid arthritis (RA). Specifically, the IL4R (A→G [I50V]) single nucleotide polymorphism (SNP) has been associated with early joint erosion,[1] and the FcγRIIb (T→C [I232T]) SNP is a candidate factor for rapid radiologic joint damage.[2] Their association with radiographic progression during treatment with anti-TNF agents is unclear. The purpose of this study was to examine radiographic progression through 26 weeks in pts treated with adalimumab plus methotrexate (ADA+MTX) or placebo (PBO)+MTX according to 3 candidate genetic markers: IL4R I50V SNP, HLA-DRB1 shared epitope (SE), and FcγRIIb I232T SNP.

Methods: MTX-naïve pts ≥18 years old with RA <1 year and active disease (DAS28[CRP] >3.2, ESR ≥28 mm/h or CRP ≥1.5 mg/dL), and either >1 erosion, RF+, or anti-CCP+ were randomized to ADA+MTX (n=515) or PBO+MTX (n=517) for 26 wks. This analysis presents radiographic outcomes, including the percentage (%) of pts with progression in modified Total Sharp Score (ΔmTSS >0.5) and rapid radiographic progression (RRP, ΔmTSS >1.5) from baseline (BL) to 26 wks by IL4R I50V SNPs (AA, AG, or GG), HLA-DRB SE copy number (0x, 1x, 2x), and FcγRIIb I232T SNPs (TT, TC, CC). Multiple imputation analyses were used to assess radiographic data.

Results: Genetic data were available for 451 PBO+MTX and 443 ADA+MTX pts. The number (%) of pts with available radiographic data at wk 26 by genotype is lower than that of those genetically analyzed (**Figure**). The distribution of alleles was similar between treatment groups for IL4R and SE; however, the FcγRIIb SNPs were unequally distributed: the PBO+MTX group had more TC and fewer TT pts. BL demographics were similar across alleles, except a higher proportion of anti-CCP+ pts were noted with increasing SE copies. There were no consistent patterns of influence of IL4R SNP, SE copy number, or FcγRIIb SNP on the % of pts with ΔmTSS >0.5 (**Figure**) or RRP at wk 26.

Figure. Percentage of Patients With Radiographic Progression at Week 26



Conclusion: Regardless of genetic background, a higher % of pts in the PBO+MTX group exhibited radiographic progression compared with ADA+MTX. Based on previous studies,[1–2] it is somewhat unexpected that neither the IL4R nor the FcγRIIb SNP influenced radiographic progression. Possible reasons for this difference may be that the study population was pre-selected for pts with risk for aggressive erosive disease, the analysis was performed after a shorter duration of treatment, and the overall increase in mTSS was moderate. Further exploration is warranted to determine any potential interactions in response to anti-TNF agents.

Characterization of a New Category of Autoinflammatory Disease Associated with Nucleotide Oligomerization Domain2 Gene Mutations: An Expanded Cohort Study. Qingping Yao, Le Chu Su, Lan Zhou, Bijal Jayakar and Bo Shen. Cleveland Clinic, Cleveland, OH

Background/Purpose: Autoinflammatory diseases are characterized by seemingly unprovoked episodes of inflammation, without high titer autoantibodies or antigen specific T cells, and derive from genetic variants of the innate immune system. Clinically, there are patients with autoinflammatory phenotypes of unidentified genetic causes, thus posing diagnostic challenges. Modern molecular and genetic tools would enable a better disease classification. We previously described a small number of patients with autoinflammatory phenotypes associated with nucleotide oligomerization domain (NOD2) gene mutations. Herein, we report a cohort of 17 patients to further characterize this disease entity.

Methods: Seventeen patients with autoinflammatory phenotypes of unknown diagnoses were enrolled and studied between January 2009 and April 2011. The NOD2 gene testing in these patients was performed by sequencing of all 12 coding exons (Center for Genetic Testing in Saint Francis, Oklahoma).

Results: All seventeen patients were non-Jewish Caucasians, with 8 being male. The mean age at disease diagnosis was 39.5 years (range 17–72) and disease duration was 4.7 years (range 1–10). Typical clinical presentations were weight loss (7/17), self limiting fever (10/17), dermatitis (15/17) and inflammatory polyarthritis (14/17), with prominent hip symptoms. There were gastrointestinal symptoms inconsistent with inflammatory bowel disease in 11 patients, granulomas of the skin and gut in 2, and recurrent chest pain in 2, with 1 having pleuritis and pericarditis. Nine had sicca-like symptoms which did not fulfill the diagnostic criteria of Sjogren syndrome. Seven patients had increased acute phase reactants in serum. While the 17 patients had negative tests for autoantibodies for classic connective tissue diseases and systemic vasculitis, all carried the NOD2 gene mutation $IVS8^{+158}$ with 6 having concurrent R702W mutation. Of interest, there was no reported family history in most patients. However, there were 3 female sibs from a single family who presented with similar symptoms and shared $IVS8^{+158}$. Most patients appeared to have mild form of disease which required symptomatic treatment. Dermatitis was primarily treated with topical steroid creams but required small to high dose prednisone in some cases. Arthritis typically did not respond to nonsteroidal anti-inflammatory drugs (NSAIDs). Some patients seemed to respond to sulfasalazine but not to methotrexate. A trial of TNF inhibitors in 3 cases did not improve inflammatory arthritis and abatacept trial in another case did not seem to benefit either. Serositis associated symptoms responded well to a short course of high dose prednisone in 1 case but not to colchicine or NSAIDs.

Conclusion: Our expanded cohort study further supports the new disease category with characteristic clinical phenotypes, which somewhat resembles pediatric Blau syndrome. However, the new entity does not seem rare and may be polygenic. Its association with the NOD2 mutations suggests $IVS8^{+158}$ may be entertained as a genetic marker for the diagnosis of the disease. Further clinical, genetic and etiopathogenic study of the disease is warranted.

A Putative Functional Polymorphism in the *IL21* 3'-UTR Flanking Region Is Tagged by *IL21* Lupus-Associated Variants and Alters Gene Expression *in Vitro*. Travis Hughes and Amr H. Sawalha Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: We have previously reported, and recently localized, replicated and confirmed the genetic association between *IL21* polymorphisms and the susceptibility to SLE with a genome-wide significance. Two SNPs located within *IL21* and its 3'-UTR flanking region, rs907715 and rs6835457, explain the genetic association in this locus. Herein, we seek to identify putative functional polymorphisms for which the previously observed polymorphisms might serve as a proxy.

Methods: We conducted a scan for genetic polymorphisms in the *IL21* locus that are in LD ($r^2>0.8$) with the two previously reported lupus-associated markers (rs907715 and rs6835457) in Hapmap3 and among polymorphisms in the 1000 Genomes Project. We used luciferase reporter assays to interrogate the *cis*-acting effects of a putative functional polymorphism on *IL21* gene expression.

Results: We identified a total of 9 additional SNPs in high LD with the previously characterized genetic effect within the *IL21* locus using the CEU European-derived samples. The observed LD block formed by these polymorphisms is centered around *IL21* and does not extend to encompass other genes in the region. One polymorphism, rs2175679, is located within a putative regulatory region downstream of *IL21* which is enriched for H3K4me1, H3K4me3, CTCF, and a number of transcription factor binding sites in ENCODE data sets. These data suggest this region to possess enhancer and/or insulator function downstream of *IL21* which might be modified by this non-coding G/T polymorphism. Indeed, luciferase levels using constructs with the G-allele variant are significantly increased relative to those of the T-allele variant in rs2175679 (1.5-fold, $P = 0.007$). The G allele of rs2175679 is the allele which corresponds to the lupus-associated risk allele of both rs907715 and rs6835457.

Conclusion: A common non-coding variant in *IL21* 3'-UTR flanking region might contribute to increased lupus susceptibility by altering the transcriptional regulation of *IL21*.

Sex-Specific Genetic Architecture of Systemic Lupus Erythematosus. Travis Hughes[1], Adam Adler[1], J.T. Merrill[1], Jennifer A. Kelly[1], Kenneth Kaufman[2], Adrienne Williams[3], Carl D. Langefeld[4], Gary S. Gilkeson[5], Elena Sanchez[1], Javier Martin[6], Elizabeth E. Brown for PROFILE[7], Patrick M. Gaffney[8], Kathy L. Moser[8], Tomothy J. Vyse[9], Marta E. Alarcon-Riquelme[10], Judith A. James[11], Robert H. Scofield[12], John B. Harley[13], Bruce C. Richardson[14] and Amr H. Sawalha[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma CIty, OK, [3]Wake Forest University, Winston-Salem, [4]Wake Forest University Health Sciences, Winston-Salem, NC, [5]Division of Rheumatologyand Immunology, Medical University of South Carolina, Charleston, SC, [6]Instituto de Parasitologia y Biomedicina Lopez-Neyra (CSIC), Granada, Spain, [7]University of Alabama at Birmingham, Birmingham, AL, [8]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [9]King's College London, Guy's Hospital, London, United Kingdom, [10]Oklahoma Medical Research Foundation, Center for Genomics and Oncological Research Pfizer-University of Granada-Junta de Andalucia, Oklahoma City, OK, [11]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK, [12]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, US Department of Veterans Affairs Medical Center and Department of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [13]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH, [14]University of Michigan, Ann Arbor, MI

Background/Purpose: Systemic lupus erythematosus is a sexually dimorphic autoimmune disease which is more common in women, but affected men often experience a more severe disease. The genetic basis of sexual dimorphism in lupus is not clearly defined. Here, we examine sex-specific genetic effects among lupus-susceptibility loci.

Methods: A total of 18 lupus-associated autosomal genetic loci were genotyped in a large set of lupus patients and controls of European descent, consisting of 5,932 female and 1,495 male samples. Sex-specific genetic association analyses were performed. Sex-gene interaction was further validated using both a parametric (logistic regression) and non-parametric (multifactor dimensionality reduction) methods. We examined aggregate differences in sex-specific genetic risk by calculating a cumulative genetic risk score for lupus in each individual and comparing average genetic risk between men and women.

Results: We observe a significantly higher cumulative genetic risk for lupus in men than in women. We report significant sex-gene interaction in the HLA region and *IRF5* genes whereby male lupus patients possess a significantly higher frequency of risk alleles than their female counterparts. We also report that the genetic effect observed in *KIAA1542* is specific to female lupus patients, and does not seem to play a role in lupus in men.

Conclusion: Our data indicate that men require a higher cumulative genetic load to develop lupus compared to women. This observation suggests that the higher prevalence of lupus in women, and the more severe lupus phenotype in men could be related to autosomal genes.

Recognition of High Risk and Protective HLA-DRB1 Alleles with Respect to Need for Biologic Therapy in a Cohort of 226 Patients with Rheumatoid Arthritis. Surabhi Waghmare[1], Andrew Cairns[2], Clare Matthews[3] and Gary D. Wright[4]. [1]Musgrave Park Hospital-Belfast Health and Social Care Trust, Belfast, BT9 7JB, United Kingdom, [2]Musgrave Park Hospital-Belfast Health and Social Care Trust, Belfast, United Kingdom, [3]Ulster Hospital-South Eastern Trust, Belfast, United Kingdom, [4]Musgrave Park Hospital, Belfast, United Kingdom

Background/Purpose: Studies have shown association of shared epitope (SE) containing HLADRB1 alleles, with increased susceptibility and severity of RA.However their effect on treatment response still remains unexplored. Aim of this study is to identify "treatment prognostic marker" alleles, which are likely to increase the odds of needing biologics and ones rendering a protective effect against their use.

Methods: 226 Caucasion Northern Irish RA patients (mean age 59.3+/−SD13.8y), checked for HLADRB1 haplotype, were treated over 6 years as per standard practice lead by clinical response. Biologics were commenced as per British Society of Rheumatology criteria i.e. active RA in spite of 2 DMARDS trial, measured by disease activity index (DAS28)>5.1 at 2 occasions, monthly apart. Outcome measured at 6 years, was risk of needing biologic therapy; expressed as relative risk and odds ratio. Frequency of each of 30 DRB1 alleles was measured in 2 groups (biologic vs. non-biologic therapy), statistical significance determined by Chi-square test. Differences in the need for biologic therapy in relation to allele types was analysed, statistical significance determined using Chi-square test (when not possible, Fisher's test). Null hypothesis was rejected conventionally with $p<0.05$.

Results: 1. Alleles *401 and *404 were seen more frequently in biologic group (Allele*401:54.9% in biologic vs. 34.9% in non-biologic group, $p=0.010$; Allele*404:17.6% in biologic vs.7.4% in non-biologic group, $p=0.030$). **2**. Allele*1501 occurred more frequently in non-biologic group (21.6% in biologic vs. 36.6% in non-Biologic group, $p=0.045$). **3.** Presence of any one of *401 and *404 allele increased the risk needing biologic therapy, RR 1.89; OR 2.26 (CI 1.17 to 4.39, $p=0.014$) compared to those without them (52.9% vs. 37.7%). *401 and *404 were identified as High Risk Alleles (HRA) for needing biologics. **4.** The above risk increased further, RR 3.63; OR 6.91 (CI 1.70 to 28.09, $p=0.010$) when both alleles are HRA i.e. each allele in the allele pair was either *401 or *404 compared no HRA (9.8% vs. 2.3%). **5.** When patients with any one of the traditional "SE containing alleles" (*101,*401,*404,*405,*408,*1001) were compared to those without them (60.8% vs. 49.7%), an increased risk of needing biologics, RR 2.05; OR 2.42 (CI 1.11 to 5.2868, $p=0.023$) was seen. Of note, HRAs *401 and *404 were included in these SE containing alleles. **6.** In patients with 2 SE alleles, there was a further increased risk of needing biologic therapy, RR 2.6; OR 3.4 (CI 1.24 to 9.3202, $p=0.014$) compared to patients with no SE alleles (2% vs.1.1%) **7.** However, when *401 and *404 was excluded in points 5 and 6, there was no increased risk for biologics (OR 0.8214 and 0 in point 5 and 6, respective p values of 0.23 and 1). **8.** Allele *1501 seemed to offer a protective effect against needing Biologics (RR 0.5537; OR 0.477, CI 0.2288 to 0.9945, $p=0.045$).

Conclusion: Alleles *401 and *404 are dominantly associated with increased risk of needing biologic therapy. This risk is increased further if both alleles are HRA. Although SE containing alleles collectively increased risk, majority of this effect was due to *401 and *404. Presence of *1501 allele may exert protective effect and may reduce the likelihood of needing biologics.

160

Investigation of Caucasian Rheumatoid Arthritis Susceptibility Loci in African Patients with the Same Disease. Sebastien Viatte[1], Edward Flynn[1], Mark Lunt[1], Joanne Barnes[1], Madeleine Singwe-Ngandeu[2], Sylvette Bas[3], Anne Barton[1] and Cem Gabay[3]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]Unit of Rheumatology, Department of Internal Medicine, School of Medicine, University of Yaoundé, Yaoundé, Cameroon, [3]Division of Rheumatology, University Hospitals of Geneva, 26 Avenue Beau-Séjour, 1211 Geneva 14, Switzerland

Background/Purpose: The largest genetic risk to develop rheumatoid arthritis (RA) arises from a group of alleles of the HLA DRB1 locus ("shared epitope", SE). Recent genome wide and candidate gene association studies in Caucasians have identified over 30 confirmed single nucleotide polymorphisms (SNPs) predisposing to disease (susceptibility loci). We previously reported a lower prevalence of the SE in RA patients in Cameroon compared to European patients, despite a similar proportion of anti-CCP positivity. We aimed in the present study to investigate the contribution of United Kingdom (UK) RA susceptibility SNPs to RA susceptibility in Cameroon.

Methods: RA cases and controls from Yaoundé, Cameroon were genotyped for a panel of Caucasian putative RA susceptibility SNPs using Sequenom MassArray technology. Genotype data was also available for 4524 UK cases and 3781 UK controls (reference cohort) and for 500 cases and 500 controls from another UK cohort (validation cohort). Using the reference cohort, a Caucasian cumulative aggregate genetic-risk score (GRS) was calculated, in order to predict RA susceptibility of individuals, as the sum of the weighted risk-allele counts. The ability of the GRS to predict RA in small sample sizes was tested in 200 random samples of the validation cohort.

Results: After genotyping quality control, data on 63 SNPs was available for analysis in 43 Cameroon RA cases and 44 controls. Only 2 SNPs, both mapping to CCL21, were associated with RA: rs951005 (frequency of the A allele in controls: 47%, in cases: 65%, $p=0.01$) and rs2812378 (similar frequencies).

11% of SNPs tested were completely absent in Cameroonian samples, having minor allele frequency (MAF) of over 10% in the UK; these included SNPs mapping to the PTPN22 and ILRA loci. 71% of the remaining SNPs showed a MAF differing by > 10% between the UK and Cameroon.

Among 54 SNPs with data available in the UK reference cohort, 41 showed an association with RA at $p<0.05$. Those SNPs were selected to compute the GRS. The GRS showed a strong association with RA in the UK validation cohort (beta coefficient: 0.80, $p=3.0\times10^{-13}$). In 200 random samples of the validation cohort, 68% showed an association between the GRS and RA at $p < 0.05$. However, the GRS did not predict RA in Cameroon samples (beta coefficient: −0.17, $p=0.77$) and this difference was statistically significant ($p<0.005$).

Conclusion: The MAF of Caucasian RA susceptibility SNPs are different between UK and Cameroon samples. Several confirmed RA susceptibility polymorphisms, including PTPN22, are not detectable in the Cameroon population. The genetic risk of developing RA conferred by a set of 41 SNPs is significantly different in the UK and in Cameroon, despite a similar proportion of anti-CCP positive RA. Taken together, these observations strengthen the hypothesis that RA susceptibility SNPs are at least partially different in different ethnic backgrounds.

161

Germinal and Somatic Abnormalities of the *TNFAIP3* Gene Support a Two-Hit Hypothesis of Lymphomagenesis in Autoimmune Diseases. Xavier Mariette[1], Saida Boudaoud[2], Gaetane Nocturne[1], Thierry Lazure[2], Joanne Nititham[3], Kimberly E. Taylor[4], Eric Hachulla[5], Jean Jacques Dubost[6], Jacques-Eric Gottenberg[7], Lindsey A. Criswell[8] and Corinne Miceli-Richard[9]. [1]Bicêtre University Hospital, Le Kremlin Bicetre, France, [2]INSERM U1012 - Université Paris XI, Le Kremlin Bicêtre, France, [3]University of California, CA, [4]University of California, San Francisco, San Francisco, CA, [5]Internal Medicine, Lille CEDEX, France, [6]CHU Gabriel Montpied, Clermont-Ferrand, France, [7]Strasbourg University Hospital, Strasbourg, France, [8]University of California San Francisco, San Francisco, CA, [9]Hopital Bicêtre, Le Kremlin Bicêtre, France

Background/Purpose: The pathophysiology of lymphomas in auto immune disease (AID), particularly primary Sjögren's syndrome (pSS), involves persistent inflammation and activation of autoimmune B cells leading to NF-kB activation. The *TNFAIP3* gene encodes the A20 protein which is a central gatekeeper of NF-kB activation. Germinal abnormalities in *TNFAIP3* have been associated with different AID and somatic mutations of the gene have been observed in several lymphoma subtypes, particularly MALT lymphoma, the lymphoma subtype most frequently associated with pSS. We aimed to investigate whether *TNFAIP3* abnormalities are involved in the lymphomagenesis process in pSS.

Methods: A cohort of 584 pSS patients including 24 patients with lymphoma (ASSESS + KB cohort) and 451 controls of Caucasian ancestry, addressed by 48 AIMs, was used for genetic studies. 3 SNPs encompassing the *TNFAIP3* locus located on 6q23 (rs13192841, rs2230926 and rs6922466) and known to be associated with SLE and/or RA were genotyped. Case control association tests were performed. Quantitative PCR (qPCR) was used for assessing the level of TNFAIP3 mRNA according to genotype. Then complete sequencing of the 9 *TNFAIP3* exons was performed in germinal DNA from 35 pSS patients with lymphoma and in lymphoma DNA extracted from tumoral paraffin sections from 16 of the 35.

Results: The 3 *TNFAIP3* SNPs were not significantly associated with risk of pSS. However, multivariate analysis demonstrated a significant association between the rs2230926 SNP (coding for an amino acid substitution in exon 3) and pSS complicated by lymphoma: OR= 3.36 (95%CI 1.34 – 8.42) p= 0.0097. Complete *TNFAIP3* gene sequencing of germinal DNA from 35 patients with pSS and lymphoma confirmed the presence of the rs2230926 risk variant in 9/35 (25.6%) pSS patients (MAF: 12.8% vs 6% in the 451 controls, OR= 2.3 [95%CI 1.09 – 4.9]; p= 0.04). Based on qPCR, the

expression level of A20 mRNA was significantly decreased in patients carrying the G minor allele (p=0.004). Moreover, we identified a novel germinal abnormality: a deletion of 24 nucleotides in exon 1 that leads to the suppression of a binding site for the Sp1 transcriptional factor in 4/35 patients (11.4%) vs 3/97 (3.1%) in controls and 5/119 (4.2%) in pSS patients without lymphoma (p=0.13). Overall, 11/35 patients (31.4%) with pSS and lymphoma had germinal variants of the *TNFAIP3* gene with potential functional consequences. Based on *TNFAIP3* sequencing, comparison of germinal and tumoral TNFAIP3 DNA among 16 patients with pSS and lymphoma revealed that 4 patients (25%) exhibited the rs2230926 risk variant and 4 other patients (25%) had a loss of heterozygosity in lymphoma DNA for rs2230926, rs661561, rs5029948 and/or rs2307859. This result will be further investigated with FISH. Overall, 8/16 patients (50%) had a functional abnormality of the *TNFAIP3* gene within germinal or lymphoma DNA.

Conclusion: Among patients with pSS and lymphoma, functional abnormalities of the *TNFAIP3* gene were present in germinal and lymphoma DNA of 31% and 50%, respectively. These data strongly support a two-hit process for lymphomagenesis in autoimmunity, in which both germinal and somatic abnormalities of A20 lead to impaired control of NFkB activation and an increased risk of lymphoma.

Investigation of the Interaction Between Smoking and TRAF1/C5 on Radiological Severity of Inflammatory Polyarthritis. Lily M. Wheeler, Sebastien Viatte, Suzanne Verstappen, Deborah P. Symmons, Jane Worthington and Anne Barton. Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom

Background/Purpose: A number of factors have been identified as contributing to the severity of rheumatoid arthritis (RA), including SNP markers at the TRAF1/C5 region (rs2900180 and rs10760130). The role of smoking in RA disease severity is debated in the literature. We investigated whether smoking status conditions the association of TRAF1/C5 severity variants in patients with recent onset inflammatory polyarthritis (IP).

Methods: Data were collated from the Norfolk Arthritis Register, a prospective inception cohort for recent onset IP recruited from both primary and secondary care. X-rays were taken on patients who satisfied the ACR criteria for RA at one year and on all patients at 5 years follow-up. DNA and X-ray data were available for 1860 patients and X-ray with smoking data for 1789 patients. The interaction between smoking status at baseline and the carriage of polymorphisms at the TRAF1/C5 region with radiological damage, as measured using the Larsen score or the presence of erosions, was investigated longitudinally to include repeat measurements in the same individual at different time points. Interaction was defined as significant departure from a multiplicative model of the individual odds ratios (OR).

Results: Smoking status was not associated with erosions, whilst the carriage of rs2900180 alleles was significantly associated with erosions (OR: 1.82 (95% CI 1.1, 3.0), p-value 0.019). An association was found in ever smokers (OR 3.39 (95% CI 1.7, 6.8), p-value 0.001); when stratified into current smokers and previous smokers, this association was significant in previous smokers (OR: 4.09 (95% CI 1.7, 9.6), p-value 0.001). The OR followed the same direction for current smokers (OR 2.25 (95% CI 0.7, 7.7), p-value 0.196), but not for non-smokers (OR: 0.61 (95% CI 0.2, 1.6), p-value 0.307). The interaction between ever smoker status and the carriage of rs2900180 departed significantly from multiplicativity (interaction OR: 5.56 (95% CI 1.8, 17.6), p value 0.004). The interaction between previous smoker status and the carriage of rs2900180 departed significantly from the multiplicative model (interaction OR: 6.83 (95% CI 2.0, 23.7), p-value 0.003); however the interaction was not significant in current smokers. Consistent results and a significant interaction were also found when using the Larsen score as outcome variable in longitudinal modelling. Total smoking duration and the length of time between smoking cessation and disease onset were, independently, highly significantly correlated with erosions in previous smokers—if the smoking duration is longer, there is a higher the risk of erosive disease. Analysis of rs10760130 showed similar patterns of associations and interactions.

Conclusion: These results demonstrate an interaction between ever smoker status and the carriage of markers at the *TRAF1/C5* region on erosive disease in IP/RA patients. These findings support a model of RA pathogenesis in which smoking prevalence and time prior to disease onset affects the development of erosive disease in genetically predisposed individuals and underlines the importance of gene-environment interactions. We are currently validating these findings in another large data set.

Identification of Clinical and Genetic Factors That Influence the Response to Methotrexate in Japanese Rheumatoid Arthritis Patients: Genome-Wide Association Study. Taku Suzuki[1], Katsunori Ikari[1], Yoshiaki Toyama[2], Atsuo Taniguchi[1], Nao Nishida[3], Katushi Tokunaga[3], Hisashi Yamanaka[1] and Shigeki Momohara[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Keio University, Tokyo, Japan, [3]Department of Human Genetics, Graduate School Of Medicine, University of Tokyo, Tokyo, Japan

Background/Purpose: Methotrexate (MTX) is the anchor drug for the treatment of rheumatoid arthritis (RA).The aim of this study was to identify clinical and genetic factors that influence the response to MTX in Japanese RA patients.

Methods: The present study is part of IORRA (Institute of Rheumatology RA cohort) project with an enrollment of nearly 5000 RA patients. Of these, 2244 patients, who received MTX therapy, were enrolled in this study. Efficacy of MTX treatment at six months after the first administration was evaluated using European League Against Rheumatism (EULAR) response criteria. First, the association between clinical factors and EULAR response of MTX treatment was studied using multiple regression analysis (independent variable: MTX dose, sex, age of onset and rheumatoid factor status). The analysis was performed using the R software package. Then, we performed a genome-wide association study (GWAS) to define genetic factors that influence response to MTX treatment in 132 RA patients using the detected clinical factors as covariates. Affymetrix Genome-Wide Human SNP Array 6.0 that included more than 906,600 single nucleotide polymorphisms (SNPs) was used for GWAS (Filtering criteria: genotype call rate 0.9 per SNP and per individual, minor allele frequency 0.05, P value for Hardy-Weinburg equilibrium test 0.0001). Logistic regression analysis implemented in PLINK was used to test the association.

Results: Initial dose of MTX had a significant impact on EULAR response of MTX treatment (P=0.0002), while the other factors did not show any association. There were 580,254 autosomal SNPs from 132 patients that met filtering criteria. Twenty-six SNPs associated with the response to MTX treatment at $P<1\times10^{-4}$, but none of them could reach genome-wide significance levels.

Clinical factors associated with response to MTX treatment

	estimate	P
MTX dose	0.082	0.0002
gender	−0.046	0.71
age of onset	0.001	0.81
RF	0.000	0.13

Conclusion: While initial MTX dose was significantly associated with EULAR response of MTX treatment in Japanese RA patients, our GWAS demonstrated that the SNPs did not have any significant effect on the response to MTX treatment.

164

Genome-Wide Association Study of Rheumatoid Arthritis, Stratified by Smoking Status. Darren Plant[1], Deborah P. Symmons[1], Jane Worthington[1], David Strachan[2] and Anne Barton[1]. [1]University of Manchester, Manchester, United Kingdom, [2]St George's, University of London, London, United Kingdom

Background/Purpose: Tobacco smoking is well recognised as a major preventable risk factor for the development of rheumatoid arthritis (RA); however the mechanism of action remains unclear. Cigarette smoke condensates induce proinflammatory cytokine expression from lung epithelial cells, whilst deimination of the amino acid arginine to citrulline in alveolar macrophages occurs in individuals who smoke. Interestingly, the most compelling genetic risk factor for RA development is conferred by human leukocyte antigen *(HLA)-DRB1*, with the greatest risk seen in smokers who have a positive titre for autoantibodies to citrullinated peptide (anti-CCP). These data support gene environment interactions in RA patients. We hypothesised that non-HLA genetic risk markers for RA may also be modified by smoking status. In order to test this, we conducted genome-wide association (GWA) analyses in UK individuals, stratified by smoking habits.

Methods: 1,312 UK RA patients (never smoked (n=492), past smoker

(n=558) and current smoker (n=262)) along with 1,480 controls (never smoked (n=426), past smoker (n=712) and current smokers (n=342)) were genotyped for a total of 459,446 single nucleotide polymorphisms (SNPs), using the affymetrix 500k array (www.wtccc.org). GWA analyses were performed within each of the three smoke status groups. Markers with minor allele frequency >5% and demonstrating moderate association ($p < 10^{-5}$) with RA susceptibility in the initial analyses were selected for replication. The replication dataset comprised 715 UK RA patients (never smoked (n=260), past smoker (n=340) and current smoker (n=115)), genotyped using the Sequenom MassArray platform; and 5,016 UK 1958 birth cohort controls (www.b58cgene.sgul.ac.uk; never smoked (n=1,448), past smoker (n=2,365) and current smokers (n=1,203)), genotyped using the illumina 550k array. Anti-CCP data were available for 1,307 (81% positive) patients in the discovery and 643 (81% positive) patients in the validation sample.

Results: 14 SNP markers were included in a Sequenom plex for replication. One SNP failed to genotype successfully, leaving 13 markers available for analysis. The major allele of the marker rs1733717, mapping to the mannan binding lectin *(MBL)-2* gene, correlated with a reduced risk of RA development in all smoking groups in the discovery sample. This finding was replicated in past smokers (OR 0.50 (95%CI 0.15, 0.86)) $p=1.9E^{-6}$). The marker rs6679677 mapping to *PTPN22* was correlated with RA risk in all smoking groups in the discovery and replication sample. No other marker replicated convincingly. Results remained qualitatively the same following stratification by anti-CCP status.

Conclusion: These data support a role for *MBL2* as a modifier of RA susceptibility irrespective of smoking status and suggest that the increase in risk of RA conferred by *PTPN22* is not modified by smoking history. Larger sample sizes are likely to be required to exclude further gene-smoking interactions as modifiers of RA susceptibility risk.

Genome-Wide Association Analysis of Rheumatoid Arthritis Patients Treated with Anti-TNF Medication. Marieke J.H. Coenen[1], Masha Umicevic-Mirkov[1], Judith A. Wessels[2], Sita H. Vermeulen[1], Erik J. Toonen[1], Annette T. Lee[3], Remco R. Makkinje[1], Wietske Kievit[1], Hans Scheffer[1], Tim L. Jansen[4], Ellen A. Dutmer[5], Timothy R.D. Radstake[6], Mart A.F. van de Laar[7], Pilar Barrera[1], Piet L.C. van Riel[1], Henk-Jan Guchelaar[2], Peter K. Gregersen[8] and Barbara Franke[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Feinstein Institute Med Rsch, Manhasset, NY, [4]Medical Centre Leeuwarden, Netherlands, [5]Gelderse Vallei Hospital, Ede, Netherlands, [6]Radboud University Nijmegen Medical Centre, Nymegen, Netherlands, [7]Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [8]Feinstein Institute Medical Reschearch, Manhasset, NY

Background/Purpose: Treatment strategies blocking tumour necrosis factor (anti-TNF) have proven very successful in patients with rheumatoid arthritis (RA). However, a relevant subset of patients does not respond for reasons that are unknown. Although there is some indication that genetic variants may influence the response to TNF blockers, there are currently no means of identifying these patients prior to treatment start.We aimed at identifying genetic factors predicting anti-TNF treatment outcome in patient with RA using a genome-wide association approach. We aimed at identifying genetic factors predicting anti-TNF treatment outcome in patient with RA using a genome-wide association approach.

Methods: We selected patients with RA treated with antibodies directed against TNF from the Dutch Rheumatoid Arthritis Monitoring (DREAM) registry and the database of Apotheekzorg, which facilitates the Dutch distribution of adalimumab. Disease activity scores (DAS) 28 at baseline and after 14 weeks were available of 872 patients. Single nucleotide polymorphisms (SNPs) were genotyped using the Illumina HumanHap550-Duo BeadChip or the Human660W-Quad. Association analysis using the DAS28 change as outcome was performed (co-variates DAS28 at baseline and methotrexate as co-medication) using the whole genome association analysis toolset in PLINK.

Results: 516168 SNPs passed quality control. No findings passed the threshold for genome-wide significance (p-value $\leq 1\times10^{-8}$). Eight SNPs showed suggestive association with DAS28 change with a p-value$<10^{-6}$. Seven of these were located in genes (*ALK, NKAIN3, CETP, CICP10, L3MBTL3, PBX3, RPL18P1*). The top associated gene *ALK* ($p=8.11\times10^{-7}$) is involved in apoptosis one of the working mechanisms of anti-TNF. Pathway analysis, including all SNPs with a p-value $<10^{-4}$, was performed using Ingenuity. This resulted in the identification of four gene networks, two of these could be linked to apoptosis. In addition the second largest network linked the genes to TNF and its downstream signalling pathway. Replication of the top 50 associated SNPs in ~1500 RA patients treated with anti-TNF is ongoing.

Conclusion: The GWA approach is a potent tool for the identification of new candidate biomarkers predicting anti-TNF response. Suggestive findings will be replicated in larger, independent patient cohorts to prove whether the identified SNPs are associated with treatment outcome.

An Insertion Mutation in the MDFIC (MyoD Family Inhibitor Domain Containing) Gene Defines a Novel Autoinflammatory Syndrome Associated with Lymphedema. Ahmet Gul[1], Duran Ustek[2], Gulen Hatemi[3], Hulya Azakli[2], Zeliha Emrence[2], Fulya Cosan[2], Aris Cakiris[2], Neslihan Abaci[2], Muzaffer Arikan[2], Atilla Cakar[2], Nil Arisoy, Ozgur Kasapcopur[3] and Huri Ozdogan[3]. [1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Istanbul University, Istanbul, Turkey, [3]Rheumatology, Istanbul, Turkey

Background/Purpose: Autoinflammatory syndromes encompass an expanding spectrum of disorders characterized by seemingly unprovoked inflammatory attacks resulting from inborn errors of the innate immune system. We previously described two patients, who were second degree cousins with shared features of recurrent inflammatory attacks lasting 3–10 days since the first year of life. These attacks are characterized by fever, erythematous/urticarial rash with hyperesthesia, serositis and edema on the face and extremities. The latter feature did not resolve completely between the attacks later in the course of the disease, and both patients eventually developed a lymphedema symmetrically affecting lower extremities and genitalia. Because of autosomal recessive inheritance pattern and availability of 3-generation family members, we aimed to identify the responsible gene using a homozygosity mapping approach.

Methods: Genomic DNA was isolated from 18 family members including two index patients; and all were genotyped using the human 370CNV SNP chip of Illumina. Homozygosity mapping was carried out to identify the candidate genomic regions using the SNP Variation Suite v7 of the Golden Helix. A targeted 385K Capture Array was prepared using the genomic DNA of four family members by NimbleGen for the mapped region; and all coding regions of the known genes were then deep sequenced using the GS-FLX 454 Titanium system (Roche Diagnostics). Confirmation of the identified variation and screening of healthy controls were done by using the classical DNA sequencing method.

Results: All individuals were successfully genotyped using the Illumina 370CNV chips. The homozygosity mapping revealed a 7.8Mb-long region in the long arm of chromosome 7 that was homozygous only in 2 patients and heterozygous in their parents; and a smaller homozygous segment was also identified in chromosome 14. We searched the mapped Chr7q31.1 region by exon sequencing of the all known 24 genes using the GS-FLX 454 system in the two index patients, one parent and one sibling. A homozygous insertion mutation in the exon 3 of the MyoD family inhibitor domain containing gene (MDFIC) was identified only in two index patients. MDFIC is a 247 amino acid long protein, and this insertion causes an amino acid changes at position 131 and 132 (p.131 M>N, p.132 H>A) and a frameshift at position 133, which inhibits the translation of its functional cysteine-rich C-terminal domain. This variation was confirmed by sequencing of genomic DNA of all the available family members. None of the screened 200 regionally matched healthy individuals was carrying this variation.

Conclusion: MDFIC gene was identified as the gene responsible for the manifestations of these two patients, who show features of autoinflammatory disorders and a later onset lymphedema. The gene is reported to be expressed in immune cells without a known function, and recent studies have indicated a role in the regulation of wnt/beta-catenin pathway. We suggest that this is a novel type of autoinflammatory disorder, and a loss-of-function mutation in the MDFIC gene may be associated with a dysregulated inflammatory response affecting the wnt/beta-catenin pathway, which may also be responsible for the development of lymphedema.

Polygenic Modeling of Genome-Wide Association Study Data Reveals Hidden Heritability of Rheumatoid Arthritis Risk. Eli A. Stahl[1], Daniel Wegmann[2], Peter Kraft[3], Henrik Kallberg[4], Fina Kurreeman[5], Peter K. Gregersen[6], Lars Alfredsson[7], Katherine A. Siminovitch[8], Jane Worthington[9], Paul de Bakker[1], Soumya Raychaudhuri[1] and Robert M. Plenge[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Department of Ecology and Evolutionary Biology, University of California, Los Angeles, CA, [3]Department of Biostatistics, Harvard School of Public Health, Boston, MA, [4]Rheumatology Unit, Department of Medicine, Karolinska Institutet at Karolinska University Hospital Solna, Stockholm, Sweden, [5]Division of Rheumatology Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [6]Feinstein Institute Medical Reschearch, Manhasset, NY, [7]Institute of Environmental Medicine, Unit of Cardiovascular Epidemiology, Karolinska Institutet, Stockholm, Sweden, [8]Mount Sinai Hospital, Toronto, ON, [9]University of Manchester, Manchester, United Kingdom

Background/Purpose: Genetic studies of rheumatoid arthritis (RA) susceptibility have identified ~40 loci to date that explain approximately 18% of disease liability, whereas >50% is thought to be genetic. We hypothesized that much of the missing heritability is due to causal variants that are tagged by common SNPs on contemporary genome-wide association study (GWAS) arrays.

Methods: We estimated missing heritability and modeled its underlying genetic architecture by analyzing six GWAS datasets totaling 5,485 seropositive rheumatoid arthritis cases and 22,609 controls of European ancestry. After removing known RA risk loci, we assessed whether the remaining >2 million SNPs in aggregate could predict risk in independent case-control collections. We then used polygenic modeling and approximate Bayesian computation to estimate distributions of the number, minor allele frequency and effect size of undiscovered common variants. Heritability analysis using mixed linear model regression analysis was used to corroborate our results. In order to understand whether these undiscovered associations tag rare or common causal variants, we simulated hypothetical case-control datasets using 1000 Genomes Project data.

Results: We found that polygenic risk scores of additive, log-odds weighted risk allele counts at independent SNPs achieving $P<0.05$ in discovery GWAS are consistently associated with RA case-control status in independent validation data ($P = 1\times10^{-9}$). Both methods estimated that an additional 20% of rheumatoid arthritis disease variance is explained by at least hundreds of SNPs in contemporary GWAS. Simulations of causal and marker variants revealed that an underlying genetic model where most of the causal alleles are common is much more consistent with our observations than models where most of causal alleles are rare.

Conclusion: We conclude that hundreds of causal variants, most of which are common in general population but with a small effect on disease risk, explain an additional 20% of variance in RA risk. Many of these causal variants are discoverable by larger GWAS. Our approach can be applied to understand genetic architecture of many complex traits where GWAS data are available.

DO Carriers of A MEFV Mutation Have Any Selective Advantage to A Pathogen Endemic In the Same Geography? Serdal Ugurlu[1], Aynur Engin[2], Gulen Hatemi[1], Gulay Ozgon[3], Elif Akyayla[3], Mehmet Bakir[2] and Huri Ozdogan[1]. [1]MD, Division of Rheumatology, Department of Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]MD, Department of of Infectious Diseases, Medical Faculty, University of Cumhuriyet, Sivas, Turkey, [3]Nesiller Genetic Lab, Istanbul, Turkey

Background/Purpose: To explain the high level of MEFV heterozygots in Mediterranean basin, it has been speculated that carriers of FMF mutations might have a selective advantage because of increased resistance to a pathogen endemic to this area. The carrier rate for MEFV gene in Sivas, a city in central Turkey is as high as 1:3. Crimean-Congo Hemorrhagic fever (CCHF) a tick-borne disease caused by an arbovirus, associated with high mortality, is also endemic in the same geographical region. This gave us a unique opportunity to test whether MEFV heterozygotes have any survival advantage in this ongoing CCHF endemic.

Methods: MEFV gene mutations were detected with PCR analysis and direct sequencing of Exon 10 and Exon 2, in 100 patients with a definite diagnosis of CCHF followed in Cumhuriyet University, Sivas / Turkey, (mean age 45.6±17, 58 M: 42 F). All CCHF patients were classified into two groups in terms of disease severity (severe and mild), according to the predictive factors for fatal outcome reported by Swanepoel et al (1). MEFV gene mutations were also analyzed with the same methods in 91 healthy blood donors (HC) living in Sivas.

Results: Among the 100 patients with CCHF, 65 had mild and 35 had severe disease. There were 11 deaths in the severe group. Among the CCHF patients 62 patients carried either an exon 10 or exon 2 mutation compared to 33 in the HC ($p<0.001$). This significant difference was due to the increase in Exon 10 mutations (41/100 vs 10/91, $p<0.001$) which disappeared when only Exon 2 mutations were considered (38/100 vs 26/91, $p>0.1$). The number of patients with 2 mutations were also significantly more common among CCHF group ($p<0.001$). Regarding exon 2 we determined a haplotype of 4 SNPs (at positions: 102, 138, 165, 202) in 32 patients compared to 9 in HC ($p<0.001$), and described 4 new mutations in Exon 10. In the mild group there were 37 and in the severe group 25 carriers ($p>0.1$). 63% of the survivors compared to 54% of those who died carried a MEFV mutation ($p>0.1$). The distribution of mutations with regard to disease severity did not reveal a significant difference. Also there was no difference between the number of mutations among survivors versus non-survivors.

Conclusion: Carrying a MEFV gene Exon 10, but not Exon 2 mutation does seem to increase the risk of developing CCHF infection however does not influence disease severity and outcome.

Elevated Expression of Inflammatory Mediators Cyclooxygenase-2, Its Product Prostaglandin E2 and Interleukin-1 Beta by Peripheral Blood Leukocytes in Symptomatic Knee Osteoarthritis. Mukundan Attur[1], Alexander Statnikov[2], Constantin F. Aliferis[2], Zhiguo Li[2], Svetlana Krasnokutsky[3], Jonathan Samuels[1], Jeffrey D. Greenberg[4], Jyoti Patel[1], Cheongeun Oh[5] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]NYU Langone, New York, NY, [3]NYU Hospital for Joint Disease, New York, NY, [4]New York University School of Medicine, New York, NY, [5]New York University, New York, NY

Background/Purpose: OA is considered a *local* joint disease, with increasing recognition of the involvement of cartilage, bone and synovium. We and others have reported that inflammatory mediators, such as PGE2 and IL-1β, are produced by OA joint tissues, where they may contribute to disease pathogenesis. In the current studies we examined whether inflammatory events occurring within joint tissues could be reflected in the plasma and PBLs of patients with OA.

Methods: Two independent cohorts of patients with OA, and a cohort of healthy control subjects, were studied: 44 patients with tibiofemoral OA and 26 healthy control volunteers comprised the NYUHJD Learning Cohort, and 150 patients with knee OA and 21 health controls were enrolled in the NYUHJD Validation Cohort.

Results: Using support vector machine (SVM) methodology we constructed a combinatorial biomarker of OA based on microarray data of the Learning Cohort. Among these probe sets representing PGE2 synthase and cyclooxygenase could classify the case vs. control with 0.83 mean AUC (95% CI 0.72– 0.95) (AUC: area under ROC curve), as estimated by 10-fold cross-validation procedure. Further cluster analysis also revealed two distinct subclasses among these OA patients: those (OA1) with increased expression (>4-fold) of inflammatory genes (e.g., IL-1β, COX-2) compared to non-OA controls and those OA patients (OA2) with expression comparable to controls. Overexpression of inflammatory genes were validated using QPCR ($p<0.0001$). In association studies, patients in the OA1 group exhibited: a) greater JSW at baseline; b) higher WOMAC pain, stiffness and decreased physical function ($p<0.0001$), c) higher VAS pain ($p<0.001$) than OA2 group. Longitudinal studies indicated that OA1 patients with increased PBL IL-1b gene expression, were at higher risk for disease progression, as measured by change in JSW at 24 months (Table 1), Similarly COX-2 overexpressors had greater JSW 3.57 ± 1.91 mm Vs 3.13 ± 1.69 compared to OA patients with less than 2 fold COX-2 expression and higher WOMAC ($p<0.033$) and VAS ($p<0.041$) pain. To determine whether OA PBLs were "primed", we measured PGE2 production by whole blood PBL cultured (24h) ex vivo. PGE2 in controls did not change, while levels in OA patients increased 300% over baseline ($p<0.01$). In these validation cohort, the mean plasma PGE2 levels in OA patients was two-fold higher than in healthy controls (72 ± 33 vs. 163 ± 64 pg/ml, $p=0.001$).

	Mean (standard deviation)		
NYUHJD Validation Cohort	**OA^{IL-1} (n=74)**	**OA^{nl} (n=100)**	**p-value**
Joint space width (JSW) in mm at baseline	3.01 (2.1)	2.5 (1.94)	0.055
JSW (mm) at 24 months	2.53 (1.96)	2.4 (1.96)	0.614
Change (JSN)	0.48 (0.88)	0.097 (0.91)	0.0079

Conclusion: There is increased inflammatory mediator gene expression (COX-2, IL-1b) in a subset of patients with SKOA, which identifies a cohort of patients with increased pain who are at increased risk for disease progression. The data indicate that inflammatory events within joint tissues of patients with SKOA are reported in peripheral blood. These transcriptome and lipidomic signals of local joint inflammation merit further study as potential biomarkers for OA disease activity and progression.

170

Genomic Deletions in *Phospholipase Cγ2* define a New Syndrome of Cold Urticaria, Antibody Deficiency and Susceptibility to Both Autoimmunity and Infection. Michael J. Ombrello[1], Elaine F. Background/Purpose: Immune dysregulation occurs when the balance of finely-tuned immune regulatory networks is altered. Genetic analyses of Mendelian disorders manifesting these seemingly antithetical features may provide new insights into the molecular mechanisms that govern immune responses. We have identified three families with a novel, dominantly-inherited complex of cold-induced urticaria, antibody deficiency, and susceptibility to autoimmunity and infection through whom we sought to better understand the interface between autoimmunity and immunodeficiency.

Methods: Genetic investigations began with SNP genotyping and separate linkage analyses in two of the families. Mutational analysis included conventional and long-range PCR assays of both genomic DNA and cDNA, with direct sequencing of the PCR products. Immunophenotyping of these three families included flow cytometric studies, measurement of serum immunoglobulins and autoantibodies, lymphocyte stimulation assays, enzymatic assays, and confocal microscopic examination.

Results: Cold urticaria was present in all affected members of each family (n=27), and immunologic abnormalities were found in 26 of 27 patients. These included antibody deficiency (72%), recurrent infection (59%), atopy (52%), and autoimmunity (48%), which included the presence of antinuclear or other autoantibodies, autoimmune thyroid disease, vitiligo, inflammatory arthritis, and undifferentiated connective tissue disease. Affected subjects had depressed serum immunoglobulins M and A, decreased numbers of circulating NK and class-switched memory B cells, and impairment of B cell central tolerance. Patients' B cells also had impaired ligand-mediated activation, which was restored at subphysiologic temperatures. Using SNP genotyping and linkage analysis, we identified a single 7Mb candidate interval on chromosome 16q (LOD=4.2) in one family, which overlapped by 3.5Mb a disease-associated haplotype identified in another family. Given its importance in B, NK, and mast cells, *PLCG2* was selected from our candidate interval for mutational screening. Sanger sequencing of *PLCG2* cDNA from purified B-cells revealed heterozygous deletions of exon 19 in two families, and exons 20–22 in the third. Long-range PCR and genomic sequencing found three family-specific deletions in *PLCG2* (4.8–8.2kb) that co-segregated perfectly with cold urticaria, but were not detected in over 400 healthy control chromosomes. Of note, five of the six deletional breakpoints were within Alu or LINE repetitive elements, suggesting a role for repetitive element-mediated recombination in their genesis. The deletions, which are within an autoinhibitory domain of *PLCG2*, caused constitutive phospholipase activity, but paradoxically resulted in diminished activation of downstream signaling pathways.

Conclusion: We describe a novel immunodysregulatory syndrome in which deletions in *PLCG2* cause signaling abnormalities in multiple leukocyte subsets and a pleiotropic phenotype encompassing both excessive and impaired immune function.

171

Ferritin and Hemochromatosis Polymorphisms Correlate with Clinical Characteristics in a Symptomatic Osteoarthritis Cohort. Lauren M. Kennish[1], Mukundan Attur[2], Xi Huang[3], Svetlana Krasnokutsky[4], Jonathan Samuels[2], Cheongeun Oh[5] and Steven B. Abramson[2]. [1]Hospital for Joint Diseases, New York, NY, [2]NYU Hospital for Joint Diseases, New York, NY, [3]New York University School of Medicine, New York, NY, [4]NYU Hospital for Joint Disease, New York, NY, [5]New York University, New York, NY

Background/Purpose: Iron may be a contributing risk factor for osteoarthritis (OA) development – increased iron is found in OA synovial fluid and is cytotoxic towards chondrocytes. Additionally, patients with hereditary hemochromatosis develop an OA phenotype that is associated with higher ferritin levels. We examined the hypothesis that serum ferritin correlates with clinical features in patients with symptomatic knee OA compared to controls and that this may be associated with hemochromatosis gene (HFE) polymorphisms.

Methods: 131 patients with symptomatic knee OA (diagnosed by ACR criteria, WOMAC score>125) and 21 controls were enrolled in a 2 year longitudinal study. Patients with inflammatory arthritis, infections, steroid use or major comorbid illnesses were excluded. Baseline clinical (age, gender, BMI, WOMAC pain score) and radiographic characteristics (Kellgren-Lawrence, KL, score) were obtained. Cross sectional peripheral blood samples were analyzed for serum ferritin at baseline and 18months by ELISA. HFE genotyping was performed.

Results: Ferritin was measured in 131 OA patients with mean age 65 years (35% men), BMI 26.5 and 20 controls with mean age 56 years (55% men), and BMI 26.5. Men were found to have higher ferritin than women – 62.5 vs. 38.2 ng/ml, p=0.0002, and ferritin correlated with increasing age (r=0.175, p=0.058). Men with OA had a trend towards higher mean ferritin than those without OA when adjusted for age (67.7 vs. 40.4ng/ml, p=0.068). In the total population, ferritin levels greater than 100ng/ml were observed in 13% of patients with OA versus 0% of controls. There was a trend towards higher ferritin in patients with baseline radiographic incidence of OA (KL 0–1: 42.3 vs. KL 2–4: 63.3ng/ml, p=0.276) and in those with more severe radiographic OA (KL 1–2: 48.1 vs. KL 3–4: 71.3ng/ml, p = 0.236). Those with a higher KL score ranging from 0 to 3 were found to have higher serum ferritin, which may be predictive of severity of OA. Baseline WOMAC pain scores in the total OA population showed a weak positive correlation with serum ferritin levels (r= 0.112, p = 0.0148); this positive correlation between WOMAC pain and ferritin was stronger in males (r=0.215, p = 0.008). OA patients had a higher frequency of homozygous HFE gene polymorphism C282Y/C282Y (2.29%) compared to controls (0%) and published population controls (0.44%), and these subjects (n=3) had higher ferritin compared to wild type (n=98) (47.4 vs 140.1ng/ml, p<0.0008).

Conclusion: Ferritin, a marker for body iron storage, increases with age and male gender. Men with OA exhibit higher ferritin levels than those without OA when adjusted for age and levels of ferritin correlated with radiographic severity and WOMAC pain scores. In selected OA patients, the presence of the C282Y/C282Y HFE gene polymorphism was associated with higher ferritin levels. Our data suggest that increased ferritin levels, possibly in part due to HFE polymorphisms, may promote cartilage damage and pain in patients with knee OA. These findings merit further investigation of ferritin as a biomarker of disease severity and progression in a larger cohort.

ACR Poster Session A
Imaging of Rheumatic Disease I: Ultrasound, Optical and Preclinical Imaging

Patients with Rheumatoid Arthritis On Anti-TNF Therapy; Responders with Major Reduction In Power Doppler Activity Can Be Identified After One Month. Hilde B. Hammer, Britt Birkelund and Tore K. Kvien. Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

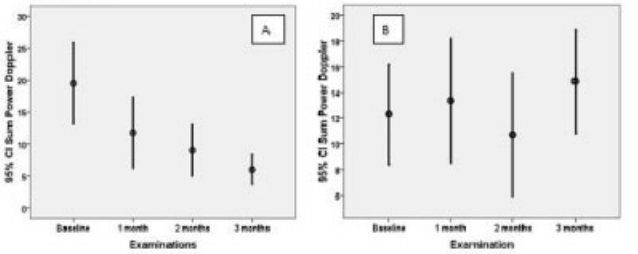
Background/Purpose: Power Doppler (PD) ultrasonography (US) detects inflammatory activity in patients with rheumatoid arthritis (RA) and is highly responsive to anti-TNF treatment. The present objective was to follow RA patients starting anti-TNF treatment with PDUS and clinical assessments to

explore whether any variable could predict a major decrease in PDUS after 3 months.

Methods: Patients with RA starting anti-TNF treatment were consecutively included and examined at baseline and after 1, 2 and 3 months with US of 36 joints and 4 tendons (wrist (radiocarpal, intercarpal and radioulnar), MCP 1–5, PIP 2 and 3, elbow, knee, talocrural, MTP 1–5, extensor carpi ulnaris and posterior tibialis tendons bilaterally). The PD and B-mode (BM) synovitis were scored semi-quantitatively (0–3), and sum scores from all joints and tendons were calculated. In addition, the patients were assessed clinically with DAS28, assessor global VAS (study nurse), ESR and CRP. Patients with at least 40% improvement of sum score PD at the 3 months examination was defined as responders. The results of US, clinical and laboratory assessments at baseline and after 1 month were explored by Mann-Whitney tests to examine for associations with the responders.

Results: A total of 50 patients were included (mean (SD) age 51.7 (13.2) years, disease duration 7.8 (5.8) years, 74% anti-CCP positive and 84% women, with 38% using Remicade, 34% Enbrel, 16% Humira and 12% Simponi). A total of 57% of the patients were defined as PD responders, and they had significantly lower DAS28, assessors global VAS and number of swollen joints ($p=0.023$–0.031) at the 3 months examination. Baseline values of sum scores PD or BM, DAS28, assessors global VAS, ESR or CRP did not separate between responders and non-responders. At 1 month examination the only variable differing between responders and non-responders was the sum score PD, with a significant reduction in sum score PD in the responders versus non-responders 7.4 (8.6) versus −0.5 (7.3) ($p = 0.002$, figure 1A and B).

Figure 1
Error bar plot (with 95% CI) of the sum PD scores in responders (A) vs non-responders (B) during treatment with anti-TNF.



Conclusion: PD activity is associated to erosions in RA patients. However, in the present study more than half of the patients achieved a major decrease in PD scores after starting anti-TNF treatment. It is an advantage to identify responders early, and the present results indicate that a significant reduction of PD activity already after 1 month predicts response to biological treatment.

173

New Aspects Concerning the Activity of Established Rheumatoid Arthritis Under a Tocilizumab Therapy. Maria Hoehle. Rheumatology, Hamburg, Germany

Background/Purpose: To determine remission of the rheumatic process, recent publications point out the importance of radiological parameters, besides scores like TJC, SJC, CrP, patient global assessment, or the SDAI. **1)** Since RA is usually a progressing inflammatory disease, native radiological diagnostics is not sufficient for portraying inflammatory activities in grades, and for comparing them with each other during the further course of the disease. Medical imaging by sonography (colour and power Doppler), as well as high-field MRI with contrast medium for the additional assessment of the cartilage/bone oedema, become increasingly important. **2)** Tocilizumab induces a rapid improvement of the patient's health-related QoL and a decrease in CrP and ESR values, but active inflammations may still exist at the joint-related structures. In order to objectify these, the use of sonography (colour and power Doppler) and high-field MRI is indispensible.

Objectives: The course of chronic active inflammatio at the affected joint structures can be quantitatively and qualitatively measured by aforementioned imaging techniques. The aim of the exact inflammation definition is to optimize the cytokine therapy and to determine the time for an OFF therapy.

Methods: 23 RA patients (17 women, 6 men), treated with tocilizumab (8 mg tcz/kg BW), were examined retrospectively. In 7 women and 4 men, tcz was given as monotherapy. At baseline and every 4 weeks DAS 28, CrP, ESR and sonography of a reference joint (wrist joint) were examined, every 6 months, additional high-field MRI. The evaluation was carried out using MRI (RAMRIS) and sonography score.

Results: In all 23 patients, in week 4 DAS value was within the normal range. In 19 patients ESR and CrP value were within the normal range. In 3 further patients (2 of which were men), the ESR and CrP values did not normalize after the second tcz infusion cycle (week 8). In one female patient, the ESR and CrP values normalized after 12 weeks. During the further course of the therapy, the ESR and CrP values in all 23 patients remained in the normal range. At baseline, in all 23 patients the activity score for MRI (RAMIS above 5),and for sonography (PD grade II, synovitis grade II, tenosynovitis grade II) were high. 1 year after the tcz therapy, a normal sonography score and RAMIS score were found in 3 female patients, in further 5 female patients after 2 years. In 16 female patients, a decrease in the score values was found after 3 months (no later than 6 months) for sonography and MRI. However, increased activities could still be seen in imaging diagnostics. The tenosynovitis activity's score value was significantly higher compared to the arthrosynovitis' score. No AE, including SAE, occurred during the observation period – except for two allergic reactions.

Conclusion: The cytokine therapy with tocilizumab leads to a rapid decrease in the inflammation laboratory parameters, and hence to a normalization of DAS 28. However, the inflammation-verifying imaging still showed inflammation at the wrist joints in 70% of the patients. The aforementioned imaging is still highly important for assessing the complete remission in rheumatological practice.

174

Metrological Properties of Composite Scoring Systems for Synovitis in Rheumatoid Arthritis: Results From a Randomized, Prospective, Multicentre Study. Peter Mandl[1], Peter V. Balint[2], Yves Brault[3], Marina Backhaus[4], Maria-Antonietta D'Agostino[5], Walter Grassi[6], Désirée van der Heijde[7], Eugenio De Miguel[8], Richard J. Wakefield[9], Isabelle Logeart[3] and Maxime Dougados[10]. [1]Medical University of Vienna, Vienna, Austria, [2]National Institute of Rheumatology and Physiotherapy, Budapest, Hungary, [3]Pfizer, Paris, France, [4]Charite University Hospital, Berlin, Germany, [5]Versailles-Saint Quentin en Yvelines University- APHP, Ambroise-Paré Hospital, Boulogne-Billancourt, France, [6]Università Politecnica delle Marche, Jesi, Italy, [7]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [8]La Paz University Hospital, Madrid, Spain, [9]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals, Leeds, United Kingdom, [10]Paris-Descartes University, Cochin Hospital, Paris, France

Background/Purpose: To propose different global composite scoring systems for measuring synovitis in rheumatoid arthritis (RA), utilizing information derived from clinical, grey-scale ultrasound (GS) and Power Doppler ultrasound (PD) examination. To evaluate intra-observer reliability, face validity, predictive validity and discriminant capacity as compared to DAS28 and SDAI. To assess the classification of patients according to disease activity using the various composite scoring systems.

Methods: This 52-week, prospective, open-label, randomized, parallel-group, multicenter, outpatient study was conducted in RA subjects with moderate disease receiving etanercept (ETN) combined with methotrexate or various DMARDs. A total of 12 different scoring systems were evaluated, based on clinical, GS and PD-derived data, and calculated according to the DAS28 or SDAI indices. In the composite indices the 28-swollen joint count (SJC) was either replaced by the number of swollen joints showing also signs of synovitis on either GS and/or PD, or supplemented by joints deemed non-swollen on clinical examination in which the presence of synovitis was detected by either GS and/or PD (Table 1). Intra-observer reliability of each proposed synovitis scoring system was calculated by intraclass correlation coefficient and standard error of measurement. Face validity was evaluated as the degree of association between CRP or ESR and each scoring system, and was assessed using Pearson's correlation coefficient. For discriminant capacity the ETN and the conventional DMARD treatment groups were evaluated separately and the difference in standardized response mean was calculated between baseline and week 12.

Results: Data from 62 patients were analyzed. Reliability, face validity and discriminative capacity were found to be similar for the composite indices as compared to their respective, clinical data-based counterparts. Using composite indices in which the SJC was supplemented also by joints in which synovitis was detected by either GS and/or PD, a significantly larger number of patients could be classified as having high disease activity at the screening visit (Table 1).

Table 1.

	LDA (no., % of patients)	MDA (no., % of patients)	HDA (no., % of patients)	Discriminant capacity (SRM, 95% CI)
DAS28 clinical	1 (1.6%)	60 (96.8%)	1 (1.6%)	0.87 (0.28; 1.50)
DAS28 GS[a]	1 (1.6%)	60 (96.8%)	1 (1.6%)	0.85 (0.28; 1.45)
DAS28 PD[b]	1 (1.6%)	60 (96.8%)	1 (1.6%)	0.80 (0.21; 1.43)
DAS28 GS/PD[c]	1 (1.6%)	60 (96.8%)	1 (1.6%)	0.79 (0.20; 1.43)
DAS28 +GS[d]	2 (3.2%)	18 (29%)	42 (67.7%)	0.70 (0.15; 1.44)
DAS28 +PD[e]	2 (3.2%)	32 (51.6%)	28 (45.2%)	0.88 (0.33; 1.61)
DAS28 +GS/PD[f]	2 (3.2%)	17 (27.4%)	43 (69.4%)	0.72 (0.15; 1.44)
SDAI clinical	24 (38.7%)	38 (61.3%)	0 (0%)	1.11 (0.25; 28.73)
SDAI GS[a]	25 (40.3%)	37 (59.7%)	0 (0%)	1.09 (0.21; 51.16)
SDAI PD[b]	31 (50%)	31 (50%)	0 (0%)	1.17 (0.27; 742 4)
SDAI GS/PD[c]	31 (50%)	31 (50%)	0 (0%)	1.17 (0.27; 742.4)
SDAI +GS[d]	6 (9.7%)	37 (59.7%)	19 (30.6%)	0.61 (−0.77; 3.43)
SDAI +PD[e]	11 (17.7%)	43 (69.4%)	8 (12.9%)	0.52 (−0.51; 1.88)
SDAI+GS/PD[f]	6 (9.7%)	36 (58%)	20 (32.3%)	0.84 (−0.24; 3.86)

[a] clinical SJC replaced by swollen joints that also show signs of synovitis on GS (grey-scale ultrasound)
[b] clinical SJC replaced by swollen joints that also show signs of synovitis on PD (Power Doppler ultrasound)
[c] clinical SJC replaced by swollen joints that also show signs of synovitis either on GS and/or PD
[d] clinical SJC supplemented by non-swollen joints showing signs of synovitis on GS
[e] clinical SJC supplemented by non-swollen joints showing signs of synovitis on PD
[f] clinical SJC supplemented by non-swollen joints showing signs of synovitis either on GS and/or PD
LDA: low disease activity (DAS28 <3.2, SDAI ≤11)
MDA: moderate disease activity (DAS28 3.2–5.1; SDAI 11.1–26)
HDA: high disease activity (DAS28>5.1; SDAI>26)
SRM: standardized response mean

Conclusion: Composite scoring systems had similar metrological properties as their clinical counterparts but allowed for a significantly larger number of patients to be reclassified to either high or moderate disease activity at the screening visit, thus influencing eligibility for biologic therapy.

175

Ultrasonography Assessment of the Hands As a Measure of Disease Activity in Rheumatoid Arthritis Patients: Correlation with DAS 28 Score. Carla Saucedo[1], Santiago Ruta[1], Javier Rosa[1], David A. Navarta[1], Maria Victoria Garcia[1], Ricardo Garcia Monaco[2] and Enrique R. Soriano[1]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires

Background/Purpose: Disease activity score (DAS) 28 is widely accepted for the assessment of disease activity in rheumatoid arthritis (RA). Ultrasound (US) has become an important tool to monitor inflammatory activity in RA patients. The objective was to correlate different US indexes constructed by the inclusion of different number of joints with the level of disease activity measured by DAS 28 in RA patients.

Methods: RA (2010 ACR/EULAR criteria) consecutive patients > 18 years old attending the outpatient Rheumatology Unit were included. Exclusion criteria were: hands surgery and/or corticosteroid injection within the last 2 months. All patients were clinically assessed by the attending rheumatologist and the level of disease activity was measured using DAS 28 score. In the same day US examination was performed by the same rheumatologist sonographer blinded to clinical data, using a My Lab 70 (Esaote) machine equipped with 6–18 MHz broad band multifrequency linear transducer. US assessment consisted in bilateral examination of the dorsal aspect of wrist, metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints. The following abnormal US findings were examined and classified as present or absent: joint cavity widening (JCW), due to synovial fluid and/or synovial hypertrophy, and power Doppler (PD) signal. Three different ultrasound indexes were constructed by the sum of JCW and PD scores of individual joints included in each index: index A including both wrists, all bilateral MCP and PIP joints (22 joints) score; index B: including both wrists, both 2nd and 3rd MCP and both 2nd and 3rd PIP (10 joints); and index C: including both wrists and both 2nd and 3rd MCP (6 joints). Correlation between the indexes and DAS28 was performed with Spearman's rho test. Receiver operating characteristic (ROC) analysis was used to evaluate the discriminative utility of each index, and detect the optimal cut off value.

Results: Sixty RA patients (85% female, mean age 59 ± 15 years, 75% were anti CCP positive, 55% were FR positive, mean DAS 28 score 3.69 ± 1.42) were evaluated. All three indexes were significantly higher in patients with active disease (table). Index C had the best correlation with DAS28 (table). Index C showed a very good discriminative value for disease activity defined as a DAS28 score >3.2 and for absence of remission defined by a DAS28 score >2.6 (area under de ROC curve = 0.75 (95% CI: 0.62–0.88) and=0.80 (95% CI:0.67–0.93), respectively). A cut off value of 3 points showed sensitivity of 88.89% and specificity of 66.67% for absence of remission defined by a DAS28 score >2.6.

Table. US indexes and their correlation with DAS28 score.

	Index A: 22 joints (both wrists and all MCP and PIP joints)	Index B: 10 joints (bilateral wrists, 2nd and 3rd MCP and 2nd and 3rd PIP)	Index C: 6 joints (bilateral wrists, and 2nd and 3rd MCP)
Correlation with DAS28 score (Spearman's rho test)	rho= 0.4513 (p=0.0003)	rho= 0.4979 (p=0.0001)	rho= 0.5020 (p<0.0001)
Mean (SD)US score in Active (DAS28>2.6; n=45) vs. inactive disease (DAS28<2.6; n=15)	12.2 (9.8) vs. 5.8 (7.2); p=0.0231	8.3 (5) vs. 3.6 (3.8); p=0.0014	6.4 (3.4) vs. 2.8 (2.6); p=0.0005

Conclusion: US indexes including JCW and PD scores showed moderate to good correlation with DAS28 score. The index with fewer included joints (6 joints) showed the best correlation and discriminative value, perhaps reflecting better clinical assessment of these limited number of joints by the rheumatologist.

176

Sensitivity to Change of the 7-Joint Ultrasound (US7) Score Among Patients with Different Musculoskeletal Diseases Under Twelve Months of Therapy. Tina M. Backhaus[1], Sarah Ohrndorf[2], Herbert Kellner[3], Johannes Strunk[4], Wolfgang Hartung[5], Horst Sattler[6], Christof Iking-Konert[7], Gerd R. Burmester[8], Wolfgang A. Schmidt[9] and Marina Backhaus[10]. [1]Berlin, Germany, [2]Charité –University Medicine Berlin,, Berlin, Germany, [3]Centre for Inflammatory Joint Diseases, Munich, Germany, [4]Cologne, Germany, [5]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, [6]Klinikum Ludwigshafen, Ludwigshafen, Germany, [7]University Hospital Hamburg Eppendorf, Hamburg, Germany, [8]Charité - Universitätsmedizin Berlin, Berlin, Germany, [9]Med Ctr Rheumatol Berlin Buch, Berlin, Germany, [10]Charite University Hospital, Berlin, Germany

Background/Purpose: Estimating the US7 score's sensitivity to change throughout a cohort of patients with different musculoskeletal disorders under various therapies (DMARD and Biologics). Comparing US7 score's results with clinical and laboratory parameters over twelve months.

Methods: 506 patients with rheumatoid arthritis (RA; 87.9%), psoriatic arthritis (PsA; 9.7%), ancylosing spondylitis with peripheral arthropathy (1.8%), undifferenciated polyarthritis (0.4%) and juvenile idiopathic arthritis (JIA; 0.2%) with a mean ± SD disease duration of 8.5 ± 9,5 years were set after a baseline examination either on a DMARD or a Biological therapy (single/ combination therapy). Musculoskeletal ultrasonography (US7 score) was done during baseline examination as well as during follow-ups after 3, 6, and 12 months. Furthermore, DAS28, CRP and ESR were assessed. According to their therapy the cohort was divided into four groups: firstline DMARD after new adjustment (26%), therapy switch from DMARD to DMARD (24%), firstline Biological after DMARD therapy (34%), therapy switch from Biological to Biological therapy (12%). One subcohort (12%) did not have any therapy after twelve months.

Results: In both DMARD groups the synovitis score and the tenosynovitis score in GSUS and PDUS as well as ESR, CRP and DAS28 significantly decreased (p<0.05) after twelve months. A significant reduction of erosions could not be detected.

Patients who received a Biological therapy for the first time after DMARD therapy illustrated a decline in the synovitis score as well as in the tenosynovitis score in GSUS and PDUS, and ESR and CRP significantly reduced (p<0.05).

In the group of patients with a switch of therapy from Biological to Biological therapy, erosions decreased significantly from 3.9 ± 4.1 to

3.2 ± 3.7 ($p<0.05$) after one year. No significant reductions in the tenosynovitis score (PDUS), ESR and CRP could be observed.

Patients with first line Biological who switched to another Biological therapy during the study achieved the lowest synovitis score (GSUS and PDUS) at baseline examination.

In the beginning, the highest erosions were detected for patients who changed from DMARD to Biologic. Nevertheless, the US7 erosions score did not decrease significantly in this group.

At baseline, lowest erosion scores had patients who took DMARDs the whole time.

Conclusion: The comparable development of the US7 score data with clinical and laboratory data illustrates its possibility to reflect therapeutic response; therefore the novel US7 score is sensitive to change. Furthermore, patients who switched from Biological to Biological therapy achieved a significant decrease of erosions after twelve months, which could not be detected for patients with only DMARD therapy.

177

Impact of the US7 Score for Diagnosis and Prognosis of Rheumatoid Arthritis In Undifferentiated Early Arthritis. Jörg Kaufmann[1], Susanne Seel[2] and Anne-Eve Roske[3]. [1]Rheumatologist, Ludwigsfelde, Germany, [2]Ambulant Centres f. Rheumatology, Ludwigsfelde, Germany, [3]Roche Pharma AG, Grenzach-Wyhlen, Germany

Background/Purpose: Therapy of early RA is characterized by an aggressive DMARD onset to prevent structural joint damage. Treatment decisions with regard to the individual risk of a persistent and/or erosive course of RA are crucial for an appropriate and cost-effective therapy to avoid under- and overtreatment. Some prediction models using clinical factors have been developed to detect RA patients at risk. One limitation of these prediction rules is a lack of inclusion of modern non-incriminating imaging techniques such as joint ultrasound (US).

The US7 score has been established as a routine tool in rheumatology to detect disease activity and for therapy monitoring to ease treatment decisions. In undifferentiated early arthritis joint US could have an impact on identification of those patients in whom persistent and/or erosive RA will develop.The aim was to compare the established prediction models Visser and Helm-van Mil (HvM) as well as the new ACR/EULAR criteria with extent of synovitis and synovial perfusion using joint US.

Methods: 95 patients with early undifferentiated arthritis were initially scored according to Visser, HvM and the new ACR/EULAR criteria. The US7 score was assessed simultaneously containing the synovial thickness (GSUS), the degree of tenosynovitis, early erosions and synovial perfusion with power Doppler (PDUS).

Results:

		Visser_ eRA	Visser_ peRA	HvM_ Pkt	HvM	ACR_ EULAR_ Pkt	Joint_Syn_ GSUS	Joint_Syn_ PDUS	US7_Score
Visser_pRA	Corr Coeff	.857**	.923**	.742**	.780**	.746**	.172	.275**	.290**
	Sig. (2-sided)	.000	.000	.000	.000	.000	.100	.008	.005
Visser_eRA	Corr Coeff		.969**	.669**	.731**	.628**	.165	.320**	.302**
	Sig. (2-sided)		.000	.000	.000	.000	.113	.002	.003
Visser_peRA	Corr Coeff			.723**	.777**	.711**	.170	.311**	.310**
	Sig. (2-sided)			.000	.000	.000	.103	.002	.002
HvM_Pkt	Corr Coeff				.937**	.734**	.308**	.302**	.377**
	Sig. (2-sided)				.000	.000	.003	.003	.000
HvM	Corr Coeff					.774**	.339**	.345**	.424**
	Sig. (2-sided)					.000	.001	.001	.000
ACR_EULAR_Pkt	Corr Coeff						.283**	.292**	.418**
	Sig. (2-sided)						.006	.004	.000
Joint_Syn_GSUS	Corr Coeff							.726**	.829**
	Sig. (2-sided)							.000	.000
Joint_Syn_PDUS	Corr Coeff								.815**
	Sig. (2-sided)								.000

**Significance level 0.01 (2-sided); *Significance level 0.05 (2-sided)

Conclusion: There is a strong correlation between the different prediction models and the joint US results. Synovial thickness as well as perfusion correlates with the risk generated by clinical factors. High US 7 scores as well as the detection of synovial perfusion in early arthritis states could be an additional indicator for persistent and/or erosive RA and helps to identify RA patients at risk who need early aggerssive DMARD therapy.

178

Introduction of a New Ultrasound Score for Large Joints: One Year Experience in Daily Rheumatologic Practice. Wolfgang Hartung[1], Herbert Kellner[2], Johannes Strunk[3], Wolfgang A. Schmidt[4], Boris P. Ehrenstein[1], Horst Sattler[5], Marina Backhaus[6] and Martin Fleck[1]. [1]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, [2]Centre for Inflammatory Joint Diseases, Munich, Germany, [3]Cologne, Germany, [4]Med Ctr Rheumatol Berlin Buch, Berlin, Germany, [5]Klinikum Ludwigshafen, Ludwigshafen, Germany, [6]Charite University Hospital, Berlin, Germany

Background/Purpose: Report of one year experience with a new standardized ultrasound score developed for large joints (**S**onogrpay **O**f **LA**rge joints in **R**heumatology: **SOLAR** score) implemented in daily reumatologic practice.

Methods: An ultrasound score was designed to determine the degree of inflammation in the shoulder, the elbow, the hip and the knee joint in patients with inflammatory joint disease. A scanning protocol has been established for each joint region with well defined planes. Synovitis and synovial vascularity were scored semiquantitatively (grade 0–3) by gray scale (GS) and power Doppler ultrasound (PDUS). The scoring range for GSUS was 0–6 for the shoulder, 0–9 for the elbow, 0–3 for the hip and 0–12 for the knee, depending on the number of defined scanning planes. The scoring range for PDUS was 0–6 for the shoulder, 0–9 for the elbow, 0–3 for the hip and 0–15 for the knee, respectively. In addition, tenosynovitis and erosions were scored for presence. Patients with arthritis were examined at baseline, as well as 3, 6 and 12 months after initiation or modification of disease modifying antirheumatic drugs (DMARD) and/or biologic therapy. C-reactive protein levels (CRP), erythrocyte sedimentation rate (ESR), rheumatoid factor (RF), anti-citrullinated peptide (anti-CCP) antibodies and the Disease Activity Score in 28 joints (DAS28) were determined. Additionally, radiographs of the affected joints were obtained when clinically indicated.

Results: Six hundred seventeen patients were enrolled. Two hundred fifty three patients already reached the twelve months visit, suffering from rheumatoid arthritis (79%), psoriatic arthritis (14%) and ankylosing spondylitis (7%). DMARD treatment had been initiated or changed in 66% (n = 168) of these patients, whereas, DMARDs plus biologics were utilized in 24% (n = 61), and biologic monotherapy in 10% (n = 24) of patients. The knee joint was examined in 146 patients (58%) as the most affected joint ("target joint"), whereas in 46 patients (25%) the shoulder, in 39 patients (15%) the elbow and in 18 patients (7%) the hip joint were evaluated. At baseline, the mean DAS28 was 4.6 and the synovitis scores were for the knee GS 5.2/PD 3.7, the shoulder GS 2.8/PD 1.7, the elbow GS 5.0/PD 2.4 and the hip GS 2.2/PD 1.1, respectively. After 3 months of therapy, DAS28 scores significantly decreased to 3.6 ($p< 0{,}001$) and the SOLAR scores fell to GS 3.2/PD 2.3 for the knee, GS 2.2/PD 1.1 for the shoulder, GS 3.3/PD 1.5 for the elbow and GS 1.3/PD 0.3 for the hip. This early response even improved within the next 9 months as documented by a further decrease in DAS 28 and the SOLAR scores at six and twelve months (s. Table 1).

		US, clinical and laboratory data (n = 253)#			
Joint region	US score/ disease activity	baseline	after 3 months	after 6 months	after 12 months
knee (n = 148)	GSUS (range 0–12)	5.2 ± 2.9	3.2 ± 2.7**	2.8 ± 2.8**	2.3 ± 2,7**
	PDUS (range 0–15)	3.7 ± 3.1	2.3 ± 2.6**	1.9 ± 2.5**	1.2 ± 2.0**
shoulder (n = 46)	GSUS (range 0–6)	2.8 ± 1.9	2.2 ± 1.6*	1.8 ± 1.4*	1.6 ± 1.6*
	PDUS (range 0–6)	1.7 ± 1.6	1.1 ± 1.5*	1.1 ± 1.4*	0.7 ± 1.2*
elbow (n = 39)	GSUS (range 0–9)	5.0 ± 2.4	3.3 ± 2.7**	2.7 ± 2.8**	2.2 ± 2.7**
	PDUS (range 0–9)	2.4 ± 2.0	1.5 ± 1.9*	1.2 ± 1.6*	0.8 ± 1.2*
hip (n = 18)	GSUS (range 0–3)	2.2 ± 0.6	1.3 ± 0.9**	0.9 ± 0.9**	0.7 ± 0.9**
	PDUS (range 0–3)	1.1 ± 1.2	0.3 ± 0.5	0.3 ± 0.5	0.2 ± 0.5
DAS 28		4.6 ± 1.3	3.6 ± 1.4	3.4 ± 1.3	3.2 ± 1.3
ESR, mm/hour		32.0 ± 22.4	22.9 ± 18.0	21.1 ± 16.2	20.3 ± 16.4

values represent the mean ± SD. US = ultrasound; GSUS = gray scale US; PDUS = power doppler US; DAS 28: Disease Activity Score in 28 joints; ESR = erythrocyte sedimentation rate. * $P < 0.05$ (2 sided significance by Kruskal-Wallis-test); ** $P < 0.001$ (2 sided significance by Kruskal-Wallis-test).

Conclusion: The SOLAR score is a feasible tool for examining patients with arthritis of large joints in daily rheumatologic practice reflecting therapeutic response within 12 months following modification or initiation of DMARD and/or biologic treatment.

179

The Impact of Ultrasonography on the Classification of Rheumatoid Arthritis with 2010 ACR/EULAR Criteria: Ultrasound-Combined Classification with Two Different Definitions of Gray-Scale Synovitis for Joint Involvement. Daiki Nakagomi, Kei Ikeda, Ayako Okubo, Taro Iwamoto, Yoshie Suzuki, Hiroaki Takatori, Kotaro Suzuki, Katsuhiko Takabayashi and Hiroshi Nakajima. Chiba University Hospital, Chiba, Japan

Background/Purpose: 2010 ACR/EULAR rheumatoid arthritis (RA) classification criteria refer to the possible use of new imaging techniques such as ultrasonography (US). However, the impact of US on the classification of RA and the optimal US definition of synovitis for this purpose have not been fully assessed with comprehensive US scanning. Therefore, the purpose of this study is to determine the impact of US assessment for synovitis on the classification of RA with 2010 ACR/EULAR criteria.

Methods: Ultrasonography was performed in cases with possible diagnosis of RA using either LOGIQ E9 (GE Healthcare), Aplio XG (Toshiba Medical Systems) or Avius (Hitachi Medical Corporation). All joint regions included in 2010 ACR/EULAR criteria except hip joints were assessed, and gray scale synovitis (GS) and power Doppler signals (PD) were recorded for each joint with semi-quantitative score (0–3). According to the prevalence of US findings in this cohort, US-synovitis was preliminarily defined either as GS>0 and/or PD>0 (mild-GS definition) or as GS>1 and/or PD>0 (moderate-GS definition). The numbers of cases who clinically fulfilled the ACR/EULAR criteria (CL-RA) were compared with those who fulfilled the criteria after replacing the joint involvement with US synovitis (US-RA).

Results: 117 cases were enrolled. The mean age was 52.1 year-old, 25 patients (21.4%) were male, and median duration of symptom was 6 months. Rheumatoid factor and anti-CCP antibody were positive in 56 cases (47.9%) and 41 cases (35.4%), respectively. The discrepancy between clinical and US assessments was frequent in wrists and knees with both US-synovitis definitions. The numbers of cases with CL-RA (mild-GS definition) and/or US-RA were 47 (40.2%) for CL-RA (+)/ US-RA (+), 12 (10.2%) for CL-RA (+)/ US-RA (−), 11 (9.4%) for CL-RA (−)/ US-RA (+), and 47 (40.2%) for CL-RA (−)/ US-RA (−), respectively (Table 1). On the other hand, the numbers of cases with CL-RA (moderate-GS definition) and/or US-RA were 56 (47.9%) for CL-RA (+)/ US-RA (+), 21 (17.9%) for CL-RA (+)/ US-RA (−), 5 (4.3%) for CL-RA (−)/ US-RA (+), and 35 (29.9%) for CL-RA (−)/ US-RA (−), respectively (Table 2).

Table 1. Classification with mild-GS (> 1) definition of synovitis

	Clinical - RA (−)	Clinical - RA (+)	Total
US - RA (−)	47 cases (40.2%)	12 cases (10.2%)	59 cases (50.4%)
US - RA (+)	11 cases (9.4%)	47 cases (40.2%)	58 cases (49.6%)
Total	58 cases (49.6%)	59 cases (50.4%)	117 cases (100%)

Table 2. Classification with moderate-GS (> 0) definition of synovitis

	Clinical - RA (−)	Clinical - RA (+)	Total
US - RA (−)	56 cases (47.9%)	21 cases (17.9%)	77 cases (65.8%)
US - RA (+)	5 cases (4.3%)	35 cases (29.9%)	40 cases (34.2%)
Total	61 cases (52.2%)	56 cases (47.8%)	117 cases (100%)

Conclusion: The result shows that the combined use of US may alter the RA classification with ACR/EULAR criteria in 19.6–22.2% of the patients assessed, depending on the definition of US-synovitis. In order to further validate the benefit and the optimal definition of US-synovitis in the diagnosis of RA, longitudinal assessment of this cohort is in progress.

Comparison of the Validity of Synovitis to Predict Structural Damage in Rheumatoid Arthritis (RA) with Regard to the Joint Examination Modality (*e.g.* clinical *versus* ultrasonographic [US]). Maxime Dougados[1], Valerie Devauchelle[2], Jean François Ferlet[3], Jacques Bentin[4], Sandrine Jousse-Joulin[2], E. Maria Atonietta D'Agostino[5], Gérard Chalès[6], Isabelle Chary-Valckenaere[7], Fabien Etchepare[8], Philippe Gaudin[9], Xavier Mariette[10] and Alain Saraux[11]. [1]Paris-Descartes University, Cochin Hospital, Paris, France, [2]Brest university medical school, EA 2216, UBO and CHU de la Cavale Blanche,, Brest, France, [3]RCTS, Lyon, France, [4]CHU-Brugmann, Brussels, Belgium, [5]Rheumatology Department Ambroise Par Hospital, Boulogne-Billancourt, France, [6]CHU RENNES, Rennes, France, [7]CHU NANCY, France, [8]G.H. Pitié-Salpêtrière, Paris, France, [9]Chu A Michallon, Grenoble, France, [10]Université Paris-Sud, Le Kremlin Bicetre, France, [11]CHU de la Cavale Blanche, Brest Cedex, France

Background/Purpose: Longitudinal epidemiological studies have demonstrated the link between the presence of synovitis at a single point of time and a subsequent structural deterioration in RA. In comparison to physical examination, US seems to be more accurate (sensitive) for the detection of synovitis. This study had the objective to compare the predictive validity of synovitis with regard to the joint examination modality (*e.g.* clinical *versus* US).

Methods: *Patients*: Definite RA (1987 ACR criteria), active (necessitating an anti-TNF therapy). *Study design*: Prospective, 2 year follow-up. *Data collected*: For each patient, 32 joints were evaluated (2 wrists, 10 MCP, 10 PIP, 10 MTP). Synovitis was collected before and after 4 months of TNF therapy using a semi-quantitative variable for both the physical examination (from 0=definitively no synovitis to 3=yes obvious and important), US mode B (from 0=absence of synovial thickening to 3=marked synovial thickening) and US Power Doppler (PD) (from 0=absence of signal, no intra-articular flow to 3=marked signal in more than half of the synovial area. US and physical examination were conducted by 2 distinct physicians. Hands and feet X-rays performed at baseline and year 2 were evaluated by another distinct physician unaware of the synovitis findings. For each X-ray, the presence of both erosion and joint space narrowing were evaluated. Moreover, for each joint, the reader noticed whether there was either an occurrence or a worsening in structural damage at year 2 in comparison to baseline. *Analysis*: Measures of association (odds ratio [OR] and 95% confidence intervals [CI] adjusted for within patient correlation and also other age, gender, disease duration, baseline DAS28 and baseline joint structural damage.) were tested between the structural deterioration defined by an occurrence or a worsening of joint space narrowing or bone erosion and the presence of synovitis (grade 0 *vs.* grade 1 or 2 or 3) defined by clinical, US mode B or US PD before and after 4 months of anti TNF therapy.

Results: Of the 77 recruited patients, 59 patients (female: 81%, age: 56±12 years, Rheumatoid Factor Positive: 73%) completed the 4 months of the study and had also a radiologic evaluation at year 2. After 2 years of follow-up, a structural deterioration was observed in 9% of the 1888 evaluated joints (16.2% of the 118 wrists, 7.0% of the 590 MCP, 7.5% of the 590 PIP, and 11.0% of the 590MTP). The increased probability to observe a structural progression in presence of synovitis was confirmed for the different joint examination modalities at baseline (OR = 2.08 [1.39;3.11] $p<0.001$ *vs.* 1.64 [1.08;2.47] $p=0{,}019$ *vs.* 1.80 [1.20;2.71] $p=0{,}005$; but only with a trend (except for US mode B modality) 4 months after anti TNF therapy (OR = 1.63 [0.96;2.76] $p=0{,}069$ *vs.* 2.12 [1.35;3.32] $p=0.001$ *vs.* 1.63 [0.93; 2.86] $p=0.086$; for t he physical examination *versus* US mode B *versus* US PD, respectively.

Conclusion: This study confirms the validity of synovitis to predict subsequent structural deterioration but suggests also that such predictive validity is similar wathever the joint evaluation modality (e.g; clinical or US).

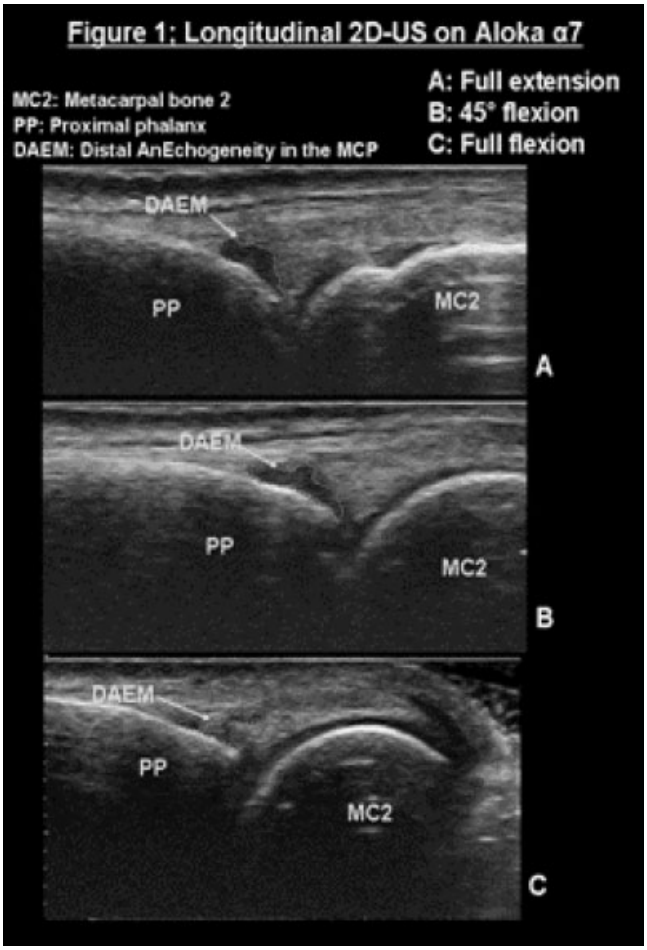
Sonographic Arthritis Remission Criteria Jeopardized by a Physiological Anechogeneity in MCP Joints. David F. Ten Cate[1], Jolanda J. Luime[2], Johanna Hazes[3], G.J. Kleinrensink[2] and Johannes W.G. Jacobs[4]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus MC - University Medical Center, Rotterdam, Netherlands, [3]Erasmus Medical Centre Rotterdam, Rotterdam, Netherlands, [4]UMC Utrecht, Utrecht, Netherlands

Background/Purpose: Ultrasonography (US) of clinically normal joints often reveals a small anechogenic area at the proximal phalanx in MCP joints, being most distinct in MCP 2. Using current US scores, this Distal AnEchogeneity in the MCP joint (DAEM) could be graded as inflammation,[1] but it is also found in healthy joints. The nature of this DAEM is not clear, however. Our aim was to identify the nature of the DAEM.

Methods: MCP2 joints of 10 healthy subjects with a DAEM and 7 RA patients were scanned bilaterally by 2D US (Aloka α7 and GE Logiq E9) and 3D US (GE Logiq E9) scans. Each joint was imaged in extension, 45° flexion and maximal flexion. (Figure 1) The joint space volume was calculated in 4 subjects and the DAEM volume in 3. Two MCP2 joints of 2 cadavers with a DAEM were scanned and injected with Fillopaq™, filling the entire joint space. Then the cadaver joints were dissected.



Results: The DAEM stayed visible when passively flexing the finger, at 45° flexion and in maximal flexion (Figure 1B and 1C, respectively). The 3D US scan showed that the DAEM is a part of the joint space, which was confirmed at dissection. DAEM dimension and volume were similar in the healthy controls and the patients. The median volume of the dorsal joint spaces was 0.09 cm^3 (range 0.04–0.14) and the median volume of the DAEM 0.02 cm^3. So the DAEM volume ranges from 15 to 50 % of the total dorsal joint space volume.

Conclusion: The anechogenic area frequently found distally in MCP2 joints of healthy controls is an extension or distal recess of the joint.[2] Sonographers should be aware of this distal recess and should take it into account, particularly when evaluating patients for remission using current US scoring systems.

No Ultrasound Specific Changes in Trochanter Enthesis in Patients with Greater Trochanter Pain Syndrome and Chronic Arthritis. Julio Ramírez[1], Isaac Pomés[1], Jaume Pomés[1] and Juan D. Cañete[2]. [1]Hospital Clínic, Barcelona, Spain, [2]Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain

Background/Purpose: To evaluate sonographic findings in greater trochanter pain syndrome in patients with spondyloarthropathies and two control groups: a first group including patients with rheumatoid arthritis and a second one with patients with degenerative joint disease.

Methods: Case-control study. Patients with unilateral greater trochanter pain syndrome were collected. A rheumatologist and a radiologist experienced in musculoeskeletical ultrasound performed the ultrasound scans of painful greater trochanter and contralateral asymptomatic trochanter (used as controls). We separately explored the gluteus medius tendon enthesis and the gluteus minor tendon enthesis. We specifically searched the following findings suggestive of tendinopathy: changes in tendon structure, cortical bone erosions (scored according to size from 0 to 3), calcifications (also rated according to size from 0 to 3), bursitis and Doppler signal (measured from 0 to 3). Because of the absence of reference measurements in trochanter enthesis, we did not measured the size of gluteus medius and minor tendons.

Results: 100 patients with unilateral greater trochanter pain syndrome were collected. 90 women and 10 men. 33 were diagnosed of seronegative spondylarthropathy according to ASAS criteria, 22 rheumatoid arthritis according to ACR criteria and 45 patients had degenerative disease. The mean age of patients was 61 years. Ultrasound enthesis abnormalities were more common in gluteus minor tendon, regardless of diagnosis (82% had erosions, 61% calcification, 37% bursitis, and 35% had alterations in the tendon structure). The percentage of calcification and bursitis was significantly higher in the symptomatic side than the contralateral in both tendons, but not erosions, equally present bilaterally. Doppler signal was not found in any patient. In subgroup analysis, there were no specific ultrasound findings in patients with spondyloarthropathies. No ultrasound differences were found between spondiloarthropaties patients and rheumatoid arthritis patients. However, when comparing SpA patients with degenerative disease patients, we found a significantly lower rate of bursitis (15% vs 40% in gluteus medius and 21% vs 49% in gluteus minor, $p = 0.024$ and 0.018 respectively). Moreover, although the total percentage of erosions and calcifications in gluteus minor did not differ between the two groups, those found in the degenerative group were larger.

Conclusion: Regardless of the underlying disease, the enthesis of the gluteus minor is the most affected enthesis in greater trochanter pain syndrome by ultrasound examination. Calcifications and bursitis are the most discriminative ultrasound findings. We could not differentiate inflammatory or mechanical origin of greater trochanter pain syndrome because of two reasons; erosions are very common in this area and, because of the depth of trochanter, no Doppler signal was detected in any patient.

183

Detection by Ultrasound of Small Calcium Deposits within Cartilage in Patients without Radiographic Chondrocalcinosis. Eric Russell, Humaira Hussain and Angel E. Checa. Drexel University College of Medicine, Philadelphia, PA

Background/Purpose: Musculoskeletal ultrasound (MSKUS) has increasingly been used in the field of rheumatology to evaluate joint pathology and has been shown to be a very sensitive tool in identifying crystalline arthropathies. We describe the sensitivity of MSKUS detection of small deposits of calcium, not visible on conventional radiography, in patients with joint symptoms attributed to other disease process, such as osteoarthritis. In addition, among patients with sonographic evidence of chondrocalcinosis, we measure the degree of cartilage loss using MSKUS, and correlate this to the presence of calcium deposits within the knee cartilage.

Methods: In the cohort of 406 patients who underwent MSKUS from January 2010 to June 2011, thirty patients with chondrocalcinosis were identified by the presence of calcium deposits using a GE LOGIQ e machine equipped with a broadband, 8–13mHz linear transducer. The presence of chondrocalcinosis was sonographically recognized as hyperechoic foci of enhancement, within the joint cartilage. Once aggregates of calcium were identified, the size was measured unless the deposit burden was too large to quantify. In addition, cartilage thickness was measured, on transverse view of a magnified sonographic image of the fully flexed knee, in the lateral femoral compartment, trochlea, and medial femoral compartment of the knee.

Results: We identified 30 patients with MSKUS evidence of aggregates of calcium within the wrist or knee cartilage. Two patients were excluded from the study since prior radiographs of the joint were not available. Of the 28 patients included in the study, 9 (32%) showed radiographic evidence of chondrocalcinosis and 19 (68%) patients had no evidence of chondrocalcinosis on prior radiographs ($p = 0.001$). Those patients with sonographic, but not radiographic chondrocalcinosis, predominately had small calcium deposition. The group with radiographic evidence of chondrocalcinosis in general showed deposits too extensive to measure on ultrasound. Cartilage thickness was not different between patients with or without radiographic chondrocalcinosis [mean (mm) = 1.96 vs. 2.0 respectively, $p = 0.84$] despite a larger calcium burden seen in the group were conventional radiography was able to detect chondrocalcinosis.

Conclusion: Musculoskeletal ultrasound was better than conventional radiography in detecting small calcium deposits in patients with symptoms attributed to other joint pathology. Knee cartilage loss was similar in both groups despite more crystal burden within the group that had evidence of both radiographic and sonographic chondrocalcinosis. Considering the low sensitivity of MRI in detecting chondrocalcinosis and our finding that radiography was insufficient to detect small calcium deposits, we conclude that MSKUS is a very sensitive tool to evaluate for small aggregates of calcium. Future controlled trials, with a larger

patient population, are needed to evaluate whether these small deposits represent a pathologic pattern and have a significant clinical impact.

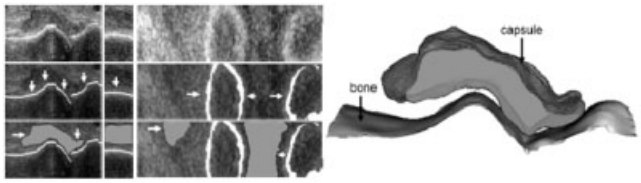
Feasibility of Volumetric Ultrasound and Automated Analysis for Rheumatic Disease. Ralf G. Thiele[1], Kedar Patwardhan[2], Kunlin Cao[2] and David Mills[2]. [1]University of Rochester, Rochester, NY, [2]GE Global Research

Background/Purpose: Two-dimensional (2D) ultrasonography (US) is a cross-sectional imaging modality that is useful for detecting typical changes in rheumatoid arthritis (RA) including synovitis and erosive disease. Inter- and intra-observer variability can be good to excellent if rheumatologists are adequately trained. Nevertheless, 2D sectional imaging can often not sufficiently capture 3D anatomic reality. True volumes of proliferative synovial tissue or erosions in RA may be better measured with 3D imaging. Most 3D US technology is optimized for obstetrical, gynecological, or cardiac indications. Availability of 3D US technology dedicated to assessment of rheumatic disease would be desirable. In addition, automated identification and capture of volumes of interest would facilitate objective and repeatable assessment of rheumatic disease. The aim of this study is to assess the feasibility of development of 3D technology dedicated to the assessment of rheumatic disease.

Methods: In this study, we obtained 31 3D datasets of 11 joints in 9 subjects, at least 6 of whom had rheumatic disease. High-frequency 3D US equipment was used (Voluson-i & RSP-6–16 probe, GE Healthcare, Wauwatosa, WI). Joints examined included MTP joints, n=3; MCP joints, n=6; PIP joint, n=1; and shoulder joint, n=1. All US studies were performed by a rheumatologist certified in musculoskeletal US, with 20 years of US experience (RT). We developed computer algorithms that look for characteristic acoustic responses to automatically identify the bone surface in the US images. This reference surface provides anatomical context to automate other clinically valuable tasks such as identification of the joint capsule.

Results: Despite realistic differences in images from multiple subjects, the majority of the 3D bone surface was successfully identified by our computer algorithm for all 11 joints. Image artifacts, irregular anatomy (e.g. large bone erosions) and areas where the bone surface was far from parallel to the US probe resulted in incorrect identification of small portions of the bone in the images of 5 of the joints. The figure shows (left top-row) 3 views of a 3D US image, automatically identified bone (middle row) and as an example of potential applications, a semi-automatically identified joint capsule over bone is shown (bottom-row).The figure also shows (right) a 3D rendering of the joint capsule and bone.



Conclusion: Development of 3D ultrasound equipment dedicated to rheumatology indications is feasible. Operator independent measurement of volumes of synovitis and erosions can help define disease status more objectively. Serial measurement of volumes of erosions and synovitis could provide valuable information about disease progression or treatment response.

US Examination of Wrists and Hands: A Comparison Between Rheumatoid Arthritis and Psoriatic Arthritis. Andrea Delle Sedie[1], Niccolò Possemato[2], Elena Sardano[3], Elisa Cioffi[4], Stefano Bombardieri[2] and Lucrezia Riente[2]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy, [3]Immunology Unit, University of Pisa, Italy, [4]School of Medicine, University of Pisa, Pisa, Italy

Background/Purpose: Very little is known about the possible differences in the involvement of joints and periarticular structures in rheumatoid or psoriatic arthritis (PsA). The main pathological features detected by US in rheumatoid arthritis (RA) are synovitis and bone erosion while, in spondyloarthropathies, entheseal inflammation is the common feature. Tendon involvement is particularly frequent and dactylitis is a typical PsA manifestation.

Aim of the study was to investigate the features of wrist and hand involvement in PsA and RA.

Methods: Bilateral ultrasound (US) examination of the wrist and hand was performed, by the same physician, in a group of subjects affected by RA (n=50; F:M=43:7; mean age: 61.3±12.7 years; disease duration: 112.9±85.5 months) and PsA (n=50; F:M=24:26; mean age: 57.4±12.5 years; disease duration: 100.2±97.4 months), using a Logiq 9 (General Electrics Medical Systems, Milwaukee, WI) with a linear probe operating at 14 MHz. We examined radiocarpal, intercarpal, metacarpophalangeal, proximal interphalangeal and distal interphalangeal (DIP) joints and flexor and extensor tendons (both in wrist and hand). The patients were recruited on a time-criteria (the last 25 patients for each diagnosis who came for an outpatient control) from the whole number of subjects referring to the US unit of our Clinic.

Results: US examination showed joint wrist synovitis in 37/50 (74%) RA and 29/50 (58%) PsA patients, hand synovitis in 33/50 (66%) and in 36/50 (72%) RA and PsA patients respectively. Tendon involvement was present in the 21/50 (42%) and 13/50 (26%) patients in the wrist and 18/50 (36%) in the hand, both in RA and PsA group. Finally, bone erosions were present in 33/50 (66%) and 29/50 (58%) RA and PsA patients respectively.

Conclusion: We did not observed significant differences in wrist or hand involvement (both in joint and tendon structures) between RA and PsA patients, even if a slightly higher frequency of wrist synovitis and tenosynovitis was present in RA group.

186

Detection of Inflammation in Early Psoriatic Arthritis by Ultrasound - a Longitudinal Study. Axel P. Nigg[1], Anna M. Malchus[1], Mathias Grünke[1], Matthias Witt[1], Joerg C. Prinz[2] and Hendrik Schulze-Koops[1]. [1]Division of Rheumatology and Clinical Immunology, Med. Poliklinik, University of Munich, Munich, Germany, [2]Department of Dermatology, University of Munich, Munich, Germany

Background/Purpose: By reasons of the phenotypic heterogeneity and the absence of reliable disease-specific biochemical markers in early psoriatic arthritis (PsA) sensitive diagnostic modalities enabling visualization of early inflammatory changes and reliable tools for monitoring the response to therapy are required. We initiated a prospective study to evaluate the utility of US in early PsA. The aims of the study are to analyse the correlation between US findings and clinical parameters, to evaluate the prognostic value of US findings as predictors for clinical outcome and to assess the sensitivity and specificity of US in detection of inflammatory changes on the individual joint level.

Methods: 30 patients with psoriasis suffering from recent onset joint pain were included. Patients were evaluated by US and clinically at baseline and after 3, 6 and 12 months. In each patient a total of 56 joints were examined by US. Grey-Scale (GS) and power doppler (PD) US findings were scored separately on a 0–3 semi-quantitative scale. In addition tendons of fingers and toes and 10 enthesial sites were scanned. Tenosynovitis and enthesitis were registered as being absent (0) or present (1). Total US synovitis/tenosynovits/enthesitis scores were calculated by adding the scores in the GSUS and PDUS modes for all joints/tendons/enthesial sites examined. Clinical assessment included joint count of 68 tender and 66 swollen joints, visual analog scale (VAS) for disease activity (patient/physician), DAS-28, Leeds dactylitis instrument, HAQ, CRP, ESR and demographic data.

Results: When considering each joint individually, a total of 1569 joints were assessed by US and clinically. GSUS detected synovitis in 213 joints (13,5%), PDUS activity was observed in 35 joints (2,2%). Subclinical US synovitis was found in 49% (GSUS) and 20% (PDUS) of all joints with pathologic US findings. With US as reference method clinical examination of joint tenderness had a sensitivity of 49%(GSUS)/71%(PDUS) and a positive predictive value of 55%(GSUS)/13%(PDUS). Joint swelling had a sensitivity of 11% (GSUS)/46%(PDUS) and a positive predictive value of 92%(GSUS)/62%(PDUS). Detection of erosions and proliferative changes in joints of fingers and toes by radiography showed a sensitivity of 3% and positive predictive value of 25% with US as reference method. At baseline the combined US joint score showed a strong and highly significant correlation with TJC68, SJC66, DAS-28 and physician global activity and a moderate significant correlation with HAQ. The US tenosynovits score correlated strongly with Leeds dactylitis instrument (LDI). Longitudinal data showed a moderate to strong correlation between relative changes in the US parameters and changes in clinical parameters through 3 months of follow-up in patients undergoing systemic treatment.

Conclusion: US is a useful instrument in the diagnosis of early PsA. US findings correlate well with clinical disease activity at baseline as well as longitudinally over the treatment course. US detects joint inflammation to a larger extent than clinically expected and confirms the presence of subclinical inflammation.

Metric Properties of Imaging Methods in Osteoarthritis of the Hand: A Systematic Review. Michael S. Saltzherr, Ruud W. Selles, Sita M.A. Bierma-Zeinstra, Galied S.R. Muradin, J. Henk Coert, Johan W. van Neck and Jolanda J. Luime. Erasmus MC - University Medical Center, Rotterdam, Netherlands

Background/Purpose: To early diagnose and detect response to therapy in hand osteoarthritis (HOA), we need imaging techniques that visualize soft tissue, cartilage and bone in multiple joints with sufficient detail. These techniques should be valid, reliable and responsive. We therefore systematically reviewed the literature on information about validity, reliability and responsiveness of imaging techniques for HOA.

Methods: We systematically searched Pubmed and Embase up to October 2010. Studies were selected if an imaging technique was used to assess HOA and quantitative data was presented on validity, reliability or responsiveness. Articles presenting only data on conventional radiography (CR) were excluded. The methodological quality was assessed by the QUADAS for validity, the QAREL for reliability and the COSMIN for responsiveness.

Results: 13 ultrasound (US), 2 MRI and 7 scintigraphy studies were eligible out of 459 unique records. US validity was evaluated in 11 studies but none used an external criterion (gold standard). Construct validity using CR as comparator (n=6) resulted in: moderate agreement for osteophytes (κ=0.51) and joint space narrowing (JSN) (κ=0.44); sensitivity of 0.72 and specificity of 1.0 for erosions; significantly more ($p<0.05$ and $p=0.01$) erosions and osteophytes on US; and R^2 of 0.62 for cartilage thickness when compared with joint space width. Greyscale synovitis (GS) and power doppler signal (PD) showed no agreement with joint pain (κ=0.10–0.14 and κ=0.06–0.16; n=2), while increased odds ratio's (4–5) were reported in 1 other study. 2 studies compared US findings in HOA patients with healthy controls: significantly more ($p<0.05$) effusion, JSN, osteophytes, GS and PD were found in HOA.

Inter- and intra-observer reliabilities ranged from very poor to very good: cartilage thickness (ICC=0.84–0.96; n=2), JSN (κ=0.64), osteophytes (κ=0.17–0.98; n=3), erosions (κ=0.91), GS (κ=0.17–1.0; n=4), PD (κ=0.09–1.0; n=4), effusion (κ=0.34). Responsiveness on GS and PD after i.m. methylprednisolone was assessed with pain as a comparator, but no significant change was found.

MRI validity of erosions was evaluated in 1 study with CR as comparator. Significantly more erosions were detected on MRI ($p<0.05$). In another study more ($p<0.05$) ligament, tendon and cartilage abnormalities, osteophytes, bone edema and erosions were detected in HOA compared to healthy controls. Inter-reliability of scoring erosions on MRI was good (κ=0.84). Responsiveness has not been assessed on MRI.

Scintigraphy correlated with joint pain (r=0.24–0.35) and CR (r=0.50–0.61; n=2), but detected less pathology than CR. Intra- and inter-observer reliability of scintigraphy were good (κ=0.61–0.84). Responsiveness on scintigraphy without intervention showed no significant change after one year, but did after four years. This correlated with changes on CR (r=0.13).

Conclusion: Limited data is available on the metric properties of imaging techniques in HOA. Scintigraphy seems less sensitive to detect pathology than CR, but US and MRI seem promising. However, there are no data on criterion validity; results on reliability vary greatly for US and are scarce for MRI; and the only study assessing responsiveness found no change.

188

New Onset Bilateral Painful Shoulder in Patients with Polymyalgia Rheumatica and Rheumatoid Arthritis: An Ultrasound Study. David A. Navarta[1], Santiago Ruta[1], Javier Rosa[1], Carla Saucedo[1], Ricardo Garcia Monaco[2] and Enrique R. Soriano[1]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires

Background/Purpose: Ultrasound (US) has shown synovial intra-articular and/or periarticular inflammation in painful shoulders from patients with polymyalgia rheumatica (PMR) and rheumatoid arthritis (RA). The feature of different US inflammation patterns may have important pathogenic and therapeutic implications. We compared US inflammatory findings in PMR and RA patients with new onset bilateral painful shoulder.

Methods: Patients with previous diagnosis of PMR (1984 Healey criteria) and RA (2010 ACR/EULAR criteria) complaining of new onset bilateral painful shoulder were included. Subjects without any known inflammatory rheumatic condition with new onset unilateral painful shoulder were assessed as control group. Exclusion criteria were: < 18 years old, oral prednisone dose > 10 mg per day, previous surgery on the shoulder, trauma or corticosteroid injection within the last 2 months. US assessment was performed bilaterally in all patients and unilaterally in controls by the same experienced rheumatologist sonographer who was blinded to clinical data. US examinations were performed with a My Lab 70 (Esaote) machine equipped with 6–18 MHz broad band multifrequency linear transducer and included the detection of subacromial-subdeltoid (SAD) bursitis, long head biceps (LHB) tenosynovitis and/or gleno-humeral (GH) synovitis by a dichotomous evaluation (presence/absence). Standardized scanning method and published reference values were used. Frequency of each feature was calculated and compared between groups by chi2 test. A p value <0.05 was considered significative.

Results: Thirty PMR patients (mean age 74 ± 8 years, 26 female/4 male), 30 RA patients (mean age 64 ± 12 years, 24 female/6 male) and 60 controls (mean age 69 ± 15, 48 female/12 male) were included for a total of 60 shoulders evaluated in each study group. SAD bursitis and LHB tenosynovitis were significantly more frequent in PMR patients than in RA and controls (table). GH synovitis was most common in RA than in PMR and controls (table). Bilateral SAD bursitis was detected in 11 out of 30 (36,6%) patients with PMR and in only 1 out of 30 (3,3%) rheumatoid arthritis patients ($p = 0.0012$) and bilateral LHB tenosynovitis was found in 9 out of 30 (30%) PMR patients in contrast with none (0/30) rheumatoid arthritis patients ($p = 0.0011$). No differences were found on bilateral GH synovitis between PMR and RA patients ($p = 0.3006$).

Table. Frequency of the different shoulder ultrasound findings in the different study groups.

	Polymyalgia rheumatica vs Rheumatoid arthritis	Polymyalgia rheumatica vs control group	Rheumatoid arthritis vs control group
Subacromial-subdeltoid bursitis	33/60 (55%) vs 11/60 (18.3%)	33/60 (55%) vs 15/60 (25%)	11/60 (18.3%) vs 15/60 (25%)
Shoulder affected/Total shoulder examined (%)	*p < 0.0001*	*p = 0.0008*	*p = 0.6576*
Long head biceps tenosynovitis	28/60 (46.6%) vs 14/60 (23.3%)	28/60 (46.6%) vs 12/60 (20%)	14/60 (23.3%) vs 12/60 (20%)
Shoulder affected/Total shoulder examined (%)	*p = 0.0074*	*p = 0.0019*	*p = 0.3754*
Glenohumeral synovitis	7/60 (11.7%) vs 16/60 (26.7%)	7/60 (11.7%) vs 4/60 (6.6%)	16/60 (26.7%) vs 4/60 (6.6%)
Shoulder affected/Total shoulder examined (%)	*p = 0.0369*	*p = 0.3426*	*p = 0.0033*

PMR, RA and controls

Conclusion: We found differences on the inflammation pattern detected by US between PMR and RA. Periarticular involvement was more frequent in PMR and intra-articular involvement was more common in RA. US might be a useful tool to determinate the musculoskeletal structure actually affected during new onset painful shoulder in these rheumatic conditions helping to take a correct therapeutic decision.

The Role of Color-Doppler-Sonography in the Diagnosis of Giant Cell Arteritis Characterized by Adventitial Inflammation of the Temporal Arteries. Francesco Muratore, Luigi Boiardi, Nicolo Pipitone, Alberto Cavazza, Giovanna Restuccia, Giuseppe Germanò, Pierluigi Macchioni, Gianluigi Bajocchi, Maria Grazia Catanoso, Luca Magnani, Fulvia Rossi, Ilaria Chiarolanza, Lucia Dardani, Andrea Caruso, Alessandra Ghinoi and Carlo Salvarani. Arcispedale S Maria Nuova, Reggio Emilia, Italy

Background/Purpose: The classic histological appearance of inflamed temporal arteries (TA) in giant cell arteritis (GCA) is transmural cell infiltration. However, periadventitial small vessel vasculitis (SVV) surrounding uninflamed TA and/or isolated vasculitis of the TA vasa vasorum (VVV) is found in a minority of patients with GCA. These patients have less frequently cranial manifestations and lower inflammatory markers at diagnosis compared to the patients with classic GCA, whereas the frequency of cranial ischemic events is similar (1).

Color-doppler-sonography (CDS) can demonstrate a hypoechogenic (inflammatory) halo in the TA from patients with GCA in approximately 70% of cases. A study found a correlation between positive CDS findings and trasmural inflammatory cell infiltration in GCA (2).

There are no data on the performance of CDS in the diagnosis of SVV and/or VVV.

The aim of this study was to evaluate the prevalence of the characteristic halo sign in the TA from patients with SVV and/or VVV and to compare it with that found in patients with classic GCA.

Methods: 30 consecutive patients with biopsy-proven SVV and/or VVV GCA who underwent CDS of the TA before TA biopsy were analyzed. Of

this 30 patients, 16 had SVV, 11 isolated VVV, and 3 associated SVV and VVV. The identified patients were randomly matched to 30 biopsy-proven classic GCA patients.

SVV was defined as aggregates of mononuclear inflammatory cells around capillaries located in the connective tissue surrounding the adventitia. VVV was defined as isolated vasculitis of TA vasa vasorum.

A hypoechoic halo > 0.4 mm around the TA lumen on CDS was considered diagnostic of GCA.

For GCA categorization using the 1990 ACR criteria, SVV or isolated VVV were not considered to represent a positive TA biopsy.

Results: Of the 30 patients with SVV and/or VVV-GCA 14 (46.6%) satisfied the ACR criteria for the classification of GCA.

Table 1 shows the comparisons between the patients with SVV/VVV and classic GCA.

Table 1. Characteristics of the patients with SVV and/or VVV versus those with classic GCA

	SVV and/or VVV (N=30)	Classic GCA (N=30)	P
Halo on CDS (%)	6/30 (20%)	23/30 (76.6%)	0,0001
Bilateral Halo on CDS (%)	1/6 (16.7%)	15/23 (65.2%)	0,064
Abnormalities of TA at physical examination (%)	8/24 (33.3%)	18/30 (60%)	0,061

Conclusion: The prevalence of the halo sign on CDS of the TA is significantly lower in patients with SVV/VVV-GCA compared with those with classic GCA.

These results suggest that CDS does not perform well in these two subsets of GCA. TA biopsy is required to confirm the diagnosis of GCA in patients with SVV- and VVV-GCA.

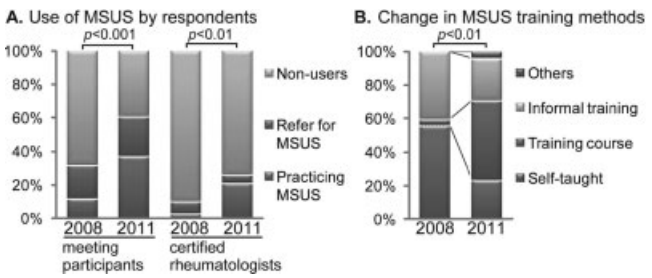
Challenges to Expanding the Clinical Application of Musculoskeletal Ultrasonography Among Rheumatologists in Japan. Maasa Hama, Kaoru Takase, Atsushi Ihata, Mitsuhiro Takeno and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background/Purpose: Our previous survey in 2008 revealed that only 22% of Japanese rheumatologists used musculoskeletal ultrasonography (MSUS) for patient management because of insufficient educational opportunities. The objective of this study is to clarify the current state of MSUS usage which is compared with MRI and to identify further challenges.

Methods: We conducted a second survey between October 2010 through January 2011 by sending questionnaires to 200 randomly selected Japanese rheumatologists, consisting of 100 participants in a meeting in 2009 on imaging in rheumatic diseases and 100 board certified rheumatologists.

Results: Among the respondents, a majority (85% and 67%, respectively) used MRI. MSUS users increased from 32% to 60% of meeting participants and from 11% to 27% of other rheumatologists. The majority of MSUS users had begun using MSUS within the previous 3 years. Whereas most respondents in the previous survey had been self-taught, in the current survey many had attended training courses or had received informal training from skilled users. Despite an increase in skills and equipment ownership, obstacles to implementing MSUS remained, most prominently a lack of time.



Conclusion: Training courses and informal training have contributed to the popularization of MSUS in Japan. To further increase MSUS usage, additional training opportunities and education about the advantages of MSUS will be needed.

191

Are Training Sessions Useful for Ultrasound Scan Evaluation of Synovitis In Rheumatoid Arthritis? Andrés Ponce[1], Juan J. Alegre[2], Manuel Castaño[3], Ricardo Gutierrez-Polo[4], Francisco G. Jiménez-Núñez[5], María P. Macarrón[6] and Jesús Garrido[7]. [1]Hospital General de Granollers, Granollers, Spain, [2]Hospital Universitario Dr Peset, Valencia, Spain, [3]Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, [4]C.H. de Navarra, Pamplona, Spain, [5]Hospital Regional Universitario Carlos Haya., Malaga, Spain, [6]Hospital Clínico San Carlos, Madrid, Spain, [7]Facultad de Psicología.Universidad Autónoma de Madrid, Madrid, Spain

Background/Purpose: US is becoming a realistic tool for synovitis assessment in rheumatoid arthritis (RA), although reliability remains as a challenging issue. Therefore, training sessions (TS) are needed to improve the intra and inter-observer reliability. However, the improvement in reliability due to TS has not been quantified. The aim of this study is to measure the reliability of the US evaluation for different joints, both before and after TS.

Methods: 6 rheumatologists expert in US evaluated the presence of synovitis and PD signal in 173 static images of joints from RA patients (45 wrists, 27 metacarpophalangeals, 25 ankles, 36 metatarsophanlangeals, 20 knees, and 20 elbows) recorded in a regular clinical setting by 65 different rheumatologists, with evaluation time limited to 1 minute per image. Fifteen to thirty days later they took a second evaluation of the images of a joint assigned to each researcher (Pre-TS). One month later a 3-hour standardization and training session (TS) took place. Fifteen days after that the rheumatologists evaluated the images following the same procedure, first all the images and, 15–30 days apart, images of assigned joint (Post-TS). Intra and inter-observer kappa were calculated, both pre-TS and post-TS.

Results: The intra- and inter-observer kappa values for each joint, pre-TS and post-TS, are shown in the following table:

	Intra-observer kappa				Inter-observer kappa			
	Power Doppler		Grey scale		Power Doppler		Grey scale	
Joint	Pre-TS	Post-TS	Pre-TS	Post-TS	Pre-TS	Post-TS	Pre-TS	Post-TS
wrist	0.562	0.769	0.319	0.644	0.684	0.760	0.373	0.478
MCP	0.710	0.913	0.578	0.777	0.568	0.699	0.359	0.551
Ankle	0.845	0.930	0.699	0.762	0.685	0.676	0.302	0.588
MTP	0.932	0.904	0.273	0.669	0.762	0.924	0.476	0.485
Knee	0.142	0.824	0.027	0.441	0.479	0.921	0.455	0.533
Elbow	0.434	0.855	0.220	0.806	0.518	0.816	0.359	0.439

After TS the magnitude of the reliability statistic kappa increased mainly for those joints that showed the lowest kappa values at the pre-TS evaluation.

Conclusion: The intra an inter-observer reliability in the evaluation of the static images, taken in regular clinical settings, improve clearly after a training session.

192

The Most Reliable Probe Position in An Rheumatoid Arthritis Wrist Is From Lister's Tubercle to Digit III, the Zorro Study. Noelia Dopazo Gonzalez[1], David F. Ten Cate[2], Antonio Mera[3], S.A. Insua Vilariño[4], Nanno Swen[5], E. Perez-Pampin[4], Juan J. Gomez-Reino[6] and Jolanda J. Luime[7]. [1]Erasmus Medical Centre Rotterdam, Rotterdam, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]General Hospital, Santiago Compostela, Spain, [4]University Clinical Hospital of Santiago de Compostela, Santiago de Compostela, Spain, [5]Medical Center Alkmaar, Alkmaar, Netherlands, [6]Hospital Clinico Universitario, Santiago, Spain, [7]Erasmus MC - University Medical Center, Rotterdam, Netherlands

Background/Purpose: Ultrasound (US) has great potential as an outcome measure in Rheumatoid Arthritis (RA), but is thought to be imperfect and operator dependent. The wrist is often involved but difficult to assess by US. [1] This, with the lack of consensus on probe positioning, has led to little and equivocal clear data on the reliability of US scanning of the wrist.[1–5] Our purpose was to find the most reliable probe position on the wrist, out of 3 probe positions, between 3 examiners.

Methods: 53 RA patients were recruited at the University Clinical Hospital of Santiago de Compostela for a scan of both wrists. Three probe positions using clear anatomical landmarks were examined: Lister's Tubercle to digit II (position 1), Lister's Tubercle to digit III (position 2) and ulnocarpal (position 3), from a lateral orientation. Three examiners (2 experienced and 1 junior ultrasonographer)

scored synovitis following a 0–3 semiquantitative scoring system. Interobserver reliability was expressed using the ICC (A,1), single measure, agreement definition.

Results: The 53 patients had a median disease duration of 57 months [range: 0–354 months] and a heterogeneous disease activity (median DAS28 of 2.83 [range 0.19–6.41]). From table 1 follows that position 2, from Lister's Tubercle to digit III, is slightly more reliable than position 1 in the GSUS examination of the wrist. For PDUS, position 1 and 2 show similar reliability. Position 3 shows poorest reliability of all positions in both GSUS and PDUS.

Table 1. Interobserver reliability, right and left wrist together

	Position 1	Position 2	Position 3
RC (GS)	0.60	0.52	0.35 (UC)
IC (GS)	0.44	0.60	–
RC (PD)	0.52	0.52	0.36 (UC)
IC (PD)	0.40	0.40	–

(RC= radiocarpal joint, IC= intercarpal joint, UC=Ulnocarpal joint, GS= Greyscale, PD= Power Doppler)

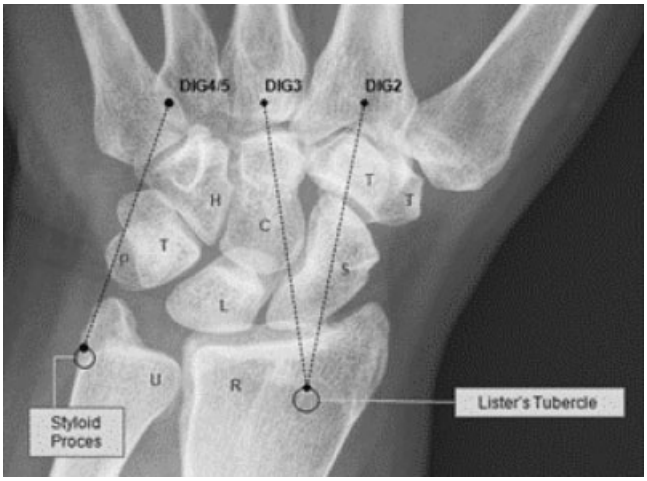


Figure 1. The three probe positions.
R=Radius, U=Ulna, S=Scaphoid, L=Lunatum, T(left)=Triquetrum, P=Pisiforme, H=Hamatum, C=Capitatum, T(middle)=Trapezoideum, T(right)= Trapezium

Conclusion: Position 2 shows the best reliability in scanning the wrist in GSUS. For PDUS position 1 and 2 show similar reliability. The reliability of GSUS and PDUS examination of the wrists of RA patients was poor for position 3 (the ulnocarpal joint). These findings suggest that position 2 should be used in daily practice.

Meta-Analysis: Improvement In Wrist Pain with US-Guided Glucocorticoid Injections As Compared to Palpation-Guided Injections. Maureen Dubreuil[1], Stephanie Greger[2], Michael P. LaValley[3], Wilmer L. Sibbitt[4] and Eugene Y. Kissin[5]. [1]Boston Medical Center, Boston, MA, [2]Boston University Medical Center, Boston, MA, [3]Boston University School of Public Health, Boston, MA, [4]University of New Mexico HSC, Albuquerque, NM, [5]Boston University, Boston, MA

Background/Purpose: This meta-analysis compares short-term change in wrist pain following ultrasound-guided (US-guided) intra-articular glucocorticoid injections with pain reduction after palpation-guided injections in persons with inflammatory arthritis or osteoarthritis.

Methods: Data sources were MEDLINE, Cochrane, BIOSIS, CINAHL, ACR/AHRP abstracts, ClinicalTrials.gov, hand-search of reviews, and recommendations from experts (USSONAR), and investigators. Studies that assessed change in pain score by Visual Analog Scale (VAS), in direct comparison of US-guided and palpation-guided injections, or with a single relevant treatment arm were included. Subject-level data was sought from authors of relevant studies.

Primary outcome was change in wrist pain at rest, by 0–10 cm (VAS) prior to injection and at 1–4 week follow-up. Mean and 95% confidence intervals (CI) for change in VAS pain were calculated for each group and study. Mean difference was calculated for comparative studies. Secondary outcome was proportion of subjects attaining Minimal Clinically Important Improvement (MCII) in VAS (defined as reduction in VAS of ≥ 20% at follow up); calculated for each group with exact binomial 95% CI. Odds ratios (ORs) of MCII were calculated for comparative studies. Mean differences in VAS pain and ORs for MCII for comparative studies were combined using random effects meta-analysis.

Results: Ten studies were eligible for inclusion, but adequate data was available for only 6 studies; 3 had both US-guided and palpation-guided treatment arms; 3 had a single relevant treatment arm. Rheumatoid Arthritis was the indication for injection in 83.3% of subjects.

Mean VAS reductions ranged from 3.8 to 5.8 for studies of US-guided injections, and from 2.1 to 5.7 for palpation-guided injections. Mean difference in VAS between treatment arms for the 3 direct comparison studies, and ranged from −0.2 to 1.3, with a random effects combined estimate of 1.0 indicating a statistically significant advantage of ultrasound. MCII attainment was 86 to 100% in the US-guided injection arms, and 71 to 96% in palpation arms. The estimated OR for MCII in direct comparison studies was 3.0 (95% CI from 0.9 to 10.1) indicating an increase in odds of MCII with ultrasound that trended toward, but did not reach statistical significance (p=0.07).

Conclusion: Ultrasound-guided glucorticoid injections to the wrist result in greater reductions in pain than palpation-guided injections, and likely provide a clinically important improvement. These data indicate a role for ultrasound guidance in patients who have inadequate reduction in pain after palpation-guided injection. Ultrasound-guidance may be indicated as the initial approach for patients with characteristics that make palpation-guided injection challenging, or for providers with limited experience performing palpation-guided injections.

Table. Mean reductions in wrist rest pain by Visual Analog Scale (VAS) and proportion of subjects attaining Minimal Clinically Important Improvement (MCII) among studies of ultrasound-guided injections and palpation-guided injections.

Steroid Injection for Plantar Fasciitis—a Placebo-Controlled Trial. Elisabeth M.A Ball[1], Helen M.A. McKeeman[2], James Burns[3], Wing Hoi Yau[3], Owen Moore[3], Claire Benson[3], Joanne Foo[3], Chris Patterson[4], Gary D. Wright[3] and Allister J. Taggart[3]. [1]Musgrave Park Hospital/Queens' University, Belfast, United Kingdom, [2]Belfast City Hospital, Belfast, United Kingdom, [3]Musgrave Park Hospital, Belfast, United Kingdom, [4]Epidemiology Research Group, Queens University Belfast, United Kingdom

Background/Purpose: Plantar Fasciitis (PF) is a common cause of heel pain and can affect quality of life and work capacity.The aim of this study was threefold - to compare steroid injection with placebo injection, to compare ultrasound-guided with palpation-guided steroid injection and to investigate the role of ultrasonography in the management of plantar fasciitis.

Methods: 65 patients with plantar fasciitis were recruited via Family Practitioner and Podiatric referrals to the Belfast Hospitals Trust between November 2008 and June 2011. Patients with a history of inflammatory arthritis and those who had received a previous steroid injection were excluded. Patients were randomised to one of three groups—ultrasound-guided steroid injection, palpation-guided steroid injection or ultrasound-guided placebo (saline) injection.The 100mm visual analogue scale (VAS) of pain and ultrasonography of the plantar fascia were performed at baseline and at the follow-up visits at 6 and 12 weeks. Blinding was applied to the participants and to the investigators performing the procedures and measuring outcomes. Analysis of covariance was used to analyse the 6 week and 12

week VAS results in the three groups using the baseline VAS levels as a covariate.

Results: The median duration of symptoms was 6 months (range 2.5–60).The mean (standard deviation) thickness of the plantar fascia at the anterior calcaneal border on ultrasound at baseline was 6.05 (1.47) mm. 22 Patients were randomised to ultrasound-guided steroid injection, 21 patients to palpation-guided steroid injection and 22 to ultrasound-guided placebo injection. No adverse events were reported. There was a significant difference in VAS scores between the groups both at 6 weeks and at 12 weeks ($p = 0.021$ and $p = 0.009$ respectively). There was a 20.8 mm (95% CI = 3.3–38.1) difference in mean VAS scores at 6 weeks between the ultrasound guided steroid group and the placebo group and a 22.6mm (95% CI = 5.4–39.8) mean difference between the palpation guided steroid group and the placebo group at 6 weeks. At 12 weeks the mean difference was 23mm (95% CI = 4–42.8) and 27mm (95% CI = 9.2–46) respectively between both groups and the placebo group. There was no significant difference in VAS scores following steroid injection between the ultrasound guided and the palpation guided groups at either time point.

Conclusion: Despite the widespread use of steroid injection only two controlled trials have compared its effect to placebo injection in plantar fasciitis. Blockey[1] showed no benefit over placebo and Crawford et al[2] showed a significant benefit at one month but not subsequently. In our study of 65 patients, steroid injection showed a clear benefit over placebo at 6 weeks and this was sustained at 12 weeks. There were no significant differences in the results achieved using ultrasound-guided or palpation-guided steroid injection.

Power Doppler Ultrasound Findings and Serum Levels of Pro- and Anti-Inflammatory Cytokines in Normal Joints. Joanne Kitchen[1] and David Kane[2]. [1]Adelaide and Meath Hospital, Dublin, Ireland, [2]Adelaide, Meath hospital Dublin (incorporating the National Children's hospital), Dublin 24, Ireland

Background/Purpose: To determine Power Doppler ultrasound findings in normal peripheral joints and to investigate the relationship between serum levels of IL-1α, IL-1β, IL-2, IL-4, IL6, IL-8, IL-10, VEGF, TNFα, and IFNγ

Methods: Thirty healthy controls (15 male, 15 female, mean age 38.9 yrs, SD 11.7) underwent 2D ultrasound of 40 joints (DAS28 joint set, ankles and metatarsophalangeal joints), with imaging in greyscale and power Doppler modes, resulting in 15,480 images for analysis. Each patient had 58 power Doppler images scored (0–3 score) and recorded, resulting in a potential maximum score of 174 for power Doppler. Serum samples were analysed for an array of pro-inflammatory and anti-inflammatory cytokines using the Evidence Investigator™ biochip array (Randox).

Results: Power Doppler signal >1 was not generally seen in normal joints apart from the wrist (41.7%). The mean total power Doppler score was 4.8 (SEM 0.624, Range 0–13) from a potentially maximum score of 174. There was no significant difference in the power Doppler scores between male and female subjects ($p=0.753$) and no significant correlation between age and power Doppler score ($r= 0.298$, $p= 0.11$). Serum samples were analysed on 26/30 control patients for an array of pro-inflammatory cytokines (IL-2, IL6, IL-8, IL-1α, IL-1β, VEGF, TNFα, IFNγ) and anti-inflammatory cytokines (IL-4, IL-10). There was a significant correlation between the VEGF concentration and the power Doppler score in the normal controls ($r = 0.395$, $p = 0.046$). There was a significant inverse correlation between the TNFα concentration and the power Doppler score ($r = -0.405$, $p=0.04$). There was no correlation with any of the other cytokines and the power Doppler scores.

Conclusion: Power Doppler signals of >1 are an uncommon feature in normal joints apart from the wrist and this study supports the use of >1 score as an appropriate cut-off of clinical abnormality when performing ultrasound assessment. Power Doppler score of the 40 joint set correlated with VEGF levels in serum but not other cytokines providing further evidence of a role for VEGF in synovial neoangiogenesis.

Lack of Correlation Between Synovial Biology and Ultrasound Features of Synovitis in Osteoarthritis. Jeannie H. Chao[1], Sanna Rosengren[2], Joshua Hillman[2], Kenneth C. Kalunian[2], Scott Ball[1], Brady K. Huang[1], Gary S. Firestein[2] and David L. Boyle[2]. [1]UCSD, La Jolla, CA, [2]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Pain and cartilage degeneration are salient features of osteoarthritis (OA). Synovitis is associated with pain and possibly disease progression, and ultrasound has been proposed as a method to assess disease activity. To identify patients that might benefit from synovitis-targeted therapies and to determine the correlation between inflammatory mechanisms and imaging, we examined the association between power Doppler ultrasound (PDUS) and molecular markers of inflammation in the synovium of end-stage knee OA

Methods: Patients meeting ACR criteria for knee OA and scheduled for arthroplasty were included and assessed using the WOMAC Osteoarthritis Index (n=18). PDUS using a high-frequency linear transducer (12 MHz, GE Logiq E) of the affected knee was performed prior to surgery. Views of the suprapatellar recess as well as lateral and medial parapatellar recesses were collected and semi-quantitatively scored for synovial thickening (ST) and Power doppler activity (PD). Regional measurements were summed to achieve composite scores. Synovium was obtained at time of arthroplasty. A high-sensitivity multiplex Western Blot technique was used to measure signaling proteins. Real-time qPCR was used to determine expression of inflammatory genes.

Results: PDUS features varied widly. Synovial thickening was observed in all patients, mean score 3.56 ± 1.76. PD scores also varied among patients, with a mean of 1.78 ± 1.63. The intraobserver reliability for ST and PD was high (kappa = 0.81 and 1, respectively). Phosphorylated signaling proteins were detectable in all synovia. For example, the mean relative expression of phospho-HSP27 was 0.718 (0.538–0.958) and 1.14 (0.78–1.67) for phospho-Stat1. Strong correlations were observed between phospho-Stat1 and phospho-Stat3 and between phospho-HSP27 and phospho-Erk. mRNA analysis was performed on 13 patients. Examples of mean relative expression of genes of interest include 0.733 (0.40–0.13) for IL1b, and 0.72 (0.38–0.14) for IL8. MMP1 and MMP3 as well as IL1β and IL8 were highly correlated. Correlations between PDUS scores with either qPCR or Western blot did not reach statistical significance. The highest correlation found was between PD and phospho-HSP27 ($R=0.44$, $p=0.0706$). Of note, IL8 expression correlated significantly with WOMAC function ($R=0.717$, $p=0.0058$), and pain subscale scores ($R=0.7044$, $p=.0072$) as well as global scores ($R=0.6399$, $p=0.0185$). CXCL13 also correlated with WOMAC function ($R=0.6863$, $p=0.0096$) and pain (0.5725, $p=0.0409$) subscale scores and global scores ($R=0.5824$, $p=0.0368$).

Conclusion: Ultrasound parameters did not significantly correlate with selected synovial biomarkers related to inflammation. Surprisingly, a clinical assessment of OA (WOMAC) best correlated with molecular measures of synovitis. Alternative imaging measures or technology are needed to improve stratification of patients and define synovitis for clinical trials or clinical decision-making. This observation also has implications for the use of ultrasound in classification criteria, such as the 2010 revised criteria for rheumatoid arthritis.

197

Comparison of Optical Coherence Tomography and High Frequency Ultrasound As Measures of Skin Thickness in Systemic Sclerosis; A Pilot Study. Andrea Murray[1], Donna Buckley[2], Graham Dinsdale[1], Tonia Moore[1], Mark Dickinson[2] and Ariane Herrick[1]. [1]School of Translational Medicine, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [2]Photon Science Institute, University of Manchester, Manchester, United Kingdom

Background/Purpose: Accurate, reliable, and non-invasive measures of skin thickness that are sensitive to small but clinically important change are badly required as outcome measures in patients with scleroderma – either localised or related to systemic sclerosis (SSc). At present the gold standard is high frequency ultrasound (HFUS), and yet even this has been relatively little studied. Optical coherence tomography (OCT) is a novel non-invasive light based imaging technique which, due to its high resolution, may provide complementary data to HFUS. HFUS penetrates deeper in skin than OCT (full dermis); however, OCT offers higher resolution (7 μm compared to 40 μm for HFUS) allowing more accurate measurement of epidermal thickness.

Our aim was to carry out a pilot study to validate OCT as a measure of skin thickness by comparison to HFUS measurements in patients with SSc and healthy controls.

Methods: 20 patients with SSc (median 61 (range 28–78) years of age; 80% female, 35% diffuse) and 20 healthy controls (50 (32–70) years of age; 70% female) were recruited. Thickness of the epidermis was assessed at 5 upper limb sites (distal digit [non-dominant, ring], proximal digit, dorsum of hand, forearm, upper arm) using HFUS and OCT. Modified Rodnan skin score (mRSS) was recorded at each site for patients with SSc.

Results: Epidermal skin thickness was significantly higher in patients, as measured by HFUS, at the digits, dorsum and forearm and as measured by OCT at the proximal digit and dorsum (Table 1). The numbers of patients with each mRSS score (0–3) at each site are shown in Table 1. Comparison of patient skin sites split into 2 groups (skin score 0–1 and 2–3) showed significant differences for both HFUS [p<0.001] and OCT [<0.001]). HFUS and OCT showed correlation with skin score when all sites were considered together (R=0.296, p=0.003 and R=0.345, p<0.001 respectively). There was no correlation [Pearson's correlation] between HFUS and OCT results for either the 40 subjects considered together (r=0.157, p=0.090) or for the 20 SSc patients alone (r=0.066, p=0.514).

Table 1.

Site of epidermal thickness (μm) measurement (dorsal aspect)	Controls (N=20)		Patients (N=20)		mRSS			
	HFUS	OCT	HFUS	OCT	0	1	2	3
Distal digit	240(33)	273(41)	264(41)* P=0.023	270(69) P=0.442	0	4	13	3
Proximal digit	244(35)	255(37)	265(41)* P=0.041	290(47)* P=0.007				
Hand	184(37)	213(26)	206(37)* P=0.031	252(35)* P<0.001	4	9	7	0
Forearm	195(35)	208(18)	223(58)* P=0.035	213(20) P=0.174	8	5	6	1
Upper arm	195(42)	215(18)	194(41) P=0.461	225(24) P=0.078	12	4	3	1

mean (SD); *p<0.05 vs control

Conclusion: 1) This preliminary study is the first step in validating the use of OCT as a measurement tool in SSc: OCT epidermal thickness was increased in proximal digit and dorsum. OCT as well as HFUS correlated with mRSS.

2) The higher resolution of OCT, combined with the higher penetration of HFUS (which can therefore also measure dermis thickness), means that the combination of HFUS and OCT gives complementary data.

3) The potential of OCT to incorporate blood flow measurement in individual vessels (optical Doppler tomography [ODT]), is another reason why OCT requires further evaluation in scleroderma: ODT should enable further investigation of the relationship between fibrosis and ischaemia.

4) OCT now needs to be applied in larger cohorts of patients with varying degrees of skin thickening, and in longitudinal studies.

198

Sensitivity and Specificity of Indocyanine Green Enhanced Optical Imaging (Xiralite) in Comparison to Magnetic Resonance Imaging and Ultrasonography. Stephanie G. Werner[1], Peter Schott[2], Sarah Ohrndorf[3], Carsten Schwenke[4], Malte Bahner[5], Bernward Kurtz[2], Marina Backhaus[6], Gerd R. Burmester[3] and Hans-Eckhard Langer[7]. [1]RHIO (Rheumatology, Immunology, Osteology) Duesseldorf, Duesseldorf, Germany, [2]Evangelisches Krankenhaus Duesseldorf, Duesseldorf, Germany, [3]Charité University Hospital, Berlin, Germany, [4]SCOSSIS, statistical consulting, Berlin, Germany, [5]mivenion GmbH, Berlin, Germany, [6]Charite University Hospital, Berlin, Germany, [7]Duesseldorf, Germany

Background/Purpose: Indocyanine green (ICG) enhanced fluorescence optical imaging (FOI) with the commercial available Xiralite system (mivenion GmbH, Berlin) is a novel imaging technology to assess inflammatory activity in arthritic conditions. We compared FOI with MRI and ultrasonography in patients with arthritis, arthralgia and healthy controls.

Methods: A total of 125 subjects was examined in 3 comparative studies. Cohort 1: 25 patients with rheumatoid or undifferentiated arthritis with high disease activity (DAS28 >3.2), cohort 2: 20 patients with early arthritis (disease duration≤24months) and cohort 3: 74 patients with arthritis or arthralgia in the hands. Six healthy individuals and 6 subjects with arthralgia without any sign of an inflammatory rheumatic disease served as control group. All patients received clinical examination (CE) and lab testing. In cohort 1 and 2 a contrast enhanced MRI of the clinically leading hand was performed. MRI was evaluated according to the OMERACT-criteria. Ultrasonography in grey-scale mode (GSUS) and power-Doppler Mode (PDUS) of the clinically leading hand was performed in cohort 3. All patients were examined by FOI using ICG as fluorophor (ICG-Pulsion® 0.1 mg/kg/BW bolus i.v., 6 minutes). Image interpretation was done on three defined phases of increased signal intensities (ISI) in the finger tips: early (P1, until strong ISI in the finger tips), intermediate (P2, during ISI in the finger tips), and late phase (P3, after decreasing of ISI in the finger tips) and for an automatically generated composite image (PrimaVista Mode, PVM). Sensitivity and specificity was calculated using MRI, GSUS or PDUS as reference.

Results: With MRI or ultrasonography as reference, FOI was more sensitive than CE (Table 1). FOI had a high sensitivity and high specificity, depending on the evaluated phase. FOI did not detect any positive findings in 97.8%–100% of joints in controls, depending on the evaluated image or phase.

Table 1. Sensitivity and specificity of FOI and clinical examination with ultrasonography or MRI as reference

FOI	MRI cohort 1 sensitivity	MRI cohort 1 specificity	MRI cohort 2 sensitivity	MRI cohort 2 specificity	PDUS cohort 3 sensitivity	PDUS cohort 3 specificity	GSUS cohort 3 sensitivity	GSUS cohort 3 specificity
FOI PVM	51%	81%	55%	92%	67%	54%	56%	57%
FOI P1	27%	94%	34%	95%	33%	90%	22%	95%
FOI P2	72%	56%	83%	69%	72%	44%	68%	50%
FOI P3	47%	89%	60%	92%	60%	69%	51%	78%
Any phase (P1–3)	76%	54%	85%	65%	74%	42%	70%	48%
CE	59%	72%	58%	90%	50%	76%	35%	79%

Abbreviations: FOI: fluorescence optical imaging; PVM: PrimaVista mode; P1: phase 1; P2: phase 2; P3: phase 3; any phase: positive in P1 or P2 or P3; PDUS: ultrasonography in power-Doppler mode (synovitis or tenosynovitis); GSUS: ultrasonography in grey scale mode (synovitis or tenosynovitis); MRI: magnetic resonance imaging (synovitis or tenosynovitis); CE: clinical examination (swollen joints)

Conclusion: FOI appears to be a valuable tool for assessing inflammation in patients with rheumatoid, undifferentiated, early arthritis or arthralgia in the hands. Sensitivity and specificity differed for PVM and P1–3. Therefore an adequate reading of a FOI sequence requires a separate reading of PVM and the phases.

199

Indocyanine Green Enhanced Optical Imaging Using for Monitoring of Treatment Response. Stephanie G. Werner[1], Felicitas Spiecker[2], Sabine Mettler[2], Gudrun Lind-Albrecht[2], Carsten Schwenke[3] and Hans-Eckhard Langer[2]. [1]RHIO (Rheumatology, Immunology, Osteology) Duesseldorf, Duesseldorf, Germany, [2]Duesseldorf, Germany, [3]SCOSSIS, statistical consulting, Berlin, Germany

Background/Purpose: Indocyanine green (ICG) enhanced fluorescence optical imaging (FOI) is a novel diagnostic technology for the assessment of inflammation in arthritis. In cross-sectional studies FOI had a good agreement with MRI and US findings (1),(2). The semiquantitative fluorescence optical imaging activity score (FOIAS) correlated with clinical (DAS 28) and MRI (RAMRI) scores of disease activity and a semiquantitative score of swelling and tenderness in the hands (locDAI). This is the first study to use FOI for the measurement of treatment response in DMARD naïve patients and in subjects with inadequate response to non-biologic DMARDs (DMARD-IR) and switch to biologica.

Methods: 33 patients with rheumatoid (RA) and psoriatic (PsA) arthritis were examined before starting treatment with DMARD or biological (visit 1) and at follow-up (visit 2 after ≥3 months). Treatment response was assessed using DAS28, locDAI and FOIAS. For locDAI swelling and tenderness were assessed separately and semiquantitativly for 15 joints of both hands (0 = no, 1 = subtle, 2 = distinct swelling/tenderness, distal interphalangeal joints (DIP) 2–5, interphalangeal joints (IP), proximal interphalangeal joint (PIP) 2–5, metacarpophalangeal joint (MCP) 1–5 and wrist, range 0–60) and a sum score was calculated. The FOI (Xiralite, mivenion GmbH, 0.1 mg/kg/BW of ICG i.v. over 6 minutes) sequences were analyzed for the automatically generated composite image (PVM) and three defined phases of FOI (P1, P2, P3). FOI findings of increased signal intensities were valued as 0=no, 1=low, 2=moderate, and 3=strong increased signal intensities. For FOIAS sum scores over all joints (DIP 2–5, PIP 2–5, IP, MCP 1–5, wrist, both hands, range 0–90) for PVM, the phases P1–3 and all phases were calculated. Standardized response means (SRM) were calculated for measurement of treatment response and Wilcoxon signed rank test was used to assess statistical significant change.

Results: The mean DAS28 at visit 1 was 4.3 and 2.9 at visit 2. All scores (DAS28, locDAI, FOIAS) showed a reduction of disease activity from visit 1 to visit 2. The mean reduction was 34% for DAS28, 47% for locDAI and 22%–34% for FOIAS. The SRMs showed high treatment response (SRM >0.8) for DAS28 (SRM −1.26) and locDAI (SRM −0.95) and moderate response (>0.5–0.8) for FOIAS (SRM −0.57 to −0.76) (3). The change from baseline was stated as statistical significant for all scores except FOIAS P1 ($p<0.05$).

Conclusion: The study suggests that FOI is a suitable tool to assess treatment response in subjects with RA and PsA. Further studies are required to test FOI as a possible additional outcome measure in clinical trails and clinical practice.

A Comparison of Optical Coherence Tomography and Clinical Assessment of Nail Disease in Psoriasis and Psoriatic Arthritis. Concepcion Castillo-Gallego[1], Sibel Aydin[2], Zoe R. Ash[3], Giusepinna Abignano[3], Paul Emery[3], Helena Marzo-Ortega[3], Francesco Del Galdo[3] and Dennis McGonagle[3]. [1]Hospital Universitario La Paz, Madrid, Spain, [2]Goztepe Training and Research Hospital, Istanbul, Turkey, [3]University of Leeds, Leeds, United Kingdom

Background/Purpose: Nail disease in psoriasis (Pso) is increasingly recognised to be of major clinical and research relevance. Clinical assessment is the only currently available tool and no objective methods have been standardized to image the nails. Optical coherence tomography (OCT) is an analogue of ultrasound, using infrared light instead of acoustic waves and has been used in the clinical setting by ophthalmologists since 1991. The axial resolution is determined by the bandwidth of the light source, which is 1–2 mm in general, limiting its use to very superficial tissues. It has also been widely investigated in dermatology, particularly in non-melanoma skin cancers.

The purpose of this study was to describe nail appearances as seen with OCT and to compare these findings in Pso and psoriatic arthritis (PsA) with clinical assessment.

Methods: A total of 290 finger nails of 17 patients (4 Pso, 13 PsA) and 12 healthy controls (HC) were scanned by OCT with a topical probe "VivoSight" (Michelson Diagnostics) and optics of Swept-source Fourier-Domain type with a laser wavelength of 1305+/− 15 nm. The investigator was blinded to the clinical details.

Signal changes within the nail and contour abnormalities by OCT were documented. Clinical nail abnormalities were independently scored by an assessor blinded to the OCT findings using the mNAPSI scoring system.

Results: OCT showed remarkably high quality images of the nail, the adjacent nail matrix and the subungual epidermis. The most striking finding was that of leukonychia, manifesting as diffuse "white" lines running obliquely along the middle third of the nail. Pits were remarkably superficial and were associated with disorders of the nail matrix keratinisation. Subungual vascularity and subungual epidermis hyperplasia could be delineated.

The mean (SD) age of patients was 54.4 (16.5) and 29.4% of them were female. The overall mean (SD) modified NAPSI scores was 12.8 (10.6) for patients with 94% (16/17) having at least one involved nail by OCT. The number of involved nails by OCT was significantly higher in patients compared to HC (median (range): 7 (0–10) vs. 1 (0–6); $p=0.001$)). When analysed per nail, patients had significantly higher number of involved nails by OCT compared to HC (106/170 (62.4%) vs. 22/120 (18.3%); $p<0.0001$). The absolute agreement between OCT and clinical assessment was 69.3%. Within patient group, OCT detected abnormalities in 33 nails (19.5%) where clinical assessment was normal.

Having a positive OCT (either signal changes or contour abnormalities) had a sensitivity and specificity of 57% and 82%, with a likelihood ratio (LLR) of 3.1 for a diagnosis of Pso. When different findings of OCT were compared, large intra-nail plate linear "calcifications" and superficial hyperkeratinisation of the nail had the highest LLRs (16.2 and 6.4, respectively). None of the HC had clinical nail disease whereas 9/12 (75%) of them had at least one involved nail by OCT.

Conclusion: These preliminary findings clearly show that OCT has great potential for the systematic characterisation of nail changes in Pso and this could have implications for diagnosis, prognosis and monitoring of therapies.

201

Adalimumab Improves Endothelial Function and Microcirculation In Rheumatoid Arthritisas Determined by Simultaneous Assessment of Brachial Artery Flow-Mediated Vasodilation and Laser Doppler Flowmetry. György Kerekes, Vanda Pongrácz, Szilvia Szamosi, Gabriella Szücs, Andrea Váncsa, Orsolya Tímár, Zoltán Csiki, Edit Végh, Pál Soltész and Zoltan Szekanecz. University of Debrecen Medical and Health Sciences Center, Debrecen, Hungary

Background/Purpose: Increased cardiovascular morbidity has become a leading cause of mortality in rheumatoid arthritis (RA). Impaired endothelial-dependent, flow-mediated vasodilation (FMD) of the brachial artery has been documented by various groups. Anti-TNF agents have been found to improve FMD in RA. However, there have been neither reports on laser doppler assessments in RA nor the effects of any biologics on laser doppler curves. Here we simultaneously assessed brachial artery FMD and laser doppler curves before and after 12 weeks of adalimumab (ADA) therapy.

Methods: First, we determined microcirculatory parameters during postoocclusive reactive hyperemia (PORH) representing endothelial function in a non-selected population of RA patients (n=46). We assessed FMD of the brachial artery using ultrasound and, simultaneously, laser Doppler PORH curves were recorded. Plasma von Willebrand Factor (vWF) levels were also determined in all patients. Then we assessed the effects of ADA treatment (40mg sc, biweekly) on microcirculatory parameters in 8 patients with early RA (disease duration ≥1 year). Vascular assessment was performed at baseline and then 2, 4, 8 and 12 weeks after the initiation of ADA treatment.

Results: After the comparison of FMD values and vWF levels with laser doppler PORH curves, significant positive correlations were found between FMD and time to max (Tmax, R=0,456, p=0,002), FMD and halftime of deceleration (TH2, R=0,435, p=0,004), and significant negative correlations were detected between vWF and Tmax (R=−0,4, p=0,009) and between vWF and TH2 (R=−0,446, p=0,003). ADA significantly decreased CRP levels ($p=0.04$) and DAS28 ($p<0.0001$). Endothelial function characterized by TH2 times improved in comparison to baseline (34.7 sec vs 26.9 sec; p=0,03), and this effect was prolonged until 8 weeks (40.5 sec; p=0,026) and 12 weeks of treatment (32.1 sec, p=0,013). After 8 weeks of treatment, significant improvement was observed in hyperemic area (AHbaseline= 1599 PUxs vs. AH8weeks =2724 PUxs, p=0,045), in 1 minute postocclusion area (APObaseline = 1469 PUxs vs. APO8weeks = 2462 PUxs, p = 0,019) and in average perfusion until peak (PtoMaxbaseline = 32,2 PU vs. PtoMax8weeks= 46,33, p=0,035).

Conclusion: The PORH test carried out with laser Doppler is a sensitive option to measure endothelial dysfunction, but only the time course of the hyperemia may be accepted as a reliable parameter. Both brachial artery FMD and laser doppler PORH assessments are useful to detect micro- and macrocirculatory endothelial dysfunction in RA patients. Treatment of early RA patients with ADA exerted favorable effects on disease activity, endothelial dysfunction and microcirculation. Early anti-TNF therapy may have important relevance for the prevention and management of vascular comorbidity in RA.

202

Development of Early Diagnostic Techniques for Rheumatoid Arthritis Using Carbone Eleven Labeled PK11195 and Carbone Eleven Labeled Ketoprofen. Satoshi Nozaki[1], Sinobu Suzuki[2], Naoko Ozaki[2], Jeffrey Encinas[2], Hisashi Doi[1], Yasuhiro Wada[1], Masaaki Suzuki[1] and Yasuyoshi Watanabe[1]. [1]RIKEN, Center for Molecular Imaging Science, Hyogo, Japan, [2]Nippon Boehringer Ingelheim Co., Ltd, Hyogo, Japan

Background/Purpose: In vivo detection of pathological insults during early stages of rheumatoid synovitis is essential to allow early anti-inflammatory treatment and prevention of joint destruction. Several PET (positron emission tomography) studies have been reported using [^{18}F]fluorodeoxyglucose ([^{18}F]FDG); however, [^{18}F]FDG is not a biomarker specific for inflammation. We undertook this study to investigate whether rheumatoid synovitis pathology and the efficacy of therapies can be visualized by PET tracers specific for the inflammatory process.

Methods: During early stages of a collagen-induced experimental rat model of rheumatoid arthritis, we performed in vivo imaging using the PET tracer (R)-[^{11}C]PK11195, which binds to the translocator protein (TSPO; also known as peripheral-type benzodiazepine receptor (PBR)), and the newly

developed PET tracer [^{11}C]Ketoprofen, used for cyclooxygenase (COX) imaging.

The rat model of arthritis was induced with an emulsion of complete Freund's adjuvant and type II collagen injected intradermally at the base of the tail. Therapy of the disease was carried out with the anti-TNFα blocker ENBREL® (Etanercept, Pfizer Co. Ltd., Japan). Paw swelling was scored as an indicator of disease severity. After three weeks, the rats were injected with 50 MBq (R)-[^{11}C]PK11195 or [^{11}C]Ketoprofen and then scanned for 90 min using a small-animal PET system "microPET®." Regions of interest for each hind paw were drawn on the summed (R)-[^{11}C]PK11195 or [^{11}C]Ketoprofen image and a standardized uptake value (SUV) was calculated. After PET imaging, the hind paws were removed and fixed in formaldehyde for immunostaining.

Results: We observed that (R)-[^{11}C]PK11195 and [^{11}C]Ketoprofen uptake on inflamed paw PET scans was significantly higher than control. The immunostaining intensity for COX-2 and TSPO were especially strong on macrophages and osteoclasts. The resulting data showed a correlation analysis between SUV and paw swelling. As compared with results from a parallel PET study with [^{18}F]FDG, both tracers accumulated much more specifically to the region where inflammation was occurring. However, after treatment of ENBREL, (R)-[^{11}C]PK11195 uptake in inflamed regions did not change compared with the untreated group. Supporting this result, the intensity of immunostaining for TSPO also showed no change in joint sections.

Conclusion: In conclusion, we developed PET imaging techniques for arthritis using (R)-[^{11}C]PK11195 and [^{11}C]Ketoprofen. We speculate that monocyte-lineage cells remain in the inflamed region after anti-TNFα treatment, but reduce their expression of cyclooxygenase, which causes pain. Consequently, by using (R)-[^{11}C]PK11195 and [^{11}C]Ketoprofen, noninvasive in vivo PET imaging for rheumatoid synovitis can provide diagnostic evidence of early synovitis and allow monitoring of inflammatory cell activity during treatment.

203

Pre-Clinical Bioimaging in a Mouse Model of Rheumatoid Arthritis. Michelle Ierna[1], Karen Smith[1], Kirsty Ross[2], Gordon Meiklejohn[1], Pasquale Maffia[3], James M. Brewer[3], Iain B. McInnes[3] and Paul Garside[3]. [1]MD Biosciences, Glasgow, United Kingdom, [2]University of Strathclyde, Glasgow, United Kingdom, [3]University of Glasgow, Glasgow, United Kingdom

Background/Purpose: The early detection of changes to molecular pathways underlying Rheumatoid Arthritis (RA) is a key goal in Rheumatology. However, the standard disease scoring methods employed in the standard mouse model of RA, Collagen Induced Arthritis (CIA) cannot adequately quantify cellular or molecular processes. Here, we show that biofluorescence imaging can track in vivo processes contributing to disease and allow comparisons to be made of therapeutic drug efficacy earlier in disease progression.

Methods: The mouse CIA model was induced in 6–8 week old male DBA/1 mice. From Day 17 of the study, n=5 mice per group were administered either PBS, 1mg/kg Dexamethasone or 1 mg/kg Methotrexate intraperitoneally (IP), 5 days per week until the termination of the study on Day 56. Cathepsin activity as measured *in vivo* by administering the protease activatable Near Infra Red Fluorescent probe ProSense 680® (ex/em: 680/700nm), 24 hours prior to biofluorescence imaging on Days 10, 28, 42 and 56. On the selected days, mice were anaesthetised using Hypnoval and Cathepsin activity in all paws was directly visualised and quantified using the Kodak FXPRO In Vivo imaging unit. Regions of interest were applied to each paw for each animal and the mean fluorescence intensity units quantified for each animal using Carestream Molecular Imaging software. The mean MFI units for each group could then be determined. Statistical analysis was performed using ANOVA followed by Tukey post-hoc analysis (Winstat).

Results: We recorded an increase in cathepsin activity in CIA animals treated with PBS (351 MFI units ± 44.2) which was significantly reduced at day 28 in both Dexamethasone (232 MFI units ± 10.5) and Methotrexate treated groups (247 MFI units ± 10.4; $p<0.05$). While both drugs significantly reduced cathepsin activity on days 28, Dexamethasone values were significantly reduced (181 MFI units ± 6.6) compared to those of the Methotrexate-treated mice on day 42 (257 MFI units ± 19.3). Furthermore, biofluorescence demonstrated significant differences between vehicle-treated and drug-treated groups at earlier times than conventional scoring, which did not distinguish significant differences between these groups until day 31.

Conclusion: In vivo biofluorescent imaging is a non-invasive, non-toxic modality which permits us to quantify molecular changes in disease-relevant sites over time in the same animal, thus allowing us to distinguish the effects of drug treatments earlier in disease progression. These studies provided information rich data from all paws in each animal at each time point, in comparison to time consuming procedures such as histological scoring where only a small cross section of tissue can be analysed at the end of the study. In vivo imaging allows researchers to monitor disease progression over time and can inform when the best time point would be to commence drug treatment and ultimately determine which drugs are suitable for movement into clinical trials.

Development of Contrast Enhanced Ultrasound Imaging and Quantification of Lymphatics in Draining Lymph Nodes of WT and TNF-Tg Mice with Inflammatory Arthritis. Yawen Ju[1], Ronald Wood[2], Lianping Xing[1], Christopher T. Ritchlin[2] and Edward M. Schwarz[1]. [1]University of Rochester, Rochester, NY, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY

Background/Purpose: Lymphatic drainage is an important mechanism to decrease inflammation in arthritis. Studies in mice have demonstrated that efferent lymph nodes (LN) with great draining capacity expand during a prolonged asymptomatic phase, and then suddenly collapse during arthritic flare. Since lymphatic flow and LN dynamics may be important biomarkers of arthritis flare, we developed *in vivo* ultrasound imaging methods to study popliteal lymph nodes (PLN) in normal (WT) and TNF-Tg mice with ankle arthritis. We examined PLNs before and after administration of saline or microbubble ultrasound contrast agents for clinical echocardiography.

Methods: TNF-Tg mice with expanding (4-month-old) or collapsed (8-month-old) PLN, and WT controls were anesthetized, and PLN were evaluated with a high-resolution small-animal ultrasound system (Visualsonics 770 with 704 scanhead). Three-dimensional images of the PLN and surrounding fat pad were acquired before and 7, 30 and 60min after saline or DEFINITY (Lantheus Medical Imaging) injection into the ipsilateral footpad. The mean signal intensity of the fat pad (FPsi) was computed using Amira software (TGS/Mercury Computer Systems). We quantified PLN volume via direct 3D segmentation at all time points. Lymphatic vessels in the PLN were segmented to derive the lymphatic volume (LV) at all time points; vessels were defined as regions with greater signal intensity than FPsi.

Results: In both WT and TNF-Tg mice with expanding PLN <5% change in FPsi was measured within animals, demonstrating the remarkably consistent echogenic signal of this tissue, and its appropriateness for normalization in longitudinal studies. Only a small change in LV signal intensity following DEFINITY injection was observed despite a 4-fold change in LV (0.01 to 0.04mm^3) and a 22% increase in PLN volume in WT; and a 2-fold increase in LV (0.09 to 0.18mm^3) and 34% increase in PLN volume in TNF-Tg mice. While similar increases in PLN volume were observed after saline injections, this treatment resulted in the loss of echogenic signal in PLN such that LV could not be defined. Similarly, collapsed PLN in the older TNF-Tg mice contained no regions with a signal greater than FPsi. Thus, their LV could not be calculated. There was also no change in PLN volume following footpad injection of either DEFINITY or saline, consistent with the known lack of afferent lymph flow to collapsed PLN.

Conclusion: We demonstrate the feasibility of phenotyping the lymphatic drainage function of murine PLN efferent in normal and arthritic joints via *in vivo* 3-D ultrasound imaging. The use of echogenic contrast vs. saline was found to be critical for segmenting the lymphatic vessels within the node, but similar changes in expanding PLN volume are detectible following injection of either agent. Since no changes in collapsed PLN are detected following injection with either agent, we find that dynamic ultrasound imaging following saline injection into afferent tissue is a translational, cost-effective, and minimally invasive approach for phenotyping draining lymph node function. Lymphatic drainage measured with ultrasound serves as a biomarker of erosive inflammatory arthritis progression in mice, and potentially in humans.

In Vivo Profiling of the Disease-Inducible Promoters Serum Amyloid A3 and S100 Calcium Binding Protein A8 for Personalized Gene Therapy in Arthritis. Eline A. Vermeij, Onno J. Arntz, Peter L.E.M. van Lent, Wim B. van den Berg and Fons A.J. van de Loo. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Local intra-articular gene therapy for arthritis, with the use of disease-inducible promoters, represents a promising alterna-

tive for coping with side effects of the conventional treatments. These disease-inducible promoters react to transcription factors that are released during inflammation and therefore only produce a reporter (luciferase) or therapeutic protein when necessary. Previously, we developed lentiviral based disease-inducible promoter reporters with a computational approach by selecting suitable promoters from endogenous genes differentially regulated in inflamed synovium of collagen-induced arthritis mice (Geurts *et al.,* 2009). Two of those promoters are the *Saa3* and *S100a8. Saa3* stands for Serum Amyloid A3, which is an acute phase protein released during inflammation. *S100a8* is a member of the alarmins, which induces signaling cascades and triggers the immune system. We have elucidated the kinetics of these two promoters in an acute arthritis model to validate the use of these promoters in gene therapy.

Methods: The kinetics of the two promoter reporter constructs were evaluated in-vivo by bioluminescent imaging in the streptococcal cell wall (SCW)–induced arthritis model. An acute joint inflammation was induced 4 days after lentivirus injection by intra-articular injection of *S. pyogenes*. At pre-defined time points after SCW injection, mice were injected with luciferin. The luciferin is converted into visible light by the luciferase that is produced under control of one of the promoters. Using a sensitive CCD camera (IVIS Lumina, Caliper Life Sciences, USA) the visible light was detected and luciferase activity was quantified. Neutrophil elastase activity (neutrophil influx) and cathepsin activity (macrophage activity) at day 1 and 4 after SCW injection was measured in vivo by using an activatable fluorescent probe (PerkinElmer Inc., USA). Histological sections of the knee joints were made and scored for cell influx and synovitis. qPCR was performed on synovial tissue to measure endogenous gene expression of the *Saa3* and *S100a8* genes.

Results: The *Saa3* promoter was strongly upregulated (120 fold) at day one of SCW arthritis, and subsided afterwards, following the course of neutrophil exudation as shown by both histology and fluorescent in vivo imaging (neutrophil elastase activity was 5 times higher at day 1 compared to day 4). The endogenous synovial *Saa3* gene expression showed the same profile. The *S100a8* promoter peaked (20 fold) at day 4 of SCW arthritis, following the course of synovitis (inflammation of the synovium) and cathepsin activity. However, the *S100a8* promoter activity did not follow the endogenous *S100a8* gene expression, which also peaked at day 1 probably due to the infiltration of *S100a8* expressing neutrophils, which are not targeted by the lentivirus.

Conclusion: This study showed that the *Saa3* promoter is a suitable promoter for gene therapy targeting the acute joint inflammatory process, whereas the *S100a8* promoter is a good candidate for gene therapy in immunologically mediated joint inflammation where macrophages play a more dominant role.

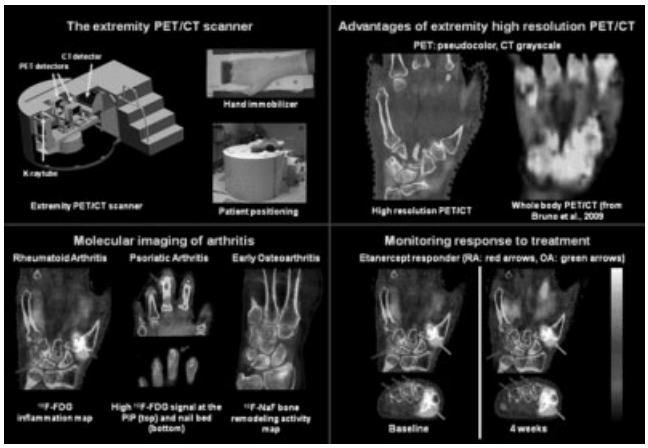
Molecular Imaging of Rheumatoid, Psoriatic and Osteoarthritis in the Hand. Abhijit J. Chaudhari[1], Andrea Ferrero[2], Felipe Godinez[2], Kai Yang[1], John M. Boone[1], Michael H. Buonocore[1], John C. Hunter[1], David K. Shelton[1], Rosalie Hagge[1], Steven W. Falen[3], Ruth D. Tesar[3], Stanley M. Naguwa[1], Nancy E. Lane[1], Siba P. Raychaudhuri[4] and Ramsey D. Badawi[1]. [1]UC Davis School of Medicine, Sacramento, CA, [2]University of California Davis, Davis, CA, [3]Northern California PET Imaging Center, Sacramento, CA, [4]Sacramento VA Medical Center/ UC Davis School of Medicine, Mather, CA

Background/Purpose: An extremity scanner capable of sequentially performing high resolution 3D molecular imaging by positron emission tomography (PET) and 3D anatomical imaging by X-ray computed tomography (CT) has been built by our group. This system is the first of its kind. We report our initial experience in using this system for (1) assessing metabolic activity (hence, inflammation) in Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Osteoarthritis (OA) of the hand, (2) monitoring early response to anti-TNF-alpha therapy in RA, and (3) characterizing bone remodeling (osteoblastic) activity in early OA.

Methods: Eight patients (5 with RA, 2 with PsA, all starting etanercept, and 1 with early OA) were recruited. Three RA patients also had OA. The RA and PsA patients were administered the radiotracer fluorodeoxyglucose (^{18}F-FDG) and were scanned at 80 ± 5 min post-injection. The scan lasted 13 min. All RA patients were scanned at baseline and at 1 month after initiation of etanercept therapy. Changes from baseline in regions of high metabolic activity were documented from PET/CT images. The PsA patients have only been scanned at baseline to date. The patient with early OA was administered the radiotracer sodium fluoride (^{18}F-NaF) and was scanned at 105 min post-injection. Images for all patients were read by consensus by three radiologists.

Results: Detailed 3D quantitative maps of molecular activity and anatomy were produced by the extremity system. Baseline scans in RA patients showed classic symptoms such as inflammation in the carpal synovium, the pisiform-triquetral compartment, at the thumb CMC joint (from OA) and at sites of erosions. In responders to etanercept (3 patients) as determined by a routine 3-month clinical exam, a reduction of >30% in maximum PET signal in the carpal synovium and pisiform-triquetral compartment was observed at 1 month. An increase of >20% at 1 month was observed in clinical non-responders (2 patients). In the PsA patients, enthesitis and inflammatory activity in the nail bed were noted at baseline and can be quantified. In the patient with early OA, high bone remodeling activity was identified at sites of subchondral cysts and the thumb CMC joint, although only very early joint space narrowing was clinically noted.



Conclusion: Our initial studies show that high resolution PET/CT molecular imaging biomarkers can potentially provide novel means for documenting the pathogenesis or RA, PsA and OA in the hand. Extremity PET/CT may prove to be a useful tool for early monitoring of response to anti-TNF-alpha inhibitor or other newer therapies.

Daily Intake of Skim Milk Powder Enriched with Glycomacropeptide and G600 Milk Fat Extract May Reduce Frequency of Gout Flares; Results From a Randomized, Controlled Trial. Nicola Dalbeth[1], Ruth Ames[1], Gregory Gamble[1], Anne Horne[1], Sumwai Wong[1], Barbara Kuhn-Sherlock[2], Alastair MacGibbon[2], Fiona M. McQueen[1], Ian R. Reid[1] and Kate Palmano[2]. [1]University of Auckland, Auckland, New Zealand, [2]Fonterra Research Centre, Palmerston North, New Zealand

Background/Purpose: Dietary modification is frequently recommended as a strategy for prevention and treatment of gout. Longitudinal observational studies have shown a clear inverse relationship between low fat dairy intake and risk of developing gout. Previous laboratory studies have identified two dairy fractions, glycomacropeptide (GMP) and G600 milk fat extract (G600), with anti-inflammatory effects in models of acute gout. The aim of this proof-of-concept clinical trial was to test the hypothesis that daily intake of skim milk powder (SMP) enriched with GMP and G600 can prevent gout flares.

Methods: This was a three month randomized, double blind controlled trial of milk products for prevention of gout flares. One hundred and twenty patients with recurrent gout flares were randomized to one of three arms; lactose powder control, SMP control, or SMP enriched with GMP and G600 (SMP/GMP/G600). Each intervention was a cream-coloured powder administered daily as a 250ml vanilla flavoured shake. The primary endpoint was change in the frequency of gout flares using a daily flare diary measured monthly for three months.

Results: The frequency of gout flares reduced in all three groups over the three month study period compared with baseline. Over the three month study period there was a significantly greater reduction in gout flares in the SMP/GMP/G600 group (Figure, ANCOVA $p_{group}=0.039$, Tukey post hoc test compared with lactose control $p=0.042$). Following treatment with SMP/GMP/G600 over the three month period, greater improvements were also observed compared with controls in pain and fractional excretion of uric acid, with a trend to greater improvement in tender joint count. Similar adverse event rates and discontinuation rates were observed between the three groups.

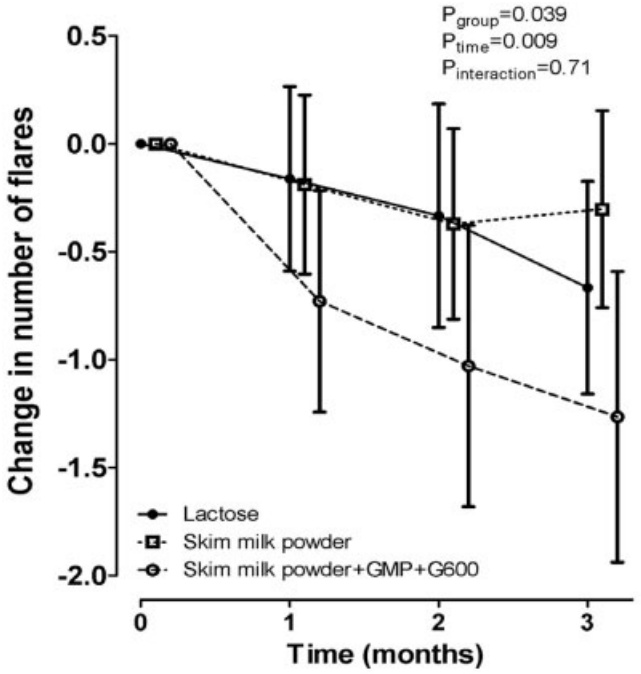

Figure. Primary endpoint: change in number of flares from baseline. ANCOVA analysis includes baseline flare frequency as a covariate. Data are presented as mean (95% CI).

Conclusion: This is the first reported controlled trial of a dietary intervention in patients with gout, and suggests that SMP enriched with GMP and G600 may reduce the frequency of gout flares.

208

Validation of the Measurement of Tophi with Magnetic Resonance Imaging As An Outcome Measure for Chronic Gout. Fernando Perez-Ruiz[1], Aranzazu Urresola[2], Diana Gorostiza[3] and Begoña Canteli[4]. [1]Hospital De Cruces, Baracaldo, Spain, [2]Radiology Division. Hospital de Cruces., Baracaldo, Spain, [3]Radiology Division, Hospital de Cruces, Baracaldo, Spain, [4]Radiology Division. Hospital de Cruces, Baracaldo, Spain

Background/Purpose: Magnetic Resonance Imaging (MRI) has not yet fully validated to measure tophi in patients with gout. This study intends to validate MRI for the measurement of tophi in the knee joint fulfilling the OMERACT filter.

Methods: Digital images from 41 RNM procedures of knee joints were stored in a prospective study in 19 patients with tophaceous gout, 28 at baseline (3 bilateral), and 13 during follow-up (1 bilateral) while on urate-lowering therapy in a prospective, open study approved by the Ethics & Investigation Committee. All patients had crystal-proven gout, synovial fluid samples obtained from the knee joints.

After completion of the study, images were retrieved and evaluated twice in a randomized, blinded fashion by two observers, readings being separated by a 3-month period. Lateral-lateral (LL), anterior-posterior (AP) and cranial-caudal (CC) maximal diameters were measured for every tophus from the best imaging sequence. Both baseline and follow-up images were used for intra-reader and inter-reader accuracy. Reduction of tophi was assessed in the LL, AP, and CC diameters, changes being corrected by time exposed to ULT in months, the smallest detectable change (SDC) was estimated as twice the standard deviation of the difference of the averages of the measurements, and effect size with Guyat′s method.

