Variable	Low BAFF (<10.7) (%, N=98)	Med BAFF (10.7–11.4) (%, N=110)	High BAFF (>11.4) (%, N=84)	P-value	Adjusted P-value for Race
Physician global assessment >1	9.2	20.9	27.4	0.006	0.026
SLEDAI ≥2	35.7	66.4	71.4	<.0001	<.0001
Age at visit ≤ 30	7.1	12.7	16.7	0.14	0.27
> 30	92.9	87.3	83.3		
Urine Protein/Creatinine Ratio (≥0.5)	3.1	13.6	15.5	0.011	0.058
Anti-dsDNA ≥ 10	10.2	19.1	39.3	<.0001	<.0001
C3 <79	5.1	13.6	19.1	0.015	0.011
C4 <12	4.1	11.8	17.9	0.012	0.0064
ESR >20	36.5	54.7	63.1	0.001	0.0077

Table 3. Association between SLICC/ACR Damage Index and BAFF in SLE

Variable	Low BAFF (<10.7) (%, N=98)	Med BAFF (10.7–11.4) (%, N=110)	High BAFF (>11.4) (%, N=84)	P-value	Adjusted P-value for Race
Cataract	30.6	23.6	9.5	0.0024	0.0011
Cognitive impairment	16.3	7.3	2.4	0.0033	0.0027
Seizure	9.2	4.6	1.2	0.048	0.078

Conclusion: BAFF gene expression level is strongly associated with Coombs positivity, leukopenia, autoantibodies and low complement. Surprisingly, it is negatively associated with neurological damage. The associations between BAFF gene expression and clinical characteristics were studied at the RNA level and need to be verified at the protein level.

Decreased Breast Cancer Risk In SLE: Can a Genetic Basis Be Determined? Sasha Bernatsky[1], Douglas Easton[2], Alison M. Dunning[2], Rosalind Ramsey-Goldman[3], Caroline Gordon[4], William Foulkes[5], Kyriaki Michailidou[2] and Ann E. Clarke[6]. [1]McGill UHC/RVH, Montreal, QC, [2]University of Cambridge, United Kingdom, [3]Northwestern University, Chicago, IL, [4]University of Birmingham, Birmingham, United Kingdom, [5]McGill University, Montreal, QC, [6]Research Institute of the McGill Univ. Health, Montreal, QC

Background/Purpose: Recent work has also demonstrated an important decrease in certain non-hematologic cancers, such as breast cancers in

women with SLE. The reason behind this phenomenon is unknown. Our purpose was to explore whether risk alleles of the SNPs predisposing to SLE might be protective against breast cancer (in women in the general population).

Methods: The literature was reviewed and 17 SLE SNPs were identified as of potential interest. We assessed these SNPs, which are known to be associated with SLE risk, in terms of the available data on their occurrence in women with breast cancer, in the general population. To do this we used the most up to date breast cancer GWAS data, involving 37,012 cases and 40,069 controls from 33 studies in the National Cancer Institute Cancer Genetic Markers of Susceptibility (CGEMS) collaboration and the United Kingdom Breast Cancer Association Consortium (BCAC).

Results: Only two of the SLE-related SNPs that we studied appeared to be negatively associated with breast cancer in the GWAS data. This was rs1801274 (on chromosome 1, position 159746369), with an odds ratio, OR of 0.936687 (p-value 0.037549); and rs9888739 (on 16, position 31220754) with an OR of 0.907551 (p value 0.049899).

Conclusion: Population-based GWAS breast cancer data suggest possible protective roles for two lupus-related SNPs. This is hypothesis-generating only; due to multiple testing, the significance of the associations remains unclear. Future work will use the reverse approach in GWAS of SLE populations, to determine if SNPs known to be associated with breast cancer are in fact represented less often in SLE than in the general population.

Cystatin C Is Associated with Inflammation but Not Atherosclerosis In Systemic Lupus Erythematosus. Ratchaya Lertnawapan[1], Aihua Bian[2], Young Hee Rho[1], Paolo Raggi[3], Annette Oeser[4], Joseph F. Solus[4], Tebeb Gebretsadik[2], Ayumi Shintani[2] and C. Michael Stein[4]. [1]Div.of Clinical Pharmacology and Rheumatology, Dept.of Medicine and Pharmocology, School of Medicine, Vanderbilt University, Nashville, TN, [2]Vanderbilt Medical Center, Nashville, TN, [3]Div.of Cardiology, Emory University, Atlanta, GA, [4]Vanderbilt University, Nashville, TN

Background/Purpose: Even mild renal impairment is associated with increased atherosclerosis and cardiovascular mortality. Cystatin C, a novel measure of renal function, is more sensitive than conventional creatinine-based measures for the detection of subtle renal impairment. Increased cystatin concentrations are also associated with cardiovascular risk, independent of conventional measures of renal function. We examined the hypothesis that cystatin C is elevated in systemic lupus erythematosus (SLE) and is associated with coronary atherosclerosis.

Methods: We measured serum cystatin C, creatinine, TNF- α and IL-6 concentrations, coronary artery calcium score (CACS), Framingham risk score (FRS), Modified Diet in Renal Disease estimated glomerular filtration rate (MDRD-eGFR) and other clinical parameters in 118 patients with SLE and 83 control subjects. The independent association between concentrations of cystatin C and SLE was evaluated using multivariable linear regression models, and the relationship between renal measures and coronary calcium was assessed with multivariable proportional odds logistic regression models.

Results: Cystatin C concentrations, but not serum creatinine or MDRD-eGFR, were significantly higher in patients with SLE than controls (1.11 [IQR: 0.84–1.31] mg/L vs. 0.89 [IQR: 0.76–0.99]mg/L; $P<0.001$ after adjusting for age, race and sex and MDRD-eGFR). In SLE cystatin C was significantly correlated with SLEDAI ($P=0.05$), SLICC ($P=0.04$), ESR ($P=0.001$), CRP ($P=0.04$), TNF-α ($P=0.008$) and IL-6 concentrations ($P=0.01$) after adjustment for age, race and sex. However, cystatin C was not significantly correlated with coronary calcium score in SLE (unadjusted $P= 0.31$; after adjustment for age, race, sex and Framingham risk score $P=0.98$).

Conclusion: Cystatin C concentrations were higher in patients with SLE than control subjects even after adjustment for a conventional creatinine-based measure of GFR. Cystatin C was significantly correlated with several markers of inflammation in SLE but was not associated with coronary atherosclerosis. Subtle renal dysfunction does not appear to be directly associated with accelerated atherosclerosis in SLE.

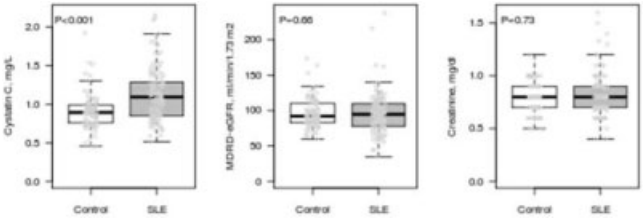

Figure 1. Concentrations of Cystatin C, Creatinine and MDRD-eGFR in Control Subjects and Patients with SLE.

A New 30-Year Cardiovascular Risk Prediction Score Does Not Differ in Women with Systemic Lupus Erythematosus and Control Subjects. Vivian K. Kawai[1], Joseph F. Solus[1], Annette Oeser[1], Young Hee Rho[1], Paolo Raggi[2], Aihua Bian[3], Tebeb Gebretsadik[3], Ayumi Shintani[3] and C. Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]Div.of Cardiology, Emory University, Atlanta, GA, [3]Vanderbilt Medical Center, Nashville, TN

Background/Purpose: Lupus primarily affects young women and is associated with accelerated atherosclerosis and increased risk of coronary heart disease (CHD). Conventional 10-year CHD risk prediction scores, such as the Framingham risk score, perform poorly and are not different in patients with SLE and controls. Long-term cardiovascular risk scores that take into account the cumulative effect of risk factors present in early adulthood have been developed specifically to assess CHD risk in younger populations and could be more suitable for risk prediction in SLE. We examined the hypothesis that a new long-term cardiovascular risk prediction model, the Framingham Heart Study 30-year risk score, is higher in women with lupus compared to controls. Age is the strongest risk factor for coronary atherosclerosis. Thus, we also examined the hypothesis that the 30-year risk score predicts the presence of subclinical coronary atherosclerosis better than age in women with SLE.

Methods: We performed a cross-sectional, case-control study of 121 women with lupus and 65 control subjects matched for age, sex and race. Subjects with diabetes or CHD were excluded. Demographic, clinical and laboratory data and coronary artery calcium scores (CACS) were recorded and 30-year risk scores were calculated. The 30-year risk score estimates the probability of having a cardiovascular event (%) in the next 30 years. The Wilcoxon rank sum test was used to compare the 30-year risk score in lupus and controls, and in lupus patients with and without CAC. We used the area under the receiver operating characteristic curve (AUC) to quantify the ability of the 30-year risk model to discriminate subclinical atherosclerosis (presence of CAC) in SLE and we compared it with AUC for age.

Results: The 30-year risk score did not differ significantly in women with lupus and controls (5.0 [2.7–9.5] % vs. 6.3 [2.2–11.5] %, $p=0.75$, Fig 1) despite the more frequent presence of CAC in lupus (21/121, 17%) compared to controls (4/65, 6%) ($p=0.033$). SLE patients with CAC had higher 30-year risk scores than those without (14.5 [6.5–17.9] % vs. 4.5 [2.4–7.6] %, $p<0.001$); however, the ability of the 30-year risk model to identify patients with CAC did not differ significantly from that of age alone (AUC 0.746, 95% CI (0.616, 0.875) vs. AUC=0.773, 95% CI (0.660, 0.886), $p=0.41$ (Fig. 2).

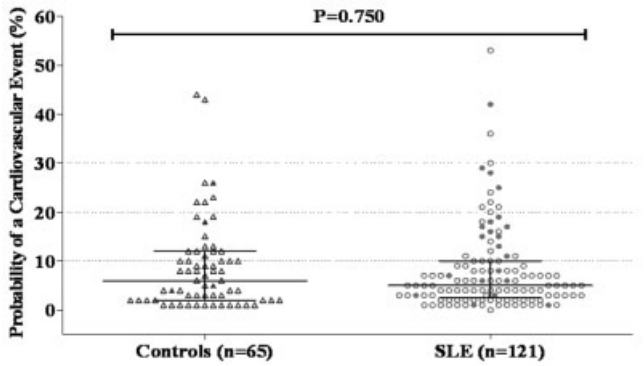

Figure 1.

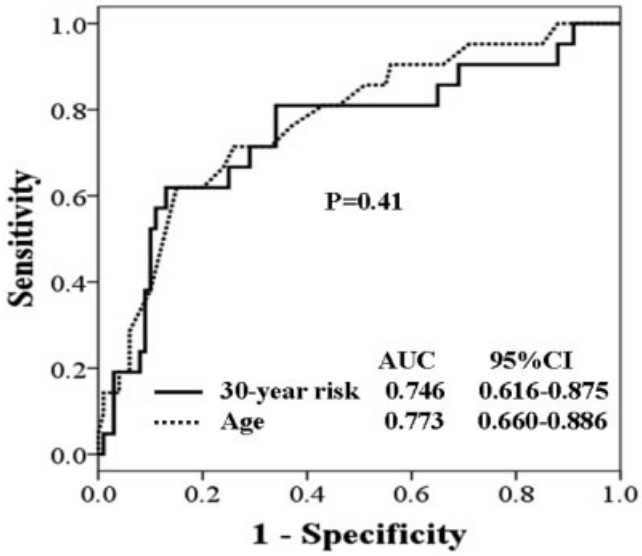

Figure 2.

Conclusion: The 30-year CHD risk prediction score is not different in patients with SLE and controls and its ability to predict subclinical atherosclerosis in SLE is similar to that of age alone.

Development of Damage and Death in a Large Cohort of SLE Patients. Chee-Seng Yee[1], Deva Situnayake[2], Simon J. Bowman[3], Veronica Toescu[1], Richard A. Hickman[1] and Caroline Gordon[1]. [1]University of Birmingham, Birmingham, United Kingdom, [2]Sandwell and West Birmingham NHS Trust, Birmingham, United Kingdom, [3]University Hospital Birmingham, Birmingham, United Kingdom

Background/Purpose: To determine the development of damage and death in a large cohort of SLE patients.

Methods: This was a prospective longitudinal study of SLE patients under regular follow-up at a single centre, that was set up in 1989. SLE patients were included if they achieved the 4th ACR criteria for SLE within 3 years at the time of recruitment. Data were collected on damage (SLICC/ACR damage index) every 12 months. Information on death was provided by the Office for National Statistics. The censure date for analysis was 31st December 2007. Analysis was with survival analysis and standardised mortality ratio (SMR) was calculated. Cox proportional hazards model was used to determine predictors of damage and death (results in hazards ratio (HR)).

Results: There were 382 patients (92.4% women, 51.6% Caucasian, 22% South Asian, 20.7% Afro-Caribbean). Median follow-up was 5.1 years (range 0.2–18.1) and mean age at recruitment was 36.3 years (SD 13.3). There were 26 deaths and 266 items of damage occurring in 123 (32.2%) patients. For those who died, the mean age was 51.4 years (SD 18.8) and mean disease duration was 5.8 years (SD 3.9). The causes of death were infection 10 (38.4%), cardiovascular 8 (30.8%), cancer 3 (11.5%), ARDS 2 (7.7%), active SLE 1 (3.8%), cardiac tamponade 1 (3.8%) and pulmonary hypertension 1 (3.8%). SMR for this cohort was 1.6 (95% CI: 1.1, 2.3), being highest in the younger age group and there is decreasing trend with age towards the general population rate after menopause (Table 1). The distribution of damage was musculoskeletal 59 (22.2%), neuropsychiatric 54 (20.3%), ophthalmic 33 (12.4%), renal 21 (7.9%), pulmonary 20 (7.5%), cardiac 19 (7.1%), cutaneous 18 (6.8%), gastrointestinal 15 (5.6%), malignancy 10 (3.8%), vascular 7 (2.6%), diabetes mellitus 7 (2.6%) and premature menopause 3 (1.1%). The rate of development of damage or death appears to be stable throughout the period of follow-up (Table 2). Prior damage (HR 1.37, 95% CI: 1.26, 1.48) and older age at diagnosis (HR 1.03, 95% CI: 1.02, 1.04) were predictive of development of damage or death, while gender and ethnicity were not.

Table 1. Standardised mortality ratio for cohort of SLE patients

Age group (years)	SMR (95% CI)
20–24	5.3 (1.3, 21.1)
25–34	3.7 (1.4, 9.8)
35–44	1.6 (0.5, 5.0)
45–54	2.6 (1.2, 5.4)
55–64	0.8 (0.3, 2.6)
65–74	1.3 (0.5, 3.3)
75–84	1.1 (0.3, 4.4)
≥85	15.2 (2.1, 107.6)

Table 2. Incidence rate of development of damage or death over period of follow-up at 3 yearly intervals

Period of follow-up (year)	Person-years at risk	Number of death or new items of damage	Incidence rate, per 1000 person-years (95% CI)
0–3	984.6	126	128.0 (107.5, 152.4)
3–6	627.9	70	111.5 (88.2, 140.9)
6–9	403.3	32	79.4 (56.1, 112.2)
9–12	228.0	26	114.0 (77.6, 167.5)
12–15	96.8	8	82.6 (41.3, 165.2)
15–18	37.7	5	132.5 (55.2, 318.4)

Conclusion: In this cohort, SLE patients have premature mortality as compared to general population and the risk is highest in the younger age group. The most common causes of death were infections and cardiovascular disease. The development of damage and death appears to be stable throughout follow-up. The most common damage was in the musculoskeletal, neuropsychiatric and ophthalmic systems.

590

Depression in Systemic Lupus Erythematosus, Dependent or Independent of Severity of Disease. Eric van Exel[1], Jonathan Jacobs[1], Lindy-Anne Korswagen[1], Alexandre Voskuyl[1], Max Stek[1], Joost Dekker[2] and Irene Bultink[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Reade, Centre for Rehabilitation and Rheumatology, VU University Medical Centre, Department of Rehabilitation Medicine, EMGO Institute and Department of Psychiatry, Amsterdam, Netherlands

Background/Purpose: Depression is one of the most commonly reported neuropsychiatric symptoms in systemic lupus erythematosus (SLE) patients. We set out to further unravel the relation between depression and SLE, hypothesizing that presence of depression in patients with SLE is due to increased severity of SLE.