Results: One hundred and four tophi were evaluated, means being 13, 20 and 26 mm for LL, AP, and CC diameters respectively. Concordance for detection of tophi was observed in 101/104 tophi (96.7%). Inter-observer intra-class correlations (ICC) were 0.96, 0.92, and 0.92 for LL, AP, and CC measurements respectively. Intra-reader ICC was 0.98, 0.98, and 0.95 for LL, AP, and CC measurements respectively. SDD were 1.9 mm (14%), 3.3 mm (16%), and 4.0 mm (19%) for LL, AP, and CC maximal diameters respectively. Effect size was 1.52, 0.82, and 0.87 for LL, AP, and CC diameters respectively. Regression models showed that the greater the maximal diameter (LL) at baseline ($R^2 = 0.23$) and the lower the average serum urate while on treatment ($R^2 = 0.31$) were independently associated with greater reductions in measurement (overall model $R^2 = 0.52$).

Conclusion: Measurement of tophi diameters with MRI of the knee joint has shown to be reproducible and sensible to change, especially the LL diameter. MRI deserves further investigation in randomized, controlled clinical trials as an outcome measure for patients with tophaceous gout undergoing urate-lowering therapy.

Detection of Periarticular Urate Deposits with Dual Energy Computed Tomography in Patients with Acute Gouty Arthritis. Juergen Rech[1], Michael Lell[1], Jochen Wacker[1], Georg Schett[2] and Bernhard Manger[1]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: To evaluate the diagnostic utility of a dual energy CT (DECT) scan in the assessment of periarticular sodium urate depositions in patients with acute arthritis with clinical or laboratory parameters suggestive for a gout attack.

Methods: 14 consecutive patients with signs and symptoms of an acute gout attack were included. DECT using two X-ray tubes with energies of 80 kV and 140 kV of the involved joint regions was performed. The obtained datasets were analysed using a three-dimensional material decomposition algorithm allowing colour coded visualization and differentiation of sodium urate (green) from calcium (purple).

Results: 11 of 14 patients with acute gouty arthritis without any clinical evidence of gout tophi had periarticular or peritendinous sodium urate deposits detectable by DECT. Typical locations of these deposits were ankle joints, metatarsals and at tendon insertion sites (quadriceps, patellar, and Achilles tendons).

Conclusion: A substantial proportion of patients with acute gout attacks have tissue deposits of sodium urate detectable by DECT despite the absence of tophi. This method is helpful for the detection of subclinical tophaceous gout and may be of significant diagnostic value in a setting of undifferentiated mono- or oligoarthritis.

Effects of Monosodium Urate Crystals on Chondrocyte Viability and Function; Implications for Development of Cartilage Damage in Chronic Gout. Ashika Chhana, Karen E. Callon, Bregina Pool, Dorit Naot, Gregory Gamble, Michael Dray, Fiona M. McQueen, Jillian Cornish and Nicola Dalbeth. University of Auckland, Auckland, New Zealand

Background/Purpose: Chondrocytes are important mediators of cartilage degradation in common arthropathies, including osteoarthritis and rheumatoid arthritis. In gout, focal cartilage damage occurs within the joint at sites of monosodium urate monohydrate (MSU) crystal deposition. We hypothesized that interactions between chondrocytes and MSU crystals contribute to cartilage damage in chronic gout. In this study we investigated the effects of MSU crystals on chondrocyte viability and function.

Methods: MSU crystals were prepared by recrystallisation of uric acid. Cultures of primary human chondrocytes were prepared from macroscopically normal cartilage obtained from patients undergoing knee or hip arthroplasty. These cells were cultured under non-adherent conditions using tissue culture plates coated with poly-(2-hydroxyethyl methacrylate). PicoGreen and alamarBlue assays were used to assess chondrocyte viability following culture with MSU crystals. Quantitative real-time PCR was used to determine changes in gene expression in chondrocytes cultured with MSU crystals. The clinical relevance of our *in vitro* data was further assessed in toluidine blue stained cartilage samples from patients with gout.

Results: MSU crystals reduced chondrocyte viability in a dose-dependent manner (Figure). The reduction of chondrocyte viability was specific to MSU crystals, as soluble uric acid did not alter cell viability. The effects of MSU

crystals on chondrocyte viability were unaltered by the addition of high levels of serum. Culture with MSU crystals reduced mRNA expression of type II collagen and increased mRNA expression of degradative enzymes such as matrix metalloprotease-13 (MMP-13) and A disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS)-4 and ADAMTS-5. In cartilage samples from patients with gout, cartilage adjacent to tophus was highly disordered with loss of normal architecture and reduced proteoglycan staining.

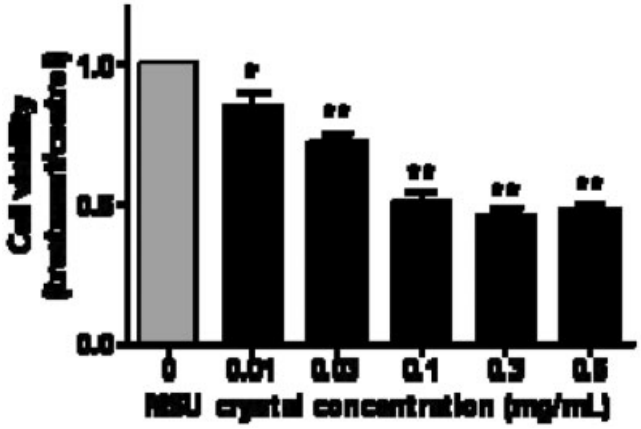

Figure. Effect of MSU crystals on primary human chondrocyte viability. Cell viability was assessed in the alamarBlue assay following 24 hours of culture with MSU crystals. Data shown are mean (SEM); one-way ANOVA ($P<0.0001$) with *post hoc* Dunnett's test *$p<0.05$, **$p<0.001$ versus control (no MSU crystals).

Conclusion: These data indicate that interactions between MSU crystals and chondrocytes may contribute to focal cartilage damage in chronic gout through reduction of chondrocyte viability and promotion of a catabolic state.

211

Confirmation of Association of Urate Transporter *SLC17A1* (*NPT1*) with Gout At a Genome-Wide Level of Significance. Tony R. Merriman[1], Amanda Phipps-Green[1], Murray Cadzow[1], Ruth Topless[1], Marilyn E. Merriman[1], Gregory T. Jones[1], Andre M. van Rij[1], Nicola Dalbeth[2], Peter J. Gow[3], Andrew Harrison[4], John Highton[5], Peter B. B. Jones[6], Lisa K. Stamp[7] and Jade E. Hollis-Moffatt[1]. [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]Middlemore Hospital, Auckland, New Zealand, [4]Hutt Hospital, Lower Hutt, New Zealand, [5]Univ of Otago Med Sch, Dunedin, New Zealand, [6]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand, [7]University of Otago, Christchurch, Christchurch, New Zealand

Background/Purpose: The major risk factor for gout is hyperuricemia. Two major gout-causing genes have been identified, *SLC2A9* and *ABCG2*, as a consequence of genome-wide association scanning for genetic variants controlling serum urate levels. Genetic variants within *SLC17A1*, which encodes for a renal urate transporter, sodium dependent transporter 1 (NPT1) have also been identified as controlling serum urate levels. Variations within *SLC17A1* have been convincingly associated with serum urate concentrations in Caucasian. Despite this, evidence for association with gout in Caucasian is equivocal, with $P=0.013$ in one study (Yang et al. Cardiovasc Circ Genet 2010;3:523–30) and $P=0.68$ in a second study (Stark K et al. PLoS One. 2009;4:e7729). This may be because of the method of ascertainment of gout, self-report or use of gout drugs (allopurinol, colchicine, probenecid), without exclusion of cases taking diuretics. Here, we aimed to investigate the effect of *SLC17A1* on gout risk in three population groups; Eastern Polynesian (New Zealand Maori and Cook Island), Western Polynesian (Samoa, Tonga, Niue) and Caucasian.

Methods: Genotyping of *rs1183201* was done using TaqMan® SNP genotyping assays, across Caucasian (421 cases, 1228 controls) and Polynesian (combined 551 cases and 518 controls) sample sets. Cases, recruited within New Zealand, were ascertained by American College of Rheumatology criteria, with exclusion of cases taking diuretics. Caucasian genotypes were combined with the publically-available Framingham Heart Study (67 cases, 4712 controls), with cases ascertained by self-report and use of gout medication, and exclusion of cases taking diuretics. Stratification owing to admixture in the Polynesian samples was controlled for using genomic control markers and STRUCTURE/STRAT software.

Results: Association was identified between *rs1183201* and gout in the Caucasian and Eastern Polynesian, but not Western Polynesian, sample sets ($OR = 0.67$, $P = 1.4 \times 10^{-7}$; $OR = 0.65$, $P_{GenomicControl} = 0.02$; and $OR = 0.70$, $P_{GenomicControl} = 0.17$, respectively). Mantel-Haenszel meta-analysis of all sample sets confirmed association of *rs1183201* with gout at a genome-wide level of significance ($OR = 0.67$, $P = 1.4 \times 10^{-11}$).

Conclusion: We have convincingly associated *SLC17A1* with gout in Caucasian, and provide evidence for association in NZ Eastern Polynesian. A *P* by meta-analysis less than the genome-wide cut-off ($P < 5\times10^{-8}$) confirms *SLC17A3* as just the third locus associated with gout, after *SLC2A9* and *ABCG2*.

212

Association with Gout of *PDZK1* Variants That Influence Metabolic Traits and Serum Urate Levels. Tony R. Merriman[1], Nicola Dalbeth[2], Jade E. Hollis-Moffatt[1], Amanda Phipps-Green[1], Ruth Topless[1], Marilyn E. Merriman[1], Peter J. Gow[3], Andrew Harrison[4], John Highton[5], Peter B. B. Jones[6], Lisa K. Stamp[7] and Sara Altaf[1]. [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]Middlemore Hospital, Auckland, New Zealand, [4]Hutt Hospital, Lower Hutt, New Zealand, [5]Univ of Otago Med Sch, Dunedin, New Zealand, [6]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand, [7]University of Otago, Christchurch, Christchurch, New Zealand

Background/Purpose: Hyperuricemia is an independent risk factor for the development of gout. Gout is associated with obesity, insulin resistance, type 2 diabetes and cardiovascular disease. Genome wide association studies have identified variants in *PDZK1* that regulate serum urate levels (Yang et al. Cardiovasc Circ Genet 2010;3:523–30), and *PDZK1* variants have also been associated with the metabolic syndrome (Junyent M et al. J Nutr 2009;139: 842–8). However, despite influencing serum urate levels at a genome-wide level, there was no evidence for association with gout in 1,100 cases and 27,183 controls (Yang et al. 2010). This may be due to the inclusion of cases taking diuretics. Significantly, the same allele of *PDZK1* variant *rs1967017* that is associated with increased serum urate levels is associated with reduced blood pressure (van der Harst et al. Hum Mol Genet 2010;19:387–92). Our aim was to use a case-control approach to examine the effects of *PDZK1* variants on the risk of gout development in New Zealand (NZ) in sample sets with cases taking diuretics excluded.

Methods: Patients were 328 Caucasians, 280 Eastern Polynesian (NZ Maori and Cook Island), and 249 Western Polynesians (Tonga, Samoa, Niue, Tokelau). Controls were 641 Caucasians, 348 Eastern Polynesians, and 144 Western Polynesians. Cases, recruited within New Zealand, were ascertained by American College of Rheumatology classification criteria, with exclusion of cases taking diuretic medication. Caucasian genotypes were combined with the publically-available Framingham Heart Study (FHS; 67 cases, 4712 controls) and Atherosclerosis Risk in Communities Study (ARIC; 153 cases, 6969 controls), with exclusion of cases taking diuretics with gout ascertained by self-report and use of gout medication for FHS and self-report for ARIC. Three *PDZK1* variants (*rs11576685, rs1284300, rs1967017*) were genotyped using Taqman. The variants were tested for association using the Mantel-Haenszel method of meta-analysis.

Results: All variants were significantly associated with gout: *rs11576685*, OR = 0.53 [0.34–0.82], $P = 0.004$; *rs1284300*, OR = 0.74 [0.59–0.93]. $P = 0.009$; *rs1967017*, OR = 1.23 [1.09–1.40], $P = 0.001$. There was no evidence for heterogeneity – all Breslow-Day *P* values were greater than 0.09.

Conclusion: The direction of association with gout of *rs1967017* is consistent with that previously reported for control of serum urate levels. None of the variants exhibit any intermarker linkage disequilibrium, implying the existence of multiple gout risk variants within the PDZK1 locus. These results suggest that *PDZK1* not only influences metabolic traits and serum urate levels, but also gout.

213

Gouty Enthesopathy: An Important Pattern of Uric Acid Deposition in Difficult to Diagnose Gout. Hailong Wang[1], Katrina N. Glazebrook[2], Steven J. Kavros[2], Clement J. Michet[1], Stephen P. Merry[3], Naveen S. Murthy[1], Bharath Manu Akkara Veetil[1], John M. Davis III[1], Thomas G. Mason II[4], Kenneth J. Warrington[1], Nisha J. Manek[1], Tanaz A. Kermani[1], Deana D. Hoganson[1], A. Kirstin Bacani[1], Cynthia H. McCollough[2] and Tim Bongartz[1]. [1]Mayo Clinic, Rochester, MN, [2]Rochester, MN, [3]Mayo Clinic, Rochester, [4]Mayo Clinic Rochester, Rochester, MN

Background/Purpose: One of the major obstacles to effective and timely management of gout is a high error rate in diagnosis, resulting in misdirected investigations and inappropriate treatment. As part of a study which evaluated the diagnostic yield of dual energy computed tomography (DECT) scanning for diagnosing gout, we have establish a cohort of patients with suspected gout based on clinical presentation but negative polarizing microscopy results. In a high number of these patients, we found imaging evidence of monosodium urate (MSU) deposition, supporting a diagnosis of gout. We set out to characterize the locations of MSU deposition in these difficult to diagnose patients in order to understand why initial routine testing (polarizing microscopy of synovial fluid) did not reveal intraarticular MSU crystals.

Methods: We prospectively included patients who had clinically suspected gout but from whom an appropriate specimen for analysis either could not be obtained, or polarizing microscopy was negative for the presence of MSU crystals. All patients underwent dual source, dual energy (80 and 140 kVP) CT scanning of the aspirated joint. Images were classified as positive or negative for MSU deposits and sites of MSU deposition were characterized.

Results: 42 patients in whom gout was considered as a possible diagnosis were included in our cohort. In these individuals, DECT scanning revealed evidence of uric acid deposition in 19 cases (45.2%).Entheses were a common location for uric acid deposition in patients with a previously negative aspiration: overall, 11 (57.9%) of the 19 patients with DECT evidence for gout did have tophaceous deposits seated in the Achilles tendon, plantar fascia, patellar tendon or triceps tendon insertion site. In the majority of patients with gouty enthesopathy, entheseal involvement was either isolated or occurred in combination with pertendinous involvement. Only 3 out of 11 patients with enthesopathy demonstrated additional deposits involving the joint space or capsule.

Conclusion: Gouty enthesopathy is a common pathology in patients whose clinical presentation is suspicious for gouty arthritis but synovial fluid analysis fails to demonstrate MSU crystals. The predominance of entheseal/tendinous MSU deposits and the frequent lack of associated MSU deposition in the actual joint space/capsule may explain the negative aspiration results in these patients. Our findings suggest that gouty enthesitis should be included in the list of differential diagnoses when evaluating patients with clinical inflammatory arthritis/periarthritis who do have risk factors for gout. In these patients, the diagnosis of gout should not be dismissed even if the synovial fluid aspiration is negative for MSU crystals. DECT appears to be a valuable diagnostic test in this subgroup of patients to confirm the presence of MSU deposition in periarticular structures.

214

Serum Uric Acid Concentration and Physical Activity: the National Health and Nutrition Examination Survey 2003–2004. Tony Ning[1], Carl Pieper[2], Virginia Byers Kraus[1], William E. Kraus[2] and Kim M. Huffman[1]. [1]Division of Rheumatology, Department of Medicine, Duke University Medical Center, Durham, NC, [2]Duke Pepper Center, Durham, NC

Background/Purpose: Physical activity improves cardiovascular risk and associates with reduced mortality, but the impact of physical activity on hyperuricemia or chronic gout is unclear. Since uric acid and insulin compete for renal excretion and exercise improves insulin resistance, physical activity has the potential to modify hyperuricemia. We hypothesized that amounts of physical activity would be inversely related to uric acid concentrations. Specific Aims: Our aim was to determine the relation between uric acid and objectively-measured physical activity.

Methods: As part of the 2003–4 Continuous National Health and Nutrition Examination Survey (NHANES), serum uric acid concentrations were measured via a colorimetric enzymatic assay, and seven days of physical activity were assessed using Actigraph accelerometers (n=3840; ages 20–85 years). Accelerometer counts, reflecting activity intensity over a one minute epoch, were used to determine bouts of exercise or total accumulated amounts of (metabolic equivalents [met]) physical activity. After accounting for sample weights, Pearson correlations were used to relate uric acid and physical activity with and without adjustments for age, gender, BMI, and creatinine.

Results: Uric acid was not related to moderate ($r=-0.0074$; $p=0.64$) or vigorous-intensity ($r=-0.019$; $p=0.24$) exercise bouts. However, while there was a direct relationship at high intensity [high met/hrs, $r=.160$ ($p<.0001$)], uric acid was inversely related to total physical activity at low and moderate intensities [low met/hrs, $r=-0.17$ ($p<.0001$); moderate met/hrs, $r=-0.056$ ($p=<0.0001$)]. When accounting for age, gender, BMI, and creatinine, these relations were not significant. Male gender ($r=-0.25$, $p<.0001$) a lower BMI ($r=-0.18$, $p<.0001$), as well as being younger in age ($r=-0.33$, $p<.0001$) were predictors of increased time in higher physical activity.

Conclusion: In a nationally representative sample of US adults, uric acid was directly related to total low and moderate intensity physical activity but not bouts of exercise. Disappearance of these relations after adjusting for age, gender, BMI and creatinine suggests that these covariates mediate physical activity and uric acid relationships. These relations might be useful in determining how physical activity can improve gout.

Serum Procalcitonin Could Be a Useful Serologic Marker for the Differential Diagnosis Between Acute Gouty Attack and Bacterial Infection. Sang Tae Choi and Jung-Soo Song, Chung-Ang. University College of Medicine, Seoul, South Korea

Background/Purpose: Acute gouty attack is an inflammatory condition secondary to a high concentration of uric acid in the blood. It is usually characterized by redness, tenderness, swelling and systemic or localized fever. These features and laboratory findings, including leukocytosis, elevation of serum erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) levels, are similar to those of infectious diseases. Moreover, there were many cases in which serum uric acid levels were not elevated in the acute gouty attack state, which made the differential diagnosis of acute gouty attack difficult. Procalcitonin is the precursor of calcitonin and increases in bacterial or fungal infection. We investigated whether or not procalcitonin levels are elevated in patients with acute gouty attack and the availability of those in differential diagnosis between acute gouty attack and bacterial infection.

Methods: This cross-sectional study included 41 patients with acute gouty attack and 75 age-matched patients with bacterial infection. The serum samples were obtained from patients during the clinically active inflammatory state. The mean duration from the development of acute gouty attack to blood sampling was 2.9 ± 2.3 days. Their serum levels of procalcitonin were measured by enzyme-linked fluorescent assay (ELFA; BioMerieux SA, France). Clinical and laboratory data were collected at the time serum samples were obtained.

Results: Patients with acute gouty attack had significantly lower serum procalcitonin levels than the patients with bacterial infection (0.078 ± 0.066 ng/mL vs 5.401 ± 14.982 ng/mL, $p = 0.003$). However, there were no significant differences between these two groups in serum ESR, CRP levels, white blood cell counts and segmented neutrophil counts. The ranges of serum procalcitonin levels were from 0.05 to 0.33 ng/mL in the acute gouty attack group and from 0.05 to 102.00 ng/mL in the bacterial infection group, respectively. There was a larger number of patients in the acute gouty attack group who had serum procalcitonin levels greater than the reference range than in the bacterial infection group (11/41, 26.8 % vs 63/76, 82.9 %, $p < 0.001$). Serum uric acid levels were statistically elevated in patients with acute gouty attack than those without it (7.50 ± 1.89 mg/dL vs 5.02 ± 1.89 mg/dL, $p < 0.001$); however, the rate of patients whose serum uric acid levels were below 6.0 mg/dL was 22.0% (9/41) among the acute gouty attack group.

Conclusion: Serum procalcitonin levels were lower in the acute gouty attack group than in the bacterial infection group. The serum procalcitonin level could be a useful serologic marker for the differential diagnosis between acute gouty attack and bacterial infection.

Gout Patient Burden Associated with Flares, Tophi, and Awareness of Uric Acid Levels In US and EU. Puja Khanna[1], Anne-Kathrin Tausche[2], Anna Forsythe[3], Amir Goren[4] and Dinesh Khanna[1]. [1]University of Michigan, Ann Arbor, MI, [2]Universitätsklinikum Carl Gustav Carus an der Technischen Universität Dresden, Dresden, Germany, [3]Savient Pharmaceuticals, Inc., East Brunswick, NJ, [4]KantarHealth, New York, NY

Background/Purpose: The prevalence of gout is increasing both in men and post-menopausal women. Although serum urate (SUA) levels have been associated with disease burden among gout patients, little research has examined the impact of tophi and the number of acute gout attacks on health-related quality of life (HRQOL), productivity, and healthcare resource utilization.

Methods: Patients with self-reported gout (n = 620) in 2010 US and EU National Health and Wellness Surveys (cross-sectional databases representative of French, German, Italian, Spanish, UK, and US populations) and the Lightspeed Research Ailment panel: n = 338 (US) and 282 (EU) were contacted. Respondents were categorized into mutually-exclusive groups based on number of gout flares in the past 12 months (0, 1–2, 3, 4–5, 6+), current presence of gouty tophus/tophi (yes, no), and SUA level awareness (yes, no). Differences on HRQOL (SF-12v2), resource use (healthcare

provider visits in last 6 months), and work and activity impairment were examined using Chi-square tests and ANOVAs for categorical and continuous variables, respectively.

Results: Majority of patients, 81.3% (n=504) were male, with mean age of 60.9 years; 31.1% were untreated with urate lowering therapy. Of 51.5% (n=319) who were on allopurinol therapy, only 9.1% (n=29) used allopurinol dose > 300mg, and 1.9% (n=6) used febuxostat. 75.6% (n=469) reported experiencing an acute gout flare in the past 12 months, and 12.3% (n=76) reported tophi. Among the 27.7% (n=172) of patients who were aware of their SUA levels (<6mg/dL −10.0%, 6 – 8mg/dL −12.1%, or >8mg/dL −5.6%), these levels correlated with number of flares experienced in the past 12 months (r_s = 0.361) and number of tophi currently present (r_s =0.282), all $p < 0.001$. Patients reported greater HRQOL burden with number of flares (see Table), and patients with tophi vs. without reported lower SF-12v2 mental (MCS) (44.4 vs. 48.6) and physical (PCS) component summary scores (36.9 vs. 41.1), plus lower SF-6D utilities (0.64 vs. 0.71). They experienced greater overall work productivity loss (40.2% vs. 21.2%), activity impairment (48.7% vs. 37.2%), and more provider visits (9.0 vs. 6.5), all $p < 0.05$. Patients aware of SUA levels had higher PCS (42.3 vs. 39.9), $p < 0.05$. In multivariable models, we predicted outcomes after adjusting for the tophi presence, number of flares, age, gender, time since diagnosis, and smoking, presence of flares (4+) were associated with MCS, PCS, and SF-6D decrements, plus activity impairment (all $p < 0.05$).

Table.

	Number of self-reported flares in past 12 months										
	0/Unknown (n=85)		1 to 2 (n=128)		3 (n=44)		4 to 5 (n=50)		6+ (n=31)		
	Mean	*SD*	Mean	*SD*	Mean	*SD*	Mean	*SD*	Mean	*SD*	*p-value*
HRQOL											
SF-12 MCS	**49.91**	*9.67*	**49.23**	*10.30*	**47.85**	*10.03*	**44.66**	*13.03*	**44.46**	*13.43*	<0.0001

Work Productivity											
% Work missed (n=234)	**6.76**	*23.15*	**5.16**	*16.23*	**4.66**	*17.42*	**1.85**	*5.11*	**8.71**	*14.99*	0.661
% Impairment at work (n=229)	**14.12**	*18.35*	**21.22**	*26.72*	**21.62**	*27.84*	**19.26**	*26.01*	**33.33**	*30.60*	0.056
% Overall work impairment (n=234)	**19.80**	*26.90*	**23.23**	*29.80*	**24.29**	*30.42*	**19.93**	*26.70*	**36.58**	*33.32*	0.197
% Activity impairment	**28.68**	*28.42*	**36.77**	*33.39*	**43.41**	*34.42*	**45.58**	*34.39*	**54.21**	*30.29*	<0.0001
Resource Use											
Number of ER visits	**0.17**	*0.45*	**0.31**	*2.32*	**0.40**	*1.05*	**0.38**	*0.75*	**0.33**	*0.81*	0.779
Number of days hospitalized	**0.44**	*1.73*	**0.65**	*4.45*	**0.82**	*3.82*	**0.38**	*1.61*	**0.68**	*2.81*	0.885
Number of traditional HCP visits	**6.91**	*8.45*	**5.68**	*6.01*	**8.29**	*10.09*	**8.02**	*8.76*	**7.40**	*6.79*	0.032

Note. Total n = 620, except where otherwise noted.

Conclusion: In patients with gout the SUA levels correlate with number of flares experienced in the past 12 months and the presence of tophi. The increase number of acute gout flares and tophi are associated with significant decrements in HRQOL, work productivity, and increased healthcare resource utilization.

217

Risk Factors for Incident Psuedogout in the General Population. Young Hee Rho, Yanyan Zhu, Yuqing Zhang and Hyon K. Choi, Boston. University School of Medicine, Boston, MA

Background/Purpose: Pseudogout, a common inflammatory arthritis of the elderly, belongs to a group of related diseases called calcium pyrophosphate deposition diseases (CPPDs), which also includes chondrocalcinosis (CC). While studies have identified the risk factors for CPPD such as osteoarthritis (OA), rheumatoid arthritis (RA), hyperparathyroidism, or use of diuretics (1), no analogous data are available for pseudogout. Although CC and pseudogout are related conditions, not all CC subjects develop pseudogout, so their risk factors may not be identical. We sought to evaluate the association between the known risk factors for CPPD and the risk of incident pseudogout in the general population.

Methods: We conducted a matched case-control study using data from The Health Improvement Network (a UK general population database of 7.3 million individuals), collected between January 1986 and May 2010. An incident case was defined as a first diagnosis of pseudogout by a general practitioner, following at least one year of enrollment in the database. Up to 5 controls were matched on age, sex, follow-up time, and practice site to each case. Purported risk factors, such as OA, RA, gout, hyperparathyroidism, hypertension, diabetes, myocardial infarction, stroke, body mass index (BMI), and diuretics (loop and thiazide) were determined before the index date of pseudogout. We performed conditional logistic regression to determine the independent associations of these factors with the risk of incident pseudogout.

Results: We identified 1527 cases of pseudogout. Among these, 981 cases (mean age: 70 years, 52% male) were matched with 4407 controls (n=5388). Four percent of the cases had pre-existing CC and 20% of the cases had a history of gout. In the final multivariate model, the risk of incident pseudogout was associated with pre-existing CC (OR 19.56, 95%CI 8.47–45.15), hyperparathyroidism (OR 6.91, 95%CI 2.71–17.63), gout (OR 4.39, 95%CI 3.49–5.53), OA (OR 2.60, 95%CI 2.19–3.10), being underweight (vs. normal weight, OR 1.81, 95% CI 1.04–3.15), RA (OR 1.65, 95% CI 1.01–2.69), and loop diuretics (OR 1.36, 95%CI 1.10–1.67) (**Table**). These associations persisted even after patients with gout were excluded to reduce the potential clinical misclassification between gout and pseudogout.

Table. Independent Risk Factors of Incident Pseudogout (n = 5388)

Purported Risk Factors	OR	95% CI	P
BMI: Underweight (<18.5 kg/m^2, 1.7%)	1.81	(1.04–3.15)	0.04
Normal Weight (18.5–24.9 kg/m^2, 25.5%)	1.00	Referent	–
Overweight (25–30 kg/m^2, 30.1%)	0.99	(0.80–1.21)	0.90
Obese (≥30 kg/m^2, 17.1%)	0.92	(0.72–1.18)	0.52
Missing (25.5%)	0.75	(0.59–0.95)	0.02
Hypertension (37.2%)	1.14	(0.93–1.39)	0.22
Diabetes (9.1%)	1.06	(0.82–1.38)	0.66
Myocardial Infarction (6.1%)	1.20	(0.89–1.61)	0.23
Stroke (4.8%)	0.97	(0.69–1.37)	0.87
Hyperparathyroidism (0.46%)	6.91	(2.71–17.63)	<.001
Rheumatoid Arthritis (1.91%)	1.65	(1.01–2.69)	0.04
Osteoarthritis (27.7%)	2.60	(2.19–3.10)	<.001
Gout (7.85%)	4.39	(3.49–5.53)	<.001
Chondrocalcinosis (0.85%)	19.56	(8.47–45.15)	<.001
Thiazides (28.9%)	0.94	(0.75–1.16)	0.55
Loop Diuretics (17.2%)	1.36	(1.10–1.67)	0.004

Conclusion: This general population study provides the first epidemiologic evidence that the risk factors for pseudogout are similar to those for chondrocalcinosis. These findings provide strong support for a common pathophysiology between the two conditions.

Is Calcium Pyrophosphate Deposition Associated with Vitamin D Deficiency? Sophia Li[1], Joshua Baker[1], Janet E. Dinnella[1], Gilda M. Clayburne[2], Joseph R. Perno[2], H. Ralph Schumacher[2] and Sally W. Pullman-Mooar[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]VA Medical Center, Philadelphia, PA

Background/Purpose: Calcium pyrophosphate deposition (CPPD) is the second most common form of crystal-associated arthropathy. Calcium pyrophosphate (CPP) crystals are biologically active particles that can contribute to joint damage and accelerate osteoarthritis. Excess accumulation of extracellular inorganic pyrophosphate (ePPi) can bind calcium and lead to CPP crystal deposition in cartilage and synovium. 25(OH) vitamin D is important for calcium homeostasis although the role of vitamin D in CPPD disease is unknown. This study examined levels of 25(OH) vitamin D in subjects with and without crystal-proven CPPD.

Methods: We performed a cross-sectional study of all patients who had a vitamin D level drawn within the past 6 months at our VA Medical Center and had an arthrocentesis performed with synovial fluid available for microscopic analysis. Synovial fluid was analyzed for presence of calcium pyrophosphate, monosodium urate (MSU), and any other crystals with the technician blinded to diagnosis or vitamin D status. Patient demographics were extracted from the electronic medical record. Non-parametric tests of significance were performed on skewed data. Simple multivariable linear and logistic regression models were performed to adjust for age, race, and renal function.

Results: We identified 11 patients who demonstrated CPP crystals in synovial fluid and 15 patients who had non-CPP containing synovial fluids. 5 of 11 patients (45.5%) with CPP crystals had vitamin D levels <20 ng/mL compared with 2 of 15 patients (13.3%) without CPP crystals. The median (intra-quartile range) vitamin D level in patients with CPPD was 16.1 (9.4, 23.6) ng/mL compared to 26.6 (19.7, 35.7) ng/mL in all other patients (p=0.02). In a multivariable model with a log-transformed

vitamin D variable as the outcome, CPPD was associated with lower vitamin D levels after adjustment for age, race, and creatinine [β: −0.23 (−0.44, −0.022) p=0.03]. Similarly, in multivariable logistic regression, higher vitamin D level (per 1 ng/mL) was independently associated with a lower probability of CPPD [OR 0.90 (0.82–1.00) p=0.04].

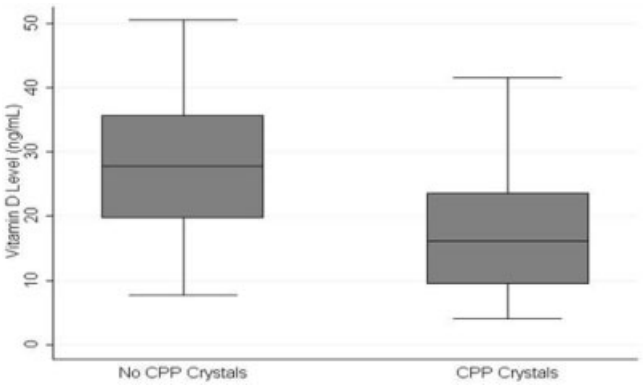

Figure 1.

Conclusion: Our study suggests that vitamin D deficiency may be another metabolic abnormality associated with CPPD. Strengths of this study include the crystal proven diagnosis and blinded assessment of synovial fluid. Limitations of this study include the small numbers which limits controlling for all potential confounders. Further study is warranted to better understand the implications of vitamin D deficiency in CPPD.

219

Illness Perceptions Predict Disability After One Year In Patients with Gout. Nicola Dalbeth[1], Keith J. Petrie[1], Meaghan House[1], Jimmy Chong[1], Wingchi Leung[1], Rini Chegudi[1], Anne Horne[1], Gregory Gamble[1], Fiona M. McQueen[1] and William J. Taylor[2]. [1]University of Auckland, Auckland, New Zealand, [2]University of Otago, Wellington, Wellington, New Zealand

Background/Purpose: Illness perceptions are key determinants of behavior directed at managing disease. Although low adherence and suboptimal disease management has been reported in patients with gout, patients' perceptions of illness have not been systematically studied. The aims of this study were to determine the illness perceptions in patients with gout, to understand how patients' perceptions are related to medication beliefs and adherence to urate-lowering therapy, and to examine the influence of illness perception on disease outcomes over time.

Methods: 142 patients with gout for <10 years were recruited from primary and secondary care settings. Participants completed a gout-specific Brief Illness Perception Questionnaire, questionnaires about medication beliefs and adherence to urate lowering therapy (ULT), and had a comprehensive assessment of gout disease activity. Serum urate, flare frequency and Health Assessment Questionnaire (HAQ-II) were recorded at baseline and after one year.

Results: Patients viewed gout as a chronic condition that was responsive to treatment but not strongly influenced by personal actions. Overall, gout was seen as having a moderate impact on their life. Most patients believed that gout was caused by dietary factors. Adherence to ULT was positively associated with a greater perceived understanding of gout, and inversely associated with perceived severity and consequences of disease. Of the clinical factors assessed, pain scores were most strongly associated with negative illness perception scores at baseline. Baseline illness perception scores (perceived severity of symptoms and consequences, lower personal and treatment control) predicted worsening musculoskeletal disability at one year, as determined by the HAQ-II (Table). This relationship was independent of baseline disability scores.

Table. Stepwise linear regression analysis of baseline factors independently associated with change in the HAQ-II score after one year. Variables included in models: age, sex, ethnicity, baseline HAQ-II score, adherence score, B-IPQ item score

Model number	Dependent variable	Predictors	Standardized β	Partial R^2	p	Model
1	Change in HAQ-II score	Baseline HAQ-II score	−0.60	0.20	<0.0001	Adjusted R^2=0.29; F=10.8; p<0.0001
		Age	0.30	0.05	0.007	
		B-IPQ consequences score	0.29	0.08	0.008	
2	Change in HAQ-II score	Baseline HAQ-II score	−0.53	0.20	<0.0001	Adjusted R^2=0.27; F=9.6; p<0.0001
		Age	0.25	0.05	0.02	
		B-IPQ personal control score	−0.23	0.05	0.03	
3	Change in HAQ-II score	Baseline HAQ-II score	−0.47	0.19	<0.0001	Adjusted R^2=0.22; F=10.9; p<0.0001
		B-IPQ treatment control score	−0.24	0.05	0.03	
	Change in HAQ-II score	Baseline HAQ-II score	−0.53	0.20	<0.0001	Adjusted R^2=0.26; F=9.5; p<0.0001
		Age	0.23	0.05	0.03	
		B-IPQ identity score	0.22	0.05	0.04	

Conclusion: Negative illness perceptions are associated with poorly controlled disease, lower adherence to ULT, and progression of musculoskeletal disability in patients with gout. These findings raise the possibility that an individualized intervention programme designed to change behaviour by altering illness perceptions may improve outcome in patients with gout.

220

Association of Insuline Resistance with Renal Clearance of Uric Acid In Phenotipically Selected Males with Gout. Fernando Perez-Ruiz. Hospital De Cruces, Baracaldo, Spain

Background/Purpose: Glut9 (SLC2A9) is a renal tubular voltage-driven sugar transporter of uric acid. Genetic studies have associated Glut9 to hyperuricemia and gout. Insulin resistance has also been associated to hyperuricemia and gout due to a reduction of renal clearance of uric acid. A direct link between renal clearance of uric acid and insulin resistance is an attractive physiopathologic hypothesis.

Methods: Consecutive male patients with crystal-proven gout were evaluated at baseline visit in a Gout Clinic. To be included, they should not be on any drug therapy, including urate-lowering therapies but low-dose colchicine for gout prophylaxis, show normal renal function (CKD 1 with no significant proteins or altered urine sediment), fasting glucose < 120 mg/dl, normal diet and alcohol avoidance. HOMA-IR was calculated with fasting serum glucose and insulin determinations. Clearance of uric acid and creatinine were calculated using 24-hour urine collections, inefficient excretion of uric acid being defined as clearance of uric acid < 6 ml/min/1.73 sqm. Hypertension, previous ethanol intake, body mass index, time from onset, age, vascular events, renal lithiasis, total cholesterol, HLD-cholesterol, LDL-cholesterol, triglycerides, glycosilated hemoglobin, number of flares, and presence of tophi were also recorded in the database. Data for numeric variables are expressed as median and inter-quartile range.

Results: Ninety-five male patients were included for analysis. Age was 53 (45–59), time from onset 5.5 (3–11) years, number of flares/year 3 (2–4), 39% polyarticular, and 38% tophaceous. Previous ethanol intake > 15 g/day, hypertension, glycosilated hemoglobin, clearance of creatinine, and HOMA-IR were associated to clearance of uric acid in bivariate regression analysis. Multivariate regression analysis showed that HOMA-IR (p<0.001) and hypertension (p=0.03) were the only variables predictive of the model. ROC curve showed that HOMA-IR cut-off >2.7 showed 81% sensitivity ad 81% specificity for classifying patients with efficient or inefficient renal excretion of uric acid.

Conclusion: Insulin resistance, but also hypertension, was associated with lower clearance of uric acid in a series of phenotype-selected male gout patients, showing a plausible link between glucose metabolism and sugar transporters of uric acid that deserves further investigation.

Impact of Acute Gout Flares on Health Related Quality of Life (HRQOL) and Productivity in Patients with Chronic Gout. Puja Khanna[1], Cleopatra A. Beaton[2], Jay E. Persselin[3], Ronald D. Hays[4], Daniel E. Furst[5], Harold E. Paulus[6], Robert Terkeltaub[7], Paul Maranian[4] and Dinesh Khanna[1]. [1]University of Michigan, Ann Arbor, MI, [2]West LA VA Medical Ctr, Los Angeles, CA, [3]VA Greater LA Healthcare Sys, Los Angeles, CA, [4]University of California, Los Angeles, [5]UCLA, Los Angeles, CA, [6]University of California, Los Angeles, Los Angeles, CA, [7]VA Medical Ctr, San Diego, CA

Background/Purpose: Acute painful episodes of arthritis are a common feature of chronic gout. We evaluated the impact of acute flares on HRQOL and productivity in patients with chronic gout in an ongoing, prospective, 1-year observational study.

Methods: Patients with chronic gout were recruited at a VA and

University Hospital. Physical exam was performed by rheumatologists and HRQOL was assessed using the SF-36 v2, HAQ-DI and the GAQ 2.0 gout-impact scale (GIS).[1] Home and work productivity was captured using the Work Productivity Survey[2]. Health care utilization was measured by UCSD Healthcare Utilization Questionnaire (HCU). Differences on these measures by acuity of the flare (≤ 4 weeks vs. >4 weeks) was examined using an alpha of 0.05 level of statistically significance.

Results: The mean age of the participants was 66 years, 92% were males, disease duration was 15 years, and mean SUA was 7.7 mg/dl. Patients who experienced a flare within 4 weeks of study visit (n=56) rated their gout as more severe on a 0–10 scale ($p< 0.01$), reported significantly more bodily pain ($p<0.007$), and greater concern on 2 of 5 GIS scales ($p<0.0001$; Table). Other domains of the SF-36 and summary scores were not statistically significant. Patients with recent flares also reported absenteeism from work for 2.6 days per month, 50% reduction in productivity for 3.5 days a month, 4.3 days per month when gout interfered with work, and a loss of 3.7 days from family and social activities due to the acute flares ($p< 0.05$ for all comparisons in patients without recent flares). Primary care visits for gout were significantly higher in those with recent flares ($p<0.03$).

Patient Characteristics	≤4 weeks n=56	> 4 weeks n=58
Age (years), mean (SD)	65.0 (11.5)	67.7 (10.0)
Duration of gout (years), mean (SD)	13.3 (12.2)	16.0 (13.2)
Severity of Gout scale (0–10 cm), mean (SD)	6.9 (2.8)	5.1 (3.4)*
Patients with X-ray evidence of erosions/ tophi n (%)	23 (41%)	15 (26%)
No. of patients with tophi on exam (%)	20 (36%)	18 (32%)
Serum Urate mg/dl, mean (SD)	7.3 (2.2)	7.7 (1.6)
# of Comorbidities (0–22), mean (SD)	4.0 (3.4)	3.7 (4.1)
Patient reported outcome measures		
SF-36 Bodily Pain (0–100), mean (SD)	39.0 (11.5)	45.1 (12.7)*
HAQ-DI (0–3), Mean (SD)	0.8 (0.6)	0.8 (0.7)
GAQ-GIS: (0–100), mean (SD)		
-Gout Concern Overall	74.3 (23.5)	59.0 (27.7)*
-Unmet Gout Treatment Needs	51.6 (19.1)	36.1 (17.8)*
-Gout Medication Side Effects	58.5 (26.2)	54.7 (27.7)
-Well Being During Attack	57.7 (27.2)	53.0 (27.3)
-Gout Concern During Attack	53.9 (26.6)	50.7 (26.5)
Work Productivity: in Days (#) **mean (SD)**		
-Work missed due to gout	2.6 (5.3)	2.5 (7.5)*
-Productivity was reduced by 50% in last month	3.5 (6.6)	2.1 (6.4)*
-Gout interfered with work in last month	4.3 (3.6)	1.5 (2.8)*
-Missed activities with family/social due to gout	3.7 (7.2)	1.3 (4.6)*
- Days requiring outside help	1.1 (4.6)	0.7 (4.1)
HCU: No. of Primary Care Doctor Visits, mean (SD)	2.4 (2.4)	1.5 (1.9)*

* $p<0.05$; Higher scores on the HAQ-DI and GIS denote worse HRQOL.

Conclusion: Acute flares have a significant detrimental impact on HRQOL and productivity in patients with chronic gout. The impact of acute flares on HRQOL may be underestimated and difficult to study in an accurate fashion due to the episodic nature of flares. Our data documents that health status, work productivity and HCU measures are feasible in patients with recent acute flares of gout.

Subjects with Gout Have a Higher Prevalence of Simple Renal Cysts Than the General Population. Eduardo M. Hasegawa[1], Ricardo Fuller[1], Maria Cristina Chammas[2], Filipe M. Mello[1] and Claudia Goldenstein-Schainberg[1]. [1]Rheumatology Division—University of São Paulo, São Paulo, Brazil, [2]Radiology Division—University of São Paulo, São Paulo, Brazil

Background/Purpose: Gout is a metabolic disease in which a variety of renal disorders may occur. The prevalence of simple renal cysts in gout patients has never been in the scope of any research previously performed. The aim of this study was to determine the prevalence of simple renal cysts in gout patients and evaluate associated risk factors for its development.

Methods: One hundred forty six (146) patients followed at our outpatient Gout Unit and 47 sex and age-matched healthy kidney donors underwent routine renal ultrasonography, using a static grey-scale and real-time B-mode units with a 3.5 or 5.0MHz transducer, to determine the presence of renal cysts. Demographic and clinical characteristics of gout patients were evaluated considering possible risk factors for the occurrence of simple renal cysts.

Results: The prevalence of simple renal cyst was 26.0% in gout patients and 10.6% in control group ($P=0.045$). Gout patients with simple renal cysts presented less renal lithiasis than those without this complication (5.2% vs 25.9%; $P=0.003$) in spite of an overall higher frequency of renal stones in gout patients compared to control group (20.5% vs. 6.3%, $P=0.025$). The presence of simple renal cyst in gout was not associated with previously reported factors such as age ($P=0.296$), male predominance ($P=0.688$), hypertension ($P=0.314$), and renal impairment ($P=0.254$). Moreover, no association with disease duration ($P=0.843$) or tophi ($P=0.616$) was observed.

Conclusion: Gout patients have an increased prevalence of simple renal cysts, and this finding was shown to be associated with a lower occurrence of nephrolithiasis. Whether renal cysts have any protective effect in the development of nephrolithiasis in gout remains to be determined.

223

Gout Vs Hyperuricemia As Risk Factors for Coronary Artery Disease – A Pilot Study. Victoria Furer, Rennie N. G. Howard, Jonathan Samuels and Michael H. Pillinger. NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Multiple studies implicate either gout or hyperuricemia is associated with increased coronary artery disease (CAD) risk. However, such studies are often limited by retrospective database methodologies, and often do not distinguish the extent to which CAD risk is associated primarily with gout, hyperuricemia, or both. We conducted a prospectively-enrolled cohort pilot study to assess the relative contributions of asymptomatic hyperuricemia (AH) and gout to CAD.

Methods: Male veterans (N=116) ages 55–85 were recruited during routine visits to the primary care clinic at the NY Harbor VA Health Care System NY Campus. All subjects underwent serum uric acid (UA) determination, gout screening (ACR clinical criteria) and CAD self-assessment. Patients with non-gout inflammatory arthritis/other systemic inflammatory disease were excluded. Enrollees were divided into 3 groups: 55 controls (no gout, UA≤ 6.8 mg/dl), 30 AH (no gout, UA>6.8mg/dl), and 31 gout. Chart review was performed (ICD-9 code identification and review of the primary care and/or cardiology note) to confirm gout, CAD and comorbidities. The primary outcomes were CAD by chart ascertainment and patient self-report. For sub-analysis, patients with AH and gout were further subdivided into equal cohorts with the lowest and highest UA levels. Summary statistics were calculated by disease group. Differences between groups were estimated by Kruskal-Wallis test for continuous measures, Chi-square test or Fisher test for prevalence and categorical measures using SPSS.

Results: The 3 groups were similar in age (controls 68.9±8.3, AH 67.7± 9.1, gout 71.3±8.6 years) and racial/ethnic composition. Serum UA (mg/dL) was higher among AH (8.0±0.9) and gout subjects (7.7±2.4) vs controls (5.6±0.79) ($p<0.05$). BMI in AH (31±7) and gout (31±4.2) subjects were elevated vs controls (28.6±11.2) ($p<0.05$). Diabetes prevalence was similar in all groups (controls 38%, AH 46.7%, gout 42%). Gout subjects had higher rates of hypertension (controls 78%, AH 86.7%, gout 93.5%), hyperlipidemia (controls 71%, AH 73.3%, gout 90.3%) and renal disease (eGFR<60) (controls 11%, AH 13.3%, gout 51.6%, $p=0.00003$), but lower smoking rates (controls 29%, AH, 13.3%, gout, 6.5%, $p=0.03$). CAD was increased among gout but not AH subjects according to both self-report and chart ascertainment (self-report: controls 27%, AH 27%, gout 42%; chart ascertainment: controls 31%, AH 27%, gout 42%). Adjustment for renal disease/smoking status did not alter the results. Gout patients with higher serum UA (≥7.9mg/dL, n=14) had more CAD vs those with lower UA (<7.9 mg/dl, n=17) (53% vs 28.6%), but our data do not permit us to distinguish whether this represents an effect of hyperuricemia or a marker for gout severity. In contrast, AH subjects had similar rates of CAD regardless of UA level.

Conclusion: This well-characterized, prospectively-enrolled cohort study suggests that the presence of gout conveys an additional level of CAD risk beyond that of hyperuricemia. Although larger studies are needed, our pilot study demonstrates the feasibility of using a prospective enrollment strategy to distinguish between hyperuricemia and gout comorbidity.

One Year Randomised Controlled Trial of SEcond Line Agents in Myositis (SELAM): Late Additional immunosuppression is Ineffective in Patients Who Have Partially Responded to Steroids. Ernest Choy[1], Patrick Gordon[2], Beverley White-Alao[2], Fowzia Ibrahim[2], Anna Kowalczyk[2], Alan Hakim[3], George Kitas[4], David A. Isenberg[5], Bridget Griffiths[6], Bryan Lecky[7], Kuntal Chakravarty[8], John Winer[9], Katalin Danko[10], Robert G. Cooper[11] and David L. Scott[2]. [1]Cardiff University, Cardiff, England, United Kingdom, [2]King's College London, London, United Kingdom, [3]Whipps Cross University Hospital, London, United Kingdom, [4]Dudley Group of Hospitals NHS Trust, Russells Hall Hospital, Dudley, West Midlands, UK, Dudley, United Kingdom, [5]University College London, London WC1E 6JF, United Kingdom, [6]Freeman Hospital, Newcastle Upon Tyne, United Kingdom, [7]Walton Centre for Neurology and Neurosurgery (WCNN), Liverpool, [8]Queen's Hospital/BHR NHS Trust, Romford, United Kingdom, [9]The Queen Elizabeth Hospital, Birmingham, United Kingdom, [10]University of Debrecen, Debrecen, Hungary, Debrecan, Hungary, [11]Hope Hospital, Salford, United Kingdom

Background/Purpose: Idiopathic inflammatory myopathies (IIM), which includes dermatomyositis and polymyositis, are conventionally treated with steroids. Immunosuppressives like ciclosporin and methotrexate are often used when patients respond incompletely to steroids. Their efficacies have not been proven in randomised controlled trials (RCTs). SELAM evaluated their benefits in a placebo-controlled factorial RCT of two immunosuppressives.

Methods: A 56 week multicentre factorial-design double-blind placebo-controlled RCT compared steroids alone with added methotrexate (15–25mg weekly), ciclosporin (5mg/kg/day) and both immunosuppressives. Adults with IIM by Bohan and Peter criteria receiving corticosteroids were enrolled if they had active disease (4/5 muscle weakness by manual muscle strength testing (MMT) in 2 or more muscle groups) and functional deficits (one or more activities of daily living). Patients with inclusion body myositis and muscular dystrophies were specifically excluded. MMT at 12 months was the primary outcome. Secondary outcomes included a Functional Rating Scale (FRS), 30 metre walking time (WT), creatine kinase (CK) and ESR. The primary outcome was analysed using a linear mixed model. Paired t-tests identified significant changes between baseline and 12 months in all primary and secondary outcomes.

Results: 58 patients were randomised. They comprised 18 males and 40 females of mean age 50 years and mean disease duration 2 years. 33 (57%) completed 12 months treatment. Full data was collected in 50 (86%). Analysis of all observed data at 12 months showed no evidence any immunosuppressive treatment was more effective than placebo therapy. The mean comparisons of MMT and all secondary outcomes by active/placebo ciclosporin and methotrexate showed no significant treatment effects. The combination of both treatments was also no more effective than placebo (Table). Paired t tests showed the patients improved significantly over 12 months as follows: MMT 15% improvement ($p<0.001$), FRS 11% ($p<0.001$), WT 13% ($p=0.001$) and CK 9%; ($p=0.024$). Only changes in CK were different in early (under 3 months) than established (4–220 months) IIM.

		Placebo n=15	Methotrexate n=12	Ciclosporin n=16	Methotrexate and Ciclosporin n=15
MMT	Baseline	65 (10)	68 (9)	66 (13)	63 (7)
	Change	14 (9)	7 (11)	6 (13)	10 (98)
30 Metre Walk	Baseline	31 (21)	35 (23)	37 (24)	35 (20)
	Change	6 (16)	8 (10)	6 (13)	9 (12)
Functional Rating Scale	Baseline	35 (4)	32 (4)	32 (5)	32 (6)
	Change	2 (4)	3 (3)	3 (5)	4 (6)

Initial and 12 months changes in key observed outcomes by trial group. Means (SD) shown

Conclusion: SELAM – one of the largest RCTs of immunosuppressives in IIM - shows no evidence they give more benefits than corticosteroids alone. Using immunosuppressives in IIM, in line with management of other rheumatic diseases, appears questionable. We need a different therapeutic approach.

225

Clinical Features and Treatment of Dermatomyositis Patients with Anti-CADM-140 (melanoma differentiation-associated protein 5: MDA5) Antibody; Recommendation of Combined Immunosuppressive Therapy with Intensive Intravenous Cyclophosphamide. Ran Nakashima, Yuji Hosono, Naoichiro Yukawa, Hajime Yoshifuji, Daisuke Kawabata, Koichiro Ohmura, Takashi Usui, Takao Fujii and Tsuneyo Mimori. Kyoto University Graduate School of Medicine, Kyoto, Japan

Background/Purpose: Recently, it have been reported that anti-CADM-140 (MDA5/IFIH1)-positive dermatomyositis (DM) patients frequently develop acute or subacute progressive interstitial pneumonia (A/SIP) with poor prognosis. In these patients, hyperferritinemia can be a marker for disease activity. To assess the pathophysiology of the disease and improve their survival, we investigated the clinical and laboratory findings including serum cytokine profiles, and assessed the efficacy of combined immunosuppressive therapy.

Methods: We compared anti-CADM-140 (+) patients (n=24) with anti-CADM-140 (−) DM patients (n=23). Serum cytokine levels (IL-1β, IL-6, IL-10, IL-12, IL-22, IFN-β, IFN-γ, TNF-α and M-CSF) were measured by ELISA or Cytometric Bead Array. Anti-CADM-140 (+) patients were divided into two groups, those survived (n=11) and those deceased (n=13), and the differences in their serum ferritin levels and clinical backgrounds were analyzed. We applied an intensive regimen of combined immunosuppressive therapy (high dose prednisolone, oral ciclosporin and intravenous cyclophosphamide (IVCY, 750–1000mg/m^2 in every other week) to anti-CADM-140 (+) patients and assessed the improvement in the survival rate.

Results: Anti-CADM-140 (+) DM patients showed significantly higher serum IL-6 and IL-10 levels and lower serum IL-12 and IL-22 levels than antibody (−) patients. There was no difference between the survived and the deceased patients with anti-CADM-140 in serum ferritin levels before treatment, but the hyperferritinemia in the deceased patients was progressively worsen irrespective of treatment. Those survived were significantly younger than those deceased (49.6 ± 9.6 vs. 58.7 ± 8.1, respectively: $p<0.05$). 14 patients developed respiratory failure and only 2 of them could survive. All patients except for two (one of them received lung transplantation) died who received immunosuppressants after the development of hypoxemia. The period from the onset of skin manifestation to the detection of IP was significantly longer in those survived than in those deceased (3.7 ± 2.9 months vs. 1.2 ± 1.1 months, respectively: $p<0.01$). The survival rate of the intensive regimen group (n=7) was higher than that of the others (n=14) (57.1% vs. 28.6%). The serum ferritin levels tended to go down about 14 days after IVCY, suggesting that IVCY may be a key drug in treatment of anti-CADM-140 (+) A/SIP patients.

Conclusion: Unregulated macrophage activation may be involved in the pathophysiology of anti-CADM-140 (+) DM and A/SIP. These patients should be treated with intensive combined immunosuppressive therapy, especially intensive IVCY, as soon as when they were diagnosed.

226

Anti-CADM-140 Autoantibody Titer Correlates with Disease Activity in Patients with Dermatomyositis and Rapidly Progressive Interstitial Lung Disease. Shinji Sato[1], Masataka Kuwana[2], Takashi Fujita[3] and Yasuo Suzuki[1]. [1]Tokai University School of Medicine, Isehara, Japan, [2]Keio University School of Medicine, Tokyo, Japan, [3]Institute for Virus Research and Graduate School of Biostudies, Kyoto University, Kyoto, Japan

Background/Purpose: Anti-CADM-140 autoantibody is specifically detected in patients with dermatomyositis (DM), especially those who have little or no muscle manifestation (clinically amyopathic dermatomyositis: CADM). Its presence is known to have a strong association with rapidly progressive interstitial lung disease (RP-ILD). Despite its diagnostic utility, the relationship between anti-CADM-140 antibody titer and disease activity is still unknown. Here, we have examined this issue using an enzyme-linked immunosorbent assay (ELISA) to measure anti-CADM-140 titers.

Methods: Serum samples from 62 patients diagnosed as having adult DM (46 with classical DM and 16 with CADM) at Keio University Hospital or Tokai University Hospital between 2000–2010 were screened for autoantibody using RNA and protein immunoprecipitation assays. Sera containing anti-CADM-140 antibody were then titered using a previously-established ELISA. Associations between anti-CADM-140 titer and clinical course and outcome were analyzed.

Results: Sera from thirteen of 62 patients with DM were found to contain anti-CADM-140 antibody. Two had classical DM and 11 had CADM. Ten patients had ILD, of whom 9 developed RP-ILD. In the latter, the mean titer of anti-CADM-140 antibody before treatment was significantly lower in those who responded to therapy and survived (responder group, n=3) than in those who did

not respond and died (non-responder group, n=6) (101.6 units vs. 351.4 units, p= 0.018). In the responder group, the mean titer of anti-CADM-140 antibody decreased to below the cut-off level after treatment, in parallel with improved respiratory symptoms (n= 3, 101.6 units vs. 1.5 units, p= 0.041, cut-off level = 8.0 units). In contrast, the mean anti-CADM-140 titer in the non-responder group did not decrease significantly and was maintained at a high level over the disease course (n=4, 364.2 units vs. 198.4 units, p=0.17). Interestingly, the anti-CADM-140 titer remained below the cut-off level after improvement of RP-ILD in the three surviving patients.

Conclusion: These results illustrate the clinical utility of anti-CADM-140 antibody to predict the development of RP-ILD as well as to monitor disease activity and to assess the response to treatment in patients with DM and RP-ILD.

227

Anti-CADM-140 Antibody, Ferritin and IL-18 Are Associated with Disease Activity of Interstitial Lung Disease in Anti-CADM-140 Antibody-Positive Dermatomyositis. Takahisa Gono[1], Shinji Sato[2], Yasushi Kawaguchi[1], Masataka Kuwana[3], Yasuhiro Katsumata[1], Masanori Hanaoka[1], Kae Takagi[1], Hisae Ichida[1], Sayumi Baba[1], Yuko Okamoto[1], Yuko Ota[1], Sayuri Kataoka[1] and Hisashi Yamanaka[1]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Tokai University School of Medicine, Isehara, Japan, [3]Keio University School of Medicine, Tokyo, Japan

Background/Purpose: The aim of this study was to investigate the precise clinical characteristics and association between the anti-CADM-140 antibody titer and disease status in patients with anti-CADM-140 antibody-positive dermatomyositis (DM).

Methods: Twenty-seven patients who presented with DM and had the anti-CADM-140 antibody were enrolled. All patients except one had the complication of interstitial lung disease (ILD). The association between clinical manifestations and clinical parameters, including the anti-CADM-140 antibody, was analyzed.

Results: The complication of rapidly progressive (RP)-ILD was revealed in twenty patients (74%). The frequencies of fatal outcome, relapse and malignancy were 33%, 4% and 4%, respectively. All patients who died had the complication of RP-ILD in the present study. Remarkably, a fatal outcome was revealed within the first 6 months after disease onset. Elderly age at onset, severely involved pulmonary function and high levels of serum ferritin were present in twenty RP-ILD patients, compared to six non-RP-ILD patients. Twenty RP-ILD patients with the anti-CADM-140 antibody was divided into the two subsets, eleven patients who died (dead subset) and nine patients who survived (living subset).The ferritin levels were significantly higher ($P = 0.017$) in the dead subset than the living subset, although KL-6, CRP and IL-18 concentrations did not differ significantly between the two subsets. The median value of the anti-CADM-140 antibody titer on admission was higher in the dead subset than the living subset. RP-ILD was refractory and progressive in the dead subset, although almost of these patients received combination therapy, including prednisolone, intravenous cyclophosphamide therapy and calcineurin inhibitor. In addition, $AaDO_2 \geq 32$ mmHg and ferritin $\geq$ 828 ng/ml upon admission were poor prognostic factors in RP-ILD patients with anti-CADM-140 antibody. In addition, we compared clinical parameters upon admission with the parameters after treatment. There was no significant difference ($P = 0.15$) between the living subset and the dead subset in the duration of evaluation after treatment. The anti-CADM-140 antibody titer was significantly lower ($P = 0.0061$) after treatment than on admission in the living subset. The anti-CADM-140 antibody disappeared after treatment in 6 (50%) of 12 living patients. On the other hand, there was no statistical significant difference ($P = 0.16$) in the dead subset between the anti-CADM-140 antibody titer upon admission as compared to the antibody after treatment. The median values of ferritin after treatment were 76 ng/ml and 1987 ng/ml in the living and dead subsets, respectively. Moreover, the levels of IL-18 were significantly lower ($P = 0.031$) after treatment in the living subset. In the dead subset, the levels of IL-18 were not significantly lower after treatment. Sustained high levels of anti-CADM-140 antibody titer, ferritin and IL-18 were present in the dead subset.

Conclusion: The anti-CADM-140 antibody is a disease-activity marker and a disease-specific marker. Serum anti-CADM-140 antibody, ferritin and IL-18 concentrations reflect the response to treatment and the status of ILD in patients with anti-CADM-140 antibody-positive DM.

228

Transcription Intermediary Factor (TIF)-1β Is a New Dermatomyositis Autoantigen. Minoru Satoh[1], Jason Y.F. Chan[1], Steven J. Ross[1], Angela Ceribelli[1], Yi Li[1], Yoshioki Yamasaki[2], Hidehiro Yamada[2], Monica Vazquez-Del Mercado[3], Marcelo Petri[4], Eric S. Sobel[1], Westley H. Reeves[1] and Edward K.L. Chan[1]. [1]University of Florida, Gainesville, FL, [2]St. Marianna University, Kawasaki, Japan, [3]Univ de Guadalajara, CUCS, Guadalajara, Mexico, [4]Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, Mexico

Background/Purpose: Each myositis specific autoantibodies (MSA) are associated with unique clinical subset and useful biomarkers in polymyositis/dermatomyositis (PM/DM). Identifying new MSA will help in monitoring PM/DM patients as evidenced recently by reports on anti-p155/140 (transcription intermediary factor-1gamma, TIF-1gamma) associated with malignancy and anti-CADM140/MDA5 associated with clinically amyopathic DM with rapidly progressive lung disease. Although new autoantibody specificities have been added, ~50% of patients with PM/DM are still without known MSA, thus identifying additional MSA is relevant. ~120kD protein recognized by serum from a patient with DM was identified as TIF-1beta and clinical features of patients who have autoantibodies to this antigen was characterized.

Methods: ~120kD protein recognized by a prototype DM serum was purified and identified by mass spectrometry. Sera from ~2200 patients with various diagnosis including 434 SLE, 119 scleroderma, and 263 PM/DM from 4 countries were tested by immunoprecipitation of ^{35}S-methionine labeled K562 cell extract. Sera that immunoprecipitated the similar protein was searched and identity of specificity was verified by immunoprecipitation, western blot, and ELISA. Clinical information was from database and charts.

Results: ~120kD protein was identified as TIF-1beta by mass spectrometry and its identity was verified by western blot using monoclonal antibodies. By immunofluorescence, anti-TIF-1beta showed fine speckled nuclear staining. Although the characteristic of the 120kD TIF-1beta band in autoradiogram was clearly distinct, it exactly comigrated with another MSA PL-12. Four cases of anti-TIF-1beta were identified; all are female, one each in Japanese, African American, Caucasian, and Mexican. Three had diagnosis of DM and one case was followed as undifferentiated connective tissue disease (UCTD) with elevated CPK but without significant muscle symptoms. This specificity was not found in SLE, scleroderma, or other conditions. A UCTD case had a history of colon cancer and cervical squamous metaplasia. The Japanese DM patient had elevated CPK (654IU/L), muscle weakness, positive biopsy and EMG, however, her myopathy was resolved without treatment. Two American patients had ~300IU/L CPK and controlled with moderate-low dose of steroid. The Mexican case also had anti-Mi-2 but coexistence of anti-TIF-1gamma (p155/140) was not seen.

Conclusion: Anti-TIF-1beta is a new dermatomyositis autoantibodies appear to be associated with mild form of myopathy. Whether it has association with malignancy as in the case of anti-TIF-1gamma or other unique features will need to be evaluated in future studies.

229

Clinical Features and Survival in Anti-PL-7 Autoantibody Positive Myositis Patients From a Single Tertiary Care Center. Arcadio Agudelo-Hernandez[1], Chester V. Oddis[2], Noreen Fertig[2], Diane Koontz[2] and Rohit Aggarwal[1]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: To describe the demographic, clinical features and survival in a cohort of anti-PL-7 autoantibody positive myositis patients from a single tertiary care center

Methods: All PL-7 (+) patients with their first evaluation between 1985–2009 were included regardless of connective tissue disease (CTD) diagnosis. Anti-PL-7 was detected using RNA and protein immunoprecipitation techniques. ANA and cytoplasmic pattern was determined by indirect immunoflourescence (IIF) using Hep2 cell. All data were collected from the registry database and medical record. Mortality data was determined using National Death Index or Social Security Death Index, and medical record review. Survival analysis was done using Kaplan Meier plots.

Results: We identified 25 PL-7 (+) patients in our cohort. Eighteen (72%) were female and 22 (88%) Caucasian with a mean (± SD) age of 55.1 (15.4) years at diagnosis. The initial CTD symptom occurred at a mean age of 49.1 (18.2), and their first evaluation at our center was at age 57.0 (13.3) with a diagnosis delay of 6.0 (10.2) years [median (IQR) = 1.08 (0.5–6.8) years]. Only 13 (52%) patients were ANA positive, whereas 23 (92%) had cytoplasmic pattern on IIF (7 speckled; 6 diffuse; 10 both diffuse and speckled). The initial diagnoses

included dermatomyositis (DM) (n=7), polymyositis (n=5), systemic sclerosis (n=1), overlap (n=7), UCTD/unknown (n=5). The most common initial CTD symptoms were Raynauds (n=9), arthralgia/arthritis (n=5), followed by muscle weakness (n=2), rash (n=2) and dyspnea (n=2). ILD was detected in 92% (23/25) of patients and 20% (5/25) had pulmonary hypertension (PHT) (3 primary/2 secondary). Most patients (19/23) developed pulmonary involvement before an established CTD diagnosis with nearly 50% having pulmonary symptoms > 6 months before the CTD diagnosis. The mean time of follow up was 4.9 (4.1) years with the cohort developing the following clinical features at some time during their course: fatigue 100%, Raynauds 84%, dyspnea 72% (n=18; 12 moderate to severe, 6 on home O_2), myalgia 48%, fever 44%, arthritis 44%, DM rash 36%, dysphagia 32%,telangectasia 32%, puffy fingers 32%,, pleurisy 16%, and mechanics hands in 5 of 8 evaluated specifically for it. Proximal muscle weakness was seen in 76% (19/25) of the cohort but nearly 50% (n=12) had mild/subtle weakness. Nineteen (76%) patients had CK elevations with a median peak CK 7 times the upper limit of normal [IQR 3.7–16.5]. The median (IQR) survival time in years for the entire cohort was poor at 6.42 (4.2–21.6) years. The 5 and 10 year unadjusted cumulative survival rates were: 66.5% (95% CI 41.8–82.6) and 30.8% (95% CI 11.7–52.4), respectively. Overall, 14 (56%) patients died during the study period with an average age at death of 59.2 (13.9) years. The most common cause of death was pulmonary in 11/14 (78.6%) patients (8 with fibrosis and 3 with PHT).

Conclusion: We describe detailed clinical features and survival of a large anti-PL-7 (+) cohort. We emphasize the importance of considering this autoantibody in patients presenting with both pulmonary symptoms and other CTD features even in the absence of clinically overt myositis. This subset of myositis is also associated with a high mortality rate.

230

The Clinical Spectrum but Not the Evolution of Antisynthetase Syndrome Is Related to the Antisynthetase Antibody Specificity: A Retrospective Analysis of 142 Patients. Baptiste Hervier[1], Hervé Devilliers[2], Raluca Stanciu[1], Eric Hachulla[3], Yurdagul Uzunhan[4], Bruno Wallaert[5], Bruno Fautrel[6], Bernard Fournie[7], Lucile Musset[8], Aude Rigolet[1], Hilario Nunes[4], Patrice Cacoub[8], Daniel F. P. Adoue[9], Zahir Amoura[8], Mohamed Hamidou[10] and Olivier Benveniste[11]. [1]Pitie-Salpetriere Hospital, APHP, UPMC Paris VI, Paris, France, [2]CHU Dijon, Dijon, France, [3]Internal Medicine, Lille CEDEX, France, [4]Hopital Avicenne, APHP, Bobigny, France, [5]CHRU, Lille CEDEX, France, [6]Université Pierre et Marie Curie - Paris 6 - Pitie Salpetriere University Hospital, Paris, France, [7]CHU, Toulouse, France, [8]CHU Pitié-Salpêtrière, Paris, France, [9]CHU Toulouse Purpan, Toulouse, France, [10]Service de médecine interne, Hôpital Universitaire de Nantes, Nantes, France, Nantes, France, [11]Pitie-Salpetriere Hospital, Paris, France

Background/Purpose: Antisynthetase syndrome (ASS) is characterized by the association of an inflammatory myositis with interstitial lung disease (ILD) and different antisynthetase antibodies (AS-Ab). The clinical spectrum and the evolution of ASS are heterogeneous. This study was conducted to examine whether this heterogeneity would be related to the AS-Ab specificity.

Methods: Patients (n=142, 47.8+/− 15.3 years at diagnosis) from 7 French tertiary hospitals from 1985–2011 were included. The association of ≥ 1 symptom with the positivity of 1 AS-Ab (anti-Jo1: n=85, anti-PL12: n=40 and anti-PL7: n=17) defined ASS. At the end of the follow-up (median = 3,4 years, 0–25), a worsening disease was defined either by an uncontrolled myositis or a pulmonary aggravation. The ASS patterns were examined by multiple correspondence & cluster analyses. Differences between worsening & stable/improving patients were tested by the Mann-Whitney (countinuous data) and the Khi-2 (categorical data) tests and defined the prognosis factors. A p value <.05 was significant.

Results: Patients presented with myositis (n=100, 70%), ILD (n=125, 88%) and other symptoms, including arthralgia (n=79, 56%), Raynaud's phenomenon (n=57, 40%) and mechanic's hands (n=24, 17%). ASS overlapping with Systemic Sclerosis (SSc) and Sjögren Syndrome (SS) occurred in 41, 29% & 51, 36% cases respectively.

At diagnosis, myositis occurred more frequently in patients with anti-Jo1-Ab (85%) rather than anti-PL12/7-Ab (43%/41%, p<0,001). The myositis was more severe as attested by a higher frequency of muscular deficit (66% vs 20%/18%, p<.001) & myogenic electromyography pattern (n=40, p=0,002) and also a higher creatin-kinase (CK) level (5058 ± 5607 IU/L vs 452±576/1129±1529, p<.001). Patients with anti-PL12/7-Ab disclosed more frequently an ILD without myositis (50%/53 vs 11%, p<.001). The other ASS parameters were not correlated with the AS-Ab subtype.

Multiple correspondence analysis showed two different ASS patterns related to the AS-Ab specificity: patients with anti-Jo1-Ab presented a more diffuse disease with myositis, ILD, arthralgia and SS or SSc overlap, whereas patients with anti-PL12/7-Ab were quite similar to each other, disclosing a disease more restricted to the lungs. Moreover, the clustering analysis isolated a pattern of patients defined by the presence of anti-Jo1-Ab, severe myositis, ILD and arthralgia.

During the follow-up period, 36 patients (29%) developed a pulmonary hypertension (defined by a systolic PAP > 37 mmHg by echocardiography) and a total of 42 (30%) patients worsened. The evolution of the disease was not correlated to the AS-Ab specificity (p=.14). However, we identified different factors predictive of a worsening disease, including lung involvement (p<.02), co-occurrence of myositis & ILD at diagnosis (p<.04), severe rhabdomyolysis (p<.002) and development of pulmonary hypertension (p<.05).

Conclusion: Based on the AS-Ab specificity, two different ASS patterns can be described: anti-Jo1-Ab pattern with severe myositis, ILD and arthralgia vs anti-PL12/7-Ab pattern with ILD but inconstant myositis. Prognosis factors, independent of AS-Ab specificity, were lung involvement, severe myositis and pulmonary hypertension

Anti-MJ/NXP-2 Antibodies Are the Most Common Specificity in a Cohort of Adult Caucasian Patients with Dermatomyositis. Angela Ceribelli[1], Micaela Fredi[2], Mara Taraborelli[2], Ilaria Cavazzana[3], Franco Franceschini[4], Angela Tincani[5], Steven J. Ross[1], Brad A. Pauley[1], Edward K.L. Chan[1] and Minoru Satoh[1]. [1]University of Florida, Gainesville, FL, [2]University of Brescia and Spedali Civili, Brescia, Italy, [3]Rheumatology Unit, University of Brescia, Brescia, Italy, Brescia, Italy, [4]University of Brescia, Brescia, Italy, [5]Rheumathology Unit, University of Brescia, Brescia, Italy, Brescia, Italy

Background/Purpose: Specific autoantibodies in patients with polymyositis/dermatomyositis (PM/DM) are associated with unique subsets, and they are useful in monitoring clinical course and predicting outcome. Anti-MJ antibodies, which recognize the nuclear protein NXP-2 in the PML (promyelocytic leukemia) nuclear bodies, are a new specificity reported in 23–25% of juvenile DM, usually associated with severe muscle atrophy, functional impairment, and calcinosis. The aim of our study is to analyze the prevalence and clinical significance of anti-MJ antibodies in a cohort of adult Caucasian PM/DM patients.

Methods: Autoantibodies in sera from 58 consecutive adult PM/DM patients (74% female, mean age 43±17, mean follow up 55 months) were analyzed by immunoprecipitation of ^{35}S-labeled K562 cell extracts, ELISA (anti-MJ, Ro52, La, Jo-1), Western Blot and Indirect Immunofluorescence (IIF). Clinical association of anti-MJ was analyzed using information from charts and database.

Results: Anti-MJ antibodies are the most prevalent specificity (10/58; 17%) in our PM/DM cohort, followed by anti-Jo-1 (10%), -p155/140 (5%), -SRP (5%), -EJ (4%), and anti-Mi-2, -SMN complex, -OJ with one case each. Anti-MJ was found in 30% of DM and 8% of PM (P = 0.02). Among 10 cases of anti-MJ, 8 were DM and 2 were PM. When clinical features of 10 cases of anti-MJ (+) vs 48 cases anti-MJ (−) were compared, DM is more common (P = 0.03) and no overlap syndrome patients were found in anti-MJ group (0% vs 13%). Age of onset (25.5 vs 46.1 years) and age at initial visit (37.6 vs 54.6 years) were younger in anti-MJ group (P = 0.002), and 2 anti-MJ (+) were pediatric onset DM. In anti-MJ (+) patients, heliotrope rash (P = 0.01) and calcinosis (P = 0.057) were common, however, none of them had heart involvement (0% vs 27%, P = 0.03), interstitial lung disease (0% vs 33%, P = 0.048), or cancer (0% vs 8%). Myopathy in anti-MJ (+) patients was well responsive to steroid therapy and elevated CPK in the last visit was not seen (0% vs 25%). Only 6/10 anti-MJ (+) showed PML body nuclear dots staining in IIF, suggesting that IIF cannot be used for screening of anti-MJ antibodies.

	Anti-MJ (+) n = 10	Anti-MJ (−) n = 48	p
Male	40%	23%	
Mean age, ys (±SD)	37.6 (±12)	54.6 (±14.8)	
DM/PM/overlap	80/20/0%	40/48/13 %	DM 0.03
Heliotrope rash	60%	19%	0.01
Calcinosis	30%	6%	0.06
Heart involvement	0%	27%	
Interstitial lung disease	0%	33%	0.05
Elevated CPK at last visit	0%	25%	

Conclusion: Anti-MJ antibodies are detected also in adult PM/DM, and they are the most frequent specificity in our cohort, found in 17% of PM/DM (30% in DM and 8% in PM). Anti-MJ (+) patients have DM of young onset, severe calcinosis, no internal organ involvement and good response of myopathy to steroid. Anti-MJ will be a useful new addition of myositis-associated autoantibodies to help clinical monitoring of patients with adult PM/DM.

232

Distinctive Pattern of Myositis-Specific Autoantibody Production Between American Caucasian and Italian Patients with Polymyositis/ Dermatomyositis. Angela Ceribelli[1], Yi Li[1], Ilaria Cavazzana[2], Franco Franceschini[2], Steven J. Ross[1], Jason Y.F. Chan[1], Brad A. Pauley[1], Eric S. Sobel[1], Westley H. Reeves[1], Edward K.L. Chan[1] and Minoru Satoh[1]. [1]University of Florida, Gainesville, FL, [2]University of Brescia, Brescia, Italy

Background/Purpose: Myositis specific autoantibodies (MSA) in patients with polymyositis/dermatomyositis (PM/DM) are associated with unique clinical subsets and clinically useful biomarkers. Difference in prevalence of MSA between different races and a role of environmental factors within the same ethnicity have been suggested. However, differences of MSA production within Caucasians have not been well characterized. The aim of our study is to analyze the prevalence of MSA in adult Caucasian patients of American vs Italian origin.

Methods: Autoantibodies in sera from consecutive adult PM/DM patients from Italy (n = 58, 74% female) and American Caucasian patients (n = 68, 77% female) were analyzed by immunoprecipitation of ^{35}S-labeled K562 cell extracts. ELISA (anti-MJ, Ro52, Jo-1), Western Blot and Indirect Immunofluorescence (IIF) were also performed to verify specificity of autoantibodies.

Results: DM was more common in Italians than Americans (47% vs. 25%, P = 0.01). In all PM/DM patients, anti-MJ was the most common specificity in Italian (10/58, 17%) and significantly more prevalent than American Caucasian (2/68, 3%, P = 0.01). In contrast, anti-Jo-1 was the most common specificity in American Caucasian and more frequent (22% vs 10%; P = 0.09) than Italian. In comparison of DM in Italian vs American Caucasian, the distinctive pattern of MSA production became more apparent: anti-MJ was 30% vs 6% and anti-Jo-1, 0% vs 18% in Italian vs American Caucasian. Prevalence of other anti-synthetase antibodies and p155/140, Mi-2, and SRP were not different in total PM/DM or DM patients. Prevalence of MSA in PM between Italian and American Caucasian also was not significantly different.

Autoantibody	PM/DM Italian (58)	PM/DM American (68)	DM Italian (27)	DM American (17)
MJ	17%[1]	3%[1]	30%	6%
p155/140	5%	3%	8%	12%
Mi-2	1.7%	3%	4%	6%
SRP	5%	3%	0	0
Jo-1	10%[2]	22%[2]	0%[3]	18%[3]
Other synthetases	5% (2 EJ, 1 OJ)	3% (1 OJ, 1 PL-12)	4% (1 EJ)	0%
SMN complex	1.7%	3%	0	0

1, P = 0.01; 2, P = 0.09; 3, P = 0.05

Conclusion: Among PM/DM patients, DM was more common in Italian and difference in MSA specificity was mainly in DM population; Italian DM has very high prevalence of anti-MJ but no anti-Jo-1 whereas anti-Jo-1 was the most common in American Caucasian. Distinctive pattern of MSA in Italian vs American DM suggests roles of genetic differences within Caucasian and/or environmental factors and that testing for anti-MJ is more relevant for certain population such as Italian. More careful studies within same race may be necessary to understand the factors affecting MSA production.

Persisting CD28^{null} T Cells, but Not Regulatory T Cells, in Muscle Tissue of Myositis Patients After Immunosuppressive Therapy. Ingela M. Loell, Jayesh Pandya, Sukanya Raghavan, Mei Zong, Vivianne Malmström and Ingrid E. Lundberg. Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are characterized by infiltration of macrophages and T cells in skeletal muscle tissue. Immunosuppressive treatment has limited effects on the number of infiltrating cells providing a basis for persistent immune reaction targeting muscle fibers. Regulatory T cells are key players in the maintenance of peripheral tolerance by controlling T cell reactivity to self-antigen. CD28^{null} T cells are a highly enriched subset of proinflammatory T cells in patients with autoimmune diseases and are suggested to be resistant to apoptosis. Our aim was to establish whether the persisting T cells in myositis tissue belong to the regulatory T cell subset or to the apoptosis resistant, proinflammatory CD28^{null} T cell subset.

Methods: Muscle tissue biopsies were obtained from 14 patients with PM/DM before and after 8(4–16) month of treatment with glucocorticoids and additional immuno-suppressive drugs. Immunohistochemistry for CD3, FOXP3 and CD28^{null} surrogate marker CD244 was performed on muscle tissue. For clinical evaluation serum creatine kinase (s-CK) and functional index (FI) of myositis was used.

Results: Patients significantly improved in Functional Index following treatment ($p=0.002$) but only one patient regained 100% muscle function. Serum CK-levels went back to normal in all patients after treatment ($p=0.004$). The CD28^{null} T cell frequencies were increased or unaffected for majority of the patients, 11 out of 14, which was statistically significant ($p<0.05$). The proportion of T_{regs} did not differ before and after treatment at group level, but for the majority of the patients the frequency was lower or unaffected (10 out of 14).

Conclusion: Despite normalized CK-levels, patients only show partial functional improvement and many displayed persistent T cells in muscle tissue post treatment. The relative number of regulatory T cells was unchanged or decreased, while the CD28^{null} T cell proportion was mainly increased post treatment suggesting that high doses of glucocorticoid treatment might impair the regulation of autoreactive/pathogenic T cells including the CD28^{null} T cell populations in affected muscle.

Proposal for the Development of An International Minimal Data Collection for Juvenile Dermatomyositis. Liza J. McCann[1], Clarissa A. Pilkington[2], L. Beard[3], Angelo Ravelli[4], Adam Huber[5] and Lucy R. Wedderburn[6]. [1]Alder Hey Children's NHS Foundation Hospital, Liverpool, United Kingdom, [2]Department of Rheumatology, Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [3]UCL Institute of Child Health, London, United Kingdom, [4]G. Gaslini Institute, Genova, Italy, [5]IWK Health Centre, Halifax, NS, [6]University College London (UCL), United Kingdom

Background/Purpose: Several groups collect prospective data on patients with juvenile idiopathic inflammatory myopathies (IIM), including the UK JDM Cohort Biomarker Study &Repository, CARRA, and Euromyositis. Datasets are partially overlapping. A consensus minimal data collection would facilitate comparison and communication between groups. We propose a new international minimal data collection, potentially valuable in trials and clinical contexts, to be collected by clinicians for all JDM patients, respecting data protection and ownership.

Methods: Variables collected within the UK JDM Cohort/Biomarker Study, CARRA, Euromyositis and a multi-national study of 27 centres in Europe/Latin America[1] were compared. Those common to at least 2 datasets were considered for inclusion, based on agreement between collaborators.

Results: To date, the group have identified 19 variables common to all data collections (UK JDM cohort, CARRA, Euromyositis and the inception cohort by Ravelli et al[1]), 16 variables common to 3 datasets and 24 variables common to 2 datasets. Collaborators have discussed each variable to determine which ones are most relevant to clinical practice and useful in research. Thereby, a minimal data collection has been proposed that includes demographic data, diagnostic data, clinical features, major organ involvement, measures of disease activity / damage (as defined by IMACS / PRINTO), health assessment questionnaires, investigations and treatment. The data collection is thought to be achievable by clinicians within their normal practice. Work is in progress to define each variable, including optional detailed collection of activity / damage indices within specialist / research environments.

Conclusion: An international minimal data collection for use in trials would allow greater understanding of disease course / prognosis, enhance international collaboration between groups, and facilitate linking to biobanks. The dataset requires testing through existing collaborations (IMACS, PRINTO etc). Collaboration with adult groups (eg. via Euromyositis) may allow harmonised data collection from paediatric to adult services, providing valuable outcome data for this rare disease.

Ravelli A, Trail L, Ferrari C et al. Long-term outcome and prognostic factors of juvenile dermatomyositis: a multinational, multicenter study of 490 patients. Arthritis Care Res (Hoboken). 2010 Jan 15;62(1):63–72.

Ethnic but not Gender Differences in Disease Manifestations in Dermatomyositis Patients. Anna Tjärnlund[1], Lisa G. Rider[2], Frederick W. Miller[2], Victoria P. Werth[3], Clarissa A. Pilkington[4], Marianne de Visser[5], Elin Forslund[1], Anthony A. Amato[6], Richard J. Barohn[7], Matteo Bottai[8], Richard Finkel[9], Harold E. Paulus[10], Gerald J. D. Hengstman[11], Matthew H. Liang[12], Jasvinder Singh[13] and Ingrid E. Lundberg[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]National Institute of Environmental Health Sciences, National Institutes of Health, Bethesda, MD, [3]Perelman School of Medicine at the University of Pennsylvania and Philadelphia V.A. Medical Center, Philadelphia, PA, [4]Department of Rheumatology, Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [5]Department of Neurology, Academic Medical Centre, Amsterdam, Netherlands, [6]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [7]Department of Neurology, University of Kansas Medical Center, Kansas City, MO, [8]Institute for Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [9]Department of Neurology, Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA, [10]University of California, Los Angeles, Los Angeles, CA, [11]Department of Neurology, Catharina-ziekenhuis, Eindhoven, Netherlands, [12]Brigham & Womens Hospital, Boston, MA, [13]University of Alabama and VA Medical Center, Birmingham, AL

Background/Purpose: Dermatomyositis (DM) is a subset of idiopathic inflammatory myopathies (IIM), which are heterogeneous rheumatic disorders characterized by inflammation of skeletal muscle and progressive weakness. New and improved treatment is needed but a significant and fundamental problem for conducting clinical trials is the inadequate classification criteria for IIM. To address this, the International Myositis Classification Criteria Project (IMCCP) was established with the aim to develop and validate new classification criteria for IIM and major subgroups of IIM. Clinical and laboratory data from 1600 IIM and comparator cases have been collected. Dissimilarities in disease manifestations among different patient groups have to be considered as classification criteria must be uniformly valid. Little, however, is known about these differences in relation to clinical phenotype for IIM. The aim of this study was to investigate ethnic or gender differences in clinical manifestations in adult DM, juvenile DM (JDM) and amyopathic DM (ADM).

Methods: We extracted data on serology, 23 muscle variables (e.g., pattern of muscle weakness) and 14 skin manifestations from the IMCCP database and assessed their prevalence among 238 DM, 233 JDM and 45 ADM patients. Comparisons were made between genders and patients of Caucasian and Asian origin. Correction for multiple testing was performed yielding a $p<0.0009$ for statistical significance.

Results: Comparisons between the two ethnic groups revealed significant differences in clinical phenotypes. For adult DM cases, several muscle variables were more prevalent among Caucasians compared to Asians and two, neck flexor weakness and muscle tenderness, remained statistically significant after correction for multiple testing. Moreover, the pattern of skin manifestations differed greatly between adult DM patients, and photodistributed violaceous erythema was found to be significantly more prevalent among Caucasians ($p<0.0001$). Fewer ethnic differences for JDM cases were found and none remained statistically significant after correction for multiple testing. As expected, the ADM patients displayed virtually no muscle manifestations and no significant differences were found. Comparison between prevalence of skin manifestations for Caucasian and Asian ADM patients showed a higher prevalence for most skin variables in Caucasians, where periungual erythema remained statistically significant after correction for multiple testing ($p<0.00001$). Autoantibody analyses revealed a difference only among JDM cases where rheumatoid factor (RF) was more prevalent in Asians than in Caucasians, but only with a $p<0.05$.

Gender analyses for serology, muscle variables and skin manifestations revealed fewer differences compared to ethnic differences, and none remained statistically significant after correction for multiple testing.

Conclusion: We found significant ethnic differences in clinical phenotypes for DM patients. Comparable analyses showed no significant gender differences. Results from this study are of importance for the continued work in defining diagnostic and classification criteria as well as defining inclusion criteria in clinical trials.

236

Initial Predictors of Poor Survival in Patients with Dermatomyositis and Interstitial Lung Disease. Masataka Kuwana[1], Shinji Sato[2], Yuichiro Shirai[1], Tsutomu Takeuchi[1] and Takashi Fujita[3]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Tokai University School of Medicine, Isehara, Japan, [3]Institute for Virus Research and Graduate School of Biostudies, Kyoto University, Kyoto, Japan

Background/Purpose: Dermatomyositis (DM) is a heterogeneous disease with varying degrees of skin manifestations, myositis, and interstitial lung disease (ILD). A variety of serum autoantibodies are identified in patients with DM or clinically amyopathic DM (CADM), including antibodies to aminoacyl-tRNA synthetase (ARS), TIF1-γ, and CADM-140. Detection of these autoantibodies is useful in diagnosis as well as in classifying patients into distinct clinical subtypes. In this study, we examined if autoantibody profiles and clinical characteristics at diagnosis were useful in predicting prognosis in patients with DM and ILD.

Methods: Seventy patients diagnosed as having DM/CADM and ILD at Keio University Hospital between 1993–2007 were selected from our database. All clinical and laboratory findings were recorded at diagnosis. Autoantibodies were identified by immunoprecipitation assays, and anti-CADM-140 antibody was confirmed by ELISA using recombinant melanoma differentiation-associated gene 5 protein. Cumulative survival rates were calculated using the Kaplan-Meier method, and equality of survival curves was tested by the Wilcoxon test. Multivariate analysis was performed using the Cox proportional hazards regression model.

Results: Eighteen (26%) were positive for anti-CADM-140 and 38 (54%) were positive for anti-ARS (13 anti-Jo-1, 10 anti-EJ, 7 anti-PL-12, 5 anti-PL-7, 2 anti-OJ, and one anti-KS). The remaining 14 patients included 2 with anti-U1RNP, 2 with anti-Ku, and one with TIF1-g (reference group). When clinical characteristics at diagnosis were compared between anti-CADM-140 and anti-ARS groups, diagnosis of CADM and skin ulceration were more common, and muscle weakness and shortness of breath at presentation, mechanic hands, Raynaud's phenomenon, and elevation of KL-6 and CK were less common in anti-CADM-140 group ($P < 0.01$ in all comparisons). The onset of disease in all patients with anti-CADM-140 occurred between June and December, but anti-ARS-positive patients did not have any recognizable seasonal pattern. CT findings showed that NSIP pattern was predominant in anti-ARS group, but organizing pneumonia (OP) pattern was common in anti-CADM-140 group ($P < 0.0001$). Cumulative survival rates were significantly worse in anti-CADM-140 than in anti-ARS or reference group ($P = 0.004$ and 0.03, respectively). All deaths in anti-CADM-140 group were caused by progressive ILD and occurred within 7 months after onset, whereas survival rates in anti-ARS group were gradually reduced and were comparable with those in anti-CADM-140 group at 10 years. By univariate analysis, diagnosis of CADM, anti-CADM-140 antibody, skin ulceration, lack of muscle weakness, and OP pattern on CT were identified as initial parameters associated poor survival ($P < 0.05$ for all comparisons). However, multivariate analysis revealed that skin ulceration was the only parameter independently associated with poor survival: odds ratio was 4.1 (1.1–16.4) and 3.8 (1.2–12.2) at 1 and 10 years, respectively.

Conclusion: Autoantibody detection is useful in predicting outcomes in DM patients with ILD at presentation. Skin ulceration at lateral naifolds due to vasculopathy is the best predictor of poor survival in DM patients.

237

Prevalence of Pulmonary Hypertension in Inflammatory Myopathies. Ashwini Mhatre, James Bena and Soumya Chatterjee. Cleveland Clinic, Cleveland, OH

Background/Purpose: In patients with polymyositis (PM) and dermatomyositis (DM), pulmonary complications can cause significant morbidity and mortality. These include interstitial lung disease (ILD), hypoventilation related to respiratory muscle weakness, and aspiration pneumonia associated with involvement of the striated muscles of the upper esophagus, cricopharyngeus, and hypopharynx. Pulmonary hypertension (PH) has been associated with other autoimmune rheumatic diseases. Though PH has been reported in a few case reports, it has been a hitherto under recognized cause of morbidity and mortality in patients with inflammatory myopathies (IM). We examined the prevalence of PH in patients with IM and compared that to the prevalence of idiopathic PH

in the general population and also to systemic sclerosis (SSc) associated PH.

Methods: Retrospective chart review of patients with a diagnosis of PM or DM based on ICD-9 codes was performed at a tertiary care center using electronic medical records (EPIC™). Prevalence of PH was suspected in this cohort based on echocardiography (TTE) or right heart catheterization (RHC) criteria.

Results: Diagnosis of IM was confirmed in 453 out of 683 charts reviewed. Seventy one patients had suspected PH based on TTE and 32 patients had diagnosis confirmed by RHC. This is significantly higher than population prevalence of PAH (15/ million, p <0.001) [Humbert et al., 2006]. The prevalence of RHC based PH was lower than that in systemic sclerosis controls (89/722, p = 0.004) [Mukerjee et al., 2003]. However, the prevalence of PH based on TTE and RHC was higher when compared to a similar study in SSc patients (62/599, p = 0.006) [Hachulla et al., 2005].

Conclusion: This is the first study to systematically investigate the prevalence of PH in IM. In our cohort of patients with IM, the prevalence of PH was significantly higher than expected. TTE was a sensitive non-invasive modality for detection of PH in these patients. In this retrospective study, all patients with IM were not routinely screened for PH, leading to its potential underestimation. Additionally, TTE diagnosis of PH was not always confirmed by RHC, leading to its potential overestimation. However, it seems apparent that PH is more common in IM than realized and should be added to the list of pulmonary complications in IM. Hence routine screening for PH in IM may be worthwhile, as its recognition might lead to better outcomes through earlier institution of vasoactive therapies.

Table. Comparison of observed prevalence compared to literature

Group	PH in IM (%)	Historical controls (%)	p-value
Confirmed PH (RHC)	32/453 (7.1%)	0.0015 [Humbert, 2006]	**<0.001**
	32/453 (7.1%)	12.3 [Mukerjee, 2003]*	**0.004**
Suspected PH (TTE)	73/453 (16.1%)	0.0015 [Humbert, 2006]	**<0.001**
	73/453 (16.1%)	10.4 [Hachulla, 2005]	**0.006**
Isolated PH #	10/453 (2.2%)	0.0015 [Humbert, 2006]	**<0.001**

* Higher prevalence of PH than the current study
\# PH without interstitial lung disease (ILD)

238

Pulmonary Hypertension in Inflammatory Myopathies: Demographic and Clinical Characteristics. Ashwini Mhatre, James Bena and Soumya Chatterjee. Cleveland Clinic, Cleveland, OH

Background/Purpose: Patients with polymyositis (PM) and dermatomyositis (DM) can have significant morbidity and mortality from pulmonary complications. These include interstitial lung disease (ILD), hypoventilation related to respiratory muscle weakness, and aspiration pneumonia associated with involvement of the striated muscles of the upper esophagus, cricopharyngeus, and hypopharynx. Pulmonary hypertension (PH) has been associated with other autoimmune rheumatic diseases. Though PH has been reported in a few case reports, it has been a hitherto under recognized cause of morbidity and mortality in patients with inflammatory myopathies (IM). We describe demographic and clinical features in patients with IM and PH.

Methods: Retrospective chart review of patients with a diagnosis of PM or DM and PH (based on ICD-9 codes) was performed at a tertiary care center using electronic medical records (EPIC™).

Results: Out of 73 patients with IM and PH, 54 (74%) were female. The mean age at diagnosis of IM was 51 years, and ranged from 18 years to 82 years. Fifty three patients (72.6%) had ILD and 22 (30.1%) were positive for Jo1 antibody. All patients but one were on prednisone. At the time of the study 51 patients (70%) were alive. 54.5% of patients who were deceased had been on warfarin compared to 28% patients that were still alive (p = 0.031). Survival was independent of the presence of ILD. Use of immunosuppressive and vasodilator therapies had no impact on survival. Patients with ILD were more likely to be non-white (p = 0.014) and were significantly younger (p = 0.010). Patients with confirmed ILD (n = 63) were significantly more likely to be female (p = 0.036).

Table 1. Mortality data

Variable	Alive (n = 51)	Dead (n = 22)	p-value
Female	39 (76.5)	15 (68.2)	0.46
Caucasian	33 (73.3)	12 (54.5)	0.12
Anti Jo1 antibody	17 (43.6)	5 (41.7)	0.91
ILD	37 (72.5)	16 (72.7)	0.99
Immunosuppressive	48 (94.1)	19 (86.4)	0.091
Vasodilator	16 (31.4)	7 (31.8)	0.97
Warfarin	14 (28.0)	12 (54.5)	**0.031**
Age at diagnosis	50.5 [41.0, 60.5]	48.0 [34.0, 65.0]	0.74

Table 2. Comparison of patients with and without ILD

Variable	No ILD (n = 20)	ILD (n = 53)	p-value
Female	18 (90.0)	36 (67.9)	0.055
Caucasian	17 (89.5)	28 (58.3)	**0.014**
Anti Jo1 antibody	2 (20.0)	20 (48.8)	0.099
Immunosuppressive	17 (85.0)	50 (94.3)	0.43
Vasodilator	3 (15.0)	20 (37.7)	0.062
Warfarin	8 (40.0)	18 (34.6)	0.67
Age at diagnosis	60.0 [43.0, 74.0]	47.5 [37.0, 58.0]	**0.010**

Conclusion: This is the first study to systematically evaluate the association between PH and IM. It suggests that PH exists in patients with IM even without ILD (isolated PH). There was no difference in mortality in patients with or without ILD. Further prospective studies are needed to evaluate the effects of therapy on progression of PH in patients with IM.

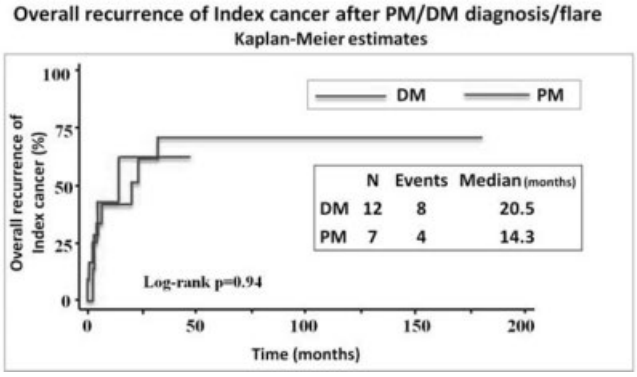
Cancer Associated Myositis: Temporal Relationship, Survival and Risk of Cancer Recurrence. Results From a Large Historical Cohort in United States of America. Christian A. Waimann, Kelechukwu A. Olejeme, Jean H. Tayar, Xiudong Lei and Maria E. Suarez-Almazor. University of Texas. M.D Anderson Cancer Center, Houston, TX

Background/Purpose: There is a well known association between cancer and myositis. However the temporal relationship between myositis and cancer development, and especially cancer recurrence, is still unclear. The aims of our study were to evaluate the temporal relationship between PM/DM and cancer diagnosis or recurrence.

Methods: Using electronic medical records, we identified a cohort of 93 patients with diagnosis of cancer and polymyositis/dermatomyositis (PM/DM) seen at a Comprehensive Cancer Center between 1998 and 2009. PM/DM diagnosis was confirmed using a stepwise procedure: 1st, definitive PM/PM according to Bohan and Peter criteria; 2nd, diagnosis made by a rheumatologist or neurologist; 3rd, full chart review by two rheumatologists. Data collected included: Age, gender, cancer and PM/DM clinical characteristics. Outcomes were: PM/DM flare (Worsening of muscle weakness and/or rash), cancer recurrence (appearance of a disease that was thought to be in remission), and death. The index cancer was defined as the cancer that was diagnosed closest to the DM/PM symptoms. Squamous and basal cells skin cancers in situ were not considered index cancer. The DM/PM diagnosis and the cancer were defined as concurrent if the time interval between the two incidences was within 6 months. Kaplan-Meier product limit method was used to estimate the overall survival (OS) and cancer recurrence outcomes. Groups were compared with the log-rank statistic (PM versus DM). Cox proportional hazards (PH) models were fit to determine the association of DM/PM disease with OS after adjustment for age and gender.

Results: 58 DM and 35 PM were included. Breast cancer was the most frequent cancer (DM 31%; PM 20%), followed by lung cancer (DM 17%; PM 12%). Adenocarcinoma was the predominant histological type (DM 60%, PM 39%). PM/DM diagnosis was concurrent with cancer diagnosis or recurrence in 40% of cases (DM 53%; PM 7%). Fifty seven percent of the PM cases versus 26% of the DM cases were diagnosed before cancer. At the moment of PM/DM diagnosis or flare, 19 patients had their cancer in remission. Sixty three percent of them developed a cancer recurrence within two years, being the first 6 months the higher risk period (Figure 1). There was no difference in OS after cancer diagnosis between PM and DM (mean survival was 5.5 and 3.9 years, respectively; log-rank p=0.96; Hazard ratio DM vs PM= 1.31, IC95:0.7=2.5).



Conclusion: In our knowledge this is the largest cancer associated myositis historical cohort in USA. Polymyositis and Dermatomyositis were concurrent with cancer diagnosis or recurrence in 40% of the cases. Almost half of the patients in remission developed a cancer recurrence within 6 months of PM/DM diagnosis or flare. There was no difference in survival between PM and DM.

Defining Clinically Relevant Changes in Core Set Activity Measures for Adult and Juvenile Idiopathic Inflammatory Myopathies (IIM). Lisa G. Rider[1], Julia A. Lee[2], Anna V. Jansen[2], Nicola Ruperto[3], Adam M. Huber[4], Chester V. Oddis[5], Brian M. Feldman[6], Peter A. Lachenbruch[7], Rohit Aggarwal[8], Frederick W. Miller[2] and IMACS and PRINTO[9]. [1]NIEHS NIH, Bethesda, MD, [2]NIEHS, NIH, Bethesda, MD, [3]PRINTO-IRCCS, Genova, Italy, [4]Dalhousie University, Halifax, NS, [5]University of Pittsburgh, Pittsburgh, PA, [6]The Hospital for Sick Children, Toronto, ON, [7]Corvallis, OR, [8]University of Pittsburgh Medical Center, Pittsburgh, PA, [9]Bethesda

Background/Purpose: Both PRINTO and IMACS have established core set measures for assessment of patients with IIM in therapeutic trials, and developed preliminary definitions of improvement combining these. Our aim was to revisit the degree of clinically meaningful change and importance of each measure in defining clinically important change, as well as to define changes in these measures that represent moderate and major degrees of improvement.

Methods: Twenty-nine pediatric and 21 adult rheumatologists and neurologists experienced in the care of IIM patients and the myositis core set measures completed a Delphi questionnaire regarding the amount of change in each core set domain deemed to be clinically significant in a trial setting.

Results: Adult and pediatric specialists provided the percentage change in each core set domain in order to classify an IIM patient as minimally, moderately and majorly improved (see Table), with general agreement between the pediatric and adult specialists. Both groups required greater change in enzyme values, and pediatric specialists also suggested slightly greater degrees of change for patient global activity and physical function. Muscle strength was ranked as the most important core set measure, followed by MD Global Activity, and there was a suggestion that additional weight of 1.5–2 fold be given to both these measures in a definition of improvement or of moderate and major response. Both groups preferred a definition based on percentage change, or one that combined percentage with absolute change. Both adult and pediatric specialists suggested 2–4 measures be required to improve for the patient to be considered improved, except both groups preferred improvement in up to 5 measures for a major degree of change. More than 80% of participants felt that muscle strength and MD Global Activity must improve for the patient to be considered clinically improved, whereas for major improvement, physical function also has to improve in adults and extra-muscular activity in pediatric patients. Deterioration of a small degree (≤ 20%) would be allowable in 1or 2 measures, but for major change no more than 1 measure may worsen, which cannot be MD Global Activity for pediatric or muscle strength for adult myositis patients.

Conclusion: These data, along with these specialists' ratings of adult and juvenile IIM patient profiles, will be used to revise the definitions of improvement for adult and juvenile myositis, and to guide the development of new criteria for moderate and major degrees of improvement.

Core Set Domain (% Change, Median)	Minimum Percent Change (Median)		Moderate Percent Change (Median)		Major Percent Change (Median)	
	Adult	Pediatric	Adult	Pediatric	Adult	Pediatric
Physician global activity assessment	20.0	20.0	30.0	40.0	50.0	60.0
Patient global activity assessment	20.0	25.0	30.0	40.0	50.0	60.0
Muscle strength (MMT or CMAS)	20.0	20.0	30.0	30.0	50.0	50.0
Physical function ([C]HAQ)	20.0	27.5	30.0	40.0	50.0	60.0
Extra-skeletal muscle disease activity	20.0	20.0	30.0	30.0	50.0	50.0
Laboratory Enzymes (CK, LDH, AST, ALT)	30.0	30.0	40.0	50.0	60.0	70.0
CHQ Physical Score (HR-QOL)	NA	22.5	NA	40.0	NA	55.0

Fatigue In IDIOPATHIC Inflammatory Myopathy (IIM): Prevalence, IMPACT and ASSOCIATION with QUALITY of LIFE. Richard CJ Campbell[1], David L. Scott[1], Patrick D. Kiely[2] and Patrick Gordon[1]. [1]King's College London, London, United Kingdom, [2]St. Georges Hospital, London, United Kingdom

Background/Purpose: Fatigue is common and has a major impact on quality of life in RA and SLE. The prevalence, severity and association with quality of life have not previously been evaluated in IIM.

Methods: 95 patients with dermatomyositis and polymyositis were recruited from 3 South London teaching hospitals. To assess the importance of fatigue, patients were first asked to rate 7 typical IIM symptoms (pain, weakness, fatigue, daily functioning, sleep, memory, gastrointestinal upset) in the order of impact on their quality of life. Patients also rated each symptom on a severity scale out of 6. Fatigue was then measured using 3 generic tools (FACIT-F, fatigue severity scale (FSS) and the vitality component of SF-36). Assessments were repeated in one quarter of patients to evaluate test-retest reliability and for comparison with age, gender and ethnicity matched healthy controls (t tests, $p<0.05$). Quality of life was measured with the SF-36 questionnaire. Spearman's correlation ($r>0.6$, $p<0.05$) evaluated fatigue against domains of quality of life. Patients were compared with population normative data for healthy patients using t tests ($p<0.05$).

Results: 89% patients had fatigue (FSS score >3). Mean fatigue was consistently high for each measure: FACIT-F 25/52 (SD 13.3); FSS 5.42/7 (SD 4.2); SF-36 vitality 40.0/100 (SD 22.13) and more than the healthy controls (FACIT-F 47.68; FSS 1.67; SF36 vitality 83.23; $p<0.001$). There was good agreement between the scales in test-retest. FACIT-F correlated with FSS ($r=0.7$; $p<0.05$) and SF36 vitality scores ($r=0.8$; $p<0.05$). 28% of respondents reported fatigue as the symptom that most impacted on their quality of life; more than any other symptom (weakness 10%, pain 21%, physical function limitation 15%, sleep 16.3%, memory and concentration 2.5% and digestive 6.3%). Mean symptom severity (3.9/6) was greater for fatigue than any other symptom. SF-36 was lower across all domains when compared with normative UK population and the healthy controls. SF-36 showed association with FACIT-F in univariate regression across all SF-36 domains ($p=0.000$).

Conclusion: Fatigue is common in IIM and impacts on quality of life more than any other typical IIM symptom. It is also highly associated with poor quality of life. If there is a causal relationship between fatigue and quality of life, the symptom may contribute to the high morbidity associated with IIM and should be a focus for further evaluation.

242

Fatigue In Idiopathic Inflammatory Myopathies (IIM) Is Not Caused by Peripheral Muscle Fatigability: Studies of Non-Volitional Quadriceps Muscle Endurance Using Repetitive Transcutaneous Stimulation. Richard CJ Campbell, Ged Rafferty, David L. Scott, Charles Rielly, Katie Ward and Patrick Gordon. King's College London, London, United Kingdom

Background/Purpose: Muscle endurance is the decline of capability of skeletal muscle to generate force with repeated activation. Fatigue is a major problem in patients with IIM. However, the relative contribution of peripheral and central factors is not known. Poor muscle endurance is likely to be a key peripheral factor. We used validated non-volitional techniques to repetitively stimulate quadriceps muscle trans-cutaneously to compare muscle endurance between IIM patients and controls. We also assessed whether there is a relationship between self-reported fatigue and muscle endurance.

Methods: Endurance Protocol: the quadriceps was stimulated repeatedly at a fixed voltage for 3 minutes (250ms on, 750ms off with a pulsed current, frequency of 30Hz). The force generated by each quadriceps contraction (Kg) was recorded throughout. Voltage was set to generate a starting contraction of 30% maximal voluntary contraction (MVC). This standardised participants for weight and strength. Self-reported fatigue was measured using the FACIT-F questionnaire. We compared mean time for initial starting force to decline to 70% between patients and controls (unpaired t tests). We also investigated whether this correlated with fatigue (FACIT-F) using Spearman's correlation.

Results: We compared 20 IIM patients (16 dermatomyositis and 4 polymositis; 10 females, 10 males) with age and sex matched controls. Fatigue measured by FACIT F and FSS was significantly reduced in the patients (table). Quadriceps power was also significantly reduced in the patients. In contrast, the endurance protocol showed no difference in the time taken to reach 70% of starting force between the patients and controls. Using Spearman's correlation, we found no relationship between measures of

fatigue (FACIT-F and FSS) and quadriceps endurance or quadriceps MVC in IIM patients.

	Patients	Controls	p
Number	20	20	
Gender/Ethnicity	10F, 10M 15 White, 5 Black	10F, 10M 17 White, 3 Black	
Mean Age (SD)	53.9 (9.78)	51.3 (8.43)	0.37
Mean FACIT-F (SD)	31 (10.26)	46 (11.90)	<0.05
Mean FSS (SD)	4.1 (1.75)	1.2 (1.28)	<0.05
MVC (Kg) (SD)	26.7 (8.82)	36.2 (7.04)	<0.05
Time to decline to 70% initial force (SD)	64.6 (17.76)	61.1 (18.25)	0.55

Conclusion: Patients with IIM have more fatigue and greater muscle weakness than matched controls. However, they show physiologically normal muscle endurance. Muscle endurance and muscle strength are also unrelated to fatigue which is almost certainly driven by central mechanisms in IIM. The impact of IIM on muscle strength over muscle endurance may influence types of rehabilitation programs offered for IIM.

243

Predictors of Experienced Fatigue in Idiopathic Inflammatory Myopathy (IIM): Psychological Factors and Pain Are More Predictive Than Disease Activity, Damage or Strength. Richard CJ Campbell[1], David L. Scott[1], Patrick D. Kiely[2] and Patrick Gordon[1]. [1]King's College London, London, United Kingdom, [2]St. Georges Hospital, London, United Kingdom

Background/Purpose: To evaluate the relationship the between experienced fatigue and a range of potential associations. Clinical (including disease activity/damage), psychological and demographic factors were assessed prospectively in a large South London population of patients with IIM.

Methods: A total of 95 patients (64.3% female, 32.7% male) with IIM attending outpatients clinics at 3 South London teaching hospitals were recruited. Experienced fatigue was measured using Functional Assessment of Chronic Illness Therapy for Fatigue (FACIT-F) and the fatigue severity scale (FSS). Other concurrent measurements included: manual muscle testing (MMT/260), health assessment questionnaire (HAQ-DI), haemoglobin, erythrocyte sedimentation ratio (ESR), creatinine kinase (CK), current prednisolone dose, the hospital anxiety and depression scale (HADS), visual analogue scales (VAS) for global health and pain, and the IMACS core data set for disease activity and damage. Outcomes were assessed for degree of association with fatigue in uni-variate regression ($p<0.05$). Backward stepwise multivariate regression models were developed with fatigue as the dependent variable. Co-linearity between variables was taken into account before modelling.

Results: Pain, disease duration, CK or prednisolone dose were not predictive of fatigue in uni-variate regression. Factors moderately predictive of fatigue ($r^2>0.3$; $p<0.05$) included: HADS anxiety, HADS depression and HAQ. Factors with small predictive value ($r^2>0.1$; $p<0.05$) for fatigue included: Haemoglobin, VAS-pain, VAS-global health, MMT/260 and summary measures of disease damage (MDI severity %, MDI extent %, MDI severity muscle) and activity (MYOACT%). In multivariate modelling, 68% of the variance in fatigue was explained by HADS depression, VAS pain, haemoglobin and severity of muscle damage index. The strongest contributions came from depression and pain. MMT/260, MYOACT% and the other measures of disease damage were no longer statistically significantly predictive of fatigue in multiple regression modelling. HAQ was co-linear ($r>0.5$) with HADS, so was not included in multivariate models.

Conclusion: In IIM, psychological factors and pain are predictive of fatigue. However, disease activity, damage and strength show much weaker relationships. It is not known whether there is a causal relationship between depression, pain and fatigue in IIM. An interventional study treating pain and depression while measuring changes in fatigue is needed.

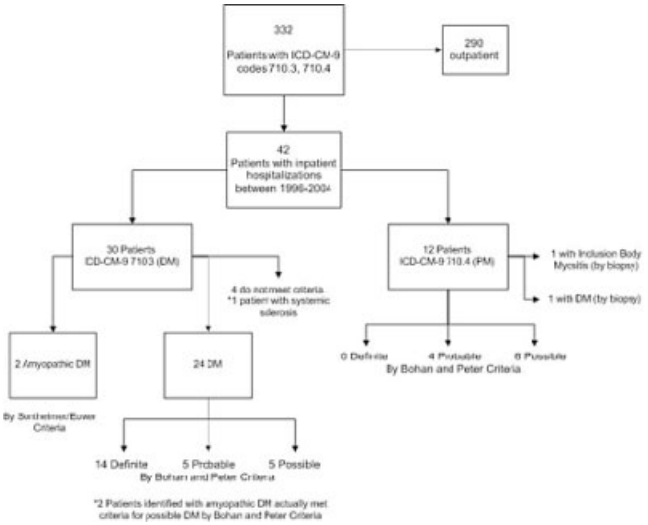
International Classification of Diseases-Clinical Modification-9 Codes for the Diagnosis of Dermatomyositis and Polymyositis in Discharge Summaries: Evidence of Acceptable Validity. Neera Narang[1], David Fiorentino[2], Eswar Krishnan[3] and Lorinda Chung[4]. [1]Stanford Univ Medical Center, Stanford, CA, [2]Stanford, Stanford, CA, [3]Stanford University, Stanford, CA, [4]Stanford Univ Medical Center, Palo Alto, CA

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are rare autoimmune diseases classically characterized by muscle inflammation. Epidemiologic studies using large administrative and hospitalization databases rely on the accuracy of the International Classification of Diseases-Clinical Modification-9 (ICD-CM-9) codes for case definitions. The purpose of this study is to evaluate the accuracy of ICD-CM-9 codes for DM and PM in hospital discharge summaries.

Methods: We identified all patients in the Stanford Hospital and Clinics database who had the ICD-CM-9 codes for DM (710.3) and PM (710.4) associated with any clinical encounters during the years 1996–2004. Of those, only patients who had hospital discharge summaries with any mention of these ICD-CM-9 codes were included in our study. We then performed a comprehensive medical record review of both inpatient and outpatient medical records to determine the proportion of patients who fulfilled accepted classification criteria for the diagnosis of DM and PM. Bohan and Peter criteria was used to classify patients as definite, probable, and possible DM or PM. Patients with clinically amyopathic DM were evaluated using the Sontheimer/Euwer criteria.

Results: A total of 332 patients with the ICD-CM-9 codes 710.3 and 710.4 were identified in the Stanford Hospital and Clinics database. 42 of these patients had inpatient hospitalizations between 1996–2004. 30 patients had ICD-CM-9 code 710.3 (DM) and 12 had ICD-CM-9 code 710.4 (PM). Of the 30 patients with ICD-CM-9 code 710.3, 24 (80%) fulfilled Bohan and Peter criteria for DM (14 definite, 5 probable, 5 possible). Of these, 8 had muscle biopsies consistent with DM. 2 additional patients met Sontheimer/Euwer criteria for amyopathic DM. 1 of the 4 patients who did not fulfill criteria for DM actually met ACR criteria for systemic sclerosis. 10 of 12 (83%) patients with ICD-CM-9 code 710.4 met Bohan and Peter criteria for PM (0 definite, 4 probable, 6 possible), however, only 2 patients had muscle biopsies consistent with PM, and 1 of the "probable" patients had a biopsy more consistent with rhabdomyolysis. The 2 other patients with 710.4 coding actually had DM and inclusion body myositis as verified by muscle biopsy.



Conclusion: Our study suggests that ICD-CM-9 codes of 710.3 and 710.4 used for coding discharge summaries are ≥ 80% accurate in identifying cases of DM and PM, respectively, who fulfill currently accepted classification criteria for at least possible disease.

245

Body Mass Index At Diagnosis Affects Disease Course In Juvenile Dermatomyositis. Anjali Patwardhan[1], Gloria Higgins[2], Charles H. Spencer[1] and Robert M. Rennebohm[3]. [1]Nationwide Childrens Hospital, Columbus, OH, [2]PRCSG, Columbus, OH, [3]Columbus Childrens Hospital, Columbus, OH

Background/Purpose: Pediatric obesity is increasing at an alarming rate. It is well known that obesity predisposes joints and bones to mechanical stress and increases musculoskeletal problems. Adipose tissue is considered an endocrine organ. Adipocytes secrete cytokines including TNF-α and IL-6, causing systemic inflammation and immune dysregulation. Obesity alters drug pharmacokinetics and affects drug dosing, blood levels and volume of distribution, possibly affecting efficacy of treatment. Obese persons may have altered sensitivity and response of the hypothalamic-pituitary-adrenal axis. Obesity also leads to a change in ACTH-mediated response to steroids, a category of drug commonly used in rheumatic diseases. We investigated the hypothesis that obesity at

diagnosis alters the disease course, response to treatment, and complication rate in juvenile dermatomyositis (JDM).

Methods: Institutional Review Board approval was obtained to retrospectively review the charts of 73 patients with JDM seen in pediatric rheumatology clinic at Nationwide Children's Hospital over the past 23 years by pediatric rheumatologists. Data on treatment and outcomes were collected up through the last clinic visit, or July 30, 2010, whichever came first. Body mass index (BMI) was calculated using 'Centers for Disease Control and Prevention—BMI calculator for children and teenagers'. We used the Wilcoxon two-sample test to compare numerical variables between the group of patients who were obese (BMI >85th percentile) and the group who were non-obese (BMI ≤85th percentile) at their initial visit. We used logistic regression to compare categorical variables between obese and non-obese groups in SAS 9.2

Results: Patient age ranged from 0–18 years. 28 patients had age- and sex-specific BMI ≥ 85th percentile, and 45 had < 85th percentile at disease onset. Average BMI of obese patients was 93rd percentile and of non-obese patients was 46th percentile. Comparatively fewer patients in the obese group received corticosteroid pulses at diagnosis (p=0.04) and developed osteonecrosis (p=0.030). Comparatively more patients in the obese group had elevated muscle enzymes at 12 months (p=0.027), developed calcinosis (p=0.03), received methotrexate for a longer time (p=0.040), continued to take steroids at last follow up (p=0.028), and continued to have active disease at 3 years (p=0.039), 5 years (p=0.039), and 10 years (p=0.027) following diagnosis.

Conclusion: JDM patients who were obese at diagnosis (BMI > 85th percentile) were less likely to receive pulse corticosteroids and had a lower incidence of osteonecrosis. On the other hand, they were more likely to have a chronic continuous and prolonged disease course, and calcinosis. It is not clear if these differences were related to treatment choices, or to metabolic differences in the two groups such as secretion of pro-inflammatory cytokines by adipose tissue, alteration of pharmacokinetics of medications, or altered sensitivity and response of the hypothalamic-pituitary-adrenal axis including response to corticosteroids in obese patients.

246

Juvenile Dermatomyositis Is a Different Disease In Children up to Three Years of Age At Onset Than In Children Above Three Years At Onset. Anjali Patwardhan[1], Charles H. Spencer[1], Gloria Higgins[2] and Robert M. Rennebohm[3]. [1]Nationwide Childrens Hospital, Columbus, OH, [2]Nationwide Childrens Hospital, Columbus, OH, [3]Columbus Childrens Hospital, Columbus, OH

Background/Purpose: Juvenile Dermatomyositis (JDM) is a different disease than dermatomyositis in adults in many ways including more vascular inflammation and vasculopathic thrombosis as previously described. We tested the hypothesis that juvenile dermatomyositis (JDM) disease course in children with disease onset at or below age three years may be different than that of children with disease onset at greater than three years of age.

Methods: Institutional Review Board approval was obtained to retrospectively review the charts of 78 patients from age 0–18 years with JDM seen in pediatric rheumatology clinic at Nationwide Children's Hospital over the past 23 years the diagnosis was made by the treating pediatric rheumatologist. Not all the patients met the Bohan and Peter criteria, as muscle biopsy and EMG were not always performed. The data regarding disease course and outcome were collected as of the last clinic follow-up. Wilcoxon 2-sample test and Chi-square test and Fisher's exact test were used to compare continuous variables and categorical variables respectively.

Results: The mean times between onset of symptoms to diagnosis in younger and older age groups were 5.6 months and 4.5 months, respectively. The younger onset group had more females (p=0.05) and their disease onset occurred less frequently during the typical winter-spring seasons (p = 0.031). The younger onset group was more likely to have a preceding fever (p=0.029) and family history of autoimmune diseases (p=0.012). The younger onset group was less likely to have heliotrope rash (p=0.04), Gottron's sign (p=0.049), capillary loop abnormalities (p=0.010), or creatinine kinase (CK, p=0.022), aspartate aminotransferase (AST, p=0.021) and aldolase (p=0.035) elevations. The younger children were more likely to have atypical histopathology (p=0.02) at presentation. The younger onset group was treated less often with pulse methylprednisolone at diagnosis (p=0.043) and less often with hydroxychloroquine (p=0.035). The mean (p=0.06) and maximum (p=0.002) duration of methotrexate therapy, and the mean (p=0.06) and maximum (p=0.016) duration of oral steroid therapy, was shorter in the younger group. Younger age group patients were more likely to experience a monocyclic course (p=0.027) and less likely to have active disease at 5 (p=0.017) and 10 years post diagnosis (p=0.019). The younger patients were less likely to have osteonecrosis (p=0.023) and more likely to die of their disease

Conclusion: There were significant differences between JDM patients with disease onset at or below age three years, compared to their older counterparts. Younger patients in our cohort had fewer typical findings at diagnosis. They were more likely to experience a monocyclic course, a shorter and milder total disease course, and a shorter maximum duration of oral steroid and methotrexate therapy. Younger patients had predominantly monocyclic disease, and a lower proportion had active disease at 5 and 10 years. In spite of having milder disease course, patients with younger onset had a higher mortality rate and a similar complication rate compared to the older onset patients, except for osteonecrosis which was higher in the older onset group

247

Comparison of Untreated Adult and Juvenile Dermatomyositis Muscle Biopsies: Difference of Inflammatory Cells Phenotyping. Samuel K. Shinjo[1], Adriana M. Sallum[2], Clovis A. Silva[1] and Suely K. N. Marie[3]. [1]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo-SP, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo (FMUSP)., São Paulo, Brazil

Background/Purpose: Inflammatory cell phenotyping in muscle fibers have been described in adult (ADM) and juvenile (JDM) dermatomyositis. Nevertheless, this alteration has not been systematically and simultaneously assessed and compared in both ADM and JDM untreated groups in a large series. Therefore, the aim was to study the cell phenotyping and MHC I and II expressions in muscle samples of untreated ADM and JDM patients, and to correlate with laboratory and clinical features.

Methods: Twenty-eight untreated ADM and 28 JDM patients, fulfilling Bohan and Peter criteria, diagnosed from 1990 to 2010, were included in this study. Routine histochemistry and immunohistochemistry (CD20 and CD68 (LSB+ system); CD4 and CD8 (EnVision-AP technique); MHC I and II (StreptoABComplex/HRP, Dakopatts)) were performed on serial frozen muscle sections. Each biopsy specimen was coded and analyzed independently by two investigators (SKS and AMES). The pathology readers were blinded to diagnosis and clinical status when the biopsies were evaluated. Inflammatory cell phenotyping was analyzed quantitatively in endomysial, perimysial, perivascular (endomysial and perimysial) areas in 10 fields (200x). Expressions of MHC I and II were assessed as negative or positive stained fibers.

Results: The mean age at disease onset was 42.0±15.9 and 7.3±3.4 years in ADM and JDM, respectively, whereas the symptoms duration before muscle biopsy were similar in both groups (9.4±11.1 and 11.3±16.0 mo, p=0.616). No statistical differences were observed regarding gender, ethnicity, frequency of constitutional symptoms and organ involvements (cutaneous, articular, pulmonary, cardiac or gastrointestinal) (p>0.050), except for the higher CK levels observed in ADM (CK: 3820.0±5332.3U/L *vs*. 1150.7±1332.3, p=0.024). The CD4 and CD8 positive cells distributions were similar in both groups in all analyzed area. The CD20 positive cells was predominantly observed in endomyosial (p=0.012) and perivascular perimysial (p=0.034) of ADM, whilst the CD68 positivity was mainly in all muscle specimen areas of ADM (p<0.001). The frequency of MHC I expression in fibers membrane (50.0 *vs*. 96.4%, p<0.001) was significantly higher in JDM than ADM, whereas MHC II expression was lower (50.0 *vs*. 14.3%, p=0.020). Additionally, all immunohistoquemical analyses were not correlated with demographic data, as well as with clinical and laboratorial features, including CK levels before muscle biopsy (p>0.050).

Conclusion: Different cells phenotyping of muscle biopsies were observed in the onset of two relevant inflammatory myopathies. Macrophages and B lymphocytes expressions in muscle fibers were a premature marker of ADM, whereas the MHC I expression in muscle fibers were evidenced in JDM.

248

Pulmonary Function Tests in Idiopathic Inflammatory Myopathy: Association with Clinical Parameters. Adrienne Prestridge[1], Gabrielle Morgan[1], Deli Wang[2] and Lauren M. Pachman[3]. [1]Children's Memorial Hospital, Chicago, IL, [2]Northwestern University's Feinberg School of Medicine, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: In adult idiopathic inflammatory myopathy (IIM), pulmonary involvement is found in close to half of patients[1] and many clinicians recommend routine screening with pulmonary function tests (PFTs).[2] Pulmonary involvement in children with IIM ranges from 18–50%, depending on the definition utilized.[3] Loss of core strength is a major component of JDM weakness. PFTs in juvenile dermatomyositis (JDM), when abnormal, are restrictive with a decreased diffusing capacity (DLCO) and have been shown to be associated with abnormal high resolution computed tomography of the chest (HRCT).[4] Correla-

tion with clinical disease parameters has not been well studied. The purpose of this investigation was to determine the association of abnormal lung function in pediatric patients with IIM with selected clinical parameters.

Methods: This is a cross-sectional study of children with a diagnosis of IIM between the ages of 5 and 21 years, who were seen for clinical care at the Children's Memorial Hospital. Those children who performed a PFT, between the years 2008 and 2011 were selected for study. Clinical parameters evaluated included: age at time of PFT, age at diagnosis, gender, ethnicity, myositis specific and associated antibodies (MSA/MAA), child myositis assessment scale (CMAS), Nailfold End Row Loop (ERL), Disease Activity Score (DAS) for muscle weakness, duration of untreated disease (DUD), muscle enzymes--including CPK, aldolase, SGOT, LDH—neopterin, Von-Willebrand Factor Antigen and flow cytometry. Comparisons were made between groups using Wilcoxon Rank Sum test for continuous variables and Chi square or Fisher exact test for dichotomous variables. We received IRB approval for this retrospective study.

Results: PFTs were considered abnormal if their total lung capacity (TLC) or DLCO was <80% predicted. Eighty five patients were included in the study, 39 with JDM, 7 with juvenile polymyositis, 38 with overlap syndromes and one with nonspecific myositis. PFTs revealed 24% of patients had decreased TLC and 31% of patients had decreased DLCO. Clinical parameters that differed in patients with either an abnormal TLC or DLCO, included race, MSA/MAA (PMScl, SCl 70), DUD, DAS for muscle and aldolase. Significant differences in patients with an abnormal TLC also included age at time of PFT, age at diagnosis, MSA/MAA (Ro), CPK and CMAS items 6, 10 and 12. Significant differences in patients with an abnormal DLCO included gender, race, MAS (U1RNP, U2RNP), neopterin and CMAS items 1 and 3.

Conclusion: Assessment of PFTs in children with IIM should be considered, since up to a third of patients have abnormalities. Concern for pulmonary involvement should be increased in patients with worse DAS for muscle strength and longer DUD. The identification of particular MSA/MAAs should also increase the requirement for screening for pulmonary complications of IIM. Further research is needed to determine which pediatric patients should be screened with PFTs in order to limit the associated morbidity secondary to pulmonary complications in IIM.

Increased Depression and Anxiety Symptoms in a Group of Dermatomyositis Patients. Elizabeth Ghazi[1], Mitchel A. Kling[2], Kathleen Propert[3], Joyce Okawa[4] and Victoria P. Werth[4]. [1]UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, [2]Philadelphia Veterans Affairs Medical Center and University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]Perelman School of Medicine at the University of Pennsylvania and Philadelphia V.A. Medical Center, Philadelphia, PA

Background/Purpose: Mood has never been studied in dermatomyositis (DM), a condition that can impact the skin, muscles, and other organs. However, it has been shown that DM patients have significantly lower quality of life (QOL) compared to other illnesses. This study compared the levels of depression, anxiety, and stress symptoms in the DM population to that of the general population. It hypothesized that facial involvement, skin damage, and muscle pain would lead to poorer mood scores and that mood scores would be highly associated with QOL scores.

Methods: This cross-sectional study evaluated depression using the following validated, self-report measures: the Patient Health Questionnaire 9 (PHQ-9) and the Depression Anxiety and Stress Scales 21 (DASS-21)-depression sub-scale (DASS-D). The DASS-21 anxiety and stress sub-scales (DASS-A and DASS-S) were used to look at anxiety and stress levels. The PHQ-9 functions as a screen, diagnostic tool, and determinant of severity, while the DASS-21 measures dimensions of mood. Skin severity was determined by the validated Cutaneous Dermatomyositis Disease Severity Index (CDASI) activity and damage scores. QOL was assessed with the validated skin-specific QOL measure, the Skindex-29. Eligible subjects required a diagnosis of DM and were seen between March and June of 2011 in Penn's autoimmune skin disease clinic. The DM group's PHQ-9 scores were compared to historic controls using a chi square test, with cut- off scores for mild and moderate to severe depression being 5 and 10, respectively. The DM group's DASS-21 median sub-scores were compared to historic controls using a Wilcoxon signed-rank test. Spearman's correlations were conducted between the mood measures and skin severity, including facial and overall skin activity and damage, and Skindex-29 scores. A point bi-serial correlation was conducted between the mood measures and the absence or presence of muscle pain.

Results: Of the 34 eligible patients, 12 of the 34 DM patients (35%) had a PHQ-9 score of 5 or greater. Of these patients with depressive symptoms, 66% had mild symptoms (score of 5–9) and 34% had moderate to severe symptoms (≥10). The DM group had a significantly greater proportion of depression versus controls using the 5 point cut-off (X^2= 4.97, p=0.03), but not when using the 10 point cut-off (X^2=1.32, p=0.25). DASS-A and DASS-D medians were significantly different from controls (W=271, p=.002; W=214, p=0.02), while the DASS-S median was not. DASS-A, DASS-D, and PHQ-9 scores all correlated with muscle pain (rpb= 0.48, 0.53, and 0.47, p=0.004, 0.001, and 0.005, respectively). The PHQ-9 and all DASS sub-scales correlated significantly with all sub-scales of the Skindex-29.

Conclusion: DM patients have more mild depressive symptoms than the general population, but similar rates of moderate to severe depression. DM patients experience more anxiety symptoms than controls. The presence of muscle pain may contribute to poorer mood. Skin specific QOL measures and mood measures are highly associated, possibly because the impact of skin disease activity on QOL mediates mood.

Background/Purpose: Inflammatory myopathies (IM) such as Polymyositis (PM) and Dermatomyositis (DM) are characterized by muscle damage and proximal muscle weakness. The muscle are enriched by alpha-actinins (ACTN) that are cytoskeletal proteins which encode a spectrin superfamily genes tissue–specific for myocardial diseases: *ACTN1* and muscle tissues (*ACTN2*, *ACTN3*). The function of ACTN heterodimers is to cross-link and bind actin, along with preserving spatial association among myofilaments. ACTN3 expression is restricted to type II fibers (100% of type IIb/x fibers and 50% of type IIa). The *ACTN3* gene is located in the region 11q13–14 and in normal conditions, translates a 901 aminoacid protein. The R577X *ACTN3* polymorphism is characterized by a non sense polymorphism resulting in the replacing of Arginine (R) by a premature stop codon (X) in the exon 16 (R577X). The homozygous XX are associated with incomplete translation resulting in lost of function of ACTN3. The R577X *ACTN3* R allele is related with strength and power muscle phenotype and the X allele is associated with endurance. Since muscle weakness is a common feature in IM, the aim of this study was to analyze the influence of the R577X *ACTN3* polymorphism in a group of Mexican patients with PM/DM.

Methods: 37 patients with Dermatomyositis (DM)/ Polymyositis (PM) and 85 healthy subjects were analyzed using PCR-RFLP for the R577X *ACTN3* polymorphism. Genotypes and alleles were analyzed. Enzymes such as CPK, LDH, AST and ALT were taken at diagnosis and recruitment to the study.

Results: We found that 36% XX of healthy subjects were polymorphic

for the R577X *ACTN3* polymorphism (18% RR and 46% RX) compared with 70% of R577X *ACTN3* polymorphic in IM (70% XX, 6% RR and 24% RX). The R allele was present in 41% and X in 59% in healthy subjects compared with 18% of the R and 82% X allele within the IM group ($p<0.001$). The polymorphic allele X, is associated with the group of IM. Although, within patients with IM, the cases carrying XX genotype had lower levels of enzymes such as CPK, AST and ALT ($p<0.01$, $p<0.01$ and $p<0.05$ respectively) compared with RX genotype.

Conclusion: In our study since 70% of IM patients were carriers of the R577X *ACTN3* polymorphic XX genotype, the lack of the protein could be a genetic factor that facilitates the muscle weakness and poor muscle resistance, besides the inflammatory damage mediated by the immune system itself.

Incidence and Prevalence of Idiopathic Inflammatory Myopathies in South Australia: A 30-Year Epidemiologic Study of Biopsy-Proven Cases. Ju Ann Tan[1], Peter J. Roberts-Thomson[2], Peter Blumbergs[3], Paul Hakendorf[4], Sally R. Cox[1] and Vidya Limaye[5]. [1]SA Pathology/Flinders Medical Centre, Adelaide, Australia, [2]Flinders Medical Centre, Adelaide, Australia, [3]Institute of Medical and Veterinary Sciences, Adelaide, Australia, [4]Flinders University, Adelaide, Australia, [5]Royal Adelaide Hospital, Adelaide, Australia

Background/Purpose: Idiopathic Inflammatory Myopathies (IIM) is a heterogenous group of autoimmune muscular disorders characterised by progressive proximal muscle weakness and inflammatory changes on muscle histology. Epidemiological data on IIM have been variable due to its rarity and heterogeneity. We aim to describe the epidemiology of a homogenously-defined population of biopsy-proven IIM in South Australia (SA).

Methods: Cases of IIM (Dermatomyositis DM, Polymyositis PM, Inclusion Body Myositis IBM) were ascertained by review of all muscle biopsy reports from the Neuropathology Laboratory, Hanson Institute from 1980–2009. All adult muscle biopsies in SA are reported in the same laboratory under the purview of an expert neuromuscular histopathologist, therefore minimizing inter-laboratory or inter-pathologist variability. Clinical correlation using the Bohan and Peter criteria was determined by review of patient medical records. The data collected was analysed for descriptive epidemiology. Binary data was tested for differences using the Pearson's chi-square test whereas continuous data was tested with the t-test. SA population denominator numbers were obtained from the Australian Bureau of Statistics.

Results: 352 biopsy-proven cases of IIM were identified between 1980–2009. The overall annual incidence of IIM appeared to be rising with a mean incidence of 8.0×10^{-6} (95% CI 7.2–8.9). This corresponded with an increasing annual incidence of IBM (*Fig 1)*. The mean incidence of DM is 1.0×10^{-6} (95% CI 0.8–1.4), PM 4.1×10^{-6} (95% CI 3.6–4.8) and IBM 2.9×10^{-6} (95% CI 2.4–3.4). We observed an IBM prevalence of 50.5 cases per million population in 2009 (95%CI 40.2–62.7). A female preponderance was noted in both DM (F:M = 2.75:1) and PM (F:M = 1.55:1) but gender distribution was almost equal in IBM (F:M = 1.1:1). Mean age at diagnosis for IBM (67.5 years) was higher than for DM (55.1 years) and PM (59.0 years). A higher proportion of DM patients reported urban dwellings and DM patients tended to be predominantly professionals.

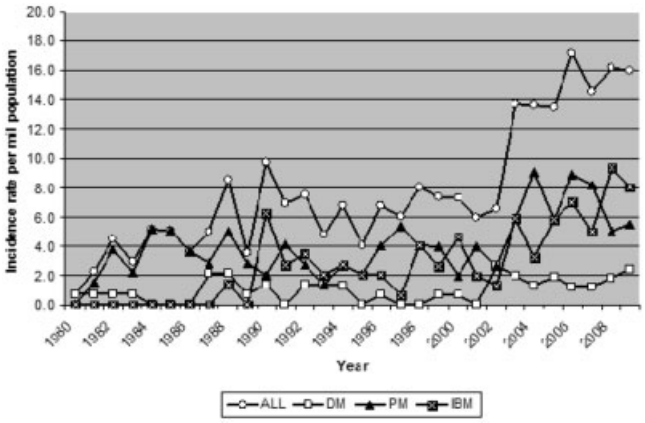

Figure 1. Annual incidence rates for all IIM cases and subsets from 1980–2009 in South Australia

Conclusion: The overall incidence of IIM is rising in SA, particularly for IBM and the prevalence of IBM is one of the highest reported to date. This may reflect an increase in the number of biopsies performed, improved histological techniques or a genuine increase in incidence.

Epigenetic Control of Muscle Repair Identified in Inflamed Muscle Biopsies From Untreated Juvenile Dermatomyositis. Min Wang[1], Hehuang Xie[1], Peter Hendrickson[1], Sheela Shrestha[1], Simone Treiger Sredni[2], Gabrielle Morgan[1] and Lauren M. Pachman[2]. [1]Children's Memorial Hospital, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: A major barrier in characterizing disease severity in order to provide effective therapy for children with Juvenile Dermatomyositis (JDM) and other Idiopathic Inflammatory Myopathies (IIM) is the lack of accessible biomarkers and prognostic indicators of disease outcome, including the child's capacity to repair damaged muscle. In JDM, the duration of untreated disease, (DUD) alters both phenotype and genotype of the child. As an important gene regulatory mechanism, DNA methylation is an essential component of normal development, and participates in the tissue's response to inflammation and disease progression, but its role in JDM has not yet been explored.

Objectives: To profile the methylation patterns in a cohort of children with IIM in order to determine the impact of methylation alterations in JDM, Polymyositis (PM) and overlap syndromes and their association with disease status.

Methods: DNA from diagnostic muscle biopsies (MBx) from 20 white girls and boys (mean age = 6.4 ± 3.5 yrs) with definite/probable JDM were tested in Group 1: five with short DUD (duration ≤2 months) and 15 with long DUD (duration >2 months) at MBx were compared with four healthy age-, gender- and race-matched controls. The DNA was tested with Illumina Methylation27 BeadChip for genome-wide methylation profiling, and the results reviewed with GenomeStudio Analysis Software. Bisulfite pyrosequencing confirmed DNA methylation in 10 additional matched controls and 71 children with a spectrum of juvenile myositis. Group 2 patient population, (50/71 girls, mean age 7.6 ± 4.1 yrs), included children classified as 41 White, 14 Hispanic and 16 others.

Results: In Group 1, 20 JDM/4 matched healthy controls, the methylation arrays documented a significant methylation difference in a total of 27 genes. Among them, 6 were homeobox genes. In addition, the WT1 gene was significantly hypomethylated in JDM ($p< 0.01$). These results were confirmed by bisulfite pyrosequencing verification. Besides JDM, other types of juvenile IIM also displayed similar hypomethylation of the homeobox and WT1 genes. In addition, hypomethylation of WT1 was concordant with increased expression of the relevant protein, Wt1, in JDM muscles, compared with matched control. Of note, protein expression of Pax 7, a unique regulator of the stem cell generated muscle satellite cells, was increased in all JDM (both long and short DUD), indicating the capacity for repair and muscle fiber regeneration,

Conclusion: These results suggest that the affected muscles of children with JDM, irrespective of DUD, have the capacity to repair, and that the homeobox and WT1 genes are epigenetically marked to participate in this process.

Speculation: There may be potential for new therapeutic approaches in which the self-renewal ability of the damaged muscles in children with IIM can be enhanced, aiding muscle repair.

Gene Expression In Affected Muscle of Patients with Polymyalgia Rheumatica and Matched Control Subjects Before and After Short-Term Prednisolone Treatment. Frederik Kreiner[1], Rehannah Borup[1], Peter Schjerling[2], Finn Cilius Nielsen[1] and Henrik Galbo[1]. [1]Rigshospitalet, Copenhagen, Denmark, [2]Bispebjerg Hospital, Copenhagen, Denmark

Background/Purpose: In polymyalgia rheumatica (PMR), the pathophysiology of symptomatic muscles is disputed. In the present study, we investigated baseline and post-treatment mRNA levels in symptomatic muscles.

Methods: Twelve glucocorticoid naïve patients (7 females and 5 men, age 73±10 years, BMI 23±4 kg/m2) with PMR just diagnosed according to the

Chuang criteria (Ann Intern Med 1982;97:672–80) and 12 controls (7 females and 5 men; 71±9 years; BMI 25±5 kg/m2) were studied.

In the fasting state, trapezius muscle biopsies were obtained before and after 14 days of prednisolone treatment (20 mg/day) from all subjects. mRNA was isolated using standard protocols and levels were determined using Affymetrix GeneChips (U133 Plus 2.0). Quantitative real-time PCR (qRT-PCR) was used for confirmation and also to more accurately measure expression levels of genes of special interest, e.g. IL6 that encodes interleukin (IL) 6, which in GeneChip runs did not differ between groups.

Results: Prednisolone treatment abolished symptoms in all patients within a few days; erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were normalized by day 14. In controls, ESR and CRP were always normal.

Using GeneChips, 565 transcripts were identified ($p<0.05$ in 2-way ANOVA testing; filtering for fold change $> \pm 1.2$); of these, 59 transcripts fulfilled all 3 criteria of being of particular interest (subset shown in table): Differences in mRNA levels ($p<0.05$ in Welch t-testing) between 1) untreated patients and controls (97 genes), and 2) untreated and treated patients (172 genes), but not between 3) untreated and treated controls. Among these genes, 6 were selected for qRT-PCR analysis; most exhibited identical or similar expression patterns compared to the GeneChip runs (table). In addition, in contrast to the GeneChip measurements, qRT-PCR analysis showed that expression of IL6 was higher in patients than in controls before treatment (1.41±0.57 vs 0.39±0.21 arbitrary units; $p=0.006$) and decreased ($p=0.029$) to levels similar to those found in controls (after treatment, patients: 0.42±0.17; controls: 0.31±0.16; $p>0.05$).

ZNF331: zinc finger protein 331	292	211	215	217

Data are mRNA levels (arbitrary units). n = 12 in all groups.
Genes in **bold face** indicates that expression levels were measured using both GeneChips and qRT-PCR.
(*) qRT-PCR measurements confirmed GeneChip findings.

Conclusion: We show that in PMR, altered expression of a number of genes, including IL6, may contribute to the pathophysiology of affected muscles. Further studies are needed to clarify the exact role of these genes in the disease.

ACR Poster Session A
Pediatric Rheumatology - Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis (JIA)
Sunday, November 6, 2011, 9:00 AM–6:00 PM

Ultrasound and Plasma Osteopontin Improve the Assessment of Remission in Oligoarticular Juvenile Idiopathic Arthritis. Miriam F. Parsa[1], Ornella J. Rullo[1], Jennifer M.P. Woo[1], David Elashoff[2], Tina Cunningham[2], Veena K. Ranganath[2], Kambiz Motamedi[2], Deborah K. McCurdy[1] and Harold E. Paulus[2]. [1]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [2]University of California, Los Angeles, Los Angeles, CA

Background/Purpose: Sustained remission is the treatment goal for children with Juvenile Idiopathic Arthritis (JIA). However, 50–75% of JIA patients meeting clinical remission (CR) criteria who discontinue medications have recurrence of disease activity within 5 years. Current CR criteria define disease states without the use of imaging or biomarkers. In patients categorized in clinical remission, musculoskeletal ultrasound may enable detection of the persistence of subclinical joint inflammation. Vascularization of inflamed JIA synovial tissue has been correlated with plasma osteopontin (pOPN) levels, a soluble cytokine that we have observed to be higher in oligoarticular JIA than healthy pediatric controls ($p=0.0002$). We hypothesize active synovitis, measured by an aggregate ultrasound inflammatory score (UIS) and pOPN, will decrease with longer durations of remission.

Methods: UIS of the knee and pOPN (by ELISA) were compared with the Juvenile Arthritis Disease Activity Score (JADAS) in four oligoarticular JIA disease states: active disease (AD), inactive disease (ID), CR on medications (CRM), and CR off medications (CR). AD patients requiring intra-articular steroid (IAS) injection had a pre-IAS and 1-month post IAS injection evaluation (UIS, pOPN, JADAS). US images were independently scored by two ultrasonographers, who were blinded to disease state. Baseline data was analyzed using the Kruskal-Wallis test to compare between states and a pairwise Wilcoxon rank sum test for post hoc pairwise comparisons.

Results: In this interim analysis of 35 study participants, median UIS strongly discriminates between disease states ($p=0.0001$). In states that are clinically indistinguishable, UIS is able to differentiate between ID and CR groups ($p<0.005$) (Figure 1). Moreover, US detects subclinical inflammation in 35% of the clinically inactive groups (ID, CRM, CR) ($p=0.0001$). In the IAS injection cohort, UIS and JADAS are significantly decreased when comparing pre-IAS and 1-month post IAS scores ($p=0.003$ for both). A strong correlation between UIS and JADAS ($r = 0.6$, $p = 0.008$) is observed, further confirming the applicability of UIS in JIA outcomes measurements. Overall p-value across disease states for pOPN is 0.0001, with the AD group exhibiting increased pOPN levels compared to both CRM and CR groups ($p=0.009$, $p=0.005$).

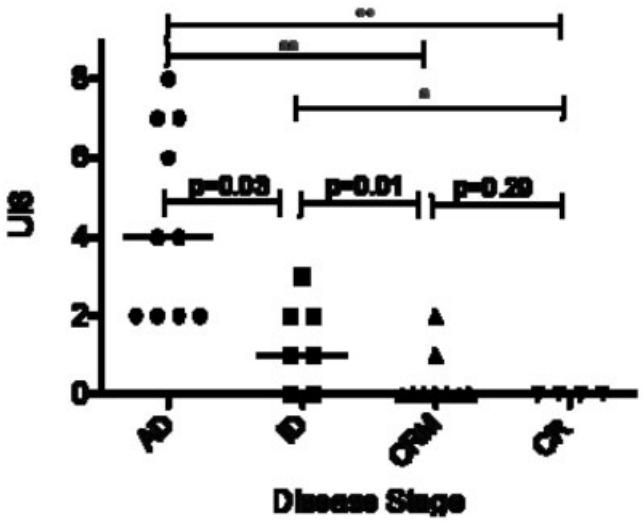

Figure 1. UIS in JIA disease stages (AD: n=12; ID: n=9; CRM: n=9; CR: n=5). Lines and p-values represent post hoc pairwise comparisons (**$p<0.0009$, *$p<0.005$).

Conclusion: The UIS may be more sensitive in the assessment of joint inflammation compared to clinical exam. UIS and pOPN levels may

differentiate patients who are in remission versus a subclinical disease state, a group that is at risk for disease flares. Confirming these associations in an expanded longitudinal cohort will allow us to construct risk assessment profiles for disease flare and will help determine the optimal duration of medical therapy in JIA.

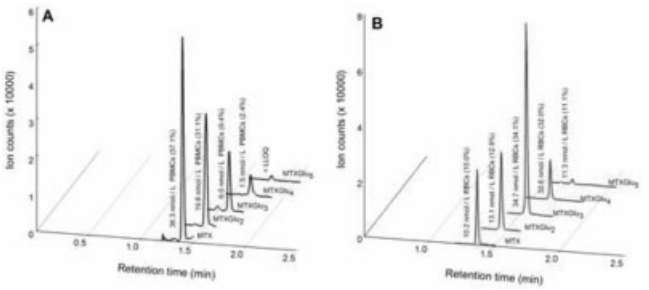
255

Measurement of Methotrexate Metabolites in Peripheral Blood Mononuclear Cells in Juvenile Idiopathic Arthritis: A More Relevant Cellular Biomarker for Drug Response? Leon van Haandel, J. Steven Leeder and ML Becker. Children's Mercy Hospital, Kansas City, MO

Background/Purpose: Regardless of age or disease subtype, considerable inter-individual variability in dose, optimal route of administration, clinical response and adverse reactions exist with methotrexate (MTX), and thus far, there are no quantitative biomarkers that can be utilized to maximize drug efficacy and minimize side effects at the level of the individual patient. Intracellular metabolism of MTX involves the formation of MTX polyglutamates ($MTXGlu_n$), which are responsible for its therapeutic effect, and long chain erythrocyte $MTXGlu_{3-5}$ have been reported to be associated with improvement in disease response in Rheumatoid Arthritis (RA). However, attempts to correlate erythrocyte $MTXGlu_n$ status with disease response to MTX in Juvenile Idiopathic Arthritis (JIA) have been less successful. Here we describe state of the art analytical methodology for the direct measurement of $MTXGlu_n$ in cells more directly associated with disease pathogenesis, the peripheral blood mononuclear cells (PBMCs).

Methods: After obtaining informed consent, 5 mL of blood was collected in EDTA vacutainer tubes. Erythrocytes, plasma and the buffy coat were separated and PBMCS were purified from the buffy coat using a Ficoll extraction per manufacturer protocol. $MTXGlu_n$ were extracted from PBMCs and RBCs by placing the sample tube in boiling water for 5 minutes, resulting in protein denaturation and liberation of the $MTXGlu_n$. Sample analysis occurred by a Waters UPLC system coupled to Xevo TQ-S tandem mass spectrometer (UPLC-MS/MS).

Results: Sample analysis by UPLC-MS/MS revealed that $MTXGlu_{total}$ concentrations between PBMCs and RBCs were within the same order of magnitude. However, the $MTXGlu_n$ distribution in PBMCs was shifted towards short chain metabolites ($MTXGlu_1$: 57.1%, $MTXGlu_2$: 31.1% and $MTXGlu_{1-2}$: 88.2%). Long chain metabolites represented only 11.8% of the intracellular drug concentration ($MTXGlu_3$: 9.4% and $MTXGlu_4$: 2.4% and $MTXGlu_5$: <LLOQ). The $MTXGlu_n$ metabolism fingerprint was therefore different when comparing PBMCs to RBCs (figure 1A, B respectively). Relative $MTXGlu_n$ distribution within the RBCs revealed a shift towards long chain $MTXGlu_{3-5}$, representing the vast majority (76.7%) of the intracellular drug concentration.



Conclusion: To our knowledge, this is the first reported method for detection of the active $MTXGlu_n$ metabolites in target PBMCs. Although RBCs represent an easily accessible source for measuring intracellular $MTXGlu_n$, from a drug effect perspective, the lack of association between increased concentrations on RBC $MTXGlu_n$ and clinical response to MTX in JIA suggests that PBMCs as effectors of disease pathogenesis may be a more relevant cell type. Additional investigation of the correlation of PBMC $MTXGlu_n$ and disease response is underway. Therapeutic drug monitoring in the PBMCs may provide clinicians a new quantitative biomarker for objective guidance of therapy in RA and JIA.

256

Malignancy and JIA: Updated Results. Sasha Bernatsky[1], Kiem Oen[2], Ciaran M. Duffy[3], Alan M. Rosenberg[4], Emily von Scheven[5], Kathleen M. O'Neil[6], Laura E. Schanberg[7], Rosalind Ramsey-Goldman[8], Jeremy Labrecque[1], Elizabeth M. Turnbull[9], Jennifer LF Lee[1] and Ann E. Clarke[1]. [1]McGill UHC/RVH, Montreal, QC, [2]University of Manitoba, Winnipeg, MB, [3]Children's Hospital of Eastern Ontario, Ottawa, ON, [4]Royal University Hospital, Saskatoon, SK, [5]UC San Francisco, San Francisco, CA, [6]Okla Univ Health Science Ctr, Oklahoma City, OK, [7]Duke University Medical Center, Durham, NC, [8]Northwestern University, Chicago, IL, [9]McGill UHC/RVH, QC

Background/Purpose: To assess cancer incidence in a very large JIA sample.

Methods: We ascertained cancer incidence within JIA clinic registries maintained at four North American pediatric rheumatology centers (University of Manitoba N=816; Montreal Children's Hospital N=650; Royal University Hospital N=364; University of Oklahoma N=192). We also assessed JIA subjects assembled from administrative data at the University of California-San Francisco pediatric centre (N=1,009). Subjects were linked to cancer registries to determine cancer risk over the observational interval, spanning 1974–2009. In-situ cancers were excluded. Person-years were calculated from the date first seen at the rheumatology clinic, and the first of: death, cancer, or end of study interval (Dec. 31, 2009). Pooling the data, we determined the number of cancers occurring over the total person-years of observation. The number of cancers expected was calculated by multiplying the person-years in the cohort by the geographically matched age, sex, and calendar year-specific cancer rates, and summing over all person-years. Given differences in cohort assembly, data from the UCSF cohort are presented separately.

Results: The cohort was 65% female; average age at JIA diagnosis was 9.2 years (SD=5.1). There was a trend for fewer females and older average age in the UCSF cohort (59%, 11.0 years) versus the other cohorts (68%, 8.0 years). The majority of cohort members were Caucasian. Subjects were observed for a total of 18,250 patient-years, with an average follow-up of 6.0 years (SD=3.4). Within this observation interval, based on regional age- and sex-appropriate cancer rates, 7.4 invasive cancers were expected, however, only 6 occurred (SIR 0.8, 95 % confidence interval, CI 0.3, 1.8). All of these were hematologic cancers, five of these being leukemia and the other being poorly specified. These cancers arose an average of 2.7 years after JIA diagnosis (the most distant event occurring 8.8 years after JIA diagnosis).

Pooling data from the clinical cohorts, the SIR for hematological cancer was 1.4 (95% CI 0.2, 5.0). One of the hematologic cancers was diagnosed very shortly after JIA diagnosis in the UCSF cohort, and in this event the JIA may have been a paraneoplastic manifestation of the hematologic cancer. Excluding this case, the point estimate for the SIR for hematologic cancers in the UCSF cohort was high (37.5) but with a very imprecise 95% CI (7.56, 109.6).

Conclusion: These data represent the most up-to-date efforts to clarify baseline JIA cancer risk. Data from the clinically confirmed cohorts do not confirm an increased cancer risk in JIA, although there is a signal for a potentially increased risk of hematological cancer. The dramatic but imprecisely defined increased risk suggested by the UCSF cohort may reflect a somewhat biased (potentially sicker) sample, compared to the other cohorts. A limitation of available data is the relatively short follow-up time. Further work is in progress.

257

Predictors of Disability in Children with Inflammatory Arthritis, Two and Three Years After First Presentation to Paediatric Rheumatology. Results From the Childhood Arthritis Prospective Study (CAPS). Roberto Carrasco[1], Joanna Cobb[1], Eileen M. Baildam[2], Helen Foster[3], Janet Gardner-Medwin[4], Alice Chieng[5], Lucy R. Wedderburn[6], Joyce Davidson[7], Kimme L. Hyrich[1], CAPS Study[8] and Wendy Thomson[1]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [3]Newcastle Hospitals NHS Trust, Newcastle, United Kingdom, [4]Royal Hospital for Sick Children, Yorkhill Hospital, University of Glasgow, Glasgow, United Kingdom, [5]Manchester Children's Hospital, Manchester, United Kingdom, [6]University College London (UCL), United Kingdom, [7]Greater Glasgow and Clyde Health Board and Royal Hospital for Sick Children, Glasgow, United Kingdom, [8]Manchester

Background/Purpose: Inflammatory arthritis (IA) in children is a chronic and often disabling disease with variable outcome. Up to one third of children are reported to have active disease progressing into adulthood although, data concerning disease course in children presenting with inflammatory arthritis in this modern treatment era are limited. The Childhood Arthritis Prospective Study (CAPS) is an ongoing prospective longitudinal inception cohort study the overall aim of which is to identify genetic and environmental predictors of short- and long-term outcome of childhood IA.

Within CAPS we have previously reported that the strongest predictor of persistent disability at one-year (as measured by the CHAQ) was moderate to severe disability at first presentation. The objective of this study was to extend the one year analysis to look at both two and three year outcomes.

Methods: CAPS recruits children <16 years with new inflammatory arthritis persisting for ≥ 2 weeks from five UK tertiary referral centres. Demographics, disease features, active and limited joint counts, CHAQ, physician's global assessment (PGA), parent's general evaluation of well-being (PGE), erythrocyte sedimentation rate (ESR) and treatment, are collected at first presentation to a paediatric rheumatologist, 6 months, then yearly. Independent predictors of moderate to severe CHAQ (CHAQ≥0.75) at two and three years in children with JIA were identified using multivariable logistic regression models. Imputation was performed in order to account for missing data.

Results: To date, 1059 children have been recruited; 901 had reached one year, 852 had reached two years and 618 three years of follow-up. Median age at presentation was 7.7 years, 63% girls. ESR, active and limited Joint counts, PGE and PGA score decreased every year for the majority of patients. Median CHAQ score was 0.75 (IQR: 0.125–1.375) at presentation and decreased to 0.25 (IQR: 0.0–1.0) at 1 year, 0.125 (IQR: 0.0–0.875) at 2 years and 0.125 (IQR: 0.0–0.75) at 3 years. Fifty percent of the children had CHAQ score ≥0.75 at presentation, 33% at 1 year, 32% at 2 years and 28% at 3 years. Amongst all the variables included in the study, moderate to severe CHAQ at presentation was the strongest predictor of moderate to severe CHAQ at one (OR 2.83 95% CI: 1.48, 5.37), two (OR 3.49 95% CI: 1.73, 7.08) and three years (OR 6.47 95% CI: 2.35, 17.8). After missing data imputation an additional predictor of a CHAQ score ≥0.75 at one, two and three years of follow up, PGE, was found.

Conclusion: Whilst the majority of children presenting with IA show continued improvement in the three years following first presentation, with many having no active or limited joints, our data show that there are still a significant proportion with moderate to severe disability. CHAQ score ≥0.75 at presentation, which was previously shown to predict disability at one year is still the strongest predictor of outcome at two and three years although an additional predictor, PGE may also be important. Future analysis will look at predictors of outcome, taking into account treatment.

Etanercept in Juvenile Idiopathic Arthritis: Who Will Benefit? Results From the Dutch ABC Register. Marieke H. Otten[1], Femke H.M. Prince[1], Wineke Armbrust[2], Rebecca Ten Cate[3], Esther P.A.H. Hoppenreijs[4], Marinka Twilt[1], Yvonne Koopman-Keemink[5], Simone L. Gorter[6], Koert M. Dolman[7], Joost F. Swart[8], J. Merlijn Van den Berg[9], Nico M. Wulffraat[8], Marion A.J. Van Rossum[10] and Lisette W.A. Van Suijlekom-Smit[1]. [1]ErasmusMC Sophia Children's Hospital, Rotterdam, Netherlands, [2]Beatrix Children's Hospital, University Medical Centre Groningen, Groningen, Netherlands, [3]Leiden University Medical Centre, Leiden, Netherlands, [4]St Maartenskliniek and Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [5]Hagaziekenhuis Juliana Children's Hospital, Den Haag, Netherlands, [6]University Hospital Maastricht, Maastricht, Netherlands, [7]St. Lucas Andreas Hospital and Reade Institute, Amsterdam, Netherlands, [8]University Medical Center Utrecht, Utrecht, Netherlands, [9]Emma Children's Hospital/ Academic Medical Centre and Reade Institute, Amsterdam, Netherlands, [10]Emma Children's Hospital / Academic Medical Center (AMC), Amsterdam, Netherlands

Background/Purpose: The pharmacological treatment approach for juvenile idiopathic arthritis (JIA) has changed substantially since the introduction of biologics with nowadays inactive disease as realistic goal. However, inactive disease is still not achieved by all patients. Identifying baseline factors which predict etanercept response could improve treatment strategies.

Methods: The Arthritis and Biologicals in Children (ABC) register (observational study, ongoing since 1999), includes all Dutch JIA patients who use or previously used biologics. Disease activity variables were retrieved prospectively at start of treatment, after 3 months, and yearly thereafter. Analyzed were all biologic-naive patients who started etanercept before October 2009 (n=262). Drug survival (i.e. median duration from start until first discontinuation due to ineffectiveness or adverse events (AEs)) was estimated with Kaplan-Meier analysis. Excellent response (inactive disease or earlier discontinuation due to disease remission) and poor response (less than 50% improvement from baseline, or earlier discontinuation due to ineffectiveness or intolerance) was evaluated 15 months after initiation of etanercept. A univariate and multivariate logistic regression analysis was performed to identify pre-defined potential baseline predictors for excellent and poor response and for occurrence of AEs.

Results: Baseline characteristics: 71% female, 18% systemic-onset subtype, median age at onset 6.9 years. In the long-term (median follow-up duration, 35.6 months), the overall majority responded to etanercept and up to 40% reached inactive disease. The median drug survival was lower for the systemic-onset subtype (29.0 months, 95% CI 11.0–47.0) than for the non-systemic subtypes (76.8 months, 95% CI 45.7–108.0). Reasons for discontinuation were: ineffectiveness in 78, AEs in 25, and remission in 39 patients. Excellent response after 15 months (85 patients, 32%) was associated with low baseline disability (OR 0.49/point increase, 95%CI 0.33–0.74), fewer disease-modifying anti-rheumatic drugs (DMARDs) used before etanercept (OR 0.64/DMARD used, 95%CI 0.43–0.95) and younger age at onset (OR 0.92/year, 95%CI 0.84–0.99). Poor response (88 patients, 34%) was associated with female gender (OR 2.12, 95%CI 1.11–4.08) and systemic-onset JIA (OR 3.24, 95%CI 1.39–7.56). However, 24% of systemic-onset JIA patients reached excellent response. Etanercept was well tolerated (0.05 serious AEs, 0.14 infectious AEs and 0.26 non-infectious AEs per patient-year of exposure). Patients developing AEs could not be identified at baseline.

Conclusion: In daily practice, etanercept is very effective and well tolerated by patients with JIA. Inactive disease was reached in up to 40% of the patients and was sustained years after initiation of etanercept. Excellent response was associated with baseline low disability and less DMARD use before etanercept. Therefore, the focus should be on strategies with early introduction of etanercept to further improve outcomes for JIA. The role of etanercept for systemic-onset JIA remains debatable. However, etanercept should not be rejected as a therapeutic option for this subtype.

Impact of Juvenile Idiopathic Arthritis on Parents' Work Absences. Rafia Rasu[1], Stephanie E. Kirbach[2], Oscar Hayes[2], Walter A. Bawa[1] and Mary A. Cifaldi[2]. [1]University of Missouri-Kansas City, Kansas City, [2]Abbott Laboratories, Abbott Park, IL

Background/Purpose: Children with juvenile idiopathic arthritis (JIA) have long-term morbidity with reduced quality of life and, therefore, require extensive parental assistance. This study aimed to evaluate the impact of children's JIA on parents' work absences compared with parents of children without JIA.

Methods: The Medstat MarketScan® claims database was assessed from 2000 to 2009 in order to identify adult parents with children who were newly diagnosed with JIA. A cohort of parents who had children without diagnoses of JIA was also identified, based on the matching of children with and without JIA. Data on parents' work absences (number of recorded absences, in hours) were analyzed using descriptive, multivariate regression, and logistic regression analyses. National estimates were calculated using parent and patient weights provided within the database.

Results: A total of 108 unweighted parents (mean age, 42.5 years) of children with newly diagnosed JIA represented a total of 3335 weighted nationally. The majority of these parents were from the south (46%), men (92%), and involved in the transportation and utilities industry (57%). Other industries represented were manufacturing (35%), oil and gas (3%), and services (3%). Demographic characteristics of control parents were similar. Children with JIA (mean age, 10.6 years) totaled 108 and represented 3528 weighted nationally. The mean (±standard error) number of reported work absences over the study period was 281.81 (±40.50) hours for parents of children who were newly diagnosed with JIA compared with 183.36 (±28.55) hours for parents of control children. Parents of children who were newly diagnosed with JIA reported 36.75 (±7.25) hours of work absences in the year prior to their children's JIA diagnosis compared with 69.01 (±18.44) hours for the year following diagnosis with JIA. Productivity loss was determined by noting parents' work absence difference 1 year before and after the diagnosis of JIA. An increase in the number of reported absences was considered to be productivity loss. After controlling for covariates, productivity loss was significantly related to the child's JIA status (with or without), parent's sex (men were more likely to have reported absences), and region (parents in the south and north-central regions were least likely to report absences compared with those in the northeast). Parents with children who had JIA were 2.78 times more likely to report productivity loss (OR=2.78; 95% CI=1.47–5.26) than parents whose children did not have JIA.

Conclusion: In this largely male population of employees, having a child with JIA resulted in significant work productivity losses, particularly in the year following diagnosis. This burden is likely experienced by both parents and represents the high level of care required by children with JIA.

260

Long-Term Safety of Etanercept Compared to Methotrexate and Combinations in Children with Juvenile Idiopathic Arthritis – Data of the German BIKER-Registry. Gerd Horneff[1], Stephanie Bischof[1] and German BIKER Registry collaborative group[2]. [1]Asklepios Clinic Sankt Augustin, Sankt Augustin, Germany, [2]Sankt Augustin

Background/Purpose: Using the data base of the German BIKER registry the long-term safety of etanercept (ETA) alone or as combination therapy compared to methotrexate (MTX) was evaluated.

Methods: Cohorts of JIA patients receiving MTX alone, ETA alone, ETA & MTX, ETA & other DMARDs without MTX or ETA & MTX & other DMARDs were identified in the database. Safety was assessed by measuring rates of adverse events including grading for seriousness. For all AEs the current medical treatment was recorded for comparison of the rate of the total number of AEs and of AEs of interest. 20% of patients were current users of nonsteroidal antirheumatic drugs and 9% received steroids when AEs were documented. Exposure years of each category of treatment were calculated from the data base. The possible influence of JIA categories, disease duration and severity, concomitant morbidity or drug history was neglected for this analysis.

Results: In total 1249 AEs (139 SAEs) were documented during > 4700 patient years. AEs of interest were cytopenias, malignancies, flares of uveitis, chronic inflammatory bowel disease (IBD) and those graded as serious. Elevated liver function tests were listed as a *control* AE since their predominance upon MTX was expected. For each AE the actual treatment was assigned.

201 AEs (30 SAEs) occurred in 737 pts on ETA alone, 260 AEs (62 SAEs) on 1059 pts on ETA & MTX, 34 AEs (8 SAEs) on 192 pts on ETA & other DMARDs without MTX, 14 AEs (5 SAEs) on 34 pts on ETA & MTX & other DMARDs, 568 AEs (19 SAEs) on 1534 pts on MTX alone. 127 AEs were reported in pts who already completely discontinued treatment with DMARDs and biologics. 46 AEs were reported on biologics other than ETA or on combination regimen of MTX with cyclosporine, leflunomide or azathioprine without ETA. Categories of treatment in relation to rates of AEs and Aes of interest per patient and per year of exposure are outlined in table 1.

Table. Adverse events and SAE (rate per 100 patient years)

	MTX	ETA	ETA+MTX	ETA+MTX+DMARD	ETA+DMARD
Total no. of patients	1534	737	1059	34	192
Total patient-years of exposure	1976	1028	1471	115	147
Total adverse events	568 (29)	201 (20)***	260 (18)***	14 (12)	34 (23)***
Total SAE	19 (1.0)	30 (2.9)**	62 (4.2)***	5 (4.4)***	8 (5.4)**
Infection	65 (3.3)	52 (5)*	87 (5.9)***	2 (1.7)	10 (6.8)
SAE-Infection	5 (0.3)	8 (0.8)*	22 (1.5)***	0	2 (1.4)
Cytopenia	10 (0.5)	7 (0.7)	2 (0.1)	0	2 (1.4)
Malignancy#	3 (0.2)	0	3 (0.2)	0	1 (0.7)
Chronic inflammatory bowel disease	0	6 (0.6)***	1 (0.1)	0	0
Uveitis	13 (0.7)	16 (1.6)**	17 (1.2)	0	2 (1.4)
Abnormal liver function	70 (3.5)	4 (0.4)***	12 (0.8)***	1 (0.9)	1 (0.7)

One additional malignancy occurred in a patient who already had discontinued treatment with ETA and MTX. Difference of numbers per patient (chi-square-test) significant at p<0.0001 ***; p<0.01 **; p<0.05 * compared to MTX alone, respectively.

Significantly more AEs occurred on MTX alone compared to ETA alone while this rate was similar if abnormal liver functions tests were substrated. SAEs were more frequent on treatment groups including ETA than on MTX alone. Infections and serious infections were more frequent on ETA alone or in combination with MTX than on MTX alone. Furthermore uveitis and IBD occurred more frequently on etanercept alone.

Conclusion: These data indicate that adverse events in all treatment groups were rare and in the majority they were minor. Some adverse events of interest seem to be associated to etanercept treatment. The possible influence of disease duration and severity, concomitant morbidity or drug history limits the conclusions that can be drawn from these observations.

261

Physician Versus Parent/Patient Assessment of Disease Activity in a Large Cohort of Patients with Juvenile Idiopathic Arthritis. Caitlin M. Sgarlat, Christina F. Pelajo, Jorge M. Lopez-Benitez and Laurie C. Miller. Tufts Medical Center, Boston, MA

Background/Purpose: Few previous large studies have examined the correlation between parent/patient versus physician assessment of disease activity though discordance between parent/patient and physician assessment has been reported in previous studies of JIA patients. Understanding the differences between parent/patient and physician assessment of disease is important for several reasons, including parent understanding of the patient's disease status, expectations about therapeutic interventions, and observations of disease progression or remission. The aims of our study were to examine the correlation between parent/patient and physician assessment of disease activity in JIA and to explore the association between parent/patient assessment of pain and parent/patient as well as physician assessment of disease activity.

Methods: The CARRAnet Registry database, a nationwide database containing information of >2,000 patients with JIA collected from May 2010 to June 2011, was used for analysis. This database contains demographics, a parent/patient pain report (0 to 10 scale with 0 = no pain and 10 = very severe pain), as well as parent/patient and physician disease activity reports (both on a 0 to 10 scale with 0 =no disease activity and 10 = very active disease), as well as other disease and medication information. Descriptive statistics were used to compare demographics of the sample population. Correlations between patient/parent and physician reports were measured with Pearson correlation coefficients.

Results: Of 2618 patients with a diagnosis of JIA, 1909 were female (73%) with a mean age of 11.5 years (±4.8). The overall parent/patient pain score was 2.5 (±2.6). The overall assessment of disease activity score was 2.5 (±2.7) while the mean physician global disease assessment score was 1.6 (±1.9). There was a positive correlation between physician and parent/patient assessment of disease activity ($c=0.50$, $p<0.001$). Parent report of pain was highly correlated with parent/patient report of disease activity ($c=0.75$, $p<0.001$), however, the correlation of parent/patient assessment of pain with physician assessment of disease activity was a much less robust association ($c=0.43$, $p<0.001$). When adjusted for pain, physician and parent/patient assessment of disease activity only had a weak correlation ($c=0.30$, $p<0.001$), indicating perceptions of pain by physicians and parents contributed strongly to assessments of disease activity.

Conclusion: We found that global assessment of disease activity between physician and parent/patient in a large cohort of patients with JIA was only modestly correlated. However, parent/patient report of pain correlated strongly with parent/patient report of disease activity but not with the physician report of disease activity. This suggests that parents or patients may take pain from JIA into more account when assessing overall disease activity, compared to physicians. These discrepancies suggest there are areas where communication between physicians and parents/patients could be improved. Poor communication may lead to difficulties regarding assessment of disease status and therapeutic efficacy and could possibly affect medication adherence and medical decision-making.

262

Psoriasis in a First-Degree Relative As An Exclusion Criterion Contributes to Classification of Children As Having Undifferentiated Juvenile Idiopathic Arthritis. Mercedes O. Chan[1], Jaime Guzman[2] and Ross E. Petty[3]. [1]BC Children's Hospita/University of British Columbia, Vancouver, BC, [2]BC Children's Hospital, Vancouver, BC, [3]BCs Children Hosptial, Vancouver, BC

Background/Purpose: According to the International League of Associations for Rheumatology (ILAR) criteria, undifferentiated juvenile idiopathic arthritis (U-JIA) includes children who meet criteria in more than 1 category or fail to meet criteria for 1 of the other 6 categories. Classification requires application of 5 exclusion criteria: 1. psoriasis in the patient or a first-degree relative; 2. arthritis beginning after the 6th birthday in an HLA-B27 positive male; 3. HLA-B27 associated disease in a first-degree relative; 4. rheumatoid factor (RF) positivity; and 5. the presence of systemic JIA (SoJIA). The most frequent reasons for categorization of a patient as U-JIA are not clear.

Methods: Two independent reviewers extracted information from available charts of children with U-JIA at our center including inclusion and exclusion criteria. Discrepancies were resolved by consensus. Charts of children classified as juvenile psoriatic arthritis (JPsA) were also reviewed to determine the necessity for the history of psoriasis in a first-degree relative to classify children in this category.

Results: Of the 21 patients classified as U-JIA, in 11 it was due to having a first-degree relative with psoriasis; in 6 it was due to having a first-degree relative with psoriasis and arthritis beginning after the 6th birthday in an HLA-B27 positive male; in 3 it was due to arthritis beginning after the 6th birthday in an HLA-B27 positive male alone; and in 1 neither HLA-B27 status nor a history of psoriasis in a first-degree relative contributed to classification.

Chart reviews of 25 children with JPsA revealed that none were classified as JPsA on the basis of a history of psoriasis in a first-degree relative alone.

The table shows the JIA categories that children would be assigned to if the exclusion criterion "history of psoriasis in a first-degree relative" and/or "arthritis beginning after the 6th birthday in an HLA-B27 positive male" were disregarded for patients currently classified as U-JIA or JPsA.

Table. Diagnostic categories children with U-JIA and JPsA would belong to if the criterion "history of psoriasis in first-degree relative" and/or "arthritis after the 6th birthday in an HLA-B27 positive male" were disregarded.

	Children with U-JIA (n=21)	Children with JPsA (n=25)			
Criterion Disregarded	1st degree relative with psoriasis (n=11)	1st degree relative with psoriasis and arthritis in a B27+ male >6 years (n=6)	Arthritis in a B27+ male >6 years (n=3)	Neither B27+ male with arthritis >6 years nor 1st degree relative with psoriasis (n=1)	1st degree relative with psoriasis
Revised Category					
Oligo	6	0	1	0	0
Systemic	1	0	0	0	0
Poly RF+	1	0	0	0	0
Poly RF-	1	0	1	0	0
ERA	1	2	0	0	0
JPsA	0	0	0	0	25
U-JIA	1	4	1	1	0

Conclusion: At our center, the exclusion criterion of history of psoriasis in a first-degree relative was the most common reason determining classification of patients in the U-JIA category; and disregarding this criterion had no impact on the classification of children as JPsA. The conclusions of this small retrospective study require confirmation in a larger patient cohort before considering revision of the ILAR criteria.

263

PD-L1 in Systemic Juvenile Idiopathic Arthritis. Susan Shenoi[1], Jing-Ni Ou[1], Claudia Macaubas[2], Elizabeth D. Mellins[2], Carol Wallace[1] and Anne M. Stevens[1]. [1]Seattle Children's Hospital, University of Washington, Seattle, WA, [2]Stanford University Med Ctr, Stanford, CA

Background/Purpose: *Systemic Onset Juvenile Idiopathic Arthritis (SJIA)* is a diagnosis of exclusion. There are no diagnostic tests for SJIA, thus identifying a diagnostic biomarker is crucial to facilitate accurate diagnosis and early treatment. *Programmed death ligand-1 (PD-L1*) is expressed on hematopoeitic and parenchymal cells and regulates self-tolerance by controlling activation of T lymphocytes. PD-L1 plays an important immunoregulatory role in the chronicity of inflammatory responses. PD-L1 expression is decreased in active systemic lupus erythematosus (SLE), an autoimmune disease with loss of lymphocyte tolerance, with normal/high PD-L1 expression in SLE remission. In contrast, elevated PD-L1 expression is associated with malignancies and acute and chronic infections.

Methods: We studied PD-L1 expression on 26 SJIA subjects and compared this to 11 subjects with polyarticular JIA and 5 healthy pediatric controls. Four SJIA subjects were recruited at Seattle Children's Hospital (SCH; new onset disease, characterized as SJIA flare). Stanford Medical Center (SMC) provided 22 samples of SJIA in different stages of diseaseactivity (SJIA subjects characterized clinically as remission (n=8), mild flare (n=11) and flare (n=3). Cells were cultured overnight without stimulation. Percentage of monocytes (Mo;CD14highCD11c+) and myeloid dendritic cells (mDC; CD14lowCD11c+) with PD-L1 expression (mean %) and MFI were quantified in peripheral blood mononuclear cells (PBMCs) by flow cytometry. For controls & SJIA subjects we also assayed activated Mo (aMo;CD14+CD11c+CD16+), natural killer (NK: CD3-CD56+CD16+) & NKT cells (CD3+CD56+).

Results: A trend toward lower % of cells expressing PD-L1 and lower MFI PD-L1 was seen in SJIA compared to controls and PolyJIA subjects:

	% PD-L1 expression (mean (SD))				
	Control (n= 5)	*Poly JIA (n= 11)*	*SJIA remission (n=8)*	*SJIA mild disease (n=11)*	*SJIA flare (n=7)*
Mo	91 (9)	97 (3)	49 (25)	46 (22)	74 (18)
mDC	53 (33)	32 (12)	33 (19)	34 (22)	36 (18)
aMo	96 (4)	–	62 (27)	62 (25)	77 (15)
NK Cells	44 (30)	–	5 (3)	2 (2)	27 (36)
NKT Cells	61 (46)	–	19 (19)	20 (20)	39 (39)
	MFI PD-L1				
Mo	8349 (5431)	29913 (10325)	5286 (8244)	2806 (3211)	3476 (29966)
mDC	2087 (1786)	1829 (927)	1715 (1845)	973 (639)	1494 (1656)

Conclusion: PD-L1 expression tends to be decreased on SJIA monocytes and NK cells compared to healthy control children. PD-L1 expression was upregulated in polyarticular JIA patients, as reported in adult rheumatoid arthritis patients. Thus, decreased PD-L1 expression in SJIA is a potential a diagnostic biomarker. Abnormal PD-L1 expression could be secondary to a defect in the PD-L1 gene or a regulatory dysfunction secondary to cytokine production.

264

Application and Examination of the Key Clinical Parameters From the 2011 ACR Recommendations for the Treatment of JIA Using Electronic Medical Record-Derived Data From a Clinical Cohort. Michael L. Miller[1], Timothy Beukelman[2], George Lales[1], Sean McKenna[1], Jason Ruprecht[1], Megan L. Curran[1] and Marisa S. Klein-Gitelman[1]. [1]Children's Memorial Hospital, Chicago, IL, [2]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Treatment decisions in the 2011 ACR Recommendations for the Treatment of JIA are based upon 4 key clinical parameters: treatment group (phenotype), prognostic features, disease activity, and current therapy. However, these key clinical parameters were based largely on expert consensus and have not been extensively studied. We used cross-sectional data from the electronic medical record (EMR) of a single academic pediatric rheumatology center to classify children with JIA according to the key clinical parameters and examine the characteristics of these patients.

Methods: We used Extract/Transform/Load methodology to extract EMR data for the most recent visit of all JIA patients seen from January – April 2011. Radiology reports were searched for text identifying erosions or joint space narrowing. Treatment group, prognostic features, disease activity, and current therapy were determined for all patients. Patients with MD (MDGA) and parent/patient global (PTGA) assessment scores of zero, joint count of zero, normal inflammatory markers (when available), and no active systemic features were determined to have no disease activity.

Results: Data from 299 patients were analyzed, median 11.7 yrs (8.0, 15.1 IQR); MDGA 2 (0,3 IQR); PTGA 1 (0,3 IQR). Distribution of MDGA scores resulted in few patients meeting criteria for high disease activity. Of 173 patients in the "History of ≤ 4 joints" group, 120 had oligoarticular JIA, 35 had enthesitis related arthritis (ERA), and 18 had undifferentiated arthritis, by ILAR criteria. Of the 105 patients in the "History of ≥ 5 joints" group, 14 had extended oligoarticular JIA, 5 ERA, 66 had polyarticular RF- JIA, 18 had polyarticular RF+ JIA, and 3 had undifferentiated arthritis. 20 patients had systemic arthritis and only 1 patient fit the active sacroiliac arthritis treatment group. Methotrexand and TNFi were used more frequently in patients with a history of ≥5 joints.

	N	Age (median, IQR)	RF+	Joint Count (median, IQR)	MDGA (median, IQR)	PTGA (median, IQR)	Current MTX use	Current TNFi use

* Patients in the "History of ≥5 joints" category were more likely to have a poor prognosis than those in the "History of ≤ 4 joints" category ($p<0.0001$, X^2 test).

Conclusion: In this cross sectional study, we found that patients with a history of ≥5 joints, all RF positive, were more likely to have indicators of poor prognosis, compared to patients with a history of ≤4 joints. In contrast, disease activity distributions were similar for the two groups. The key clinical parameters from the 2011 ACR Treatment Recommendations for JIA can be

applied to EMR-derived data in an automated fashion. Future longitudinal studies will address real-time physician guidance for treatment decisions and evaluate clinical outcomes resulting from adherence to the Recommendations.

Long-Term Efficacy and Safety of Adalimumab for up to 6 Years in Patients with Juvenile Idiopathic Arthritis. Daniel J. Lovell[1], Nicolino Ruperto[2], Andreas Reiff[3], Lawrence K. Jung[3], Gloria Higgins[3], Isabelle Koné-Paut[2], Olcay Y. Jones[3], Melissa J. McIlraith[4], Nupun Andhivarothai[5], Hartmut Kupper[6], Edward H. Giannini[3], Theresa Peterson[5] and Alberto Martini[2]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]PRINTO-IRCCS, Genova, Italy, [3]PRCSG-Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Abbott, Rungis, France, [5]Abbott, Abbott Park, IL, [6]Abbott, Ludwigshafen, Germany

Background/Purpose: Adalimumab (ADA) has been shown safe and effective in a study of juvenile idiopathic arthritis (JIA) patients (pts) aged 4–17 years when dosed every other week for up to 3 years.[1] The purpose of this report is to evaluate the long-term efficacy and safety of ADA treatment for up to 6 years in JIA pts.

Methods: Pts with polyarticular course JIA were enrolled in a phase 3, randomized-withdrawal, double-blind (DB), stratified, parallel-group study, which consisted of a 16-wk open-label (OL) lead-in, a 32-wk DB phase, and an up to 5 year OL extension (OLE) phase that included BSA dosing (24 mg/m^2, max 40 mg) prior to a switch to a fixed dose (FD) of 20 mg for patients weighing ≤30 kg, and 40 mg for those >30 kg. Pts were required to achieve an American College of Rheumatology Pediatric 30% (ACR Pedi 30) during the OL lead-in to qualify for entry into the DB phase. Responses to ADA were evaluated based on ACR Pedi 30/50/70/90 and changes in JIA core set variables relative to baseline. Pts were monitored for adverse events (AEs).

Results: Approximately 79% of patients entering the study were female, with a mean age of 11 years and a mean disease duration of 3.8 years. The mean baseline Physician's Global Assessment of disease activity (PhyGA) was 58.9, Parent's Global Assessment of overall well-being (PaGA) was 48.3,active joint count (AJC) was 17.2, and Disability Index measured by the Childhood Health Assessment Questionnaire (CHAQ) was 1.1. Among the 171 pts who enrolled in this study, 144 (84%) met ACR Pedi 30 response criteria at week 16, but 133 (78%) entered the DB phase. A total of 128 (75%) continued to the OLE (initial BSA dosing), and 106 (62%) of these pts moved on to the FD phase. Sixty-two pts completed at least 5 years in the OLE. Most pts who discontinued in the OLE were lost to follow-up or withdrew consent. The most frequent concomitant anti-rheumatic medications used during the OLE were methotrexate, non-steroidal anti-inflammatory drugs, and steroids. ACR Pedi 30/50/70/90 responses and improvements in JIA core set variables were sustained in pts who completed the study and reached ~240 weeks in the OLE phase (**Table**). Of the 171 pts who received any ADA, 16 (9.4%) discontinued due to AEs. Eleven (6.4%) pts experienced serious infectious events (SIEs), and 1 (0.6%) had an opportunistic infection (cytomegalovirus). No deaths, malignancies, TB, demyelinating disease, or lupus-like reactions were reported.

Table. Observed ACR Pedi Responses and JIA Core Variables at the Last Study Visit for all ADA-treated Pts who Completed at Least 240 Weeks in the OLE (n=62)

ACR Pedi 30/50/70/90,%	95/90/82/69
PhyGA, mean	8.9
PaGA, mean	7.5
AJC, mean	1.6
Disability Index (CHAQ), mean	0.2

ACR indicates American College of Rheumatology; AJC, active joint count; CHAQ, Childhood Health Assessment Questionnaire (range: 0–3); PaGA, Parent's Global Assessment of overall well-being (range: 0–100 mm); PhyGA, Physician's Global Assessment of disease activity (range: 0–100 mm).

Conclusion: ADA was efficacious and well tolerated in JIA patients aged 4–17 years. Clinical responses and improvements in disease activity were maintained for up to 6 years with ADA. When compared with the 3 year study results, no new safety signals were observed through 6 years of ADA treatment.[1] No malignancies or deaths were reported.

Effectiveness of Nonsteroidal Antiinflammatory Drug Monotherapy in Children with Systemic Juvenile Idiopathic Arthritis. Meredith P. Riebschleger, Jasmine Stannard, Matthew M. Davis, Sarah J. Clark and Barbara S. Adams. University of Michigan Health System, Ann Arbor, MI

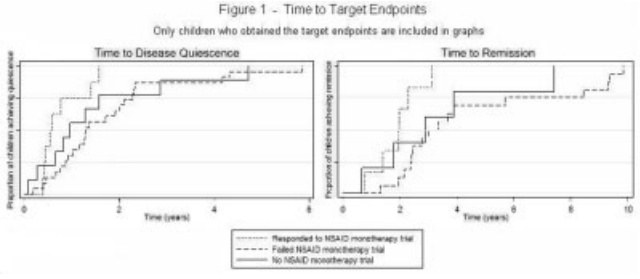
Background/Purpose: Traditionally, many pediatric rheumatologists have treated systemic juvenile idiopathic arthritis (sJIA) with a pyramid approach, starting with NSAID monotherapy prior to initiating DMARDs or biologic agents. Despite widespread use, the likelihood of response to NSAID monotherapy has not been well characterized. In addition, some clinicians have begun to advocate for the use of biologic agents as first-line therapy for all patients with sJIA, despite potential risks of pain, infection, and malignancy. The goals of this study are (1) to determine the frequency of clinical response to NSAID monotherapy in sJIA, and (2) to identify factors associated with that response.

Methods: We conducted a single-center cohort study of children aged 0–18 years who were diagnosed with sJIA between 1/1/2000 and 12/31/2009. Children who met ILAR criteria for sJIA and had at least 6 months of follow-up from the time of initial presentation were included. Outcomes included disease quiescence, defined as symptom-free with no active arthritis on exam and normal labs, if done; and remission, defined as disease quiescence off medications. Independent variables included patient demographics, disease characteristics, and medication regimens. Statistical analyses included chi square and Kruskal-Wallis tests for bivariate comparisons and time to event analyses for time to disease quiescence and remission. Continuous variables are presented as medians with interquartile ranges. Categorical variables are presented as frequencies.

Results: Of the 48 children in the cohort, 35 (73%) underwent an initial trial of NSAID monotherapy. Eight children (23%) experienced disease quiescence on NSAIDs alone and 6 achieved remission. Table 1 compares patient characteristics and clinical outcomes for the 3 groups of children in the cohort. Most children who responded to NSAID monotherapy had improvement within the first 2 months. The median delay to escalation of therapy for children who failed NSAID monotherapy was 1.2 months (IQR 0.7–1.8 months). The clinical outcomes of children who failed NSAID monotherapy were not significantly different than those of children who did not undergo a trial.

Table 1.

	Responded to NSAID monotherapy trial (N=8)	Failed NSAID monotherapy trial (N=27)	No NSAID monotherapy trial (N=13)	p value
Patient Characteristics				
Male	38%	52%	31%	42
Age at presentation (years)	2.8 (2.2–4.1)	5.4 (2.0–11.7)	5.5 (2.1–13.4)	.24
Time from onset of symptoms until presentation (years)	0.1 (0.1–0.2)	0.1 (0.1–0.2)	0.2 (0.1–0.3)	.26
Hospitalized at presentation	13%	44%	31%	.23
CRP at presentation (mg/dl)	7.3 (6.0–8.8)	7.4 (5.3–14.1)	12.2 (10.3–13.0)	.09
Suspected macrophage activation syndrome at presentation	0%	11%	31%	.11
Number of joints involved at presentation	2 (1–3)	1 (0–5)	4 (1–12)	.50
Maximum number of joints involved in the first year after presentation	2 (2–3)	8 (4–18)	10 (6–15)	<.01
Clinical Outcomes				
Achieved disease quiescence	100%	85%	69%	.17
Time to disease quiescence (years)	0.6 (0.4–1.1)	1.3 (0.9–2.3)	1.0 (0.6–1.6)	<.04
Achieved remission	75%	59%	38%	.23
Time to remission (years)	2.1 (1.5–2.4)	3.5 (2.6–7.2)	3.1 (1.9–4)	<.01



Conclusion: NSAID monotherapy is able to achieve disease quiescence in a subset of children with sJIA. A short trial of NSAID monotherapy does not appear to result in worse outcomes, even for children who fail that trial. These findings indicate that a trial of NSAID monotherapy should be considered for some children with sJIA, prior to starting more aggressive treatment with DMARDs and biologic agents.

Can Long-Term Use of Tocilizumab Induce Drug-Free Remission in Systemic Juvenile Idiopathic Arhtritis Refractory to Steroid Therapy?
Tomohiro Kubota[1], Yuichi Yamasaki[1], Junko Yasumura[2], Naomi Kuwada[3], Yukiko Nonaka[1], Tomoko Takezaki[1], Harumi Akaike[1], Yasuhito Nerome[1], Hiroyuki Imanaka[1] and Syuji Takei[1]. [1]Kagoshima University, Kagoshima City, Japan, [2]Hiroshima University, Hiroshima City, Japan, [3]Kumamoto University, Kumamoto City, Japan

Background/Purpose: Tocilizumab (TCZ), a humanized anti-human interleukin-6 receptor monoclonal antibody developed in Japan, is firstly approved in Japan as a biologic agent for systemic juvenile idiopathic arthritis (sJIA) in the world[1)]. Therefore, the purpose of this study is to investigate whether long-term TCZ therapy can induce drug-free remission in the sJIA patients refractory to conventional therapy.

Methods: Cumulative incidence of patients who attained our serial treatment goal of 1st) decreased dose of steroid less than 0.2mg/kg/day of prednisolone (PSL), 2nd) prolongation of TCZ interval from every 2w to 3w, 3rd) discontinuation of PSL, and 4th) discontinuation of TCZ was evaluated by Kaplan-Meier method. 20 patients who were resistant to 3 times of consecutive weekly intravenous methyl-prednisolone pulse therapy (3 consecutive days) in active phase and/or were refractory to long-term oral steroid therapy for more than 6 months were recruited, and treated by 8 mg/kg of TCZ for more than 6 months (max 7 years).

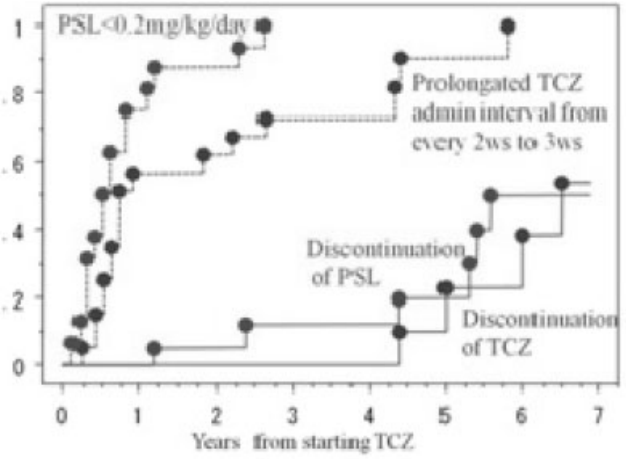

Fig: Cumulative incidence of patients attained each end-point

Results: Patient characteristics at starting TCZ were as follows: mean age was 8.5 years (2.2–20.2); mean disease duration of sJIA was 4.2 years (0.1–16.2 years); mean PSL dose was 0.5mg/kg/day (0.1–1.5).

Of 16 patients treated with more than 0.2mg/kg/day of PSL at the baseline, incidence of patient attained 1st endpoint of reduced PSL dose to <0.2mg/kg/day was 50% at 6 months and 75% at 1 year after initiating TCZ. The 2nd endpoint of prolongation of interval of TCZ administration from every 2 weeks to 3 weeks was attained in 57% of patients at 1year, in 73% at 3years, and in 91% at 5 years after starting TCZ.

Discontinuation of PSL, 3rd endpoint of this study, was attained in 12% of patients at 3years, in 20% at 5years, and in 50% at 6 years of TCZ therapy. Discontinuation of TCZ, the primary endpoint of this study, was attained in 23% of patients at 5yeras, and in 38% of patients at 6 years after TCZ induction. There were no patients who ceased TCZ therapy due to side effect during the study period (mean 4.5 years).

Conclusion: TCZ was effective and well-tolerated in Japanese sJIA patients in the long-term clinical setting. TCZ can induce drug-free remission in sJIA patients refractory to conventional steroid therapy.

Radiological Cervical Spine Involvement In Polyarticular Idiopathic Juvenile Arthritis.
Muriel Elhai[1], Ramin Bazeli[2], Veronique Freire[2], Antoine Feydy[2], Andre Kahan[1], Chantal Job-Deslandre[1] and Julien Wipff[1]. [1]Rheumatology A, Paris Descartes University, Cochin Hospital, APHP, Paris, France, Paris, France, [2]Radiology B, Paris Descartes University, Cochin Hospital, APHP, Paris, France, Paris, France

Background/Purpose: Several studies have assessed radiological involvement of the cervical spine in juvenile idiopathic arthritis (JIA) with a large range of prevalences (5–80%), but most studies have been performed in 50's, in symptomatic JIA and without differentiating subsets of JIA. In patients with a polyarticular JIA (pJIA), apophyseal joint ankylosis and atlanto-axial impaction are the most frequently described. To describe structural inflammatory cervical spine involvement in pJIA regardless of cervical symptoms and to compare observed lesions to those seen in rheumatoid arthritis (RA) using a cross-sectional observational study.

Methods: All consecutive pJIA followed in a transition program have been included in this study. Age, sex, disease duration, history of cervical manifestations (pain or limitation of motion) and medical or surgical treatments were collected. Laboratory tests (ESR, CRP, rheumatoid factors, anti-CCP and antinuclear antibodies) were performed. Standard radiographies of the cervical spine (antero-posterior, lateral view with flexion and extension and open mouth view), hands, feet and hip were analysed by two independent radiologists blinded to the diagnosis. A third reader established a consensus when required. A RA control group (<55years), matched for sex and disease duration, was recruited. Data were statistically analyzed using chi-square tests and the Student's t-test. A multivariate stepwise logistic regression analysis was also performed for all variables identified with $p \leq 0.10$. $P < 0.05$ was considered statistically significant.

Results: 58 pJIA (48 females/10 males) and 59 RA (52/7) were included. Mean age was 23.6±10.0 years and 43.2±9.6 years, respectively and mean disease duration 13.1±11.1 and 12.2±7.1 years, respectively. 60% and 80% (p=0.02) were RF positive and 57% and 79% (p=0.02) anti-CCP positive. Clinical involvement of the cervical spine was found in 42% and 44% of pJIA- and RA-patients, respectively. Radiographies showed inflammatory lesions in 38/58 pJIA (66%) and 40/59 (68%) RA-patients and respectively 3/58 and 2/59 patients underwent cervical surgery. In pJIA, the most frequent lesions were anterior atlantoaxial subluxation (53%), erosion of the odontoid process (34%), C1-C2 arthritis (26%) and apophyseal joint arthritis (26%). Cervical lesions observed in pJIA were similar to those in RA in adults except for ankylosis (8/38 vs 0/40, p<0.01). Presence of radiographic cervical lesions correlated with a more severe disease phenotype: higher number of DMARDs or biological agents per patient, more erosive disease (hands and feet) and higher frequency of surgery. In multivariate analysis, only a higher number of biological agents was associated with radiographic cervical lesions (p=0.04, OR=2.84 [1.01–7.96]). 50% of pJIA with radiographic abnormalities had no clinical symptoms.

Conclusion: Structural cervical spine involvement is a frequent manifestation in pJIA followed at adulthood, is asymptomatic in half of the cases and correlated with a more severe disease. Radiologic assessment of cervical spine should be done systematically at onset and regularly during the course of the disease regardless of clinical symptoms.

269

Use of Intra–Articular Steroid Injection in a Large Cohort of Children with Oligoarticular Juvenile Idiopathic Arthritis—the ReACCh Out Study.
Julie Barsalou[1], Ronald M. Laxer[2], Lori B. Tucker[3], Rae SM Yeung[4], Kiem Oen[5], Ciaran M. Duffy[6] and ReACCh Out Study Group[7]. [1]Montreal Children's Hospital, McGill University, Montreal, QC, [2]The Hospital for Sick Children, Toronto, ON, [3]BC Childrens Hospital, Vancouver, BC, [4]Hospital for Sick Children, Toronto, ON, [5]University of Manitoba, Winnipeg, MB, [6]Children's Hospital of Eastern Ontario, Ottawa, ON, [7]Ottawa

Background/Purpose: Oligoarticular juvenile idiopathic arthritis (oJIA) is the most common subtype of JIA. Common treatment strategies, including the use of intra-articular steroid injection (IAS), have not been studied in large patient groups over time. The aim of this study is to describe patients with oJIA enrolled in a longitudinal cohort of Canadian children with JIA who have received IAS, and to explore factors associated with its use.

Methods: Research on Arthritis in Canadian Children emphasizing Outcomes (ReACCh Out) is a longitudinal cohort of JIA patients enrolled within 1 year of diagnosis from 16 centres across Canada. All oJIA patients who completed 24 months of follow up were included in this study. Demographic and clinical information were collected at each study visit. Functional status and quality of life were measured using the Childhood Health Assessment Questionnaire (CHAQ) and the Juvenile Arthritis Quality of Life Questionnaire (JAQQ), respectively. Early IAS was defined as an IAS injection given within 3 months of JIA diagnosis. A multivariate logistic regression model was used to identify predictors of early IAS.

Results: Data for 324 oJIA patients (71% female) enrolled in the ReACCh Out study were available. The median age at symptom onset and the median age at diagnosis were 4,0 (interquartile range (IQR) 2,0–9,0) and 5,0 (IQR 2,0–9,5) years old, respectively. The median time from symptom onset to diagnosis was 4,0 (IQR 2,0–6,0) months. The oJIA subtype was further divided into an oligo-persistent (67%) and oligo-extended (14%) course (subtype unavailable in 19%). At baseline, the median number of joints considered active was 1 (IQR 1–2) and 9% of patients had a leg length discrepancy (LLD) of more than 1cm. The median baseline CHAQ score was 0,25 (IQR 0-0,75) and JAQQ score was 2,3 (IQR 1,7-3,2). One hundred and seventeen (36%) oJIA patients received at least one IAS injection during the 24 months follow-up period: 54 (46%) had an early IAS injection as compared to 63 (54%) who received a late IAS. During the 24 months follow up period, 404 IAS procedures were performed on 117 patients. In 116 cases (29%), the IAS was used as the sole therapeutic agent. In the univariate logistic regression analysis, the following baseline variables were associated with an early IAS ($p<0,1$): recruiting centre, being on medication at enrollment, antinuclear antibody positivity and a higher erythrocyte sedimentation rate. Age at diagnosis, time from symptom onset to diagnosis, subtype of oJIA, number of active joints at baseline, presence of LLD at baseline and baseline CHAQ and JAQQ scores were not significantly associated with early IAS. The multivariate logistic regression model yield no independent predictors of early IAS.

Conclusion: More than one third of children with oJIA in this large cohort received an IAS injection, with nearly half of these performed within 3 months of diagnosis. Less than one third of IAS were done without concomitant pharmacotherapy. Practice differences between pediatric rheumatology centres in this multicentre study contributed to differences in use of IAS injections. No independent predictors for receiving an early IAS were found in this cohort of patients.

270

Perception of Health Status in Young Adult Patients with Juvenile Idiopatic Arthritis: it's Good to Be Better but it's Better to Be Good. Elisa Gremese, Graziella D'Antona, Laura Messuti, Luca Petricca, Maria Rita Gigante and Gianfranco Ferraccioli. Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: The outcome of juvenile idiopatic arthritis (JIA) is generally regarded as "good", even though many patients have marked functional disability and active disease at 10 years of follow-up. Introduction of anti-TNF modified the course of JIA. The aim of the study was to evaluate quality of life (QOL) in young adults with JIA, using validated measures of functional disability and generic health status.

Methods: 29 JIA patients (>18 years old) switched from a pediatric to an adult rheumatologic setting and 29 healthy controls matched for age and sex were evaluated. Functional disability and generic health status/QOL were assessed by the Health Assessment Questionnaire (HAQ) and the Short Form 36-item health profile (SF-36), respectively. SF-36 physical summation score (PSS) and mental summation score (MSS) were considered to reduce the number of comparisons from 8 scales to 2 summary measures. A p value of < 0.05 was regarded as statistically significant.

Results: The 29 JIA patients had a mean age of 20.5 ± 2.8 years, a mean disease duration of 11.6 ± 6.3 years, an HAQ of 0.33 ± 0.47, a DAS of 1.4 ± 1.1. 82.4% were female, 8/29 (27.6%) had active joint disease, 16/29 (55.2%) were under treatment with anti-TNF agents and/or DMARDs, 13 only with DMARDs and/or NSAIDs. JIA patients showed a worse PSS ($p=0.02$) and in particular physical functioning ($p<0.001$) than healthy subjects. Taking into account only the 15 JIA patients with disease in remission and no physical disability (DAS<1.6 and HAQ=0), this group of patients presented a better MSS ($p=0.04$) and in particular of social functioning ($p=0.01$) with respect to control subjects, with no differences in physical function scores. Moreover, JIA patients taking anti-TNF drugs showed higher bodily pain score ($p=0.05$) but higher vitality score ($p=0.05$) that patients not taking them.

Conclusion: Despite the presence of a disease and the long disease duration, patients with JIA in remission and without disability had a better mental health index than control subjects, suggesting that QOL from a patient's perspective is dependent on a variety of factors, not just physical impairment and functional disability. Patients taking biologic drugs, indicative of a more aggressive disease, despite an higher component of bodily pain, had a better perception of their vital capacity.

Race and Other Risk Markers in Juvenile Idiopathic Arthritis-Associated Uveitis. Sheila Angeles-Han[1], Christina Pelajo[2], Larry B. Vogler[1], Christine W. Kennedy[3], Lori Ponder[3], Traci Leong[4], Jorge M. Lopez-Benitez[2], Carolyn Drews-Botsch[4], Sampath Prahalad[1] and for the CARRAnet investigators[5]. [1]Emory Univ School of Medicine, Atlanta, GA, [2]Tufts Medical Center, Boston, MA, [3]Emory Children's Center, Atlanta, GA, [4]Emory University School of Public Health, Atlanta, GA, [5]Stanford

Background/Purpose: Juvenile idiopathic arthritis-associated uveitis (JIA-U) is an inflammatory eye disease that occurs in 20% of children with JIA and can cause visual impairment and blindness. Risk factors associated with JIA-U include early age at arthritis onset, JIA subtype, young age, and ANA and HLA-B27 positivity. Few studies on JIA-U focus on African American (AA) children. In this population, the role of ANA is unclear, predisposition to JIA subtype differs, and there appears to be a lower risk of JIA-U compared to White (W) children. Hence, the risk for JIA-U may differ by race and should be explored. Our objective is to characterize the epidemiology and clinical course of children with JIA-U in a cohort of children with JIA in the CARRAnet Registry.

Methods: Children with JIA from pediatric rheumatology clinics in the US were enrolled in the CARRAnet Registry from May 2010 to June 2011. Demographic and disease-related data were collected from time of diagnosis to enrollment visit. Only children whose uveitis status was known were included. Children with JIA alone were compared to those with JIA and uveitis. Children with JIA-U were then compared based on race, specifically AA and W. N may vary in some characteristics since we excluded data that was missing or unknown.

Cases with missing and unknown data were excluded.

Results: The mean age of children with JIA-U was 10.8 years (±4.5), 80% were female and 3% were AA (Table 1). Compared to children without uveitis, they were more likely to be younger, female, require more medications, have less joint involvement, have oligoarticular disease, be ANA (+), and RF, anti-CCP and HLA-B27 (−). AA children with JIA-U were significantly different from W children and had decreased frequency of uveitis, were more likely to be male, and have oligoarticular or enthesitis related JIA (Table 2).

Conclusion: With current therapy, the prevalence estimate of JIA-U in the CARRAnet registry is 11% which consists of the largest database of children with JIA to date. Consistent with the AAP guidelines for uveitis screening, known risk markers such as the ANA, age at arthritis onset, and oligo persistent subtype were more frequent in our JIA-U cohort. However, gender and race may also be important. In concurrence with the literature, this cohort of JIA-U consisted of 3% AA who had a lower frequency of JIA-U compared to W children. There were significant differences in gender, and JIA subtype, although the status of ANA, RF and HLA-B27 were similar. This suggests that risk factors associated with uveitis may differ depending on race and implies that a change in the screening schedule may be appropriate, but needs further investigation.

A Meta-Analysis to Estimate the "Real" Placebo Effect in Juvenile Idiopathic Arthritis (Jia) Trials. Erkan Demirkaya[1], Roberta Galasso[1], Angelo Ravelli[2], Elena Palmisani[1], Alberto Martini[2], Angela Pistorio[3] and Nicolino Ruperto[1]. [1]IRCCS G Gaslini, Pediatria II, Reumatologia, PRINTO, Genova, Italy, [2]IRCCS G. Gaslini, Pediatria II, Reumatologia and Dipartimento di Pediatria, Università degli Studi, Genova, Italy, [3]IRCCS G Gaslini, Servizio di Epidemiologia e Biostatistica, Genova, Italy

Background/Purpose: To quantify placebo effect through a systemic review of juvenile idiopathic arthritis (JIA) trials using placebo as comparator.

Methods: This study was developed according to the PRISMA statement and pre-specified study selection, eligibility criteria, data extraction, quality assessment, and statistical analysis. Studies with parallel, cross-over or withdrawal design (open label followed by a double-blind placebo withdrawal period) were included in the analysis. Publications were retrieved from MEDLINE, Web of Science, EMBASE, and the Cochrane Controlled Trials Register from 1960 to May 2010, with literature search carried out from February to December 2010. Estimates of the placebo response rate and estimates of the placebo flare rate for the withdrawal trials with 95% Confidence Intervals (CI) were calculated.

Results: A total of 10 out of 18 trials were included in the final meta-analysis synthesis. In the 5 trials with parallel design the number of responders among the patients randomized to the placebo arms were 76/246 (30.7%) for recent studies with composite scores such as the ACR pediatric 30 criteria with a pooled placebo effect estimate (fixed effect method) equal to 30% (95% CI 24–36%).

In the withdrawal design trials the number of flared patients randomized to the placebo arms was 89/123 (72.4%) with a pooled effect estimates (percentages of placebo patients who have a flare during the double blind phase in the placebo group) equal to 74% (95% CI 67–82%).

Conclusion: This systematic review provides reference data for the mean placebo effect for parallel trials and mean placebo flare rate for trials with withdrawal design.

273

Long-Term Follow-up of Systemic Onset Juvenile Idiopathic Arthritis Patients Treated with Anakinra. Aldo Naselli[1], Andrea Accogli[1], Sabrina Chiesa[1], Jessica Tebaldi[1], Martina Finetti[2], Antonella Buoncompagni[1], Stefania Viola[1], Paolo Picco[1], Angelo Ravelli[3], Alberto Martini[2] and Marco Gattorno[1]. [1]G. Gaslini Institute, Genova, Italy, [2]IRCCS G Gaslini, Pediatria II, Reumatologia, Genova, Italy, [3]Istituto di Ricovero e Cura a Carattere Scientifico G. Gaslini, Genova, Italy

Background/Purpose: Recombinant IL-1 receptor antagonist (anakinra) is an effective treatment in a subgroup of systemic onset JIA (SoJIA). So far no information is available on the long term follow-up of SoJIA patients treated with anakinra.

Methods: Since 2005, 34 SoJIA patients (19 M, 15 F) were treated with anakinra at the staring dose of 1 mg/kg/die. Complete response was defined as the absence of systemic and articular manifestations and normal acute phase reactants at follow-up, with anakinra as a monotherapy. Other patients were considered as partial responders (still in anakinra with evidence of disease activity) or non-responders (withdrawn of Anakinra due to inefficacy or severe side effects).

Results: At baseline, the mean age was 8.4 year (range 1–17 years) with mean disease duration of 3.05 years (3 months–10.2 years). All patients had active arthritis (mean number of active joints 12.3, range 1–80), 28/34 had fever, 20/34 had skin rash. Failure of anti-TNF treatment or DMARD was observed in 11/34 and 23/34 patients respectively. Ongoing steroid treatment 33/34 patients (mean prednisone mg 0.87/kg/day, range 0.1– 3). The mean follow-up was 4.02 year (range 1.05 – 6.16). At the last follow-up 13 patients (38%) were complete responders, 5 (14%) partial responders and 16 (48%) non responder.Among complete responders, 4 patients withdrawn anakinra without relapses after a mean of 3 years of treatment, 7 are in remission using anakinra as mono-therapy, 2 patients were switched to anti IL-1 monoclonal antibody with a full response. Despite the good control of their disease 11/13 displayed at least one relapse of their disease during the follow-up with a total of 22 relapses (range 1–4 for patient). In 16 non responders patients subsequent treatments were canakinumab (1 patient), tocilizumab (5 patients), or combined immunosuppressive treatment and/or anti-TNF (10 patients), with variable response. Adverse events and complications: 13 Anakinra-treated patients had skin reactions of variable intensity and duration, in 7 patients hitching was also present without an evident skin rash. Six patients (3 responder and 3 non responders) developed a MAS during follow-up. Two non-responders patients died for acute bacterial meningitis and multi-organ failure after an episode of MAS. As previously observed, responders patients confirmed to have an higher number of active and limited joints at baseline ($p = 0.006$) and higher WBC and neutrhophils count ($p = 0.002$). These results were confirmed in the newly enrolled patients. In this latter group responder patients displayed a significantly shorter disease duration in respect to non responder patients ($p = 0.03$).

Conclusion: In responder SoJIA patients Anakinra confirm to be an effective and safe drug in the long term. The use of Anakinra is still able to dissect two distinct populations of SoJIA patients on the basis of the presence or not of a severe joint involvement with a chronic polyarticular course

274

Effects of Switching From Etanercept to Adalimumab in Juvenile Idiopathic Arthritis. Gerd Horneff[1], Ivan Foeldvari[2], Gerd Ganser[3], Johannes Peter Haas[4], Kirsten Minden[5] and Hans-Iko Huppertz[6]. [1]Asklepios Clinic Sankt Augustin, Sankt Augustin, Germany, [2]Hamburger Zentrum Kinder-und Jugendrheumatologie, Hamburg, Germany, [3]Sankt Josef Stift, Sendenhorst, Germany, [4]Childrens Hospital, Erlangen, Germany, [5]Charite, Berlin, Germany, [6]Krinikum Bremen-Mitte, Bremen, Germany

Background/Purpose: Etanercept has proved to be effective in the majority of JIA patients (pts.). Pts. who do not tolerate or do not benefit from treatment might benefit from switching to a second TNF-inhibitor.

To analyze reasons of switching and effects of switching from Etanercept to Adalimumab.

Methods: Data of the German Etanercept in JIA Registry covering a total of >1400 pts. recruited over a ten year period and followed in a multicentre, prospective observational study were used for analysis.

Results: Of a total of 115 pts. (8% of all pts.) switched from Etanercept to a second biologic, 80 patients (70%) switched to Adalimumab. This patient cohort resembles the total registry population with regard to JIA category distribution, gender, age at onset, disease duration and positivity for ANA or HLA-B27. A history of uveitis however was more frequent than in the total registry population. (13% vs. 7%, p=0.07). Reasons for switching were inefficacy or loss of efficacy of Etanercept in 60, uveitis in 12, occurrence of Crohn's disease in 1, patient's request in 2, decision of adult rheumalogist in 1 and other adverse events in 4 cases.

Upon Etanercept, all single core set response criteria showed response to treatment but also indicated residual disease activity which slightly decreased after switching to Adalimumab. When etanercept was discontinued due to inefficacy or loss of efficacy, this patient cohort still showed a PedACR30/50/70 response in 52%/34%/24% of pts., which was markedly lower than the maximum documented response rate on Etanercept in this cohort of 89%/85%/73%. After switching to Adalimumab PedACR30/50/70 response rates reincreased to 79%/74%/54%.

Active uveitis was the reason for switching in 12 pts. All but 1 of them showed a marked clinical response of their arthritis on Etanercept. In this patient sub-cohort, the PedACR30/50/70 increased slightly from 91%/67%/50% to 100%/90%/80% after switching to adalimumab.

There were only few patients who switched due to intolerance of Etanercept. In one patient Crohn's disease occurred while on Etanercept. In this patient the arthritis had responded dramatically to Etanercept and continued to be silent on Adalimumab.

During 216 treatment years on Etanercept in the pts-cohort there were 61 AEs (0.29/y) including 12 cases with uveitis flares and 11 SAE (uveitis, Crohn's, septic arthritis, flare). During 76 treatment years on ADA there were 19 AEs (0.35/y) including 2 uveitis flares and 2 SAE (both neuropsychatric).

Conclusion: Inefficacy or loss of efficacy is an uncommon reason for discontinuation of Etanercept. If this happened nevertheless Adalimumab was chosen in many patients. Switching from Etanercept to Adalimumab resulted into a decrease of disease activity parameters while the number of patients fulfilling the PedACR-criteria increased. Tolerability of both TNF-inhibitors was comparable. After failure of the first anti-TNF-fusion protein, switching to a TNF-Antibody seems reasonable in JIA.

275

Clinical and Ultrasound Outcomes of Ultrasound-Guided Ankle Injection In Juvenile Idiopathic Arthritis; An Analysis of Current Clinical Practice.
Eimear Savage[1], Laura Pascoli[1] and Madeleine Rooney[2]. [1]Belfast Hospitals Trust, Musgrave Park Hospital, Belfast BT9 7JB, Northern Ireland, [2]Arthritis Research Group, Queen's University, Belfast, United Kingdom

Background/Purpose: As part of our routine practice, musculoskeletal ultrasound is performed to identify the involved structures in the ankle region in children with Juvenile Idiopathic Arthritis (JIA). Our objective was to examine clinical and ultrasound outcomes in those who have had ultrasound directed injections of the ankle joint and/or surrounding tendon sheaths.

Methods: Twenty patients with first-episodes of swollen ankles were included: (Female 15, male 5, median age 7 years, range 1–16 years, 7 oligoarticular JIA, 9 polyarticular JIA, 2 Extended Oligoarticular JIA, 2 Psoriatic JIA). They underwent ultrasound examination of the ankle region, enabling the identification of structures involved, namely ankle joint, tibialis posterior or peroneal tendon sheaths. Ankle region was injected under US guidance, using Triamcinolone or Depomedrone depending on the structure involved. Details regarding the presence of clinical ankle swelling, ultrasound findings, ankle region injected (ankle vs. tendon sheaths) and outcomes at three, six months were noted.

Results: 38 injections to the ankle region (first episode) were recorded. Thirty-seven percent had only ankle involvement, 41% with ankle and tendon sheath involvement and 22% of episodes with involvement of the tendon sheath alone (tibialis posterior and/or peroneal tendons). At six months two had required repeat injections of the region.

Follow up of all injection episodes, showed that at 3 months 31 ankles were clinically normal, 7 ankles had remained swollen, five of which had resolved at six months. Three months post injection ultrasound findings indicated 3 ankles with effusions, 2 of which persisted at 6 months requiring repeat injections. Of the 31 ankles quiescent at 3 months,8 episodes of new synovitis/tenosynovitis involving the same or a de novo ankle structure were noted at six months. One child had an ankle effusion, the remaining 7 included either tibialis posterior or peroneus longus tenosynovitis.

Conclusion: Few studies have reported the outcome of ankle injections in JIA. We report a marked improvement in clinical ankle swelling and US findings following both injection of ankle joints and tendon sheaths using US guidance. Our results appear to be significantly better than non US guided injections. In our patients, those with Polyarticular JIA more commonly required repeated injection. Those with involvement of medial and lateral ankle tendons, in particular tibialis posterior, appear to be more likely to require repeated injections to achieve full resolution of tenosynovitis. A prospective study of targeted ankle injection under ultrasound would be beneficial to confirm these findings.

276

Parent and Patient Treatment Preferences in Juvenile Idiopathic Arthritis.
Gina A. Montealegre Sanchez[1], Kabita Nanda[1], Steven J. Spalding[2], Elizabeth B. Brooks[1], Angela B. Robinson[1], Nellie K. Coughlin[1], Andrew S. Zeft[2], Denise Costanzo[2], Hulya Bukulmez[3], Joseph Sudano[3] and Nora G. Singer[4]. [1]Case Medical Center, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Metro-Health Medical Center (MHMC) and Case SOM, Cleveland, OH, [4]Case Medical Center, MetroHealth Medical Center (MHMC) and Case SOM, Cleveland, OH

Background/Purpose: Parents of patients with Juvenile Idiopathic Arthritis (JIA) are confronted with increasingly complex treatment choices. Previous studies in adults with rheumatoid arthritis (RA) have demonstrated that demographics, disease-related factors, social support, real and perceived side effects, and trust in their physician play an important role in the process of medication decision-making. JIA is the most common chronic rheumatic disease in children; yet, there are no studies evaluating patient treatment preferences in pediatric rheumatology.

Objectives: To understand the factors that influence parents' decision-making regarding treatment for their children with JIA.

Methods: Using a multicenter cross sectional prospective study design, parents with children between the ages of 1 to 17 with a definite diagnosis of JIA were invited to participate. Questionnaires were completed by one of the parents, patient if older than 13 years of age and the physician or nurse practitioner evaluating the patient.

Results: To date, 131 eligible patients have been invited to participate. Of these, 124 subjects (95%) completed the questionnaire. In a descriptive analysis, 92% of the parents were Caucasian, 82% married, 54% reported having at least a college degree and 70% were considered to have good health literacy. Most of the children were white (88%) and female (75%), with a mean age of 10 years. Parents reported a mean disease activity of 7.13 at the time of diagnosis and associated uveitis in 20% of their children. All patients had medical insurance, 75% private insurance and 24% Medicaid. When families were asked to rank their considerations prior to initiating medical treatment for JIA, medication safety ranked as the most important, followed by efficacy, associated side effects, and physician's experience with the treatment. Pediatric rheumatologists and nurse practitioners were considered by parents and patients to be the most reliable and important source for information about arthritis (90% vs. 86%) and options for medical treatment (90% vs. 88%); results correlated with a physician trust score of 85 (range 0–100). Fifty five percent of patients older than 13 years of age reported being involved in the medication decision-making process. In our cohort, 96% of parents have used nonsteroidal antiinflammatory drugs (NSAIDs) as part of the treatment for their JIA children, 81% have used disease modifying anti-rheumatic drugs (DMARDs), 59% intra-articular joint injection (IAJI), 58% biologics, 51% systemic steroids and 22% herbal medicines. Time of initiation varied; NSAIDs, DMARDs, IAJI, biologics and systemic steroids were initiated in 95%, 51%, 63%, 34% and 14% of patients within 3 months of diagnosis. Use of DMARDs and biologics increased over time, with up to 76% and 26% respectively within 6 months of diagnosis.

Conclusion: As reported in adult patients with RA medication safety, efficacy, side effects and physician's experience were considered to be the most important factors when initiating medical treatment for JIA. Pediatric rheumatologists and nurse practitioners are the most preferred source of information about JIA and options for medical treatment.

277

Intra-Articular Infliximab Treatment of Refractory TMJ Arthritis in Children with JIA.
Randy Q. Cron[1] and Peter D. Waite[2]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]Birmingham, AL

Background/Purpose: Temporomandibular joint (TMJ) arthritis occurs in up to 80% of children with juvenile idiopathic arthritis (JIA). Untreated, TMJ arthritis leads to micrognathia, poor mouth opening, facial dysmor-

phism, and life-time disability. Unlike other joints in children with JIA, TMJ arthritis responds poorly to systemic therapy, including anti-tumor necrosis factor (TNF) agents. Nevertheless, like other joints, TMJ arthritis responds to intra-articular (IA) long-acting corticosteroids, such as triamcinalone hexacetonide (TH). However, post-IA TH TMJ injections are effective in increasing inter-incisor openings and demonstrating improvement in inflammation by MRI in only about 50% of JIA patients treated. Moreover, repeated IA TH TMJ injections yield only minimal benefits. Recently, repeated IA infliximab TMJ injections, in an adult with psoriatic arthritis and severe TMJ arthritis refractory to systemic infliximab and IA corticosteroids, notably improved TMJ symptoms and halted progression of disease as noted by CT [Scand J Rheumatol 2008;37:155]. Interestingly, considerable benefit was noted after the first infliximab injection.

Methods: Five children (3 boys & 2 girls, ranging 11–21 years) with JIA and TMJ arthritis, refractory to at least 2 rounds of IA TH TMJ injections, received IA infliximab injections for their progressive TMJ arthritis. Five mg of infliximab was injected into each TMJ under deep sedation by an experienced oromaxillofacial surgeon (PDW). Approval for the procedures was attained from the UAB University Hospital Pharmacy and Therapeutics Committee. Demographic and clinical data were abstracted from the electronic medical records, and the extent and acuity of TMJ arthritis was documented by TMJ MRI with contrast before and after IA TMJ injections. Side effects from the IA infliximab were noted if present.

Results: TMJ arthritis was progressive in 5 children with spondyloarthopathies (1 HLA-B27+ psoriatic JIA, 4 with enthesitis-related arthritis JIA, 2 of whom had inflammatory bowel disease) despite multiple prior IA TH TMJ injections. TMJ arthritis was active clinically and by MRI despite systemic anti-TNF therapy [2 on etanercept, 2 on infliximab, 1 on adalimumab, +/− methotrexate (n=3)]. At the time of the IA infliximab TMJ injections, no other joints were active by history and clinical exam. All 5 JIA patients tolerated the IA infliximab TMJ injections without any reported side effects (follow-up range, 2 to 17 months). Two of the 5 patients had follow-up TMJ MRI exams post-IA infliximab injections of the TMJs. For one patient with bilateral erosive TMJ arthritis, there was no evidence of active left arthritis and minimal synovial enhancement on the right. This was the first of 5 TMJ MRI exams that did not reveal progression of arthritis. For the other child with bilateral erosive TMJ arthritis, there was no active disease on the left but active synovial enhancement and fluid on the right. However, this was the first of 6 TMJ MRI exams without evidence of progressive arthritis.

Conclusion: IA infliximab TMJ injections in children with JIA and severe refractory TMJ arthritis appear to be safe and potentially effective means of slowing TMJ arthritis.

278

Utilization of Biologic and Non-Biologic Disease Modifying Anti-Rheumatic Drugs in the Treatment of Juvenile Idiopathic Arthritis: A Cross-Sectional Analysis of the Childhood Arthritis and Rheumatology Research Alliance Registry. Timothy Beukelman[1], Sarah Ringold[2], Trevor Davis[3], Esi M. Morgan DeWitt[4], Christina F. Pelajo[5], Pamela Weiss[6], Yukiko Kimura[7] and for the CARRAnet investigators. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]Children's Hosp Regional Med, Seattle, WA, [3]Floating Hospital for Children at Tufts Medical Center, Boston, MA, [4]Cincinnati Children's Hospital, Cincinnati, OH, [5]Tufts Medical Center, Boston, MA, [6]The Children's Hosp of Philade, Philadelphia, PA, [7]Hackensack Univ Medical Ctr, Hackensack, NJ

Background/Purpose: We characterized DMARD utilization in the treatment of JIA in clinical practice on a national level and determined patient factors associated with medication use.

Methods: We analyzed cross-sectional CARRA registry baseline enrollment data from 51 U.S. clinical sites for all children with JIA from May 2010 through May 2011. Patients were categorized into 3 discrete treatment groups comprising all categories of JIA: history of arthritis of ≤4 joints, history of arthritis of ≥5 joints, and systemic arthritis. Current and past medication use were combined. We calculated risk ratios (RR) to estimate univariate associations between patient factors and medication use. Owing to multiple comparison testing, only associations with p value <0.005 are reported.

Results: Among 1,045 children with history of ≤4 joints, 52% received methotrexate (MTX), 10% sulfasalazine (SSZ) and 1% leflunomide (LEF). MTX use was associated with psoriatic arthritis (PsA) (RR 1.5 (1.3–1.8)), uveitis (RR 1.8 (1.6–2.0)), and negatively associated with enthesitis related arthritis (ERA) (RR 0.7 (0.6–0.8)). SSZ use was associated with ERA (RR 4.0 (2.8–5.8)) and sacroiliac (SI) tenderness (RR 4.5 (3.2–6.6)). Among children with history of ≤4 joints, the only biologic class received was TNF inhibitor (TNFi) by 26% (14% of these had not received MTX, LEF, or SSZ). TNFi use was associated with PsA (RR 1.8 (1.4–2.5)), ERA (RR 1.6 (1.3–2.0)), uveitis (RR 2.0 (1.7–2.5)), inflammatory bowel disease (RR 2.5 (1.7–3.5)), SI tenderness (RR 2.0 (1.6–2.6)), and enthesitis (RR 1.8 (1.4–2.3)). TNFi use without MTX, LEF, or SSZ was associated with ERA (RR 2.9 (1.6–5.1)) and enthesitis (RR 3.3 (1.9–5.8)).

Among 1,443 children with history of ≥5 joints, 83% received MTX, 8% SSZ, and 5% LEF (only 1 of these had not received MTX). MTX use was associated with RF+ polyarthritis (RR 1.1 (1.1–1.2)), CCP antibody (RR 1.2 (1.2-1.2)), and negatively associated with ERA (RR 0.7 (0.6–0.8)). SSZ use was associated with ERA (RR 3.9 (2.8–5.6)) and SI tenderness (3.2 (2.3–4.7)). Among children with history of ≥5 joints, 56% received any biologic: 56% received any TNFi (6% of these had not received MTX, LEF, or SSZ), 4% abatacept (2 of these had not received TNFi), 1% rituximab, and 1% anakinra. TNFi use was associated with RF+ polyarthritis (RR 1.3 (1.2–1.5)), CCP antibody (RR 1.4 (1.2–1.6)), uveitis (RR 1.3 (1.1–1.4)), and psoriasis rash (RR 1.3 (1.1–1.5)). TNFi use without MTX, SSZ, or LEF was associated with ERA (RR 2.9 (1.5–5.7)) and SI tenderness (RR 2.8 (1.5–5.2)). Among TNFi users, 30% received more than 1 TNFi and 6% received 3 or more TNFi.

Among 246 children with SJIA, 81% received MTX and 13% cyclosporine (19% of these had not received MTX). MTX use was associated with polyarthritis (RR 1.4 (1.2–1.7)). Among children with SJIA, 65% received any biologic: 46% received any TNFi, 39% any IL-1 inhibitor, 5% tocilizumab, 5% abatacept, and 1% rituximab. TNFi use was associated with polyarthritis (RR 1.9 (1.3–2.8)).

Conclusion: Significant proportions of children with JIA are treated with biologic agents, particularly those with RF+ polyarthritis, uveitis, or systemic arthritis. Children with ERA are less likely to receive non-biologic DMARDs prior to TNFi use.

Health Related Quality of Life and Psychosocial Developmental Trajectory in Young Female Beneficiaries with Juvenile Idiopathic Arthritis. Lotte Haverman[1], Eefje J.A. Verhoof[1], Heleen Maurice-Stam[1], Hugo S.A. Heymans[1], D. Gerlag[2], Marion A. J. Van Rossum[1] and Martha A. Grootenhuis[1]. [1]Emma Children's Hospital/Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: It is generally recognized that for all children the fulfilling of age-specific psychosocial developmental tasks in childhood is of great importance to adjustment in adult life, including participation in society. For young adults with Juvenile Idiopathic Arthritis (JIA) this is more difficult. We assume that the achievement of psychosocial milestones while growing up (psychosocial developmental trajectory) is also related to labour participation. A part of all young adults with JIA have to apply for disability benefits. This study assessed the health related quality of life (HRQOL) and the psychosocial developmental trajectory of young female beneficiaries with JIA compared to peers from the Dutch general population.

Methods: Data from the database of the Dutch EMWAjong-study, a Dutch cross-sectional study examining psychosocial factors affecting the employment of young adults with disability benefits (Wajong) because of chronic somatic diseases or childhood derived physical limitations, were used. From the EMWAjong database, 46 young adults (11.1%) reported to have JIA; including 43 females (16.1% of all females in the EMWAjong database). The data of these 43 young females with JIA were used for analyses (age: 25.8, SD = 2.3). The participants completed the RAND-36 (HRQoL) and the Course of Life Questionnaire (CoLQ; psychosocial developmental trajectory). Differences between respondents and the peer group were tested using analysis of variance and logistic regression analysis, both by group and age. Effect sizes (d) and odds ratios (OR) were calculated.

Results: The HRQOL of the beneficiaries (N = 43) was significant lower compared to the peer group on 6 out of the 8 domains: physical ($p<0.001$, $d=2.6$), social ($p<0.001$, $d=0.8$) role limitations physical ($p<0.001$, $d=1.3$), vitality ($p<0.001$, $d=0.7$), bodily pain ($p<0.001$, $d=1.4$), health perceptions ($p<0.001$, $d=1.8$). In addition, the beneficiaries achieved fewer milestones ($p<0.01$) in the autonomy (OR 0.26), social (OR 0.23–0.39) and psychosexual domains (OR 0.38–0.47) than the peer group.

Conclusion: Young females with JIA who have to apply for disability benefits are at risk for impaired HRQOL and a delay in their psychosocial developmental trajectory. We recommend parents, health care providers, occupational therapists and schools to pay systematic attention to the development of social and independent functioning of children with JIA in order to optimise their adaptation to society at the time of transition to adulthood.

280

Enthesitis Is a Significant Predictor of Decreased Quality of Life, Function, and Arthritis-Specific Pain Across Juvenile Idiopathic Arthritis (JIA) Categories: Preliminary Analyses From the CARRAnet Registry. Pamela Weiss[1], Timothy Beukelman[2], Laura E. Schanberg[3], Yukiko Kimura[4], Robert A. Colbert[5] and CARRANet Investigators[6]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]Duke University Medical Center, Durham, NC, [4]Hackensack Univ Medical Ctr, Hackensack, NJ, [5]NIAMS NIH, Bethesda, MD, [6]Stanford

Background/Purpose: Descriptions of quality of life, function, and level of pain of JIA and differences in these outcomes between JIA categories are sparse. Additionally, the relative impact of clinical factors such as enthesitis, active joint count, and medications on quality of life, function, and pain in JIA have not been well described.

Methods: We conducted a retrospective cross-sectional study of baseline data for children with JIA who were enrolled in the CARRAnet registry between May 2010 and June 2011. The CARRAnet registry is a multicenter registry of U.S. children with rheumatic diseases organized by the Childhood Arthritis Rheumatology and Research Alliance (CARRA). Differences in clinical characteristics between JIA categories were compared using the Kruskal-Wallis or chi-square test, as appropriate. We tested whether certain clinical characteristics of JIA were associated with scores on the Childhood Health Assessment Questionnaire (CHAQ), Health Related Quality of Life (HRQOL), and parent/child arthritis-specific pain visual analogue scale (VAS) using multivariable linear and ordinal logistic regression, as appropriate.

Results: During the study period there were 2,571 patients evaluated for JIA. Patient characteristics by JIA category are presented in Table 1. Scores on the CHAQ, HRQOL, and parent/child pain VAS differed significantly between JIA categories (Table 1). Significant clinical predictors of a worse CHAQ score were a having RF+ polyarticular disease ($p=0.02$), oligoarticular extended disease ($p=0.03$), Enthesitis-related arthritis (ERA) ($p<0.01$), higher active joint count ($p<0.01$), enthesitis ($p=0.01$), and current non-steroidal anti-inflammatory (NSAID), biologic, or steroid use (all $p<0.01$). Significant clinical predictors of a worse HRQOL score were older age ($p<0.01$), systemic JIA ($p=0.01$), ERA ($p=0.02$), higher active joint count ($p<0.01$), and current NSAID, biologic, or steroid use (all $p<0.01$). Significant clinical predictors of a higher pain VAS score were older age ($p<0.01$), ERA ($p<0.01$), higher active joint count ($p<0.01$), enthesitis ($p<0.01$), and current NSAID, biologic, or steroid use (all $p<0.01$). The pair-wise correlation between standardized z-scores of physician global assessment of disease activity and parent/patient-reported CHAQ, HRQOL, and arthritis-specific pain VAS scores were low (0.37, 0.30, and 0.43, respectively).

Table. Patient characteristics by JIA subtype

	Systemic	Poly RF-	Poly RF+	Oligo persistent	Oligo extended	PsA	ERA	Undifferentiated	p-value
N (%)	232 (9)	761 (30)	190 (7)	697 (27)	210 (8)	161 (6)	268 (10)	52 (2)	
Active joint count, median (IQR)	0 (0, 2)	0 (0, 2)	1 (0, 4)	0 (0, 1)	1 (0, 2)	0 (0, 2)	1 (0, 2)	0 (0, 1)	<0.01
Enthesitis N (%)	2 (1)	10 (1)	2 (1)	2 (0.5)	6 (3)	11 (7)	62 (24)	3 (6)	<0.01
CHAQ, median (IQR)	0.1 (0, 0.6)	0.1 (0, 0.6)	0.3 (0, 0.7)	0 (0, 0.3)	0.1 (0, 0.6)	0.1 (0, 0.5)	0.3 (0, 0.6)	0.3 (0, 0.6)	<0.01
Parent/child pain VAS	1 (0, 4)	2 (0, 5)	2 (1, 5)	1 (0, 3)	1 (0, 4)	2 (0, 4)	3 (1, 6)	2 (0, 4)	<0.01
HRQOL N(%)	51 (22)	157 (21)	29 (15)	221 (32)	54 (26)	38 (24)	41 (16)	13 (25)	<0.01
Excellent	85 (37)	323 (43)	74 (39)	305 (44)	100 (48)	65 (40)	110 (41)	23 (44)	
Very good	81 (35)	246 (32)	75 (40)	154 (23)	53 (25)	56 (35)	99 (37)	15 (29)	
Good	11 (5)	29 (4)	11 (6)	9 (1)	2 (1)	2 (1)	16 (6)	1 (2)	
Poor	2 (1)	1 (<1)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	
Very Poor									
Physician global VAS, median (IQR)	1 (0, 3)	1 (0, 2)	2 (0, 3)	1 (0, 2)	1 (0.3)	1 (0.2)	1 (0, 2)	1 (0, 2)	<0.01

Conclusion: Significant differences on the CHAQ, HRQOL, and parent/child pain VAS exist across JIA categories. The ERA category consistently predicted worse scores on all 3 measures. Enthesitis is a previously unrecognized significant predictor of decreased function and increased pain. Future studies should investigate how to better quantify enthesitis and its response to therapy.

281

A Cross Sectional Study of Juvenile Idiopathic Arthritis in African American Children Compared with Non-Hispanic White Children in the Childhood Arthritis and Rheumatology Research Alliance Registry. Sampath Prahalad[1], Sheila Angeles-Han[1], Christina F. Pelajo[2], Christine W. Kennedy[1], Lori Ponder[1], Jorge M. Lopez-Benitez[2], Larry B. Vogler[1] and CARRANet Investigators[3]. [1]Emory University School of Medicine, Atlanta, GA, [2]Tufts Medical Center, Boston, MA, [3]Stanford

Background/Purpose: JIA is the most common chronic childhood arthropathy with an estimated prevalence of ~1/1000 children under 16 years of age. Although JIA affects male and female children of all races, there are only few epidemiologic investigations in small cohorts that describe the characteristics of JIA in African American (AA) children. Our objective is to compare disease characteristics between AA and Non-Hispanic White (NHW) children with JIA enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, the largest multicenter observational Registry.

Methods: Children with JIA from pediatric rheumatology clinics in the US were enrolled in the CARRAnet Registry from May 2010 until June 2011. Demographic and disease-related data were collected from time of diagnosis to enrollment visit. Children reporting Hispanic ethnicity and those who categorized themselves as more than one race were excluded. Non-Hispanic African American children with JIA were compared with Non-Hispanic White children with JIA. Nominal variables were compared using Chi square or Fisher's exact tests. Continuous variables were compared using Student's T test.

Results: In all, 2167 NHW children and 125 AA children were analyzed. Table 1 shows demographic and disease characteristics of NHW and AA children. AA children with JIA were significantly older at disease onset, presentation and enrollment less likely to be female and have a family history of autoimmunity. There were significant differences in the frequencies of different JIA subtypes between AA and NHW children. AA children were more likely to have RF+ polyarticular JIA and less likely to have psoriatic JIA or uveitis. Laboratory variables demonstrated that AA children with JIA were less likely to have positive ANA and HLA B27, and more likely to have confirmed RF and CCP compared to NHW children. The differences in age of onset between AA and NHW children persisted after excluding polyarticular RF+ JIA (6.0 vs 8.4 years; $p < 2.5\times10^{-6}$).

Table 1. Characteristics of NHW and AA children with JIA*

	NHW	AA	p
Total Number	2167	125	
Age at baseline visit (mean ±SD)	11.4 ± 4.7	12.8 ± 4.4	**$<7\times10^{-9}$**
Age at symptom onset (mean ± SD)	6.2 ± 4.3	8.8 ± 4.3	**$<4\times10^{-9}$**
Age first seen by pediatric rheumatologist (mean ±SD)	7.1 ± 4.5	9.5 ± 4.5	**0.0009**
Gender: females	1594 (73)	78 (62)	**0.006**
Income	.	.	**$<1\times10^{-7}$**
<U$49,999	475 (26)	60 (63)	
U$50,000- 99,999	670 (36)	29 (30)	
>U$100,000	710 (38)	6 (6)	
Health insurance	2116 (99)	117 (99)	0.66
Family history of autoimmunity	577 (27)	22 (18)	**0.03**
JIA subtype	.	.	
ERA	223 (10)	7 (10)	0.14
Oligoarticular extended	193 (9)	5 (4)	**0.02med**
Oligoarticular persistent	593 (27)	22 (18)	0.06
Polyarticular RF-	660 (31)	27 (22)	**0.03**
Polyarticular RF+	108 (5)	24 (19)	**1×10^{-7}**
Psoriatic	150 (7)	2 (2)	**0.02**
Systemic-onset	168 (8)	20 (16)	**0.001**
Undifferentiated	62 (3)	6 (5)	ns
Uveitis	258 (12)	5 (4)	**0.008**
Measures of disease	.	.	
CHAQ (mean)	0.34	0.58	**0.0004**
MD Global (mean)	1.52	2.55	**$<8\times10^{-5}$**
Laboratory tests	.	.	
Positive ANA	970 (50)	36(34)	**0.001**
Positive HLA-B27	168 (14)	5 (6)	**0.05**
Confirmed RF positive	64 (9)	17(33)	**1×10^{-7}**
Anti-CCP positive	61 (8)	17(27)	**1×10^{-7}**
Treatment	.	.	.
Use of systemic steroids	1456 (68)	83 (70)	0.64
Use of DMARD ever	1675 (78)	91 (76)	0.66
Use of biologic ever	967 (45)	67 (55)	**0.03**

* All values are N(%) of those tested/reporting data for particular variables, except as indicated.

Conclusion: This is the largest described cohort of AA children with JIA, and we confirm reports of differences in disease characteristics reported in smaller earlier studies. Compared to non-Hispanic White children with JIA, African American children with JIA demonstrate significant differences in disease characteristics. Specifically they are older at disease onset, are more likely to have RF/CCP positive polyarthritis and are less likely to have uveitis, psoriatic arthritis, ANA or HLA B27. These observations support that the phenotype of JIA is different in African American children with JIA.

Development of Consensus Treatment Plans for New-Onset Systemic Juvenile Idiopathic Arthritis. Esi Morgan DeWitt[1], Timothy Beukelman[2], Peter A. Nigrovic[3], Karen Onel[4], Sampath Prahalad[5], Rayfel Schneider[6], Matthew Stoll[7], Norman T. Ilowite[8], Carol A. Wallace[9] and Yukiko Kimura[10]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Chicago, Chicago, IL, [5]Emory Children's Center, Atlanta, GA, [6]Hospital for Sick Children, University of Toronto, Toronto, ON, [7]UT Southwestern Medical Center, Dallas, TX, [8]Children's Hospital Montefiore, Bronx, NY, [9]Childrens Hosp & Regional Med, Seattle, WA, [10]Hackensack Univ Medical Ctr, Hackensack, NJ

Background/Purpose: Currently, there is significant variability in the therapeutic approaches to new onset systemic Juvenile Idiopathic Arthritis (sJIA), as evidenced by surveys using case presentations administered to Childhood Arthritis and Rheumatology Research Alliance (CARRA) members. Understanding the comparative effectiveness of these diverse therapeutic approaches would likely result in better health outcomes. We therefore aimed to derive consensus based treatment plans, standardized assessment intervals and data collection plans for clinical use to facilitate comparative effectiveness studies for new-onset sJIA.

Methods: Case-based surveys were administered to CARRA members to identify prevailing treatments for new-onset sJIA. A 2-day consensus conference in April 2010 employed modified nominal group technique to formulate preliminary treatment plans and determine important data elements for collection. Follow-up surveys were employed to refine the plans and assess clinical acceptability.

Results: The CARRA sJIA Core Workgroup developed standardized treatment approaches, and a recommended schedule of visits and monitoring parameters. Four treatment plans were developed: 1) a corticosteroid based plan, 2) a methotrexate based plan with corticosteroids, 3) an anti-IL1 (anakinra) based plan, and 4) an anti-IL6 (tocilizumab) based plan. The biologic DMARD-based plans are to be used with or without corticosteroids. A survey of the CARRA membership was conducted in December 2010 to assess the acceptability and feasibility of these strategies. There was a 63% response rate (133 of 211 surveyed), of which 92.6% expressed willingness to follow 1 of the initial 3 treatment plans listed above. 82% concurred that an anti-IL6 based treatment arm should also be offered, which became the basis for development of the fourth treatment plan. Consensus was reached at the 78–85% level for all topics posed (specific details of treatment plans, ability to use plans). A feasibility study estimated that over 250 patients could be enrolled in these plans per year, and that physicians would likely enroll one-third to one-quarter of the patients in each of the original 3 plans.

Conclusion: The use of consensus derived standardized treatment plans for new onset SJIA is feasible and acceptable to most North American rheumatologists who are members of CARRA. Four treatment approaches to the first 9 months of treatment will be published as frameworks for use. Coupled with standardized data collection at routine intervals, use of these treatment plans will serve as the basis for rigorous study of comparative effectiveness of the regimens as used in clinical practice.

283

Juvenile Idiopathic Arthritis (Jia) Affected Sibling Pairs Present High Correlation for ANA and ILAR Category. Giovanni Filocamo, Clara Malattia, Ivan Foeldvari, Valda Stanevicha, Susan Nielsen, Troels Herlin, Chris Pruunsild, Francesco Zulian, Zsolt Balogh, Frank Dressler, Ingrida Rumba, Maria Giannina Alpigiani, Elisabetta Cortis, Fernanda Falcini, Ralf Trauzeddel, Giuseppina Calcagno, Loredana Lepore, Maria Alessio, David Glass, Susan Thompson, Alberto Martini and Nicolino Ruperto. IRCCS G Gaslini, Pediatria II, PRINTO, Genova, Italy

Background/Purpose: 1) To investigate the clinical phenotypes and demographic characteristics of affected sibling pairs (ASPs) with juvenile idiopathic arthritis (JIA). 2) To provide an international resource of JIA DNA samples and a base of knowledge from which all genes contributing to the pathogenesis of JIA can be identified.

Methods: This is a cross-sectional multicentric study in which all paediatric rheumatology centres belonging to the PRINTO network were asked to participate. PRINTO asked to provide demographic and clinical characteristics of the ASPs through electronic format and to collect DNA samples of JIA familiar cases, including all first degree relatives, deriving from the different centres.

Results:

Table 1. Demographic, clinical features and concordance between the sibs (2 or more within the same family) of the 106 individual affected sibpairs with JIA

	N (%)	Mean (SD)	Median	Min	Max	Conc.
Male	25 (24)					0.24
Female	81 (76)					0.79
Onset age &endash;years		6.6 (4.4)	6.2	0.5	16.3	
JIA category	0 (0)					0.79
Systemic arthritis	61 (57.6)					/
Oligoarthritis persistent	18 (17)					0.85
Oligoarthritis extended	21 (19.8)					0.5
Polyarthritis RF negative	2 (1.9)					0.9
Polyarthritis RF positive	3 (2.8)					1
Psoriatic arthritis	0 (0)					0.67
Enthesitis related arthritis	1 (0.9)					/
Other						0
Presence of ANA	56 (56)					0.78
Absence of ANA	44 (44)					0.68
Presence of iritis	11 (10)					0.36
Absence of iritis	86 (81)					0.9

Conclusion: Preliminary results confirm the findings of earlier studies showing familial aggregation of clinical features among ASPs. In our study we observed high concordance of the presence of antinuclear antibodies (ANA), providing evidence for a genetic background in this disease. The DNA samples collected will allow to develop future studies on JIA.

284

How Important Is Early Magnetic Resonance Imaging of the Temporomandibular Joint for the Treatment of Children with Juvenile Idiopathic Arthritis? Rotraud K. Saurenmann[1], Raphael Hauser[1], Silke Schroeder[1], Elvira Cannizzaro[1], Lukas Muller[2] and C.J. Kellenberger[1]. [1]University Children's Hospital, Zurich, Switzerland, [2]Center for dental, oral and maxillofacial diseases, Zurich, Switzerland

Background/Purpose: Temporomandibular joint (TMJ) arthritis is very common in children with juvenile idiopathic arthritis (JIA) but often clinically asymptomatic. Magnetic resonance imaging (MRI) is the most reliable examination method for early TMJ arthritis but in young children sedation is often required.

Study Aims: To evaluate how many patients with newly diagnosed JIA will profit from an early MRI of the TMJ for the management of their arthritis.

Methods: The database of our clinic was searched for all patients with a date of diagnosis of JIA between January 2007 and December 2010. The charts of all patients from this inception cohort were reviewed for MRI of the TMJ, diagnosis of TMJ involvement and JIA treatment.

Results: We found 147 patients with newly diagnosed JIA during this period. In 111 (76%) at least 1 MRI of the TMJ was available. Reasons why no TMJ MRI was done were parents' refusal (10), MRI of other locations (7) and fixed orthodontic appliances (16). A diagnosis of TMJ arthritis based on synovial enhancement on MRI was made in 91/111 (81%) patients. The first MRI was done at a median interval of 5 months from the diagnosis of JIA, and 61/111 patients (55%) required sedation for their first MRI. TMJ arthritis was diagnosed in 53/61 (87%) requiring sedation and in 35/50 (70%) patients without sedation ($p = 0.03$). Following the first TMJ MRI, intra-articular steroid injections were performed into 107 TMJs of 60 patients. 48/147 (33%) patients received at least one DMARD to control their disease, and in 12/48 (25%) the first DMARD was started following the first TMJ MRI. Factors associated with TMJ involvement as demonstrated by MRI were JIA subtype ($p= 0.007$) and a younger age at diagnosis of JIA ($p= 0.04$).

Conclusion: In our cohort of newly diagnosed JIA patients TMJ arthritis was very common. Early TMJ MRI led to changes in treatment in 65% of patients with additional joint injections in 60 patients and start of systemic medication in 12 patients. We especially recommend performing TMJ MRI in young children even if they require sedation, as they have an increased rate of TMJ involvement.

285

Clinical and Immunological Effects of Etanercept on Juvenile Idiopathic Arthritis in China. Caifeng Li, Xiaohua Tan, Xiaohu He, Weiying Kuang, Yifang Zhou, Jiang Wang, Tongxin Han, Junmei Zhang, Jing Gao and Chao Li. Beijing Children's Hospital affiliated to Capital Medical University, Beijing, China

Background/Purpose: To study clinical effects and immunological mechanism of Etanercept in the treatment of Juvenile Idiopathic Arthritis (JIA).

Methods: (1) Clinical Observation:During October 2006 to February 2011, 241cases of refractory JIA patients were enrolled. All of them were given Etanercept(production of CPGJ, 0.4mg/kg/dose, given twice weekly, subcutaneous injection) with typical JIA treatment regimen. The course of Etanercept treatment was at least 3 months. We collected and recorded the clinical data before Etanercept treatment and at 2 weeks, 1, 3, 6, 12, 24 and 48 months after its use, respectively. We analyzed ACR Pedi 30/50/70 response rate according to the clinical data, and also analyzed inflammation indexes (ESR, CRP, HGB, WBC and serum ferritin), as well as observed the radiology image changing. Meanwhile, we recorded the side effect of Etanercept. (2) Immunology Study: During October 2006 to September 2009, 103cases of refractory JIA patients were enrolled. We collected peripheral serum from JIA patients before Etanercept treatment and at 2 weeks, 1, 3, 6, 12 and 24 months after treatment. We tested the level of TNF-α, IL-1β, IFN-γ and IL-6 by ELISA method. All data analyses were performed with the SPSS 11.5 software.

Results: 241 cases of JIA patients were enrolled, 120 boys and 121 girls. The age was between 2–18 years, mean age was 10 years. There were 67 cases of ERA, 93 cases of Poly JIA, 40 cases of SoJIA (11 cases of MAS among SoJIA patients) and 2 cases of JPsA. (1) Clinical effect: The ACR Pedi 30/50/70 response rates were 48%, 26% and 13% at 2 weeks after Etanercept treatment. The ESR and CRP level of all JIA patients were decreased significantly compared with baseline ($P<0.01$). The ACR Pedi 30/50/70 response rates were 74%, 58% and 23% after 6 months. 1.8% children with severe bone destruction had improved significantly by imaging after one year treatment. (2) Immunological effects: Compared with baseline, the serum TNF-α, IL-1β, IFN-γ level of all JIA patients were decreased after treatment ($P<0.05$). The serum IL-6 level of ERA and Poly JIA patients improved significantly ($P<0.05$), but SoJIA patients didn't improve significantly ($P>0.05$).Among the SoJIA patients who mainly suffered from joint symptoms at the later disease stage, inflammation indexes and clinical symptoms improved after using Etanercept. The safety of the drug: there were only 4 cases of JIA patients had temporary skin rashes within 2 weeks of the drug administration. The rashes disappeared automatically in several days, there was no influence on drug administration. 1 case of patient discontinue of the medication due to tuberculosis infection after one year of treatment, but without clinical symptom.

Conclusion: Etanercept could relief clinical symptoms, controll inflammation reaction and decrease the dosage of steroid in all types of JIA. But the effects of Etanercept on SoJIA patients with systemic symptoms or MAS was limited. The effect of Etanercept on Poly JIA and ERA was significant. Etanercept could control the clinical symptoms might be due to reducing serum inflammatory cytokines level.

286

Effectiveness and Safety of Switching Between Biologics in Juvenile Idiopathic Arthritis; Results From the Dutch ABC Register. Marieke H. Otten[1], Femke H.M. Prince[2], Janneke Anink[1], Marion A. J. Van Rossum[3], Esther P.A.H. Hoppenreijs[4], Simone L. Gorter[5], Wineke Armbrust[6], Koert M. Dolman[7], Yvonne Koopman-Keemink[8], Joost F. Swart[9], J. Merlijn Van den Berg[10], Nico M. Wulffraat[9], Rebecca Ten Cate[11] and Lisette W.A. Van Suijlekom-Smit[12]. [1]ErasmusMC Sophia Children's Hospital, Rotterdam, Netherlands, [2]Brigham and Women's Hospital, Boston, MA, [3]Emma Children's Hospital/Academic Medical Center (AMC), Amsterdam, Netherlands, [4]St Maartenskliniek and Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [5]University Hospital Maastricht, Maastricht, Netherlands, [6]Beatrix Children's Hospital, University Medical Centre Groningen, Groningen, Netherlands, [7]St. Lucas Andreas Hospital and Reade Institute, Amsterdam, Netherlands, [8]Hagaziekenhuis Juliana Children's Hospital, Den Haag, Netherlands, [9]University Medical Center Utrecht, Utrecht, Netherlands, [10]Emma Children's Hospital/ Academic Medical Centre and Reade Institute, Amsterdam, Netherlands, [11]Leiden University Medical Center, Leiden, Netherlands, [12]ErasmusMC Sophia Childrens Hospital, Rotterdam, Netherlands

Background/Purpose: The introduction of biologics has led to dramatic improvements in juvenile idiopathic arthritis (JIA). However, despite this treatment success, some patients need to discontinue these agents because of a lack of effectiveness or intolerance. Little is known about the effectiveness and safety of switching to a second or third biologic for JIA patients who failed their first.

Methods: The Arthritis and Biologicals in Children (ABC) register (observational study, ongoing since 1999), includes all Dutch JIA patients who use or previously used biologics. Data on the course of the disease are prospectively retrieved, including when biologics were discontinued or type of biologic switched, until transfer to the adult care. Drug survival (i.e. median duration from start until discontinuation due to ineffectiveness or adverse events (AEs)) for the first, second, and third course biologics was estimated with Kaplan-Meier. AE-rates within 1 year after start of the first, second and third course biologic were calculated.

Results: Of the 411 JIA patients who started their first biologic, 88 patients (21%) switched to a second, and 28 (7%) patients to a third course biologic. Of the 88 patients who switched, 81 started etanercept as first biologic, and switched from etanercept to adalimumab (n=46), to infliximab (n=21) or to anakinra (n=14). Patients who also started a third course biologic most often switched between the anti-TNF-alpha agents only (n=19). The median follow-up duration since start of the second course biologic was 14.2 (4.2–29.4) months, and since start of the third course biologic 21.1 (IQR 3.4–33.6) months. Patients who switched to a second biologic had more often the systemic subtype ($p<0.000$), and at start of the first biologic higher disability scores ($p=0.001$) and more joints with arthritis ($p<0.000$) than patients who did not switch. Ineffectiveness of treatment (primary non-response or loss of response) was the most frequently reported reason for switching. At 12 months of treatment, drug survival of the first course biologics (83% (95% CI 79–87%)) was higher than for the second course (48% (95% CI 36–61%)), and third course 64% (95% CI 44–84%). The drug survival of the second course biologics was not different for subtype (systemic vs. non-systemic subtypes), type of second biologic started, and reason for switch. The AE-rates within 1 year after start were 0.21 AEs/patient-year for the first course, 0.20 AEs/patient-year for the second course, and 0.17 AEs/patient-year for the third course.

Conclusion: In daily practice, switching between biological agents occurred frequently. The observed switching patterns seem to be influenced by the availability of biologics within the study period. Risk factors for switching were the systemic-onset subtype and at start of the first biologic high disability scores and many joints with arthritis. While the drug survival of the first course was higher, still 48% of the switchers continued their second biologic after 12 months of treatment. Switching to a second (and third) course biologic seems to be safe and a reasonable option.

Evaluation of Rheumatoid Factor Isotype Levels and Anti-Cyclic Citrullinated Peptide Antibody Isotype Levels in Juvenile Idiopathic Arthritis Patients At Baseline and Post-Treatment. Brooke E. Gilliam[1], Reema H. Syed[1] and Terry L. Moore[2]. [1]Saint Louis University, St. Louis, MO, [2]Saint Louis University, Saint Louis, MO

Background/Purpose: To investigate the effect of treatment on serum levels of rheumatoid factor (RF) isotypes and anti-cyclic citrullinated peptide (CCP) antibody isotypes in a cohort of juvenile idiopathic arthritis (JIA) patients.

Methods: Sera from 22 JIA patients, including 12 with IgM RF-positive polyarthritis and 10 with IgM RF-negative polyarthritis, were collected at baseline and one year following treatment. IgM and IgA RF were measured by enzyme-linked immunosorbent assay (ELISA) using cut-offs established by the manufacturer. Anti-CCP antibody isotypes (IgA, IgG, and IgM) were measured by ELISA.

Results: At baseline 55% and 36% were positive for IgM and IgA RF, while 36%, 36%, 27% were positive for anti-CCP antibody isotypes (IgA, IgG, and IgM, respectively). IgM RF, IgG and IgM anti-CCP antibody positivity was limited to IgM RF-positive polyarticular JIA patients. At one-year follow-up, IgM and IgA RF were positive in 55% and 32%, respectively. Anti-CCP antibody isotypes were positive in 27% (IgA), 18% (IgG), and 18% (IgM) of JIA patients. The serum levels of IgA RF were reduced by 35%, while IgM RF was only reduced by 8.3%. IgM anti-CCP antibodies were reduced by 49% following treatment, followed by IgG anti-CCP antibodies at 45%, and IgA anti-CCP antibodies at 20%. While all patients were not considered asymptomatic at follow-up, their disease had been well-controlled. The decreased in serum autoantibody levels was associated with this decreased disease activity.

Conclusion: All autoantibody levels markedly decreased in the JIA patients at follow-up, with the exception of IgM RF in the IgM RF-positive polyarthritis patients. Overall, fewer patients were positive for autoantibodies after one year. This lowering in autoantibody levels indicates good clinical response. Measurement of IgA RF and all 3 anti-CCP antibody isotypes may provide indication of how well JIA patients respond to treatment and indicate changes in disease activity.

288

Current Evidence of Methotrexate Efficacy in Childhood Chronic Uveitis: A Systematic Review and Meta-Analysis. Gabriele Simonini[1], Priyamvada Paudyal[2], Gareth T. Jones[2], Rolando Cimaz[1] and Gary J. Macfarlane[2]. [1]Anna Meyer Children's Hospital, Florence, Italy, [2]University of Aberdeen, Aberdeen, United Kingdom

Background/Purpose: To summarize evidence regarding the effectiveness of Methotrexate (MTX) in the treatment of childhood autoimmune chronic uveitis.

Methods: A systematic search of articles published between January 1990 and February 2011 was conducted using following electronic databases: EMBASE, Ovid MEDLINE, EBM Reviewers–ACP Journal Club, all Cochrane library, and EBM Reviews–Database of Abstracts of Reviews of effects. Reference list and citations of those identified were also screened to find out relevant papers. Studies investigating the efficacy of MTX, as a single immunosuppressant medication in the treatment of chronic autoimmune uveitis, refractory to therapy with topic treatment and/or systemic treatment, in children (≤16 yrs) were eligible for inclusion. Primary outcome measure was the improvement of intraocular inflammation as Tyndall, as defined by the SUN working group criteria. When reported and available, tapering and/or stopping systemic steroid administration, improvement in visual acuity post MTX treatment, discontinuation of MTX, time for remission, time on remission, and safety of treatment were also considered as additional secondary additional outcomes. We determined a combined estimate of the proportion of children in the eligible studies responding to MTX. The effect measure for each study was therefore the proportion of people classified as responders.

Results: The initial search identified 246 articles, of which 52 were potentially eligible. A total of 9 articles that satisfied the eligibility criteria remained in the analysis All of the included studies were retrospective chart reviews. Number of children in these studies ranged from 3 to 25 and the dose of MTX varied from 7.5 mg/mq^2 to 30 mg/mq^2. Altogether, 95 children out 135 included responded to the treatment. The pooled analysis suggested that MTX has favourable effect in the improvement of intraocular inflammation: 0.73 (95% CI: 0.66–0.81), with a likelihood of improvement of 2.7.

Conclusion: The available evidence supports the use of MTX in the treatment of childhood chronic uveitis: patients on MTX can expect a 73% probability of improvement in intraocular inflammation; however randomised controlled trials on MTX are necessary before a firm conclusion can be drawn on efficacy.

289

Characteristics of Anti-Cyclic Citrullinated Peptide Antibody and/or Rheumatoid Factor Positive Juvenile Idiopathic Arthritis in the Childhood Arthritis and Rheumatology Alliance Registry. Sampath Prahalad[1], Sheila Angeles-Han[1], Lori Ponder[1], Christine W. Kennedy[1], Larry B. Vogler[1] and CARRANet Investigators[2]. [1]Emory Children's Center, Atlanta, GA, [2]Stanford

Background/Purpose: JIA is a common chronic arthropathy with a prevalence of ~1/1000 in children under 16 years of age. The ILAR classification criteria categorize JIA into seven subtypes. Of these, rheumatoid factor (RF) positive polyarthritis resembles adults with seropositive RA. It is now recognized that anti-cyclic citrullinated protein antibodies (CCP) are highly specific for RA. Prior reports of CCP in children with JIA have been in modest sized cohorts from single institutions. Our objective is to characterize children with RF/CCP positive-JIA enrolled in the CARRANet Registry.

Methods: Children with JIA from pediatric rheumatology clinics in the US were enrolled in the CARRAnet Registry from May 2010 until June 2011. Demographic and disease-related data were collected from time of diagnosis to enrollment. Children who were positive only for CCP (RF negative) were compared with children who were positive for two out of three tests for biomarkers of RA: RF initial (RFI), RF confirmatory (RFC), and CCP. Nominal variables were compared using Chi-square or Fisher's exact tests. Continuous variables were compared using Student's T test.

Results: In all, of 2725 children with JIA in the database, 535 were reported as not having been tested for either RF/CCP. Children who were not tested for RF/CCP had an earlier onset age than children who were tested (5.2 vs. 6.7 years, p <0.0001). In those tested for RF and/or CCP, the prevalence of CCP was 11.4% (number positive/number tested = 112/978), RFI was 10.9% (234/2141), and RFC was 12.7 % (124/971). Of 937 children tested **for both** RFI and CCP, 82 % were negative for both, 10.4% positive for both, 1.8% positive for CCP only and 6.4% positive for RF only. Characteristics of children positive for CCP only compared to those who had at least two out of three positive tests are shown in **Table 1**. Except for subtype distribution, there were no differences. By contrast, the 35 children who were positive only for RFI were significantly younger compared to those who had at least 2 out of 3 positive tests, 6.5 vs. 10.9 years, p <0.0001. 32 individuals were positive for RFI, but were negative for RFC. 18 of these also had a negative CCP when tested. There were 12 children who had 2 positive RFs, but had a physician assigned diagnosis of a JIA subtype other than RF positive polyarticular or undifferentiated JIA (Systemic 2, RF negative poly 1, persistent oligoarthritis 6, psoriatic 2, ERA 1).

Table 1. Characteristics of CCP and RF positive children with JIA*

	CCP only	2 out of RFI, RFC and CCP	p
Total Number	16	153	
Age at symptom onset (mean ±SD)	9.3 (5.2)	10.9 (3.8)	ns
Demographic features	.	.	.
Female gender	13	133	ns
Hispanic ethnicity	4	42	ns
African ancestry	4	24	ns
Family history of autoimmunity	2	33	ns
Family history of RA	0	12	ns
Physician assigned JIA subtype	.	.	.
ERA	0	2	ns
Oligoarticular extended	2	1	<0.001
Oligoarticular persistent	3	8	ns
Polyarticular RF-	6	1	<0.0001
Polyaticular RF+	3	131	<0.0001
Psoriatic	1	2	ns
Systemic-onset	1	2	ns
Undifferentiated	0	5	ns
Measures of disease	.	.	.
CHAQ (mean)	0.43	0.46	ns
MD Global (mean)	2.6	2.4	ns
Imaging evidence of damage	4	62	ns
Current joint count (mean)	5.7	3.4	ns
Treatment	.	.	.
Use of systemic steroids	13	119	ns
Use of DMARD ever	15	144	ns
Use of biologic ever	10	109	ns

* All values are N, except as indicated. CCP: anti cyclic citrullinated protein antibody. RFI: Rheumatoid factor, initial. RFC: rheumatoid factor, confirmatory. ns: not significant.

Conclusion: This is the largest described cohort of RF/CCP positive children with JIA. Although ILAR criteria require testing of all children for RF, 21% of children with JIA in the CARRANet registry did not have reports of being tested for RF, possibly underestimating the number of children with RF positive JIA. The prevalence of RFI and CCP are comparable. A number of children with RFI were negative when retested for RF. Inclusion of CCP positivity in future revisions of the JIA criteria will improve the specificity of diagnosing childhood onset RA.

290

Investigating children's beliefs about Juvenile Arthritis: A Study Using Cognitive Interviewing. Daniela Ghio[1], Wendy Thomson[2], Eileen M. Baildam[3], Kimme Hyrich[2], Michael W. Beresford[3], Carol Lydon[4], Olivia Lloyd[3], Gavin Cleary[3], Liza J. McCann[5], Childhood Arthritis Prospective Study (CAPS)[6], Fiona Ulph[1] and Lis Cordingley[7]. [1]School of Psychological Sciences, University of Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [3]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [4]Alder Hey, Liverpool, United Kingdom, [5]Alder Hey Children's NHS Foundation Hospital, Liverpool, United Kingdom, [6]Manchester, United Kingdom, [7]School of Community Based Medicine, University of Manchester, Manchester, United Kingdom

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic illness in childhood. An understanding of how children make sense of their JIA symptoms is important for long-term management and treatment. There is increasing recognition that outcomes such as pain and disability are associated with an individual's beliefs about illness. In adults, beliefs about inflammatory arthritis were found to predict disability and quality of life

independently of disease activity (Graves et al, 2009). Beliefs have been assessed in adults using the Illness Perception Questionnaire (IPQ: Weinman et al, 1996). The aim of this study was to investigate the extent to which IPQ items can be understood by young people with JIA and the extent to which responses were associated with verbal ability and parent's beliefs.

Methods: Data were collected from 18 young people aged 11–16 diagnosed with JIA using cognitive interviewing (Willis et al, 1991). This involved two techniques, "think aloud" where participants describe their thoughts as they complete IPQ items and verbal probing where the interviewer elicits specific information about responses. All interviews were audio-recorded, transcribed and analysed using content analysis and thematic analysis. Participants also completed the British Picture Vocabulary Scale (Dunn, & Dunn, 1997) a measure of children's vocabulary to investigate whether verbal ability influences their responses to the IPQ items. Parents of participants completed written13 open-ended questions on their beliefs about their child's JIA which were analysed thematically.

Results: The analysis indicated that IPQ domains mapped onto illness concepts that were relevant to the young people with JIA, however, some individual items and response options may need adapting to take account of less abstract ways of thinking about illness and symptoms. Of particular interest were items assessing controllability of JIA and understanding of cause. Most participants believed they had a good understanding of their symptoms, but felt that their views were less well represented by IPQ items assessing beliefs about the causes of JIA. Difficulties were also found in relation to items asking about emotions with participants apparently disagreeing with IPQ items despite revealing that they felt emotional. Ability to complete the IPQ did not seem to depend upon verbal fluency. As anticipated, children's beliefs about JIA were largely reflected in the accounts of their parents.

Conclusion: There is a recognised need to capture patient reported outcome and process measures using valid, reliable and acceptable tools. For younger patients this presents particular challenges. The findings from this study indicate that children and young people with JIA find the domains assessed by the IPQ relevant but it did have specific limitations. We also gained some additional insights into the ways in which children's beliefs are influenced by those of their parents. Findings from this study will be used to adapt the IPQ for children with JIA in order to understand the long-term influences of children's beliefs upon outcomes including pain and disability.

291

The Impact of ANA Titer Levels on Risk of Uveitis Development in Juvenile Idiopathic Arthritis. Meghan J. Ho[1], Rotraud K. Saurenmann[2], Pascal N. Tyrrell[3] and Susanne M. Benseler[3]. [1]University of Toronto, Toronto, ON, [2]University Children's Hospital, Zurich, Switzerland, [3]The Hospital for Sick Children, Toronto, ON

Background/Purpose: Uveitis is the most severe extra-articular involvement of juvenile idiopathic arthritis (JIA). Evidence of positive anti-nuclear antibody (ANA) is a known risk factor for development of uveitis in JIA, but thresholds for considering an ANA titer positive remain undefined. The impact of ANA titer on uveitis risk for children presenting with different clinical phenotypes of JIA is also unknown. The aims of the study were to describe the characteristic presenting features of JIA patients, to determine the overall association of ANA titer and development of uveitis, and to define the utility of ANA titers for individual uveitis risk prediction in clinical practice.

Methods: A single center cohort of children with JIA diagnosed between July 1984-June 2002, first seen at the Hospital for Sick Children before June 30, 2003 and followed for a minimum of 1 month was studied. Children not meeting the ILAR criteria for JIA diagnosis or with missing ANA titers were excluded from the database. Descriptive statistics and comparative analysis were performed on demographic, clinical and ANA laboratory data to characterize the study population. Logistic regression analysis was used to determine the association between ANA titer and uveitis development and the contribution of ANA titer to uveitis risk in the context of age and gender.

Results: A total of 715 children were identified and entered into the study (495 female, mean age 6.1 years; 220 male, mean age 7.6 years), in which 329 were ANA+ and 386 were ANA-. Girls diagnosed with JIA at a younger age were most at risk of developing uveitis (for every decreasing year: OR=1.3, 95% CI: 1.2–1.4). Children that were ANA+ at diagnosis were more likely to develop uveitis when accounting for age and gender (ANA titer <1/160: OR=3.4, 95% CI: 1.8–6.3; ANA titer >=1/160: OR=4.0, 95% CI: 2.3–6.9). A high ANA titer (>= 1/160) was found most often in the oligoarticular subtype (41%), followed by the polyarticular subtype (26%). Diagnosis subtype was not found to better explain the risk of uveitis development than ANA titer at diagnosis in the age and gender-adjusted model.

Conclusion: Age, gender, and ANA status (positive or negative) are important factors to consider when estimating the risk of uveitis development. ANA titer levels were also found to affect the risk of developing uveitis in JIA. These results can be used to inform the uveitis screening practices of pediatric rheumatologists and ophthalmologists in patients with JIA. The relationship between ANA titer levels and the different JIA subtypes needs to be further examined.

292

Safety and Efficacy of Tocilizumab Treatment In Children with Systemic Juvenile Idiopathic Arthritis. Ekaterina Alexeeva, Rina Denisova, Saniya Valieva, Tatyana Bzarova, Kseniya Isayeva, Tatyana Sleptsova and Elena Mitenko. Scientific Center of Children's Health, Moscow, Russia

Background/Purpose: To evaluate safety and efficacy of tocilizumab treatment in children with systemic onset of juvenile idiopathic arthritis (JIA).

Methods: A retrospective observational study on JIA patients taking tocilizumab (n=39). Tocilizumab was administered intravenously at a dose of 8 mg/kg every 2 weeks during 2 months then every 4 weeks. All patients received DMARDs. Efficacy end points included the American College of Rheumatology (ACR) Pediatric 30 (Pedi 30), Pedi 50, Pedi 70, and Pedi 90 criteria for improvement.

Results: A total of 39 patients (21 boys and 18 girls) were included in this Median age was 7,5 years (range; 3 to 15 years) and median disease duration was 4,2 years (range; 0.5 to 8,3 years). A total of 16 of the 39 patients (25%) entered 52 weeks of continuous tocilizumab treatment. The frequently observed non-severe adverse events were nasopharyngitis, upper respiratory tract infection and gastroenteritis. No cases of opportunistic infections, malignancies, autoimmune diseases, or death were reported. One case of pneumonia. 21 patients had incidences of neutropenia.The ACR Pedi 30, 50, 70 and 90 were achieved by 82%,50%, 27% and 12% of patients at Week 4 (N=36), and by 100%, 81%, 69%, and 50% of patients at Week 24 (N=18), and by 100%, 85%, 78%, and 57% of patients at Week 52 (N=16), respectively.

Conclusion: Clinical improvements in the signs and symptoms of systemic JIA were also achieved in favorable levels in tocilizumab in the treatment of children with JIA.

293

Evaluation of the Association Between Ethnicity and Disease Activity and Severity in a Large Cohort of Patients with Juvenile Idiopathic Arthritis. Christina F. Pelajo[1], Sheila Angeles-Han[2], Sampath Prahalad[3], Caitlin M. Sgarlat[1], Trevor Davis[1], Laurie C. Miller[1] and Jorge M. Lopez-Benitez[1]. [1]Floating Hospital for Children at Tufts Medical Center, Boston, MA, [2]Emory University, Atlanta, GA, [3]Emory Children's Center, Atlanta, GA

Background/Purpose: The impact of ethnicity on disease activity and severity in patients with juvenile idiopathic arthritis (JIA) is not well understood. Studies in large samples are needed to explore this association, since this could affect the future care of minorities with JIA. The aims of this study were to examine the association between ethnicity and disease activity in patients with JIA, and to determine the association of ethnicity with disease severity and disability in this population.

Methods: CARRAnet, a US database containing information (collected between May 10 and Jun 11) on almost 3,000 subjects with JIA, was used. Demographic variables were compared between Hispanic (or Latino) patients and non-Hispanic patients. Mann-Whitney and Chi-square tests were used to compare indicators of disease activity (number of active joints, physician assessment of disease activity, parent/subject assessment of disease activity, and parent/subject pain score), as well as imaging evidence of joint damage, and Childhood Health Assessment Questionnaire (CHAQ) scores between ethnicities. A linear regression model was used to determine the association of ethnicity with number of active joints in JIA.

Results: The sample analyzed included 2,704 patients with JIA (277 Hispanic and 2,427 non-Hispanic). Table 1 shows the demographic variables by ethnicity. Income and health insurance status were higher in non-Hispanics. RF-positive polyarticular JIA, positive RF and anti-CCP, as well as use of systemic steroids were more frequent in Hispanics.

Table 1. Demographic variables

Variable	Hispanic	Non-Hispanic	p-value
Age at baseline visit (mean ± SD)	11.3 ± 5.2	11.5 ± 4.7	0.59
Age at onset of symptoms (mean ± SD)	6.7 ± 4.5	6.4 ± 4.4	0.28
Age first seen by pediatric rheumatologist (mean ± SD)	7.7 ± 4.8	7.3 ± 4.6	0.23
Gender (females) % (N)	74 (206)	73 (1765)	0.56
Income (US$) % (N)			**<0.0001**
<25,000	20 (56)	10 (234)	
25,000–49,999	23 (64)	14 (348)	
50,000–74,999	13 (36)	16 (386)	
75,000–99,999	11 (31)	14 (343)	
100,000–150,000	11 (30)	19 (468)	
Above 150,000	5 (13)	12 (286)	
Unknown	17 (46)	15 (361)	
Health insurance % (N)	95 (264)	98 (2364)	**0.01**
JIA subtype % (N)			**<0.0001**
Enthesitis-related arthritis	8 (21)	11 (255)	
Oligoarticular extended	6 (17)	9 (206)	
Oligoarticular persistent	26 (73)	27 (647)	
Polyarticular RF−	23 (63)	30 (728)	
Polyarticular RF+	18 (50)	6 (144)	
Psoriatic arthritis	4 (10)	6 (157)	
Systemic-onset	11 (31)	9 (208)	
Undifferentiated	3 (8)	2 (53)	
Laboratory tests % (N)			
Positive ANA	44 (120)	44 (1052)	0.06
Positive HLA-B27	6 (16)	8 (185)	0.48
Confirmed RF positive	13 (32)	4 (92)	**<0.0001**
Anti-CCP positive	11 (28)	4 (83)	<0.0001
Treatment % (N)	44 (80)	43 (706)	**0.02**
Use of systemic steroids	18 (32)	12 (195)	
-Prior	76 (210)	77 (1859)	
-Current	48 (132)	46 (1100)	0.59
Use of DMARD ever			0.75
Use of biologic ever			

In the univariate analysis the number of active joints, the physician assessment of disease activity, and the parent subject/assessment of disease activity did not differ between ethnicities. However, the parent/subject pain score was significantly higher (worse) in Hispanics (3.0±2.9) than in non-Hispanics (2.5±2.6) (p=0.02). In the analysis of disability and disease severity, CHAQ was significantly higher (worse) in Hispanic patients (0.5±0.6) than in non-Hispanic (0.3±0.5) (p=0.0005), as well as imaging evidence of joint damage (32% vs. 24%) (p=0.008). In the multivariate linear regression analysis, the number of active joints was significantly higher in Hispanics than in non-Hispanics (p=0.03), after adjusting for confounders (income, health insurance, JIA subtype, positive RF, positive anti-CCP, use of intra-articular steroids, oral steroids, IV steroids, DMARDs, and biologics).

Conclusion: Hispanic patients with JIA had higher disease activity (determined by number of active joints and parent/subject pain score) than non-Hispanic patients, as well as higher disease severity (by imaging evidence of joint damage) and disability (by CHAQ). Since ethnicity influences disease activity, severity, and disability, different management and treatment plans should be planned accordingly.

Gene Expression Profiling Reveals Dysregulation of Innate Immune Genes in Synovial Fluid Mononuclear Cells of Patients with Enthesitis Related Arthritis. Amita Aggarwal[1], Arpita Myles[2] and Amit Tuteja[3]. [1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Lucknow, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Science, Lucknow, India, [3]The center for Genomic applications, New Delhi, India

Background/Purpose: Enthesitis related arthritis (ERA) category of juvenile idiopathic arthritis (JIA) is said to arise in genetically predisposed individuals in response to environmental triggers. Gene expression profiling has helped identify new pathogenic pathways in other JIA categories and have opened new avenues for therapy like IL-1Ra in Systemic JIA. Data on ERA is limited thus we studied expression profile of ERA patients' peripheral blood and synovial fluid mononuclear cells (PBMCs and SFMCs). PBMCs from polyarticular JIA (polyJIA) patients and healthy subjects were used as controls.

Methods: RNA from PBMCs of ERA, polyJIA patients and healthy controls (n=17, 8, 8) and 7 ERA SFMCs were converted to labelled cRNA and hybridised to Illumina Human WG-6_v3_BeadChip chips. Expression profiles were analysed using Genespring software. Genes differentially expressed at a fold-change cut-off of ≥ 2.0 and detection p values of < 0.05 were subjected to hierarchical clustering and pathway analysis. Selected genes of interest were validated at RNA and protein level.

Results: Although ERA PB could be distinguished from ERA SF, control PB and polyJIA PB using supervised clustering, yet, there was no statistically significant difference in PBMC gene expression of ERA, polyJIA and control groups. However, there was significant difference between gene expression profile of SFMCs and PBMCs of patients with ERA, with 131 genes being overexpressed and 216 being under-expressed in SFMCs. 182 genes were involved in 13 pathways, none of which was significantly dysregulated as per gene ontology analysis. Amongst these, highest number of genes (36) had an immunological function. Out of these CD1b, CD1d, MHC class II alpha and beta chain, soluble CD163, chemokines CXCR3 and CXCL16 were over expressed whereas genes related to NK cell function, namely, Granzyme H, KLRF1, KIR3DL3, NKG7 and other genes like CD244, CD248, FAIM3 were under-expressed.

Conclusion: ERA SFMC has a distinct gene expression profile from PBMCs and had higher expression of genes associated with antigen presentation, scavenger function, chemotaxis and proteases whereas genes involved in NK cell function, cell adhesion and inhibitors of apoptosis were under-expressed. All these genes have been associated with pathology of several inflammatory diseases, including rheumatoid arthritis and other JIA categories. Therefore, we hypothesise that they may contribute to disease exacerbation in ERA.

295

KIR-HLA Gene Combinations in JIA-Associated Uveitis. Miriam F. Parsa[1], Deborah K. McCurdy[1], Ornella J. Rullo[1], Jennifer M.P. Woo[1], Tina Cunningham[2], Jennifer Thorne[3], Ralph D. Levinson[4], Raja Rajalingam[2] and Gary N. Holland[4]. [1]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [2]University of California, Los Angeles, Los Angeles, CA, [3]Johns Hopkins University, Baltimore, MD, [4]Jules Stein Eye Institute, University of California, Los Angeles, Los Angeles, CA

Background/Purpose: HLA class I-specific killer cell immunoglobulin-like receptors (*KIR*) gene and *HLA* gene combinations have been associated with autoimmune uveitis (e.g. birdshot chorioretinopathy (BCR) and Vogt-Koyanagi-Harada syndrome (VKH)). KIR-HLA genotypes that provide weak inhibition and strong activation may stimulate NK cells and NK-like T cells, thereby increasing susceptibility to autoimmune disease. In oligoarticular juvenile idiopathic arthritis (JIA), uveitis is one of the most serious complications and affects approximately 20% of patients. Given the importance of *HLA* Class I and *KIR* gene combinations in other forms of autoimmune uveitis, we hypothesize that an interplay between these genes contributes to the pathogenesis of uveitis in JIA. This study identified KIR gene combinations in Caucasian children with JIA with and without uveitis and compared them with healthy Caucasian controls.

Methods: The study population consisted of pediatric patients with oligoarticular JIA, with and without uveitis. DNA samples were typed for 16 *KIR* genes using a gene-specific PCR typing system. We analyzed the presence or absence of 16 KIR genes in patients with uveitis, patients without uveitis, and published healthy controls (n = 195). Data was analyzed using Fisher's exact tests and Spearman correlation.

Results: A total of 41 (58% with uveitis) DNA samples were collected and isolated from whole blood then genotyped for the 16 KIR genes. The B Haplotype T4 cluster (2DL5-3DS1–2DS5-2DS1) was present more frequently in controls (p<0.05) compared with JIA patients. In previous studies, KIR3DP1, -2DL4, -3DL2, -3DL3 were considered framework genes and present in all adults with autoimmune uveitis. These findings were replicated in our pediatric sample (p = 0.0001). There was no association of KIR genotype in JIA patients with or without uveitis as compared with controls.

Conclusion: In this small sample size, B Haplotype genes (T4 cluster), known to be activating in nature, were found more frequently in healthy controls, suggesting a protective effect against JIA. We did not find an association between KIR gene frequencies and JIA-associated uveitis. We are expanding our sample size to confirm this association, as well as identifying cognate HLA ligands. Uveitis remains a significant risk for disability in JIA; therefore, developing a risk prediction model will allow for aggressive screening and disability prevention.

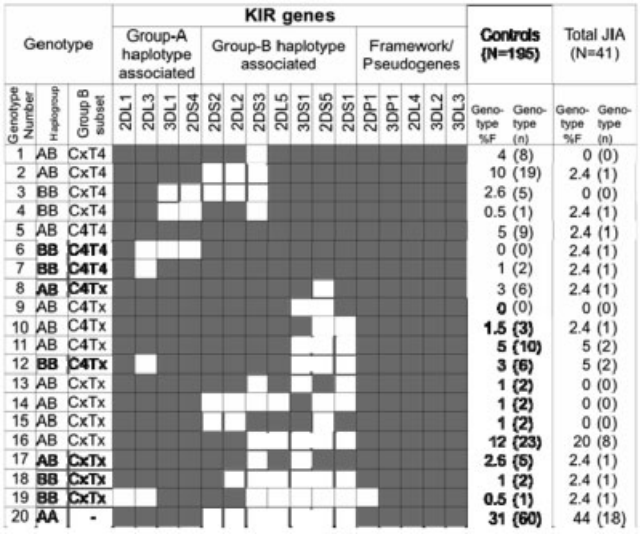

Figure 1. The presence and absence of 16 KIR genes are indicated as shaded and white boxes respectively. 15 distinct genotypes were found in the JIA group, each genotype represented by a row. Genotype frequency is presented as percentage frequency (%F) and defined as the number of individuals (N) divided by the number of individuals (n) in the given study group.

Antigenic Targets and Pathogenicity of Anti-Endothelial Cell Antibodies in Kawasaki Disease. Rie Karasawa, Mayumi Tamaki and Kazuo Yudoh. Institute of Medical Science, St. Marianna University School of Medicine, Kawasaki, Japan

Background/Purpose: Anti-endothelial cell antibodies (AECA) are autoantibodies detected frequently in patients with vasculitis and are thought to be involved in pathophysiology of vasculitis, including Kawasaki disease (KD). The pathophysiological role of AECA, however, is still uncertain. We tried to detect and identify target proteins of AECA comprehensively by proteomics. Furthermore, we investigated clinical importance of them in patients with KD.

Methods: We separated proteins extracted from HUVEC and HeLa cells respectively by 2-dimensional electrophoresis and then transferred them onto membranes. By WB using serum samples from patients with vasculitis, we detected antigens that were positive only in the HUVEC samples but not in the HeLa cell samples. We next identified the detected proteins by peptide mass finger-printing. After that, we characterized antigenecity by preparing recombinant antigens and antibodies to them.

Results: One of the identified 63 proteins was found peroxiredoxin2 (Prx2), an anti-oxidative enzyme. IgG antibodies to Prx2 were detected in 60% of the patients with KD, but not in healthy controls. On the other hand, IgM and IgA antibodies to Prx2 were not significant in patients with KD. Interestingly, IgG antibodies to Prx2 were detected in all tested KD patients with coronary artery lesions. In contrast, IgM and IgA antibodies to Prx2 weren't detected in them. In addition, IgG antibodies to Prx2 were detected in 9% of the patients with polyarteritis nodosa, small and medium vessel vasculitis. WB using cell lysate proved expression of Prx2 not only in HUVEC but also in other endothelial cells (ECs), including human coronary artery endothelial cells (HCAEC). The anti-Prx2 antibodies also increased various inflammatory cytokine secretion significantly, in particular, G-CSF in HCAEC. The addition of anti-Prx2 antibodies to ECs resulted in increased concentration of H2O2 in cell lysate from the ECs. Anti-Prx2 antibodies induced increased expression of adhesion molecule, such as E-selectin. Furthermore, apoptosis was detected in the ECs treated with anti-Prx2 antibodies. We measured anti- Prx2 IgG titers / serum IgG on the pre- and posttreatment (within a month after therapy) in 7 KD patients treated by IVIG. As a result, the titers on the posttreatment significantly decreased in all the tested KD patients. The duration of fever (>37.5°C) was significantly longer in the anti-Prx2 positive group than the anti-Prx2 negative group in KD patients. However, there was no significant difference in two inflammatory markers, white blood cell counts and C-reactive protein, between the both groups.

Conclusion: IgG antibodies to Prx2 would be a useful marker for KD. The anti-Prx2 antibodies may cause vascular dysfunction by inducing expression of endothelial adhesion molecules, inflammatory cytokine production, apoptosis and inhibition of anti-oxidative activity of Prx2 by binding Prx2 on ECs.

Measuring S100A12 and Vascular Endothelial Growth Factor Can Differentiate Familial Mediterranean Fever and Early Onset Sarcoidosis From Systemic Juvenile Idiopathic Arthritis. Yuichi Yamasaki, Yasuhito Nerome, Tomohiro Kubota, Yukiko Nonaka, Harumi Akaike, Tomoko Takezaki, Hiroyuki Imanaka, Yoshifumi Kawano and Syuji Takei. Kagoshima University, Kagoshima City, Japan

Background/Purpose: A new consensus is now emerging that systemic juvenile idiopathic arthritis (sJIA) may be one of the autoinflammatory disease based on clinical and pathological mimicry. In fact, many children with autoinflammatory diseases such as familial Mediterranean fever (FMF) and early onset sarcoidosis (EOS) were initially diagnosed as sJIA[1)], a much more common febrile disease in children. Therefore, we examined serum levels of IL-6, S100 protein, and vascular endothelial growth factor (VEGF) so that measuring these biomarkers could be a screening test to differentiate these febrile conditions before undergoing a genetic testing.

Methods: Serum samples were obtained from 19 patients, 3 patients with FMF, 4 with EOS, and 12 with sJIA. Diagnosis of FMF and EOS were confirmed by gene examination. In these 19 patients, serum levels of IL-6, S100A12 and VEGF were examined by ELISA in both active (CRP>1.0 mg/dl) and inactive phase.

Results: In active phase of patients, serum IL-6 level did differ in all disease groups. However, serum S100A12 levels were significantly high in both s-JIA ($p<0.001$) and FMF ($p<0.001$) patients compared with EOS patients (Figure 1). On the other hand, high levels of serum VEGF was observed only in s-JIA patients but not in FMF or EOS patients even though they were in active phase ($p<0.001$) (Figure 2).

In inactive phase of patients, no significant difference was observed in serum VEGF levels among the three disease groups. On the other hand, high levels of S100A12 were observed only in FMF patients who were non-treated or colchicine resistant.

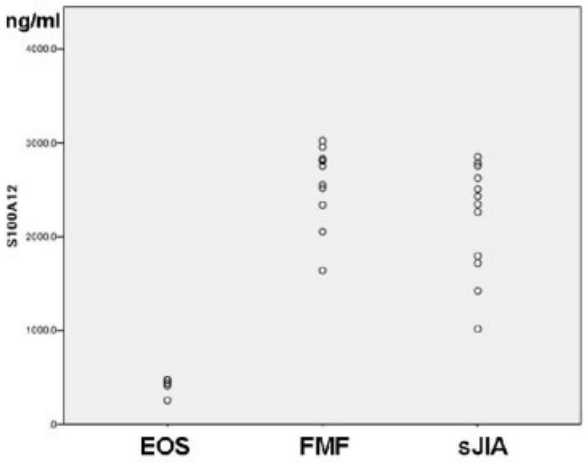

Fig1 : serum S100A12 level of EOS, FMF and sJIA in active phase

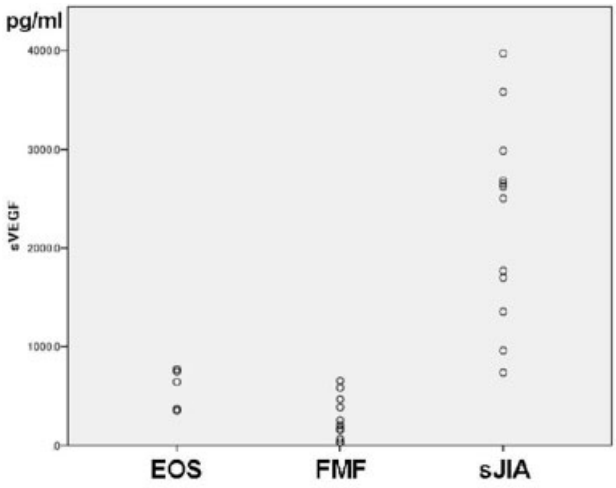

Fig2 : serum VEGF level of EOS, FMF and sJIA in active phase

Conclusion: Measuring serum S100A12 and VEGF levels at a time may be useful in differentiating FMF or EOS patients from patients clinically diagnosed as sJIA.

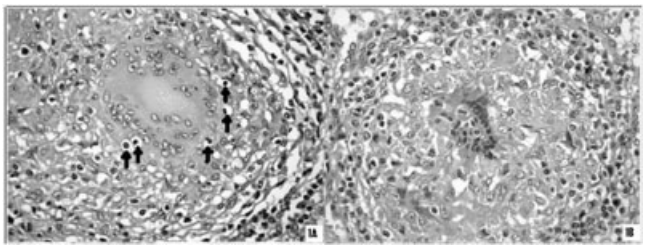
Emperipolesis and Cell Death in NOD2-Related Blau Syndrome and Crohn's Disease. Carl EI Janssen[1], Carlos D. Rose[2], A. Naranjo[3], Brigitte Bader-Meunier[4], Rolando Cimaz[5], Miroslav Harjacek[6], Pierre Quartier[7], Rebecca Ten Cate[8], Caroline Thomée[9], Isabelle Cleynen[1], Tammy M. Martin[10], Gert De Hertogh[1], Tania Roskams[1], Valeer J. Desmet[1] and Carine H. Wouters[11]. [1]University Hospital Leuven, Leuven, Belgium, [2]duPont Hospital for Children, Wilmington, DE, [3]Hospital de G C Dr Negrin, Las Palmas GC, Spain, [4]Hôpital Necker, Paris, France, [5]Anna Meyer Children's Hospital, Florence, Italy, [6]Zagreb, [7]IRCCS G. Gaslini, Pediatria II, PRINTO, Paediatric Rheumatology, Genova, Italy, [8]PO Box 9600, Leiden, Netherlands, [9]Centre Hospitalier, Luxembourg, Luxembourg, [10]Oregon Health & Science Univ, Portland, OR, [11]University Hosp Gasthuisberg, Leuven, Belgium

Background/Purpose: Blau Syndrome (BS), a rare autoinflammatory disease characterized by non-caseating granulomas, is caused by gain-of-function mutations in NOD2. Crohn's disease (CD) is associated with intestinal granulomas, and SNPs in NOD2. Emperipolesis, the 'inside round about wandering' of lymphocytes within other cells is a typical feature of Rosai-Dorfman disease, and seen occasionally in malignancies. Cell survival and cell death are possible outcomes for both the engulfed and engulfing cells. In the present study we investigate emperipolesis and cell death in BS and CD granulomas.

Methods: Morphological and immunohistochemical study of granulomas was undertaken in 8 BS and 7 pediatric CD biopsies, using H&E and immunohistochemistry for leukocyte markers (CD68, CD4, CD8, CD20), cytokines (IFNγ, IL6, IL10, IL17, TGFβ, TNFα) and death-proteins (Bcl2, Fas, FasL, activated caspase 3).

Results: All BS biopsies showed polycyclic granulomas with large lymphocytic coronas and extensive emperipolesis of lymphocytes within multinucleated giant cells (MGCs). This was associated with macrovesicular/microvesicular degeneration of lymphocytes inside MGCs (Fig1a), and MGC death (Fig1b). Emperipolesis selectively involved CD4+ T cells. In addition, vesicles and degenerative remnants inside MGCs stained strongly for IL-6 and IL-17. A moderate expression of Bcl2 was present, Fas and FasL expression were seen in emperipoletic lymphocytes and MGCs but caspase 3 was virtually absent. In contrast, CD biopsies demonstrated simple isolated granulomas with subtle lymphocytic coronas; emperipolesis was sporadically found in a few biopsies, and was associated with crystalline inclusions, but not with MGC death.



Conclusion: Emperipolesis of CD4+lymphocytes is an important feature of BS and is associated with MGC death. NOD2 mutations causing NF-*k*B hyperactivation and influencing autophagy pathways may be involved. In CD with NOD2-SNPs, emperipolesis is exceptional and crystalline inclusions are present.

299

Novel Mutation of the *LPIN2* Gene in Majeed Syndrome. Response to IL-1 Inhibition. Troels Herlin[1], Mette Bjerre[2], Bente Fiirgaard[1], Gitte Kerndrup[3], Henrik Hasle[1] and Polly J. Ferguson[4]. [1]Aarhus University Hospital, Aarhus N, Denmark, [2]Aarhus University Hospital, Aarhus C, Denmark, [3]Vejle Hospital, Denmark, [4]University of Iowa Carver College of Medicine, Iowa City, IA

Background/Purpose: Majeed syndrome is a rare, syndromic form of chronic recurrent multifocal osteomyelitis (CRMO) first described in 1989. The syndrome starts during infancy with recurrent relapses of osteomyelitis typically associated with fever, congenital dyserythropoietic anemia (CDA) and often neutrophilic dermatosis (Sweet syndrome). Homozygous mutations in the *LPIN2* gene located on the short arm of chromosome 18 have been identified as being responsible for the Majeed syndrome. Aim of study was to report a novel mutation in the *LPIN2* gene detected in two brothers with Majeed syndrome and to describe the clinical characteristics and response to treatment.

Methods: Two Turkish brothers (13 months (Y) and 29 months old (M) with consanguinity of the parents were admitted with relapsing episodes of pain and 'pseudoparalysis' of upper and lower extremities since the age of 3 and 6 months, respectively. No concomitant fever has occurred during the attacks. *LPIN2* gene re-sequencing was performed on each of the affected child.

Results: Whole body MRI of the elder brother (M) revealed osteomyelitic changes of the metaphyses of tibiae, left fibula and left radius. Biopsy from lesions showed no malignancy and negative bacterial cultures. Both showed significant hypersedimentation (ESR 92 mm/hr (Y) and 96 mm/hr (M)), slight thrombocytosis, and moderate anemia (Hb 9.0 (Y) and 9.7 (M) g/dl). Bone marrow aspiration was consistent with congenital dyserythropoietic anemia (CDA) with 6%–9% bi- or multinucleated erythrocytes. *LPIN2* gene re-sequencing of each affected child revealed a homozygous 2 bp deletion (c.1312_1313delCT) resulting in an early truncation of the protein (L438fs+16X), which confirmed the diagnosis in both patients. Clinically, both were refractory to the treatment with corticosteroids and TNFα inhibition (etanercept). Elevated plasma levels of proinflammatory cytokines (IL-1β, IL-6, IL-8, TNFα) did not change significantly during the treatment. In M, rapid clinical and laboratory improvement was observed after introduction with anakinra (1.7 mg/kg/d), which has not yet been introduced to Y.

Conclusion: We describe a novel mutation of the *LPIN2* gene in two Turkish brothers with Majeed syndrome. Although our patients also presented with CDA none of them had fever during the attacks nor dermatological changes unlike previously described patients with Majeed. IL-1 inhibition showed promising clinical and laboratory results.

Incidence and Identification of Citrullinated Proteins in Synovial Fluid of Juvenile Idiopathic Arthritis Patients. Brooke E. Gilliam[1], Melinda R. Reed[2], Anil K. Chauhan[1], Amanda Dehlendorf[1] and Terry L. Moore[3]. [1]Saint Louis University, St. Louis, MO, [2]Ozarks Medical Center, West Plains, MO, [3]Saint Louis University, Saint Louis, MO

Background/Purpose: To identify citrullinated autoantibodies, α-enolase and fibrinogen specifically, in juvenile idiopathic arthritis (JIA) synovial fluid (SF) and determine their role in the pathogenesis of JIA.

Methods: SF samples were obtained from 7 JIA patients, including 1 with IgM rheumatoid factor (RF)-positive polyarthritis, 2 with IgM RF-negative polyarthritis, and 4 with oligoarthritis. Two osteoarthritis (OA) SF samples were analyzed as non-inflammatory controls. SF were transferred to PVDF membrane and probed with antibodies to peptidyl arginine deiminase (PAD)-4, PAD-2, native α-enolase, and native fibrinogen. Citrullinated proteins were also identified. SF samples were immunoprecipitated with antibodies to fibrinogen and α-enolase. Citrullinated fibrinogen and α-enolase were then detected using the anti-modified citrulline (AMC) kit.

Results: PAD-2 and PAD-4 were observed in all JIA and OA SF samples. Intensity for PAD-2 was greater in the group of JIA patients who also demonstrated reactivity with anti-citrulline. Native α-enolase was present in all JIA samples, with 5 samples showing considerable activity. Trace amounts of α-enolase were evident in OA SF. Native fibrinogen was detected in all JIA SF samples, while neither OA sample demonstrated reactivity. Western blot analysis showed that 3/7 JIA patient samples, 2 polyarthritis and 1 oligoarthritis, contained multiple citrullinated proteins. No citrullinated proteins were detected in OA SF. Western blot analysis of SF immunoprecipitated for fibrinogen using AMC detection showed citrullination of the same 3 JIA SF samples. Immunoprecipitation with α-enolase, followed by AMC detection, yielded no detection of citrullinated α-enolase in JIA or OA SF.

Conclusion: The abundance of citrullinated proteins in JIA SF may be characteristic of inflammation, as seen in rheumatoid arthritis (RA) and spondyloarthritis. The presence of PAD-2 and citrullinated proteins in JIA SF suggests a role for PAD-2 in deimination of SF proteins, as seen in inflammatory arthritis. Presence of anti-PAD-4 antibodies has shown significant association with destructive disease in RA. Few studies have evaluated citrullination of proteins in JIA. Here we have shown the detection of citrullinated proteins at the site of inflammation, specifically identifying citrullinated fibrinogen and citrullinated α-enolase.

Familial Periodic Fever Syndrome with Congenital Dyserythropoetic Anemia and Non-Bacterial Osteomyelitis. Sarah Keidel and Nick Wilkinson. Nuffield Orthopaedic Centre, Oxford, United Kingdom

Background/Purpose: The periodic fevers are a group of heritable disorders characterized by episodic fever and raised inflammatory markers, and are due to monogenic mutations of the innate immune system. We present a family of 3 patients with periodic fever, congenital dyserythropoetic anemia, synovitis, non-bacterial osteomyelitis and probable resolution by the 2nd decade. We compared with existing literature and undertook genetic analysis to provide prognostic information to the family.

Methods: Three females from a Pakistani family of four had a history of congenital dyserythropoetic anemia and infantile episodic fevers associated with non-bacterial osteomyelitis of the tibiae and failure to thrive. There was a history of parental and maternal grandparental consanguinity. The mother was asymptomatic after the age of six, the elder daughter was well by age eight with only occasional knee pain, and the youngest daughter (2.5yo at latest review) was improving with reduced frequency of fevers, increasing weight, and normal development. We compared the features of these patients with other periodic fevers and requested genetic analysis.

Results: This family's profile fits with conditions that include chronic recurrent multifocal osteomyelitis (CRMO), including Majeed syndrome (caused by LPIN2 gene mutations) and DIRA (deficiency of interleukin1–receptor antagonist syndrome caused by IL1RN mutations). However, atypical for Majeed syndrome was the isolated involvement of the tibiae, attenuation with age, and probable resolution in childhood[1]. The presence of fever and lack of skin abnormalities was against the diagnosis of DIRA[2]. Genetic sequence analysis on each of the family members was performed; no mutations of the PSTPIP2 or IL1RN genes were present. However, a homozygous mutation in exon 17 of the LPIN2 gene (c.2207A>G) was found in both parents and siblings, including the asymptomatic father. This mutation has not been reported to cause Majeed syndrome[3].

Conclusion: We present a unique family with an uncharacterized periodic fever syndrome of good prognosis, possibly representing a forme fruste of Majeed syndrome. At this point, the relevance of the genetic findings within this family's LPIN2 gene is unclear. We welcome collaboration in identifying patients with similar clinical features and conducting further genetic studies.

Evaluation of An Autoantibody Profile in Pediatric- and Adolescent-Onset Systemic Lupus Erythematosus and Their Association with Disease-Associated Manifestations. Brooke E. Gilliam[1], Amanda K. Ombrello[2], Rufus W. Burlingame[3], Peri H. Pepmueller[1] and Terry L. Moore[4]. [1]Saint Louis University, St. Louis, MO, [2]National Institutes of Health, Bethesda, MD, [3]INOVA Diagnostics, Inc., San Diego, CA, [4]Saint Louis University, Saint Louis, MO

Background/Purpose: To evaluate an autoantibody profile in pediatric- and adolescent-onset systemic lupus erythematosus (SLE) patients to determine the clinical and statistical associations with disease-related manifestations.

Methods: Sera from 53 SLE patients and 22 healthy individuals were collected. Antibodies to C1q, histone, chromatin, ribosomal P, double-stranded (ds) DNA, and high avidity (HA) dsDNA were measured by enzyme-linked immunosorbent assays. Patient records were evaluated for clinical and laboratory associations.

Results: Significantly elevated levels of all measured autoantibodies were found in SLE patients when compared to healthy individuals ($p<0.05$). The most prevalent autoantibody measured in the SLE cohort was anti-C1q antibodies, found in 60% of SLE patients. Anti-C1q antibodies correlated significantly with proteinuria, fever, urinary casts, and decreased complement levels ($p<0.05$). Antibodies to C1q, dsDNA, histone, and chromatin were significantly elevated in patients with active disease compared to those who were asymptomatic. Anti-C1q and anti-histone antibodies were significantly elevated in patients with class III/IV nephritis compared to class I/II/V nephritis. SLE patients with active nephritis demonstrated significantly elevated levels of anti-C1q antibodies compared to those without active nephritis (191U v. 80U, $p<0.05$), also exhibiting 100% sensitivity for active nephritis, proteinuria, and urinary casts. Chart-documented anti-dsDNA antibodies were positive in 28 SLE patients, INOVA anti-dsDNA antibodies in 25 patients, and HA anti-dsDNA antibodies in 8 patients. Anti-histone antibodies correlated significantly with leukopenia, hemolytic anemia, anti-dsDNA and HA anti-dsDNA antibodies.

Conclusion: Our findings indicate the importance of measuring anti-C1q antibodies in pediatric/adolescent-onset SLE patients because elevated anti-C1q antibody levels indicate renal disease activity, demonstrating significant correlation with proteinuria, urinary casts, and active nephritis. The HA anti-dsDNA antibody ELISA may eliminate potential false-positive results and provide a more accurate assessment by eliminating low avidity, weakly bound antibodies detected by traditional assays. Overall, antibodies to C1q, histone, dsDNA, and HA dsDNA exhibited the strongest association with clinical features, indicating the relevance of measuring all of these antibodies in the pediatric and adolescent SLE population.

303

Juvenile Systemic Lupus Erythematosus and Juvenile Dermatomyositis Are Marked by Distinct Profiles of Soluble Apoptosis Molecules. Bernadete Liphaus[1], Maria H. B. Kiss[2], Solange Carrasco[3], Clovis A. A. Silva[1] and Claudia Goldenstein-Schainberg[4]. [1]Instituto da Criança, Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [3]Disciplina de Reumatologia, Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [4]University of São Paulo, São Paulo, Brazil

Background/Purpose: Conflicting results concerning the role of soluble apoptosis related molecules and their relationship to childhood rheumatic diseases still remains. Therefore, the aim of this study was to quantify sFas, sFasL, sTRAIL and sBcl-2 levels in sera from patients with Juvenile Systemic Lupus Erythematosus (JSLE) and evaluate their association with nephritis and disease activity biomarkers.

Methods: Soluble apoptosis molecules were measured in sera from 43 patients with JSLE (36F:7M, mean age=14.3, range 8.2–20.8 yrs according to revised ACR criteria) and 74 gender and age-matched controls (39 disease controls—26 Juvenile Idiophatic Arthritis (JIA), 13 Juvenile Dermatomyosistis (JDM); 35 healthy individuals). Commercial solid phase ELISA kits were used to quantify sFas, sFasL, sTRAIL and sBcl-2, in duplicate for each sample, following the manufacturer's instructions. Lupus activity biomarkers including SLEDAI score, ESR, serum anti-dsDNA (by quantitative ELISA), C3 and C4 (by standard methods) levels were evaluated at the moment of blood withdraw. Thirty JSLE patients presented active disease (SLEDAI ≥4) and 32 had nephritis. For statistical analysis, nonparametric Kruskal-Wallis test and Spearman's rank were performed, with P value < 0.05 considered significant.

Results: JSLE patients presented increased levels of sFas and sTRAIL, decreased concentrations of sFasL and similar sBcl-2 levels compared to healthy

controls, which were all related to active but not inactive disease (Table). SLEDAI score correlated positively with sFas (r=0.52; p=0.001), while anti-dsDNA, C3, C4, ESR and renal involvement had no association with soluble proteins. Of note, JIA patients had sFas, sFasL, sBcl-2 and sTRAIL levels similar to controls, but remarkably JDM patients presented a 2-fold higher sBcl-2 level compared with all control groups.

Table. Serum concentrations of soluble apoptosis molecules (sFas, sFasL, sTRAIL and sBcl-2) in patients with JSLE, disease controls (JDM and JIA) and healthy individuals.

Diagnosis (N° patients)	sFas (pg/ml)	sFasL (ng/ml)	sTRAIL (pg/ml)	sBcl-2 (mg/ml)
JSLE (43)	188.1 ± 69.2*	0.08 ± 0.1[#]	691.3 ± 631.8[#]	7.4 ± 8.6
Active JSLE (30)	199.1 ± 74.0**	0.06 ± 0.06**	731.7 ± 639.3**	6.1 ± 3.9
Inactive JSLE (13)	162.8 ± 50.0	0.14 ± 0.2	604.2 ± 631.7	10.9 ± 16.5
JDM (13)	126.2 ± 78.1	–	612.5 ± 486.3	16.6 ± 9.1[§]
JIA (26)	166.7 ± 84.3	0.31 ± 0.4	473.4 ± 437.8	6.7 ± 10.4
Healthy controls (35)	133.2 ± 80.6	0.36 ± 0.4	346.6 ± 251.1	9.3 ± 9.6

The results are presented as mean ± SD. *p<0.01, JSLE vs healthy controls and JDM; [#]p<0.01, JSLE vs controls; [§]p<0.01, JDM vs healthy controls, JSLE and JIA; **p<0.01, active JSLE vs controls; — only one JDM patient had detectable sFasL.

Conclusion: Increased levels of sFas and sTRAIL, decreased concentrations of sFasL and similar sBcl-2 levels in JSLE indicates a distinct profile of increased induction of apoptosis compared to JIA and JDM. This particular proapoptotic profile may contribute to perpetuation of JSLE, since it is typically present during active disease. Furthermore, increased sBcl-2 may indicate a different role of apoptosis in JDM, which deserves further investigation.

Background/Purpose: The most prevalent autoinflammatory syndromes (AIS) with an identified genetic defect are: Familial Mediterranean Fever (FMF); Tumoral necrosis fator (TNF) Receptor Associated Periodic Syndrome (TRAPS); Pediatric Granulomatous Arthritis (PGA); Cryopyrin Associated Periodic Syndromes (CAPS), which includes Neonatal Onset Multisystem Inflammatory Disease (NOMID) or Chronic Infantile Neurological Cutaneous and Articular (CINCA) syndrome, Muckle-Wells Syndrome (MWS) and Familial Cold Autoinflammatory Syndrome (FCAS); and Mevalonate Kinase Deficiency (MKD) or Hyper—IgD and periodic fever Syndrome (HIDS). The objectives of this Brazilian multicenter study were to assess the clinical and laboratory characteristics of patients with a clinical suspicion of AIS from the five regions of the country, and to determine the prevalence of identifiable genetic defects.

Methods: A cross-sectional multicenter study was performed and included 102 patients from 22 Pediatric Rheumatology centers distributed in the 5 Brazilian regions. All patients had a clinical diagnosis of one of the following disorders: CAPS, TRAPS, FMF, MKD and PGA. Demographic, clinical and laboratory findings and treatment related variables were collected for each patient. One of the five AIS-related genes (*CIAS1*, *TNFRSF1A*, *MEFV*, *MVK* and *NOD2*) was evaluated in each patient by direct DNA sequencing based on the most probable clinical suspect. The exonic regions and flanking intronic sites of these genes were amplified by polymerase chain reaction (PCR) using specific primers for each gene. The DNA fragments were directly sequenced in both directions and all mutations detected were confirmed in a second PCR product amplification followed by sequencing.

Results: The clinical diagnoses of the 102 patients were: CAPS in 28 patients, TRAPS in 31, FMF in 17, MKD in 17 and PGA in 9. The most frequent clinical findings present in the 102 patients were: fever (85%), arthralgia (61%), abdominal pain (56%) and skin rash (49%), while the most prevalent laboratory findings included: increased erythrocyte sedimentation rate (ESR) (81%), increased C reactive protein (CRP) (78%), anemia (48%) and leukocytosis (46%). The therapies received by all the 102 patients were: corticosteroids (52%), methotrexate (29%), colchicine (25%), cyclosporine (11%), anti-TNF treatment (9%), thalidomide (8%) and anti-IL1 (2%). Of the 102 patients, 32 (31%) had a confirmed genetic diagnosis by evaluation of only one gene per patient: 6/28 (21%) CAPS patients, 7/31 (23%) TRAPS, (41%) 7/17 FMF (41%), 4/17 (24%) MKD and 8/9 (89%) PGA. Within the 28 CAPS patients, 4 of the 13 (31%) NOMID patients had a mutation detected, while 2 of the 8 (25%) FCAS and none of the 7 MWS subjects had a confirmed genetic diagnosis. Seven (27%) of the different 26 mutations identified were novel, such as T433I and K173E in *CIAS1*, G87S and D122H in *TNFRSF1A*, A21V in *MVK*, and D512H and Y563H in *NOD2*. One TRAPS patient was homozygous for the G87S mutation.

Conclusion: This was the first Latin-American study evaluating the prevalence of AIS in a large country and demonstrated one third of genetically confirmed patients at first genetic evaluation.

305

Pathway-Based Analysis Identifies Significant Enrichment of Apoptosis, Immune and Fibrosis Genes Associated with Cardiac Manifestations of Neonatal Lupus. Paula S. Ramos[1], Miranda C. Marion[1], Carl D. Langefeld[1], Jill P. Buyon[2] and Robert M. Clancy[2]. [1]Wake Forest School of Medicine, Winston-Salem, NC, [2]New York University School of Medicine, New York, NY

Background/Purpose: Cardiac manifestations of neonatal lupus, comprising atrioventricular conduction defects and cardiomyopathy, occur in fetuses exposed to anti-Ro/SSA antibodies, and carry substantial mortality. Several lines of evidence support a fetal genetic risk, including increased recurrence rates, concordance of monozygotic twins, and discovery associations in a recent published genome-wide association study (GWAS). Regarding the latter, while the non-HLA autoimmune disease loci did not correlate with cardiac neonatal lupus, we did observe a significant increase in inflation factor for the autoimmune-associated SNPs (i.e., 1.22 vs 1.01; $P < 0.03$, autoimmune vs. whole genome SNPs), suggesting collectively an enrichment of association with these loci. Thus, we evaluated enrichment of associations in specific pathway-related genes such as those that are based on the proposed pathogenesis which invokes an injury cascade initiated by antibody binding to apoptotic cardiocytes and subsequent inflammation and tissue fibrosis.

Methods: We used Ingenuity Pathway Analysis to compile a list of all genes with immune (n=1,993 genes) and fibrotic (n=327 genes) functions. To narrow down the specific immune-related pathways, we tested for enrichment in specific candidate immune pathways: apoptosis (2,283 genes), T cell function (980 genes), cell infiltration (311 genes), innate immune cell function (1,381 genes), interferon (102 genes), TLRs (10 genes) and calcium channels (13 genes). We then tested for an enrichment of admixture and genomic control adjusted significant P-values (at alpha=0.001) in SNPs that met quality control criteria. We performed linkage disequilibrium based SNP pruning so that only independent SNPs were used when calculating the enrichment of significant P-values.

Results: We observed a strong enrichment (P<E-09) of significant SNPs in both immune (n=8,262 SNPs) and fibrosis-related pathways (n=1,577 SNPs); the enrichment persisted after excluding the extended HLA region (n=8,100 immune SNPs, P=5.01E-04; n=1,556 fibrotic SNPs, P=2.27E-09). As a control, genes with bone functions (n=568 genes) did not exhibit enrichment (P=0.21; 2,891 SNPs outside of the HLA). When we analyzed the specific candidate immune pathways, the apoptosis- (P=7.67E-07; 10,211 SNPs), T cell- (P=2.23E-04; 3,804 SNPs), innate immune cell- (P=2.53E-06; 5,736 SNPs), and interferon- (P=1.64E-03; 294 SNPs) related pathways continued to show an enrichment of significance (results reported after exclusion of the extended HLA region).

Conclusion: These data exhibit highly significant enrichment of associations in apoptosis-, innate- immune-, and fibrosis-related genes, and suggest that these genes are likely involved in predisposing to cardiac manifestations of neonatal lupus.

A Novel Mutation in the *PSTPIP1* Gene is Associated with An Autoinflammatory Disease Distinct From Classical Pyogenic Arthritis, Pyoderma Gangrenosum and Acne Syndrome. Dirk Holzinger[1], Judith Austermann[1], Peter Lohse[2], Ivona Aksentijevich[3], Steven Holland[4], Marco Gattorno[5], Carlos Rodríguez-Gallego[6], S. Fessatou[7], Bertrand Isidor[8], S. Tokio[9], Jon Bernstein[10], Barry Sampson[11], Cord Sunderkoetter[12], Dirk Foell[13] and Johannes Roth[13]. [1]University Muenster, Muenster, Germany, [2]University Munich, Munich, Germany, [3]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [4]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, [5]G. Gaslini Institute, Genova, Italy, [6]Dr. Negrín University Hospital, Las Palmas de Gran Canaria, Spain, [7]Attikon Hospital, Athens, Greece, [8]Centre Hospitalo-Universitaire, Nantes, France, [9]Nagoya City University, Tokyo, Japan, [10]Stanford University Medical Center, CA, [11]Charing Cross Hospital, London, United Kingdom, [12]Muenster, Germany, [13]University of Muenster, Muenster, Germany

Background/Purpose: Hyperzincaemia and hypercalprotectinaemia, a rare condition within the spectrum of autoinflammatory diseases, is associated with recurrent infections, hepatosplenomegaly, arthritis, anemia, cutaneous inflammation, and failure to thrive. So far, no genetic cause has been identified in these patients. While the clinical appearance is heterogeneous, all affected individuals present with extremely elevated S100A8/S100A9 (calprotectin) serum concentrations (0.9–12.0 g/l (normal range $<$ 0.001 g/l)). The clinical phenotype of 8 patients was characterized. Screening of candidate genes *PSTPIP1* and *MEFV* was performed in 8 hyperzincaemia and hypercalprotectinaemia patients to identify disease-causing mutations.

Methods: Serum concentrations of S100A8/S100A9 were analyzed by an ELISA assay in 8 patients with hyperzincaemia and hypercalprotectinaemia and compared to PAPA patients with and without treatment. Candidate exons were amplified by PCR and sequenced on an ABI 3130 Genetic Analyzer.

Results: Seven of the eight patients were heterozygous carriers of a glutamic acid 250 (GAG)→lysine (AAG)/p.Glu250Lys/E250K substitution in exon 11 of the *PSTPIP1* gene. S100A8/S100A9 concentrations were extremely elevated in these patients (0.9–12 g/l) compared to seven patients presenting with classical PAPA symptoms (0.02–0.35 g/l), whose levels again were significantly higher compared to normal controls.

Conclusion: The PSTPIP1 E250K mutation causes an autoinflammatory disorder known as hyperzincaemia and hypercalprotectinaemia. The disease causes a heterogeneous spectrum of symptoms that only partially overlaps with the presentation of the classical PAPA syndrome. Elevated S100A8/A9 levels are a common hallmark and biomarker of disorders caused by mutations in the *PSTPIP1* gene.

Cytokine Expression Array Analysis Segregates Oligoarticular Juvenile Idiopathic Arthritis Patients At Risk of Disease Extension. Sorcha Finnegan, Madeleine Rooney and David S. Gibson. Arthritis Research Group, Queen's University, Belfast, United Kingdom

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common form of childhood arthritis with a prevalence of approximately one in 1000. It consists of a heterogeneous group of inflammatory disorders, within which there are a number of clinical subgroups. Diagnosis and assignment to a particular subgroup can be problematic and at present it is very difficult to predict disease progression from ≤ 4 joints (persistent oligo) to the more severe form which involves > 4 joints (extended oligo) within six months of disease onset. We investigated cytokines commonly involved in JIA to understand how their expression within the synovial joint levels relate to disease extension.

Methods: We used Biochip Array Technology (Randox Laboratories Ltd., UK) to simultaneously measure the levels of 12 different cytokines in 18 treatment-naïve JIA patients (mean disease duration 6 months, mean patient age 6.5 years). 120 ul of each patient's synovial fluid were added to a single 9×9 mm biochip and samples were run overnight on the Evidence Investigator ™ (Randox Laboratories Ltd., UK). Each sample was probed for EGF, IL 1α, IL 1β, IL 2, IL 4, IL-6, IL-8, IL-10, IFN-γ, MCP 1, TNF α and VEGF.

Results: Of the 12 analytes measured 3 were found at significantly elevated levels in the extended compared to the persistent oligoarticular group. TNF α was significantly higher ($p = 0.02$) in the extended (47.6 pg/ml) compared to the persistent patients (17.3 pg/ml). IL8 was raised ($P<0.05$) in the extended group as was IL1B ($p=0.05$) (extended= 30.4 pg/ml, persistent= 3.6 pg/ml for IL1B). EGF, IL 1α, IL 2, IL 4, IL-6, IL-10, IFN-γ, MCP 1 and VEGF levels were not significantly altered between the two groups.

Conclusion: Presently it is difficult to predict whether disease will spread to > 4 joints in a child who initially presents with oligoarticular JIA. If disease extension can be reliably predicted, more effective treatment could be initiated in a timely fashion. A prior histological study revealed differences in the synovial tissue of the two subgroups. However, synovial fluid is more accessible and the identification of increased levels of TNFA, IL8 and IL1B represents an initial step in the process of understanding the pathological differences between subgroups. An expanded cohort will be used in the future to test the predictive strength of a multi-analyte cytokine panel.

308

Circulating IP-10 and MCP-1 Levels in Active Localized Scleroderma. Katherine Kurzinski[1], Christina Kelsey[1], Thaschawee Arkachaisri[2], Carol A. Feghali-Bostwick[3] and Kathryn S. Torok[1]. [1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]KK Women's and Children's Hosp, Singapore, Singapore, [3]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Localized scleroderma (LS) is a fibrotic autoimmune disease of the skin and underlying tissues that primarily affects children. T-helper (Th) cell subsets and their associated cytokines are thought to contribute to the pathogenesis of LS and systemic sclerosis (SSc). Traditionally, a Th2 predominant response has been supported, but more recent data also implicate Th1, Th17, and various chemokine involvement. This study was designed to further evaluate the serum cytokine and chemokine profiles of patients with active pediatric LS.

Methods: Serum samples were obtained from pediatric LS, adult LS, pediatric SSc patients and healthy pediatric controls. All LS patients had active disease at the time of sample collection, defined clinically by the presence of new, expanding, and/or erythematous lesions, and were naïve to systemic therapy. Using Luminex technology, 27 cytokines and chemokines from Th1, Th2, and Th17 subsets were evaluated. Nonparametric analyses were performed to compare cytokine/chemokine levels between groups and to determine relationships between individual analyte levels and clinical parameters $p < 0.05$.

Results: Circulating levels of IP-10 and MCP-1 were significantly elevated in pediatric LS, adult LS, and pediatric SSc when compared with healthy controls (see Table). IP-10 levels correlated with mLOSDI, a validated skin damage measure for LS patients ($r_s=0.644$, $p=0.001$), and with the number of anatomical sites affected ($r_s=0.515$, $p=0.012$). IP-10 levels were also significantly higher in LS patients with positive single stranded DNA (ssDNA) antibodies.

		IP-10 (pg/ml)		MCP-1 (pg/ml)	
Group	n	Median	IQR	Median	IQR
Pediatric LS	23	407.59	201.99–1278.93	371.17	341.55–577.01
Adult LS	32	358.72	233.68–1435.05	652.5	415.97–938.58
Pediatric SSc	11	435.47	262.04–779.76	843.65	472.14–2101.77
Healthy Control	10	208.08	124.81–259.08	132.89	74.33–214.34

Conclusion: Elevated levels of IP-10, an IFN-γ-associated chemokine, and MCP-1, a profibrotic chemokine, were seen in pediatric and adult LS and SSc, suggestive of a shared pathogenesis between the diseases. Moderate to strong correlations were observed between IP-10 levels and the number of sites affected and ssDNA antibodies, indicating that IP-10 may be a predictor of disease severity in LS patients. Future investigation into the roles of IP-10 and MCP-1 and their association with Th cell lineages in LS will help lead to a greater understanding of the disease pathogenesis and to the development of more efficacious therapies.

Presence and Significance of Anti-Citrullinated Type II Collagen and Anti-Citrullinated Vimentin Antibodies in Juvenile Idiopathic Arthritis Patients. Brooke E. Gilliam[1], Anil K. Chauhan[1] and Terry L. Moore[2]. [1]Saint Louis University, St. Louis, MO, [2]Saint Louis University, Saint Louis, MO

Background/Purpose: Anti-cyclic citrullinated peptide (CCP) antibodies in juvenile idiopathic arthritis (JIA) have been identified as an important indicator for destructive disease, as is the case in rheumatoid arthritis (RA).

While the role of anti-CCP antibodies in RA and JIA has become better understood, the identity of the target proteins of this modification has remained elusive. In this study, we evaluated serum from patients with various subtypes of JIA to investigate the presence of anti-citrullinated type II collagen (CII) and anti-citrullinated vimentin antibodies, and their association with rheumatoid factor (RF) and anti-CCP antibody isotypes. Additionally, our previous published data on anti-citrullinated fibrinogen and α-enolase antibodies will also be considered.

Methods: Sera were obtained from 25 JIA patients, 19 sytemic lupus erythematosus patients (SLE) patients, and 10 healthy children. All sera were measured for antibodies against citrullinated and native CII and vimentin by enzyme linked immunosorbent assays. Results were compared to anti-CCP antibody isotypes and RF isotypes, anti-citrullinated fibrinogen antibodies and anti-citrullinated α-enolase antibodies. The relationship between anti-citrullinated antibodies and joint damage and disease activity were also investigated. All results were correlated with clinical parameters.

Results: Eleven of 25 (44%) JIA patients were positive for anti-citrullinated CII, while 5/25 (20%) were positive for citrullinated vimentin. Six patients showed no reactivity to any of the measured anti-citrullinated antibodies, while 3 were only reactive to anti-citrullinated fibrinogen antibodies. The most common combination of positivity was anti-citrullinated CII antibodies with anti-citrullinated fibrinogen or anti-citrullinated α-enolase antibodies with 3 JIA patients each. None of the JIA patients showed reactivity to more than 2 citrullinated antibodies. JIA patients' positive for erythrocyte sedimentation rate and IgA anti-CCP antibodies demonstrated elevated levels of anti-citrullinated vimentin antibodies. Anti-citrullinated vimentin antibodies correlated significantly with anti-citrullinated α-enolase antibodies and anti-citrullinated fibrinogen antibodies ($p<0.05$). Anti-CII antibodies correlated significantly with anti-citrullinated vimentin antibodies, anti-citrullinated fibrinogen antibodies, citrullinated α-enolase antibodies, and IgA and IgG anti-CCP antibodies ($p<0.05$).

Conclusion: In addition to our previous study showing the presence of anti-citrullinated fibrinogen and α-enolase antibodies in JIA, we have also shown that anti-citrullinated and anti-citrullinated vimentin antibodies can also be detected in JIA sera. JIA patients exhibited a diverse citrullinated autoantibody repertoire, indicating the significance of measuring these specific citrullinated autoantibodies in JIA patients.

Pathogenesis Study of Infantile-Onset, Severe Pustular Psoriasis Reveals a *De Novo* Mutation in *CARD14* Causing Psoriasis Which Responds Clinically to IL-12/23 Blocking Treatment with Ustekinumab. Nadia Habal[1], Yongqing Chen[2], Catherine Jordan[3], Yin Liu[2], Dawn C. Chapelle Neal[4], Deborah Stone[5], Damaris Garcia[5], Nicole Plass[6], Edward Cowen[4], Chyi-chia Lee[4], Michelle Lowes[7] and Raphaela T. Goldbach-Mansky[8]. [1]NIH/NIAMS, Bethesda, MD, [2]NIAMS, Bethesda, MD, [3]Washington University Division of Human Genetics, Saint Louis, MO, [4]NIAMS/NIH, Bethesda, MD, [5]Translational Autoinflammatory Disease Section, Office of the Clinical Director NIAMS, Bethesda, MD, [6]National Institutes of Health Clinical Center, Bethesda, MD, [7]Laboratory for Investigative Dermatology, The Rockefeller University, New York, NY, [8]NIH Building 10 Room 6D47B, Bethesda, MD

Background/Purpose: Monogenic autoinflammatory disorders in young children have provided us with insights into key inflammatory pathways that have helped to elucidate the pathogenesis of genetically complex and more common diseases. A pediatric patient with non familial, early onset and treatment resistant pustular psoriasis may provide new insights into the pathogenesis of psoriasis and was investigated genetically and immunologically.

Methods: A 4-year old female patient had pustular psoriasis involving 100% of her skin and nails and was unresponsive to treatments with methotrexate, cyclosporine, the TNF inhibitor infliximab, and the recombinant human IL-1 receptor antagonist, anakinra. Clinical and genetic assessment for skin infections, cutaneaous malignancies and the autoinflammatory syndrome, DIRA, were negative, patient was also negative for HLA Cw6 and B27. Genetic analysis of *CARD14,* a recently identified gene causing familial psoriasis was tested, and skin biopsies were stained for CARD 14, IL-12, IL-23 and IL-17. Treatment with ustekinumab (Stellara) was initiated.

Results: The patient harbored a *de-novo CARD14* mutation (p.Glu138Ala) that was not detected in both parents. The mutations enhanced NF-kB activation in mutant and wildtype CARD14 transfected HEK293 cells. Further upregulation by TNF-α stimulation that was seen with wildtype constructs was not observed in the constructs with the mutant allele. The patient had a dramatic clinical response to ustekinumab therapy with complete resolution of skin and nail findings. Delay in therapy led to recurrence of rashes on her leg but responded to retreatment. Immunohistochemistry of the skin showed presence of CARD 14 staining mainly in the keratinocytes in the epidermis and increased staining of IL-23 and IL-17 in mononuclear infiltrating cells in the inter-phase and epidermis before treatment, which was reduced after treatment with ustekinumab. IL-12 was present in the papillary dermis in a psoriasis case, but to a much lesser degree in our patient before treatment and was negative after treatment.

Conclusion: This is a first case with a *de novo* mutation causing pustular psoriasis and confirms the notion that sporadic mutations can cause common diseases. Our data suggest that upregulation of the IL-12/IL-23/p40 effector pathway is mediated by CARD14 signaling. Although the role of CARD14 protein in immune cells in the development of psoriasis remains elusive our observations raise the possibility of an important role of keratinocytes in the pathogenesis of psoriasis and possibly other inflammatory skin disorders.

ACR Poster Session A
Rheumatoid Arthritis Clinical Aspects I: Rheumatoid Arthritis Classification, Disease Activity and Remission; Biomarkers and Predictors of Response
Sunday, November 6, 2011, 9:00 AM–6:00 PM

Defining Rheumatoid Arthritis From Radiographic Erosive Abnormalities in the Light of the ACR/EULAR 2010 Criteria. Cédric Lukas[1], R. Knevel[2], Annette H.M. van der Helm-van Mil[3], Nathalie Rincheval[4], Désirée van der Heijde[5] and Bernard G. Combe[6]. [1]Montpellier 1 University, Lapeyronie Hospital, 371, Avenue du Doyen Gaston Giraud, 34295 Montpellier Cedex 5, France, Montpellier, France, [2]LUMC, Department of Rheumatology, Leiden, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Institut Universitaire de Recherche Clinique, Montpellier, France, [5]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [6]Hopital Lapeyronie, Montpellier, France

Background/Purpose: Definition of rheumatoid arthritis (RA) with regard to the new 2010 ACR/EULAR criteria can be made based on the presence of radiographic abnormalities ("*erosions typical of RA*"). This work reports results from a EULAR taskforce aiming at defining these RA-specific erosive lesions.

Methods: Patients from the French observational ESPOIR cohort had arthritis ($\geq$1 swollen joint) lasting for between 6 weeks and 6 months, and had not been treated before inclusion. The relationship between baseline radiography (eroded joints on hands and feet) and the start of methotrexate (MTX) during the first 12 months of the disease was evaluated. The test characteristics/performance of radiography (sensitivity, specificity, negative and positive- predictive values and likelihood ratios) were tested against the start of a treatment (regarded as the gold standard to define RA, similarly as in the development of the new diagnostic criteria). Different number and sites of eroded joints were considered to define "abnormal radiography", and the respective characteristic tests were derived.

	N (%)	Se	Sp	PPV	NPV	LR+	LR−	AUC
no erosions	325 (45)				reference			
≥1 joint	398 (55)	0.60	0.57	0.84	0.27	1.38	0.71	0.58
≥2 joints	264 (45)	0.51	0.69	0.86	0.27	1.64	0.71	0.60
≥3 joints	179 (35)	0.42	0.81	0.89	0.27	2.16	0.72	0.61
≥4 joints	134 (29)	0.35	0.85	0.89	0.27	2.29	0.77	0.60
> 4 joints	97 (23)	0.28	0.92	0.92	0.27	3.46	0.78	0.60

Results: 723 patients (77% women) had both clinical follow-up and baseline radiographic assessment suitable for the scheduled analyses: 46% were rheumatoid factor-, 39% anti-CCP2 positive. 325 patients (45%) had no detectable erosion, 398 (55%) had at least 1, and 134 (19%) at least 4 eroded joints. Expectedly, definition of "*radiographic abnormality*" by an increasing number of eroded joint was related to increased specificity and decreased sensitivity. Presence of more than 4 eroded joints resulted in the highest specificity (92%) and positive predictive value (92%). Influence of the eroded site (*MCP*, *MTP*, *IP* or *wrist joints*) or their combinations had no clear influence, except for the wrist involvement which showed low sensitivity (12%) but high specificity (91%) of being treated by MTX. Se = sensitivity, Sp = specificity, PPV = positive predictive value, NPV = negative

predictive value, LR+ = positive likelihood ratio, LR- = negative likelihood ratio

Conclusion: These results show that the presence of erosions in the wrist or in more than 4 joints is very specific for RA. Further discussion should aim at choosing an optimal cutoff to define "*typical abnormalities*" of RA.

312

Comparison of the 1987 ACR and 2010 ACR/EULAR Classification Criteria for Rheumatoid Arthritis in Clinical Practice. Ewa H. Berglin[1] and Solbritt M. Rantapaa-Dahlqvist[2]. [1]Umeå university, Umea, Sweden, [2]Umeå University, Umea, Sweden

Background/Purpose: To compare the application of 1987 ACR and 2010 ACR/EULAR classification criteria for rheumatoid arthritis (RA) in clinical practice**.**

Methods: The medical records of patients (pts) attending the Rheumatology department of Umeå university hospital with diagnosis of arthritis except for crystal diseases were studied. Pts fulfilling the following criteria were included: (1) presence of synovitis in at least one joint at first presentation (2) no other diagnosis than RA better explaining the synovitis (3) duration of symptoms < 1 year at first presentation (4) ≥ 1 year of follow-up from first visit. IgM-rheumatoid factor (RF; Waaler-Rose test), ACPA (Eurodiagnostica or Phadia), and erosions on hand and wrist radiographs at inclusion and initiation of DMARDs during the first year were recorded. Fulfilment of the 1987 ACR and the 2010 ACR/EULAR criteria was evaluated at the first visit and the sensitivity and specificity for each criteria set estimated with initiation of methotrexate (mtx) during the first year and clinical diagnosis of RA at follow-up as outcome measures.

Results: 1026 medical records were screened from which 313 patients (65% women, 60 % RF positive, 64% ACPA positive, 17% erosions) with the mean age (±SD) of 56 (± 16.4) years and median (range) duration of symptoms of 4 (0.25–11.5) months were included. A total of 233 patients (74%) fulfilled the 2010 ACR/EULAR, 164 (52 %) the 1987 ACR criteria and 157 (50 %) both sets of criteria at first visit. The agreement between the two sets of criteria was 73%. The frequency of fulfilment of 2010 ACR/EULAR criteria was significantly higher in pts ≥ 56 years compared with pts < 56 years (79 % vs. 68 % $X^2 = 5.01$, $p = 0.025$). No difference was found for the 1987 ACR criteria between pts ≥ and < 56 years. The frequency of fulfilment of neither 1987 ACR nor 2010 ACR/EULAR criteria did differ between pts with duration of symptoms < or ≥ 4 months. The 2010 ACR/EULAR was tested with cut-off point 7 points which increased the sensitivity for mtx first year to 76 % and decreased the specificity to 63 %.

	Outcome: Mtx first year		Outcome: RA (rheumatologist opinion at one year follow-up	
	RA (1987 criteria)	RA (2010 criteria)	RA (1987 criteria)	RA (2010 criteria)
All pts; n = 313				
Sensitivity, %	64	84	68	91
Specificity, %	82	52	86	65
AUC	0.774	0.743	0.837	0.842
Pts < 56 years; n = 131				
Sensitivity, %	61	78	69	91
Specificity, %	82	61	90	79
AUC	0.770	0.715	0.899	0.896
Pts ≥ 56 years; n = 182				
Sensitivity, %	67	89	72	91
Specificity, %	82	53	82	52
AUC	0.780	0.773	0.786	0.795
Pts with duration of symptoms < 4 months at baseline; n = 128				
Sesitivity, %	64	82	66	89
Specificity, %	80	48	84	66
AUC	0.756	0.707	0.818	0.837
Pts with duration of symptoms 4–12 months at baseline; n = 185				
Sensitivity, %	65	85	70	92
Specificity, %	88	56	87	65
AUC	0.783	0.771	0.854	0.845

Conclusion: 2010 ACR/EULAR criteria had higher sensitivity but lower specificity than 1987 ACR criteria in this cohort of early arthritis patients. The 2010 ACR/EULAR criteria were significantly more often fulfilled in pts ≥ 56 years. Raising the cut-off point of 2010 ACR/EULAR criteria to 7 points would decrease the sensitivity but increase the specificity of that criteria set.

313

The 2010 ACR/EULAR Classification Criteria for Rheumatoid Arthritis: Earlier Diagnosis At the Expense of Increased Heterogeneity. Maria J. H. de Hair[1], K. A. Lehmann[1], Marleen G. H. van de Sande[1], Karen Maijer[1], Danielle M. Gerlag[1] and Paul P. Tak[2]. [1]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [2]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam The Netherlands, Amsterdam, Netherlands

Background/Purpose: Recently, new classification criteria for rheumatoid arthritis (RA) have been developed. We examined the implication of the use of the new criteria in clinical practice in a very early arthritis cohort.

Methods: 301 early arthritis patients (arthritis duration < 1 year; DMARD naive) included between 2002 and 2010 in the early arthritis cohort of the Academic Medical Center Amsterdam were studied. Baseline diagnosis was assessed applying 1987 ACR and 2010 ACR/EULAR criteria for RA as well as established diagnostic criteria for other rheumatic diseases. Diagnostic and prognostic (self limiting, persistent non-erosive and persistent erosive disease) data after 2 year follow up were available of 239 and 186 patients, respectively. We evaluated in the subset of patients classified as UA when applying 1987 ACR criteria the fulfillment of 2010 ACR/EULAR criteria and tested the sensitivity, specificity and positive and negative predictive value of the 2010 ACR/EULAR criteria at baseline using RA diagnosis according to 1987 ACR criteria after 2 years follow up as gold standard. In addition, we compared the clinical picture using the two criteria sets at baseline.

Results: Median disease duration at baseline in the whole cohort was 3.0 months (range 0–12). At baseline 28% fulfilled the 1987 ACR criteria compared to 45% for the 2010 ACR/EULAR criteria for RA. This percentage increased to 36% and 55%, respectively, after 2 years follow up. Fifty- three per cent of all patients included had UA at baseline when applying 1987 ACR criteria compared to 36% when applying 2010 ACR/EULAR criteria, which decreased to 44% and 22%, respectively, after 2 years follow up. Of the patients classified as UA at baseline when 1987 ACR criteria were applied, 36% fulfilled 2010 ACR/EULAR criteria already at baseline. Of the patients initially classified as UA at baseline when 1987 ACR criteria were applied, but who fulfilled 1987 ACR criteria after 2 years follow up, 85% already fulfilled 2010 ACR/EULAR criteria at baseline, confirming the increased sensitivity of the new criteria. Eighty-eight per cent of the patients fulfilling 1987 ACR criteria for RA after 2 years follow up fulfilled 2010 ACR/EULAR criteria at baseline, with a specificity of 0.76. The positive and negative predictive values were 0.77 and 0.91, respectively. Of the patients fulfilling 1987 ACR criteria at baseline 67% was IgM-RF and/or ACPA positive compared to 62% for patients fulfilling 2010 ACR/EULAR criteria at baseline. Four per cent of the RA patients fulfilling 1987 ACR criteria at baseline presented with monoarthritis compared to 9% of the patients fulfilling 2010 ACR/EULAR criteria at baseline. Of the patients fulfilling 1987 ACR criteria for RA at baseline 2% had self-limiting disease, compared to 12% of the patients fulfilling the 2010 ACR/EULAR criteria at baseline.

Conclusion: Use of the 2010 ACR/EULAR criteria clearly allows earlier diagnosis of RA, although some patients with self-limiting disease may be falsely diagnosed with RA. Patients fulfilling 2010 ACR/EULAR criteria during early disease are less likely to be autoantibody positive and more likely to have monoarthritis than those fulfilling 1987 ACR criteria.

2010 American College of Rheumatology/European League Against Rheumatism Rheumatoid Arthritis Criteria Classifies 67% of Systemic Lupus Erythematosus and 38% of Psoriatic Arthritis As Rheumatoid Arthritis: Implications for Real World Use. Lauren M. Kennish[1], Monalyn Labitigan[2], Sam Budoff[3], Maria T. Filopoulos[1] and Yusuf Yazici[4]. [1]Hospital for Joint Diseases, New York, NY, [2]New York University, New York, NY, [3]Vanderbilt University, Nashville, TN, [4]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: The new 2010 ACR/EULAR criteria for rheumatoid arthritis (RA) have been designed to classify early onset RA and target patients who would benefit from rapid initiation of methotrexate therapy. It is not known how these criteria perform to identify RA in patients with arthritis seen in routine clinical care. The criteria have been studied in RA cohorts but not in patients with other conditions that may mimic RA. The purpose of this study is to test the validity of the 2010 RA criteria in a general rheumatology practice to determine how well it can distinguish RA from other types of inflammatory arthritides.

Methods: 126 consecutive new and established patients from a general rheumatology practice were recruited consecutively after screening by their primary rheumatologist and included if they had joint symptoms between 8/1/2010-4/30/2010. The ACR/EULAR RA criteria were applied, as laid out by the task force, by a single rheumatologist with questions followed by a targeted musculoskeletal and extra-articular exam. The patients were followed retrospectively and prospectively for additional exam findings, laboratory and radiographic tests, and physician diagnosis not present at time of screening. The gold standard for the diagnosis of RA was the primary rheumatologist's diagnosis. Sensitivity and specificity were calculated.

Results: 126 patients were recruited for the study, and 112 were analyzed. They had a mean age of 48.2 years, with 77.7% women, an average duration of disease of 5.3 years, and 25% were new patients diagnosed within the last six months. 30 (26.8%) patients had a primary diagnosis made by their physician of RA, the rest had psoriatic arthritis (PsA) n=24 (21.4%), systemic lupus erythematosus (SLE) n=24 (21.4%), osteoarthritis (OA) n=12 (10.7%), and other rheumatic conditions n=22 (19.6%). The sensitivity and specificity of the 2010 criteria in classifying RA were 97% and 55%, respectively, compared with the 1987 RA criteria which were 93% and 76%, respectively. The 2010 criteria as applied to this group of patients had a poorer positive predictive (44% vs 61%) and a similar negative predictive value (98% vs 97%) compared with the 1987 criteria. In patients with a known diagnosis of RA, 96.7% met the 2010 criteria. In the combined population of those without a rheumatologist diagnosis of RA, 45.1% fulfilled the 2010 criteria. More specifically, 66.7% of SLE patients, 50% of OA, 37.5% of PsA, and 27.2% of others (2 Sjogren's syndrome, 2 spondyloarthritis, 1 gout and 1 mixed connective tissue disease) fulfilled the new criteria and could have been classified as RA.

Conclusion: We believe this is the first study to examine the new 2010 ACR/EULAR RA criteria in a broad spectrum of rheumatologic diseases seen in routine care. These criteria are more sensitive in classifying RA patients compared with the 1987 criteria. However, the criteria have low specificity, and will therefore incorrectly label those as having RA when in fact they may have another type of inflammatory arthritis, as seen among these patients. Physicians need to be aware of this when applying the new criteria for classifying their patients for any purpose.

Performances of the 2010 ACR/EULAR Classification Criteria of Rheumatoid Arthritis: Comparison with 1987 ACR Criteria in the Community-Based Vera Cohort. Julia Nicolau Jr.[1], Patrick Boumier[2], Alain Daragon[1], Othman Mejjad[1], Jean-François Ménard[1], Sophie Pouplin[1], Olivier Vittecoq[3], Patrice Fardellone[2] and Xavier Le Loët Sr.[3]. [1]Rouen University Hospital, Rouen, France, [2]Amiens University Hospital, Amiens, France, [3]Rouen University Hospital and Inserm U 905, Rouen, France

Background/Purpose: To compare performances of 1987 American College of Rheumatology (ACR) and 2010 ACR/EULAR (EUropean League Against Rheumatism) classification criteria of rheumatoid arthritis (RA) in the VErA (Very Early Arthritis) cohort.

Methods: VErA cohort had a community-based recruitment and was conservatively treated during the 2 first years. It comprised 310 patients included between 10–1988 and 01–2002: ≥18 year old, ≥ 2 swollen joints for ≥ 6 weeks and ≤ 6 months, naïve of DMARD and steroids. This cohort was not used to develop 2010 criteria. 1987 ACR and 2010 ACR/EULAR criteria were applied at baseline in the whole population and using tree algorithm; the sensitivity and specificity were determined using as outcome measure the 3 experts consensual diagnosis at 6 years.

Results: Characteristics of the overall population were: female 68%; median age 52 years [19–84]; swollen joint count 7 [2–37]; tender joint count 6 [0–58]; DAS 28 2.95 [0.45–7.53]; mean HAQ 0.75 [0–2.9] ESR 18mm/1st h [1–110]; CRP 7mg/l [5–206]; IgM RF+ 22.6% and anti-CCP+ 23.2%; ≥1 erosion 16.8%. 41 patients had alternative diagnoses (algorithm step 1). Among the 269 other patients at baseline, 67.7% and 59.5% fulfilled the 2010 ACR/EULAR and 1987 ACR criteria respectively. The ACR/EULAR 2010 criteria sensitivity was significantly higher: 85.9% *vs* 77.9% (Mc Nemar's test 0.023); the specificity was similar (59.0% *vs* 64.1%). The discriminative ability of 2010 ACR/EULAR and 1987 ACR criteria was comparable (p<0.09) with areas under the curve 0.81–0.76 respectively. Moreover the ROC curves showed that the score ≥6, proposed by the 2010 criteria for classification as definite RA, was relevant.

Conclusion: Using a very early community-based cohort the 2010 ACR/EULAR criteria classified slightly more patients with RA than the 1987 ACR criteria but otherwise they performed similarly than the older ones. Moreover the ≥6 score seems relevant.

316

The New EULAR/ACR Classification ACPA Cutoff Levels Are Markers of Poor Radiological Outcome in Early Rheumatoid Arthritis. Jose Alfredo Gomez Puerta[1], Virginia Ruiz Esquide[1], M. V. Hernandez[1], Eduard Graell[2], Sonia Cabrera[3], M. J. Gómara[4], Juan D. Cañete[5], Isabel Haro[4] and R. Sanmarti[1]. [1]Hospital Clinic of Barcelona, Barcelona, Spain, [2]Hospital Parc Tauli, Sabadell, Spain, [3]Hospital Clinic of Barcelona., Barcelona, Spain, [4]IQAC-CSIC, Barcelona, Spain, [5]Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain

Background/Purpose: The recent proposed EULAR/ACR criteria for rheumatoid arthritis (RA) were established in part as a useful tool for identify and classified patients with early RA. The cutoff level of 3 times upper limit of normal (ULN) for ACPA antibodies have been pondered as an additional criteria item. Its value as prognostic marker in terms of radiological progression has not been established yet.

Aims: To analyzed the relation of high titers levels of ACPA according to EULAR/ACR criteria with radiological progression in a cohort of patients with early RA.

Methods: We conducted a prospective open-label study that included early RA patients from 2 referral centers. All patients were treated with a similar therapeutic protocol with DMARD. ACPA antibodies were determined by a second-generation anti-CCP2 ELISA test (Eurodiagnostica). We classified 3 populations according to ACPA titers: negative (<29 IU, using own cutoff), positive at low titers (< 3 times ULN) and positive at high titers (> 3 ULN). Additionally, positive ACPA patients were divided as low positive or high positive using median values (293 IU). The minimal clinically-important difference (MCID) was used as a measure of Larsen radiographic progression, with a change of two or more units in the Larsen score considered as indicative of progression after one year in early RA.

Results: One hundred and fifty-five patients were included, 83% of female gender. The mean age was 54.7 ± 14.9 years, with a mean disease duration of 9.7 ± 6.6 months. Rheumatoid factor was positive in 76.3% and ACPA in 75.7%. At baseline Larsen score was 1.9 ± 6.9 and erosion joint count was 0.4 ± 1.3. Thirty percent of patients had Larsen score ≥1 and the18.6% had erosion joint count ≥1.

At baseline, 23% of patients were negative for ACPA, 11% of patients were positive at low titers (<3 ULN) while 65% of patients had high titers of ACPA (>3 ULN).

After two years of follow-up those patients classified as ACPA positive at high titers had a higher radiological progression than those patients with ACPA negative or ACPA positive at low titers (See Table). When radiological progression was analyzed according to median levels, there were no differences among ACPA positive at low titers and ACPA positive at high titers.

Table. Radiological progression (Δ Larsen score ≥ 4) after 2 years of follow-up according to ACPA titers (categorized by cutoff and median)

		No progression		Progression		p value
		No.	%	No.	%	0,033
ACPA (> 3 ULN)	Negative	30	83	6	16	
	Low titers	13	76	4	23	
	High titers	65	65	35	35	
	Total	108		45		0,204
ACPA (Median)	Negative	30	83	6	16	
	(<median)	38	64	21	35	
	(>median)	40	68	18	31	
	Total	108		45		

Conclusion: After two years of follow-up, patients with early RA with high titers of ACPA according new EULAR/ACR criteria had greater radiographic progression than those patients ACPA negative or positive at low titers. ACPA titers could have not only classification utility but also prognosis implications.

317

Very High Specificity of Anti-Citrullinated Peptide Antiboldies (ACPA) in a Tertiary Medical Center. Meriem Ridene[1], Jeremie Dion[2], Makoto Miyara[3] and Bruno Fautrel[4]. [1]Tunis Medecine University, Tunis, Tunisia, [2]Faculté paris 7 Dénis-Diderot, Paris, France, [3]Université Pierre et Marie Curie—Paris 6, Pitié-Salpêtrière University Hospital, Paris, France, [4]Université Pierre et Marie Curie—Paris 6—Pitie Salpetriere University Hospital, Paris, France

Background/Purpose: Anti-cyclic citrullinated peptide (ACPA) antibodies have been shown to be a specific marker for the diagnosis of rheumatoid arthritis (RA)./To assess the ACPA specificity and positive predictive value through the long term experience of a tertiary university medical center.

Methods: We collected information about all the patients detected positive for anti-CCP antibodies between 2003 and 2010 (October). Detection was based on an enzyme linked immunosorbent assay (ELISA) using the anti-CCP2 kit (Diasorin. Anthony France). We focused on patients with titres of anti-CCP; i. e., superior to 90 IU. All medical charts were reviewed by 2 investigators (RM, DJ) to assess patient main clinical and biological characteristics.

Results: Between 2003 and 2010, 12 476 ACPA testing were performed: 808 were positive (≥ 30IU), 623 highly positive (≥ 90IU). Clinical features were available for all 623 cases (443 female) near aged 54.4 (DS= 14.7).The diagnosis made by the physician in charge of the patients are presented in the table. 23 patients have non auto-immune disease specially, infections (n=2): HIV, coetaneous candida; neurological (n=4): mitochondrial myopathy, peripheral motor neuron disease, autoimmune encephalopathy, cerebral accident; chronic widespread pain (n=6), other Rheumatologic (n=6): SPID, microcrystalline arthropathies, knee arthrosis, monoarthritis, non determined rheumatism and other (n=5). None of the patients was diagnosed with neoplasm. PPV was 88, 7%.

	N° (%)	Anti-CCP (IU) (Average/Median)
Definitive or probable RA	553 (88.7%)*	1739/605
Probable RA associated with another Connectivite Tissue disease (CTD)	10 (1.6%)**	5835/2080
Other auto-immune disease		
Sjogren Syndrome	10 (1.6%)	1057/543
Systemic Lupus Erythematous	2 (0.3%)	1295/1295
Spondylarthritis	10 (1.6%)	1138/764
Mixed Connective	3 (0.5)	162/872
Connective and vasculitis	2 (0.3%)	829/829
Other	4 (0.6%)	203,4/79
Non auto-immune disease		
Non auto-immune disease	23 (3.7%)	558/295

* (88, 8% positif for RF)
** (87, 4 %positif for RF)

Conclusion: In a tertiary university center in which patients with complex, misleading or confusing diseases are referred, ACPA test remains highly specific and is associated with high PPV.