Methods: We studied 102 patients with SLE (mean age 44.4 yrs, 88% female, mean disease duration 7.8 yrs), all fulfilling the ACR classification criteria for SLE. Severity of SLE was determined with the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and the Systemic Lupus International Collaborative Clinics Damage Index (SDI), representing disease activity and organ damage. We used the Beck Depression Inventory score, a validated screening instrument able to detect major depression and to estimate the prevalence of depression. A cut off score of 14 points or higher represents presence of major depression. As a proxy for treatment of depression we assessed the number of patients using anti-depressants.

Results: The mean Beck Depression Inventory score was higher in SLE patients ($n=102$) compared to the Beck Depression Inventory scores derived from an European population based study (ODIN study, $n=7934$), (10.1 points in patients with SLE vs 5.6 points in subjects from ODIN, $p<0.001$). 27.5% of all SLE patients had a major depression ($n=28$). Only 7% of these depressed patients used anti-depressant medication.

There was no difference in disease characteristics, disease activity score (SLEDAI) and organ damage index (SDI) between SLE patients with and without depression (all $p>0.1$). The number of years of education was significantly lower in SLE patients with a depression compared to those without a depression (9.5 yrs. vs 12.2 yrs, $p=0.004$).

Conclusion: The mean Beck Depression Inventory score, i.e. a proxy for prevalence of depression, is almost doubled in SLE patients compared to the mean Beck Depression Inventory score from a large pan European population based study. Surprisingly, we found no association between

disease characteristics or severity of SLE and presence of depression, determined with the Beck Depression Inventory score.

Finally, we found that the number of depressed SLE patients treated with anti-depressant medication is very low, suggesting that depressed SLE patients are not adequately recognized and treated for depression. For depressed SLE patients, this study provides clues that screening for depression in SLE patients should be done routinely, and that psychiatric counseling for these patients should be readily available.

591

A Prospective Study of Seizures in Systemic Lupus Erythematosus. John G. Hanly[1], Murray B. Background/Purpose: Seizure disorders are serious manifestations of neuropsychiatric systemic lupus erythematosus (NPSLE). We wished to determine the frequency, attribution and outcome of seizures in a long-term study of SLE.

Methods: The study was conducted by an international research network of academic centers. Patients were enrolled close to the time of SLE diagnosis and assessed annually for up to 10 years for the occurrence of seizures and other NP events using the ACR case definitions. The attribution of seizures to SLE and non-SLE causes was determined centrally using a priori decision rules. Physician outcome scores of seizure disorders were recorded on a 7 point Likert scale. Patient outcomes were derived from the mental (MCS) and physical (PCS) component summary scores of the SF-36. Statistical analyses included Cox regression for time-to-seizure resolution (adjusting for correlation of multiple seizures in the same patient) and linear regression for MCS and PCS summary scores by generalised estimating equations (adjusting for correlation between multiple MCS and PCS measurements for the same patient).

Results: Of the 1631 enrolled patients 89.4% were female and the mean ($\pm$ SD) age was 35.0 $\pm$ 13.4 years. The mean disease duration at enrollment was 5.6 $\pm$ 4.8 months and the mean length of followup was 3.5 $\pm$ 2.9 years. A total of 75/1631 (4.6%) patients had $\geq$ 1 seizure with the majority (79%) having a single event. In these 75 patients there were a total of 91 seizures (66% generalized; 34% focal) of which 78/91 (86%) were attributed to SLE. Although seizures occurred over the entire observation period, the majority presented early in the disease course with a median (range) interval from the time of diagnosis of SLE to onset of first seizure of 0.14 (-0.50 – 7.57) years. More patients with seizures attributed to SLE stopped taking anti-seizure drugs at the first followup assessment compared to patients with seizures attributed to non-SLE causes (19/66=29% vs. 2/12=17%) and similarly by the second followup assessment (32% vs. 11%). Using physician assessment, those seizures attributed to SLE were more likely to resolve (59/78, (76%)) compared to seizures attributed to non-SLE causes (7/13, (54%)). Using patient self-report the mean ($\pm$ SD) MCS score in patients with seizures and no other NP events was comparable to patients without NP events (45$\pm$13.1 vs. 48.5 $\pm$ 10.9; p=0.21). A similar outcome was seen in the mean ($\pm$ SD) PCS scores (40.0 $\pm$ 10.8 vs. 42.8 $\pm$ 11.2; p=0.34).

Conclusion: Most seizures in SLE patients are attributable to lupus and occur in close proximity to the time of diagnosis of SLE. In the majority of cases the seizures resolve, do not require long-term anti-seizure medication and are not associated with a negative impact on mental or physical health-related quality of life.

592

Predictors of Seizures in Systemic Lupus Erythematosus. John G. Hanly[1], Murray B. Urowitz[2], Li Su[3], Caroline Gordon[4], Sang-Cheol Bae[5], Jorge Sanchez-Guerrero[6], Juanita Romero-Diaz[7], Daniel Wallace[8], Ann E. Clarke[9], Sasha Bernatsky[10], E.M. Ginzler[11], Joan T. Health, Montreal, QC, [10]McGill UHC/RVH, Montreal, QC, [11]SUNY-Downstate Medical Center, Brooklyn, NY, [12]Oklahoma Medical Research Foundation, Oklahoma City, OK, [13]University College London, London, United Kingdom, [14]Johns Hopkins University School of Medicine, Baltimore, MD, [15]Toronto Western Hospital, Toronto, ON, [16]Toronto Western Hospital, University of Toronto, Toronto, ON, [17]A, Manchester, United Kingdom, [18]Landspital Univ Hospital, Reykjavik, Iceland, [19]University of North Carolina at Chapel Hill, Chapel Hill, NC, [20]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [21]University of Alabama at Birmingham, Birmingham, AL, [22]Northwestern University Feinberg School of Medicine, Chicago, IL, [23]Allegheny Singer Research Institute, Pittsburgh, PA

Background/Purpose: Neuropsychiatric (NP) manifestations of SLE include seizure disorders. Our objective was to determine which clinical and laboratory variables were associated with seizures in a long-term prospective study of SLE patients.

Methods: A multi-center, international, research network enrolled patients within 15 months of fulfilling ACR criteria for SLE and performed annual assessments for up to 10 years. Seizures and other NP manifestations were recorded using the ACR case definitions. Decision rules determined the attribution of seizures to SLE and non-SLE causes. Clinical variables included demographic characteristics, disease duration, educational status, medication utilization, global SLE disease activity (SLEDAI-2K) and cumulative organ damage (SLICC/ACR Damage Index (SDI)) computed with and without NP variables. Plasma/serum samples were available at enrollment for the determination of the following autoantibodies: lupus anticoagulant, anticardiolipin, anti-β_2 glycoprotein-I, anti-ribosomal P and anti-NR2 glutamate receptor antibodies. The association between clinical and serological variables and the risk of the first occurrence of seizures was examined by univariate and multivariate Cox regression analysis.

Results: The 1631 enrolled patients were predominantly female (89.4%) with a mean ($\pm$ SD) age of 35.0 $\pm$ 13.4 years and mean disease duration of 5.6 $\pm$ 4.8 months. The mean followup was 3.5 $\pm$ 2.9 years. Over this period 75/1631 (4.6%) patients had $\geq$ 1 seizure with a total of 91 seizures of which 78/91 (86%) were attributed to SLE. Multivariate analysis indicated a significantly higher risk of seizures with African race/ethnicity (HR (CI): 1.97 (1.07–3.63); p=0.02) and lack of post-secondary education (1.97 (1.21–3.19); p<0.01) after adjustment for age at diagnosis and gender. In order to examine the effect of prior organ damage and medication use, the analysis was restricted to those seizures

occurring after the enrollment visit (n=20). In these patients higher SDI scores calculated without NP variables were associated with an increased risk of subsequent seizures (SDI=1: 3.71(1.38–9.95); SDI=2or3: 1.33(0.27–6.46); SDI≥4: 6.44(0.72–57.2); p=0.04). After adjustment for prior medication, this risk was less significant (p=0.07) demonstrating some confounding between disease severity and medication. Prior use of anti-malarial drugs in the absence of immunosuppressive agents was the most notable treatment effect on seizures (0.07 (0.01–0.66); p=0.02). There was no association with SLEDAI scores or between any of the autoantibodies detected at enrollment with subsequent seizures.

Conclusion: The risk of seizures in SLE patients is higher in patients of African race/ethnicity, lower educational status and organ damage outside of the nervous system. The association with lupus related therapies is complex but anti-malarial drugs may have a protective effect.

593

Plasma Levels of Osteopontin Identify Patients At Risk for Organ Damage in Systemic Lupus Erythematosus. Ornella J. Rullo[1], Jennifer MP Woo[1], Alice DC Hoftman[1], Miriam F. Parsa[1], David Elashoff[2], Paul Maranian[3], Jennifer M. Grossman[4], Bevra H. Hahn[4], Maureen A. McMahon[3], Deborah K. McCurdy[1] and Betty P. Tsao[3]. [1]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [2]University of California, Los Angeles, Los Angeles, CA, [3]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [4]UCLA David Geffen School of Medicine, Los Angeles, CA

Background/Purpose: Osteopontin (OPN) is involved in adhesion and migration of monocytes and T cells, and has been implicated in post-inflammatory fibrosis of lung and kidney. We have established that circulating plasma OPN (cOPN) is increased in pediatric SLE patients (pSLE; age of onset <18 years; n = 72), compared with healthy controls (p = 0.0007), and that cOPN is associated with ACR/SLICC damage index (SDI) scores >0 (p = 0.006). This study assessed whether increased cOPN might precede the development of organ damage in pSLE.

Methods: 23 pSLE patients have been followed for 12 months with cOPN measured by ELISA at 6 month intervals, SLEDAI at 3 month intervals and disease flare, and SDI at every 6 months. An adult cohort of 23 SLE patients with plasma, SLEDAI and SDI collected at 6 month intervals was obtained for confirmation. Time-adjusted cumulative disease activity (adjusted-mean SLEDAI, or AMS) was calculated using area under the curve of serial SLEDAI measurements. Statistical analysis was performed using Student's t test, Pearson's correlation, Fisher's exact test, multivariate regression modeling, and receiver operator characteristic (ROC) curves.

Results: By logistic regression, independent risk factors for active SLE (SLEDAI ≥ 4) at study enrollment for both cohorts were: increased cOPN (OR = 1.5, p = 0.002) and shorter disease duration (OR = 0.9, p = 0.05), but not gender or C4. Baseline cOPN of highest versus lowest quartile was associated with increased cumulative disease activity at 6 months (AMS = 9.6 vs. 2.2, p = 0.0003 in pSLE; and 4.6 vs. 2.7, p = 0.01 in adult SLE). This association was strongly supported by the positive correlation between baseline cOPN with 6-month AMS: r = 0.67 (p = 0.0002) in pSLE and r = 0.54 (p = 0.01) in adult SLE. Furthermore, in multivariate linear regression models of the combined cohort, baseline cOPN levels were independent predictors of AMS over the subsequent 6 months (p = 0.01) and 12 months (p = 0.002), but gender, disease duration, C4, lifetime prednisone dose, and non-white race were not. Increased baseline cOPN were associated with pSLE and adult SLE patients exhibiting increased SDI (n = 5 and 4, respectively) over the 12 month period compared to those with a stable SDI (t-test p = 0.003 and 0.1, respectively). Cumulative disease activity was associated with increases in SDI in pSLE (mean AMS of 8.2 in SDI>0 vs. 2.2 in SDI=0; p < 0.0001) and adult SLE (4.8 vs. 2.8; p = 0.03). The area under the ROC curve for cOPN as predictor of AMS (score ≥ 4) at 12 months was 0.828 (Figure 1). By logistic regression, independent risk factors for change in SDI at 12 months were: cOPN (OR 1.3, p = 0.02), AMS (OR 1.05, p = 0.03), and cumulative prednisone exposure (OR 1.15, p = 0.03), but not disease duration and gender.

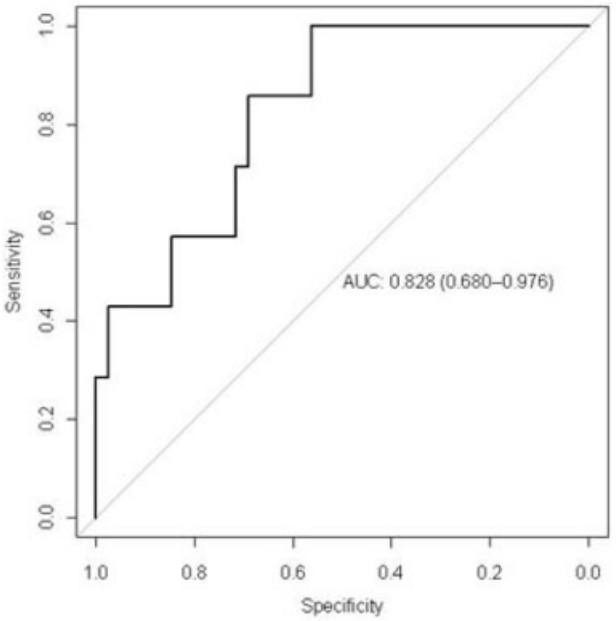

Figure 1. Receiver-operating characteristic (ROC) curve of baseline cOPN sensitivity and specificity to indicate SLE patients (total n = 46) with high cumulative disease activity (AMS ≥ 4; n = 7). A cut-off of cOPN = 19.1 ng/ml (2 standard deviations above the mean for young, healthy controls) has a sensitivity of 86% and specificity of 67% for determining high AMS, with a negative predictive value of 96%.

Conclusion: High circulating OPN levels predicted increased cumulative disease activity and organ damage in both pediatric and adult SLE patients.

594

All-Trans Retinoic Acid Sustains the Stability and Function of Natural Regulatory T Cells From Human and Patients with SLE. Qin Lan[1], Julie Wang[1], Hui-Ming Fan[2], David Brand[3], Hejian Zou[4], Zhong-Min Liu[2] and Song G. Zheng[1]. [1]University of Southern California, Los Angeles, CA, [2]Shanghai East Hospital, Tonji University, Shanghai, China, [3]VA Medical Center, Memphis, TN, [4]Huashan Hospital, Shanghai, China

Background/Purpose: CD4+Foxp3+ natural regulatory T cells (nTregs) play a key role in the prevention of autoimmune diseases. However, recent studies have also demonstrated nTregs are instable in the inflammatory milieu and therapeutic effect of nTregs to the established autoimmune diseases was unsatisfactory. We previously reported that nTregs pretreated with all-trans retinoic acid (atRA) become stable and functional in the inflammatory condition in animal model. It is unclear whether atRA treated nTregs from healthy subjects and patients with SLE could sustain the stability and functionality of nTregs.

Methods: $CD4^+CD25^+CD127^-$ nTregs sorted from PBMCs of healthy donors and SLE patients were expanded *in vitro* with anti-CD3/CD28-coated beads (1 bead to 3 cells) and IL-2 (300U/ml) in the presence or absence of IL-1β (10ng/ml) and IL-6 (10ng/ml) for 3 days. atRA (100nM) or DMSO control was added to some wells. In other experiments, nTregs pretreated with atRA or DMSO for five days, then were widely washed and re-stimulated with IL-1 and IL-6 for three days. Intracellular and soluble productions of IL-17 and IFN-γ were measured by FACS and Elisa respectively. IL-1βRI, IL-6R and related signaling molecule expression was analyzed by FACS and western blot. Foxp3 and other regulatory T cells related phenotypes were measured by FACS. Suppressive activities of these cells *in vitro* and *in vivo* were measured by a standard assay and xeno-GVHD humanized animal model as we previously reported.

Results: We found that nTregs mostly lost Foxp3 expression and suppressive activities *in vitro* and *in vivo* when they were stimulated with IL-1β and IL-6. Some of nTregs become Th1, or Th17 or both Th1/Th17 cells. However, addition of atRA to the cultures, or nTregs that had been primed with atRA, enabled the nTregs to be resistant to T effector cell conversion, sustain Foxp3 expression and suppressive activity. Adoptive transfer of these cells to SCID γ common chain KO mice markedly prolonged the survival of these mice received human PBMC compared to mice received PBMC alone and PBMC + control nTregs. Similarly, atRA primed nTregs isolated from active SLE patients also displayed stable phenotypic and functional characteristics with nTregs from healthy controls.

Conclusion: We suggest that addition of atRA to the nTregs expanded *in vitro* may represent a novel strategy to manipulate nTregs for treating SLE and other human autoimmune diseases.