318

Evaluation of the Patients with Early Arthritis by 2010 RA Criteria in Conjunction with MRI of Wrists and Finger Joints. Mami Tamai[1], Kazuhiko Arima[1], Masataka Uetani[1], Naoki Iwamoto[1], Junko Kita[1], Akitomo Okada[1], Tomohiro Koga[2], Shin-ya Kawashiri[1], Kunihiro Ichinose[1], Satoshi Yamasaki[1], Hideki Nakamura[1], Hiroaki Ida[3], Tomoki Origuchi[1], Kiyoshi Aoyagi[1], Katsumi Eguchi[4] and Atsushi Kawakami[1]. [1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Nagasaki University School of Medicine, Nagasaki, Japan, [3]Kurume University School of Medicine, Kurume, Japan, [4]Sasebo City General Hospital, Sasebo, Nagasaki, Japan

Background/Purpose: 2010 rheumatoid arthritis (RA) criteria was published last year and are going to be applied in the clinical field of rheumatology. We have also been investigating a prediction rule for RA using magnetic resonance imaging (MRI) of wrists and finger joints at Nagasaki University. We have tried to examine the utility of MRI of wrists and finger joints in conjunction with 2010 RA criteria toward patients with early undifferentiated arthritis at our cohort.

Methods: Two hundred patients with early arthritis, who are not better explained by other diagnosis than RA at entry whose mean duration of symptoms is 3 months, were consecutively enrolled into this study. Japan College of Rheumatology-certified rheumatologists have examined the patients for at least 1 year. At entry, all of the patients were examined by gadolinium-diethylenetriamine pentaacetic acid (Gd-DTPA)-enhanced MRI of both wrists and finger joints. Patients were evaluated by 2010 RA criteria at the initial visit. Diagnosis of RA was defined by the initiation of disease-modifying antirheumatic drugs (DMARDs) therapy during the first year. Diagnostic performance of 2010 RA criteria in conjunction with MRI of wrists and finger joints were investigated.

Results: At least one swollen joints were found in 138 patients at entry, being examined for further analysis. 2010 RA criteria classified RA at sensitivity 76.3 %, specificity 70.7 %, positive predictive value (PPV) 86.0 %, negative predictive value (NPV) 55.8 % and accuracy 76.4 %. However, twenty-three out of 52 patients, who had not been classified as RA at entry by 2010 RA criteria, developed RA at 1 year. Bone edema was defined as most RA-specific MRI finding. If we considered the patients to have RA in case bone edema is found, the diagnosis of RA was made at sensitivity 87.6% and specificity 65.9% in whom 2010 RA criteria at entry was less than 6.

Conclusion: MRI findings, especially bone edema, are quite useful to assist the diagnostic performance of 2010 RA criteria.

319

Comparison of the 1987 and 2010 Classificatioh Criteria for Rheumatoid Arthritis in a Population of Patients with Early Arthritis. Ana M. Ortiz Garcia, Ana M. Fernández-Ortiz, Silvia Pérez-Esteban, Rosario Garcia-Vicuña and Isidoro González-Alvaro. Hospital Universitario de La Princesa. IIS Princesa, Madrid, Spain

Background/Purpose: The 1987 classification criteria for rheumatoid arthritis (RA) were developed after studying a population with long-standing disease. However, the current paradigm in the management of RA is to initiate DMARD treatment as soon as possible. Since, it was considered that 1987 classification criteria are less effective to identify RA when applied in patients with early arthritis (EA), a new set of criteria for the classification of RA has been developed and recently published. These new criteria need to be tested in different populations and settings. The objective was to compare the two sets of criteria for the classification of RA (1987 and 2010) in a population of patients with EA.

Methods: We analyzed data from 260 patients (81% women) of our EA register, which includes patients with at least one swollen joint for at least four weeks and with symptoms for less than one year. The age at onset was 50 [38–62] years (median [p25-p75]) and the duration of the disease in the first visit 5.3 [3.1–8.1] months. Rheumatoid factor (RF) was positive in 34.4% of patients (nephelometry; positive > 20 IU / ml [min: 0–max: > 3.000]) and anti-CCP antibody in 28.6% (ELISA, RA Inmunoscan Euro-Diagnostica, positive > 50 IU / ml [min: 0–max: 3125]). For the purposes of applying the 2010 criteria, the upper limit of C-reactive protein was considered 0.8 mg/dl and of ESR 10 or 15 mm/h (men and women, respectively). We performed a descriptive analysis of patients who met the criteria for RA 1987 and 2010 in the first visit. The gold standard was considered the diagnosis of the patient's attending rheumatologist after two years of follow up. In these conditions the prevalence of AR in our population was 40% of cases. This gold standard was considered for estimating sensitivity, specificity, positive and negative predictive value (PPV and NPV respectively) and likelihood ratio (LR) + and − of each of the sets of classification criteria.

Results: At the first visit, 134 patients (51.5%) were classified as RA with the 2010 classification criteria and 116 patients (44.6%) when the 1987 criteria were applied. Results from the statistical analysis carried out for both sets of criteria are shown in the following table:

	Sensitivity	Specificity	PPV	NPV	LR+	LR−
2010	88.2%	72.2%	67.2%	90.5%	3.17	0.163
1987	85.3%	81.6%	75%	89.6%	4.65	0.18

PPV: positive predictive value; NPV: negative predictive value; LR: likelihood ratio

Conclusion: In our EA population there are no relevant differences in RA disease identification when the 1987 or the 2010 classification criteria are implemented except for a higher specificity for the 1987 set. This finding could be related to the relatively long duration of the disease when our patients enter in the register.

This work was partially supported by RETICS Program, RD08/0075 (RIER) and FIS 080754 from Instituto de Salud Carlos III (ISCIII)

New Index to Assess the Improvement From the Worst Rheumatoid Arthritis Activity without Formal Joint Count. Naoto Yokogawa, Kota Shimada, Yoshiki Nagai, Takahiro Nunokawa, Shinichi Inada and Shoji Sugii. Tokyo Metropolitan Tama Medical Center, Tokyo, Japan

Background/Purpose: Rheumatoid arthritis (RA) is a life-long disabling disease. No composite indices can measure the disease activity without formal joint count and estimate the worst disease activity. Routine Assessment of Patient Index Data 3 (RAPID3) is a validated index which does not require formal joint count. Because most patients remember the worst level of disability and pain, the worst disease activity can be estimated using the method of RAPID3 (worst RAPID3). We proposed a new index to assess the improvement of the disease activity from the worst ever (%RAPID3).

Methods: The proportion of the improvement from the worst in RAPID3 was defined as %RAPID3. [%RAPID3=(Worst RAPID3−Current RAPID3)/Worst RAPID3)×100].

We measured RAPID3, worst RAPID3, and %RAPID3 along with the traditional indices which require joint count such as Disease Activity Score (DAS28), Clinical Disease Activity Index (CDAI), and Simplified Disease Activity Index (SDAI). We set the remission criteria of %RAPID3 using the the American College of Rheumatology/European League Against Rheumatism provisional definition of remission. We compared the sensitivity and specificity of each remission criteria.

Results: Sixty-nine RA patients were included in this study. Seventeen patients (24.6%) were categorized in remission. By %RAPID3 cut-off of 75, we can screen the patients in remission with the highest sensitivity (100%). The sensitivity and specificity of each remission criteria were summarized in Table 1.

Table 1.

	Sensitivity (%)	Specificity (%)
SDAI remission	82.4	88.5
CDAI remission	82.4	88.5
DAS28 remission	82.4	69.2
RAPID3<3	82.4	82.7
RAPID3<2	76.5	88.5
%RAPID3≥a80	88.2	78.9
%RAPID3≥a75	100	65.4
%RAPID3≥a70	100	61.5

Conclusion: % RAPID3 is the only disease activity index which can reflect the total improvement in the disease course. Complementary use of RAPID3 and %RAPID3 may provide the most practical and patient-oriented strategy in all RA patients.

321

Benefits of the Implementation of Specialized Clinics in Rheumatoid Arthritis for Rule Out False Positives of Disease and Osteoarthritis As a Frequent Cause of Misdiagnosis. Pedro Santos-Moreno[1], Felipe Gonzalez-Malaver[2], Luisa Fernanda Amador[1], Claudia Guzman-Saltis[2], Maria F. Cubides[1], Ana Milena Arbelaez[1] and Rafael Valle-Onate[2]. [1]Biomab IPS, Bogota, Colombia, [2]Universidad Militar, Bogota, Colombia

Background/Purpose: The lack of expertise in the diagnosis of rheumatoid arthritis (RA) has led to misdiagnosis of patients with the disease, which has had clinical, pharmaco-economic and social consequences. The objective of this study was to describe the clinical and demographic characteristics of a cohort of patients with misdiagnosis of RA, emphasizing in Osteoarthritis (OA) as one of the most frequent causes of erroneous diagnosis of RA and the beneficial role of a specialized in RA clinic for rule out false positive patients.

Methods: In a specialized center in RA for the past 6 months were followed 2204 patients with presumptive diagnosis of this disease (patients were seen and remitted to the center by general practitioners, internists, physiatrists and other related specialties).

Included in the study patients were evaluated by a rheumatologist; it was made a complete medical history; it was measured rheumatoid factor and anti-citrullinated antibodies, and other laboratories depending on each case-.Also was performed x-rays of hands, and in some cases of persistent doubt about the diagnosis was requested comparative MRI of hands.

Afterwards, patients with false positive diagnosis of RA were analyzed for obtain information about those diseases which can misdiagnosis RA.

Statistical analysis was performed using STATA10. It was applied Shapiro-Wilk test to assess the kind of distribution of data. Afterwards, it was used Wilcoxon's test (for these not normally distributed data) obtaining medians for each variable.

The analysis of continuous variables was performed descriptively by presenting summary statistics and P values. For categorical data, absolute and relative frequency was calculated. The difference of medians showed a statistically significant in each of the variables analyzed, given by a P value < 0.05 for all of them.

Results: Of all the 2204 patients evaluated, in 1186 patients (53.8%) had confirmed the diagnosis of RA. It was found that 1018 patients (46.2%) were misdiagnosed with RA. Of these "false positives" diagnoses were found the following entities: 729 osteoarthritis patients (71.6%), systemic lupus erythematosus 72 patients (7%), Sjogren syndrome 30 patients (2.9%), spondyloarthropathies 23 patients (2.3%) and other diagnoses 16.2% of the population remaining.

As was seen, OA still with 729 patients (71.6%) the disease most often led to misdiagnosis. 230 patients (37%) were men, and 499 patients (63%) women. The average age was 54.3 years. Many of these patients had diagnosis of RA and were receiving disease-modifying drugs (DMARDs) continuously on average during the last 4.5 years.

Conclusion: This study shows that OA is the main distraction in the misdiagnosis of AR with serious clinical, social and pharmaco-economic implications associated.

Also demonstrate the urgent need for the implementation of specialized clinics in RA avoiding internists and the development of effective education strategies for primary care physicians and related specialties to conduct a proper diagnosis of RA.

322

Rheumatoid Arthritis Case Validation Strategies in Large Research Databases: The Women's Health Initiative Experience. Brian T. Walitt[1], Rachel Mackey[2], Lewis Kuller[2], Kevin D. Deane[3], William Robinson[4], V. Michael Holers[5], Russell Tracey[6], Yuefang Chang[2] and Larry W. Moreland[2]. [1]Washington Hospital Center, Washington, DC, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Colorado School of Medicine, Aurora, CO, [4]Stanford Univ School of Med, Stanford, CA, [5]Univ of Colorado School of Med, Aurora, CO, [6]Colchester, VT

Background/Purpose: Research of rheumatoid arthritis (RA) epidemiology and outcomes using large databases is often limited by insufficient case validity. Employing serologic measurements of anti-cyclic citrullinated peptide (anti-CCP) antibody and rheumatoid factor (RF) is a potential method to improve diagnostic validity of the RA case definition in large research databases. We report on our RA validation experiences in the Women's Health Initiative (WHI).

Methods: A previous validation study (J Rheumatol 2008; 356:811–8) collected and reviewed medical records at two WHI sites to determine RA case validity with definitions based on self-reported RA status, Disease Modifying Anti-Rheumatic Drug (DMARD) use, and responses of subjects to the Connective Tissue Screening Questionnaire (CSQ). In this current study, baseline blood samples of this validation cohort of women self-reporting RA (n=345) were additionally tested for anti-CCP2 (Axis-Shield, Dundee, Scotland) and RF by nephelometry. Positive and Negative Predictive Values were then calculated considering these additional factors.

Results: The addition of autoantibody studies increased the Positive Predictive Value (PPV) of the RA case definition (Table 1). When only two variables are considered, self-report RA and anti-CCP2 provide the highest PPV (76.9%). When anti-CCP2 results are combined with either DMARD use or CSQ results, the PPV is 100% but excludes all seronegative cases. The most valid definition that includes seronegative RA cases is 'self-report RA + DMARD or Self-report RA + anti-CCP2 + RF (PPV 63.6%). False negatives are minimized in these case, definitions as evidenced by Negative Predictive Values >90%.

Table 1. Positive and Negative Predictive Values of Rheumatoid Arthritis Case Definitions

Definition Used:	Positive Predictive Value	Negative Predictive Value
Self-Report RA	14.8%	–
Self-Report RA + CCP2	76.9%	93.9%
Self-Report RA + RF	44.6%	94.1%
Self-Report RA + DMARD*	62.2%	93.9%
Self-Report RA + DMARD + CCP2	100%	91.8%
Self-Report RA + DMARD + RF	78.9%	88.7%
Self-Report RA + DMARD OR Self-Report RA + CCP2	58.3%	95.3%
Self-Report RA + DMARD OR Self-Report RA + CCP2 + RF	63.6%	95.3%
Self-Report RA + CSQ	39.1%	94.9%
Self-Report RA + CSQ + CCP2	100%	91.8%
Self-Report RA + CSQ + RF	77.3%	92.4%
Self-Report RA + CSQ OR Self-Report RA + CCP2	40.3%	95.9%
Self-Report RA + DMARD + CSQ	82.4%	91.4%
Self-Report RA + DMARD + CSQ + CCP2	100%	90.4%
Self-Report RA + DMARD + CSQ OR Self-Report RA + CCP2	83.3%	93.6%

* Current standard RA case definition in the WHI

Conclusion: Serologic measurements improve the test characteristics of RA case definitions in the WHI. Diagnostic validity approaches 100% if only seropositive RA cases are considered.

323

Evaluation of Definitions of Rheumatoid Arthritis Remission by Assessing Radiographic Progression in the Leiden Early Arthritis Cohort. Annette H.M. van der Helm-van Mil[1], Rachel Knevel[1], Ferhan Qureshi[2], William C. Manning[2], Guy Cavet[2], T.W.J. Huizinga[3] and Douglas J. Haney[2]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Crescendo Bioscience, Inc., South San Francisco, CA, [3]Leiden University Medical Centre, Leiden, Netherlands

Background/Purpose: Clinical remission is increasingly seen as a desirable and realistic objective in the management of Rheumatoid Arthritis (RA). Useful definitions of clinical remission should identify patients at reduced risk of progressive joint damage. A novel multi-biomarker test for disease activity (MBDA) in rheumatoid arthritis has recently been developed and validated. We set out to evaluate whether the MBDA test can augment existing classifications of remission.

Methods: Subjects were members of the Leiden Early Arthritis Cohort. Those included in the current study met the 1987 ACR criteria for RA. Patients and visits were selected non-randomly to have greater rates of radiographic progression than the overall RA cohort, to increase our ability to evaluate predictors of progression. The pre-specified MBDA algorithm combined the concentrations of 12 biomarkers to produce scores from 1–100. MBDA score and other variables were assessed at 271 study visits and evaluated for prediction of progression over the following 12 months. Subjects with change in Sharp-van der Heijde Score (ΔSHS) ≤3 were classified as non-progressors. The pre-test and post-test odds of non-progression were calculated for definitions of remission based upon DAS28CRP (<2.32), EULAR/ACR Boolean criteria[1] (SJC28≤1, TJC28≤1, GH≤1, CRP≤1mg/dL), or MBDA score (≤25). Definitions of remission were evaluated using the positive likelihood ratio[1]. In addition, we evaluated whether a high MBDA score (>44) provides information about the risk of progression of a patient in remission based on DAS28CRP.

Results: The positive likelihood ratio (PLR) for non-progression over 12 months of an MBDA score ≤25 vs >25 was 4.73 (95% CI = [1.67, 15.0]). PLRs were greater than 1 but not statistically significant for DAS28CRP <2.32 (PLR = 1.38; 95% CI = [0.90, 2.38]) and the EULAR/ACR Boolean criteria (PLR = 1.78; 95% CI = [0.72, 5.17]). Similar relative performance was observed with other ΔSHS thresholds for non-progression. For patients in DAS28CRP remission, those with a high MBDA score were 2.3 times as likely (95% CI = [1.1, 3.7]) to have progressive joint destruction during the next year.

Conclusion: In a cohort of early arthritis patients, MBDA score ≤25 is an indicator of limited radiographic progression over 12 months. Among patients in DAS28CRP remission, high MBDA scores identify those at elevated risk of progression. MBDA results may provide a useful adjunct to clinical assessment in estimating risk of radiographic progression.

TNF-Like Ligand 1A Is a Promising Biomarker of Disease Activity In Rheumatoid Arthritis. Yoo Jin Hong, Yun Jong Lee, Kichul Shin, Byoung Youg Choi, Hye Won Kim, Sung Hae Chang, In Ah Choi, Eun Young Lee, Eun Bong Lee and Yeong Wook Song. Seoul National University Hospital, Seoul, South Korea

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation of multiple joints. TNF-like ligand 1A (TL1A), a ligand belonging to the TNF superfamily, is expressed by endothelial cells, lymphocytes, monocytes and plasma cells. These are also the key cell lineages participating in the pathogenesis of RA. Moreover, TL1A is up-regulated by proinflammatory cytokines TNF-a and IL-1. We thereby examined the serum and synovial fluid levels of TL1A in patients with RA. In addition, we investigated the relationship between serum TL1A concentration and clinical parameters in RA patients.

Methods: Serum samples were obtained from 232 patients with RA and 29 with osteoarthritis (OA). Thirty-eight and 27 synovial fluid (SF) samples were collected from respective group of patients. Additional 45 serum samples before and after (14 weeks) anti-TNF-a treatment were collected from RA patients. TL1A concentrations were measured by ELISA. Clinical parameters were acquired at the time of sampling.

Results: Serum concentrations of TL1A in RA patients were significantly higher than those in OA patients (mean ± SD, 1327.4 ± 3858.8 pg/ml vs. 150.3 ± 269.6 pg/ml, p< 0.0001). The SF levels of TL1A were elevated in patients with RA compared with those in OA (965.7 ± 1617.2 vs. 271.4 ± 238.9, p= 0.013). Levels of TL1A were significantly increased in SF than serum in matched samples (RA; p= 0.006, OA; p< 0.0001). Serum levels of TL1A decreased substantially with anti-TNF-a treatment (p= 0.002). Serum levels of TL1A correlated well with DAS28-ESR (r= 0.170, p= 0.021), DAS28-CRP (r= 0.166, p= 0.037), SDAI (r= 0.201, p= 0.016), CDAI (r= 0.195, p= 0.011) and rheumatoid factor positivity (r= 0.876, p= 0.044).

Conclusion: Serum and SF levels of TL1A were significantly increased in RA patients compared with OA patients, and correlated well with clinical parameters representing disease activity. Our results support that TL1A could be a potential biomarker in assessing disease activity and treatment response in RA patients.

Prevalence of Remission in Early RA—A Comparison of New Remission Criteria to Established Criteria. Bindee Kuriya[1], Ye Sun[2], Gilles Boire[3], Boulos Haraoui[4], Carol A. Hitchon[5], Janet E. Pope[6], J. Carter Thorne[7], Edward Keystone[2], Diane S. Ferland[8] and Vivian Bykerk[9]. [1]University of Toronto, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]Institut de Rhumatologie, Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]St. Joseph's Health Care, University of Western Ontario, London, ON, [7]Newmarket, ON, [8]LaSalle, QC, [9]Brigham & Women's Hospital, Boston, MA

Background/Purpose: New RA remission (REM) criteria have been proposed by ACR/EULAR.We evaluated the prevalence and agreement between REM definitions in the Canadian Early ArThritis CoHort (CATCH).

Methods: The % of patients (pts) in REM at 12 months based on 5 definitions were considered: DAS28 <2.6, DAS28 <2.0, CDAI </=2.8, SDAI </=3.3 and ACR/EULAR which requires TJC </=1 plus, SJC </=1, plus CRP </=1 mg/dL and patient global assessment (Pt-VAS) </=1 on a 0–10 cm VAS scale. Patients with complete data were included. Differences in core components for each REM definition were qualitatively described. Kappa-statistics of agreement between criteria were performed.

Results: Of 331 pts, 74% met 1987 and 91% met 2010 ACR criteria for RA; 76% were female, mean (SD) age was 52 (14.4) years and mean (SD) symptom duration was 6.3 (3.0) months. At baseline, the cohort had moderate-to-high disease activity according to all scores. Most were RF+ (63%) or anti-CCP+ (83%). Triple DMARD was the most common therapy. By 1 year, the % of pts who achieved REM by >/= 1 definition ranged from 22%–453% (Table). Higher TJC, SJC, Pt-VAS and MD-VAS were seen for DAS28-based definitions. Biologic use was similar for all definitions (range 6–10%). The ACR/EULAR criteria had substantial agreement with SDAI (k= 0.75) and CDAI (k=0.73). Agreement was fair with DAS28<2.6 (k=0.32) and DAS28<2.0 (k=0.35).

Table. Comparison of core components of remission definitions at 12 months.

	DAS28 <2.6	DAS28 <2.0	SDAI </=3.3	CDAI </=2.8	ACR/EULAR
Number in REM, (%)	176 (53)	118 (36)	88 (27)	83 (25)	73 (22)
Core Components					
TJC (%)					
0–2	129 (73)	94 (80)	79 (90)	76 (92)	73 (100)
>2–5	29 (16)	18 (15)	8 (9)	5 (6)	0
>5	18 (11)	6 (6)	1 (1)	2 (2)	0
SJC (%)					
0–2	129 (73)	97 (82)	83 (94)	79 (95)	73 (100)
>2–5	36 (20)	20 (17)	4 (5)	4 (5)	0
>5	11 (7)	1 (1)	1 (1)	0	0
CRP, mean ± SD mg/L	0.3 ± 0.4	0.3 ± 0.4	0.3 ± 0.3	0.4 ± 0.5	0.3 ± 0.2
Pt-VAS, mean ± SD mm	1.8 ± 2.2	1.8 ± 2.2	0.6 ± 0.8	0.5 ± 0.7	0.3 ± 0.4
MD-VAS, mean ± SD mm	0.8 ± 1.1	0.7 ± 1.0	0.2 ± 0.5	0.2 ± 0.3	0.3 ± 0.6

Conclusion: The prevalence of clinical REM ranged between 22 and 53% among this early RA cohort. Achievement of REM was lowest using the strict ACR/EULAR criteria and there was poor agreement between these criteria and frequently used DAS-based definitions. Thus, the choice of definition influences the proportion able to achieve REM and this has implications for long-term outcomes, choice of therapy and quality of care standards.

Factors Associated with Relapse of Remission in Rheumatoid Arthritis. Leslie R. Harrold[1], George Reed[1], David H. Collier[2], Grace S. Park[2], Hong Chang[3], Andrew S. Koenig[4], Katherine C. Saunders[5], Debra J. Zack[6], Joel M. Kremer[7] and Jeffrey D. Greenberg[8]. [1]UMass Medical School, Worcester, MA, [2]Amgen Inc., Thousand Oaks, CA, [3]Tufts Medical Center, Boston, MA, [4]Pfizer Inc., Collegeville, PA, [5]CORRONA, Inc., Southborough, MA, [6]Amgen Inc, Thousand Oaks, CA, [7]Albany Medical College and The Center for Rheumatology, Albany, NY, [8]New York University School of Medicine, New York, NY

Background/Purpose: The goal of treatment in patients with rheumatoid arthritis (RA) is achievement of remission. However, little is known regarding persistency of remission. Therefore we proposed to assess factors associated with relapse of remission in a multi-centered observational registry within the United States (the Consortium of Rheumatology Researchers of North America: CORRONA).

Methods: From among 5,525 biologic naïve RA patients within CORRONA initiating a new nonbiologic disease modifying antirheumatic drug (nbDMARD) or TNF blockade (TNFi), we identified those who were not in remission at the time of drug initiation, achieved remission (Clinical Disease Activity Index [CDAI ≤ 2.8]) while on the drug at a follow-up visit within 12 months, and had at least one follow-up visit. Disease relapse (e.g., loss of remission) was defined as a CDAI>2.8 or adding an additional nbDMARD or biologic. Survival analyses and Cox proportional hazards models were used in both nbDMARD and TNFi initiators separately to assess the likelihood of relapse after adjusting for covariates assessed at the first visit in remission, including age, sex, race, education, insurance, comorbidities, disease duration, and concomitant medication use as well as clustering by physician.

Results: There were 377 nbDMARD initiators who met inclusion criteria of whom 74% women, with a mean age was 58.3 years, mean disease duration of 7.6 years and 42% used methotrexate. The median time until flare was 166 days (interquartile range=177 days) with an estimated 56%, 28%, 16% and 14% still in remission at 6, 12, 24 and 36 months respectively. No socio-demographic or clinical factors were predictive of a flare in those using nbDMARDs. There were 401 TNFi initiators who met inclusion criteria of whom 76% were women, with a mean age of 54.4, mean disease duration of 6.1 years and 81% were receiving concomitant methotrexate. The median time until flare was 182 days (interquartile range=251days) with an estimated 61%, 39%, 25% and 20% still in remission at 6, 12, 24 and 36 months respectively. Increasing age (HR 1.02; 95% CI 1.00–1.03), being disabled (HR 1.78; 95%CI 1.04–3.01), Medicaid insurance (HR 2.38, 95% 1.40–4.03) and having gastroesophageal reflux disease (GERD) (HR 3.89; 2.48–6.09) were all associated with an increased likelihood of relapse in TNFi initiators.

Conclusion: Relapses in remission occurred in the majority of patients newly initiated on nbDMARDs or TNFi in the first three years of therapy. Factors associated with relapse in TNFi initiators were older age, disability, insurance status and GERD.

Current Smoking and Hypertension Are Associated with Synovitis As Measured by Ultrasonography in Therapy-Naive Patients with Recent Onset Arthritis: Results from an Early Arthritis Cohort. Gisela Westhoff[1], Georg Schett[2], Edmund Edelmann[3], Matthias Schneider[4], Angela Zink[5] and Marina Backhaus[6]. [1]German Rheumatism Research Center Berlin, Berlin, Germany, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Rheumatologische Gemeinschaftspraxis, Berufsverband Deutscher Rheumatologen e.V, Bad Aibling, Germany, [4]Heinrich-Heine-University, Duesseldorf, Germany, [5]Deutsches Rheumaforschungszentrum and Charité University Medicine, Berlin, Germany, [6]Charite University Hospital, Berlin, Germany

Background/Purpose: Smoking is a well known risk factor for the development of cardiovascular disease and rheumatoid arthritis (RA). Smoking also compromises response to therapy in established RA. Data on the effects of smoking on very early, untreated arthritis are rare. We therefore investigated the association between smoking and synovitis as measured by a semi-quantitative ultra-sonography score in therapy-naïve patients with recent onset arthritis.

Methods: Baseline data of 163 therapy-naive patients with either RA or undifferentiated arthritis (disease duration <6 months) of an ongoing early arthritis inception cohort were used. Demographic and disease specific data as well as smoking habits and cardiovascular risk factors (CV) were recorded. Synovitis was determined by B-mode ultrasonography, using a semi-quantitative score (no =0 to severe synovitis =3) of 5 synovial sites in 3 hand joints. Correlates of an above-average synovitis score (SynSc ≥5 of 0–15, μ 4.2±3.3; 44% of all patients) were determined using multivariate analyses, adjusting for age and sex.

Results: At first visit, patients had a symptom duration of 13±7 weeks. All were preliminarily diagnosed with either RA (56%) or uA; 71% were classified as having RA according to the new ACR/EULAR classification criteria. CV risk factors were common at first visit, with 38% of the patients having at least one. Prevalent hypertension (29%) and hypercholesterolemia (10%) were the most frequent. 34% of the patients smoked at inclusion and 28% had stopped smoking before the onset of arthritis. Patients with hypertension were significantly older than patients without (65 vs. 49 years, P <0.001) and those currently smoking were significantly younger than non-smokers (47 vs. 56 years, P <0.001). Multivariate regression analyses revealed older age (upper vs. lower tertile: OR 6.0, 95% CI 2.1–17.2, P = 0.001), hypertension (OR 2.5, 95% CI 1.04–5.8, P = 0.040) and current smoking (OR 3.4, 95% CI 1.4–7.3, P = 0.007) as significant risks for above-average synovitis scores (SynSc ≥5). Hypertension gained high significance when age was removed from the analysis (OR 4.11, 95% CI 1.9– 8:8, P <0.001).

Conclusion: Our data show that current smoking, hypertension as well as age are associated with synovitis as measured by ultrasonography in untreated patients with recent onset arthritis. It may be suggested that age, smoking and hypertension cause endothelial damage and thus increase the vulnerability of tissues for synovitis.

328

Near Misses of ACR/EULAR Criteria for Remission: Effects of Patient Global Scores on the Boolean and Index Based Definitions. Paul Studenic[1], Josef Smolen[2] and Daniel Aletaha[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: The ACR/EULAR criteria allow definition of remission by two means: the Boolean approach requires swollen and tender joint counts (SJC, TJC), as well as C-reactive protein (CRP in mg/dL) and patient global assessment (PGA in cm) to be ≤1; the index based definition requires the Simplified Disease Activity Index (SDAI, linear sum of SJC, TJC, CRP, PGA, and physician global (MDGA)) to be ≤3.3. It has been argued that high PGA, if unrelated to RA disease activity, may prevent patients from fulfilling these criteria. We aimed to quantify the relevance of PGA in the definition of remission by the new ACR/EULAR criteria in a patient cohort from clinical practice.

Methods: We identified all visits of RA patients from an observational, prospective RA outpatient database. We investigated the proportion of patients who fulfilled only 3 of the 4 required Boolean criteria. Among those, we identified the proportion of patients who did not reach the criteria because of PGA, SJC, TJC or CRP.

We also looked at the proportion of patients fulfilling the index based definition (which allows scores of some variables to be >1 through compensation by other variables with lower scores), but who did not achieve Boolean criteria because of PGA.

In a next step we estimated the impact of PGA that is potentially unrelated to

RA disease activity (e.g. related to secondary fibromyalgia) as a reason for failure to classify as remission. To this end, we investigated the disconnect of PGA and MDGA, by identifying those who were rated by the MD as ≤1cm or not.

Results: We identified 8242 visits of 794 RA patients (81% female, 68% rheumatoid-factor (RF) positive, mean disease duration: 7.6 years). Four of five (82%) of these patients had at least one visit, where they fulfilled just 3 of the 4 required Boolean criteria: among those, PGA was the major reason for not achieving the criteria (53%; n=344; mean PGA=3.3cm), followed by SJC (21%), CRP (16%), and TJC (10%). Almost 1 in 4 of the patients (23.5%) who failed the Boolean criteria because of PGA fulfilled the index based definition of remission.

238 patients (69.2%) with Boolean criteria failure due to PGA had a disconnect of PGA and MDGA (i.e. PGA >1 & MDGA ≤1cm; mean disconnect: 2.8 cm). One third (31.9%) of those patients did fulfill the index based remission criteria. These patients showed significantly lower pain, PGA (mean PGA=1.7cm) and less disconnect of PGA and MDGA, than those not fulfilling index based criteria (mean PGA=3.7cm). Similar results were obtained when using the Boolean- and index-based definitions for clinical practice which exclude CRP from the respective formulae.

Conclusion: The majority of patients who fail to reach the Boolean definition of remission due to PGA are assessed as <1cm on the physician global. By means of the index based criteria, one third of these patients were classifiable as being in remission, because a slight elevation of the PGA above 1 was compensated by other variables in the index being <1. Thus PGA elevations unrelated to RA disease activity may need to be considered in clinical practice in patients who fail to classify as remission by both, the Boolean and, to a somewhat smaller extent, the index based criteria.

329

Combinations of Anti-Citrullinated Peptide Antibodies with Rheumatoid Factor Isotypes Reveal An Attribute Associated with Disease Activity in Rheumatoid Arthritis Patients Treated with Methotrexate. Thierry Dervieux[1], Cole Harris[2] and Joel M. Kremer[3]. [1]Exagen Diagnostics, Albuquerque, NM, [2]Exagen Diagnostics, [3]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Previous reports have established that anti-citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF) isotypes may predict disease severity in rheumatoid arthritis (RA). We sought to determine whether specific combinations/multi-biomarker panel of ACPA and RF isotypes (IgM, IgG and IgA) were associated with disease activity in RA patients treated with methotrexate (MTX).

Methods: The study was multicentered, cross sectional, and enrolled 232 patients with established RA (74% females, median age 63yrs, median duration of disease 10 yrs) under MTX therapy (median dose 15mg/week) for at least three months (median 35 months). Disease activity score (DAS) was calculated and used to differentiate patients with low disease activity (DAS≤3.2; 82 patients, 35%) from those with medium to high disease activity (DAS>3.2; 150 patients, 65%). ACPA measured consisted of second generation anti-cyclic citrullinated peptide antibodies (anti-CCP2) (Euroimmune, Lübeck, Germany; Eurodiagnostica, Malmö, Sweden), third generation anti-CCP3.1 (Inova Diagnostics, San Diego, CA) and anti-mutated citrullinated vimentin antibodies (anti-MCV, Orgentech, Germany). IgM, IgG and IgA RF isotypes were from Inova Diagnostics. All serological markers were measured using validated enzyme linked immunosorbent assays. Data analysis consisted of Receiver operating characteristic (ROC) curves and data mining algorithms (COPERNA platform) to determine the optimal combination of cutoffs differentiating low from high disease activity. Models were developed using a training set of 155 patients and validated independently in a test set of 77 patients.

Results: Univariate ROC analyses in the training set revealed that anti-CCP2 (Euroimmune, AUC=0.577, p=0.078), anti-MCV (AUC=0.584, p=0.056) and IgA RF isotype (AUC=.587, p=0.023) differentiated low from high disease activity. IgG and IgM RF levels were not associated with disease activity in this population of RA patients. Data mining algorithms established that an attribute consisting of anti-MCV (cutoff> 20 units, 63% positive), antiCCP2 (cutoff >7 units, 62% positive) and IgA RF (cutoff> 11 units, 31% positive) was associated with higher disease activity (Table). The findings were significant in the training and tests set. Overall, carriers of the attribute (positivity for at least 2 of three markers, 59% of patients) were 3.8 fold more likely (OR=3.6 CI95%: 2.1–6.8; p<0.01) to present with high disease activity than none carriers. These findings remained significant after adjusting for covariate such as age, disease duration, MTX dose and duration of treatment.

	Training set (n=155)	Test set (n=77)	Overall (n=232)
Sensitivity	68.0%	73.6%	70.0%
Specificity	60.0%	62.5%	61.0%
Accuracy	65.2%	70.1%	66.8%.

Conclusion: Selective combinations of ACPAs and IgA RF isotype contribute to disease activity in RA.

330

Disease Duration As a Determinate Factor of Disease Activity and Radiographic Progression in Rheumatoid Arthritis. Tahmina Ferdousi, Andrew S. Koenig and Thomas V. Jones. Pfizer Inc., Collegeville, PA

Background/Purpose: Clinical evidence has established the importance of early, aggressive treatment of RA to decrease disease activity and prevent joint damage.[1] The relationship between disease duration and disease activity is not well understood. The objective of this analysis is to examine the relationships between disease duration, disease activity, and inhibition of radiographic progression in patients treated with etanercept (ETN) + MTX or MTX monotherapy.

Methods: Subjects from 2 clinical trials (TEMPO and COMET) were pooled and stratified by short (≤2 years) and long (>2 years) disease duration. Subjects randomized to receive ETN 50 mg weekly + MTX or MTX alone for 52 weeks were included. Disease activity as measured by DAS28 and SDAI was assessed at week 24 and compared to the mean rates of change in mTSS and with radiographic non-progression (mTSS ≤0.5) for each disease duration category and by treatment group. Stratified and multivariate regression analyses (observed data) were performed to determine the relationships between variables.

Results: Among subjects in the ETN+MTX group who achieved DAS28 remission (<2.6) at week 24, the mean (SD) change in mTSS was significantly (P<0.05) lower in those with long duration [–1.38 (2.94)] compared to those of short duration [–0.12 (2.86)]. In the MTX group, mean (SD) change in mTSS was similar in those with long and short duration (Table). Among ETN+MTX subjects who achieved DAS 28 remission, the majority achieved radiographic non-progression regardless of disease duration (long 82.4% vs short 77.1%, p=0.4473), although the trend was towards a higher proportion of subjects with long duration achieving non-progression. Similar findings for radiographic non-progression were observed for MTX subjects who achieved DAS 28 remission (long 68.4% vs short 61.3%, p=0.5742). Among ETN+MTX subjects who achieved SDAI remission (≤3.3) at week 24, the mean (SD) change in mTSS was similar (p=0.3375) in those with long [–1.14 (1.93)] and short [–0.37 (4.14)] duration. Similar findings were observed for the MTX group who achieve SDAI remission [–0.67 (0.76) vs 0.44 (1.78), p=0.1162]. A trend towards a lower rate of radiographic progression was observed in subjects with long duration regardless of treatment. Disease duration was significantly associated with radiographic progression (P<0.05) independent of treatment, DAS 28, or SDAI score at week 24.

Table. Subjects with short and long disease duration by disease duration and radiographic progression at week 24

		ETN + MTX		MTX	
DAS28	**Disease Duration**	**n**	**mTSS Mean Change (SD)**	**n**	**mTSS Mean Change (SD)**
Remission (≤2.6)	≤2 years	109	−0.12 (2.85)	62	0.45 (5.38)
	>2 years	51	−1.38* (2.94)	19	0.55 (2.61)
Low (2.6<3.2)	≤2 years	49	0.11 (1.70)	30	2.03 (5.23)
	>2 years	20	−1.35* (2.37)	15	−0.13 (2.64)
Moderate (3.2≤5.1)	≤2 years	79	0.16 (3.61)	88	2.72 (6.42)
	>2 years	63	−0.63 (3.19)	73	1.49 (7.66)
High (>5.1)	≤2 years	17	0.91 (3.52)	36	8.78 (22.14)
	>2 years	16	−0.59 (3.23)	33	1.07* (4.42)

* P<0.05 versus short disease duration (≤2 years) within each disease duration category per treatment group.

Conclusion: Inhibition of radiographic progression and achievement of non-progression was robust, regardless of disease duration; although the trend was towards greater inhibition patients with longer duration. Caution should be used when interpreting these findings due to the limited number of subjects in the sub-groups. Further analyses will assess the impact of baseline estimated radiographic change and other factors on the relationship between disease duration and treatment response.

331

Routine Assessment of Patient Index Data-3 (RAPID3), a Patient-Reported Index to Guide a Treat-to-Target Strategy for Rheumatoid Arthritis in Usual Care. Martin J. Bergman[1], Theodore Pincus[2] and Isabel Castrejón[2]. [1]Taylor Hospital, Ridley Park, PA, [2]NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Treat-to-target according to the disease activity score (DAS28) in patients with rheumatoid arthritis (RA) has resulted in better outcomes in 7 clinical trials. However, DAS28 is not available at most patient visits, because laboratory test results are pending and formal quantitative joint counts are not recorded. The clinical disease activity index (CDAI) does not require complex calculations or laboratory tests, but does require formal joint counts. RAPID3 (routine assessment of patient index data 3) includes only the 3 patient self-report questionnaire measures in the RA Core Data Set—physical function, pain and patient estimate of global status—and can be calculated in 5 seconds on a multidimensional health assessment questionnaire (MDHAQ), versus about 120 seconds for DAS28 or CDAI. We analyzed a treat-to-target strategy in the care of patients with RA at one rheumatology practice setting according to 3 indices: DAS28, CDAI and RAPID3.

Methods: All patients in this setting complete a multidimensional health assessment questionnaire (MDHAQ) at each visit. RAPID3 scores are the sum of physical function, pain and patient global estimate, each scored 0–10 (total 0–30), with levels of severity: high=>12, moderate=6.1–12, low=3.1–6 and remission=0–3. All RA patients have a physician/assessor 28 joint count, physician global estimate of status, and erythrocyte sedimentation rate (ESR) at each visit, so that DAS28, CDAI and RAPID3 are scored. The treatment target is low disease activity/severity, i.e., a score of ≤10 for CDAI, ≤3.2 for DAS28 and ≤6 for RAPID3. The 3 indices were compared for low activity/severity or remission versus high or moderate activity/severity at baseline and 3-month follow-up, according to percent agreement and kappa statistics.

Results: At baseline, low activity/severity or remission was seen in 10 of 34 patients (29%) according to DAS28, 6 (18%) according to CDAI, and 5 (15%) according to RAPID3. Three months later, low activity/severity or remission was seen in 11 (32%) by DAS28, 13 (38%) by CDAI, and 16 (47%) by RAPID3. Kappas of DAS28 vs RAPID3 were 0.09 at baseline and 0.45 at 3 months, of CDAI vs RAPID3 0.46 at baseline and 0.22 at 3 months, and of DAS28 vs CDAI 0.52 at baseline and 0.40 at 3 months, indicating fair-to-moderate agreement, other than baseline DAS28 vs RAPID3, for which 68% of patients were nonetheless classified similarly by the two indices. Agreement for low activity/severity or remission versus high or moderate activity/severity was seen for 62%–85% of comparisons of RAPID3 with DAS28 or CDAI.

DAS28	High/Moderate (>3.2)	Low/Remission (≤3.2)	Agreement vs RAPID3	Kappa vs RAPID3	Agreement vs CDAI	Kappa vs CDAI
Baseline	24 (71%)	10 (29%)	68%	0.09	82%	0.52
3 mo	23 (68%)	11 (32%)	73%	0.46	71%	0.36
CDAI	**High/Moderate (>10)**	**Low/Remission (≤10)**				
Baseline	28 (82%)	6 (18%)	85%	0.46	NA	NA
3 mo	21 (62%)	13 (38%)	62%	0.22	NA	NA
RAPID3	**High/Moderate (>6)**	**Low/Remission (≤6)**				
Baseline	29 (85%)	5 (15%)	NA	NA	85%	0.46
3 mo	18 (53%)	16 (47%)	NA	NA	62%	0.22

Conclusion: RAPID3 appears similar to DAS28 and CDAI to recognize low activity/severity or remission versus high or moderate activity/severity to guide a treat-to-target strategy for RA in usual care settings.

332

Successful Maintenance of Remission Defined by the New ACR/EULAR Criteria Leads to Better Functional Outcomes in Rheumatoid Arthritis in Daily Practice, Especially in Patients with Early RA, Based on the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) Cohort. Kumi Shidara, Eiichi Tanaka, Eisuke Inoue, Yohei Seto, Ayako Nakajima, Shigeki Momohara, Atsuo Taniguchi and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Remission has become a therapeutic target in the management of patients with rheumatoid arthritis (RA). New remission criteria were proposed by ACR/EULAR to achieve better patient outcomes in 2010. However, the clinical outcomes of RA patients in daily practice who satisfy the new criteria have not been well elucidated. To evaluate long-term functional outcomes in RA patients who satisfied the new ACR/EULAR or DAS28 remission criteria in daily practice based on a cohort of RA patients.

Methods: We established a large observational cohort of RA patients, IORRA (Institute Of Rheumatology, Rheumatoid Arthritis) cohort, in our institute beginning in October 2000. Clinical parameters including physician's assessment, patient's assessment, and laboratory data are collected twice yearly (in April and October). Those RA patients who were in DAS28 remission in April 2008 (baseline) and who completed all IORRA assessments every 6 months from April 2008 to October 2010 (six data collections) were selected for this study. All patients were evaluated whether or not they achieved the ACR/EULAR or DAS28 remission criteria at every data collection. Functional disability was assessed by J-HAQ, the validated Japanese version of HAQ. Boolean trial, Boolean practice, SDAI remission, and CDAI remission were used as ACR/EULAR remission criteria. Among those patients, the percentages whose J-HAQ score progressed during the observation period were calculated.

Results: A total of 915 RA patients in DAS28 remission at baseline who completed all IORRA data collections in the succeeding 3 years were selected (females, 76.3%; mean age, 57.6 years; mean RA disease duration, 11.7 years; mean DAS28, 2.0; mean J-HAQ, 0.32). Percentages of patients whose J-HAQ progressed during the observation period among patients who had continuously achieved remission defined by Boolean trial, SDAI, Boolean practice, CDAI, and DAS28 in all six data collections were 6.2% (10/161), 8.5% (21/247), 5.7% (10/175), 7.1% (16/227), and 14.2% (45/318), respectively. In contrast, the percentages of patients whose J-HAQ progressed was higher among patients who did not fulfill the remission criteria continuously during the 3 years of observation. When patients satisfied the Boolean trial, SDAI, Boolean practice, CDAI, and DAS28 remission criteria in only one of the six data collections during the succeeding 3 years, percentages of patients whose J-HAQ score progressed were 30.8%, 47.4%, 31.7%, 47.1%, and 57.1%, respectively. This was more apparent in patients with a shorter duration of RA than in those with long-term disease.

Conclusion: Remission defined by the new ACR/EULAR resulted in better functional outcomes in RA patients compared to that of DAS28 remission in daily practice. However, maintenance of remission for a longer period of time is important for preventing patients from progression of disability as assessed by J-HAQ using any criteria of remission. This is more important in patients in earlier disease stages than patients with established disease. Thus, introduction and maintenance of remission in early-stage disease is recommended to achieve better functional outcomes in RA patients.

333

The Relationship Between Time in Remission and Functional Status in Rheumatoid Arthritis. Femke H.M. Prince[1], Siri Lillegraven[2], Vivian P. Bykerk[1], Nancy A. Shadick[3], Bing Lu[1], Michelle A. Frits[1], Christine K. Iannaccone[1], Michael E. Weinblatt[1] and Daniel H. Solomon[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital / Diakonhjemmet Hospital, Boston, MA, [3]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA

Background/Purpose: It is presumed that patients with rheumatoid arthritis (RA) in sustained remission have a more favorable outcome. Our objective was to describe change in functional outcome in relation to the number of annual examination in remission in RA patients.

Methods: We analyzed annually collected disease activity variables and outcomes from a prospective, observational, single-center RA cohort, including participants with at least two years follow-up (n=871). Remission was determined by the DAS28-CRP4<2.6, SDAI<=3.3 and 2010 ACR/EULAR criteria. The outcome of functional status was measured using the multidimensional HAQ (mdHAQ) and data were analyzed using linear mixed models. For a secondary analysis we examined the relationship between remission and the minimal clinical important improvement (MCII) in mdHAQ (set at −0.3). In the secondary analysis, subjects with mdHAQ<0.5 at baseline were excluded since improvement is unlikely.

Results: Subjects in remission at one or more annual examinations, regardless of the remission criteria, had a more favorable outcome of mdHAQ compared to subjects who never reached remission ($p<0.001$). In addition, more time points in remission produced more favorable outcomes (see **Figure**). After 4 years of follow-up, more subjects (72%) with >60% of time in DAS28 remission reached the MCII compared to subjects with <60% ($p=0.03$) or no examinations in remission ($p<0.001$). When stratifying according to baseline mdHAQ, subjects with

a low mdHAQ (0–0.5) at baseline remained at approximately the same level when in DAS28 remission (mean change mdHAQ= −0.004), while subjects with a high mdHAQ (1.0–3.0) at baseline showed improvement in functional status during DAS28 remission (mean change mdHAQ= −0.504, p<0.001) after 4 years.

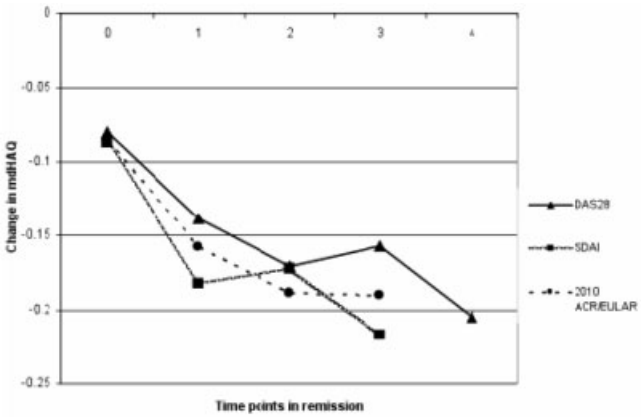

Figure. Change in mdHAQ score in relation to the number of time points in remission. For instance, for patients in DAS28 remission at 4 time points mdHAQ improved with 0.21 per year compared with the improvement of 0.14 per year of patients with only 1 time point in DAS28 remission.

Conclusion: In our study, subjects with more annual examinations in remission experienced greater improvement in mdHAQ. During sustained remission, subjects with high baseline mdHAQ scores improved more than those with lower baseline mdHAQ.

334

Using the Patient Activity Score (PAS-2) to Assess Rheumatoid Arthritis Disease Activity: Bias From the Presence of Comorbid Musculoskeletal Conditions. John T. Schousboe[1], Peter D. Kent[2], Tawatchai Paisansinsup[1], Scott L. Glickstein[1] and Eric S. Schned[1]. [1]Park Nicollet Health Services, Minneapolis, MN, [2]Park Nicollet Clinic, Minneapolis, MN

Background/Purpose: Self-report measures of pain and functional status have been proposed as outcome measures that can be followed to assess rheumatoid disease activity and quality of care for RA patients. The Patient Activity Score (PAS-2) (highly similar to the RAPID-3), is a measure combining self-reported pain, patient global assessment, and Health Assessment Questionnaire-II into a global score. Other musculoskeletal conditions also affect these outcomes. We hypothesized that RA accompanied by fibromyalgia, degenerative spondylosis, or knee, hip, or generalized osteoarthritis is associated with higher pain, impaired function, and higher PAS-2 scores than RA unaccompanied by any of these comorbid musculoskeletal conditions.

Methods: All patients seen in the rheumatology department of a large urban integrated health care delivery organization are asked to fill out the PAS-2 at each clinic visit. The study population was all patients with a primary or secondary diagnosis of RA (ICD-9 code 714.0) seen in rheumatology between July 1, 2010 and December 31, 2010. The presence of comorbid fibromyalgia (729.1), degenerative spondylosis (721.90 or 721.91), knee osteoarthritis (OA) (715.96), hip OA (715.95), or generalized OA (715.89), was identified by two or more encounters with a primary or secondary diagnosis of the comorbid condition within the three years prior to the RA visit date. The three components of the PAS-2 and overall PAS-2 scores were modeled as four-level ordinal variables due to skewed distributions. The associations between PAS-2 and each of its three component scores and RA with one of the five comorbid conditions compared to RA with no musculoskeletal comorbidity were estimated with ordinal logistic regression models.

Results: The mean PAS-2 score (standard deviation) and the odds ratios (95% C.I.) for one level increase of PAS-2 with each comorbid musculoskeletal condition compared to its absence (adjusted for age, sex, race, use of DMARD or biologic therapies, use of neuropathic pain agents, the other four comorbid conditions, and provider) were as follows:

Diagnosis	PAS-2 Score (SD)	Association with one level change of PAS-2 compared to RA alone (OR, 95% C.I.)
RA alone (n = 758, 56.6%)	7.7 (6.4)	–
RA +Fibromyalgia (n = 82, 6.1%)	14.8 (6.2)	**3.8 (2.5–5.8)**
RA + Degenerative Spondylosis (n = 32, 2.4%)	16.4 (6.4)	**6.2 (1.9–20.1)**
RA + Knee OA (n = 192, 14.3%)	10.3 (6.4)	1.1 (0.7–1.6)
RA + Hip OA (n = 15, 1.1%)	13.5 (6.3)	2.7 (0.7–9.8)
RA + Generalized OA (n = 430, 32.1%)	10.7 (6.6)	**1.7 (1.3–2.4)**

The multivariable-adjusted associations of RA plus comorbid musculoskeletal conditions compared to RA alone with pain, patient global assessment, and HAQ-II score were similar to the associations with PAS-2 score.

Conclusion: Co-morbid generalized OA is common among patients with RA and is associated with a moderate increase in PAS-2 scores compared to RA alone. Co-morbid fibromyalgia or degenerative spondylosis substantially increase PAS-2 scores among those with RA. Use of the PAS-2 as an outcome measure in observational studies of RA therapies or RA quality of care in clinical practice may lead to underestimation of the effects of RA therapies, quality of RA care and potential overtreatment with RA medications if the presence of musculoskeletal comorbid conditions is not taken into account.

335

Application of the New American College of Rheumatology/European League Against Rheumatism Rheumatoid Arthritis Remission Criteria in a United States Cohort. Iris Navarro-Millan[1], Lang Chen[1], Jeffrey D. Greenberg[2] and Jeffery R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]New York University School of Medicine, New York, NY

Background/Purpose: The ACR and the EULAR proposed an RA remission definition for clinical trials that uses very stringent levels of disease activity for RA. The applicability and usefulness of this definition in a real-world setting where comorbidities and other factors could impact measurement of RA disease activity is not clear.

Objectives: Using data from participants enrolled in the Consortium of Rheumatology Researchers of North America (CORRONA) cohort:

1) To determine the distribution of pain, fatigue, disability, and ESR in patients that meet the ACR/EULAR RA remission criteria
2) To determine the prevalence of RA remission by different RA therapies and comorbidities

Methods: RA patients in CORRONA who met the provisional ACR/EULAR remission criteria (TJC ≤ 1, SJC ≤ 1, CRP ≤ 1 mg/dL and patient global ≤ 1) at any CORRONA visit were identified. If remission was observed at more than 1 CORRONA visit, the last visit was used. Descriptive statistics were used to describe pain (0–10 Visual Analog Scale [VAS], fatigue (0–10 VAS), disability (mHAQ), and ESR (<10, 10–20, >20mm/hr). The prevalence of remission was then evaluated in subgroups of patients using various RA therapies and with comorbidities of interest.

Results: A total of 2,105 individuals met the ACR/EULAR remission criteria in the CORRONA registry. A majority of patients in remission had low pain scores (85% with pain ≤ 1) and low fatigue scores (73% with fatigue ≤ 1). A total of 78% of patients had mHAQ = 0. Approximately one-half of patients in remission had ESR < 10, and an additional one-quarter had an ESR between 10 and 20mm/hr. The overall prevalence of remission in CORRONA was 8%. The likelihood of remission varied by RA treatment between 4 and 10% (Table). Remission was less common among RA patients treated with prednisone (1%- 6%, depending on dose) compared to those on no prednisone (13%). There were also significant differences in the prevalence of remission by different comorbidities (Table).

Table. Proportion of RA in remission by RA Treatment and Comorbidities

	Frequency n (%)	p-value
DMARD/Biologic treatment		0.0003
MTX monotherapy	582 (8)	
MTX + DMARD	200 (9)	
DMARDs w/o MTX	208 (8)	
TNF monotherapy	273 (10)	
TNF + DMARD	638 (10)	
Non-TNF Biologic monotherapy	27 (4)	
Non-TNF Biologic + DMARD	52 (4)	
Prednisone (mg/day)		<0.0001
None	873 (13%)	
< 5	128 (6%)	
5–10	99 (2%)	
> 10	39 (1%)	
COPD		0.0003
Yes	14 (4)	
No	1880 (10)	
Diabetes		<0.0001
Yes	116 (5)	
No	1989 (8)	
Fibromyalgia		0.0025
Yes	0 (0)	
No	549 (9)	
Smoking		<0.0001
Current	211 (5)	
Not current	1493 (8)	

Conclusion: Among patients in remission according to the new ACR/EULAR definition, the domains of pain, fatigue and disability were generally concordant with the factors in the remission criteria. The overall prevalence for RA remission was low (8%) and varied modestly by RA treatments and common comorbidities. These new remission criteria appear feasible to apply in real-world settings.

336

Discrepancy Between Boolean Remission and DAS28 Remission Is Dependent on the Differences in Number of Swollen Joints and Patient Global Assessment in Daily Practice, Based on the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) Cohort. Eiichi Tanaka, Kumi Shidara, Eisuke Inoue, Yohei Seto, Ayako Nakajima, Atsuo Taniguchi, Shigeki Momohara and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: The new remission criteria for rheumatoid arthritis (RA) by ACR/EULAR are expected to predict better patient outcome, however, there are substantial discrepancies between various remission criteria. We need to analyze which variables have a strong influence on achievement of the new ACR/EULAR remission criteria among RA patients with DAS28 remission based on a cohort before applying the new remission criteria in daily practice.

Methods: The Institute of Rheumatology, Rheumatoid Arthritis (IORRA) is a hospital-based observational cohort of RA patients. Complete medical information including physician's and patient's global assessment and laboratory data have been collected biannually. The subjects in this study were RA patients who participated in IORRA in October 2010, and were in DAS28 remission (DAS28 < 2.6). Boolean-based remission for clinical trials (Boolean trials) /clinical practice (Boolean practice), the Simplified Disease Activity Index (SDAI) remission and the Clinical Disease Activity Index (CDAI) remission were used as ACR/EULAR remission. Factors that affected the discrepancy between DAS28 remission and ACR/EULAR remission were analyzed. Univariate analysis was used to evaluate the differences in clinical features between patients with and without ACR/EULAR remission by each ACR/EULAR remission criteria. Multivariate logistic regression and analysis of deviance were conducted to determine the significance of effects on achieving each ACR/EULAR remission.

Results: We studied 2162 RA patients (39.0%) with DAS28 remission (female, 79.0%; mean age, 57.1 years; mean RA duration, 11.6 years; and mean DAS28, 1.98) among 5545 RA patients who participated in IORRA in October 2010. Among these patients, the numbers achieving Boolean trials, SDAI remission, Boolean practice and CDAI remission were 1169 (54.1%), 1602 (74.1%), 1205 (55.7%) and 1536 (71.0%), respectively. The patients with each ACR/EULAR remission were significantly older age, shorter RA disease duration, fewer tender and swollen joints, better patient's and physician's global assessment, and higher ESR compared to those without the respective ACR/EULAR remission. Having a better patient's global assessment and a smaller number of tender and swollen joints were the factors most significantly contributing to achievement of each ACR/EULAR remission criteria by multivariate logistic regression. The patient's global assessment and the number of swollen joints had a significant impact on achievement of each ACR/EULAR remission criteria by analysis of deviance. The combination of the patient's global assessment and the number of swollen joints accounted for 74.1%, 68.0%, 86.9% and 68.5% of the contribution to achieving Boolean trials, SDAI remission, Boolean practice and CDAI remission, respectively.

Conclusion: Of the remission criteria applicable to daily practice, Boolean remission is a more stringent than DAS28 remission, and the difference is mainly dependent on the patient's global assessment and number of swollen joints. Thus, patient management aimed at improving the patient's global assessment and number of swollen joints is critical for tight control of disease activity targeting to Boolean remission.

337

Comparison of Disease Activity Score Using Erythrocyte Sedimentation Rate and C-Reactive Protein In African-Americans with Rheumatoid Arthritis. Ashutosh Tamhane[1], David Redden[1], Gerald McGwin[1], Elizabeth Brown[1], Andrew Westfall[1], Richard J. Reynolds[1], Laura B. Hughes[1], Doyt L. Conn[2], Leigh F. Callahan[3], Beth L. Jonas[3], Edwin A. Smith[4], Richard Brasington[5], Larry W. Moreland[6] and S. Louis Bridges Jr.[7]. [1]Univ of Alabama at Birmingham, Birmingham, AL, [2]Emory Univ School of Medicine, Atlanta, GA, [3]Univ of North Carolina, Chapel Hill, NC, [4]Med Univ of South Carolina, Charleston, SC, [5]Washington Univ School of Med, St. Louis, MO, [6]University of Pittsburgh, Pittsburgh, PA, [7]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Racial/ethnic differences in genetic polymorphisms that influence CRP levels exist. However, data on differences between erythrocyte sedimentation rate (ESR) versus C-reactive protein (CRP) based Disease Activity Scores (DAS28) is lacking in African-Americans with Rheumatoid Arthritis (RA).

Methods: Analysis included participants (N=120) from the cross-sectional arm of the CLEAR Registry (African-Americans with RA) for whom both standard ESR and CRP-based DAS28 were available. Additionally, based on the study-data novel DAS28-CRP values (with and without age-sex adjustment) were calculated using regression. Agreement measures between standard ESR-based and (standard and novel) CRP-based DAS28 were examined.

Results: Mean age at enrollment was 54.5 years, median disease duration was 9 years and 85% were women. Standard DAS28-ESR was significantly higher than the standard DAS28-CRP (means: 4.7 vs. 3.9; $p<0.001$). When disease activity was categorized (high, moderate, low, remission) using conventional cut-offs (5.1, 3.2, and 2.6) overall agreement between the standard DAS28-ESR and DAS28-CRP was 59% and the standard DAS28-CRP underestimated disease activity in 40% of participants. With the novel DAS28-CRP agreement with the standard DAS28-ESR improved to 79% and underestimation decreased to 8%; adjustment for age-sex did not greatly increase agreement (82%) or decreased underestimation (6%).

Conclusion: These findings have implications for assessment or treatment response in clinical trials as well as in treatment decisions in individual patients. Significant improvement in agreement was achieved using simple modification of the standard DAS28-CRP measure. However, whether population-specific measures are needed or a universal DAS28-CRP measure could be derived using variety of databases remains to be examined.

338

Trajectory of Anti-Cyclic Citrullinated Peptide Antibodies and Rheumatoid Factor Over Time Does Not Predict Disease Activity in the Canadian Early Arthritis Cohort. Lillian J. Barra[1], V. Bykerk[2], Janet Pope[3], Ye Sun[4], Boulos Haraoui[5], Carol A. Hitchon[6], Diane S. Ferland[7], J. Carter Thorne[8], Edward Keystone[4] and Gilles Boire[9]. [1]University of Western Ontario, London, ON, [2]Brigham & Women's Hospital, Boston, MA, [3]Univ of Western Ontario, London, ON, [4]Mount Sinai Hospital, Toronto, ON, [5]Institut de Rhumatologie, Montreal, QC, [6]University of Manitoba, Winnipeg, MB, [7]LaSalle, QC, [8]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [9]CHUS - Sherbrooke University, Sherbrooke, QC

Background/Purpose: Autoantibodies associated with Rheumatoid Arthritis (RA) consist of Rheumatoid Factor (RF) and anti-citrullinated protein

antibodies, including anti-Cyclic Citrullinated Peptide (anti-CCP). It has been reported that the presence of these antibodies is associated with worse outcomes.[1] Our objective is to determine whether anti-CCP and RF remain stable over time and whether changes in these autoantibodies predict outcomes in Early Inflammatory Arthritis (EIA).

Methods: Data was collected from the Canadian Early Arthritis Cohort (CATCH), a prospective multicentre observational cohort of patients ≥ 16 years of age with symptom duration of 6 weeks up to 12 months and ≥ 2 swollen joints or ≥ 1 swollen small joint of the hand and ≥ 1 of positive rheumatoid factor, positive anti-CCP, morning stiffness ≥ 45 minutes, good response to non-steroidal anti-inflammatories or positive metatarsal-phalangeal squeeze test. Subjects were included in the analyses if anti-CCP and RF values were available at baseline and at least one follow-up visit.

Results: Baseline and follow-up anti-CCP and RF values were available in 361 and 340 patients respectively of the 1330 subjects enrolled in CATCH. Mean follow-up time was 21 months (range 3–72 months). At baseline, 198 (54.8%) were anti-CCP positive. Of these, 18 (9.1%) became anti-CCP negative during the follow-up period. Interestingly, 39 (23.9%) of anti-CCP negative patients became positive. RF positivity at baseline was 197 (57.9%) and 40 (20.4%) of these patients became negative at follow-up. 18 (12.5%) RF-negative patients seroconverted after a mean of 15.6 months. Patients who were RF and/or anti-CCP positive at baseline did not have worse outcomes at follow-up and changes in anti-CCP or RF over time did not predict erosive disease, DAS28 score or DAS28 remission.

Conclusion: Anti-CCP positivity appears relatively stable in EIA patients with positive anti-CCP at baseline. However, a large proportion of initially anti-CCP negative patients seroconverted later in disease. RF is more variable throughout disease course and shows a potential to convert and revert. Trajectories of anti-CCP and RF over time do not appear to predict clinical outcomes. These results are consistent with those from another large, recently published North American EIA cohort[2].

Patients with Early Rheumatoid Arthritis Determined to Be Inadequate Responders After 12 Weeks May Still Have Substantial Improvement in Core Set Measures. Results from an Early Arthritis Cohort. Pooneh S.Akhavan[1], Vivian Bykerk[2], Ye Sun[3], Gilles Boire[4], J. Carter Thorne[5], Janet Pope[6], Carol A. Hitchon[7], Boulos Haraoui[8], Diane S. Ferland[9], Edward Keystone[1] and CATCH Investigators[10]. [1]University of Toronto, Toronto, ON, [2]Brigham & Women's Hospital, Boston, MA, [3]Mount Sinai Hospital, Toronto, ON, [4]CHUS - Sherbrooke University, Sherbrooke, QC, [5]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [6]Univ of Western Ontario, London, ON, [7]University of Manitoba, Winnipeg, MB, [8]Institut de Rhumatologie, Montreal, QC, [9]LaSalle, QC, [10]Toronto, ON

Background/Purpose: ACR or EULAR response criteria have been used in trials and also in routine clinical practice to guide treatment decisions in RA. Patients who fail to achieve DDAS28 ≥1.2 or ACR20 are generally considered inadequate responders.To evaluate clinical improvement in individual core set measures in patients considered inadequate responders using DAS28 and ACR composite measures of disease activity.

Methods: Patients with early RA who were enrolled and prospectively followed in the Canadian Early Arthritis Cohort (CATCH) were studied. Patients receiving DMARD therapy for 3 months who failed to achieve DDAS28 ≥ 0.6, DDAS28 ≥ 1.2 or ACR20 were examined for 20% and 30% improvement in their disease activity core set measures.

Results: 416 patients with mean age 52.5 yr (14.3)(SD), disease duration 6.1 mo (3.0), Tender Joint Count (TJC) 9.2 (7.1), Swollen Joint Count (SJC) 8.2 (6.2) and DAS28 5.1(1.6) at baseline were included in this analysis. At 3 months 197(47%) patients had not achieved ACR20, 304 (73%) had not achieved ACR50 and 348 (84%) had not achieved ACR70. Half of included patients had DAS28 improvement < 1.2 and in 142 (34%) patients DAS28 improvement was < 0.6 at 3 months. About a third of patients with DDAS28 < 0.6 had 30% improvement in TJC, SJC, patient and physician global. This proportion varied from 30% to 44% in patients with DDAS28 < 1.2 and from 20–41% in patients who did not achieve ACR20. Mean core set measure improvement in patients with DAS28<0.6 was found to vary from 18% (patients global) to 26% (SJC). Thirty seven percent of patients with DDAS28< 0.6 achieved HAQ Minimal Clinically Improvement (MCID)[0.22]. This proportion was 42% for patients with DDAS28<1.2 or 35% in patients who failed to achieve ACR20.

Conclusion: A substantial proportion of patients who fail to achieve a significant improvement in composite measures of disease activity frequently used in clinical studies may still exhibit substantial improvement in their individual core set measures. These findings should be considered when making treatment decisions in real world clinical settings and identifying patients with an inadequate clinical response.

340

Performance of the American College of Rheumatology/European League Against Rheumatism (2011) Remission Definition Versus Disease Activity Score, 28-Joint Disease Activity Score and American College of Rheumatology Criteria. Karla Chiapas-Gasca, Luis M. Amezcua-Guerra and Angélica Vargas. Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico

Background/Purpose: Remission has become the treatment goal in rheumatoid arthritis (RA). Current remission criteria have several limitations, the more frequently used are the ACR, DAS and DAS28; so recently, ACR/EULAR proposed a new remission definition. Objective: to compare the performance of the ACR/EULAR remission definition versus DAS, DAS-28 and ACR criteria.

Methods: Between February 21st and June 10th, 2011, we analyzed the medical records of 198 consecutive outpatients attending our Rheumatology Department. Inclusion criteria were: diagnosis of RA according the ACR 1987 criteria. The database include demographic data, comorbidity, disease duration, extraarticular manifestations, rheumatoid factor (RF), anti-cyclic citrullinated protein antibodies (anti-CCP), erythrocyte sedimentation rate (ESR), C reactive protein (CRP) and drug therapy. Remission was calculated with DAS, DAS28, ACR remission criteria and the ACR/EULAR provisional remission definition. Data are expressed as percentages or mean with standard deviation (SD). Associations were calculated by the unweighted Cohen's kappa (k) index with 95% confidence intervals (95%CI) Differences were estimated by chi-square or unpaired t tests as appropriate.

Results: 47 of the 198 patients fulfilled the ACR/EULAR provisional remission definition; since this is the method we are assessing, in table 1 we report patients characteristics according this evaluation. There was no significant difference according therapy. The distribution of patients in remission and not remission according to each criterion is shown in table 2. The κ index between ACR/EULAR vs ACR was 0.61 (0.50–0.72), ACR/EULAR vs DAS was 0.37 (0.27–0.47), ACR/EULAR vs DAS28 was 0.42 (0.32–0.52), ACR vs DAS was 0.57 (0.47–0.68), ACR vs DAS28 0.57 (0.46–0.67), and DAS vs DAS28 0.75 (0.66–0.84). DAS criteria were met by 111 patients, DAS 28 by 103 and ACR by 74. Only 43 of the 198 patients fulfilled remission criteria for all methods.

Table 1. Characteristics of patients according ACR/EULAR results

	Remission (n=47)	Not remission (n=151)	*p*
Women (%)	41 (87.2)	135 (89.4)	NS
Age	52.7 ± 14.8	53.5 ± 15	NS
Duration of the disease	10.8 ± 10.2	12.7 ± 8.6	NS
Extra-articular manifestations (%)	10 (21.2)	61 (40.3)	0.009
Positive RF (%)	45 (95.7)	143 (94.7)	NS
Positive anti-CCP (%)	41 (91.1)	134 (88.7)	NS
ESR in mm/h	21.02 ± 9.9	29.07 ± 11.3	<0.0001
CRP in mg/L	3.48 ± 1.85	12.8 ± 25.7	0.01
DAS	0.93 ± 0.17	1.8 ± 0.75	<0.0001
DAS28	1.82 ± 0.33	3.27 ± 1.29	<0.0001
Morning stiffness, +	1 (2.1)	47 (31.1)	<0.0001
Fatigue, +	0 (0)	50 (33.1)	<0.0001
Joint tenderness, +	5 (10.6)	106 (70.1)	<0.0001
Tenderness on examination, +	3 (6.3)	104 (68.8)	<0.0001
Joint/tendon sheath swelling, +	6 (12.7)	126 (83.4)	<0.0001
Patients with swollen/tender areas out of DAS28	0 (0)	57 (37.7)	<0.001

Data are expressed in mean ± SD unless otherwise specified. NS, no significance; +, positive

Table 2. Patients on remission according the different criteria

Criteria	Remission	Not remission
ACR	74	124
DAS	111	87
DAS28	103	95
ACR/EULAR	47	151

Conclusion: The recently proposed ACR/EULAR remission definition seems to be more stringent to discriminate patients on remission, whereas remission is easier to achieve with DAS and DAS-28.

341

What Is A Realistic Treatment Target in Rheumatoid Arthritis: Remission or Minimal Disease Activity? Yvonne M.R. de Punder[1], Jaap Fransen[1], Wietske Kievit[1], Pieternella Houtman[2], Henk Visser[3], Mart A.F.J. van de Laar[4] and Piet LC van Riel[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Medical Centre Leeuwarden, Leeuwarden, Netherlands, [3]Alysis Care Group, Arnhem, Netherlands, [4]Arthritis Centre Twente, Medisch Spectrum Twente and University Twente, Enschede, Netherlands

Background/Purpose: Treatment targets for RA do shift towards remission of disease activity. However, remission does not occur regularly in practice and the question may be raised what currently is the appropriate treatment target: remission or low disease activity? This is especially relevant in patients treated with anti-TNF. The objective in this study was to analyze the prevalence of remission and minimal disease activity (MDA) and the residual disease activity according to the new ACR/EULAR remission criteria, MDA, and DAS28<2.6, in RA patients treated with anti-TNF.

Methods: In the DREAM biological registry the prevalence of DAS28<2.6, MDA and ACR/EULAR remission criteria was measured in patients six months after starting a TNF blocker. The variable Patient Global Assessment of disease activity (PtGA) was only available in a subsample and was replaced by VAS Pain, as no systematic difference appeared between PtGA and VAS Pain in this subsample. Residual disease activity during MDA or remission was calculated, measured by the percentage of patients with swollen and tender joints, elevated acute phase reactants, and pain.

Results: Six months after initiation of anti-TNF, the prevalence of DAS28<2.6 was 26% and prevalence of MDA was 32%, while ACR/EULAR remission was reached by 6,7% of patients. The low prevalence of ACR/EULAR remission was due to the cut point of the patient's global assessment/pain item. Exclusion of the variable VAS Pain increased the prevalence of ACR/EULAR remission to 21%. Residual disease activity was highest in the most lenient criteria and occurred most on the level of SJC and PtGA: At least one swollen joint in DAS28<2.6, MDA and ACR/EULAR remission was present in resp. 51%, 54% and 34% of patients. VAS Pain > 1 cm was present resp. 64%, 67% and 0%. When the patient reported variable was left out of the definition of ACR/EULAR remission, 68% of patients scored VAS Pain >1. Accordingly, absence of tender and swollen joints and CRP<1 mg/dl was reached by 190/1679 patients (11%). However, 125 (66)% of these patients would not be in remission according to the complete ACR/EULAR remission criteria because VAS Pain was >1.

Conclusion: In daily clinical practice, MDA and DAS28<2.6 are realistic treatment targets with sufficient prevalence, while in turn residual disease activity still is present. ACR/EULAR remission criteria leave little residual disease activity, but might be too stringent due to the strict cut point on Patient Global Assessment of Disease Activity.

342

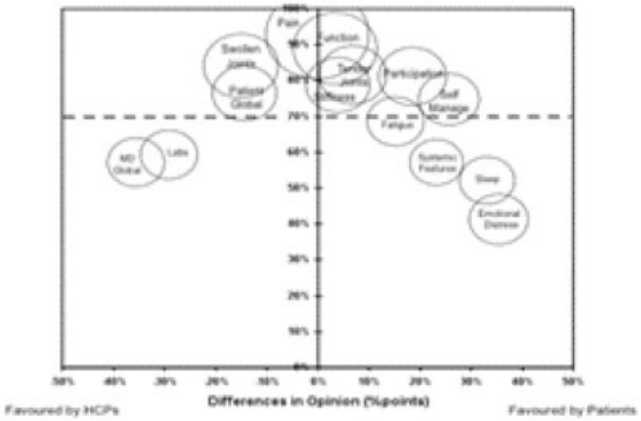
Consensus Among Patients and Health Care Professionals for Essential Domains to Assess Disease Flares in Rheumatoid Arthritis: Results of Final OMERACT Delphi. Susan J. Bartlett[1], Thasia G. Woodworth[2], Clifton O. Bingham III[3], Rieke Alten[4], Christoph Pohl[5], Ernest Choy[6], Sarah Hewlett[7], Tessa Sanderson[7], Annelies Boonen[8], Vivian Bykerk[9], Amye L. Leong[10], Vibeke Strand[11], Daniel E. Furst[12], Robin Christensen[13] and OMERACT Flare Working Group. [1]McGill University, Montreal, QC, [2]Leading Edge Clinical Research, Stuart, FL, [3]Johns Hopkins University, Baltimore, MD, [4]Rheumatology Schlosspark-klinik, Berlin, Germany, [5]Schlosspark Klinik, Berlin, Germany, [6]Cardiff University, Cardiff, ENGLAND, United Kingdom, [7]University of the West of England, Bristol, United Kingdom, [8]University Hospital Maastricht, Maastricht, Netherlands, [9]Brigham & Women's Hospital, Boston, MA, [10]Bone & Joint Decade, Santa Barbara, CA, [11]Stanford University, Palo Alto, CA, [12]UCLA Medical School, Los Angeles, CA, [13]Copenhagen, Denmark

Background/Purpose: Although the term "flare" is often used to describe episodes of disease worsening, no established definition currently exists for rheumatoid arthritis (RA). As a result, little is known about the impact of RA flares on treatment outcomes such as function, disability, health-related quality of life and work productivity. The goal of the OMERACT RA Flare Group is to establish a framework to assess RA flares from both patient and health care professional (HCP) perspectives and develop a measurement tool for use in research and clinical settings.

Methods: Flare was defined as a worsening of disease activity of sufficient intensity and duration to result in consideration of a change of therapy. Formative research to identify relevant domains included focus groups/surveys with patients, stakeholder interviews and a literature search. An international group of patients and HCPs participated in subsequent rounds of Delphi exercises to rate candidate domains as "essential" or "not essential." Core domains were defined *a priori* as those with ≥70% support from all participants.

Results: Results are from the final Delphi round conducted through December 2010. Participants included 125 patients from 10 countries and 108 HCPs from 23 countries. Patients had a mean (± SD) age of 56 ±12 yrs and disease duration of 18 ± 12 yrs. HCPs included physicians from clinical practice/research (79%) and industry (6%), allied health providers (8%), researchers (6%) and undisclosed (1%), with 17 ± 11 yrs clinical rheumatology experience. Most (>82%) had participated in earlier surveys.

Core domains identified include: *Pain* (93%), *Function* (89%), *Swollen Joints* (84%), *Tender Joints* (81%), *Participation* (81%), *Stiffness* (79%), *Patient Global Assessment* (76%) and *Self-Management* (75%); *Fatigue* (68%) will receive further consideration. Domains which did not reach the level of consensus will continue to be explored separately. The figure below shows the pooled proportions and relative strength of agreement between groups; bubble size reflects estimate precision.



Conclusion: As part of the process to develop a measure, core domains of RA flare were identified by patients and HCPs: *Pain, Function, Swollen Joints, Tender Joints, Stiffness, Participation, Patient Global Assessment* and *Self Management*, with *Fatigue* receiving additional consideration. Next steps include identifying potential items for each domain and conducting studies to validate and refine the measurement tool.

343

Development and Validation of a New Disease Activity Index As a Numerical Sum of 4 Variables, Including Erythrocyte Sedimentation Rate and/or C-Reactive Protein, to Assess Rheumatoid Arthritis. Isabel Castrejón[1], Loreto Carmona[2], Ana M. Ortiz[3], Miguel A. Belmonte Serrano[4], Juan A. martínez-López[5] and Isidoro González-Alvaro[3]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Universidad Camilo José Cela, Villanueva de la Cañada, Spain, [3]Hospital Universitario de La Princesa. IIS Princesa, Madrid, Spain, [4]Hospital General de Castellon, Castellon, Spain, [5]Fundación Jimenez Díaz, Madrid, Spain

Background/Purpose: To describe the development and validation of an activity index in early arthritis that can be used in daily practice and clinical research without special computing.

Methods: The HUPI (Hospital Universitario la Princesa Index) was driven from patient data analysis of an early arthritis cohort. It is the sum of four variables graded from 0 to 3: tender and swollen 28-joint counts, patient global assessment, and acute phase reactants, erythrocyte sedimentation rate (ESR) and/or C-reactive protein (CRP). The 0–3 score of each variable was based on its quartile distribution in our cohort. To develop HUPI we assayed different combinations of

these four variables considering differences by gender and age. For its validation the following were tested: feasibility, internal consistency (Cronbach's alpha), convergent validity (Pearson's *r* coefficients with other activity measures), accuracy by the area under the ROC curve (AUC) with minimum disease activity (MDA) as external criteria and sensitivity to change by the AUC using a change higher than 10 between baseline and the 6 month evaluation on physician assessment and on DAS28-ESR as external criteria of change.

Results: The analysis comprised 202 patients (756 visits) of whom 77% were women, mean age at onset of the disease was 53±16, 70% diagnosed of RA and 30% of undifferentiated arthritis. The best version of HUPI was defined as the sum of the scores reached by each variable in accordance to the following table:

Score	0	1	2	3
TJC28				
Female	0	1–2	3–6	>6
Male	0	1	2–3	>3
SJC28	0	1–2	3–4	>4
GDA Patient	0–15	16–30	31–50	>50
ESR				
Female	0–15	16–20	21–30	>30
Male	0–10	11–15	16–20	>20
CRP (mg/dl)	<0.10	0.11–0.8	0.81–1.50	>1.50

TJC: tender joint count; SJC: swollen joint count; GDA: global disease assessment; ESR and/or CRP can be used depending on which one is available. When both were available the mean score of them was used.
HUPI shows a reasonable internal consistency (Cronbach's α 0.63) and it correlates well with activity measures like DAS28 (r=0.89), and SDAI (r=0.70), but slightly worse with functional index HAQ (r=0.69). HUPI has a high accuracy, it discriminates MDA state (AUC=0.956) better than DAS28-ESR (0.929; p=0.001) and DAS28-CRP (0.945; p=0.07) and similar to SDAI (0.956; p=ns), and its sensitivity to change (AUC= 0.902) is slightly superior than those of DAS28-ESR (0.864; p=ns), DAS28-CRP (0.889; p=ns) and SDAI (0.791; p=0.01).

Conclusion: HUPI is an index easy to calculate, valid, and a sensitive tool for the assessment of disease activity in patients with early arthritis, both on clinical research and on routine practice.

This work has been partially supported by a grant of MEICA Project (Genoma España).

344

Investigation of the Relationship Between Patient-Centered Factors and Baseline Disease Activity (DAS28) in Rheumatoid Arthritis (RA). Rita Prajapati[1], Darren Plant[2], Deborah Maskell[2], Ann W. Morgan[3], Anthony G. Wilson[4], John Isaacs[5], Lis Cordingley[1] and Anne Barton[1]. [1]University of Manchester, Manchester, United Kingdom, [2]The University of Manchester, Manchester, United Kingdom, [3]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [4]Sheffield Uni /Medical School, Sheffield, United Kingdom, [5]University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom

Background/Purpose: The disease activity score (DAS28) is a composite score made up of clinical, biological and a patient self-report measure. As an indicator of current disease activity it, it is an important part of the eligibility criteria for starting anti-tumour necrosis factor (TNF) therapy in rheumatoid arthritis (RA). Clinical, demographic and genetic factors may play a role in influencing baseline disease activity, but the contribution of patient-centred factors such as patients' views of their illness have not yet been thoroughly explored. The aim of this study was to identify which illness beliefs were associated with baseline disease activity in RA.

Methods: An observational study of patients about to commence anti-TNF therapy was undertaken. Patients completed measures of mood (Hospital Anxiety and Depression Scale[HAD] Zigmond & Snaith, 1983), of beliefs about RA (Brief Illness Perception Questionnaire [BIPQ]; Broadbent et al, 2006), beliefs about RA treatment (Beliefs about Medicines Questionnaire [BMQ] Horne et al 1999), of self-efficacy (General Self Efficacy Scale; Schwarzer & Jerusalem, 1995). Using baseline DAS28 as the outcome variable, statistical analyses in the form of regression modelling were performed in STATA.

Results: Complete data were available on 322 patients. A significant association with baseline DAS28 was associated with item 5 of the brief IPQ (coef 0.16, p<0.001), the identity domain, which asks how much patients experience symptoms from their rheumatoid arthritis. Upon breakdown of the DAS28, item 5 of the brief IPQ correlated with tender joint counts (coef 0.66, p=0.019), erythrocyte sedimentation rate (ESR) (coef 2.0, p=0.03), and the visual analogue scale (VAS) (coef 3.71, p<0.0001). To explore whether these associations were mediated by other pathways, we found anxiety and depression correlated strongly with illness perception (p<0.0001). No significant associations were detected between baseline DAS28 and anxiety, depression or self-efficacy.

Conclusion: Illness cognitions, particularly patients' perception of symptoms, play a key role in influencing baseline disease activity in RA. Future work investigating the pathways by which illness representations in influencing treatment response may provide key insights into why some patients respond to biologic agents, whilst others fail.

345

To Screen Remission without Formal Joint Count: Analysis of Routine Assessment of Patient Index Data 3 in Japanese National Database. Naoto Yokogawa[1], Kota Shimada[1], Shoji Sugii[1] and Shigeto Tohma[2]. [1]Tokyo Metropolitan Tama Medical Center, Tokyo, Japan, [2]Clinical Research Center for Allergy and Rheumatology, Sagamihara National Hospital, National Hospital Organization, Sagamihara, Japan

Background/Purpose: American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) set a provisional definition of remission in rheumatoid arthritis (RA) as a stringent but achievable goal: scores on the tender joint count, swollen joint count, CRP (in mg/dl), and patient global assessment (0–10 scale) are all ≤1. Precise formal joint count is crucial to classify remission however formal joint count is not easy even to expert rheumatologists. Routine Assessment of Patient Index Data 3 (RAPID3) is an index which does not require formal joint count. RAPID3 less than 3 was proposed as a remission criteria in the past however not validated in the new remission criteria.

Methods: Modified Health Assessment Questionnaire (mHAQ) is still widely used in Japan to assess patient function capacity. To utilize the existing data of mHAQ, modified RAPID3 (mRAPID3) was defined as follows: mRAPID3 (scale:0–30) =[mHAQ (scale:0–3)x10/3] + [Patient pain VAS (scale:0–10)]+[Patient global VAS (scale:0–10)]. After validation of mRAPID3, a method to convert from RAPID3 to RAPID3 was developed. In the National Database of Rheumatic Diseases by iR-net in Japan (NinJa), we compared RAPID3 with the indices that include a formal joint count, such as the traditional Disease Activity Score (DAS28), Clinical Disease Activity Index (CDAI), and Simplified Disease Activity Index (SDAI). A cut-off RAPID3 of 90% sensitivity for the ACR/EULAR provisional definition of remission was calculated.

Results: By regression analysis using 147 patients' data at our hospital, a conversion method was formulated: RAPID3=0.288+1.034xm RAPID3(p<0.0001) (Figure 1).

In NinJa 2009, 4479 patients were analyzed. RAPID3 showed good correlation with DAS28, CDAI, and SDAI (Spearman rank correlation coefficient: rho 0.65, 0.73, 0.73).

By the ACR/EULAR provisional definition of remission, 675 patients (15.1%) were categorized as remission. The sensitivity and specificity for the remission criteria of DAS28, CDAI, and SDAI were shown in Table 1. RAPID3 less than 2 revealed sensitivity of 90.5% and specificity of 79.4%.

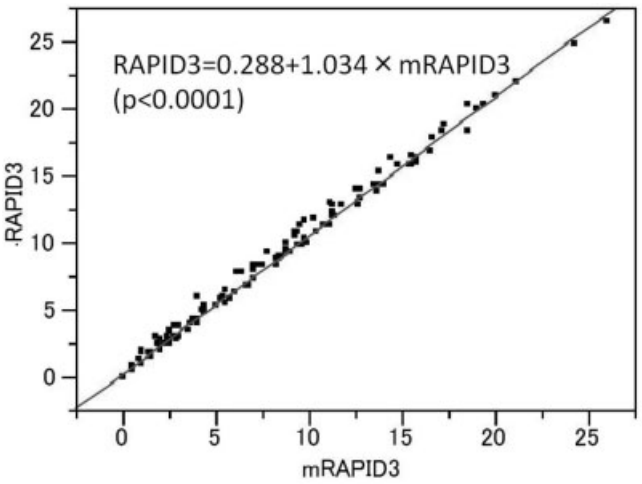


Figure 1. Regression analysis of RAPID3 and mRAPID3 in 147 patients

Table 1. Sensitivity and specificity for the ACR/EULAR provisional definition of remission

NÅÅ4479	Sensitivity (%)	Specificity (%)
SDAI remission	91	93
CDAI remission	89.3	93.8
DAS28 remission	76.9	84.7
RAPID3<2	90.5	79.4
RAPID3<3	95.4	31.6

Conclusion: RAPID3 less than 2 can successfully screen the RA remission without formal joint count.

346

The Clinical Characteristics of Rheumatoid Arthritis Patients in Clinical Remission: Many Faces of DAS-28 Remission. Kyeong Min Son[1], Inje Kim[2] and Hyun Ah Kim[1]. [1]Hallym university sacred heart hospital, Kyunggi, South Korea, [2]Hallym University Kangdong Sacred Heart hospital, Seoul, South Korea

Background/Purpose: DAS-28 is widely used to define remission of rheumatoid arthritis (RA) in clinical settings, including clinical trial. The aim of this study was to observe the clinical characteristics of RA patients in DAS-28 remission. In addition, the extent of foot and ankle involvement in RA patients with DAS-28 remission was explored.

Methods: RA patients who visited rheumatology clinic of Hallym University Sacred Hospital were evaluated with DAS-28 including ankle and foot MTP joint evaluation since August, 2010. Patients who were treated with disease-modifying anti-rheumatic drugs for at least 3 months and who were in DAS-28 remission (DAS<2.6) were included in this study.

Results: A total of 119 patients were included. Mean age was 51 years and 72.3% were female. Mean disease duration was 46.6±43.0 months. Rheumatoid factor and anti-CCP positivity at the start of treatment was 59.4% and 46.6% respectively. At the time of remission, patients were treated with methotrexate (54.6%), hydroxychloroquine (43.7%), leflunomide (13.4%) and biologic agent (etanercept n=4, adalimumab n=1, tocillizumab n=4, Golimumab n=1, Abatacept n=1) (9.2%). Corticosteroid was used in 75.6% of patients with mean daily dose of 3.4mg prednisolone. Mean DAS-28 was 1.83(range 0.14–2.59) at the time of remission. Mean swollen and tender joint count within 28 joints at the time of remission was 0.5(range 0–6) and 1.3(range 0–13), respectively. Mean erythrocyte sedimentation rate and C-reactive protein were 6.0 mm/hr and 1.0 mg/L. Twelve percent and 39.5% of patients in clinical remission had swollen and tender joint in either foot MTP or ankle joinst, respectively (mean swollen and tender joint count 0.3{range 0–8} and 1.0{range 0–9}). 5.9% and 9.2% of patients in clinical remission had swollen and tender joint in either foot MTP or ankle joint without involvement of 28 joints included in DAS-28.

Conclusion: Our result shows that RA patients with DAS-28 remission sometimes have residual disease activity including ankle and foot joint involvement. DAS28 remission may have insufficient construct validity and should be used with caution in clinical practice.

347

Clinical Outcome in Early Undifferentiated Arthritis Is Best Predicted by a Combination of Baseline Clinical Features and Serum Biomarkers. Carol A. Hitchon[1], Gilles Boire[2], Michael Centola[3], Andrew Lloyd[4], Richard Kay[4] and Hani S. El-Gabalawy[1]. [1]University of Manitoba, Winnipeg, MB, [2]CHUS - Sherbrooke University, Sherbrooke, QC, [3]Oklahoma Medical Research Fdn, Oklahoma City, OK, [4]Astra-Zeneca, Cheshire, United Kingdom

Background/Purpose: Clinical outcome of patients with early undifferentiated arthritis (EUA) is variable and only partially predicted by clinical features at presentation. Biologically relevant markers reflecting pathogenic mechanisms may aid in identifying UA at risk of persistent disease. We sought to determine if biologically relevant markers reflecting pathogenic mechanisms aid in identifying UA patients who respond to standard treatment or enter remission after one year.

Methods: Patients with early undifferentiated arthritis not meeting ACR 1987 criteria for another arthropathy and with symptoms of less than one year received standard DMARD therapy aimed at disease remission. EULAR treatment response and clinical remission (DAS28CRP<2.6) were assessed at one year. Baseline pre-treatment serum was tested for ACPA, MMP3, MMP9, TIMP1, TIMP2, (by ELISA) and a panel of 23 cytokines (by Luminex multiplex assay). Random Forest/gradient boost methods with K class loss of function were used to determine the contribution of clinical variables, cytokines and MMPs to predicting clinical outcomes. Multiple iterations (2000–5000) were done for each analysis and the best cross validation iteration chosen to reflect best accuracy without over fitting the data. The following models were generated: baseline clinical variables alone, baseline biomarkers alone and baseline clinical and biomarkers.

Results: UA patients (n=123; 72% female, mean age 48 (15), baseline DAS28CRP3 3.67(1.22), mHAQ 0.48(0.48) were treated with DMARDs at the discretion of their physician. At one year, 66% has a good or moderate EULAR response and 52% were in remission. Baseline tender joint count and crp were the best clinical predictors of remission in UA (predictive accuracy 79%). The predictive accuracy was increased with the inclusion of baseline treatment naïve MMP and cytokine biomarkers (model accuracy 92%, PPV 97%, NPV 89%). Baseline MMP3, CRP, TJC, IL6, IL8 and mHAQ were the most important predictors in this model. Biomarkers added modestly to prediction accuracy for EULAR treatment response in UA (80% clinical alone, 83% clinical and biomarkers). The sample size was too small to evaluate predictors of UA evolving to RA. Baseline and one year paired biomarker assays were available on 49 Manitoba patients. Change in biomarker level in combination with baseline clinical features had accuracy 96%, DAS tjc28, sjc28, ip10, vegf, il8, mip1, il12, eotaxin, mmp).

Conclusion: Clinical variables are important in predicting clinical outcomes in EUA however, biomarkers provide increased predictive value over clinical factors alone. The best combination of biomarkers needs further evaluation.

348

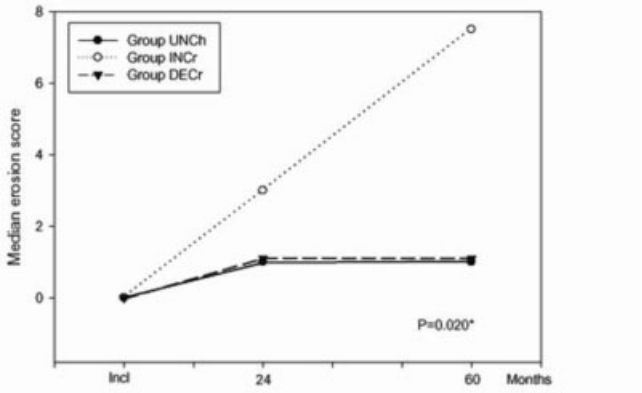
Early Increase In Serum-COMP Is Associated with Joint Damage Progression Over the First Five Years In Patients with Rheumatoid Arthritis. Maria LE Andersson[1], Bjorn Svensson[2], Ingemar F. Petersson[3], Ingiald Hafstrom[4], Kristina Albertsson[4], Kristina Forslind[5], Dick Heinegard[6] and Tore Saxne[7]. [1]R&D centre, Spenshult Hospital for Rheumatic Diseases, Oskarstrom, Sweden, Oskartrom, Sweden, [2]Paulinsvag 7D, Bastad, Sweden, [3]Lund University Hosp, Lund, Sweden, [4]Karoliska Institute, Stockholm, Sweden, [5]Lund, Sweden, [6]University of Lund, Lund, Sweden, [7]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden

Background/Purpose: Serum-COMP has shown promise as a prognostic indicator in rheumatoid arthritis (RA). However, serum concentrations may to some extent be genetically determined and thus reflect levels of cartilage matrix turnover not related to disease (Williams et al, 2006). We have examined if changes in serum-COMP early in the disease course of RA correlate with joint damage progression in hands and feet after 5 years.

Methods: In all 348 patients (64% women) included in the BARFOT study in Sweden from 1997 to March 1999 were examined. Their median age (range) was 58 years (16–84), and median disease duration 6.0 months. Serum-COMP was analysed at inclusion and after 3 months by ELISA (AnaMar, Lund). Based on changes in serum-COMP over the first 3 months, three subgroups of patients were defined: unchanged serum-COMP levels (change ≤ 20%) (group UNCh), increasing levels (increase > 20%) (group INCr) and decreasing levels (decrease > 20 %) (group DECr).Radiographs of hands and feet were obtained at inclusion and after 5 years and scored by the van der Heijde modification of the Sharp (SHS) method. The smallest detectable change in SHS was 5.8. Radiographic progression was defined as a change of total score of 5.8 or more.

Results: For all patients the median (range) serum COMP level at inclusion was 12.7 U/L (4.5–32.0). Group UNCh, with no change in serum-COMP consisted of 142 (41%) patients, group INCr, with increasing levels consisted of 34 (10%) patients and group DECr with decreasing COMP-levels of 172 (49%) patients. Group INCr had an increased risk of radiographic joint damage progression (total SHS) compared with group UNCh, OR 2.8 (95% CI 1.26–6.38), p=0.011. Group DECr did not differ in this respect from group UNCh. After 5 years the patients in group INCr had higher erosion score compared to the other groups, figure 1. There were no significant differences between the groups regarding JSN score (p=0.19) or total Sharp score (p=0.07). Group INCr had the lowest levels of serum-COMP at baseline compared with the other groups, p<0.01 and higher ESR than group DECr, 42 (2–140) vs. 27 (2–115), p=0.02. There were no differences between the groups at inclusion regarding age, gender, disease duration, DAS28, HAQ or CRP.

Figure 1 Median erosion score in the groups from inclusion to 60 months follow-up



Group UNCh, patients with unchanged serum-COMP levels from inclusion to 3 months follow-up (change ≤ 20%).
Group INCr, increasing serum- COMP levels from inclusion to 3 months follow-up (increase > 20%)
Group DECr, decreasing serum-COMP levels from inclusion to 3 months follow-up (decrease > 20 %)

Kruskall-Wallis between groups at 60 months

Conclusion: Early increase in serum-COMP in RA patients suggesting altered activity in the process of pathological cartilage turnover was in this study associated with joint damage progression over a 5 year period. These findings merit further studies to clarify whether early changes in serum-COMP may contribute to the clinician's assessment of prognosis.

349

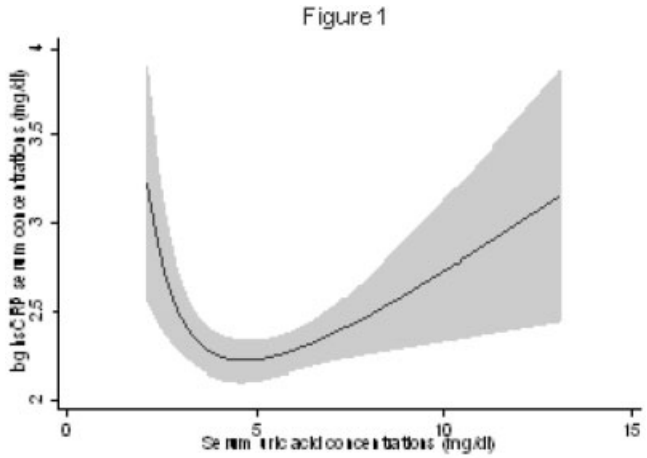
Is There An Association Between Uric Acid and Inflammation in Patients with Rheumatoid Arthritis? Paola de Pablo[1], Vasileios F. Panoulas[2], Karen MJ Douglas[2], Christopher D. Buckley[1] and George Kitas[2]. [1]University of Birmingham, College of Medical & Dental Sciences, School of Immunity & Infection, Rheumatology, Birmingham, United Kingdom, [2]Dudley Group of Hospitals NHS Trust, Russells Hall Hospital, Dudley, West Midlands, UK, Dudley, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA), a chronic inflammatory disease, is associated with cardiovascular morbidity and mortality. High-sensitivity C-reactive protein (hsCRP), a biomarker of inflammation, is an independent predictor of future vascular events in the general population. Previous studies have suggested that serum uric acid (SUA) may have a direct role in atherogenesis and large epidemiologic studies have observed an independent association between SUA and CRP in the general population. However, it is unclear whether this association holds in the context of a "high-grade" chronic inflammatory disease, such as RA. The purpose was to evaluate the association between SUA and hsCRP levels in a cohort of patients with RA.

Methods: We used data from a cohort of 400 consecutive patients with RA meeting ACR criteria for RA classification. Participants were recruited from routine outpatient clinics at the Department of Rheumatology, Dudley Group of Hospitals, United Kingdom, between 1 August 2004 and 31 July 2006 1. A priori we excluded participants with concomitant gout. We performed linear regression analyses of log transformed hsCRP on SUA concentrations, adjusting for potential confounders. We used fractional polynomial regression to evaluate the association between SUA and hsCRP, adjusting for age, gender, smoking, seropositivity, hypertension, diabetes, creatinine levels, glomerular filtration rate (GFR<60), body mass index (BMI), and use of medications such as diuretics, antihypertensives, aspirin, and statins. Sensitivity analyses included further adjustment for presence of the metabolic syndrome, disease activity score (DAS28), and medications used for RA management (i.e. DMARDS, biologics and steroids).

Results: After excluding participants with concomitant gout, the study sample included 385 participants with RA. Of those, 74% were female, 76% were seropositive, 67% were ACPA positive, 70% were hypertensive and 10% had diabetes. Mean age was 61 years (SD±12) and mean disease duration was 12.6 years (SD±10.6). Men had higher SUA and hsCRP concentrations than women [SUA mean (±SD): 6.04 (±1.35) vs. 4.88 (±1.46) mg/dl; hsCRP median (IQR): 10 (6–22) vs. 8 (5–19) mg/dl, respectively]. ACPA positive participants had higher SUA and hsCRP levels than those who were ACPA negative. There was a non-linear association between SUA and hsCRP concentrations (overall p-value=0.01) independent of BMI age, gender, smoking, seropositivity, hypertension, diabetes, creatinine levels, GFR<60, BMI, and medications (Figure 1). Sensitivity analyses showed similar results (overall p-value=0.02).

Figure 1



Conclusion: Serum uric acid concentrations are independently associated with hsCRP among individuals with RA. The physiologic basis of this association, as well as its significance in terms of the articular and vascular phenotype of RA require further exploration.

350

Baseline Serum Levels of CXCL13 Are Associated with Ultrasonographic Synovitis and Predict Power Doppler Persistency in Early Rheumatoid Arthritis. Antonio Manzo, Serena Bugatti, Francesca Benaglio, Barbara Vitolo, Monica Todoerti, Garifallia Sakellariou, Roberto Caporali and Carlomaurizio Montecucco. Division of Rheumatology, University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia, Italy

Background/Purpose: The course of rheumatoid arthritis (RA) is highly variable among different patients. To optimise management, individual's outcomes need to be recognised as early as possible. Novel biological markers specifically reflecting the severity of synovial inflammation at presentation could be more predictive than routine clinical and laboratory assessments. Here we aimed at investigating the associations of baseline serum levels of CXCL13 (sCXCL13), a chemokine critically involved in B and T cell recruitment and cooperation within lymphoid and extra-lymphoid sites, with changes in clinical and ultrasonographic (US) disease activity in patients with recent-onset RA over a 12 months follow-up.

Methods: Study subjects were 161 early RA patients (disease duration < 1 year) treated according to a disease activity score (DAS)-driven step-up protocol aimed at low disease activity (LDA, DAS28<3.2). US examination of hands was performed at baseline and 12 months. Power Doppler (PD) synovitis was scored (0–3), with overall scores as the sum of each joint score. sCXCL13 was assessed by ELISA at baseline and, in 87 patients, after 2 months of therapy. sCXCL13 levels were analysed in relation to the following outcomes at 12 months: clinical LDA and remission according to conventional DAS28 and SDAI cut-off values, total PD score and US remission (total PD score = 0).

Results: At baseline, sCXCL13 levels were associated with objective and semi-objective measures of disease activity, such as the swollen joint count (rho 0.22, p=0.009), the evaluator global assessment of disease activity (rho 0.26, p=0.002), the erythrocyte sedimentation rate (ESR) (rho 0.41, p<0.0001) and C-reactive protein (CRP) levels (rho 0.41, p<0.0001). Confirming the specific relationship with measures of synovitis, sCXCL13 significantly correlated with baseline PD scores (rho 0.26, p=0.006). When compared to CRP, only sCXCL13 retained independent predictive value for the PD score. Furthermore, differently from CRP, sCXCL13 levels were significantly higher in ACPA-positive patients [96.82 (95%CI 72.61–117.19) vs 68.53 (95%CI 54.37–75.03), p=0.001]. sCXCL13 levels appeared mostly unchanged after 2 months of therapy (mean difference 4.62, 95% CI −3.37 11.4, p=0.27), as opposite to the other clinical and laboratory parameters which all significantly decreased. Baseline sCXCL13 did not predict clinical outcomes at 12 months. Rather, sCXCL13 levels were the only independent predictor of the 12 months PD score (p=0.02) and PD remission (p=0.04), irrespective of initial PD scores, disease activity status, acute phase reactants and autoantibodies. Using the Receiver Operating Characteristic curve, the relative risk of US remission was averaged 60% higher in patients with baseline sCXCL13 <106.75 pg/ml (OR 3.56, 95%CI 1.44–8.79).

Conclusion: CXCL13 emerges as a new biological marker in early RA,

accurate in assessing the severity of sinovitis and its persistency over time in response to conventional treatments.

A Novel Multi-Biomarker Disease Activity Score (Vectra™DA algorithm score) Reflects Clinical Disease Activity Score and Health Assessment Questionnaire for Rheumatoid Arthritis in the BeSt Study. Shintaro Hirata[1], Linda Dirven[2], Guy Cavet[3], Yijing Shen[4], Michael Centola[5], Willem F. Lems[6], Tom W.J. Huizinga[2], Cornelia F. Allaart[2] and Yoshiya Tanaka[1]. [1]University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Crescendo Bioscience, South San Francisco, CA, [4]Geron Corporation, Menlo Park, CA, [5]Oklahoma Medical Research Foun, Oklahoma City, OK, [6]VU University Medical Center, Amsterdam, Netherlands

Background/Purpose: Disease activity measurement is the cornerstone of tight control and treat to target strategies, and is recommended by ACR and EULAR guidelines. A novel multi-biomarker based disease activity (MBDA) score has been validated in a broad RA population. However, the utility of the MBDA for evaluating disease activity and for predicting functional disability specifically in very early RA patients has not been investigated.The purpose of the study is to confirm the utility of the MBDA score as a novel disease activity index and as a predictor of Health Assessment Questionnaire (HAQ), in the BeSt study, a cohort of very early RA patients.

Methods: We analyzed 124 RA patients in the BeSt study. Clinical data and serum samples were available from 180 visits, 91 at baseline (BL) and 89 at year 1. The MBDA score combines 12 serum biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, Leptin, Resistin, CRP, SAA) in a pre-specified algorithm, resulting in a score between 1 and 100. Associations between continuous variables were evaluated by Pearson's correlation. MBDA scores for groups stratified by DAS28 were compared by one-way factorial ANOVA. The association of categorical variables was assessed by Fisher's exact test.

Results: The MBDA score was correlated to DAS28 (cor = 0.66, $p < 0.0001$). Similar results were obtained for DAS28CRP, and the original DAS. ΔMBDA score was also correlated to ΔDAS28 (cor = 0.54, $p < 0.0001$). MBDA scores in groups stratified by EULAR disease activity (DAS28 < 3.2, 3.2 to 5.1, and > 5.1) were significantly different ($p < 0.0001$). MBDA score could discriminate low disease activity (DAS28 < 3.2) with area under ROC curve of 0.83 ($P < 0.0001$). Correlation between MBDA score and HAQ-DI (cor = 0.51, $p < 0.0001$), and also ΔMBDA and ΔHAQ-DI (cor = 0.47, p = 0.0003) were significant. Furthermore, the group with MBDA low disease activity (MBDA ≤ 28) at year 1 showed significantly higher ratio of HAQ remission (HAQ-DI ≤ 0.5) (68.6%) than that of the other group (36.8%; p=0.041).

Conclusion: The MBDA score reflects current clinical disease activity and can track changes in disease activity over time. In addition to DAS, the MBDA score is associated with HAQ in early RA patients. Furthermore, the MBDA score indicates HAQ remission.

352

Polymorfisms In IL15 Associate with Progression of Joint Destruction In Rheumatoid Arthritis; A Multi Cohort Study. R. Knevel[1], A. Krabben[1], Elisabeth Brouwer[2], M.D. Posthumus[3], T. Saxne[4], E. Lindqvist[5], A. G. Wilson[6], Diederik P.C. de Rooy[1], N. Daha[1], M.P.M. van der Linden[1], René E.M. Toes[1], Tom W.J. Huizinga[1] and Annette H.M. van der Helm-van Mil[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands, [3]Berenkoog 28, Alkmar, Netherlands, [4]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden, [5]Lund University Hospital, Lund, Sweden, [6]Sheffield Uni /Medical School, Sheffield, United Kingdom

Background/Purpose: IL15 affects T-cell activation and proliferation. In RA IL15 levels are increased in serum and synovial fluid and are correlated to disease activity. Data are emerging that IL15 affects osteoclastogenesis as well. We therefore investigated *IL15* as a candidate gene for rate of joint destruction in RA.

Methods: Caucasian RA-patients included in four independent cohorts were studied; the total number of patients was 1,418 and the total number of hand and feet X-rays 4,885. X-rays were scored using the Sharp-van der Heijde or Larsen scores. For each patient the radiological progression rate was estimated. Three of the four cohorts had repeated radiographs of their patients, providing a sensitive estimation of the progression rate. First, explorative analyses were performed on 600 early RA-patients enrolled in the Leiden Early Arthritis Clinic. 25 SNPs, that together completely tagged IL15, were genotyped. Subsequently, SNPs with significant associations were typed in three other cohorts (from Lund, Groningen and Sheffield). Analyses were adjusted for age, gender or treatment if appropriate. For each cohort, the effect sizes indicated a relative increase of the progression rate per year in the presence of a genotype, and as such are comparable. An inverse weighting meta-analysis was done on the data of all cohorts.

Results: Five SNPs were significantly associated with rate of joint destruction in the first cohort and were typed in the other cohorts. Four of these SNPs were significant in the meta-analysis (Figure 1). Patients homozygous for the minor allele of rs6821171 had a 0.96 (95%CI 0.92–0.99) fold rate of joint destruction per year compared to other patients (P=0.01). Patients homozygous for the minor allele of rs7667746, rs7665842 and rs4371699 all had a 1.07 fold progression rate per year compared to the patients with only one or no minor allele (respectively 95%CI 1.03–1.10 P<0.001, 1.03–1.12 P<0.001, 1.02–1.12 P=0.01). These three SNPs were in close LD (r2 0.5–0.8, D'=0.97–1). Haplotype analyses of these SNPs resulted in two haplotypes; one consisting of all minor and the other of all major alleles. The estimated effects of the haplotypes on joint destruction were comparable to the results of the individual SNP analysis.

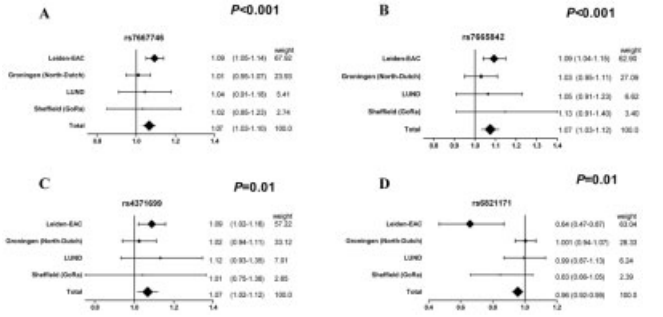

Figure 1. Depicted are the results of the meta-analyses of the four significant SNPs. The effect sizes indicate a relative increase in rate of joint destruction of patients homozygous for the minor allele compared to patients with only one or no minor allele.

Conclusion: Genetic variants in IL-15 are associated with the progression rate of joint destruction in RA.

353

Identification of Patients Who Could Require Early Biologic Therapy by Developping a Matrix Predicting Rapid Radiographic Progression in Early Rheumatoid Arthritis Patients Treated by Methotrexate. A Study Based on the ESPOIR Cohort Data. Bruno Fautrel[1], Benjamin Granger[2], Bernard G. Combe[3], Xavier X. Le Loet[4] and ESPOIR Scientific Committee[5]. [1]Université Pierre et Marie Curie - Paris 6 - Pitie Salpetriere University Hospital, Paris, France, [2]Université Pierre et Marie Curie - Paris 6; AP-HP, Paris, France, [3]Hopital Lapeyronie, Montpellier, France, [4]CHU de ROUEN, Rouen CEDEX, France, [5]Paris

Background/Purpose: Although international guidelines recommend to start very rapidly synthetic DMARDs in early rheumatoid arthritis (ERA), some patients will fail to respond adequately and thus display rapid radiographic progression(RRP) as soon as the first year of the disease. To identify, by developing a prediction matrix, ERA patients at risk of RRP despite early synthetic DMARD initiation, who thus could justify biologics as first line agents.

Methods: The ESPOIR cohort included between 2002 and 2005 813 patients with early arthritis of less than 6 months disease duration. Among them, 398 received a synthetic DMARD – either MTX or LEF – for ≥ 3 months within the 1st year of follow-up. The structural damage progression on X-rays was measured by the Sharp/van der Heijde score (vSHS) and RRP was defined as an increase of the vSHS ≥ 5 points during the 1st yr. RRP determinants were estimated bivariately with the Student or Mann-Whitney U tests for continuous and the exact Fisher test for categorical variables ($p < 0.1$), and multivariately with a stepwise logistic regression. A matrix was then developed to predict at the patient level the probability of RRP.

Results: Main patient characteristics were: mean age 49.3 yrs, female 73.6%, FR+ or ACPA+ 62%, typical RA erosion 18.1% (central reading), ACR/EULAR 2010+ 86.4%, mean DAS28 5.35, mean swollen joint count (SJC) 8.1, mean tender joint count (TJC) 8.9, mean CRP 25.R mg/L. During

the 1st year, the mean vSHS progression was 1.7 ±5.0 and 46 patients (11.6%) were classified as rapid radiographic progressors.

In the bivariate analysis, variables associated with RRP were SJC, CRP, ACPA and RF status, typical RA erosion. In the logistic regression, all but RF remain significantly associated with RRP. The fit of the model was good with an area under the curve (AUC) of 0.765. A prediction matrix was then built after determination of the most discriminating threshold for each variable (Table).

Table. Prediction matrix for rapid radiographic progression (ΔvSHS ≥ 5 points) based on baseline characteristics

		Absence of typical RA erosion on X-ray			Presence of typical RA erosion on X-ray			
		SJC < 14	14 ≤ SJC < 20	SJC ≥ 20	SJC < 14	14 ≤ SJC < 20	SJC ≥ 20	RRP Risk
ACPA+	CRP ≥ 33	0.13	0.15	0.35	0.38	0.41	0.69	
	4 ≤ CRP < 33	0.12	0.13	0.33	0.36	0.39	0.67	>40%
	CRP < 4	0.05	0.06	0.18	0.19	0.22	0.47	>20%
ACPA−	CRP ≥ 33	0.04	0.05	0.14	0.16	0.18	0.41	>10%
	4 ≤ CRP < 33	0.04	0.05	0.13	0.14	0.16	0.39	<10%
	CRP < 4	0.02	0.02	0.06	0.07	0.08	0.21	

Conclusion: The ESPOIR matrix enables the identification of patients at high risk of RRP. Compared to previously reported matrices, the ESPOIR matrix requires higher thresholds for SJC.

354

Local Swelling and Prolonged Local Pain in a Large Joint Are Independent Predictors of Damage in That Joint in Recent Onset Rheumatoid Arthritis Patients. M. van den Broek[1], L. Dirven[1], H.M. Kroon[1], M. van Oosterhout[2], K.H. Han[3], P.J.S.M. Kerstens[4], Tom W.J. Huizinga[1], W. F. Lems[5] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Groene Hart Hospital, Gouda, Netherlands, [3]Maasstad Hospital, Rotterdam, Netherlands, [4]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [5]VU University medical center, Amsterdam, Netherlands

Background/Purpose: To assess the association between local swelling and pain in the large joints in the first 2 years after diagnosis of RA with radiological damage in these joints after 8 years.

Methods: Two-year clinical data and 8-year radiological data from the BeSt study, a randomized controlled trial designed to assess 4 different treatment strategies, were used. Two-year clinical data were chosen because disease activity was highest in these years and clinical symptoms were unlikely to be caused by large joint damage. Patients were treated according to a disease activity steered protocol. Radiographs were scored by an experienced radiologist (HK) using the Larsen score (ranging from 0–5 in each joint). Swelling and pain in these joints were assessed 3-monthly, with exception of swelling in the hips. The association between swelling and pain in each large joint (at least once, or prolonged, i.e. at least 2 consecutive visits) and joint damage in this joint was assessed using generalized estimating equations. Swelling (model 1), pain (model 2) and swelling and pain (model 3) were entered as predictors, adjusted for baseline age, ESR, and body mass index (BMI), gender and time-averaged DAS, treatment strategy, rheumatoid factor (RF) or anti-citrullinated protein antibodies (ACPA), or a combination of these variables. Large joint damage (yes/no) was the outcome measure.

Results: Clinical and radiological data were available in 290 patients. Joint damage was observed in 64/532 (12%) shoulders, 51/538 (9.5%) elbows, 141/541 (26%) wrists, 67/521 (13%) hips, 95/528 (18%) knees and 39/544 (7%) ankles. Damage in at least 1 large joint was found in 64% of patients. Local pain and swelling in the first 2 years after diagnosis were most often observed in the wrists and ankles. Local swelling at least once in the first 2 years was independently associated with joint damage of the large joints, with an odds ratio (OR) of 1.8 (95% C.I. 1.3–2.3) (Table 1). Prolonged swelling and prolonged pain were both independent predictors of local joint damage, with an OR of 2.5 (95% C.I. 1.8–3.4) for prolonged swelling and of 1.4 (95% C.I. 1.05–1.9) for prolonged pain. Other independent predictors were baseline ESR (OR 1.01, 95%C.I. 1.001–1.02) and the presence of RF or ACPA (OR 2.2, 95% C.I. 1.3–3.8), or a combination of these two (OR 2.4, 95% C.I. 1.5–4.0).

Table 1. The association between local swelling, pain or swelling and pain with joint damage.

		At least once	At least 2 consecutive
Model 1	Swelling	2.0 (1.5–2.6)	2.9 (2.1–3.9)
Model 2	Pain	1.7 (1.2–2.2)	1.9 (1.4–2.5)
Model 3	Swelling	1.8 (1.3–2.3)	2.5 (1.8–3.4)
	Pain	1.4 (0.99–1.9)	1.4 (1.05–1.9)

Conclusion: Local swelling and prolonged local pain in a large joint in the first 2 years after diagnosis of RA are independent predictors of later joint damage in that joint. These results suggest that local control of inflammation might be beneficial to prevent damage.

355

Calprotectin in Rheumatoid Arthritis: Relation with Disease Activity in a Transversal and Longitudinal Study. Miriam García-Arias[1], Alejandro Balsa[2], Dora Pascual-Salcedo[3], Susana Ramiro[4], Patricia Alcocer[1], Sara García Carazo[1] and Emilio Martín Mola[2]. [1]Rheumatology. La Paz Hospital, Madrid, Spain, [2]Rheumatology. La Paz Hospital. IdiPaz, Madrid, Spain, [3]Immunology. La Paz Hospital. IdiPaz, Madrid, Spain, [4]Immunology. La Paz Hospital, Madrid, Spain

Background/Purpose: Biomarkers are useful in the management of rheumatoid arthritis (RA) by enabling assessment of disease severity and monitoring of response to therapy. Calprotectin, a major leucocyte protein, has shown to correlate with clinical and laboratory markers of activity in several inflammatory diseases. The objective of this study is to analyze the relation between calprotectin and disease activity in RA patients and to evaluate changes in calprotectin levels during treatment. Also, this study investigates whether baseline calprotectin levels can predict response to treatment.

Methods: Two different cohorts of patients were studied. One transversal study included 60 patients with different disease activity according to DAS28: 15 (25%) were in clinical remission, 15 (25%) had low disease activity, 15 (25%) had moderate activity and 15 (25%) had high disease activity. In the second cohort, 20 patients who started biological treatment, 10 responders and 10 non responders, were longitudinally evaluated at three different time points. Disease activity was measured by DAS28 and SDAI. Serum calprotectin levels were determined by ELISA. Non parametric test and Pearson correlation analysis were using to perform the univariate analysis. A linear mixed model for longitudinal data was adjusted to analyzed changes in calprotectin.

Results: In the transversal study serum concentrations of calprotectin correlated significantly with swollen joint counts ($r=0.41$; $p<0.01$), erythrocyte sedimentation rate ($r=0.28$; $p<0.05$), C reactive protein ($r=0.37$; $p<0.01$) and disease activity (DAS28 $r=0.27$; $p<0.05$ and SDAI $r=0.40$; $p<0.01$). Patients with higher disease activity had higher calprotectin levels as compared with patients with mild, low disease activity and remission, according to both DAS28 (6.80 ± 4.19 vs 3.93 ± 2.41 vs 3.51 ± 1.80 vs 4.34 ± 3.10, $p<0.05$) and SDAI (7.73 ± 4.87 vs 4.97 ± 2.27 vs 3.99 ± 3.83 vs 3.29 ± 1.60, $p<0.01$). In the longitudinal study, serum calprotectin levels decreased during treatment in responders (6.23 ± 0.47 vs 3.47 ± 0.47 vs $3,03 \pm 0.47$, $p<0.0001$), but no differences in calprotectin were found in non responders (6.72 ± 1.65 vs 6.03 ± 1.65 vs 6.72 ± 1.65, $p=0.94$). There were no differences between basal calprotectin levels in responders as compared with non responders (6.23 ± 3.52 vs 6.72 ± 3.50, $p=0.85$). No correlation between changes in calprotectin levels and changes in disease activity was found in the mixed model ($p=0.85$).

Conclusion: Calprotectin correlates with clinical and laboratory markers of disease activity in RA patients. Thus, calprotectin may be a promising marker in the assessment and monitoring of disease activity. However, baseline calprotectin levels were not predictive for response to treatment.

356

Moderate and Heavy Alcohol Use Is Associated with Less Patient-Derived Inflammation and Better Health-Related Quality of Life in Female Swedish Rheumatoid Arthritis Patients. Data From BARFOT, a Multicenter Study on Early RA. Maria K. Söderlin, Sofia Symeonidou, Maria Andersson and Stefan Bergman. R&D Center, Oskarström, Sweden

Background/Purpose: Earlier studies report a positive effect of alcohol use on disease activity rheumatoid arthritis (RA). The aim of this study was to study alcohol use and its effects on disease activity in Swedish RA patients.

Methods: Between 1992 and 2005, 2800 patients were included in the BARFOT early RA study in Sweden. Disease Activity Score 28 joints (DAS28), C-reactive protein (CRP), Health Assessment Questionnaire (HAQ), rheumatoid factor (RF), general health and pain visual analog scales (VAS), and drug treatment were registered at inclusion and at

follow-up at 3, 6 and 12 months and 2, 5, 8 and 15 years. EULAR response and remission criteria were applied at the same follow-up points. In 2010, a self-completed postal questionnaire was sent to 2102 patients (all prevalent patients) in the BARFOT study enquiring about life style factors. Alcohol use was assessed using the self-completed validated questionnaire AUDIT-C.

Results: In 2010 1238/1460 (85%) of the patients had data on alcohol use: 11% were non-drinkers, 67% moderate drinkers and 21% heavy drinkers. Women who drank moderately or heavily had lower patient-reported disease activity and higher health-related quality of life (HRQL) in a cross-sectional analysis in 2010, but no effect of alcohol use on disease activity was seen in men. For current smokers alcohol use was only associated with fewer patient-derived swollen joints. Female moderate and heavy drinkers had lower physician-reported DAS28 levels up to 5 years of follow-up, which were driven by lower ESR levels. Alcohol use did not emerge as an independent predictive factor for higher EuroQol, HAQ or VAS scores in multivariate regression models adjusted for sex, age, disease duration, smoking status and socioeconomic status.

Conclusion: A total of 21% of patients were heavy drinkers. Women who drank moderately or heavily had best patient-derived disease activity and HRQL, but no effect of alcohol on patient-derived disease activity was seen in men. Women drinking heavily or moderately had lower physician-reported DAS28 up to 5 years of follow-up due to lower ESR.

357

Plasma Talin Is a New Diagnostic and Monitoring Marker for Rheumatoid Arthritis. Kensei Tsuzaka[1], Yuka Itami[1], Naoshi Shinozaki[2] and Morishita Tetsuo[1]. [1]Dept of Internal Medicine, Ichikawa General Hospital,TDC, Ichikawa, Chiba, Japan, [2]Cornea Center, Ichikawa General Hospital, TDC, Ichikawa

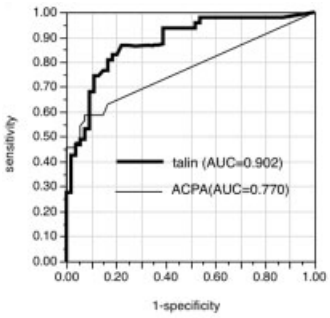
Background/Purpose: Anti-CCP antibody (ACPA) has been reported to as a useful and highly specificity marker for the diagnosis of rheumatoid arthritis (RA). However, more sensitive diagnostic biomarker might be expected because the sensitivity of ACPA in early RA has been shown to be lower than expected. Talin is a protein that completes the link between integrins and the actin cytoskeleton, and plays an important role in the establishment of focal adhesions. In this paper, we focused on plasma talin as a diagnostic marker for RA.

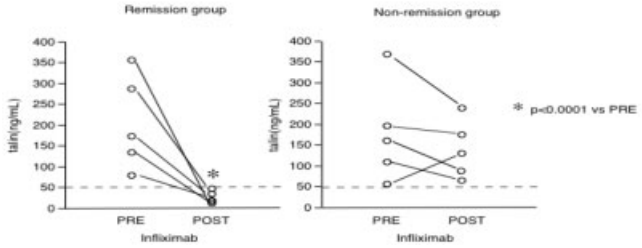
Methods: RA was diagnosed as the 2010 Rheumatoid Arthritis Classification Criteria. Plasma and sera were obtained simultaneously from 50 RA patients (Age, 60.9±14.4 y/o; DAS28, 5.23 ± 1.11) and 70 controls (Ctrl) (30 osteoarthritis (OA) patients, 20 SLE patients, and 20 normal healthy controls (NC)). Twenty-two (44.0 %) of these 50 RA patients were early-onset (≤ 6 months) RA and 39 (78.0 %) of these patients were untreated at the time of collecting blood. Plasma talin was quantified using a sandwich ELISA with anti-talin capture and detecting antibodies. Serum ACPA was measured using a commercial ELISA kit. Plasma was obtained at baseline and 14 weeks after treatment with IFX from 5 RA patients who entered remission (SDAI<3.3) (Remission group) and 5 RA patients who did not enter remission (Non-remission group) at 14 weeks after IFX treatment.

Results: Plasma level of talin was significantly ($p<0.0001$) higher in RA patients (177.3 ± 167.3 ng/mL) than in OA (28.8 ± 29.7 ng/mL), SLE (38.1 ± 38.0 ng/mL), and NC (41.9 ± 51.3 ng/mL), respectively. The area under ROC curve (AUC) of talin (0.902) was larger than AUC of ACPA (0.770) in differentiation between RA and Ctrl (Fig.1). Moreover, the sensitivity of talin (82.3%) for the diagnosis of RA was higher than that of ACPA (58.0%), rheumatoid factor (Rf) (76.1%), and MMP-3 (74.0%) while its specificity (85.1%) was higher than that of Rf (57.0%) and MMP-3 (55.3%) (Table.1). Interestingly, the plasma level of talin before treatment (PRE) was significantly ($p<0.001$) down-regulated to the normal range (<50 ng/mL) after IFX treatment (POST) in Remission group whereas it did not reduce to the normal range in Non-remission group (Fig. 2).

Table 1.

	Sensitivity (%)	Specificity (%)
talin	82.3	85.1
ACPA	58.0	90.8
Rf	76.1	57.0
MMP-3	74.0	55.3





Conclusion: Our findings suggest clinical usefulness of plasma talin as a new diagnostic and monitoring biomarker for RA.

358

Serum 14-3-3η: A Rheumatoid Arthritis Biomarker. Walter P. Maksymowych[1], Robert Landewe[2], Désirée van der Heijde[3], Paul-Peter Tak[4] and Anthony Marotta[5]. [1]University of Alberta, Edmonton, AB, [2]Academic Medical Center, Amsterdam, Netherlands, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [4]Professor of Medicine/ Director, Division of Clinical Immunology and Rheumatology, Amsterdam, Netherlands, [5]Augurex Life Sciences Corp, North Vancouver, BC

Background/Purpose: Intracellular 14-3-3 proteins represent a family of ubiquitously expressed chaperonins consisting of seven highly conserved isoforms. Only one isoform, 14-3-3η, is significantly detected in arthritis and is differentially expressed extracellularly in rheumatoid arthritis (RA) compared to healthy controls and may have independent diagnostic utility from other RA serological markers. This study compared 14-3-3η serum expression in patients with RA versus ankylosing spondylitis (AS) and in autoimmune (AI) disease controls.

Methods: Levels of serum 14-3-3η were measured in 267 patients, 135 RA, 67 AS and 65 AI controls, using an investigational-grade 14-3-3η ELISA to evaluate the biomarker's differential expression in RA. Mean (SD) age for RA patients (72% female) was 59.4 (12.7) and 41.9 (13.2) for AS patients (25% female). Diagnosis was according to ARA 1987 and modified New York criteria, respectively. RA patients were on standard DMARDs but naïve of biological therapy. AI controls included 10 each of psoriasis, ulcerative colitis, type 1 diabetes, SLE, Crohn's, and 5 each of primary Sjogren's, scleroderma, and multiple sclerosis. Two-tailed t-tests and Mann-Whitney u-tests were used to compare group differences in serum concentrations. ROC curves were generated and diagnostic utility estimated by area under the curve and likelihood ratios (LR) for various 14-3-3η serum concentration cut-offs.

Results: 14-3-3η mean and medium serum concentrations were significantly higher in RA subjects at 4.58 and 1.12ng/ml, respectively compared to AS (0.14 and 0.02ng/ml; $p<0.0001$) and AI (0.21 and 0.03ng/ml; $p<0.0001$). The area under the ROC curve for RA versus AS was 0.86 (95%CI 0.81 to 0.91; $p<0.0001$) and RA versus AI was 0.85 (95%CI 0.79 to 0.90; $p<0.0001$). There were no differences in mean or median 14-3-3η serum concentrations between the AS and AI groups. A best cut-off level of 0.23ng/ml provides a positive likelihood ratio (LR+) of 5 and a negative likelihood ratio (LR-) of 0.30 for RA versus AS. For 14-3-3η levels above 0.72 and 0.88ng/ml, LR+ was 10 and 36, and LR- was 0.40 and 0.47, respectively.

Conclusion: Differential expression of 14-3-3η in RA versus AS and its absence in a wide range of other autoimmune disorders supports its utility as a diagnostic marker in RA.

359

Can Anti-Cyclic Citrullinated Peptide Antibody Negative Rheumatoid Arthritis Be Subdivided in Clinical Subphenotypes?. Diederik P.C. de Rooy[1], Annemiek Willemze[1], Bart Mertens[2], Tom W.J. Huizinga[1] and Annette H.M. van der Helm-van Mil[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leiden University Medical Center, Netherlands

Background/Purpose: Studies investigating genetic risk factors for susceptibility to Rheumatoid Arthritis (RA) studied anti-citrullinated peptide antibody (CCP)-positive-RA more frequently than anti-CCP-negative RA. One of the reasons for this is the perception that anti-CCP negative RA may include patients that fulfilled criteria for RA but belong to a wide range of diagnoses. We aimed to evaluate the validity of this notion and explored whether clinical subphenotypes can be discerned within anti-CCP-negative RA.

Methods: 318 patients with anti-CCP-negative RA (1987 ACR-criteria), included in the Leiden Early Arthritis Clinic between 1993 and 2006, were studied for baseline characteristics and radiological progression data during a mean follow-up of 5 years. Grouping was studied both at variable and patient level. Principal Components Analysis and Partial Least Squares regression were applied to study for clustering of variables. A Cluster Analysis was performed in order to look for clustering of patients.

Results: The simultaneous presence of patient characteristics at disease presentation was observed for several groups; however the 3 largest groups of patients' characteristics explained only 26.5% of the total variance. Plotting the contribution of each patient to these 3 groups did not reveal clustering of patients. Comparable observations were done when data on progression of joint destruction were studied in relation to baseline clinical data. A Cluster Analysis, evaluating whether patients resemble each other, revealed no grouping of patients. Altogether, no clinically distinguishable subphenotypes were observed.

Conclusion: This study suggests that in studies assessing risk factors in anti-CCP negative RA, all patients can be studied as one group.

Elevated Plasma Soluble TREM-1 Levels Is Correlated with Disease Activity in Rheumatoid Arthritis. Sang Tae Choi[1], Eun-Jin Kang[2] and Jung-Soo Song[1]. [1]Chung-Ang University College of Medicine, Seoul, South Korea, [2]Busan Medical Center, Busan, South Korea

Background/Purpose: Triggering receptor expressed on myeloid cells 1 (TREM-1) is an immunoglobulin-like cell surface receptor mainly expressed on neurtophils, monocytes and macrophages. TREM-1 serves as a critical amplifier of inflammatory signaling, and its expression is increased in the synovium of rheumatoid arthritis (RA) patients. It can exist as a soluble form. In this study, we investigated whether plasma soluble TREM-1 (sTREM-1) levels are elevated in patients with RA and whether its levels are correlated with disease activity and other parameters.

Methods: This cross-sectional study included 71 patients with RA and 50 age- and sex- matched healthy controls. Plasma samples were obtained from patients with RA during active and inactive disease status and from controls. We assessed clinical characteristics and laboratory parameters including the erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and disease activity score 28 (DAS28). Their plasma levels of sTREM-1 and tumor necrosis factor (TNF)-α were quantitatively measured by enzyme-linked immunosorbent assay (ELISA).

Results: Patients with RA had significantly higher plasma sTREM-1 levels than healthy controls (170.10 $\pm$ 84.71 pg/mL vs 97.41 $\pm$ 40.64 pg/mL, $p < 0.001$). In RA patients, the plasma sTREM-1 levels were correlated with DAS28, ESR, and CRP ($r = 0.329$, $p = 0.005$; $r = 0.241$, $p = 0.043$; $r = 0.314$, $p < 0.001$, respectively), but not with plasma TNF-α levels. Plasma sTREM-1 levels in the patients with active disease status (DAS28 $\geq$ 3.2) were significantly higher than those without it (208.89 $\pm$ 100.14 pg/mL vs 150.29 $\pm$ 68.70 pg/mL, $p = 0.005$).

Conclusion: Patients with RA had higher levels of plasma sTREM-1 compared to healthy controls. The plasma sTREM-1 levels were correlated to DAS28, ESR, and CRP. The soluble form of TERM-1 may be useful as a disease activity marker in RA.

361

Investigation of a Multi-Biomarker Disease Activity (Vectra DA) Signature and Algorithm Score in Rheumatoid Arthritis Patients with Low Disease Activity: The REMIRA Study. Margaret H. Ma[1], Saroja Ramanujan[2], Guy Cavet[2], Douglas J. Haney[2], Xiaoyan Zhao[2], P. Scott Eastman[2], Gabrielle H. Kingsley[1], David L. Scott[3] and Andrew P. Cope[1]. [1]King's College Hospital, London, United Kingdom, [2]Crescendo Bioscience, Inc., South San Francisco, CA, [3]King's College Hospital, Dulwich, United Kingdom

Background/Purpose: With intensive therapy, low disease activity (LDA) states and remission are becoming increasingly common in patients with RA. Yet, discriminating true remission from persistent sub-clinical disease remains a challenge. Thus, there is an urgent need to improve the definition of LDA using a wider range of clinical and laboratory variables. A multi-biomarker signature that combines levels of 12 serum biomarkers to produce a score between 1 and 100 was recently validated as a test for RA disease activity. We examined the use of this multi-biomarker disease activity (MBDA) test in assessing the heterogeneity of LDA states and differentiating remission vs. non-remission.

Methods: RA patients on stable therapy with $<$10 yrs disease duration and DAS28ESR$\leq$3.2 were recruited to the REMIRA study. Concentrations of 12 protein biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, YKL-40, MMP-1, MMP-3, leptin, resistin, SAA, CRP) were determined by immunoassay in baseline serum samples and used to generate MBDA scores according to a pre-specified algorithm. Association between the MBDA score and clinical remission was assessed by calculating the area under the ROC curves (AUROCs) for various definitions of remission, including the ACR/EULAR 2011 Boolean definition. Comparison of biomarker concentrations between remission and non-remission LDA patients was performed using the Wilcoxon test and a fixed-sequence procedure to control for the effects of multiple testing.

Results: 70 RA patients with mean(SD) age of 58(14) and disease duration of 50(31) months were recruited. 61% were female, 82% were Caucasian, 14% were Afro-Caribbean, 4% were Asian, and 68% were seropositive. Mean DAS28ESR was 1.84(0.83); mean DAS28CRP was 1.98(0.69). Wide variation in biomarker levels and profiles was seen across the cohort. SAA was most suppressed and EGF most elevated relative to historical data. The MBDA score was significantly associated with remission vs. non-remission (AUROC=0.74, 95% CI=(0.60,0.85), p$<$0.001 for Boolean remission; similar for other criteria). Individually, IL-6, CRP, and SAA were significantly lower in remission than in non-remission patients. Although proinflammatory biomarkers were generally lower in remission, a small subgroup of patients had elevated biomarkers and MBDA scores despite being in clinical remission.

Table 1. Concentrations of biomarkers differing between remission and non-remission LDA patients, as classified by the ACR/EULAR Boolean definition. IQR=Inter-Quartile Range

Biomarker	Median (IQR) LDA/remission	Median (IQR) LDA/non-remission	p-value
IL-6 [pg/ml]	6.0 (4.4–8.0)	10 (6.6–17)	0.001
CRP [mg/L]	1.4 (0.52–2.3)	2.4 (1.1–7.2)	0.009
SAA [mg/L]	0.93 (0.57–1.5)	1.6 (0.90–3.1)	0.01

Conclusion: The REMIRA LDA cohort is heterogeneous as reflected by wide biomarker variation. The MBDA score can differentiate between LDA/remission and LDA/non-remission and has a potential role for disease activity assessment in LDA patients. Longitudinal follow-up may improve our understanding of the relationship between elevated biomarkers and disease progression in patients in clinically-judged remission.

Serum 25 OH Vitamin D Levels Are Low in North American Native Populations with Early Inflammatory Arthritis but Do Not Correlate with Clinical Activity or Outcome. Carol A. Hitchon, Neeloffer Mookherjee, Keng Wong, Christine A. Peschken, Peter Nickerson and Hani S. El-Gabalawy. University of Manitoba, Winnipeg, MB

Background/Purpose: Low 25 OH vitamin D (VitD) levels have been associated with inflammatory arthritis and with disease activity. North American Native (NAN) populations have a high prevalence of shared epitope, rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA), and worse clinical

outcomes than Caucasians from the same geographical area. We sought to determine the prevalence of vitD deficiency and the contribution of VitD to disease severity and outcomes in a cohort of NAN and Caucasians with early inflammatory arthritis.

Methods: NAN and Caucasians with early inflammatory arthritis (<12 months symptoms, 1+ active joint), were followed for one year and clinical outcomes (remission, EULAR treatment response) determined. Disease activity was measured using the DAS28(3variable) CRP composite score. Treatment was at the discretion of the attending rheumatologist. Shared epitope was determined by DNA sequencing. VitD levels were measured in baseline serum by ELISA and categorized as deficient (<25 nmol/L), insufficient (25- <75 nmol/L), optimal (75–250 nmol/L) or toxic (>250 nmol/L). Statistical significance was considered as $p<0.05$ using non-parametric Mann Whitney U and Chi2 tests and multivariate regression models.

Results: At baseline, 77% of EIA had insufficient (61%) or deficient (16%) levels of VitD. Baseline VitD levels were lower in NAN compared to Caucasian even after correcting for season of first visit 49 (32) vs 59 (30) nmol/L $p=0.008$) and NAN were more likely to be deficient (25% vs 11% $p=0.006$). No associations with gender, serology (RF and/or ACPA), shared epitope, baseline disease activity DAS28 (3variable)CRP, individual components, or ESR) or smoking status were seen. Baseline VitD levels were not associated with clinical outcomes of remission or treatment response in univariate or multivariate models. Repeated VitD levels were available at 6 months (n= 50) and 12 months (n=164) on selected subjects without adjustment of vitD supplementation. At one year, the majority had vitD levels similar to their baseline vitD category, 33 (20%) improved and 28 (12%) worsened. No significant seasonal variability was seen. Change in VitD correlated with DAS28(3variable)CRP at one year ($r= -0.215$ $p=0.01$) but not with change in DAS28(3variable) CRP p=NS).

Conclusion: The prevalence of VitD deficiency is high in this Canadian cohort of early inflammatory arthritis especially for NAN. However, serum levels do not correlate with disease activity or outcome. In this high risk NAN population, low VitD may be more important in predisposing individuals to future inflammatory arthritis.

A New Definition of Treatment Response in Rheumatoid Arthritis: Identification of the Critical Difference in Disease Activity. Frank Behrens[1], Michaela Koehm[1], Eva C. Scharbatke[2], Stefan Kleinert[2], Geerd Weyer[3], Rieke Alten[4], Hans Peter Tony[2] and Harald Burkhardt[1]. [1]CIRI/Rheumatology, J.W. Goethe-University, Frankfurt/Main, Germany, [2]Rheumatology, University of Würzburg, Würzburg, Germany, [3]Biostatistics, ICRC, Berlin, Germany, [4]Rheumatology Schlossparkklinik, Berlin, Germany

Background/Purpose: Situational effects and measurement errors inducing fluctuations in disease activity measurements complicate the evaluation of a clinically meaningful therapeutic response in rheumatoid arthritis (RA). To itemize this complexity, a statistical approach was used to determine a critical difference (dcrit) defining valid criterion for clinical response as assessed by the Disease Activity Score-28 joints (DAS28).

Methods: The population comprised a total number of 728 RA patients with stable response to DMARD, steroid or biological therapy (including TNF-inhibitors and Rituximab) derived from three different clinics in Germany (University Würzburg (n=50), University Frankfurt (n=51), Berlin (n=50)) and from a prospective observational study with Adalimumab. Patients were included with stable therapy and disease course from months 12 to 24 after therapy initiation. To evaluate changes in DAS28 score, DAS28 scores at 12, 18 and 24 months were subjected to an ANOVA model to determine the error of measurement which was used to establish a 95% one sided confidence interval (95% CI) for decrease occurring by chance within the range of normal fluctuations. The limit of the confidence region defined the critical difference (dcrit) in disease activity for a reliable change in a single patient.

Results: The overall dcrit value in the 728 patient populations was detected at 1.75. Values for dcrit were comparable in all evaluated subgroups, regardless of treatment centre, class of therapy (DMARDs or biologics including TNF-inhibitors and Rituximab), or baseline disease activity (Table).

	All patients	DAS28 M12		Class of therapy		Age		Gender	
		≤3.2	>3.2	DMARDs	Biologics	≤60 years	>60 years	male	female
n	728	393	335	57	671	460	268	167	561
dcrit	1.75	1.57	1.79	1.90	1.73	1.74	1.77	1.65	1.78

Conclusion: Based on our data, a dcrit value of 1.8 (DAS28 improvement of 1.8 points) signifies an individual therapeutic response that exceeds the threshold of random fluctuation. The dcrit value determined by statistical analysis of expected variation in DAS28 scores higher than the DAS28 change required to achieve a good EULAR response (1.2 points) and is independent of baseline activity, which may make it more convenient for clinical use. Further studies in larger populations will be required to confirm the utility of the dcrit value in determining therapeutic response. However, our data suggest that a dcrit value of 1.8 has the potential to guide treatment decisions in daily clinical practice and to facilitate research on treatment responders.

Characterization of TLR7 and TLR8 in Rheumatoid Arthritis. Nathan D. Chamberlain[1], Michael Volin[2], Richard M. Pope[3], Arthur M. Mandelin II[3] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL, [3]Northwestern Univ Med School, Chicago, IL

Background/Purpose: The aim of the study was to characterize the expression of TLR7 and TLR8 in rheumatoid arthritis (RA) synovial tissue and to examine their regulation and pathogenic role in RA monocytes and macrophages.

Methods: Expression of TLR7 and TLR8 was determined in RA, osteoarthritis (OA) and normal (NL) synovial tissues employing immunohistochemistry. Expression and regulation of TLR7 and TLR8 was determined in RA peripheral blood (PB) monocytes and *in vitro* differentiated macrophages by real-time RT-PCR and ELISA. Next, the mechanism by which TLR7/8 ligation mediates the proinflammatory response in RA PB macrophages was examined using Western blot analysis and ELISA.

Results: We found that in RA, TLR7 immunostaining was markedly higher in synovial tissue lining and sublining macrophages compared to NL synovial tissue. TLR8 immunostaining was greatly increased in RA synovial tissue lining compared to OA and NL synovial tissue. Additionally, sublining macrophages had greater TLR8 expression in RA compared to NL synovial tissue. Further expression of TLR7 and TLR8 was significantly elevated in RA synovial fluid macrophages and RA PB monocytes compared to RA and NL PB macrophages by real-time RT-PCR. Expression of TLR7 is reduced when RA PB monocytes differentiate to macrophages, however in PB macrophages TLR7 expression levels can be induced by IL-17 and IL-8 while PB monocytes are unresponsive to stimulation. In contrast, TLR8 expression is modulated by LPS and IL-1b in both RA PB monocytes and macrophages. To determine whether RA PB monocytes and macrophages respond to TLR7/8 ligation, cells were exposed to different doses of a potent synthetic agonist of TLR7/TLR8, R848 (100 ng/ml and 1mg/ml), and screened for transcription (6h) and production (24h) of proinflammatory factors, TNF-a, IL-6 and CCL2. Secretion of TNF-a and IL-6 were dose dependently increased by R848 stimulated RA PB monocytes and macrophages. However, production of CCL2 did not follow a dose responsive increase in RA PB monocytes or macrophages. Although TLR7/8 expression was greatly elevated in RA PB monocytes compared to RA PB macrophages, ligation of these receptors with the highest dose of R848 tested (1mg/ml) resulted in production of comparable levels of TNF-a, IL-6 and CCL2 in both cell types. With this highest dose of R848 similar levels of TNF-a and CCL2 were produced from RA PB macrophages which were greater than IL-6 production in these cells. We next inhibited pathways in R848 activated RA PB macrophages to determine signaling intermediates contributing to TLR7/8-mediated proinflammatory factor production. R848 mediated activation of the p38 pathway (15 min) occurs prior to that of ERK, AKT or NF-kB (35 min). We chose to examine the regulation of R848-induced CCL2 since this chemokine was comparably produced from RA PB monocytes and macrophages following lower and higher doses of R848. While inhibitors to NF-kB and PI3K suppressed R848-induced CCL2 secretion 3 fold in RA PB macrophages, inhibition of p38 or ERK pathways was ineffective in this process.

Conclusion: We identify for the first time, regulators of TLR7 and TLR8 expression in their target cells, macrophages, and document the role of TLR7/8 ligation in the pathogenesis of RA.

365

TLR5; A Novel and Unidentified Inflammatory Mediator in Rheumatoid Arthritis. Nathan D. Chamberlain[1], Michael Volin[2], Richard M. Pope[3], Arthur M. Mandelin II[4] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL, [3]Northwestern Univ Med School, Chicago, IL, [4]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: Previous studies strongly support the role of TLR2 and 4 in the pathogenesis of rheumatoid arthritis (RA) and experimental arthritis models however the regulation and pathogenic effect of TLR5 is undefined in RA.

Methods: Expression of TLR5 in RA, osteoarthritis (OA) and normal (NL) synovial tissue (ST) was determined by immunohistochemistry. Employing real-time RT-PCR regulating factors of TLR5 expression were determined in RA monocytes and macrophages. In the same cells, production of proinflammatory factors and/or the mechanism by which these factors were induced was examined following TLR5 ligation.

Results: In this study we demonstrate that in both RA and OA, TLR5 staining was markedly higher on synovial lining and sublining macrophages compared to NL tissue. Therefore we asked whether expression of these factors was increased in RA *in vitro* differentiated peripheral blood (PB) and synovial fluid macrophages compared to normal PB monocytes and *in vitro* differentiated macrophages. Expression of TLR5 was elevated 9- and 35-fold in RA synovial fluid macrophages compared to RA and NL PB macrophages respectively by real-time RT-PCR. Levels of TLR5 were 7- and 3-fold greater in RA PB monocytes compared to RA PB macrophages and normal monocytes. We further demonstrate that TLR5 expression was modulated by TNF-a in RA monocytes and by IL-17 and IL-8 in RA macrophages however expression levels of TLR5 was suppressed by TLR4 ligation in both cell types. Next, we asked whether RA monocytes and macrophages respond to the ligation of flagellin to TLR5. For this purpose RA PB monocytes and macrophages were activated with different doses of flagellin (10–100 ng/ml) and cells were screened for transcription (6h) and production (24h) of proinflammatory factors such as TNF-a, IL-6 and CCL2. Generally, transcription but not the secretion of TNF-a, IL-6 and CCL2 was dose dependently increased with flagellin stimulation in RA PB monocytes and macrophages. Although TLR5 expression was greatly elevated in RA PB monocytes compared to RA PB macrophages, TLR5 ligation resulted in higher (TNF-a) or comparable levels of proinflammatory factors (IL- 6 and CCL2) in RA PB macrophages compared with RA PB monocytes. Similar levels of TNF-a and IL-6 were produced from RA PB monocytes and macrophages following TLR5 ligation which were lower than CCL2 production in these cells. We next inhibited pathways in flagellin activated RA PB macrophages in order to determine signaling intermediates contributing to flagellin-mediated proinflammatory factor production in these cells. We found that flagellin-mediated activation of the p38 and AKT pathways (5 min) occurs prior to that of ERK (35 min) or NF-kB (15 min). We chose to examine the regulation of flagellin-induced CCL2 since this chemokine had the highest production level in RA macrophages. While inhibitors to NF-kB and PI3K suppressed flagellin-induced CCL2 secretion by 3- to 6-fold ($p < 0.05$), inhibition of p38 or ERK pathway did not reduce the levels of CCL2 in RA macrophages.

Conclusion: These results suggest that macrophages in RA synovial tissue and fluid are an important source of TLR5. These observations also suggest that TLR5 may be a potential therapeutic target in RA.

366

Methyl Supplementation of Rheumatoid Arthritis Synovial Fibroblasts Attenuates Their Aggressive Behaviour. Emmanuel Karouzakis[1], Maria Berdasco[2], Astrid Jungel[1], Caroline Ospelt[1], Andrew Filer[3], Karim Raza[3], Renate E. Gay[1], Beat A. Michel[1], Christopher D. Buckley[3], Manel Esteller[2], Steffen Gay[1] and Michel Neidhart[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Bellvitge Institute for Biomedical Research, Barcelona, Spain, [3]School of Immunity and Infection, MRC Center for Immune Regulation, Birmingham, United Kingdom

Background/Purpose: Previously, we reported that global genomic hypomethylation in rheumatoid arthritis synovial fibroblasts (RASF) contributes to the intrinsically activated phenotype. Therefore, the reversal of hypomethylation in RASF might reduce their state of activation. Since, methyl supplementation with Folate, L-methionine and Vitamin B12 has been shown to increase DNA methylation, we treated RASF with this combination and measured the adhesion, migration and invasion.

Methods: Global hypomethylation was measured in genomic DNA of osteoarthritis SF (OASF, n=5), early RASF (n=4) and RASF (n=8) by High Performance Liquid Chromatography (HPLC). Hypomethylated RASF (n=2 patients) were cultured in DMEM/ F12 medium (control) supplemented with 10 (HS) fold excess amount of folate, vitamin B12 and L-methionine for 1 month. After the last day of treatment, DNA methylation was assessed by staining of nuclei with 5-methylcytosine antibodies. Mean fluorescence intensity (MFI) was calculated from the histograms. In addition, the ability of the RASF to adhere to a variety of extracellular matrixes (ECM) such as fibronectin, collagen types I and II were tested with a cell adhesion assay. The effect of methyl supplementation on the migratory properties of RASF was analysed by scratch assay. The untreated or treated RASF were implanted together with normal human cartilage into the SCID mouse model of RA.

Results: RASF and early RASF revealed a lower percentage of total 5-methylcytosine (5-MeC) than the OASF (RASF: 3.8±0.22 % 5-MeC, $p<0.0001$, n=8; early RASF: 4.4±0.15% 5-MeC, $p<0.0028$, n=4; OASF: 5.5±0.12 % 5-MeC, n=5). The supplementation with methylation compounds increased the percentage of 5-MeC in comparison to normal treated RASF in patient 1 (Patient 1: control 7.31; HS 18.92 MFI, Patient 2: control 9.18; HS 9.18 MFI). The steady treatments of RASF with HS methylation supplementation inhibited the migration of cells as shown by scratch assays in both patients. However, HS treatment of RASF did not change the cell adhesion to fibronectin and collagen types. Most interestingly, the steady HS treatment of RASF from patient 1 that responded to the treatment *in vitro* showed reduced invasion and perichondrocytic degradation in the *in vivo* SCID mouse invasion model (invasion score: control 2.25±0.27; HS 1.26±0.26, $p<0.03$, n=5; perichondrocytic score: control 1.91±0.18; HS 1.17±0.23, $p<0.01$, n=5).

Conclusion: Reversal of DNA hypomethylation in RASF inhibits the migratory and invasive properties of the RASF and might be used as a novel therapeutic approach to inhibit cartilage destruction in rheumatoid arthritis.

Endogenous gp96 in Rheumatoid Arthritis Synovial Fluid Promotes Macrophage Activation Through TLR2 Signaling. Qi Quan Huang[1], Robert Birkett[1], Andrea Dorfleutner[1], Renee E. Koessler[1], Christopher V. Nicchitta[2] and Richard M. Pope[1]. [1]Northwestern University Medical School, Chicago, IL, [2]Duke university Medical Center, Durham, NC

Background/Purpose: We have recently demonstrated that endoplasmic reticulum stress response protein gp96 is highly expressed in joints of patients with rheumatoid arthritis (RA) and that recombinant gp96, purified from *E.coli* activates macrophages primarily via TLR2 signaling. However, no studies have ever documented that the potential TLR ligand expressed in the RA joint is capable of activating through TLR signaling.

Methods: Supernatants from HeLa cells infected with a recombinant adenoviral (Ad) vector expressing gp96 NTD (gp96HeLa) or Ad control supernatants (CMV-HeLa) were harvested. The ability of the gp96-HeLa and gp96 in RA synovial fluids (SFs) to activate HEK-TLR2 (HEK2) and HEK-TLR4 (HEK4) cell lines and human and murine macrophages was determined by the activation of NF-kB and the expression of TNFa, IL-6 or IL-8. Cell surface gp96 was identified by flow cytometry.

Results: RA SFs induced the expression of TNFa and IL-8 ($p < 0.01$) by control macrophages, and this activation was suppressed by neutralizing antibodies to TLR2 ($p<0.05$) and TLR4 ($p=0.06$). To determine if endogenous gp96 in RASF mediates macrophage activation, SFs were stratified on the basis of gp96 concentration, quantified by ELISA, and macrophage activation examined. RA SFs with gp96 concentrations >800 ng/ml (n=4), but not those with lower concentrations of endogenous gp96, demonstrated significant suppression by a neutralizing anti-gp96 antiserum for both TNFa ($p<0.03$) and IL-8 ($p<0.03$) mRNA. RA SF was also capable of activating HEK2 and HEK4 cells. However, only HEK2 activation by the RA SFs with gp96 >800 ng/ml were suppressed by pre-incubation of the SFs with the neutralizing anti-gp96 antiserum ($p<0.02$). Further, macrophages isolated from SFs of RA patients expressed increased cell surface gp96, compared with monocytes from RA or healthy donor peripheral blood. Neutralizing gp96 antibody suppressed the spontaneous expression of TNFa by RA SF macrophages compared with control rabbit serum ($p<0.05$), suggesting that cell surface gp96 contributed to the constitutive activation observed with RA SF macrophages. To confirm the ability of mammalian expressed gp96 to activate through TLR2, gp96-HeLa activated HEK2, but not HEK4 cells, while CMV-HeLa activated neither cell line. The HEK2 activation was suppressed by a neutralizing anti-gp96 antibody. Additionally gp-96-HeLa,

but not CMV-HeLa, activated human macrophages, that was inhibited by neutralizing antibody to TLR2, but not TLR4. Lastly, gp96-HeLa activated murine bone marrow derived microphages from WT and TLR4-/- mice, but not TLR2-/- mice. Together these observations document that gp96 in RA SF and mammalian cell-expressed gp96, in the absence of endotoxin, is an agonist of TLR2 signaling.

Conclusion: These data for the first time document the presence of a functional, endogenous TLR2 ligand in inflamed RA joints, employing RA SFs and RA SF macrophages. Data also demonstrates inhibition of gp96 in RA SF or RA SF macrophages resulted in reduced macrophage activation. These observations document the potential role of endogenous TLR ligands in the pathogenesis of RA and support targeting the TLR2 signaling pathway as a therapeutic option in RA.

Functional Changes of Bone Marrow Derived Mesenchymal Stem Cell Through Adipogenesis. A Possible *in Vitro* Model of Bone Edema in Rheumatoid Arthritis. Satoshi Yamasaki[1], Akitomo Okada[2], Tomohiro Koga[1], Shin-ya Kawashiri[1], Mami Tamai[1], Hideki Nakamura[1], Tomoki Origuchi[1] and Atsushi Kawakami[2]. [1]Nagasaki University School of Medicine, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background/Purpose: Bone oedema is a pathological change in rheumatoid arthritis (RA) that is detectable by magnetic resonance imaging. A histological examination of the lesion revealed that adipose tissue, which normally occupies the bone cavity, is replaced by inflammatory cells such as monocytes, fibroblasts, and osteoclasts. Mesenchymal stem cell (MSC), which is abundant in bone marrow, is a multi-potent stem cell that can differentiate into adipocytes. In the present study, we tested the roles of MSC in the formation of bone oedema, and in the onset and progression of RA.

Methods: Adipogenesis of bone marrow-derived human MSC was induced by standard adipogenic induction medium (hMSC Differentiation BulletKit", Adipogenic, Lonza Walkersville Inc.) in the presence or absence of cytokines including tumor necrosis factor α (TNFα), interleukin (IL)-1β, IL-6, and Transforming growth factor β (TGFβ). The transcript makers for adipogenesis such as *ppar*, *ap2* and *lpl* were determined by polymerase chain reaction. The cytokine productions from MSC were comprehensively analyzed by Human Inflammation Antibody Array 3 (RayBiotech, Inc.), and further confirmed by ELISA. The wound-healing assay was performed to determine the locomotive abilities. The expression of F-actin were evaluated by fluorescent Phalloidin to examine the expression and structures of stress fibers.

Results: TNFα, IL-1β, IL-6 and TGFβ strongly inhibited the adipogenesis of MSC, however, the mRNA expression levels of adipogenesis gene markers in the MSC treated with these cytokines were comparable with the non-treated cell. IL-6 production from MSC was significantly reduced after the adipogenesis induction. The wound-healing assay demonstrated that the mobility of MSC after adipogenesis was clearly reduced compared to that of undifferentiated MSC. Consistent with these findings, the structure of stress fibers visualized by F-actin staining was disrupted in MSC after adipogenesis.

Conclusion: The facts that the inflammatory cytokines blocked the adipogenesis of MSC imply that inflammation contributes to the formation of bone oedema through the replacement of adipose tissue with undifferentiated MSC. Secondly, adipogenesis attenuates the abilities of MSC to produce IL-6 and to migrate, which suggest that bone oedema containing undifferentiated MSC can produce IL-6 and invade into surrounding tissues just like a pannus in RA joint. Therefore, bone oedema should be regarded as a hallmark of active RA and an important therapeutic target for the disease.

369

Dopamine D2-Like Receptor Signaling Inhibits Human Osteoclast Differentiation From Monocytes. Kentaro Hanami[1], Kazuhisa Nakano[2], Kunihiro Yamaoka[1], Kazuyoshi Saito[1] and Yoshiya Tanaka[1]. [1]University of Occupational & Environmental Health, Japan, Kitakyushu, Japan, [2]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Osteoclasts in the synovium of rheumatoid arthritis (RA) play an important role for bone destruction of the affected joints. It is known that increased sympathetic nervous activity increases both osteoclast differentiation and osteoclast activity, leads to bone loss. A major neurostransmitters dopamine transmits signals via five different seven-transmembrane G protein-coupled receptors termed D1-D5, modifying cAMP levels in the cell. However, the involvement of sympathetic nervous system in bone metabolism remains unknown. Therefore, we have assessed the relevance of dopaminergic signaling to differentiation and function of human osteoclasts using chemical compounds that modify the dopamine signaling.

Methods: Human $CD14^+$ cells isolated from peripheral blood mononuclear cells (PBMCs) from healthy donor were cultured with M-CSF (50ng/ml) and RANKL (50ng/ml) for 14 days to obtain osteoclast-like cells. Multinuclear cells positive for TRAP-staining were counted under microscope as osteoclast-like cells and absorptive function was evaluated by pit formation assay. Dopamine-receptor subtypes on $CD14^+$ cells were analyzed by flow cytometer. Intracellular cAMP concentrations of $CD14^+$ cells cultured for 4 days with M-CSF were measured using a cAMP enzyme-immunoassay kit.

Results: All dopamine receptor subtypes were similarly expressed on human $CD14^+$ cells. When $CD14^+$ cells were cultured with M-CSF for 4 days, further enhanced expression of all subtypes was observed. By the addition of dopamine (0.1–100nM) to the culture from day 4 onwards, the number of TRAP-positive cells decreased in a dose-dependent manner and maximum reduction from 122 ± 12 /cm^2 (mean $\pm$ SEM) in controls to 29 ± 8 /cm^2 ($p<0.01$) was observed at 10 nM of dopamine. When D2-like receptor agonists, such as pramipexole (5–500pg/ml) or quinpirole (0.1–10nM), were added, the number of osteoclast-like cells also decreased in a dose-dependent manner. This dopamine-mediated decrease of osteoclast-like cells was inhibited by pretreatment with pertussis toxin, a Gai inhibitor or haloperidol, a D2-like receptor antagonist, but not with a D1-like receptor antagonist SCH-23390. Intracellular cAMP concentration was also decreased with addition of pramipexole at day 4 in a dose-dependent manner, while a D1-like receptor agonist SKF38393 had no effect on both intracellular cAMP and osteoclast differentiation. Furthermore, the total pit areas per dentin slice also markedly decreased with the addition of dopamine, pramipexole, or quinpirole from day 4 onwards.

Conclusion: We here demonstrate that dopaminergic D2-like receptor signaling directly inhibits osteoclast differentiation and function with decrease cAMP levels in the pre-osteoclast. From these results, we first document the pivotal mechanism of regulation of osteoclasts through sympathetic nervous system and a novel therapeutic target for bone destruction in RA as well as osteoporosis.

Downregulation of Mcl-1 by Ursolic Acid, a Pentacyclic Triterpenoid, Sensitizes Rheumatoid Arthritis Synovial Fibroblasts for TRAIL-Induced Apoptosis. Carolyn Zielinski, Maria Beamer and Salahuddin Ahmed. Department of Pharmacology, University of Toledo College of Pharmacy & Pharmaceutical Sciences, Toledo, OH

Background/Purpose: In rheumatoid arthritis (RA), enhanced expression of Mcl-1 contributes significantly to the resistance of synovial fibroblasts to apoptosis. In the present study, we evaluated the effect of ursolic acid (UA), a potent anti-inflammatory pentacyclic triterpenoid, on TRAIL-induced apoptosis in RA synovial fibroblasts.

Methods: Effects of UA (2.5–20 μM) and TRAIL (100 ng/ml), alone or in combination, on the cultured RA synovial fibroblast morphology and cell viability were determined through 72 hours of observation by microscopy and a colorimetric MTT cell viability assay. Caspase-3 activity was determined by a colorimetric assay. Apoptosis was measured by the cleavage of poly-ADP-ribose polymerase (PARP). Western blotting was used to evaluate the apoptosis mediators, Bcl-2, Mcl-1, Noxa, and Bax; the cell survival protein Akt; and nuclear translocation of nuclear factor-κB (NF-κB).

Results: UA (2.5–20 μM) decreased the cell viability of RA synovial fibroblasts in a dose-dependent manner and synergistically enhanced TRAIL-induced cell death by ~15% as compared to the UA alone treated group. Importantly, UA (5–20 μM) selectively induced RA synovial fibroblast Mcl-1 degradation within 24 hours of treatment, with no marked effect on the expression levels of Bcl-2 or Bax ($p<0.05$; $n=3$–5). In addition, UA treatment dose-dependently induced the expression of BH3-only Noxa, which may partly contribute to the inhibition of Mcl-1 expression by UA ($p<0.05$; $n=3$). Inhibition of Mcl-1 by UA resulted in the sensitization of RA synovial fibroblasts to TRAIL-induced PARP cleavage and apoptotic cell death. The addition of MG132 (a proteasome inhibitor; 10 μM) blocked the inhibitory effect of UA on Mcl-1 expression and downstream apoptotic events, implicating the proteasomal degradation of Mcl-1 as a fundamental mechanism of RA synovial fibroblast sensitization to apoptosis by UA. Furthermore, evaluation of the signaling events showed that UA specifically blocked the constitutive and TRAIL-activated phospho-Akt expression and the nuclear translocation of NF-κB to induce apoptosis in RA synovial fibroblasts.

Conclusion: Our novel findings indicate that UA itself induces apoptosis and further sensitizes RA synovial fibroblasts to TRAIL-induced apoptosis by specifically blocking Mcl-1 expression partly through Noxa expression. Thus, UA may be a promising adjunct therapeutic option in regulating the invasive growth of synovial fibroblasts in RA.

Expression Levels of the Nicotinic Acetylcholine alpha7 Receptor on Monocytes and Synovial Tissue of Rheumatoid Arthritis Patients. Frieda. A. Koopman, Maria J. H. de Hair, Danielle M. Gerlag, Paul P. Tak and Margriet Vervoordeldonk. Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: The cholinergic anti-inflammatory pathway is a potential new therapeutic target for the treatment of rheumatoid arthritis (RA). Preclinical studies have confirmed the therapeutic potential of targeting the alpha 7 subunit of the nicotinic acetylcholine receptor family (α7nAChR). Agonists of the nAChR are known to inhibit the production of pro-inflammatory cytokines from human monocytes and macrophages through the stimulation of alpha7 subunit in vitro. In view of the possible new treatment options, we investigated the expression of the α7nAChR on monocytes of RA patients. In addition, we evaluated the effect of methotrexate (MTX) treatment on the expression levels.

Methods: Monocytes from healthy subjects (n=9) and RA patients (n=9) were isolated from fresh blood using density gradient fractionation. These patients used methotrexate (MTX) monotherapy. Monocytes were analysed by flow cytometry using CD14-APC (1:12.5) and α-bungarotoxin-FITC-labeled (α-bgt-FITC, 1:10) antibodies. In addition, synovial tissue was collected from early RA patients (n=18). Synovial tissue was also available from 6 of these 18 patients after 6 months, when patients were using MTX monotherapy. Frozen sections were stained for α7nAChR using the polyclonal rabbit anti-α7nAChR antibody (Abcam, 2 ng/ml) and evaluated by digital image analysis.

Results: The α7nAChR could be detected on monocytes from both RA patients and healthy subjects (mean CD14+/α-bgt+ cells: 49.7% [range 1.44–94.1] versus 44.05% [range 10.26–95.52], respectively; P=0.75). Of interest, significantly lower α7nAChR expression ($r = -0.831$, $p = 0.034$) was observed after MTX treatment with a dose-dependent effect, independent of DAS28 values. The α7nAChR expression in the RA synovium was also significantly reduced after 6 months of MTX treatment (mean α7nAChR positive cells: 2334 [range 714–3840] versus 1639 [range 188–3363], p=0.03).

Conclusion: The α7nAChR is expressed by peripheral blood monocytes in health and disease, consistent with the view that the cholinergic anti-inflammatory pathway plays an important regulatory role in the immune system. MTX treatment reduces the expression levels of α7nAChR both in the peripheral blood and in the synovium, suggesting an unfavorable effect of MTX on this pathway.

372

***RasGRP1* and *RasGRP3* Expressed in Lymphocytes From Rheumatoid Arthritis Patients Have An Anti-Inflammatory Role.** Marie-Laure Potier[1], Thibault Vandhuick[2], Céline Derambure[1], Martine Hiron[1], Olivier Boyer[1], Xavier Le Loët[2], Olivier Vittecoq[2] and Thierry Lequerré[2].[1] Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [2]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France

Background/Purpose: RasGRP is a member of the CDC25 family of Ras guanyl nucleotide exchange factors. RasGRP1 is expressed in T and B cells whereas RasGRP3 is only expressed in B cells. These proteins are involved in T cell receptor and B cell receptor signalling. Indeed, Ras activation stimulates various effector systems, leading to changes in genes expression which are critical for T or B cell development and activation during the cellular immune response. In previous studies, it has been shown that *RasGRP1* and *RasGRP3* were dysregulated in peripheral blood mononuclear cells (PBMC) and synovium from rheumatoid arthritis (RA) patients leading to the question of *RasGRP1* and *RasGRP3* involvement in RA pathophysiology. To measure *RasGRP1* and *RasGRP3* gene expression level in B and T cells from both RA and spondylarthropathy (SpA) patients compared to healthy controls (HC) in order to confirm their dysregulation in RA.

Methods: PBMC were isolated from whole venous blood of 24 RA patients [53 ± 15 years old (yo)] with active disease (DAS28 = 4.98 ± 1.32), 18 patients with active SpA (45 ± 12 yo; BASDAI = 55.2 ± 16.1 / 100) and 19 HC (32 ± 9 yo). After negative cell selection, total RNA from B ant T cells were extracted. Immunofluorescence staining was performed to check the cell purity by flow cytometry. *RasGRP1* and *RasGRP3* expression levels were measured by qRT-PCR and their transcripts were compared by PCR.

Results: *RasGRP1* was more expressed in T cells than in B cells (x 3.5; $p<0.0001$) while *RasGRP3* was more expressed in B cells than in T cells (x 8; $p<0.0001$). Moreover, *RasGRP1* was significantly overexpressed in T cells from RA ($p<0.05$) and SpA ($p<0.005$) patients in comparison with those from HC. Surprisingly, *RasGRP1* was also significantly overexpressed in B cells from RA patients ($p<0.05$) in comparison with those from HC. *RasGRP3* expression level was similar in RA or SpA patients and HC whatever the cellular lineage (B and T cells). Moreover, *RasGRP1* expression level in T cells was inversely correlated with the disease activity measured by DAS28 in RA patients ($p<0.05$). Otherwise, two *RasGRP1* variants are expressed in T cells from RA patients compared to HC. Moreover, a minority of RA patients have *RasGRP3* full length transcript in B cells. Indeed, we found the major form of 1.6 Kb expressed both in controls and RA patients. Nevertheless, this shorted variants remains to identify.

Conclusion: This study has shown for the first time the *RasGRP1* and *RasGRP3* overexpression respectively in human T cells and B cells. Moreover, *RasGRP1* is overexpressed in T and B cells from RA patients and only in T cells from SPA patients. Furthermore, we identified different *RasGRP1* and *RasGRP3* variants in B and T cells from RA patients compared to HC; these variants correspond to deletions of exons that remain to be confirmed. Otherwise, the inverse correlation between *RasGRP1* expression in T cells from RA patients and disease activity score confirms the hypothesis of the anti-inflammatory role of RasGRP1. In addition, *RasGRP1* expression in B cells induces apoptosis of these one. Therefore, specific *RasGRP1* overexpression in B and T cells opens broad perspectives for research and therapy.

Circadian Rhythms of Cellular Immunity In Rheumatoid Arthritis. Cornelia M. Spies[1], Timo Gaber[1], Paula Hoff[1], Jeannine Mazuch[1], Bert Maier[1], Martin Hahne[1], Cindy Strehl[1], Cam Loan Tran[1], Natascha Soboleva[1], Alexander Stoehr[2], Ferenz L. Lohanatha[1], Markus Wagegg[1], Monique Fangradt[1], Manuela Jakstadt[1], Doerte Huscher[2], Gerd R. Burmester[1], Jacqueline Detert[1], Achim Kramer[1] and Frank Buttgereit[1]. [1]Charité – Universitätsmedizin Berlin, Berlin, Germany, [2]German Rheumatism Research Center (DRFZ), Berlin, Germany

Background/Purpose: The knowledge about circadian rhythms of clinical findings and humoral immunity in rheumatoid arthritis (RA) has already led to the development of glucocorticoid chronotherapy (Buttgereit et al., Lancet, 2008). In contrast, there is little information on circadian rhythms of cellular immunity. For this reason, in this pilot study we investigated cellular, humoral and molecular circadian parameters in postmenopausal female patients with RA in comparison to healthy controls.

Methods: Peripheral blood samples from postmenopausal female patients with active RA (DAS 28 ≥ 4.2) (n=5) and postmenopausal female healthy controls (n=5) were taken every 2 hours over 24 hours for flow cytometric analysis, multiplex suspension array of 28 cytokines and quantitative RT-PCR of clock gene expression in isolated CD14+ monocytes. Furthermore, macrophages were lentivirally transduced with a *Bmal1*-promotor driven luciferase reporter construct to analyze endogenous circadian rhythm dynamics. Statistical analysis was performed by Cosinor analysis of the groups.

Results: The clock gene *RevErbα* displayed a significant circadian expression pattern in both RA patients and healthy subjects, whereas *Per2* and *Per3* were rhythmically expressed in the control group only. The endogenous circadian rhythm of macrophages of RA patients was unchanged to healthy controls regarding period length, whereas the amplitude tended to be lower. The frequency of *CD3-CD56+ natural killer (NK) cells, Interleukin-8 Receptor (IL-8R) expressing CD4+ T helper and CD8+ cytotoxic T cells*, respectively, and *CXCR4 expressing CD4+ T helper and CD8+ cytotoxic cells*, respectively, showed a significant circadian rhythm in both RA-patients and healthy subjects. In contrast, a significant circadian rhythm was detectable for *CD3+CD56+ NK T cells* only in healthy controls and for *IL-8R+ monocytes* only in RA patients. Of note, *CCR7* did not show a circadian expression. Using multiplex suspension array of different cytokines and chemokines, a significant circadian variation was detectable only for the expression of *MCP-1* in healthy controls.

Conclusion: Our findings show for the first time that clock gene expression and endogenous circadian rhythms in immune cells of RA patients are disturbed. In particular, NK cells and chemokine receptor expressing cells display circadian rhythms of expression with characteristic peak phases.

Exclusive detection of significant rhythms in healthy subjects may indicate a loss of "normal" rhythm in RA, whereas exclusive detection in RA patients may suggest an establishment of "inflammatory" rhythms. These findings provide new insights into the chronobiology of RA and may have therapeutic implication.

Aberrant Basal and TLR-Stimulated Expression of TSLP in Rheumatoid Synovial Fibroblasts. Michele Bombardieri[1], Yvonne NW Kam[1], Andrew Filer[2], Christopher D. Buckley[2] and Costantino Pitzalis[1]. [1]Centre for Experimental Medicine and Rheumatology, QMUL, London, United Kingdom, [2]School of Immunity and Infection, MRC Center for Immune Regulation, Birmingham, United Kingdom

Background/Purpose: Thymic stromal lymphopoietin (TSLP) is an interleukin-7-like cytokine which is a strong activator of dendritic cells mainly leading to a Th2 polarization. Recent studies in the collagen-induced arthritis (CIA) model demonstrated that TLSP is an important pro-inflammatory cytokine capable of exacerbating disease severity via a T-cell dependent mechanism. Here we investigated the expression of TSLP and its receptor (TSLPR) in the synovium of rheumatoid arthritis (RA) patients and in rheumatoid synovial fibroblasts (RASF), in basal conditions and upon stimulation with Toll-like receptors (TLR) ligands.

Methods: mRNA expression of TSLP in RASF, osteoarthritis (OASF) and RA dermal fibroblasts (RADF) in basal conditions or upon stimulation with TLR2, TLR3 and TLR4 ligands was assessed by Taqman PCR (QT-PCR). Intracellular and soluble TSLP protein expression was assessed by immunocytochemistry and ELISA, respectively. The expression of TSLP and TSLPR in the rheumatoid synovium of 40 RA patients was investigated by QT-PCR and immunohistochemistry.

Results: RASF and, to a lesser extent OASF, displayed significantly higher constitutive mRNA expression compared to RADF (between 8–16 fold basal increase in RASF vs RADF). In vitro stimulation of TLR3 and TLR4, but not TLR2 on RASF led to strong induction of TSLP (~20-fold increase with TLR3) mRNA expression which peaked at 8h and return to baseline values at 48h. In response to TLR3, cytoplasmic staining of TSLP was strongly increased in RASF but not RADF, while soluble TSLP was time-dependently released in the supernatant of TLR3-stimulated RASF (~100pg/ml) but was undetectable in RADF. Finally, expression of TSLP mRNA was observed in all the RA samples examined while TSLPR was significantly increased in patients with follicular synovitis.