Monocyte Chemoattractant Protein-1 and Pentraxin in Systemic Lupus Erythematosus. Adnan Kiani[1], Thor Ueland[2], Pal Aukrust[2], Laurence S. Magder[3], Ivana Hollan[4] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]The Oslo University, Oslo, Norway, [3]University of Maryland, Baltimore, MD, [4]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway

Background/Purpose: Pentraxin 3 (PTX3), a member of the same family as C reactive protein, has been shown to be associated with vascular inflammation. Monocyte Chemoattractant Protein-1 (MCP-1) is a chemokine also associated with atherosclerosis. We determined the association of these potential biomarkers with subclinical atherosclerosis measured by coronary artery calcium (CAC), carotid intima-media thickness (IMT) and carotid plaque in SLE at two years followup.

Methods: 148 SLE patients (91% female, 64% Caucasian, 31% African-American, 5% others, mean age 45 yrs) had measurement of subclinical atherosclerosis (coronary artery calcium CAC, carotid intima-media thickness (IMT) and carotid plaque.

Results: Values of MCP-1 ranged from 34–668pg/ml (mean=183, SD=101) and PTX3 from 0.16–25ng/ml (mean=2.2, SD=2.6).

Table 1. Shows the association between MCP-1, PTX3 and coronary calcium at baseline.

	Proportion (%) with detectable coronary calcium at baseline	p-value
MCP-1 level (n=148)	17/31 (35%)	0.41
Low	25/53 (47%)	
Medium	22/47 (47%)	
High		
PTX3 level (n=148)	21/51 (41%)	0.75
Low	22/46 (48%)	
Medium	21/51 (41%)	
High		

The lowest rate of CAC was among those with low levels of MCP-1, but this difference was not statistically significant.

Table 2. Shows the association between MCP-1, PTX3 and the mean carotid IMT.

	Baseline IMT		Change in IMT	
	Mean IMT	P-value	Mean change from baseline to follow-up	P-value
MCP-1 level	0.57	0.70	0.08	0.88
Low	0.59		0.09	
Medium	0.57		0.09	
High				
PTX3 level	0.58	0.38	0.10	0.69
Low	0.58		0.09	
Medium	0.56		0.08	
High				

Table 3. Shows the association between MCP-1, PTX3 and carotid plaque.

	Proportion (%) with carotid plaque at baseline	p-value	Proportion (%) with carotid plaque at follow-up[1]	p-value
MCP-level	7/47 (15%)	0.71	7/37 (19%)	0.72
Low	11/52 (21%)		8/39 (21%)	
Medium	8/47 (17%)		9/34 (26%)	
High				
PTX3 level	13/51 (25%)	0.14[2]	8/34 (24%)	0.93
Low	8/46 (17%)		8/36 (22%)	
Medium	5/49 (10%)		8/40 (20%)	
High				

[1] Among those who were negative for carotid plaque at baseline.
[2] P=0.046 for the test for trend providing modest evidence that the proportion with carotid plaque decreases as PTX levels increases.

Conclusion: MCP-1 and PTX3 have been associated with atherosclerosis in the general population. In general, the PTX3 levels seen in this study were equivalent to those seen in controls in other studies. MCP-1 and PTX3 in SLE were not associated with any marker of subclinical atherosclerosis. In fact, PTX3 even appeared to be protective against carotid plaque.

Increase In Vitamin D Improves Urine Protein/Creatinine Ratio and Complement In Systemic Lupus Erythematosus. Michelle Petri[1], Kayode J. Bello[1], Hong Fang[1] and Laurence S. Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Vitamin D deficiency has been associated with a number of chronic and autoimmune conditions including systemic lupus erythematosus (SLE). We investigated whether a change in vitamin D levels was associated with disease activity, in vitamin D deficient SLE patients on vitamin D supplements, after a follow-up period of 68 weeks (July 2009 – December 2010).

Methods: 802 SLE patients were followed for 68 weeks. Serum vitamin D levels were measured as part of routine clinical care. SLE patients determined to have low levels of 25 OH Vitamin D (<40 ng/mL) were supplemented with 50,000 units Vitamin D weekly, with Ca/D 200 units twice daily. The physician's global assessment (PGA) and SLEDAI were measured at all visits and routine laboratory tests were also done. Linear regression models were used to estimate the association between change in vitamin D and change in various measures of disease activity. The dependent variables analyzed in the models were change in PGA, SLEDAI, urine protein/creatinine Ratio, C3, C4, anti-dsDNA, and prednisone dose. The independent variable was change in Vitamin D. Generalized estimating equations were used to account for repeated observations from the same patients.

Results: The SLE patients were 91% female, mean age 44.9, 54% Caucasian, 38% African-American, 8% other ethnicity. At baseline, the mean PGA (0–3 VAS) was 0.6 $\pm$ 0.7 and mean SELENA-SLEDAI was 2.2 $\pm$ 2.9. The mean 25 OH Vitamin D at baseline was 29.7 $\pm$ 14.4.

Vitamin D levels were not associated with PGA and SLEDAI. However, there was significant improvement in the urine protein/creatinine ratio, serum C3 and C4.

Table. Effect of change in Vitamin D on disease activity by univariate analysis

	Estimated change in variable per 10 units increase in 25 (OH) Vit D	P-Value
Physician Global Assessment	-0.010 ± 0.007	0.16
SELENA-SLEDAI	-0.017 ± 0.034	0.61
Urine Protein/Creatinine Ratio	-0.020 ± 0.008	0.009
Serum C3 (mg/dL)	0.796 ± 0.266	0.003
Serum C4 (mg/dL)	0.206 ± 0.063	0.001
Anti-dsDNA	-0.075 ± 1.109	0.95
Prednisone (mg)	-0.133 ± 0.070	0.057

Conclusion: In this SLE population, there was no change in global clinical disease activity even with long follow-up. However, we found a statistically significant improvement in urine protein/creatinine ratio and low complement. The analysis suggests that Vitamin D supplementation in SLE patients may have beneficial effects on lupus nephritis that deserve future study.

597

The Contribution of Cell Bound Complement Activation Products to the Diagnosis of Systemic Lupus Erythematosus. Kenneth C. Kalunian[1], W. Chatham[2], Elena M. Massarotti[3], Cole Harris[4], R.A. Furie[5], Jill P. Buyon[6], Eliza F. Chakravarty[7], Emily C. Somers[8], Puja Chitkara[9], Rachel L. Gross[10], Kyriakos A. Kirou[11], Joyce Reyes-Thomas[12], Rosalind Ramsey-Goldman[13], Christine Hsieh[14], Chaim Putterman[15], Thierry Dervieux[16] and A. Weinstein[17]. [1]UCSD School of Medicine, La Jolla, CA, [2]UAB Arthritis Clinical Intervention Program, Birmingham, AL, [3]Brigham and Women's Hospital, Boston, MA, [4]Exagen Diagnostics, [5]North Shore-LIJ Health System, Lake Success, NY, [6]NYU School of Medicine, New York, NY, [7]Stanford University, Palo Alto, CA, [8]University of Michigan, Ann Arbor, MI, [9]SDAMC, San Diego, CA, [10]Albert Einstein College of Medicine, New York, NY, [11]Mary Kirkland Center for Lupus Care, Hospital for Special Surgery, New York, NY, [12]Albert Einstein College of Med, Bronx, NY, [13]Northwestern University Feinberg School of Medicine, Chicago, IL, [14]University of Chicago, Chicago, IL, [15]Albert Einstein College of Medicine, Bronx, NY, [16]Exagen Diagnostics, Albuquerque, NM, [17]Washington Hospital Center, Washington, DC

Background/Purpose: Previous studies have established the utility of cell-bound complement activation products (CB-CAPS) as diagnostic biomarkers for systemic lupus erythematosus (SLE). The purpose of this study was to demonstrate the value of CB-CAPs in combination with antinuclear (ANA) and anti-double-stranded DNA (anti-dsDNA) antibodies for the diagnosis of SLE.

Methods: Fourteen centers participated in this cross-sectional study that enrolled SLE patients who met the ACR classification criteria, patients with other rheumatic diseases and healthy subjects. Serological markers (ANA, anti-dsDNA and anti-mutated citrullinated vimentin antibodies [anti-MCV]) were measured using enzyme-linked immunosorbent assays. Complement receptor 1 levels on erythrocytes (E-CR1) as well as complement C4d levels on erythrocytes (E-C4d), platelets (PC4d), and B cells (BC4d) were determined by flow cytometry. Statistical analyses utilized multivariate logistic regression, area under receiver operating characteristic (ROC) curves, and calculations of diagnostic sensitivity and specificity.

Results: A total of 210 SLE patients (90.5% females, mean age 42y), 178 patients with other rheumatic diseases (80.3% females, mean age 57y), and 205 healthy individuals (65.8% females, mean age 41y) participated. The group of patients with other rheumatic diseases consisted mainly of rheumatoid arthritis patients (n=120, 67%) and patients with systemic sclerosis (n=21, 12%). Table I indicates the percentage positivity for serological markers together with EC4d, BC4d, PC4d and ECR1 net mean fluorescence intensity (MFI) in each of the three groups.

Table. Diagnostic assay results among SLE, other diseases and healthy subjects. (Net MFI: Net Mean Fluorescence intensity).

	SLE	Other diseases	Normal Healthy
ANA >20 units (normal ≤ 20)	88.5%	41.0%	9.3%
anti-dsDNA > 301 units (normal ≤ 301)	29.5%	3.9%	0.5%
Anti-MCV >70 units (normal ≤ 70)	1.9%	36.0%	0.5%
EC4d Net MFI (CI 95%)	17.6 (15.2–20.0)	6.3 (5.7–6.8)	5.3 (4.6–6.1)
BC4d Net MFI (CI 95%)	110.4 (96.3–124.5)	34.9 (26.1–41.6)	23.5 (21.4–25.6)
PC4d Net MFI (CI 95%)	16.2 (12.0–20.5)	3.6 (3.0–4.2)	2.0 (1.2–2.8)
ECR1 Net MFI (CI 95%)	13.3 (12.4–14.1)	16.1 (15.1–17.1)	20.7 (19.6–21.7)

Anti-dsDNA was an insensitive (29.5%) yet highly specific (>95%) marker for SLE. Among 523 anti-anti-dsDNA negative individuals, a multivariate logistic regression analysis revealed that SLE was associated with ANA positivity ($p<0.001$), anti-MCV negativity ($p<0.001$), and elevation of both EC4d and BC4d ($p<0.001$) (ROC area=0.907). An Index score corresponding to a weighted sum of these four markers was 0.80 (CI95%: 0.45;1.15) in SLE, −2.91 (CI95%: −3.21;−2.61) in other rheumatic diseases, and −2.87 (CI95%: −3.03;−2.71) in healthy subjects. A combination of anti-dsDNA positivity and the Index score (using a cutoff of zero) yielded 81% sensitivity for SLE, and 86.0% specificity in distinguishing SLE from other rheumatic diseases (97.1% specificity in distinguishing SLE from healthy subjects).

Conclusion: This multicenter study demonstrates that an assay panel combining anti-dsDNA, ANA, anti-MCV, EC4d and BC4d is highly sensitive and specific for the diagnosis of SLE.

598

Predictors of Organ Damage At the Time of Systemic Lupus Erythematosus Diagnosis, and of Rates of Increase in Damage After Diagnosis. Sneha Purvey[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: The SLICC/ACR Damage Index (SDI) has become the accepted measure of permanent organ damage in SLE. Multiple cross-sectional and several prospective studies have examined predictors or associates of damage. We now report a new statistical analysis of the damage experience of patients in the Hopkins Lupus Cohort.

Methods: 2063 SLE patients (92.4% female, 56.3% Caucasian, 37% African-American, mean age 48.1 years) were included. The SLICC/ACRDamage Index was calculated from diagnosis onwards in a prospective cohort. We explored predictors of damage at the time of diagnosis, and predictors of change in damage score over time after diagnosis using two linear regression models.

Results: The mean SDI score of the cohort at diagnosis was estimated to be 0.82 and the mean rate of progression in SDI score was 0.10 per year. The variables associated with greater rate of progression in organ damage were male gender ($P=0.0015$), African-American ethnicity ($P=0.0001$), lower income ($P=0.0001$), higher disease activity at first cohort visit (by SLEDAI) ($P=0.0001$), higher SDI score at diagnosis ($P=0.0001$), lupus anticoagulant ($P=0.0001$), hypertension ($P=0.0001$), proteinuria ($P=0.0001$), corticosteroid use ($P=0.0001$), and immunosuppressive use ($P=0.0001$). In the multivariate analysis, higher age at diagnosis, low income, lupus anticoagulant, hypertension, proteinuria, corticosteroid use, and immunosuppressant use remained independent predictors. Hydroxychloroquine use was protective ($P=0.0001$).

Conclusion: The most important demographic predictors of progression were low income, older age at diagnosis, male gender, and low education. The serologic test associated with progression was the lupus anticoagulant, not anti-dsDNA or other antiphospholipid antibodies. Patients already damaged at diagnosis had a higher rate of progression. Disease activity and corticosteroid use clearly increased the rate of progression, as expected. Hydroxycholoquine use was protective against damage progression. These data clearly point to the need for effective prophylactic therapy for the lupus anticoagulant and the need for tight control of disease activity, without reliance on corticosteroids.

599

Time to Recovery From Proteinuria in Lupus Nephritis Patients Receiving Standard of Care Treatment. Zahi Touma[1], Murray B. Urowitz[1], Dominique Ibanez[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: The level of proteinuria is an important measure to document improvement in lupus nephritis. The recovery time from abnormal levels of proteinuria has not been well described with standard treatment.

To determine the recovery time from proteinuria in lupus nephritis patients receiving standard treatment. To determine whether the initial level of proteinuria predicts the percentage of patients who improve and the time to improvement.

Methods: We studied all lupus nephritis patients registered at the Lupus Clinic; 1970–2011. Proteinuria was defined as ≥0.5g/24 hours as defined by SLEDAI-2K.

Patients with proteinuria and at least one of the urinary sediments (hematuria, pyuria or casts) present for 2 consecutive visits were enrolled. Patients were grouped into: group 1 as 0.5–0.9g/day, group 2 as 1–2g/day and group 3 as ≥2g/day. Recovery from proteinuria was defined as proteinuria <0.5g/24 hours. We determined the time to recovery from proteinuria in all patients and in each of the 3 groups separately with Kaplan-Meier curve.

Results: 244 patients (F 85%) were identified. 58% were Caucasian, 17% Black, 14% Asian, and 11% other. Age at diagnosis of lupus was 28.0±12.4 years, age and duration of lupus at start of study was 34.0±12.2 and 6.0±6.5 years, respectively. The mean length of follow-up period was 2.3±2.7 years. SLEDAI-2K was 16.9±6.8 at the start and 7.9±7.2 at the end of the study.

53% of the patients recovered from proteinuria within 2 years while 74% recovered within 5 years (Table 1 and Figure 1).

Table 1. Time to recovery from proteinuria

Patients	Time	1 Year	2 Year	3 Year	4 Year	5 Year
All (n=244)		30%	53%	63%	70%	74%
Proteinuria 0.5–0.9g/d (n=29)		45%	77%	86%	91%	91%
Proteinuria 1–1.9g/day (n=74)		38%	54%	64%	72%	72%
Proteinuria ≥2g/day (n=111)		16%	42%	50%	60%	67%
Proteinuria≥1 g/day (n=185)		25%	47%	55%	65%	69%

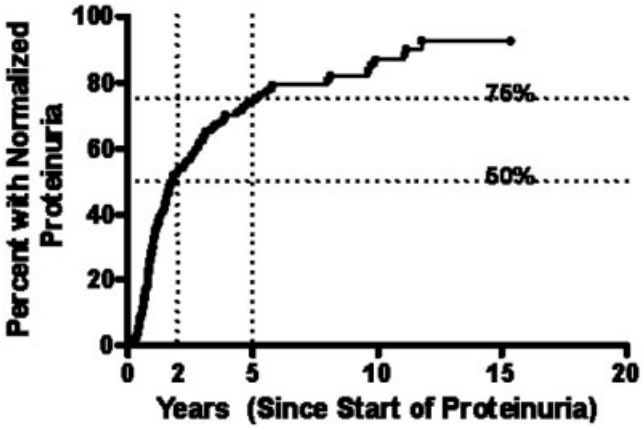

Figure 1. Kaplan-Meier curve for time to recovery from proteinuria in all patients.