Conclusion: Here we demonstrated that the pro-arthritogenic and pro-inflammatory IL-7-like cytokine TSLP and its receptor TSLPR are abundantly expressed in the rheumatoid synovium. In addition, we showed that RASF but not RADF display an aberrant expression of TSLP in basal conditions which is further stimulated upon TLR3 and TLR4 ligations. Overall, these data strongly support a pivotal role for RASF in the dysregulated production of TSLP in the rheumatoid synovium, suggesting that the TSLP/TSLPR pathway contributes to chronic inflammation in RA.

EBV Infection In the Rheumatoid Synovium: Relationship with Ectopic Lymphoid Structures, In Situ Autoantobody Production and CD8 T Cell Activation. Cristina Croia[1], Michele Bombardieri[1], Barbara Serafini[2], Eliana M. Coccia[2], Martina Severa[2], Stephen Kelly[1], Francesca Aloisi[1] and Costantino Pitzalis[1]. [1]Centre for Experimental Medicine and Rheumatology, QMUL, London, United Kingdom, [2]Istituto Superiore di Sanita', Rome, Italy

Background/Purpose: The ubiquitous ψ-herpesvirus Epstein-Barr virus (EBV) infects B cells and modifies their differentiation programme leading to B cell activation and immortalization. Increasing evidence supports a link between EBV and common B cell-related autoimmune diseases, i.e. multiple sclerosis (MS), myasthenia gravis (MG) and Sjogren's syndrome. Recent data demonstrated that ectopic B cell follicles in the brain of MS and the thymus of MG patients are preferential sites of EBV persistence and reactivation. Here we aimed to investigate the role of EBV in B cell dysregulation and autoimmunity in the RA synovium by analysing its relationship with ectopic lymphoid structures (ELS), B cell infiltration, in situ autoantibody production and cytotoxic immune response.

Methods: Forty RA synovial biopsies were characterized for the degree of B cell infiltration, the presence of ELS with germinal center-like structures (GC-LS) and the status of EBV latent and productive infection using immunohistochemistry (IHC), double immunofluorescence (IF), in situ hybridization (ISH) and real-time RT-PCR.

Results: Using IHC and IF all 10 RA samples with GC-LS and 17 with high/medium B cell infiltration displayed evidence of EBV infection. Conversely, EBV+ cells were not detected in 13 RA samples with low/absent B cells. Latent EBV infection (LMP2A and EBER) was detected in a significant proportion of B cells, particularly within ELS. Using standard real-time RT-PCR, 40% of RA cases with high B cell infiltration were found LMP2A+, while after selective pre-amplification we observed that 100% of the RA cases were positive for LMP2A and LMP1 and 60% for EBER. In addition, numerous CD138+ plasma cells expressed the EBV early lytic antigen BFRF1 and were in close contact with CD8+ and/or granzyme B+ cells. Interestingly, a significant proportion of BFRF1+ plasma cells displayed reactivity against citrullinated fibrinogen. Finally, markers of productive viral infection (gp350/220, p160) were seldom found in RA samples with ELS.

Conclusion: Overall, these findings suggest that a dysregulated EBV infection likely exert an important role in the activation and differentiation of auto-reactive B cells within the RA synovium and might be partly responsible for the activation of a cytotoxic T cell response.

376

Chemerin Activates Fibroblast-Like Synoviocytes In Patients with Rheumatoid Arthritis. Kayoko Kaneko[1], Yoshishige Miyabe[1], Aiko Takayasu[1], Shin Fukuda[1], Chie Miyabe[1], Masashi Ebisawa[1], Waka Yokoyama[1], Kaori Watanabe[2], Toshio Imai[3], Kenzo Muramoto[4], Yuya Terashima[5], Takahiko Sugihara[6], Kouji Matsushima[5], Nobuyuki Miyasaka[2] and Toshihiro Nanki[1]. [1]Graduate School of Medicine and Dentistry, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]KAN Research Institute, Inc., Chuo-ku, Kobe, Japan, [4]Eisai Co., Ltd,, Tsukuba-shi, Ibaraki, Japan, [5]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [6]Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan

Background/Purpose: Chemerin is a chemotactic agonist identified as a ligand for ChemR23, expressed on macrophages and dendritic cells (DC). Chemerin is produced as a precursor protein, prochemerin, and is converted into active chemerin through the C-terminal six or seven amino acids processing by protease, produced by neutrophils and mast cells in inflammatory sites. In this study, we analyzed the expression of chemerin and ChemR23 in the synovium of rheumatoid arthritis (RA), and the stimulatory effects of chemerin on fibroblast-like synoviocytes (FLS) from RA

Methods: Expression of chemerin and ChemR23 in the RA and osteoarthritis (OA) synovium was examined by immunohistochemistry. ChemR23-expressing cells in the RA synovium were identified by double staining analysis. ChemR23 expression by FLS was evaluated by western blotting. Expression of chemerin, interleukin-6 (IL-6), CCL2 and matrix metalloproteinase-3 (MMP-3) from FLS was analyzed by enzyme-linked immunosorbent assay. FLS cell motility was evaluated by scrape motility assay. Phosphorylation of p44/42 mitogen-activated protein kinase (ERK1/2), p38 mitogen-activated protein kinase (MAPK) and Akt in FLS was analyzed by western blotting.

Results: Strong immunohistochemical staining for chemerin was noted on endothelial cells and synovial lining and sublining cells in the RA synovium. Widespread immunostaining for ChemR23 was noted in RA samples, with dense staining on the sublining cells. In contrast, the expression of chemerin and ChemR23 in the synovium of OA was minimal. Double staining analysis showed the expression of ChemR23 on most of $CD68^+$ macrophages, $CD1a^+$ immature DC, and on a few of DC-$LAMP^+$ mature DC. Interestingly, ChemR23 was also expressed on vimentin$^+$ FLS. *In vitro*, chemerin and ChemR23 were expressed on unstimulated FLS. Tumor necrosis factor-a and interferon-g upregulated chemerin production from FLS in dose-dependent manner. Chemerin enhanced the production of IL-6, CCL2 and MMP-3 by FLS, and the cell motility of FLS. The effects of chemerin on FLS were mediated by activation of ERK1/2, p38 MAPK and Akt. Inhibition of the ERK1/2, p38 MAPK, and Akt signaling pathways significantly suppressed chemerin-induced IL-6 production. Moreover, blockade of p38 MAPK and Akt pathways, but not that of ERK1/2, inhibited the chemerin-enhanced cell motility.

Conclusion: Chemerin and ChemR23 interaction may play an important role in the pathogenesis of RA, through the activation of FLS.

377

α-Defensin-1 Is Increased in the Synovial Fluid of Rheumatoid Arthritis Patients and Induces IL-6 and IL-8 Expression in Fibroblast-Like Synoviocytes. Joong Kyong Ahn[1], Jiwon Hwang[2], Jaejoon Lee[2], You Sun Lee[3], Chan Hong Jeon[4], Eun-Mi Koh[2] and Hoon-Suk Cha[2]. [1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Samsung Medical Center, Sunkyunkwan University School of Medicine, Seoul, South Korea, [3]Samsung Changwon Hospital, Changwon, South Korea, [4]Soonchunhyang University College of Medicine, Bucheon, South Korea

Background/Purpose: Fibroblast-like synoviocytes (FLS) play an essential role in the pathophysiology of rheumatoid arthritis (RA). Neutrophils are the most abundant cell type in the acute synovial effusion of RA patients. α-defensin-1 is released into the extracellular milieu from neutrophils during inflammation. Little is known about the role of α-defensin-1 for the development of joint inflammation in RA. Thus, we assessed the concentration of α-defensin-1 in synovial fluid (SF) of RA patients and osteoarthritis (OA) patients and evaluated the association between its concentration and clinical characteristics. We also investigated the effect of α-defensin-1 on the expression of IL-6 and IL-8 in rheumatoid FLS.

Methods: The concentrations of SF α-defensin-1 from 51 RA patients and 21 OA patients were measured using ELISA. Real-time PCR was performed to measure the expression of IL-6 and IL-8 mRNA at 8 hours after stimulation with α-defensin-1(15 ug/ml) in rheumatoid FLS (n=5).

Results: Patients with RA were composed of 47 female (92.1%) and 4 male patients, with a mean age of 54.3 ± 1.8 years, and mean disease duration of 81.1 ± 9.9 months. Forty-one patients (80.4%) were rheumatoid factor positive. Thirty-three patients (64.7%) had erosion on radiographic imaging. The SF α-defensin-1 concentration was significantly increased in RA patients compared to OA patients (39.3 ± 3.5 vs. 18.0 ± 5.6 ng/ml, p=0.002). Seropositive RA patients had significantly higher concentration of SF α-defensin-1 compared to seronegative patients (43.1 ± 3.8 vs. 20.8 ± 5.0 ng/ml, p=0.006). RA patients with ESR>50mm/hr or CRP>2mg/dl had significantly higher concentration of SF α-defensin-1 compared to patients with lower level of ESR or CRP, respectively (46.0 ± 3.9 vs. 21.7 ± 5.0 ng/ml, p=0.001; 48.2 ± 4.4 vs. 29.2 ± 4.7 ng/ml, p=0.005). SF α-defensin-1 concentration was more increased in RA patients with erosive change than non-erosive patients (43.1 ± 4.2 vs. 32.2 ± 5.8 ng/ml), although this difference did not reach statistical significance. There was no significant difference in SF α-defensin-1 level according to disease duration and age at disease onset. Both IL-6 and IL-8 mRNA expressions were significantly increased (13.34 ± 22.89-fold increase and 2.89 ± 1.49-fold increase, respectively, $p < 0.05$) at 8 hrs after α-defensin-1 stimulation in rheumatoid FLS.

Conclusion: SF α-defensin-1 concentration is increased in RA patients, especially in patients with positive RF and higher level of ESR and CRP. α-defensin-1 induced proinflammatory cytokine expression in RA FLS. These findings suggest that α-defensin-1 may play an important role as a potential inflammatory mediator for the development of joint inflammation in RA.

378

Extracellular 14-3-3η: An Early Rheumatoid Arthritis Pathogenic Factor. Anthony Marotta[1], Vivian Bykerk[2], Katherine A. Siminovitch[3], Maarten Boers[4], Robert Landewe[5], Désirée van der Heijde[6], Paul-Peter Tak[7], M. C. Genovese[8], Michael E. Weinblatt[9] and Walter P. Maksymowych[10]. [1]Augurex Life Sciences Corp, North Vancouver, BC, [2]Brigham & Women's Hospital, Boston, MA, [3]Mount Sinai Hospital, Toronto, ON, [4]VU University Medical Center, Amsterdam, Netherlands, [5]Academic Medical Center, Amsterdam, Netherlands, [6]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [7]Professor of Medicine/ Director, Division of Clinical Immunology and Rheumatology, Amsterdam, Netherlands, [8]Stanford University Medical Center, Palo Alto, CA, [9]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [10]University of Alberta, Edmonton, AB

Background/Purpose: 14-3-3 proteins are ubiquitously expressed intracellular chaperonins. We previously showed that the η isoform is 1) uniquely expressed in the synovial fluid and serum of patients with inflammatory arthritis 2) differentially expressed in established rheumatoid arthritis (RA) and 3) a novel extracellular mediator that may contribute to the disease process. This study examines 14-3-3η serum levels and its pathophysiological role in early disease.

Methods: Serum 14-3-3η was measured in 37 DMARD-naïve early RA patients, 25 from the Toronto Early Arthritis Cohort (TEACH) and 12 from the intensified-COBRA cohort, and 50 osteoarthritis (OA) controls using an investigational-grade 14-3-3η ELISA. 2-tailed t-tests and Mann-Whitney u-tests were run to compare group differences in serum concentrations. An ROC curve was generated and sero-positivity rates of 14-3-3η, rheumatoid factor (RF) and anti-citrullinated cyclic peptide (anti-CCP) were evaluated. To examine the effects of 14-3-3η on intracellular signalling in monocytes, THP-1 monocytic cells were stimulated with 12.5ng/ml of recombinant human 14-3-3η (0–30min) and activation of the MAPK signalling cascades (ERK, JNK/SAPK and p38) were assessed by immunoblot analysis using phosphospecific antibodies. The mRNA levels of IL-1β, IL-8, CCL2/MCP-1 and CCL4/MIP1- β following 18h incubation with a dose range of 0.10 to 100ng/ml of recombinant human 14-3-3η or vehicle were assessed by RT-PCR. Densitometry was used to measure % change with stimulation above control.

Results: Mean and median 14-3-3η serum concentrations in RA patients [TEACH (3.13 & 0.63ng/ml) and i-COBRA (5.90 & 1.43ng/ml)] were significantly higher than in OA controls (0.32 & < 0.20ng/ml), p-values <0.0006 and <0.0001, respectively. The corresponding areas under the ROC curve were 0.72 (95%CI 0.58–0.86) and 0.87 (95%CI 0.72–1.00) for TEACH and i-COBRA RA patients versus OA. 14-3-3η, RF and anti-CCP positivity were 60%, 32% and 44% in TEACH and 82%, 82% and 82% in i-COBRA. 72% of TEACH and 100% of i-COBRA RA patients were positive for any one of the three markers. Stimulation of THP-1 cells with 14-3-3η activated ERK and JNK/SAPK by 227% and 87% above control at 5 and 2 min, respectively. No activation of p38MAPK was observed at any of the time points. 14-3-3η was associated with potent induction of transcripts of early pro-inflammatory factors, with IL-8 (47% increase at 0.1ng/ml) and MIP-1β (53% increase at 0.25ng/ml) being the most sensitive followed by MCP-1 (44% increase at 0.5ng/ml) and IL-1β (49% increase at 5ng/ml).

Conclusion: 14-3-3η is differentially expressed in the serum of patients with early RA compared to OA controls and is a novel factor that may contribute to pathological processes involved in early disease. 14-3-3η serum expression when combined with standard serological RA tests may mark early RA.

379

TNFα Modulates the Expression of Circadian Clock Genes in Rheumatoid Synovial Cells. Kohsuke Yoshida[1], Akira Hashiramoto[2], Nao Shibanuma[3], Kazuko Shiozawa[4] and Shunichi Shiozawa[5]. [1]Kobe University Graduate School of Health Sciences, Kobe, Japan, [2]Kobe University Graduate School of Medicine/ The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan, [3]The Center for Rheumatic Diseases, Kobe University Hospital/Kobe Kaisei Hospital, Kobe, Japan, [4]Rheumatic Diseases Center, Konan Kakogawa Hospital, Kakogawa, Japan, [5]Kobe University Graduate School of Health Sciences and Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Background/Purpose: Circadian rhythm in mammals is organized by transcriptional and/or posttranscriptional machineries regulating the core clock genes including *Clock* (circadian locomotor output cycles kaput), *Bmal1* (brain and muscle Arnt-like protein 1), *Per* (Period), and *Cry* (Cryptochrome). The transcription factor BMAL1/CLOCK complex activates *Per* and *Cry* gene transcription by binding to E-box motif in the promoter region. Thereafter, PER and CRY proteins inhibit the binding of BMAL1/CLOCK complex to E-box in a feedback fashion, resulting in generation of oscillating circadian expression of *Per* and *Cry* genes. We previously showed the regulation between biological clocks and arthritis in that the expression of *Bmal1*, *Per1/2* and *Dbp* (D site of albumin promoter binding protein), also known as a clock controlled gene, was disturbed in the synovium of experimental arthritis in mice, and *Cry* regulated TNFα in mouse embryonic fibroblast (J Immunol. 2010;184:1560–5). Here we examine, by using primary cultured human rheumatoid synovial cell, the effect of TNFα on the expression of circadian clock genes and found that TNFα was the key modulator for the expression of clock genes.

Methods: Primary cultured rheumatoid synovial cells were synchronized upon incubation with 50% horse serum for 2 hours, and then stimulated with TNFα. Total RNA was extracted from synovial cells every 8 hrs until 32 hrs' culture period, and mRNA expression of clock genes (*Bmal1*,*Clock*, *Per1/2*, *Cry1/2*, *Dbp*) were analyzed by real-time PCR. Synovial cells were transfected with the luciferase reporter vector containing the human *Per2* promoter to measure the transcriptional activity of *Per2* gene.

Results: The expression of *Per2* mRNA in unstimulated synovial cells was highest at 24 hrs after serum incubation. However, the expression of *Per2*

mRNA was inhibited between 24 and 32 hrs by the stimulation with TNFα. Further, transcriptional activity of *Per2* gene was significantly inhibited by TNFα by luciferase reporter assay. Since the promoter region of *Per2* gene contains three E-box and another DBP binding motif D-box, we next examined the effect of TNFα on the expression of *Bmal1*, *Clock* and *Dbp* mRNA. As results, the expression of *Dbp* mRNA was significantly inhibited upon incubation with TNFα while those of *Bmal1* and *Clock* were increased, suggesting that inhibition of DBP expression, induced by TNFα, was involved in the inhibition of *Per2* expression in synovial cells as well.

Conclusion: TNFα significantly modulates the expression of circadian clock genes in rheumatoid synovial cells, and thereby may contribute to the pathogenesis of RA.

TL1A Induces the Production of Follicular Helper T Cells in Rheumatoid Arthritis. Xia Li[1], Rui Liu[1], Qian Wu[1], Jing Zhao[2], Xiaolin Sun[2], Zhanguo Li[3] and Lingyun Sun[1]. [1]The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing 210008, China, Nanjing, China, [2]Peking University People's Hospital, Beijing, China, [3]Peking University People's Hospital, 11 Xizhimen South Street, Beijing, 100044, PR China, Beijing, China

Background/Purpose: Tumor necrosis factor (TNF)-like protein 1A (TL1A) is a member of the TNF superfamily which is a T-cell costimulator. It can increase IFN-γ production of $CD4^+$ T cells by acting in synergy with IL-12 and IL-18. Furthermore, TL1A also promotes type 17 T-helper (TH17) cell functions and responses. Follicular helper T (TFH) cells can provide a helper function to B cells, so they play a key role in the pathogenesis of rheumatoid arthritis (RA). The purpose of this study is to examine the hypothesis that TL1A might induce the production of TFH cells in RA.

Methods: Concentrations of TL1A in sera were measured by ELISA. TL1A relative mRNA expression was assessed by RT-PCR and the percentages of $CD4^+CXCR5^+PD\text{-}1^+$ T cells were analyzed by flow cytometry in peripheral blood mononuclear cells (PBMC) from RA patients and healthy controls. PBMC from RA patients were stimulated with different concentrations of TL1A (10ng/ml, 20ng/ml and 50ng/ml) after TCR engagement and then $CD4^+CXCR5^+PD\text{-}1^+$ T cells were evaluated.

Results: The results showed that concentrations of TL1A in sera of RA patients (789.29±622.42ng/ml, n=97) were significantly higher than that of healthy controls (518.12±134.52ng/ml, n=50, $p<0.05$). The relative mRNA level of TL1A from RA patients (5.702±4.342, n=17) was enhanced compared to healthy controls (2.168±3.024, n=11, $p<0.05$). In addition, the percentages of circulating TFH cells from RA patients (9.197%±0.686%, n=23) were increased in comparison with healthy controls (7.029%±0.465%, n=14, $p<0.05$). After TCR engagement the different concentrations of TL1A (10, 20 and 50ng/ml raised circulating TFH cells production compared with no TL1A stimulation(22.92%±6.567%), and 50ng/ml of TL1A(29.17%±7.253%) was more effective than 10ng/ml (26.21%±7.055%) and 20ng/ml (27.84%±7.123%) in inducing TFH cells production(n=6).

Conclusion: These results suggest that increased TL1A expression from RA patients might upregulate circulating TFH cells that support B cell survival and antibody secretion.

381

CD15s Expression Pattern in the Synovial Tissue of Patients with Rheumatoid Arthritis and Its Role in RASF Migration. Birgit Zimmermann[1], Sebastian Ullrich[2], Nina Kesel[2], Markus Rickert[3], Jürgen Steinmeyer[3], Stefan Rehart[4], Angela Lehr[4], Udo Schumacher[2], Ulf Müller-Ladner[5] and Elena Neumann[5]. [1]University of Gieβen, Bad Nauheim, Germany, [2]University Medical Center Hamburg, Hamburg, Germany, [3]University Hospital Gieβen and Marburg, Gieβen, Germany, [4]Markus-Hospital, Frankfurt, Germany, [5]Justus-Liebig-University of Gieβen, Bad Nauheim, Germany

Background/Purpose: It is well known that the tetrasaccharide CD15s is a ligand for E-selectin. In the extravasation of leukocytes, this interaction mediates the primary adhesion to the endothelial cells of the vessel wall. Recently, we could show that rheumatoid arthritis (RA) synovial fibroblasts (SF) are able to migrate over a long distance in the SCID-mouse model of RA. This was facilitated by leaving the synovial tissue and migration through the vascular system to distant cartilage matrix followed by cartilage invasion. To elucidate the underlying mechanisms, we analyzed the role of CD15s and E-selectin in the interaction of SF with endothelial cells to characterise the extravasation process of RASF.

Methods: Cultured RASF and synovial tissue of different RA patients were stained for CD15s by immunohistochemistry. To link CD15s expression with general inflammation, the presence of CD15s positive cells was correlated with serum CRP. To show the adherence of RASF to E- and P-selectin, a flow chamber assay was used. RA- and OASF were perfused with different flow rates through a capillary of μ-Slides coated with 30 μl E-, P-selectin solution or 100 % FCS as negative control. Using an inverse microscope and a video camera system, the rolling, tethering and adherent cells were recorded and quantified. Using the SCID mouse model of RA, E-and P-selectin deficient SCID mice as well as normal SCID mice were compared for RASF migration. For this approach, at the ipsilateral site (I) human cartilage was implanted together with RASF and at the contralateral site (C) cartilage without RASF. After 45 days, the implants were removed and evaluated histologically.

Results: Cultured RASF expressed CD15s. Interestingly, CD15s expression on RASF was higher when cultured in RPMI in contrast to culture in DMEM. CD15s was detectable in most RA synovial tissues. The presence of CD15s positive cells in the synovial tissue of RA patients correlated with an increased systemic CRP level. RASF rolling, tethering and adhesion was increased in E-selectin coated slides in comparison to OASF in the flow chamber assay (RASF: 0.55 dyn/cm: 16 cells, 0.89 dyn/cm: 5.5 cells and 1.77 dyn/cm: 3.5 cells per visual field; OASF: 0.55 dyn/cm: 12.5 cells, 0.89 dyn/cm: 1 cell and 1.77 dyn/cm: 1 cell per visual field). No SF bound to P-selectin or FCS coated capillaries were detectable. A reduced RASF invasion was observed in E-/P-Selectin deficient mice at the contralateral, RASF-free implantation side when compared to normal SCID mice after 45 days ($E\text{-/P-selectin}^+$ (I): 1.56±0.64; (C): 2.23±0,60 vs. $E\text{-/P-selectin}^-$: (I) 1.81±0.72; (C):1.69±0.74).

Conclusion: CD15s, a selectin-ligand, was detectable on cultured RASF, and CD15s expressing cells were detectable in the synovium and correlated with increased CRP levels. With respect to RASF migration, the attachment of RASFs to the vessel wall appears to be dependent on E-selectin expression in contrast to P-selectin expression. Therefore, the CD15s/E-selectin interaction seems to be a key step in RASF extravasation.

382

Leptin Stimulates Interleukin-6 Production *Via* phosphorylation of Signal Transducer and Activator of Transcription-3 in Rheumatoid Synovial Fibroblasts. Sei Muraoka, Natsuko Kusunoki, Hirahito Endo, Toru Suguro and Shinichi Kawai. Toho University School of Medicine, Tokyo, Japan

Background/Purpose: Leptin is one of the adipose tissue-secreted cytokines (adipocytokines) which regulate central metabolic conditions, however, it has a number of other functions including immune system and inflammation. Serum leptin concentration was elevated and associated with serum C-reactive protein concentration in patients with rheumatoid arthritis (RA) (Yoshino T, et al. *Intern Med* 2011; 50: 269). The aim of this study is to determine the effects of leptin on production of proinflammatory cytokines in rheumatoid synovial fibroblasts (RSF).

Methods: Synovial tissues were obtained at total knee replacement operation from patients with RA who gave written consent to use their tissue for research. RSF were harvested from the synovial tissues of these patients. After 24h incubation with various concentrations of leptin, the productions of interleukin (IL)-1β, tumor necrosis factor (TNF) -α, and IL-6 in the culture medium were detected by respective ELISA kit. An RNAi was introduced into RSF to down-regulate the expression of Ob-Rb. We next examined effect of JAK (Janus tyrosine kinase) -2 inhibitor, AG490 on production of IL-6. Leptin receptor mRNAs were detected by RT-PCR. STAT-3 (Signal transducer and activator of transcription-3) and phosphorylated STAT-3 (p-STAT-3) in RSF were determined by Western blot analysis.

Results: The concentrations of TNF-α and IL-6 were enhanced in concentration-dependent manners by addition of leptin (up to 300nM), however, the concentration of IL-1β was not changed. We detected leptin receptor Ob-Rb and Ob-Re mRNAs by RT-PCR in RSF. Leptin-induced IL-6 production was decreased by Ob-Rb mRNA knockdown in RSF. AG490 also decreased leptin-induced IL-6 production. Since Ob-Rb is a member of IL-6 receptor family, we measured STAT-3 and p-STAT-3 by Western blot analysis. Enhancement of p-STAT-3 by addition of leptin was observed in RSF. This effect was not affected by neutralization of IL-6 by anti-IL-6 antibody.

Conclusion: STAT-3 regulates cell proliferation and migration, and mediates vascular function. In this study, we demonstrated that leptin possibly

is one of the proinflammatory cytokines to up-regulate IL-6 production *via* phosphorylation of STAT-3 in RSF. Leptin and JAK-STAT pathway may represent a new alternative therapeutic target in the treatment of RA.

383

Mechanisms Underlying the Generation of Soluble IL-6 Soluble Receptor (sIL-6R) in Rheumatoid Arthritis: mRNA Alternative Splicing and Proteolytic Cleavage As Independent Contributors. Jose Ramon Lamas[1], Luis Rodriguez-Rodriguez[2], Pilar Tornero-Esteban[2], Lydia Abasolo[2], Jezabel Varade[1], Roberto Alvarez-Lafuente[1], Esther Villafuertes[2], Jose Hoyas[2], Elena Urcelay[1] and Benjamin Fernandez-Gutierrez[2]. [1]Hospital clinico San Carlos, Madrid, Spain, [2]Department of Rheumatology, Hospital Clinico San Carlos, Madrid, Spain

Background/Purpose: Given that IL-6 bioactivity is greatly modulated through trans-signalling by sIL-6R/IL-6 complexes, the aim of this study was to describe the contribution of proteolytic cleavage and alternative splicing mechanisms in the generation of soluble forms of IL-6 receptor (sIL-6R) and their pathological relevance in rheumatoid arthritis (RA).

Methods: RA patients were randomly selected from a cohort of subjects previously genotyped for the non-synonymous polymorphism rs8192284 (A>C) of the IL-6R gene resulting in an amino acid change located at the proteolytic cleavage site (D358A). Expression of the membrane-bound IL-6 receptors (IL-6R and gp130) was evaluated in different peripheral blood populations by flow cytometry. Plasma concentrations of sIL-6R, soluble gp130, the sIL-6R/IL-6 complexes and the proteolytic enzyme responsible for the cleavage (TACE/ADAMTS17) were measured by ELISA. The contribution of alternative splicing in the generation of sIL-6R was assessed by qRT-PCR.

Results: No differences were found in IL-6R membrane expression according to the rs8192284 variation. sIL-6R plasma levels were positively associated with the presence of the C allele, AA: 79.36±5.8 ng/ml, AC: 100.50±4.05 ng/ml, CC: 128.9±6.8 ng/ml, $p < 0.0001$. Only 32% of the IL-6 present in plasma was not bound to sIL-6R. The contributions of alternative splicing and TACE concentrations were independent of the genotype studied.

Conclusion: Both mechanisms of sIL-6R generation coexist in RA. The rs8192284 polymorphism determines differences in sIL-6R plasma levels through differential proteolytic cleavage efficiency mediated by TACE. In addition, most IL-6 molecules form IL-6/sIL-6R complexes, suggesting the important contribution of trans-signalling in modulating the biological effects of IL-6 in RA.

384

IL-21 and IL-21 Receptor Expression in the Inflamed Synovium From Patients with Rheumatoid Arthritis. Ditte Tornehave[1], Berit O. Krogh[1], Henning Bliddal[2], Niels H. Søe[3] and Dorthe Lundsgaard[1]. [1]Novo Nordisk A/S, Måløv, Denmark, [2]Copenhagen University Hospital at Frederiksberg Hospital, Frederiksberg, Denmark, [3]Gentofte Hospital, Hellerup, Denmark

Background/Purpose: The aim of the present study was to investigate expression of IL-21 and IL-21 receptor (IL-21R) and to characterize receptor-positive cells in the synovium from patients with rheumatoid arthritis (RA).

Methods: In-situ hybridization studies investigating IL-21 and IL-21R mRNA expression were performed on synovial tissues from patients with RA (n=6) and normal synovial samples (n=2). Immunohistochemical studies investigating IL-21R protein expression were performed on synovial tissues, including synovectomy samples, from patients with RA (n=26) and normal synovial samples (n=4). Characterization of the IL-21R-positive cells was performed by double immunofluorescence staining on arthroscopic and synovectomy samples from RA patients (n=9) and normal synovial samples (n=5) with markers for T cells (CD3), B cells (CD20), plasma cells (CD138), and macrophages (CD68).

Results: IL-21 mRNA expressing cells were present in the synovium from 5/6 patients with RA but not in normal synovial samples (0/2). IL-21 mRNA positive cells were present only in lymphoid aggregates in the sublining layer. IL-21R mRNA expressing cells were present in the synovium from 6/6 patients with RA and 2/2 normal samples. IL-21R mRNA expressing cells were present in lymphoid aggregates and stroma in the sublining layer and in the lining layer. IL-21R immunopositive ($IL\text{-}21R^+$) cells were present in the synovium from 26/26 patients with RA and in 4/4 normal samples. The $IL\text{-}21R^+$ cells in the sublining layer were present in lymphoid aggregates and stroma in 22/24 and 18/26 RA patients, respectively. Few $IL\text{-}21R^+$ cells were present in the stroma of the sublining layer from normal synovium. In the synovial lining $IL\text{-}21R^+$ cells were present in 22/22 patients with RA and in 4/4 normal samples. There was an overlap in distribution of IL-21R mRNA and protein in RA and normal synovium. Double immunostainings for IL-21R and T cells, B cells, plasma cells and macrophages revealed presence of $IL\text{-}21R^+CD3^+$ T cells in the synovium from 9/9 RA patients with 25–50% double-positive T cells. $IL\text{-}21R^+CD20^+$ B cells were present in 7/9 RA patients with close to 50% double-positive B cells. $IL\text{-}21R^+CD138^+$ plasma cells were present in 6/9 RA patients with close to 50% double-positive plasma cells. The $IL\text{-}21R^+CD20^+$ B cells and $IL\text{-}21R^+CD138^+$ plasma cells were found in lymphoid aggregates in close proximity to $CD3^+$ T cells. $IL\text{-}21R^+CD68^+$ macrophages were present in the sublining layer in 9/9 RA patients and 1/5 normal samples with 25–50% double-positive macrophages. The $IL\text{-}21R^+CD68^+$ macrophages were present in lymphoid aggregates and stroma. In 8/9 RA patients and 5/5 normal samples all $IL\text{-}21R^+$ cells in the synovial lining were $CD68^+$ macrophage-like synoviocytes.

Conclusion: We found that both IL-21 and IL-21R expressing cells are present in the inflamed synovium from RA patients. The $IL\text{-}21R^+$ cells have been identified as T cells, B cells, plasma cells and macrophages. These data suggest that in the synovium, locally produced IL-21 can activate $IL\text{-}21R^+$ T cells, B cells, plasma cells and macrophages. IL-21 therefore represents a promising target for treatment of rheumatoid arthritis.

385

Regulation of DNA Methylation by Pro-Inflammatory Cytokines in Rheumatoid Arthritis. Kazuhisa Nakano[1], David L. Boyle[2] and Gary S. Firestein[2]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Rheumatoid arthritis fibroblast-like synoviocytes (RA FLS) exhibit a unique aggressive phenotype that contributes to the cytokine milieu and joint destruction. While the pathogenesis of partial transformation is not fully understood, epigenetic mechanisms are one possible explanation. DNA methylation is a major epigenetic determinant that modulates gene expression, and abnormal methylation is associated with dyregulated cell function. DNA methyltransferases (DNMTs) are critical enzymes involved in establishing proper control of DNA methylation. Global hypomethylation has been described in RA FLS, but the mechanisms have not been defined. We hypothesized that persistent exposure of pro-inflammatory cytokines can contribute to DNA hypomethylation through decreased of DNMT expression, thereby contributing to the aggressive phenotype of FLS.

Methods: FLS were obtained from RA and osteoarthritis (OA) synovium at total joint replacement and studied in the 4th through 7th passage. Gene expression was determined by qPCR and protein expression by Western blot analysis. Nuclear extracts and genomic DNA were purified from control or stimulated FLS. DNMT activity was measured with a functional assay and global methylation was determined by an immunoassay that detects methylcytosine.

Results: Unstimulated RA and OA FLS expressed similar amounts of DNMT1, -3a, and -3b mRNA (n=10 each; n.s.). Western blot showed abundant DNMT1 and DNMT3a protein, but only trace amounts of DNMT3b. DNMT1 and DNMT3a mRNA expression were decreased when FLS were stimulated with IL-1β (2 ng/ml) for 24 hr (49±8% and 58±6% respectively; $p<0.01$). Dose responses with IL-1 showed significant suppression of DNMT expression with concentrations as low as 1 pg/ml. DNMT mRNA levels decreased rapidly, with significant suppression after 2 to 8 hrs of IL-1 stimulation. DNMT functional activity was also decreased by IL-1 when FLS were cultured continuously for 14 days with IL-1β (74.0±6.5% of control, n=11, p=0.0012). 14-days exposure to the DNMT1 inhibitor 5-aza-dC decreased global DNA methylation in OA FLS (78.7±10% of control, n=6, $p<0.05$), but not in RA FLS (105±6.7% of control, n=6, p=0.22).

Conclusion: Exposure to pro-inflammatory cytokines in the synovium decreases DNMT expression and potentially suppresses DNA methylation. The inability of 5-aza-dC to alter RA FLS global methylation suggests that DNMT3a is primarily responsible for DNA methylation in RA, while DNMT1 contributes to methylation OA FLS. These data suggest that the rheumatoid synovium can imprint FLS by altering DNA methylation and potentially inducing a more aggressive phenotype.

386

A Transcriptional Profile Present in CD4+ T-Cells of Patients with Undifferentiated Arthritis Predicts the Future Development of Seronegative Rheumatoid Arthritis and Implicates IL-6 in Disease Evolution. Arthur G. Pratt[1], Dan Swan[2], Sarah Richardson[1], Gillian Wilson[3], Catharien Hilkens[1], David Young[1] and John D. Isaacs[1]. [1]Newcastle University, Newcastle Upon Tyne, United Kingdom, [2]Newcastle University, Newcastle-upon-Tyne, United Kingdom, [3]Freeman Hospital, Newcastle-upon-Tyne, United Kingdom

Background/Purpose: The diagnosis of seronegative RA remains challenging in the early arthritis clinic. Recent GWAS data strongly implicate CD4+ T-cells in the pathogenesis of seropositive RA. Our objectives were to identify biomarker(s) present in CD4+ T-cells, or in serum, that identified patients with undifferentiated arthritis (UA) destined to develop seronegative RA.

Methods: Total RNA was isolated from highly purified peripheral blood CD4+ T-cells of early arthritis clinic patients. Paired serum samples were also stored. Microarray analysis of 111 RNA samples was performed using the Illumina® platform, and differential transcript expression confirmed using real-time quantitative PCR (discovery cohort). Machine learning approaches were used to test the utility of a classification model amongst an independent validation cohort of 62 patients presenting with UA. Cytokine measurements were performed using a highly sensitive electro chemo-luminescence detection system (Mesoscale Discovery®).

Results: A 12-gene expression "signature" predicted the subsequent development of RA amongst ACPA-negative UA patients in the validation cohort (sensitivity 85%, specificity 75%). The signature had a predictive value equivalent to the Leiden score in these patients and provided enhanced predictive power in combination with the Leiden score. The 12-gene signature contained an over-representation of STAT3-target genes, and pathway analysis confirmed that genes functionally involved with CD4+ T-cell survival, including STAT pathway components, were deregulated in early RA. Baseline levels of serum IL-6 (which signals primarily via STAT3) distinguished anti-CCP negative RA from non-RA inflammatory arthritis patients matched for CRP (corrected $p<0.05$). Furthermore the expression of STAT3-inducible genes correlated with circulating serum IL-6 levels, and incubation of purified CD4+ T-cells with IL-6 replicated the in vivo 'signature'.

Conclusion: We have identified a 12-gene transcriptional signature with similar predictive utility to the Leiden score for the evolution of UA to ACPA-negative RA. Part of the signature appears to be IL-6 driven, and circulating IL-6 may also provide a useful biomarker for UA patients destined to develop ACPA-negative RA.

Interleukin-22 Serum Levels Are Associated with Radiographic Progression in Rheumatoid Arthritis. Jan Leipe[1], Markus A. Schramm[1], Mathias Grunke[1], Michael Baeuerle[2], Matthias Witt[2], Axel P. Nigg[1], Christiane Reindl[1], Claudia Dechant[1], Alla Skapenko[1] and Hendrik Schulze-Koops[1]. [1]Division of Rheumatology and Clinical Immunology, Med. Poliklinik, University of Munich, Munich, Germany, [2]Medizinische Poliklinik, Munich, Germany

Background/Purpose: To study the role of interleukin (IL)-22 in rheumatoid arthritis (RA).

Methods: IL-22 serum levels were measured in patients with early, treatment-naive RA (n=49) and for control in 45 age- and sex-matched healthy individuals. Patients were assessed clinically and radiographically at baseline and followed-up for two years. IL-22 serum levels were correlated with parameters of disease activity, serological markers, demographic factors, and the incidence of erosions.

Results: 24 of 49 RA patients demonstrated elevated IL-22 levels compared to the range of healthy controls. At baseline, 33% (8/24) of the patients with elevated IL-22 serum levels demonstrated bone erosions, whereas only one patient (4%) from the group with normal IL-22 had erosions. During the two years of follow-up, six additional patients with increased IL-22 at baseline developed erosions. In contrast, none of the patients in whom IL-22 levels were normal developed erosions despite similar treatment regimens. Multivariate regression analysis accounting for other parameters predictive for erosions, such as the presence of rheumatoid factor or anti-cyclic citrullinated peptide antibodies and disease activity, revealed that elevated IL-22 baseline levels were independently and significantly associated with erosive RA.

Conclusion: IL-22 is elevated in the serum of half of the RA patients. Elevated serum IL-22 allows discriminating patients with different radiographic progression and indicates a possible involvement of IL-22 in the pathophysiology of RA.

388

Serum Cytokine Levels Predict Mortality Among Postmenopausal Women Reporting Rheumatoid Arthritis. Jeremy Sokolove[1], William H. Robinson[2], Brian T. Walitt[3], Kevin D. Deane[4], Yuefang Chang[5], Russell Tracy[6], V. Michael Holers[7], Lewis Kuller[5], Larry W. Moreland[5] and Rachel Mackey[5]. [1]Stanford University, Palo Alto, CA, [2]Stanford University, Stanford, CA, [3]Washington Hospital Center, Washington, DC, [4]University of Colorado School of Medicine, Aurora, CO, [5]University of Pittsburgh, Pittsburgh, PA, [6]University of Vermont, Colchester, VT, [7]Univ of Colorado School of Med, Aurora, CO

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased risk of total mortality, which is in part explained by increased cardiovascular (CV) mortality. We sought to determine whether levels of plasma cytokines could further inform risk of mortality among the anti-CCP2+ and anti-CCP2 negative RA population.

Methods: We performed multiplex profiling of 17 cytokines in stored baseline plasma from postmenopausal women sampled from the Women's Health Initiative (WHI) study cohort who self-reported RA. We additionally assessed for the presence of anti-CCP2 antibodies and rheumatoid factor (RF) using commercial ELISA kits and the HLA shared epitope (SE) by PCR. Cox proportional hazards regression was used to model the relationship of plasma cytokine levels (in quartiles) to total mortality using follow-up data through April 2009 (mean (SD) follow-up time= 10.2 (3.0) years). Analyses were weighted to reflect the sampling from the WHI cohort. Women with a baseline report of CVD or cancer were excluded. To maximize true clinical RA diagnoses, we limited our analysis to women who were either 1) anti-CCP2+ (n=512; 71 deaths), or 2) anti-CCP2 negative (n=272; 36 deaths) with self-reported use of disease modifying anti-rheumatic drugs.

Results: The women in this study had a mean age of 62.8 years at baseline and 64.5% were white. Among anti-CCP2+ subjects, higher levels of IL-1b, IL-2, IL-6, IL-13, and MCP-1 predicted higher total mortality in age-adjusted models. After additional adjustment for RF, SE and additional risk factors including hypertension, ever smoking, and ethnicity, only higher IL-6 remained a significant predictor of total mortality (HR (95%CI) for highest quartile (Q4) vs. lowest quartile (Q1)=3.03, 1.14–8.03; $P=0.02$).

Among anti-CCP2 negative subjects, higher plasma MCP-1 levels strongly predicted total mortality and this relationship persisted even after adjustment for RF, SE, and additional risk factors (HR Q4 vs. Q1: 3.20, 1.13–9.02). Interestingly, elevated plasma IL-2, was associated with reduced age-adjusted mortality (HR Q4 vs. Q1: 0.40, 0.16–0.99; p=0.02). However, this association was attenuated after adjustment for RF, SE, hypertension, ever smoking, and ethnicity (HR Q4 vs. Q1=0.49, 0.18–1.33, p=0.06).

Conclusion: In addition to the increased mortality rates we have previously reported among anti-CCP2+ subjects, elevated levels of serum cytokines, especially IL-6, predict a further increased risk of total mortality. Among anti-CCP2 negative subjects, higher levels of MCP-1 and lower levels of IL-2 were associated with increased risk of total mortality. The mortality risk associated with lower levels of plasma IL-2 perhaps suggests spontaneous activation of autoreactive T cells as has been associated with RA as well as CVD.

389

Treatment-Related Changes in Weight and Adipokine Levels and Associations with Radiographic Progression in Rheumatoid Arthritis. Joshua Baker[1], Gary Toedter[2], Daniel G. Baker[3] and Joan Marie Von Feldt[4]. [1]University of Pennsylvania, Philadelphia, PA, [2]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Malvern, PA, [3]Centocor R & D, a division of Johnson & Johnson Pharmaceutical Research and Development, LLC, Malvern, PA, [4]Univ of Pennsylvania/Philadelphia VAMC, Philadelphia, PA

Background/Purpose: Body mass and changes in weight may be predictors of radiographic outcomes in rheumatoid arthritis (RA). Adipocytokines have been

implicated in disease outcomes, however, associations with weight and disease-specific measures are unclear.

Methods: 100 randomly-selected subjects from the Go-BEFORE Trial of golimumab had adiponectin and leptin levels performed as part of a multi-analyte panel at baseline and 24 weeks of treatment. Radiographic data was available at baseline and 52 weeks. Using spearman correlations and logistic regression analysis, associations between baseline and treatment-related changes in weight, cytokines, and adipokines, and their independent association with disease activity and radiographic scores were assessed.

Results: Adiponectin and leptin were associated with BMI at baseline. On average, subjects gained weight during treatment (Mean increase in BMI 0.42 (1.12) kg/m^2 $p<0.001$). Both leptin and adiponectin tended to increase over the first 24 weeks of the trial. Changes in leptin were highly correlated with changes in weight ($p<0.0001$), whereas changes in adiponectin were negatively correlated with Il-6, TNF-a, and CRP levels (all $p<0.01$), but not BMI ($p>0.5$). No available baseline or longitudinal variables independently predicted changes in weight. Greater increase in weight was independently associated with a lower probability of radiographic progression at 52 weeks. Adiponectin and leptin were *not* independently associated with radiographic changes in multivariable models.

Table 1. Spearman correlations and of the association between changes in adiponectin and leptin (Δ) with continuous and dichotomous clinical treatment and response variables.

Continuous Variables	Δ Adiponectin	Δ Leptin
Δ BMI	−0.027	**0.37‡**
Δ CRP	**−0.36‡**	0.069
Δ TNF	**−0.25†**	0.047
Δ IL-6	**−0.29†**	0.066
Δ DAS28(CRP)	−0.16	−0.14

* $p<0.05$, †$P<0.01$, ‡$P<0.001$

Table 2. Multivariable logistic analysis of the associations between body mass, changes in body mass, and adiponectin with the risk of radiographic progression (defined as a vdHS change of >0.5). (N=86)

	Model 1*		Model 2*		Model 3*	
	OR (95% CI)	p	OR (95% CI)	p	OR (95% CI)	p
Baseline BMI (per 1 kg/m^2)	0.92 (0.80–1.06)	0.2	0.93 (0.81–1.08)	0.4	0.94 (0.81–1.10)	0.4
Δ BMI (per 1 kg/m^2 increase)	0.45 (0.24–0.85)	0.01	0.49 (0.25–0.94)	0.03	0.46 (0.24–0.90)	0.02
DAS28(CRP)	–	–	1.16 (0.68–1.99)	0.6	1.18 (0.68–2.04)	0.6
Δ DAS28(CRP)	–	–	1.43 (0.92–2.25)	0.1	1.35 (0.85–2.13)	0.2
Adiponectin (per 1 μg/mL)	–	–	–	–	1.26 (0.89–1.78)	0.2

* Also adjusted for age, race, sex, treatment group, CCP status, and a high vdHS at baseline.

Conclusion: Treatment-related increases in adiponectin correlate inversely with changes in inflammatory markers, whereas changes in leptin correlate positively with changes in body weight. Greater increases in weight at 24 weeks are associated with less radiographic change at 1 year, independent of adipokines and other disease severity measures.

B Cell Activating Factor (BAFF) Binding Receptors (BBR) on B Cells: Characterization in Patients with Rheumatoid Arthritis (RA) Receiving Anti-TNF-a Agent Infliximab (IFX). Lara Valor[1], Diana Hernandez[2], Geraldine Cambridge[3], Maria J. Leandro[3], Lina Martinez-Estupiñan[1], Luis Carreño[1] and Inmaculada de la Torre[1]. [1]Gregorio Marañón Hospital, Madrid, Spain, [2]Gregorio Maranon Hospital, Madrid, Spain, [3]University College of London, London, United Kingdom

Background/Purpose: B-cells play a cardinal role in the pathogenesis of RA as demonstrated by the effectiveness of Rituximab (RTX). Expression of BBR on B-cells namely BAFF-R, TACI (transmembrane activator and calcium-modulating and cyclophilin ligand interactor) and BCMA (B-cell maturation molecule) are key controllers of B cell survival and maturation. Dysregulation of BBR may contribute to the pathogenesis of RA and to re-establishment of disease after Rtx (1). Anti-TNFa agents are also effective in treating RA. TNFa has been shown to reduce CD38+ germinal center (GC) B cells and peripheral blood memory B cells (2). It remains unclear whether these 2 therapeutic targets are mechanistically linked. We have therefore analysed BBR expression on B-cells in response to the anti-TNFa agent IFX in patients with RA.

Methods: We included 23 patients with RA on IFX: 12 not in remision (DAS28>2.6) and 11 in remision (DAS28<2.6) and healthy controls (HC; n=12). Using multiparametric flow cytometry we measured % of naïve and memory B cells expressing BBR in peripheral blood, using combinations of directly conjugated monoclonal antibodies to CD19, CD27, IgD, CD38, BAFF-R, TACI and BCMA.

Results: Despite similar expression of BAFF-R on naïve and memory B-cells of active and inactive RA patients compared to HC, we found significatively increased TACI expression on memory B-cells (CD19+CD27+) of active and inactive patients compared to HC ($p=0.01$ and $p=0.004$, respectively), with the postGC compartment (CD19+IgD-CD38+) most affected vs. HC ($p=0.03$ and $p=0.01$ respectively). No changes in TACI expression on naïve B-cells (CD19+CD27-) were found. A significantly lower % of B cells expressed BCMA on naïve population (active and inactive RA vs. HC; $p=0.01$ and $p=0.06$, respectively). This was found in both naïve mature (CD19+IgD++CD38+) in active and inactive RA vs. HC ($p=0.01$ and $p=0.001$, respectively) and naïve transitional B cells (CD19+IgD+CD38++) in active and inactive RA vs. HC ($p=0.0007$ and $p=0.01$, respectively). % memory B-cells expressing BCMA+ were also lower (active and inactive RA vs. HC, $p=0.01$); affecting more the plasmablast compartment(CD19+IgD-CD38+++) (active and inactive RA vs. HC; both $p=0.03$) with a tendency for even lower BCMA on Post-GC memory B-cells in inactive RA on infliximab when compared to active patients ($p=0.04$).

Conclusion: Our data supports the concept that major disruption of BBR receptor expression is present in patients with RA. Whilst, after BCDT, restablishment of disease has been related to impared BAFF-R expression on the repopulating naive B-cell subset (1), IFX may influence maintenance of BAFF-R expression on both naïve and memory B-cell pools, in, both active or inactive disease. Blocking TNF a could restore the defect on the maturation-survival process on naïve B cell in patients with RA, preventing short lived B cells from becoming antibody-producing plasmacells. However, as active RA patients on anti-TNF therapy show increased TACI and decreased BCMA expression only on memory B-cells, suggesting that, defects in the memory B-cell pool might persist due to contributions by other mediators. Tumor Necrosis Factor Blocking Therapy Alters Oxidative Stress and Hypoxia-Induced Mitochondrial Mutagenesis in Inflammatory Arthritis. Monika Biniecka[1], Aisling Kennedy[1], Chin Teck Ng[1], Ting C. Chang[1], Emese Balogh[1], Edward Fox[2], Douglas J. Veale[1], Ursula Fearon[1] and Jacintha N. O'Sullivan[3]. [1]Translation Rheumatology Research Group, Dublin, Ireland, [2]Department of Pathology, University of Washington, Seattle, WA, [3]Department of Surgery, Trinity Centre for Health Sciences, St James's Hospital, Dublin, Ireland

Background/Purpose: To investigate if successful anti TNF-α treatment alters the levels of early mitochondrial genome alterations which can play a crucial role in governing clinical response or resistance. Furthermore, we determine if TNF-α blocking therapy changes the levels of synovial lipid peroxidation, further confirming the relationship between hypoxia, oxidative damage and mitochondrial mutagenesis.

Methods: Eighteen inflammatory arthritis patients underwent synovial tissue oxygen (tpO_2) measurements and clinical assessment of disease activity (DAS28-CRP) at baseline (T0) and three months (T3) after starting biologic therapy. Synovial tissue lipid peroxidation (4-HNE), T and B cell specific markers and synovial VEGF were quantified by immunohistochemistry. Synovial levels of random mitochondrial DNA (mtDNA) mutations were assessed using Random Mutation Capture (RMC) assay.

Results: 4-HNE levels pre/post anti TNF-α therapy were inversely correlated with *in vivo* tpO_2 ($p<0.008$; $r=-0.60$). Biologic therapy responders showed a significantly reduced 4-HNE expression ($p<0.05$). High 4-HNE expression correlated with high DAS28-CRP ($p=0.02$; $r=0.53$), TJC-28 ($p=0.03$; $r=0.49$), SJC-28 ($p=0.03$; $r=0.50$) and VAS ($p=0.04$; $r=0.48$). Strong positive association was found between the number of 4-HNE positive cells and CD4+ cells ($p=0.04$; $r=0.60$), CD8+ cells ($p=0.001$; $r=0.70$), CD20+ cells ($p=0.04$; $r=0.68$), CD68+ cells ($p=0.04$; $r=0.47$) and synovial VEGF expression ($p=0.01$; $r=063$).

In patients whose *in vivo* tpO_2 levels improved post treatment, significant reduction in mtDNA mutations and DAS28-CRP was observed ($p<0.05$). In contrast in those patients whose tpO_2 levels remained the same or reduced at T3, no significant changes for mtDNA mutations and DAS28-CRP were found.

Conclusion: There is a close association between oxidative stress, mitochondrial mutagenesis and clinical responses to TNF blocking therapy in inflammatory arthritis patients. The greater mitochondrial mutation burden in synovial tissue is associated with higher hypoxia levels *in vivo* and these significant mitochondrial genome alterations are rescued following successful anti-TNF treatment.

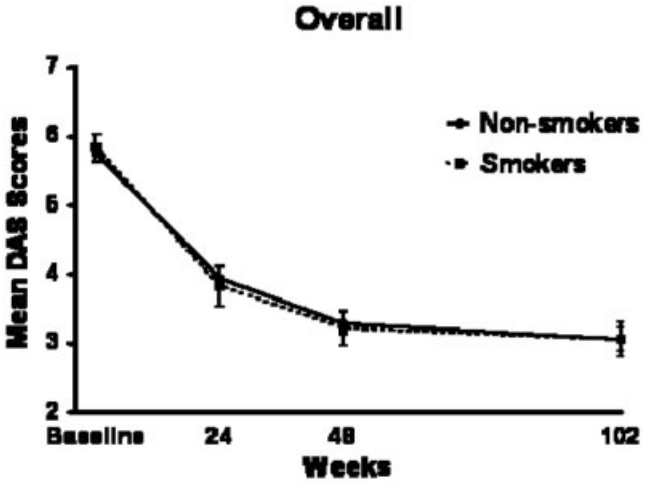
Active Smoking Is Not Associated with Treatment Response In Early Rheumatoid Arthritis In a Large Randomized Blinded Trial. Leann Maska[1], James R. O'Dell[2], Jeffrey R. Curtis[3], S. Louis Bridges Jr.[4], Larry W. Moreland[5], Stacey Cofield[6] and Ted R. Mikuls[7]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Univ of Nebraska Med Ctr, Omaha, NE, [3]Univ of Alabama-Birmingham, Birmingham, AL, [4]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [5]University of Pittsburgh, Pittsburgh, PA, [6]Univ of Alabama at Birmingham,, Birmingham, AL, [7]Omaha VA and University of Nebraska, Omaha, NE

Background/Purpose: Cigarette smoking has emerged as a major environmental risk factor for the development of rheumatoid arthritis (RA). Recent studies have suggested current smoking leads to lower treatment response rates with methotrexate (MTX) and biologics in RA. Knowledge of whether tobacco exposure reduces treatment efficacy is important as smoking could represent a modifiable factor in optimizing RA treatment strategies.

Methods: Study subjects included participants with early RA (< 2 years duration, autoantibody-positive or with radiographic erosions) enrolled in the Treatment of Early Aggressive RA (TEAR) trial. TEAR is a randomized, blinded, placebo-controlled clinical trial (RCT) comparing early intensive therapy versus step-up to one of two combinations of medications (MTX + etanercept vs. MTX + hydroxychloroquine + sulfasalazine (triple therapy)). The primary outcome of this analysis was mean DAS28 between 48 and 102 weeks by cotinine status, adjusting for baseline disease activity. Serum cotinine was measured using a commercially available ELISA at baseline and 48 weeks. Detectable concentrations at both visits served as an indicator of persistent tobacco exposure. In an independent RA cohort (n = 691) we found that any detectable serum cotinine yielded excellent concordance with self-reported current smoking (area under the ROC curve 0.90). Patients with inconsistent smoking status at weeks 0 and 48 were excluded.

Results: After excluding subjects for whom serum was not available (n = 192), and those with discordant cotinine category at the two time points (n = 34), a total of 412 subjects were analyzed with 293 (71%) categorized as non-smokers and 119 (29%) as current smokers. Mean age of those included was 50 years, disease duration 3.7 months, and baseline DAS28 score 5.8. No significant difference in dropout rate existed based on smoking status. There was no difference in the primary outcome based on smoking status ($p=0.881$) (See Figure), nor were there differences in outcomes of analyses stratified by TEAR treatment groups (data not shown). Using secondary outcomes of 'good' response or 'remission' as defined by EULAR response criteria, there was again no difference based on smoking status overall or by treatment group at any time point. LOCF imputation method was used for sensitivity analysis of all subjects with baseline serum available, with no significant difference of change in DAS observed. The frequency of SAEs including all infections, respiratory infections, and pneumonia was similar between smokers and nonsmokers both overall and based on treatment assignment.



Conclusion: Among 412 patients enrolled in an RCT of early aggressive RA, smoking status did not affect treatment response in early combination vs. step-up therapy, or biologic agent versus triple therapy. Smoking status also does not appear to be correlated with frequency of SAEs in this population.

393

Effect of Disease Modifying Anti-Rheumatic Drugs (DMARDs) On Anti-CCP2 and Anti-Citrullinated Protein Antibody (ACPA) Levels During Longitudinal Assessments In Rheumatoid Arthritis Patients. Makoto Soejima[1], Aarat M. Patel[1], Danielle Goudeau[1], Donald M. Jones[1], Christine L. Amity[1], Lynne M. Frydrych[1], Dawn McBride[1], Derek Sippel[1], Heather Eng[2], David Kyle[2], Melissa Saul[2], Stephen R. Wisniewski[2], Larry W. Moreland[1] and Marc C. Levesque[1]. [1]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [2]Univ of Pittsburgh, Pittsburgh, PA

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are specific markers for rheumatoid arthritis (RA) and may have a pathogenic role in the development of rheumatoid synovitis. ACPA are produced by B cells and some studies suggest that TNF regulates B cell development. Therefore, the purpose of these studies was to determine the effect of TNF antagonists on ACPA levels and to correlate these changes with changes in B cell subsets in patients with RA.

Methods: 115 RA patients with 3 longitudinal samples in the University of Pittsburgh Medical Center Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry and 226 RA patients with 4 longitudinal samples in the Treatment of Early Aggressive Rheumatoid Arthritis (TEAR) study were clinically assessed at each visit. Quantitative serum levels of ACPA were measured using ELISAs. B cell subsets were analyzed using flow cytometry. The effect of treatment on ACPA levels and on B cell subset numbers were analyzed using a mixed effects regression model, ANOVA, and t-test. Disease activity was controlled for in the analyses.

Results: Age, sex, race, rheumatoid factor (RF), and disease activity scores at baseline were similar among the different treatment groups within each cohort. ACPA levels changed following therapy and changes in ACPA levels were similar in the TEAR and RACER cohorts. ACPA levels decreased during the first 6 months of oral DMARD and TNF antagonist therapy. After 6 months, ACPA levels declined further in patients treated with oral DMARDs but returned to baseline levels in patients treated with TNF antagonists. This resulted in significant differences in ACPA levels between these groups (for TEAR subjects, $p=0.0015$ for anti-CCP2 (cyclic citrullinated peptide), $p=0.0045$ for anti-P6c (citrullinated fibrinogen peptide) and $p=0.0058$ for anti-P20c (citrullinated fillagrin peptide)). The percentages of pre-switch IgD^+CD27^+ and post-switch IgD^-CD27^+ memory B cells in RA patients treated with TNF antagonists were significantly lower than in healthy control subjects and subjects treated with oral DMARDs only ($p=0.0018$ and $p=0.0018$, respectively). The percentage of naïve B cells was higher among RA subjects treated with TNF antagonists compared to subjects treated with oral DMARDs only ($p=0.0068$).

Conclusion: We found a differential effect of oral DMARD therapy versus anti-TNF therapy on ACPA levels in patients with RA. After 6–12 months of treatment, TNF therapy was associated with an increase in ACPA levels, a lower percentage of peripheral blood (PB) pre-switch IgD^+CD27^+ and post-switch IgD^-CD27^+ memory B cells and with an increase in naïve

B cells. Naïve B cells in RA patients as compared to healthy subjects have been reported to produce higher levels of autoreactive antibodies. Taken together, these studies suggest that TNF blockade in RA patients may initially lower ACPA levels via diminished inflammation within the synovium where ACPA are produced. However, TNF blockade later leads to increased numbers of naïve autoreactive B cells that subsequently lead to increased ACPA levels.

Adalimumab Added to Methotrexate and Intra-Articular Glucocorticoid Increases Remission Rates At One Year In Early, DMARD-Naïve Patients with Rheumatoid Arthritis—An Investigator-Initiated Randomized, Controlled, Double-Blinded Study. Kim Hørslev-Petersen[1], Merete L. Hetland[2], Peter Junker[3], Jan Pødenphant[4], Torkell Ellingsen[5], Palle Ahlqvist[6], Hanne M. Lindegaard[3], Asta Linauskas[7], Annette Schlemmer[8], Mette Y. Dam[9], Ib Hansen[10], Hans Chr Horn[6], Anette Jørgensen[9], Sophie B. Krintel[2], Johnny Raun[1], Christian G. Ammitzbøll[9], Julia Johansen[2], Mikkel Østergaard[11] and Kristian Stengaard-Pedersen[9]. [1]University of Southern Denmark, Graasten, Denmark, [2]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [3]Odense University Hospital, Odense C, Denmark, [4]Copenhagen University at Gentofte,, Hellerup, Denmark, [5]University Hospital, Silkeborg, Denmark, [6]Vejle Hospital,, Vejle, Denmark, [7]Vendsyssel Hospital, Hjørring, Denmark, [8]Aalborg Hospital, Aalborg, Denmark, [9]Arhus University Hospital, Aarhus, Denmark, [10]Viborg Hospital, Viborg, Denmark, [11]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark

Background/Purpose: To assess efficacy and safety, including remission rates by adding adalimumab (ADA) to methotrexate (MTX) and intra-articular glucocorticoid (triamcinolone) in patients with early DMARD-naïve rheumatoid arthritis (RA) fulfilling the ACR 1987 criteria.

Methods: DMARD naive RA patients with disease duration < 6 months (n=180) were randomized 1:1 to MTX 7.5 mg weekly + ADA 40 mg (ADA) every other week or MTX + placebo (PLA). At week 0, 4, 8, and 12 followed by every 3rd month up to 12 months, patients had triamcinolone injections into swollen joints (max 4 joints or max 4ml/visit). In addition the patients were contacted fortnightly during the first 3 months and monthly thereafter. If disease activity was suspected, an extra visit was scheduled and swollen joints were injected. MTX was increased to 20 mg/week within two months. If persisting DAS28(CRP)>3.2 after three months, sulphasalazine 2g/day and hydroxychloroquine 200mg/day were added. Patients with persistent DAS28(CRP)>3.2 in spite of triple therapy were excluded and started rescue biologic medication. NSAID, muscle relaxants, or medium or strong analgesics were not allowed. Clinical response was assessed according to DAS28(CRP), SDAI and ACR/EULAR remission criteria. Primary analysis was by ITT with last observation carried forward. Completer analysis and ITT without imputations were also performed and gave similar results (not shown). Differences between groups were tested by Mann-Whitney or by Pearson's chi-square test.

Results: At baseline no significant differences were seen between MTX+PLA and MTX+ADA: 69%/63% were women, median age was 54.4/56.2 years, disease duration 83/84 days, anti-CCP positive 70%/60%, IgM-RF positive 74%/70%, DAS28(CRP) 5.4/5.3, tender joint count (40) 16/15, swollen joint count (40) 11/10, patient's VAS pain 58/63mm and fatigue 54/67mm, doctor's VAS global 51/57mm, HAQ 1.0/1.1. Data for MTX after 12 months and use of triamcinolone 0–12 months are presented in the table. Triple therapy was added in 25/17 patients (p=0.25). 80/81 patients completed the study. 2/4 patients started rescue biologic medication. Serious adverse advents were reported in 13 patients, including three with malignancies (urothelial, lung and non-melanoma skin cancer). The frequency of DAS28(CRP)<3.2 (primary outcome) did not differ significantly between the groups, but in the MTX+ADA group significantly more patients achieved clinical remission (DAS28, SDAI and ACR/EULAR remissions) at 12 months (secondary outcome) (table).

	MTX+PLA	MTX+ADA	p
Number of patients	91	89	–
Methotrexate (mg/week) 12 months	20 (7/25)	20 (7.5/20)	0.33
Triamcinolone (ml) 0 – 12 months	7 (2/17.8)	5.4 (1.8/16.6)	0.084
DAS28 (CRP) 12 months	2.2 (1.3/4.5)	1.7 (1.2/5.2)	0.0007
DDAS28 (CRP) 0–12 months	−3.0 (−0.2/−5.0)	−3.2 (−0.2/−5.7)	0.11
DAS28 (CRP)<3.2; 12 months	81%	84%	0.74
DAS28 (CRP)<2.6; 12 months	49%	74%	0.0011
SDAI ≤ 3.3; 12 months	40%	63%	0.0028
ACR/EULAR (28 joints) remission; 12 months	31%	48%	0.0241
ACR/EULAR (40 joints) remission; 12 months	27%	47%	0.0098

Values are medians(5%/95% percentiles) unless otherwise stated (%).

Conclusion: In DMARD naïve patients with early RA, excellent disease control was achieved by a targeted step-up strategy using methotrexate and intra-articular glucocorticoid injections. Addition of adalimumab to methotrexate and intra-articular glucocorticoid improved the remission rates considerably. The treatments were well tolerated.

395

Tocilizumab Improves Arterial Stiffness Compared with Abatacept In Patients with TNF Blockers-Resistant Active Rheumatoid Arthritis.An Open Label Randomized Controlled Trial. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1] and Kazuhiko Hatta[2]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Hatta Clinic, Kure, Japan

Background/Purpose: Rheumatologists need to develop primary prevention strategies for cardiovascular disease(CVD) in rheumatoid arthritis (RA) patients.To compare the effect of tocilizumab(TCZ) plus methotrexate (MTX), with the effect of abatacept(ABT) plus MTX on arterial stiffness in TNF blockers resistant active RA patients, in a open label randomized study design.

Methods: RA patients were eligible if they had active disease despite treatment with MTX plus TNF blockers. All patients have no steroids, and no previous history of CVD. 32 patients with moderate to severe active RA patients (DAS28 >3.2) were randomly assigned to receive TCZ plus MTX (n=16) or ABT plus MTX (n=16). All patients with worsening disease activity at week 12, the patients were allowed to escape to another group (by clinician's judgment).Arterial stiffness was assessed with cardio-ankle vascular index (CAVI) and augmentation index corrected for a heart rate of 75 beats per minute (AIx@75) at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data was collected at regular visits.CAVI was calculated by the following formula:CAVI= $2\rho/dP \times \ln(Ps/Pd)PWV2$, where Ps is systolic blood pressure, Pd is diastolic blood pressure, PWV is pulse wave velocity, dP is Ps– Pd,ρ is blood density.CAVI measures arterial wall stiffness independent of blood pressure and it is superior to PWV as an index of arterial stiffness.

Results: The characteristics of each group at baseline were not significantly different. 15 each in the TCZ and ABT groups completed 24 weeks.CAVI and AIx@75 were attenuated significantly by TCZ (CAVI; week 0–week 24, 0.92±0.15 m/s, $p = 0.02$) (AIx@75; week 0–week 24, 3.59±0.33%, $p = 0.03$).On the other hand, CAVI and A,hx@75 were not attenuated significantly by ABT (CAVI; week 0–week 24, 0.22±0.11 m/s, $p = 0.52$) (AIx@75; week 0–week 24, 0.98±0.21%, $p = 0.66$). The change (week 0–week 24) CAVI and AIx@75 of the TCZ group were significantly improvement than those of the ABT group (TCZ vs. ABT, CAVI: $p = 0.024$; AIx@75: $p=0.032$). TCZ and ABT did not significantly change carotid intima-media thickness (week 0–week 24, TCZ: 0.00±0.11 mm, ABT: −0.00±0.13 mm), and did not produce significant changes in carotid artery plaque (week 0–week 24, numbers of combined grade 0/1/2/3/4, TCZ: −1/1/0/0, ABT: −1/0/−0/0). There were no significant changes either within ratio of serum total cholesterol (TC) to high-density lipoprotein cholesterol (week 0–week 24, TCZ: 0.02±0.04; ABT: 0.03±0.03) ($p>0.05$). In the TCZ, TC was significantly increased (week 0–week 24, −18.0±5.2 mg/dL, $p = 0.03$). There were no significant changes within the ABT group in TC (ABT: −2.0±0.6 mg/dL; $p=0.75$). The change TC levels of the TCZ group were significantly higher than those of the other groups (TCZ vs. ABT, $p = 0.034$). DAS28 and CRP improved significantly in both groups (week 0–week 24; DAS28, TCZ: −2.13±0.35, ABT: −2.20±0.42) (CRP, TCZ: 22.3±3.2 mg/l, ABT: 19.5±2.3 mg/l) ($p<0.05$). They were no significant difference between groups.

Conclusion: TCZ improves arterial stiffness compared with ABT and in TNF blockers resistant RA. If RA patients were resist TNF blocker, we might think the patients were treated by TCZ than ABT.

396

Tocilizumab Monotherapy Improves BONE Mineral Density AS Well AS TNF Blockers PLUS Methotrexate with Methotrexate-RESISTANT Activerheumatoid Arthritis. AN OPEN-Label RANDOMIZED CLINICAL TRIAL. T-BONE TRIAL. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1] and Kazuhiko Hatta[2]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Hatta Clinic, Kure, Japan

Background/Purpose: To compare the effects of tocilizumab (TCZ) monotherapy, and infliximab (IFX) plus methotrexate(MTX), and adalimumab(ADA) plus MTX, respectively on bone mineral density (BMD) in patients

with rheumatoid arthritis (RA; without osteoporosis) patients despite MTX treatment, in a prospective open-label randomized controlled design.

Methods: 42 RA patients with moderate to severe active disease (DAS28 > 3.2) despite MTX treatment were randomly assigned to receive TCZ (8mg/kg per 4 weeks) alone (n=14), IFX (3–10mg/kg per 8 weeks) plus MTX (n=14), or ADA (40mg per 2 weeks) plus MTX (n=14). All patients have no previous history of lumbar and hip fractures. Patients receiving or having received bisphosphonates or hormone replacement therapy, steroids, or any biologics were excluded. The dosage of all disease modifying anti-rheumatic drugs had been stable for at least 8 weeks prior to enrollment. The primary outcomes were changes in lumbar and femoral BMD by dual-energy X-ray absorptiometry, secondary outcome were serum osteocalcin and serum crosslaps from baseline to12 months. Clinical data were collected at regular visit. All patients were taking calcium (1 g/day) and vitamin D (800 IU/day).

Results: The characteristics of each group at baseline were not significantly different. In all groups there was significant increase from baseline to 12 months in BMD in the spine (month12-baselineTCZ: BMD 0.04±0.002 g/cm^2, $p < 0.001$; T-score, $p < 0.001$; Z-score, $p < 0.01$; IFX: BMD 0.03±0.004 g/cm^2, $p < 0.001$; T-score, $p < 0.001$; Z-score, $p < 0.01$; ADA: BMD 0.03±0.003 g/cm^2, $p < 0.001$; T-score, P < 0.001; Z-score, $p < 0.01$) and the femoral neck (TCZ: BMD 0.03±0.002 g/cm^2, $p < 0.001$; T-score, $p < 0.001$; Z-score, $p < 0.01$; IFX: BMD 0.03±0.006 g/cm^2, $p < 0.001$; T-score, $p < 0.001$; Z-score, $p < 0.01$; ADA: BMD 0.02±0.008g/cm^2, $p < 0.001$; T-score, $p < 0.001$; Z-score, $p < 0.01$). The change (month12-baseline) BMD were no significant differences between each group in BMD in spine or in femoral neck. In all groups there was significant increase from baseline to 12 months in osteocalcin serum levels (month 12-baseline, TCZ:7.2±0.65 ng/ml, p<0.01; IFX: 6.2±0.85 ng/ml, p<0.01;ADA: 6.8±0.76 ng/ml p<0.01) and significant decrease in crosslaps serum levels (month 12-baseline, TCZ: −3.2±0.28 ng/ml, p<0.01;IFX: −2.9±0.45 ng/ml, p<0.01; ADA: −2.5±0.66 ng/ml p<0.01) but no change in serum calcium was observed. There were no significant differences between each group in osteocalcin serum levels or in crosslaps serum levels. However, the changes in markers of bone metabolism and BMD were not correlated in all groups. HAQ score, DAS28-ESR score, and CRP improved significantly in all groups from baseline to 12 months ($p<0.05$). They were no significant difference between groups.

Conclusion: The data support the hypothesis that TCZ monotherapy may exert beneficial effects on bone metabolism in active RA patients despite MTX to the same extent as IFX or ADA plus MTX. We need further studies to compare the effects of TCZ alone, and TCZ plus MTX on BMD in patients with RA patients despite MTX treatment.

397

Efficacy, Safety and Pharmacokinetics of Vidofludimus, a Novel Oral Immunomodulator, in Patients with Active Rheumatoid Arthritis on Methotrexate Background Therapy: The COMPONENT Study. Stanislaw Sierakowski[1], Bruno Dietrich[2], Bernd Hentsch[2] and Aldo Ammendola[2]. [1]Medical University Bialystok, Bialystok, Poland, [2]4SC AG, Planegg-Martinsried, Germany

Background/Purpose: Vidofludimus is an oral immunomodulator inhibiting dihydroorotate dehydrogenase (DHODH) and the expression of pro-inflammatory cytokines including interleukin-17 (IL-17A and IL-17F) and INF-gamma. In the presented Phase II COMPONENT study efficacy, safety, and pharmacokinetics of vidofludimus in combination with methotrexate (MTX) has been evaluated in rheumatoid arthritis (RA) patients. Vidofludimus has previously successfully completed a Phase IIa study in inflammatory bowel disease (IBD).

Methods: Primary endpoint of this randomized, double-blind, placebo-controlled Phase II study was ACR20 response at week 13. Secondary endpoints included ACR50, ACR70, DAS28, safety and pharmacokinetics. 241 patients were enrolled in two study arms across 28 sites in Eastern Europe. The first arm received 35 mg vidofludimus QD plus MTX over 13 weeks, the second arm received placebo plus MTX. Eligible patients must have had active RA, have received weekly doses of MTX (10–25 mg/week) for a minimum of 3 months prior to Day 1 dosing, and a stable MTX dose for at least 6 weeks prior to Day 1 dosing.

Results: ACR20 response improvement of the vidofludimus group compared to placebo was statistically significant (p<0.05) at week 2 (16.7% vs. 6.9%) and week 8 (46.7% vs. 31.9%), but did not reach statistical significance at week 13 (50.0% vs. 44.8%). The vidofludimus group also reported higher ACR50 (25.8% vs. 17.2%) and ACR70 (12.5% vs. 6%) response rates compared to placebo at week 13. DAS28 (CRP) response rate of vidofludimus also was significantly higher compared to placebo at week 4 (55.8% vs. 42.3%). Mean change of CRP (ESR) at week 13 compared to baseline was −1.82 mg/l (−3.98 mm/h) for vidofludimus and 1.38 mg/l (3.18 mm/h) for placebo. Mean changes of RA-specific parameters (joint counts, disease activity, pain, HAQ) were similar in both groups at week 13. In contrast to preclinical interaction studies, a substantial decrease of vidofludimus plasma concentrations below levels detected in earlier clinical trials has been observed with increasing MTX doses.

Vidofludimus was safe and well tolerated. No obvious differences in the adverse event profile between the vidofludimus and placebo group were observed. In particular, there were no relevant increases of diarrhea, neutropenia, anemia, hypertension, cholesterol or liver enzyme levels. Only one serious adverse event was reported in the vidofludimus group which was judged as unlikely drug-related. No deaths occurred. These safety results were consistent with previous clinical trial results in RA and IBD.

Conclusion: Certain efficacy endpoints (ACR20/DAS28) have been statistically significant at specific time points during the treatment period, though vidofludimus missed the primary ACR20 efficacy endpoint of the COMPONENT study at week 13. Decreases in objective inflammatory parameters CRP and ESR strongly support a general anti-inflammatory effect of vidofludimus. These results and the very clean safety profile indicate that a vidofludimus dose of 35 mg QD might be not high enough to show statistically significant results in RA. In addition, the observed drug interaction of vidofludimus with MTX may have hampered the full anti-inflammatory activity of vidofludimus.

398

Rituximab and Methotrexate but Not TNF-Blockers Are Associated with Impaired Antibody Response Following Pneumococcal Vaccination Using 7-Valent Conjugate Vaccine (Prevenar®) In Patients with Established Rheumatoid Arthritis. Meliha C. Kapetanovic[1], Carmen Roseman[1], Göran Jönsson[2], Lennart T. Truedsson[3], Tore V. Saxne[1] and Pierre Geborek[1]. [1]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden, [2]Dept of Clinical Sciences Lund, Section of Infectious Diseases, Lund, Sweden, [3]Dept of Clinical Sciences Lund, Section of Microbiology, Immunology and Glycobiology, Lund, Sweden

Background/Purpose: To investigate the impact of anti-rheumatic treatments including methotrexate (MTX), TNF blockers, rituximab (RTX), abatacept and tocilizumab on antibody response following pneumococcal vaccination using 7-valent conjugate vaccine (Prevenar®) in patients with established RA.

Methods: Altogether, 294 patients with established RA and 86 patients with spondylartropathy (SpA) including psoriatic arthritis received one dose of 0.5 ml Prevenar® intramuscularly. The RA treatment groups (number of participants, % female, mean age (years)) were studied: MTX (85; 79; 62); anti-TNF as monotherapy (79; 87; 60); anti-TNF+MTX (89; 78; 60); RTX as monotherapy (15; 80; 68); RTX+MTX (10; 70; 56); abatacept (10; 100; 57) and tocilizumab (5; 100; 62). SpA patients on NSAIDs/analgesics (86; 39; 52) served as controls. Levels of serotype specific IgG against 23F and 6B were measured at vaccination and 4–6 weeks after vaccination using standardised ELISA. Antibody response ratio (ARR) calculated on logarithmic values as ratio post/prevaccination antibody levels were compared between treatment groups. Positive antibody response (posAR) was defined as ≥2 ARR.

Results: ARR different significantly between the groups for both serotypes (univariate analysis of variance, ANCOVA; p<0.001). Compared to controls, all other RA treatments groups showed significantly lower ARR except for patients treated with anti-TNF as monotherapy for both serotypes (p-value between 0.023 and <0.001). Furthermore, patients receiving RTX as monotherapy or RTX+ MTX showed significantly decreased ARR compared to anti-TNF as monotherapy and MTX alone. None of RTX treated patients had posAR for serotype 6B which was the reason that predictors of positive immune response were studied only for serotype 23F. After adjustment for age and sex in logistic regression model, MTX treatment predicted impaired posAR (p= 0.038; OR 0.5; 95% CI 0.31–0.97) as well as RTX (p<0.001; OR 0.09; 95% CI 0.03–0.3).

Conclusion: MTX and RTX but not TNF-blockers are associated with impaired antibody response following vaccination with heptavalent pneumococcal conjugate vaccine (Prevenar®) in this cohort of patients with established RA. Insufficient statistical power precluded detailed studies of abatacept and tocilizumab on vaccination response.

399

Genetic Variations within the CD6 and Syntaxin Binding Protein 6 Genes Associated with Response to Tumor Necrosis Factor Alpha Inhibitors in Danish Patients with Rheumatoid Arthritis Treated in Routine Care. Sophine B. Krintel[1], Giuseppe Palermo[2], Assaf Wool[3], Julia S. Johansen[4], Laurent Essioux[2], Ehud Schreiber[3], Tomer Zekharya[3], Pinchas Akiva[3], Mikkel Østergaard[1] and Merete L. Hetland[5]. [1]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [3]Compugen Ltd., Tel Aviv, Israel, [4]Copenhagen University Hospital at Herlev, Copenhagen, Denmark, [5]Copenhagen University Hospital at Glostrup, on behalf of DANBIO, Copenhagen, Denmark

Background/Purpose: Tumor necrosis factor alpha (TNFα) inhibitors have greatly improved treatment of patients with rheumatoid arthritis (RA). However, at least 30% of the patients do not respond and no validated predictive biomarker has been identified. Lack of response and risk of adverse drug reactions emphasize the need for predictive biomarkers. We aimed to investigate genetic variations associated with response to TNFα inhibitors in Danish patients with moderate to severe RA treated in routine care.

Methods: In the nationwide DANBIO registry we identified 237 TNFα inhibitor naive patients with RA (81% women, median age 56 years (interquartile range 44–64), disease duration 6 years (2–14.3)) who initiated treatment with infliximab (n=160), adalimumab (n=56), and etanercept (n=21) according to national guidelines between 1999 and 2008. The patients were registered in DANBIO at onset of treatment and followed prospectively. Clinical response was assessed at week 26 using EULAR response criteria. Over 200 genetic variations were tested for association with response. Genomic segments were amplified by polymerase chain reaction, and genotyped by either Sanger sequencing or fragment analysis. We tested the association between genotypes and EULAR good response versus no response, and EULAR good response versus moderate/no response using Fisher's exact test.

Results: Median disease activity score (DAS28) at baseline was 5.1 decreasing to 3.6 at week 26. Sixty-eight (29%) patients were EULAR good responders, while 81 (34%) patients were moderate responders and 88 (37%) patients were non responders. A 19 base pair insertion within the CD6 gene was associated with EULAR good response versus no response (OR=4.43, 95% CI: 1.99–10.09, p=7.211 × 10-5, minor allele frequency (MAF) =0.15) and with EULAR good response versus moderate/no response (OR=4.54, 95% CI 2.29–8.99, p= 3.336 × 10-6). A microsatellite within the syntaxin binding protein 6 (STXBP6) on chromosome 14 was associated with EULAR good response versus no response (OR=4.01, 95% CI 1.92–8.49, p=5.067 × 10-5, MAF=0.25). Patients with one of these variations were more likely to achieve a EULAR good response compared to patients without these variations (OR=5.8; 95% CI 2.50–14.24; p=3.623 × 10-6).

Conclusion: Genetic variations within the CD6 gene and the STXBP6 gene were significantly associated with EULAR good response in a cohort of Danish patients with RA treated with TNFα inhibitors in routine care. This suggests that genetic variations within these genes may influence response to TNFα inhibitors and therefore may be useful as predictive biomarkers in patients with moderate or severe RA treated with TNFα inhibitors.

A Calcineurin Inhibitor FK506 Suppresses Joint Destruction in Patients with Early Rheumatoid Arthritis and Low Disease Activity. Yoshiya Tanaka[1], Shinichi Kawai[2], Tsutomu Takeuchi[3], Kazuhiko Yamamoto[4], Shinya Tani[5], Toshiyuki Okada[5] and Nobuyuki Miyasaka[6]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [2]Toho Uni Sch of Med, Tokyo, Japan, [3]Keio University School of Medicine, Tokyo, Japan, [4]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [5]Astellas Pharma Inc., Tokyo, Japan, [6]Tokyo Medical and Dental University, Tokyo, Japan

Background/Purpose: A multicenter, randomized, double-blind, placebo-controlled study of the calcineurin inhibitor FK506 (tacrolimus) was performed in patients with early-stage RA and a poor response to DMARDs (*Modern Rheumatology*, in press). In this paper, background factors related to suppression of joint destruction by FK506 were clarified and subanalysis was performed in patients with those factors to assess a change in the total Sharp score (ΔTSS).

Methods: A 52-week, multicenter, randomized, double-blind, placebo-controlled study was performed in 123 patients with RA for no more than 3 years who showed a poor response to DMARDs and were randomized to additional FK506 (3 mg/day) or placebo while continuing their previous therapy. Univariate analysis was performed in patients with X-ray films obtained in week 12 or later to examine the factor contributing most to ΔTSS<0.5 in week 52. Subanalysis was done in the patients with this factor to examine the primary endpoint (ΔTSS in week 52) and the secondary endpoints (ACR improvement criteria, EULAR improvement criteria, and safety) of this study. Missing data on X-ray films were supplemented by extrapolation and other missing data were obtained by LOCF.

Results: A baseline CRP level<1.5 mg/dL was extracted by univariate analysis as the factor contributing most to ΔTSS<0.5 in the FK506 group by week 52. Then subanalysis was performed of the patients with a baseline CRP<1.5 mg/dL. Significant differences of patient background were not observed between the groups. The primary endpoint (ΔTSS in week 52) was 2.67±5.40 (n=29) in the FK506 group and 8.05±10.32 (n=31) in the placebo group, and was significantly smaller in the FK506 group (p=0.017: analysis of covariance with the baseline data and with or without concomitant MTX as covariates) (Table). The FK506 group also had a significantly higher percentage of patients with a moderate response or better by EULAR criteria in week 52 (Table). Both groups had a similar incidence of adverse drug reactions.

Radiographic progression in week 52 (baseline CRP<1.5 mg/dL)

	FK506 (n=29)	Placebo (n=31)	*p*-value
ΔTSS	2.67 ± 5.40	8.05 ± 10.32	0.017

Clinical outcome in week 52 (baseline CRP<1.5 mg/dL)

	FK506 (n=32)	Placebo (n=31)	*p*-value
EULAR good/moderate (%)	78.1	51.6	0.030

Conclusion: Addition of FK506 to DMARDs significantly suppressed disease activity and joint destruction in patients with early rheumatoid arthritis and low disease activity who had a disease duration≤3 years, a CRP<1.5 mg/dL, and a poor response to oral DMARDs.

401

One Year Efficacy and Safety Results of a Phase II Trial of Secukinumab in Patients with Rheumatoid Arthritis. Mark C. Genovese[1], Patrick Durez[2], Hanno B. Richards[3], Jerzy Supronik[4], Eva Dokoupilova[5], Jacob A. Aelion[6], Sang-Heon Lee[7], Christine E. Codding[8], Herbert Kellner[9], Takashi Ikawa[10], Sophie Hugot[3], Gregory Ligozio[11] and Shephard Mpofu[3]. [1]Stanford University, Palo Alto, CA, [2]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium, [3]Novartis Pharma AG, Basel, Switzerland, [4]NZOZ Centrum Medyczne Artur Racewicz, Bialystok, Poland, [5]Medical Plus s.r.o, Uherske Hradiste, Czech Republic, [6]Arthritis Clinic, Jackson, TN, [7]Konkuk University Medical Center, Seoul, South Korea, [8]Health Research of Oklahoma, Oklahoma City, OK, [9]Centre for Inflammatory Joint Diseases, Munich, Germany, [10]Kobe–Konan Yamate Clinic, Kobe, Japan, [11]Novartis Pharmaceuticals Corporation, East Hanover, NJ

Background/Purpose: To assess the efficacy and safety of secukinumab (AIN457) in patients with active rheumatoid arthritis (RA) despite stable methotrexate (MTX) up to Week 52.

Methods: Adult RA patients (n=237) on MTX were randomized equally to receive monthly s.c injections of secukinumab 25mg, 75mg, 150mg, 300mg or placebo. The primary endpoint was the proportion of patients achieving American College of Rheumatology (ACR) 20 at Week 16. After Week 16, responders on secukinumab remained on the same dose whereas doses were escalated in non-responders at Week 20 (except patients dosed initially on 300mg who remained on the same dose). All placebo patients were switched to secukinumab 150mg. Patients were followed through Week 52.

Results: Demographics and baseline characteristics were comparable across all groups. ACR20 responder rates at Week 16 were higher with secukinumab 75mg, 150mg and 300mg (47%, 47% and 54%, respectively) *vs* placebo (36%) but did not reach statistical significance.

Responders on secukinumab maintained their ACR20 response from Week 24 to 52. Improvement in ACR20 response rates at weeks 24 and 52 were seen in patients who remained on secukinumab 150mg for the entire study [15/20 (75%) and 18/20 (90%), respectively]. Through Week 52, responders who remained on secukinumab 150mg had further improvement in ACR50 and ACR70 with the highest increases seen in ACR70 [4/20 (20%)

and 8/20 (40%) at weeks 24 and 52, respectively] as did responders who switched from placebo to secukinumab 150mg [1/18 (6%) and 4/18 (22%) at weeks 24 and 52, respectively] (Figure 1).

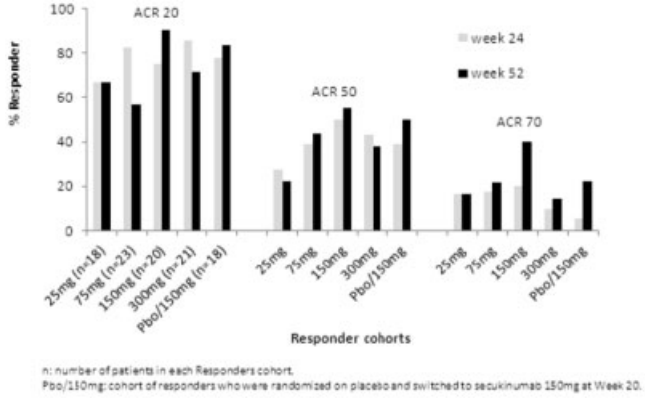

Figure 1. ACR20, ACR50 and ACR70 response rates in Week-16 responders at weeks 24 and 52.

DAS28-CRP reductions were sustained up to Week 52 in responders. Responders who remained on secukinumab 150mg had improvement in HAQ scores (−0.6 at Week 24 *vs* −0.8 at Week 52). Non-responders did not gain much additional efficacy benefit after dose escalation as assessed by ACR20/50/70 and DAS28-CRP. The overall rates of AEs at Week 52 remained comparable to data seen at Week 20 (60–70%) and most AEs were mild to moderate in severity and did not lead to study discontinuation (6.9%). The rate of infections was 31.9% overall. Twenty one (9.7%) SAEs were reported including 6 cases of serious infections without dose relationship. There were 3 malignancies and no deaths up to Week 52.

Conclusion: The primary efficacy endpoint was not achieved in this trial possibly due to an unexplained increase in ACR20 in the placebo group between weeks 12 (24%) and 16 (36%). However, ACR20-responders at Week 16 experienced maintenance or improvement of efficacy through Week 52 with highest efficacy in patients who remained on 150mg throughout the trial. Patients on secukinumab who were non-responders at Week 16 did not gain much additional efficacy benefit after dose escalation. Secukinumab was well tolerated and the rate and frequency of AEs remained stable over time without unexpected safety findings.

402

Subcutaneous (SC) Abatacept (ABA) Versus Intravenous (IV) ABA in Patients (pts) with Rheumatoid Arthritis: Long-Term Data From the ACQUIRE (Abatacept Comparison of Sub[QU]cutaneous versus Intravenous in Inadequate Responders to MethotrexatE) Trial. Mark C. Genovese[1], Arturo Covarrubias Cobos[2], Gustavo Leon[3], Eduardo F. Mysler[4], Mauro W. Keiserman[5], Robert M. Valente[6], Peter T. Nash[7], J. Abraham Simon Campos[8], Wieslawa Porawska[9], Jane H. Box[10], Clarence W. Legerton III[11], Evgeny L. Nasonov[12], Patrick Durez[13], Ramesh Pappu[14], Ingrid Delaet[14], Julie Teng[14] and Rieke Alten[15]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]Calle Maiz No 49, Mexico, Mexico, [3]Instituto De Ginecologia Y Reproduccion, Lima, Peru, [4]OMI, Buenos Aires, Argentina, [5]Pontiphycial Catholic Univ, Porto Alegre, Brazil, [6]Arthritis Center of Nebraska, Lincoln, NE, [7]University of Queensland, Brisbane, Australia, [8]Centro De Especialidades Médicas, Merida, Mexico, [9]Poznański Ośrodek Medyczny 'Novamed', Poznań, Poland, [10]Box Arthritis & Rheumatology of the Carolinas, Charlotte, NC, [11]LowCountry Rheumatology, Charleston, SC, [12]Institue of Rheumatology, Moscow, [13]Université Catholique de Louvain, Brussels, Belgium, [14]Bristol-Myers Squibb, Princeton, NJ, [15]Schlosspark-Klinik, Berlin, Germany

Background/Purpose: Efficacy and safety of IV ABA is well established in RA. The ACQUIRE trial showed comparable safety and efficacy in SC vs IV ABA over 6 mths[1]; here, we present 18-mth data from the long-term extension (LTE).

Methods: ACQUIRE was a Phase IIIb, 6-mth, double-blind (DB) double-dummy study of pts with active RA (≥10 swollen and ≥12 tender joint count [TJC and SJC], CRP ≥0.8 mg/dL) refractory to MTX. Pts were randomized to SC ABA (125 mg/week) with IV ABA loading (~10 mg/kg) on Day 1 or IV ABA (~10 mg/kg) on Days 1, 15, 29 and every 4 wks for 6 mths; all pts received MTX. After 6 mths pts could enter the open-label LTE to receive SC ABA 125 mg/week. Safety, immunogenicity (by electrochemiluminescence), and efficacy (ACR 20, 50 and 70 and HAQ-DI responses [improvement from baseline (BL) ≥0.3]) were assessed for pts treated with ≥1 dose of ABA in the LTE. Efficacy data are as-observed; not all pts reached later timepoints at time of analyses.

Results: Of 1372 pts entering the LTE, 1222 (89.1%) remained on therapy at time of reporting. Overall mean BL RA duration was 8 yrs, TJC and SJC were 30 and 20, and HAQ-DI was 1.7; characteristics were similar between groups. Median (SD) ABA exposure was 22 (3.8) mths. The IR (events/100 pt–yrs) of SAEs in the LTE was comparable with that seen with SC ABA in the DB period (9.00 [95% CI: 7.69–10.55] and 9.02 [6.31–12.90], respectively) and did not increase with increasing exposure (not shown). The IR of overall and serious infections in the LTE did not increase vs the DB period (47.64 [44.01–51.58] vs 84.62 [74.50–96.11] and 1.97 [1.41–2.74] vs 1.48 [0.62–3.56] respectively) and did not increase with increasing exposure (not shown). Opportunistic infections in the LTE included 3 TB cases and 2 candidiasis cases; no opportunistic infections were observed in the DB period. Injection site reactions occurred in 24 (1.7%) pts in the LTE (none serious). ABA-induced antibodies occurred in 39/1365 (2.9%) pts in the LTE; 4/11 pts with anti-CTLA4 antibodies eligible for testing were positive for neutralizing antibody. Immunogenicity did not affect efficacy, safety or ABA pharmacokinetics (data not shown). ACR responses up to Mth 24 were maintained from Mth 6 and comparable between original SC vs IV groups (Fig). DAS28 remission rates (95% CIs) were 24 (21–27) [n=685] vs 25% (22–28) [n=688] at Day 169 and 32 (22–42) [n=85] vs 31% (20–41) [n=72] at Day 729 in the original SC vs IV groups, respectively. HAQ responses (95% CIs) were 73 (69–76) [n=691] and 68% (65–72) [n=672] at Day 169 and 63 (53–73) [n=87] and 56% (45–67) [n=77] at Day 729 in the original SC and IV groups, respectively. At the time of analyses, most patients had not completed the later timepoints (Days 617, 729).

	Original treatment group	Patients with available data at each visit*												
		15	29	57	85	113	141	169	253	365	449	533	617	729
ACR 20	SC abatacept	685	687	684	685	687	685	686	685	661	648	587	325	86
	IV abatacept	665	668	668	669	670	671	670	667	652	635	572	312	76
ACR 50	SC abatacept	688	690	687	686	686	684	689	683	663	648	588	324	85
	IV abatacept	669	673	671	672	670	671	672	668	653	635	571	311	77
ACR 70	SC abatacept	689	689	688	686	689	690	690	685	666	650	586	326	87
	IV abatacept	669	673	670	672	669	671	671	666	655	637	571	312	78

*Not all patients reached later timepoints at time of data analysis; SC=subcutaneous; IV=intravenous

Conclusion: Over 24 mths, SC ABA showed acceptable safety, with high pt retention, similar to the IV experience. Efficacy was comparable between SC and IV groups; ACR and HAQ responses and DAS28 remission rates were maintained in the LTE.

403

Safety Profile of Subcutaneous Abatacept Focusing on Clinically Relevant Events in Patients with Rheumatoid Arthritis (RA) and up to 4.5 Years of Exposure. Rieke Alten[1], Jeffrey L. Kaine[2], Edward Keystone[3], Peter T. Nash[4], Ingrid Delaet[5], Keqin Qi[5] and Mark C. Genovese[6]. [1]Rheumatology Schlossparkklinik, Berlin, Germany, [2]Sarasota Arthritis Center, Sarasota, FL, [3]Mount Sinai Hospital, Toronto, ON, [4]University of Queensland, Brisbane, Australia, [5]Bristol-Myers Squibb, Princeton, NJ, [6]Stanford Univ Medical Center, Palo Alto, CA

Background/Purpose: Biologic therapies for RA can increase the risk of some safety events such as infections, autoimmune events and malignancies. Furthermore, with subcutaneous (SC) biologics, some patients (pts) may experience injection site reactions (ISRs), such as burning and stinging[1]. Integrated analyses of clinical trial data are important to monitor these events over the long term. Here, we investigate such events using integrated clinical

trial data of SC abatacept in a large group of pts with RA refractory to traditional DMARDs.

Methods: Data from the short- and long-term periods of five SC abatacept RA clinical trials were pooled; one Phase IIa and two Phase IIIb randomized controlled trials (ACQUIRE, ALLOW), and two Phase IIIb open-label studies (ATTUNE, ACCOMPANY). Safety events were assessed for pts who received ≥1 dose of SC abatacept (125 mg/week fixed dose). Overall and 6-mthly (up to Mth 24) incidence rates (IRs) were calculated as number of patients with events per 100 patient–years (p–y) of exposure, with 95% confidence intervals (CIs). IRs post Mth 24 not shown due to low pt numbers at time of data analysis.

Results: The analysis included 1879 pts with 3086 p–y of exposure. Mean (range) exposure was 20 (2–56) mths; 1191 pts had >18 mths of exposure. Serious infections occurred at an IR (95% CI) of 1.94 (1.50–2.50), in 59 (3.1%) pts; the most frequent (IR>0.10) were pneumonia (0.36 [0.20–0.65]), urinary tract infection (0.16 [0.07–0.39]) and gastroenteritis (0.13 [0.05–0.35]). TB, pulmonary TB and peritoneal TB were recorded in one pt each (0.03 [0.00–0.23] each). Malignancies excluding non-melanoma skin cancer occurred at an IR of 0.68 (0.45–1.05) in 21 (1.1%) pts. The most frequent (IR>0.10) malignancies were basal cell carcinoma (0.46 [0.27–0.77]), breast cancer and squamous cell carcinoma of skin (0.16 [0.07–0.39] each). Autoimmune events occurred with an IR of (1.28 [0.93–1.75]) in 39 (2.1%) pts. The most frequent (IR>0.10) autoimmune events were psoriasis (0.29 [0.15–0.56]) and Sjögren's syndrome (0.19 [0.09–0.43]). IRs of serious infections, malignancies and autoimmune events did not increase with increasing exposure (Table). ISRs occurred with an IR of (2.22 [1.74–2.82]) in 66 (3.5%) pts; the most frequent were erythema, hematoma, pain and pruritus (0.46 [0.27–0.77] each). Events were mostly (94%) mild in intensity; two pts discontinued due to ISRs. ISRs mainly occurred during the first 6 mths (Table).

Table 1. Incidence rates of events in pts receiving SC abatacept (N=1879)

Mths	0–6	6–12	12–18	18–24
Serious infections*	2.42 (1.60–3.68)	2.12 (1.33–3.36)	1.28 (0.66–2.46)	1.51 (0.68–3.36)
	n = 22	n = 18	n = 9	n = 6
Malignancies excl. NMSC	0.44 (0.16–1.17)	1.17 (0.63–2.17)	0.56 (0.21–1.49)	0.25 (0.03–1.75)
	n = 4	n = 10	n = 4	n = 1
Autoimmune events†	1.54 (0.91–2.60)	0.94 (0.47–1.87)	0.99 (0.47–2.08)	1.75 (0.84–3.68)
	n = 14	n = 8	n = 7	n = 7
Total ISRs†	5.59 (4.24–7.38)	0.72 (0.32–1.59)	1.30 (0.68–2.50)	0
	n = 50	n = 6	n = 9	

* Subset of serious adverse events; †Pre-specified based on a list of MedDRA preferred terms; Data are IR (95% CI); NMSC = non-melanoma skin cancer; ISR=injection site reaction; Mths 0–6 is Day 1–Day 180, Mths 6–12 is Day 181–Day 360, Mths 12–18 is Day 361–Day 540, Mths 18–24 is Day 541–Day 720.

Conclusion: These pooled safety data, from 1879 pts with up to 4.5 yrs of treatment and 3086 p–y of exposure, demonstrate that long-term treatment with SC abatacept is well tolerated, and does not lead to an increase in infections, malignancies or autoimmune events over time. ISRs were generally mild and infrequent. Data presented here are consistent with observations for IV abatacept[1].

Efficacy, Safety and Pharmacokinetics of Subcutaneous Abatacept in Patients with Rheumatoid Arthritis, with or without An Intravenous (IV) Loading Dose. Peter T. Nash[1], Charles L. Ludivico[2], Ingrid Delaet[3], Keqin Qi[3], Bindu Murthy[3], Michael Corbo[4] and Jeffrey L. Kaine[5]. [1]University of Queensland, Brisbane, Australia, [2]East Penn Rheumatology Associates, East Stroudsburg, PA, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Bristol-Myers Squibb (at time of study), Princeton, NJ, [5]Sarasota Arthritis Center, Sarasota, FL

Background/Purpose: Use of IV abatacept is well established in pts with RA. Pivotal trials of SC abatacept ± MTX have shown efficacy. Some trials included an IV abatacept loading dose to rapidly achieve therapeutic steady-state drug concentrations (C_{minss} ≥10 μg/mL). We evaluated open-label data from two Phase III trials to examine the 3-mth efficacy and clinical pharmacokinetics (PK) of SC abatacept (125 mg/wk), with/without IV loading, in pts with established DMARD-refractory RA.

Methods: In the initial open-label (OL) period of the ALLOW trial, pts received SC abatacept + MTX, with IV loading on Day 1 (~10 mg/kg according to weight; SC + IV load). In the OL ACCOMPANY trial, pts were stratified to SC abatacept ± MTX, with no IV load (SC only). Pts in both trials had RA refractory to biologic or non-biologic DMARDs. Data up to Mth 3 for disease activity (DAS28-CRP) and physical function (HAQ-DI) were based on pts with data available (clinically meaningful responses [CMRs] defined as reductions of ≥1.2 in DAS28 and ≥0.3 in HAQ-DI). PK was assessed for both trials using a validated ELISA to determine abatacept serum trough concentrations (C_{min}).

Results: A total of 167 pts entered ALLOW and received SC abatacept+ IV load, 100 pts entered ACCOMPANY and received SC only (± MTX). Mean (SD) baseline demographics were generally similar between studies, although baseline disease was less severe in SC + IV versus SC only pts; tender and swollen joints were 14.3 (10.3) and 11.0 (5.7) vs 24.1 (16.2) and 17.2 (12.1), DAS28 was 4.7 (0.9) vs 5.4 (1.4) [n=98] and HAQ-DI was 1.3 (0.7) vs 1.4 (0.7) [n=99]. Mean (SD) disease duration was 7.5 (8.0) yrs vs 10.1 (11.1) yrs in SC + IV versus SC only pts, respectively. All SC + IV pts and 81% of SC only pts had previously failed MTX; 11 and 23% of pts had previously received biologics. Improvements in DAS28 and HAQ-DI were generally comparable with or without IV load (Table); CMRs were observed in both trials by ≤Mth 2. By Mth 3, mean (SD) DAS28 was 3.2 (1.3) vs 3.8 (1.4) for SC + IV vs SC only, respectively, and HAQ-DI was 0.7 (0.7) vs 1.1 (0.7). Mean (SE) changes in DAS28 from baseline to Mths 1, 2 and 3 were –1.00 (0.07), –1.35 (0.08) and –1.53 (0.10) for SC + IV and –0.85 (0.11), –1.35 (0.12) and –1.57 (0.14) for SC only. Occurrence of serious adverse events, including infections, was similar with or without IV load. PK assessments indicated target therapeutic C_{min} was achieved by Day 15 in 88% of pts in the SC only study. C_{minss} concentrations were achieved by Mth 2 in both trials and remained consistent to Mth 3 (Table).

Mean percentage change from baseline (95% CI)	ALLOW (SC + IV load)	ACCOMPANY (SC only)		
	DAS28 (CRP)	HAQ-DI	DAS28 (CRP)	HAQ-DI
Month 1	−21.7 (−24.8, −18.7)	−27.3 (−32.6, −22.0)	−14.2 (−19.1, −9.3)	−21.3 (−28.7, −13.9)
	n = 165	n = 166	n = 95	n = 94
Month 2	−28.0 (−31.5, −24.6)	−37.7 (−44.7, −30.8)	−24.0 (−28.4, −19.6)	−29.8 (−37.5, −22.1)
	n = 164	n = 163	n = 96	n = 93
Month 3	−31.6 (−35.5, −27.7)	−44.6 (−51.8, −37.5)	−27.8 (−32.8, −22.9)	−32.2 (−40.4, −24.0)
	n = 161	n = 163	n = 94	n = 92
Geometric mean (CV%) of C_{min} (μg/mL)	**ALLOW (SC + IV load)**		**ACCOMPANY (SC only [without MTX − with MTX])**	
Month 0.5 (Day 15)	Not collected		11.2 (44) − 13.7 (30)	
			n = 81	
Month 2	27.0 (37)		21.7 (47) − 24.4 (28)	
	n = 144		n = 86	
Month 3	27.6 (40) n = 132		20.4 (41) − 28.8 (37)	
			n = 86	

CI = confidence interval; ALLOW = Evaluation of **A**batacept Administered Subcutaneous**L**y in Adu**L**ts With Active Rheumat**O**id Arthritis: Impact of **W**ithdrawal and Reintroduction on Immunogenicity, Efficacy and Safety; ACCOMPANY = **A bataC**ept in Subje**C**ts with Rheumat**O**id Arthritis Ad**M**inistered **P**lus or Minus Background MTX Subcut**AN**eous**lY**; SC = subcutaneous; IV = intravenous; DAS28 = Disease Activity Score 28; CRP = C-reactive protein; HAQ-DI = Health Assessment Questionnaire-Disability Index; CV = co-efficient of variation; C_{min} = serum trough concentration.

Conclusion: Comparable improvements in clinical efficacy were observed over the first 3 mths, with or without IV loading. Target PK values required for efficacy were achieved in both regimens, and the majority of pts achieved therapeutic abatacept concentrations by Day 15 without IV loading. These data, although a non-comparative cross-study assessment, support the hypothesis that IV loading may not be needed to achieve desired efficacy with SC abatacept.

Prevention of Cartilage Destruction by Etanercept (PRECEPT) Study: the Comparison of Joint Destruction Between Low-Dose and Standard-Dose Etanercept in Rheumatoid Arthritis. Masahiro Tada, Tadashi Okano, Yuko Sugioka, Kenji Mamoto, Shigeyuki Wakitani, Hiroaki Nakamura and Tatsuya Koike. Osaka City University Medical School, Osaka, Japan

Background/Purpose: The efficacy and safety of etanercept (ETN) in patients with rheumatoid arthritis (RA) have been demonstrated in clinical trials. The combination therapy of ETN and methotrexate could inhibit the progression of joint destruction and repair the bone erosion. However, it is a fact that biologics therapy forces patients to an economic burden. To reduce the treatment cost of biologic agents, low-dose ETN has been administered without evidence in real world practice. Although clinical symptom might be improved by low-dose ETN, it has not been reported whether low-dose ETN could inhibit joint destruction. To evaluate the prevention of joint destruction and clinical efficacy of low-dose ETN (25mg/W), we compared with standard-dose ETN (50mg/W) in RA patients.

Methods: This prospective, randomized, open-label study was registered

with the UMIN Clinical Trials Registry (UMIN000001798). This study was conducted at 7 sites in Japan between July 2008 and February 2010. 70 patients were randomly assigned to receive either ETN 50mg or 25mg at subcutaneous injection for 52 weeks. The primary end point of this study was the variation of modified total Sharp score (TSS), and the secondary end points were variation of disease activity score 28 (DAS28), modified Health Assessment Questionnaire (mHAQ), and adverse events. TSS was performed at baseline and after one year. No progression was estimated as *delta* TSS <= 0.5 and no progression rate was compared between groups. DAS28 and mHAQ were calculated at baseline and after 4, 8, 12, 24 and 52 weeks. No progression rate was analysed by Fisher's exact probably test. The characteristics between groups were tested using the Mann-Whitney and Fisher's exact probably test.

Results: Patients had mean disease duration of 9.2 years, DAS28 of 5.45, and annual progression of TSS of 26.1 at baseline. There were no significant differences in all parameters between groups at baseline (Table 1). At week 52, no progression rate of 25 mg/W group (36.7%) was significantly less than that of 50mg/W group (67.7%) (P = 0.041). *Delta* TSS of 25mg/W (1.03) was higher than that of 50mg/W group (−0.13) in Table 2. DAS 28 was significantly improved at week 4 and the effect of treatment lasted for one year in both groups, without significant differences between groups. There were no differences in mHAQ and adverse events between groups.

Table 1. Characteristics of patients at baseline

	Etanercept 25mg/W	Etanercept 50mg/W
Age, years (±SD)	61.7 ± 11.8	59.6 ± 10.0
Women, no. (%)	74.3	85.7
Weight, kg (±SD)	55.3 ± 9.0	51.9 ± 10.1
BMI, kg/m^2 (±SD)	22.8 ± 2.7	21.4 ± 3.0
Disease duration, years (±SD)	9.0 ± 8.0	9.3 ± 6.5
DAS28 - ESR (±SD)	5.36 ± 1.24	5.53 ± 1.25
SDAI (±SD)	23.9 ± 13.5	25.7 ± 12.9
mHAQ score (±SD)	0.9 ± 0.6	1.0 ± 0.6
modified total Sharp score (±SD)	136.5 ± 107.2	183.2 ± 102.6
Erosion score (±SD)	74.2 ± 65.4	99.3 ± 64.4
Joint space narrowing score (±SD)	62.3 ± 43.2	83.9 ± 39.3
Annual TSS progression (±SD)	24.6 ± 23.4	27.5 ± 21.0

Table 2. Change in radiographic scores at week 52

	Etanercept 25mg/W	Etanercept 50mg/W
modified total Sharp score	1.03 (−0.23 to 2.29)	−0.13 (−1.46 to 1.20)
Erosion score	0.47 (−0.22 to 1.16)	−0.26 (−1.00 to 0.48)
Joint space narrowing score	0.56 (−0.15 to 1.28)	0.13 (−0.65 to 0.91)

Conclusion: Low-dose ETN was not inferior to standard-dose ETN in the effect on clinical manifestations. However, from the viewpoint of joint destruction suppression, it was inferior to the effect of standard-dose ETN.

No Change in the Levels of PPD Reaction During Treatment with TNF Inhibitors in Rheumatoid Arthritis Patients in Japan, a Country with High Morbidity of Tuberculosis. Shotaro Yamamoto, Shino Takatori, Masahiro Iwamoto, Katsuya Nagatani, Kohei Ikenoya and Seiji Minota. Jichi Medical University, Tochigi, Japan

Background/Purpose: TNF inhibitors (TNFi) may depress cell-mediated immunity resulting in a higher incidence of tuberculosis among RA patients. Post-marketing surveillance of infliximab in Japan revealed 14 cases of tuberculosis out of 5,000 (0.28%) that developed after starting infliximab. The morbidity is ~6 times higher than that in the general population in Japan. To estimate the level of cell-mediated immunity and the risk of tuberculosis reactivation, levels of PPD reaction were examined before and after treatment with TNFi.

Methods: Of 209 RA patients treated with TNFi (infliximab or etanercept) for more than 1 year, written informed consent was obtained from 91 (43.5%), who were included in this study. The study group included: 76 females, 15 males; age, 55.3 ± 14.3 years; infliximab 40, etanercept 51; prednisolone dose at the start, 3.7 ± 2.9 mg/day; and duration of TNFi treatment, 2.5 ± 1.0 years. DMARDs used simultaneously with TNFi included methotrexate in 69, sulfasalazine in 16, bucillamine in 6, actarit in 4, leflunomide in 1, tacrolimus in 1, and azathioprine in 1. The PPD reaction level was measured 48~72 hr after intra-dermal injection and categorized as: diameter < 10 mm, negative (N); ≥ 10 mm, weakly positive (WP); ≥ 10 mm with induration, intermediately positive (IP); and IP with double-circumscribed erythema, vesicles or necrosis, strongly positive (SP). PPD skin tests were performed before and after > 1 year of continuous TNFi. All patients with IP and SP received prophylaxis with isoniazid as recommended.

Results: Just before the introduction of TNFi, 49.4%, 20.9%, 22.0% and 7.7% of the patients showed PPD reactions of N, WP, IP and SP, respectively, and after >1 year of TNFi, 48.3%, 22.0%, 17.6% and 12.1% exhibited PPD reactions, respectively. There was no significant difference in the reactions before and after TNFi-treatment (Wilcoxon signed rank test [p = 0.652]). PPD reaction levels were in the same category in 54.9%, decreased by more than 1 category in 23.1% and increased by more than 1 category in 22.0%, and highly correlated with a Spearman's correlation coefficient of 0.491 (p < 0.001). Only one patient initially SP became WP, whereas, no patients initially SP became N. This patient had been in clinical remission of RA after TNFi-treatment and showed no sign of compromised immunity. Two patients initially N became SP at the second PPD test. Both were in clinical remission of RA, and showed no sign of tuberculosis.

Conclusion: Higher positivity rates for PPD reaction in this study compared to other studies may be due to BCG inoculation, which is routine in Japan. Overall, levels of PPD reaction stayed unchanged before and after > 1 year of continuous TNFi. Two patients initially N became SP without any sign of tuberculosis; this could be due to a booster effect of PPD or a dormant reactivation of tuberculosis that cured spontaneously. One patient who became WP after the initial SP needs to be followed carefully for possible immunosuppression. Since no RA patients developed overt tuberculosis until now, recommended prophylaxis against tuberculosis would be appropriate.

Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor, in the Treatment of Rheumatoid Arthritis: Open-Label, Long-Term Extension Studies up to 36 Months. J. Wollenhaupt[1], J. C Silverfield[2], E. B. Lee[3], S. Wood[4], K. Soma[5], L. Wang[5], H. Nakamura[6], Y. Komuro[6], C. I. Nduaka[5], D. Gruben[5], S. H. Zwillich[5] and J. D. Bradley[5]. [1]Teaching Hospital of the University of Hamburg, Hamburg, Germany, [2]Tampa Medical Group, P.A., Tampa, FL, [3]Hanyang University Hospital, Seoul, [4]Pfizer Inc., Groton, NJ, [5]Pfizer Inc., Groton, CT, [6]Pfizer Inc., Tokyo, Japan

Background/Purpose: Tofacitinib (CP-690,550) has recently reported efficacy and safety data in pts with active rheumatoid arthritis (RA) in randomized Phase 3 studies of up to 12 months (mo) treatment duration. Here we report the safety and tolerability of tofacitinib and the durability of clinical response up to 36 mo in long-term extension (LTE) studies in pts with RA.

Methods: Data were pooled from two Phase 2/3, open label studies (NCT00413699, NCT00661661) involving pts who had participated in prior randomized studies of tofacitinib (PRST). Treatment was initiated with either 5 or 10 mg tofacitinib twice daily (BID). The baseline was that of the PRST for pts who enrolled within 14 days of PRST participation; if enrollment was >14 days after PRST participation, baseline was the start of the LTE study. The primary endpoints were laboratory safety and adverse event (AE) reports. Secondary endpoints included ACR20, ACR50, and ACR70 response rates, DAS28-4(ESR), and the HAQ-DI. Data are reported for all patients regardless of dose.

Results: A total of 3227 pts were treated for a total duration of 3118 patient-years (pt-y); mean (maximum) duration of treatment was 349 (1456) days (d). 441 pts (13.7%) discontinued from the LTE studies: 223 (6.9%) due to AEs and 42 (1.3%) due to insufficient clinical response. A total of 7747 treatment-emergent AEs (TEAEs) were reported in 2135 patients (66.2%). The most commonly reported class of TEAEs was infections and infestations (39.7%), followed by gastrointestinal disorders (18.8%), musculoskeletal and connective tissue disorders (15.9%), and investigations (11.7%). The most frequent investigator-reported TEAEs (n, %) by MedDRA preferred term were nasopharyngitis (322, 10.0%), upper respiratory tract infection (236, 7.3%) and urinary tract infection (150, 4.6%). Serious AEs were reported in 337 pts (10.9%) with an incidence rate per 100 pt-y of 11.34 (95% CI 10.20, 12.62). Serious infection events were reported in 93 pts (2.9%) with an incidence rate per 100 pt-y of 3.01 (95% CI 2.45, 3.68).

Decreased hemoglobin (≥2 g/dL from baseline, or hemoglobin <8) was observed in 81 pts (2.5%). Raised aminotransferases (>3 × upper limit of normal) were observed in 1.7% (alanine) and 1.1% (aspartate) of evaluable pts. Moderate to severe neutropenia (absolute neutrophil count [ANC] $<1.5 \times 10^3/mm^3$) was reported in 16 pts (0.5%); no serious neutropenia (ANC $<0.5 \times 10^3/mm^3$) was reported. Confirmed increase in creatinine (≥33% from baseline) was noted in 393 (12.2%) pts. Mean overall values for laboratory safety tests were stable over time.

ACR20, ACR50, and ACR70 response rates were consistent over time

between Mo 1 and 36. At Mo 1, ACR20, ACR50, and ACR70 response rates for patients initially treated with tofacitinib 5 or 10 mg BID were 71.0%, 47.3%, and 26.3%, respectively; corresponding rates at Mo 36 were 72.7%, 52.3%, and 35.2%, respectively.

Mean DAS28-4(ESR) was 6.25 at baseline, and was reduced to approximately 3.5 between Mo 1 and 36. Mean HAQ-DI score was 1.41 at baseline and improved to approximately 0.8 between Mo 1 and 36.

Conclusion: Treatment with tofacitinib at doses of 5 or 10 mg BID in pts with RA demonstrated a well-tolerated safety profile and sustained long-term efficacy over a 36-mo period.

408

Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor, or Adalimumab Versus Placebo in Patients with Rheumatoid Arthritis on Background Methotrexate: A Phase 3 Study. R.F. van Vollenhoven[1], R. M. Fleischmann[2], S. B. Cohen[3], E. B. Lee[4], G. Meijide[5], S. Wagner[6], S. Forejtova[7], S. H. Zwillich[8], D. Gruben[8], T. Koncz[9], G. Wallenstein[8], S. Krishnaswami[8], J. D. Bradley[8], B. Wilkinson[8] and the ORAL Standard investigators[10]. [1]Karolinska Institute, Stockholm, Sweden, [2]Metroplex Clinical Research Center, Dallas, TX, [3]Metroplex Clinical Research Centre, Dallas, TX, [4]Seoul National University, Seoul, South Korea, [5]Hospital Ntra. Sra. de la Esperanza, Santiago de Compostela, Spain, [6]Internistische Schwerpunktpraxis für Rheumatologie, Halle, Germany, [7]Revmatologicky ustav no 5, Prague, Czech Republic, [8]Pfizer Inc., Groton, CT, [9]Pfizer Inc., New York, NY, [10]Groton, CT

Background/Purpose: Tofacitinib (CP-690,550) is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator in rheumatoid arthritis (RA). This 12-month (Mo) study (NCT00853385) compared the efficacy and safety of tofacitinib and an active comparator, adalimumab (ADA), vs placebo (PBO) in pts with active RA with inadequate response to methotrexate (MTX).

Methods: Pts on background MTX were randomized in a 4:4:4:1:1 ratio to 1 of 5 sequences: tofacitinib 5 mg BID; 10 mg BID; ADA 40 mg subcutaneous injections (Q2W); PBO advanced to tofacitinib 5 mg BID; and PBO advanced to 10 mg BID. All pts self-administered injections Q2W (ADA or PBO). Pts on PBO advanced to tofacitinib at Mo 6, or at Mo 3 if non-responders (<20% reduction from baseline in swollen/tender joint counts).

Results: 717 pts were treated. Pts were comparable at baseline for age, disease duration, HAQ-DI, DAS28, and %RF positive. Tofacitinib 5 and 10 mg BID were statistically superior to PBO for all primary efficacy endpoints (Table). ADA was also superior to PBO for these endpoints. Significant ACR20, ACR50, and HAQ-DI responses were seen vs PBO by Mo 1. Efficacy results for tofacitinib and ADA were numerically similar for all outcomes. About half the pts in the tofacitinib 5 and 10 mg BID, ADA, and PBO groups experienced ≥1 adverse event (AE). Most AEs were mild; the % of pts who experienced a serious AE (SAE) was numerically higher in the tofacitinib groups. There were 2 deaths: sepsis syndrome (5 mg BID) and cardiac arrest (ADA), and 2 pts with pulmonary tuberculosis (both 10 mg BID). In Mo 0–3, serious infection events were reported for 3 (5 mg BID), 4 (10 mg BID), and 1 (PBO) pts; in Mo 3–6, for 2 (5 mg BID), 1 (10 mg BID), and 2 (ADA) pts. Decreases in mean neutrophil counts were seen with tofacitinib and ADA; increases in LDL and HDL, and small increases in serum creatinine were seen with tofacitinib. Safety results for Mo 6–12 for tofacitinib and ADA were consistent with safety for Mo 0–6 (Table).

Table. Primary and selected secondary efficacy endpoints and safety data

Efficacy		5 mg BID n=204	10 mg BID n=201	ADA 40 mg SC Q2W n=204	PBO n=108

† Non-responder imputation; ‡mixed-effect longitudinal linear model; NA, not applicable

Conclusion: Tofacitinib demonstrated rapid, significant, and clinically meaningful reductions in signs and symptoms of RA and physical function. No new tofacitinib safety signals were detected. Efficacy results with tofacitinib and ADA, when both were given on MTX background, were similar.

409

Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor: Analysis of Infections and All-Cause Mortality Across Phase 3 and Long-Term Extension Studies in Patients with Rheumatoid Arthritis. S. Cohen[1], S. C. Radominski[2], P. Asavatanabodee[3], S. P. Wood[4], K. Soma[4], C. I. Nduaka[4], L. Wang[4], D. Gruben[4], H. Valdez[5], S. H. Zwillich[4] and J. Bradley[4]. [1]Metroplex Clinical Research Centre, Dallas, TX, [2]Universidade Federal do Paraná, Curitiba, Brazil, [3]Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand, [4]Pfizer Inc., Groton, CT, [5]Pfizer Inc., New York, NY

Background/Purpose: Tofacitinib (CP-690,550) is a novel oral, selective Janus kinase inhibitor being investigated in Phase 3 (P3) as a targeted immunomodulator for the treatment of RA. Here we show pooled P3 and long-term extension (LTE) infection and mortality data for pts with RA.

Methods: Data were pooled from five randomized double-blind P3 RA studies. Most studies required stable background DMARDs to which tofacitinib was added (NCT IDs: 00960440, 00847613, 00856544, 00853385); one study evaluated tofacitinib monotherapy (NCT ID: 00814307). Pts from these studies had the option to join pts from P2 studies in one of two open-label, LTE studies (NCT IDs: 00413699, 00661661). LTE pts were treated with tofacitinib 5 or 10 mg twice daily (BID) and generally continued their background DMARD therapy as appropriate.

Deaths in the P3 programs and those that occurred after February 25, 2009 in the LTE studies were classified by an independent, blinded Cardiovascular Safety Endpoint Adjudication Committee (CV-SEAC).

Results: A total of 3030 pts with RA from P3 and 3227 from LTE studies were included in the analyses, resulting in approximately 2000 and 3000 pt-years (pt-y) of exposure to tofacitinib, respectively (Table). In the P3 studies, there were a total of 12 CV-SEAC-classified all-causality deaths (5 due to infections, 3 other [noncardiac], 2 cardiac, 1 trauma and 1 cause unknown) and 2 deaths with adjudication not available. In the LTE studies, there were a total of 8 CV-SEAC-classified all-causality deaths (3 due to infection, 2 other [noncardiac], 1 cancer, 1 cardiac, and 1 cause unknown) and 12 deaths were not adjudicated.

Concerning infections, the most common treatment-emergent infection adverse events (AEs) (>5% in any treatment group) in LTE studies were nasopharyngitis, upper respiratory tract infection, urinary tract infection, bronchitis, herpes zoster, and influenza. Infection AEs in P3 studies were all <5% in any treatment group. Most infection AEs were mild or moderate and discontinuation due to infection was infrequent (approximately 1–2%). There was no apparent increase in the rate of non-serious or serious infections over time. The rates of infection events were similar regardless of whether pts received tofacitinib as monotherapy or with background DMARDs. Although the rate of serious infections among tofacitinib 10 and 5 mg BID groups was similar in P3, in the LTE studies that rate for 10 mg BID was approximately twice that of 5 mg BID (4.9 vs 2.3 /100 pt-y). Events of opportunistic infections, including tuberculosis, were uncommon.

Table. Exposure estimates and incidence rates of all-cause mortality and serious infections in tofacitinib P3 and LTE studies

	P3 studies			LTE studies
	Tofacitinib All doses N = 3030	Placebo N = 681	Adalimumab N = 204	Tofactinib All doses N = 3227
All-cause mortality				
Deaths, n (%)	12 (0.40)	1 (0.15)	1 (0.49)	20 (0.62)
Exposure, pt-y	2098	203	179	3118
Incidence rate, events/100 pt-y (95% CI)	0.572 (0.325, 1.007)	0.494 (0.070, 3.505)	0.559 (0.079, 3.967)	0.641 (0.414, 0.994)
Serious infections				
Unique pts with events, n (%)	61 (2.0)	3 (0.44)	3 (1.5)	93 (2.9)
Exposure, pt-y	2094	202	179	3101
Incidence rate, events/100 pt-y (95% CI)	2.912 (2.266, 3.743)	1.482 (0.478, 4.594)	1.679 (0.542, 5.206)	2.999 (2.448, 3.675)

Conclusion: In P3 and LTE studies, mortality rates were consistent with the expected rate in pts with active RA, including those receiving therapy with other DMARDs. The safety profile of tofacitinib with regard to infection AEs was consistent with the previously reported P2 experience and no new safety signals were observed.

410

Impact of Body Mass Index on Response to Etanercept Therapy in Subjects with Moderately Active Rheumatoid Arthritis in the PRESERVE Trial. Josef S. Smolen[1], Annette Szumski[2], Andrew S. Koenig[2] and Thomas V. Jones[3]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Pfizer Inc., Collegeville, PA, [3]Pfizer, Inc, Collegeville, PA

Background/Purpose: The role of adipose tissue in immune-mediated inflammatory diseases such as rheumatoid arthritis (RA) has not been well studied. Patients with RA and a high body mass index (BMI) have demonstrated significantly less radiographic joint damage[1–2] than those with low BMI. Paradoxically, in a recent study, increasing BMI was negatively correlated with clinical response to biologic therapy in patients with active RA.[3] The relationship between BMI and responses to etanercept (ETN)-methotrexate (MTX) treatment was assessed in subjects with moderately active RA in the PRESERVE trial.

Methods: Subjects with DAS28 >3.2 and ≤5.1 despite stable doses of oral MTX received open-label ETN 50 mg once weekly (QW) plus MTX (titration to ≤25 mg/week through week 28) for 36 weeks (Period 1). Posthoc analyses of response by BMI category at baseline were conducted in subjects who received ≥1 treatment dose and had Week-36 assessments. For continuous outcomes, BMI trend was analyzed as an ordered category in ANCOVA models, adjusted for baseline response; for dichotomous outcomes, BMI trend was analyzed as ordered BMI categories from a CMH test of non-zero correlation. Analyses were also conducted in rheumatoid factor positive (RF+) and RF negative (RF-) subgroups.

Results: Of 761 subjects analyzed, 386 subjects (50.7%) had a baseline BMI of <25 kg/m^2, 248 (32.6%) had a BMI of 25–<30 kg/m^2, and127 (16.7%) had a BMI of ≥30 kg/m^2. Significant negative correlations ($P<0.05$) were observed between BMI categories of <25, 25–<30, and ≥30 kg/m^2 and Week-36 adjusted mean changes for DAS28 (−2.1, −2.1, and −1.8, respectively), CDAI (−12.3, −12.0, −10.4), and SDAI (−12.9, −12.7, −10.8), but not for HAQ (−0.6, −0.5, −0.5) or annualized change in mTSS (0.3, 0.5, 0.4). Similar correlations between BMI and Week-36 changes were seen in RF+ subjects (n=550); tests in RF− subjects (n=207) were not adequately powered due to the small BMI ≥30 subgroup (n=33). Increasing BMI was associated with a significant decreasing trend ($P<0.05$) in the proportion of subjects achieving Week-36 remission based on DAS28 (<2.6), CDAI (≤2.8), and SDAI (≤3.3) and normal HAQ (≤0.5) but not radiographic non-progression (annualized Δ mTSS ≤0).

Summary of Responses to ETN-MTX Therapy by BMI Category at Week 36 in Subjects With Moderate RA

		% of Subjects (n/N)			P
	Variable	BMI <25 kg/m^2	BMI 25–<30 kg/m^2	BMI ≥30 kg/m^2	value*
DAS28	Remission (<2.6)	70.8 (271/383)	68.1 (171/251)	56.7 (72/127)	0.01
	LDA (<3.2)	87.5 (335/383)	86.5 (217/251)	79.5 (101/127)	0.05
CDAI	Remission (≤2.8)	29.5 (113/383)	28.0 (70/250)	17.3 (22/127)	0.02
	LDA (<10)	85.4 (327/383)	81.2 (203/250)	78.7 (100/127)	0.06
SDAI	Remission (≤3.3)	27.7 (105/379)	26.7 (66/247)	16.0 (20/125)	0.02
	LDA (<11)	86.8 (329/379)	83.8 (207/247)	81.6 (102/125)	0.13
HAQ	Normal (≤0.5)	60.1 (230/383)	58.2 (145/249)	44.1 (56/127)	0.01
mTSS	Non-progression (Δ≤0)	82.1 (294/358)	83.2 (193/232)	81.5 (97/119)	0.99

* From a Cochran-Mantel-Haenszel (CMH) test of the non-zero correlation between ordered BMI categories and ordered Week-36 response categories. DAS28 = Disease Activity Score based on a 28-joint count; CDAI = Clinical Disease Activity Index; SDAI = Simplified Disease Activity Index; HAQ = Health Assessment Questionnaire; mTSS = modified Total Sharp Score

Conclusion: Subjects with moderate RA and higher BMIs demonstrated a diminished clinical response after 36 weeks of etanercept-MTX treatment compared with their counterparts with lower BMIs. Consistently high rates of radiographic non-progression were seen independent of BMI. Similar trends were found in RF+ subjects. Further research is needed to evaluate the relationship between adipose tissue, treatment outcomes, and RF in RA.

Risk of Malignancy in Australian Rheumatoid Arthritis Patients Treated with Tumour Necrosis Factor Inhibitors. Sharon Van Doornum[1], Margaret P. Staples[2], Lynette March[3], Marissa N. Lassere[4] and Rachelle Buchbinder[5]. [1]The University of Melbourne, Melbourne, Australia, [2]Cabrini Institute and Monash University, Malvern, Australia, [3]University of Sydney, Insitute of Bone and Joint Research, Royal North Shore Hospital, St Leonards NSW, Australia, [4]St. George Hospital, Kogarah, Australia, [5]Cabrini Institute and Monash University, Malvern, Victoria, Australia

Background/Purpose: To investigate the risk of cancer in Australian rheumatoid arthritis (RA) patients treated with tumour necrosis factor inhibitors (TNFi).

Methods: The Australian Rheumatology Association Database (ARAD) is a national prospective database established to monitor the long term outcomes of biologic therapy in Australian patients with inflammatory arthritis. Data concerning drug therapy and morbidity are collected from patients at 6-monthly intervals using self-reported questionnaires. Ascertainment of cancers is achieved using histology confirmed cancer and/or linkage with national cancer statistics. We compared the incidence of cancer in "biologic-naïve" RA patients with the incidence of cancer in RA patients after commencement of TNFi therapy. Person-years of exposure for biologic-naïve patients were calculated from birth until cancer diagnosis, death, commencement of a TNFi or analysis cut-off date. For TNFi-treated patients, exposure began at the start date of TNFi therapy and continued until cancer diagnosis, death or analysis cut-off date. The relative risk (RR) of cancer after exposure to TNFi therapy was calculated by comparison with the biologic-naïve RA patients using the Mantel-Cox method with a logrank test of significance, with adjustment for age, gender and smoking status.

Results: We identified 2962 RA patients in ARAD, including 808 patients who never received TNFi treatment and 2154 patients who did receive treatment with TNFi therapies. Of the "never TNFi-treated" group, 70% were female, 80% had ever taken methotrexate and 56% had ever taken prednisolone. Of the "TNFi-treated" group, 73% were female, 97% had ever taken methotrexate and 88% had ever taken prednisolone. Follow-up was 19,158 person-years for the patients receiving TNFi therapies and 38,313 person-years for biologic-naïve patients. The table shows the number of cancers in both groups and the adjusted relative risk of cancer in the TNFi treated RA patients compared with the biologic-naïve RA patients.

Site	Biologic-naïve RA 38,313 patient years	TNFi-treated RA 19,158 patient years	RR*	95% CI
All cancers, n	152	63	**2.20**	**1.62–2.98**
Melanoma, n	30	14	**2.65**	**1.41–4.96**
Non-melanoma skin cancer, n	150	98	**3.36**	**2.56–4.35**
Lung, n	7	6	2.48	0.79–7.82
Breast, n	29	7	1.47	0.63–3.45
Bowel, n	21	1	0.28	0.05–1.69
Prostate, n	20	11	2.12	0.99–4.56
Thyroid, n	5	1	1.68	0.19–15.11
Kidney, n	4	2	2.21	0.29–17.05
Cervix, n	9	1	1.36	0.22–8.56
Lymphoid cancers, n	8	7	**6.52**	**2.11–20.18**

* adjusted for gender, age and smoking status

The adjusted relative risk of melanoma, non-melanoma skin cancer and lymphoma was significantly increased in the TNFi-treated RA patients. Restricting the analysis to those RA patients who ultimately received TNFi therapy (ie a before and after comparison) did not change the results significantly.

Conclusion: Using ARAD data we found a significantly increased risk of lymphoma and skin cancer in Australian RA patients who have received TNFi therapy compared to RA patients who are biologic-naïve. These observational registry data must be interpreted with caution, particularly in light of possible differences in disease severity between the compared groups, however this study provides an important signal which warrants further investigation.

412

Clinical Response within 12 Weeks As a Predictor of Future Low Disease Activity in Early RA Patients: Results From the TEAR Trial. Jeffrey R. Curtis[1], Theresa McVie[2], Ted R. Mikuls[3], James R. O'Dell[4], S. Louis Bridges Jr.[5], Larry W. Moreland[6] and Stacey Cofield[7]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, [3]Omaha VA and University of Nebraska, Omaha, NE, [4]Univ of Nebraska Med Ctr, Omaha, NE, [5]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [6]University of Pittsburgh, Pittsburgh, PA, [7]Univ of Alabama at Birmingham,, Birmingham, AL

Background/Purpose: Predicting future clinical treatment outcomes based upon early clinical response would be useful to help optimize RA management. However, there is no validated method to allow one to predict response for patients with early RA. We derived and validated a clinical prediction rule to predict low disease activity (LDA) at 1 year among early RA patients participating in the Treatment of Early Aggressive Rheumatoid Arthritis (TEAR) trial.

Methods: We identified TEAR participants who were not in LDA (defined as DAS28 < 3.2) 24 weeks after beginning methotrexate (MTX) and who added either etanercept (E) or sulfasalazine / hydroxychloroquine (triple therapy, or TT). Among these individuals (derivation cohort), predictors within the next 12 weeks were evaluated to characterize LDA 1 year later. Multivariable logistic regression was used to derive a clinical prediction rule which was scaled to approximate the likelihood of response ranging from 0 – 100%. Variables were selected based upon change in the Akaike's Information Criteria (AIC). Validation of the prediction rule was performed using data from TEAR participants randomized to start MTX+E or TT at baseline ((validation cohort); the outcome for the validation cohort was LDA at 48 weeks.

Results: Among the 186 RA patients in the derivation cohort, mean ± SD age was 50 ± 13 years, median RA disease duration 3.3 +- 6.0 months, mean DAS28 4.9 ± 1.1, mean BMI 30.3 +- 7.6, and 90% RF+. Factors identified in the best-performing prediction model included age, body mass index (BMI), and DAS28 at time of treatment escalation and at 6 and 12 weeks later. A number of additional factors were not predictive of response

By 12 weeks after treatment escalation, 24% of patients were predicted to be responders with 91% accuracy; 39% of patients were predicted to be non-responders with 82% accuracy, and the remaining 37% of patients were classified as 'uncertain responders' at 12 weeks. There were minimal differences in the performance of the prediction rule between MTX+E vs. TT patients.

In the validation cohort (n=103) that tested the prediction rule, 14% of patients were predicted to be responders with 93% accuracy, and 50% of patients were predicted to be non-responders with 73% accuracy; the remaining 36 % of patients were classified as 'uncertain' responders at week 12. In both the derivation and validation cohorts, approximately 80% of patients could be predicted by 12 weeks to be responders or non-responders at 1 year if >= 80% overall accuracy was considered acceptable. Greater accuracy was possible at the expense of fewer patients being able to be classified at 12 weeks.

Conclusion: In a clinical trial of patients with early RA, clinical data collected early after starting or escalating DMARD/biologic treatment could predict LDA at 1 year with high accuracy. In the patients predicted to be non-responders, treatment could be changed earlier to optimize outcomes.

413

Association of Tuberculosis with Anti-Tumor Necrosis Factor Therapy in Asia Using a Number Needed to Harm Approach. B. Tang[1], S. Navarra[2], L. Lu[3], H. Y. Lin[4] and M. U. Rahman[5]. [1]Pfizer Inc., New York, NY, [2]University of Santo Tomas Hospital, Manila, Philippines, [3]Jiaotong University School of Medicine, Manila, Philippines, [4]Veterans General Hospital, Taipei, [5]University of Pennsylvania/Pfizer, Collegeville, PA

Background/Purpose: The risk of tuberculosis (TB) is a major concern for anti-tumor necrosis factor (anti-TNF) therapies, and the association between TB and anti-TNFs are well studied. The risk of developing TB may be higher with the use of monoclonal antibodies (greater risk with adalimumab [ADA], and infliximab [IFX]) compared with the recombinant soluble TNF-receptor etanercept (ETA). The French Research Axed on Tolerance of Biotherapies (RATIO) registry showed that the standardized incidence ratios (SIR) of TB in patients receiving ADA and IFX were statistically different from control groups while SIR of ETA was not statistically different from the control group. No data are available on the relative risks in Asia where TB is endemic. The purpose of this study was to evaluate the risk of TB in patients who are candidates for anti-TNF therapy in Asia.

Methods: SIR of TB for 3 anti-TNF therapies (ADA, IFX and ETA) were based on a published study from the RATIO registry as Asia-specific relative risk data are not currently available. In order to evaluate the impact of anti-TNF therapy on TB in Asia, the 2009 World Bank report of country-specific TB incidences was used to determine the absolute risks. The relative risks and the number needed to harm (NNH; the number of individuals needed to be exposed to the risk factor for one individual to develop the disease) were calculated for each anti-TNF therapy. A sensitivity analysis was performed based on the 95% CI of SIR for each anti-TNF. The number needed to treat (NNT) to avoid one TB event by using ETA instead of ADA or IFX was also calculated.

Results: The RATIO registry reported the SIR of TB as 12.2 (95% CI 9.7, 15.5) for all anti-TNFs. The individual SIRs were 29.3 (95% CI 20.3, 42.4) for ADA, 18.6 (95% CI 13.4, 25.8) for IFX, and 1.8 (95% CI 0.7, 4.3) for ETA. Fifteen Asian countries were included in this analysis (Table). According to the World Bank report the baseline TB incidence among the 15 Asian countries ranged from 0.02 (Japan) to 0.44 (Cambodia). The NNH ranged from 8–163 for ADA, 12–256 for IFX, and 126–2646 for ETA. The sensitivity analysis by 95% CI of the SIRs indicated the results were consistent. The NNH ranged from 5–235 for ADA, 9–355 for IFX, and 53–6803 for ETA.

Table. The relative risks of TB, NNH, and NNT for each anti-TNF therapy in patients in Asia

Country	Baseline incidence (%)	Projected incidence of TB with anti-TNFs (%)			NNH for TB with anti-TNFs			NNT with ETA instead of ADA or IFX to avoid one TB event	
		ADA	IFX	ETA	ADA	IFX	ETA	ADA	IFX
Cambodia	0.44	13.0	8.2	0.8	8	12	126	8	13
Philippines	0.28	8.2	5.2	0.5	12	19	198	13	21
Pakistan	0.23	6.8	4.3	0.4	15	23	241	16	26
Bangladesh	0.23	6.6	4.2	0.4	15	24	247	16	26
Vietnam	0.20	5.9	3.7	0.4	17	27	278	18	30
Indonesia	0.19	5.5	3.5	0.3	18	28	294	19	31
India	0.17	4.9	3.1	0.3	20	32	331	22	35
Thailand	0.14	4.0	2.5	0.2	25	39	406	27	43
China	0.10	2.8	1.8	0.2	36	56	579	38	62
Korea	0.09	2.6	1.7	0.2	38	60	617	40	66
Taiwan	0.09	2.6	NA	0.2	39	NA	637	42	NA
Malaysia	0.08	2.4	1.5	0.1	41	65	669	44	72
Hong Kong	0.08	2.4	1.5	0.1	42	66	678	44	73
Singapore	0.04	1.1	0.7	0.1	95	149	1543	101	165
Japan	0.02	0.6	0.4	0.04	163	256	2646	173	283

NA, not available on market

Conclusion: While taking into account the limitations inherent in applying the RATIO registry data to Asian incidences of TB, the NNH for ADA and IFX appear to be several-fold lower than ETA in Asia. The NNT with ETA instead of ADA or IFX to avoid one TB event is also low. The lower risk of developing TB with ETA relative to ADA and IFX may be more pronounced and more clinically relevant in Asia given the higher endemicity of TB. Further studies using real-world practice data in Asia are suggested.

Background/Purpose: Rheumatoid arthritis (RA) and primary osteoporosis (OP) induce bone fragility. In this study we aimed at identifying differences in the mechanisms involved in bone fragility by comparing gene expression between RA and OP bone samples with similar fracture risk factors.

Methods: Patients with RA submitted to hip replacement surgery were recruited. Trabecular bone microarchitecture was assessed by micro-computed tomography and bone mechanical behavior by compression tests. Bone cell activity was analyzed by studying gene expression. RA patients compared with OP patients were matched for bone mineral density (BMD) and major clinical fracture risk factors (age, gender, BMI, FRAX).

Results: Twenty four patients were included, ten with RA, seven with primary established OP and seven with normal BMD. Bone microarchitecture did not differ between the groups, but mechanical bone properties were similarly decreased in RA and primary OP patients compared to the normal BMD group. RA bone microenvironment, compared to primary OP, had a gene expression profile characterized by upregulated pro-osteoclastogenic cytokines and Dkk-1, increased RANKL/OPG ratio, paralleled by raised expression of factors that promote osteoblastic activity, but with low COL1A1 expression.

Conclusion: Bone fragility in RA patients is induced by an unbalanced bone turnover that is qualitatively different from the pathobiologic phenomena that occur in primary OP. The type of bone gene disturbances is suggestive of a pivotal role for Dkk-1 in this process, suggesting that it could be used as a therapeutic target to prevent RA bone damage.

Effect of Sirukumab on Hepcidin Levels and Markers of Anemia: Results of a Phase 2b Trial in Patients with Active Rheumatoid Arthritis Despite Methotrexate Therapy. Gary Toedter[1], Sarah Sague[2], Xiaoying Wu[2], Mark Curran[3] and Benjamin Hsu[4]. [1]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Malvern, PA, [2]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, [3]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA, [4]Centocor R&D, a division of J&J Pharmaceutical R& D, LLC/Univ. of Pennsylvania, Malvern/Philadelphia, PA

Background/Purpose: Anemia of chronic inflammation is found in patients with rheumatoid arthritis (RA). Studies have found that RA patients with anemia are more likely to have more severe joint damage (Peeters HR, et al. Ann Rheum Dis. 1996; 55: 162–168). Hepcidin is a peptide hormone that regulates iron homeostasis, is elevated in anemic conditions, and is up-regulated by interleukin-6 (IL-6). IL-6 is also elevated in RA. Sirukumab (CNTO136), a human anti-IL-6 monoclonal antibody, was investigated for efficacy in a Phase 2b dose ranging study of patients with active RA despite concurrent methotrexate treatment. This analysis examines if sirukumab treatment had positive effects in RA patients anemic at baseline (week 0) by reducing hepcidin and increasing hemoglobin through week 12 of treatment.

Methods: Serum samples collected in the Ph2b study at week 0, day 5, week 2, and the pre-specified week 12 primary endpoint were analyzed for hepcidin, hemoglobin, and anemia-related markers (ferritin, iron, total iron biding capacity, unsaturated iron bind capacity). Patients were treated with SC placebo (PBO; n= 30) or SC sirukumab 100 mg 2QW, 100 mg 4QW, 50 mg 4QW (n=30 for each arm), or 25 mg 4QW (n=31).

Results: The overall ACR 50 response at week 12 to sirukumab was 24.0% (PBO 3.3%). At week 0, 5/30 (16.7%) of PBO and 37/121 (30.6%) of sirukumab-treated patients were anemic. In the anemic patients, the mean week 0 hepcidin concentrations were 25.1 ng/mL in the PBO group, and 87.4 ng/mL in the sirukumab-treated patients. At week 12, the sirukumab- treated patients mean hepcidin concentration was significantly reduced to 38.1 ng/mL ($p=0.0029$), while the PBO mean hepcidin concentration was unchanged (31.4 ng/mL; $p=0.6250$). No dose-response of sirukumab on serum hepcidin concentration was seen. Hemoglobin levels in the anemic patients increased in the sirukumab-treated patients (10.6 g/dL at week 0; 11.8 g/dL at week 12; $p<0.001$) but were unchanged in the PBO group (10.2 g/dL at week 0; 9.8 g/dL at week 12; $p=0.6250$). By week 12, no patients in the PBO group normalized hemoglobin levels, while 19 patients in the sirukumab-group normalized hemoglobin (51.4% of the week 0 anemic patients). All of the measured anemia-related markers correlated significantly with post-treatment hepcidin concentrations. There was no relationship between ACR20 or ACR50 response at week 12 and normalization of hemoglobin.

Conclusion: Sirukumab was effective in reducing serum concentrations of hepcidin through week 12 of treatment. Serum hemoglobin levels in anemic patients increased significantly following sirukumab treatment, with half of the patients normalizing hemoglobin levels. This indicates that in addition to demonstrating efficacy, treatment of RA patients with sirukumab may be effective in reversing inflammation-related anemia.

Body Mass Index Is Associated with Decreased Response to Initial and Delayed Treatment with Dose Escalated Infliximab in Patients with Recent Onset Rheumatoid Arthritis. L. Heimans[1], M. van den Broek[1], L. Dirven[1], A.A. Schouffoer[1], I. Speyer[2], P.J.S.M. Kerstens[3], T.W.J. Huizinga[4], W.F. Lems[5] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Bronovo Hospital, Den Haag, Netherlands, [3]Jan van Breemen Research Institute|Reade, Amsterdam, Netherlands, [4]Leiden University Medical Centre, Leiden, Netherlands, [5]VU University medical center, Amsterdam, Netherlands

Background/Purpose: Patients with established RA with a high Body Mass Index (BMI) respond less well to delayed treatment with a fixed dose of TNF-blocker infliximab (IFX).[1] The aim of this study was to assess the relationship between BMI and the response to initial and delayed treatment with IFX with dose escalation to a maximum of 10 mg/kg in recent onset RA patients treated according to a disease activity score (DAS) steered treatment protocol.

Methods: In a post-hoc analysis of the BeSt study, outcome of treatment with IFX and methotrexate (MTX) was assessed and compared between BMI-categories. (table 1) Initial treatment with IFX (3mg/kg/8 weeks, after a loading dose) and MTX was started in 120 patients. In addition, in 109 patients, IFX and MTX were started after they had failed on 3 treatment steps with disease modifying antirheumatic drugs (DMARDs). In case of insufficient response (DAS >2.4), the IFX dose was increased to 6, then 7.5 and a maximum of 10 mg/kg. Adequate response to IFX was defined as having a DAS ≤2.4 for at least 6 months on the IFX initial dose of 3 mg/kg. Failure to respond was defined as being assigned to another treatment regimen because of insufficient response to the maximum IFX dose. Response could be defined as adequate or insufficient in 143 patients. The association between BMI and failing to respond to IFX was assessed with multivariate regression analyses, adjusted for baseline DAS, age, sex, smoking, and anti-citrullinated protein antibody (ACPA)-status.

Results: Outcome of treatment could be defined in 143 patients, of whom 96 received IFX as initial treatment. Patients were categorized as having a normal BMI (<25), being overweight (BMI >25 but <30) or being obese (BMI >=30), according to the WHO classification criteria. No statistically significant differences were found in other baseline characteristics between the three groups. The proportion of rapid responding patients was significantly lower in overweight patients (68%) and obese patients (64%), compared to patients in the normal BMI category (84%). BMI was an independent predictor of failure to respond, with odds ratios (OR) of 2.9 (95% CI 1.1;8.0) for the overweight group and 3.6 (95%

CI 1.0;12.6) in the obese group. (table 1) Other independent predictors of failure to respond were female gender (OR 3.4 (95% C.I. 1.05;11.3)) and high baseline DAS (OR 2.1 (1.3;3.6)).

Table 1. BMI and failure to respond to IFX

BMI category*	n	Crude Odds ratio 95%C.I.	Adjusted# Odds ratio 95% C.I.
<25	52	*ref*	*ref*
25–<30	66	2.6 (1.0; 6.4)	2.9 (1.1; 8.0)
>=30	25	3.1 (1.0; 9.4)	3.6 (1.0; 12.6)

*BMI according to WHO classification of adult normal weight, overweight and obesity. #Adjusted for age, sex, smoking, baseline DAS and anti-citrullinated protein antibody (ACPA)-status.

Conclusion: These results confirm that BMI is associated with response to IFX, with overweight and obese patients more often failing to treatment with IFX than patients with normal BMI, even when IFX is increased to the maximum dose (10mg/kg).

Clinical and Radiographic Implications of Time to Treatment Response in Early Rheumatoid Arthritis Patients with Baseline Levels of Disease Activity Reflective of a Clinical Practice Setting. Edward Keystone[1], Michael E. Weinblatt[2], Boulos Haraoui[3], Benoit Guerette[4], Neelufar Mozaffarian[5], Shufang Liu[5], Benjamin Wolfe[5] and Arthur Kavanaugh[6]. [1]University of Toronto, Toronto, ON, [2]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [3]Institut de Rhumatologie, Montreal, QC, [4]Abbott, Rungis, France, [5]Abbott, Abbott Park, IL, [6]University of California San Diego, San Diego, CA

Background/Purpose: A retrospective analysis of the PREMIER trial demonstrated that in early RA patients (pts) on methotrexate (MTX) both the timing and magnitude of a clinical response determines long-term outcomes. Cohort data reveal that the baseline (BL) disease activity of pts in clinical trials is often more severe than that in clinical practice. This study aimed to evaluate the association of clinical responses occurring by 12 weeks (wks) or 24 wks with long-term outcomes in MTX-treated pts from PREMIER who had BL levels of disease activity more closely resembling those observed in "real world" practice.

Methods: In this post hoc analysis, observed data from MTX-pts in PREMIER who had BL DAS28(CRP) ≤6.0 were evaluated in the context of the total MTX population [mean DAS28(CRP) =6.3]. Pts were categorized as early- or delayed-responders (R) based on clinical measures [50%/70% improvement in ACR response criteria or improvement in DAS28(CRP) >1.2] at 12 and 24 wks: early-R achieved the clinical target by wk 12 and maintained it at wk 24; delayed-R did not achieve the target at wk 12 but met it by wk 24. Long-term outcomes for early- and delayed-R were the percentage in DAS28(CRP) remission (<2.6) or with rapid radiographic progression [RRP, ΔmTSS >3) at 52 wks; odds ratios (95% CI) were used to compare outcomes of early- and delayed-R.

Results: A total of 72 of the 199 evaluable MTX-pts had BL DAS28(CRP) ≤6.0 [mean (SD) DAS28(CRP) =5.5 (0.4)]. The percentages of pts who achieved early and delayed responses were 29.2% and 27.8% for ACR50, 13.9% and 18.1% for ACR70, and 58.8% and 22.1% for DAS28(CRP) improvement >1.2; all percentages were comparable with those in the total MTX population. Long-term outcomes were somewhat better for pts with lower DAS28(CRP) at BL, although the trends observed in the overall population remained: early-R, irrespective of the magnitude of the response, had better clinical and radiographic outcomes at wk 52 (**Table**). Delayed-R with an ACR50 or improvement in DAS28(CRP) >1.2 had significantly reduced odds of achieving remission at wk 52. In fact, pts with delayed responses needed to reach an ACR70 by wk 24 to have comparable odds of reaching remission at wk 52. Delayed-R, regardless of the magnitude of response, also had a high proportion of RRP at wk 52. Indeed, pts with delayed ACR70 responses had an RRP prevalence of >30%.

Table. Association of Baseline Disease Activity and Time to Clinical Response With Week 52 Outcomes

Population	Responder Type	Response by Week 12	Response by Week 24	DAS28 (CRP) <2.6 (%)	Odds Ratio[a] (95% CI)	mTSS >3, RRP (%)	Odds Ratio[a] (95% CI)
Total MTX Population	Early	ACR50R	ACR50R	64		23	
	Delayed	ACR50NR	ACR50R	31	4.13 (1.81, 9.42)*	47	0.35 (0.15, 0.81)*
	Early	ACR70R	ACR70R	94		18	
	Delayed	ACR70NR	ACR70R	51	15.15 (1.82, 126.31)*	40	0.32 (0.08, 1.30)
	Early	ΔDAS28[b]>1.2R	ΔDAS28>1.2R	39		41	
	Delayed	ΔDAS28>1.2NR	ΔDAS28>1.2R	12	4.73 (1.56, 14.29)*	53	0.61 (0.29, 1.29)
Baseline DAS28 (CRP) ≤6.0	Early	ACR50R	ACR50R	86		19	
	Delayed	ACR50NR	ACR50R	45	7.33 (1.63, 33.08)*	35	0.44 (0.11, 1.82)
	Early	ACR70R	ACR70R	100		10	
	Delayed	ACR70NR	ACR70R	69	>999 (<0.001, >999)	31	0.25 (0.02, 2.70)
	Early	ΔDAS28>1.2R	ΔDAS28>1.2R	64		33	
	Delayed	ΔDAS28>1.2NR	ΔDAS28>1.2R	20	7.14 (1.72, 29.68)*	47	0.55 (0.16, 1.85)

[a] Odds ratio for early (wk 12) versus delayed (wk 24) responders.
[b] ΔDAS28 is improvement in DAS28(CRP).
R = responder; NR = non-responder.
* Statistically significant.

Conclusion: MTX-pts with lower BL DAS28(CRP) achieved somewhat better clinical and radiographic outcomes at wk 52 than the overall MTX-population. Still, pts who did not achieve a strong clinical response by wk 12 had a lower likelihood of achieving remission and were at increased risk of developing RRP compared with early-R. Therefore, these data lend support to the applicability of the findings in PREMIER to pts with lower BL disease activity, a population that may be more reflective of RA pts typically seen in a rheumatology clinic.

Rapid Radiological Progression in the First Year of Rheumatoid Arthritis Predicts Both Disability and Radiological Joint Damage Progression Over 8 Years of Targeted Treatment. M. van den Broek[1], L. Dirven[1], A.J. Dehpoor[1], J.K. de Vries-Bouwstra[1], Y.P. Goekoop-Ruiterman[2], A.J. Peeters[3], P.J.S.M. Kerstens[4], Tom W.J. Huizinga[1], W. F. Lems[5] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]HAGA hospital, The Hague, Netherlands, [3]Reinier de Graaf Gasthuis, Delft, Netherlands, [4]Jan van Breemen Research Institute|Reade, Amsterdam, Netherlands, [5]VU University medical center, Amsterdam, Netherlands

Background/Purpose: To assess whether rapid radiological progression in the first year of treatment of RA is associated with functional disability and progressive joint damage over 8 years of tight control targeted treatment.

Methods: All patients with radiological data at baseline and after 1 year from the BeSt study were used in this analysis. All patients were dynamically treated with medication adjustments aimed at achieving a disease activity score (DAS) =<2.4, measured three-monthly. Rapid radiological progression (RRP) was defined as an increase of >= 5 points Sharp v/d Heijde Score (SHS) as scored after the first year of treatment. Functional ability over 8 years, measured 3-monthly with the Health Assessment Questionnaire (HAQ), was compared in patients with and without RRP using linear mixed models, adjusted for treatment group, baseline ESR, SHS and rheumatoid factor (RF), anti-citrullinated protein antibody-status (ACPA) or a combination of RF and ACPA. Subsequently, disease activity score (DAS) over time was added to this model.

Results: RRP was observed in 102/463 (22%) patients. Patients with RRP were more often treated with initial monotherapy (74% vs. 41%) than patients without RRP and more often RF (82% vs. 60%) and ACPA (77% vs. 55%) positive, with a higher baseline ESR (53 mm/hr vs. 37 mm/hr). They also had a higher baseline HAQ (1.5 vs. 1.4, p=0.04).

Over 8 years, despite relatively equal suppression of DAS in both groups, patients with RRP had a statistically and clinically significantly higher HAQ (difference 0.22, 95% C.I. 0.09–0.34) (figure 1). After adjustment for DAS over time, this difference was 0.15 (0.05–0.26). Patients with RRP in the first year had more joint damage progression in year 1 to year 8 (figure 2).

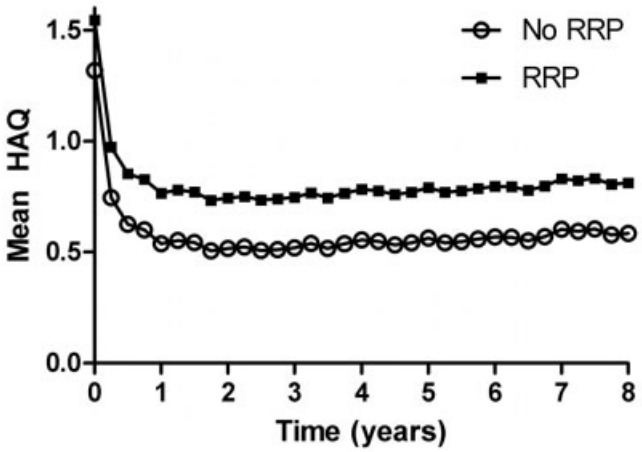

Figure 1. Mean HAQ over time, adjusted for treatment strategy, baseline ESR and SHS and RF and/or ACPA (using linear mixed models) for patients with and without RRP in year 1.

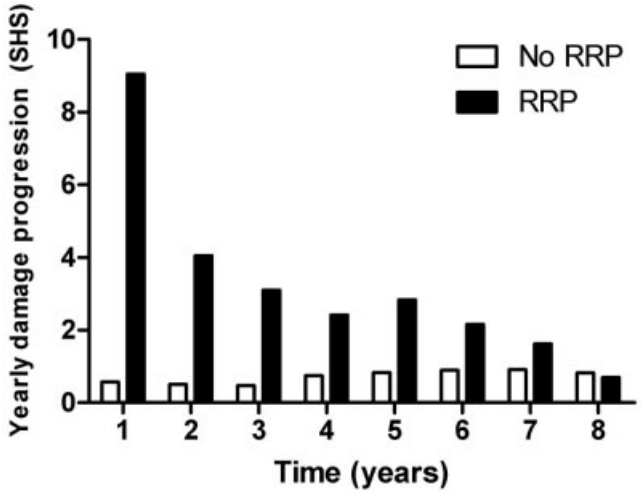

Figure 2. Mean yearly joint damage progression for patients with and without RRP in year 1.

Conclusion: In a tight control cohort of recent onset RA patients with treatment targeted at DAS =<2.4, rapid radiological progression in year 1 is an independent predictor of functional disability over 8 years. Approximately one third of the difference in functional ability between patients with and without RRP is explained by differences in disease activity. Patients with rapid radiological progression in the first year of treatment continue to have more joint damage progression in subsequent years than patients without RRP.

No Deterioration of Glucose Levels During Oral Glucose Tolerance Tests Following High-Dose Prednisolone Treatment in Early Active Rheumatoid Arthritis. Debby den Uyl[1], Daniel H. van Raalte[2], Michael T. Nurmohamed[3], Willem F. Lems[1], Johannes W.J. Bijlsma[4], Jos N. Hoes[4], Ben A.C. Dijkmans[5] and Michaela Diamant[2]. [1]VU University medical center, Amsterdam, Netherlands, [2]VU University medical center, Diabetes Center, Amsterdam, Netherlands, [3]Reade, Centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands, [4]UMC Utrecht, Utrecht, Netherlands, [5]Reade, Centre for Rehabilitation and Rheumatology and VU University Medical Centre, Department of Rheumatology, Amsterdam, Netherlands

Background/Purpose: Glucocorticoids (GCs) are frequently used in the treatment of rheumatoid arthritis (RA) due to their strong anti-inflammatory properties. However, GCs may induce glucose intolerance and even clinically overt diabetes by reducing insulin sensitivity and, as recently shown, by impairing insulin secretion. Additionally, inflammation as such is also associated with impaired glucose metabolism. Here we studied the interaction of the anti-inflammatory and diabetogenic effects of GCs in patients with early, active RA. This study was set up to evaluate the effects of one-week treatment with prednisolon 30mg or 60mg QD on insulin secretion and insulin sensitivity in patients with active, early RA.

Methods: Drug-naive patients with early, active RA (n=41) were randomised to prednisolone 60mg QD or prednisolone 30mg QD. Before and after 1 week of treatment, a frequently-sampled 75-g oral glucose tolerance test (OGTT) was performed after an overnight fast. The area under the curve (AUC) for glucose, insulin and C-peptide concentration were calculated. Beta-cell function was estimated by the insulinogenic index (IGI): $(I_{30}-I_0)/(G_{30}-G_0)$ and the AUC_{CP}/AUC_G ratio. Glucose tolerance state was assessed according to ADA guidelines. Insulin sensitivity was estimated by oral glucose insulin sensitivity (OGIS) index.

Results: Patients (age: 55±13 years, BMI: 25.0±4.1 kg/m^2) had active disease: DAS44 score: 4.0±0.8 and C-reactive protein (CRP): 17 (5–37) mg/L. At baseline, 56% of the patients had impaired glucose tolerance and 7% unknown type 2 diabetes mellitus (T2DM). ESR and CRP levels were associated with AUC_G (β=2.484; 95% CI 0.097–4.872, P=0.04 and β=2.360; 95% CI 0.163–4.501, P=0.04 respectively). Treatment with both prednisolone dosages reduced CRP levels significantly. Mean AUC glucose, insulin and c-peptide did not change in both arms. At individual level the glucose tolerance state improved in 22%, while the T2DM incidence increased to 24% (P<0.001), evenly distributed across the groups. Beta-cell function (IGI*)* improved during PRED60 treatment (P=0.02), and PRED30 treatment (P=0.04). There were no significant differences between the two treatment groups. Disease duration was positively associated with changes in AUC_G (β=3.733; 95% CI 1.077–6.390, P=0.004) and with deterioration of glucose profile (OR=1.068; 95% CI 1.016–1.122, P=0.01).

Conclusion: Short-term exposure to 60 or 30 mg PRED q.d. improved disease activity without deterioration of glucose tolerance in patients with active RA. These data suggest that the diabetogenic effects of high-dose prednisolone treatment can be counteracted by the anti-inflammatory properties of GCs, at least during short-term treatment. Given the individual differences, monitoring is recommended.

420

Effects of the Oral SYK Inhibitor, Fostamatinib (R788), on Health-Related Quality of Life in a Phase II Study of Active Rheumatoid Arthritis. Michael E. Weinblatt[1], Arthur Kavanaugh[2], Mark C. Genovese[3], David A. Jones[4], Theresa K. Musser[5], Elliott B. Grossbard[5] and Daniel B. Magilavy[5]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of California San Diego, San Diego, CA, [3]Stanford University, Palo Alto, CA, [4]AstraZeneca, Macclesfield, United Kingdom, [5]Rigel Pharmaceuticals, South San Francisco, CA

Background/Purpose: Fostamatinib (R788), an oral spleen tyrosine kinase inhibitor, met its primary signs and symptoms efficacy endpoint in a 6-mo, phase II, multicenter, randomized, double-blind, placebo (pbo)-controlled study in patients with rheumatoid arthritis (RA) who failed to respond to methotrexate (MTX) (NCT00665925).[1] This current analysis assessed the impact of fostamatinib on health-related quality of life (HRQL) measures in this phase II study.

Methods: RA patients with prior long-term MTX treatment (n=457) were randomized to receive fostamatinib (150 mg qd [n=152]/100 mg bid [n=152]) or pbo (n=153), and background MTX. Patients self-administered the American College of Rheumatology (ACR) patient-reported outcomes (PRO) core set: pain (visual analog scale [VAS]); patient's global assessment (PtGA) of disease activity [VAS]; and physical function (Health Assessment Questionnaire-Disability Index [HAQ-DI]) at baseline, Week (Wk) 1, 2, 4, 6, 8, 12, and 24. HRQL (Short Form-36 [SF-36]) was assessed at baseline and Wk24, and fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-Fatigue]) was assessed at baseline, Wk12, and 24. The main analyses compared the mean changes from baseline between the treatment groups using a generalized linear model. A responder analysis of the proportion of patients achieving a minimum clinically important difference (MCID) in each treatment group used the Cochran Mantel-Haenszel test. All tests of statistical significance were 2-sided; α=0.05.

Results: The study population had a duration of RA in excess of 8 years.[1] ACR responder rates were significant with fostamatinib 100 mg bid vs pbo (ACR20: 67% vs 35%; ACR50: 43% vs 19%; p≤0.001).

Fostamatinib 100 mg bid significantly improved pain, PtGA, and physical function at Wk1 vs pbo ($p \leq 0.001$), and was sustained throughout the trial (24 wks) (Table). Also, by Wk24, a significantly greater proportion of patients receiving fostamatinib 100 mg bid achieved MCID for pain, PtGA, and physical function vs pbo (73.3% vs 62.0% [$p < 0.05$] for pain; 74.0% vs 55.4% [$p \leq 0.01$] for PtGA; 74.8% vs 55.8% [$p \leq 0.01$]) for physical function). A significant improvement in the SF-36 physical component summary (PCS) was seen with fostamatinib 100 mg bid vs pbo at Wk24 ($p \leq 0.001$, including for each SF-36 physical domain), as well as for fatigue ($p < 0.05$) but not for the SF-36 mental component summary (Table). Moreover, at Wk24, a significantly greater proportion of patients (achieved the SF-36 PCS MCID with fostamatinib 100 mg bid vs pbo (72.9% vs 57.6%; $p \leq 0.01$) and a numerically greater percentage for fatigue (59.8% vs 48.6%; $p \geq 0.05$).

Table 1. Results of the main PRO analyses

		Mean change from baseline		
		Pbo	Fostamatinib	
			150 mg qd	100 mg bid
Pain	Wk 1	4.5 (20.7)	10.3 (19.4)*	15.4 (22.0)**
	Wk 24	17.8 (27.0)	23.0 (24.1)	31.3 (28.1)**
PtGA	Wk 1	4.4 (20.2)	8.3 (19.4)	14.6 (23.3)**
	Wk 24	16.7 (26.6)	20.3 (25.3)	29.1 (25.9)**
Physical Function	Wk 1	0.06 (0.41)	0.24 (0.43)**	0.22 (0.39)**
	Wk 24	0.34 (0.67)	0.54 (0.66)*	0.65 (0.74)**
Other PROs				
SF-36 physical component summary	Wk 24	4.9 (8.5)	5.9 (9.0)	8.5 (8.7)**
SF-36 mental component summary	Wk 24	3.7 (10.7)	2.0 (10.7)	4.0 (10.5)
FACIT-Fatigue	Wk 24	4.5 (9.8)	5.7 (10.3)	7.4 (10.9)*

Data are mean (SD). Difference from pbo: *$p < 0.05$; **$p \leq 0.001$.
PRO, patient-reported outcome; ACR, American College of Rheumatology; PtGA, patient's global assessment; HAQ-DI, Health Assessment Questionnaire-Disability Index; SF-36, Short Form-36; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; SD, standard deviation; pbo, placebo.

Conclusion: In this phase II study, 100 mg bid fostamatinib significantly improved HRQL outcomes including physical function, pain, fatigue, and overall physical health status. Phase III clinical trials of fostamatinib in RA are in progress.

Epistasis in Folate Mediated One Carbon Metabolism Contributes to High Disease Activity in Two Cohorts of Rheumatoid Arthritis Patients Receiving Long Term Methotrexate Therapy. Thierry Dervieux[1], J. M. Kremer[2], Rebecca Roberts[3] and Lisa K. Stamp[3]. [1]Exagen Diagnostics, Albuquerque, NM, [2]Albany Medical College and The Center for Rheumatology, Albany, NY, [3]University of Otago, Christchurch, Christchurch, New Zealand

Background/Purpose: Previous reports have established that single nucleotide polymorphisms (SNPs) in folate mediated one carbon metabolism contribute to Methotrexate (MTX) efficacy in patients with rheumatoid arthritis (RA). Our objective was to evaluate whether epistasis (gene-gene interactions) would contribute to disease control in two cohorts of RA patients treated with MTX.

Methods: The study was multicentered, cross sectional, and enrolled 424 patients from the United States (n=252) and the New Zealand (n=172). All patients presented with established RA (74% females, median age 63yrs) and were treated with MTX monotherapy (median dose 15mg/week) for at least three months (median 39 months). The majority of patients (>95%) in both cohorts were Caucasians. Disease activity score (DAS) was calculated and used to differentiate patients with high disease activity (DAS>5.1) from those with low to medium disease activity (DAS≤5.1). A total of 12 SNPs in folate (RFC-1, MTHFR, MTHFD1, MS, GGH, SHMT1), purine (ATIC, AMPD1) and pyrimidine (TYMS) pathways were measured using standard molecular methods. Data analysis consisted of univariate logistic regression and multifactor dimensionality technique (MDR). MDR detects non-linear gene-gene interactions by combining predisposing genotypes of high disease activity (predisposing genetic attribute) into two separate groups depending on whether they are more common in patients presenting with high disease activity or not. The robustness and significance of the model was tested through cross validation consistency (CVC, 10-fold) and 1000-fold permutation testing.

Results: High disease activity was observed in 11.8% of patients enrolled. Using univariate analysis, none of 12 SNPs measured were significantly associated with high disease activity when the two cohorts were combined ($p > 0.06$). However, MDR analysis revealed a nonlinear pattern of interactions between genes controlling 1-carbon derivatives synthesis of tetrahydrofolate (MTHFD1 G1958A), thymidylate (TYMS *2/*3), and purines (ATIC C347G). The stepwise addition of the three genetic variants increased the testing accuracy from 0.584 (ATIC C347G) to 0.635 (ATIC C347G + MTHFD1 G1958A + TYMS *2/*3) (Table). The constructed predisposing genetic attribute pooling higher and lower likelihood of poor disease control in two separate groups revealed a 7.2 fold (CI 95%: 3.4–15.3) greater likelihood of high disease activity in carriers (43%) versus non carriers ($p < 0.001$). Sensitivity was 81% and specificity was 62%. These findings were significant in both US (OR=6.6 CI95%: 2.8–15.8; $p < 0.01$) and NZ cohorts (OR=6.9 CI95%: 1.3–35.0; $p < 0.001$).

Conclusion: These hypothesis generating data suggest that epistasis in folate mediated one carbon metabolism may contribute to disease control in RA patients treated with MTX.

Table. Multifactor dimensionality reduction analysis

Model	Training accuracy	Testing accuracy	CVC	P value
ATIC C347G	0.601	0.584	10/10	0.178
ATIC C347G+ MTHFD1 G1958A	0.652	0.582	5/10	0.196
ATIC C347G+ MTHFD1 G1958A+ TYMS *2/*3	0.721	0.635	10/10	0.018

CVC: cross validation consistency. ATIC: 5-Aminoimidazole-4-carboxamide ribonucleotide formyltransferase; MTHFD1: methylenetetrahydrofolate dehydrogenase; TYMS: Thymidylate Synthetase.

422

Patterns of Pain Medication Use Among Rheumatoid Arthritis Patients From 2000–2010. Yvonne C. Lee[1], Frederick Wolfe[2] and Kaleb D. Michaud[3]. [1]Brigham and Women's Hospital, Boston, MA, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]Univ of Nebraska Med Ctr & National Data Bank for Rheumatic Diseases, Omaha, NE

Background/Purpose: Over the past decade, several new biologic disease modifying antirheumatic drugs (DMARDs) were approved for the treatment of rheumatoid arthritis (RA). Concurrently, many changes occurred in the treatment options for pain. Two cyclooxygenase-2 inhibitors were removed from the market, and central-acting pain modulating agents were approved for the treatment of fibromyalgia and chronic musculoskeletal pain. We examined patterns and predictors of pain medication use among RA patients in a large, prospective observational cohort.

Methods: The study population included 15,006 RA patients followed at semi-annual intervals between 2000 and 2010. Pain medication use was defined as any patient report of: 1) non-steroidal anti-inflammatory drugs (NSAIDs), 2) weak opioids, 3) strong opioids, or 4) central-acting pain-modulating drugs (tricyclic antidepressants, serotonin-norepinephrine reuptake inhibitors, gabapentin and pregabalin) during each calendar year. Pain and fatigue were assessed using visual analog scales (0–10). Disability was assessed using the Health Assessment Questionnaire (HAQ). General estimating equations (GEE) and predictive margins were used to adjust prevalence rates for demographic variables, pain, disability, mood and fatigue. GEE was also used to examine associations between clinical characteristics and pain medication usage.

Results: In this cohort of established RA patients, HAQ scores increased from 0.98 to 1.09 between 2000 and 2010, while overall pain levels remained steady (between 3.7 and 3.9). Biologic DMARD use increased from 18.9% to 38.3%, whereas prednisone use decreased from 35.1% to 28.2%. When examining specific types of pain medication use, different trends emerged. NSAID use declined from 67.3% to 41.4%, whereas strong opioid use increased from 2.6% to 6.0% (Figure). The use of central-acting agents also increased from 8.7% to 15.8%. Female sex was associated with increased use of NSAIDs, weak opioids and central-acting agents ($P < 0.005$), whereas male sex was associated with increased use of strong opioids ($P = 0.02$). Obesity was associated with increased use of NSAIDs, weak opioids and central-acting agents ($P <$

0.02), whereas low body mass index (BMI) was associated with increased use of strong steroids ($P = 0.004$). Both past and current smoking was associated with opioid use ($P < 0.003$). Pain severity, poor mood and fatigue were associated with increased use of all types of pain medications ($P < 0.05$).

Conclusion: Despite increases in biologic DMARD therapy, pain levels remained the same over the past 10 years. Although NSAID use declined, all other types of pain medication use increased. Clinical characteristics, including sex, BMI and smoking, were differentially associated with specific types of pain medication use.

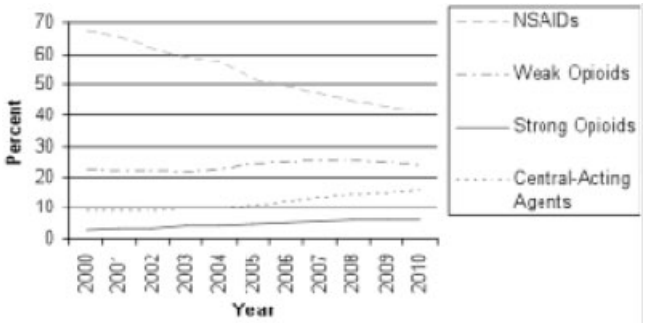

Figure. Patterns of pain medication use among RA patients from 2000-2010.

The Effect of Anti-Tumor Necrosis Factor Therapy with Two Different Doses of Golimumab on Radiographic Progression in Definite Ankylosing Spondylitis: 4-Year Results. Jürgen Braun[1], Desirée van der Heijde[2], Kay-Geert Hermann[3], Xenofon Baraliakos[4], Atul Deodhar[5], Anna Beutler[6], Michael Mack[6], Weichun Xu[7], Benjamin Hsu[8], Robert D. Inman[9] and GO-RAISE Clinical Investigators. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Charite Medical School, Berlin, Germany, [4]Ruhr-University Bochum, Herne, Germany, [5]Oregon Health & Science University, Portland, OR, [6]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA, [7]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, [8]Centocor R&D, a division of J&J Pharmaceutical R& D, LLC/Univ. of Pennsylvania, Malvern/Philadelphia, PA, [9]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON

Background/Purpose: Three clinical trials in which structural spinal changes in patients with ankylosing spondylitis (AS) treated with tumor necrosis factor (TNF) antagonists over 2 years (yrs) were assessed in comparison to a historical cohort have indicated that such therapy may not alter radiographic progression as quantified by the modified Stokes Ankylosing Spondylitis Spinal Score (mSASSS). Longer-term data are scarce. The purpose of this analysis was to assess the effects of two different dosages of the anti-TNF agent golimumab (GLM) on radiographic progression in patients (pts) with AS through 2 and 4 yrs of treatment.