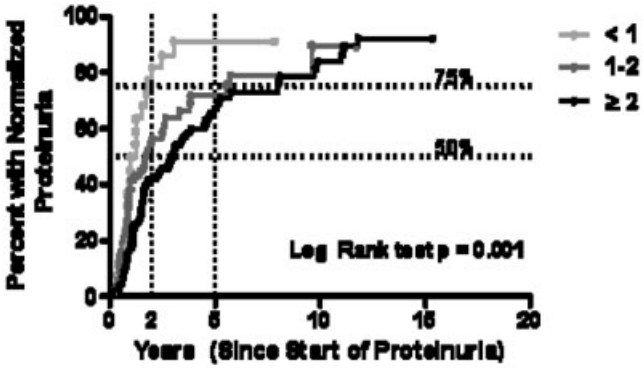

Figure 2. Kaplan-Meier curve for time to recovery from proteinuria in 3 groups.

The level of proteinuria at baseline visit predicted the time to improvement and the percentage of patients who improved. Patients with a higher level of proteinuria at baseline needed a longer time to normalize their proteinuria (Table 1 and Figure 2).

Conclusion: Almost 50% of the lupus nephritis patients normalize their proteinuria by year 2 and others continue to improve over time; 74% recovered by year 5. The level of proteinuria at baseline visit predicts the percent of patients who respond over time and also the time to improvement.

Proposal for a Reliable and Feasible Algorithm for the Identification of Antinuclear Antibodies. Kaline M.C. Pereira, Alessandra Dellavance and Luis E. C. Andrade. Universidade Federal de São Paulo and Fleury Health and Medicine Laboratories, Sao Paulo, Brazil

Background/Purpose: Antibodies to Sm, RNP, SS-A/Ro, SS-B/La, Scl-70 and Jo-1 (known as extractable nuclear antigens - ENA) are particularly relevant in the diagnosis of systemic autoimmune rheumatic diseases (SARD). The known clinical associations of anti-ENA antibodies were originally defined on the basis of double immunodiffusion (DID) assay, which is cost-effective and extremely specific, but has limited sensitivity, is time-consuming, needs qualified personnel and is not appropriate for automation. Solid phase assays (ELISA and similar), in turn, are highly sensitive and ready for automation, but show variable diagnostic performance and often yield unexpected positive results. The present study analyzed the diagnostic performance of six ELISA kits and DID for determination of anti-ENA antibodies and proposes an algorithm combining ELISA and DID for efficient high throughput.

Methods: 290 serum samples from patients with well characterized autoimmune (ACR criteria) and non-autoimmune rheumatic diseases, chronic viral hepatitis, and healthy controls were tested for anti-ENA antibodies by DID and six ELISA kits according to manufacturer's instructions. Clinical diagnosis was the gold standard for determining the diagnostic performance of each assay. An algorithm combining a screening step by ELISA and a confirmatory step by DID was applied to 16,485 samples for which anti-ENA antibodies had been ordered in a large clinical laboratory.

Results: The sensitivity of ELISA tests for the detection of anti-ENA was higher than DID for all ELISA kits. The sensitivity of anti-Sm for the diagnosis of systemic lupus erythematosus (SLE) was 6.7% in DID and ranged from 18.6% to 44.2% in ELISA kits. The same was observed with anti-Scl-70 regarding the diagnosis of systemic sclerosis (SSc) (13.8% sensitivity by DID; 28.6 to 37.9% by ELISA) and anti-Jo-1 for polymyositis (PM) (5.9% sensitivity by DID; 9.5 to 17.7% by ELISA). In contrast the positive predictive value (PPV) of antibodies to Sm, Scl-70, and Jo-1, was 100% for SLE, SSc and PM, respectively, when assayed by DID, but had an average of 52.2% (ranging from 0 to 100%), when assayed by ELISA. ELISA, but not DID, yielded several anti-ENA positive results in non-SARD patients, such as those with chronic hepatitis, ankylosing spondylitis and osteoarthritis, and even in healthy individuals. No sample with a positive result in DID was negative in ELISA, what allowed the proposal of a two-step algorithm based on ELISA screening and confirmation by DID. With such algorithm only 17% of 16,485 samples were positive by ELISA and required confirmation by DID. In comparison to the standard one-step DID operation, this strategy resulted in a 60% reduction in the operation cost, and a significant reduction in the turn-around time from 96h to 24h in over 80% of the samples.

Conclusion: The proposed algorithm, whose effectiveness was demonstrated in the autoantibody routine of a large clinical laboratory, takes advantage of the best features of each method, ie, speed, automation and higher sensitivity of the EIA and the high specificity and positive predictive value of DID, allowing the report of highly reliable positive results with genuine value to the clinician.

Longitudinal Assessment of SLE Disease Activity: BILAG-2004, SLEDAI-2000 or Both? Chee-Seng Yee[1], Caroline Gordon[1], David A. Isenberg[2], Bridget Griffiths[3], Lee- Suan Teh[4], Ian N. Bruce[5], Yasmeen Ahmad[6], Anisur Rahman[7], Athiveeraramapandian Prabu[1], Mohammed Akil[8], Neil J. McHugh[9], Christopher Edwards[10], DP. D'Cruz[11], Munther A. Khamashta[12] and Vernon Farewell[13]. [1]University of Birmingham, Birmingham, United Kingdom, [2]University College London, London WC1E 6JF, United Kingdom, [3]Freeman Hospital, Newcastle Upon Tyne, United Kingdom, [4]Royal Blackburn Hospital, Blackburn, United Kingdom, [5]A, Manchester, United Kingdom, [6]The Department of Rheumatology, Betsi Cadwaladr University Health Board (West), Llandudno, LL30 1LB, UK, Wales, United Kingdom, [7]University College London, London, United Kingdom, [8]Sheffield Center Rheumatic Dis, Sheffield South Yorkshire, United Kingdom, [9]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [10]Southhampton General Hospital, Southampton, United Kingdom, [11]St. Thomas' Hospital, London, United Kingdom, [12]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [13]MRC Biostatistics Unit, Cambridge, United Kingdom

Background/Purpose: This analysis was to compare the responsiveness of BILAG-2004 and SLEDAI-2000 indices and to determine if there was any added value in combining the two indices.

Methods: This was an analysis of a longitudinal study of SLE patients where data were collected on BILAG-2004, SLEDAI-2000 and therapy at every visit. The external responsiveness of the indices was assessed by determining the relationship between change in disease activity and change in therapy between two consecutive visits. The indices were compared by assessing the main effects of the indices using logistic regression. The recently developed new methods of analysing BILAG-2004 system scores, BILAG-2004 systems tally (BST) and simplified BST (sBST), were also assessed. Receiver operating characteristics (ROC) curves analyses were used to describe the performance of these indices individually or in various combinations of the two. Sensitivity, specificity, PPV, NPV and AUC were estimated.

Results: There were 1414 observations from 347 patients. Both indices maintained an independent relationship with change in therapy when com-

pared. Tables 1 and 2 summarises the performance of the two indices and various combinations of the two, as dichotomous variables.

Table 1. Sensitivity, specificity, PPV, NPV and AUC of deterioration in disease activity on increase in therapy

Deterioration in score	Sensitivity % (95% CI)	Specificity % (95% CI)	PPV % (95% CI)	NPV % (95% CI)	AUC
BILAG-2004 deterioration in score	53.9 (48.6, 59.1)	92.8 (90.7, 94.4)	68.7 (62.4, 74.3)	87.3 (85.0, 89.2)	0.73
SLEDAI-2000 Increase ≥ 1	47.4 (41.6, 53.2)	82.4 (80.0, 84.6)	44.2 (39.0, 49.5)	84.2 (81.6, 86.5)	0.65
SLEDAI-2000 Increase ≥ 3	28.7 (23.7, 34.2)	95.4 (94.0, 96.5)	64.8 (56.8, 72.0)	82.0 (79.5, 84.3)	0.62
BILAG-2004 deterioration in score or SLEDAI-2000 Increase ≥ 1	65.1 (59.4, 70.4)	79.2 (76.5, 81.7)	47.9 (43.2, 52.7)	88.5 (86.1, 90.6)	0.72
BILAG-2004 deterioration in score or SLEDAI-2000 Increase ≥ 3	58.3 (52.7, 63.6)	90.6 (88.4, 92.4)	64.5 (58.8, 69.8)	88.1 (85.8, 90.0)	0.74

Table 2. Sensitivity, specificity, PPV, NPV and AUC of improvement in disease activity on decrease in therapy

Improvement in score	Sensitivity % (95% CI)	Specificity % (95% CI)	PPV % (95% CI)	NPV % (95% CI)	AUC
BILAG-2004 improvements (with no deterioration)	54.1 (49.4, 58.7)	65.2 (62.2, 68.0)	48.0 (43.6, 52.4)	70.5 (66.7, 74.0)	0.60
BILAG-2004 improvement to C/D (with no deterioration)	52.8 (48.1, 57.3)	66.1 (63.1, 68.9)	48.0 (43.5, 52.5)	70.2 (66.4, 73.7)	0.59
SLEDAI-2000 Decrease ≥ 1	38.7 (34.7, 42.9)	77.0 (74.2, 79.6)	50.0 (45.1, 54.9)	67.9 (64.4, 71.2)	0.58
SLEDAI-2000 Decrease ≥ 4	18.8 (15.4, 22.7)	90.3 (88.2, 92.1)	53.5 (46.2, 60.6)	65.2 (62.0, 68.3)	0.55
SLEDAI-2000 Decrease ≥ 4 with no BILAG-2004 deterioration (similar to SRI)	1.5 (0.8, 2.9)	98.9 (97.9, 99.4)	44.4 (23.5, 67.6)	62.8 (59.8, 65.7)	0.50
BILAG-2004 improvements with no SLEDAI-2000 increase ≥ 1	48.2 (43.8, 52.6)	70.0 (67.2, 72.7)	48.8 (44.2, 53.5)	69.5 (65.9, 72.8)	0.59
BILAG-2004 improvements (and no deterioration) with no SLEDAI-2000 increase ≥ 1	48.2 (43.8, 52.6)	70.0 (67.2, 72.7)	48.8 (44.2, 53.5)	69.5 (65.9, 72.8)	0.59
BILAG-2004 improvements (and no deterioration) with no SLEDAI-2000 increase ≥ 3	52.9 (48.3, 57.5)	66.3 (63.3, 69.1)	48.3 (43.8, 52.8)	70.3 (66.6, 73.8)	0.60
BILAG-2004 improvement to C/D (and no deterioration) with no SLEDAI-2000 increase ≥ 1	47.1 (42.8, 51.4)	70.8 (68.0, 73.5)	48.9 (44.2, 53.6)	69.2 (65.7, 72.6)	0.59
BILAG-2004 improvement to C/D (and no deterioration) with no SLEDAI-2000 increase ≥ 3	51.6 (47.0, 56.2)	67.2 (64.2, 70.0)	48.3 (43.8, 52.9)	70.0 (66.3, 73.5)	0.59

Both indices had better performance when analysed as non-dichotomous variables (predominantly counts or continuous variables). The AUC from ROC analysis for increase in therapy are: BILAG-2004 system scores 0.75, BST 0.83, sBST 0.81, SLEDAI-2000 variables (change in score and previous visit score) 0.76, combination of BST and SLEDAI-2000 variables 0.84, and combination of sBST and SLEDAI-2000 variables 0.83. The AUC from ROC analysis for decrease in therapy are: BILAG-2004 system scores 0.65, BST 0.66, sBST 0.65, SLEDAI-2000 variables 0.63, combination of BST and SLEDAI-2000 variables 0.67, and combination of sBST and SLEDAI-2000 variables 0.67. There was minimal improvement in the performance when SLEDAI-2000 variables were combined with BST or sBST.

Conclusion: We recommend the use of counts or continuous variables, due to improved efficiency and performance over dichotomous variables, in clinical trials. BST and sBST appear to have better performance than SLEDAI-2000 in assessment of SLE disease activity longitudinally, especially for deterioration in disease activity. There is minimal benefit in combining the indices. These findings should be investigated further with trial data.

602

Post Hoc British Isles Lupus Assessment Group Index Mucocutaneous Organ Domain Item Analysis of Systemic Lupus Erythematosus Patients Treated in Phase 3 Belimumab Clinical Trials. Susan Manzi[1], Dafna Gladman[2], Sandra Navarra[3], Jorge Sanchez-Guerrero[4], David D'Cruz[5], William Freimuth[6], Z. John Zhong[6], Greg Keenan[6] and BLISS-52 and BLISS-76 Study Groups[7]. [1]Allegheny Singer Research Institute, Pittsburgh, PA, [2]Toronto Western Hospital, Toronto, ON, [3]University of Santo Tomas Hospital, Manila, Philippines, [4]University Health Network/Mount Sinai Hospital, Toronto, ON, [5]St. Thomas' Hospital, London, United Kingdom, [6]Human Genome Sciences, Inc., Rockville, MD, [7]Multicenter

Background/Purpose: To determine the belimumab treatment effect on the individual mucocutaneous organ system items of the Classic British Isles Lupus Assessment Group Index (BILAG) data from the BLISS studies.

Methods: The BILAG index is made up of 8 organ system domains. The focus of this analysis is on the mucocutaneous organ system, one of the most common organ systems involved in systemic lupus erythematosus (SLE). The data from BLISS-52 (NCT00424476) and BLISS-76 (NCT00410384) studies were pooled by treatment cohort (placebo, 1 mg/kg, and 10 mg/kg) to evaluate the effect of belimumab treatment in combination with standard therapy relative to standard therapy alone. The overall mucocutaneous organ system results showed more improvement for patients treated with belimumab and standard therapy compared to those treated with standard therapy alone, so to identify those items contributing to this effect each of the 18 items within the mucocutaneous organ system examination and symptom recording tool were analyzed. The post hoc analysis included only subjects who had an item scored as present at baseline and each item required a minimum of 20 subject observations per arm to be able to make any comparisons. The analysis evaluated each item for subjects scored not-present at week 52 among subjects with the same, worsening, or new/recurrent disease at baseline (dropout=failure). This analysis showed the number of subjects who had mucocutaneous organ system item involvement at baseline that were able to resolve these manifestations by week 52.

Results: The improvement in the overall mucocutaneous organ system domain results were 39.1%, 47.9%, and 47.6%, for placebo, belimumab 1 mg/kg, and belimumab 10 mg/kg respectively. The results from the 7 items that met the threshold criteria are shown in Table 1.

Table 1. Mucocutaneous Item Scored as Improvement (Not Present) at Week 52 Among Patients With Mucocutaneous Disease at Baseline (dropout = failure)

	Placebo	*Belimumab 1 mg/kg*	*Belimumab 10 mg/kg*
BILAG Mucocutaneous Organ System Domain	(39.1%)	(47.9%)	(47.6%)
P-value[1]		<0.05	<0.05
BILAG Mucocutaneous Item			
Maculopapular Eruption-mild	38/118 (32.2%)	76/143 (53.1%)	61/136 (44.9%)
P-value[1]		0.0006	0.0386
Active Discoid Lupus Localized	21/66 (31.8%)	24/55 (43.6%)	30/60 (50.0%)
P-value[1]		0.1805	0.0374
Alopecia - Severe, Active	12/31 (38.7%)	13/27 (48.1%)	21/33 (63.6%)
P-value[1]		0.4690	0.0450
Alopecia - Mild	94/252 (37.3%)	110/256 (43.0%)	119/251 (47.4%)
P-value[1]		0.1925	0.0217
Small Mucosal Ulceration	67/116 (57.8%)	59/92 (64.1%)	67/111 (60.4%)
P-value[1]		0.3496	0.6903
Malar Erythema	103/258 (39.9%)	90/231 (39.0%)	97/225 (43.1%)
P-value[1]		0.8281	0.4780
Periungual Erythema	19/51 (37.3%)	35/52 (67.3%)	18/38 (47.4%)
P-value[1]		0.0021	0.3386

[1]P-values are nominal and were obtained from the likelihood ratio test from the comparison between the placebo group and each of the belimumab groups.

Conclusion: This post hoc analysis provides directional perspective on the effect of belimumab treatment on some of the items in one of the most common organ systems involved in SLE. The favorable responses are consistent with the response in the overall mucocutaneous organ system. A larger study with more subjects with baseline involvement would be needed to more thoroughly elucidate more of the individual mucocutaneous items. Further analyses of the other BILAG organ domains are planned.