Methods: Pts (n=356) were randomly assigned (1:1.8:1.8) to subcutaneous injections of PBO, GLM 50mg, or GLM 100mg q4weeks (wks). At wk16, pts in the PBO or 50mg groups with <20% improvement in both total back pain and morning stiffness entered early escape (EE) to GLM 50 or 100mg, respectively. At wk24, pts still receiving PBO crossed over (CO) to GLM 50mg. Lateral view radiographs of the cervical and lumbar spine were performed at baseline, wk104 and wk208. Radiographs were read by 2 independent, central, trained readers using mSASSS methodology (range 0–72).

Results: Among all randomized pts, median time since first AS symptoms was 11.0 yrs. Treatment groups were comparable with regard to age, gender, BASDAI, BASFI, BASMI, CRP, mSASSS, and baseline syndesmophytes. Overall mean changes in mSASSS were 1.1 at wk104, with no obvious treatment group differences, and 3.6 at wk208, with numerically larger changes in the GLM 100mg group (Table). Due to wide distribution of change values, the numerical differences in mean change in mSASSS for the 100mg group or for the 19 radiographically evaluable pts who dose-escalated from 50 to 100mg via EE (data not shown) are not significant by ANOVA on the van der Waerden normal scores. At wk 104 and wk 208, 23.1% and 35.1% of pts had a definitive change (>2 points) in mSASSS.

Table. Baseline and change from baseline in mSASSS

	PBO→GLM 50mg[1] (n=66)	GLM 50mg[2] (n=111)	GLM 100mg[3] (n=122)	All GLM (n=299)
Baseline	16.1 (18.7)	11.7 (16.4)	13.5 (18.9)	13.4 (18.0)
Mean (SD)	7.9	3.1	3.5	4.0
Median				
Wk104	1.6 (4.6)	0.9 (2.7)	0.9 (3.9)	1.1 (3.7)
Mean (SD) change	0.0	0.0	0.0	0.0
Median change	17 (25.8%)	22 (19.8%)	30 (24.6%)	69 (23.1%)
% pts with change >2				
Wk208	3.2 (8.6)	2.4 (6.6)	4.9 (10.6)	3.6 (8.9)
Mean (SD) change	0.5	0.0	1.1	0.5
Median change	22 (33.3%)	34 (30.6%)	49 (40.2%)	105 (35.1%)
% pts with change >2				

[1] Pts in this group either met the early escape criteria at wk16 or crossed over to GLM 50mg at wk24.
[2] Includes pts who did (n=19) and did not (n=92) meet the early escape criteria at wk16.
[3] Includes pts who did (n=25) and did not (n=97) meet the early escape criteria at wk16.

Conclusion: Changes in mSASSS from baseline to wk104 and wk208 indicated that anti-TNF treatment with GLM does not prevent radiographic progression in the spine of pts with AS. There was a trend to more radiographic changes in the group with the higher GLM dosage.

424

Increased Visceral Adiposity During Anti Tnfa Treatment for Inflammatory Rheumatic Disease Is Associated with Various Changes on Serum Adipokines: A 2 Year Prospective Study. Eric Toussirot[1], Laurent Mourot[2], Nhu Uyen Nguyen[3], Malika Bouhaddi[4], Daniel Wendling[5] and Gilles Dumoulin[6]. [1]Rheumatology and CIC Biotherapy 506, Besançon, France, [2]University of Franche Comté, Besançon, France, [3]department of Physiology, Besançon, France, [4]Physiology, France, [5]Minjoz University Hospital, Besancon, France, [6]Department of Physiology, France

Background/Purpose: TNFa blocking agents are very effective in rheumatoid arthritis (RA) or ankylosing spondylitis (AS) and has been associated with weight gain. Adipokines are proteins produced by the adipose tissue with many physiologic functions and can also influence the inflammatory response. Certain adipokines could represent a link between the immune response, the metabolic functions and the nutritional status. We evaluated the long term effects of anti TNFa treatment on body weight, body composition and distribution. The changes on the serum levels of adipokines (leptin, adiponectin and resistin) and ghrelin, a gastric peptide involved in appetite regulation were also studied.

Methods: 20 patients (6F) were evaluated (12 AS [modified NY criteria], age [mean ± SD]: 40.7 ± 16.1 yrs; and 8 RA [ACR criteria], age 60.5 ± 9.7 yrs; mean disease duration: 9.6 ± 9.8 yrs). They received infliximab (2), etanercept (6) or adalimumab (12). Body weight, body mass index (BMI), serum levels of adipokines and ghrelin were measured (IRMA) at baseline and then at months (M) 1, 3, 6, 12, 18 and 24. Body composition was evaluated at baseline and then at M6, 12 and 24. Total and regional body fat and lean masses were measured by total body DEXA (Lunar iDXA). Adiposity was calculated as the ratio between total fat tissue and total lean mass + total fat tissue. Fat distribution was evaluated as the relative proportion of fat tissue in the android (central) and the gynoid (hip and thigh) regions.

Results: There was a slight but significant increase in body weight (+ 1.35 kg) and BMI (+ 0.55 kg/cm^2) ($p<0.005$). All the patients responded to the treatment with clinical improvement and decline of erythrocyte sedimentation rate and CRP ($p<0.01$). Although fluctuating during the study, leptin and resistin levels did not significantly change. By contrast, adiponectin increased at M1, and then decreased slowly and reached lower values at M24 compared to baseline (baseline: 12.1 ± 4.8; M24: 11.4 ± 5.4 mg/ml; p= 0.01). We also observed a rapid decline in ghrelin which remained low until the end of the study (baseline: 1256 ± 387; M24: 1117 ± 429 pg/ml; p= 0.035). Lean mass and fat mass in the gynoid

region did not change while there was a significant increase at M24 in adiposity (+ 1.36%; NS), in total fat mass (+ 2.4 kg; p= 0.003) and in fat tissue located in the android region (+ 366 g; p= 0.025).

Conclusion: Long term administration of TNFa blocking agents was associated with gain of body weight and BMI. Leptin and resistin levels fluctuated while ghrelin decreased. However, TNFa blockade is associated with a modest but significant gain in total fat and especially fat in the android region. It is known that abdominal or visceral adipose tissue is associated with the development of atherosclerosis. These changes, together with the decrease in adiponectin serum levels, could negatively influence the cardiovascular risk of these patients.

425

Glucosteroid Treatment in Early Arthritis Leads to Increased Fat Mass Despite Reduced Disease Activity. Karin Britsemmer[1], Dirkjan van Schaardenburg[1], W. F. Lems[2] and Michael T. Nurmohamed[1]. [1]Jan van Breemen Research Institute / Reade, Amsterdam, Netherlands, [2]VU University medical center, Amsterdam, Netherlands

Background/Purpose: Several studies provided evidence for excess cardiovascular (CV) morbidity and mortality in rheumatoid arthritis (RA). Rheumatoid cachexia, defined as an decreased lean body mass and an increased truncal fat distribution, is one of the possible predictors for CV morbidity. Rheumatoid cachexia may improve with anti-rheumatic treatment. Evidence on changes in body composition is scarce, therefore we studied the changes in body composition and the association with glucocorticoid (GC) use in patients with early arthritis during the first year.

Methods: Consecutive patients from our early arthritis cohort with a disease duration of <2 years, at least 2 swollen joints and no prior DMARD treatment were investigated. At baseline and 12 months, body composition was assessed by whole body dual-energy X-ray absorptiometry (Lunar DXA). Fat mass was reported as total body fat mass (BFM), truncal fat mass (TFM) and fat mass of arms and legs (FMAL). Lean mass was reported as total lean body mass (LBM) and lean mass of arms and legs (LMAL). Truncal fat distribution reflects the proportion of truncal fat, calculated as the FMT divided by the FMAL, and body fat percentage was calculated as the BFM divided by the total body mass. Clinical assessment included the 28 joint Disease Activity Score (DAS28) and body mass index (BMI)

Results: Of 100 patients (mean age 52 [13], 68% female, median symptom duration 2.3 [1.9] months, mean DAS28 4.9 [1.3]), 85% had RA according to the ACR/EULAR criteria, the others had undifferentiated arthritis. 74% used GCs in the first year (mean oral daily dose 7.6 (2.6) mg). DAS28 decreased and FMAL increased significantly in both the GC+ and GC– groups, however, these changes were more pronounced in the GC+ versus the GC– group (table 1). After one year BMI, total BFM, FMAL, LMAL and BF% had increased significantly in the GC+ group. These differences in body composition were not observed in patients without GC treatment. There were no significant correlations between changes in DAS28 and changes in body composition measurements.

Table 1. Changes in body composition after 1 year in early arthritis patients with and without glucocorticoid (GC) use

	GC+ baseline	GC+ after 1 year	GC–baseline	GC–after 1 year	p-value‡
DAS28	5.2 (1.4)	2.7 (1.2) *	4.1 (1.2)	2.8 (1.2) *	<0.001
BMI, kg/m2	25.9 (4.7)	26.6 (4.9) *	24.6 (4.7)	24.9 (5.2)	ns
Total BFM, kg	27.0 (9.9)	28.5 (10.7) *	25.7 (9.8)	25.9 (10.3)	ns
TFM, kg	14.9 (7.3)	15.5 (7.0)	13.8 (7.5)	14.0 (7.6)	ns
FMAL, kg	11.5 (4.1)	12.2 (4.4) *	11.1 (3.0)	11.1 (3.3)	0.027
Total LBM, kg	45.7 (8.9)	45.8 (8.6)	43.4 (9.6)	43.1 (8.4)	ns
LMAL, kg	20.0 (4.5)	20.2 (4.5) *	18.8 (4.4)	19.0 (4.4)	ns
BF%	0.35 (0.09)	0.37 (0.09) *	0.35 (0.08)	0.35 (0.08)	ns
TFD	1.31 (0.57)	1.30 (0.49)	1.22 (0.51)	1.21 (0.47)	ns

* significant change in GC+ group (p<0.05;
# significant change in GC– group (P<0.05);
‡ differences in change between GC+ and GC– groups

Conclusion: In this early arthritis cohort there were unfavorable changes in body fat composition after one year in GC users, that were not observed in GC nonusers. This effect occurred despite a greater decrease of disease activity in the group of GC users, which would be expected to favorably influence body fat distribution.

426

Anti Tumour Necrosis Factor Therapy Is Associated with Reduced Mortality From Ruptured Abdominal Aortic Aneurysm: Results From the British Society for Rheumatology Biologics Register. Audrey SL Low[1], James B. Galloway[1], Louise K. Mercer[1], Rebecca Davies[1], Mark Lunt[1], Kath D. Watson[1], British Society for Rheumatology Biologics Register (BSRBR) control centre consortium[1], Kimme L. Hyrich[1], William G. Dixon[1], Deborah PM Symmons[1] and On behalf of the BSRBR[2]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]British Society for Rheumatology, London, United Kingdom

Background/Purpose: People with RA are at increased risk of mortality from atherosclerotic cardiovascular events such as myocardial infarction and cerebrovascular disease. Less is known about peripheral vascular disease in RA; in particular abdominal aortic aneurysm (AAA) rupture. The aim of this analysis was to explore the influence of anti-TNF therapy on the mortality from AAA rupture.

Methods: People with RA who had recently started anti-TNF therapy were recruited by the BSRBR from 2000–2008. Alongside this cohort, a biologic-naive comparator group treated with non-biologic disease modifying agents (nbDMARD) was also recruited. Patients were followed up by physician and patient questionnaires and flagged with the national death register. All patients were followed until 07/31/2010 or death, whichever came first. Mortality from AAA was identified from International Classification of Diseases 10 (ICD-10) codes I71.3 or I71.4 on the death certificate. The standardised mortality ratio (SMR) with 95% confidence intervals (CI) was calculated for AAA for both anti-TNF and nbDMARD cohorts with reference to the general population. Cox regression models were used to compare mortality rates of AAA between the anti-TNF and nbDMARD cohorts, with adjustment made using an inverse probability of treatment weighting (IPTW) model. Hazard ratios (HR) were calculated.

Results: 12051 patients treated with anti-TNF and 3767 patients treated with nbDMARD contributed to this analysis, with 63807 and 14892 person-years of follow-up respectively. 9 deaths from ruptured AAA were identified (3 in anti-TNF cohort; 6 in nbDMARD cohort), of which 2 were peri-operative (1 per cohort). There was a trend towards increased mortality from ruptured AAA in the nbDMARD cohort compared to the general population: SMR 2.7 (1.0–5.9) but this effect was not observed in the anti-TNF cohort: SMR 0.6 (0.1–1.7). After adjustment, patients ever exposed to anti-TNF were less likely to have died from a ruptured AAA compared to patients in the nbDMARD cohort: HR 0.08 (0.01–0.39).

Conclusion: This is further evidence supporting a biological link between TNF and atherosclerosis. Differences in the SMR could be explained by other factors e.g. hypertension and smoking. Strengths of this study include the size of the cohort and the completeness of death and cause of death ascertainment. Limitations include the low number of outcomes of interest which precluded examining for an influence of response to therapy or an effect of treatment duration.

	nbDMARD (n=3767)	Anti-TNF (n=12051)
Person-years of follow-up	14892	63807
Mean age (SD)	60.1 (12.4)	56.2 (12.3)
Females (%)	72.4	76.2
Median disease duration (IQR)	6 (1–15)	11 (6–19)
Mean DAS28 (SD)	5.1 (1.3)	6.6 (1.0)
Number of deaths from ruptured AAA	6	3
Mortality rate per 100,000 person-years	40	5
Standardised mortality ratio (95%CI)	2.7 (1.0–5.9)	0.6 (0.1–1.7)
Hazard ratio (unadjusted)	Referent	0.09 (0.02–0.38)
Hazard ratio (IPTW)*	Referent	0.08 (0.01–0.39)

Tocilizumab Monotherapy and Tocilizumab Plus Disease-Modifying Antirheumatic Drugs in a US Rheumatoid Arthritis Population with Inadequate Response to Anti-Tumor Necrosis Factor Agents. Michael E. Weinblatt[1], Joel M. Kremer[2], John J. Cush[3], William Rigby[4], Lichen Teng[5], Natasha Singh[5], Raymond L. Malamet[6] and Mark C. Genovese[7]. [1]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [2]Albany Medical College and The Center for Rheumatology, Albany, NY, [3]Baylor Research Institute, Dallas, TX, [4]Dartmouth Medical School, Lebanon, NH, [5]Roche, Nutley, NJ, [6]Genentech, South San Francisco, CA, [7]Stanford University, Palo Alto, CA

Background/Purpose: ACT-STAR, a 24-wk, prospective, open-label, US study, demonstrated similar safety/tolerability/efficacy with tocilizumab (TCZ) monotherapy (MONO) or TCZ+DMARD combination (COMBO) in adult patients (pts) with moderate-to-severe active RA who had an inadequate response (IR) to current biologic or nonbiologic DMARDs. Efficacy of TCZ MONO was also previously demonstrated in a randomized trial of methotrexate-IR or naïve patients (AMBITION), but it is important to understand the risk-benefit profile of TCZ MONO specifically in the difficult-to-treat population of anti-TNF-IR pts. Therefore, a subanalysis of ACT-STAR was conducted to compare the safety/efficacy of TCZ MONO or COMBO therapy in anti-TNF-IR pts.

Methods: In ACT-STAR, pts on nonbiologic DMARDs alone or combined with biologic DMARDs were randomized to 2 TCZ COMBO groups (4 mg/kg [TCZ 4]+DMARD or 8 mg/kg [TCZ 8]+DMARD); pts on biologic DMARD monotherapy before baseline were assigned to TCZ 8 MONO. Biologic DMARDs were discontinued before baseline. At wk 8, pts randomized to TCZ 4+DMARD who did not achieve ≥20% improvement in joint counts had TCZ dose increased to 8 mg/kg; from week 12 onward pts on TCZ 4+DMARD had dose increased at investigator's discretion. Pts on TCZ 8+DMARD could have TCZ dose decreased at any time for safety. We reviewed safety/efficacy results for pts who previously received anti-TNF agents. Primary outcome was number (%) of pts with serious adverse events (SAEs) and serious infection events (SIEs). Secondary variables included ACR20/50/70 and DAS28 scores.

Results: The anti-TNF-IR subset in the intent-to-treat population comprised 552 pts (TCZ 4+DMARD=202; TCZ 8+DMARD=221; TCZ 8=129). Baseline disease characteristics in each group are shown in the table. Incidence rates of SAEs and SIEs were similar between COMBO groups and higher than those in the MONO group (Table). Most common SIEs were cellulitis and pneumonia; 2 pts in TCZ 4+DMARD group experienced GI perforations. Week 24 ACR response rates and DAS28 remission are also shown in the table for each treatment group (comparable to results for the overall population). At wk 24, pts in each group achieved a statistically significant change from baseline in DAS28 score ($P<0.0001$) (Table).

Table. Baseline Characteristics, Efficacy and Safety in the Anti-TNF-IR Subset of ACT-STAR

	Treatment Group		
Parameter	**TCZ 4/8+DMARD**	**TCZ 8+DMARD**	**TCZ 8 Monotherapy**
Baseline Characteristics			
n (intent-to-treat population, anti-TNF-IR)	202	221	129
RA disease duration (yrs), mean (SD)	12.7 (9.81)	12.0 (8.57)	13.2 (9.93)
DAS28 score, mean (SD)	5.78 (1.024)	5.65 (0.997)	6.13 (0.942)
Swollen joint count, mean (SD)	19.0 (11.53)	19.1 (10.62)	22.0 (12.00)
Tender joint count, mean (SD)	29.4 (14.30)	29.4 (15.70)	34.3 (16.26)
CRP (mg/dL), mean (SD)	1.70 (2.450)	1.43 (2.080)	1.85 (3.123)
Patients using ≥2 previous anti-TNF agents,%	45.8%	54.6%	53.2%
Efficacy (intent-to-treat population, anti-TNF-IR)			
Week 24 ACR20 response,% of pts	43.1	48.9	47.3
Week 24 ACR50 response,% of pts	22.8	22.6	20.9
Week 24 ACR70 response,% of pts	6.9	8.1	5.4
Change from baseline in DAS28 score at week 24, mean (SD)	−1.76 (1.283) $P<0.0001$	−1.85 (1.373) $P<0.0001$	−1.95 (1.445) $P<0.0001$
DAS28 remission at week 24,% of pts	17.6	22.8	15.7
Safety			
n (safety population, anti-TNF-IR)	203	240	109
AEs, Total Patients With ≥1, n (%)	170 (83.7)	200 (83.3)	87 (79.8)
AEs causing discontinuation	21 (10.3)	10 (4.2)	4 (3.7)
Total Patients With ≥1, n (%)	6 (3.0)	1 (0.4)	1 (0.9)
Infections and infestations	4 (2.0)	1 (0.4)	–
Gastrointestinal disorders	4 (2.0)	1 (0.4)	–
Skin and subcutaneous tissue disorders			
SAEs, Total Patients With ≥1, n (%)	15 (7.4)	19 (7.9)	5 (4.6)
Most common	2 (1.0)	2 (0.8)	2 (1.8)
SAEs (≥1%), n (%)	3 (1.5)	3 (1.3)	–
Cellulitis	2 (1.0)	–	–
Pneumonia			
Coronary Artery Disease			
SIEs, Total Patients With ≥1, n (%)	9 (4.4)	9 (3.8)	2 (1.8)
Most common SIEs (≥1%), n (%)	2 (1.0)	2 (0.8)	2 (1.8)
Cellulitis	3 (1.5)	3 (1.3)	–
Pneumonia			
Deaths, n (%)	1 (0.5)	–	–

Conclusion: In this refractory, US population of pts failing at least 1 anti-TNF, SAE and SIE rates were comparable in COMBO groups, but higher than those in the MONO group. This subanalysis represents the first data assessing TCZ monotherapy specifically in anti-TNF-IR patients, demonstrating equivalent efficacy at the 8 mg/kg dose to TCZ+DMARD combination therapy and a positive risk-benefit profile. These results may have important implications for the use of TCZ monotherapy in the refractory population of patients who have failed therapy with an anti-TNF agent.

428

14-3-3η, a Novel Mediator Upregulated by TNFα, Reflects Clinical Response to Anti-TNFα Therapy. Walter P. Maksymowych[1] and Anthony Marotta[2]. [1]University of Alberta, Edmonton, AB, [2]Augurex Life Sciences Corp, North Vancouver, BC

Background/Purpose: TNFα targeted therapies are routinely used in the treatment of RA and despite their efficacy, patient response remains heterogeneous. This underscores the unmet need for biomarkers to assist in the identification of likely responders. 14-3-3 proteins are intracellular proteins mediating several key signalling pathways but one isoform, 14-3-3η, has been detected extracellularly in the joints and serum of patients with arthritis. It has been described as a specific RA serum marker and as a novel drug target based on its induction of key factors, including TNFα, that are involved in the pathogenesis of RA. We investigated the direct effects of TNFα on 14-3-3η and whether its clinical expression reflects response to anti-TNFα therapy.

Methods: To examine the stimulatory effects of TNFα on 14-3-3η, monocytic THP-1 cells were stimulated with 50ng/ml, for 18h and % induction was determined through densitometry. Serum 14-3-3η was measured in a cohort of 74 RA patients who were refractory to standard DMARDs and candidates for anti-TNF therapy at pre-treatment and approximately 15 weeks post-treatment using an investigational-grade 14-3-3η ELISA. EULAR classification criteria were used to define good, moderate or non-response. Two-tailed paired and unpaired t-tests and Mann-Whitney U-tests were used to determine group differences in 14-3-3η levels pre-treatment and its modifiability post-treatment. Correlations were calculated between 14-3-3η and clinical variables using the Pearson chi-square.

Results: Stimulation of monocytes with TNFα resulted in a 30% increase in 14-3-3η transcripts. A good EULAR response was observed in 15 of the 74 patients (20%). The mean (SD) and median levels of 14-3-3η were higher in those who failed to achieve a good EULAR response [mean = 7.56 (8.28), median = 2.52ng/ml] compared to the good EULAR

responders [mean = 4.23 (6.86), median = 0.72ng/ml], with median differences being statistically significant (p=0.015). Post-treatment 14-3-3η serum levels were significantly lower than pre-treatment (mean difference of 0.93ng/ml (95% CI 0.089 to 1.78, t=2.21, p=0.031) indicating that serum 14-3-3η levels are modifiable with anti-TNFα therapy. There were no significant correlations between pre-treatment clinical variables and serum levels of 14-3-3η. For the whole cohort, Δ14-3-3η correlated moderately with ΔESR (r=0.35, p=0.002), ΔHAQ (r=0.28, p=0.016) and ΔCRP (r=0.25, p=0.036). A subset analysis of good EULAR responders (15 patients, 10 females) versus non-responders (17 patients, 11 females) revealed no correlation in the Δ14-3-3η with the change in clinical variables in non-responders but a high correlation with ΔESR (r=0.89, p<0.00001), ΔCRP (r=0.68, p=0.006) and importantly ΔDAS (r=0.56, p=0.009) in good responders.

Conclusion: 14-3-3η is up-regulated by TNFα in vitro and its serum levels are lower in patients who respond well to anti-TNFα therapy. Serum 14-3-3η expression is modifiable with anti-TNF therapy. In patients with good EULAR response, serum 14-3-3η levels correlate strongly with measures of clinical improvement. 14-3-3η should be further investigated as a promising candidate biomarker that predicts response to anti-TNF therapy.

429

Evaluation of the Association Between Disease Activity and Risk of Serious Infections in Subjects with Rheumatoid Arthritis When Treated with Etanercept or Disease -modifying Anti-rheumatic Drugs. Paul Emery[1], G. Gallo[2], C. L. Morgan[3], C. J. Currie[4], C. D. Poole[3] and Henk Nab[5]. [1]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [2]Pfizer, Rome, Italy, [3]Pharmatelligence, Cardiff, United Kingdom, [4]Cardiff University, Cardiff, United Kingdom, [5]Pfizer Europe, Rome, Italy

Background/Purpose: It has been reported that there is increased risk of serious infections (SI) when subjects are switched from disease modifying anti-rheumatic drugs (DMARD) therapy to a biologic. This increased risk is not seen following longer-term use of biologics and its aetiology is unknown. The purpose of this study was to determine if the rates of SI in subjects switched to etanercept (ETN), compared with a DMARD reference cohort, correlated with the level of disease activity.

Methods: Anonymised data on ETN and DMARD treated subjects were provided by the British Society of Rheumatology Biologics Register (BSRBR), a prospective observational study monitoring the long-term safety of TNF inhibitors and standard DMARDs in rheumatoid arthritis (RA) patients. At baseline subjects underwent detailed clinical assessment by a rheumatologist. Consultants and subjects completed follow-up questionnaires every six months for three years, then annually by consultants only for two years. Disease activity was measured using the DAS28. Infections were considered serious if they led to hospitalisation or the use of intravenous antibiotics or death. The risk of SI was compared in two ways at six months and for the entire period of follow-up. Firstly, using a simple calculation of the rate per 1000 person years (py) for each aggregated level of the DAS28. Secondly, using a multivariate Cox model. Models were specified using a forward manual inclusion method for parameters where significance was P<0.05.

Results: ETN n=3,470, DMARD n= 1,365. There were differences in baseline characteristics: ETN subjects were significantly younger (55.4 vs. 59.5 yrs; P<0.001) but with a longer duration of RA (13.6 vs. 9.6 yrs; P<0.001) compared to DMARD subjects. ETN subjects had significantly greater disease activity (DAS28 6.5 vs. 5.7; P<0.001) and greater disability (HAQ 2.07 vs. 1.68; P<0.001). In a combined analysis for the whole observational period, there was an association between DAS28 and risk of SI. Where DAS28 ≤5, the infection rate was 27.1 per 1,000 py. This increased to 40.5 per 1,000 py at DAS28 >6 and ≤7, and 64.2 per 1,000 py at DAS28 >8. In Cox regression models, DAS28 was associated with a 16% increase in hazard ratio for each integer increase in the score (HR = 1.17, 95% CI 1.08–1.27; p<0.001). Other significant variables were age, gender, baseline HAQ score and comorbidity index. Treatment type was not significant in the model, ETN vs. DMARD (HR =1.07, 95% CI 0.86–1.32; p=0.561).

Conclusion: There was a linear association between DAS28, and the risk of SI. This infers that reducing disease activity would reduce the likelihood of SI. These data support the hypothesis that it is disease activity per se that is associated with SI. With long term follow up, treatment type was not associated with SI. It is important to note that these are observational data, and further corroboration is required.

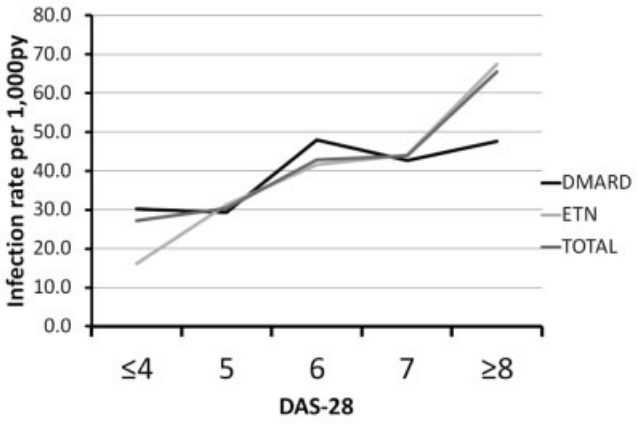

Figure 1. Crude rate of infection by DAS28

A Nationwide Survey on Patient's Versus Physician's Evaluation of Biological Therapy in Rheumatoid Arthritis in Relation to Disease Activity and Route of Administration: The Be-Raise Study. Jan Lenaerts[1], Bert Vander Cruyssen[2], H. Mielants[3], Rene Westhovens[4], Patrick Durez[5] and Dirk Elewaut[6]. [1]Department of Rheumatology, Catholic University Leuven, Belgium, Reuma-instituut Hasselt Belgium., Hasselt, Belgium, [2]OLV Hospital Aalst and St-josephs hospital Bornem, Aalst, Belgium, [3]University Hospital, Gent, Belgium, [4]University Hospital KU Leuven, Leuven, Belgium, [5]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium, [6]Gent University Hospital, Ghent, Belgium

Background/Purpose: The Belgian Be-raise survey aimed to explore how patients experience their current treatment with biologicals and correlate this with the treating physician's opinion.

Methods: This is a nationwide cross-sectional survey in which all Belgian rheumatologists were invited to participate. Each rheumatologist could include 10 RA patients treated with a biological for at least 6 months. Both patients and physicians completed a similar extensive questionnaire, but were blinded for each other's judgments. Questions covered various items on current treatment (including participation, compliance and practical issues); in this abstract we focus on patients satisfaction with disease control and compare this to the perception of the treating rheumatologist. Most questions were reported on a 0–10 likert scale. Good satisfaction was defined by a score of ≥9

Results: As of April 2011, 478 questionnaires were available from 255 intravenously (IV) treated and 223 subcutaneously (SC) treated patients coming from 37 centers and 63 rheumatologists, which represents about one third of all Belgian rheumatologists. Patients were treated with Etanercept (17.7%), Adalimumab (26.9%), Certolizumab (0.8%) Golimumab (2%), Rituximab(10.2%), Abatacept (7.7%), Infliximab (21%) orTocilizumab (13.6%). The mean DAS-28-CRP was 2.8. 46% of patients were in remission, 18% had low disease activity, 34% moderate disease activity and 3% high disease activity.

The patient satisfaction on the overall control of RA symptoms was higher (44% scored≥9)) than this of the treating physician (35%), regardless of the route of administration (p<0.005). In addition, no differences were seen for the patients treated with an IV compared to a SC administration. In striking contrast herewith, the physicians perception of satisfaction with disease control was markedly lower for IV treated patients (31% scoring ≥9)) as opposed to SC treated patients (47%) (p< 0.01). Further regression analyses, corrected by a propensity score for IV/SC allocation (including amongst others sex, age, professional status and disease duration) revealed that patients are significantly more satisfied of the way of administration when they are also comfortable about disease control (OR = 4.6, 95% CI 3.0–7.1) whereas IV or SC route (OR = 0.89,

95% CI 0.57 – 1.38) or the frequency of administration (OR = 0.74, 95% CI 0.48–1.13, p = NS) did not affect the appreciation of therapy. This is again contrasted with the physicians appreciation of the patient's score: IV use was consistently rated lower than SC use (OR = 0.54, 95% CI = 0.33 – 0.89, p = 0.017), irrespective of disease activity or the frequency of therapy administration.

Conclusion: There is a considerable mismatch between patients and rheumatologists appreciation on the route of administration of biological therapy in RA. Physicians consistently consider iv biological therapy to be less satisfactory, whereas the patients appreciation is independent of the route of administration. Overall, the data underscore the importance of patient reported feedback in overall assessment of biological treatment regimens.

431

Combination of Disease-Modifying Antirheumatic Drugsprohibits the Need of Early Initiation of Biologicals, Independent of Glucocorticosteroids. A clinical trial to Investigate Different Induction Therapies in Early Rheumatoid Arthritis. P.H.P. de Jong[1], Johanna Hazes[2], P.J. Barendregt[3], A.M. Huisman[4], D. van Zeben[4], P.A. van der Lubbe[5], A.H. Gerards[5], M.H. de Jager[6], P.B. de Sonnaville[7], B.A. Grillet[8], Jolanda J. Luime[9] and A.E.A.M. Weel[3]. [1]University Medical Center, Rotterdam, Netherlands, [2]Erasmus Medical Centre Rotterdam, Rotterdam, Netherlands, [3]Maasstad Hospital, Rotterdam, Netherlands, [4]Sint Franciscus Gasthuis, Rotterdam, Netherlands, [5]Vlietland Hospital, Schiedam, Netherlands, [6]Albert Schweitzer Hospital, Dordrecht, Netherlands, [7]Admiraal de Ruyter hospital, Goes, [8]Zorgsaam hospital, Terneuzen, Netherlands, [9]Erasmus MC - University Medical Center, Rotterdam, Netherlands

Background/Purpose: The recently published EULAR treatment guideline recommend treatment targeted to achieve remission or at least low disease activity within 3 months and definitely within 6 months. Recommended treatment for DMARD naïve patients is Methotrexate (MTX) with or without glucocorticoids (GCs). Combination therapy however is not recommended, because well proven evidence of superior efficacy is suggested to be lacking. Furthermore possible drug toxicities might influence the choice of induction therapy. To compare the 3 month clinical efficacy of: (1) combination DMARD vs. MTX mono-therapy and (2) oral GCs bridging therapy vs. 1 dose of intramuscular (im) GCs in patients with early RA.

Methods: For this study data are used of a currently ongoing single-blinded randomized clinical trial in patients ≥18 years with recent-onset arthritis (tREACH). We included patients who had a high probability (> 70%) according to their likelihood of progressing to persistent arthritis based of the prediction model of Visser. The Visser algorithm and 2010 criteria for RA have similar discriminative abilities to identify patients at risk of persistent arthritis at 1 year. Patients were randomized into 3 induction therapy strategies: (A) Combination therapy (MTX 25 mg + Sulphasalazine (SASP) 2 gr. + Hydroxychloroquine (HCQ)) 400 mg with im GCs (Depomedrol 120mg), (B) Combination therapy with an oral GCs tapering scheme (starting 15 mg) and (C) MTX with oral GCs similar to B. In case of *'treatment failure'*, defined as DAS>2.4, medication is intensified to MTX with a biological.

We investigated following response parameters: treatment failure, EULAR response criteria and decrease in DAS and HAQ. Statistical comparison between the baseline characteristics and clinical response parameters of all treatment arms were made by the student's t-test, χ^2 test, or the Wilcoxon rank-sum test, when appropriate.

Results: We random allocated 279 patients (mean symptom duration: 166 days, 59% ACPA pos and 16% with erosive disease) over 3 treatment arms. Baseline characteristics per arm are given in table 1.

Table 1. Baseline characteristics of patients with a high probability to develop a persistent arthritis

	A. Combination therapy + intramuscular GCs (n = 91)	B. Combination therapy + oral GCs (n = 93)	C. MTX + oral GCs (n = 95)

HAQ, *mean (95% CI)*	0.53 (0.39–0.67)	0.54 (0.40–0.67)	0.72 (0.56–0.87)
ΔHAQ (T3–T0), *mean (95% CI)*	−0.40 (−0.28 to −0.53)	−0.41 (−0.28 to −0.54)	−0.41 (−0.26 to −0.55)

Abbreviations: MTX = Methotrexate, SASP = Sulphasalazine, HCQ = Hydroxychloroquine, GC = glucocorticosteroids, CI = Confidence Interval
* moderate to high disease activity
1: P<0.05 B vs. C and P<0.01 A vs. C
2: P<0.05 B vs. C
3: P<0.01 A/B vs. C
4: P<0.05 B vs. C

Conclusion: In patients with early RA according to the new ACR/EULAR 2010 a combination of DMARDs (MTX + SSZ + HCQ) are superior to MTX monotherapy in achieving low disease activity. Furthermore both intramuscular and oral GCs can be used as bridging therapy.

432

Sustained Remission in Anti-TNF Treated Rheumatoid Arthritis Patients. Observational Data From Southern Sweden. Jon T. Einarsson, Pierre Geborek, Tore Saxne and Meliha C. Kapetanovic. Dept of Clinical Sciences, Lund, Section of Rheumatology, Lund University, Sweden, Lund, Sweden

Background/Purpose: Remission is increasingly becoming a treatment goal in rheumatoid arthritis (RA) patients and DAS28 remission criteria are widely used, despite their limitations. The purpose of this study was to study frequency, duration and predictors of sustained remission (SR), defined as DAS<2.6 for at least 6 months, in patients with established RA treated with anti-TNF drugs in the observational setting of Southern Sweden.

Methods: Patients with a clinical diagnosis of RA initiating any anti-TNF treatment between March 1999 and December 2009 were eligible for this study. Disease and treatment characteristics at baseline and at each follow up were retrieved from the South Swedish Arthritis Treatment Group register (SSATG). The registry was searched for patients fulfilling the DAS28 remission criteria on at least two occasions ≥3 months after treatment initiation. Remission time was defined as time between first visit with DAS28<2.6 and first visit with DAS28>2.6. To compensate for intercurrent diseases patients were allowed to have DAS28>2.6 at one occasion given that they fulfilled the remission criteria for at least 6 months before and afterwards. All data were assessed by one researcher (JTE) who identified patients fulfilling the SR definition. Possible baseline predictors of SR were studied using multivariate binary logistic regression models.

Results: Of 3446 initiated treatments, 481 (14 %) treatments fulfilled SR criteria. Of these, 222 (6 %) were still in remission at last follow up. 181

treatments escaped remission. Of these 159 remained on the original treatment, 2 stopped, and 23 switched to another biologic. Altogether 77 patients in the SR group stopped the original treatment, 15 (0.4 %) due to remission. Mean time before SR was achieved was 18 months, range 0–100. Number of treatments, time to- and duration of SR, stratified according to SR ever, ongoing, escape, and 1st,2nd or 3rd anti TNF course are given in the table. Predictors for reaching SR were (OR; 95%CI): male gender 1.83; 1.5–2.3, low age 0.83, 0.8–0.9, low HAQ 0.43 0.4–0.5, low DAS28 0.68; 0.6–0.8, methotrexate treatment 1.64; 1.3–2.1), and no previous biologic treatment OR 1.66; 1.3–2.1.

Conclusion: SR was not common in RA patients on TNF inhibitors in the observational setting and in general required long time to be reached. However, patients achieving SR remained in remission for a substantial period of time. Male gender, and lower age, low DAS or HAQ, concomitant methotrexate, and no previous biological treatment at treatment initiation were positive predictors of SR.

Risk of Fatal Infection and Malignancy Related to Use of Anti-Tumor Necrosis Factor-Alpha Biologics by Rheumatoid Arthritis Patients. Veena Thyagarajan[1], Heather Norman[2], Kimberly Alexander[3], Pavel Napalkov[3] and Cheryl Enger[1] [1]OptumInsight, Ann Arbor, MI, [2]OptumInsight, Waltham, MA, [3]Genentech, Inc., South San Francisco, CA

Background/Purpose: Rheumatoid arthritis (RA) may be treated with biologics which inhibit the pro-inflammatory cytokine tumor necrosis factor alpha (aTNF). The pro-inflammatory and apoptotic properties of TNF play a role in controlling infection and reducing malignant cell formation. This study estimated the risks of fatal infection and fatal malignancy among RA patients treated with aTNF biologics.

Methods: A retrospective cohort study of RA patients who initiated treatment with adalimumab (ADA), etanercept (ETN), or infliximab (INF) (including aTNF naïve and aTNF switchers) from January 2000 to December 2008 was conducted using the Normative Health Information (NHI) database, an administrative database of a large US healthcare insurer. Patients were followed for the occurrence of fatal infection and fatal malignancy. aTNF therapy was identified in the NHI database by procedure claims for physician-administered drugs and by pharmacy dispensings for patient-administered drugs. Current exposure for physician-administered drugs was defined according to prescribing guidelines for RA plus 30 days and by recorded days supply in pharmacy records for patient-administered drugs plus 30 days. Study outcomes were identified by external linkage to the National Death Index database. Unadjusted incidence rates (IRs) per 1,000 person-years (PY) for study outcomes were calculated for each aTNF. Intent-to-treat analysis was the primary analysis for fatal malignancy where exposure status is based on the aTNF on which the person entered the cohort, regardless of whether the patient discontinued the drug or switched to another aTNF during follow-up. Time-on-drug analysis was the primary analysis for fatal infections where exposure status is based on current exposure with exposure censored upon treatment discontinuation or switch to a different aTNF. The association between baseline covariates and fatal infection were estimated with unadjusted ORs and 95% CIs for each covariate.

Results: 7,734 patients initiated ADA, ETN, or INF (13,296 PY for fatal malignancy; 10,710 PY current exposure for fatal infections). 21 fatal malignancies were identified. The IR for fatal malignancy was 1.24 (95% CI: 0.42–2.96) among ADA initiators, 1.57 (95% CI: 0.78–2.87) among ETN initiators, and 1.84 (95% CI: 0.87–3.48) among INF initiators. 12 fatal infections, including 2 fatal opportunistic infections, were identified. The IR for fatal infection was 0.78 (95% CI: 0.15–2.49) during current ADA exposure, 0.88 (95% CI: 0.30–2.10) during current ETN exposure, 0.83 (95% CI: 0.23–2.21) during current INF exposure, and 1.16 (95% CI: 0.32–3.09) during no current drug exposure. An increased unadjusted OR of fatal infection was observed with baseline chronic lung disease (OR: 13.62; 95% CI: 2.98–51.16), cardiovascular disease (OR: 10.12; 95% CI: 2.22–37.96), and steroidal estrogen use (OR: 4.79; 95% CI: 1.52–15.12).

Conclusion: The occurrence of fatal malignancy and fatal infection was rare. Risks for fatal malignancy and fatal infections were similar across aTNFs. The small number of outcomes limits inference of these risk estimates and prevented inclusion of baseline covariates into an adjusted model.

434

Early Reductions in Tissue Inflammation with Tocilizumab As Either Monotherapy or in Combination with Methotrexate: 12-Week Unblinded Results From a Magnetic Resonance Imaging Substudy of a Randomized Controlled Trial. Philip G. Conaghan[1], Charles G. Peterfy[2], Julie DiCarlo[2], Ewa Olech[3], Alan R. Alberts[4], Jeffrey A. Alper[5], Jenny Devenport[6], Andrew M. Anisfeld[6] and Orrin M. Troum[7]. [1]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [2]Spire Sciences LLC, San Francisco, CA, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]West Broward Rheumatology Associates, Inc., Tamarac, FL, [5]Jeffrey Alper MD Research, Naples, FL, [6]Genentech, South San Francisco, CA, [7]USC Keck School of Medicine, Santa Monica, CA

Background/Purpose: Tocilizumab (TCZ) monotherapy (MONO) has been shown to be superior to methotrexate (MTX) in achieving clinical reduction of disease activity in rheumatoid arthritis (RA).[1] A 24-week (wk) interim analysis of the double-blind phase 3b ACT-RAY study[2] showed no additional clinical benefit from adding MTX to TCZ vs switching to TCZ+PBO in patients with an inadequate response to MTX. It is important to determine if tissue inflammation, an important predictor of radiographic damage, is reduced in an analogous pattern. While MRI results from the blinded TCZ±MTX population have been reported,[3] this analysis examined effects of MRI measures of synovitis (SYN), osteitis (OST), and erosion (ERO) through wk 12 after therapy initiation by treatment assignment in patients with erosive RA.

Methods: In the ACT-RAY study, RA patients with inadequate response to MTX were randomized to continue stable MTX or receive placebo (PBO), both in combination with TCZ 8 mg/kg IV every 4 wks. In a substudy of this trial (N=63), 0.2T extremity MRI of one hand (metacarpophalangeal joints 1–5) and wrist was acquired at baseline (BL) and wks 2, 12, and 52. MRIs were quality-controlled and scored by 2 blinded radiologists by a RAMRIS method. Change in scores from BL through wk 12 for the TCZ+MTX and TCZ+PBO groups in this substudy are compared to evaluate early effects on joint inflammation between the two treatment regimens.

Results: BL mean RAMRIS scores showed high disease severity and burden in both groups (Table). Decreases in SYN and OST were observed at wk 2 and became statistically significant in both groups by wk 12. No significant changes from BL in mean ERO score emerged (Table). BL osteitis scores were higher in the PBO group; the proportion of patients who experienced improvements ≥Smallest Detectable Change (SDC) for both SYN and OST was higher in the PBO group than in the MTX group. Similar numbers of patients experienced ERO progression vs regression in each group (Table). During this period, no patient in the TCZ+PBO group and only 1 (3.3%) patient in the TCZ+MTX group developed a newly eroded bone.

Table. Mean Values and SDC-Based Classification of RAMRIS Scores

	TCZ+MTX (N = 31)					TCZ+PBO (N = 32)				
Mean RAMRIS Score	BL (n = 31)	Wk 2 (n = 31)	BL to Wk 2 Δ (95% CI) (n = 31)	Wk 12 (n = 30)	BL to Wk 12 Δ (95% CI) (n = 30)	BL (n = 32)	Wk 2 (n = 32)	BL to Wk 2 Δ (95% CI) (n = 32)	Wk 12 (n = 29)	BL to Wk 12 Δ (95% CI) (n = 29)
SYN	7.2	7.1	−0.1 (−0.5, 0.3)	6.3	−0.9* (−1.6, −0.2)	7.4	6.5	−0.9† (−1.5, −0.4)	5.7	−1.9‡ (−2.8, −1.0)
OST	7.8	7.6	−0.2* (−1.3, 0.9)	4.4	−3.6† (−6.5, −0.7)	11.1	10.3	−0.7 (−1.8, 0.3)	5.5	−5.1* (−8.6, −1.6)
ERO	19.4	19.4	0.0 (−0.4, 0.5)	19.2	−0.3 (−1.2, 0.6)	16.0	16.2	0.2 (−0.0, 0.5)	16.6	0.0 (−0.6, 0.6)

* $P<0.01$, † $P<0.001$; ‡ $P<0.0001$.
Wilcoxon Signed Rank test for no change from BL within group; Percentile interval: 95% CI of mean change from BL within group.

	TCZ+MTX (N=30) n (%)		TCZ+PBO (N=29) n (%)	
Classification Derived from SDC[a] at Wk 12	Regressors (Change ≤ SDC)	Progressors (Change ≥ SDC)	Regressors (Change ≤ SDC)	Progressors (Change ≥ SDC)
SYN	7 (23.3)	1 (3.3)	11 (37.9)	0
OST	6 (20.0)	0	9 (31.0)	1 (3.4)
ERO	3 (10.0)	2 (6.7)	3 (10.3)	2 (6.9)

[a] SDC values at wk 12:
SYN: 1.71
OST: 4.27
ERO: 1.51

Conclusion: These MRI data (previously blinded for TCZ±MTX, but now unblinded to evaluate TCZ+MTX and TCZ+PBO groups separately) demonstrate that TCZ is associated with early suppression of SYN and OST, with no mean increase in ERO score observed through wk 12. The similarities

in MRI findings between TCZ+PBO and TCZ+MTX groups suggest that continuation of MTX in combination with TCZ or switching to TCZ MONO are equally beneficial for early suppression of joint inflammation. TCZ MONO may be an appropriate alternative to TCZ+MTX in patients who are intolerant or unwilling/unable to take MTX.

Infliximab Versus Placebo in Adult Patients with ACPA Positive Undifferentiated Arthritis. Patrick Durez[1], Laurent Meric de Bellefon[1], Genevieve Depresseux[1], Adrien Nzeusseu Toukap[1], Bernard Lauwerys[1] and Frédéric. A. Houssiau[2]. [1]Cliniques Universitaires St Luc, Brussels, Belgium, [2]Université catholique de Louvain, Brussels, Belgium

Background/Purpose: Patients (pts) with Undifferentiated Arthritis (UA), positive for ACPA antibodies are at high risk of progressing to Rheumatoid Arthritis (RA). TNF plays a key role in the pathogenesis of RA. Very early treatment with the combination of Methotrexate and Infliximab (IFX) in a small cohort of UA showed a benefit in clinical symptoms and reduction of MRI evidence of synovitis and erosions[1].

Objectives: To assess whether IFX is more effective than placebo (Pbo) in preventing the development of RA in adult pts with UA at high risk of the development of RA. Other end points were clinical response and synovitis assessed by MRI and synovial biopsy.

Methods: This was a randomized, double-blind, Pbo-controlled, two-arm parallel design study of 12 months to the primary endpoint (proportion of pts who developed RA by ARA 2007 criteria). Pts with UA and symptomatic clinical synovitis of ≥1 joints and ACPA positivity were randomized 1:1 to IFX (3 mg/kg) or Pbo at week 0, 2, 6, 14 and 22, after which treatment was terminated. NSAIDs/stable low-dose oral corticosteroid (≤5 mg/day prednisone or equivalent) were permitted but no DMARDs. Pts who developed RA at any time were discontinued and could receive standard of care. Paired synovial biopsies were harvested by needle-arthroscopy at baseline and at week 12 from the knee of 8 Pbo and 8 IFX patients.

Results: 30 pts were randomized (mean age: 48 +/− 12 yrs; mean duration of arthritis: 0.34 +/− 0.53 yr; mean CRP level: 1.67 +/− 2.23 mg/dL); 7 had preexisting erosions. By 1 yr, 11/15 pts treated with IFX developed RA vs 10/15 Pbo-treated pts (Kaplan Meier, log rank p=0.868). At week 14, peak ACR 20, 50, 70 responses were observed respectively in 71.4%, 42.9%, 28.6% pts treated with IFX vs 21.4%, 0%, 0% treated with Pbo. Remission DAS28CRP rate was observed in 50% in the IFX group vs 21.4% in the Pbo group. Pbo and IFX did not display any differential effect on semi-quantitative evaluation of synovial CD3, CD15, CD20, CD68 and CD138 positive cells between baseline and week 12.

No severe safety issue was observed except one case of severe hepatotoxicity induced by Isoniazid.

Conclusion: IFX is effective in ACPA positive UA patients but did not prevent the progression to definite RA. In a majority of these patients, longterm DMARDs therapy is indicated.

Predicted Versus Observed Radiographic Progression in a Randomized Trial. Ronald F. van Vollenhoven[1], Heléne Hanses[1], Kristina Forslind[2], Pierre Geborek[3], Ingemar F. Petersson[3], Sofia Ernestam[4] and Johan Bratt[4]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Helsingborgs Lasarett and Lund University, Lund, Sweden, [3]Lund University, Lund, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden

Background/Purpose: Radiological progression is a key outcome in early RA. We previously developed a method of predicting radiological progression based on the patient's report of symptom duration and the radiological damage at first examination[1]. In the SWEFOT trial[2], 487 patients with early RA were given MTX, and those who had not responded after 3–4 months (DAS28>3.2) were randomized to MTX+SSZ+HCQ ("Triple therapy") vs. MTX+infliximab ("anti-TNF"). The others continued on MTX ("MTX-responders"). Here, we employed analysis of prediction radiological progression (prediction of progression in early RA, POPERA) to these 3 patient groups from the SWEFOT trial.

Methods: Hand and foot X-rays were obtained at baseline and after 1 and 2 years, and analyzed by the Sharp-van der Heijde (SvdH) method. Predicted progression over 1 and 2 years was calculated as the SvdH score at baseline divided by the duration of symptoms in months × 12 and × 24, respectively. The analyses were based on intention-to-treat without imputations. Additional analyses focused on patients in the randomized arms of the trial who had discontinued the trial (i.e. they had "failed" the randomized treatment) and on the patients who maintained the randomized treatment for the full two years ("completers"). Comparisons between predicted and observed progression were done by non-parametric testing.

Results: In patients who had failed both MTX monotherapy and subsequent randomized triple-therapy treatment, the observed radiological progression was numerically similar to predicted progression. In all three groups of patients, observed radiological progression was reduced from predicted by 67–101% (table). After 12 months, the reduction in progression was numerically greater for MTX-responders and for patients randomized to anti-TNF than for those randomized to triple therapy, but the difference was not statistically significant. After 24 months, anti-TNF therapy provided significantly greater reduction of progression compared to triple therapy in both ITT and responder analyses, and for anti-TNF completers the reduction of progression was also significantly greater than that seen in MTX responders (p=0.004).

	MTX responders	Triple therapy ITT	Anti-TNF ITT	Triple therapy completers	Anti-TNF completers
At 12 months	75.7%	67.1%	77.9%	75.5%	81.0%
At 24 months	80.6%	85.7%*	94.1%*	85.5%**	101.2%**

* Triple therapy vs. anti-TNF (ITT) p<0.02
** Triple therapy vs. anti-TNF (responders) p<0.05

Conclusion: The progression observed in patient who failed their first 2 antirheumatic therapies was close to predicted, indirectly supporting the validity of this method. The overall results demonstrated significant reductions of radiological progression in patient groups who were successfully treated with MTX and in those who were included in either group of the randomization. Over 24 months, the reduction of predicted radiological progression was significantly greater in anti-TNF treated patients than in the triple therapy group.

A Novel SYK Specific Inhibitor for the Treatment of Rheumatoid Arthritis. Eun-Ho Lee[1], Sun-Hwa Chang[1], Hae Jun Hwang[1], Jang-Sik Choi[1], Dong Sik Jung[1], Sung Ho Park[1], Sun Ju Wang[1], Il Hwan Yang[1], Sang Yeop Lee[1], Jung-Ho Kim[1], Ho-Juhn Song[2], Jaekyoo Lee[2], Jong Sung Koh[2], Se Won Kim[1] and Jung Kun Kim[1]. [1]OSCOTEC Inc., Choongnam, South Korea, [2]GENOSCO, Cambridge, MA

Background/Purpose: Spleen tyrosine kinase (SYK) is known to a key mediator of immunoreceptor signalings in various cell-types. Those immunoreceptors are well known to have important roles in the pathological changes of immune disease, such as rheumatoid arthritis, allergy and asthma. Currently SYK is considered as the one of the promising targets for RA treatment. SKI-O-259, a novel oral SYK-specific inhibitor, is under development as an inflammation modulator for the treatment of rheumatoid arthritis. We have characterized its SYK-specific *in vitro* profiles and evaluated *in vivo* efficacy in mouse collagen-induced arthritis (CIA) model.

Methods: *In vitro* efficacy and selectivity of SKI-O-259 was evaluated in kinase assays. Effects on the immune and inflammatory cells were assessed from FcRg-, FcRe- and BCR-mediated cells based assays and western blot analysis. *In vivo* efficacy of SKI-O-259 was carried out in the mouse CIA model. *In vitro* and *in vivo* pharmacokinetic studies, CYP450 inhibition assay, hERG inhibition assay and mouse toxicity studies were also performed. R406 or its pro-drug, R788 was used as a reference to compare pharmaceutical profiles with SKI-O-259.

Results: SKI-O-259 showed potent inhibitory effect on SYK (IC_{50} of 19.5 nM). It was highly specific for SYK in a panel of 138 kinases at 100 nM. Its potency and specificity were also confirmed from isolated cell-free assays. SKI-O-259 effectively inhibited FcRg-, FcRe- and BCR-mediated signaling pathway with IC_{50} ranging from 56.7 to 410 nM. Interestingly *in vitro* SYK inhibition activities were maintained relatively constant in the presence of 10% serum. Also, SKI-O-259 showed sufficient potency in the physiologically relevent concentration of 1.5 mM ATP. Orally administered SKI-O-259 showed significant and dose-dependent inhibition of paw edema comparable to a reference in the mouse CIA models. SKI-O-259 showed a good *in vivo* pharmacoki-

netic profiles after single oral administration (Cmax: 402 ng/ml, AUC: 1627 ng*h/mL, and $T_{1/2}$: 3.1 hr). No significant inhibitions of CYP450 isozymes and hERG were observed. Oral maximum tolerated doses were higher than 2000 mg/kg in the single dose toxicity study and higher than 500 mg/kg in the 5-day repeated dose toxicity study in mice.

Conclusion: Our results suggest that SKI-O-259 is a potent SYK inhibitor with high target selectivity and feasibility under physiologically relevant condition of serum and ATP. SKI-O-259 showed a potent anti-arthritis effect after oral administration along with a good pharmacokinetic and safety profiles. Therefore, SKI-O-259 is a novel and potential candidate for orally available RA drug.

Background/Purpose: No randomized head-to-head trial compared rituximab (RTX) to abatacept (ABA) in rheumatoid arthritis (RA), and their effectiveness was only compared to placebo, synthetic DMARDs, and infliximab (for abatacept). We aimed to compare the efficacy of RTX with ABA in patients included in the French Society of Rheumatology registries.

Methods: The French Society of Rheumatology has set up "AutoImmunity and Rituximab" (AIR) and "Orencia and Rheumatoid Arthritis" (ORA) 5-year independent prospective registries using the same protocol. Patients have been included between 2006 and 2010 in 92 centers for AIR, 84 centers for ORA, including 72 centers common for both, by the same clinicians. Data have been collected by the same trained clinical nurses in both registries. The primary efficacy outcome was EULAR response. Secondary efficacy outcomes were low disease activity and remission. A propensity score weighted outcome model was used to adjust for group diffences.

Results: Among the 3028 RA patients included in AIR(n= 1995) and ORA (n= 1033), 2396 had already a follow-up longer than 4 months, including 2240 with no prior treatment with RTX or ABA. Thus, 2240 patients, including 1732 patients treated with RTX and 508 treated with ABA, were presently analyzed. DAS28 data were available at baseline and 6 months in 828 patients treated with RTX and 364 patients treated with ABA. The main baseline differences concerned the proportion of patients with a history of cancer (12.6% and 6.1%, respectively), number of prior synthetic DMARDs (3.1±1.4, and 2.8±1.4, respectively), DAS28 (5.6±1.2 and 5.3±1.3, respectively) and without any previous anti-TNF (21.2% and 10.7%, respectively). At 6 months, 511 (61.7%) patients treated with RTX were EULAR responders, including 173 (20.9%) good and 338 (40.8%) moderate response and 214 (58.8%) patients treated with ABA were EULAR responders, including 80 (22.0%) good and 134 (36.8%) moderate response. Median DAS28 decrease was −1.3±1.4 and −1.2±1.6, respectively. Before adjustment with propensity score, EULAR response (good and moderate), low disease activity and remission rate were not statistically different between patients treated with RTX or ABA (61.7% vs 58.8%, 23.6% vs 28.8% and 12.2% vs 15,9%, respectively). After multivariate regression analysis adjusted on the propensity score, no significant difference was observed between RTX and ABA, regarding EULAR response (OR=1.00, 95%IC=[0.84–1.20]), low disease activity (OR=0.86, 95%IC=[0.70–1.05]) and remission (OR=0.79, 95%IC=[0.61–1.02]).

Conclusion: The present study presents the first to date comparison of efficacy between RTX and ABA in RA, using the same protocol for data collection, in patients depending on the same healthcare system, with similar disease characteristics and included during the same period. No significant difference was observed between RTX and ABA on the evaluated efficacy endpoints. Further comparisons of tolerance and drug retention rate are currently ongoing. The similar response observed in RA in real life with RTX and ABA at the level of a population emphasizes the need for the identification of predicting factors of efficacy for each of these drugs in the perspective of personalized medicine.

Interferon Type I Signature Predicts Non Response to Rituximab in Rheumatoid Arthritis. Hennie G. Raterman[1], Saskia Vosslamber[1], Michael T. Nurmohamed[2], Willem F. Lems[1], Maarten Boers[1], Ben A.C. Dijkmans[3], Cornelis L. Verweij[1] and Alexandre E. Voskuyl[1]. [1]VU University medical center, Amsterdam, Netherlands, [2]Reade, Centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands, [3]Reade, Centre for Rehabilitation and Rheumatology and VU University Medical Centre, Department of Rheumatology, Amsterdam, Netherlands

Background/Purpose: B Lymphocyte depletion therapy is effective in rheumatoid arthritis (RA). However, about 35% of RA patients do not respond to rituximab (RTX). Identification of nonresponders before initiation of RTX would prevent unnecessary costs, risk for adverse effects and delays in effective treatment. We investigated whether baseline gene expression levels can predict RTX nonresponse.

Methods: Genome–wide gene expression profiling in whole peripheral blood of 14 consecutive RA patients starting RTX (test cohort) was performed using Illumina® HumanHT beadchip microarrays. Nonresponse was defined in two ways: ΔDAS28 $<$ 1.2 and EULAR non response Supervised cluster analysis on gene expression profiles based on difference in disease activity score (DAS28) after 6 months RTX) was used to identify genes expressed differentially between responders and non-responders. The predictive capacity of the genes of interest was subsequently assessed in a validation cohort (n = 28) by quantitative real-time PCR. The clinical potential of the possible predictive genes was determined based on Receiver Operating Characteristics (ROC)-curve analysis.

Results: In the test cohort 6/14 patients were nonresponders defined as ΔDAS28 $<$ 1.2. Genome-wide gene expression analysis revealed that only interferon response genes (IRG) were significantly differentially expressed with ΔDAS nonresponse. High IRG expression levels of a cluster of 5 IRG strongly predicted nonresponse: Area Under Curve (AUC): 0.92 ($p = 0.01$) for ΔDAS28 $<$ 1.2 and 0.82 ($p = 0.05$) for EULAR nonresponse. In the validation cohort AUC was 0.74 ($p = 0.04$) and 0.70 ($p = 0.09$), respectively. Logistic regression demonstrated an inverse association between IRG expression levels and clinical response defined as ΔDAS28 $>$ 1.2 (OR: 0.33, 95% C.I.: 0.13–0.79, $p = 0.013$). Adjustment for positivity for IgM rheumatoid factor, ACPA or previous use of more than 1 TNF blocking agent did not influence these results.

Conclusion: High baseline IRG expression levels are a potential biomarker to predict RTX nonresponse.

440

Remission Induction Therapy with Methotrexate and Prednisone in Patients with Early Rheumatoid and Undifferentiated Arthritis. K.V.C. Wevers-de Boer[1], L. Heimans[1], K. Visser[1], H.K. Ronday[2], T.H.E. Molenaar[3], P.E.H. Seys[4], C. Bijkerk[5], M.L. Westedt[6], W. De Beus[7], P.B. de Sonnaville[8], T. Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, Netherlands, [3]Groene Hart Hospital, Gouda, Netherlands, [4]Franciscus Hospital, Roosendaal, Netherlands, [5]Reinier de Graaf Gasthuis, Delft, Netherlands, [6]Bronovo Hospital, The Hague, Netherlands, [7]MCH, The Hague, Netherlands, [8]Admiraal de Ruyter Hospital, Goes

Background/Purpose: To assess the proportion remission after 4 months of treatment with methotrexate (MTX) and a tapered high dose prednisone in patients with undifferentiated arthritis (UA) and early rheumatoid arthritis (RA). To identify independent predictors for remission.

Methods: IMPROVED is a multicenter clinical study in patients with recent onset RA ($<$ 2 years symptoms) and UA, with a baseline Disease Activity Score (DAS) $\geq$ 1.6. 610 patients were included, 479 (79%) patients could be classified as RA patients (according to the 2010 criteria), 121 (20%) patients could not (UA). All patients started MTX 25 mg/wk and prednisone 60 mg/day tapered to 7.5 mg/day in 7 weeks, aimed at achieving remission, defined as DAS $<$ 1.6. Percentages remission after four months were compared between RA and UA. Independent predictors for remission were identified using univariate followed by multivariate logistic regression.

Results: At baseline, RA patients had a higher mean DAS (SD) than UA patients (3.34 (0.92) vs 2.70 (0.66), P<0.001), were more often female (70% vs 60%, P=0.05) and ACPA positive (68% vs 3 %, P<0.001) and had more involvement of small joints (100% vs 93%, P<0.001). After 4 months, remission was achieved in 61% of the patients without a difference between RA and UA (61% vs 64%, P=0.51). ACPA positive RA patients achieved more remission (68% vs 51%, P=0.001) compared to ACPA negative RA patients, but had a lower mean baseline DAS (3.20 (0.89) vs 3.64 (0.94), P<0.001). Of the ACPA negative RA patients, those who achieved remission had a shorter median symptom duration than those who did not (13 (8–26) vs 20 weeks (10–31), P=0.02). Independent baseline predictors for remission in all patients were low joint counts, low HAQ, ACPA positivity, male sex, short symptom duration and low Body Mass Index (BMI) (Table).

Table. predictors of remission in the total study population identified with univariate and multivariate regression analysis.

Univariate regression	Odds	95% CI
Diagnosis RA	0.87	0.57–1.33
Baseline DAS	0.49	0.40–0.59
Baseline HAQ	0.43	0.32–0.56
Age (years)	1.00	0.99–1.02
Symptom duration (weeks)	0.99	0.99–1.00
Male sex	2.23	1.52–3.27
ACPA positivity	1.63	1.16–2.28
BMI (kg/m^2)	0.94	0.90–0.98
Small joints*	0.93	0.90–0.95
Large joints*	0.71	0.65–0.79
Multivariate regression		
Small joints*	0.96	0.93–0.99
Large joints*	0.80	0.72–0.90
Baseline HAQ	0.63	0.46–0.88
Symptom duration (weeks)	0.99	0.98–0.99
Male sex	2.06	1.35–3.14
ACPA positivity	1.49	1.01–2.19
BMI (kg/m^2)	0.94	0.90–0.98

* Number of swollen and/or tender joints

Conclusion: Remission induction with MTX and a tapered high dose of prednisone results in similarly high remission percentages in RA (61%) and non-RA (64%) patients after four months. Independent predictors for remission in the total study population indicate that early treatment while disease activity is relatively low, might be most effective, even if ACPA is positive and regardless of fulfilling the ACR 2010 criteria.

441

Treatment Outcomes Based on Methotrexate Dose Range in Patients with Rheumatoid Arthritis Receiving Etanercept Plus Methotrexate Versus Methotrexate Alone. Roy Fleischmann[1], Andrew S. Koenig[2], Ronald Pedersen[2], Tahmina Ferdousi[2] and Eustratios Bananis[2]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Pfizer Inc., Collegeville, PA

Background/Purpose: Methotrexate (MTX) is often the first DMARD prescribed for the treatment of RA and has been shown to be more effective in reducing disease activity when combined with biologic therapies than when used alone.[1–3] The aim of this analysis is to assess the possibility of an optimal dose range of MTX in combination with etanercept (ETN) for the treatment of RA that results in optimal treatment response.

Methods: In the COMET study (NCT00195494), MTX-naïve subjects were randomized to receive either MTX+ETN 50 mg per week or MTX monotherapy for 52 weeks. Subjects started with a low MTX dose (7.5 mg/week) and were titrated up to a maximum of 20 mg/week by week 8, if needed. After week 8, MTX dose was stable unless an AE or intolerability. Subjects with a known, stable MTX dose after week 8 were included in this post-hoc analysis. Subjects in both treatment arms were divided into 3 MTX dose ranges (low 7.5–12.5 mg; medium 12.6–17.5 mg; high 17.6–20 mg). The percentage of subjects in each MTX dose group was assessed according to DAS28/DAS44 remission, EULAR, and ACR responses at week 52 utilizing T-tests and Fisher's exact test to compare between and within each treatment group.

Results: 414 subjects (220 ETN+MTX; 194 MTX) from the COMET trial were included in this analysis. Subjects who dropped out due to lack of efficacy were considered non-responders. The majority of subjects randomized to the ETN+MTX treatment group were categorized in the high MTX dose range (50.5%) followed by the medium (27.3%) and low (22.3%) dose ranges. Subjects in the MTX monotherapy treatment group had a similar distribution trend (high 68.0%; medium 21.6%; low 10.3%). Subjects receiving low dose MTX in either treatment arm had less severe disease at baseline (DAS28, DAS44, CRP, ESR, HAQ, mTSS, ESR, CCP+, RF+); especially in the ETN+MTX group which reached statistical significance for DAS28, DAS44, CRP and HAQ. Baseline disease characteristics were not significantly different between treatment arms across MTX dosage groups except for DAS44 in the low dosage group ($P<0.05$) and HAQ in the medium dosage group ($P<0.001$). Subjects in the medium MTX dose category for both treatment groups exhibited better responses for all outcomes except DAS44 <1.6 and HAQ ≤0.5 (Table). In comparison between treatment groups, ETN+MTX was superior in all outcome measures compared to MTX monotherapy across MTX dose ranges, especially in the high MTX dosage group.

Table. Treatment outcomes at week 52

	MTX N=194			ETN+MTX N=220		
MTX Dose Category	Low (≤12.5 mg)	Medium (12.6–17.5 mg)	High (≥17.6)	Low (≤12.5 mg)	Medium (12.6–17.5 mg)	High (≥17.6)
n	20	42	132	49	60	111
Median MTX Dose (mg)	10	15	20	7.5	15	20
% DAS28<2.6	20.0	40.5	32.6	46.9	58.3	55.0 ($P<0.001$)
% DAS44<1.6	35.0	38.1	31.1	49.0	55.0	55.0 ($P<0.001$)
% ACR70	14.3	43.2	32.8	41.7 ($P<0.05$)	57.6	52.3 ($P<0.01$)
% HAQ ≤ 0.5	35.0	52.4	41.5	66.7 ($P < 0.05$)	59.3	54.9 ($P<0.05$)
% Good EULAR Response	45.0	61.9	50.8	73.5 ($P < 0.05$)	83.3 ($P<0.05$)	72.1 ($P<0.001$)
% Mod/Good EULAR Response	80.0	88.1	83.3	95.9	100.0 ($P < 0.01$)	91.9
% mTSS Δ ≤ 0.5	61.1	64.3	51.6	80.9	90.0 ($P < 0.01$)	73.9 ($P<0.001$)

P-values represent significance between treatment groups of the same MTX dose range category (e.g. High MTX treatment group vs high MTX+ETN treatment group).

Conclusion: Patients achieve higher treatment responses with medium and high doses of MTX; however, the moderate MTX dose category consistently trended toward higher improved outcome measures in both treatment groups. Regardless of MTX dose, the ETN+MTX group was more efficacious than MTX monotherapy across dose categories, including the inhibition of radiographic progression. The ETN+MTX group was statistically superior in the highest dose category except moderate/good EULAR response.

No Increased Malignancy Risk in Tumor Necrosis Factor-α Antagonists Treated Adult Rheumatoid Arthritis Patients: A Meta-Analysis of 29 Randomized Controlled Trials. Guillaume Moulis, Agnès Sommet, François Montastruc, Laurent Sailler, Jean-Louis Montastruc and Maryse Lapeyre-Mestre. Toulouse University Hospital, INSERM U1027, University of Toulouse, France, Toulouse, France

Background/Purpose: The risk of malignancies on anti-TNF-α therapies is controversial. We conducted a meta-analysis (MA) of randomized controlled trials (RCTs) restricted in a first analysis to arms treating adult rheumatoid arthritis patients in line with the New Drug Application (NDA) and including the five marketed anti-TNF-α.

Methods: We conducted a search strategy to identify published double-blind RCTs with an exposure to TNF-α antagonists in line with NDA for more than 12 weeks in MEDLINE, CENTRAL and ISI Web of Science by two evaluators. Unpublished trials were assessed through the ACR and EULAR abstracts, the scientific evaluation of the drugs leading to marketing approval and clinicaltrials.gov. Quality of RCTs was assessed with Delphi list and Oxford scale. Authors and laboratories were contacted to provide missing data particularly regarding the occurrence of malignancies. Random-effect MAs were conducted on pooled data to assess the risk of cancers overall, solid tumors, hematological malignancies, skin cancers, non-melanoma skin cancers (NMSC) and melanomas. Null values were treated with continuity corrections (three methods tested). In case of multiple anti-TNF-α arms in a

RCT, we first considered for the analysis the arm in line with NDA. Sensitivity analyses were performed pooling all anti-TNF-α arms regardless of the dose. We conducted intention to treat (ITT) and per protocol (PP) surveys. Publication bias was assessed by Egger test.

Results: Among 2037 published references and 22 unpublished trials, we selected 29 trials for MA. Whatever the model (ITT or PP), there was no significant excess cancer risk when TNF-α antagonists were administered in line with NDA or pooling all doses in treatment group. Odds ratio in PP analysis for anti-TNF-α in line with NDA was 0.80 95%CI [0.50–1.29]. Odds ratio in ITT analysis for anti-TNF-α used whatever the dose was 1.18 95%CI [0.78–1.79]. Similar results were found for the various types of malignancies and with the three continuity corrections tested. For each model, there was no heterogeneity (Cochran's Q>10%, I^2=0%) and no publication bias (Egger's test: p= 0.55). In univariate metaregression, there was no difference between the five TNF-α antagonists and the estimation of overall cancer risk (p>0.05 in PP and ITT analyses).The increased risk in ITT compared with PP analyses can be explain by i) a gain of power, ii) a dose-effect relation and iii) a bias of diagnosis. Indeed, more patients are lost to follow-up or withdraw the trials in placebo arms, which may lead to overestimate the cancer risk on anti-TNF therapies. PP analysis prevents this bias, but it increases odds in placebo groups whatever the continuity correction used. So it may be not appropriate for very sparse events (hematological neoplasm and melanoma).

Conclusion: The risk of cancer the first year of treatment is not increased in patients exposed to TNF-α antagonists whatever the method used for analysis, particularly when drugs are used at recommended doses.

443

Risk of Herpes Viruses Infections (HSV, VZV) During Anti-TNF Therapy in Patients With Inflammatory Rheumatic Diseases Systematic Review and Meta-Analysis. Hélène Che, Jacques Morel, Bernard G. Combe and Cédric Lukas. Hopital Lapeyronie, Montpellier, France

Background/Purpose: TNFblockers have shown efficacy in inflammatory rheumatic diseases (IRD) and are now widely used. They are related with an increased risk of infections, especially bacterial ones but little is known about the reactivation of herpes zoster infections.To assess the risk of herpes zoster infections in patients with IRD treated with TNF blockers by performing a systematic review and meta-analysis based on available reported data in the literature.

Methods: A systematic literature search was performed to January 2011, in Medline, Embase, Cochrane library and abstracts from ACR and EULAR congresses from 2006 to 2010. Studies were included if they reported the respective incidences of herpes infections in anti-TNF and conventional DMARDs-treated patients, for meta-analysis. The Mantel-Haenszel method was used to provide a pooled odds-ratio (OR) estimate and a 95% confidence interval (CI) in anti-TNF versus conventional DMARDs. Statistical heterogeneity was assessed on the basis of the Q test (χ^2), using a significance level of 0.05. Incidence of severe herpetic infections (multidermatomal lesions or requiring hospitalization or intravenous treatment) was extracted and reported when available.

Results: The literature search identified 655 articles and 134 congress abstracts, of which 21 articles and 29 abstracts were included in the study. Among these, 2 articles [1, 2] and 2 abstracts [3, 4] allowed a meta-analysis to estimate the relative risk of herpes infections, with a total follow up of 112 001 patient-years (PA) (68 037 PA in biologics group and 43 964 PA in conventional DMARDs group). Based on these 4 registries, the pooled OR was 1.65 [95%CI 1.39–1.95] without significant heterogeneity (I^2=42%) (figure). Proportions of severe herpes infections, reported in the US and German populations were respectively 4.9% and 20.9% [1,2]. In the British registry, the respective rates were 6% and 0.02% with biologics and conventional DMARDs. Other articles reported incident herpetic infections in patients treated with TNF blockers, but could not be pooled in the meta-analysis due to the lack of a comparison group.

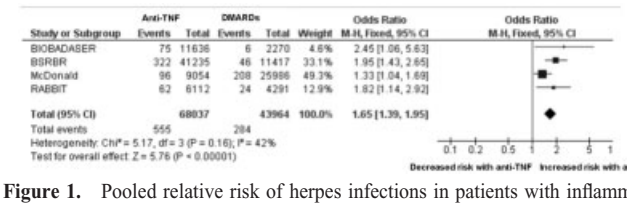

Figure 1. Pooled relative risk of herpes infections in patients with inflammatory rheumatic diseases: TNF blockers vs conventional DMARDs.

Conclusion: This meta-analysis of registries shows a significant increased risk of herpes zoster infections up to 65% in patients with IRD treated with TNF blockers. These data raise the issue of a systematic prophylactic treatment in patients with anterior herpetic infections, or vaccination in naive patients.

Early Versus Delayed Retreatment with Rituximab (RTX) in Relation to Long Term Clinical Response—Data From the CERERRA Collaboration. Elisabeth Lie[1], Katerina Chatzidionysiou[2], Evgeny L. Nasonov[3], Galina Lukina[3], Karel Pavelka[4], Dan C. Nordström[5], Matija Tomsic[6], Cem Gabay[7], Ioan Ancuta[8], Piet LC van Riel[9], Juan J. Gomez-Reino[10], João E. Fonseca[11], Merete L. Hetland[12], Ulrik Tarp[13], Ronald F. van Vollenhoven[2] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Karolinska Institute, Stockholm, Sweden, [3]Institute of Rheumatology, Moscow, Russia, [4]1Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [5]ROB-FIN, Helsinki University Central Hospital, Helsinki, Finland, [6]University Medical Centre Ljubjana, Ljubljana, Slovenia, [7]Geneva University Hospitals, for the SCQM registry, Geneva, Switzerland, [8]Cantacuzino Hospital, Bucharest, Romania, [9]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [10]Hospital Clinico Universitario, Santiago, Spain, [11]Lisbon Academic Medical Center, on behalf of Rheumatic Diseases Portuguese Register (Reuma.pt), Lisbon, Portugal, [12]Copenhagen University Hospital at Glostrup, on behalf of DANBIO, Copenhagen, Denmark, [13]Aarhus University Hospital, Aarhus, Denmark

Background/Purpose: Open-label extensions of RCTs have shown sustained clinical response with repeated courses of RTX in rheumatoid arthritis (RA). However, there has been a lack of data on retreatment and long term effectiveness in patients (pts) treated with RTX in clinical practice. Our objective was to characterize pts receiving early vs. delayed retreatment with RTX during the 1st year and compare long-term responses.

Methods: 10 European biologics registries provided anonymized data sets of pts treated with RTX in clinical practice for analysis of pooled data. Pts were grouped as having received early (up to approx. 7 months after baseline) or delayed (after approx. 8–13 months) retreatment; pts not retreated the 1st year were excluded. Baseline (BL) characteristics, and year 1 and year 2 DAS28 states and changes were compared. Due to heterogeneity in timing of follow-up visits, overall mean DAS28 was calculated for the period 3–12 months and for year 2. Two-samples T, Mann-Whitney U and Chi^2 tests were applied as appropriate. The main effectiveness outcome was mean DAS28 during year 2. Associations between retreatment group and longitudinal DAS28 values and low disease activity (DAS28 ≤3.2; LDA) were examined by generalized estimating equations (GEE).

Results: 932 pts were retreated the 1st year (496 pts with 'early' and 436 pts with 'delayed' retreatment). 83.9%/83.5% were female, 79%/81% RF pos (p=0.39), and 83%/78% received concomitant DMARDs at baseline (BL) (p=0.07). Pts had used mean 2.7 vs. 2.6 (p=0.38) prior synthetic and 0.86 vs. 0.97 (p=0.50) prior biologic DMARDs, and 40% vs. 44% were biologics naïve (p=0.24). Pts in the early group were significantly younger (50.1 vs. 53.7 years, p<0.001). Mean DAS28 was similar for months 3–12 overall, but higher in the early group at 6 months and higher in the delayed group at 9 and 12 months (Table). 27% of pts in the early group also received a third course of RTX within month 13. 82% in the early vs. 90% in the delayed group had >18 months follow-up time, and mean(SD) total number of RTX courses from baseline through year 2 was 2.75(0.95) vs. 2.52(0.72) (p=0.001). Overall year 2 mean DAS28 and ΔDAS28 BL to year 2 were very similar (Table). Proportions of EULAR good response, LDA and remission were also similar between groups across year 2 visits. The GEE analyses showed no significant associations between timing of retreatment (early vs. delayed) and DAS28 value or LDA state neither during months 3–12 (p=0.38 for DAS28/

p=0.34 for LDA), year 2 (p=0.41/p=0.93), or the two periods combined (p=0.61/p=0.27).

	Early retreatment n=496	Delayed retreatment n=436	p-value
BL DAS28	6.22	6.08	0.08
DAS28 months 3/6/9/12	4.42/4.51/4.11/4.21	4.26/4.05/4.95/4.51	0.07/<0.001/<0.001/0.01
DAS28 month 3–12	4.36	4.42	0.44
ΔDAS28 BL to month 3–12	−1.86	−1.66	0.01
DAS28 year 2	4.16	4.10	0.58
ΔDAS28 BL to year 2	−2.06	−2.03	0.77
ΔDAS28 month 3–12 to year 2	−0.22	−0.32	0.30

Conclusion: Younger pts who with higher disease activity and greater functional impairment at BL were more likely to have earlier relapses leading to retreatment. Perhaps owing to more frequent retreatment, their results over 2 years were similar to pts retreated at longer intervals. These results suggest that certain subsets of pts for whom earlier retreatment should be considered, may be identified.

RAPID3 (Routine Assessment of Patient Index Data 3) At Week 12 Predicts Progression of Joint Damage At Year 1 in Rheumatoid Arthritis Patients Treated with Certolizumab Pegol Plus Methotrexate. Edward Keystone[1], Owen Davies[2] and Kristel Luijtens[2]. [1]University of Toronto, Toronto, ON, [2]UCB, Brussels, Belgium

Background/Purpose: The RAPID3 (Routine Assessment of Patient [Pt] Index Data 3) pt-derived assessment of disease activity has been demonstrated to correlate with DAS28 in pts treated with certolizumab pegol (CZP).[1] Previous post-hoc analyses have shown that a lack of improvement in DAS28 by Week (Wk) 12 predicts failure to achieve low disease activity at Wk 52.[2,3] The objective of this post-hoc analysis was to investigate if RAPID3 or EULAR response criteria predict structural joint damage (change from baseline [BL] in modified Total Sharp score [mTSS]) in RA pts treated with CZP + methotrexate (MTX) or placebo (PBO) + MTX.

Methods: Data from pts treated with CZP 200 mg + MTX or PBO + MTX in RAPID 1 (NCT00152386) were analyzed. At Wk 12, pts were categorized according to good, moderate or poor proposed RAPID3 or EULAR DAS28(ESR) response criteria. Data were pooled for pts in each group achieving a good or moderate RAPID3 or EULAR response, and progression of joint damage was evaluated in good/moderate vs poor RAPID3 or EULAR responders. Radiographic non-progression was defined as a change of ≤0.5 units from baseline in mTSS. For mTSS, linear extrapolation was used.

Results: At Wk 12, the majority of CZP + MTX pts had good/moderate RAPID3 or EULAR responses (CZP 200 mg + MTX vs PBO + MTX: RAPID3, 66.8% vs 23.5%; EULAR, 77.6% vs 29.1%). Mean RAPID3 scores at BL were similar between Wk 12 response groups for RAPID3 (range: 15.10–16.99) and EULAR (range: 15.62–16.93) criteria. At BL, mean and median mTSS were similar between Wk 12 response groups (RAPID 3: mean = 35.29–45.14, median = 19.75–24.50; EULAR: mean = 35.94–47.65, median = 20.00–21.50). At Wk 52, pts with a poor RAPID3 or EULAR response at Wk 12 had a greater increase in mTSS from BL than those pts with a good/moderate response; differences between categories were greatest in the PBO + MTX group (Table). Furthermore, fewer pts with a poor RAPID3 or EULAR response at Wk 12 were mTSS non-progressors vs pts with a good/moderate RAPID3 or EULAR response at Wk 12; differences between categories were greatest in the PBO + MTX group. There was greater inhibition of radiographic progression with CZP + MTX vs PBO + MTX irrespective of the level of response at Wk 12 (good/moderate or poor) and how response was determined (RAPID3 or DAS28).

Table. Percentage of patients with structural joint damage at Wk 52 according to RAPID3 or EULAR response at Wk 12

		Change in mTSS from BL at Wk 52, mean (SD)	mTSS non-progressors at Wk 52, %
RAPID3 response at Wk 12*			
CZP 200 mg + MTX	Good/moderate (n = 246)	0.22 (5.98)	79.7%
	Poor (n = 117)	0.87 (4.98)	70.1%
PBO + MTX	Good/moderate (n = 44)	1.67 (4.63)	63.6%
	Poor (n = 135)	3.25 (8.65)	51.1%
EULAR response at Wk 12**			
CZP 200 mg + MTX	Good/moderate (n = 284)	0.23 (5.11)	78.5%
	Poor (n = 79)	1.14 (7.36)	68.4%
PBO + MTX	Good/moderate (n = 52)	1.00 (4.55)	69.2%
	Poor (n = 127)	3.63 (8.79)	48.0%

* RAPID3 response criteria: good = improvement >3.6 units AND final score <6; moderate = improvement >3.6 AND final score ≥6 OR improvement 1.8–3.6 AND final score ≤12; poor = improvement <1.8 OR improvement 1.8–3.6 AND final score >12.
** EULAR response criteria: good = DAS28(ESR) <3.2 and an improvement from baseline >1.2; moderate = DAS28(ESR) <3.2 AND improvement 0.6–1.2, OR DAS28(ESR) 3.2–5.1 AND improvement >1.2 OR 0.6–1.2, OR DAS28(ESR) >5.1 AND improvement >1.2; poor = DAS28(ESR) <3.2 OR 3.2–5.1 OR >5.1 AND improvement <1.2, OR DAS28(ESR) >5.1 AND improvement 0.6–1.3.

Conclusion: In this post-hoc analysis, RAPID3 or EULAR responses at Wk 12 predicted progression of structural joint damage at Wk 52, particularly in pts who received PBO + MTX. These results suggest that both RAPID3 or EULAR response criteria can be used as predictors, offering the physician the choice of clinical- or pt-focused prediction tools. For RA pts receiving MTX, assessing RAPID3 response at Wk 12 could be used to aid treatment decision making.

Pretreatment Synovial Transcriptional Profile Predicts Early and Late Clinical Response in Rheumatoid Arthritis Patients Treated with Rituximab. Vanessa E. Hogan[1], Cecile TJ Holweg[2], David F. Choy[2], Sarah Kummerfeld[2], Jason Hackney[2], Yko Teng[3], Michael J. Townsend[2] and Jacob M. Van Laar[4]. [1]Newcastle University, Newcastle, United Kingdom, [2]Genentech Research and Early Development, South San Francisco, CA, [3]Leiden University Medical Centre, Leiden, Netherlands, [4]Musculoskeletal Research Group, Newcastle, United Kingdom

Background/Purpose: The development of personalized medicine is contingent on the identification of biomarkers that represent disease relevant pathogenic pathways and predict response to therapy. We postulated that transcriptomics of synovial tissue from rheumatoid arthritis (RA) patients could be used to construct a response specific gene expression profile.

Methods: We conducted a proof-of-concept study in 20 RA patients treated with rituximab, who underwent arthroscopy of clinically inflamed joints to allow sampling of synovial tissue before and after treatment with rituximab. Clinical response was defined using DAS28 scores. Gene expression of 125 genes was assessed using high throughput semiquantitative mRNA analysis to identify genes associated with clinical response. Statistical analysis was performed using principle components analyses, Spearman correlation, and t-tests with correction for multiple testing.

Results: Based on principal components analysis and unsupervised hierarchical cluster analysis of baseline gene expression, patients in our study could be categorised in two groups with distinct gene expression profiles, an inflammatory and a remodelling profile. These two groups were associated with distinct clinical, laboratory and histological features of inflammation. In an attempt to predict response, a composite gene score (GS) was constructed based on genes that correlated strongly with change in disease activity score (dDAS) between baseline and month 3.

Besides an expected strong correlation with dDAS at month 3 (Rho=0.76, P=0.0001), the baseline GS also significantly correlated with dDAS at month 7 and with the conclusion of the study (month 21–24) after treatment (Rho=0.55, P=0.01 and Rho=0.50, P=0.02, respectively). In addition, the GS significantly correlated with the inflammatory component of the DAS28 score, ESR, at baseline (Rho=0.69, P=0.0008), but not with swollen or tender joint counts or visual analogue scale. Another strongly correlating baseline variable with baseline GS was with thickness of the lining layer (R=0.74, P=0.006), suggesting that some of the GS genes might be expressed by cells residing in the synovial lining. A number of positive predictor genes included in the gene score represented macrophage and T-cell rather than B-cell biology, while the negative predictor genes were involved in bone and cartilage biology and the interferon-a pathway. Patients with a high signature score, mostly clinical responders (9/11), showed higher expression of the positively correlated genes with dDAS and lower expression of the negatively correlated genes, whilst the opposite was true for patients with a low score who were mostly non-responders (6/9).

Conclusion: In our study, we created a baseline synovial gene expression score, representing mainly macrophage, T-cell biology and tissue remodeling processes, that significantly predicted both early and late response to rituximab in RA patients.

Sulfasalazine and Its Metabolites Inhibit Platelet Function in Patients with Inflammatory Arthritis. Paul A. MacMullan[1], Anne M. Madigan[1], Nevin Paul[2], Aaron J. Peace[2], Paola M. Bagaglia[1], Ahmed Alagha[2], Kevin B. Nolan[2], Dermot Kenny[3] and G M. McCarthy[1]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]RCSI, Dublin 2, [3]RCSI, Dublin 2, Ireland

Background/Purpose: Patients with inflammarory arthritis (IA) are at increased risk of adverse cardiovascular events. Sulfasalazine therapy has been shown to decrease this risk, independent of disease severity. Previous evidence suggests that sulfasalazine inhibits platelet thromboxane synthetase, but its effecs on platelet function are unknown.Therefore, we decided to assess the effect of sulfasalazine and its metabolites on platelet function in patients with IA.

Methods: 135 consecutive patients with an established diagnosis of IA were screened. Those with a history of cardiovascular disease (CVD), taking anti-platelet agents or NSAIDs were excluded. A total of 32 patients were investigated, 15 taking sulfasalazine and 17 taking other DMARDs and no sulfasalazine. Platelet function in response to multiple agonists was tested, and these 2 cohorts were compared to 15 patients with stable CVD on long-term aspirin. The effect of sulfsalazine and its metabolites on arachidonic acid (AA) induced platelet aggregation was also tested *in vitro*, in samples from healthy donors (n=18).

Results: Demographics, CVD risk factors, and disease activity indices were similar in the Sulfasalazine and Other DMARDs groups. AA-induced platelet aggregation was significantly inhibited in the Sulfasalazine group (9±7%) and comparable to that in the Aspirin group (10±6%), (see Figure). In contrast, there was no effect on AA-induced platelet aggregation in the Other DMARDs group (77±12%), ($p<0.001$). Sulfasalazine therapy had no effect on platelet function in response to the other agonists. Sulfasalazine and its metabolites (5-aminosalicylic acid and sulfapyridine) exerted an additive and dose-dependent inhibitory effect on AA-induced aggregation *in vitro* ($p<0.001$).

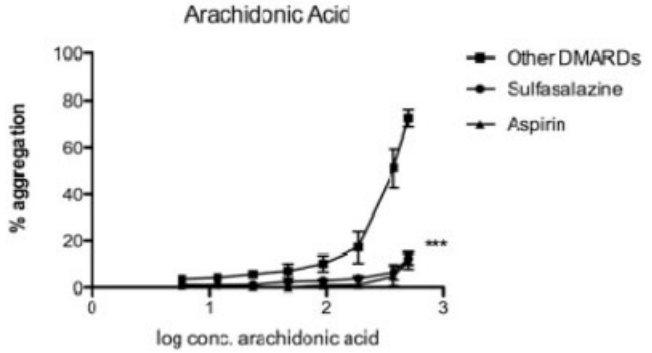

Figure. Platelet aggregation in response to arachidonic acid is significantly inhibited in both the Sulfasalazine and Aspirin group compared to those on Other DMARDs. *** $p<0.001$.

Conclusion: The inhibition of AA-induced platelet aggregation by sulfasalazine is comparable to that achieved by aspirin, and is dependent on both sulfasalazine and its metabolites. This is a potential mechanism that may contribute to the known cardioprotective effect of sulfasalazine in patients with IA.

Impact of Tumor Necrosis Factor Inhibition on Healthcare Costs in Patients with Rheumatoid Arthritis. Walter P. Maksymowych[1], Nguen Xuan Thanh[2], Joanne Homik[1], Cheryl CM Barnabe[3], Liam Martin[3], Susan G. Barr[3] and Arto Ohinmaa[1]. [1]University of Alberta, Edmonton, AB, [2]Institute of Health Economics, Edmonton, AB, [3]University of Calgary, Calgary, AB

Background/Purpose: Linkage of patient registry data and administrative databases enables a powerful assessment of treatment efficacy and associated costs in real world practice. The objective of our study is to assess the impact of anti-tumor necrosis factor (anti-TNF) therapy for rheumatoid arthritis (RA) on total and RA-attributable healthcare costs in an inception cohort of biologic treated patients compared to patients on standard disease-modifying antirheumatic drug (DMARD) therapy, accounting for confounding by indication.

Methods: A pharmacovigilance registry captures clinical treatment and safety parameters for RA patients treated with either standard DMARDs or one of the three available anti-TNF agents. Provincial healthcare administrative databases for fiscal years 2004/2005 to 2008/2009, including physician billing claims, ambulatory care visits, and hospitalizations were linked to the clinical database to analyze the cost of physician visits, emergency room and other ambulatory care visits, and hospitalizations per treatment group. A propensity score matching technique was used to compare the costs in those patients receiving a first anti-TNF agent to patients receiving DMARDs only, patients initially on DMARDs but then switched to anti-TNF therapy, and those patients requiring a switch to another anti-TNF agent. Variables included in logistic regression to estimate propensity scores were socio-demographic characteristics, medical co-morbidities, disease duration and functional severity at baseline as measured by the HAQ score. We estimated the 95% confidence intervals for the differences between groups using a bootstrap method. All costs were standardized to 2008 Canadian dollars. We also specifically considered RA-attributable costs associated with diagnostic codes.

Results: We provide results on 1,086 patients from our cohort who had at least 3 months of administrative data available. The mean annual cost per patient associated with physician visits, emergency room visits, and hospitalizations was higher in patients who had to switch to another anti-TNF agent for inefficacy or adverse events relative to patients who responded well to their first anti-TNF agent without adverse events (Table 1). Patients remaining on DMARD therapy and those eventually moving to anti-TNF therapy had non-statistically higher costs. In each group about 30% of all costs were directly RA-attributable.

Table 1. Annual mean healthcare costs, and percentage of cost directly attributable to RA (in parentheses) per patient in the four treatment groups

Cost category	First Anti-TNF-only (n=731)	Anti-TNF, switch (n=212)	DMARD-only (n=75)	DMARD, switch (n=68)
Total cost	4,849 (29.1%)	7,374* (31.1%)	6,898 (29.1%)	5,832 (30.4%)
Hospital	2,008 (31.7%)	3,349* (38.4%)	2,909 (31%)	2,486 (28.8%)
Emergency room	238 (22.3%)	458* (22.3%)	434 (9.9%)	393 (15.3%)
Outpatient clinic	986 (11%)	1,631* (10.5%)	1,558 (16.9%)	1,231 (26.7%)
Physician	1,617 (39.3%)	1,936* (38.9%)	1,997* (40%)	1,722 (38.8%)

* Total costs statistically significantly (95% Confidence Intervals) differences from first anti-TNF-only group.

Conclusion: As expected, patients requiring a switch in anti-TNF therapy have higher healthcare costs. Patients responding well to their first anti-TNF agent have the lowest healthcare costs. Over two-third of healthcare costs in RA patients are not related to RA directly, indicating significant disease co-morbidity in our rheumatic disease patients.

Trend of Tumor Necrosis Factor Inhibitors Use Among Patients with Rheumatoid Arthritis: Analysis From the Consortium of Rheumatology Researchers of North America Registry. Pim Jetanalin[1], Susan P. Messing[2], Kimberly Kaukeinen[2], Joel M. Kremer[3] and Susan J. Lee[1]. [1]University of California San Diego, La Jolla, CA, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY, [3]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Studies have suggested that early institution of biological therapies in rheumatoid arthritis (RA) can improve clinical outcomes, decrease disability, and retard radiographic progression. With the development of the new ACR/EULAR criteria for RA combined with efforts for early referral and aggressive therapy, we hypothesize that tumor necrosis factor inhibitors (TNF-I) are being used earlier in RA patients. Using the Consortium of Rheumatology Researchers of North America (CORRONA) registry, we sought to determine if the pattern of TNF-I use has changed over time.

Methods: Data on demographics (age, sex, race, education) and disease characteristics (seropositivity, disease duration) were obtained from 27,412 RA patients in the CORRONA registry. Patients starting on first TNF-I were divided into 3 equal groups of ~1,000 patients spanning 3 time periods (2000–05, 2006–08, 2009–11). Each interval was analyzed for pattern of TNF-I use, disease activity (DAS28, CDAI, MD VAS for global disease, patient VAS for pain and global function), and DMARDs use.

Results: Of the 15,270 RA patients who were TNF-I naïve at enrollment, 3,031 patients were started on TNF-I at one of the CORRONA visits. The racial composition was similar in TNF-I naïve and TNF-I initiated group with 83% Caucasians, 6% Hispanics, 8% African Americans, and 1% Asians. The majority were female (74–76%) with seropositive disease (RF and/or CCP, 72–75%). Compared to patients who remained TNF-I naïve, TNF-I initiators were younger (60.1 ± 13.9 years vs 56.7 ± 13.5 years) with longer disease duration (7.6 ± 9.5 years vs 8.5 ± 9.3 years) and more active disease (HAQ 0.33 vs 0.43, CDAI 12.8 vs 15.9) with $p<0.0001$ for all. TNF-I initiators were more likely to have college education with OR 1.15, $p<0.0001$. When assessed over 2000–05, 2006–08, 2009–11 time period, patients in 2009–11 were being started on TNF-I earlier (disease duration 9.9 vs 8.5 vs 6.9 years respectively, $p<0.0001$). Compared to 2000–05, TNF-I initiators in 2009–11 had less disease activity (CDAI 17.1 vs 15.5 $p=0.002$, MD VAS global disease 29.0 vs 26.1 $p=0.004$, SJC 6.1 vs 4.5 $p<0.0001$) at the start of TNF-I. The number of prior DMARDs failed before starting TNF-I also decreased over time from 1.7 to 1.3 ($p<0.0001$). In multivariate analysis, patients with college education, worse functional disability (HAQ), and higher number of prior failed DMARDs were more likely to start TNF-I. Interestingly, the number of *new* TNF-I initiators in the CORRONA registry decreased from 53% in 2002–05 to 12% in 2009–11. Despite this decrease in the number of new TNF-I initiators, the overall prevalence of TNF-I use among RA patients increased over the recent years (31% in 2000 to 41% in 2011) suggesting persistence of TNF-I use once patients are started on TNF-I for the treatment of RA.

Conclusion: With the proven efficacy of TNF-I coupled with earlier diagnosis and referral, there is a trend towards earlier initiation of TNF-I at shorter disease duration and lower disease activity. Instead of traditional slow step-up approach, physicians are starting TNF-I sooner and after failing a fewer number of DMARDs. Despite an overall lower % of patients starting TNF-I, it is still widely used with 41% of all RA patients on TNF-I.

Dermatologicals Manifestations Induced by Tumor Necrosis Factor Antagonists Therapy in Rheumatic Diseases. Incidence Rate in BIOBADASER 2.0 Registry. Maria Victoria Hernández Miguel[1], Miguel A. Descalzo[2], Loreto Carmona[3], Melina Meineri[1], Sonia Cabrera[4], Maria Eugenia Gomez Caballero[4], Jose Alfredo Gomez Puerta[1], Virginia Ruiz Esquide[1], Julio Ramirez[1], Juan D. Cañete[5] and Raimon Sanmarti[1]. [1]Hospital Clinic of Barcelona, Barcelona, Spain, [2]Spanish Society of Rheumatology, Madrid, Spain, [3]Universidad Camilo José Cela, Villanueva de la Cañada, Spain, [4]Hospital Clinic of Barcelona., Barcelona, Spain, [5]Hospital Clínic de Barcelona., Barcelona, Spain

Background/Purpose: Biologic therapy has proven efficacy in several rheumatic diseases in the last decade, but, recently, different cutaneous manifestations associated with these treatments have been described. Our purpose was to analyze the incidence rate and characteristics of cutaneous adverse events (CAE) in patients with inflammatory rheumatic diseases treated with TNF antagonists therapy.

Methods: We analyzed all patients diagnosed of inflammatory rheumatic diseases treated with TNF antagonists therapy and included in the spanish registry of safety in biological treatments (BIOBADASER), in which our hospital is a participant, that have developed a CAE (as a main symptom) since 2000 to November 2010. The sociodemographic and clinical characteristics collected were: age, gender, diagnosis of rheumatic disease, type of CAE (classified as: local or systemic cutaneous manifestation related to treatment administration (CTA); infection; malignancy; development of autoimmune disease (AD)) and CAE outcome. We calculated the incidence rate of CAE events per 1000 patients-years of exposure with 95% confidence intervals (CI). Risk factors for CAE in all patients exposed to TNF antagonists were investigated assuming a Poisson distribution of the data. Results were expressed as incidence rate ratio (IRR) with their 95% CI.

Results: During these 10 years, 5437 patients (61% female, mean age 55 (SD=14years) received TNF antagonists therapy. Main diagnoses were: 2957 patients with rheumatoid arthritis (RA) (54%); 968 ankylosing spondylitis (AS) (18%); 926 psoriatic arthritis (PsA) (17%); 463 chronic arthritis (CA) (9%) and 123 chronic immune mediated diseases (CID). Biological therapy received was: infliximab 2504 patients, etanercept 1605, adalimumab 1328. The global incidence rate of CAE was 54 [95%CI 51–57] per 1000 p-y. According to the type of CAE, the incidence rates were: infection (most were *herpes zoster* and cellulitis) 27 [25–29]; CTA 16 [14–17]; AD (psoriasis, vitiligo, alopecia areata, cutaneous lupus, polychondritis, morphea, dermatomyositis) 5 [4–6]; malignancy 3 [3–4]. We found a higher rate of CAE for infliximab (IRR in multivariate analysis: 1.26 (1.05–1.52) ($p<0.05$), concomitant use of leflunomide (1.46 (1.17–1.83) $p<0.001$), concomitant glucocorticoids (1.36 (1.16–1.61) $p<0.001$), and in women (1.5 (1.27–1.77) ($p<0.001$).

Conclusion:TNF antagonists therapy is frequently associated with the development of cutaneous manifestations that, sometimes, requires treatment withdrawal with a favourable outcome. Most frequents CAE were infections and those related to treatment administration, although different autoimmune diseases could also been developed.

451

Tofacitinib Reduces Interleukin-6 and Matrix Metalloproteinase-3 Production and Inhibits Cartilage Destruction in Rheumatoid Arthritis. Kunihiro Yamaoka[1], Satoshi Kubo[1], Keisuke Maeshima[2], Koshiro Sonomoto[1], Kazuhisa Nakano[3], Norifumi Sawamukai[1], Masao Nawata[1], Kazuyoshi Saito[1] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Oita University, Faculty of Medicine, Yufu, Japan, [3]University of California San Diego, La Jolla, CA

Background/Purpose: Tofacitinib, a tyrosine kinase inhibitor targeting Janus kinase (JAK), has recently gained attention due to its prompt clinical response and efficacy in treating rheumatoid arthritis (RA). It has been shown to inhibit JAK1 and JAK3 known to be crucial for multiple cytokine signaling pathways. However, its precise mechanism of action in RA patients remains unknown. We herein analyzed the effect of tofacitinib in RA patients and a chimera mouse model of RA.

Methods: [Investigation 1] Fifteen RA patients enrolled in the tofacitinib clinical trials were randomized to 1, 3, 5 or 10mg BID for 12 weeks. Blood was collected at 0 and 12 weeks and serum stored for further cytokine measurement by ELISA. [Investigation 2] Synovium from RA patients undergoing joint replacement was implanted in severe combined immunodeficiency (SCID) mice (SCID-huRAg mouse). Tofacitinib was administered via osmotic mini-pump and serological and histological examinations were performed.

Results: [Investigation 1] Patient background: mean age; 56.4 years, mean disease duration; 95.1 months, methotrexate (MTX) and tofacitinib were administered in all 15 patients, median doses were 9.4 mg/week and 4.1 mg BID respectively, glucocorticoids were administered in 6 patients, median dose was 5.4 mg/day. Baseline characteristics of the disease activity was as follows; SDAI 30.0, DAS28 (ESR) 6.3, HAQ 1.1, CRP 21.0mg/l, ESR 57.1mm/h, MMP-3 259.3ng/ml, RF 216.2U/ml. All these parameters decreased after 12 weeks treatment with statistical difference ($P<0.05$) as follows; SDAI13.8, DAS28(ESR) 4.0, HAQ 0.8, CRP 8.1mg/l, ESR 30.9mm/h, MMP-3 149.9ng/ml, RF 150.8U/ml. Among the multiple cytokines measured, IL-6 and IL-8 tended to decrease, from 52.2pg/ml to 28.2pg/ml ($p<0.05$) and from 41.7pg/ml to 29.5pg/ml (not significant), respectively. Among the clinical parameters measured, there was a statistically significant correlation between reduction of IL-6 and reduction of MMP-3.

[Investigation 2] In SCID-huRAg mouse, marked growth of RA-derived synovium and its apparent invasion into cartilage were observed. However, when

tofacitinib was administered, invasion of synovial tissue into cartilage was markedly suppressed. In order to investigate the relevance with our findings in investigation 1, cytokines were measured utilizing SCID-huRAg mouse serum after administration of tofacitinib for 7 days. Interestingly, tofacitinib significantly decreased production of human IL-6 and IL-8 as well as human MMP-3 from 29.79 pg/ml to 2.89pg/ml, 17.89 pg/ml to 4.22 pg/ml and 65.96 pg/ml to 33.13 pg/ml respectively.

Conclusion: Tofacitinib improved disease activity in patients with RA and high baseline disease activity within 12 weeks. Serum IL-6 and IL-8 concentration was decreased in both RA patients and SCID-huRAg mouse in connection with reduced MMP-3 in RA patients and suppressed cartilage destruction in mouse. These results indicate that tofacitinib possesses the ability to reduce inflammation by suppressing IL-6 production and consequently inhibiting cartilage destruction in the initial several months of administration.

452

One Single Infusion of Rituximab 1g Might Be Sufficient in the Long-Term Management of Rheumatoid Arthritis Patients Responding to a First Cycle of Rituximab (2 × 1g): Results of a 2-Year Multi-Center Randomized Controlled Trial. Maxime Dougados[1], Stephanie Rouanet[2], Jean Sibilia[3], Bernard G. Combe[4], Xavier X. Le Loet[5], Jacques G. Tebib[6], Rosemary Jourdan[7] and Xavier Mariette[8]. [1]Paris-Descartes University, Cochin Hospital, Paris, France, [2]Roche, Neuilly sur Seine, France, [3]Service de rhumatologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France, Strasbourg, France, [4]Hopital Lapeyronie, Montpellier, France, [5]CHU de ROUEN, Rouen CEDEX, France, [6]Centre Hosp Lyon Sud, Pierre Benite, France, [7]Roche, Neuilly Sur Seine, France, [8]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: To assess the symptomatic efficacy and the safety profile of 2 dose regimens of rituximab (RTX) in patients (pts) who had a EULAR response (good or moderate) 6 months after a 1st cycle of 2 infusions of RTX 1g and who necessitated subsequent therapy

Methods: *Patients:* Definite rheumatoid arthritis (1987 ACR criteria); active disease (DAS >3.2 and either swollen joint count ≥6 and tender joint count ≥6 or CRP ≥10 mg/l or ESR ≥28 mm/1st hour; refractory or intolerant to at least one anti-TNF. *Study design and allocated treatments*: The 1st 24 week-period was a prospective, multi-center non-controlled trial followed (from week 24 to week 104) by a randomized, controlled trial. At week 0, the 1st cycle of RTX consisted of 2 × 1g RTX two weeks apart. At week 24, pts who experienced a EULAR response were randomized to receive RTX 1g in one single infusion (Arm A) or the licensed dose of RTX 2 × 1g (Arm B) as subsequent retreatment following assessment of disease activity every 6 months (*e.g.* DAS >3.2). *Outcome measures*: DAS28-CRP, number of required cycles of RTX, time to a second retreatment. *Analysis*: Non inferiority of Arm A versus (vs.) Arm B on the DAS28-CRP Area Under the Curve (AUC) during 104 weeks, with a non-inferiority margin defined by 20% of the mean DAS AUC of the reference group (δ=444). Main analysis was performed on the per-protocol (PP) and intention to treat (ITT) population using a covariance analysis that included baseline DAS value as covariate.

Results: Of the 234 screened pts, 224 received the 1st cycle of RTX. DAS28-CRP changed from 5.8±0.9 to 4.2±1.2 at week 24, resulting in a EULAR response in 152 patients (71%). Pts (n=152) were randomized in the 2nd part of the study (ITT: 70/Arm A and 73/Arm B) without any inter-group difference (females: 82%; age: 56±11 years; disease duration: 13±9 years; anti-CCP positivity: 84%; DAS28-CRP: 3.7±0.9). Following withdrawals and major protocol deviations, the final PP population was 51pts/Arm A and 49/Arm B. The DAS28-CRP AUC at week 104 (PP population) was 2761±508 in Arm A and 2666±490 in Arm A vs. Arm B, resulting in an adjusted inter-group difference of 51.4 with a 95% CI of [−131.2; 233.9] demonstrating the non-inferiority of retreatment in Arm A vs. Arm B. Similar results have been shown for the ITT population. The number of required cycles per year after the first retreatment was similar in both arms (1.0±0.3), as was the estimated median time to a second retreatment using the Kaplan-Meier method (263 and 255 days in Arm A vs. B, respectively). During the study the percentage of any and serious adverse events was similar (92% and 29% vs. 96% and 37% in Arm A vs. B, respectively). The percentage of pts with an IgG level below 6.82 g/L (LLN) at week 104 was 2% (1/48) and 11% (6/53) in Arm A vs. B (p=0.12). The percentage of serious infections was 12% (8/66) and 3% (2/68) in Arm A vs. B (p=0.05) corresponding to a serious infection rate of 7.2 and 1.5/100 pt-yrs.

Conclusion: This study suggests that in case of a EULAR response after a first cycle of 2 infusions of RTX 1g, retreatment with a RTX 1g single infusion provides similar clinical outcomes compared with 2 × 1g infusions. The structural (radiographic) effect of these 2 strategies was not assessed in this study.

453

Patients' Preferences for the Treatment of Moderate to Severe Rheumatoid Arthritis. A. Brett Hauber[1], Christine Poulos[1], Juan Marcos Gonzalez[1], Sarika Ogale[2], Dalia Moawad[2] and Adam Turpcu[2]. [1]RTI Health Solutions, Research Triangle Park, NC, [2]Genentech, South San Francisco, CA

Background/Purpose: Biologic treatments for rheumatoid arthritis (RA) vary in terms of both the time required to administer treatment and the frequency of treatment. This study estimates patients' preferences for RA treatment attributes.

Methods: Patients with moderate to severe RA completed a web-enabled survey with a series of treatment-choice questions. The severity of self-reported RA symptoms was determined by the Routine Assessment of Patient Index Data 3 (RAPID3) score (ranging from 0 to 30). The treatment-choice questions required subjects to choose between two hypothetical RA treatments with differing levels of six treatment attributes including response rate (ranging from 40–75%), mode of administration (injection or infusion), treatment time (ranging from 10 minutes to 4 hours), treatment frequency (once per week, once every two weeks, once per month, and two times [two weeks apart] every six months), and the risks of immediate, mild and severe treatment reactions (which both ranged from 1% to 25%). An index of the importance of each treatment attribute, in terms of impact on treatment choice, was estimated using a mixed-logit choice model controlling for patient-specific characteristics. The index ranged from 0 to 10, with 10 being most important and 0 being not important at all.

Results: Among the 901 patients who completed the survey, 505 were in the RA Information, Services and Education group (www.risesupport.com) and 396 were members of an online web panel. Sixty percent of the sample was 55 years of age or older, 75% were female, and 29% of patients had at least a bachelor's degree. The majority of respondents had some difficulty dressing themselves (67%), getting out of bed (66%), walking outdoors (61%), washing themselves (59%), picking items off the floor (74%), getting out of a vehicle (74%), walking 2 miles (88%), and participating in recreational activities (95%). The average RAPID3 score was 14.3, and 94% of patients had a score greater than 6, indicating moderate or severe RA. Most patients (77%) used an oral medicine prescribed by a physician, 30% received regular injections of medicine, and 18% received regular infusions.

The chance of an immediate, serious treatment reaction was the most important treatment attribute (Figure 1). The second most important treatment attributes were the frequency of infusions and the treatment response rate, which were equally important. The frequency of injections was less important than treatment response rate, as was the amount of time needed to administer infusions. The least important attribute was the chance of an immediate, mild treatment reaction.

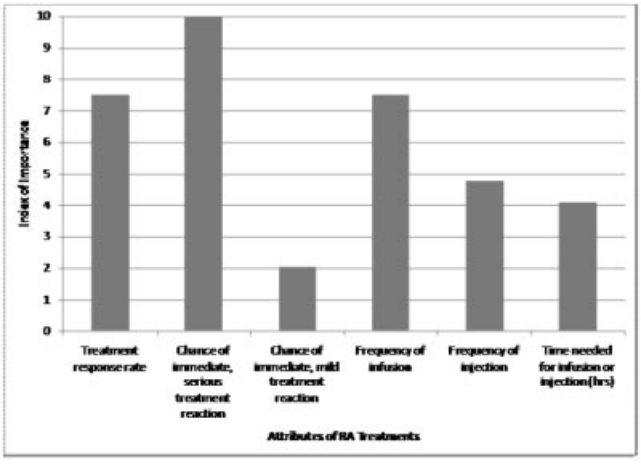

Figure 1. Relative importance of attributes of RA treatments

Conclusion: In addition to concerns over safety and efficacy, convenience attributes of RA treatment such as frequency of administration are important to patients and could play an important role in the choice of treatment.

Simvastatin and Toll-Like Receptor-2 Mediated Signaling Augment Apoptosis and reactive Oxygen Species Associated Gene Expression in Rheumatoid Arthritis Synoviocytes. Mohammad Saeed Khan[1], Krishnaswamy Kannan[1] and Robert Ortmann[2]. [1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]University of Arkansas, Little Rock, AR

Background/Purpose: Statins (HMG-CoA reductase inhibitors) exert beneficial effects on lipoprotein metabolism, but also possess anti-inflammatory properties. However, the molecular mechanisms subserving such immunomodulatory activities remain unclear. Signaling through Toll-like receptors (TLR) pathway has been implicated in the pathogenesis of rheumatoid arthritis (RA). TLRs 2, 3, 4 and 7 are expressed by cells within the RA joint and in particular, TLR2 was found to be highly expressed at the sites of bone erosion suggesting the importance of TLR2 in inflammatory arthritis. TLR2 activation is an essential step in RA animal models. The purpose of this study was to examine the anti-inflammatory effects of simvastatin, in the presence of an activated TLR2 signaling pathway, *in vitro* by using synoviocyte cell lines derived from control subjects and patients with RA.

Methods: Fibroblast-like synoviocyte (FLS) cell lines derived from normal healthy subjects and RA were obtained commercially and were maintained in complete synoviocyte medium supplemented with 2% FCS and growth factors. Cells (10^5 cells/well) were grown in 12 well plates and treated with Simvastatin in triplicates for 4 hours and subsequently washed and then treated with TLR2 ligand (Pam3CSK4, 100ug/ml) for 24-hours. Cytotoxicity was assessed by Alamar blue assay and apoptosis by flow cytometry based Annexin V staining method. Gene expression analysis of 84-Reactive oxygen species (ROS) associated genes was performed using a real time PCR array profiling kit from SABiosciences (catalog # PAHS-065).

Results: Simvastatin mediated cytotoxicity in RA derived FLS (RA-FLS) was lower than control synoviocytes. Increasing doses of simvastatin followed by TLR2 ligation led to increased cytotoxicity in both normal and RA-FLS. Flow cytometry analysis by annexin V staining showed that apoptosis was the cause of the cytotoxicity. Interestingly, the basal apoptosis was higher in normal synoviocytes compared to RA-FLS (14% vs 4.3%). TLR2 stimulation alone increased apoptosis in both normal and RA-FLS (16.4% / 9.7%). Upon treatment with 30 μM simvastatin followed by TLR2 ligation, significantly increased apoptosis was observed in both normal and RA-FLS (25% vs 24.8%) suggesting a synergistic effect. Gene expression analysis of ROS associated genes demonstrated that GSR, TXNRD1, and PRDX1 genes were significantly upregulated in RA-FLS upon treatment with simvastatin alone, or in combination with TLR2 ligation. SOD2, MT3, and PTGS2 were upregulated by simvastatin and TLR2 ligand in a synergistic fashion.

Conclusion: The basal apoptosis in RA-FLS was lower than normal synoviocytes. However, *in vitro* exposure of simvastatin followed by TLR2 ligation resulted in significant increase of apoptotic events as well as upregulation of gene expression of ROS metabolizing enzymes/proteins in RA-FLS. Thus simvastatin may exert its anti-inflammatory effect in RA by increasing apoptosis of RA-FLS and preventing ROS associated joint damage by upregulating protective genes.

Symptomatic Subcutaneous Anti-Tumor Necrosis Factor-Treated Rheumatoid Arthritis Patients Improve Following An Active Switch to Golimumab: An Initial 14 Week Assessment. J. Eugene Huffstutter[1], Rebecca Bolce[2], Shelly P. Kafka[3], Lawrence H. Brent[4], Jim Wang[5], Raphael J. DeHoratius[2], Trev Sprabery[2] and Dennis Decktor[2]. [1]Arthritis Associates PLLC, Hixson, TN, [2]Janssen Services, LLC, Horsham, PA, [3]Mountain State Rheumatology, Clarksburg, WV, [4]Albert Einstein Med Ctr, Philadelphia, PA, [5]Johnson & Johnson Pharmaceutical Research and Development, LLC, Belle Mead

Background/Purpose: GO-SAVE is a Phase 3b, multicenter, switch assessment of the efficacy of subcutaneous (SC) and intravenous (IV) golimumab (GLM) in rheumatoid arthritis (RA) patients who have inadequate disease control despite treatment with etanercept (ETN) or adalimumab (ADA). The primary objective of GO-SAVE is to assess the efficacy of GLM at week 14 in patients with active RA and an inadequate response to therapy with ETN or ADA.

Methods: Patients with active RA (defined as DAS28 score $\geq$ 3.6 and $\geq$ 6 swollen and $\geq$ 6 tender joints) who were currently receiving methotrexate (MTX) and anti-TNFa therapy with ETN or ADA were switched to GLM. Patients entered the screening period 6 weeks prior to receiving GLM (week −6), remained on their original anti-TNFa therapy, and were re-screened again at week 0. All eligible patients were actively switched to open-label GLM 50 mg SC injections at weeks 0, 4, 8 and 12. The primary endpoint was ACR 20 response at week 14. Here, we report the results of our interim analysis.

Results: Of the first 200 patients enrolled, all were included in the interim modified intention-to-treat (mITT) population analysis, and 160 were eligible for the interim per protocol population analysis. 163 patients (81.5%) were female and 37 patients (18.5%) were male; mean age was 55.9 ±11.26 years and mean disease duration was 9.8 ±9.70 years. At baseline, the mean number of swollen and tender joints was 18.8 ±11.93 and 32.3 ± 16.61, respectively, and the mean DAS28 (ESR) score was 6.2± 0.87. 106 patients (53%) were switched from their ongoing treatment of ETN, and 94 patients (47%) were switched from ADA. 35 patients from this study population had been previously exposed to both ETN and ADA, but not concomitantly. At week 14, 67 of the 200 patients (33.5%; 95% CI: 27%, 40%) achieved the primary endpoint of ACR 20 response; 36 (18% CI:12.7%, 23.3%) and 43 (21.5%CI:15.8%, 27.2%) patients responded by week 1 and week 2, respectively. In the per protocol analysis, 62 of the 160 patients (38.8%; 95% CI: 31.2%, 46.3%) achieved an ACR20 response at week 14, while 37 patients (23.1%CI:16.6%, 29.7%) responded as early as week 2. A clinically meaningful EULAR response was achieved in 101patients (50.5%; 95% CI: 43.6%, 57.4%) with a mean DAS28 improvement of 1.50 ($p<0.001$) from baseline. In the per protocol analysis, 58.1% of patients achieved a EULAR response by week 14. HAQ improved with a mean of 0.19 (95%CI: 0.123, 0.265, $p<0.0001$) with 39% of the patients demonstrating a clinically meaningful improvement of $\geq$ 0.22 from baseline. Prior to week 14, 31 (15.5%) of the 200 patients discontinued the study agent; 5 patients (16.1%) withdrew due to an adverse event (AE). 122 (61%) of the 200 patients experienced AEs and 9 patients (4.5%) experienced serious AEs. Injection site reactions were reported in 5 (2.5%) patients.

Conclusion: GLM improves signs and symptoms in patients with moderate or severe RA who were responding inadequately to ETN or ADA, with responses observed as early as week 1. Over half of the treated patients also achieved a DAS28-defined EULAR response. GLM was safe and well-tolerated. Additional results obtained from the on-going GO-SAVE clinical trial will further the understanding of clinical response in this population.

456

Baseline Serum Interferon Beta/Alpha Ratio Predicts Response to Tumor Necrosis Factor Alpha Inhibition in Rheumatoid Arthritis. Rachna Aggrawal[1], Beverly S. Franek[1], Marlena Kern[2], Peter K. Gregersen[2] and Timothy B. Niewold[1]. [1]University of Chicago, Chicago, IL, [2]Feinstein Institute for Medical Research, Manhasset, NY

Background/Purpose: Response to tumor necrosis factor alpha (TNF-α) inhibition is heterogenous in rheumatoid arthritis (RA). Previous studies have suggested that circulating type I interferon (IFN) levels may predict treatment response to TNF-α inhibitors and other biological agents in RA. Prediction of likely responders prior to initiating therapy would represent a major advance in biological treatment strategies for RA.

Methods: We studied sera from 32 RA patients from the ABCoN Consortium pre-treatment and 4–6 weeks after beginning treatment with TNF-α inhibitors, selecting patients who either had a good response or no response at 14 weeks by EULAR criteria. 27 of the 32 subjects were of European ancestry. Total serum type I IFN activity as well as IFN-α vs. IFN-β activity were measured using a functional reporter cell assay. Data were available regarding baseline and follow up disease activity score (DAS), EULAR response criteria at 14 weeks, anti-CCP antibody titer, and type of TNF-α inhibitor used.

Results: An increased ratio of IFN-β/IFN-α >1.3 in the pre-treatment serum sample was associated with lack of response by EULAR criteria at 14 weeks ($p=0.009$). Similarly, higher IFN-β/IFN-α ratio was positively correlated with higher DAS score at 14 weeks (Spearman's rho= 0.57, $p=0.0075$). Anti-CCP antibody titer and type of TNF-α inhibitor did not influence this relationship. In follow up sera at 4–6 weeks, the EULAR non-responders were more likely to have increased total type I IFN activity than good responders ($p=0.008$), and this increase was characterized by a shift toward increased IFN-α as compared to good responders ($p=0.039$).

Conclusion: Increased pre-treatment serum IFN-β/IFN-α ratio was strongly associated with non-response to TNF-α inhibition by EULAR criteria at 14 weeks. A previous study of IFN-β/IFN-α ratio and response to TNF-α inhibiton in Hispanic-American RA patients reported an association, although in a different direction than our predominantly European ancestry population. This may represent a population-specific difference, and both studies support the potential utility of serum type I IFN in predicting outcome of TNF-α inhibition in RA.

457

Validation of Algorithms Using Genome-Wide SNP Analysis for Prediction of Remission Criteria for Infliximab or Etanercept-Treated Rheumatoid Arthritis Patients Using Multiple Medical Cohorts. Tsukasa Matsubara[1], Satoru Koyano[2], Keiko Funahashi[2], Takafumi Hagiwara[1], Takako Miura[1], Kosuke Okuda[1], Takeshi Nakamura[1], Akira Sagawa[3], Takeo Sakurai[4], Hiroaki Matsuno[5], Tomomaro Izumihara[6], Eisuke Shono[7], Kou Katayama[8], Toyomitsu Tsuchida[9], Mitsuyoshi Iwahashi[10], Tomomi Tsuru[11] and Motohiro Oribe[12]. [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [4]Inoue Hospital, Takasaki, Japan, [5]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [6]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [7]Shono Rheumatology Clinic, Fukuoka, Japan, [8]Katayama Orthopedic Rheumatology Clinic, Asahikawa, Japan, [9]Tsuchida Clinic, Chiba, Japan, [10]Higashi-Hiroshima Memorial Hospital, Higashi-hiroshima, Japan, [11]PS Clinic, Fukuoka, Japan, [12]Oribe Rheumatism and Internal Medicine Clinic, Oita, Japan

Background/Purpose: Achievement of remission in infliximab (IFX) and etanercept (ETN) treatment is currently one of the most important matters in RA treatment. However, there is no method for prediction of remission criteria. In our first and second cohorts, we established and validated SNP algorithms for prediction of remission or non-remission among IFX or ETN-treated RA patients (Matsubara T, et al., *The 72nd annual meeting of the ACR* San Francisco, CA, USA (2008) Matsubara T, et al., *The 73rd annual meeting of the ACR* Philadelphia, PA, USA (2009)). In this study, we then validated the third population sample by using the first and second population algorithms.

Patients and Methods: The first population sample included 187 RA patients, the second, 206 patients, and the third, 145 patients, for a total of 538 patients from eleven hospitals in different regions of Japan. Remission criteria was determined by DAS28(CRP) within 24–30 weeks after the initiation of treatment with the biologics. Case-control analyses between 285,548 SNPs and remission was examined by Fisher's exact test. We selected 5, 10 or 20 SNPs associated with IFX or ETN-remission which were common in both analyses of the first and second population ($p < 0.05$). We scored the relationship between each SNP and responsiveness, the estimated total score of 5, 10 or 20 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in remission: +1 point, hetero allele: 0 points, and homo allele in the majority of non-remission: −1 point), and then examined relationships between remission and non-remission, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)), and sensitivity (true positive/(true positive+false negative)) of the algorithms for remission with infliximab or etanercept ranged from 60–71% in the validation using third population sample. It is therefore suggested that these SNP algorithms can predict remission prior to the initiation of treatment with infliximab and etanercept.

Conclusion: These highly accurate algorithms using SNP analysis may be useful in the prediction of remission before treatment with infliximab or etanercept, and in this way can contribute to future tailor-made treatment with biologic agents.

458

52-Week Results of Clinical, Radiographic and Pharmacokinetic Assessments: Golimumab, a Human Anti-TNF Monoclonal Antibody, Administered Subcutaneously Every Four Weeks in Patients with Active Rheumatoid Arthritis Despite Methotrexate Therapy. Yoshiya Tanaka[1], Masayoshi Harigai[2], Tsutomu Takeuchi[3], Hisashi Yamanaka[4], Naoki Ishiguro[5], Kazuhiko Yamamoto[6], Minoru Kanazawa[7], Yoshinori Murakami[8], Toru Yoshinari[9], Daniel G. Baker[10], Nobuyuki Miyasaka[11] and Takao Koike[12]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [2]Tokyo Medical and Dental Univ, Tokyo, Japan, [3]Keio University School of Medicine, Tokyo, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [6]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [7]Director of Respiratory Center Professor of Respiratory, Medicine Saitama Medical University, Moroyama, Iruma-Gun, Saimata, Japan, [8]Janssen Pharmaceutical KK, Tokyo, Japan, [9]Mitsubishi Tanabe Pharma Corporation, Osaka, Japan, [10]Centocor R & D, a division of Johnson & Johnson Pharmaceutical Research and Development, LLC, Malvern, PA, [11]Tokyo Medical and Dental University, Tokyo, Japan, [12]Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background/Purpose: To assess the efficacy and safety of golimumab-(GLM) in Japanese patients (pts) with active RA despite MTX therapy.

Methods: GO-FORTH is a multicenter, randomized, double-blind, placebo(PBO)-controlled study in pts with active RA despite MTX. Pts were randomized to SC PBO, GLM50 mg, or GLM100 mg q4 wks. All pts received MTX 6–8 mg orally/wk. Pts with <20% improvement in SJC/TJC entered early escape(EE) at wk 16 in a blinded manner so that PBO→GLM50 mg and GLM50 mg→100 mg. Pts receiving GLM100 mg continued the same dose. Pts who did not enter EE continued initial therapy until wk 24. After wk 24, pts who entered EE maintained the wk 24 regimen. Pts randomized to PBO who did not enter EE crossed over (CO) to GLM50 mg at wk 24. Primary endpoint was the proportion of pts achieving ACR20 at wk 14. Secondary variables included ACR20, ACR50, ACR70, DAS28 and HAQ, and changes from BL to wks 24/52 in total vdH-modified Sharp (vdH-S) score. Data were analyzed using the all patients receiving ≥1 dose of study treatment. Missing clinical response data were not imputed. For vdH-S score, treatment grp comparisons at wks 24/52 were based on randomized grps regardless of EE/CO status. Missing data were imputed using median change from BL in total vdH-S scores (TSS) of all pts or by linear extrapolation. Wk 24 data have been reported; wk 52 results of nonparametric analyses using the van der Waerden method are now reported.

Results: 261 pts received treatment (88 PBO, 86 GLM50 mg, 87 GLM100 mg). Both GLM doses were significantly better than PBO in improving signs and symptoms/physical function through wk14 (PBO-controlled period). After wk 24, all pts received either GLM50 mg or 100 mg, and wk 14 efficacy was sustained thorough wk 52 in all grps. At wk 52, both of GLM50 mg and 100 mg yielded significantly less radiographic damage than PBO and pts who received 100 mg continued to exhibit less progression through wk 52 (Table). The proportions of pts with changes in TSS greater than the smallest detectable change (SDC) were significantly lower in GLM- vs. PBO-treated pts at wks 24 and 52. Significantly more pts treated with GLM 100 mg vs. PBO had no progression (change in TSS<0) at wk 52. Median serum GLM concentrations were approximately dose proportional and appeared to have reached steady-state by wk12.

The incidence of adverse events (AEs) through wk 52 was 89.1% in all GLM-treated pts. Among all AEs, the system organ class with the highest incidence by treatment grp (except for pts who CO GLM50 mg→100 mg) was "Infections and Infestations." Through wk 52, serious AEs occurred in 1.1%, 9.3% and 6.9% of PBO, GLM50 mg only and GLM100 mg only treated pts, respectively. There were no deaths and no tuberculosis. A colon cancer was reported in GLM50 mg grp.

	PBO	GLM	
		50 mg	100 mg
n	88	86	87
Change from BL in TSS mean ±SD	5.2±10.7	2.4±8.0 p=0.0101	0.9±5.2 p<0.0001
Pts with progression based on TSS >SDC=4.33 n(%)	30(34.1)	14(16.3) p=0.0069	10(11.5) p=0.0004
Pts with change ≤0 in TSS from BL n(%)	44(50.0)	51(59.3) p=0.2179	59(67.8) p=0.0166

Conclusion: Treatment with GLM50 mg and 100 mg+MTX significantly improved signs/symptoms and inhibited progression of structural damage vs. PBO+MTX. The GLM+MTX safety profile was similar to other anti-TNF agents.

459

Sick Leave and Disability Pension in Patients with Early Rheumatoid Arthritis Randomized to Infliximab Plus Methotrexate or Triple Therapy: One-Year Results. Jonas Eriksson[1], Martin Neovius[2], Johan Bratt[3], Ingemar F. Petersson[4], R.F. van Vollenhoven[5], Pierre Geborek[6] and Sofia Ernestam[7]. [1]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Solna, Sweden, [3]Karolinska Univ Hosp Huddinge, Stockholm, Sweden, [4]Musculoskeletal Sciences, Dept of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [5]The Karolinska Institute, Clinical Trials Unit, Stockholm, Sweden, [6]Lund University, Lund, Sweden, [7]Karolinska University Hospital, Huddinge, Sweden

Background/Purpose: In early RA patients in whom methotrexate (MTX) has failed, adding infliximab to MTX was clinically superior to triple therapy (MTX+sulfasalazine+hydroxycloroquine) with 39% vs 25% achieving EULAR good response at 1y (Lancet 374:459; 2009). The aim of this study was to evaluate whether this clinical superiority translated into greater improvement in work ability.

Methods: RA patients with <1y symptom duration were recruited from 15 rheumatology clinics in Sweden. Patients who did not achieve low disease activity after 3–4 months MTX therapy were randomized to infliximab+MTX or triple therapy. The study population was restricted to patients <64y at baseline, and the outcome at 12 months after randomization was mean days/month of sick leave and disability pension. Complete outcome data for all patients and time points were retrieved from the Swedish Social Insurance Agency. Analysis of covariance (ANCOVA) was used on the intention to treat (ITT) population, including all randomized patients.

Results: Of 210 eligible patients, 109 were randomized to infliximab+MTX and 101 to triple therapy. Seven patients in the infliximab+MTX and four in the triple therapy group never received study drug. At baseline, mean days/month of sick leave and disability pension were 17 (SD 13; median 16) in the infliximab+MTX group and 17 (SD 13; median 16) in the triple therapy group (**Figure**). At 6 months, mean days/month had decreased by 2.7 and 3.2 in the respective treatment groups (ANCOVA difference −0.7, 95%CI −3.1 to 1.8). Corresponding means at 12 months were 4.2 and 4.0 (ANCOVA difference 0.0, −2.8 to 2.8). In a modified ITT analysis, including patients receiving at least one dose of assigned treatment, similar differences were seen at 12 months (0.3, −2.6 to 3.3). Analyses based on last/baseline observation carried forward or per-protocol gave similar results, and adjustment for various baseline characteristics did not change the overall results.

Conclusion: Work ability improved significantly from baseline in this early RA cohort on combination therapy after an insufficient response to MTX, with no difference between the treatment arms. However, the average did not return to the premorbid level (6 months before randomization), underscoring the need for more effective interventions in this regard.

Golimumab, A Human Anti-TNF Monoclonal Antibody, Administered Subcutaneously Every Four Weeks As Monotherapy in Patients with Active Rheumatoid Arthritis Despite DMARD Therapy: 52-Week Results of Clinical, Radiographic and Pharmacokinetic Assessments. Tsutomu Takeuchi[1], Masayoshi Harigai[2], Yoshiya Tanaka[3], Hisashi Yamanaka[4], Naoki Ishiguro[5], Kazuhiko Yamamoto[6], Minoru Kanazawa[7], Yoshinori Murakami[8], Toru Yoshinari[9], Daniel G. Baker[10], Nobuyuki Miyasaka[11] and Takao Koike[12]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Tokyo Medical and Dental Univ, Tokyo, Japan, [3]University of Occupational and Environmental Health, Japan, Kitakyushu, Fukuoka, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [6]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [7]Director of Respiratory Center Professor of Respiratory, Medicine Saitama Medical University, Moroyama, Iruma-Gun, Saimata, Japan, [8]Janssen Pharmaceutical KK, Tokyo, Japan, [9]Mitsubishi Tanabe Pharma Corporation, Osaka, Japan, [10]Centocor R & D, a division of Johnson & Johnson Pharmaceutical Research and Development, LLC, Malvern, PA, [11]Tokyo Medical and Dental University, Tokyo, Japan, [12]Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background/Purpose: To assess the efficacy and safety of golimumab (GLM) as monotherapy in Japanese patients (pts) with active rheumatoid arthritis (RA) despite DMARD therapy.

Methods: GO-MONO is a multicenter, randomized, double-blind, placebo (PBO)-controlled study in pts with active RA despite treatment with DMARDs. Pts were randomized to SC PBO, GLM50 mg, or GLM100 mg q4 wks as monotherapy. At wk16, pts in the PBO group (grp) crossed over (CO) GLM50 mg q4 wks. Primary endpoint was the proportion of pts achieving ACR20 at wk 14. Secondary endpoints included ACR50, ACR70, and ACR-N, changes from baseline (BL) to wks 14/24/52 in DAS28 and HAQ, and changes from BL to wks 24/52 in total modified vdH-Sharp (vdH-S) score. Data were analyzed using all patients receiving ≥1 dose of study treatment. Missing data imputation was not done for the data of signs and symptoms/physical function. Comparisons of vdH-S score at wks 24 and 52 were between GLM and PBO grps, based on the original randomized grps even for PBO pts who CO to 50 mg after wk16. Missing data were imputed using median change from BL in total vdH-S scores (TSS) of all pts or by linear extrapolation. The results of the non-parametric data analyzed using van der Waerden method is being reported. Wk 24 data were previously presented; data through wk 52 are now reported.

Results: 308 pts received treatment (105 PBO, 101 GLM50 mg, and 102 GLM100 mg). At wk14, GLM50 mg and 100 mg grps had significantly greater improvements in signs and symptoms of RA and physical function vs PBO. Efficacy response was maintained through wk 52. At wk 24, GLM100 mg grp had significantly less radiographic progression (RP) vs PBO. At wk 52, both GLM50 mg and 100 mg grps had significantly less RP vs PBO (table). The proportion of pts with changes in TSS greater than the smallest detectable change (SDC) was lower in GLM50 mg and 100 mg grps than PBO at wk 52. Significantly more GLM100 mg-treated pts had no progression, defined as change in TSS < 0, vs PBO-treated pts at wk 52. The incidence of AEs up to Week 52 was 82.0% (242/295 pts, 973 events) among all GLM-treated pts. Serum GLM levels increased in a dose-proportional manner, with steady state reached at week 12 and it was maintained through wk 52. Among the AEs, the system organ class that showed the highest incidence was "Infections and Infestations". The incidences of serious AEs in PBO, PBO→GLM50 mg, GLM50 mg and 100 mg grps were 2.9%, 7.6%, 5.9%, and 5.9%, respectively. There were no deaths and no tuberculosis. One breast cancer was reported in GLM100 mg grp.

	PBO	GLM	
		50 mg	100 mg
n	105	101	102
Change from BL in TSS Mean ±SD	6.9±12.5	3.3±6.4 p=0.0118	3.2±18.0 p<0.0001
Pts with progression based on TSS >SDC=4.04, n(%)	44(41.9)	28(27.7) p=0.0328	19(18.6) p=0.0003
Pts with change ≤0 in TSS from BL n(%)	37(35.2)	46(45.5) p=0.1316	54(52.9) p=0.0103

Conclusion: Both doses of GLM significantly improved signs and symptoms of RA and physical function compared with PBO. The GLM50 mg and GLM100 mg grps had significantly less RP vs PBO at wks 24 (GLM100 mg only) and 52 (both dose grps). GLM monotherapy was well-tolerated with safety profile similar to other anti-TNF agents.

461

Impact of Different Biologic Agents on the Improvement of Fatigue. Anja Strangfeld[1], Matthias Schneider[2], Jörg Kaufmann[3], Andreas Krause[4], Angela Zink[5] and Joachim Listing[6]. [1]Deutsches Rheumaforschungszentrum, Berlin, Germany, [2]Heinrich-Heine-University, Duesseldorf, Germany, [3]Rheumatologist, Ludwigsfelde, Germany, [4]Immanuel Krankenhaus Berlin-Buch, Berlin, Germany, [5]Deutsches Rheumaforschungszentrum and Charité University Medicine, Berlin, Germany, [6]German Rheumatism Research Centre, Berlin, Germany

Background/Purpose: Fatigue is a factor significantly affecting the physical health of patients and limiting their social live. It was reported lately that TNFα leads to prolonged brain activity upon nociceptive stimulation, which is rapidly reversed with TNF-blockade. It was shown that this is not primarily linked to the anti-inflammatory effects of TNF-inhibition. Due to the effects of TNFα in the central nervous system our aim was to examine whether the relative improvement of fatigue is different for the various biologic agents.

Methods: We used data from the German biologics register RABBIT which observes more than 9,500 patients with rheumatoid arthritis (RA) from start of treatment with any approved biologic agent or with a new DMARD. In the current analysis, only patients with a follow-up of at least 6 months and a minimum of two DMARD failures were included. Fatigue was measured on a 0 to 10 numerical rating scale (NRS) at baseline, and after 3 and 6 months. Multiple logistic regression was used to compare the treatment with various

biologic agents to non-biologic DMARD treatment regarding a) the chance of achieving 'no fatigue' (value <= 1) at six months and b) the chance of clinically significant improvement (change in fatigue score of 3 or more) in patients who had a baseline score of at least 3. Adjustment was made for the following baseline variables: fatigue, DAS28, functional capacity (measured by the Hannover Functional Status Questionnaire (FFbH)), co-morbid conditions (4 subgroups), previous treatment with biologics (yes/no), treatment with glucocorticoids (no, <10mg/d >=10mg/d), pain and morning stiffness >=30 minutes.

Results: Data of 5,432 patients with a mean age of 55 years and disease duration of 12 ± 9 years were available for the analysis. At baseline, patients had a mean fatigue score of 5.5 ±2.7, a DAS28 of 5.5 ±1.3 and 59% of full function. Fatigue improved to 4.2 ±2.7 at six months. Patients treated with biologics improved significantly more frequently by a score of 3 or higher than DMARD treated patients. This was also found if patients with similar improvement in DAS28 scores were compared (data not shown). Anti-TNF treated patients had compared to DMARD controls a significantly higher chance of achieving 'no fatigue' already at three months (data not shown) and at six months (Tab).

Table. Adjusted odds ratios (OR) and corresponding adjusted frequencies of patients achieving 'no fatigue' (<= 1 on a 0 to 10 scale) or a clinically significant improvement of ≥ 3 points.

		No fatigue at 6 months		Clin. significant improvement	
	No. of patients	Adj. OR	Adj. frequency (%)	Adj. OR	Adj. frequency (%)
DMARD	1,068	Referent	11.7 [10–14]	Referent	26.6 [23–30]
Etanercept	1,249	1.7 *	18.3 [16–21]	2.1 *	43.8 [40–47]
Infliximab	516	1.6 *	17.4 [14–21]	1.8 *	39.3 [34–45]
Adalimumab	1,389	1.4 *	15.6 [14–18]	1.9 *	40.2 [37–43]
Rituximab	840	1.2	13.8 [11–17]	1.7 *	37.5 [33–43]
Abatacept	182	1.1	13.1 [8–20]	1.6 *	37.0 [28–47]
Tocilizumab	188	1.5	16.6 [12–23]	1.9 *	41.3 [32–51]

* $p < 0.05$

Conclusion: Treatment with a biologic agent improved fatigue significantly more frequently than with a conventional DMARD. This finding is supported by experimental research in which Hess et al (1) observed that blocking TNFα does not only have anti-inflammatory effects but also an impact on processes in the CNS.

462

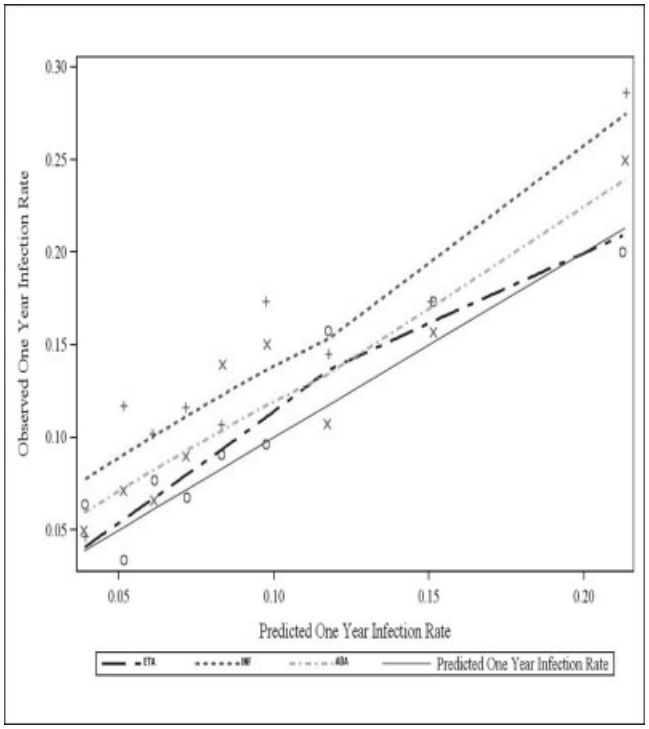
Does the Association Between Anti-TNF Biologics and Serious Infections in Rheumatoid Arthritis Patients Vary by Comorbidity Burden? Jeffrey R. Curtis[1], Fenglong Xie[2], Paul M. Muntner[2], Lang Chen[2], Kenneth G. Saag[2] and Elizabeth S. Delzell[2]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: In many studies, anti-TNF therapy is associated with an increased risk for serious infections. It is unclear whether this risk is incrementally increased for patients with a high baseline infection risk on the basis of older age or comorbidities that are independently associated with infections. We evaluated associations between anti-TNF agents and serious infection according to patients' baseline risk for infection.

Methods: We studied new users of infliximab, etanercept, and adalimumab among RA patients enrolled in Medicare/Medicaid during 2000–2006. Using an infection prediction score, we calculated person-specific 1-year predicted risk of hospitalized infection based upon factors measured in the 1 year prior to biologic use; these factors included age, demographics, comorbidities, and oral glucocorticoids.

The subsequent 1-year observed risk of hospitalized infection was compared among users of etanercept, infliximab and adalimumab and to predicted risk in the absence of anti-TNF exposure. Associations were evaluated on the risk difference and risk ratio scale to evaluate effect modification according to baseline predicted infection risk. Cox proportional hazards models compared the pairwise infection risk for each of the 3 anti-TNF agents, controlling for decile of the infection risk score. The observed and predicted risks of infection were plotted for each decile and smoothed using LOWESS curves.

Results: Among 7537 RA patients initiating inflixiumab (n=3036), etanercept (n=2253) and adalimumab (n=2248), the overall observed one year risk of infection was 15.3, 13.1, and 13.7 per 100 person years, respectively. Infection risk was highest for infliximab users (p = 0.01 for infliximab vs. etanercept, p=0.15 for infliximab vs. adalimumab, and p=0.23 for etanercept vs. adalimumab). Comparing inflixumab to the other two anti-TNF agents and to predicted risk, there was a relative constant risk difference of 2–3 per 100 person-years according to baseline predicted infection risk (Figure). The relative risk ratio varied, ranging from 1.5 at the low end of predicted risk down to 1.0 at the higher end of predicted risk.



Conclusion: The risk of serious infections for anti-TNF agents was incrementally increased by a fixed absolute difference irrespective of age, comorbidities, and other factors that contributed to infection risk. The clinical importance of an increased relative risk for infection is likely to be most relevant for patients with low baseline infection risk; in contrast, the relative risk increase was small for patients with a high baseline risk. Older patients and those with high comorbidity burdens should be reassured that the magnitude of incremental risk with anti-TNF agents does not appear to be greater for them than for lower risk patients.

A Preliminary Report of Remission Induction with Two Therapeutic Strategies with Infliximab or High Dose Intravenous Steroids for the Treatment of Rheumatoid Arthritis. Jackie L. Nam[1], Edith Villeneuve[2], Philip G. Conaghan[3], Elizabeth Hensor[4], Helen I. Keen[5], Roshan Amarasena[6], Andrew K. Gough[7], Philip Helliwell[3], Ann W. Morgan[3], Mark Quinn[8], Michael J. Green[9], Richard Reece[10], Richard Wakefield[3] and Paul Emery[3]. [1]NIHR Leeds Musculoskeletal Biomedical Research Unit, LIMM, University of Leeds., Leeds, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Unit, Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [3]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [4]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [5]UWA, Perth, Australia, [6]Salford Royal Foundation trust, Manchester, United Kingdom, [7]Harrogate District Hospital, Harrogate, United Kingdom, [8]The York Hospital, York Teaching Hospital NHS Foundation Trust, York, United Kingdom, [9]York Teaching Hospital NHS Foundation Trust, Harrogate, United Kingdom, [10]University of Leeds, Leeds, United Kingdom

Background/Purpose: Early intensive treatment strategies have demonstrated good clinical outcomes for patients with rheumatoid arthritis (RA). Infliximab (IFX) and the use of high dose steroids have shown to be effective for remission induction. Objectives**:** To compare the efficacy of methotrexate (MTX) + IFX vs. MTX + high dose intravenous (IV) steroid as induction therapy, together with dose and treatment modification according to predefined disease activity measures in patients with DMARD naïve RA.

Methods: The IDEA study is a 78 week multicentre randomised controlled study of 112 patients with early (symptom duration of >3 and <12 months) DMARD naïve RA (1987 ACR criteria, DAS>2.4). Patients were randomised to one of 2 groups –IFX or steroid/placebo. Treatment was blinded until week 26 then pragmatically guided by disease activity scores according to a pre determined therapeutic regime. The IFX group received: IFX 3mg/kg (weeks 0, 2, 6, 14, 22) + MTX 10mg weekly increasing to 20mg by week 6 with IFX dose modification (increase or stopping) depending on DAS 44 from week 26. The steroid/placebo group received: IV methylprednisolone 250mg at week 0, placebo infusions at weeks 2, 6, 14, 22 + MTX 10mg weekly increasing to 20mg by week 6; from week 26 treatment was escalated stepwise as follows if DAS >2.4: add sulphasalazine (SSZ) and hydroxychloroquine (HCQ), then stop SSZ+ HCQ and add leflunomide (LEF), then one of the following combinations: MTX s/c +LEF or MTX + ciclosporin or MTX+ LEF + prednisolone 5–7.5mg daily. Additional IM methylprednisolone 120mg was administered if DAS >2.4 (weeks 6, 14, 22, 38, 50 and 62) for both groups. Other biologics were also allowed from week 26 according to NICE guidelines. Remission data are reported here.

Results: Baseline characteristics were similar in the 2 patient groups. At week 2 remission (DAS <1.6) was achieved in 22.2% (12/54) in the IFX group and 8.9% (5/56) in steroid/placebo group (p=0.054). At week 26, 33.3% (18/54) and 44.6% (25/56) in the in the IFX and steroid/placebo groups respectively were in remission (p=0.224). At week 50, a greater percentage achieved remission in the IFX group (IFX 51.9% (28/54) vs. steroid/placebo 35.7% (20/56), p=0.088. By week 78, similar remission rates were seen in the two groups (IFX 48.1% (26/54) vs. steroid/ placebo 51.8% (29/56), p= 0.703).

Conclusion: Early and sustained remission rates were achieved using an intensive treatment strategy with IFX as induction therapy. Similar remission rates were achieved using with high dose IV steroids; although some reduction was seen at 50 weeks this was regained at week 78. Analysis of the radiographic data will be of interest in providing further information regarding the effects of the two therapeutic strategies on bone damage.

464

The Immunogenicity of Infliximab, Adalimumab and Etanercept in Rheumatoid Arthritis, Ankylosing Spondylitis, Psoriatic Arthritis, Crohn's Disease and Ulcerative Colitis—a Quantitative and a Qualitative Review. Sandra Garcês[1], Jocelyne Demengeot[2], Gj Wolbink[3], L. Aarden[4] and Elizabeth Benito-Garcia[5]. [1]Instituto Gulbenkian Ciência; Hospital Garcia de Orta, Oeiras, Portugal, [2]Instituto Gulbenkian Ciência, Oeiras, Portugal, [3]Reade/Jan van Breemen Institute Research Center, Amsterdam, Netherlands, [4]Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands, [5]BioEpi, Research Center, Oeiras, Portugal

Background/Purpose: Despite the beneficial effects of aTNF alpha agents on the systemic rheumatic and inflammatory bowel diseases, a significant proportion of patients cannot sustain a therapeutic response over time. An increasing body of literature highlights immunogenicity as one of the main factors behind therapeutic failure and infusion-related adverse events. Given the recent recommendations by the EMEA to monitor immunogenicity in clinical practice, it is important to reevaluate the impact of anti-biologic antibodies on drug efficacy and safety.

We conducted a meta-analysis to assess the influence antibodies against infliximab, adalimumab and etanercept on therapeutic efficacy/effectiveness and the influence of concomitant immunosuppression in anti-biologic antibodies production, in patients with rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, Crohn′s disease and ulcerative colitis.

Methods: A systematic literature search of Medline, Embase and Cochrane Library was conducted trough May 2011, complemented with the reference lists of articles and consultation with experts. We included clinical trials and observational studies. Seventeen studies met our inclusion criteria. Fixed-effects models (Mantel-Haenszel method) were initially used for clustering results and random-effects models according to the Laird method were introduced whenever statistically significant heterogeneity existed, examined by calculating the χ^2 test for heterogeneity and the I^2 measure of inconsistency. The effects of individual study and population characteristics were evaluated by meta-regression.

Results: Overall, the presence of anti-biologic antibodies reduced the therapeutic response rate (RR, 95% CI varied from 0.05 to 0.53). Subgroup analysis revealed that the concomitant use of Methothrexate (MTX) was a significant source of heterogeneity. When high proportion of patients was receiving concomitant MTX (≥74%) the effect size reduction was smaller (RR 0.68, 95% CI 0.58 to 0.79) than in studies where a lower proportion of patients were co-treated with MTX (RR 0.20, 95% CI 0.11 to 0.35). The effect is independent of the type of the disease. The concomitant use of immunosupressors reduced the proportion of patients with detectable anti-biologic antibodies by about 50% (RR varied from 0.26 to 0.82). In the subgroup analysis we verified that when RIA was used to detect anti-biologic antibodies the effect size reduction was larger (RR 0.36, 95% CI 0.28 to 0.45) than in studies where the antibodies were detected by ELISA methods (RR 0.66, 95% CI 0.57 to 0.76).

Conclusion: There is evidence of an increased risk of therapeutic failure in patients with anti-biologic antibodies, which although modulated by MTX, remains very significant. Aside from clinical impact, immunogenicity can also alter drug safety profile. Concomitant immunosuppression reduces but do not abrogate anti-biological production. The type of assays employed to assess anti-biologic antibodies can influence the results. Routine assessment of immunogenicity will help us to design more cost-effective strategies, tailored to each patient.

ACR Poster Session A
Sjögren's Syndrome
Sunday, November 6, 2011, 9:00 AM–6:00 PM

465

Effect of Caphosol® On the Symptoms of Xerostomia Associated with Primary and Secondary Sjögren's Syndrome. Stephanie Mathew[1], Angelique N. Collamer[2], Athena S. Papas[3] and Daniel F. Battafarano[4]. [1]United States Air Force SAUSHEC, Fort Sam Houston, TX, [2]Langley AFB Hospital, Langley AFB, VA, [3]Tufts School of Dental Medicine, Boston, MA, [4]Brooke Army Medical Ctr, San Antonio, TX

Background/Purpose: Sjögren's syndrome is a common autoimmune disorder affecting up to 4% of the general population, resulting in lymphocytic infiltration of exocrine glands and subsequent xerophthalmia and xerostomia. Effective and tolerable therapies for xerostomia are lacking. Caphosol®, a supersaturated calcium and phosphate electrolyte solution, has been successful in treating radiation and chemotherapy induced mucositis and xerostomia. This study evaluated the potential benefit of Caphosol® on Sjögren's syndrome patients reported oral health, quality of life and xerostomia symptoms.

Methods: Rheumatology clinic patients diagnosed with primary or secondary Sjögren's syndrome with symptomatic xerostomia were recruited to participate in an IRB approved study. Prior to enrollment, patients were assessed with a 6 minute un-stimulated salivary flow rate, and were eligible if they produced less than 0.6mL/minute of saliva. Exclusion criteria included those on a highly restricted sodium diet (less than 1 gram per day), inability to provide written consent or self-mix the solution. Patients were allowed to continue all medications, with the exception of other oral solutions used for the purpose of treating dry mouth. During the study period patients could not start new saliva replacement preparations, anticholinergic or antimuscarinic medications. Following the initial evaluation, patients were provided Caphosol® solution, as well as detailed guidance on its administration and instructed to use it 2 to 10 times daily. Enrolled patients answered validated questionnaires (HAQ, SF-36, Xerostomia Inventory and New York Bluestone mouth feel) at baseline and 3 months to assess quality of life and symptoms of xerostomia.

Results: Thirty-eight patients met inclusion criteria and consented to participate, 95% (36/38) were female, 66% (25/38) Caucasian, with a mean age of 56 (range 38–67). Twenty-five patients (66%) had secondary Sjögren's syndrome associated with rheumatoid arthritis (10), scleroderma (5), systemic lupus erythematosis (3), undifferentiated connective tissue disease (3), mixed connective tissue disease (2), relapsing polychondritis (1) and Behçet's disease (1). Twenty-four patients were included in the statistical analysis, 22 used Caphosol® more than 2 times daily. Three patients failed to use the solution, 2 withdrew consent and 7 did not return the questionnaires in the allotted time.

At 3 months, a statistically significant improvement in the symptoms of dry mouth (p 0.05), and ability to swallow problematic foods (p 0.025) when compared to baseline was found in those patients using the solution at least 2 times daily. However, no statistically significant quality of life improvement, as measured by the HAQ and SF-36 questionnaires was found.

Conclusion: In this pilot study, the supersaturated calcium and phosphate electrolyte solution Caphosol® improved symptoms of xerostomia in Sjögren's syndrome patients. Caphosol® is an effective option for the treatment of xerostomia in Sjögren's syndrome. Longer studies may be

necessary to evaluate for potential quality of life improvements with extended Caphosol® use.

466

Responsiveness of Disease Activity Indices (ESSPRI, ESSDAI) in Patients with Primary Sjögren's Syndrome Treated with Rituximab. Petra M. Meiners, Suzanne Arends, Elisabeth Brouwer, Arjan Vissink and Hendrika Bootsma. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: To evaluate the responsiveness of the ESSPRI and ESSDAI in patients with primary Sjögren's syndrome (pSS) treated with rituximab.

Methods: Twenty-eight pSS patients who were treated with rituximab (1000 mg) infusions at days 1 and 15 were included. Clinical data, including ESSPRI and ESSDAI, were collected prospectively at baseline and 16, 24, 36, 48 and 60 weeks after treatment. Internal responsiveness was assessed using standardized response means (SRM) and effect sizes (ES). SRM and ES <0.5 were interpreted as small, between 0.5 and 0.8 as moderate and >0.8 as large. External responsiveness was assessed using Spearman's correlation coefficients.

Results: Median (range) ESSPRI and ESSDAI at baseline were 6.7 (0.3–9.0) and 8 (2–18), respectively. Both indices improved significantly after treatment. SRM and ES for ESSPRI and ESSDAI were ≥ 0.8 at week 16, decreased afterwards and were larger for ESSDAI than for ESSPRI. SRM and ES values for patient (patGDA) and physician (phyGDA) global disease activity, and rheumatoid factor (IgM-Rf) broadly followed the pattern of those of ESSPRI and ESSDAI. SRM and ES for stimulated whole salivary flow were small at all time-points. Furthermore, at baseline and form most change scores, moderate correlations were found between ESSPRI and patGDA and between ESSDAI and phyGDA. No significant correlation was found between ESSPRI and ESSDAI.

Conclusion: This is the first study to demonstrate that the recently developed ESSPRI and ESSDAI are sensitive to measure change in disease activity after therapeutic intervention. This supports the usefulness of these indices for future clinical trials in pSS patients. Responsiveness of ESSPRI was less prominent than for ESSDAI.

Characterization of Anti Sjögren's Syndrome Nuclear Antigen-1 (SSNA-1) Novel Autoantibody in Patients with Primary Sjögren's Syndrome. Kaori Hiruma[1], Kazuhisa Nozawa[1], Keigo Ikeda[2], Ayako Yamaguci[1], Iwao Sekigawa[2], Edward K.L. Chan[3] and Yoshinari Takasaki[1]. [1]Juntendo University School of Medicine, Tokyo, Japan, [2]Juntendo University Urayasu Hospital, Tomioka, Urayasu, Chiba, Japan, [3]University of Florida, Gainesville, FL

Background/Purpose: Sjogren's syndrome nuclear antigen-1 (SSNA-1)/nuclear antigen of 14 kDa (NA14) is a novel autoantigen which were recently identified. SSNA-1 belongs to a coiled coil protein superfamily and the coiled coil proteins are known to often elicit autoimmune reaction in Sjogren's syndrome. Although we previously have reported that autoantibody against SSNA-1 was often produced in patients sera with primary Sjogren syndrome (pSS), the detailed autoantigen characteristics about the SSNA-1 remains poorly described. Therefore, we conducted the present study to clarify characteristics of SSNA1 regarding clinical association of pSS and mechanism of the autoantibody production.

Methods: Total 332 sera with various rheumatic diseases including pSS positive for standard autoantigens (SS-A/SS-B, centromere, U1-RNP, ds-DNA, Jo-1, and nucleolar related proteins) were obtained from serum bank of our university hospital approved by the local ethics committee. Reactivity for recombinant SSNA-1 protein in these autoimmune sera was measured by direct ELISA and immunoblotting. Statistical analysis was performed by χ^2test compared to those of normal control. SSNA-1, interferon γ inducible protein of 10 kDa (IP-10) and B cell-activating factor belonging to the TNF family (BAFF) expression in human salivary cells line (HSG) was monitored by quantitative real-time PCR. Serum levels of IP-10 and BAFF were measured by sandwich ELISA. IIF analysis was performed to characterize staining pattern of anti-SSNA-1 antibody.

Results: High frequency of positive sera against SSNA-1 was observed in anti- SS-A/SS-B, centromere, and U1-RNP positive autoimmune sera significantly compared to normal controls, and was not observed in anti-ds-DNA, Jo-1 and nucleolar related proteins positive autoimmune sera. Although the anti-SSNA-1 antibody was predominantly recognized in pSS among various systemic rheumatic diseases as we expected, patients with mix connective tissue disease (MCTD) showed high prevalence of anti-SSNA antibody as well as pSS. IIF analysis revealed that anti-SSNA-1 monoclonal antibody stained only G2-M phase mitotic cells and did not stain G1-S phase cells. IFNγ treatment resulted in 10-fold increase of SSNA-1 mRNA expression on the HSG cells. Serum levels of IP-10 and BAFF, which were also positively regulated by IFNγ in HSG cells, were statistically greater in anti-SSNA-1 positive sera with pSS compared to those in the anti-SSNA-1 negative sera.

Conclusion: In the present study, we clarified that anti-SSNA-1 antibody is frequently recognized in anti-SS-A/SS-B, centromere, and U1-RNP positive autoimmune sera. The production of anti-SSNA-1 antibody had unique disease specificity for pSS and MCTD. In addition, SSNA-1 appeared to be classified as novel mitotic apparatus autoantigen. Regarding to an important factors of the anti-SSNA-1 autoantibody production, IP-10 and BAFF played an important role for the autoantibody production. Overexpression of IP-10 and BAFF induced by abnormal IFNγ regulation in pSS may possibly induce autoreactive T cells infiltration and abnormal B cells activation in salivary gland with pSS consequently resulting in anti-SSNA-1 autoantibody production.

Early Reconstitution of Autoreactive B-Cells After Rituximab Treatment in Primary Sjögren's Syndrome. Wayel H. Abdulahad, Henko Tadema, Arjan Vissink, Minke G. Huitema, Jetske Anema, Petra M. Meiners, Pieter C. Limburg, Cees GM Kallenberg, Frans Kroese and Hendrika Bootsma. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: B-cell depletion therapy with rituximab (RTX) leads to improvement of salivary and lacrimal gland function for at least 6–9 months in patients with primary Sjögren's syndrome (pSS). However, clinical symptoms of pSS re-appear at the time that B-cells return in the peripheral blood. This observation offers the possibility to analyze the impact of RTX on reconstitution of autoreactive B-cells in pSS-patients. In the present study, we aimed to assess the effect of RTX-treatment on anti-Ro52/60 and anti-La autoantibody-producing B-cells in patients with pSS.

Methods: Seventeen patients with pSS were treated with RTX on days 1 and 15. To study the effect of RTX on depletion/reconstitution of autoreactive B-cells, peripheral blood mononuclear cells (PBMCs) were isolated from pSS-patients (at baseline and 5, 16, 24, 36, 48 and 60 weeks after RTX treatment) and from age- and sex-matched healthy controls (HC, n=12). These PBMCs were stimulated for 12 days with CpG-ODN and IL-2 to induce polyclonal B-cell activation and antibody production. *In vitro* produced autoantibodies to the Ro60-, Ro52-, and La- proteins were measured in supernatants by ImmunoCAP assay. Presence of circulating Ro52/60-specific B-cells was determined by flowcytometry, using APC-conjugated recombinant Ro52/60. To characterize the phenotype of autoreactive B-cells, $CD19^+$ cells were sorted into 4 subsets on the basis of surface expression of IgD and CD27. These 4 subsets were separately co-cultured with autologous B-cell-depleted PBMCs (ratio 1:10 cells), and stimulated with CpG-ODN/IL-2 to analyze the levels of *in vitro* produced autoantibodies. In addition, B-cell numbers and phenotypes were examined by flowcytometry in fresh blood samples at aforementioned time points.

Results: At baseline, B-cells from all pSS-patients produced high levels of anti-Ro60 and low levels of anti-Ro52 autoantibodies, whereas anti-La autoantibodies were detected in 7 out of 17 pSS-patients only. No autoantibody production was observed in HCs. *In vitro* autoantibody production in pSS-patients was disappeared at weeks 5 and 16 after B-cell depletion, reappeared at week 24, and reached baseline levels at week 36 post-RTX-treatment. At 36 weeks, reconstituted B-cell numbers were, however, still decreased as compared to their numbers at baseline. In addition, increased frequencies of Ro60-binding B-cells were observed in peripheral blood of pSS-patients by FACS analysis. Furthermore, B-cell-sorting experiments clearly demonstrated that IgD^- memory B-cells were the major producers of anti-Ro60 autoantibodies.

Conclusion: Circulating autoreactive B-cells in pSS-patients, bearing the phenotype of IgD^- memory cells, produce high levels of anti-Ro60 autoantibodies. These autoreactive B-cells were successfully depleted by RTX, but early reconstituted despite the low numbers of regenerated B-cells. RTX-treatment might induce emerging autoreactive B-cells which in turn could be in favor of a more specific targeting of IgD^- memory B-cells in pSS-patients.

469

A Novel Cell-Based Assay for Inhibitory Anti-Muscarinic Type 3 Receptor Antibodies in Patients with Sjögren's Syndrome. Michael W. Jackson[1], Isabell Bastian[1] and Thomas P. Gordon[2]. [1]Flinders University and Flinders Medical Centre, Adelaide, Australia, [2]Flinders Medical Centre, Bedford Park, Australia

Background/Purpose: Primary Sjögren's syndrome (SS) is a systemic autoimmune disorder characterized by exocrine failure and widespread autonomic dysfunction. Functional autoantibodies directed against the muscarinic type 3 receptor (M3R) have been postulated to underpin gastrointestinal, bladder and cardiac dysfunction in SS *(Cai et al, Arthritis Res Ther 2008;10:R31)*, and we have recently demonstrated that SS IgG acts specifically at the M3R to disrupt cholinergic neurotransmission and motility in murine gastrointestinal tissues *(Park et al, Arthritis Rheum, 2011, 63: 1426–34)*. To date, detailed studies correlating the presence in patients of anti-M3R antibodies and symptoms of autonomic dysfunction have been hampered by a lack of suitable screening assays *(Dawson et al, Arthritis Rheum 2004;52:2984–95)*. Hence, the aim of the current study was to develop a cell-based assay to screen patient IgG samples for anti-M3R activity.

Methods: HEK293 cells (2×10^5) were transiently transfected in 96 well culture plates for 24 hours with DNA encoding the human M3R, and with the pGL4.33 vector (Promega) containing a luciferase gene driven by the serum response element promoter. Cells were then incubated for 4 hours in the presence of the cholinergic agonist, carbachol, (0.3 to 100 μM) and patient IgG (4 mg/ml) characterised as positive (M3R+; n = 4) or negative (M3R-; n = 2) for inhibitory anti-M3R activity, as determined by the in vitro bladder strip assay *(Waterman et al, Arthritis Rheum 2000;43:1647–54)*. IgG from healthy donors (n = 6) was used as controls. Luciferase gene activity was determined on a DTX 880 MultiMode Detector (Beckman Coulter).

Results: M3R+ IgG, but not control or M3R- IgG, significantly inhibited carbachol-induced luciferase activity across a range of carbachol concentrations, with a maximum inhibition of approximately 40%. M3R+ IgG had no effect on luciferase activity in the absence of carbachol, or in cells transfected with the pGL4.33 vector alone. The inhibitory action of the autoantibody on carbachol-induced receptor activity was non-competitive, consistent with allosteric modification of receptor signalling.

Conclusion: We have developed a real-time cell-based bioassay incorporating a luciferase reporter to detect inhibitory anti-M3R antibodies in IgG from patients with SS. The assay does not rely on direct detection of immobilised antibody at the receptor, thereby overcoming the limitations of conventional immunological techniques such as ELISA or Western blotting. The results from the cell assay compare favourably with those from whole-tissue in vitro assays (*Waterman et al, Arthritis Rheum 2000;43:1647–54; Cavill et al, Arthritis Rheum 2003;48:3597–02)*, thereby combining the sensitivity of ex-vivo tissues with the convenience of a 96-well assay format. The bioassay should facilitate both detailed pharmacological characterization of the mechanism of antibody action at the M3R, and the screening studies required to establish the role of anti-M3R antibodies in mediating the autonomic dysfunction associated with SS.

470

Immunological Differences in Sicca Patients Based on Age. Andreea Coca, Tracey Sanford, Mustimbo Roberts, Jason Englert, Jennifer H. Anolik and Ignacio Sanz. University of Rochester, Rochester, NY

Background/Purpose: Sjogren's syndrome is a chronic autoimmune disease that affects primarily the lacrimal and salivary glands. It may occur as a primary disorder (pSS) or secondary to other autoimmune disease. With a prevalence ranging from 0.1 to 0.6%, it is considered a common immunological disease. Despite the fact that most people develop the disease in mid-life, its presentation at extremes of age is not uncommon. The focus of this study is to analyze the age related disease discrepancies in patients with early and established Sjogren's syndrome.

Methods: Our cohort included patients that fulfill the American European Consensus Group criteria for the diagnosis of Sjogren's syndrome (AECG group). Early sicca (ES) group are patients that have subjective and/or objective dryness, some evidence of autoimmune disregulation (positive ANA, and/or Ro/La) but do not fulfill the AECG criteria. We collected demographic and laboratory data (anti-Ro, anti-La, ANA, RF, IgG, ESR, CBC, % lymphocytes, C3, C4, VAS for subjective oral and ocular dryness, Schirmer test, unstimulated whole sialometry - UWS). We excluded patients with head and neck radiation, hepatitis C infection, AIDS, sarcoidosis, graft vs. host disease, use of anticholinergic drugs. The data was analyzed using unpaired t-test.

Results: We included in the analysis 52 AECG and 33 ES. By breaking down these two groups based on age (< and > than 50 y/o) we observed a trend: younger patients had more immunological activation than older people and less dryness (better Schirmer, better VAS for oral and ocular dryness and UWS in ES only). Younger pSS patients perceived less subjective dryness, but it was the opposite for early disease. As such, more patients with leucopenia ($p=0.02$), higher IgG levels ($p<0.05$) and higher % lymphocytes ($p<0.05$) were observed in younger AECG patients. In the sicca population we observed more statistically significant differences in the population younger than 50 y/o: more patients had increased RF levels, positive anti-Ro, anti-La and the combination of both, as well as higher IgG levels and better Schirmer test higher (all $p<0.05$).

AECG		#	%ANA	%RF	%Ro	%La	WBCs	%Ro La	% hypergam	ESR >30	% lymph	Schirmer	VAS ocular	VAS oral	UWS
	<50	16	87.5	37.5	68.7	50	7.5	50	50	56.2	13.3	4	7.8	10.6	1.2
	>50	36	69.4	41.6	77.7	47.2	5.6	41.6	16.6	27.7	9	3.4	21.3	14.9	1.2
			NS	NS	NS	NS	p=0.02	NS	p<0.05	NS	p<0.05	NS	p=0.07	NS	NS
pre-SS	<50	14	78.5	28.5	64.2	35.7	4.8	35.7	35.7	7.6	14.2	21	11.1	18.3	3.1
	>50	19	57.8	5.2	42.1	0	5.9	0	0.2	15.7	5.2	10.6	9.6	2.1	2.1
			NS	p<0.05	p<0.05	p<0.05	NS	p<0.05	p<0.05	NS	NS	p=0.03	NS	NS	NS

Conclusion: In our cohort of Sjogren's we have observed that those younger than 50 y/o tend to have more of an active immunological disease (higher number had autoantibodies, hypergammaglobulinemia) but less subjective dryness. This trend was more obvious and statistically significant in pre-clinical disease, (higher number of patients with RF, positive anti-Ro, anti-La, and hypergammaglobulinemia). As this active immunological phenotype seems more pronounced early on, it could suggest a "burned-out disease" by the time the classical pSS phenotype establishes itself.

Our main limitation comes from the small number of patients. We are actively recruiting patients into this database, as we recognize the need for larger sample size to validate our results.

471

In Vivo Confocal Microscopic Evaluation of Corneal Morphology and Innervation in Primary Sjögren's Syndrome and Non-SS Dry Eye: A Monocentric Cross Sectional Study. Chiara Baldini[1], Giovanna Gabbrielli[2], Pasquale Pepe[1], Valentina Varanini[2], Francesco Ferro[1], Francesca Fanucci[2], Chiara Notarstefano[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Opthalmology Unit, Pisa, Italy

Background/Purpose: To analyse with confocal microscopy (CM) the *in vivo* corneal structure and sub-basal plexus nerves in patients with primary Sjögren's syndrome (pSS) and non-SS dry eye. *Secondary aims*: to correlate CM findings with routinary performed tear function tests (Schirmer-I test, Break up time (BUT), Green Lissamine staining (GLS)); to evaluate the usefulness of CM in the differential diagnosis between pSS and non-SS dry eye..

Methods: Twenty eyes from 10 consecutive patients with pSS (AECG criteria) and 14 eyes from 7 consecutive patients with a diagnosis of non-SS dry eye were investigated in this cross-sectional study. Exclusion criteria included: corneal dystrophy/inflammation; systemic therapies with known corneal toxicity; topical antiglaucoma drugs, steroids, or NSAIDs; use of contact lenses; previous interventions of ophthalmic surgery. Each subject had both eyes examined; the same ophthalmologist analysed all the CM images. Tear function test (Schirmer-I test, BUT, GLS) were performed in all the cases. CM parameters taken into consideration included: basal epithelial integrity (evaluated according to grading (0–2)), pachymetric data, keratocyte activation (evaluated according to grading (0–2)), cell densities of the superficial and basal epithelium, number of nerves (evaluated according to grading (0–5), tortuosity, and fiber reflectivity of the sub-basal plexus (evaluated according to grading (0–4)). Chi-square, ANOVA and t-test were used for statistical analysis.

Results: Table 1 reports patients' demographic, clinical and serological data. Tear function tests and CM parameters are also summarised in Table 1. As expected, we found that clinical and serological data and routinary performed tear function tests had a limited value in differentiating pSS from non-SS dry eyes. On the contrary, CM pachymetric data and the cell densities of the superficial epithelium were significantly lower in pSS vs non-SS dry eye ($p<0.0001$). No correlation was detected between CM data and tear function tests.

	pSS	Non-SS dry eye	p-value
Patients n°	10	7	
Age (M±SD)	53 ± 9	43 ± 15	ns
Xerostomia	8/10	5/7	ns
Salivary Gland Enlargement	2/10	0/7	ns
Arthralgia	7/10	0/7	0.01
Low C3/Low C4	2/10	0/7	ns
Leukopenia	3/10	1/7	ns
Hypergammaglobulinemia	4/10	0/7	0.08
Antinuclear antibodies	10/10	2/7	0.01
Anti-Ro/SSA	4/10	0/7	0.08
Anti-La/SSB	2/10	0/7	ns
Rheumatoid Factor	8/10	0/7	0.003
Schirmer-I test (M±SD)	4.9 ± 2.3	5.6 ± 1.9	ns
BUT	6.2 ± 1.3	6.7 ± 1.3	ns
Green Lissamine (eyes)	8/20	4/14	ns
Corneal tickness (M±SD)	**507 ± 34**	**584 ± 13**	**<0.0001**
Basal epithelium cell density (M±SD)	5918 ± 415	6017 ± 290	ns
Superficial epithelium cell density (M±SD)	**966 ± 44**	**1346 ± 121**	**<0.0001**
Number of nerves (grade≤2)	14/20	8/14	ns
Tortuosity (grade≥3)	10/20	8/14	ns
Reflectivity (grade≥3)	9/20	8/14	ns
Keratocyte activation (grade =2)	1/20	0/14	ns
Basal epithelial integrity (grade =2)	16/20	14/14	ns

Conclusion: This study demonstrated that pSS patients had a reduced corneal tickness and a lower cell density of the superficial corneal epithelium in comparison to non-SS dry eye subjects, shedding new lights on the potential role of CM in the diagnostic armamentarium of the disease.

472

Assessment of Minor Salivary Gland Innervation in Sjögren's Syndrome: A Feasibility Study. Alan N. Baer[1], Ying Liu[1], Anthony L. Keyes[2], Jean Kim[1] and Michael Polydefkis[1]. [1]Johns Hopkins University, Baltimore, MD, [2]John Hopkins, Baltimore, MD

Background/Purpose: Salivary gland dysfunction in Sjögren's syndrome (SS) correlates poorly with the severity of sialoadenitis, as assessed by minor salivary (lip) gland biopsy. Impaired innervation of the salivary gland has thus been postulated to contribute to glandular dysfunction in SS. We sought to determine the feasibility of quantifying minor salivary gland innervation in SS and sicca control patients.