603

Vascular Cell Adhesion Molecule-1 and Neutrophil Gelatinase-Associated Lipocalin in Systemic Lupus Erythematosus. Adnan Kiani[1], Hong Fang[1], Tianfu Wu[2], Laurence S. Magder[3], Chandra Mohan[4] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Texas, Southwestern Medical Center at Dallas, Dallas, TX, [3]University of Maryland, Baltimore, MD, [4]University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: Vascular cell adhesion molecule-1 (VCAM-1), an adhesion molecule, is involved in the progression of glomerular and tubulointerstitial injury. Neutrophil gelatinase-associated lipocalin (NGAL), a member of the lipocalin superfamily, has been shown to rise in both acute and chronic kidney damage. Both VCAM-1 and NGAL have been found at high levels in the urine of patients with active lupus nephritis. We investigated both as potential biomarkers for lupus nephritis.

Methods: VCAM-1 and NGAL were measured during 1 to 8 clinic visits in 107 SLE patients (91% female, 51% African-American, 36% Caucasian, 4% Asian, 4% Hispanic and 5% others) for a total of 190 visits by ELISA (R&D). Mean age was 41 years. We analyzed the relationship between these potential urine biomarkers and the urine protein/creatinine atio (urine Pr/Cr), the SLICC Renal Activity Score, SLEDAI renal descriptors and other clinical variables.

Results: VCAM-1 levels were strongly associated with the physician's global estimate of disease activity (0.0002), the renal Visual Analog Scale (<0.0001), the urine protein/creatinine ratio (p<0.0001) and SLICC Renal Activity Score (p<0.0001). VCAM-1 levels were also associated with a urine pr/cr ≥0.5

(<0.0001). NGAL was not associated with any measure of disease activity, nor with lupus serologies (Table 1).

Table 1. Mean (SD) Log-transformed and Normalized (by urine creatinine) VCAM-1 and NGAL, by Clinical Variables at Each Visit

Clinical Variables at Each Visit	VCAM-1		NGAL	
	Mean (SD)	P-value*	Mean (SD)	P-value*

Diabetes mellitus	0.08 (0.08)	0.30	0.17 (0.22)	0.69
Present (n=20)	0.18 (0.34)		0.15 (0.31)	
Absent (n=170)				
Use of ACE/ARB inhibitor	0.14 (0.15)	0.0488	0.13 (0.16)	0.16
Yes (n=132)	0.24 (0.55)		0.20 (0.48)	
No (n=58)				
SLICC Renal Activity Score	0.26 (0.25)	<0.0001	0.14 (0.14)	0.17
>=4 (n=64)	0.09 (0.13)		0.12 (0.15)	
<4 (n=107)				

* P-values are based on a mixed effects model to account for the fact that some patients contributed multiple observations.

Conclusion: Urine VCAM-1 had a strong association with measures of disease activity, including multiple renal activity descriptors. Use of ACE inhibitors or ARB may reduce it. However, in contrast to previous SLE studies, NGAL failed to show any association with lupus nephritis. Further study of urinary VCAM-1 with long-term renal outcomes is justified.

604

Chinese Systemic Lupus Erythematosus Treatment and Research Group Registry: Prevalence and Risk Factors of Pulmonary Arterial Hypertension and Interstitial Lung Disease in Chinese Patients with Systemic Lupus Erythematosus. Qian Wang Jr.[1], Mengtao Li[1], Jiuliang Zhao[1], Xiaofeng Zeng[2] and Chinese SLE Treatment and Research Group (CSTAR)[3]. [1]Peking Union Medical College Hospital, Beijing, China, [2]Peking Union Medical College Hospital, Peking Union Medical College, Beijing, China, [3]Beijing, China

Background/Purpose: Pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) are associated with high morbidity and mortality in patients with systemic lupus erythematosus (SLE), while large population-based data are lacking. The Chinese SLE Treatment and Research Group (CSTAR) has developed a network registry for SLE patients. We aimed to investigate the prevalence and risk factors of PAH and ILD in a large cohort of Chinese SLE patients in CSTAR database.

Methods: Detailed records of registered SLE patients were investigated. Data related to PAH and ILD were extracted. Patients were assigned into PAH group when estimated systolic pulmonary artery pressure by echocardiography was over 36mmHg as well as valvular disease, cardiomyopathy and ILD were excluded. Patients were assigned into ILD group when specific features (grand-glass, bibasilar reticulonodular or symmetric fibrotic opacities) were demonstrated on high resolution computerized tomography without alternative etiology. Potential risk factors were assessed by multivariate logistic regression analysis.

Results: Among 1980 patients included for PAH evaluation, 77 (3.9%) met the diagnostic criteria of PAH. The incidences of lupus nephritis, pleuritis, pericarditis, hypocomplementemia, anti-SSA and anti-ribonucleoprotein (RNP) were significantly higher than those without PAH. SLE disease activity index (SLEDAI) was significantly higher in PAH group than controls. Pericarditis, pleuritis, and anti-RNP were independent risk factors for PAH. (Table 1.)

Table 1. Risk factors for SLE associated PAH

	PAH group (n=77)	Non-PAH group (n=1903)	*P*-value (univariate analysis)	Odds radio (95% CI)	*P*-value (multivariate analysis)
Lupus nephritis	42 (56.8%)	726 (39.1%)	0.002		
Pleuritis	27 (36.5%)	146 (7.9%)	<0.001	2.834 (1.459–5.505)	0.002
Pericarditis	30 (40.5%)	157 (8.4%)	<0.001	4.609 (2.432–8.735)	<0.001
Hypocomplementemia	61 (82.4%)	1222 (65.7%)	0.003		
Anti-RNP	12 (15.6%)	160(8.4%)	0.028	2.229 (1.080–4.563)	0.030
Anti-SSA	29 (37.7%)	440(23.1%)	0.003		
SLEDAI	12.78 ± 7.08	9.50 ± 7.12	<0.001		

PAH = pulmonary arterial hypertension; anti-RNP = anti-ribonucleoprotein; SLEDAI = Systemic Lupus Erythematosus Disease Activity Index; PGA = physician global assessment.

86 (4.2%) out of 2024 included patients were diagnosed by ILD. ILD group had higher incidences of initial renal and respiratory symptoms, higher incidences of oral ulcer, pleuritis and proteinuria and lower incidence of lupus-specific rash on registration and higher SLEDAI than controls with statistic significance. Oral ulcer, pleuritis, proteinuria were independent risk factors, while lupus-specific rash was protective factor for SLE associated ILD. (Table 2.)

Table 2. Risk factors for SLE associated ILD

	ILD group (n=86)	Non-ILD group (n=1938)	*P*-value (univariate analysis)	Odds radio (95% CI)	*P*-value (multivariate analysis)
Initial renal symptoms	32 (37.2%)	454 (25.8%)	0.024		
Inial respiratory symptoms	9 (10.5%)	78 (4.4%)	0.017		
Oral ulcer	29 (33.7%)	381 (21.6%)	0.011	2.007 (1.257–3.205)	0.004
Pleuritis	15 (17.4%)	116 (6.6%)	0.001	2.511 (1.356–4.651)	0.003
Protenuria	41 (47.7%)	591 (33.6%)	0.010	1.637 (1.041–2.574)	0.033
Lupus rash	21 (24.4%)	668 (38.0%)	0.012	0.529 (0.319–0.879)	0.014
SLEDAI	11.02 ± 6.99	9.32 ± 7.01	0.028		

ILD = interstitial lung disease; SLEDAI = Systemic Lupus Erythematosus Disease Activity Index.

Conclusion: The prevalence of PAH and ILD was low in Chinese SLE patients from CSTAR database. Higher disease activity, as demonstrated by serositis, proteinura and oral ulcer, may contribute to the development of PAH and ILD in SLE and thus prompt immunosuppressive therapy may be warranted.

605

The BILAG-2004 Systems Tally—a Novel Way of Analysing the BILAG-2004 Scores. Chee-Seng Yee[1], Caroline Gordon[1], David A. Isenberg[2], Bridget Griffiths[3], Lee- Suan Teh[4], Ian N. Bruce[5], Yasmeen Ahmad[6], Anisur Rahman[7], Athiveeraramapandian Prabu[1], Mohammed Akil[8], Neil J. McHugh[9], Christopher Edwards[10], DP. D'Cruz[11], Munther A. Khamashta[12] and Vernon Farewell[13]. [1]University of Birmingham, Birmingham, United Kingdom, [2]University College London, London WC1E 6JF, United Kingdom, [3]Freeman Hospital, Newcastle Upon Tyne, United Kingdom, [4]Royal Blackburn Hospital, Blackburn, United Kingdom, [5]A, Manchester, United Kingdom, [6]The Department of Rheumatology, Betsi Cadwaladr University Health Board (West), Llandudno, LL30 1LB, UK, Wales, United Kingdom, [7]University College London, London, United Kingdom, [8]Sheffield Center Rheumatic Dis, Sheffield South Yorkshire, United Kingdom, [9]Royal National Hospital, Bath, United Kingdom, [10]University of Southampton, Southampton, United Kingdom, [11]St. Thomas' Hospital, London, United Kingdom, [12]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [13]MRC Biostatistics Unit, Cambridge, United Kingdom

Background/Purpose: The BILAG-2004 index has 9 separate categorical system scores which pose a challenge to longitudinal analysis of

disease activity in clinical studies. We propose a novel method to record the number of systems in which activity increases, decreases or remains the same between two time points and express this as a tally (BILAG-2004 systems tally, BST). The aim of this exploratory analysis was to assess the appropriateness and performance of this novel method.

Methods: This was an analysis of a multi-centre longitudinal study of SLE patients where data were collected on the BILAG-2004 index and therapy at every visit. External responsiveness with multinomial logistic regression was used to examine the appropriateness of BST with change in therapy as the reference standard. It was anticipated that the tally of worsening or persistently active disease would be significantly associated with treatment increase and the tally of improving activity would be significantly associated with treatment reduction. Results were reported in coefficient and 95%CI. Receiver operating characteristics (ROC) curves analysis was used to assess the performance of this approach.

Results: There were 1414 observations from 347 patients. BST was a data driven simplification of the BILAG-2004 system scores and its derivation was suggested from external responsiveness analysis of the original 9 system scores. It had 6 components (Table) and showed the expected significant association with change in therapy. This was further simplified into 3 components (simplified BST, sBST), by combining persistent significant activity and deteriorations (major and minor) into one category (number of systems with active/worsening disease), and combining the improvements (major and minor) into another category (number of systems with improving disease). Similarly, sBST showed the expected significant association with change in therapy: active/worsening disease component with treatment increase (coefficient 2.08, 95%CI: 1.72–2.43) and improving disease component with treatment reduction (coefficient 0.43, 95%CI: 0.21–0.65). ROC curves analyses demonstrated that both versions had similar good performance characteristics in predicting increase in therapy with area under curve (AUC) for BST 0.83 and sBST 0.81, whereas the AUC for the original BILAG-2004 index systems score was 0.75.

Table. External responsiveness of the BILAG-2004 systems tally with multinomial logistic regression

BILAG-2004 systems tally	Number of Observations	Increase in Therapy Coefficient (95% CI)	Decrease in Therapy Coefficient (95% CI)
Number of systems with major deterioration (change of Grade B/C/D/E to A or Grade D/E to B)	170	2.82 (2.34, 3.30)	−0.22 (−0.79, 0.35)
Number of systems with minor deterioration (change of Grade C to B)	103	1.88 (1.22, 2.55)	
Number of systems with persistent significant activity (no change from Grade A or B)	79	1.64 (1.21, 2.06)	−0.02 (−0.63, 0.59)
Numbers of systems with minor improvement (change of Grade A to B or B to C)	188	−0.28 (−0.73, 0.17)	−0.38 (−0.79, 0.03)
Number of systems with major improvement (change of Grade A to C/D or Grade B to D)	173	0.18 (−0.26, 0.63)	0.33 (0.04, 0.62)
Number of systems with persistent minimal or no activity (change of Grade C/D/E to C/D/E)	1414	0	0

Conclusion: The novel BST and sBST provide an alternative method to analyse BILAG-2004 disease activity longitudinally. Both are clinically relevant and meaningful which may provide a more efficient way of analysing clinical trials results. With better efficiency, fewer patients will be required in trials without jeopardising the power of the study and this will reduce the cost of running such studies.

606

Seasonal Variation In the Activity of Systemic Lupus Erythematosus. Alí Duarte-García[1], Hong Fang[1], Chi Hung To[2], Laurence S. Magder[3] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Chelsea Heights, Hong Kong, Hong Kong, [3]University of Maryland, Baltimore, MD

Background/Purpose: To determine if there is any seasonal influence on the activity of systemic lupus erythematosus (SLE) overall and by individual organs.

Methods: The study group comprised 2,102 patients with SLE who were recruited to participate in a prospective longitudinal cohort study. In this cohort, 92.3% of the patients were women, the mean + SD age of the patients was 47.9 + 13.9 years, 56.3% were Caucasian, 37.1% were African-American and 3.1% were Asian. Global disease activity was recorded by the SELENA SLEDAI and the Visual Analog Scales for each organ system on a 0 to 3 scale. Mean disease activity scores were computed for each month of the year, and a p-value assessing the hypothesis of no monthly differences was calculated. For those with evidence of significant monthly differences we identified the months with highest levels of disease activity.

Results: Photosensitive rash was more frequent in spring and summer months ($P<0.0001$). There was significantly more activity of arthritis in spring and summer by both SELENA SLEDAI ($P=0.0057$) and joints Visual Analog Scale ($P=0.0045$). A decrease in renal activity was found in the summer months, compared to the rest of the year ($P=0.0397$). Serositis captured by the Visual Analog Scale had higher activity in August to October ($P=0.0019$). Anti-dsDNA levels were significantly higher during October and November ($P<0.0001$). There was significant variation of anticardiolipin levels and lupus anticoagulant ($P<0.0001$ and $P=0.0003$ respectively). We found a significant variation in activity through the year captured by SELENA SLEDAI ($P=0.0484$).

Table. Seasonal variation in activity of SLE

	P-value for monthly differences in disease activity	Months with highest levels of activity
Photosensitive rash		
SELENA SLEDAI	<.0001	April to September
Visual Analog Scale	0.0015	April to September
Arthritis		
SELENA SLEDAI	0.0057	May to October
Visual Analog Scale	0.0045	May to October
Central nervous system		
SELENA SLEDAI	0.0638	August to November
Serositis		
Visual Analog Scale	0.0340	August to October
Raynaud's	<.0001	November to May
Renal activity	0.0397	November to May
Anti-dsDNA	<.0001	September to November
Low complement	<.0001	March to June
Lupus anticoagulant	0.0003	October, November

Conclusion: In this cohort, joint activity is also increased during the spring and summer, lagging behind skin by one month. However, renal activity is opposite, being lower in the summer months. Anti-dsDNA and renal activity appear to peak in the fall-winter (in concert with a similar peak in infections). These seasonal variations likely reflect environmental factors that influence disease activity, including ultraviolet light and infections.

Predictors of Corticosteroid Tapering in Systemic Lupus Erythematosus Patients. Zaki Abou Zahr[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Organ damage in SLE patients is highly associated with the use of corticosteroids. Doses of prednisone below 6 mg daily are associated with reduced organ damage. We now report on the largest prospective cohort study of predictors of prednisone tapering in SLE patients who are on just 5 mg daily.

Methods: 866 SLE patients (91% female, 50% Caucasian, 43% African-American, mean age 43 years) who consented for a cohort study from 1987 through 2009 were included. The analysis was based on patient visits when the previously prescribed dose of prednisone was 5 mg/day. We then examined the proportion of times the patient's dose was reduced to below 5 mg/day ("tapering"). Among those patients who tapered and were followed for at least one year thereafter, we examined the proportion whose prednisone dose remained below 5mg/day for at least one year ("Successful Tapering"). Rates of tapering and successful tapering were calculated for patient subsets based on demographic and clinical characteristics.

Results: The analyses showed that Caucasians, younger patients, patients with a higher level of education, lower disease activity, or absence of urine protein were more likely to have a taper. However, successful tapering was not dependent on age, ethnicity, or education. As expected, successful tapering was more frequent in those with lower disease activity. Successful tapering was achieved more often after the year 2000.

Table 1. Proportion of Visits that Resulted in Prednisone Tapering, by Patient Characteristics.

Variable	Group	Proportion (%) Tapering	P-value
Sex	Male	56/683 (8%)	.33
	Female	765/6934 (11%)

	5–1	155/320 (48%)	
	>1	26/61 (43%)	
SELENA SLEDAI	0	159/262 (61%)	0.0121
	1–2	105/190 (55%)	
	3+	112/233 (48%)	
C3	Low	92/182 (51%)	0.2
	Normal	280/494 (57%)	
C4	Low	70/140 (50%)	0.25
	Normal	302/534 (57%)	
Anti-dsDNA	Absent	267/467 (57%)	0.07
	Present	104/219 (50%)	
Urine Protein	Absent	304/549 (55%)	0.501
	Present	64/121 (53%)	

[1] Based on a model that treats the predictors as continuous variables.

Conclusion: Our study suggest that successful tapering of prednisone below 5 mg has increased since the year 2000, which may reflect the greater knowledge of the long term harm of chronic corticosteroid use. Caucasians, younger age, higher level of education, and absence of proteinuria predicted tapering, but not successful tapering. Lower disease activity was the only major clinical variable that significantly predicted successful tapering to a dose of less than 5 mg.

608

Results of a French Multicenter Randomized Prospective Study (the PLUS Study) on Reduction of Systemic Lupus Erythematosus Flares Through Adaptation of the Dosage of Hydroxychloroquine to Its Whole-Blood Concentration. Nathalie Costedoat-Chalumeau[1], L. Galicier[1], O. Aumaitre[1], C. Francès[1], Véronique Le Guern[2], F. Lioté[1], A. Smail[1], N. Limal[1], L. Perard[1], H. Desmurs-Clavel[1], B. Asli[1], C. Grandpeix[1], Olivier Pourrat[3], F. Ackermann[1], T. Papo[1], B. Brihaye[1], O. Fain[1], J. Stirnemann[1], Moez Jallouli[1], J. Cohen[1], Marie-Laure Tanguy[1], Js Hulot[1], L. Musset[1], Zahir Amoura[1] and the investigators of the PLUS study[1]. [1]CHU Pitié-Salpêtrière, Paris, France, [2]Cochin Hospital, Paris, France, [3]CHU poitiers, Poitiers, France

Background/Purpose: Blood Hydroxychloroquine concentration [HCQ] varies widely among patients. We have previously demonstrated that low blood HCQ concentration [HCQ] is a marker for and a predictor of systemic lupus erythematosus (SLE) flares [Costedoat-Chalumeau, Arthritis Rheum, 2006]. These findings led us to perform a prospective study to determine the potential benefits of individualizing HCQ dosing schedules aimed at maintaining the [HCQ] · 1000 ng/ml.

Methods: SLE patients treated with HCQ for at least 6 months, with stable disease and a SELENA-SLEDAI ≤12, and without neither known retinopathy nor suspected non adherence, were included in this randomized, double-blind, placebo-controlled, multicenter (n=37) trial and had a centralised [HCQ] dosage. Patients with [HCQ] ranging between 100 and 750 ng/ml were eligible for randomisation between no daily dosage change (group 1) and increased HCQ dosage to obtain a [HCQ] · 1000 ng/ml (group 2). All randomised patients received 4 tablets/day (including HCQ and placebo), and were followed-up at 1, 3, 5, and 7 months.

Results: 573 subjects were included. At day 0, the median SLEDAI was 2.02 ± 2.4. The median [HCQ] was 857 [0–3316] ng/ml. There was an inverse correlation between [HCQ] and disease activity measured by SELENA-SLEDAI (p=0.023).

10 patients were excluded for major non-adherence ([HCQ]<100 ng/ml), 354 had early study discontinuation ([HCQ]>750 ng/ml), and 209 were eligible for randomisation (100< [HCQ] <750 ng/ml). 33 patients were not randomised due to patient refusal (n=11), contra-indications (ophthalmological n=8, and renal insufficiency n=1), SLE flares between inclusion and randomization (n=4), non-adherence recognition (n=4), pregnancy (n=2) or other causes (n=3). 5 dropped out just after randomization. Then, 171 patients were analyzed.

Median [HCQ] significantly increased between inclusion and randomisation (548 [102–749] to 613 [35–2005]; P<0,001), meaning before any therapeutic action. Median [HCQ] were similar between group 1 (n = 84) and group 2 (n = 87) at randomization (623 [193–1610] versus 591 [35–2005]; p = 0.2), and were significantly higher in group 2 at M1 (1250 [9–3253] vs 733 [185–1700]; p<0.001), M3 (1362 [44–4005] vs 661 [239–1797]; p <0.001), M5 (1428 [33–3282] vs 718 [194–2013]; p <0.001) and M7 (1271 [13–3311] vs 665 [80–1578]; p <0.001).

The number of SLE flares was similar in both groups (26.2% vs 27.6%; p = 0.83). Many patients in group 1 had [HCQ] in the therapeutic range and conversely, XXX patients in group 2 had low [HCQ]. When we mixed both groups, the comparison of patients with [HCQ] < 1000 and those with [HCQ] · 1000 during the 7 months of follow-up showed a rate of SLE flares of 18/53 (34%) and 8/36 (22%) respectively (p=0.23).

Conclusion: We confirm that low [HCQ] is associated with higher SLE activity. We failed to demonstrate that the adaptation of HCQ dosage reduces SLE flares in patients with low [HCQ]. However, the knowledge of low [HCQ] and the inclusion in the study improved treatment

adherence, allowing many patients to reach higher [HCQ]. Patients with higher [HCQ] during the study had a trend toward a reduction of SLE flares although not statistically significant.

ClinicalTrials.gov: NCT00413361

Background/Purpose: Only one biologic agent has been approved for use in SLE, but some are used off-label in various settings. In order to obtain information systematically regarding this, members of the SLICC group initiated the International Registry for Biologics in SLE (IRBIS). The objective of this study was to analyse the use of biologics in SLE, and assess results achieved with the most commonly used off-label biologic, rituximab (RTX).

Methods: IRBIS investigators were asked to provide retrospective data on all patients treated with a biologic for SLE at their center. Standardized case report forms were used to collect demographic, disease-specific and treatment data at the time of biologic initiation and at yearly follow-up. Data from the first 23 reporting centers are presented.

Results: 359 patients were treated off-label with RTX, and additional groups of patients were exposed to belimumab (n=44, trial-extension), epratuzumab (n=21, trial-extension), abatacept (n=4), etanercept (n=3) and adalimumab (n=1). For the RTX treated group, age (mean±SD) was 41.3±13.3 and 91% were female. The majority (76 %) were Caucasian, and smaller proportions were Southeast Asian, Asian/Indian, African-American, Latino, Afro-Caribbean or other (each <10%). Disease duration when RTX was initiated was 9.2±7.8 years. SLEDAI at start was 11.3±7.6, SLICC-damage index 1.4±1.5 and glucocorticoid dosage 17.0±15.2 mg. At baseline, concomitant glucocorticoids were used in 91% of the patients compared to 75% at follow-up. Previous treatments (n=300) include cyclophosphamide (n=144), mycophenolate mofetil (n=117), azathioprine (n=114), methotrexate (n=56) and other immunosuppressives (ISs, n=76). Most patients (78%) had been treated with one or two different ISs prior to RTX, 20% had been treated with three ISs and the remaining 2% with four or five ISs. Two different dosing regimens for RTX were used: 375 mg/m2 × 4 (52%) and 1000 mg × 2 (48%). Concomitant cyclophosphamide was used in 39% of patients. The major organ manifestations leading to RTX treatment were lupus nephritis (LN, 48%), hematological (21%), musculoskeletal (9%), skin disease (9%), CNS (4%) and other (9%). Disease-control (n=84%) and disease-control plus steroid-sparing (16%) were given as reasons for choosing a biologic. At 1-year follow-up (n=123, 1 year ±3.5 months) both SLEDAI and GC dose had decreased to 4.2±3.5 (n=106) and 7.9±7.0 mg (n=89), respectively (paired samples, p<0.0001 for both comparisons). Exclusion of patients started on additional immunosuppressives (n=24) did not change SLEDAI or GC dose significantly. SLEDAI at baseline was higher in LN than in non-LN patients but similar at follow-up. Overall, 1000 mg × 2 was used more often but both dosing regimens appeared equally effective in LN.

Conclusion: Rituximab was the off-label biologic used most commonly in this multi-center international lupus cohort and was used for LN as well as for a range of other SLE manifestations. At one-year follow-up both lupus activity and concomitant glucocorticoid dosage had decreased even when no other immunosuppressive treatments had been introduced. The two RTX dosing regimes appeared equally effective for LN treatment.

Differences in Autoantibody Profiles, Disease Activity (SLEDAI) and Damage (SDI) Scores Between Childhood-Onset Lupus and Adult-Onset Lupus: A Meta-Analysis. Brieanna Livingston[1], Ashley Bonner[2] and Janet E. Pope[3]. [1]University of Western Ontario, London, ON, [2]McMaster University, Hamilton, ON, [3]St. Joseph Health Care London, London, ON

Background/Purpose: In systemic lupus erythematosus (SLE), autoantibodies and other lab tests are used for diagnosis, correlate with clinical manifestations, and provide important prognostic information. Age at disease onset impacts the autoantibody profile, lab test results, disease activity and damage in SLE. Two commonly used indices, SLEDAI and SDI, measure disease activity and damage respectively. Our objectives were to conduct a systemic literature review and meta-analysis of all studies that directly compared childhood-onset SLE (cSLE) to adult-onset SLE (aSLE) to: (1) determine which autoantibodies and lab tests vary with age at disease onset, and (2) quantify the differences in SLEDAI and SDI scores between cSLE and aSLE.

Methods: A literature search of the MEDLINE/PubMed, EMBASE, CINAHL, and SCOPUS databases until January 2011 was conducted to identify relevant articles. Study quality was assessed using the STROBE checklist. Two independent reviewers determined eligibility criteria. Study sample characteristics, autoantibody profiles, lab test results and SLEDAI and SDI scores were extracted from each study. Pooled odds ratios and mean differences were calculated assuming random effects, and between-study heterogeneity was estimated using the I^2 statistic.

Results: Of the 484 studies identified, 19 were eligible. The total number of SLE patients was 7519. Mean trial quality was 18/32, ranging from 8 to 29. Several statistically significant differences were found: anti-dsDNA antibody (OR 1.97; P=0.001) and IgG/IgM antiocardiolipin antibody (OR 1.66; P=0.002) were more common in cSLE. Rheumatoid factor was less frequent in cSLE (OR 0.53; P=0.01). Children had higher disease activity {SLEDAI} (OR 4.73; P=0.0004), but damage {SDI} was not different between cSLE and aSLE (OR 0.50; 95% CI −0.13 to 1.14).

Conclusion: The results of this meta-analysis suggest that cSLE may have different autoantibody profiles, laboratory tests, and more disease activity than aSLE.

Why Do Lupus Patients Go to the Emergency Department in the United States? Marina Scolnik[1], Ajitha Mannalithara[2], Enrique R. Soriano[1] and Gurkirpal Singh[2]. [1]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Stanford University School of Medicine, Palo Alto, CA

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are often seen in the Emergency Department (ED) and hospitalized for complications of their disease. While there are several studies on reasons for hospitalization in SLE patients, there is little information on epidemiology, causes or economics of ED visits in these patients.

Methods: The US Nationwide Emergency Department Sample (NEDS) is a stratified random sample of all ED visits in community hospitals in the US. It contains almost 28 million records annually for ED visits from over 980 hospitals that can be weighted to produce reliable national estimates of the 125 million annual ED visits. We recognized SLE ED visits using International Classification of Diseases (ICD-9) code 710.0. CDC's Clinical classification software (CCS) diagnoses of consultation and hospitalization were identified. Comorbidities were analized through ICD-9 codes. SLE ED visits were compared with ED visits from other causes in the general population.

Results: A total of 81,378 ED visits in SLE patients were identified in 2008. 91.2% of lupus ED visits were in women, with a mean age 40.2 years (Table 1). SLE patients had more hypertension and chronic renal failure (23.2% vs 15.7% and 9.1 % vs 2.1%) and smoked more (11.1% vs 8.8%). They were hospitalized significantly more often than general ED population (34.2% vs 16.8%) and males were hospitalized more often than females with lupus (42.99% vs 33.83%, $p<0.0001$). However, mortality at ED or after hospitalization was lower than the general population (0.25% vs 0.61%). Main CCS diagnoses at ED visit are shown in table 2, stratified by age and gender. 25.1% of SLE patients (n= 20391) went to ED because of the disease itself and this was also the principal cause of hospitalization (36.6% of hospitalizations). Non specific chest pain, headache, infections (pneumonia, skin or urinary) and musculoskeletal complains followed as other diagnoses. Cardiovascular events were only seen in older lupus patients. Sickle cell anemia appeared in association with lupus in male children. Costs per ED visit were higher for SLE patients (1864.9 vs 1674.8 US dollars) (table 1).

Table 1. Patients' characteristics

	Lupus patients	Non lupus patients

Achieving Consensus on Quality Indicators for Pediatric Systemic Lupus Erythematosus. Joshua D. Pendl[1], Matthew C. Hollander[2], Shannen L. Nelson[1], Xolti Morgan[3], Nicolino Ruperto[4], Michael W. Beresford[5], Marisa Klein-Gitelman[6], Marilynn G. Punaro[7], Anne M. Stevens[2], Tadej Avcin[8], Graciela Espada[9], Tsz-Leung Lee[10], Yu-Lung Lau[10], Jennifer L. Huggins[1], Esi Morgan Dewitt[1] and Hermine Brunner[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Seattle Children's Hospital, Seattle, WA, [3]University of Cincinnati, Cincinnati, OH, [4]PRINTO-IRCCS, Genova, Italy, [5]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [6]Children's Memorial Hospital, Chicago, IL, [7]Texas Scottish Rite Hospital, Dallas, TX, [8]University Children's Hospital Ljubljana, Ljubljana, Slovenia, [9]Childrens Hosp Ricardo Gutierrez, Buenos Aires, Argentina, [10]The University of Hong Kong, Hong Kong, Hong Kong

Background/Purpose: Quality Indicators (QI) are retrospectively measurable elements of practice performance for which there is evidence or consensus that can be used to assess the quality of care provided. Consensus-derived QI for pediatric systemic lupus erythematosus (pSLE) could serve as international benchmarks to assess the quality of patient care. By regularly monitoring adherence to QI in a clinical setting, targeted interventions may be implemented to improve the quality of medical care that patients with pSLE receive.

Methods: Based on the medical literature, a Delphi survey was created and distributed to the physician membership of PRES, PANLAR, CARRA and the ACR via e-mail. Consensus was considered 80% agreement or higher.

Results: There was consensus (97%) among the 297 respondents that simply applying QI developed by the ACR and EULAR for adults with SLE was insufficient and that distinct QI for pSLE were needed. Respondents concurred that 5 of the 20 ACR and 5 of the 23 EULAR adult QI are also suitable for pSLE in their current form (Table 1). An additional 14 ACR and 17 EULAR adult QI might be useful for pSLE after modifications. Consensus (>80% agreement) or near consensus (>70% agreement) was reached among respondents that all categories of adult QI are still useful for children with the exceptions of "Pregnancy" and "Reproductive Health," which achieved lower levels of agreement (Table 2).