Methods: Minor salivary gland lobules were obtained for this study at the time of diagnostic lip biopsy from 7 female patients with suspected SS who had consented to an IRB-approved protocol. One to two glands from each patient were fixed, cryoprotected, and sectioned at 50 μM intervals. Three-five randomly-selected 50 μM sections were stained immunohistochemically with rabbit anti-human polyclonal PGP9.5 antibody. The density of glandular nerve fibers was assessed by an unbiased stereology methodology and the laboratory personnel were blinded to the diagnoses of the patients.

Results: A dense network of small nerve fibers was visualized in each of the minor salivary glands. There were no qualitative differences in nerve fiber morphology. The clinical features and nerve fiber densities of the 7 patients are summarized in the Table.

Patient	Final diagnosis	Age	Lip biopsy	Salivary gland scintigraphy	KCS	Anti-SS-A/ anti-SS-B	Nerve density (mean ± SD)
LS	Primary SS	46	Normal	Minimal dysfunction	+	positive	4.5 ± 1.2
MB	Primary SS	59	FLS, FS=ND	Impaired tracer uptake	+	positive	4.7 ± 1.4
JT	Primary SS	42	FLS, FS=2.4	Impaired tracer uptake and discharge	+	positive	4.0 ± 2.0
NW	Secondary SS	63	FLS, FS=2.9	Not done	+	negative	2.6 ± 1.0
KK	Primary SS	57	FLS, FS=1.3	Impaired tracer uptake	+	positive	2.7 ±1.0
FB	Sicca	47	Non-specific chronic sialoadenitis	(S/P bilateral superficial parotidectomy)	+	negative	4.9 ± 0.8
BH	Sicca	32	normal	Impaired tracer uptake	+	negative	4.7 ± 0.7

KCS: keratoconjunctivitis sicca; FLS: foçal lymphocytic sialoadenitis; FS: focus score; ND: not determined due to surface area <4 mm²

Nerve fiber densities were markedly lower in 2/5 SS patients. The mean nerve fiber densities were 3.7 ± 1.0 for the SS patients and 4.8 ± 0.2 for the sicca control patients (p=0.07).

Conclusion: In this feasibility study, we established a methodology for assessing the innervation of minor salivary gland lobules in patients with SS. The minor salivary gland lobules are richly innervated and significant decreases in nerve fiber density can be detected in select SS patients. More studies are in progress to assess the nerve fiber subtypes and the correlation of nerve fiber density with clinical and histopathologic parameters.

473

Improved Assessment of Parotid Gland Dysfunction with Scintigraphy in Sjögren's Syndrome. Anthony L. Keyes, Rebecca L. Manno, Margaret Mills, John Petronis and Alan N. Baer. Johns Hopkins University, Baltimore, MD

Background/Purpose: The optimal method for assessing parotid gland function by scintigraphy has been debated. We chose to compare the initial slope of radiotracer uptake by the parotid glands with more conventional measures of net uptake ratio and maximal count time as a means to differentiate patients with Sjogren's syndrome (SS) from sicca control patients.

Methods: Parotid scintigraphy was performed on 20 patients as part of their evaluation for suspected or established SS. A diagnosis of SS was assigned to 10 of these patients, based on the 2002 AECC criteria. The results of the parotid scintigraphy were not utilized in this classification. For each patient, the time-activity curve of radiotracer uptake by the parotid glands was assessed by the net uptake ratio (ratio of maximum count and the count at 60 seconds) and the maximal count time (time at which the maximum count was reached). These results were referenced to a prior study which defined the range of values in a group of healthy controls (J Nuc Med 1998; 39:1260). The slopes of the time-activity curves to the point of maximal counts were assessed by linear regression.

Results: The mean slopes of radiotracer uptake were 1.03 ± 0.7 counts/sec and 0.97 ± 0.7 counts/sec respectively for the left and right parotid glands of the SS patients and 3.36 ± 2.7 counts/sec and 3.17 ± 0.98 counts/sec respectively for the left and right parotid glands of the sicca control patients. These differences were statistically significant for the left parotid gland (p=0.023, Student t-test) and trended to significance for the right parotid gland (p=0.0548). A slope value of 1.6 counts/sec best differentiated the two groups. Thus, the initial slope for radiotracer uptake was less than 1.6 counts/sec for 8/10 left parotid and 9/10 right parotid scans of the SS patients and more than 1.6 counts/sec for 8/10 left parotid and 8/10 right parotid scans of the sicca controls. Using a published range of values for normal individuals, the net uptake ratios were more than 2 standard deviations from the norm for 8/10 left parotid and 6/10 right parotid scans in the sicca controls and 10/10 left parotid and 9/10 right parotid scans for the SS patients.

Conclusion: Measurement of the initial slope of radiotracer uptake by the parotid glands provided better differentiation of SS from sicca control patients than assessment of net uptake ratios. This observation suggests that the same slope calculation in a group of healthy controls would yield a more narrow range of normal values for radiotracer uptake in parotid scintigraphy and increase the clinical utility of the test.

474

Diagnostic Validity of Major Salivary Gland Ultrasonography for Sjogren's Syndrome: Echostructure, Gland Size and Döppler Waveform Analysis. Divi Cornec[1], Sandrine Jousse-Joulin[2], Alain Saraux[1], Luc Bressollette[1], Jacques-Olivier Pers[1], Thierry Marhadour[3], Sylvie Boisramé-Gastrin[1], Pierre Y. Youinou[4] and Valerie Devauchelle-Pensec[5]. [1]Brest Occidentale University, Brest, France, [2]Brest university medical school, EA 2216, UBO and CHU de la Cavale Blanche,, Brest, France, [3]CHU La Cavale Blanche, Brest, France, [4]Brest Univ Medical School, Brest, France, [5]Brest University Medical School, Brest, France

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic auto-immune disorder affecting primarily exocrine glands. Ultrasonography (US) coupled with power doppler (PD) is a simple and non-invasive tool, which can be used to assess major salivary gland changes during pSS. Our objective was to define diagnosis performance of US PD in patients suspected for pSS.

Methods: 147 patients with suspected pSS (sicca, parotidomegaly or suggestive extra-glandular features) were prospectively included between

2006 and 2011. Mean age was 57.1±12.7 years, female percentage 91.2%, and mean duration of the symptoms 6.6±6.7 years. 60 patients fulfilled 2002 AECG criteria and were considered as pSS. The other diagnoses were idiopathic sicca (n=54), secondary SS (n=14), drug-induced sicca (n=15) and diabetes (n=4). US was performed in all patients by the same experienced operator, who was blinded to the diagnosis. Both bilateral parotid and submandibular glands were examined. The echostructure of each gland was quoted on a 0–4 scale as previously published, and the maximal score for each patient was considered for analysis, as well as the 0–16 sum of the scores of the 4 glands. Parotid length and width were measured in longitudinal and transversal planes, and submandibular glands in longitudinal plane. The surface of the glands was measured drawing the outlines on the screen, and calculated with the following formula: length*width/2. Parotid blood flow was studied through Döppler waveform analysis of the transverse facial artery, without and during stimulation with lemon juice. Resistive index (RI) was computed as the difference between peak systolic and end-diastolic velocities over the peak systolic velocity.

Results: The mean echostructure score sum was significantly higher in the pSS group than in the non-pSS (6.78±5.79 vs 1.58±3.4, p<0.001). Using ROC curve analysis, we determined ≥5/16 as the ideal cut-off, with 55.0% sensitivity (Se) and 88.6% specificity (Sp). However, the ROC curve of the maximal score of a single gland was very similar, and a cut-off ≥2/4 led to 60.0% Se and 85.2% Sp. The correlation coefficients between the echostructure of the different glands in a given patient were high: right vs left parotid (0.95), right vs left submandibular (0.97), right parotid vs submandibular (0.78), left parotid vs submandibular (0.80). All measures of parotid size were similar between the 2 groups, but the calculated surface of the submandibular glands was significantly lower in pSS patients (1.47±0.68 cm^2 vs 1.66±0.56, p=0.005 for the right side, and 1.47±0.61 vs 1.59±0.60, p=0.047 for the left side). No differences were found between the 2 groups concerning pre- and post-stimulation RI.

Conclusion: The assessment of major salivary gland echostructure represents a non-invasive and easy-to-perform tool for the diagnosis of pSS with good sensitivity and specificity, and should be included in future diagnostic criteria of pSS. Other measurements, including gland size and Döppler analysis of arterial flow, seem to be of less interest.

475

Nailfold Capillary Changes in Patients with Primary Sjogren's Syndrome: Comparison to Controls. Richa Mishra[1], Anupama Shahane[1], Liang Wu[2] and Frederick B. Vivino[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]Penn Presbyt Med Ctr, Philadelphia, PA

Background/Purpose: Nailfold capillaroscopy is a reliable way to distinguish between primary Raynaud's phenomenon (RP) and secondary RP associated with systemic sclerosis (SSc). It's role in the diagnosis of Sjögren's syndrome has not been well characterized. Purpose of this study was to assess prevalence of nailfold capillary changes in patients (pts) with primary Sjögren's syndrome (PSS), non autoimmune sicca controls (chronic sialadenitis) and healthy normal controls, which will help us to determine the utility of this technique for the diagnosis of PSS.

Methods: This prospective study was conducted on pts who met the American European Consensus Group (AECG) criteria (Vitali et al, 2002) for PSS (n=61), pts with biopsy proven chronic sialadenitis (n=6) and healthy normal controls (n=35). Healthy normal controls included patients with no sicca symptoms or history of autoimmune disease. Patients with diagnosis of secondary SS were also excluded. All participants filled out medical questionnaires to determine the prevalence of RP, risk factors for cardiovascular disease and other comorbidities. Using a stereo dissecting microscope nailfold capillaries of the 2nd to 5th fingers bilaterally were examined under controlled environmental conditions, photographed and scored.

A semiquantitative rating scale to score each capillary abnormality was adopted (1= Normal, 2= Dilatation >20 and < 50 micrometer, 3= Dilatation >50 micrometer, 4= Hemorrhage, 5= Drop out, 6= Neoangiogenesis). The scores for the eight digits were added together and divided by eight to calculate the total mean capillary score.

Results: A total of 111 patients were included in the study. Nailfold capillaroscopy photmicrographs of 102 patients were analyzed and 9 patients had be excluded because of poor picture quality due to dark skin. Eighty seven % of patients were female.

Table 1.

	Primary Sjögren's syndrome		Chronic sialadenitis		Controls	
	RP+	RP−	RP+	RP−	RP+	RP−
No. of pts	25	36	1	5	2	33
Mean Total Score (±SD)	31 (±10)	28.38 (±11)	14	22 (±12)	19 (±2)	13.27 (±9)
Mean Total Score of the Group (±SD)	29.45 (±11)		20.6 (±12)		13.6 (±9)	

Patients with PSS had the highest prevalence of RP among all 3 groups and significantly higher mean total capillaroscopy scores compared to healthy controls (p <0.0001) and pts with chronic sialadenitis (p = 0.07). The most common abnormality in PSS was capillary drop out.

Conclusion: The prevalence and severity of nailfold capillary changes in pts with PSS is significantly higher than that of nonautoimmune sicca pts and healthy controls. Capillary changes may occur in the presence or absence of RP. These results suggest that diagnostic sensitivity of AECG classification criteria or other criteria sets for PSS could be further improved by addition of simple variable like nailfold capillaroscopy scores.

476

A Step Toward New Diagnostic Criteria in Sjögren's Syndrome: Contribution of Major Salivary Gland Ultrasonography and Blood B-Cell Subset Profiling. Divi Cornec[1], Alain Saraux[1], Sandrine Jousse-Joulin[2], Thierry Marhadour[3], Jacques-Olivier Pers[1], Beatrice Cochener[1], Pierre Youinou[1] and Valerie Devauchelle-Pensec[4]. [1]Brest Occidentale University, Brest, France, [2]Brest university medical school, EA 2216, UBO and CHU de la Cavale Blanche,, Brest, France, [3]CHU La Cavale Blanche, Brest, France, [4]Brest Occidentale university, Brest, France

Background/Purpose: The clinical diagnosis of primary Sjögren's Syndrome (pSS) is mainly based on the AECG classification criteria, published in 2002. They do not include salivary gland ultrasonography (SGUS) and B-cell subset profiling, which have recently shown promising performance for the diagnosis of pSS. The aim of this prospective study was to determine their diagnostic value, and to suggest modifications of the classification criteria.

Methods: This study was conducted in a prospective monocentric cohort of patients with suspected pSS (sicca symptoms, parotidomegaly or extraglandular manifestations suggestive of pSS), included between 2006 and 2011. Clinical examination, basic biology, immunological tests and minor labial salivary gland biopsy (SGB) were performed systematically. SGUS was standardized and performed on bilateral parotid and submandibular glands, and their echostructure was quoted on a scale between 0 and 4, as previously published. The maximal score of one of the glands was considered for analysis. For blood B-cell subset profiling, the ratio (Bm2+Bm2')/(eBm5+Bm5) was determined using flow cytometry. A ratio ≥5 has been shown suggestive of pSS. The gold standard for the analysis was a clinical diagnosis of pSS performed by a group of experts blinded to the results ultrasonograophy and Blood B cells.

Results: 185 patients have been included in the study (mean age 56.5±12.9 years, symptoms duration 6.4±6.7 years, 91.4% females). 78 patients had pSS, of whom 62 (79.5%) fulfilled AECG criteria. Other diagnoses were idiopathic sicca (n=54), secondary SS (n=27), drug-induced sicca (n=22) and diabetes (n=4). No differences were found between the 2 groups concerning age, disease duration, and sex ratio. All items of AECG criteria were significantly associated with the diagnosis of pSS. SGUS was performed in 147 patients. ROC analysis determined an ideal cut-off of ≥2 on the 0–4 scale, for a 63.0% sensitivity (Se) and a 97.3% specificity (Sp). 37/72 pSS and 17/98 non-pSS patients had a (Bm2+Bm2')/(eBm5+Bm5) ratio ≥5. The sensibility of this test was 51.4% for a 82.7% specificity. Higher cut-off led to an increased Sp but a lower Se (≥6.5: Se 40.3%, Sp 92.9%; ≥9: Se 26.4%, Sp 98.0%). Logistic regression analysis selected only 5 items independently predictive of pSS diagnosis: xerostomy, Schirmer test, SGB, SSA/SSB positivity and SGUS. A weighted score was constructed using these variables: (Xerostomy × 2) + Schirmer + (SGB × 2) + (SSA/SSAB × 2) + SGUS. After ROC analysis, we found that a score ≥5/8 had a 84.9% Se and a 97.2% Sp, compared to 79.5% and 98.6% for AECG criteria. The area under the ROC curve of our criteria was higher than of AECG criteria (0.966 vs 0.891).

Conclusion: In this study, B-cell subset profiling was suggestive of pSS, but was not independent from other items. SGUS has an important diagnostic value for pSS, and modifications of AECG criteria including this item notably improve their diagnostic performance. The diagnostic value of such criteria have to be confirmed in other studies.

477

High Risk of Human Papillomavirus Type 58 Infections and of Cervical Squamous Intraepithelial Lesions in Sjogren 's Syndrome Patients. Miansong Zhao Sr. Beijing Shijitan Hospital,Capital Medical University, Beijing, China

Background/Purpose: To determine rates of human papillomavirus (HPV) infections, abnormal cervical smears, and squamous intraepithelial lesions (SIL) among women with Sjogren 's syndrome.

Methods: We investigated 35 women with Sjogren 's syndrome.

71 with abnormal smears from colposcopy clinics, and 20 community subjects with normal smears. Polymerase chain reaction results for viral DNA and HPV-58 sequencing data were correlated to cytology and colposcopic findings. Ethical permission for this investigation was provided by the Research Ethics Committee of Beijing Shijitan Hospital-,Capital Medical University.

Results: Sjogren 's syndrome and colposcopy patients were more likely (P <0.05) to be HPV positive (20[57%] and 39 [55%] patients, respectively) and HPV-58 DNA positive (22 [63%] and 23 [33%] patients, respectively) than community subjects (0% HPV DNA positive and 0 [0%] HPV-58 DNA positive).Sjogren's syndrome patients were also more likely to be HPV-58 DNA positive than colposcopy patients (P <0.05). Sjogren's syndrome patients with a high HPV-58 viral load more frequently had SIL (n=6) than those with a low HPV-58 viral load (n=1; P <0.05). HPV and HPV-58 DNA positivity were not associated with previous or current drug therapy for Sjogren 's syndrome patients.

Conclusion: Women with a Sjogren 's syndrome diagnosis had elevated levels of HPV infections, abnormal cervical cytology, and SIL.

478

Monoclonal Gammapathy Is Associated with Ten-Fold Risk of Hematologic Disorders in Primary Sjögren Syndrome. Anne-Laurence Tomi[1], Raphaèle Seror[2], Stephan Pavy[3], Corinne Miceli-Richard[4] and Xavier Mariette[5]. [1]Bicetre university hospital, Le Kremlin-Bicêtre, France, [2]Bicetre university hospital, LE Kremlin-Bicetre, France, [3]Hopital Bicetre, Paris, France, [4]Hopital Bicêtre, Le Kremlin Bicêtre, France, [5]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: To assess the relationship between the presence of monoclonal gammapathy (MG) and incidence of hematologic disorders in primary Sjögren Syndrome (pSS).

Methods: Three hundred fifty-two pSS patients (from the cohort followed in the Department of Rheumatology of Bicêtre Hospital between 2000 and 2008) according to the 1993 European Classification Criteria were screened for the presence MG using immunofixation technique; 15 (4,3%) had lymphoma and 6 (1,7%) had multiple myeloma (MM). Each patient with MG was paired with 2 age and sex matched pSS controls. Clinical characteristics of patients with and without MG were compared in univariate and multivariate analyses to look for factors associated with MG. The frequency of malignant hematologic disorders was compared between these 2 groups. Also, serum BAFF levels will be measured using ELISA (R&D Systems, Minneapolis, Minnesota) and compared.

Results: Twenty-six (7,4%) patients had MG (88% female, median age of 66,0 [IQR=56,5–76,5] years, median disease duration of 7,8 [IQR=3,1–12,7] years, 85% with sialadenitis [Focus score >1], 69% had anti-Ro/SSA and/or anti-La/SSB antibodies). The MG were Ig G kappa (32%), Ig G lambda (20%), Ig M kappa (16%), Ig M lambda (12%), Ig A kappa (4%), biclonal gammapathy (16%).

Compared with the 52 matched controls, cutaneous involvement (p=0,011), high LDH level (p=0,044), cryoglobulinaemia (p=0,003), low C4 level (p=0,027), and higher gammaglobulin level on serum protein electrophoresis (p=0,037) were significantly associated with the presence of MG in univariate analysis. Multivariate analysis only retained low C4 (aOR= 0.46 per 0,1 unit ;p=0.039) and higher gammaglobulin level (aOR= 1.21 [1,05–1,41]; p=0,011).

Overall, 10 (38,5%) patients with MG had malignant hematologic disorders (4 lymphomas: 1 mantle cell, 1 marginal zone, 1 lymphocytic, 1 hepatic MALT and 6 MM: 4 stage III and 2 stage I) compared with 3 (1 marginal zone lymphoma, 1 ocular MALT lymphoma, 1 chronic lymphoid leukemia) in the control group (p=0,001). At screening, in the MG group, 6 (all the 4 lymphomas and 2 MM) of the 10 hematological disorders were previously known; the 4 remaining MM have been diagnosed during the follow-up upon an increase of the M-component (n=2), appearance of cytopenia (n=1) or bone lesions (n=1) (median follow-up of patients with MG= 4,6 [IQR=1,8-8,1]years). The 3 lymphoid malignancies of the control group have been previously diagnosed and no relapse or new hematologic malignancy was diagnosed during the follow-up (median follow-up= 3,4 [IQR= 0–5,8]years). The frequency of MM in the MG group was significantly higher than in the non MG group (p=0.001). The overall risk of hematologic disorders was estimated: OR=10.21 [2.18–54.22].

The results of the comparison of BAFF levels will be presented at the meeting.

Conclusion: In this cohort, 1.7% of patients with pSS developed MM, supporting the fact that beyond the well-known risk of lymphomas, there is also an increased risk of MM in pSS. MG is a strong risk factor of lymphomas but also MM. Patients with MG should therefore be screened and also carefully followed to look for the presence or emergence of both lymphomas and multiple myelomas.

479

Follow up of Primary Sjögren Syndrome Patients Presenting Positive Anti-Cyclic Citrullinated Peptides Antibodies. Yang-Seon Ryu[1], Eun-Ji Kim[1], Ji-Min Kim[1], Jennifer Lee[1], Seung-Ki Kwok[1], Ji Hyeon Ju[2], Sung Hwan Park[3] and Ho-Youn Kim[2]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul, South Korea, [3]Rhematism Research Center, Seoul, South Korea

Background/Purpose: Anti-cyclic citrullinated peptide antibodies(anti-CCP antibodies) are very useful for the diagnosis of rheumatoid arthritis(RA) and associated with articular erosions. The specificity of anti-CCP antibodies in the diagnosis of RA was reported about 97.4%. Because of its higher specificity to RA, we assessed of clinical features in primary sjögren syndrome patients presenting positive anti-CCP antibodies.

Methods: We conducted a retrospective medical record review of 405 patients who were diagnosed primary primary sjogren syndrome at the first visit in the rheumatology department of Seoul St. Mary's Hospital between June 1996 and June 2011. Patients fulfilled the 2002 American-European consensus group revised criteria for primary sjogren syndrome. An anti-CCP antibody ELISA was performed according to manufacturer's instructions with the cutoff at 20 units. We have followed up 37 of 405(8.9%, mean age 54±10.9 years) patients who initially presented positive anti-CCP antibodies. Presence of arthritis were evaluated by ultrasonographic findings, x-ray and physical examination about swelling, tenderness.

Results: We analysed of 405 patients who were diagnosed primary sjogren syndrome at the first presenting signs, 38 of 405(8.9%) patients were positive anti-CCP antibodies and there was close relationship between anti-CCP antibodies level and arthritis. Its Pearson's correlation coefficients was 0.416(P<0.001). And then we analysed correlation coefficient of rheumatoid factor titer and arthritis, that was shown 0.194(P<0.001). It seemed like anti-CCP antibodies had higher association with arthritis than rheumatoid factor titer in primary sjogren syndrome patients. But 405 primary sjogren syndrome patients have observed, 50(12%) patients have progressed to secondary sjogren's syndrome. 30(7.2%) patients have been progressed to RA who fulfill the 2010 ACR criteria for RA. Patients who have been progressed to RA, their mean duration of progression to RA was 49±31.1 months. 5(16%) of 30 patients were negative anti-CCP antibodies, 23(76.7%) of 30 patients were positive anti-CCP antibodies, 2(6.7%) were not checked. Comparing two goups of progressed RA and not progressed RA whithin positive anti-CCP antibodies patients who were diagnosed primary sjogren syndrome at the first presenting signs, the mean duration of observed was shown shorter, 49±31.1 months to 29±27 months.

Conclusion: There was close relationship between anti-CCP antibody titer and arthritis in primary sjogren syndrome patients. But we have followed up primary sjogren syndrome patients who was positive anti-CCP antibody. About 49 months later, 23(76.7%) patients were progressed to RA who had originally been diagnosed primary sjogren syndrome. Testing for anti-CCP antibodies in primary sjogren syndrome patients presenting arthritis allows the prediction of progression to RA.

480

Low Levels of Vitamin-D are Associated with Neuropathy and Lymphoma Among Patients with Sjögren's Syndrome. Nancy Agmon-Levin[1], Howard Amital[2], Athanasios G. Tzioufas[3], Marcus López Hoyos[4], Blaz Rozman[5], Shaye Kivity[1], Ilan Ben Zvi[1], Inga Efes[1], Yinon Shapira[1] and Yehuda Shoenfeld[6]. [1]Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, Tel-Hashomer, Israel, [2]Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, Tel-hashomer, Israel, [3]Medical School-Univ of Athens, Athens, Greece, [4]Servicio Inmunología Hospital Universitario Marqués de Valdecilla Santander Spain, Santander, Spain, [5]University Medical Centre, Ljubljana, Slovenia, [6]Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, Ramat Gan, Israel

Background/Purpose: Primary Sjögren's syndrome (SS) is a chronic autoimmune disease primarily involving the exocrine glands. SS clinical picture ranges from exocrinopathy to systemic disease affecting the lung, kidney, liver, skin, musculockeletal and the nervous system. The morbidity of SS is mainly determined by extraglandular disease and increased prevalence of lymphoma[1]. Environmental and hormonal factors, such as vitamin-D may play a role in the pathogenic process and disease expression[2]. Thus, we aimed to evaluate the association between vitamin-D concentrations and the manifestations of SS.

Methods: Vitamin-D levels were determined in 176 SS patients and 140 matched healthy volunteers utilizing the Liaison chemiluminescent immunoassays (DiaSorin-Italy), and correlated with clinical and serological manifestations of SS.

Results: Vitamin-D levels were comparable between SS patients and control 20.5±10ng/ml and 21.6±10ng/ml respectively. Peripheral neuropathy or neuropathic pain were diagnosed in 23% of patients and associated with lower vitamin-D levels (18.6±5.5ng/ml vs. 22.6±8ng/ml (p=0.04)). Lymphoma was diagnosed in 4.3% of SS patients that showed vitamin-D deficiency 13.2±6.25ng/ml as compared with SS patients without lymphoma (22±8 ng/ml; p=0.03). Other clinical and serological manifestations did not correlate with vitamin-D status.

Conclusion: In this study, low levels of Vitamin-D correlated with the presence of peripheral nerve involvement and lymphoma among SS patients. The link between vitamin-D neuropathy and lymphoma was reported in other conditions, and may support a role for vitamin-D in the pathogenesis of these processes as well as a beneficial effect for vitamin-D supplementation.

Background/Purpose: Sjögren's syndrome (SS) is a clinically heterogeneous autoimmune disease characterized by exocrine gland dysfunction that involves both innate and adaptive immune responses. A complex genetic architecture has been hypothesized; however, genetic studies to date have been primarily limited to candidate gene studies. We used high-density genotyping arrays to perform a genome-wide association scan (GWAS) in an unbiased manner to identify SS susceptibility loci.

Methods: We have established the Sjögrens Genetics Network (SGENE) to assemble a large cohort of samples for large-scale genetic studies. We used the Illumina OMNI1-Quad arrays containing >1.1 million variants in a discovery cohort of 424 European-derived SS cases and 728 healthy controls. Stringent quality control criteria, adjustments for population stratification, and standard GWA statistical methodologies were used to compare allele frequencies between cases and controls. A total of ~774,000 single nucleotide polymorphisms (SNPs) were tested for association to SS in our final GWA dataset (P_{omni}). A secondary analysis was performed using data from 1398 additional controls from the Illumina iControl database typed on the HumanHap 550 with ~289,000 SNPs in common with the OMNI1-Quad. For replication, we used a DNA pooling approach in an independent collection of 450 cases and controls of European descent, and also genotyped using the OMNI1-Quad arrays (P_{pool}). Weighted Z-scores were used to determine meta-P-values for combined discovery and replication data (P_{meta}).

Results: The most significantly associated region with risk of SS was the major histocompatibility complex (MHC), with 1304 SNPs exceeding a genome-wide significance threshold of 5×10E-8. The peak association was observed in HLA-DRA within P_{omni}=1.68×10E-23 and replicated with P_{pool}=8.47×10E-5, leading to a P_{meta}=6.92×10E-29. Additional results across the extended MHC support association with multiple loci throughout this region. Evidence for novel genetic associations outside of the MHC were also observed. A SNP between PIK3R1 and SLC30A5 was found to be associated with SS in both the discovery and replication cohorts resulting in P_{meta}=7.55×10E-8. Association (P_{meta}<10E-5) with SS was also identified with SNPs in or near CTNNA2, VASP, FGFR1OP2, and LCK. In addition, we observed association with SNPs previously implicated as risk factors for SS, including IRF5 (P_{meta}=2.66×10E-8) and BLK (P_{meta}=6.66×10E-5).

Conclusion: We have performed the first GWAS in SS, and have identified PIK3R1/SLC30A5, CTNNA2, VASP, FGFR1OP2, and LCK as putative risk loci. We have also confirmed associations previously reported with MHC, IRF5, and BLK. Currently, we are genotyping ~1500 SNPs in >3200 subjects to replicate additional effects observed in the discovery phase.

482

Sympathetic and Parasympathetic Abnormalities in Primary Sjögren's Syndrome (pSS) Patients Assessed in Outpatients Using Real-Time Digital Autonomic Nervous System (ANS) Monitoring. Nikolay P. Nikolov[1], Stanley R. Pillemer[1], Vladimir Bakalov[2], Lolita Bebris[1], Joe Colombo[3] and Gabor G. Illei[1]. [1]NIDCR/NIH, Bethesda, MD, [2]NIH, Bethesda, MD, [3]Ansar Medical Technologies, Inc, Philadelphia, PA

Background/Purpose: Autonomic nervous system (ANS) function abnormalities have been reported in pSS and may be important in pathogenesis of the disease. The aim of this study was to evaluate cardiovascular (CV) ANS function in pSS by ambulatory real-time digital monitoring.

Methods: Standardized ambulatory ANS testing was done on 109 consecutive pSS patients and 34 age- and sex-matched adult healthy volunteers (HV) using ANX 3.0 (ANSAR, Inc.). Caffeine and ANS active medications were not allowed on the testing day. Beat-to-beat heart rate, brachial blood pressure, and respiratory activity (RA) were recorded at 5 min baseline (BL), sitting and in response to reflex CV challenges of deep breathing (DB) at 6 breaths/min, Valsalva maneuver (VM) and standing for 5 min. Heart rate variability (HRV) was assessed by time-domain and statistical analyses. ANS activity was assessed by combined spectral analysis of HRV and RA to account for vagal (parasympathetic) control of respiration and expressed as inspiration:expiration (I:E) Ratio, Valsalva Ratio and 30:15 Ratio, CV responses to DB, VM, and standing respectively. Sympathetic/Parasympathetic (S/PS) balance was computed as the

ratio of low frequency area (LFa) and high frequency area (RFa) that are measures of S and PS activity respectively. Statistical analysis was performed using non-parametric ANOVA testing and regression models (SAS, Inc).

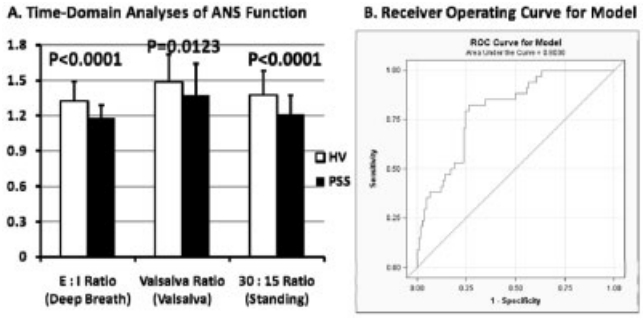
Results: Small significant differences in HRV between HV and pSS were seen for the three main time-domain analysis variables I:E Ratio, Valsalva Ratio, and 30:15 Ratio, (Figure 1A) indicating low cardiovagal tonus.

Both S (LFa) and PS (RFa) CV responses to DB, VM, and Standing challenge were significantly lower in pSS compared with HV (Table 1) while maintaining the S/PS balance (LFa/RFa Ratio).

Table 1. Spectral Analyses, Change from Baseline

	HV (n=34)	PSS (n=109)	Wilcoxon Test, p value
LFa (Sympathetic Function)			
Deep Breathing	6.39	1.55	0.0012
Valsalva	52.75	32.08	NS
Standing	3.45	1.45	0.0117
RFa (Parasympathetic Function)			
Deep Breathing	42.7	15.92	0.0351
Valsalva	5.15	3.32	0.0077
Standing	0.65	−0.04	0.0047

Further, E:I and 30:15 ratios were independently predictive of the diagnosis of pSS by a logistic regression model, also reflected by the area under the receiver operating curve=0.8030 (Figure 1B).



Conclusion: ANS function testing in pSS outpatients identified abnormalities in both S and PS CV function that may reflect a primary failure in one and compensatory decreased output in the other. Unexpectedly, the E:I and 30:15 ratios were found to independently predict the diagnosis of pSS in this cohort that warrants further study.

483

Fine Specificity of Antibodies Against Ro52, Ro60, and La Antigens in Sjögren's Patients with Neuropathies and Demyelinating Syndromes. Julius Birnbaum, Livia Casciola-Rosen, Laura Gutierrez and Alan N. Baer. Johns Hopkins University, Baltimore, MD

Background/Purpose: The respective association of neuropathies and demyelinating manifestations in Sjögren's patients with fine antibody specificities against Ro52, Ro60, and La antibodies has not been rigorously assessed. Knowledge of such antibody associations might suggest different immunologic signatures. We therefore sought to compare patterns of antibody specificities for Sjögren's patients with or without neurological complications. We also evaluated patterns and predictors of misclassification, by measuring the clinical laboratory assignment of antibody status, against a "gold standard" of fine antibody specificity assessed by ELISA (for Ro52 and La antibodies), and by immunoprecipitation (for Ro60 antibodies).

Methods: In sera from a prospectively evaluated Sjögren's cohort of 83 patients enriched with neurological disease, Ro52 and La antibodies were assayed using a commercially available ELISA kit (INOVA Diagnostics). 35S-methionine labeled Ro60 was generated from cDNA by in-vitro transcription translation (IVTT) using a commercially available kit (Stratagene). Ro60 antibodies were assayed by immunoprecipitation using 35-S methionine labeled Ro60 generated by IVTT as source material.

Results: There were 19 patients with demyelinating disease (8 patients with Neuromyelitis Optica/NMO), 43 patients with peripheral neuropathies (2 of whom also had demyelinating disease), and 23 "glandular" patients without demyelinating or peripheral neuropathy syndromes. Ro52 or Ro60 antibodies were detected in 100% (8/8) NMO patients, versus 60.9% (14/23) "glandular" patients (p=0.04), versus 65.1% [28/43] neuropathy patients. 85.7% (12/14) "glandular" Sjögren's patients had antibodies concomitantly targeting Ro52 and Ro60, whereas 45.4% (20/44) patients with neurological disease of either subtype had isolated antibody specificities which separately targeted either Ro52 or Ro60 (p=0.04). Antibodies against La were found less frequently in patients with neuropathies and demyelinating syndromes (21.7%, 13/60), compared to "glandular" disease (43.4%, 10/23, p=0.05). The sensitivity/specificity for the commercial laboratory assessment of Ro antibody status (against the "gold standard" assessing for *either* Ro52 or Ro60 by ELISA or immunoprecipitation) was 67.2%/96.0%, with a kappa of 0.52. The sensitivity/specificity for the commercial laboratory assessment of La antibody status (against the gold standard of La by ELISA) was 54.5%/80.4%, with a kappa of 0.35.

Conclusion: "Glandular" Sjögren's patients have antibody specificities usually directed against Ro52 **and** Ro60, whereas patients with neurological disease may have antibodies directed against **either** Ro52 **or** Ro60. NMO in Sjögren's disease is strongly associated with Ro52 and/or Ro60 antibodies. The high misclassification rate of Ro and La antibody status may contribute to the underdiagnosis of Sjögren's in patients with demyelinating syndromes and neuropathies, and may justify inclusion of fine Ro52, Ro60, and La antibody specificities even in routine clinical practice.

484

Salivary Genomic Biomarkers for Primary Sjögren's Syndrome: Correlation with Minor Salivary Gland Lymphocyte Focus Score and Serum Interleukin-17, 21, 23 Level. Sung-Hoon Park[1], Ji Hun Kim[1], Seong-Kyu Kim[2], Jung-Yoon Choe[3], Sang-Hyon Kim[4] and Ji-Yoon Kim[5]. [1]Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegu, South Korea, [2]Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegue, South Korea, [3]Arthritis and Autoimmunity Research Center, Catholic university of Daegu, School of mediine, Daegu, [4]Dongsan Medical Center, Keimyung University, Daegu, South Korea, [5]Dongsan Medical Center, Keimyung University, School of medicine, Daegu, South Korea

Background/Purpose: To evaluate the expression level of salivary FCGR3B, GBP-2, GAPDH mRNA in primary Sjögren's syndrome(pSS) and to investigate its correlation with minor salivary gland lymph focus score-(LFS) and serum Interleukin(IL)-17, 21, 23 Level.

Methods: Saliva samples were collected from 8 female patient with pSS(age = 38 ~ 55, mean ± SD = 46.13±6.01) and healthy female controls(age = 33 ~ 45, mean ± SD = 39.75 ± 5.12) using our standardized saliva collection protocols for comparative analysis. Subject should refrain from eating, drinking, or oral hygiene procedures for at least 1 hour prior to collection. After collection, the saliva samples were immediately mixed with RNAprotect Saliva Reagent(Qiagen, Hilden, Germany) to the RNA in the saliva sample was stabilized and then centrifuged at 10,000g for 10 minutes. The supernatant was removed from the pellet, immediately aliquoted, and stored at −80°C. cDNA was synthesized with oligo-d(T), Improm- II TM 5 × reaction buffer, 25mM $MgCl_2$, 10mM dNTP, Improm-II TM reverse transcriptase, 25°C 5min, 42°C 60min, 70°C 15min. cDNAs were analyzed by real time quantitative PCR(RT-PCR) in a Finnzymes DyNAmoTMSYBR green qPCR kit (Finnzymes, Beverly, MA, USA). The primer sequences were FCGR3B forward primer, 5′-CAG TGG TTT CAC AAT GTG AA-3′; FCGR3B reverse primer, 5′-ATG GAC TTC TAG CTG CAC-3′, GBP-2 forward primer, 5′-GGA TAT ATT TGG CCC TTT AGA AGA A-3′; GBP-2 reverse primer, 5′-CTT TTT CCT TTT CTG AGA GTG ACT G-3′, GAPDH forward primer 5′-GAA GGT GAA GGT CGG AGT-3′; GAPDH reverse primer, 5′-GAA GAT GGT GAT GGG ATT TC-3′. The results were analyzed with LightCycler software (Bio-rad).

Results: There was no statistical difference in age between patients and healthy control group. In pSS group, GBP-2 mRNA level was 16.36±35.25 and was significantly correlated with serum IL17 level(94.54±254.65pg/ml, p=0.004) and IL23 level(16.24±22.56pg/ml, p=0.005) by Spearman's

correlation. FCGR3B mRNA level and LFS(3.25±2.55) was not correlated with serum cytokine level. FCGR3B mRNA level was significantly correlated with the patient's age(p=0.003). GAPDH mRNA level was not detectable in the patient group.

Conclusion: GBP-2 mRNA level in saliva of pSS patients was significantly correlated with serum IL17 and IL23 level. Pathophysiologic relevance and possibility of genomic biomarker should be investigated in larger population in the future.

BLK Polymorphisms Are Associated with Sjogren's Syndrome Only in Patients with Anti-SSA Antibodies. Corinne Miceli-Richard[1], Joanne Nititham[2], Kimberly E. Taylor[3], Céline Verstuyft[1], Laurent Becquemont[1], Ryad Tamouza[4], Xavier Puechal[5], Eric Hachulla[6], Jacques-Eric Gottenberg[7], Lindsey A. Criswell[8] and Xavier Mariette[9]. [1]Hopital Bicêtre, Le Kremlin Bicêtre, France, [2]University of California, CA, [3]University of California, San Francisco, San Francisco, CA, [4]Paris, France, [5]Le Mans General Hospital, Le Mans, France, [6]Internal Medicine, Lille CEDEX, France, [7]Strasbourg University Hospital, Strasbourg, France, [8]University of California San Francisco, San Francisco, CA, [9]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: Primary Sjögren's syndrome (pSS) shares a number of pathogenic mechanisms with systemic lupus erythematosus (SLE), including an IFN type I signature illustrated by genetic association with *STAT4* and *IRF5* in both diseases and involvement of B cells. Polymorphisms of genes involved in B-cell function, such as *BLK,* have been associated with lupus and recently to pSS. Our goal for this study was to determine whether *BLK* polymorphisms are associated with risk of pSS.

Methods: Our study population included 624 pSS patients and 577 control individuals of French Caucasian ancestry. A total of 9 SNPs located within the BLK locus, as well as 48 AIMs (Ancestry Informative Markers), were genotyped among patients and controls. Principal components analysis of the AIM data identified 32 cases and 53 controls with evidence of non-European ancestry and these subjects were removed from subsequent association analyses. Case control association tests were performed among the remaining 592 pSS and 524 controls for the 9 BLK SNPs and tested for independence. Subphenotype analyses were performed to determine whether genetic association results differed substantially according to the presence of anti-SSA auto-antibodies (328 SSA+ and 264 SSA-), systemic manifestations (N=307), cryoglobulinemia (N=60) or lymphoma (N=24).

Results: We observed significant evidence of association with pSS for 3 SNPs within the *BLK* locus. The rs13277113 A allele was the most significantly associated *BLK* variant with an OR of 1.30 (95% CI 1.06–1.58), $p = 9.10^{-3}$. Two other BLK SNPs were associated with pSS: the rs12677843 T allele: OR of 1.29 (95% CI 1.06–1.56), $p = 9.7.10^{-3}$ and the rs2736340 T allele: OR of 1.28 (95% CI 1.05–1.56), $p = 1.2.10^{-2}$. For these 3 SNPs, there were differences between anti-SSA positive and anti-SSA negative patients suggesting that these associations were restricted to anti-SSA positive patients. Comparison of anti-SSA positive patients to controls revealed 2 additional SNPs associated with anti-SSA positive pSS: the rs922483 T allele: OR of 1.28 (95% CI 1.03–1.60), $p = 2.0.10^{-2}$ and the rs12549796 T allele: OR of 1.24 (95% CI 1.01–1.53), $p = 3.7.10^{-2}$. Case-only analyses comparing patients with systemic manifestations, cryoglobulinemia, or lymphoma versus patients without each of these manifestations did not demonstrate significant association. Conditional haplotype analysis suggested that haplotypes comprised of 2 SNPs (rs13277113 and rs1382563) contribute to risk of pSS (p=0.019).

Conclusion: We replicated the study from Nordmark et al (1) and found additional *BLK* SNPs that contribute to the risk of pSS. These results provide an additional example of shared genetic susceptibility to SLE and pSS. BLK is a gene involved in B-cell function and studying functional consequences of these polymorphisms may provide clues to the mechanisms of B cell activation in these 2 autoimmune diseases.

Interferon-Alpha Activation in Relation to Pro-Inflammatory Cytokines and Anti-Ro/La Response in Primary Sjøgren's Syndrome. Johannes C. Nossent[1], Maureen Rischmueller[2], Andrea Becker-Merok[1] and Sue Lester[2]. [1]University of Tromsø, Tromso, Norway, [2]Queen Elizabeth Hospital, Adelaide, Australia

Background/Purpose: Interferon type I activation is a major pathway in the pathogenesis of systemic autoimmune diseases. While up regulation of type I IFN genes has been described in salivary glands and PBMC, there are few data on circulating IFNa2 in primary Sjøgren's syndrome (pSS). We investigated the frequency, clinical and serological correlates of increased levels of circulating IFNα2 in pSS patients.

Methods: Cross sectional study of patients with established pSS (n= 83). Healthy controls (HC) (n= 27) and patients with Systemic lupus Erythematosus (SLE) (n=87) served as comparators.Cytokine levels were determined on stored sera by a highly sensitive seven-plex bead immunoassay with BAFF measured by commercial ELISA. Associations between increased IFN-a, clinical measures and serological biomarkers were analyzed by nonparametric methods.

Results: IFNα2 was increased in 48.2% of pSS patients versus 64.4% in SLE (p=0.03) and 7.2% in HC (p<0.01). pSS patients with increased IFNα had significantly higher levels of IL-1b, IL-6, IL-10, IL-12, TNFα and GM-CSF, while IL-15 and BAFF did not differ from patients with normal IFNα (51.8%). In pSS patient with increased IFNα2 levels, the mean number of elevated cytokines was five (range 1–8) versus 0.5 (range 0–3) in patients with normal IFNα2 (p<0.001). Increased IFNα2 did not associate with scores for fatigue, sleepiness or urogenital symptoms, low C4 or leucopenia, but was associated with increasing diversity of the anti-Ro/La antibody response (p=0.04 for linear trend) and higher titers of IgG and RF. In the 43 patients with normal IFNα2, there was no activation of other cytokines in 24 (56%) with increased BAFF (30%) and IL-6 (18%) accounting for most cytokine abnormailities in this group.

Conclusion: High circulating levels of IFNα2 are found in nearly half of all pSS patients, where they are accompanied by multiple cytokine activation and a diversified anti-Ro/La response. In the remaining pSS patients cytokine activation is uncommon suggesting a different underlying pathophysiology.

Cathepsin S Activity Measurements in Tears As a Putative Marker of Sjögren's Syndrome. Jay Zhu[1], Daniel G. Arkfeld[1], W. Stohl[1], Srikanth R. Janga[2], J. Martin Heur[3], John Irvine[3] and Sarah F. Hamm-Alvarez[2]. [1]USC Keck School of Medicine, Los Angeles, CA, [2]University of Southern California School of Pharmacy, Los Angeles, CA, [3]Doheny Eye Institute, Los Angeles, CA

Background/Purpose: Sjögren's syndrome (SjS) is a chronic autoimmune disease characterized by inflammation and destruction of the moisture-producing glands in the body. For 4 million patients in the U.S., this process leads to the landmark symptoms of dry eye and dry mouth as well as many possible systemic complications. Despite the prevalence of SjS, current diagnostic methods remain inexact due to a lack of sensitive and specific testing. It is also difficult to distinguish the autoimmune-mediated keratoconjunctivitis sicca (dry eye) from that associated with other types of dry eye seen extensively in ophthalmology practices. Recent studies performed with non-obese diabetic mice indicated increased expression of the protease, cathepsin S, in the tears and lacrimal glands of this established SjS model[1]. This study seeks to explore the feasibility of measuring cathepsin S (CATS) in the tears of patients as a prelude to exploring its correlation with clinical manifestations of SjS.

Methods: Tears were acquired from 173 patients in an all-comers trial conducted in the USC Rheumatology Clinic and the Doheny Eye Institute Cornea Clinic using extraction onto Schirmer's strips. Tear proteins were eluted from the strips and CATS activity was assayed within 4 hrs. of collection and normalized to sample protein. Control studies indicated there was no loss of catalytic activity during this period.

Results: The average CATS value for all patients in the study was 2142 fluorescence units (FU) per 20 ug of total protein (standard error = 210 FU/20ug protein). The average CATS value for the 8 patients in the study with SjS was 5352 FU/20 ug protein (SE = 1430 FU/20 ug protein), and the average value for all non-SjS patients was 1931 FU/20 ug protein (SE = 198 FU/20 ug protein). This represented a threefold increase for SjS patients over non-SjS patients. The average CATS value for the 57 patients from the rheumatology clinic was 2556 FU/20 ug protein (SE = 410 FU/20 ug protein) while the average CATS value for the 116 patients from the cornea clinic was 1958 FU/protein (SE = 243 FU/20ug protein).

Conclusion: This study shows the feasibility of measuring the enzymatic activity of biomarker proteins in tear samples collected from patients. In particular, they support the potential of CATS as a biomarker indicative of SjS. A new clinical study is ongoing which further explores the validity of this biomarker in a patient population in which SjS patients as well as patients with non-autoimmune keratoconjunctivitis sicca are more extensively represented.

Background/Purpose: Recent data from animal models and patients with primary Sjögren's syndrome (pSS) suggest that follicular T helper cells (Tfh), which secrete predominantly IL-21, might contribute to the marked B-cell activation observed in pSS. We aimed to investigate serum IL-21 level and its correlation with autoantibody secretion, markers of B-cell activation and disease activity in pSS

Methods: 400 patients with pSS have been included in the 5-year prospective multicenter ASSESS cohort (Assessment of SyStemic features and Evolution of primary Sjögren's Syndrome) since 2006. Clinical data and disease activity using the ESSDAI score have been collected homogeneously. DNA, RNA and serum were collected at inclusion and immediately frozen. Central assessment of serum IL-21 was performed using Ebioscience assay. IL-21 and IL-21R gene polymorphism (rs2221903, rs3093301, rs907715 were genoyped.

Results: Serum IL-21, assessed in 331 patients, was significantly higher in pSS (median: 342 pg/ml, 25^{th}–75^{th}: 181–588) than in healthy controls (82 [55–118] pg/ml, $P< 0.0001$). Patients with either anti-SSA or anti-SSA and SSB antibodies had more frequently detectable IL-21 than patients without anti-SSA nor anti-SSB antibodies (94.9% vs 87.0%, $P= 0.02$). Serum IL-21 was correlated with IgG ($r=0.24$, $P< 0.0001$), kappa ($r= 0.11$, $P= 0.04$) and lambda ($r= 0.15$, $P= 0.006$) free light chains of immunoglobulins, but not with BAFF or beta2-microglobulin. No association was found between IL-21 or IL-21 gene polymorphisms and serum IL-21 level. IL21 was significantly correlated with systemic disease activity assessed by the ESSDAI ($r=0.2$, $P= 0.0009$). In patients with marked systemic disease activity (ESSDAI equal or superior to 7 corresponding to the 75^{th} value of ESSDAI scores of all the patients), serum IL-21 was significantly increased (median 512.6 vs 329.9 pg/ml in patients with ESSDAI<7, $P= 0.009$).

Conclusion: Serum IL-21 level is increased in pSS. This increase is not determined by the assessed gene polymorphisms. The increase of IL-21 is associated with increased systemic disease activity and marked B-cell activation. Targeting IL-21 or follicular T helper cells might therefore represent a promising therapeutic perspective in pSS.

Rhodus[5], Lida Radfar[4], M. Bart Frank[1], Robert H. Scofield[11] and Kathy L. Moser[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Hefner Eye Care and Optical Center, Oklahoma City, OK, [3]University of Santo Tomas, Taguig City, Philippines, [4]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [5]University of Minnesota, Minneapolis, MN, [6]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH, [7]Harvard Clinical and Translational Science Center, Boston, MA, [8]Valley Bone & Joint Clinic, Grand Forks, ND, [9]Universidad del Rosario-Corporacion para Investigaciones Biologicas, Bogota, Colombia, [10]Univ of Minnesota, Minneapolis, MN, [11]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, US Department of Veterans Affairs Medical Center and Department of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background/Purpose: Sjögren's syndrome (SS) is a progressive, heterogeneous autoimmune exocrinopathy. We chose to perform global gene expression profiling (GEP) in order to better understand the molecular pathways involved in the pathophysiology of SS. We present the largest GEP analysis to date in SS.

Methods: A total of 48803 mRNA transcript levels were measured using the Illumina HumanWG-6 v3.0 Expression BeadChip in 215 European American SS cases and 65 healthy controls. Raw intensity values were background subtracted and probe level analysis was performed using the LUMI package for R. After quantile normalization, Welsh t-tests, q-values (to correct for multiple testing) and fold changes (FC) were calculated. Differentially expressed (DE) genes between cases and controls were selected using 1) maximum expression values > 32, 2) $q<0.05$ and 3) $|FC| >1.25$ or <0.8. Ingenuity Pathway Analysis was utilized to identify canonical pathways among the DE genes.

Results: A total of 1117 genes were DE between SS cases and controls ($7.20\times10E\text{-}24<q<0.05$). Phospholipase A2, group X (PLA2G10) was the most up-regulated gene in SS cases ($FC=84.45$), while transembrane protein 45A (TMEM45A) was the most down-regulated ($FC=-29.17$). Twenty interferon inducible (IFI) genes were among the top 114 DE genes ($q<1\times10E\text{-}10$), of which interferon alpha-inducible protein 27 (IFI27) demonstrated the greatest fold change ($FC=22.4$; $q=1.0\times10E\text{-}17$). Indeed, the top canonical pathway was the interferon signaling pathway,

with 13 of this 34 pathway's genes (38%) DE in our dataset (Fishers p=4.85×10E-12) (Table 1). Another disregulated pathway included genes involved in recognition of bacteria and viruses with 16.9% of this pathway's genes DE in our dataset (Fishers p=3.73×10E-7). Top ranked genes previously implicated in SS included TAP2, an antigen presentation gene reportedly associated with SS in Japanese and Columbian cases (rank 69; q=3.2×10–13; FC=1.44); CXCL10, a Th1-chemokine that regulates immune responses and is up-regulated in SS salivary glands (rank 79; q=1×10E-12;FC=2.69); and MUC1, a human mucin previously found to be associated with dry eyes and dry mouth (rank 104; q=3.66×10E-11; FC=1.54). Common functions observed included cellular movement, growth and proliferation, development, function and maintenance and cellular death. Genes implicated in liver hepatitis as well as cardiac and renal necrosis were also up-regulated in SS cases.

Table 1. Genes in top SS canonical pathways

Pathway	Gene Symbol	Gene Name	Fold Change	FDR q-value
Interferon Signaling	IFIT3	interferon-induced protein with tetratricopeptide repeats 3	3.08	5.82E-19
	OAS1	2',5'-oligoadenylate synthetase 1, 40/46kDa	2.91	2.77E-11
	IFIT1	interferon-induced protein with tetratricopeptide repeats 1	2.89	9.37E-07
	MX1	myxovirus resistance 1, interferon-inducible protein p78	2.49	4.06E-16
	IFI35	interferon-induced protein 35	1.72	1.64E-12
	STAT2	signal transducer and activator of transcription 2, 113kDa	1.60	1.36E-16
	SOCS1	suppressor of cytokine signaling 1	1.58	4.32E-09
	STAT1	signal transducer and activator of transcription 1, 91kDa	1.54	9.13E-18
	BAX	BCL2-associated X protein	1.39	8.49E-04
	JAK2	Janus kinase 2	1.36	3.16E-07
	TAP1	transporter 1, ATP-binding cassette, sub-family B (MDR/TAP)	1.36	1.61E-09
	IRF9	interferon regulatory factor 9	1.33	3.34E-11
	IFITM1	interferon induced transmembrane protein 1 (9–27)	1.30	4.06E-05
Recognition of Viruses and Bacteria	OAS3	2'-5'-oligoadenylate synthetase 3, 100kDa	4.18	1.26E-09
	C1QC	complement component 1, q subcomponent, C chain	2.89	1.97E-05
	OAS2	2'-5'-oligoadenylate synthetase 2, 69/71kDa	2.15	7.57E-15
	EIF2AK2	eukaryotic translation initiation factor 2-alpha kinase 2	2.05	2.05E-20
	C1QB	complement component 1, q subcomponent, B chain	2.05	1.29E-04
	IFIH1	interferon induced with helicase C domain 1	1.90	1.63E-20
	DDX58	DEAD (Asp-Glu-Ala-Asp) box polypeptide 58	1.85	1.28E-17
	IRF7	interferon regulatory factor 7	1.85	7.66E-14
	C3AR1	complement component 3a receptor 1	1.77	7.38E-15
	C1QA	complement component 1, q subcomponent, A chain	1.63	5.78E-05
	CASP1	caspase 1, apoptosis-related cysteine peptidase (interleukin 1, beta, convertase)	1.39	2.79E-10
	TICAM1	toll-like receptor adaptor molecule 1	1.31	1.72E-03

Conclusion: The results demonstrate a role for not only innate but also adaptive immunity in SS and overexpression of interferon-related genes continues to play a strong role in this disorder. Additional cellular processes appear to be involved in SS that provide hypotheses to better understand this disorder. Clearly, many of the up-regulated genes are strong candidates for disease biomarkers or susceptibility.

Cellular microRNAs and Sjögren's Syndrome: Candidate Regulators of Autoimmune Response and Autoantigen Expression. Efstathia K. Kapsogeorgou, Vasiliki C. Gourzi, Nikolaos C. Kyriakidis, Menelaos N. Manoussakis, Haralampos M. Moutsopoulos and Athanasios G. Tzioufas. Pathophysiology Dept, School of Medicine, National University of Athens, Greece, Athens, Greece

Background/Purpose: Sjögren's Syndrome (SS) is characterized by humoral responses against the Ro/SSA and La/SSB ribonucleoproteins, whereas elevated expression of these autoantigens has been described in the salivary glands (SG) and the SG epithelial cells (SGEC) of SS patients. The mechanisms implicated in the regulation of their expression are not defined. Recently, a novel post-transcriptional regulatory mechanism of gene expression, involving small RNA molecules, called microRNAs (miRNAs), has been identified. Deregulated expression of miRNAs has been implicated in the pathogenesis of autoimmune diseases, including SS. Herein, we sought to investigate the role of miRNAs that are predicted to target Ro/SSA and La/SSB autoantigens in SS. Therefore, we studied their expression in SG tissues, SGECs and peripheral blood mononuclear cells (PBMC) of SS patients and controls.

Methods: The miRNAs that target the Ro (Ro52/TRIM21 and Ro60/TROVE2) and La mRNAs were predicted by the miRecords database (http://mirecords.biolead.org), which enables the simultaneous analysis by the 11 most recognized miRNA target prediction programs. The expression of miRNAs was analyzed by real-time PCR in total RNA extracted from SG-tissues, SGECs and PBMC obtained from 14 SS patients and 13 sicca-controls. Statistically significant differences in miRNA expression between SS patients and sicca-controls were evaluated by non-parametric Mann-Whitney analysis.

Results: The miRecords computational analysis identified 430, 1258 and 377 miRNAs that target the Ro52/TRIM21, Ro60/TROVE2 and/or La/SSB mRNAs, respectively. Subsequently, to narrow the number of the miRNAs that target the Ro/SSA and La/SSB mRNAs to an investigable amount, the miRNAS that are predicted to target both Ro (Ro52/TRIM21 and/or Ro60/TROVE2) and La mRNAs, and identified by at least four miRecords-included databases were selected. This approach lead to the identification of eleven miRNAs (let-7b, miR-16, miR-129-5p, miR-153, miR-181a, miR-200b, miR-200b*, miR-223, miR-483-5p, miR-573 and miR-583) that target human Ro/SSA and La/SSB mRNAs. miRs 129-5p, 153, 573 and 583 were not expressed in any of the samples studied, miR-200b* was not found to be expressed in PBMCs. The miRNAs let-7b, miR-16, miR-181a, miR-200b, miR-200b*, miR-223 and miR-483-5p, were expressed in SG tissues, SGECs and PBMCs. Mann-Whitney analysis revealed that miR-181a in SG tissues, miR-200b in SGECs and miR-223 in PBMCs were significantly upregulated in SS patients compared to sicca-controls (mean±SE: 43.89±18.6 *vs* 5.525±1.292, p=0.02, 2426±511.1 *vs* 965±243.3, p=0.03 and 986200±503300 *vs* 50310±13910, p=0.02 in SS *vs* CT, respectively). Finally, down-regulated expression of let-7b mi-RNA was observed in SGECs derived from SS patients that had autoantibodies against Ro/SSA and/or La/SSB proteins compared to negative patients (p=0.02)

Conclusion: Our findings implicate miR-181a, miR-200b, miR-223 and let-7b in SS pathogenesis. However, further functional studies are needed to enlighten the role of the deregulated miRNAs in disease pathogenesis and autoantigen expression.

Background/Purpose: Sjögren's syndrome (SS) is a systemic autoimmune disease characterized by lymphocyte infiltration into the salivary and lachrymal glands, leading to dry mouth and eyes. The presence of functional autoantibodies against muscarinic type 3 receptor (M3R) in SS has been reported. However, the pathological role of these autoantibodies in the development of SS still remains to be elucidated.

Methods: Purified IgGs were obtained from normal (control) and primary SS patients' sera (pSS IgG). Internalization of M3R and clathrin was analyzed by biochemical assay and immunofluorescence confocal microscopy in human submandibular gland (hSMG) acinar cells. Cytoplasmic free Ca^{2+} concentration ($[Ca^{2+}]_i$) was measured by microspectrofluorimetry.

Results: Incubation of hSMG cells with pSS IgG (1mg/ml) significantly decreased M3R expression levels at the membrane. Carbachol-induced $[Ca^{2+}]_i$ transients (CICTs) in these cells were also inhibited by pSS IgG. In contrast to pSS IgG, control IgG had no effect on both the M3R expression level and CICTs. We found that binding of pSS IgG to M3R induces phosphorylation of M3R, and that pSS IgG-induced M3R internalization is prevented by lysosomal inhibitor, chloroquine. In addition, pSS IgG decreased membrane clathrin expression, which was inhibited by atropine. Our immunofluorescence study further confirmed that pSS IgG induces a co-localization of M3R with clathrin and subsequent internalization of M3R.

Conclusion: pSS IgG induces an internalization of M3R partly through a clathrin-mediated pathway. The results suggest M3R internalization as a potential mechanism to explain the exocrinopathy seen in pSS patients.

Analysis of M3R Reactive T Cell Epitopes in M3R Induced Autoimmune sialoadenitis. Naomi Matsuo, Hiroto Tsuboi, Mana Iizuka, Yuya Kondo, Isao Matsumoto and Takayuki Sumida. Division of Clinical Immunology, Doctoral Program in Clinical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan

Background/Purpose: M3 muscarinic acetylcholine receptor (M3R) functions as key receptor for salivary and lacrimal secretion. Recently, M3R has been the focus of our interest for autoantigen of Sjögren syndrome (SS). Our previous studies have shown that Rag1$^{-/-}$mice transferred with splenocytes of M3R$^{-/-}$ mice immunized with M3R peptides mixture (N-terminal, 1st, 2nd, 3rd extracellular loops) developed sialoadenitis like SS (M3R induced autoimmune sialoadenitis; MIS). Moreover, we have shown that M3R reactive T cells play a crucial role in MIS. However, the epitope of M3R reactive T cells remains unclear. This study was carried out to clarify the major T cell epitopes of M3R molecular in MIS.

Methods: 1) M3R$^{-/-}$ mice were immunized with synthesized peptides mixture coding the extracellular domains of murine M3R (N-terminal, 1st, 2nd, 3rd extracellular loops) by intradermal administration. On day 10, these mice were boosted with M3R peptides mixture. On day 20, spleens were isolated from these mice and splenocytes were cultured with each M3R peptide. The cytokines (IL-17, IFN-g and IL-4) production from M3R reactive T cells was measured by ELISA. 2) M3R$^{-/-}$ mice were immunized with M3R 1st extracellular loop peptide alone, which was the candidate for the dominant T cell epitope. On day 10, these mice were boosted with M3R 1st loop peptide. On day 20, spleens were isolated from these mice and splenocytes were cultured with each M3R peptide. The cytokine production from M3R 1st loop reactive T cells was measured by ELISA. 3) The splenocytes of M3R$^{-/-}$ mice immunized with M3R 1st loop peptide were transferred into Rag2$^{-/-}$mice. On day 45 after transfer, Rag2$^{-/-}$mice were sacrificed and the salivary glands were histologically examined by H-E and immunohistochemical stainings. The cervical lymph nodes and splenocytes were cultured with each M3R peptide and the cytokines production from M3R 1st loop reactive T cells was measured by ELISA.

Results

1) The production of IL-17 and IFN-g against M3R 1st extracellular loop in vitro were much higher than that to the other domains of M3R.

2) M3R 1st extracellular loop reactive T cells could produce much more IL-17 and IFN-g but not IL-4.

3) In Rag2$^{-/-}$ mice transferred with splenic T cells immunized with M3R 1st loop developed mild sialoadenitis. M3R 1st extracellular loop reactive T cells in cervical lymph nodes were able to produce IL-17.

Conclusion: We suggested that the major T cell epitope of M3R molecular might be 1st extracellular loop in MIS and IL-17 production may induce autoimmune sialoadenitis.

The Sjogren's Syndrome-Related Autoantigen Ro52 Is a Pro-Apoptotic Molecule Upon Oxidative Stress. Siti NA Jauharoh[1], Seiji Kawano[1], Jun Saegusa[1], Takeshi Sugimoto[1], Daisuke Sugiyama[1], Osamu Tokuno[1], Chiyo Kurimoto[1], Yumiko Nobuhara[2], Yuji Nakamachi[1], Bambang Ardianto[3] and Shunichi Kumagai[1]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]Saiseikai Nakatsu Hospital, Osaka, Japan, [3]Gadjah Mada University Faculty of Medicine Department of Child Health, Yogyakarta, Indonesia

Background/Purpose: Ro52/TRIM21, is an autoantigen, which has been known to play important roles in the pathogenesis of several systemic autoimmune diseases, such as systemic lupus erythematosus (SLE) and Sjögren's syndrome. Recent studies revealed that Ro52 has an E3 ligase activity and may ubiquitinate cellular, as well as nuclear, proteins important for anti-viral immunity. It has been reported that IFN-a induces Ro52 translocation from the cytoplasm to the nucleus in a p53-dependent manner. We have previously reported that during stress exposure, Ro52 undergoes stimulating agent-specific intracellular translocation.

Methods: In the present study, to investigate the role of Ro52 upon stress exposure, we performed transient transfection with siRNA against Ro52 on HeLa cells. These transfectants were stimulated with H_2O_2, diamide, IFN-α and γ-irradiation, and were then subjected to Annexin-V fluorescent staining and TUNEL assay for apoptosis detection. Furthermore, to elucidate whether the nuclear translocation of Ro52 is required in Ro52-mediated apoptosis, we analyzed the expression of Ro52 protein on the nuclear and cytoplasmic fractions by Western blot analysis.

Results: We found that the Ro52^{low} HeLa cells were significantly more resistant to apoptosis induced by H_2O_2, as well as various other types of stimuli, compared to those of the control HeLa cells. Moreover, we showed that H_2O_2 and IFN-α, but not diamide or γ-irradiation, induced the translocation of Ro52 protein from the cytoplasm to the nucleus.

Conclusion: Our data suggested that Ro52 may be a pro-apoptotic molecule and the nuclear translocation of Ro52 is not necessary in Ro52-associated apoptosis.

VIP/VPAC System Involved in the Interaction of Primary Sjögren Syndrome Immune Cells and a Human Salivary Gland Epithelial Cell Line. Vanesa C. Hauk[1], Laura Fraccaroli[1], Esteban Grasso[1], Rosanna Ramhorst[1], Alicia Eimon[2], Osvaldo Hubscher[2] and Claudia Perez Leiros[1]. [1]School of Exact and Natural Sciences-CONICET, Buenos Aires, Argentina, [2]CEMIC, Buenos Aires, Argentina

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic inflammatory and systemic autoimmune disease with a prevalence of 0.3–0.5%. The clinical hallmark of pSS is a progressive oral and ocular dryness that poorly correlates with the extent of inflammatory infiltrates of exocrine glands. Evidence of aberrant expression of inflammatory mediators and apoptosis of glandular epithelial cells has been proposed as early events in pSS pathogenesis. Vasoactive Intestinal Peptide (VIP) is a pleiotropic secretory and vasodilator neuropeptide with potent immunomodulatory effects in various animal models of chronic inflammation. Also, we have recently proposed an anti-apoptotic effect of VIP on murine acinar epithelial cells through VPAC1 subtype of VIP receptors. The aim of this work was to study the role of VIP / VPAC system in the interaction of monocytes from pSS patients with a human salivary gland epithelial cell line.

Methods: Monocytes were isolated from peripheral blood of women with pSS (Vitali C et al., 2002) (n=26) and age-matched healthy women as the control group (n=10). Mononuclear cells were analyzed by flow cytometry and reverse transcription-quantitative polymerase chain reaction (RT-qPCR) for cytokines, chemokines and VIP receptors before and after activation with lipopolysaccharide (LPS) and also after co-cultures with salivary epithelial cells (HSG cell line) in the presence or absence of 100 nM VIP.

Results: We found an increased expression of VPAC2 subtype of VIP receptors on pSS monocytes compared with healthy control patients ($P<0.05$, Student) that was differentially modulated by LPS and VIP. CD14 positive cells from pSS but not from control subjects showed increased expression of IL-12 after co-culture with epithelial cells which was partially reversed by VIP. Moreover, only pSS cells induced the expression of inflammatory and migration markers on epithelial cells after co-cultures with a 2.2 fold increase of Toll like receptor 4 TLR4 ($P<0.05$ vs. basal expression) and Monocyte chemotactic protein-1 (MCP-1) among other molecules.

Conclusion: These observations support that salivary gland epithelial cells could be actively involved in the priming of peripheral monocytes of pSS patients and that VIP / VPAC system might have a role in this interaction.

495

Regulatory T Cell Subset Defect in a Mouse Model of Sjögren Syndrome. Scott M. Lieberman[1], Portia A. Kreiger[2] and Gary A. Koretzky[3]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Nemours/A.I. DuPont Hospital for Children, Wilmington, DE, [3]University of Pennsylvania, Philadelphia, PA

Background/Purpose: CD4$^+$Foxp3$^+$ regulatory T cells (Tregs) are a specialized population of lymphocytes which prevent autoimmunity in normal hosts. Sjögren syndrome is an autoimmune disease characterized by destruction of lacrimal and salivary glands resulting in profound ocular and oral dryness. Studies in Sjögren syndrome demonstrate normal or elevated Treg numbers in peripheral

blood and normal in vitro function, but these assays for global Treg dysfunction fail to detect defects in specific Treg subsets. In the nonobese diabetic (NOD) mouse model of Sjögren syndrome, females develop earlier and more severe sialadenitis while males develop primarily dacryoadenitis. Here, we use a new NOD-based transfer model of Sjögren syndrome to evaluate the role of Treg subset defects in disease development.

Methods: Sjögren-like disease was induced by transfer of cervical lymph node cells, either whole or depleted of Tregs, to immunodeficient NOD-SCID mice that have no lymphocytes and do not develop autoimmunity. Seven weeks following adoptive transfer, dacryoadenitis and sialadenitis were quantified by an experienced, blinded pathologist using a standard focus score.

Results: Transfer of whole cervical lymph node cells from female NOD mice to female NOD-SCID mice resulted in sialadenitis with minimal or no dacryoadenitis, a pattern similar to disease in intact female NOD mice. Interestingly, dacryoadenitis developed in recipients of cervical lymph node cells depleted of the Treg-enriched $CD4^+CD25^+$ population and was abrogated by co-transfer of this population.

Conclusion: Female NOD mice harbor a lacrimal gland-protective (but not salivary gland-protective) Treg subset within the organ-draining cervical lymph nodes, suggesting spontaneous sialadenitis is due to dysfunction of salivary gland-protective Tregs. Whether male NOD mice have a similar, but lacrimal gland-specific, Treg subset defect is under investigation.

A Chimeric Human-Mouse Model of Sjogren's Syndrome. Nicholas Young, Alexandra Friedman and Wael N. Jarjour. The Ohio State University Medical Center, Columbus, OH

Background/Purpose: Sjogren's Syndrome (SjS) is a chronic autoimmune disorder that results in the persistent inflammation of moisture producing glands. In addition to the lacrimal and salivary gland response, systemic inflammation is also observed to different extents. Despite recent advances in the understanding of this disease, the pathogenic mechanisms remain to be elucidated. Although animal models have been useful in characterizing some disease aspects, an ideal model for early drug discovery is not available.

Methods: In this work, peripheral blood mononuclear cells (PBMCs) from healthy subjects and patients with SjS were isolated and injected into immuno-incompetent mice. This transgenic mouse strain is commonly known as NOD *scid* gamma (NSG) and can not produce functional T cells, B cells, and NK cells due to several induced mutations. Moreover, this mouse has been shown to have more successful engraftment of PBMCs than any other strain. Before initial injection, PBMCs from SjS patients and healthy controls were characterized though flow cytometry with markers directed against major cell subtypes. Upon euthanization, tissue from multiple organs was harvested and heparinized blood was collected for additional cytometric analysis.

Results: Isolated PBMCs from SjS patients were found to contain approximately 65% CD3+ T cells, with approxiametely 55% being CD4+ and 8% CD8+. Monocytes (12%), NK cells (3%), and B cells (7%) were also detected in these samples. Isolated PBMCs were then adoptively transferred into NSG mice. H&E stains of tissues from SjS adoptive transfers revealed a dramatic multi-organ inflammatory response which pronounced infiltrate observed in the lacrimal and salivary glands. Tissue sections of mice transferred with healthy PBMCs showed significantly less infiltrate into these target organs. Interestingly, flow cytometry of the blood collected showed a slightly decreased presence in both CD3+/CD4+ and CD3+/CD8+ cells. However, no monocytes, NK cells, and B cells of human origin were detected. When the salivary and lacrimal glands of mice transferred with SjS PBMCs were examined further with immunohistochemistry (IHC), the infiltrate consisted largely of CD4+ cells with some CD8+ cells present. Notably, B cells were also detected in the infiltrate of these glands, but to a lesser extent. The localization of inflammation to the lacrimal and salivary gland targets may explain the presence of B cells in these organs, while not found using flow cytometry.

Conclusion: This adoptive transfer model of SjS uses PBMCs isolated from patients and displays pronounced target organ infiltrate. Continued efforts with this model will characterize the inflammatory response further, both in cellular infiltrate and organ involvement, and optimize experimental conditions. Ultimately, this novel chimeric human-mouse model using primary human SjS cells will offer a unique experimental environment in which to test therapeutics and investigate disease pathology.

The Majority of Micrornas in Serum and Saliva Is Concentrated in Exosomes. Alessia Gallo[1], Mayank Tandon[1], Gabor G. Illei[2] and Ilias Alevizos[1]. [1]NIDCR, Bethesda, MD, [2]NIDCR/ NIH #10 1N110, Bethesda, MD

Background/Purpose: MicroRNAs (miRNA) are small regulatory RNA molecules with important roles in a variety of physiological and pathological processes. miRNA signatures from both unfractionated human fluids, like serum and saliva and from exosomes showed promise as diagnostic biomarkers, but the relative contribution of exosomal miRNAs to whole serum microRNAs has not yet been explored.

Methods: We first optimized a protocol to isolate exosomes from a very small amount of fresh and frozen serum and saliva. The isolation of microvescicles was done using different centrifugation and ultra centrifugation steps. The purity of exosome preparations were confirmed by electron microscopy and by Western blot using exosome specific antibodies (CD63, TSG101). The expression of selected microRNAs isolated either from exosomes or the exosome-free supernatant were compared by TaqMan RT-qPCR. We tested miR-150, miR-146a, miR-574, miR101, miR107, miR16, miR678 and miR13 in serum samples and miR202, miR203, miR1273d, and miR22 in saliva samples.

Results: The centrifugation and ultracentrifugation steps allowed to have a very clean isolation of exosomes and subsequently a higher quality miRNA preparation, compared to the whole serum and the supernatant. The expression of all tested miRNAs in the pellet was at least 8 fold higher compared to the supernatant. The difference ranged from 8–128 folds (3–7 cycles). Most miRNAs were either undetectable (Cycles Threshold >35) or detectable at a very low level in the exosome-free supernatant.

Conclusion: These results show that the majority of miRNAs in the serum and saliva is packaged within microvesicles, primarily exosomes and not found free circulating in human samples. Even though, the exosome isolation could mean an extra-step, it is maybe necessary to reliably detect miRNAs which are present at low concentration in human fluids.

Deep Sequencing of Small RNAs Reveals Novel MicroRNAs in Minor Salivary Glands of Sjögren's Syndrome Patients. Mayank Tandon[1], Alessia Gallo[1], Gabor G. Illei[2] and Ilias Alevizos[2]. [1]NIDCR, Bethesda, MD, [2]NIDCR/ NIH #10 1N110, Bethesda, MD

Background/Purpose: Sjögren's Syndrome (SS) is a complex autoimmune disease of the salivary gland with an unknown etiology, so a thorough characterization of the transcriptome would facilitate our understanding of the disease. We use ultra deep sequencing of small RNAs from Sjögren's patients and healthy volunteers, primarily to identify and discover novel miRNA sequences that may play a role in the disease.

Methods: Total RNA was isolated from minor salivary glands of healthy volunteers (n=3) and patients with either high (n=3) or low (n=3) salivary flow. RNA from individuals was pooled and sequenced on the SOLiD 4 platform using the small RNA protocol from Applied Biosystems. Prediction of mature miRNAs from the sequenced reads was done using miRanalyzer and expression was validated using custom Taqman qPCR assays. Additional validation was performed on several cell lines, including human salivary gland (HSG) cells, Jurkat cells, and primary culture cells from patient salivary glands and fibroblasts.

Results: The number of total reads generated, as well as the reads mapped during each step of the analysis, was greatly varied between samples. The Low Flow sample generated more reads (~26 million) than the Healthy Volunteer sample (~15 million). However, a smaller proportion of those reads was matched to the human genome in Low Flow patients, 3.6% compared to 27.8% in Healthy Volunteers, suggesting an elevated level of exogenous sequences in patients. We also validated the presence of six previously unidentified miRNA sequences in patient samples and in several cell lines, and one shows promise as a biomarker candidate. This novel miRNA is elevated 4.6-fold in patients with high salivary flow and 12.5-fold in patients with low salivary flow when compared to healthy volunteers.

Conclusion: Sequencing small RNAs in the salivary gland is largely unprecedented, but here we show the feasibility of discovering novel miRNAs and disease biomarkers by sequencing the transcriptome of pooled patient samples.

499

Subclinical Peripheral Synovitis Detected by ultrasound In Patients with Axial Spondyloarthritis. Pascal Zufferey[1], Cecile Mouly Jr.[1], Hans Rudolf Ziswiler[2] and Jean Dudler[3]. [1]Rheumatology, Lausanne, Switzerland, [2]Rheumatology, Bern, Switzerland, [3]HFR Fribourg-Hôpital Cantonal, Fribourg, Switzerland

Background/Purpose: Peripheral arthritis is considered fairly rare in patients with axial Spondyloarthritis (SpA), with about 30% of them suffering from the classical oligoarthritis. However, many of them complain of pain in the small peripheral joints, in the absence of obvious synovitis. Musculoskeletal ultrasound (US) can demonstrated subclinical synovitis in rheumatoid arthritis (RA), synovitis relevant in term of disease activity and treatment strategies.

The goal of the present study was to determine the prevalence of small joint synovitis in SpA identified by ultrasonography as compared to RA patients and controls, and if those synovitis were relevant in terms of disease activity and function.

Methods: The Swiss Sonography in Arthritis and Rheumatism (SONAR) group has developed a reproducible semi-quantitative score for synovitis in RA using OMERACT criteria. The score includes B mode and Doppler evaluation of metacarpophalangeal and proximal interphalangeal joints 2 to 5, wrist, elbows and knees (22 joints, grade: 0 to 3, maximum of 66 points each).

40 consecutive patients fullfilling the ASAS classification criteria for axial SpA without history of oligoarthritis, 20 gender and age-matched controls without rheumatologic diseases and 40 consecutive RA patients (19 in remission [DAS28 <2.6], 10 in low activity [$2.6 <$ DAS28 > 3.4] and 11 with moderate activity ($3.5 <$ DAS28 >5.1) were evaluated using the SONAR score by ultrasonographer blinded to any clinical parameters. A corresponding 28-joints counts was performed by two investigators in patients and controls, while patients and controls also completed self-evaluation assessments for disease activity (BASDAI), general function (BASFI), hand function (m-SACRAH) and quality of life (HAQ). Furthermore, BASMI and DAS28 were determined in SpA and DAS28 in RA patients.

Results: 34% of SpA patients had significant synovitis by US evaluation using a B mode score > 8 a cut-off value for significance (value set to classify $<$ 10% of controls (mean: 5.9) and $>$ 90% of the active RA (DAS28 $\geq$ 2.6). SpA score remained mostly mild, with a mean B mode score (12) not significantly higher than RA in remission (7.1). Only active RA (DAS >3.5) had significantly higher echographic scores for B mode (17), Doppler score or number of synovitis with grade > 1, compared to all other groups.

In a preliminary analysis, BASDAI, BASFI, BASMI, m-SACRAH, DAS28 and CRP were not significantly different in SpA patients with or without echographic synovitis, and no correlation was found between any variables and the echographic scores, on the contrary to RA patients were echographic synovitis severity did significantly correlate to clinical variables

Conclusion: one third of the patients with axial SpA have significant small joints peripheral synovitis detected by echography. The significance of such demonstration remained undetermined as no clear correlation between the severity of the synovitis and the various parameters was found in SpA patients, on the contrary to RA.

Cardiometabolic Abnormalities in Moderate-to-Severe Plaque Psoriasis with and without Psoriatic Arthritis: The PRISTINE Trial. M. Elaine Husni[1], Abrar A. Qureshi[2], Annette Szumski[3], Andrew S. Koenig[3] and Debbie H. Robertson[3]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Brigham and Women's Hospital, Boston, MA, [3]Pfizer Inc., Collegeville, PA

Background/Purpose: Individuals with psoriasis and psoriatic arthritis (PsA) have increased morbidity and mortality, which has largely been related to cardiovascular disease (CVD).[1,2] CVD risk factors such as diabetes[3] are more common in patients with psoriasis. In the PRISTINE trial (NCT00663052), a randomized, double-blind, etanercept trial, cardiometabolic parameters were assessed in psoriasis subjects with and without PsA.

Methods: Subjects with moderate-to-severe plaque psoriasis were divided into 2 groups, PsA+ and PsA-, based on patient history. Baseline demographic/disease characteristics were analyzed using one-way ANOVA. Categorical baseline variables were analyzed by a Cochran-Mantel-Haenszel (CMH) test of general association. Associations between baseline frequency of metabolic syndrome and quartiles of the Psoriasis Activity and Severity Index (PASI) were assessed by CMH test. For each PsA+/− subgroup, a logistic model of baseline metabolic syndrome analyzed gender as a predictor, adjusting for baseline PASI. For each subgroup, differences in mean baseline PASI between BMI <30 and ≥ 30 kg/m^2 were assessed by two-sample t test.

Results: Subjects (n=273) were 70% male and 64% white, with mean age 44 y, mean BMI 28.3 kg/m^2 (males)/29.6 kg/m^2 (females), and mean baseline PASI 21; mean psoriasis duration was 17 y and PsA duration was 8 y. The cardiometabolic characteristics of PsA+ and PsA- subjects are shown (table). Metabolic syndrome was seen in 44%, 48%, 44%, and 40% of PsA+ subjects and 42%, 44%, 36%, and 41% of PsA- subjects with PASI <13.7, ≥ 13.7–<18.7, ≥ 18.7–<26.5, and ≥ 26.5, respectively ($P \leq 0.73$ and $P \leq 0.75$, correlations of PsA+ and PsA- vs PASI quartile). Metabolic syndrome was significantly more prevalent in females vs males in the PsA+ subgroup (adjusted OR, 3.2; $P<0.05$) but not in the PsA- subgroup (adjusted OR, 1.3; $P=0.44$). Mean baseline PASI was not significantly different between BMI <30 and ≥ 30 kg/m^2 in either subgroup.

Baseline cardiometabolic parameters in subjects with psoriasis with and without PsA

	Subjects, n (%)		
Cardiometabolic Parameter	**PsA+ (N = 84)**	**PsA− (N = 189)**	**P value**
Metabolic syndrome[a]	37 (44)	77 (41)	0.61
Large waist circumference[b]	61 (73)	130 (70)	0.65
Low HDL cholesterol[c]	21 (25)	48 (25)	0.95
Elevated triglycerides[d]	30 (36)	63 (33)	0.70
Elevated blood pressure[e]	61 (73)	105 (56)	0.01
Elevated glucose[f]	29 (35)	50 (27)	0.18
Diabetes[g]	18 (21)	17 (9)	<0.01
Diabetes + prediabetes[g]	44 (52)	77 (41)	0.07
Hypertension[h]	52 (62)	50 (27)	<0.001
	Mean Score/Level (SD)		
Framingham 10-year % risk	6.3 (6.6)	5.3 (6.1)	0.21
Reynolds 10-year % risk	4.3 (4.5)	3.9 (6.1)	0.01
Plasma NT-proBNP, pg/mL	87.8 (128.0)	57.4 (119.4)	0.06
High sensitivity CRP[i], mg/L	11.5 (17.5)	5.51 (7.7)	0.02

[a]Satisfied 3/5 criteria. [b]Europe: ≥102/≥88 cm (M/F); Asia, Cent/S America: ≥90/≥80 cm (M/F). [c]Fasting HDL-C <1.0/<1.3 mmol/L (M/F) or receiving drug treatment. [d]Fasting triglycerides ≥1.7 mmol/L or receiving drug treatment. [e]SBP ≥130 or DBP ≥85 mm Hg or receiving drug treatment with history of hypertension. [f]Fasting glucose ≥100 mg/dL or on drug treatment. [g]Diabetes = HbA1c >6.4% or medical history or receiving drug treatment; prediabetes = HbA1c 5.7–6.4% (2010 ADA criteria). [h]Medical history or receiving drug treatment. [i]Normal CRP level ≤3.0 mg/L.

Conclusion: Metabolic syndrome and other CVD risk factors were common in psoriasis with and without PsA. Women with PsA were significantly more likely to have this syndrome than men with PsA. A significantly higher proportion of subjects with diabetes and hypertension, and significantly greater Reynolds % risk and C-reactive protein, were observed in PsA+ subjects vs PsA- subjects. No significant associations were seen between the severity of psoriasis and metabolic syndrome or BMI in either subgroup. Clinicians need to be attentive to cardiometabolic biomarkers in those affected by psoriasis and PsA to help reduce overall cardiovascular disease risk.

Impact of Uveitis On the Phenotype of Patients with Recent Inflammatory Back Pain. Data From the DESIR Cohort. Daniel Wendling[1], Clément Prati[2], Christophe Demattei[3], Corinne Miceli-Richard[4], Jean-Pierre Daures[3] and Maxime Dougados[5]. [1]Minjoz University Hospital, Besancon, France, [2]CHU J Minjoz, Besancon, France, [3]CHU, Nimes, France, [4]Hopital Bicêtre, Le Kremlin Bicêtre, France, [5]Paris-Descartes University, Cochin Hospital, Paris, France

Background/Purpose: Influence of uveitis on clinical, epidemiological and imaging features in patients with inflammatory back pain (IBP) related to spondyloarthritis (SpA) needs to be known.

Objectives: To determine the prevalence of uveitis in patients with recent IBP suggestive of SpA, and to investigate the influence of uveitis on the overall features of patients presenting with recent IBP.

Methods: The DESIR cohort is a prospective, multicenter French cohort of patients with early IBP (Calin or Berlin criteria) (>3 months and <3 years of duration) suggestive of SpA according to the investigator, including 708 patients (mean age 33.8 years, 53.8% female, 57.3% HLA B27 positive). Uveitis was defined by an ophthalmological episode diagnosed as uveitis by an ophthalmologist, or a painful red eye episode of at least 48 hours duration and/or necessitating local steroids. Data on the baseline demographic characteristics, functional status and quality of life, imaging features (standard X-Rays, MRI, Ultrasounds), BMD, and blood tests were compared in patients with and without uveitis. Both the date of the first symptom of IBP and the symptoms of uveitis were recorded, as well as the date of the visit. Factors associated with the presence of uveitis were identified both by uni and multivariate analysis (logistic regression).

Results: The prevalence of uveitis in the DESIR cohort was 8.47% [95%CI 6.58–10.83] (n=60/708 patients). Uveitis occurred after the first symptoms of IBP in 45%, before in 37%, and simultaneously (±1month) in 18% of the cases. Presence of uveitis was significantly associated in univariate analysis with pain in cervical spine, infection preceding (less than 3 months) inflammatory disease, previous diagnosis of inflammatory bowel disease, some dimensions of SF36 (mental and physical health, relation), presence of Achilles enthesitis, elevated leukocyte count, serum creatinin levels, radiological hip involvement, and chronic sacro iliac MRI lesions. Uveitis is not associated with fulfilment of diagnosis criteria, HLA-B27, BASDAI, BASFI, ASDAS, BMD. A stepwise multivariate analysis found an association between uveitis and: pain in cervical spine, infection preceding inflammatory disease, previous diagnosis of inflammatory bowel disease, physical health limitation of SF36 (Table).

	Uveitis (n=60)	No uveitis (n=648)	Adjusted OR	p-value
pain in cervical spine	31 (51.7%)	243 (37.5%)	2.09 [1.17–3.73]	0.01
infection preceding inflammatory disease	8 (13.3%)	22 (3.4%)	5.75 [2.29–14.40]	0.0002
previous diagnosis of inflammatory bowel disease	5 (8.3%)	16 (2.5%)	3.38 [1.07–10.66]	0.04
physical health limitation of SF36	56.7 ± 41.4	44.0 ± 39.1		0.001

Conclusion: In recent IBP suggestive of SpA, uveitis is associated with some particular rheumatologic and extra rheumatologic features. Our data, and in particular the association with IBD and infection might suggest a role of environmental factors in the incidence of uveitis in SpA.

Cardiovascular Events Are Related to High Levels of HDL-Cholesterol In Ankylosing Spondylitis. Anne Grete Semb[1], Tore K. Kvien[1], Rana Fayyad[2], David A. DeMicco[2], John LaRosa[3], John Betteridge[4], Terje R. Pedersen[5] and Ingar Holme[5]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Pfizer Inc, New York, [3]State University of New York health Science Centre, New York, [4]Middelsex Hospital, London, United Kingdom, [5]Oslo University Hospital-Ullevaal, Oslo, Norway

Background/Purpose: We evaluated lipids and apolipoproteins as predictors of cardiovascular mortality and morbidity (CVMM) in patients with spondyloarthritis (SpA); ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

Methods: To obtain patients with AS and PsA who were followed over time and had a CV endpoint, we used a pooled analysis of 2 CV secondary prevention studies (IDEAL and TNT) and a primary CV prevention study (CARDS). Number of participants was 21727. Fifty of these had AS, 36 had PsA, and 21641 did not have AS or PsA (non-SpA). There was no heterogeneity across the 3 trials concerning the proportion of CVMM in the different treatment groups for AS and PsA.

Results: Baseline data were similar across AS, PsA and non-SpA, except that there were more male AS patients. The AS patients used less aspirin and the PsA patients had more hypertension and higher BMI than non-SpA. Atherogenic lipids were lower in AS, but not in PsA, compared to non-SpA. The HR per 1 SD increase in baseline lipids for future CVMM was calculated (Table). Surprisingly, both HDL and ApoA-1 were significantly associated with CVMM in AS, in contrast to PsA and non-SpA. The interaction test for HDL and ApoA-1 in AS vs. non-SpA was highly significant: p<0.0001 and p=0.0003 respectively, but not significant for the atherogenic lipids in AS. None of the interaction tests were significant for PsA (Table).

Table. HR (95% CI) of CVMM for 1 SD increase in baseline lipid/apolipoprotein in subgroups of AS, PsA and non-SpA participating in the IDEAL, TNT and CARDS studies, adjusted for age, gender and treatment

Lipid/ Apolipoprotein	AS (n=50) HR (95% CI)	p-value	PsA (n=36) HR (95% CI)	p-value	nonSpA (n=21641) HR (95% CI)	p-value
Total Cholesterol	1.39 (0.82, 2.40)	0.23	1.01 (0.44, 2.31)	0.98	1.10 (1.07, 1.14)	<0.0001
LDL	1.37 (0.78, 2.41)	0.28	0.94 (0.42, 2.14)	0.89	1.13 (1.09, 1.16)	<0.0001
HDL	3.67 (1.49, 9.06)	0.005	1.03 (0.49, 2.15)	0.94	0.86 (0.84, 0.89)	<0.0001
ApoB	1.19 (0.69, 2.05)	0.54	1.27 (0.62, 2.57)	0.52	1.14 (1.11, 1.18)	<0.0001
ApoA1	1.89 (1.02, 3.54)	0.05	0.79 (0.34, 1.89)	0.60	0.88 (0.85, 0.91)	<0.0001

*Hazard ratio (HR) of CVMM for per 1 SD increase in baseline lipid/apolipoprotein
CVMM=Cardiovascular morbidity and mortality, AS=ankylosing spondylitis, PsA=psoriatic arthritis (PsA), Non-SpA= non-spondyloarthritis, HR=hazard ratio, CI=confidence interval

Conclusion: Increased levels of HDL and ApoA-1 were associated with increased risk of CVMM in patients with AS, whereas these lipids were protective in non-SpA. These observations are preliminary and need confirmation in larger trials.

503

The Degree of Spinal Inflammation Is Similar in Patients with Axial Spondyloarthritis Who Report High or Low Levels of Disease Activity— a Cohort Study. Uta Kiltz[1], Xenofon Baraliakos[1], Pantelis Karakostas[1], Manfred Igelmann[2], Ludwig H. Kalthoff[3], Claudia Klink[4], Dietmar MJ Krause[4], Elmar Schmitz-Bortz[5], Martina Floerecke[1], Matthias Bollow[6] and Juergen Braun[1]. [1]Ruhr-University Bochum, Herne, Germany, [2]Private Rheumatology office, Bochum, Germany, [3]Private rheumatology office, Herne, Germany, [4]Private rheumatology office, Gladbeck, Germany, [5]Private rheumatology office, Hattingen, Germany, [6]Augusta Krankenanstalten, Bochum, Germany

Background/Purpose: Patients with axial spondyloarthritis (axSpA) may already have established radiographic changes in the sacroiliac joints, classified as ankylosing spondylitis (AS) or non-radiographic axial SpA (nraxSpA). International recommendations for the management of axSpA have set the cut off for the minimal clinical disease activity required to fulfill criteria for anti-TNF therapy at a BASDAI level of 4 - based on a convention arbitrarily proposed some years ago. However, the level of inflammatory activity as demonstrated by magnetic resonance imaging (MRI) or elevated CRP levels in patients who report moderate disease activity is unknown. The objective of this study was to systematically compare the clinical, laboratory and imaging data of patients with axSpA, stratified by the level of disease activity: BASDAI <4 and ≥4.

Methods: A total of 100 consecutive patients with axSpA who had never been treated with TNF-blockers were included. Data on demographics (gender, age, symptom duration, comorbidities, use of concomitant medication) were collected, and standardized assessment tools (BASDAI, BASFI, ASDAS, NRS pain, physicians′s and patient′s global assessment, ASQoL, SF-36) applied, laboratory parameters (CRP, HLA-B 27 status) measured, and spinal MRI and x-rays performed and quantified with established scoring systems (mSASSS, RASSS and Berlin score). Data were stratified according to the correspondent BASDAI level ≥4 or <4.

Results: AS was diagnosed in 56 and nraxSpA in 44 patients, mean age 40.2±10.4 years; 57% male, mean disease duration 6.4±8.4y, 88% HLA-B27 positivity. Almost all patients took NSAIDs (94%), 54% continuously. More than half of the patients had spinal inflammation to some degree (60%). The stratification based on BASDAI levels showed statistically significant differences in most clinical parameters—but not for inflammation as measured by either CRP or MRI: nraxSpA patients with BASDAI <4 versus (vs) ≥4 had 0.9±1.4 and 0.5±0.6 inflammatory lesions/patient, respectively (p=0.6), while AS patients with BASDAI <4 vs ≥4 had 3.6±3.7 and 2.7±3.0 inflammatory lesions/patient, respectively (p=0.4).

Table. Differences between patients with nraxSpA and AS stratified according to BASDAI level

	BASDAI	AS	nraSpA	p for AS vs. nraSpA	p for BASDAI < vs. ≥4
Patient's global	<4	2.4 ± 1.6	2.1 ± 2.1	0.26	<0.001
	≥4	6.2 ± 2.2	5.7 ± 2.2	0.37	
BASFI	<4	1.2 ± 1.1	0.8 ± 0.7	0.39	<0.001
	≥4	4.8 ± 2.1	3.3 ± 2.2	0.02	
ASQoL	<4	2.0 ± 2.4	2.3 ± 3.1	0.89	<0.001
	≥4	9.0 ± 4.2	8.4 ± 4.1	0.26	
CRP (mg/l)	<4	10.7 ± 8.34	5.7 ± 6.9	0.037	0.824
	≥4	11.6 ± 13.63	5.4 ± 6.8	0.005	
N inflamed lesions/ patient (MRI)	<4	3.5 ± 3.5	1.0 ± 1.4	0.004	0.550
	≥4	2.7 ± 3.0	0.5 ± 0.6	0.008	

Conclusion: The striking result of this study in patients with axSpA is that there is not only no correlation between widely used clinical assessments of disease activity and more objective measurements of inflammation such as CRP serum levels and MRI but that the BASDAI cut-off ≥ 4 needs to be reevaluated. These data clearly challenge the concept of the arbitrarily set clinical cut off BASDAI≥4 since the burden of inflammation and most clinical measures were quite comparable in patients with nraxSpA and established AS - irrespective of BASDAI levels. These data confirm and justify the inclusion of patients with nraxSpA in the recent recommendations for anti-TNF therapy.

504

The Swedish Early Psoriatic Arthritis (SwePsA) Registry. 5-Year Follow-up: Higher Disease Activity, Greater Functional Impairment and Worse Outcome for Women Compared to Men. Elke Theander[1], Tomas Husmark[2], Gerd-Marie Alenius[3], Per Larsson[4], Annika Teleman[5], Mats Geijer[6] and Ulla R. C. Lindqvist[7]. [1]Department of Rheumatology, Skåne University Hospital, Lund University, Malmö, Sweden, [2]Depart ment of Rheumatology, Falu Hospital, Falun, Sweden, [3]Department of Public Health and Clinical Medicine, Rheumatology, Umeå University Hospital, Umeå, Sweden, [4]Department of Rheumatology, Karolinska University Hospital, Stockholm, Sweden, [5]Spenshult Rheumatological Hospital, Oskarstrom, Sweden, [6]Department of Radiology, Skåne University Hospital, Lund University, Lund, Sweden, [7]Department of Medical Scie nces, Rheumatology, University Hospital, Uppsala university, Uppsala, Sweden

Background/Purpose: SwePsA intends to describe the course of disease during early psoriatic arthritis (PsA) in a real life clinical setting in Sweden. Here we present results from a 5-year follow-up of 206 patients and analyse predictors of unfavourable outcome.

Methods: In 6 Swedish centres patients with signs suggestive of PsA were included in the registry within 2 years from symptom onset. Two-hundred and six patients fulfilling CASPAR (1) or ASAS (2) criteria who had passed the 5-year follow-up visit were included. DAS-28 and DAPSA (3) were used as disease activity measures. Clinical remission (defined as no tender or swollen joints and normal ESR and CRP) and Minimal Disease Activity (MDA) (4) were used as outcome measures. Patterns of joint involvement and medication were assessed.

Results: Mean age at baseline:46 years, younger in male (n=88) than female (n=118) patients (48 vs 43 years).

DAS-28 was 3.4 at baseline and 2.6 at 5-year follow-up, significantly higher in women (3.7 and 2.9) than in men (2.9 and 2.1) at both visits. Likewise DAPSA scores were significantly higher in women (22.9 and 14.0) than in men (14.9 and 9.9) at both visits. The degree of improvement (delta DAS-28 and delta DAPSA) was similar in women and men. A larger proportion of men were in MDA state or remission at 5-year follow-up (50% vs 30% and 36% vs 23%). While women had significantly more often polyarticular disease at baseline (52% vs 33%) and also kept that pattern over the 5 years (21%), men had more often axial or mono/oligoarticular disease at baseline or converted to it during follow-up.

Despite higher disease activity in women there was a trend towards less DMARD treatment (40% of women vs 34% of men had never been treated with DMARDs). The use of biologics did not differ (7% vs 6%).

Predictors of MDA or remission at 5-year follow-up were male gender, low HAQ and short delay between symptom onset and inclusion, mono/oligoarticular or axial disease pattern at baseline, for MDA also low DAS-28, DAPSA, TJC, PGA and pain VAS. In multivariate analysis male gender, axial disease, shorter delay between symptom onset and inclusion and preserved physical functioning at inclusion independently predicted better outcome. Exclusion of patients with axial disease only did not change the results.

Conclusion: In early PsA male gender, axial disease, short delay between symptom onset and diagnosis, as well as preserved function at diagnosis are predictors of favourable outcome at 5-year follow-up. Early recognition of PsA and active treatment may be important particularly in women with polyarticular disease.

Gender Differences in the Correlation of Self-Reported Functional Status with Spinal Mobility in Patients with Ankylosing Spondylitis. Pooja N. Patel[1], Roozbeh Sharif[2], Shervin Assassi[3], Lianne S. Gensler[4], Laura A. Diekman[5], Thomas J. Learch[6], Michael H. Weisman[7], Michael M. Ward[8] and John D. Reveille[2]. [1]University of Texas, Houston, Houston, TX, [2]University of Texas Health Science Center at Houston, Houston, TX, [3]Univ of Texas Health Science, Houston, TX, [4]UCSF, San Francisco, CA, [5]UT Health Science Center, Houston, TX, [6]Cedars-Sinai, Los Angeles, CA, [7]Cedars Sinai Med Ctr, Los Angeles, CA, [8]NIAMS/NIH, Bethesda, MD

Background/Purpose: Spinal damage in patients with ankylosing spondylitis (AS) can result in physical limitation. Previous studies have reported clinical and psychological factors correlate with self-reported functional status in AS patients. In the current study, the association of functional status with measurements of spinal mobility (AS-Metrology) was evaluated. Also examined was the the impact of gender, disease duration, and anti-tumor necrosis factor (TNF)α treatment on this association.

Methods: Patients enrolled in the **P**rospective **S**tudy of **O**utcomes in **A**nkylosing **S**pondylitis (PSOAS) cohort were studied. PSOAS is a multi-ethnic, multi-center cohort of patients with AS in the United States. The study investigators performed the following measurements of spinal mobility: cervical rotation and flexion, occiput-to-wall distance, chest expansion, modified Schober, lateral lumbar flexion, and hip internal/external rotation. In addition, the patients' perceived functional limitation was recorded by the Bath AS Functional Index (BASFI). Linear regression was used to examine the association of the BASFI score with concomitantly recorded spinal mobility measures at enrollment. Considering potential effect modifiers, the interaction term of BASFI with the following variables was examined: disease duration, gender, and anti-TNF α treatment.

Results: Overall, 436 patients were included in the analysis: median age of 42.3 years, 70% male, 77% Caucasian, and median disease duration of 16.3 years. HLA-B27 was detected in 85% of subjects. BASFI score correlated with AS-Metrology ($p<0.001$). The analysis of potential effect modifiers indicated the presence of a statistically significant interaction between gender and BASFI with regard to its association with AS-Metrology ($p<0.05$). Subgroup analysis based on the gender indicated male patients have a stronger correlation between BASFI and AS-Metrology, compared to female patients (table-1). Though some of the AS-Metrology variables were not normally distributed, analysis of log transformed variables did not affect the results.

Conclusion: AS-Metrology is associated with BASFI score and this correlation is statistically stronger among men compared to women. These findings support the hypothesis that other factors might play an important role in perceived functional status among women with AS.

Table 1. Subgroup analysis of correlation between BASFI and AS metrology based on gender

Patients with Non-Radiographic Axial Spondyloarthritis Differ From Patients with Ankylosing Spondylitis in Several aspects—Results of a Cross-Sectional Cohort Study. Uta Kiltz[1], Xenofon Baraliakos[2], Pantelis Karakostas[2], Manfred Igelmann[3], Ludwig H. Kalthoff[4], Claudia Klink[5], Dietmar MJ Krause[6], Elmar Schmitz-Bortz[7], Martina Floerecke[2], Matthias Bollow[8] and Juergen Braun[2]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Ruhr-University Bochum, Herne, Germany, [3]Private Rheumatology office, Bochum, Germany, [4]Private rheumatology office, Herne, Germany, [5]Private rheumatology office, Gladbeck, Germany, [6]Gladbeck, Germany, [7]Private rheumatology office, Hattingen, Germany, [8]Augusta Krankenanstalten, Bochum, Germany

Background/Purpose: Patients with axial spondyloarthritis (SpA) may already have established radiographic changes in the sacroiliac joints and the spine or not—the former are classified as having ankylosing spondylitis (AS), the latter as pre- or non-radiographic axial SpA (nraxSpA) according to the ASAS criteria. The nature and the relationship of these subentities are incompletely understood. The objective of this stufy was to study the patients' clinical data and their view of the current disease status in relation to laboratory markers and spinal inflammation (MRI) in patients with AS and nraxSpA.

Methods: A total of 100 consecutive patients with a diagnosis of axial SpA who had never been treated with TNF antagonists were studied and the results compared to those of laboratory parameters, spinal x-rays and MRIs which were scored by the mSASSS and the Berlin score, respectively. Standardized clinical assessment tools were used (NRS pain, BASDAI, ASDAS, BASFI, ASQoL, SF-36).

Results: AS was diagnosed in 56 and nraxSpA in 44 patients. Patients with established nraxSpA and AS did not differ much in many clinical variables (BASDAI, BASFI, ASQoL) but the proportion of males (32% vs 72%) and the extent of inflammation were clearly lower in nraxSpA vs AS patients: CRP (5.7±6.6 vs 11.6±12.6), ASDAS (2.2±0.8 vs 2.9±0.9), Berlin score (0.8±1.2 vs 3.1±3.2) and mSASSS: 2.4±3.5 vs 13.2±20.7 (all $p<0.01$). The frequency of typical comorbidities (uveitis, psoriasis, CED or enthesitis), nor in the actual medication regarding NSAIDs or sulfasalazine differed between the groups. These results were confirmed by multivariate analyses adjusted for gender, CRP and mSASSS at baseline.

Table 1. Comparison between the two analyzed subgroups for all measured parameters.

	nraSpA	AS	p
Age (y)	39.1 ± 9.8	41.2 ± 10.9	0.455
Symptom duration (y)	9.4 ± 9.5	12.8 ± 10.7	0.085
NRS pain	4.0 ± 2.1	4.7 ± 2.7	0.244
Physician′s global assessment	2.7 ± 1.7	3.5 ± 1.9	0.064
Patient′s global assessment	4.0 ± 2.7	4.6 ± 2.7	0.265
BASDAI	3.6 ± 1.7	4.2 ± 2.2	0.194
BASFI	2.4 ± 2.1	3.2 ± 2.4	0.054
SF-36 MCS	45.0 ± 12.3	47.5 ± 11.5	0.382
SF-36 PCS	39.0 ± 9.0	36.5 ± 10.2	0.192
ASQoL	5.6 ± 4.8	6.0 ± 4.8	0.712

Conclusion: These data largely confirm earlier data showing that the disease burden in nraxSpA and established AS is similar. Interestingly, these subgroups did not differ much in clinical variables but in CRP levels and the extension of inflammation detected by MRI – both were higher in patients with AS. Expectedly, male patients were more prone to develop structural changes. Although this study was 'only' cross-sectional the data shows that a large group of patients with axSpA has not developed structural changes after almost 10 years of symptom duration. We propose that patients with nraxSpA should not be regarded as pre-radiographic AS but rather as non-radiographic axial SpA – a subgroup that is less prone to develop new bone formatio It will be interesting to see whether and how many of these patients will develop AS in the further disease course.

[1]Hospital Garcia de Orta, Almada, Portugal and Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Hospitais da Universidade de Coimbra, Coimbra, Portugal and Leiden University Medical Center, Leiden, Netherlands, [3]Hospital Garcia de Orta, Almada, Portugal, [4]Instituto Português de Reumatologia, Lisboa, Portugal, [5]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisboa, Portugal, [6]Centro Hospitalar do Alto Minho, Hospital de Ponte de Lima, Ponte de Lima, Portugal, [7]Hospitais da Universidade de Coimbra, Coimbra, Portugal, [8]Centro Hospitalar de Lisboa Ocidental, Hospital Egas Moniz, Lisboa, Portugal, [9]Centro Hospitalar de Lisboa Norte, Hospital de Santa Maria, Lisboa, Portugal, [10]Maastricht University Medical Center, Maastricht, Netherlands, [11]Leiden University Medical Center, Leiden, Netherlands, [12]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: The Ankylosing Spondylitis Disease Activity Score (ASDAS) is the new index to measure disease activity in Ankylosing Spondylitis (AS). Our aim was to address validity and discriminatory aspects of the ASDAS, as well as to analyse the performance of the ASDAS disease activity states and response criteria in the setting of an observational cohort of patients with AS starting biological therapies.

Methods: Patients with AS under biological therapy and followed in the Portuguese register of rheumatic diseases (Reuma.pt) were included in this analysis. Reuma.pt is used as an electronic medical record and assessments are performed by rheumatologists. All patients with baseline data were used for cross-sectional analysis (n = 264). For the longitudinal analyses, follow-up visits at 12 and 24 weeks and with an ASDAS-CRP available were required (n = 109). Pearson coefficients were calculated to establish the correlation between disease activity measurements at baseline. Discrimination between patients with low versus high disease activity according to the patient's global assessment (PGA) was analysed as the standardised mean difference (SMD). The percentage of patients within each ASDAS disease activity state at each time point and the percentage of patients achieving ASDAS improvement criteria at 12 and 24 weeks were determined and the latter were compared with other response measures.

Results: The ASDAS showed a good correlation with the PGA (0.66), and simultaneously a good correlation with acute phase reactants (CPR 0.61; ESR 0.52). The ASDAS was discriminatory, with similar SMDs to the ones from BASDAI. Results were consistent for the whole population as well as in subgroups of baseline CRP (at a cutoff of 5g/l) and disease duration (at a cutoff of 5 years). ASDAS disease activity in states showed a clinically meaningful shift from high to low over time (Table 1). The same pattern was found in the subgroups of CRP and disease duration. The ASDAS improvement criteria identified more patients with clinically meaningful improvement than the classical criteria did (Table 2), and the same results were also found in the subgroups of CRP and disease duration.

Table 1. Longitudinal evolution of ASDAS disease activity states

Time point	N	ASDAS < 1.3 N (%)	1.3 ≤ ASDAS < 2.1 N (%)	2.1 ≤ ASDAS < 3.5 N (%)	ASDAS > 3.5 N (%)
Baseline	109	0 (0%)	3 (2.8%)	46 (42.2%)	60 (55.0%)
12 weeks	109	33 (30.3%)	25 (22.9%)	42 (38.5%)	9 (8.3%)
24 weeks	109	30 (27.5%)	29 (26.6%)	40 (36.7%)	10 (9.2%)

Table 2. Percentage of patients achieving different improvement criteria

	12 weeks (n = 91)	24 weeks (n = 91)
Δ ASDAS ≥ 1.1	57 (62.6%)	55 (60.4%)
Δ ASDAS ≥ 2.0	36 (39.6%)	34 (37.4%)
Δ BASDAI ≥ 2.0	46 (50.6%)	46 (50.6%)
BASDAI50	40 (44.0%)	37 (40.7%)
ASAS20	51 (56.0%)	51 (56.0%)
ASAS40	42 (46.2%)	44 (48.4%)

Conclusion: The ASDAS is a discriminatory instrument for disease activity in the setting of usual clinical practice.

508

Prevalence and Treatment Patterns of Psoriatic Arthritis in the Health Improvement Network. Alexis Ogdie[1], Thorvardur Love[2], Kevin Haynes[3], Yiding Yu[3], Nicole Seminara[3], Hyon K. Choi[4] and Joel Gelfand[3]. [1]University of Pennsylvania, Philadelphia, PA, [2]Landspitali University Hospital, Reykjavík, Iceland, [3]University of Pennsylvania., Philadelphia, PA, [4]Boston University School of Medicine, Boston, MA

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis. Prevalence in the general population has been estimated at 0.1–0.25% but large population-based studies have not been performed. The Health Improvement Network (THIN) is an electronic medical record database representative of the UK general population and can be used to perform high quality, population-based epidemiology studies. We aimed to determine the prevalence of PsA in THIN and describe the therapies prescribed.

Methods: Seven Read codes (similar to ICD9 codes) for PsA and 26 codes for psoriasis were identified. Patients were considered to have PsA or psoriasis if they ever had a code consistent with that diagnosis. Cohort entry occurred at the PsA diagnosis. Multilex drug codes for disease modifying antirheumatic drugs (DMARDs) on or after cohort entry were analyzed using STATA 11.0 (College Station, TX).

Results: Of 8.05 million patients (all ages) registered with a THIN practice between 1995–2009, 8586 patients had at least one Read code for PsA recorded and 165,903 at least one Read code for psoriasis. The prevalence of PsA in THIN was 0.11% (95%CI: 0.10–0.11) and among psoriasis patients was 5.2% (95%CI: 5.1–5.3). Of the 8586 patients, 6855 (79.8%) were between age 18–90, 51.5% were male and 48.5% were female. Prescription records indicated that of the 6855, 3492 patients (50.9%) had received a DMARD on or after cohort entry; 2461 (35.9%) had received methotrexate, 1827 (26.7%) sulfasalazine, 389 (4.9%) leflunamide, 174 (2.5%) cyclosporine, 135 (2.0%) azathioprine, and 16 (0.2%) TNF-alpha inhibitors. Of patients receiving DMARDs, 64.9% have only ever been prescribed one DMARD. Aside from DMARDs, 5427 (79.2%) had received non-steroidal anti-inflammatory agents, 1618 (23.6%) oral corticosteroids, 1349 (19.7%) tramadol, and 287 (4.2%) received opiates.

Conclusion: This is the largest population based study of PsA to date. The prevalence of PsA and DMARD use are consistent with previous population based estimates in the US and Northern Europe. Limitations include the unclear recording of biologic medications in THIN (only 0.2% of patients have a recorded biologic) and a definition of PsA based on a diagnostic code rather than CASPAR criteria. The code for psoriasis has a positive predictive value of 90%; work to confirm that a code reflects the true clinical state in PsA is ongoing. Given the large population of PsA patients, THIN is an important resource for the study of PsA.

509

The Risk of Malignancy in a Large Cohort of Patients with Psoriatic Arthritis. Rachel L. Gross[1], Julie S. Schwartzman-Morris[1], Michael Krathen[2], George Reed[3], Hong Chang[2], Katherine C. Saunders[4], Mark C. Fisher[5], Chaim Putterman[1], Philip J. Mease[6], Alice B. Gottlieb[2] and Anna R. Broder[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Tufts Medical Center, Boston, MA, [3]University of Massachusetts, Worcester, MA, [4]CORRONA, Inc., Southborough, MA, [5]Massachusetts General Hospital, Boston, MA, [6]Seattle Rheumatology Associate, Seattle, WA

Background/Purpose: There are few studies examining malignancy incidence in patients with Psoriatic Arthritis (PsA), and an increased malignancy risk in this population is often extrapolated from studies of patients with Rheumatoid Arthritis (RA) and Psoriasis. Knowledge of malignancy risk can help providers in counseling patients and aid in treatment decisions regarding the use of immunomodulatory medications. Therefore, we sought to determine the incidence rate and patient characteristics predictive of malignancy in a large observational cohort of patients with PsA, the CORRONA registry.

Methods: We included all patients with a diagnosis of PsA followed by CORRONA from 8/2003 to 8/2010. Patients with a previous history of malignancy and those with less than two CORRONA study visits for PsA were excluded. All cases of malignancy reported at CORRONA visits underwent an independent medical record review by two study investigators, and only confirmed cases were included in the analysis. Malignancy incidence rates with 95% confidence intervals were calculated. We then used Poisson regression models to determine patient specific variables predictive of first malignancy.

Results: Of the 4428 patients enrolled in CORRONA, 2977 (mean age 51.2 ±12.5 years, 51.7% female) were eligible for our analysis, with 40 confirmed cases of malignancy during a total of 7156 patient-years of follow-up. The overall incidence rate (IR) of malignancy was 5.59 (95% CI 3.99–7.61) per 1000 patient years of follow-up, as compared to an IR of 5.44 (95% CI 4.56–6.32) in the RA CORRONA cohort[1]. The IR of lymphoma was 0.42 (95% CI 0.086–1.23) and of non-melanoma skin cancer was 2.10 (95% CI 1.17–3.46), versus 0.70 (95% 0.39–1.02) and 1.89 (95% CI 1.37–2.41) respectively in the RA CORRONA cohort[1]. Incidence rates by cancer type are summarized in Table 1. In our Poisson regression model, both older age of onset of PsA ($p<0.001$, IRR=1.06, 95% CI 1.03–1.09) and longer disease duration ($p<0.001$, IRR=1.07, 95% CI=1.03–1.11) were predictive of first malignancy. CDAI and history of either methotrexate or anti-tumor necrosis factor use were not significant predictors.

Table 1. Incidence of Malignancy in CORRONA PsA Cohort

Cancer type	Events	IR per 1000 patient years (95% CI's)
All cancers	40	5.59 (3.99, 7.61)
Non-Melanoma Skin Cancer (NMSC)	15	2.10 (1.17, 3.46)
All cancers excluding NMSC	25	3.49 (2.26, 5.16)
Solid	20	2.80 (1.71, 4.32)
Hematologic	5	0.70 (0.23, 1.63)
Breast	7	1.94 (0.78, 4.00)
Prostate	3	0.85 (0.18, 2.49)
Lymphoma	3	0.42 (0.086, 1.23)
Colorectal	3	0.42 (0.086, 1.23)
Melanoma	3	0.42 (0.086, 1.23)

Conclusion: This is the first study to investigate malignancy incidence in a large U.S. cohort of patients with PsA. The incidence rate of malignancy in PsA patients appears similar to patients with Rheumatoid Arthritis in the CORRONA registry, and future analysis is planned to formally compare incidence rates between these two groups and with U.S. general population databases. Both older age of onset of PsA and longer disease duration were independent risk factors for development of malignancy in this Psoriatic Arthritis cohort.

Hand Bone Loss in Patients with Psoriatic Arthritis: Sub Analysis From IMPACT-2 Study Comparing Infliximab and Placebo. Mari Hoff[1], Arthur Kavanaugh[2] and Glenn Haugeberg[3]. [1]PhD, Trondheim, Norway, [2]University of California San Diego, San Diego, CA, [3]PhD, Kristiansand, Norway

Background/Purpose: The hallmark of bone involvement in rheumatoid arthritis (RA) is bone loss presenting on X-rays as erosions and periarticular osteoporosis, both features driven by osteoclast activation. In contrast, X-ray changes in psoriatic arthritis (PSA) can include both new bone formation and bone destruction, indicating that both osteoblasts and osteoclasts are activated. In RA, anti-TNF treatment has been shown to reduce the rate of hand bone loss. To our knowledge there are no data on the effect of anti-TNF treatment on hand bone loss in PsA. The objective was to examine changes in hand bone loss at 24 and 54 weeks in patient with PsA treated with infliximab or placebo.

Methods: The IMPACT study compared the efficacy of infliximab (INFX) to placebo (PLA) in patients with PSA [1]. Patients with persistent disease activity could enter early escape at week 16, and all remaining placebo patients crossed over to infliximab at week 24. The present sub analyses included a subset of 37 patients from the 60 patients with the

largest radiographic changes at 24 weeks, equally divided according to treatment and positive/negative X-ray changes. Hand bone loss was assessed by digital X-ray radiogrammetry bone mineral density (DXR-BMD), calculated from digitized radiographs (Sectra, Sweden) [2]. DXR-BMD percentage change from baseline to 24 and 52 weeks was evaluated. Non-parametric group comparisons and correlation analyses were performed.

Results: Mean age was 46.8 yrs, 42% were females and mean disease duration was 8.1 yrs. 53% were using methotrexate and 13% oral steroids at baseline. Patients had a high disease activity with mean CRP of 3.47 mg/dl. The median changes in DXR-BMD for all patients were −0.38% at 24 weeks (N=37) and −0.04% at 54 weeks (N=26). While stratifying for treatment there was a suggestion at 24 weeks that the infliximab group lost less bone than the placebo group (−0.24% INFX vs. −0.50% PLA, p=0.50) while at 54 weeks there was greater difference in DXR-BMD change between the two groups (+0.41 % INFX vs. −0.51% PLA, p=0.06). In the placebo group, four patients went trough early escape. There were no significant correlation between radiographic change and DXR-BMD loss at 24 weeks (r= 0.02, p=0.90) or at 54 weeks (r=−0.04, P=0.87).

Conclusion: Our data indicate that hand bone loss in PsA patients treated with anti-TNF is not only arrested but may in fact ameliorate. These findings are in contrast to what has been reported in RA where bone loss only has been shown to be reduced. The results from our study support the hypothesis that both osteoclasts and osteoblasts are involved in the pathophysiological mechanisms of bone involvement in PsA.

511

Early Disease Characteristics of Enthesitis-Related Arthritis Reveals Elevated TGF-Beta. Hemalatha Srinivasalu[1], Michael Barnes[2], Gerlinde Layh-Schmitt[3], Michael M. Ward[4] and Robert A. Colbert[3]. [1]NIAMS NIH, Nemours/Alfred I duPont Hospital for Children, Bethesda, MD, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]NIAMS NIH, Bethesda, MD, [4]NIAMS/NIH, Bethesda, MD

Background/Purpose: Enthesitis-related arthritis (ERA) is a subtype of Juvenile idiopathic arthritis (JIA) as defined by ILAR. Most ERA cohorts have been established retrospectively, and consequently there is a paucity of data on early disease characteristics of ERA. The purpose of this study was to examine an inception cohort of ERA and determine correlation between serum cytokine levels and disease manifestations.

Methods: Thirty-seven patients who satisfied ILAR criteria for ERA were included in the study. At their baseline visit, information about demographics, active joint & enthesis count, Schober, presence of eye disease, family history of HLA-B27-associated disease, CHAQ score, physician global, lab analyses including CBC, ESR, CRP, HLA-B27, ANA, RF and imaging studies when indicated, were collected. Serum collected at the baseline visit from patients and healthy controls were analyzed by ELISA for IL-22, IL-23, GM-CSF, IFN-gamma, IL-6, IL-10, IL-12p70, MCP-1, TNF-alpha, G-CSF, IL-17, IP-10, MIP-1alpha and TGF-beta1. Mann-Whitney U tests, one-way ANOVA, and Tukey's multiple comparison tests were performed for statistical analyses.

Results: The median interval from disease onset to enrollment was 5.4 months (IQR 2.05–9.8). Seventy eight percent were males, median age 12 years (IQR 10.15–13.65) and 89% were Caucasian. Positivity of HLA-B27 was 59% (19 of 32 tested) and that of ANA was 25% (4 of 16 tested). The median ESR was 8 (IQR 4–17), CRP 0.3 (IQR 0.3–0.7). The median active joint count was 1 (IQR 0–4) and the median enthesis count was 4 (IQR 2–6). One patient had acute anterior uveitis. Radiological evidence of arthritis was present in 35% of patients; only one patient had sacroiliitis. One patient (2.7%) had back pain and 2 patients (5.4%) had SI joint pain. Ninety three percent of patients were on NSAIDs and 33% had GI complaints at their baseline visit. There was a prior history of joint injection in 27% of patients and a family history of HLA-B27-associated disease in 16% of patients. Levels of IL-22 were lower in ERA patients compared with controls (p=0.0397). TGF-beta1 was elevated in ERA patients compared to controls (p=0.0075). Further, levels of TGF-beta1 were significantly elevated in patients with a history of GI complaints when compared to healthy controls (p=0.0082) and when compared to patients without GI complaints ($p<0.05$). Levels of TGF-beta1 were elevated in patients without arthritis when compared to controls ($p<0.05$). There was no difference in TGF-beta1 levels on comparing patients by presence of enthesitis, HLA-B27 status and inflammatory markers.

Conclusion: This study informs us on the early disease characteristics of ERA. TGF-beta1 has been reported to be elevated in the serum of patients with ankylosing spondylitis. To our knowledge, this is the first study reporting elevation of serum TGF-beta1 in patients with ERA. This finding correlates with earlier studies we have published on evidence for a TGF-beta1 peripheral blood gene expression signature in ERA patients. Additionally, TGF-beta is known to be elevated in chronic gut inflammation; its elevation in patients with GI complaints seen in our cohort suggests a role of gut inflammation in early ERA.

512

Clinical Predictors Associated with Severe Radiographic Sacroilitis in Axial Spondyloarthritis. Grace Yoon[1], Thomas J. Learch[2], John C. Davis[3] and Lianne S. Gensler[4]. [1]UCSF, San Franciscao, CA, [2]Cedars-Sinai, Los Angeles, CA, [3]Genentech Inc, South San Francisco, CA, [4]UCSF, San Francisco, CA

Background/Purpose: Sacroilitis is the hallmark radiographic feature of Axial Spondyloarthritis (ASpA). To date, there has been little published on the predictors of radiographic severity of sacroilitis. The objective of this study was to determine if there were clinical predictors of severe sacroilitis, as defined by completely fused sacroiliac joints (grade 4 according to the New York classification scale).

Methods: We studied 151 consecutive ASpA subjects who met Assessment of SpondyloArthritis (ASAS) criteria for axial SpA. All subjects underwent radiographic imaging using the anterior-posterior pelvis view. Right and left sacroiliac joints were scored by 2 of the investigators (LG, TL). The average of the scores was then calculated and used in the analysis. Forty two patients were found to have bilateral grade 4 sacroilitis and 109 patients were calculated to have less than grade 4 sacroilitis. Demographics and clinical variables were collected at the time the radiograph was obtained. Statistical analysis was performed using the student t-test and wilcoxan ranksum for continuous variables and a chi-square analysis for dichotomous variables. A multivariate logistic regression was performed adjusting for age and gender.

Results: Severe sacroilitis was significantly associated with non-Caucasian ethnicity, disease duration and a history of total hip arthroplasty. Having a first degree relative with Ankylosing Spondylitis (AS) was also a predictor of severe sacroilitis as was smoking tobacco as measured by pack years (Table 2).

Table 1. Univariate Analysis

Predictor	Sacroilitis < grade 4 (n = 109)	Sacroilitis = grade 4 (n = 42)	P value
Age (years)	37.7 ± 10.0	41.9 ± 13.2	.16
Gender (% male)	64	79	.09
Ethnicity (% non-Caucasian)	**34**	**57**	**.009**
% Modified NY criteria	64	100	<.0001
Disease duration (years)	**13.3 ± 9.8**	**20.1 ± 11.4**	**.0007**
HLA B27 positivity (%)	81	89	.25
Age at onset	**24.4 ± 9.3**	**21.8 ± 8.5**	**.05**
History of Uveitis (%)	47	40.5	.46
History of peripheral symptoms (%)	58	49	.32
Total hip arthroplasty (%)	**3**	**14**	**.008**
Family history of AS in a first degree relative (FDR) (%)	**10**	**32**	**.002**
On biologic (%)	31	41	.28
Smoking (pack years)	**1.4 ± 4.3**	**6.2 ± 12.8**	**.04**
Employed (%)	83	73	.19
Education (years)	16.6 ± 2.5	15.2 ± 3.9	.1
BASDAI (0–100)	37.3 ± 24.6	38.3 ± 20.5	.67
Inflammation score (0–100)	41.3 ± 31	33.1 ± 24.5	.2
ASDAS (ESR)	15 ± 10.3	14 ± 8.1	.85
ASDAS (CRP)	14.1 ± 9.52	13.8 ± 8.4	.99
BASFI (0–100)	**23.3 ± 24.3**	**33.4 ± 26**	**.02**
ESR (mm/hour)	15.9 ± 20.9	17.3 ± 16.6	.29
CRP (g/dL)	**6.7 ± 12.3**	**9.9 ± 11.4**	**.006**

Table 2. Multivariate Logistic Regression (after adjustment for age and gender)

Predictor	Odds ratio	P value	95% Confidence Interval
Non-Caucasian ethnicity	3.3	.02	1.26; 8.79
Disease duration	1.07	.05	1; 1.13
Total hip arthroplasty	27.9	.0004	2.84; 274.3
Family history of AS (in a FDR)	4.65	.01	1.44; 15
Smoking (pack years)	1.13	.006	1.04; 1.23

Conclusion: Severe radiographic sacroilitis appears to be associated with predictable characteristics like disease duration and total hip arthroplasty, but also appears to be associated with less reported characteristics such as familial AS and tobacco use. Smoking may be a modifiable risk factor for the development of severe radiographic AS.

513

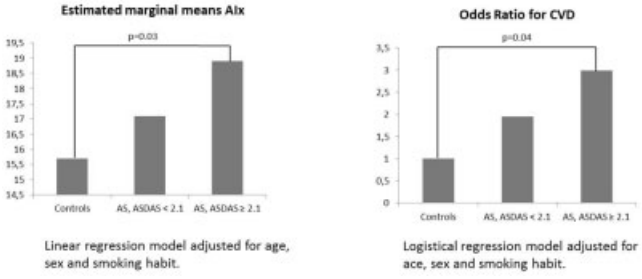
Increased Risk of Cardiovascular Disease in Patients with Active Ankylosing Spondylitis. Inger Jorid Berg[1], Sella Provan[2], Hanne Dagfinrud[3], D.M.F.M. van der Heijde[4], Tore K. Kvien[3] and Anne Grete Semb[3]. [1]Diakonhjemmet Hospital, 0319 Oslo, Norway, [2]Diakonhjemmet hospital, Oslo, Norway, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: The increased risk of cardiovascular disease (CVD) in inflammatory joint diseases cannot be explained by traditional risk factors. There are studies suggesting a higher risk of CVD in patients with ankylosing spondylitis (AS). The aim of this study was to compare prevalence of established CVD and levels of Augmentation Index (AIx), a surrogate marker of CVD risk, between a cohort of AS patients and a population control group and to evaluate the influence of disease activity measured by the ankylosing spondylitis disease activity score (ASDAS).

Methods: In 2008–2010 161 patients from the Oslo area with AS and 134 controls were examined. The AS patients were evaluated as a part of the 5-year longitudinal follow-up of a cohort of hospital-recruited patients diagnosed according to the New York classification criteria. The control population was randomly selected by Statistics Norway. AIx estimation, measuring arterial stiffness, was performed using the Sphygmocor apparatus. The ASDAS score was calculated using the appropriate BASDAI questions and CRP levels. The ASDAS cutoff was set at 2.1 dividing patients into low-moderate and high-very high disease activity. Statistical analyses were performed in SPSS 17.0 using bivariate tests as appropriate. Validity of the results was confirmed in logistical and linear regression models adjusted for age, sex and smoking habits.

Results: The groups were comparable regarding demographic data (AS vs. controls): age (50.7 vs. 52.6 p=0.17), gender/male (61.9% vs. 58.5% p=0.52) and smoking (56.4% vs. 60.4% p=0.48), but as expected there were significant differences regarding ESR (16 vs. 8 p<0.001) and CRP (3 vs.1 p<0.001). Total cholesterol was significant lower in the AS group compared to controls: (mean±SD) 5.41± 1.12mmol/l vs. 5.75±0.96mmol/l p=0.008. In subgroup analyses AIx was significantly higher in the high-very high ASDAS compared to controls 19 (CI 16.9–21.0) vs16 (CI 14.7–17.6). Odds ratio for CVD was 3.0 (CI 1.04–8.62) in high-very high ASDAS compared to controls. The subgroup analyses are presented in Figure 1.

Figure 1
Levels of AIx and OR for CVD compared across AS disease activity, measured by ASDAS, and population controls.



Linear regression model adjusted for age, sex and smoking habit.

Logistical regression model adjusted for ace, sex and smoking habit.

Conclusion: We found significantly higher odds ratio (OR) for established CVD among patients with active AS despite the total AS group having significantly lower total cholesterol. The increased risk of CVD was further confirmed by a significantly increased AIx in patients with high ASDAS. The results indicate that there might be a higher risk of CVD in AS patients with the most active disease.

514

Differences Between Women and Men with Recent Onset Axial Spondyloarthritis: Results From the DESIR Cohort. Anne Tournadre[1], Bruno Pereira[1], Agnes Lhoste[1], Jean Jacques Dubost[1], Jean Michel Ristori[1], Pascal Claudepierre[2], Maxime Dougados[3] and Martin Soubrier[1]. [1]CHU CLERMONT-FERRAND, Clermont-Ferrand, France, [2]Paris-Est University; LIC EA4393; APHP, Henri Mondor Hospital, Creteil, France, [3]Paris-Descartes University, Medicine Faculty; UPRES EA-4058; APHP, Cochin Hospital, Paris, France

Background/Purpose: To characterize clinical and imaging differences between men and women with early axial spondyloarthritis (SpA).

Methods: 708 patients with recent inflammatory back pain and possible diagnosis of SpA were included in the DEvenir des Spondylathropathies Indifférenciées Récentes (DESIR) cohort, a prospective longitudinal multicentric cohort in France. Clinical and imaging features between men and women fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axial SpA were compared using univariate analysis. Significant variables in univariate analysis were re-tested as dependent variables in multivariate regression models adjusted for age.

Results: The table shows significant differences (p values < 0.05) between men and women with SpA according ASAS classification criteria. Mean duration of axial symptoms, HLA B27 status, response to NSAID, history or current symptoms suggestive of peripheral joint arthritis, presence of enthesiopathy, extraarticular involvement, spinal mobility assessed by the the Bath Ankylosing Spondylitis Metrology Index, and the Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) were not different.

Table. Comparison of baseline characteristics between men and women with SpA. (mean ± SD or % of patients)

	Men (n=239)	Women (n=236)	p-value
age (years)	31.92 ± 8.4	34.05 ± 8.7	<0.05
BASG	45 ± 2.6	52.5 ± 2.65	0.004
BASDAI	39.59 ± 20.44	46.52 ± 19.87	<0.001
BASDAI fatigue	49.7 ± 0.15	60.8 ± 0.15	<0.001
Intensity of axial pain (NRS*)	4.25 ± 2.8	5.18 ± 2.76	0.001
Intensity of peripheral joint pain (NRS*)	2.78 ± 2.76	3.32 ± 2.81	<0.05
Localization of symptoms to cervical spine	29.3%	44.1%	<0.05
Localization of symptoms to buttock	69.9%	79.7%	<0.05
BASFI	26.84 ± 21.23	32.66 ± 23.28	<0.05
SF-36 Mental Health score	55.06 ± 21.35	47.9 ± 19.72	0.001
SF-36 Physical Health score	52.58 ± 21.03	45.16 ± 19.20	<0.001
HAQ-AS	0.47 ± 0.39	0.61 ± 0.44	<0.001
AS-Qol	7.96 ± 4.99	10.23 ± 4.79	<0.001
Radiological sacroiliitis (Obvious change and/or fusion)	45.1%	32.9%	<0.05
MRI inflammatory lesions of the sacroiliac joints	58.9%	40.3%	<0.001
MRI inflammatory lesions of the spine:			
− Lumbar spine	−23.3%	−9.9%	<0.001
− Thoracic spine	−27%	−10.9%	<0.001
− Cervical spine	−6.1%	−2.3%	<0.05

* NRS, numerical rating scale

Conclusion: Women with early axial SpA according to ASAS classification criteria had less radiological and MRI abnormalities than men despite higher functional impairment. Differences in the disease expression in women may be confounding factors to establish the diagnosis of SpA and to assess the disease activity.

515

Poor Agreement Between Enthesitis on Whole-Body Magnetic Resonance Imaging and Enthesitis on Clinical Examination in Patients with Early Axial Spondyloarthritis—Results From the ESTHER Trial At Baseline. In-Ho Song[1], Kay-Geert Hermann[2], Hildrun Haibel[1], Christian Althoff[2], Denis Poddubnyy[1], Joachim Listing[3], Anja Weiβ[3], Bruce Freundlich[4], Martin Rudwaleit[5] and Joachim Sieper[1]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Charite Medical School, Berlin, Germany, [3]German Rheumatism Research Centre, Berlin, Germany, [4]University of Pennsylvania, Philadelphia, PA, [5]Ev. Krankenhaus Hagen-Haspe, Hagen, Germany

Background/Purpose: In patients with early axial spondyloarthritis (SpA) with a disease duration of < 5 years to assess the agreement between enthesitis on whole-body magnetic resonance imaging (MRI) and enthesitis by clinical examination.

Methods: At baseline 76 patients with early axial SpA were examined for enthesitis by clinical examination and by whole-body MRI. The following 7 enthesitis sites were assessed by MRI (M) and clinical examination (C): manubriosternal synchondrosis (M)/ first costosternal joint (C) (1 site), lower rip insertions at the sternum (M)/ 7th costochondral joints (C) (2 sites, each left and right), pelvic rim (M)/ iliac crest (C) (2 sites, each left and right), proximal insertion of Achilles tendon/ plantar fascia (M/C) (2 sites, each left and right). Kappa values were calculated to assess agreement between MRI findings and clinical examination. MRI enthesitis assessment was performed by two radiologists in consensus approach.

Results: By clinical enthesitis assessment in the above described locations 108 enthesitic sites were found in 40 out of 76 (60.5%) patients. The most frequently affected location was the iliac crest (45 sites in 30 patients) followed by the 7th costosternal joint (26 sites in 16 patients), the insertion of the Achilles tendon/plantar fascia (22 sites in 14 patients) and the 1st costosternal joint (15 sites in 15 patients) (table 1).

Table 1.

MRI enthesitis location	Clinical examination enthesitis location	Number of positive enthesitic sites on MRI	Number of positive enthesitic sites on clinical examination	Agreement*
Synchondrosis manubriosternalis	First Costosternal joint	3 sites in 3 patients	15 sites in 15 patients	1
Lower rip insertions at the sternum (Rip)	Seventh Costosternal joint	Right: 0 sites in 0 patients	11 sites in 11 patients	0
		Left: 0 sites in 0 patients	15 sites in patients	0
		Both: 0 sites in 0 patients	26 sites in 16 patients	0
Pelvic rim (Bec)	Crista iliaca/ Spina iliaca anterior superior/Spina iliaca posterior superior	Right: 1 site in 1 patient	23 sites in 23 patients	1
		Left: 1 site in 1 patient	22 sites in 22 pts	0
		Both: 2 sites in 1 patient	45 sites in 30 patients	1
Achilles tendon insertion (Ach)	Prox. Achilles tendon insertion	Right: 2 sites in 2 patients	9 sites in 9 pts	0
		Left: 2 sites in 2 patients	13 sites in 13 pts	1
		Both: 4 sites in 3 patient	22 sites in 14 patients	1

* 1= yes, 0= no.

Of MRI examination in the above described locations 9 enthesitic sites were found in 6 out of the 76 patients. The most frequently affected sites were the manubriosternal synchondrosis (3 sites in 3 patients), followed by the Achilles tendon insertion (4 sites in 3 patients).

67 out of 76 patients scored the enthesitis question (BASDAI question 4) of the BASDAI ≥1.

The kappa values in terms of single enthesitic sites between MRI and clinical examination was only 0.038. The kappa value on a patient level was also only −0.011. Kappa between clinical examination and self-assessment by BASDAI question 4 was 0.1. In all patients enthesitic only 3 enthesitic sites were found to be positive in both by MRI and clinical examination at the same time.

Conclusion: Clinical and MRI enthesitis was found in 52.6% and 7.9% of patients in the above mentioned enthesitis sites with early axial SpA, respectively. The agreement between clinical and MRI enthesitis assessment was poor.

516

Difference in Clinical Presentation of Patients with Spondyloarthritis with a Positive MRI of the SI Joints and/or HLA-B27 Positivity. R. van den Berg, M. Reijnierse, T.W.J. Huizinga and D.M.F.M. van der Heijde. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: The SPondyloArthritis Caught Early (SPACE)-cohort is set-up in the Leiden University Medical Center (LUMC) aiming to diagnose and treat patients with axial spondyloarthritis (SpA) early. Unlike previous criteria sets, the new ASAS axial SpA criteria rely importantly on the presence of active MRI abnormalities of the SI-joints and on HLA-B27 positivity. The goal is to investigate the difference in presentation of patients with an abnormal vs. a normal MRI of the SI-joints and presence vs. absence of HLA-B27.

Methods: All patients with back pain (>3 months, but <2 years; onset <45 years) were included and underwent a diagnostic work-up; MRI and X-rays of the SI-joints and laboratory assessments. All patients were classified according to various classification criteria (ESSG, Amor, ASAS axial SpA, and modified New York criteria). A comparison was made between the patients presenting with a positive vs. a negative MRI of the SI-joints; and between HLA-B27 positive and HLA-B27 negative patients.

Results: In 6/133 patients no MRI was made and they were excluded from further analyses. 3/38 patients not fulfilling any classification criteria set had a positive MRI as only SpA-feature, and 2/38 had only one other SpA-feature in addition to HLA-B27 positivity. The remaining 95 patients fulfilled one or more classification criteria sets. Male patients had more frequently sacroiliitis on MRI than female patients (p=0.04), but were not more frequently HLA-B27 positive (p=0.27). Sacroiliitis on X-ray was more frequently present in patients with MRI+ than in patients with MRI- (p<0.001). Therefore, more patients in the MRI+ group fulfilled the modified New York criteria than in the MRI- group (p=0.003). HLA-B27+ patients had more frequently a positive family history and a history of uveitis than HLA-B27- patients (p<0.001 and p=0.01 respectively). Also, more HLA-B27+ patients fulfilled the ESSG and Amor criteria than HLA-B27- patients (p=0.03 and p=0.004 respectively). The distribution of other SpA-features and the level of disease activity among MRI+ and MRI- patients, and among HLA-B27+ and HLA-B27- patients was remarkably similar (table 1).

Variable	MRI+ group N=28 vs MRI− group N=99		HLA-B27+ group N=42 vs HLA-B27− group N=85	
Male, N (%)	***14 (50.0)***	***29 (29.3)***	17 (40.5)	26 (30.6)
Age (years) onset back pain, mean ± SD	32.5 ± 8.5	29.2 ± 8.9	27.9 ± 8.3	30.0 ± 9.0
Duration (months) back pain, mean ± SD	15.0 ± 7.1	13.1 ± 7.5	12.6 ± 7.6	14.0 ± 7.3
HLA-B27 positive, N (%)	11 (39.3)	31 (31.3)	–	–

Good response to NSAIDs, N (%)	9 (32.1)	31 (31.3)	14 (33.3)	26 (30.6)
Elevated ESR/CRP, N (%)	5 (17.9)	18 (18.2)	10 (23.8)	13 (15.3)
Preceding infection, N (%)	0 (0.0)	4 (4.0)	2 (4.8)	2 (2.4)
Peripheral arthritis, N (%)	4 (14.3)	15 (15.2)	6 (14.0)	14 (16.7)
Psoriasis, N (%)	3 (10.7)	10 (10.1)	4 (9.5)	9 (10.6)
Alternating buttock pain, N (%)	7 (28.0)	14 (14.4)	8 (20.0)	13 (15.9)
BASDAI mean ± SD (N=126)	4.4 ± 2.2	4.5 ± 2.0	4.1 ± 2.3	4.6 ± 1.9
ASDAS mean ± SD (N=126)	2.7 ± 0.9	2.8 ± 0.9	2.6 ± 1.0	2.8 ± 0.8
ESSG, N (%)	11 (39.3)	56 (56.6)	***28 (66.7)***	***39 (45.9)***
AMOR (6 pnt), N (%)	12 (42.9)	35 (35.4)	***23 (54.8)***	***24 (28.2)***
ASAS axial, N (%)	***24 (85.7)***	***31 (31.3)***	***39 (92.9)***	***16 (18.8)***
Modified New York, N (%)	***6 (21.4)***	***4 (4.0)***	5 (11.9)	5 (5.9)

Italics are statistically significantly different.

Conclusion: The presence and distribution of SpA-features as well as the level of disease activity in MRI+ and MRI-patients and in HLA-B27+ and HLA-B27- patients is similar. Sacroiliitis on X-ray and male gender are associated with MRI positivity; a positive family history and uveitis are associated with HLA-B27 positivity. ESSG and AMOR criteria are associated with HLA-B27 positivity but not MRI+, modified New York criteria with MRI+, and ASAS axial SpA criteria with both MRI+ and HLA-B27 positivity.

Comparing 2 Referral Strategies to Diagnose Axial Spondyloarthritis: The Recognizing and Diagnosing Ankylosing Spondylitis Reliably Study. J. Sieper[1], S. Srinivasan[2], O. Zamani[3], H. Mielants[4], D. Choquette[5], Karel Pavelka[6], Anne Gitte Loft[7], P. Gehér[8], D. Danda[9], T. Reitblat[10], Fabrizio Cantini[11], C. Ancuta[12], S. Erdes[13], H. Raffayova[14], AC Keat[15], JS Hill Gaston[16] and N. Vastesaeger[17]. [1]Charitè Berlin, Campus Benjamin Franklin, Berlin, Germany, [2]Merck, Sharp & Dohme Corporation, Rahway, NJ, [3]Rheumazentrum Favoriten, Wien, Austria, [4]University Hospital, Gent, Belgium, [5]Institute of Rheumatology of Montreal, Montreal, QC, [6]1Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [7]Vejle Hospital, Vejle, Denmark, [8]Semmelweis University, Budapest, Hungary, [9]Christian Medical College, Vellore, India, [10]Barzilai Medical Centre, Ashkelon, Israel, [11]Stabilimento Ospedaliero Misericordia, Prato, Italy, [12]G.T. Popa Center for Biomedical Research, Iasi, Romania, [13]Scientific Institute of Rheumatology, Moscow, Russia, [14]National Institute of Rheumatic Diseases, Pieš □ any, Slovakia, [15]Northwick Park Hospital, Harrow, United Kingdom, [16]Univ of Cambridge/Clin Med, Cambridge, United Kingdom, [17]Merck, Sharp & Dohme Corporation, Brussels, Belgium

Background/Purpose: Improved referral from primary care (PC) allows shortening the time to diagnosis of axial spondyloarthritis (SpA), which may lead to better treatment and improved prognosis. The objective of the RecognizIng and Diagnosing Ankylosing Spondylitis Reliably(RADAR) study was to determine which of 2 referral strategies, when used by physicians for chronic back pain (CBP) patients, is superior in diagnosing definite axial SpA by rheumatologists.

Methods: Primary-care referral sites in 16 countries were randomized (1:1) to refer CBP patients to a rheumatologist according to 1 of 2 referral strategies: *Strategy I*, 1 of 3 criteria—inflammatory BP (IBP), HLA-B27+, sacroiliitis on imaging (SI); or *Strategy II*, 2 of 6 criteria—IBP, HLA-B27+, SI, family history, good response to NSAIDs, extra-articular manifestations (EAMs). The rheumatologist then established a diagnosis. The primary analysis compared the proportion of patients diagnosed with axial SpA depending on the referral strategy used. Reported are: usage of referral criteria in PC, concordance with rheumatologist, sensitivity, specificity, predictive values (PV), and likelihood ratio of the criteria to make a diagnosis.

Results: Subjects had CBP of unknown origin >3 months, onset before age 45, and no diagnosis of axial SpA or ankylosing spondylitis established yet. Strategy I was used at 135 primary-care sites to refer 504 subjects of which 35.6 were diagnosed with axial SpA. Strategy II was used at 143 primary-care sites to refer 568 subjects of which 39.8% were diagnosed with axial SpA. (For both strategies: delta: 4.40%, 95%CI: –7.09% to 15.89%, ns.) IBP was the most used referral criterion, and rheumatologist concordance was high (Table). PV for SI, HLA-B27, or EAMs judged positive by PC physicians were 72.5, 76.1, and 55.6%, respectively, and +/– 40% for other criteria. Negative PV and sensitivity of IBP judged by rheumatologists was >85%, but positive PV and specificity was <50%. NPV and/or sensitivity of any other single criterion was <80%. Analysis of alternative strategies showed that referral on 2 of 2 criteria performed poorly, whereas many 2 of 3 strategies, most of which included SI, performed well. But only the strategy with SI, HLA-B27, and IBP had sensitivity, specificity, NPV, and PPV >80%.

Referral Criteria and Rheumatologist Results

Criterion	Usage by Referring Physician			Concordance with Rheumatologist		
	Strategy 1 (%)	*Strategy 2 (%)*	*Combined (%)*	*Strategy 1 (%)*	*Strategy 2 (%)*	*Combined (%)*
SI	137 (27.2)	204 (35.9)	341 (31.8%)	90 (68.2)	120 (61.5)	210 (64.2)
HLA-B27	87 (17.3)	97 (17.1)	184 (17.2)	82 (97.6)	87 (96.7)	169 (97.1)
IBP	469 (93.1)	546 (96.1)	1015 (94.7)	376 (84.5)	425 (86.2)	801 (85.4)
EAMs		112 (19.7%)			98 (89.1)	
Family history		66 (6.2)			42 (76.4)	
NSAID response		428 (75.4)			240 (60.2)	

Conclusion: This is the first international randomized study to show that a referral strategy for CBP based on 3 criteria performs as well as one with 6 and leads to diagnosis of axial SpA in >35% of patients. IBP was nearly always used, showed good concordance with rheumatologists, and had high sensitivity and NPV. Combining IBP with other criteria such as HLA-B27 and SI increases the likelihood of diagnosis.

518

Associations Between Axial and Peripheral Signs of Ankylosing Spondylitis and the Acute Phase Response: A Prospective Longitudinal Study in 411 Patients. Siddharth Bethi[1], Abhijit Dasgupta[1], Michael H. Weisman[2], Thomas J. Learch[3], Lianne S. Gensler[4], John C. Davis[5], John D. Reveille[6] and Michael M. Ward[1]. [1]NIAMS/NIH, Bethesda, MD, [2]Cedars Sinai Med Ctr, Los Angeles, CA, [3]Cedars-Sinai, Los Angeles, CA, [4]UCSF, San Francisco, CA, [5]Genentech Inc, South San Francisco, CA, [6]University of Texas Health Science Center at Houston, Houston, TX

Background/Purpose: The value of acute phase reactants as outcome measures in ankylosing spondylitis (AS) is often questioned. Although erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels are associated with peripheral joint involvement, it is not clear if they are also associated with axial manifestations. We investigated associations between musculoskeletal exam findings and ESR and CRP in AS. The objectives were to investigate whether the acute phase response was associated with axial signs, with peripheral signs, or with both; to determine if signs were associated with ESR and CRP accounting for BASDAI; and to determine if the ESR or CRP had a stronger association with physical signs of AS.

Methods: We examined 411 patients with AS in a prospective longitudinal study at 4 centers. Patients were examined at intervals of 4 to 6 months for up to 5 years. On each visit, we scored the number of swollen and tender joints, number of tender entheses, and measured cervical rotation and lateral flexion, chest expansion, hip rotation, Schober test, and lumbar lateral flexion. ESR and CRP were measured at each visit. We tested associations between each physical exam sign and ESR and CRP longitudinally using mixed linear models, adjusted for age, gender, months from study entry, ethnicity, education level, duration of AS and examining rheumatologist. Analyses used log-transformed ESR and CRP as the dependent variables, so models estimate the % change in median ESR (or CRP) with 1 unit change in the physical exam measure.

Results: Patients (69% men; median age 40.1 years; median duration of AS 13.8 years) had a median of 3 visits (range 1–6; total visits 1620). There was substantial intra-patient variation in ESR and CRP levels. The exam feature most strongly associated with acute phase response was the swollen joint count. In patients with 3 or more swollen joints, the median ESR was 17.5% higher and the median CRP was 74.5% higher than in those with no swollen joints (table). Less hip rotation was associated with higher ESR but not CRP. Tender joint count and enthesis count were not associated with ESR or CRP. Axial signs were associated with ESR and CRP independent of peripheral signs and BASDAI. Patients with a higher chest expansion had a lower acute phase response: with every 1 cm increase in chest expansion the median ESR was 3.4% lower and CRP was 12.2% lower. Lumbar lateral flexion was associated with both ESR and CRP, while cervical flexion and Schober test were also associated with CRP. Adjusting for physical signs, neither BASDAI item was associated with ESR, but BASDAI 5+6 was associated with CRP.

Measures	% Change in median ESR	P	% Change in median CRP	P
Cervical rotation (per 10 degrees)	0.3%	0.60	3.6%	0.10
Cervical lateral flexion (per 10 degrees)	−0.6%	0.31	**−5.8%**	0.005
Occiput to wall (per cm)	−0.2%	0.53	−1.0%	0.32
Chest expansion (per cm)	**−3.4%**	<0.0001	−12.2%	<0.0001
Schober (per cm)	−0.5%	0.46	**−5.9%**	0.04
Lateral flexion (per cm)	**−1.1%**	0.003	−4.3%	0.0006
Hip rotation (per 10 degrees)	**−2.8%**	0.007	4.8%	0.29
Enthesis	−0.3%	0.57	−3.1%	0.13
Bad hip=1 vs. 0	−7.5%	0.31	−7.4%	0.75
Bad hip=2 vs. 0	−6.4%	0.41	−3.0%	0.89
Bad hip=3 vs. 0	−10.4%	0.21	13.5%	0.65
Tender joints=1 vs. 0	0.8%	0.76	−1.9%	0.88
Tender joints=2 vs. 0	−3.2%	0.31	−1.7%	0.90
Tender joints=3+ vs. 0	−1.1%	0.81	9.9%	0.53
Swollen joints=1 vs.0	2.8%	0.61	20.6%	0.24
Swollen joints=2 vs. 0	−3.0%	0.66	**56.2%**	0.03
Swollen joints=3+ vs. 0	**17.5%**	0.05	74.5%	0.02
BASDAI2	0.9%	0.12	0.9%	0.69
BASDAI 5+6	0.9%	0.17	**4.6%**	0.05

Conclusion: Acute phase response is associated with both axial and peripheral signs of AS. These associations were above and beyond patient

reported symptoms. CRP had stronger associations than ESR and was associated with more axial signs, suggesting it is the preferred measure.

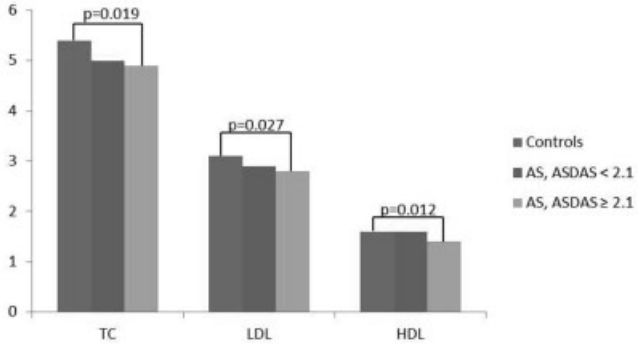
Low Lipid Levels are related to Disease activity in Ankylosing Spondylitis. Inger Jorid Berg[1], Anne Grete Semb[2], Désirée van der Heijde[3], Hanne Dagfinrud[2], Sella Provan[4] and Tore K. Kvien[2]. [1]Diakonhjemmet Hospital, 0319 Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [4]Diakonhjemmet hospital, Oslo, Norway

Background/Purpose: Despite an increased risk of cardiovascular disease in ankylosing spondylitis (AS), low lipid levels have been reported. The aim of this study was to evaluate the assosiations between disease activity measured by the AS disease activity score (ASDAS) and lipid levels.

Methods: In 2008–2010 161 patients from the Oslo area with AS and 134 controls were examined. The AS patients were evaluated as a part of the 5-year longitudinal follow-up of a cohort of hospital-recruited patients diagnosed according to the mNew York classification criteria. The control population was randomly selected by the Statistics Norway. Both groups underwent the same examinations. The ASDAS score was calculated using the appropriate BASDAI questions and CRP levels. The ASDAS cut off was set at 2.1 between low-moderate and high-very high disease activity. Statistical analyses were preformed in SPSS 17.0. Bivariate tests were used to compare the groups. Lipid levels were compared between patients and controls by linear regression models adjusted for age, sex and use of statins and the estimated marginal means were calculated.

Results: The groups were comparable regarding demographic data (AS vs controls): age (years) (50.7 vs. 52.6 p=0.17), gender/male (61.9% vs 58.5% p=0.52) and use of statins (13.5% vs 12.1% p=0.74), but levels of acute phase reactants were as expected different (ESR 16 vs. 8 p<0.001; CRP 3 vs. 1, p=0.001). In adjusted analysis atherogenic lipids were lower in the whole AS group compared to controls: Total cholesterol 5.10mmol/l (CI 4.89–5.30) vs. 5.33mmol/l (CI 5.11–5.55), p=0.05 and LDL 2.87mmol/l (CI 2.68–3.06) vs. 3.11mmol/l (CI 2.91–3.32), p=0.03, whilst there was no significant difference in HDL levels between AS and controls (1.54mmol/l (CI 1.45–1.63) vs. 1.56mmol/l (CI 1.47–1.66), p=0.73). Within the AS patients, lipid levels were lower in patients with high-very high ASDAS vs. low-moderate ASDAS. This difference was significant for HDL; 1.43mmol/l (1.31–1.55) vs. 1.61mmol/l (CI 1.48–1.64), p=0.01, but not significant for total cholesterol; 4.91mmol/l (CI 4.61–5.21) vs. 5.05mmol/l (CI 4.74–5.37), p=0.42 and LDL; 2.74mmol/l (CI 2.46–3.02) vs. 2.80mmol/l (2.51–3.09), p=0.71. The estimated marginal means lipid levels split across disease activity levels are presented in figure 1.



Conclusion: Patients with AS have lower lipids than controls. We also found a trend in the direction of lower lipid levels in patients with high disease activity measured by ASDAS.

520

Circulating Mediators of Bone Remodelling in Patients with Psoriatic and Rheumatoid Arthritis Treated with Anti-TNF-Alpha Therapy. Agnes Szentpetery[1], Harjit P. Bhattoa[2], Peter Antal-Szalmas[2], Zoltan Szekanecz[3] and Oliver M. FitzGerald[1]. [1]St. Vincent's University Hospital, Dublin, Ireland, [2]University of Debrecen, Medical and Health Science Center, Debrecen, Hungary, [3]University of Debrecen Medical and Health Sciences Center, Debrecen, Hungary

Background/Purpose: Dickkopf-1 (Dkk-1), an inhibitor of Wnt signalling, receptor activator of nuclear factor kappa B ligand (RANKL), an osteoclast differentiation factor and its soluble inhibitor osteoprotegerin (OPG) are key regulators of bone remodelling activity. Both rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are characterised by bone erosion; but bone formation is also a feature in PsA. The molecular basis of the different patterns of bone remodelling is unknown. It has been shown that TNF-alpha inhibits bone formation by up-regulating Dkk-1 and promotes osteoclastogenesis by stimulating RANKL production. The effect of anti-TNF-alpha on soluble mediators of bone remodelling in RA and PsA has not previously been compared in a prospective study design.

The aim of this study was to: (1) compare both the very early (1 month) and more long-term (12 months) effects of anti-TNF-alpha treatment on serum Dkk-1, RANKL and OPG in patients with RA and PsA; and (2) to explore associations between circulating mediators of bone remodelling and measurements of clinical parameters.

Methods: RA and PsA patients with active disease were recruited following a decision to start anti-TNF-alpha therapy. Serum was analysed for Dkk-1, RANKL and OPG by ELISA at baseline, 1 month and 12 months. Clinical assessments including ESR, CRP, and DAS28-CRP were recorded at all time points.

Results: 62 patients (35 RA, 27 PsA) were recruited. Mean disease duration was 9 years. Serum Dkk-1 and RANKL levels did not change in either RA or PsA during the course of the study. OPG levels were significantly higher at 1 year compared to 1 month in RA (p=0.03) whilst there was no significant difference in OPG observed in PsA during the study. Dkk-1 and RANKL levels were not significantly different comparing RA with PsA at any time point while Dkk-1 levels were lower at 1 year approaching significance (p=0.08). RANKL levels were lower at all time points in PsA. OPG levels were lower in PsA compared to RA at all time points with a significant reduction at 1 year (p=0.01). OPG/RANKL ratio reflecting remodelling balance was similar and did not change significantly in either RA or PsA during the course of the study.

OPG levels were correlated with ESR (r=0.42, p=0.04) and CRP levels (r=0.46, p=0.02) at baseline in PsA, whilst OPG levels were associated with ESR (r=0.43, p=0.04) and CRP (r=0.46, p=0.03) at 1 year in RA. No correlations were found between Dkk-1 and RANKL and markers of disease activity.

Conclusion: This study indicates differences in the regulation of bone remodelling between RA and PsA. Dkk-1 and RANKL levels may be lower in PsA consistent with both the fewer erosions and the accelerated bone formation seen in this disease. OPG, but not Dkk-1 and RANKL, is associated with markers of systemic inflammation in RA and PsA but increases further with effective treatment in RA suggesting that there is uncoupling between factors that drive inflammation and those responsible for erosive change.

521

Spondyloarthritis: A Clinical Comparison Between Men and Women. Jacqueline E. Paramarta, Leen E. De Rycke, Carmen A. Ambarus, Paul P. Tak and Dominique L. Baeten. Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Many studies report a male predominance in ankylosing spondylitis (AS), the most prevalent and typical form of spondyloarthritis (SpA). As AS represents only part of the SpA spectrum, an alternative explanation is that the disease has no gender bias but is less typical or severe (including progression towards new bone formation) in females. With the recent treatment advances it becomes increasingly important to recognize also less typical presentations as early as possible in the disease course. The aim of this study was to assess whether gender affects the clinical presentation of SpA in terms of prevalence, symptoms and severity.

Methods: 175 patients presenting on a dedicated SpA outpatient clinic fulfilling the European Spondyloarthropathy Study Group (ESSG) criteria were recruited in a prospective inception cohort. The patient's and physician's global assessment of disease activity visual analogue scale (VAS), Bath Ankylosing Spondylitis Disease Activity (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), 68 swollen and tender joint count, Schober, ESR and CRP were measured. Parametric tests were used for normally distributed data and non-parametric tests for non-normally distributed data.

Results: The demographic and clinical characteristics are shown in Table 1. The cohort included 93 men and 82 women, who had a comparable age and disease duration. The prevalence of the SpA subtypes AS, undifferentiated

spondyloarthritis (USpA), inflammatory bowel disease related SpA (IBD-SpA) and reactive arthritis (ReA) was not significantly different between men and women. Only psoriatic arthritis (PsA) was significantly more common in men (32% vs. 18%). Classification into axial versus peripheral SpA showed no gender difference as axial disease was more common in both genders. Also HLA-B27 positivity (47% and 48%, respectively) and sacroiliitis on conventional X-ray (61% and 56%, respectively) were similar in males and females. The BASDAI (4.3 in men and 5.3 in women) and ESR (7 mm/h in men and 14 mm/h in women) were slightly but significantly higher in females. The other disease activity parameters were comparable. This trend towards higher disease activity in women was found in all SpA subtypes. Accordingly, anti-TNF therapy was more often initiated in women (39%) than in men (26%) during follow-up.

Table 1. Demographic and clinical characteristics

	Men (n=93)	Women (n=82)	*P*
Age, mean (SD) years	44.1 (12.3)	45.5 (13.2)	NS
Age at disease onset, median (range) years	34.0 (9.1–62.1)	38.6 (17.2–75.6)	NS
Disease duration, median (range) years	4.0 (0.0–46.8)	3.0 (0.0–31.1)	NS
AS, %	46.2	37.8	NS
PsA, %	32.3	18.3	0.035
USpA, %	18.3	28.0	NS
ReA, %	3.2	0.0	NS
IBD-SpA, %	11.8	22.0	NS
HLA-B27 positive, %	47.1	47.9	NS
Inflammatory back pain, %	74.2	81.7	NS
Peripheral arthritis, %	60.2	57.3	NS
Sacroiliitis low grade, %	15.1	17.1	NS
Sacroiliitis high grade, %	46.2	39.0	NS
Patient's global assessment VAS, median (range)	48 (0–98)	57.5 (4–100)	NS
Physician's global assessment VAS, median (range)	38.5 (2–90)	42.5 (1–81)	NS
BASDAI, median (range)	4.3 (0.0–8.5)	5.3 (0.4–9.2)	0.011
BASDAI ≥4, %	53.3	70.5	0.023
ASDAS <1.3 (inactive disease), %	23.7	20.3	NS
1.3≤ ASDAS <2.1 (moderate disease activity), %	32.9	18.8	NS
2.1≤ ASDAS≤3.5 (high disease activity), %	42.1	57.8	NS
ASDAS >3.5 (very high disease activity), %	1.3	3.1	NS
Swollen joint count, median (range) 0–66 joints	0 (0–26)	0 (0–8)	NS
Tender joint count, median (range), 0–66 joints	0 (0–34)	0 (0–21)	NS
Schober, mean (SD) centimetres	4.1 (1.3)	3.8 (1.0)	NS
ESR, median (range) mm/h	7 (1–55)	14 (2–61)	0.001
CRP, median (range) mg/l	2.6 (1.0–73.6)	4.0 (1.0–209.3)	NS

Conclusion: Gender does not profoundly affect the clinical presentation of SpA, with exception of a male predominance in the PsA subtype and slightly higher disease activity in females. These data emphasize the need for early diagnosis and adequate treatment of SpA independently of the gender of patients.

522

Evidence for a Link Between Inflammation and Radiographic Progression in Ankylosing Spondylitis. Nigil Haroon[1], Nathalie Morency[2], Richard J. Cook[3], Ker-Ai Lee[3], Stephanie Wichuk[2], Proton Rahman[4], Dafna D. Gladman[1], Robert D. Inman[1] and Walter P. Maksymowych[2]. [1]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [2]University of Alberta, Edmonton, AB, [3]University of Waterloo, Waterloo, ON, [4]St. Claires Mercy Hospital, St. Johns, NF

Background/Purpose: Controversy exists as to the possible link between inflammation and the development of radiographic progression in ankylosing spondylitis (AS). Studies of tumor necrosis factor (TNF) blockers have shown no impact while prospective cohort data have as yet not shown consistent associations between markers of inflammation and progression. Imaging data suggest that new bone may develop following resolution of inflammation with TNF blockers. This hypothesis formed the basis for this prospective analysis aimed at assessing not only baseline CRP but also the change in CRP following TNF blocker therapy as a predictor of radiographic progression over 2 years in patients with SpA.

Methods: The Spondyloarthritis Research Consortium of Canada (SPARCC) cohort comprises patients with AS followed prospectively with clinical and radiographic outcomes. Readers scored X-rays obtained at baseline and year 2 using the mSASSS method. Pre-specified dependent variables were: 1) change in mSASSS >0 and >2 units from baseline through 2 years, 2) development of new syndesmophytes at year 2, 3) spur and ankylosis score (SAS: score for ankylosis = 3 and spur = 2 per vertebral corner). Multivariate analyses were controlled for age, sex, disease duration, biologic treatment, and baseline radiographic score.

Results: Baseline and 2-year radiographs were available on 241 patients with AS according to the modified New York criteria. Mean (SD) age was 40.5 (13.3) years, males 81.1%, mean (SD) disease duration 20 (11.2) years), 48.9% received TNF blockers, and 51.1% received standard therapies. At baseline, mean (SD) mSASSS was 15.1 (20.7) and mean (SD) SAS was 12.3 (20.7). Mean (SD) change in mSASSS and SAS over 2 years was 1.8 (3.8) and 1.9 (4.9), respectively, 20.6% had mSASSS progression > 2 units, and 28.6% developed ≥1 new syndesmophyte. The mean (SD) baseline and 2-year CRP were 13.85 (20.6) and 7.11 (12.5) respectively. The mean (SD) 2-year change in CRP in the standard therapy group was −1.69 (11.56) and −11.02 (26.12) in those on TNF blockers (p = 0.0023). Multivariate linear regression analysis with either the mSASSS or the SAS as dependent variable showed that both CRP and 2-year reduction in CRP were independent predictors of progression in patients receiving TNF blocker therapy but not in patients on standard therapies (Table).

	Dependent variable	Multivariate Full Model Est	95%CI	P value
Baseline CRP	**SAS**	0.18	0.04, 0.31	0.01
Δ CRP	**SAS**	0.20	0.04, 0.36	0.01
Baseline CRP	**mSASSS**	0.15	0.02, 0.27	0.02
Δ CRP	**mSASSS**	0.14	−0.03, 0.29	0.05

Conclusion: Our data not only support a link between inflammation, as measured by CRP, and radiographic progression but are also consistent with the hypothesis that progression may follow resolution of inflammation.

Serum Levels of Adiponectin and Insulin Resistance Are Increased in Patients with Psoriatic Arthritis Compared to Those with Psoriasis Alone. Lihi Eder[1], Remy Pollock[1], Fawnda Pellett[2], Jai Jayakar[3], Arane Thavaneswaran[1], Daniel Pereira[2], Cheryl Rosen[2], Vinod Chandran[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]University of Western Ontario, London, ON

Background/Purpose: The metabolic syndrome (MetS), a cluster of metabolically interrelated cardiovascular and diabetic risk factors, has become a major public health challenge worldwide. The prevalence of MetS is higher in patients with Psoriatic Arthritis (PsA) and psoriasis compared to healthy controls. The aim of this study was to compare the levels of biomarkers related to the MetS in patients with PsA and cutaneous psoriasis without arthritis (PsC).

Methods: This cross-sectional study included two groups of patients: those with PsA who met the CASPAR criteria and patients with PsC who were diagnosed by a dermatologist. All patients with PsC were assessed by a rheumatologist to rule out inflammatory arthritis. The presence of MetS was determined according to the IDF criteria[1]. Fasting serum levels of insulin, adiponectin and leptin were measured. The HOmeostasis Model Assessment for Insulin Resistance (HOMA-IR) was calculated as follows: [fasting insulin (μU/ml) × fasting glucose (mmol/L)]/22.5. Information about smoking status, alcohol consumption and psoriasis activity (by Psoriasis Area and Severity Index (PASI)) was collected. HOMA-IR, adiponectin and leptin were log-transformed. Continuous variables were compared using the t-test and Chi square test was used for discrete variables. Multivariate regression models were used to compare the association of MetS, adiponectin and HOMA-IR with PsA compared to PsC after adjusting for age, gender, race, use of Disease Modifying Anti-Rheumatic Drugs (DMARDs), anti-TNFα agents, alcohol consumption, smoking and PASI score.

Results: 251 PsA and 173 PsC patients were analyzed. Their mean age

was 51.8±12.8 and 40.8% of them were females. The mean duration of psoriasis and PsA was 23.1±14.7 and 14.9±11.2, respectively. 26.2% of the patients were using anti-TNFα agents and 40.1% of them were using DMARDs. The prevalence of obesity (BMI>30) was higher in the PsA group (39.7% vs. 30.2%, p<0.05). The prevalence of MetS was higher in PsA patients compared to PsC however, did not reach statistical significance (40.2% vs. 32.4%, p=0.1). The HOMA-IR and adiponectin level were higher in PsA patients compared to PsC (HOMA-IR (mmol/L × μU/ml)): 3.37±2.95 vs. 2.74±2.84, p=0.04, adiponectin (μg/ml): 8.81±5.19 vs. 7.45±4.51, p=0.009). Serum levels of leptin were not significantly different between the two groups. In multivariate regression analysis PASI score (OR 1.8, 95% CI 1.2–2.7, p=0.005) and the use of anti-TNFα agents (OR 1.8, 95% CI 1.1–2.9, p=0.02) were associated with MetS. HOMA-IR was significantly associated with PsA (p=0.01), use of anti-TNFα agents (p=0.02), age (p=0.04) and male gender (p=0.05). Adiponectin was significantly associated with PsA (p=0.004), female gender (p<0.001) and age (p=0.005).

Conclusion: The occurrence of MetS is associated with anti-TNFα therapy and severity of psoriasis. Serum adiponectin levels and insulin resistance are increased in PsA patients compared to PsC.

Anti TNFα Agents Are More Effective Than Methotrexate in Preventing Radiographic Joint Damage Among Patients with Psoriatic Arthritis in a Clinic Setting. Lihi Eder[1], Arane Thavaneswaran[1], Vinod Chandran[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Clinical trials have demonstrated that anti TNFα agents reduce the progression of radiographic joint damage in patients with psoriatic arthritis (PsA). This effect has not been evaluated in observational studies that reflect clinical practice. The aim of this study was to determine whether anti TNFα agents are more effective than methotrexate (MTX) in preventing the progression of radiographic joint damage in patients with PsA in a clinic setting.

Methods: A cohort analysis of patients followed prospectively from 1978 to 2010 at a large PsA clinic was performed. Patients were followed at 6–12 month intervals according to a standard protocol. Patients who received an anti TNFα agent were compared to those treated with MTX. In order to minimize selection bias, only patients who started to receive MTX prior to the year 2000 (before anti TNFα agents were available in Canada) were selected. Additional inclusion criteria included: 1) the presence of joint erosions 2) the presence of inflammatory peripheral arthritis at baseline. Patients who discontinued their treatment before the completion of 1 year were excluded. Radiographs of the hands and feet were performed at baseline (less than 12 month prior to the initiation of the medication), 1–2 years (Time 1) and 3–4 years (Time 2). Radiographic joint damage in 42 joints was scored according to the modified Steinbrocker score (mSBS).The outcome variable was an increase in mSBS (defined as >1 in mSBS units). Multivariate logistic regression analysis was used to compare progression in radiographic joint damage between the two treatment groups after adjustment for potential confounders.

Results: 65 patients treated with an anti TNFα agent and 70 patients treated with MTX were analyzed. Their mean age was 46.8±12.5 years, 37.7% were females and the mean duration of PsA at initiation of treatment was 11.9±9.1 years. 70.1% of the patients were treated with etanercept, 12.3% with infliximab, 12.3% with adalimumab and 4.6% with golimumab. The proportion of patients who demonstrated progression of radiographic damage score at Time 1 and Time 2 compared to baseline was higher in the MTX group compared to the anti TNFα group (Time 1: 34/50 (68%) vs. 22/39 (56.4%) p=0.03, Time 2: 42/50 (84%) vs. 27/36 (75%), p=0.005, respectively). The multivariate regression analyses showed that MTX treatment was associated with an increase in radiographic damage compared to anti TNFα therapy (Time 1: Odds Ratio (OR) 3.53, 95% Confidence Interval (CI) 1.29–9.65, p=0.03, Time 2: OR 4.66, 95% CI 1.57–13.81 p=0.004) after adjusting for age, sex, duration of PsA, active and swollen joint counts, baseline mSBS and duration of follow-up.

Conclusion: In a clinic setting, PsA patients receiving anti TNF treatment had a better radiographic outcome compared to those treated with MTX.

526

Association Between Clinical Factors and Radiographic Severity in Ankylosing Spondylitis. Tae-Jong Kim[1], Seung-Hun Lee[2], Kyung-Bin Joo[3] and Tae-Hwan Kim[4]. [1]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [2]South Korea, [3]Hanynag University, Seoul, South Korea, [4]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

Background/Purpose: The most characteristic bony changes in ankylosing spondylitis (AS) are growth of new bone and formation of syndesmophytes, possibly leading to ankylosis and spinal fusion. The objective of this study was to examine the association between clinical factors and radiographic severity in AS

Methods: A total of 1000 AS patients who met the modified New York criteria were recruited. To use the modified Stoke AS Spinal Score (mSASSS), cervical and lumbar spinal radiographs were examined by two experienced bone and joint radiologists (KB Joo, SH Lee) to validate the results. The inter-observer variability was also assessed. A review of the clinical parameters was conducted to investigate the associations between clinical factors and the radiographic progression.

Results: The mean age was 35.1(8.7), and the mean disease duration was 11.9(6.9) years. 85.9% were men and 945 patients (94.5%) were HLA-B27 positive. The frequency of juvenile onset AS and peripheral arthritis were 28.1% and 40.7%, respectively. The scores of mSASSS were different between gender (male 22.0±18.9, female 12.6±11.2, p=0.009). As expected, symptom duration has a good relationships with radiographic changes (r=0.412, p<0.001) after age and gender adjusted. The mSASSS of adult onset AS was higher, comparing to Juvenile onset (15.3±10.2, 11.4±8.5, p < 0.05). The patients with peripheral arthritis have lower radiologic scores, comparing to ones without arthritis (11.2±5.2, 16.3±8.5, p < 0.05). Multiple linear regression analysis showed that gender, type of onset, peripheral arthritis, and symptom duration still had an influence on radiographic change score. Unfortunately, no correlations were found between radiographic score and clinical parameters, such as uveitis, B27 positivity, familial history, and use of biologic agent.

Conclusion: Radiographic spinal changes in patients with AS are seen more often in men and those with long symptom duration. Clinical factors such as, juvenile onset AS and peripheral arthritis are negative predictors of radiographic progression in AS. More long term follow up studies are needed to assess the clinical predictors of radiographic change

527

Rheumatologist's Expert Opinion Is An Important Determinant of Tumor Necrosis Factor Blocking Agent Prescription in Axial Spondyloarthritis: Results From the Swiss Clinical Quality Management Axial Spondyloarthritis Cohort. Almut Scherer[1], Ulrich Weber[2], Pascale Exer[3], Juerg Bernhard[4], Jean Dudler[5], Giorgio Tamborrini[6], Bettina Weiss[2], Ruediger Mueller[7], Beat A. Michel[6], Rudolf O. Kissling[2], Adrian Ciurea[6] and on behalf of the SCQM Rheumatologists[8]. [1]SCQM Foundation, Zurich, Switzerland, [2]Balgrist University Hospital, Zurich, Switzerland, [3]Private Rheumatology Practice, Basel, Switzerland, [4]Buergerspital, Solothurn, Switzerland, [5]Hôpital Cantonal, Fribourg, Switzerland, [6]Department of Rheumatology, University Hospital, Zurich, Switzerland, [7]Cantonal Hospital, St. Gallen, Switzerland, [8]Scqm, Switzerland

Background/Purpose: To investigate the determinants of anti-TNF agent (aTNF) prescription in patients (pts) with non-radiographic spondyloarthritis (nrSpA) and definite ankylosing spondylitis (AS) if the fulfillment of the modified NY criteria (mNYc) is not mandatory and a BASDAI >=4 not required for reimbursement.

Methods: 741 pts fulfilled the mNYc (AS), while 162 mNYc-negative pts fulfilled the ASAS axial SpA criteria (nrSpA) in the Swiss Clinical Quality Management (SCQM) axial SpA cohort. Pts were recruited by rheumatologists in private practice (53%), non-academic (28%) and academic (19%) centers since 2004. Data on demographics, medication, ESR and CRP levels were collected and standardized assessment tools applied. A similar proportion of AS and nrSpA pts were treated with aTNF in SCQM-SpA (74% [95% CI 70–77] vs. 71% [64–77]). Two logistic multiple regression models of potential determinants for aTNF prescription were performed with the following variables: age, disease duration, classification as AS or nrSpA, sick leave, BASFI, BASMI, physician's global assessment (PhysGA), peripheral arthritis, and quality of life (EuroQol). BASDAI and CRP were additionally included as

continuous variables in model 1, ASDAS was included in model 2. We controlled for gender and type of recruiting center.