Table 1. Consensus on ACR and EULAR adult SLE Quality Indicators that are useful to pSLE in their current form

Quality Indicator	ACR/EULAR
IF a patient has a flare after having achieved remission of kidney disease, THEN diligent follow-up of renal disease is needed.	EULAR
IF a patient with pSLE is on immunosuppressive therapy, THEN an inactivated influenza vaccination should be administered annually, unless contraindicated.	ACR
IF a patient with pSLE is pregnant, THEN anti-SSA, anti-SSB, and anti-phospholipid antibodies should be documented in the medical record.	ACR
IF a patient is prescribed a new medication for pSLE (e.g., NSAIDs, DMARDs, or glucocorticoids), THEN a discussion with the patient about the risks versus benefits of the chosen therapy should be documented.	ACR
IF a patient has pSLE, THEN lifestyle modifications (smoking cessation, weight control, exercise) are likely to be beneficial for patient outcomes and should be encouraged.	EULAR
IF a patient with pSLE has proliferative lupus nephritis, THEN glucocorticoids in combination with immunosuppressive agents (cyclophosphamide, mycophenolate mofetil) should be used for treatment.	EULAR
IF a patient has newly diagnosed lupus nephritis, THEN renal biopsy, urine sediment analysis, proteinuria, and kidney function should all be assessed.	EULAR
IF a patient has pSLE, THEN education about sun avoidance should be documented at least once in the medical record (e.g., wearing protective clothing, applying sunscreens whenever outdoors, and avoiding sunbathing).	ACR
IF a patient is diagnosed with proliferative pSLE nephritis (WHO or ISN/RPS class III or IV), THEN therapy with corticosteroids combined with another immunosuppressant agent should be provided and documented within 1 month of this diagnosis, unless contraindicated.	ACR
IF a patient with pSLE has major neuropsychiatric manifestations (optic neuritis, acute confusional state/coma, cranial or peripheral neuropathy, psychosis, and transverse myelitis/myelopathy), THEN immunosuppressive therapy should be considered.	EULAR

Table 2. Percentage of expert respondents (n=297) who agreed that the following categories of QI for adults with SLE were still applicable to children with pSLE

Quality Indicator Domain	% Agreement
Renal Disease/Lupus Nephritis	88%
Growth and Development	88%
Quality of Life Including School Function	88%
Drug Monitoring	87%
Diagnosis	86%
Control of Overall Disease Activity	85%
Neuropsychiatric Lupus	82%
Anti-Phospholipid Antibodies	81%
General Preventative Strategies	77%
Avoidance of Overall Disease Damage	76%
Contraception/Reproductive Counseling	76%
Osteoporosis	73%
Cardiovascular Disease	72%
Reproductive Health	65%
Pregnancy	41%

Conclusion: There is great demand among pediatric rheumatologists to develop QI for pSLE. Initial agreement has been reached about the types and domains of QI for pSLE, but additional discussion and consensus formation under consideration of the medical evidence is needed to finalize a set of QI for pSLE. This distinct set of QI could be used to define and improve standard of care treatment for children and adolescents with pSLE.

613

Effect of Hydroxychloroquine and Statin Therapy on Pro-Inflammatory Cytokines and Disease Activity in a Lupus Cohort. Rohan Willis[1], Praveen Jajoria[1], Brock E. Harper[1], Emilio B. Gonzalez[1], M. Petri[2], Ehtisham Akhter[2], Hong Fang[2] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Multiple cytokines play a role in the immune dysregulation seen in SLE and the local inflammatory responses that ultimately lead to tissue injury. IL6, TNFα, sCD40L, IFNα and IFN inducible cytokines such as MCP1 and IP10 are correlated with disease activity as measured by the SLEDAI, SLAM-R, ESR and anti-dsDNA antibody titres. Elevated VEGF and IL1β levels have been demonstrated in patients (pts) with antiphospholipid syndrome.

Both hydroxychloroquine (HCQ) and statins have proven clinical efficacy in treating SLE patients. There is however limited data highlighting the effect HCQ and statins have on biomarkers of disease activity in SLE. As such we sought to determine the proinflammatory biomarkers elevated in these pts and the effect that HCQ or statin therapy has on their levels and on disease activity.

Methods: Pts were selected from a longitudinal cohort and were included if placed on HCQ or statin therapy during follow-up and had stored serum or plasma samples taken before and after commencement of therapy at least 6 months apart. Serum samples from age and sex matched controls with no evidence of inflammatory disease were used for comparison. Concurrent use of prednisone greater than 10mg/day or change in use or dose of other immunosuppressive agents precluded inclusion. Samples from 30 controls and 61 paired samples from SLE pts were analyzed. IFNα2, IL1β, IL6, IL8, IP10, MCP1, TNFα, VEGF and sCD40L levels were determined by the MILLIPLEXMAP human cytokine/chemokine panel assay (Millipore, Billerica, MA). This assay utilizes flow cytometry, microspheres, lasers, digital signal processing and traditional chemistry in a multiplex format. Disease activity was assessed using SLEDAI scores.

Results: VEGF, IP10, sCD40L, IFNα2 and TNFα were significantly elevated (p= <0.0001 – 0.0478) in SLE pts compared to controls while MCP1 and IL8 were significantly lower. No difference was seen with IL6 and IL1β. Both statin and HCQ therapy resulted in decreased SLEDAI scores although these were not statistically significant (p= 0.07 and 0.30 respectively). Elevated VEGF, IP10, sCD40L, IFNα2 or TNFα at baseline were reduced by 16.3 – 41.0% as a result of statin therapy and by 15.4 – 44.9% as a result of HCQ therapy. When considering all subjects in the SLE cohort, the changes in biomarkers were not statistically significant.

Conclusion: This study shows that proinflammatory cytokines in SLE patients are significantly elevated when compared to controls. Although the treatment with HCQ or with statins produced a decrease in the levels of cytokines in the subjects where those markers were elevated at baseline, no differences were seen in SLEDAI scores after the treatment with HCQ or statins, possibly due to the limited sample size (due to a strict inclusion/exclusion criteria) and/or the relatively low disease activity scores of the subjects in this lupus cohort.

Cytokines	Ctrls/ Median	SLE/ Median	p-value	# elevated baseline samples HCQ therapy(%)	% reduction in elevated samples after HCQ/mean	# elevated baseline samples statin therapy(%)	% reduction in elevated samples after statin/mean

Increased Disease Activity Measure in Systemic Lupus Erythematosus Is Adversely Associated with Pregnancy and Pregnancy Outcomes. Lisa A. Davis[1], Vincent M. Davis[1], Laura Trupin[2], Jinoos Yazdany[3], Edward Yelin[4] and Joann Zell[5]. [1]Univ of Colorado School of Med, Aurora, CO, [2]UC San Francisco, San Francisco, CA, [3]University of California San Francisco, San Francisco, CA, [4]UCSF, San Francisco, CA, [5]National Jewish Health, Denver, CO

Background/Purpose: Systemic lupus erythematosus (SLE) is a disease that primarily affects women of childbearing age. Issues surrounding pregnancy are therefore of vital importance in caring for these patients. We studied women with a diagnosis of SLE in a prospective manner to examine factors associated with pregnancy and risk factors for poor pregnancy outcomes.

Methods: The Lupus Outcomes Study (LOS) is a large, yearly telephone questionnaire administered to a community-based sample of patients who meet the American College of Rheumatology criteria for SLE. We used data from 2003 through 2009 to identify pregnancies among women <50 years of age who did not report a hysterectomy, resulting in 2065 person-years of observation among 595 women. Each observation was treated as an independent observation in the analyses. We examined the following primary outcome variables: individual instances of pregnancies, live births, and miscarriages/stillbirths. Predictor variables from the year that the pregnancies occurred were used and included: demographics [age, poverty, smoking]; disease activity/severity measures [Systemic Lupus Activity Questionnaire (SLAQ) score, anti-phospholipid antibodies (aPL), and the presence of renal disease]; and use of medications [hydroxychloroquine (HCQ), etc.]. Logistic regression was used to examine factors associated with pregnancy (N=526 observations). Among those who reported a pregnancy, we used logistic regression to investigate factors associated with live births (N=51) and with miscarriage/stillbirth (N=50).

Results: We prospectively captured 55 individual pregnancies, which resulted in 8 induced abortions, 3 tubal pregnancies, 33 live births and 11 miscarriage/ stillbirths. Pregnancy was inversely associated with age, SLAQ score, and use of HCQ, and pregnancy was associated with being married (see Table). Only SLAQ score was inversely associated with incident live births. SLAQ score was also associated with miscarriage/stillbirth.

Table. Predictors of pregnancy, live births, and miscarriage/stillbirth in the LOS cohort

	Predictors of pregnancy amongst reproductive-aged women, N=526				Predictors of live births amongst women with incident pregnancies, N=51				Predictors of miscarriage/stillbirth amongst women with incident pregnancies, N=50			
Variable	OR	95% CI		p-value	OR	95% CI		p-value	OR	95% CI		p-value
Age	0.85	0.80	0.90	**0.00**	0.98	0.88	1.08	0.64	0.95	0.82	1.11	0.53
Married	3.00	1.59	5.67	**0.00**								
Positive aPL lab	1.51	0.76	3.00	0.24								
History of renal disease	0.56	0.20	1.56	0.27								
Smoking status	1.77	0.49	6.48	0.39								
SLAQ score	0.94	0.88	0.99	**0.03**	0.93	0.86	1.01	**0.08**	1.18	1.03	1.35	**0.02**
Below poverty line	1.02	0.35	2.98	0.97								
Use of HCQ in the last year	0.47	0.23	0.95	**0.04**								

*Key: aPL = anti-phospholipid antibody laboratory, at least one lab value positive; SLAQ = Systemic Lupus Activity Questionnaire measure; HCQ = hydroxychloroquine

Conclusion: Live birth rates among individual instances of pregnancy observed in the LOS (70.2%) were similar to other studies (71–92%). The inverse association of SLAQ scores with pregnancy and pregnancy outcomes may be due to a biological etiology, or it may reflect that those who have active disease avoid pregnancy and/or choose to end pregnancies. Surprisingly, we found that the use of hydroxychloroquine was inversely associated with the total number of individual pregnancies. The reasons for this association are unclear, but one hypothesis that requires exploration is that this finding represents the practice of rheumatologists and/or patients avoiding HCQ when conception is planned.

Urinary λ Free Light Chain Concentration Is Associated with Disease Activity and Response to Treatment in Proliferative Lupus Nephritis. Masanori Hanaoka, Takahisa Gono, Yasushi Kawaguchi, Hirotaka Kaneko, Yumi Koseki, Yasuhiro Katsumata, Kae Takagi, Hisae Ichida, Sayumi Baba, Yuko Okamoto, Yuko Ota, Sayuri Kataoka and Hisashi Yamanaka. Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: The aim of the present study was to evaluate whether serum or urinary free light chain (FLC) is a useful biomarker for proliferative lupus nephritis (PLN) in patients with systemic lupus erythematosus (SLE).

Methods: Forty-three patients in whom renal biopsy was performed at our institute from 2004 to 2006 were consecutively enrolled in the present study. All patients were diagnosed with SLE based on the classification criteria of the American College of Rheumatology and suffered from some active SLE-associated symptoms. The evaluation of clinical parameters included renal markers (24 h-creatinine clearance [CCr] and quantification of proteinuria), immunological markers (IgG, complement component 3 and anti-dsDNA antibody), SLE disease activity index (SLEDAI) (with and without renal score), and serum and urinary FLC. Enrolled patients were divided into the following two subsets: a PLN group (WHO class III and IV) and non-PLN group (WHO class I, II and V). Clinical characteristics were compared between the two subsets. In addition, serum and urinary FLC were measured before and after immunosuppressive treatment in a separate group of 8 patients who were prospectively enrolled from 2009 to 2010 in the present study.

Results: The frequencies of WHO class I, class II, class III, class IV and class V lupus nephritis were 9 (21%), 7 (16%), 8 (19%), 10 (23%) and 9 (21%), respectively, in 43 retrospectively enrolled patients. Hypoalbuminemia ($P = 0.0077$), hypocomplementemia ($P = 0.0083$), elevation of anti-dsDNA antibody ($P < 0.0001$), SLEDAI ($P = 0.0013$) and SLEDAI without renal score ($P = 0.0013$) were significantly higher in the PLN group compared to the non-PLN group. Both serum and urinary FLC were not significantly correlated with SLEDAI in either subset, although significant correlation was found between anti-dsDNA antibody titer and SLEDAI. Urinary λ-FLC concentrations were significantly ($P = 0.008$) higher in the PLN group than the non-PLN group, although serum κ-FLC and λ-FLC, serum IgG and urinary κ-FLC concentrations did not differ significantly between the two subsets. Although complement, anti-dsDNA antibody and CCr were not associated with the quantification of proteinuria in both the subsets, urinary λ-FLC was significantly correlated ($R^2 = 0.35$. $P = 0.0096$) with the quantification of proteinuria in the PLN group. In contrast, there was no significant association between the quantification of proteinuria and urinary λ-FLC in the non-PLN group. To evaluate the association between the response to immunosuppressive treatment and serum or urinary FLC concentrations, a separate group of 8 patients (1 patient with WHO class II, 6 patients with WHO class III and 1 patient with WHO class V) were prospectively enrolled in the present study. The decline index in urinary λ-FLC was more significant after treatment, compared with those in anti-dsDNA antibody ($P = 0.0156$) and serum λ-FLC ($P = 0.0039$). Moreover, urinary λ-FLC was not detected after treatment in any patient.

Conclusion: Urinary λ-FLC, but not serum FLC, not only is associated with disease activity but is also useful for the evaluation of response to treatment for PLN.

616

Lymphoproliferative Disorders in Patients with Systemic Lupus Erythematosus At the University of Michigan. Jason S. Knight and Emily C. Somers. University of Michigan, Ann Arbor, MI

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at higher risk of lymphoproliferative disorders (LD), in particular non-Hodgkin's lymphoma, than the general population. Most reports focus on LD diagnosed *after* SLE, and exclude concurrent and preceding LD. We performed this study to better characterize the timing, histopathology, and therapy of LD in patients with SLE.

Methods: We identified 13,296 cases of LD in the University of Michigan (UM) tumor registry (diagnosed 1980–2008) and 10,539 potential SLE patients from the UM billing/lab databases (data available 1988-present) with either an ICD-9-CM code for SLE or anti-double-stranded DNA (dsDNA) autoantibodies. Forty-five patients were confirmed to have *both* LD by histopathology and SLE by ACR (≥4) criteria.

Results: Of the 45 patients diagnosed with both LD and SLE, 38 (84%) were female and 38 (84%) white; 7 (16%) had co-existing Sjogren's syndrome and 2 (4%) end-stage renal disease (with kidney transplant) secondary to SLE. Autoantibodies were positive as follows: anti-dsDNA in 24/41 (59%), anti-Smith 2/35 (6%), and anti-phospholipid 21/40 (53%). Of these 45 patients, 29 (64%) were diagnosed with LD ≥1 year *after* diagnosis with SLE and 16 (36%) LD *before (or concurrent with)* SLE. Of the 29 patients with LD after SLE, 27 (93%) had hematologic manifestations of SLE and 7 (24%) lupus nephritis; prior to diagnosis with LD, 15 (52%) were treated with any immunosuppression and 8 (28%) cyclophosphamide specifically. Among these 29 patients, malignant diagnoses were as follows: 13 (45%) with diffuse large B-cell lymphoma (DLBCL), 6 (21%) indolent lymphoma, 4 (14%) leukemia or a related disorder, 3 (10%) Hodgkin's disease, and 1 (3%) each Burkitt's lymphoma, T-cell lymphoma, and multiple myeloma. Of the 13 patients with DLBCL, 10 (77%) presented with stage IV disease and 11 (85%) extranodal disease. Eleven DLBCL patients were treated with CHOP or R-CHOP; 6 (55%) died (all within 14 months), 1 (9%) had active disease at last follow-up (11 months), and 4 (36%) achieved durable remission. Of the 16 patients diagnosed with LD *before* (or *concurrent with)* SLE, 9 (56%) were diagnosed with LD >2 years before SLE; these patients tended to have early-stage LD and were in remission prior to SLE diagnosis. Seven patients (44%) were diagnosed with LD and SLE concurrently; no particular type of LD predominated. All 7 patients had serology consistent with SLE, and 6 (86%) were treated with hydroxychloroquine; only 1 (14%) required immunosuppression (methotrexate) targeted at SLE. In terms of their LD, 6/7 (86%) achieved remission or stable disease.

Conclusion: Almost two-thirds of patients were diagnosed with LD ≥1 year *after* diagnosis with SLE; DLBCL was the most common type of LD in this group, and the DLBCL patients usually presented with advanced-stage disease. One-third of patients were diagnosed with LD *before (or concurrent with)* SLE; these patients tended to have early-stage LD and an excellent response to therapy. In the patients diagnosed concurrently, the SLE symptoms may have brought their LD to clinical attention early, possibly resulting in better outcomes.

617

Disease Activity and Quality of Life in Refractory Cutaneous Lupus Erythematosus Patients Initiated on Immunosuppressive Therapy. Aileen Y. Chang[1], Elizabeth Ghazi[2], Joyce Okawa[1] and Victoria P. Werth[1]. [1]Perelman School of Medicine at the University of Pennsylvania and Philadelphia V.A. Medical Center, Philadelphia, PA, [2]UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ

Background/Purpose: Immunosuppressives are used as systemic therapy for antimalarial-refractory cutaneous lupus erythematosus (CLE), despite limited evidence for their use. This study aimed to demonstrate response to immunosuppressives in a cohort of CLE patients using a disease-specific activity measure and a skin-specific quality of life measure.