Results: 497 pts had complete data sets for all the evaluated variables (239 AS and 51 nrSpA pts with aTNF start after enrollment and 149 AS and 40 nrSpA pts without biologic treatment at two consecutive observations in the cohort). The percentage of pts with BASDAI>=4 was slightly higher in treated nrSpA than in AS pts (82% vs. 75%, n.s.). In the group without aTNF, 52% of nrSpA and 48% of AS pts had a BASDAI >=4. Mean BASDAI was 4.8 in AS and 5.1 in nrSpA pts (p=0.2). Mean ASDAS was 4.2 in AS and 3.9 in nrSpA pts (p=0.05). The logistic regression model 1 revealed that rheumatologists assigned aTNF preferentially to pts with peripheral arthritis and higher BASDAI, CRP and PhysGA levels, with the lowest contribution for BASDAI (Table). ASDAS, arthritis and PhysGA were strongly associated with aTNF start in model 2.

Table. Predictors of aTNF initiation in two regression models

	Variables	OR	95% CI	p Value
Model 1	BASDAI	1.22	1.04–1.45	0.018
	CRP	1.03	1.01–1.05	0.006
	PhysGA	1.40	1.23–1.60	<0.00001
	Arthritis	2.27	1.42–3.69	0.0007
Model 2	ASDAS	1.50	1.21–1.87	0.0002
	PhysGA	1.40	1.23–1.60	<0.00001
	Arthritis	2.39	1.50–3.88	0.0003

Conclusion: In the context of non-restrictive reimbursement criteria, comparable proportions of nrSpA and AS pts are treated with aTNF, matching similar levels of disease activity in the two groups. The determinants of aTNF initiation found here represent a more comprehensive concept of disease activity including the rheumatologist's expert opinion and reflect the predictive factors of a good treatment response.[1] ASDAS seems moreover to better determine aTNF prescription than BASDAI.

Dyslipidemia in Patients with Seronegative Spondyloarthropathies. Charalampos Papagoras[1], Theodora E. Markatseli[1], Ioanna Saougou[1], Haralampos J. Milionis[2] and Alexandros A. Drosos[3]. [1]Fellow in Rheumatology, Ioannina, Greece, [2]Assistant Professor of Internal Medicine, Ioannina, Greece, [3]Professor of Medicine/Rheumatology, Ioannina, Greece

Background/Purpose: Chronic arthritis, particularly rheumatoid arthritis (RA), has been associated with a pro-atherogenic lipid profile and premature atherosclerosis. Patients with seronegative spondyloarthropathies (SpA) also seem to be in greater risk for cardiovascular disease than the general population. However, data on the serum lipid levels of patients with SpA are far less than for RA.

Methods: We studied the serum lipid profile of patients with SpA and compared it with non-SpA controls. A case-control study was conducted in which cases were non-diabetic patients with SpA and controls were age and sex-matched apparently healthy volunteers. In all study participants, we measured serum levels of total cholesterol (Chol), triglycerides (Trg), high density lipoprotein cholesterol (HDL), low density lipoprotein cholesterol (LDL), Apolipoprotein AI (ApoAI), ApoB, ApoE and lipoprotein (α) [Lp(α)], while body mass index (BMI) and waist-to-hip ratio (WHR) were also calculated. In SpA patients, disease activity markers (ESR, CRP, BASDAI, BASFI, DAS28 and PASI, when applicable) were recorded as well.

Results: One hundred and fifty SpA patients [73 with ankylosing spondylitis (AS), 71 with psoriatic arthritis (PsA) and 6 with other forms of SpA] and 150 controls were studied. As shown in Table, SpA patients had significantly greater WHR, lower levels of Chol, Trg, HDL, a higher Chol/HDL ratio, lower levels of ApoB, ApoE, Lp(α) and a lower ApoB/ApoAI ratio. Focusing separately on the PsA and AS subgroups, a particular pattern of dyslipidemia involving lower HDL and a higher Chol/HDL ratio is a persistent finding. In the SpA group, correlation analysis revealed a statistically significant association of ESR with HDL (r=−0.222, p=0.003), ApoAI (r=−0.224, p=0.003) and ApoB/ApoAI ratio (r=0.221, p=0.004). In the PsA subgroup, significant correlations also emerged between ESR and HDL (r=−0.362, p<0.001), Chol/HDL (r=0.236, p=0.023), ApoAI (r=−0.338, p=0.001) and ApoB/ApoAI (r=0.315, p=0.003). Similar associations were observed between CRP and the above parameters as well. In the AS subgroup, a correlation of CRP with HDL (r=−0.223, p=0.049) and ApoAI (r=−0.31, p=0.007) was found. Except DAS28 which correlated significantly with HDL (r=−0.312, p=0.042), ApoAI (r=−0.352, p=0.026) and ApoB/ApoAI (r=0.334, p=0.035) in the PsA subgroup, no other significant correlations between BASDAI, BASFI or PASI and lipid parameters were observed.

Table. An thropometric measures and serum lipid levels in SpA patients, AS and PsA subgroups and the corresponding control groups

Parameter	*SpA (N=150)*	*Controls (N=150)*	*AS (N=73)*	*Controls (N=73)*	*PsA (N=71)*	*Controls (N=71)*

ApoB/ApoAI	0.671 ± 0.208**	0.774 ± 0.275	0.682 ± 0.219*	0.855 ± 0.29	0.671 ± 0.201	0.665 ± 0.218

*p≤0.001, **p<0.01, †p<0.05, ¶ p=0.059, for comparison of patients versus age-and-sex matched controls

Conclusion: SpA patients show several metabolic disturbances, spanning from increased abdominal fat to lipoprotein level perturbations. The most consistent alteration encountered in most patients is a lower level of HDL and an unfavorable Chol/HDL ratio. Many of these alterations correlate significantly with inflammatory markers or DAS28.

530

Body Mass Index Influences the Response to Infliximab in Ankylosing Spondylitis. Sébastien Ottaviani[1], Yannick Allanore[2], Florence Tubach[3], Blandine Pasquet[3], Olivier Meyer[4] and Philippe Dieude[5]. [1]APHP, Paris, France, [2]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [3]APHP, Hôpital Bichat, Paris, France, [4]Hopital Bichat, Paris, France, [5]APHP, Hopital Bichat, Paris, France

Background/Purpose: The excess of adipose tissue in obese individuals may have immunomodulating properties and pharmacokinetics consequences. The aim of this study was to determine whether body mass index (BMI) affects response to infliximab (IFX) in ankylosing spondylitis (AS) patients.

Methods: In 155 patients retrospectively included with active AS, the BMI was calculated before initiation of IFX treatment (5 mg/kg intravenously). After 6 months of treatment, change from baseline in BASDAI, VAS pain, CRP level and total dose of NSAID was dichotomized with a threshold corresponding to a decrease of 50% of initial level of the measure, into binary variables assessing response to IFX (namely, VAS50, CRP50, NSAID50). Whether BMI was predictive of response to therapy according to theses different definitions was assessed with logistic regression.

Results: Multivariate analysis revealed that a lower BMI was associated with a positive BASDAI50 response after 6 month of IFX therapy (P = 0.0003). When analyses were performed according to the 3 WHO BMI categories, similar results were observed when response to IFX was defined by BASDAI50 ($P < 0.0001$), VAS50 ($P < 0.0001$), CRP50 ($P = 0.0279$) and NSAID50 ($P = 0.0077$).

Conclusion: This study provides the first evidence that a higher BMI negatively influences the response to IFX in AS. These data are in line with recent findings observed in rheumatoid arthritis. They raise the points of the consideration of BMI to assess to response to IFX and the pharmacological impact of fat tissue.

The Role of CRP and Peripheral Disease in Achieving ASDAS Response to Anti-TNF Therapy in 397 Patients with Ankylosing Spondylitis. Karen Minde Fagerli[1], Elisabeth Lie[2], D.M.F.M. van der Heijde[3], Marte S. Heiberg[1], Erik Rødevand[4], Cecillie Kaufmann[5], Knut Mikkelsen[6], Synnøve Kalstad[7] and Tore K. Kvien[2]. [1]Diakonhjemmet hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Trondheim, Norway, [5]Vestre Viken, Drammen, Norway, [6]Lillehammer Hosp for Rheumatic Diseases, Lillehammer, Norway, [7]Tromsø, Norway

Background/Purpose: BASDAI has been the most commonly used outcome measure for assessing efficacy of TNF-inhibitors (TNFi) in ankylosing spondylitis (AS). However, BASDAI is solely patient-reported. ASDAS is a recently developed composite disease activity score incorporating an inflammatory marker (CRP or ESR). It has not been well studied if ASDAS performs similarly in patients with elevated CRP vs. normal CRP and patients with swollen joints vs. patients without swollen joints.

Objectives: To compare the response to TNFi according to different response criteria in patients with and without swollen joints as well as with and without elevated CRP.

Methods: Data for these analyses were extracted from the NOR-DMARD register where adult patients with inflammatory arthropathies starting a new DMARD treatment have been consecutively included and followed longitudinally with assessments at 3, 6 and 12 months and then yearly. Patients with AS starting a TNFi who had complete data for calculating ASDAS-CRP at baseline and 3 months were selected for the current analyses. Cut-point for elevated CRP was selected as 10 mg/L. The presence of a swollen joint was based on evaluation of the 28-joint count as well as feet. Selected response criteria were ASDAS clinically important improvement ($\Delta \geq 1.1$), ASDAS major improvement ($\Delta \geq 2.0$), ASAS20, ASAS40, BASDAI50, BASDAI 2-point change and BASDAI response (BASDAI50 and/or BASDAI 2-point change).

Results: 397 patients starting a TNFi were included in the analyses (70.2% males, 91.2% HLA B27 positive, mean (SD) age 42.7 (11.2) yrs, disease duration 11.8 (11.2) yrs, BASDAI 5.4 (2.1) and ASDAS 3.4 (1.1), median (IQR) CRP 9.0 (5.0–20.5) mg/L). 42.8% of patients had CRP levels ≥ 10 and 21.3% had at least one swollen joint. A significantly higher proportion of patients with a CRP ≥ 10 showed a response as compared to patients with a CRP < 10 with all response criteria (table). This difference was most pronounced using ASDAS response criteria, but the % with ASDAS clinically important improvement in the patients with CRP < 10 was still in the same range as picked up with other response measures. When comparing the patients with or without swollen joints there was only a significant difference in achieving ASDAS major improvement.

Table. Percentages achieving response according to different criteria

	Overall	CRP (mg/L)			Swollen joints		
		≥10	<10	p-value*	Present	Absent	p-value*
ASDAS clinically important improvement	52.4	75.3	35.2	<0.001	56.1	50.2	0.38
ASDAS major improvement	26.7	44.1	13.7	<0.001	39.0	22.8	0.004
ASAS 20	61.4	61.8	43.6	<0.001	53.7	50.2	0.62
ASAS 40	36.0	44.1	30.0	0.004	40.2	34.7	0.37
BASDAI 50	43.1	50.6	37.4	0.01	43.2	40.2	0.71
BASDAI 2 points	49.4	57.6	43.2	0.005	56.1	46.9	0.17
BASDAI response	54.2	61.8	48.5	0.01	57.3	52.5	0.46

* Chi-square test.

Conclusion: AS patients starting a TNFi who had a baseline CRP ≥ 10 more frequently achieved a response compared to patients with CRP < 10. These findings were seen for ASDAS responses but also for measures that do not include inflammatory markers. The response rate for ASDAS clinically important improvement was similar to responses for other measures and the findings support the use of ASDAS as a response measure also in patients with normal CRP and without swollen joints.

532

Prevalence of Psoriatic Arthritis in Dermatological Patients with Psoriasis. Joerg C. Henes[1], Michael Eisfelder[2], Anette Adamczyk[3], Björn Knaudt[3], Felix Jacob[3], Eva-Maria Zuipa[1], Ralf Denfeld[4], Jürgen Lux[5], Armin Philipp[4], Carolin Steigleder[4], Martin Kleinhans[4], Nicole Oster[4], Gerhard Fierlbeck[3] and Ina Kötter[6]. [1]University Hospital Tuebingen, Tuebingen, Germany, [2]Private practice, Rottweil, Rottweil, Germany, [3]University Hospital Tuebingen, Department of dermatology, Tuebingen, Germany, [4]Private practice, Stuttgart, Germany, [5]Private practice, Tuebingen, Germany, [6]Department of Internal Medicine II, Rheumatology Division, Tübingen, Germany

Background/Purpose: The existing data on prevalence of psoriatic arthritis (PsA) among patients with psoriasis in the literature vary between 5.8 and 40%. Recently, a new screening questionnaire in German language has been validated by Haerle et al.. This GEPARD (German Psoriasis Arthritis Diagnostic questionnaire) has a sensitivity and specificity of 89% and 69.1% for ≥4 questions answered "yes".

Methods: Two dermatologic hospitals and 9 private dermatologic practices were involved. All consecutive patients with psoriasis were asked to fill out the questionnaire without the help of the physician and send them to the study centre. All patients with ≥4 positive questions were invited for a rheumatological examination. Patients with known PsA (question 7 answered "yes") received a second questionnaire with regard to the history and treatment of PsA. 30% of patients with known arthritis were interviewed by a telephone call and if diagnosis was uncertain were invited for a rheumatological evaluation. Those patients with a positive questionnaire who denied coming were considered as having no arthritis. The rheumatologic assessment consisted of physical examination and laboratory tests including inflammatory markers, rheumatoid factor, anti-CCP antibodies and HLA B27. All patients with peripheral arthralgia received ultrasound of the joints including Doppler and X-ray of hands, feet and affected joints. In those patients with marginal changes or spinal complaints magnetic resonance imaging (MRI) was added. The CASPAR criteria were used for the diagnosis of PsA.

Results: 404 questionnaires were evaluated. 204 patients (50.5%) had answered ≥4 questions with "yes" of whom 38.2% (n=78) had a known PsA. 126 patients were invited for a clinical examination and 23% (n=29) refused to come. 98 patients with suspected PsA had a clinical evaluation at the study centre. In 49% (n=48) the CASPAR criteria were not fulfilled and in 44.9% (n=44) a new PsA was diagnosed. In two patients anti-CCP antibodies and a symmetrical arthritis made the diagnosis rheumatoid arthritis more plausible. 6.1% already had the diagnosis of PsA. In addition to the clinical evaluation the diagnosis was confirmed by radiological assessment using X-ray in 69.4% (n=68), powerdoppler ultrasound in 83.7% and MRI in 39.8%. All together, of the 404 patients 44 (10.9%) were newly diagnosed having a PsA and 78 (19.3%) had a known PsA whereas 282 (69.8%) were found to have no signs of PsA. Thus the prevalence PsA among patients with psoriasis in this study was 30.2%. There were no significant differences in the patients with or without definite arthritis regarding CRP or ESR, HLAB27, gender or severity of psoriasis. Only dactylitis was significantly associated with definite PsA.

Conclusion: This study uses a validated questionnaire in the forefront of a clinical evaluation in patients with suspected PsA. By using this approach the prevalence of PsA was higher than that in recent studies in Germany, UK and the United States and supports findings from Scandinavia. With nearly 50% positive questionnaires for patients without PsA the specificity should be improved.

533

Predictors of ASDAS Major Improvement in Patients with Ankylosing Spondylitis Receiving Their First TNF Inhibitor. Results From a Longitudinal Observational Study. Karen Minde Fagerli[1], Elisabeth Lie[2], Marte S. Heiberg[1], D.M.F.M. van der Heijde[3], Synnøve Kalstad[4], Knut Mikkelsen[5], Cecillie Kaufmann[6], Erik Rødevand[7] and Tore K. Kvien[2]. [1]Diakonhjemmet hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Tromsø, Norway, [5]Lillehammer Hosp for Rheumatic Diseases, Lillehammer, Norway, [6]Vestre Viken, Drammen, Norway, [7]Trondheim, Norway

Background/Purpose: TNF inhibitors (TNFi) have been proven highly efficacious in reducing symptoms and inflammation in patients with AS. However, not all patients show a good response to therapy, while treatment is expensive and has potentially serious side effects. Identification of predictors of a good response might aid decision-making and improve the benefit/risk ratio in patients selected to start TNFi.

Objectives: To determine predictors of ASDAS major improvement ($\Delta \geq 2.0$) after 3 months of treatment with TNFi in TNFi-naive patients.

Methods: Data was extracted from the NOR-DMARD register where adult patients with inflammatory arthropathies starting a new DMARD treatment are consecutively included and followed longitudinally in 5 rheumatology departments in Norway. For this analysis AS patients who were treated with their first TNFi and who had complete data for calculation of ASDAS at baseline and 3 months were included [N=249; 90.7 % HLA B27 positive, 67.9 % males, mean (SD) age 41.9 (11.1) years, disease duration 10.1 (10.8) years, BASDAI 5.36 (1.98) BASFI 4.30 (2.20) and ASDAS 3.38 (0.96)]. The following variables were selected for univariate logistic regression analyses with 3-month ASDAS major improvement as the dependent variable: age, sex, disease duration, baseline CRP, HLA B27 status, smoking (ever/never), educational level, presence of swollen peripheral joints (28 joints + feet), and BASDAI, BASFI, physician and patient global assessments. Variables yielding a p-value < 0.25 were included in a subsequent multivariate logistic regression analysis, and non-significant variables were removed from the model one at the time (starting with the least significant variable), checking for confounding. Clinically relevant interactions were tested in the final main-effects model. Appropriate tests for linearity and goodness of fit were performed.

Results: ASDAS major improvement was achieved by 32.1 % of the patients at 3 months. All variables except disease duration, smoking and level of education

were significant predictors in univariate analyses and included as covariates. BASDAI was excluded from multivariate analysis due its correlation with patient global and BASFI. Age, sex, baseline CRP level, HLA B27 status and higher baseline patient global assessment were independent predictors of ASDAS major response at 3 months, and constituted the final logistic regression model. The fit of the model was satisfactory (Hosmer-Lemeshow goodness of fit test: p=0.50) and model accuracy was 79.0%.

Table. Logistic regression model for predictors of ASDAS major response at 3 months.

Variable	Odds ratio	95 % CI	p-value
Age	0.96*	0.92–0.99	0.021
Male sex	4.70	1.99–11.1	<0.001
CRP ≥10	7.77	2.28–9.93	<0.001
HLA B27 positivity	6.64	1.39–31.7	0.018
Patient global	1.78**	1.46–2.17	<0.001

* Odds ratio for one year increase in age. ** Odds ratio for a 10-mm increase on a 0–100 mm VAS.

Conclusion: Lower age, male sex, CRP ≥10, HLA B27 positivity and higher baseline patient global assessment were identified as independent predictors of achieving ASDAS major improvement at 3 months for AS patients starting their first TNFi.

534

Differences in Comorbidities Related to Rheumatoid Arthritis and Psoriatic-Arthritis: Data From Large Prospectiv Observational Studies. Frank Behrens[1], Diamant Thaci[2], Hanns-Martin Lorenz[3], Brigitte Krummel-Lorenz[4], Lothar Meier[5], Holger Gnann[6], Gerd Greger[7], Bianca Wittig[7] and Harald Burkhardt[1]. [1]CIRI/Rheumatology, J.W. Goethe University, Frankfurt/Main, Germany, [2]Klinik für Dermatologie, Venerologie und Allergologie, J.W. Goethe University, Frankfurt/Main, Germany, [3]Medizinische Klinik und Poliklinik, Universität, Heidelberg, Germany, [4]CIRI/Endokrinologikum, Frankfurt/Main, Germany, [5]CIRI/Rheumatologische Schwerpunktpraxis, Hofheim, Germany, [6]Abteilung Biostatistik, GKM Gesellschaft für Therapieforschung mbH, München, Germany, [7]Abbott GmbH & Co KG, Wiesbaden, Germany

Background/Purpose: To examine the impact of Rheumatoid Arthritis and Psoriatic Arthritis on the prevalence of type II diabetes, obesity, and osteoporosis.

Methods: Cross-sectional comparative analyses of baseline characteristics of two cohorts of patients with long-lasting rheumatoid arthritis (RA), and psoriatic arthritis (PsA) enrolled in prospective observational multi-centre studies. Patients with active RA (n= 4640) or PsA (n=1467) and either an inadequate response or intolerance to conventional or biologic disease-modifying therapy who had enrolled in observational studies of adalimumab. Baseline prevalence rates of type II diabetes, obesity, and osteoporosis and the odds ratios with 95% confidence intervals (CI) for identified risk factors were calculated.

Results: Prevalence rates revealed a discordant relationship between type II diabetes and osteoporosis in RA compared with PsA. Whereas the PsA cohort exhibited a higher rate of type II diabetes than the RA cohort, particularly in patients over 60 years of age (19.1% vs 10.9%; P=.0003), the frequency of osteoporosis was reduced (6.0% vs 21.8%; P<.0001) in PsA independent of age and gender. Systemic inflammation is unlikely to be the sole explanation for these differences, as the diabetes prevalence was higher in PsA while the RA patient cohort exhibited more severe inflammatory disease as evidenced by serologic and clinical parameters of inflammation. An impact of constitutional factors on comorbidity is indicated by a significantly higher mean body mass index (BMI) independent of age or gender in PsA. Logistic regression uncovered rheumatoid factor seropositivity as a previously unidentified serological marker for increased risk of osteoporosis in PsA patients (odds ratio= 3.319 [95% CI, 1.822 to 6.045]).

Conclusion: Patients with PsA have a higher rate of type II diabetes and an elevated BMI, but reduced levels of systemic inflammation and a lower prevalence of osteoporosis than patients with RA. The observed differences between RA and PsA patients do not support the concept of systemically released proinflammatory mediators as a dominant contributor to comorbidities in distinct inflammatory disorders. Our data thus suggest that disease-specific factors beyond inflammation impact the development of comorbidities in patients with inflammatory disorders.

Sustained Improvement of Spinal Mobility, Physical Function, and Quality of Life in Patients with Ankylosing Spondylitis: 5-Year Results. Désirée van der Heijde[1], Maxime A. Breban[2], Dale G. Halter[3], Gino DiVittorio[4], Johan Bratt[5], Fabrizio Cantini[6], Sonja Kary[7], L. Steven Brown[8], Hartmut Kupper[7], Tracy F. Nicholson[9] and Philip J. Mease[10]. [1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Hopital Ambroise Pare, Boulogne, France, [3]Houston, TX, [4]Mobile, AL, [5]Karolinska Univ Hosp Huddinge, Stockholm, Sweden, [6]Stabilimento Ospedaliero Misericordia, Prato, Italy, [7]Abbott GmBH & Co KG, Ludwigshafen, Germany, [8]Abbott Laboratories, Abbott Park, IL, [9]Abbott Laboratories, [10]Seattle Rheumatology Associate, Seattle, WA

Background/Purpose: Ankylosing Spondylitis (AS) is a chronic, inflammatory disease of the axial skeleton characterized by back pain and radiographic sacroiliitis that can progressively restrict spinal mobility. In patients (pts) with AS treated with adalimumab (ADA), previous reports demonstrated improved spinal mobility, physical function, and quality of life as early as 12 and 24 wks. [1,2] In this post hoc analysis, the long-term maintenance of those improvements was assessed through 5 yrs and the correlation between spinal mobility and clinical, functional, and quality-of-life outcomes were evaluated.

Methods: ATLAS was a phase 3, multicenter, double-blind trial of pts with active AS randomized to ADA 40 mg every other week or placebo (PBO) for 24 wks followed by an open-label extension up to 5 yrs. Improvements in spinal mobility were evaluated using linear BASMI($_{ln}$), including individual assessment of cervical rotation in degrees, lumbar flexion, lumbar side flexion, intermalleolar distance, and tragus-to-wall distance in cm. Additional outcomes included BASDAI, total back pain, CRP, BASFI, SF-36 Physical Component Summary (PCS), and the AS Quality of Life (ASQOL) questionnaire. Spearman's rank correlation was used to evaluate the relationship between BASMI$_{ln}$ and clinical, functional, and quality-of-life outcomes at 12 wks and 5 yrs of exposure.

Results: A total of 315 pts (208 ADA/107 PBO) were randomized, of which 311 received at least one dose of ADA. Improvements in BASMI$_{ln}$ were sustained through 5 yrs (table), with a mean change of −0.6 from baseline. Of the individual components, lumbar side flexion, cervical rotation, and intermalleolar distance appeared to drive change in overall BASMI$_{ln}$. Improvements in disease activity, function, and quality of life were also sustained through 5 yrs. BASMI$_{ln}$ was significantly correlated with all evaluated clinical outcomes (P<0.001), with the highest correlation observed between BASMI$_{ln}$ and BASFI at 12 wks and 5 yrs, (r=0.51 and 0.64, respectively).

Table. Spinal Mobility, Disease Activity, Physical Function and Quality of Life with Long-Term Adalimumab

Assessments (N=BL/Wk12/Yr1/Yr3/Yr 5)	Exposure to Adalimumab mean (SD)				
	Baseline*	Week 12	Year 1	Year 3	Year 5
BASMI$_{ln}$ (N=309/309/282/233/124)	4.4 (1.7)	4.0 (1.8)	3.8 (1.8)	3.7 (1.8)	3.7 (1.8)
Lumbar flexion, cm (N=309/309/282/233/124)	3.9 (3.4)	4.0 (3.2)	4.0 (2.8)	3.9 (2.8)	3.7 (2.2)
Lumbar side flexion, cm (N=306/306/279/230/120)	9.5 (5.4)	10.9 (5.9)	11.5 (5.9)	11.7 (6.1)	11.8 (6.2)
Cervical rotation, degrees (N=307/307/282/233/125)	46.3 (22.1)	50.1 (21.5)	53.7 (22.1)	54.9 (22.9)	57.2 (23.7)
Intermalleolar distance, cm (N=305/305/279/231/123)	93.9 (25.8)	100.4 (28.8)	103.9 (27.7)	106.1 (23.6)	105.5 (24.1)
Tragus to wall distance, cm (N=307/307/280/231/124)	15.8 (6.1)	15.5 (5.7)	15.6 (5.6)	15.5 (6.1)	16.0 (6.3)
BASDAI, 0–10 cm VAS (N=310/310/282/234/124)	6.0 (2.0)	3.6 (2.5)	2.8 (2.4)	2.5 (3.3)	1.8 (1.9)
Total back pain, 0–100 mm VAS (N=310/310/282/234/125)	62.0 (23.9)	37.5 (29.1)	28.1 (26.8)	22.8 (24.4)	16.4 (20.5)
CRP, mg/dL (N=308/308/279/230/123)	1.8 (2.3)	0.6 (1.2)	0.6 (1.1)	0.5 (1.1)	0.4 (0.7)
BASFI, 0–100 mm VAS (N=310/310/282/234/125)	51.7 (23.7)	35.5 (25.8)	29.0 (25.3)	24.3 (23.7)	20.9 (21.0)
SF-36 PCS (N=278/278/278/230/165)	32.6 (8.0)	39.5 (10.1)	42.2 (10.7)	44.5 (9.8)	44.4 (10.0)
ASQOL, 0–18 (N=284/284/281/233/169)	10.3 (4.4)	7.1 (5.3)	5.6 (5.0)	4.7 (4.7)	4.8 (4.8)

*Baseline is last observation prior to first dose of ADA. Baseline summarized for those that have at least 12 weeks of exposure to ADA.

Conclusion: Treatment with ADA up to 5 yrs demonstrated sustained benefits in spinal mobility, disease activity, physical function, and quality of life in pts with active AS. The results of this analysis suggest that early and long-term improvements in mobility with ADA treatment may correlate with improved functional ability.

Adenosine Receptor Signaling in Keratinocyte Proliferation and Implications for Caffeine and Methotrexate Therapy. Gideon Smith[1], Andrew G. Franks[2], Bruce N. Cronstein[3] and Edwin SL Chan[1]. [1]New York University School of Medicine, New York, NY, [2]New York University, New York, NY, [3]New York Univ Medical Center, New York, NY

Background/Purpose: Methotrexate is highly effective in psoriasis, the classic disorder of keratinocyte proliferation. However, the mechanisms of methotrexate's antiproliferative effects in keratinocytes remains unclear. We previously demonstrated that adenosine mediates the anti-inflammatory effects of methotrexate. Here we investigate whether adenosine directly affects keratinocyte proliferation.

Methods: Normal adult human primary epidermal keratinocytes were cultured in dermal cell basal medium (37C, in 5% CO2). Cultures were supplemented with keratinocyte growth kit. Once 70–80% confluent, cell cultures were starved for 24 hours and then incubated with test substances. Proliferation was assessed by ELISA calorimetry of BrdU uptake.

Results: Incubation of keratinocytes with methotrexate produced a statistically significant reduction in proliferation versus control (DMSO) (1μM, 24 hrs, 57.8+/−2.1%, vs control, n=4, p<0.001). This was partially reversed via pre-treatment with the A2A antagonist ZM241385 (1μM, 24hrs, 78.8+/−2.2%, vs control n=4, p<0.001) or caffeine, a non-selective adenosine receptor antagonist (1μM, 24hrs, 74.1+/−0.9%, vs control n=4, p<0.05). This was also statistically significantly different from methotrexate alone (ZM241385, p<0.001). However, there was no effect on the anti-proliferative effects of methotrexate when pre-treated with the A2B antagonist MRS1754 (1μM, 24 hrs, 57.6+/−1.1% vs control, n=4, p<0.001).

Keratinocyte proliferation was also inhibited by incubation with the adenosine A2A receptor agonist CGS21680 (56.8+/−12.9% vs control, n=4, p<0.001). This effect was again blocked by pre-treatment with ZM241385 and caffeine. However, BAY60–6583, an A2B agonist, also reduced keratinocyte proliferation (1μM, 24hrs for each, 40.8+/−5.1% vs control, n=4, p<0.001), an effect blocked by MRS1754 and caffeine.

Conclusion: While methotrexate may act in psoriasis and psoriatic arthritis through its anti-inflammatory effects on lymphocytes, it also has direct anti-proliferative effects on keratinocytes acting via the A2A receptor. More importantly, we have also demonstrated that keratinocytes are also inhibited by A2B stimulation suggesting a new target for purinergic therapy development. In addition we have provided a potential mechanism for methotrexate therapeutic failure in psoriatic patients with high caffeine intake.

537

The Prevalence of Carotid Artery Plaques Is Higher in Patients with Psoriatic Arthritis Compared to Those with Psoriasis Alone. Lihi Eder[1], Jai Jayakar[2], Sutharshini Shanmugarajah[2], Arane Thavaneswaran[1], Daniel Pereira[2], Vinod Chandran[2], Cheryl Rosen[2] and Dafna D. Gladman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Cardiovascular morbidity is increased in patients with psoriatic arthritis (PsA) and psoriasis. Carotid Intima-Media Thickness (cIMT) and Carotid Plaque Area (CPA) serve as surrogate measures for cardiovascular diseases. No study to date has compared the extent of sub-clinical atherosclerosis between PsA and cutaneous psoriasis without arthritis (PsC). We hypothesize that PsA patients are at increased cardiovascular risk compared to PsC.

To compare the extent of atherosclerosis, as measured by cIMT and CPA, in patients with PsA and PsC.

Methods: In this cross-sectional study we compared patients with PsA from a large clinic to those with PsC. Psoriasis patients underwent an assessment by a rheumatologist to exclude inflammatory arthritis. Ultrasonographic measurements of CPA and c-IMT were performed using a high resolution optimized ultrasound system for carotid imaging. The area of each plaque was measured by tracing the perimeter with a cursor around the borders of each atherosclerotic plaque. Total plaque area was recorded as the sum of all plaques in the right and left carotid arteries. cIMT was measured as the distance between the intima-lumen interface and the media-adventitia border. PsA and psoriasis patients were matched by age and gender. The outcome variables were transformed into log of c-IMT and square root of CPA. Linear regression model for paired data was used to compare the outcome variables between the two groups. Multivariate regression analysis was used to adjust for the following variables: weight, smoking, systolic and diastolic blood pressure, serum levels of glucose, cholesterol and triglyceride and the use of antihypertensive, glucose-lowering and lipid-lowering medications.

Results: Overall, 107 matched pairs of PsA and PsC patients were included in the study. The mean age of the study population was 53±11.4 years and 45.8% were females. There was no significant difference in the prevalence of hypertension, diabetes mellitus, dyslipidemia, weight and smoking between the two groups. Both measures of atherosclerosis were higher in PsA patients compared to PsC (cIMT: matched difference of 0.02 (Log of μm), p=0.05, CPA: matched difference 0.077 (cm^2), p=0.01). However after adjustment for cardiovascular risk factors only CPA remained significantly increased in PsA compared to PsC (estimate 0.075, p=0.04). There was no significant association between measures of disease activity/damage and atherosclerosis although there was a trend for an increase in cIMT with the use of biologic agents (estimate 0.025, p=0.07).

Conclusion: Ultrasonographic measures of carotid atherosclerosis are increased in patients with PsA compared to those with PsC.

Sclerostin Predicts Radiographic Progression in Patients with Ankylosing Spondylitis on Standard Therapies but Not in Patients on Tumor Necrosis Factor Blockers. Walter P. Maksymowych[1], Nathalie Morency[1], Stephanie Wichuk[1], Barbara Conner-Spady[1] and Georg Schett[2]. [1]University of Alberta, Edmonton, AB, [2]University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Sclerostin (SCL) is a potent suppressor of new bone formation and lower levels have been reported in ankylosing spondylitis (AS) compared to healthy controls. One report also suggests that lower levels are linked to structural progression in AS[1]. This was a limited analysis that only assessed 46 patients on standard therapies and did not address age, sex, disease duration, or treatment as confounders in the regression model. A preliminary report has also implicated bone specific alkaline phospahatse (BAP) as predictive of progression in SpA but is limited for the same reasons[2]. In this prospective study, we aimed to assess the predictive capacity of SCL and BAP in a broader spectrum of patients with AS that includes those on TNF blocker therapies.

Methods: The study cohort comprised 190 patients with SpA, 82 (43.2%) on TNF blocker therapy, followed prospectively with clinical and radiographic outcomes. Controls were 50 age and sex-matched healthy individuals. SCL and BAP were measured by enzyme-linked immunosorbent assay (ELISA). We analyzed the effect of TNF blocker therapy on levels of SCL (n = 66) and BAP (n = 100). Readers scored X-rays obtained at baseline and year 2 using the mSASSS method. Pre-specified dependent variables were: 1) 2-year change in mSASSS, 2) development of new syndesmophytes at 2 years, 3) mSASSS rate of progression. Multivariate regression analyses were controlled for age, sex, disease duration, TNF blocker treatment, and baseline radiographic score.

Results: BAP was significantly increased in patients versus controls (p = 0.0004) while comparisons between patients and controls for SCL were not significant. SCL correlated with age in SpA patients (r = 0.45, p<0.0001) and correlated inversely with BAP in controls (r = 0.37, p = 0.009). Mean (SD) level (pg/ml) of SCL increased significantly from 0.59 (0.24) to 0.66 (0.27) (p = 0.0002) while BAP increased significantly from 20.8 (8.8) to 23.08 (9.4) (p<0.0001) after TNF blocker therapy. SCL correlated significantly with baseline mSASSS score (r = 0.25, p = 0.007) in the entire cohort. SCL was a significant independent predictor of mSASSS progression in patients on standard, but not TNF blocker, therapy while BAP predicted progression only in the TNF therapy group (Table). The ratio of BAP/SCL was the best predictor of progression in patients on standard therapies. Change in SCL or BAP after TNF blocker therapy was not predictive of progression.

Biomarker	Treatment	Coefficient (95%CI)	P value
SCL	Standard	−0.96 (−1.74–0.19	0.02
BAP/SCL ratio	Standard	0.02 (0.01–0.03)	0.003
BAP	TNF	−0.10 (−0.19–0.01)	0.04

Conclusion: The assessment of SCL as a prognostic indicator in SpA is confounded by age and treatment. SCL predicts progression only in patients on standard therapies. Future studies must fully explore the effects of confounders.

Clinical Features of Pustulotic Arthro-Osteitis. Jun-ichi Fukushi, Yasuharu Nakashima, Ken Okazaki, Taro Mawatari, Masanobu Ohishi, Yasutaka Tashiro and Yukihide Iwamoto. Kyushu University, Fukuoka, Japan

Background/Purpose: Palmoplantar pustulosis (PPP) is a chronic skin lesion associated with intraepidermal sterile pustules of the palms and soles. Bone lesions of PPP are known as pustulotic arthro-osteitis (PAO). PAO is found in about 10% of Japanese patients with PPP, and has also been reported in rare cases in Caucasians. However, the characteristic features of PAO, including the most effective therapy, have not yet been clarified.

Methods: We reviewed 54 cases with PAO who were treated at Kyushu University Hospital within the past 15 years. Patients without the typical skin rash, even if they had anterior chest pain, were excluded from the study. There were 19 males and 35 females, with an age range at onset from 18 to 75 years (mean: 47.2 years). The average follow-up period was 18 months.

Results: The onset of skin lesions preceded arthro-osteitis in 25 cases, and it was simultaneous in 17 cases. In 4 cases, arthro-osteitis preceded the skin lesions. Elevations in CRP, ESR and ALP were seen in 75%, 70% and 21% of the cases, respectively. Arthro-osteitis was observed in the anterior chest wall in 44 cases (81%). Peripheral arthritis and spinal lesions were observed in 14 (26%) and 9 (16%) cases, respectively. Twenty-six cases (48%) were treated with NSAIDs alone, which was effective in most of the cases. NSAIDs were also used in combination with predonisone in 5 cases. In 9 cases who did not respond to NSAIDs, salazosulfapyridine was used, and 6 of these cases showed improvement of pain and a decrease in CRP.

Conclusion: We reviewed 54 cases with PAO. The skin lesions preceded, or occurred simultaneously, with arthro-osteitis in most of the cases. In addition to anterior chest wall lesions, which were the most common finding, peripheral arthritis and spinal lesions were also observed in about 20% of the cases. NSAIDs were effective in about half of all the cases. Salazosulfapyridine and oral steroids may therefore be a potentially useful treatment regimen for cases refractory to NSAIDs.

541

High Prevalence of Spondyloarthritis Among First Degree Relatives of Patients with Familial Mediterranean Fever: Further Evidence for a Link Between the Two Disorders. Servet Akar[1], Ozgul Soysal[2], Dilek Solmaz[2], Vedat Gerdan[2], Fatos Onen[1] and Nurullah Akkoc[1]. [1]Professor, Izmir, Turkey, [2]MD, Izmir, Turkey

Background/Purpose: Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever and serositis. It is associated with the missense variations of Meditteranean fever (MEFV) gene. There is some evidence that spondyloarthritis (SpA) including ankylosing spondylitis (AS) is more prevalent in FMF patients. Moreover we and other groups showed M694V, the most penetrant MEFV variation, may be an additional susceptibility factor for AS. Therefore in the present study we investigated the prevalence of SpA and AS in first-degree relatives (FDRs) of FMF patients.

Methods: The FDRs (> 16 years old) of 201 consecutive unrelated FMF patients were invited to the outpatient clinic. They were examined according to a standard protocol to capture patients with SpA. Presence of inflammatory back pain (IBP) was judged according to the Calin and Berlin criteria. Standard pelvic X-rays of the sacroiliac joints (SIJ) were performed in all patients. The diagnosis of SpA and AS were made based on the European Spondyloarthritis Study Group (ESSG) and the modified New York (mNY) criteria, respectively.

Results: The 201 probands had 1039 FDRs, who were over 16 years-old. Of them, 892 were alive. Ninety-six FDRs who could not be reached after at least three attempts and 84 FDRs with FMF were not included in the study. Of the remaining 712 FDRs, 319 agreed to participate of whom 233 (73%) reported back pain. IBP was present in 32 patients (13.7%) according to Calin criteria and in 20 patients (8.6%) according to Berlin criteria. Thirty-six FDRs were diagnosed as having SpA and five of them as having AS. One additional patient with AS was identified when the medical records of the 393 non-attending invitees were reviewed. The prevalence of SpA and AS among 712 FDRs were calculated as 5.1% and 0.8%, respectively. Based on a prevalence of 1.09% of SpA and 0.49% of AS found in a previous study conducted in our region, the risk ratio was estimated as 4.6 (95%CI; 2.9 to 7.4) for SpA and 1.7 (95%CI; 0.7 to 4.3) for AS in all the relatives. When only the parents (n=275) were considered, the risk ratios for SpA and AS, were 6.9 (95%CI; 4.1 to 11.9) and 2.94 (95% CI; 1.02 to 8.41). Furthermore, two patients with Behcet's syndrome, two patients with rheumatoid arthritis and one patient with un-differentiated arthritis were detected in the study population.

Conclusion: The higher frequency of SpA among the FDRs of the FMF patients and the higher prevalence of AS among the parents, are in line with the previously published studies which have reported high prevalence of sacroiliitis or SpA in FMF patients.

542

The Presence of HLA-B15 Determines the Clinical Presentation and Outcome in Colombian's Patients with Spondyloarthropathies. John Londono[1], Paola Peña[2], Ana Santos[3], Wilson Bautista-Molano[2], Consuelo Romero Sanchez[2], Mabel Avila[4], Marlon Porras[4], Calos Jaramillo[3], G. Vargas-Alarcon[5] and Rafael Valle-Oñate[6]. [1]Universidad de La Sabana, Chía, Colombia, [2]Spondyloarthritis Group. Rheumatology Division. Hospital Militar Central/Universidad de La Sabana. Bogotá. Colombia, Bogotá, Colombia, [3]Universidad de Los Andes, Bogota, Colombia, [4]Spondyloarthritis Group. Rheumatology Division. Hospital Militar Central/Universidad de La Sabana. Bogotá. Colombia, Bogota, Colombia, [5]Instituto Nacional de Cardiologia Ignacio Chavez, Ciudad de Mexico DF, Mexico, [6]Spondyloarthritis Group. Rheumatology Division. Hospital Militar Central/Universidad de La Sabana, Bogotá, Colombia

Background/Purpose: In patients with Spondyloarthropathies (SpA) the association with the HLA-B15 has been previously established: 35/228 patients were positive for this allele, while only was present in 2/100 controls: OR 5.3CI95%: 1.8–17.6. (EULAR2011–4847).To determine differences in clinical presentation and outcomes of the disease among HLA-B15+, HLA-B27+ and non B27-B15 patients.

Methods: 435 of a total of 574 patients with SpA according to ESSG classification criteria and had completed HLA typing were selected. Comparisons with HLA-B27+, B15 and non B27-B15 were made to the main clinical features; disease-related background and the commitment level of the sacroiliac joints.

Results: The main findings are presented in the table:

VARIABLE	HLA-B15(+) n=52	HLA-B27(+) n=179	OTHER HLA-B n=203
Age (y)	31.8 ± 10.6	34.9 ± 10.1	35.5 ± 13.03
Age of onset (y)	26.9 ± 9.2	27.3 ± 10.4	29.2 ± 10.6
Evolution (y)	4.7 ± 5.2*	7.9 ± 10.3	6.4 ± 8.6
Sex(M/F)	33/19 1.7:1*	145/34 4.2:1	128/76 1.6:1
u-SpA	25 (48.1%)*	35 (19.6%)	102 (50.2%)
AS	10 (19.2%)	92 (51.4%)*	43 (21.2%)
ReA	17 (32.7%)*	51 (28.5%)	47 (23.2%)
PsA	0 (0%)	1 (0.1%)	11 (5.4%)
Family history for SpA	5 (9.6%)*	10 (5.6%)	12 (5.9%)
Inflammatory back pain	11 (21.1%)	50 (27.9%)	60 (29.5%)
SCHOBER	15.4 ± 3.7	14.7 ± 2.9	14.7 ± 2.1
X-ray Sacroilitis <II	26 (50%)*	51 (28.6%)	151 (74.4%)
X-ray Sacroilitis ≥II	26 (50%)	128 (71.4%)*	52 (25.6%)
Occiput to wall distance (cm)	0.2 ± 1.4	1.3 ± 3.5	0.5 ± 1.7
ASAS Axial criteria	36 (69.2%)	178 (99.4%)*	84 (41.4%)
ASAS Peripheral criteria	41 (78.8%)	161 (89.9%)	203 (100%)

Conclusion: Patients HLA-B15 positive initiated the disease at an earlier age and had a shorter time of evolution, the predominance of males was lower, with a greater proportion of patients with u-SpA and a lower degree of compromise of sacroiliacs joint. This seems to be a pattern of presentation of the disease.

543

Rituximab (RTX) Therapy for Psoriatic Arthritis (PsA). M. Esther Jimenez Boj[1], Jozef Rovensky[2], Tanja A. Stamm[1], H. Raffayova[3], Burkhard F. Leeb[4], Klaus P. Machold[5] and Josef Smolen[6]. [1]Medical University of Vienna, Vienna, Austria, [2]Vurch, Piestany, [3]National Institute of Rheumatic Diseases, Piestany, Slovakia, [4]State Hospital Weinviertel,Lower Austrian Centre for Rheumatology, Stockerau, Austria, [5]Vienna Med Univ, Vienna, Austria, [6]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Psoriatic arthritis is a chronic and frequently destructive arthropathy which, in contrast to rheumatoid arthritis (RA), is usually negative for autoantibodies including rheumatoid factor (RF). The current treatment armamentarium comprises several synthetic disease modifying antirheumatic drugs (DMARDs) and TNF inhibitors. In contrast, several other biological agents are available for the treatment of RA. RTX is one of them but is apparently primarily effective in RF-positive patients, although some efficacy has been reported also in RF-negative individuals. It has not yet been assessed in PsA and there have been reports on reactivation of psoriasis in some RTX treated patients. Therefore it deemed appropriate to assess the potential benefit of RTX in PsA initially in an open label study. Here we evaluated the efficacy and safety of RTX in an exploratory, open label study of patients with PsA.

Methods: Nine patients with PsA underwent RTX at 1000mg twice within 14 days and were evaluated, among other traditional variables, by DAS28, DAPSA, BASDAI, HAQ and PASI. Patients were followed monthly for 6 months. Changes in scores were calculated using Kruskal-Wallis test.

Results: Baseline demographics showed an age of 50±11, disease duration of arthritis 9±7 and psoriasis of 12 ± 7 years; mean swollen and tender joint counts (SJC 66, TJC68) were 12±7 and 23±10, respectively. RTX was tolerated well and there were no serious adverse events. Over 6 months, DAS28 improved from a median (IQR) of 6.2 (5,9;6.4) to 4.9 (4.3;5.4), DAPSA from 52.0 (39.5;58.5) to 32.5 (21.5;54.3) and HAQ from 1.5 (1.3;1.6) to 1.0 (0.75;1.6) (all $p \leq 0.05$). C-reactive protein and PASI did not change signicantly. BASDAI decreased from 6.2 (5.2; 7.4) to 5.3 (3.8; 6.9; p=n.s).

Conclusion: In this exploratory, open label study, RTX therapy exhibited significant efficacy in PsA patients with long-standing disease. In particular, composite scores decreased and physical function improved beyond the minimal clinically important difference. Over the 6 months of observation, RTX was well tolerated and there was no reactivation of psoriasis. These data suggest that RTX may have efficacy in PSA and warrant testing this hypothesis in a double blind controlled clinical trial.

544

Expression of Dendritic Cell-Specific Transmembrane Protein (DC-STAMP) and Osteoclast Precursor (OCP) Frequency in Psoriasis (PsC) Patients Who Develop Psoriatic Arthritis (PsA). Yahui Grace Chiu[1], Sutharshini Shanmugarajah[2], Dafna D. Gladman[2], Ben Panepento[1], Sharon Moorehead[1], Lihi Eder[2], Vinod Chandran[2], Rick Barrett[1] and Christopher Ritchlin[1]. [1]University of Rochester, Rochester, NY, [2]Toronto Western Hospital, Toronto, ON.

Background/Purpose: Approximately 20% of psoriasis (PsC) patients (pts) develop psoriatic arthritis (PsA) within 10 years after PsC onset. Identification of an arthritis biomarker in PsC would facilitate early intervention with the potential to delay and/or prevent the onset of psoriatic arthritis (PsA). Previously, we reported an increased frequency of circulating osteoclast precursors (OCP) in one third of PsC pts, and examined the potential of Dendritic Cell-Specific Transmembrane Protein (DC-STAMP), a transmembrane protein required for monocyte fusion during osteoclast (OC) formation, as an arthritis susceptibility biomarker in PsC. Four major DC-STAMP expression patterns were identified in human PBMC, in which OC counts increase from pattern I to pattern IV. Healthy controls usually belong to DC-STAMP pattern I, whereas PsA pts manifest DC-STAMP patterns II-IV. Herein we present the data on DC-STAMP and OCP on 10 PsC pts who developed PsA in the International Research Team (IRT) registry..

Methods: PsC and PsA pts were diagnosed by rheumatologists according to a standard criterion and enrolled in the IRT registry. Patients were evaluated annually or earlier if they developed joint pain. Diagnosis of new PsA onset was based on the Classified Criteria for Psoriatic Arthritis (CASPAR) criteria. The DC-STAMP pattern and OCP frequencies were examined in pts by flow cytometry and cell culture.

Results: Between 2006 and 2011, 516 PsC pts were enrolled in the IRT registry and 22 pts developed PsA. The DC-STAMP and OCP frequency were analyzed on 43 PsC pts who did not develop PsA and 10 pts who developed PsA as shown in the table below. For 10 pts who developed PsA, 3 samples were collected before PsA onset and 7 samples were collected on or after PsA diagnosis. Among these 7 subjects, 3 pts were on methotrexate and 1 was on etanercept at the time of blood draw.

Pattern		I	II	III	IV
DC-STAMP	PsC	12	15	11	5
	PsA	2	1	5	2
OCP frequency	PsC	629 + 1036	839 + 1213	286 + 353	1039 + 1064
	PsA	28 + 40	850 + 0	360 + 318	775 + 576

70% of PsC pts who developed PsA had patterns III or IV compared to 37% of PsC patients who had not developed PsA. Consistent with our previous finding, DC-STAMP pattern IV was associated with the highest OCP frequencies.. Nail disease and increased PASI score were two risk factors associated with PsA onset.

Conclusion: These data suggest that DC-STAMP may be a susceptibility marker for arthritis in PsC patients. The lower levels of circulating OCP in some PsA compared to PsC pts may reflect increased migration of these cells into inflamed joints. Additional studies with these biomarkers on PsC pts at risk for arthritis in the IRT registry are in progress.

Radiographic Progression in Ankylosing Spondylitis – Results After up to 8 Years of Infliximab Treatment. Xenofon Baraliakos[1], Hildrun Haibel[2], Joachim Listing[3], Joachim Sieper[4] and Juergen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [3]German Rheumatism Research Centre, Berlin, Germany, [4]Charité – Campus Benjamin Franklin, Berlin, Germany

Background/Purpose: Therapy with TNF-blockers is clinically efficacious in patients with active AS. Improvement of spinal inflammation was demonstrated by MRI but inhibition of radiographic progression has not been shown. Hypothetical considerations have suggested TNF blockers could worsen structural changes. Baseline (BL) radiographic damage is the only significant predictor for further radiographic progression in AS. We compared the long-term course of radiographic changes in AS patients treated with infliximab ('aTNF') vs. a historical cohort (Herne cohort, 'HC') with retrospectively collected patients who were never treated with TNF blockers.

Methods: Overall, 22 patients were included in aTNF and 34 in HC, based on the availability of lateral x-rays of the cervical and lumbar spine at BL and after 8 years. The radiographs, mostly performed in 2-year intervals, were scored by two blinded readers using the mSASSS in concealed time order. The expectation-maximation (EM) algorithm was used to impute missing radiographs at year 4. Mann-Whitney test was used for simple comparisons between both cohorts. ANCOVA was applied to compare radiographic progression between both cohorts after adjustment for BL status. The progression between year 4 and year 8 was compared by means of non-parametric ANCOVA and by taking the status at BL and the radiographic progression between BL and 4y into account.

Results: Patients in the aTNF group had higher BASDAI (6.2±1.4 vs 4.3±1.4 in HC) and BASFI (5.3±1.4 vs. 3.4±1.5, both $p<0.0001$) levels at BL. HC patients were older, had a longer disease duration and were less frequently HLA B27-positive. The degree of baseline radiographic damage was similar in both groups (13.2± 17.6 in aTNF vs. 14.2± 13.8 in HC, p=0.26). Both groups showed significant radiographic progression after 8y (20.2±21.4 in aTNF and 25.9±17.8 in HC (both $p<0.001$). Similar radiographic progression was seen in the groups between BL and 4y (4.1 units in aTNF and 4.3 in HC (p=0.51). After adjustment for baseline mSASSS and for the rate of radiographic progression during the first 4y, less radiographic progression between 4y and 8y was found in aTNF (2.9 units), vs. HC (7.4 units) (p=0.029). In contrast, adjusting for age (p=0.61), symptom duration (p=0.42), HLA-B27 (p=0.10), BASDAI (p=0.53) and BASFI (p=0.38) at BL did not significantly influence radiographic progression. The number of new syndesmophytes/patient after 8y in patients without BL-syndesmophytes did not differ between groups (0.8±1.6 in aTNF vs. 2.6±4.7 in HC, p=0.36). This was in contrast to the patients with BL-syndesmophytes: less new syndesmophytes developed in the aTNF group (1.3±4.5) vs. HC (3.3±1.9), (p=0.032).

Conclusion: This study shows ongoing radiographic progression in patients with established AS over 8 years. Taking into account the relatively low patient numbers and the nature of the historical cohort, these data show no evidence that continuous anti-TNF therapy leads to increased radiographic progression in AS. It seems even possible that long-term anti-TNF therapy may decrease radiographic damage. This is also backed by the result that less new syndesmophytes developed in anti-TNF treated patients.

547

Cardio-Metabolic Risk Profile of Patients with Psoriatic Arthritis and Psoriasis. Yih Chang Lin[1], Kiyoko Uno[1], Neil J. Korman[2], Neil Borkar[2], Katherine Wolski[1], Danielle Brennan[1], Vaibhav Pawar[2], Stephen J. Nicholls[3] and M. Elaine Husni[1]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]University Hospitals-Case Medical Center, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland

Background/Purpose: Incremental increase in inflammatory pathways in psoriatic arthritis (PsA) may contribute to an even higher cardiovascular (CV) risk and metabolic syndrome (MetSyn) as compared to psoriasis (PsO) alone. This study aims to establish if presence of inflammatory joint disease in patients with psoriasis is a risk factor for MetSyn.

Methods: 252 patients with psoriatic diseases were prospectively recruited from two tertiary care referral centers. PsA was diagnosed after satisfying the CASPAR criteria and confirmed by board certified rheumatologist, while PsO was diagnosed by a board certified dermatologist. The clinical database was used to determine prevalence of conventional CV risk factors and MetSyn profiles for patients with and without DMARD therapy (both non-biologic and biologics). MetSyn was defined by NCEP/ATP III criteria. Comparisons between PsA and PsO were tested using t-tests and chi-squares. Univariable and multivariable odds ratios (ORs) were calculated to determine the association of PsA and MetSyn.

Results: 145 PsO patients (58%) and 107 PsA patients (42%) were included in the study. There was similar gender distribution (p 0.784), prior CV event (p-value 0.891), and family history of CV risk (p 0.161). However, there was difference in age distribution (p 0.004) and disease duration (p <0.001). PsA patients have significantly higher prevalence of hypertension, obesity, CRP, hypertriglyceridemia, hyperglycemia, and MetSyn with p <0.011, <0.01, 0.03, <0.02, 0.01, <0.01 respectively compared with PsO. In addition, PsA patients who are not on active DMARDs therapy have significantly higher prevalence of MetSyn (p <0.001) and increased Framingham risk score (p 0.005) as compared to PsO. However, the significance was lost when patients were analyzed on DMARDs treatment (p 0.568 and 0.717 respectively). PsO with inflammatory joint disease was found to be a risk factor for MetSyn (unadjusted OR 2.658 (95% CI [1.518–4.653])). After adjustment for age, family history of CV risk, CRP, and treatment with DMARDs, inflammatory arthritis remained significant risk factor for MetSyn (OR 3.423, 95% CI [1.431–8.189]).

Table 1. Adjusted ORs for MetSyn risk factors

Covariates	Adjusted ORs (95% CI)	p-value
PsA vs. PsO	3.423 (1.431, 8.189)	0.006
Age	1.033 (1.005, 1.061)	0.020
Family history of CV risk	3.568 (1.368, 9.305)	0.009
log CRP	1.590 (1.169, 2.164)	0.003
DMARDs (Biologic and Non biologic)	2.336 (1.049, 5.200)	0.038

Conclusion: Our results suggest that presence of inflammatory joint disease in patients with psoriasis is a significant risk factor for MetSyn. PsA patients also have significantly higher prevalence of conventional CV risk factors and higher Framingham risk scores as compared to PsO. However, there is no significant difference once patients are on active DMARDs treatment for psoriatic diseases.

548

Approaching Psoriatic Arthritis - Comparing the Patients's Perspective to Physicians' Evaluations. Matthias Englbrecht, Stefan W. H. Dandorfer, Monika R. Ronneberger, Veronika Lang and Georg Schett. University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: To date, we hardly now anything about the comparability of physician's to patient's evaluation of disease related-symptoms in psoriatic arthritis (PsA). To investigate the relation of physician's to patient's evaluation of symptoms in PsA.

Methods: We examined 55 outpatients by referring to the GRAPPA core set of disease related symptoms for PsA including visual analogue scales for general pain, global status, arthritis and psoriasis related symptoms (i.e. status of peripheral joints, spinal involvement, enthesitis, involvement of the skin and the nails) and other symptoms (fatigue & sleep disorders). The second part of the questionnaire consisted of symptom interrelations of arthritis and psoriasis according to the individually experienced magnitude and patients were asked to complete the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). The corresponding physician evaluated the patient's condition by using VAS for global status, disease activity of arthritis and psoriasis, and additional comparative measures (i.e. TJC68/SJC66, the Psoriasis Area and Severity Index, the Nail Psoriasis Severity Index and the Maastricht Ankylosing Spondylitis Enthesitis Score with gradation for tendon specific pain). After transformation for better comparability of scores, these measures where compared to the corresponding VAS-ratings of the patient by calculating 95% confidence intervals of differences.

Results: On average, when comparing the magnitude of interrelations, patients evaluated symptoms of arthritis [95%CI:4.29; 5.71] to be worse than symptoms of psoriasis [95%CI:1.58; 3.00] or additional symptoms such as fatigue or sleep disorders [95%CI:2.19; 3.20]. When looking at 95%CI of average differences of VAS evaluations between patients and physicians for global status, arthritis and psoriasis, appraisals differed considerably with patients stating higher ratings (indicated by 95%CI > 0; global status: [95%CI:0.66; 1.79], rheumatic disorders: [95%CI:0.30; 1.33], psoriatic disorders: [95%CI:0.54; 1.58]). These results where confirmed in corresponding 95%CIs and t-tests with respect to physician-patient comparisons when applying comparative measures ($p \leq 0.02$, see Table 1).

Table 1 Comparison of average ratings on patient's VAS and comparative measures

	Dimension 1	Dimension 2	Dimension 3	Dimension 4	Dimension 5	Dimension 6
Comparative measures (Mean ± SD)	TJC68 (1.92 ± 2.15)	SJC66 (0.62 ± 0.75)	BASDAI (3.92 ± 2.28)	MASES (1.35 ± 1.69)	PASI (0.2 ± 0.29)	NAPSI (0.64 ± 1.13)
Patient VAS (Mean ± SD)	Global Pain (3.81 ± 2.82)	Disorders of joints (3.87 ± 2.72)	Global disease activity (3.99 ± 2.80)	Enthesitis (2.57 ± 2.76)	Skin disease activity (2.1 ± 2.58)	Nail disease activity (1.21 ± 1.83)
p-value of dependent samples t-test (p-value)	7.15 (< 0.001)***	18.46 (< 0.001)***	0.38 (0.70)	3.73 (< 0.001)***	5.76 (< 0.001)***	2.41 (0.02)*
95% CIs of difference (VAS – comparative measure)	[1.40; 2.48]	[2.67; 3.84]	[-0.43; 0.83]	[0.58; 1.91]	[1.24; 2.57]	[0.09; 1.62]

Conclusion: In general, patients gave significantly higher ratings to some disease-related symptoms than physicians did. Hence, when investigating the perceived disease impact it seems necessary to take into account both sides of the coin—the patient's as well as the physician's perspective.

549

Radiological Characteristics of the Calcaneal Spurs in Psoriatic Arthritis. Mohammed Abufayyah[1], David Salonen[2], Arane Thavaneswaran[3], Vinod Chandran[1] and Dafna D. Gladman[3] [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]University Health Network, Toronto, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Inflammation at the entheses is a distinguishing feature of psoriatic arthritis (PsA). Enthesitis at the heel is the most common location; irregular spiculated calcifications often at sites of enthesis such as the Achilles and plantar fascia insertions on the calcaneous. This study aimed to 1) describe the morphological features and measurements of plantar calcaneal spurs on weight bearing lateral foot radiographs in subjects with PsA and controls and 2) determine radiological features that differentiate between inflammatory & non-inflammatory calcaneal spurs.

Methods: Weight bearing lateral foot radiographs of 101 subjects with PsA and 38 control subjects without inflammatory arthritis were examined for plantar calcaneal and Achilles spurs. Three measurements were taken from each radiograph: plantar spur base, mid-segment, and length in millimeters as shown in Figure 1. The differences in radiographic measurements, and the presence of fluffy periostitis of the plantar spurs were then compared between PsA patients and controls.

Results: Of the 101 subjects with PsA, 76 (75%) had at least one plantar calcaneal spur and 32 (31.5%) had at least one Achilles tendon spur, compared to 18 (47%) and 3 (8%) respectively in control group (p=0.004). The presence of fluffy plantar periostitis was identified in 14 PsA subjects but in none of the controls (p=0.01). The dimensions of plantar spurs were significantly different between groups (table 1); Logistic regression identified that gender and mid-segment distinguished patients with PsA from controls.

Table 1. Demographics, Radiological characteristics and Measurement of Calcaneal Spurs:

Variable	Mean (stdev) or Frequency (%) PsA n=101	Controls n=38	p-value
Gender (M/ F)	65 (64.4%)/36 (35.6%)	15 (39.5%)/23 (60.5%)	0.008
Age	41.1 (10.8)	49.2 (14.7)	0.003
Obesity	42 (44.7%)	6 (46.1%)	0.92
DISH	4 (4.0%)	0 (0.0%)	0.21
Achilles Spurs	32 (31.5%)	3 (8%)	0.004
Plantar Spurs	76 (75.0%)	18 (47.5%)	0.002
Bilateral	56	11	
Unilateral	20	7	
Fluffy plantar periostitis	14 (8.4%)	0 (0.0%_)	0.01
Base (mm)	7.1 (2.8)	4.6 (1.5)	<0.0001
Mid (mm)	4.9 (2.2)	2.3 (0.9)	<0.0001
Length (mm)	4.5 (2.1)	4.2 (1.7)	0.57

Figure 1. Lateral radiograph with measured dimensions of plantar spur; (A) Spur base; (B) Mid-segment; and (C) Spur length.

Conclusion: In this observational study we found that calcaneal spurs are more common in subjects with PsA, and that a higher midsegment measurement was associated with PsA. This study provides radiological differentiating features between inflammatory and non-inflammatory spurs including the presence of fluffy plantar periostitis and broad based and mid-segment dimensions.

Smoking Is Associated with Syndesmophyte Development in Ankylosing Spondylitis. Dilek Solmaz[1], Servet Akar[2], Ismail Sari[3], Ozgul Soysal[1], Vedat Gerdan[1], Fatos Onen[2] and Nurullah Akkoc[2]. [1]MD, Izmir, Turkey, [2]Professor, Izmir, Turkey, [3]Dokuz Eylul University School of Medicine, Izmir, Turkey

Background/Purpose: Information on risk factors for the severity of spinal involvement in ankylosing spondylitis (AS) is limited. In this cross-sectional study we examined the association of the presence of syndesmophytes with smoking, which has been suggested to be related to a more severe disease course by some authors, and with the presence of calcaneal enthesophytes, which may be an indicator of a tendency to bone formation in AS.

Methods: We included 114 patients with AS (77 male [67.5%] with a mean age of 40.7 ± 11.4 years) who had available lateral heel radiographs and vertebral X-rays for review. All patients fulfilled the modified New York criteria. Two independent readers evaluated the vertebral and lateral heel radiographs for the presence of syndesmophytes and enthesophytes at the insertion of the *achilles* tendon or *plantar* fascia. In cases of disagreement consensus was reached by second reading session. All clinical and demographic data, including disease activity (BASDAI), functional (BASFI) and mobility (BASMI) scores at the time of radiographic examination and the highest available ESR and CRP levels as well as the smoking status were obtained from the medical records. The relation of the variables with syndesmophyte formation was evaluated with phi coefficient or Spearman's rho. Logistic regression model was used to identify the independent risk factors for the presence of vertebral syndesmopytes.

Results: Clinical and demographic features of the patients are summarized in table 1. A total of 61 (53.5%) patients had syndesmophytes and 73 (64%) had calcaneal enthesophytes. There were moderate and substantial agreement between the two readers in regard with the presence of vertebral syndesmophytes (k=0.706) and calcaneal enthesophytes (k=0.846). Univariate analysis revealed the presence of syndesmophytes was associated with smoking status, the presence of calcaneal enthesophytes as well as age, sex, highest available ESR, BASFI and BASMI (table 2). After multivariate logistic analysis smoking status, male sex, BASMI score and age remained significantly associated with the presence of syndesmophytes (table 2).

Table 1. Characteristics of the study group

	AS patients (n=114)
Age, mean ± SD	40.7 ± 11.4
Male sex: n (%)	77 (67.5)
Disease duration, mean ± SD (years)	6.7 ± 7.9
Symptom duration, mean ± SD (years)	15.1 ± 10.1
Ever-smoker: n (%)	81 (71.7)
Education Level, mean ± SD (years)	9.2 ± 4.0
ESR, mean ± SD	43.2 ± 28.6
CRP, mean ± SD	33.6 ± 42.1
BASDAI, mean ± SD	3.1 ± 2.6
BASFI, mean ± SD	3.5 ± 2.2
BASMI, mean ± SD	3.8 ± 1.9
ASDAS ESR, mean ± SD	2.7 ± 1.1
ASDAS CRP, mean ± SD	2.7 ± 1.1

Table 2. Factors associated with and independently predict the presence of syndesmophyte formation.

Variables	The presence of vertebral syndesmophyte *Rho or phi*	*p*	OR (95% CI)	*P*
Age	0.394	<0.001	1.09 (1.02–1.7)	0.008
Sex	0.218	0.020	4.95 (1.3–18.7)	0.018
Ever-Smoker	0.236	0.012	6.26 (1.46–26.73)	0.013
ESR	0.277	0.003	1.01 (0.99–1.03)	0.102
BASFI	0.314	0.001	1.07 (0.85–1.34)	0.534
BASMI	0.467	<0.001	1.63 (1.16–2.30)	0.005
Calcaneal entesophytes	0.254	0.007	1.53 (0.47–4.97)	0.472

Conclusion: Smoking, male sex, age and BASMI scores are independently associated with structural damage in AS. The association between the presence of calcaneal enthesophytes and syndesmophytes, which was present in univariate analysis but which disappeared after multivariate logistic regression analysis, needs to be further explored in future prospective studies.

551

Three Phenotype Profiles Are Revealed by Cluster Analysis in Early Inflammatory Back Pain Suggestive of Spondyloarthritis (SPA). Results From the DEvenir Des Spondyloarthropathies Indifferenciées Récentes (DESIR) Cohort. Maria-Antonietta D'Agostino[1], Philippe Aegerter[2], Maxime A. Breban[3] and Maxime Dougados[4]. [1]Versailles-Saint Quentin en Yvelines University- APHP, Ambroise-Paré Hospital, Boulogne-Billancourt, France, [2]Versailles-Saint Quentin en Yvelines University- APHP, Ambroise-Paré Hospital,, Boulogne-Billancourt,, France, [3]Hopital Ambroise Pare, Boulogne, France, [4]Paris-Descartes University, Paris, France

Background/Purpose: SPA spectrum refers to a variety of skeletal and extra-articular inflammatory manifestations that may combine differently among patients. The objective of the study was to examine whether SPA disease manifestations at baseline would combine according to an ordered or random pattern in patients with early inflammatory low back pain (IBP) and suggestive of SPA.

Methods: Baseline clinical and demographic characteristics, as well as imaging (i.e. pelvic X-rays, pelvic MRI and peripheral entheses ultrasound) and biological data (including HLA-B27) of patients included in the French multicenter DESIR cohort of early (< 3 yrs duration) IBP suggestive of SPA were analysed by multiple correspondence analysis in order to graphically assess the association between the studied manifes-

tations. Several methods of cluster analysis using those variables were then performed to identify subgroups of patients with similar characteristics.

Results: Seven hundred and eight patients were included into the Cohort. Among the 700 analysed patients cluster analysis allowed us to classify 688 patients in 3 major groups (table 1). Cluster A contained a majority of men, with predominant isolated axial manifestations, and higher frequency of uveitis and positivity of HLA-B27. Cluster B predominantly consisted of women, with higher frequency of peripheral signs (including vascularisation at entheses by power Doppler ultrasound (PDUS)), psoriasis and younger onset of disease symptoms. Cluster C was composed by patients with predominant axial symptoms, equal distribution of sex, highest presence of pelvic X-rays and MRI positivity, and lower prevalence of HLA-B27 positivity.

Table 1.

Characteristics	Cluster A (n = 163)	Cluster B (n = 209)	Cluster C (n = 316)	Global P^+
Sex (% of men)	61%	28%	49%	<0.0001
Age at onset (<40 ys)	76%	69%	88%	0.0027
Duration of symptoms (>24 months)	31%	24%	37%	0.007
Arthritis (% of yes)	45%	95%	40%	<0.0001
Enthesitis (% of yes)	40%	82%	32%	<0.0001
Dactylitis (% of yes)	13%	31%	2%	<0.0001
Uveitis (% of yes)	14%	9%	5%	0.003
Psoriasis (% of yes)	14%	32%	7%	<0.0001
IBD* (% of yes)	1.2%	4%	2%	ns
HLA-B27 + (% yes)	61%	36%	28%	<0.0001
X Rays sacroiliitis (% of yes)	16%	21%	36%	<0.0001
MRI sacroiliitis (% of yes)	34%	24%	47%	<0.0001
Vascularized PDUS enthesitis°(% of yes)	15.7%	23%	8.5%	0.004

* IBD=inflammatory bowel diseases; °at least one; $^+$Kruskal-Wallis test.

Funding: The DESIR cohort is supported by an unrestricted grant from PFIZER France

Conclusion: Cluster analysis of SPA manifestations among patients with early IBP allowed us to clearly identify at baseline 3 different groups of clinical phenotypes. Ongoing follow up will allow to determine whether these clusters may correspond to different severity patterns.

552

Atherosclerotic Burden In Patients with Psoriatic Arthritis and Psoriasis: Do They Differ? Yih Chang Lin[1], Kiyoko Uno[1], Neil Borkar[2], Danielle Brennan[1], Vaibhav Pawar[2], Katherine Wolski[1], Neil J. Korman[2], Stephen J. Nicholls[3], Soo Hyun Kim[4] and M. Elaine Husni[1]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]University Hospitals - Case Medical Center, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, [4]Cleveland Clinic, Cleveland, OH

Background/Purpose: Both psoriatic arthritis (PsA) and psoriasis (PsO) has each been shown to have increased cardiovascular (CV) morbidity. This study was aimed to identify the presence of atherosclerotic burden in patients with PsA and PsO. We investigated the hypotheses that the incremental inflammatory pathways in PsA of both skin and joint will have greater atherosclerotic burden than PsO alone.

Methods: 178 patients with psoriatic disease were prospectively enrolled from two tertiary-care referral centers. PsA was diagnosed after satisfying the CASPAR criteria and confirmed by board certified rheumatologist, while PsO was diagnosed by a board certified dermatologist. Common carotid intima media thickness (cIMT) was measured using high resolution B mode ultrasonography. cIMT was summarized with means ± SD or medians (Q1-Q3). Comparisons were made using Student's t-test and Wilcoxon rank-sum test.

Results: Our study cohort included 59 PsA patients and 119 PsO patients. The groups were comparable with regards to gender distribution, smoking history, alcohol use, diabetes status, and CV co-morbid diseases (stroke, MI, PVD, diabetes and other cardiovascular diseases). As anticipated, PsO patients were younger compared to PsA patients ($p < 0.01$). cIMT measurements were significantly higher in patients with PsA showing greater mean cIMT (0.70 vs. 0.66, p 0.048) and maximum cIMT (1.13 vs. 0.98, p 0.01).

Conclusion: Our patients with PsA demonstrated a greater carotid intima thickness compared with PsO patients. PsA affecting both skin and joint may increase their atherosclerotic burden compared to PsO alone. Further study is needed to elucidate the mechanism that inflammatory arthritis may contribute a greater risk than skin alone.

553

Inhibition of Hyaluronan Synthesis with 4-Methylumbelliferone In NZBWF1/J Mice Is Associated with Improved Renal Function and Reduced Renal Inflammation. Susan Yung, Wan Wai Tse, Mel Chau and Tak Mao Chan. The University of Hong Kong, Hong Kong SAR, Hong Kong

Background/Purpose: Lupus nephritis is a severe complication of systemic lupus erythematosus and an important cause of renal failure. We have previously demonstrated that hyaluronan (HA), an important extracellular matrix component that possesses inflammatory activities, is increased in the kidneys of patients with lupus nephritis. To delineate the role of HA in the pathogenesis of lupus nephritis, this study investigated the effect of 4-methylumbelliferone, a specific inhibitor of HA synthesis, on clinical, serologic and expression of inflammatory mediators in a murine lupus nephritis model.

Methods: Female NZBWF1/J mice with established nephritis and proteinuria >3g/l were randomized to receive treatment with sterile PBS, vehicle alone (1% Arabic Gum in PBS) or 4-methylumbelliferone in 1% Arabic Gum (4-MU, 3g/kg/day) for 2, 4, 8 and 12 weeks by oral gavage (n=6 for all time points for each group), after which time mice were sacrificed and blood collected for the assessment of serum levels of creatinine and urea. Kidneys were harvested for histologic assessment and expression of inflammatory mediators. Spot urine was obtained for the measurement of albumin-to-creatinine ratios. Six mice with established disease were also sacrificed at the beginning of the study to obtain baseline clinical, serologic and histologic data.

Results: Overall survival of mice treated with PBS, Arabic Gum and 4-MU was 75.5%, 78.8% and 90.0% respectively after 12 weeks treatment (P=NS). Serum HA levels increased in a time-dependent manner in PBS and vehicle treated mice, which was associated with increased periglomerular and tubulointerstitial expression of HA. Treatment of mice with 4-MU for 12 weeks reduced serum HA levels by 30% and reduced HA expression to near normal levels in both renal compartments. Urine albumin-to-creatinine ratio and serum levels of urea and creatinine increased in both PBS and vehicle treated mice with increasing progression of disease, whilst these abnormalities were significantly decreased in 4-MU treated mice after 12 weeks treatment ($P<0.05$ for all compared to both control groups). Suppression of HA synthesis in MU-treated mice was associated with reduced IgG and C3 deposition in glomeruli and decreased expression of $CD4^+$ T cells, $CD19^+$ B cells, and macrophages compared to PBS and Arabic Gum treated mice.

Conclusion: These results suggest that hyaluronan plays an important role in the pathogenesis of lupus nephritis and suppression of its synthesis can ameliorate disease manifestations in lupus nephritis.

554

Carabin, a Negative Regulator of B Cells, Points Out a New Defective Biological Pathway In Systemic Lupus Erythematosus. Jean-Nicolas Schickel[1], Jean-Louis Pasquali[1], Anne Soley[1], Anne-Marie Knapp[1], Marion Decossas[1], Luc Marcellin[2], Anne-Sophie Korganow[1], Thierry Martin[1] and Pauline Soulas-Sprauel[1]. [1]IBMC, Strasbourg, France, [2]Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Background/Purpose: The mechanisms of B-cell dependent autoimmunity are not entirely elucidated, but could notably result from a faulty negative regulation of mature B cells. Indeed, intrinsic defects of several B-cell negative regulators lead to the development in mice of a systemic lupus erythematosus (SLE)-like disease, with production of antinuclear autoantibodies, sometimes associated to the development of a glomerulonephritis (GN). Carabin is a known negative regulator of T cells that inhibits calcineurin and Ras pathways. Considering the important molecular similarities of antigen receptor signaling in T and B cells, including the role of Ras and Calcineurin pathways in BCR signaling, we decided to evaluate the role of Carabin in B cells, which is currently unknown, and to look for signs of autoimmunity in Carabin deficient mice.

Methods: We analyzed the phenotype of Carabin knock-down (KD) A20 B cells, we generated Carabin knock-out (KO) and B cell specific conditional KO mice, and analyzed B cell functions and autoimmune symptoms in these animals.

Results: Upon BCR stimulation, Carabin deficient B cells accelerate Erk phosphorylation. In vivo, Carabin is not involved in B cell development and in the basal secretion of immunoglobulins. However, Carabin deficiency

clearly impacts on the function of mature Carabin deficient B cells. Indeed, Carabin deficient mice speed up both T-dependent and T-independent B cell responses. Moreover, CpG-DNA treatment of non autoimmune-prone Carabin deficient mice induces a prolonged overproduction of anti-DNA autoantibodies and a lupus-like mesangial type II glomerulonephritis, with large immune deposits. Finally, B cell Carabin expression is low in young (NZB/NZW)F1 mice (spontaneous model of lupus) before the appearance of the disease, is associated with increased Erk phosphorylation, and is also low in a subset of lupus patients.

Conclusion: Our results support the idea that Carabin is a negative regulator of early B cell responses, and that its deficiency in mice can lead to autoimmunity, providing a dual stimulation of the BCR and TLR pathways. In addition, we show that Carabin expression is low in B cells from (NZBxNZW)F1 mice and from a subgroup of patients with quiescent SLE. Taken together, these results depict Carabin as a new player in autoimmunity.

555

TWEAK/Fn14 Pathway Blockade Attenuates Renal Disease In Autoantibody-Induced Nephritis. Yumin Xia[1], Sean Campbell[1], Leal Herlitz[2], Jennifer S. Michaelson[3], Linda C. Burkly[3] and Chaim Putterman[4]. [1]Albert Einstein College of Med, Bronx, NY, [2]Columbia Presbyterian Medical Center, [3]Biogen Idec, Cambridge, MA, [4]Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: TNF-superfamily (TNFSF) members are instrumental in the pathogenesis of lupus and lupus nephritis. Previously, we found that TWEAK (TNFSF12)-mediated activation of its receptor, Fn14, stimulates the secretion of MCP-1, RANTES and IP-10 by mesangial cells and podocytes. TWEAK also modulates renal cell survival and proliferation. Thus, we hypothesized that TWEAK blockade may be therapeutically beneficial in autoantibody-mediated nephritis.

Methods: Nephrotoxic serum nephritis (NTN), a murine model for lupus nephritis, was used to study the relevance of the TWEAK/Fn14 pathway in the pathogenesis of renal disease induced by pathogenic antibodies.

Results: We induced NTN by passive transfer of pre-formed nephritogenic rabbit antibodies into 129 Fn14 knockout (KO) and wildtype (WT) mice. On days 7, 14, and 21 after antibody transfer, Fn14 KO mice had significantly decreased levels of proteinuria as compared to Fn14 WT mice (day 7: 61±24 vs 220±42 mg/dl, $p<0.01$; day 14: 99±50 vs. 678±205 mg/dl, $p=0.02$; and day 21: 101±49 vs. 678±205 mg/dl, $p=0.02$). Moreover, crescent formation and tubular dilatation were significantly decreased in Fn14 KO vs. WT mice (**Figure 1**), as were MCP-1, RANTES, and IP-10 kidney mRNA expression levels. To confirm the protective effect of TWEAK inhibition with a pharmacological approach, we induced nephrotoxic nephritis in 129 Fn14 WT mice and initiated treatment with an anti-TWEAK monoclonal antibody (mAb) or an isotype matched control Ig. Similar to the results in the Fn14 KO mice, significant amelioration of proteinuria and improvement in renal histology was observed in mice with induced nephritis receiving treatment with an anti-TWEAK mAb. Anti-TWEAK mAb treatment did not appear to affect the systemic immune response, as no alteration in the murine anti-rabbit IgG subclass antibody titers was evident.

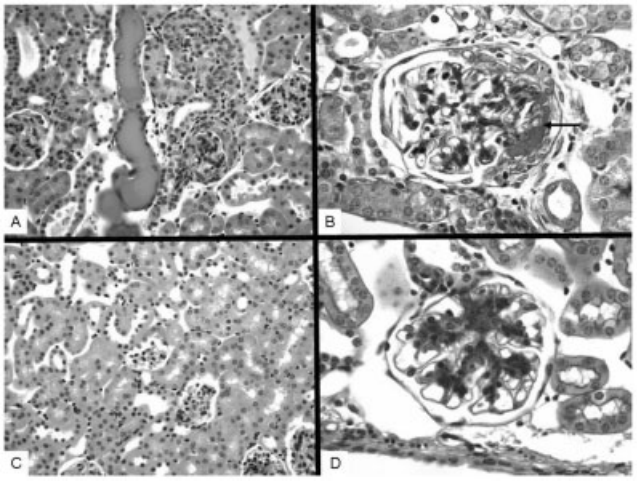

Figure 1. NTN induced in Fn14WT (A & B) and Fn14KO mice (C &D). Panel A shows a large proteinaceous tubular cast as well as mild interstitial inflammation. Also present are 3 glomeruli, one of which shows a crescent. Panel B shows a glomerulus with a large PAS-positive immune deposit (arrow) as well as a segmental overlying cellular crescent. Panel C shows a representative picture of the essentially normal tubulointerstitium seen in Fn14KO mice, with only occasional proteinaceous casts. Panel D shows a representative glomerulus from a Fn14KO mouse. While PAS positive immune deposits are seen in the mesangium, endocapillary proliferation and crescent formation were rare.

Conclusion: TWEAK/Fn14 interactions promote the pathogenesis of nephritis in the NTN model, apparently playing an important role in the cascade of pathologic events locally in the kidney rather than by impacting the systemic immune response. Therefore, disrupting TWEAK/Fn14 interactions may be an innovative approach for the treatment of lupus and other antibody-induced renal diseases.

556

Deficiency of the TWEAK Receptor Fn14 Is Protective In the MRL-Lpr/Lpr Mouse Model of Lupus Nephritis. Yumin Xia[1], Jing Wen[1], Jennifer S. Michaelson[2], Linda C. Burkly[2] and Chaim Putterman[3]. [1]Albert Einstein College of Med, Bronx, NY, [2]Biogen Idec, Cambridge, MA, [3]Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: Inhibition of various TNF superfamily (TNFSF) ligand-receptor interactions has proven to have significant therapeutic effects in murine models of lupus and in human disease. Previously we showed that TWEAK (TNFSF12)/ Fn14 (TNFRSF12a) interactions may play a role in the pathogenesis of lupus nephritis (LN). Renal mesangial cells, podocytes, and tubular cells express Fn14, the receptor for TWEAK. TWEAK engagement of Fn14 induces these kidney resident cells to produce multiple inflammatory mediators including MCP-1 and RANTES, which have been conclusively shown to play a role in the pathogenesis of experimental LN. In the chronic graft versus host (cGVH) model, transfer of alloreactive splenocytes to B6 mice results in anti-nuclear antibody generation and renal Ig deposition leading to glomerular proteinuria reminiscent of lupus. In this model, genetic deficiency of Fn14, or treatment with an anti-TWEAK mAb, decreased kidney inflammation and proteinuria without affecting systemic autoantibodies. These studies suggested that inhibition of TWEAK/Fn14 interactions might be efficacious in spontaneous models of lupus.

Methods: We assessed the role of the TWEAK/Fn14 pathway in the pathogenesis of LN by evaluating the effect of Fn14 deficiency in the well-established MRL/lpr spontaneous mouse model of lupus.

Results: We found that kidney Fn14 expression was significantly increased in MRL/lpr mice at 26 as compared to 7 weeks of age, while splenic Fn14 expression actually decreased over time. Kidney TWEAK mRNA expression in MRL/lpr mice was also increased over time, significantly higher by 19 as compared to 7 weeks of age, and further increased and significantly higher in MRL/lpr as compared to MRL/+ mice by 26 weeks of age.

At 26 weeks of age, MRL/lpr Fn14 WT mice (n=10) had significantly higher levels of proteinuria (1022±317 mg/dl) as compared to MRL/lpr Fn14KO (n=9) (38±8 mg/dl, $p=0.01$) (**Figure 1**).

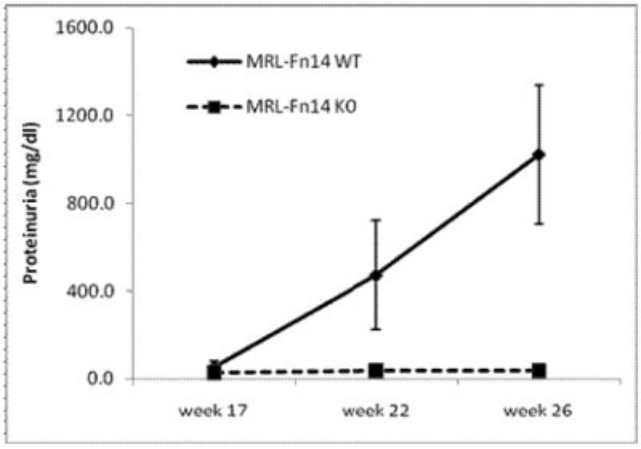

Figure 1.

To determine whether reduced severity of nephritis was due to a decrease in the titer of circulating antibodies, we compared serum autoantibody titers

in MRL/lpr Fn14 WT and KO mice. There were no differences between the groups in anti-dsDNA antibody titers at the various time points, suggesting that TWEAK likely acts by modulating events locally in the kidney.

Conclusion: TWEAK/Fn14 interactions are instrumental in the pathogenesis of LN in the MRL/lpr mouse model. Our results suggest that blocking the effects of TWEAK may be a novel therapeutic approach to the treatment of the kidney disease associated with SLE without inducing systemic immunosuppression.

557

Interferon Regulatory Factor-4 deficient Lupus-Prone MRL/*Lpr*Mice Show Strong Propensity for Th1 Polarity and Develop Granulomatous Lesions in Multiple Organs. Hidemaru Sekine[1], Takeshi Machida[1], Eiji Suzuki[2], Christopher Reilly[3], Xian Zhang[4], Phil Ruiz[5] and Gary S. Gilkeson[6]. [1]Fukushima Medical University, Fukushima, Japan, [2]Medical University of South Carolina, Charleston, SC, [3]Virginia Tech, Blacksburg, VA, [4]Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC, [5]University of Miami, Miami, FL, [6]Division of Rheumatologyand Immunology, Medical University of South Carolina, Charleston, SC

Background/Purpose: The transcription factor interferon regulatory factor-4 (IRF-4) is a member of the IRF family of transcription regulators and required for Ig-production/maturation of B cells and development of Th2 and Th17 cells. Previously, we found *Irf4* gene deficient MRL/*lpr* lupus-prone mice develop dermatitis, ear necrosis and diffuse proliferative glomerulonephritis without serum autoantibodies and glomerular immune complex (IC)/C3 depositions. Furthermore, the mice exhibited significantly increased $CD4^+$ T cells with enhanced IFN-γ producing Th1 cells in their spleens. These results suggested a skewed Th1 phenotype in $Irf4^{-/-}$ MRL/*lpr* mice.

Methods: To further define the mechanisms of the disease in $Irf4^{-/-}$ MRL/*lpr* mice, we performed kinetic analysis of splenocyte populations in 6, 12, and 24 weeks old $Irf4^{-/-}$ and $Irf4^{+/+}$ (w.t.) MRL/*lpr* and C57BL/6 mice by flow cytometry. Splenocytes from 12-week-old mice were sorted into $CD4^+$ naïve ($CD44^{low}CD62L^{high}$), memory ($CD44^{high}$ $CD62L^{high}$), and effector ($CD44^{high}CD62L^{low}$) T cells, and stimulated with PNA/ionomycin. Cytokine production was detected by intracellular cytokine staining and flow cytometry. Histopathological analysis of livers, lungs, and spleens in 24 week old animals was performed in addition to analysis of their kidneys, skin, and ears.

Results: By 24 weeks-of-age, all $Irf4^{-/-}$ MRL/*lpr* mice developed whitish spleens characterized by formation of fibrous areas between the lymphoid areas, expansion of lymphoid populations in white pulp area with loss of architecture, and histiocyte proliferation. In addition, 5 of the 10 $Irf4^{-/-}$ MRL/*lpr* mice developed multiple granulomatous lesions in their livers and/or lungs characterized by infiltration of lymphocytes and formation of multinucleated giant cells including Langhans-type giant cells. In contrast, neither whitish spleen nor granulomatous lesion was observed in age-matched w.t. MRL/*lpr,* $Irf4^{-/-}$C57BL/6 or w.t. C57BL/6 mice. At 12 weeks-of-age, $Irf4^{-/-}$ MRL/*lpr* mice had significantly increased splenic $CD4^+$ T cells with differentiation into memory $CD4^+$ T cells (12 wks; $5.9\pm1.9\times10^7$ vs $1.1\pm0.3\times10^7$, $p = 0.021$) and effector $CD4^+$ T cells (12 wks; $3.6\pm1.1\times10^7$ vs $1.1\pm0.3\times10^7$, $p = 0.038$) compared to age-matched w.t. MRL/*lpr* controls. Similar trends were observed between 24 weeks old $Irf4^{-/-}$ and w.t. C57BL/6 mice. Intracellular cytokine analysis showed a significantly increased population of IFN-γ-producing memory $CD4^+$ T cells in the spleens of $Irf4^{-/-}$ MRL/*lpr* mice compared to w.t. MRL/*lpr* mice ($47.5\pm3.3\%$ vs $33.4\pm2.4\%$, $p = 0.026$). Furthermore, we found significant IFN-γ production in naïve $CD4^+$ T cells from $Irf4^{-/-}$ MRL/*lpr* mice, while minimal to no IFN-γ production was noted in naïve $CD4^+$ T cells from MRL/*lpr* mice ($33.1\pm6.5\%$ vs $0.96\pm0.4\%$, $p = 0.008$).

Conclusion: Our results indicate that IRF-4 plays an important role in the regulation of Th1 polarity and affects disease expression in MRL/*lpr* mice. Our results also indicate that their pathogenesis in $Irf4^{-/-}$ MRL/*lpr* mice is independent of autoantibodies/IC-mediated mechanisms, and is most likely dependent on autoreactive Th1 cell-mediated mechanisms.

558

TNFα Inhibition Prevents Peri-Glomerular Resident Renal Macrophage Accumulation and Activation in SLE Nephritis. Ramalingam Bethunaickan[1], Yiting Tang[2] and Anne Davidson[3]. [1]Feinstein Institute for Medical research, Manhasset, NY, [2]Feinstein Institute for Medical Research, Manhasset, [3]Feinstein Institute for Medical Research, Manhasset, NY

Background/Purpose: TNFα antagonists are therapeutic in several autoimmune diseases but they may also precipitate SLE. In mouse models of SLE, TNFα is protective in the early disease stages but it is overexpressed in inflamed kidneys in late disease and contributes to renal damage. Consistent with both protective and pro-inflammatory roles of TNFα in SLE, TNFα blockade improved proteinuria in patients with SLE nephritis but increased autoantibody titers. The purpose of our experiments was to investigate the mechanism for efficacy of TNFα inhibition in a murine model SLE nephritis.

Methods: NZB/W mice were treated with a low dose of IFNα-expressing adenovirus at the age of 12 weeks. Once autoantibodies appeared in the serum at Day 21, treatment was started with fully murine TNFR2-Ig, 50ug three times per week. Mice were monitored at two week intervals for proteinuria and serum autoantibodies. Groups of mice were sacrificed at intervals after treatment and systemic immune activation was evaluated by flow cytometry of spleen cells and ELISpot for autoantibody producing B cells. Renal disease was evaluated by histology, immunohistochemistry, flow cytometry and real-time PCR quantitation of inflammatory mediators.

Results: TNFR2-Ig did not prevent the onset of proteinuria, but the proteinuria followed a remitting relapsing course and longevity of the mice was remarkably prolonged compared with untreated controls. Treatment did not decrease titers of autoantibodies, the percentage or numbers of activated T and B cells in the spleens, or the number of autoantibody producing B cells as assessed by ELISpot assay and there was no change in renal immune complex deposition. The onset of proteinuria in NZB/W mice is associated with an increase in renal macrophages ($CD11b/F4/80^{hi}/CD11c^{int}$) and an influx of dendritic cells ($CD11b/F4/80^{lo}/CD11c^{hi}$) together with marked upregulation of CD11b on resident renal $F4/80^{hi}$ macrophages. Kidneys from TNFR2-Ig treated mice had a significant decrease in the percentage and total number of renal $F4/80^{hi}$ cells, but not $CD11c^{hi}$ cells. In NZB/W mice, renal dendritic cells are located only in lymphoid cell aggregates whereas macrophages are located in the peri-glomerular region and in a cuff around lymphoid aggregates. Kidneys from TNFR2-Ig treated mice retained lymphoid aggregates containing $CD11c^{hi}$ and $F4/80^{hi}$ cuffs but peri-glomerular accumulation of $F4/80^{hi}$ macrophages was virtually absent. Real-time PCR analysis revealed a significant decrease in renal expression of chemokines CCL2 and CCL5, of the endothelial activation marker VCAM-1, of genes involved in tissue remodeling and of the markers of proximal tubule damage LCN2 and KIM-1.

Conclusion: TNFα decreases the renal inflammatory response to immune complex deposition by inhibiting the glomerular expression of chemokines and endothelial activation. This decreases the recruitment of peri-glomerular and interstitial renal macrophages that play a role in tissue remodeling and prevents the activation of renal tubular cells that follows exposure to an inflammatory urinary ultrafiltrate. Lymphoid aggregates appear to accumulate in the kidneys in a TNFα independent manner and are not sufficient to induce terminal renal damage.

559

Increased Expression of Ribonuclease Prolongs Survival in Murine Lupus. Xizhang Sun[1], Nalini Agrawal[1], Lena Tanaka[1], Martha Hayden-Ledbetter[1], Kelly L. Hudkins[1], Charles E. Alpers[1], Silvia Bolland[2], Jeffrey A. Ledbetter[1] and Keith B. Elkon[1]. [1]University of Washington, Seattle, WA, [2]NIH, NIAID, Rockville, MD

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multisystem autoimmune disease characterized by the presence of high titer autoantibodies directed against self nucleoproteins. These antibodies interact with antigens to form immune complexes (ICs) that deposit in the kidneys, skin and vasculature. In addition to directly inducing tissue injury, nucleoprotein containing ICs are endocytosed by plamacytoid dendritic cells (pDC) and, following activation of intracellular TLR 7 and 9, stimulate the production of type 1 interferon (IFN). Evidence supporting the pre-eminence of TLR7 as the main inducer of IFN-a in mice include increased expression of TLR7 in BXSB mice and amelioration of disease in MRL/lpr mice deficient in TLR7 but not TLR9. In humans with SLE, the importance of TLR7 is also evident because the IFN signature is best correlated with anti-RNP containing autoantibodies and polymorphisms associated with increased TLR7 expression are observed in males with SLE.

Goals: Since i) RNA is the critical component of ICs that stimulate TLR7 to induce IFN-a and ii) degradation of RNA with RNase attenuates IFN-a production in an *in vitro* bioassay, we asked whether increasing RNase concentrations *in vivo* would be effective in ameliorating disease in lupus-prone mice.

Methods: C57BL/6 (B6) mice that overexpress TLR7 (TLR7 transgenic (Tg) mice) develop a lupus-like disease with autoantibodies and the deposi-

tion of ICs in the kidneys. They have a median survival of ~ 6 months). We created a mouse strain, JLC, on the B6 background that overexpressed bovine RNase. The mice were healthy and exhibited no apparent changes in lymphoid composition in the spleen or lymph nodes. We then crossed the JLC mice to TLR7 transgenic mice (TLR7 Tg) to create RNase × TLR7 doubleTg (DTg) mice. Two cohorts were studied: Cohort A was sacrificed at 3–4 months for immunological studies and cohort B was a survival study (n = 20 in each group) that was terminated at 12 months. Kidneys were examined by light microscopy, Mac2 staining as well as indirect immunofluorescence for IgG and C3 deposition.

Results: In both single RNAse Tg as well as DTg mice, RNase was secreted into the serum and increased expression levels were detected by an ELISA as well as by a functional enzyme assay in RNA coated agar gels (serum enzyme diffusion or SRED). In Cohort A mice sacrificed at 3–4 months, we observed statistically significant reductions in PAS staining, glomerular tuft size as well as less macrophage infiltration (all $p < 0.05$) in the kidneys. In Cohort B, there was a statistically significant increase in survival in DTg as compared to TLR7 Tg mice (mean survival of 6 and 9 months for single versus DTg respectively, $p < 0.01$). When the study was terminated at 12 months, examination of the kidneys revealed that there was reduced IgG and C3 deposition in DTg as opposed to single TLR7 Tg mice in surviving mice ($p < 0.05$).

Conclusion: Our results indicate that increased expression of RNase significantly attenuates kidney damage in a lupus mouse model and also significantly improves survival. This novel form of treatment encourages nuclease based therapies to be considered for ameliorating SLE in the future.

Laquinimod Inhibits Disease Severity and Progression in Mouse Models of Lupus: Alone and in Combination with Standard of Care Agents. Joel F. Kaye, Revital Etzyoni, Rotem Keshet-Katz, Emanuel Raymond and Eran Blaugrund. Teva Pharmaceuticals Ltd, Netanya, Israel

Background/Purpose: Laquinimod (LAQ; TV-5600) is a synthetic compound being developed by Teva for the treatment of multiple sclerosis (MS). Laquinimod has demonstrated therapeutic effect in various experimental autoimmune models, including animal models of Experimental Encephalitis (EAE), Inflammatory Bowel Disease, Guillain-Barré Syndrome and Type I Diabetes. The mechanism of action of laquinimod in these models includes the reduction of leukocyte infiltration and modulation of the cytokine milieu. Furthermore, gene expression studies from MS patients have shown that laquinimod modulates the expression of genes related to inflammation and antigen presentation. These promising findings indicate that laquinimod acts as an immunomodulator, targeting a pivotal pathway of autoimmunity, and prompted the present study to evaluate its effect on disease progression in mouse models of SLE.

Methods: Female (NZBxNZW) F1 and MRL/lpr mice were obtained from The Jackson Laboratory (Bar Harbor, ME). Proteinuria (PU) was measured by a semi-quantitative procedure using reagent strips for urine analysis (Albustix, Bayer). Once PU was present in at least 20% of mice, the mice were divided into experimental groups and treatment was initiated. Mice were treated with LAQ (PO daily), Cyclophosphamide (CTX; 50mg/kg IP weekly), Mycophenolate mofetil (MMF; 30 or 100mg/kg IP daily)) or Dexamethasone (Dexa; 0.5mg/kg IP daily). The levels of proteinuria and serum anti-dsDNA antibodies were measured over the treatment period. At study termination, organs were removed for histopathology as well as analysis of immune complex deposition (ICD) in the kidneys.

Results: Treatment with LAQ (0.2, 1, 5 & 25mg/kg) in NZB/W mice resulted in dose dependent reduction of anti-dsDNA antibody levels, almost complete inhibition of proteinuria from as low as 0.2mg/kg, and significant dose dependent prolongation of survival. Analysis of ICD in the kidneys of mice following 12 weeks of treatment showed that mice treated with laquinimod (5mg/kg) had significantly less deposits than vehicle- or CTX-treated animals. Finally, we explored the effect of combining LAQ with either MMF or Dexa. In both of these studies, combining 1mg/kg LAQ with a low dose (30mg/kg) of MMF or with Dexa enhanced the effect of each compound alone. Conversely, neither compound interferes with the potency of laquinimod.

In the MRL/lpr model of lupus, animals were monitored until their urine proteinuria reached >200 mg/dL at which time they were enrolled in the study and treated with either 1 or 5 mg/kg of LAQ or 100 mg/kg MMF for 12 weeks. LAQ treatment resulted in reduction of proteinuria and anti-dsDNA levels throughout the study. Histopathological analysis of organs showed that laquinimod treatment reduced glomerulonephritis, salivary gland inflammation, splenomegaly and symptoms of lupus arthritis.

Conclusion: Here we show that laquinimod effectively inhibits disease progression in both NZB/W and MRL/lpr spontaneous mouse model of lupus. These data suggest that the immunomodulator laquinimod is a promising new oral drug for treating SLE, and as such we have commenced clinical trials in both Lupus Nephritis and Lupus Arthritis.

Impaired Inhibition on B Cell Activation by Bone Marrow-Derived Mesenchymal Stem Cells with Decreased CCL2 Expression in MRL/Lpr Mice. Nan Che, Xia Li and Lingyun Sun. the Affiliated Drum Tower Hospital of Nanjing University Medical School, Jiangsu 210008, China P.R, Nanjing, China

Background/Purpose: Bone marrow–derived mesenchymal stem cells (BM-MSCs) are multipotent cells characterized by immunomodulatory properties and are therefore considered a promising cell therapy for autoimmune diseases. It has been shown that BM-MSCs from healthy donors are able to inhibit the activation of B cells in vitro and in vivo. Our previous study revealed that BM-MSCs from patients with systemic lupus erythematosus (SLE) possessed some dysfunctions. This study aimed to assess whether inhibition on B cell activation by BM-MSCs in MRL/lpr mice, an animal model of SLE, was impaired and the possible mechanisms involved in this process.

Methods: BM-MSCs were isolated and expanded from either C57BL/6J or MRL/lpr mice. The effects of BM-MSCs on the proliferation and differentiation to plasma cells of normal splenic B cell isolated from C57BL/6J mice were evaluated in vitro. And the differential expression of CCL2 on BM-MSCs from C57BL/6J or MRL/lpr mice was detected. Lupus mice were treated with these two different BM-MSCs respectively, and the levels of serum autoantibodies and immunoglobulin deposition in the kidney were monitored.

Results: BM-MSCs from C57BL/6J mice inhibited the proliferation and differentiation to plasma cells of B cells in vitro. This inhibitory effect was mediated by soluble factors, including CCL2, as neutralizing CCL2 could abolish the suppressive effect on B cells mediated by normal BM-MSCs. Inhibition on B-cell proliferation and differentiation by BM-MSCs from MRL/lpr mice was impaired, partially resulted from down-regulated expression of CCL2. The addition of processed CCL2 restored inhibitory effects of BM-MSCs from MRL/lpr mice on B-cells. In vivo treatment with BM-MSCs from MRL/lpr mice did not reduce the levels of serum pathological antibody production and immunoglobulin deposition in the kidney compared with treatment with BM-MSCs from C57BL/6J mice.

Conclusion: Our findings suggest that inhibitory effects of BM-MSCs on B-cell are mediated by soluble factors including CCL2. Impaired inhibition of BM-MSCs from MRL/lpr mice on B-cell maybe attributes to the down-regulation of CCL2 expression, which may play an important role in the pathogenesis of SLE.

***Yaa*-Mutation Induces Phenotype Shift From Rheumatoid Arthritis to Systemic Lupus Erythematosus in FcgRIIB-Deficient B6 Mice.** Hirofumi Amano, Shinya Kawano, Toshiyuki Kaneko, Aya Sato-Hayashizaki, Lin Qingshun, Yoshinari Takasaki and Sachiko Hirose. Juntendo University School of Medicine, Tokyo, Japan

Background/Purpose: We previously obtained a FcγRIIB-deficient C57BL/6 (B6) congenic strain of mice, which spontaneously developed severe rheumatoid arthritis (RA). The development of systemic lupus is accelerated by the *Yaa* (*Y-linked autoimmune acceleration*) mutation, which is a consequence of a translocation from the telomeric end of the X chromosome containing the *Tlr7* gene onto the Y chromosome. To examine the effect of the *Yaa* mutation on the autoimmune disease phenotype in this strain, we established B6.FcγRIIB$^{-/-}$.*Yaa* mice by introducing *Yaa* mutation into the RA-prone FcγRIIB-deficient B6 mice.

Methods: The *Yaa* mutation was introduced into FcγRIIB$^{-/-}$ mice from B6.*Yaa* mice. Serum levels of RF, IgG antibodies against double-stranded DNA and chromatin were measured using ELISA. The severity of renal disease was monitored by biweekly testing for proteinuria.Histopathological examination was also performed.

Results: The disease phenotype shifted from RA to SLE in B6.FcγRIIB$^{-/-}$.*Yaa* mice.They did not develop RA, instead they showed the marked increase in serum levels of rheumatoid factor and SLE-related autoantibodies such as anti-chromatin and anti-ds DNA antibodies. These developed glomerulonephritis with the high incidence of positive proteinuria even at 6 months of age.

Conclusion: The present studies suggest that the common genetic pathways play a role in the disease process shared by RA and SLE, and the environmental factors such as the stimulation of innate immune system may control separate autoimmune diseases RA and SLE.

Anti-Interleukin 23 Antibody Alleviates Nephritis in MRL/*Lpr*lupus-Prone Mice. Ourania Kampagianni, George C. Tsokos and Vasileios C. Kyttaris. Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background/Purpose: Interleukin-23 (IL-23) dependent IL-17$^+$ T helper lymphocytes (Th17) are potent inducers of tissue inflammation and have been associated with autoimmunity. We have previously shown the importance of IL-23/IL-17 axis in development of lupus nephritis and demonstrated that IL-23 receptor deficiency prevents the development of nephritis in lupus-prone mice. The aim of this study is to determine whether treatment of lupus-prone mice with an anti-IL-23 blocking antibody mitigates nephritis.

Methods: 9-week old MRL/*lpr* lupus-prone mice were injected intraperitoneally three times a week with 20 μg of rat anti-mouse IL-23 antibody, or equal amount of rat anti-mouse IgG as control, for 7 weeks. Proteinuria was monitored by weekly urine collection. Serum samples were obtained at three different time points (start, middle and at the end of treatment). The mice (N=3 for each group) were subsequently sacrificed and spleen and lymph nodes were extracted for cell cultures, where cytokine production and gene expression were analyzed.

Results: The anti-IL-23-treated mice (treated group) had significantly less proteinuria at the end of the study when compared to IgG treated (control group) (average albumin/creatinine ratio; treated: 4.1 mg/gr vs. control: 14.6 mg/gr). After 7 weeks, spleen and lymph nodes lymphocytes were activated *in vitro* with anti-CD3 and anti-CD28 antibodies; the supernatants were collected 24 hours later and tested for cytokine concentration. The anti-IL-23 antibody treatment decreased the production of IL-17A (treated: 208.6±69.1 pg/mL vs. control: 632.0±366.4 pg/mL) and IL-6 (treated: 427.8±114.7 pg/mL vs. control: 820.3±82.3 pg/mL). On the contrary IFNγ did not differ between the groups.

Using targeted mRNA screening for inflammation related genes, we found that anti-IL-23 treatment resulted in a decrease by 79% of the levels of the chemokine receptor CCR2 in T cells, suggesting that IL-23 plays a significant role in lymphocyte trafficking in these mice.

Immunoglobulin and anti-dsDNA levels, which were already very high at the beginning of the treatment, did not change with this short anti-IL-23 treatment.

Conclusion: Treatment of lupus-prone mice with anti-IL-23 antibody leads to decreased production of Th17 related cytokines and amelioration of kidney disease. These results urge the development of IL-23 targeting therapeutic regimens in systemic lupus erythematosus patients.

Dysregulation of Clade A Serine Protease Inhibitor Expression in Murine and Human Lupus. Jack Hutcheson[1], Kamala Vanarsa[1], Soyoun Min[1], Tianfu Wu[1] and Chandra Mohan[2]. [1]University of Texas, Southwestern Medical Center at Dallas, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: The serine protease inhibitor (Serpin) superfamily acts to limit tissue damage and excess apoptosis caused by proteases by irreversibly binding their targets. Defects in serpin function have been associated with a number of diseases including alpha 1-trypsin deficiency, Alzheimer's disease, prostate cancer, and Crohn's disease. SerpinA3 is an interferon-mediated acute phase inflammatory response protein which binds certain cathepsins, kallikreins and other serine proteases. Despite its documented role in acute inflammation, the exact role of serpinA3 in a chronic inflammatory condition such as systemic lupus erythematosus (SLE) is unclear.

Methods: To investigate disease pathways in lupus, spleens were collected from 6-month-old MRL/lpr, NZM2410, and B6.Sle1.Sle3 lupus-prone and B6 lupus-resistant strains of mice, and subjected to a microarray transcriptomic analysis. To confirm the results from the microarray analysis, quantitative real-time PCR (qPCR), western blot, and immunofluorescence assays were performed. To determine if these data were of clinical relevance, sera from adult patients with mild non-renal (n=21), severe non-renal (n=4), or active renal (n=43) SLE were screened by ELISA. Matched healthy adults served as controls (n=10).

Results: Several clade A serpins were shown by microarray to be upregulated in the spleens of MRL/lpr lupus-prone mice as compared to lupus-resistant B6 mice. One serpin in particular, serpinA3g (serpinA3 in humans, or alpha 1-antichymotrypsin), has successfully been validated by qPCR, where gene expression was 4.56-fold higher in MRL/lpr spleen as compared to B6 mice (P=0.003) and expression was 3.54-fold higher than lupus-prone B6.Sle1.Sle3 mice (P=0.005). Protein levels of serpinA3g were confirmed to be increased in the spleens, kidneys, and livers of MRL/lpr mice as compared to B6 mice, while B6.Sle1.Sle3 mice displayed intermediate expression, by western blot and confocal microscopy. The latter experiment revealed multiple splenic cells expressing SerpinA3, including macrophages and neutrophils, as well as some B cells. Further investigation of serpinA3 levels in SLE patient sera revealed a 1.67-fold (P=0.0002), 1.41-fold (P=0.08), and 1.87-fold (P<0.0001) increase in mild non-renal, severe non-renal, or active renal SLE patients, respectively, as compared to healthy controls. However, serpinA3 levels did not correlate with the SLE disease activity index.

Conclusion: The serine protease inhibitor serpinA3 (serpinA3g in mice) is increased in both patients and mice with SLE. Whether serpinA3 is elevated in a disease-causative manner or whether it is elevated in response to increased inflammation (and serine proteases) is yet to be determined. The molecular mechanism for this increase in lupus and its role within the kidneys are under further investigation.

565

IL-21R Is Required for the Systemic Accumulation of Activated B and T Lymphocytes in MRL^{lpr}Mice. Andrew L. Rankin[1], Tatyana Andreyeva[1], Yijun Carrier[2], Mary Collins[3], Cheryl L. Nickerson-Nutter[3], Deborah Young[2] and Kyri Dunussi-Joannopoulos[3]. [1]Pfizer, Inc., Cambridge, MA, [2]Colleague, Cambridge, MA, [3]Pfizer, Cambridge, MA

Background/Purpose: IL-21 is a pleiotropic cytokine that can influence the activation and proliferation of both B and T cells. We previously showed that the development of lupus-like disease manifestations in MRL^{lpr} mice could be prevented by blocking IL-21 pharmacologically. We generated IL-21R deficient MRL^{lpr} mice to examine the impact of loss of IL-21R signaling on the systemic lymphocyte activation and accumulation observed in MRL^{lpr} mice.

Methods: C57Bl/6.IL-21R$^{-/-}$ mice were backcrossed with MRL^{lpr} mice to generate MRL^{lpr}.IL-21R$^{-/-}$ mice. Disease development in MRL^{lpr}.IL-21R$^{-/-}$ mice was monitored in a time-course study that included assessment of proteinuria (Albustix, Bayer), histologic examination of renal pathology and gross evaluation of skin lesions. B and CD4$^+$ T cell activation status was examined using standard flow cytometric based methods.

Results: MRL^{lpr}.IL-21R$^{-/-}$ mice exhibited significantly decreased proteinuria, lymphadenopathy and reduced severity of cutaneous lesions and renal inflammatory infiltrates. Splenomegaly was reduced in MRL^{lpr}.IL-21R$^{-/-}$ and resulted from a profound reduction in CD4$^+$ T cells, B cells and DN T cells. The vast majority of CD4$^+$ T cells in MRL^{lpr} mice bore an activated cell surface phenotype (CD44^{hi} CD62^{lo}), which was significantly reduced in MRL^{lpr}.IL-21R$^{-/-}$ mice. Significantly reduced titers of anti-dsDNA antibodes were present in MRL^{lpr}.IL-21R$^{-/-}$ mice and correlated with a dramatic reduction in numbers of splenic germinal center B cells and plasma cells. In addition, both T follicular help and T extrafollicular helper cells, which are key promoters of antibody responses, were significantly reduced in MRL^{lpr}.IL-21R$^{-/-}$ mice.

Conclusion: IL-21R is required for the development of inflammatory lesions in both the kidney and skin of MRL^{lpr} mice. Moreover, the systemic lymphoaccumulation observed in MRL^{lpr} mice is dependent on signals delivered via IL-21R. Our data demonstrate that multiple populations of activated B and T lymphocytes depend on IL-21R for their accumulation. The profound dampening of lymphocyte effector activation in the absence of IL-21R signaling suggests that blockade of the IL-21 pathway may be a promising therapy B and T cell mediated autoimmune diseases such as SLE.

566

Role of CD5 $^+$ B Cells in the Suppression of Fatal Autoimmunity in Lupus-Prone Mice. Yuriy Baglaenko[1], Nan-Hua Chang[2], Evelyn Pau[3] and Joan E. Wither[2]. [1]University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, University Health Network, Toronto, ON, [3]Toronto Western Research Institute, Toronto, ON

Background/Purpose: Although mapping studies suggest the presence of a lupus-susceptibility locus on NZB chromosome 4 (c4), introgression of

this interval onto the B6 background leads to expansion of Natural Killer T (NKT) and $CD5^+$ B cells in the absence of autoimmunity. To further investigate the role of this locus in autoimmunity, bicongenic mice were produced with the c4 locus and a NZB c1 interval previously shown to promote high titre anti-nuclear antibodies (ANAs) and fatal renal disease. Surprisingly, bicongenic c1c4 mice had increased survival, reduced renal disease and a bias towards less-pathogenic IgG1 autoantibodies when compared to c1 mice. Notably, c1c4 mice retained the expansion of NKT and $CD5^+$ B cells. Previous studies with NKT cell knockout mice revealed no effect on disease suppression in c4 mice, and examination of NKT cell activation in c1c4 mice showed no differences in the majority of mice. These findings suggested that NKT cells may have a limited role in disease suppression. Since a functional deficiency of $CD5^+$ regulatory B cells has been proposed to promote autoimmunity in SLE patients, we sought to investigate their role in suppressed c1c4 mice.

Methods: Splenocytes from 4 month old B6, c1, c4, and c1c4 mice were stimulated for 4.5 hours with LPS, PMA, and ionomycin in the presence of GolgiStop. Freshly isolated or stimulated cells were stained for cell surface markers that discriminate between various cell subsets, fixed, permiabilized, and then stained for intracellular IL-10 or Foxp3. Serum levels of anti-ssDNA IgG antibodies were measured by ELISA.

Results: There was a significant increase ($p<0.05$) in IL-10 producing B cells in c4 and c1c4 mice when compared to c1 and B6 controls. These cells were predominantly $CD5^+CD1d^{int}CD19^{hi}$. This finding suggests that the $CD5^+$ B cells in c1c4 and c4 mice may play a suppressive role. Notably, the IL-10 producing B cells in c1c4 mice are phenotypically distinct from previously documented regulatory populations that are reported to have a $CD5^+CD1d^{hi}CD19^{hi}$ phenotype. To further investigate the possible role of IL-10 producing B cells in the regulation of autoimmunity in c1c4 mice, the relationship between the frequency of IL-10 producing B cells and autoantibody levels was examined. There was a significant negative correlation ($r2 = 0.63$, $p = 0.0196$) between the levels of IgG anti-ssDNA IgG and the frequency of IL-10 producing B cells in c1c4 but not B6 mice. No correlation was seen between autoantibody levels and the proportion of NKT cells. Since B regulatory cells have been implicated in the expansion of $CD25^+$ $Foxp3^+$ T regulatory cells, the proportion of these cells was quantified. c4 and c1c4 mice had similar levels of T regulatory cells to c1 mice. There was no correlation with autoantibody levels in c1c4 mice. These data suggests that if the IL-10 producing cells in our model are regulating autoimmunity they are acting independently of T regulatory cells.

Conclusion: Taken together, these data indicate the presence of a phenotypically novel IL-10 producing B cell population in c4 mice that may play a role in suppressing fatal autoimmunity in c1c4 mice.

567

Effects of Fasudil Treatment on Lupus Pathogenesis in NZB/W F1 Female Mice. Roslynn A. Stirzaker[1], Partha S. Biswas[1], Sanjay Gupta[1], Weijia Yuan[1], Li Song[1], Uma Chandrasekaran[1], Govind Bhagat[2] and Alessandra B. Pernis[1]. [1]Hospital for Special Surgery, New York, NY, [2]Columbia University, New York, NY

Background/Purpose: The serine-threonine kinase ROCK2 becomes activated in wild-type $CD4^+$ T cells under T_H17 skewing conditions and phosphorylates IRF4, a transcription factor absolutely required for production of IL-17 and IL-21, two cytokines implicated in the pathogenesis of lupus. In contrast to T cells from non-autoimmune mice, $CD4^+$ T cells from mice that spontaneously develop lupus such as MRL/lpr mice aberrantly activate ROCK2 under neutral conditions. We previously found that treatment of MRL/lpr mice with the ROCK inhibitor Fasudil reduces IL-17 and IL-21 production, and ameliorates autoimmune symptoms, including anti-dsDNA antibody production, immune-complex deposition, and proteinuria. To evaluate whether ROCK inhibition could be broadly effective for the treatment of lupus we have investigated whether administration of Fasudil could also ameliorate lupus in NZB/W F1 mice, another well-established lupus model. We hypothesized that Fasudil would have a protective effect on the spontaneous development and/or progression of lupus in NZB/W F1 mice by inhibiting the activation of immune cells.

Methods: Female NZB/W F1 mice were administered Fasudil Monohydrochloride Salt (100mg/kg) continuously in their drinking water starting at 18 or 24 weeks of age, or were left untreated ($n=10$ per group). Development of nephritis was monitored by regular screening for the presence of proteinuria, and animals underwent regular weighing to monitor weight gain/loss and ensure equivalent water intake amongst the three groups. Surviving mice were sacrificed at the cessation of treatment at 44 weeks of age, and kidneys and spleen were harvested for histopathological analysis. Flow cytometry was used to examine lymphocyte subsets in spleens, and IL-17 and IL-21 gene expression was evaluated by real-time RT-PCR of spleen samples. Serum anti-dsDNA levels and specific Ig isotypes were measured by ELISA.

Results: Fasudil treatment of female NZB/W F1 mice resulted in significantly reduced number of plasma cells compared to untreated mice. No differences in the expression levels of splenic IL-17 and IL-21 were noted. Strikingly, Fasudil treatment caused a significant decrease in the levels of serum anti-dsDNA antibodies and of all serum Ig isotypes investigated (IgG_1, IgG_{2a}, IgG_{2b}, IgG_3, IgM and IgA), and there was a modest but significant decrease in IgG and C3 deposition and in the degree of glomerulonephritis. Importantly the development of severe proteinuria and mortality was significantly reduced in Fasudil treated mice when treatment was started at 18 weeks of age.

Conclusion: This pilot study demonstrates that administration of Fasudil to lupus-prone NZB/W F1 female mice improves a number of pathological features, and may represent a potential treatment for SLE. Further studies are required to further characterize the precise mechanisms by which ROCK inhibition ameliorates lupus pathogenesis in NZB/W F1 mice.

568

The PD-1 Pathway Promotes Survival and Continuing Function of $CD4^+$ regulatory T Cells in (New Zealand Black × New Zealand White) F_1 Lupus-Prone Mice. Maida Wong[1], Antonio La Cava[2] and Bevra H. Hahn[3]. [1]UCLA, Los Angeles, CA, [2]Univ of California Los Angeles, Los Angeles, CA, [3]UCLA David Geffen School of Medicine, Los Angeles, CA

Background/Purpose: Programmed death-1 (PD-1) has been regarded as a negative regulatory signal in T cells. Previously, we have induced tolerance by administration of pConsensus (pCons), an autoantibody Ig-based peptide, which induces both $CD4^+$ and $CD8^+$ $Foxp3^+$ regulatory T cells (T_{reg}), which decrease nephritis and prolong survival. In particular, $CD4^+$ T_{reg} have reduced expression of PD-1 compared to untreated controls. PD-1 is important in T cell regulation of autoimmunity, as young BWF_1 females treated with a neutralizing antibody against PD-1 resulted in reduced anti-dsDNA production, delayed onset of proteinuria and improved survival. We hypothesized that regulation of signaling through PD-1 is required for maintenance of functional T_{reg} and subsequent control of autoimmunity in BWF_1 lupus mice, and that regulatory capacity of the cells is sustained at least in part by resistance to apoptosis, resulting in T_{reg} survival.

Methods: Antibody against PD-1 or control isotype-matched IgG were injected i.p. into naïve vs. pCons-treated BWF_1 mice. Foxp3, PD-1 and Fas expression, were assessed by flow cytometry. Signaling pathway array was performed on the $CD4^+$ T_{reg} at the mRNA level.

Results: In contrast to naïve BWF_1 mice (where numbers of $CD4^+$ T_{reg} decline over time), anti-PD-1 or pCons treatments maintained total numbers of functional suppressive $Foxp3^+CD4^+CD25^+$ T cells between 10 and 40 weeks of age. These $CD4^+$ T_{reg} from the anti-PD-1 or pCons treated mice had decreased PD-1 expression by MFI. Fas was one of the candidate molecules in the apoptotic pathways that was downregulated in splenic $CD4^+$ T_{reg} upon pCons-tolerization or blockade of PD-1. Fewer of these $CD4^+$ T_{reg} had Fas expression, and they were more resistant to spontaneous apoptosis. They suppressed $CD4^+CD25^-$ T cell proliferation and induced apoptosis in B cells, resulting in suppression of autoantibodies.

Conclusion: These data suggest that PD-1 is central in control of at least some regulatory T cells that suppress autoimmunity. Low expression of PD-1 correlated with resistance to apoptosis with decreased Fas expression on the $CD4^+$ regulatory T cells. It is likely that expression of PD-1 on regulatory/suppressor T cells must be finely tuned to permit the cells to survive and retain suppressive capacities. One mechanism by which PD-1 sustains these T_{reg} is by reducing their susceptibility to apoptosis, which may relate to alteration of expression of the Fas/FasL pathway.

569

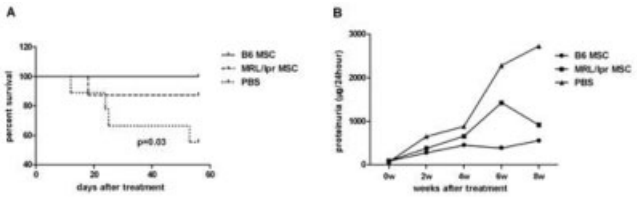
Differential Effect of Autologous Versus Allogeneic Mesenchymal Stem Cell Transplantation in Lupus Prone Mice. Fei Gu[1], Ivan Molano[2], Lingyun Sun[3] and Gary S. Gilkeson[4]. [1]Division of Rheumatology and Immunology,Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, SC, [3]The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [4]Division of Rheumatologyand Immunology, Medical University of South Carolina, Charleston, SC

Background/Purpose: Lupus is a systemic autoimmune disease characterized by the production of autoantibodies and end organ damage from

immune complex deposition. Mesenchymal stem cells (MSCs), multipotent non-haematopoietic stem cells, support haematopoiesis and can differentiate into cells of the mesenchymal lineage. MSCs home to areas of tissue injury and participate in tissue repair, and possess anti-inflammatory and immunosuppressive properties. Defects in MSCs function are reported in cells derived from lupus prone mice and lupus patients. Thus, a key question in the use of MSCs in autoimmune diseases is whether MSCs from lupus donors are defective and thus not suitable for autologous transplantation.

Methods: MRL/*lpr* mice were treated with a single intravenous injection of 10^6 allogeneic C57BL/6J MSCs (n=8), MRL/*lpr* MSCs (n=8), or phosphate buffered saline (PBS) (n=10) at 17 to 20 weeks of age at during active disease. All mice were sacrificed at 8 weeks after treatment and bone marrow and kidneys were harvested. Serum anti-dsDNA antibody and 24 hour proteinuria were assessed by enzyme-linked immunosorbent assay. Bone marrow IgG-secreting plasma cells were characterized by flow cytometry as identified by surface CD138 and intracellular IgG expression. Kidney pathological slides were stained with haematoxylin and eosin (H&E) and scored in a blinded fashion. The average intensity of glomerular immune complex deposition in five independent fields of one kidney section per animal was quantitated. Data are summarized as mean±SE. Statistical analysis was performed using GraphPad Prism version 5.0. The statistical significance value was set at $p<0.05$.

Results: MSCs transplanted from B6 donors, but not MRL/*lpr* donors, significantly enhanced survival in MRL/*lpr* mice compared to control PBS injected animals ($p=0.03$) (Fig.A). B6-derived MSCs significantly decreased 24 hour proteinuria at 8 weeks after treatment compared to control ($p<0.01$), but MRL/*lpr*-derived MSCs did not (Fig.B). Neither source of MSCs impacted serum anti-dsDNA antibody levels. B6-derived MSCs-treated animals, but not MRL/*lpr*-derived MSCs treated animals, had significantly fewer plasma cells in bone marrow and reduced C3 deposits in glomeruli compared to control ($p<0.05$). MSCs administration did not significantly impact the overall renal pathology scores, though there was a trend towards lower scores in the B6 group versus the other two.



Conclusion: B6-derived MSCs significantly improved MRL/*lpr* survival when given at peak disease activity. B6-derived MSCs transplantation led to less proteinuria, decreased plasma cells in the bone marrow, and reduced C3 deposits in glomeruli. These results indicate MSCs transplantation at time of peak disease does impact disease and suggest that allogeneic sources of MSCs may be preferred to autologous sources.

Enhanced Survival of Anergic Self-Reactive B Cells in New Zealand Black Chromosome 1 Congenic Mice. Nan-Hua Chang, Christina Loh, Evelyn Pau, Yuriy Baglaenko and Joan E. Wither. Toronto Western Research Institute, University Health Network, Toronto, ON

Background/Purpose: Lupus is characterized by loss of B cell tolerance to nuclear antigens leading to auto-antibody (Ab) production. In this study we have explored the mechanisms leading to this loss of tolerance using B6.NZBc1(96–100cM) (c1) mice. These mice have a homozygous NZB interval containing the *Nba2* locus that results in production of anti-nuclear Abs. To determine the mechanism leading to this breach of tolerance, soluble hen egg white lysozyme (sHEL) and anti-HEL immunoglobulin (Ig) transgenes (Tg) were bred onto the c1 background to generate IgTg or double transgenic (dTg) mice. We previously showed that c1 dTg mice produce anti-HEL Ab, indicating a breach of anergy. In this study we investigated the immune mechanisms leading to this breach.

Methods: Splenocytes from dTg mice were stimulated with anti-IgM $F(ab)'_2$ Ab or HEL for 18 hrs and B cell apoptosis was measured. Mixed hematopoietic chimeric mice (MC) were produced by mixing B6.CD45.1.Ig and c1.Ig bone marrow (BM) in a 1:1 ratio and injecting into irradiated sHEL or non-Tg (B6.CD45.1 × c1)F_1 recipient mice. Mice were analyzed 12 weeks later by flow cytometry of splenic and BM cells. Ab producing cells were measured by ELISpot. Calcium mobilization was assessed using Indo-1 labeled immature IgTg B cells obtained from culture of BM cells with IL-7 for 5 days.

Results: In dTg c1 mice, anergic B cells demonstrated altered function with enhanced upregulation of CD86 following anti-IgM stimualtion, decreased apoptosis in response to anti-IgM or sHEL stimulation, and increased PI3 kinase signaling. These findings suggest that an intrinsic B cell defect breaches anergy, however the presence of IgG anti-HEL antibodies in dTg mice raised the possibility that abnormal T cell help also contributes to this process. To determine the relative role of B and T cell defects in the breach of tolerance in dTg mice, MC mice were produced where both B6 and c1 B cells are exposed to the same environment. Increased numbers of IgM^{a+} and anti-HEL Ab producing cells were found in the spleens of sHEL MC mice as compared control sHEL mice reconstituted with just B6 IgTg BM cells, suggesting a breach of B cell tolerance in MC mice. Although the proportion of B6 B cells in the BM of sHEL MC mice was equivalent to or slightly increased over the proportion of c1 B cells, there was a 1.5 to 3 fold increase in IgTg c1 vs. B6 splenic B cells. Consistent with enhanced survival of c1 anergic B cells, the proportion of freshly isolated IgTg B cells that were PI^+ in sHEL MC mice was significantly higher for B6 vs. c1 cells. Notably, both B6 and c1 splenic B cell populations had similar proportions of T1, T2, follicular, and marginal zone cell subsets, and in mice where there were significant numbers of endogenous F_1 non-Tg B cells, anergic cells were appropriate excluded from the mature B cell repertoire. Nevertheless, c1 B cells in sHEL MC mice expressed increased levels of costimulatory molecules vs. B6 B cells. In support of intrinsically altered B cell function in c1 mice, immature IgTg c1 B cells mobilized less calcium than IgTg B cells.

Conclusion: Intrinsic B cell signaling abnormalities that lead to enhanced survival of anergic B cells contribute to the breach of tolerance in c1 mice.

Mirna-Let-7a Increases IL-6 Production in Mouse Mesangial Cells. Cristen Chafin, Nicole Regna and Christopher Reilly. Virginia Tech, Blacksburg, VA

Background/Purpose: Recent evidence supports a role for epigenetic alterations in the pathogenesis of systemic lupus erythematosus (SLE). MicroRNAs (miRNAs) are endogenous epigenetic regulators of gene repression whose expression is altered in many diseases, including SLE. We sought to determine the miRNA expression pattern in mesangial cells from NZB/W and NZW mice to determine if alterations in miRNAs contribute to disease pathogenesis. We found many consistent differences between the responses to aging in each mouse strain and chose to further define the role of the miRNA-let-7a in mesangial cell function. It is predicted that IL-6, which contains the binding site of miR-let-7a in its 3' untranslated region (UTR), is regulated by miR-let-7a.

Methods: Mouse mesangial cells were isolated from 8 week old New Zealand Black/White (NZB/W) and New Zealand White (NZW) mice using kidney dissection, differential sieving, collagenase digestion, and antibody labeling followed by magnetic separation. A purified mesangial cell population was obtained by magnetic cell separation using anti-integrin $\alpha 8$ which is specific for mesangial cells in the glomerular tissue. Next, miRNAs were isolated using the *mir*Vana miRNA isolation kit (Applied Biosystems, TX, USA). Microarray analyses were performed using mouse miRNA array chips (Chip ID miRMouse 10.0 version). RT-PCR was used to confirm miRNA gene chip expression data using the endogenous miRNA snoRNA202 as a control. We found miR-let-7a to be increased in NZB/W mice compared to NZW mice. MiR-let-7a inhibitors and mimics were transfected into cultured mesangial cells for 24 hours after which the cells were stimulated with LPS and IFN-γ. The supernatants and the cells were collected after 24 hours of stimulation. The supernatants were analyzed by ELISA and the microRNAs were isolated and analyzed by RT-PCR.

Results: The mesangial cells of pre-diseased NZB/W mice expressed higher levels of miR-let-7a (4.8 fold by microarray; 5.5 fold by RT-PCR) than age-matched NZW mice. Using computational target ranking systems, we identified IL-6 as a potential regulatory target of miR-let-7a. The mimic-transfected mesangial cells expressed higher levels of miR-let-7a while the inhibitor-transfected cells expressed levels less than base line (7.7 fold and 0.8 fold, respectively). Intriguingly, overexpression of miR-let-7a mimics in cultured mesangial cells induced greater IL-6 production than the miR-let-7a inhibitor when stimulated with LPS/IFN-γ.

Conclusion: These data show that NZB/W mice have higher miR-let-7a expression than the parental NZW strain. In addition, increased miR-let-7a expression increases IL-6 production in stimulated cells but not in non-stimulated cells. Overexpression of miR-let-7a in mesangial cells can result in upregulation of IL-6 expression which in turn can contribute to the proin-

flammatory microenvironment of the kidney. Because miR-let-7a binds to the 3' UTR of IL-6, further investigations using IL-6 reporter transfection assays will be performed to confirm the interaction of miR-let-7a on IL-6 production. Our findings suggest the inhibition of miR-let-7a may be a possible therapeutic for the dysregulation of IL-6 in lupus patients.

Oral Delivery of a Tolerogenic Peptide Reduces Disease Severity and Prolongs Survival in SLE-Prone Mice. Brian Skaggs, Elaine Lourenco and Bevra H. Hahn. UCLA David Geffen School of Medicine, Los Angeles, CA

Background/Purpose: Most therapeutic agents currently in use to treat SLE are predominantly immunosuppressive agents with limited specificities. More specific therapies that target defined pathogenic mechanisms that drive SLE could be more effective and safer therapeutic options. Multiple groups have illustrated that inducing tolerance in SLE-prone mice with a variety of molecules ameliorates disease symptoms and increases survival. We examined if oral administration of various forms of a tolerogenic peptide could affect SLE disease progression and survival. Our laboratory has shown that this peptide is effective at slowing disease progression when delivered intravenously, but we wanted to see if it would be effective when delivered orally as this method of drug delivery would allow for easier clinical translation.

Methods: The pCons peptide, based on heavy chain protein sequences of anti-double stranded DNA antibodies, induces tolerance when administered intravenously through upregulation of regulatory T cells. Six different forms of pCons, including multiple antigenic peptides (MAP) and cyclic peptides (cyc) made up of both L- and D-amino acids, at three different concentrations (10, 100 and 500 micrograms), were fed to BWF1 SLE-susceptible mice (8/group) once per week for 30 weeks. D-amino acids were utilized to avoid gut peptidase/protease digestion, and the MAP and cyc forms were used to increase pCons stability. Proteinuria was measured weekly. Serum was collected monthly and tested for the presence of anti-DNA antibodies, total IgG, and transforming growth factor beta expression. Survival was measured through 47 weeks of age.

Results: Mice fed 100 micrograms of L-MAP or D-MAP had significantly less cumulative proteinuria, less serum anti-dsDNA antibody levels, and less serum IgG than controls. In addition, animals in these groups also survived significantly longer than controls with a corresponding increase in serum TGFbeta, implying a protective role for pCons-induced regulatory T cells.

Conclusion: Oral administration of a tolerogenic peptide is a safe, effective method for ameliorating SLE disease manifestations and prolonging survival in SLE-prone mice. Induction of oral tolerance using modified pCons peptides could lead to a novel method of targeted therapy for human SLE.

Negative Regulatory Role of TCR zeta Chain in the Pathogenesis of Systemic Lupus Erythematosus Through Lipid Rafts. Guo-Min Deng, Jessica Beltran and George C. Tsokos. Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by high production of autoantibodies and multi-organ tissue damages. T cells have been revealed to exert a crucial role in the pathogenesis of SLE. The phenomenon of T cell receptor (TCR) zeta chain down-regulation has been described in SLE and other diseases including rheumatoid arthritis, cancer, and infectious diseases. However, the role of TCR zeta chain in the pathogenesis of SLE is unknown.

Methods: To understand the role of TCR zeta chain, we have developed an in vivo experimental system by using TCR zeta chain knockout mice to determine the role of TCR zeta chain in the pathogenesis of immune diseases.

Results: We found that TCR zeta chain deficient mice can spontaneously develop inflammation in multi-organ tissues. Poly: (ic) treatment promotes development of multi-organ tissue damages in TCR zeta chain knockout mice. Furthermore, we observed that more severe inflammation developed in TCR zeta chain knockout mice than wild mice with transplant of Bm 12 mouse splenocytes in graft-versus-host disease model. We also found that Bm12 mice with transplant of splenocytes from TCR zeta chain mouse develop more severe multi-organ tissue inflammation than splenocytes from wild type mouse. We discovered that cellular immunity not humoral immunity plays an important role in development of multi-organ tissue inflammation. T cells with TCR zeta chain deficiency spontaneously develop high levels of lipid raft clustering and high expression of CD44 and IFN-gamma.

Conclusion: This indicates that TCR zeta chain plays a negative regulatory role in the pathogenesis of SLE and other immune-mediated diseases through lipid rafts.

Leptin Impinges on the Clearance of Autoimmune T Cells in Murine Lupus. Gil Amarilyo[1], Noriko Iikuni[2], Bevra H. Hahn[3] and Antonio La Cava[4]. [1]University of California, Los Angeles, Los Angeles, CA, [2]UCLA, CA, [3]UCLA David Geffen School of Medicine, Los Angeles, CA, [4]Univ of California Los Angeles, Los Angeles, CA

Background/Purpose: Leptin, a pro-inflammatory adipokine, is elevated in systemic lupus erythematosus (SLE) patients and accelerates proteinuria in lupus-prone (NZB × NZW)F1 (BWF1) mice. However, the role of leptin in the induction and maintenance of autoimmune response in SLE has been only partially explored. Since the availability of self antigen through apoptotic material has been shown to play a key role in the autoimmune pathogenesis of SLE, we investigated whether leptin can influence phagocytosis and clearance of apoptotic T cells in SLE.

Methods: We investigated the ability of BWF1 mice to phagocyte apoptotic cells in vivo. Labeled apoptotic T cells were injected into the intraperitoneal cavity of BWF1 mice pretreated with thioglycolate for the activation of local macrophages. A group of recipient mice received leptin, another group received leptin blockers, and a third group that received vehicle served as control. Macrophages were isolated from the peritoneal fluid and the ingestion of apoptotic cells by macrophages was evaluated via costaining in flow cytometry and confocal microscopy. Parallel in vitro experiments using macrophages of thyoglycolate-treated BWF1 mice incubated in vitro with labeled apoptotic T cells in the presence or not of scalar doses of leptin were also performed.

Results: In vitro and in vivo experiments showed that leptin facilitated the phagocytic uptake of apoptotic cells by inflammatory macrophages in BWF1 lupus mice, thus providing an increased availability of autoantigen (uptake of apoptotic cells in the peritoneal macrophages was 2.6± 2.1% versus 13.4 ± 3.2% in the no leptin vs leptin-treated, $P<0.02$). Leptin treatment also modulated apoptotic cell clearance, possibly contributing to the maintenance of the autoimmune process ($P<0.03$ in the comparison between leptin treated mice versus controls).

Conclusion: Leptin modulates phagocytosis and clearance of apoptotic cells in lupus-prone BWF1 mice. Ongoing experiments are exploring the possibility that a differential role of leptin in young mice vs old animals could lead to excess free autoantigen that would favor the development of humoral immune responses to self antigens in an earlier stage. Later in life, the increased phagocytosis of apoptotic cells could favor self-antigen availability to the adaptive immune system, and thus the perpetuation of autoimmunity.

575

Dispensability of APRIL to Development of Systemic Lupus Erythematosus (SLE) In SLE-Prone NZM 2328 Mice. Chaim O. Jacob[1], Shunhua Guo[1], Noam Jacob[1], Rahul Pawar[2], Chaim Putterman[3], William J. Quinn III[4], Michael P. Cancro[4], Thi-Sau Migone[5] and William Stohl[1]. [1]University of Southern California Keck School of Medicine, Los Angeles, CA, [2]Albert Einstein College of Med, Bronx, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]University of Pennsylvania School of Medicine, Philadelphia, PA, [5]Human Genome Sciences, Rockville, MD

Background/Purpose: In contrast to the large body of evidence that links BAFF with SLE, the evidence linking the closely related APRIL to SLE is limited at most. Given that APRIL can co-stimulate B cells, induce Ig class switching, and promote plasma cell (PC) survival, APRIL, *a priori*, may be an important (co-)contributor to SLE pathogenesis and, thereby, represent an appropriate therapeutic target in SLE. To date, there have been no studies in either murine or human SLE that have solely targeted APRIL. Accordingly, we sought to determine the role for APRIL in the development of SLE by studying SLE-prone NZM 2328 (NZM) mice genetically deficient in APRIL.

Methods: NZM.*April*$^{-/-}$ and NZM.*Baff*$^{-/-}$ mice were generated by introgressing the *April*$^{-/-}$ and *Baff*$^{-/-}$ genotypes, respectively, into SLE-prone NZM wild-type (WT) mice by a marker-assisted selection protocol that included markers for those regions identified as SLE susceptibility loci in NZM mice. NZM.*Baff*$^{-/-}$.*April*$^{-/-}$ mice were generated by intercrossing NZM.*Baff*$^{-/-}$ and NZM.*April*$^{-/-}$ mice. Mice were evaluated for lymphocyte

phenotype by flow cytometry; for serum total IgG and IgG autoantibody levels by ELISA; for serum BAFF levels by ELISA; for glomerular deposition of IgG and C3 by immunofluorescence; for renal histopathology by staining with H&E, periodic acid-Schiff, Masson's trichrome, and Jones' silver methenamine; and for clinical disease, as assessed by development of severe proteinuria (≥3+ by dipstick on 2 consecutive evaluations).

Results: Despite identical serum BAFF levels, NZM.*April*$^{-/-}$ mice, in comparison to WT mice, harbored increased spleen B cells, T cells, and PC; increased serum levels of IgG anti-chromatin antibodies; and decreased numbers of bone marrow (BM) PC. At 5 months and 8 months of age, glomerular deposition of IgG and C3 was similar in NZM.*April*$^{-/-}$ and WT mice, whereas renal histopathology tended to be more severe in NZM.*April*$^{-/-}$ mice than in WT mice. Development of clinical disease was identical in NZM.*April*$^{-/-}$ and WT mice, with severe proteinuria starting to develop at 5 months of age and 50% of the mice in each cohort being affected by 7–8 months of age. Despite being identically deficient in BAFF, BM (but not spleen) PC and serum IgG anti-chromatin and anti-dsDNA antibody levels were lower in NZM.*Baff*$^{-/-}$.*April*$^{-/-}$ mice than in NZM.*Baff*$^{-/-}$ mice, whereas renal immunopathology in each cohort was equally mild. Clinical disease did not develop in either NZM.*Baff*$^{-/-}$.*April*$^{-/-}$ or NZM.*Baff*$^{-/-}$ mice through the time of sacrifice (8 months of age).

Conclusion: APRIL is dispensable for development of full-blown SLE in NZM mice. Moreover, the elimination of both APRIL and BAFF had no discernable effect on development of renal immunopathology or clinical disease beyond that of elimination of BAFF alone. The reduction in BM PC in hosts doubly-deficient in APRIL and BAFF beyond that in hosts deficient only in BAFF raises concern that combined antagonism of APRIL and BAFF may lead to greater immunosuppression without concomitant increase in clinical efficacy.

576

Fn14 Deficiency Ameliorates Neuropsychiatric Disease In MRL-Lpr/Lpr Lupus Prone Mice. Jing Wen[1], Yumin Xia[1], Jennifer S. Michaelson[2], Linda C. Burkly[2], Maria Gulinello[1] and Chaim Putterman[3]. [1]Albert Einstein College of Med, Bronx, NY, [2]Biogen Idec, Cambridge, MA, [3]Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: Neuropsychiatric disease in SLE (NPSLE) is one of the earliest manifestations of human lupus, with 60% of patients developing NPSLE symptoms within the first year of diagnosis. Brain involvement is thought to be a primary manifestation of SLE activity, given this early disease onset and the potential for patients to respond to immunosuppressive therapy. However, optimal treatment for NPSLE has yet to be determined.

TWEAK is a TNF superfamily ligand that mediates pleiotropic effects through its receptor, Fn14, including the stimulation of proinflammatory cytokine expression by astrocytes, as well as endothelial, epithelial, and other non-hematopoeitic cell types. TWEAK also induces neuronal death, and increases blood brain barrier permeability. Furthermore, TWEAK-inducible mediators, including MCP-1, MMP-9, and IL-6, are implicated in NPSLE. Thus, we hypothesized that the TWEAK/Fn14 pathway may be involved in the pathogenesis of NPSLE.

Methods: 129 Fn14 knockout (KO) mice were backcrossed 8 generations onto MRL-lpr/lpr (MRL/lpr) mice to generate MRL-lpr, Fn14 deficient (Fn14KO) mice. Female MRL/lpr Fn14KO mice were compared to age and gender matched MRL/lpr wild type (Fn14WT) and MRL/+ mice at young (10–20 weeks old) and older (20–40 weeks old) ages. The development of neuropsychiatric disease was investigated using a comprehensive neurobehavioral assessment battery, including forced swim, anhedonia, open field, object recognition, object placement, and social preference tests. In addition, serum and urine were serially obtained for measurement of autoantibodies and proteinuria, respectively, and CSF was obtained at sacrifice.

Results: There were no abnormalities in the behavior of MRL/lpr Fn14 WT and KO mice or differences between the strains in total and center track distances in the open field, indicating no major sickness behavior or musculoskeletal disability at the time points tested. One manifestation of NPSLE is depression-like behavior, which can be assessed as increased immobility in the forced swim test. While MRL-lpr Fn14 WT mice displayed significant depressive like behavior, immobility was significantly decreased in MRL/lpr Fn14 KO mice and was no different from MRL/+ controls. Ahedonia, as evaluated by a lack of the normal preference for sweetened drinks and which was evident in MRL-lpr Fn14 WT mice, was also normalized in MRL/lpr Fn14 KO mice. Finally, while MRL/lpr Fn14 WT mice displayed impaired cognitive function in the object placement test, MRL/lpr Fn14 KO mice performed normally. Interestingly, the observed neurobehavioral abnormalities were selective, with no evidence of anxiety or loss of social preference in MRL/lpr Fn14 WT mice. At the time neurobehavioral deficits were observed in the younger mice, there were no significant differences in autoantibody titers or renal function between MRL-lpr Fn14 WT and KO mice.

Conclusion: Fn14 deficient MRL/lpr mice exhibit improved neurobehavioral characteristics, suggesting that the TWEAK/Fn14 interactions are instrumental in the pathogenesis of neuropsychiatric disease in MRL-lpr mice. Furthermore, blockade of the TWEAK/Fn14 pathway may represent a novel therapeutic approach for the treatment of primary NPSLE.

Restoration of Regulatory T Cells-Th17 Cells Balance in Systemic Lupus Erythematosus Through Vitamin D Supplementation. Benjamin Terrier[1], Yoland Schoindre[2], Guillaume Geri[3], David Saadoun[4], Kubéraka Mariampillai[5], Michelle Rosenzwajg[6], David Klatzmann[6], Jean-Charles Piette[3], Patrice Cacoub[3] and Nathalie Costedoat-Chalumeau[3]. [1]Pitié-Salpêtrière Hospital, Paris, France, [2]Foch Hospital, Suresnes, France, [3]CHU Pitié-Salpêtrière, Paris, France, [4]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [5]Pitié-Salpétrière Hospital, Paris, France, [6]Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Paris, France

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with perturbations in regulatory T cells (Tregs), T helper lymphocytes producing interleukin (IL)-17 (Th17 cells) and B cells. Immunomodulatory effects of vitamin D were recently described in vitro, notably the expansion of Tregs able to suppress inflammatory responses and the decrease of Th17 cells. Objective. To evaluate tolerance and immunologic and clinical effects of vitamin D supplementation in SLE.

Methods: In this monocenter prospective study, we measured vitamin D level in SLE patients (according to the revised ACR criteria). Patients with hypovitaminosis D (< 30 ng/mL) and stable dosage of prednisone and/or immunosuppressant agents received vitamin D supplementation: 100 000 UI of cholecalciferol per week for 4 weeks, followed by 100 000 UI per month for 6 months. Patients were screened at day 0 (D0) and at month 2 (M2) and 6 (M6) after the beginning of vitamin D supplementation. The end points were tolerance, immunologic effects and clinical efficacy.

Results: Among 24 patients, 20 (20 women, age 31±8 years) had low vitamin D levels and received vitamin D supplementation. Treatment was safe with no hypercalcemia or lithiasis. Serum 25(OH)D levels dramatically increased from 18.7±6.7 at D0 to 51.4±14.1 ($p<0.001$) at M2 and 41.5±10.1 ng/mL ($p<0.001$) at M6. Disease activity assessed by the SLEDAI was 2.9±2.5 at D0, 2.6±2.5 at M2 ($p=0.67$) and 1.9±1.8 at M6 ($p=0.16$). Anti-DNA levels decreased from 177±63 at D0 to 124±67 at M2 ($p<0.05$) and 103±36 UI/mL at M6 ($p<0.01$). The percentage of Tregs (CD4+CD25hiCD127-FoxP3+) increased under vitamin D supplementation (3.5±1.2% at D0 to 4.6±1.3% at M2 and 4.3±1.4% at M6, $p<0.001$ and $p<0.01$, respectively) with a similar trend between naïve and activated memory Tregs. This was associated with an increased expression of molecules associated with suppression of Tregs (i.e. GITR and LAP). A decrease in Th17 (2.0±1.1% at D0 to 1.6±0.9% at M2 and 2.0±1.3% at M6, $p<0.01$ and $p=0.81$, respectively) and Th1 cells (16.9±6.7% at D0 to 11.0±5.1% at M2 and 13.6±6.5% at M6, $p<0.01$ and $p<0.05$, respectively) was observed mainly after 2 months of vitamin D supplementation. We also observed a decrease in class-switched memory B cells (28.1±14.5% at D0 to 24.7±12.6% at M2 and 27.6±14.6% at M6, $p<0.05$ and $p=0.65$, respectively) and HLA-DR+ CD8+ T cells (46.0±15.0% at D0 to 40.8±16.8% at M2 and 36.1±18.2% at M6, $p=0.12$ and $p<0.001$, respectively).

Conclusion: This is the first study to report the immunologic effects of vitamin D supplementation in vivo during SLE. Vitamin D modulates the Tregs-Th17 balance by increasing Tregs and decreasing the Th17 cells, and decreases Th1 cells and memory B cells. This study suggests the beneficial

role of vitamin D in SLE which needs to be confirmed in randomized controlled trials.

578

Safety Profile of Belimumab, a B-Lymphocyte Stimulator–Specific Inhibitor, in Phase 2 and 3 Clinical Trials of Patients with Active Systemic Lupus Erythematosus. D.J. Wallace[1], S. Navarra[2], M. Petri[3], A. Gallacher[4], R. Gúzman[5], M. Thomas[6], R.A. Furie[7], O. Zamani[8], R.A. Levy[9], R.F. van Vollenhoven[10], S. Cooper[11], Z.J. Zhong[11], W. Freimuth[11], L. Pineda[11], R. Cervera[12] and BLISS-52 and -76 and LBSL02/99 Study Groups[13]. [1]Cedars-Sinai/UCLA, Los Angeles, CA, [2]University of Santo Tomas Hospital, Manila, Philippines, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Hospital Británico de Buenos Aires, Buenos Aires, Argentina, [5]IDEARG, SaludCoop, Bogotá, Colombia, [6]Kerala Institute of Medical Sciences, Kerala, India, [7]North Shore-LIJ Health System, Lake Success, NY, [8]Rheumazentrum Favoriten, Wien, Austria, [9]Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil, [10]The Karolinska Institute, Stockholm, Sweden, [11]Human Genome Sciences, Inc., Rockville, MD, [12]Hospital Clinic, Barcelona, Spain, [13]Multicenter

Background/Purpose: To present integrated safety data of belimumab in 3 double-blind studies of systemic lupus erythematosus (SLE), including the full wk-76 data from BLISS-76.

Methods: Safety data from 2133 patients with SLE who participated in one phase 2 (LBSL02, N=449) and two phase 3 (BLISS-52, N = 865; BLISS-76, N = 819), multicenter, double-blind, clinical studies of belimumab were evaluated. Belimumab (1 and 10 mg/kg in all studies; 4 mg/kg in LBSL02 only) or placebo was given by intravenous (IV) infusion on days 0, 14, and 28, and q28d thereafter for 52 weeks in LBSL02, 48 weeks in BLISS-52, and 72 weeks in BLISS-76. All patients received ≥1 standard therapy (or a combination), eg, corticosteroids, antimalarials, immunosuppressants, and nonsteroidal anti-inflammatory drugs. Clinical and laboratory assessments were performed during scheduled visits and adverse events (AEs) were evaluated as they occurred. AE rates were based on the double-blind, placebo-controlled phase 2 and phase 3 studies. Malignancy rate was based on exposure to belimumab in all SLE studies (phases 1–3 and open-label continuation; IV and subcutaneous routes).

Results: Rates of AEs overall, by severity and seriousness, and as the cause of discontinuations were similar between placebo and belimumab. Depression was more common with belimumab 1 and 10 mg vs standard therapy alone (6.1% and 5.2% vs 3.7%, respectively). The suicidality rate was the same across treatment groups (0.1%). Infection rates, including lower respiratory infections, as well as infusion/hypersensitivity reactions were numerically higher with belimumab, while all others were comparable with placebo. In all belimumab SLE studies (double-blind and continuation), the rate/100 patient-years (pt-y) of malignancy (excluding nonmelanoma skin cancer) was 0.45, and of mortality was 0.55. No single cause of death predominated; etiologies included infection, cardiovascular disease, and suicide.

Table. Integrated Safety Data Through Wk 76[a]

	Standard Therapy Plus		
	Placebo (N = 675) % Patients	Belimumab 1 mg/kg (N = 673) % Patients	Belimumab 10 mg/kg (N = 674) % Patients
AE in general	92.7	93.3	93.0
Discontinuation due to AE	7.4	6.4	6.8
Serious/severe AE	22.4	24.1	23.3
Death	0.4	0.7	0.9
Infection in general	67.4	71.9	70.8
Discontinuation due to infection	1.2	0.7	0.6
Serious/severe infection	6.8	7.6	6.1
Infection of special interest

Malignant neoplasm	0.3	0.7	0.4

Malignant Neoplasm/Mortality With Belimumab vs Placebo

	Phase 2/3 Double-blind, Placebo-Controlled		All SLE Studies (Double-blind and Continuation)	
	Placebo (N = 675) (692 pt-y)	Belimumab (N = 1458) (1516 pt-y)	Placebo (N = 688) (702 pt-y)	Belimumab (N = 1982)[f] (3976 pt-y)
Malignant Neoplasm[c,d]				
Patients with events, n (%)	2 (0.3)	3 (0.2)	2 (0.3)	18 (0.9)
Rate/100 patient-years (95% CI)	0.29 (0.04–1.04)	0.20 (0.04–0.58)	0.28 (0.03–1.03)	0.45 (0.27–0.72)
Mortality[e]				
Patients with events, n (%)	3 (0.4)	11 (0.75)	3 (0.4)	22 (1.1)
Rate/100 patient-years (95% CI)	0.43 (0.09–1.27)	0.73 (0.36–1.30)	0.43 (0.09–1.25)	0.55 (0.35–0.84)

[a] Pooled data of belimumab 1 and 10 mg/kg compared with placebo; the 4-mg/kg dose (n = 111) was included only in LBSL02, where its safety profile was similar to that of placebo and belimumab 1 and 10 mg/kg in LBSL02; no malignancy, death, or hypersensitivity was reported with the 4-mg/kg dose; [b]there were 2 cases of latent tuberculosis (TB), 1 extrapulmonary TB, 2 *Mycobacterium* non-TB (1 atypical extrapulmonary and 1 avium complex pulmonary), 1 cytomegalovirus pneumonia, 1 coccidioidomycosis, and 1 *Acinetobacter* sepsis after day 0; [c]excludes non-melanoma skin cancer; [d]malignancy rate/100 pt-y of 0.53 (95% CI: 0.48, 0.59) was reported in an international SLE cohort followed for an average of 8 y (76,948 pt-y) (Bernatsky S, Boivin JF, Joseph L, et al. An international cohort study of cancer in systemic lupus erythematosus. *Arthritis Rheum*. 2005;52:1481–90); [e]mortality rate/100 pt-y of 1.63 (1.54, 1.72) was reported in an international SLE cohort followed for an average of 8 y (76,948 pt-y) (Bernatsky S, Boivin JF, Joseph L, et al. Mortality in systemic lupus erythematosus. *Arthritis Rheum*. 2006;54:2550–7); [f]includes phases 1–3 and open-label continuation studies in SLE as of February 2011.

Conclusion: Based on data from 2133 patients (with >4600 pt-y of exposure), belimumab was generally well tolerated when used in combination with a wide range of standard SLE therapy. (ClinicalTrials.gov: NCT00071487/00583362; NCT00424476; NCT00410384.)

Safety of a Quadrivalent Human Papillomavirus (HPV) Vaccine in Patients with Systemic Lupus Erythematosus. Chi Chiu Mok[1], Pak To Chan[1], Ling Yin Ho[2], Ka Lung Yu[1] and Chi Hung To[1]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Tuen Mun Hospital, Hong Kong SAR, Hong Kong

Background/Purpose: The quadrivalent human papillomavirus (HPV) vaccine (GARDASIL) is a recombinant vaccine which provides protection against infection of the HPV serotypes 6,11,16 and 18. The objective of the current study is to evaluate the safety of GARDASIL in patients with SLE in terms of disease flares and adverse effects.

Methods: Patients who fulfilled ³4 ACR criteria for SLE were recruited to receive vaccination of GARDASIL. Inclusion criteria: (1) age between 18 and 35 years; (2) Having received a stable dose of prednisolone and/or other immunosuppressive agents within 3 months of study entry; (3) informed consent could be obtained. The vaccine was given by intramuscular injection at baseline, 2 months and 6 months. Disease activity scores (SLEDAI), physicians' global assessment scores (PGA) on disease activity, disease flares (SELENA flare instrument) and levels of C3, C4, anti-dsDNA were assessed at baseline, month 2 and month 6. Adverse events reported by the patients were also recorded.

Results: Fifty female patients were recruited. The mean age was 25.8±3.9 years and the mean disease duration was 6.6±4.5 years. The median SLEDAI score at study entry was 4 (IQR 1.75–4.0). None of the patients had SELENA flares at baseline compared to preceding status. The mean anti-dsDNA, C3, C4 and anti-C1q levels were 131±112IU/mL (NR<50), 0.80±0.23g/dL (NR0.75–1.61), 0.15±0.07g/dL (NR0.14–0.44) and 16.0±18.9RU/mL (NR<20), respectively. At month 12, the seroconversion rates of antibodies to HPV types 6,11,16 and 18 in SLE patients and controls were 82%, 89%, 95%, 76% and 98%, 98%, 98%, 80%, respectively. In SLE patients, there were no significant changes in the titers of anti-dsDNA, complements, anti-ENA index, anti-C1q, SLEDAI and PGA scores from baseline to month 2, 7 and 12. There were 1 mild/moderate lupus flare at month 0–2, 2 mild/moderate lupus flares at month 3–6 and 7 mild/moderate lupus flares at month 7–12, which were controlled with usual treatment regimens. The overall rate of disease flares (0.2/patient/year) of the SLE participants was similar to that of 50 SLE controls matched for age and disease duration who did not participate in this study (0.2/patient/year; p>0.99). Erythema and pain at injection sites was the commonest adverse event (AE) (5% of participants) and the frequency of AEs experienced by SLE patients and controls was similar.

Conclusion: The quadrivalent HPV vaccine (GARDASIL) is effective and safe in patients with inactive SLE, and does not induce an increase in serological activity or clinical lupus flares.

A Risk Management Program Led by a Nurse Improves Cardiovascular and Osteoporosis Risk Management in a Specialized Lupus Clinic. Anne Cymet[1], Carolina Landolt-Marticorena[2], Dafna D. Gladman[3], Paul R. Fortin[2] and Murray B. Urowitz[2]. [1]University Health Network, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease associated with significant morbidity and mortality. Individuals with lupus develop premature cardiovascular disease and osteoporosis. The purpose of this study was to examine whether a risk management program given by a nurse and integrated with lupus medical care improved cardiovascular and osteoporosis risk management.

Methods: Patients prospectively followed at the Lupus Clinic were divided into two groups: 1) those receiving a nurse led intensive risk factor assessment and modification intervention and 2) those receiving usual care. Patients in group 1 underwent cardiovascular and osteoporosis risk assessment and were counseled on risk reduction strategies according to their needs. Cardiovascular risk reduction consisted of lifestyle modifications including smoking cessation, dietary changes and weight management. Hypertension and abnormal lipid levels were monitored and treatment initiated by physician per clinic guidelines The osteoporosis program consisted of documentation of bone mineral density (BMD) by DEXA scan, determination of vitamin D levels and risk reduction strategies included optimization of vitamin D and calcium intake, recommendations about the use of osteoporosis preventive medication and encouragement of weight bearing exercises.

Results: The study cohort consisted of 786 patients: 458 patients seen by the nurse and 328 receiving usual care. The two groups had similar demographics, disease duration and activity. The group receiving the nurse led risk management program showed significant improvement in a number of domains when compared to the usual care group. Appropriate initiation of lipid lowering therapy was significantly higher in the risk management group (33.9% vs 11.5%, $p < 0.0001$). In patients seen by the nurse 49.2% underwent BMD scans and 85.3 % were initiated on Vitamin D whilst in the control population only 24.1 % ($p < 0.0001$) underwent imaging and 72.2% were placed on vitamin supplementation ($p < 0.0001$).

Conclusion: A risk management program led by a dedicated nurse improves adherence to lupus cardiovascular and osteoporosis risk modification strategies. The impact of this intervention in reducing long term risk stratification, cardiovascular and osteoporotic complications, and long-term adherence to preventive strategies will be assessed in future studies.

Antimalarials: A Window of Opportunity to Improve the Influenza A/H1N1 Vaccine Response in Lupus Patients Under Immunosuppressive Agents. Eduardo F. Borba[1], Carla G.S. Saad[1], Sandra G. Pasoto[1], Ana L. G. Calich[1], Nadia E. Aikawa[1], Ana C. M. Ribeiro[2], Julio C. B. Moraes[2], Elaine P. Leon[1], Luciana P.C. Seguro[1], Lissiane K. N. Guedes[1], Clovis A. Silva[1], Celio Goncalves[2], Ricardo Fuller[3], Suzimara A. Oliveira[1], Maria A. Ishida[4], Alexander R. Precioso[5] and Eloisa Bonfa[6]. [1]University of Sao Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [3]University of Sao Paulo, São Paulo, Brazil, [4]Adolfo Lutz Institute, Sao Paulo, Brazil, [5]Butantan Institute, Sao Paulo, Brazil, [6]Faculdade de Medicina da Universidade de São Paulo (FMUSP), Sao Paulo, Brazil

Background/Purpose: The recent WHO recommendation that the 2010–2011 trivalent seasonal influenza vaccine must contain the A/California/7/2009/H1N1–like virus reinforces the need for an extensive evaluation of its immunogenicity and safety in systemic lupus erythematosus (SLE) patients, particularly those under immunosuppressive therapy.

Methods: A total of 555 SLE patients and 170 healthy controls were vaccinated with a single dose of a nonadjuvanted preparation. Clinical/laboratory data, treatment and adverse events were monitored prevaccination and 21 days postvaccination. Anti-H1N1 titres, the percentages of seroprotection (SP), and seroconversion (SC) were evaluated.

Results: After immunisation, lower SP (64.7%; 95%CI 60.7–68.7 vs. 84.1%; 95%CI 78.6–89.6; $p<0.0001$) and SC rates (60.7%; 95%CI 56.7–64.8 vs. 80.0%; 95%CI 74.0–86.0; $p<0.0001$) were observed in SLE compared to controls, whereas an equivalent response was detected for the SLE no therapy group (SP, 74.7%; 95%CI 64.8–84.5; $p=0.10$; and SC, 72.0%; 95%CI 61.8–82.1; $p=0.18$). A treatment analysis comparing the SLE no therapy group revealed analogous SP (vs. 78.0%; 95%CI 70.1–85.9, $p=0.60$) and SC (vs. 69.5%; 95%CI 60.7–78.3, $p=0.75$) for antimalarial monotherapy. Regarding those without antimalarials, a reduced response for prednisone (SC, $p=0.04$), prednisone daily dose >20 mg (SC, $p=0.028$), immunosuppressors (SP, $p=0.037$; and SC, $p=0.035$) and for the concomitant use of prednisone >20 mg + immunosuppressors (SC, $p=0.038$) was observed. In contrast, the association of antimalarials with prednisone >20 mg (SC, $p=1.00$), with immunosuppressors (SC, $p=0.54$) and with prednisone >20 mg + immunosuppressors (SC, $p=0.09$) resulted in a comparable immunoresponse for the SLE therapy group.

Conclusion: Antimalarials may be a promising, inexpensive candidate to improve pandemic influenza A H1N1/2009 response in lupus patients under immunosuppressive therapy. This finding predicts a window of opportunity for other autoimmune conditions (ClinicalTrials.gov, number NCT01151644).

Defensins and Cardiovascular Disease In Systemic Lupus Erythematosus. Stefan Vordenbäumen, Oliver Sander, Ellen Bleck, Matthias Schneider and Rebecca Fischer-Betz. Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disorder with an increased long-term mortality mostly due to arteriosclerosis. Besides traditional risk factors, SLE inherent mechanisms which are not yet identified contribute to arteriosclerosis. In an attempt to identify such a putative factor, we analyzed if defensins are related to cardiovascular disease in SLE. Defensins are immunomodulatory peptides which were recently suggested to modulate angiogenesis and whose blood levels were reported to be elevated in SLE.

Methods: 72 SLE patients fulfilling the 1982 ACR criteria were prospectively evaluated over 6 years. At baseline, serum levels of human beta defensin 2 (hBD2) and the neutrophil alpha defensins (human neutrophil peptides, HNP) were determined by ELISA from stored samples. Cardiovascular risk factors were assessed and the occurrence of cardiovascular events (CVE: stroke, claudication, angina pectoris, myocardial infarction) was recorded. Measurement of the intima media thickness (IMT) and of the extent of plaques of the carotid arteries was carried out by ultrasound in 42 of 72 patients at baseline and at 4 years. Log-transformed defensin levels (log-hBD2 and log-HNP) showed normal distribution according to Kolmogorov-Smirnov test and were used for further analyses.

Results: SLE patients who experienced a CVE (n = 13) had significantly higher log-hBD2 values (3.73 vs. 3.40 log(ng/ml), $p <.05$). According to receiver-operating-characteristics analysis, log-hBD2 was moderately discriminative (AUC 0.68). At the cut-off point (3.3 log(ng/ml)), the likelihood-ratio for CVE was 2.23, specificity 85% and sensitivity 34%. In order to identify other variables predictive of CVE, bivariate linear regression analysis was carried out and the number of traditional cardiovascular risk factors (dyslipidemia, hypertension, positive family history, age, smoking, diabetes) was identified to correlate to the incidence of CVE (r^2 0.35, $p <.05$). In a binary logistic regression analysis, log-hBD2 contributed to a model also incorporating the amount of cardiovascular risk factors as explanatory variables for the incidence of CVE (regression coefficient 1.84, odds-ratio 6.3, $p <.05$, likelihood ratio test for the model X^2 13.56, $p <.005$). Employing this model to the population tested, 81.9% of events were predicted correctly. Moreover, SLE patients with progressive IMT (n = 10) showed increased log-hBD2 and log-HNP values (3.76 vs. 3.37 log(ng/ml) and 2.52 vs. 2.36 ng/ml respectively, $p <.05$). Both defensin-levels also showed some correlation to the extent of plaques at baseline (hBD2: r^2 0.10; HNP r^2 0.12, $p <.05$). Neither log-hBD2 nor log-HNP were correlated to traditional cardiovascular risk factors, suggesting an independent effect.

Conclusion: The determination of serum HNP and especially hBD2 may be an indicator of arteriosclerosis and of progressive cardiovascular disease in SLE patients independent of traditional cardiovascular risk factors. Further studies involving more subjects and repeated measurement of defensin-levels are warranted.

583

Differences Between Male and Female Systemic Lupus Erythematosus In a Multi-Ethnic Population. Tan Tze Chin[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Male systemic lupus erythematosus (SLE) has been thought to be similar to female SLE, but there is lack of consensus in past studies. Comparisons between male and female SLE in a large SLE cohort were made.

Methods: 1979 patients in a longitudinal cohort were included in the analysis. The results were based on the chi-square test (SAS Institute, Cary, NC, USA). A p-value ≤ 0.05 was considered statistically significant.

Results: The cohort consisted of 157 men (66% Caucasian, 34% African-American) and 1822 women (60% Caucasian, 40% African-American). The mean followup was 6.02 (range: 0–23.73) years. Men were more likely to have renal, hematological, serological and thrombotic events than women. Renal and cardiovascular damage were more prevalent in men. In both African-American and Caucasian SLE, men were more likely to have cardiac and renal damage. In general, differences between males and females were more numerous and striking in Caucasians, especially in term of men having more lupus nephritis, more abnormal serologies, and more thrombosis.

Table 1. Comparison between Male and Female SLE

* Fisher's exact test was used for expected counts less than 5.
§ Adjusted for ethnicity, age at last assessment, and duration of SLE at last assessment.

Conclusion: Our study suggests that there are major clinical differences between male and female SLE. Surprisingly, the differences between male and female SLE also depend on ethnicity. Future SLE studies will need to consider both ethnicity and gender to understand these differences.

584

Sustained Disease Improvement and Safety Profile Over the 1500 Patient-Year Experience (6 years) with Belimumab in Patients with Systemic Lupus Erythematosus. J.T. Merrill[1], R.A. Furie[2], D.J. Wallace[3], W. Stohl[4], W. Chatham[5], A. Weinstein[6], J. Mckay[7], E.M. Ginzler[8], Z.J. Zhong[9], L. Pineda[9], J. Klein[9], W. Freimuth[9], M. Petri[10] and LBSL02/99 Study Group[11]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]North Shore-LIJ Health System, Lake Success, NY, [3]Cedars-Sinai/UCLA, Los Angeles, CA, [4]USC/Keck School of Medicine, Los Angeles, CA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Washington Hospital Center, Washington, DC, [7]Oklahoma State University Center for Health Sciences, Tulsa, OK, [8]SUNY Downstate Medical Center, Brooklyn, NY, [9]Human Genome Sciences, Inc., Rockville, MD, [10]Johns Hopkins University School of Medicine, Baltimore, MD, [11]Multicenter

Background/Purpose: To update belimumab safety and efficacy data over 6 y in patients with active SLE.

Methods: 449 SLE patients with SELENA-SLEDAI score ≥ 4 were enrolled in a phase 2 study of belimumab 1, 4, or 10 mg/kg, vs placebo, plus standard of care for 52 wk. All placebo patients switched to belimumab 10 mg/kg at wk 56; prior belimumab patients continued on the same dose or switched to 10 mg/kg. At wk 80, all patients electing to enter a continuation study received belimumab 10 mg/kg. Adverse events (AEs) were assessed in all patients at each study visit. Analyses of disease activity included SLE Responder Index (post-hoc analysis: improvement in SELENA-SLEDAI [≥ 4 points], no new BILAG A or 2 new BILAG B scores, and no Physician's Global Assessment worsening [<0.3 points] vs baseline), BILAG A/B flares, SELENA-SLEDAI Flare Index (SFI), and biomarker changes. Efficacy assessments were limited to patients who were autoantibody-positive (antinuclear antibody titer $\geq 1:80$ or anti-double-stranded DNA ≥ 30 IU/mL) at baseline. All results are presented by 1-y intervals through 6 y of belimumab treatment.

Results: 296 of the original 449 patients (66%) entered the continuation trial. At the end of the 6-y interval, 208 patients remained on study. Total belimumab exposure was approximately 1500 patient-y. Rates of AEs/100 patient-y remained stable/decreased over 6 y (table). Five patients treated with belimumab died over 6 y; no single cause predominated and etiologies included aspiration pneumonia with subsequent sepsis and respiratory failure, infection, cardiovascular disease, and suicide. The SRI rate with belimumab was 46% at wk 52 (vs 29% with placebo; $p < 0.05$), increasing to 55%–61% through 6 y of open-label

treatment. The frequency of 1 new BILAG A or 2 new B flares with belimumab was 38% at 1 y vs 44% with placebo, decreasing to 11% at 6 y of open-label treatment. The frequency of all SFI flares with belimumab was 84% (severe 17%) at 1 y vs 85% (severe 19%) with placebo, decreasing to 42% (severe 5%) at 6 y. Patients on belimumab had increases in complement (C3 or C4) levels over 6 y. Autoantibody levels (anti-Smith, anti-double-stranded DNA, anticardiolipin-immunoglobulin-G) generally decreased over time. In 283 patients taking corticosteroids at baseline, corticosteroid use decreased over time with a mean reduction of 34% and an absolute reduction of 4.7 mg/d at 6 y vs baseline.

AE Incidence (rate per 100 patient-y) in Patients Treated With Belimumab[a]

	Interval[b]					
	1 (0−1 y)	2 (1 −2 y)	3 (2 −3 y)	4 (3 − 4 y)	5 (4 −5 y)	6 (5 −6 y)
Patients, n [patient-y]	336 [320.1]	339 [299.1]	274 [258.1]	248 [234.2]	223 [215.8]	208 [171.9]
Overall AEs	326 (101.8)	322 (107.7)	260 (100.8)	237 (101.2)	211 (97.8)	167 (97.2)
Serious AEs	55 (17.2)	52 (17.4)	49 (19.0)	31 (13.2)	41 (19.0)	25 (14.5)
Overall infections	254 (79.4)	237 (79.2)	192 (74.4)	181 (77.3)	145 (67.2)	104 (60.5)
Serious infections	17 (5.3)	14 (4.7)	8 (3.1)	8 (3.4)	6 (2.8)	7 (4.1)
Malignancies[c]	0	2 (0.7)	1 (0.4)	1 (0.4)	3 (1.4)	2 (1.2)
Mortality	3 (0.8)	0	1 (0.4)	1 (0.4)	0	0

[a]Data presented as no. of patients with AE (no./100 patient-y) unless specified; [b]interval 1 includes only patients treated with belimumab (and not placebo) during the 52-wk, double-blind study (except mortality data includes 2 deaths during the 52-wk, double-blind period and 1 death during the extension period); intervals 2–6 (and interval-1 mortality data; n = 424, 374.0 patient-y) include all belimumab-treated patients, including those originally randomized to placebo who subsequently switched to belimumab; [c]excluding nonmelanoma skin cancer; including unspecified malignancy of lungs.

Conclusion: Belimumab added to standard SLE therapy was well tolerated for its intended indication in patients remaining on treatment over 6 y in an open-label study. Five patients died over 6 y; no single cause predominated. Autoantibody-positive patients treated with belimumab showed sustained improvement in disease activity, and declines in BILAG and SFI flares over 6 y accompanied by reductions in corticosteroid use and autoantibody levels. (NCT00071487/NCT00583362.)

Background/Purpose: Multiple gene expression signatures occur in SLE. Because of the interest in anti-BAFF therapy in SLE, we explored the association between BAFF gene expression and clinical observations in SLE patients.

Methods: 292 SLE patients (58.9% Caucasian, 33.9% African-American, 91.1% female, mean age 46.0±11.9 years) were enrolled in a prospective observational study. At baseline, the BAFF gene expression levels were determined in peripheral blood RNA using Affymetrix chips. Clinical associations, based on the cumulative history and the same-day visit disease activity, were then determined. The results were based on the chi-square test (SAS Institute, Cary, NC, USA). P-values were then adjusted for race. A p-value ≤0.05 was considered statistically significant.

BAFF gene expression was high (> 11.4) in 28.8%, medium (10.7–11.4) in 37.7% and low (<10.7) in 33.6%. Medium to high signature was more common in African-Americans than Caucasians. Clinically, the gene signature was associated with more leukopenia and serologically with Coombs, more autoantibodies (anti-dsDNA, anti-Sm, anti-Ro, anti-La, and anti-RNP) and low complement. However, it was not associated with antiphospholipid antibodies (not shown in the table). The same-day visit disease activity was found to be higher in higher BAFF group. In terms of SLICC/ACR Damage Index, the gene expression was associated with less cataract, cognitive impairment and chronic seizure but not associated with other organ damage (not shown in the table).

Results:

Table 1. Association between cumulative history characteristics and BAFF in SLE

Variable	Low BAFF (<10.7) (%, N=98)	Med BAFF (10.7–11.4) (%, N=110)	High BAFF (>11.4) (%, N=84)	P-value	Adjusted P-value for Race
Race African-American	27.6	39.1	34.5	0.005	N.A.
Caucasian	70.4	54.6	51.2		
Other	2.0	6.4	14.3		
Malar rash	51.0	56.4	45.2	0.31	0.30
Discoid rash	15.3	21.8	16.7	0.44	0.61
Photosensitivity	61.2	51.8	50.0	0.25	0.47
Oral Ulcer	63.3	48.2	48.8	0.057	0.13
Arthritis	76.5	74.6	71.4	0.73	0.61
Serositis	46.9	51.8	44.1	0.55	0.60