Methods: This longitudinal cohort study prospectively evaluated response to antimetabolite immunosuppressives in CLE patients using a validated disease outcome measure, the CLE Disease Area and Severity Index (CLASI), and a validated skin-specific quality of life measure, the Skindex-29. Patients eligible for the study were those who presented from January 2007 to July 2010 at a university's cutaneous autoimmune disease clinic, met criteria for having CLE, and had at least 2 visits with CLASI activity scores measured. Of these eligible patients, those initiated on an antimetabolite (methotrexate, mycophenolate, or azathioprine) with pre- and post-treatment (Tx) CLASI scores were identified. Patients who had previously failed an antimetabolite or non-antimalarial systemic therapy were excluded. Response was defined as either a 4-point or 20% decrease in CLASI score and was determined by comparing the score at the pre-Tx visit with the first post-Tx visit. Skindex-29 subscale scores (Emotions, Functioning, Symptoms) were also assessed.

Results: 128 eligible patients were identified. Of 5 patients initiated on methotrexate, 4 (80%) demonstrated response at their first post-Tx visit with a decrease in median (interquartile range [IQR]) CLASI activity score from 24 (14–33) to 12 (5–17) ($p=0.07$), over a median (IQR) Tx duration of 3.7 (2.1–3.9) months. Of 4 patients initiated on mycophenolate, 2 (50%) demonstrated response at their first post-Tx visit with a decrease in median (IQR) CLASI score from 4.5 (2.0–7.0) to 1.0 (0.0–2.0) ($p=0.18$), over a median (IQR) Tx duration of 4.0 (2.7–4.5) months. Of 4 patients initiated on azathioprine, 0 demonstrated response at their first post-Tx visit, over a median (IQR) Tx duration of 3.4 (2.6–5.6) months. For 6 responders out of 13 patients initiated on an antimetabolite, the mean (95% confidence interval [CI]) Emotions score decreased from 64.2 (32.5, 95.8) to 39.1 (18.5, 59.8) ($p=0.04$), Functioning score decreased from 53.0 (26.8, 79.2) to 28.1 (10.6, 45.6) ($p=0.07$), and Symptoms score decreased from 55.4 (31.1, 79.6) to 36.3 (20.3, 52.3) ($p=0.07$). For the 7 non-responders, the mean (95% CI) Emotions, Functioning, and Symptoms score were unchanged: 65.4 (41.1, 89.3) to 64.6 (43.5, 85.8) ($p=0.89$); 39.0 (19.7, 58.2) to 41.1 (19.7, 62.4) ($p=0.69$); 57.7 (42.0, 73.3) to 56.1 (27.6, 84,6) ($p=0.81$), respectively. Differences in pre-Tx CLASI score, age, sex, smoking status, and Tx duration between responders and non-responders were not statistically significant.

Conclusion: Half of CLE patients with antimalarial-refractory disease responded to the addition of an antimetabolite. Response in disease activity was accompanied by an improvement in skin-specific quality of life measures. Larger studies of systemic therapies that focus on both disease and quality of life outcomes in CLE are needed.

Higher Education Level is Associated with Decreased Compliance in an Urban Multi-Ethnic Lupus Cohort. Rachel L. Gross, Dawn M. Wahezi, Chaim Putterman and Irene Blanco. Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: Systemic Lupus Erythematosus (SLE) disproportionably affects non-whites. Worse disease outcomes in minorities may not be adequately explained by genetic or environmental factors, and compliance with treatment may account for such disparities. Our aim was to determine rates and predictors of medication compliance in our cohort of SLE patients.

Methods: Patients were recruited from the Einstein Lupus Cohort, a multi-ethnic cohort followed at the university hospitals of Albert Einstein College of Medicine. Medication compliance was assessed using a validated 19-item questionnaire, the Compliance Questionnaire Rheumatology (CQR). Patients with medication compliance of ≥80% as predicted by the weighted questionnaire responses were categorized as compliant. Participants also completed self-reported measures of compliance and the Beliefs about Medicine Questionnaire (BMQ) to determine factors influencing compliance. Demographic and clinical characteristics of compliant and non-compliant participants underwent bivariate analysis using the Chi square test for categorical variables and the Mann-Whitney U test for continuous variables. Variables of interest from the bivariate analysis and those with a p-value< 0.20 were further evaluated using a multivariate logistic regression model.

Results: 89 patients (42 Hispanic, 43 Blacks, 4 other races; 92% female) who met 4/11 ACR criteria for SLE were included in the analysis with a median age of 37y (IQR 25–48) and disease duration of 8y (IQR 3–15). 48% (43/89) of patients (52% (22/42) Hispanics, 44% (19/43) Blacks) were compliant with medications as measured by the CQR. Several factors were associated with non-compliance on bivariate analysis. Non-compliant patients had more concerns regarding their medications as measured by a higher mean BMQ-concerns score (14.5± 4.1 v. 12.3± 3.8; $p=0.02$). Other factors that trended towards predicting decreased compliance include: education level above high school (OR=0.43, $p=0.06$), yearly income < $15,000 (OR=0.48, $p=0.13$), and the use of mycophenylate mofetil (OR=0.31, $p=0.12$). Age, race, gender, disease duration, SLEDAI score, self-reported compliance, insurance status, total number of medications and steroid dose were not associated with compliance.

In our multivariate analysis, patients with more than a high school education were 78% less likely to be compliant (OR=0.22, $p=0.01$). Patients with higher BMQ concerns score also trended towards being less compliant (OR=0.86, $p=0.058$). In addition, non-English speakers (OR 12.4, $p=0.04$) and those with an annual income > $15,000 (OR=3.5, $p = 0.045$) were more likely to be compliant.

Conclusion: Non-compliance with medication was common in this urban minority lupus cohort, and is associated with higher education levels, low income, primary language, and increased medication concerns. This surprising finding of lower compliance among more educated SLE patients may be due to more independent decision making, or less trust of physicians in this population. These factors suggest areas of intervention that may improve compliance.

Distribution of Urine Protein/Creatinine Ratio by Urinalysis Protein Dipstick Score In Systemic Lupus Erythematosus. Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Lupus nephritis occurs in over 50% of patients with systemic lupus erythematosus (SLE). As a traditional rapid screening test, the urinalysis protein by dipstick is limited in that it does not quantify proteinuria. In this study, we investigated the distribution of urine protein/creatinine ratios with a simultaneous urine dipstick score in SLE patients.

Methods: 1277 SLE patients (92% female, 55% Caucasian, 36% African-American, 8% other ethnicities, mean age at entry 41.6 years) were included. Univariate analysis was used to determine the distribution of urine protein/creatinine ratio by urine dipstick score. The urine dipstick protein scores were 0 (n=6980), trace (n=2381), 1+ (n=1887), 2+ (n=808), 3+ (n=437), and 4+ (n=36).

Results:

Table 1. Distribution of Urine Protein/Creatinine Ratio by Urinalysis Protein Dipstick

	Urine Pr/Cr Ratio				
Urine Dipstick Score	5% Quantile	25% Quantile	50% Quantile (Median)	75% Quantile	95% Quantile
0	0	0	0.06	0.10	0.21
trace	0	0.06	0.09	0.14	0.34
1	0	0.05	0.15	0.34	0.90
2	0.09	0.45	0.89	1.59	3.43
3	0.50	1.28	2.44	4.17	10.14
4	0.17	1.34	2.10	4.00	8.18

Table 2. Proportion of Urine Protein/Creatinine greater than 0.5 by Urinalysis Protein Dipstick

Urine Dipstick Score	Proportion (%) with Urine Pr/Cr Ratio ≥ 0.5
0	0.7%
Trace	2.4%
1	15.5%
2	71.9%
3	95.2%
4	94.4%

Conclusion: This study demonstrated the wide distribution of urine protein/creatinine ratio for any urine dipstick of 1+ or greater. Given the current standard that 0.500 grams of urine protein would trigger a renal biopsy for lupus nephritis, the data show that a urinalysis dipstick of 1+ could include that range. Thus, any urinalysis dipstick protein of 1+ or higher should lead to quantification with a spot urine protein/creatinine ratio or to a 24 hour urine protein/creatinine ratio.

620

Avoidance of Major Bleeding Complications Post Renal Biopsy In Lupus Nephritis Patients with Co-Existing Antiphospholipid Syndrome. Natasha Jordan, Ahlem I. Chaib, Shirish Sangle, Fahim Tungekar, Munther Khamastha, Tarun Sabharwal, Ian Abbs and David P. D'Cruz. Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom

Background/Purpose: Renal biopsy remains the gold standard investigation of lupus nephritis. However it is not without potentially significant complications. In a previous retrospective review of 148 renal biopsies in 137 lupus nephritis patients at our centre over an 8 year period (1999–2007), 8.1% experienced minor bleeding and 7.4% developed major haemorrhagic complications. Major bleeding complications were significantly more common in those with coexisting Antiphospholipid syndrome and/or antiphospholipid antibodies (aPL).

Modification of our renal biopsy protocol was undertaken implementing strict management of anticoagulation, hypertensive control and biopsy tract plugging with gelofoam. The purpose of this study was to examine the current rate of bleeding complications post renal biopsy.

Methods: A prospective review of post biopsy bleeding complications following 48 renal biopsies (2007–2010) was undertaken. All biopsies were performed on native kidneys by an experienced radiologist. Prior to biopsy, coagulation parameters were checked and anaemia and thrombocytopenia were corrected. Following biopsy, patients were maintained under observation for 24 hours, monitoring for hypotension, tachycardia, gross haematuria, and abdominal pain. Anticoagulation was strictly monitored with switching from warfarin to heparin one week prior to the procedure until two weeks post biopsy. Renal biopsy was only performed when patients were normotensive (<140/90).

Major complications were defined as those requiring post procedural intervention such as blood transfusion, surgical revision of hematoma, embolisation, nephrectomy or death. Minor complications including subcapsular hematomas, perinephric hematomas or hematuria requiring close observation only.

Results: 47 lupus nephritis patients underwent renal biopsy (48 biopsies) since implementation of the new renal biopsy protocol. Minor bleeding occurred in 6 patients (12.5%) with 3 events in SLE patients, 3 in SLE/aPL and none in SLE/APS. There were no major bleeding complications.

Table 1. Patient demographics pre and post modification of renal biopsy protocol.

	Renal biopsies 1999–March 2007	Renal biopsies April 2007–present
	148 biopsies (137 patients)	48 biopsies (47 patients)
Gender	119 females 18 males	40 females 8 males
Mean age	35.31 years	35.04 years
SLE	49 (33.1%)	25 (52.1%)
SLE/APS	35 (23.7%)	8 (16.7%)
SLE/APL	64 (43.2%)	15 (31.2%)
Hypertension	67 (45.3%)	15 (31.25%)
Mean serum creatinine (mg/dl):		
Bleeding group	188.91	130.33
Non-bleeding group	117.79	93.92
Warfarin therapy	35 (23.6%)	6 (12.5%)
Aspirin therapy	33 (22.3%)	17 (35.4%)

Table 2. Rate of bleeding complications pre and post modification of renal biopsy protocol.

	Bleeding complications prior to protocol modification			
	No bleeding complication	Overall Bleeding Rate	% Minor Bleed	% Major Bleed
SLE	46	3 (6.1%)	2 (4.1%)	1 (2.0%)
SLE/APL	53	11 (17.2%)	6 (9.4%)	5 (7.8%)
SLE/APS	26	9 (25.7%)	4 (11.4%)	5 (14.3%)
Total	125	23 (15.5%)	12 (8.1%)	11 (7.4%)

	Bleeding complications post protocol modification			
	No bleeding complication	Overall Bleeding Rate	% Minor Bleed	% Major Bleed
SLE	22	3 (12%)	3 (12%)	0%
SLE/APL	12	3 (20%)	3 (20%)	0%
SLE/APS	8	0%	0%	0%
Total	42	6 (12.5%)	6 (12.5%)	0%

Conclusion: A significant finding in this study is the higher rate of serious bleeding events in SLE/aPL patients and SLE/APS compared to the SLE patient group post renal biopsy. Identification of these at risk patients prior to renal biopsy and close clinical monitoring minimizing procedure associated morbidity and mortality.

621

Serum Macrophage Migration Inhibitory Factor In Systemic Lupus Erythematosus with Long-Term Remission and Its Relationship to Chronic Glucocorticoid Exposure. Yoko Wada[1], Hiroe Sato[1], Daisuke Kobayashi[1], Takeshi Nakatsue[1], Shuichi Murakami[1], Takeshi Kuroda[1], Masaaki Nakano[2] and Ichiei Narita[1]. [1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]Niigata University School of Medicine, Niigata, Japan

Background/Purpose: Macrophage migration inhibitory factor (MIF) is a unique pro-inflammatory cytokine that can be induced by glucocorticoid, and acts as a physiological counter-regulator of the anti-inflammatory effects of glucocorticoid. It is thought to be involved in the development and progression of atherosclerosis, and also plays a potent role in the onset of autoimmune disorders including rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Although a positive correlation between the serum level of MIF and disease activity has already been reported in patients with SLE, the role of this inflammatory cytokine in SLE patients who achieve long-term remission remains unknown in terms of chronic glucocorticoid exposure and the association of chronic complications such as dyslipidemia and accelerated atherosclerosis. We examined the contribution of MIF in SLE patients with long-term remission, especially in terms of inflammatory status, serum lipid profile, atherosclerosis, and chronic glucocorticoid exposure.

Methods: Sixty-five patients who had achieved long-term remission of SLE were recruited. All of them fulfilled the American College of Rheumatology criteria for the classification of SLE, their daily dosage of prednisolone had been fixed at less than 15 mg for more than 12 months, and there had been no signs of SLE flare-up for more than 3 years. Written informed consent was obtained from each participant. Serum levels of MIF, acute inflammatory reactants including highly sensitive C-reactive protein (HS-CRP) and serum amyloid-A protein (SAA), serum lipid profiles, common carotid artery intima-media thickness (CCA-IMT), and cumulative and current dosage of prednisolone were examined in each subject, and analyzed using Pearson's correlation coefficient and stepwise multiple regression. Sex- and age-matched normal subjects (n=20) and patients just diagnosed as having SLE before glucocorticoid administration (n=20) were also recruited as controls.

Results: The level of serum MIF was 9.86 ± 8.44 ng/ml (mean ± SD) in the SLE patients with long-term remission, being significantly higher than that in normal subjects (4.07 ± 1.87 ng/ml, p=0.0025), and lower than that in SLE patients with active disease (16.7 ± 16.6ng/ml, p=0.02). In the SLE patients with long-term remission, the serum MIF level was correlated with serum triglyceride (correlation coefficient = 0.267, p=0.03) and the cumulative dosage of prednisolone (correlation coefficient = −0.268, p=0.03), but had no association with CCA-IMT, other serum lipids, or acute inflammatory reactants. Stepwise multiple regression analysis also selected serum triglyceride as a positive independent variable (rho = 0.295) and the cumulative dosage of prednisolone as a negative independent variable (rho = −0.281).

Conclusion: The serum MIF level does not reflect acute inflammatory status or current atherosclerosis, but is affected by the level of serum triglyceride and the cumulative, but not current, dosage of prednisolone in SLE patients with long-term remission.

622

Association of Lupus Nephritis Class with Poor Longterm Outcomes. Michelle Petri and Hong Fang. Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Lupus nephritis is a common manifestation of SLE. We investigated the association between renal biopsies by the International Society of Nephrology (ISN) class in SLE and poor renal outcome, defined not just by renal failure, but also by nephrotic syndrome and thrombosis.

Methods: 503 SLE patients (39.4% Caucasian, 49.5% African-American, 89.5% female, mean age of diagnosis 28.8 ± 12.0) with biopsy-proven lupus nephritis (LN) were selected as the study population in a longitudinal cohort study. The renal biopsies were classified according to the International Society of Nephrology/Renal Pathology Society (ISN/RPS) as class I (minimal mesangial lupus nephritis), class II (mesangial proliferative lupus nephritis), class III (focal lupus nephritis), class IV (diffuse lupus nephritis), class V (membranous lupus nephritis) and class VI (advanced sclerosing lupus nephritis).

Results:

Table. Association of outcome with renal biopsy

Class of renal biopsy	All	Caucasian	African-American	% Nephrotic Syndrome	% Renal failure	% Any thrombosis
II	44 (8.8%)	17 (38.6%)	27 (61.4%)	20 (45.5%)	9 (20.5%)	14 (31.8%)
III	80 (15.9%)	35 (43.8%)	35 (43.8%)	32 (40.5%)	10 (12.5%)	19 (23.8%)
IV	166 (33.0%)	69 (41.6%)	68 (41.0%)	99 (60.4%)	58 (34.9%)	53 (31.9%)
V	97 (19.3%)	35 (36.1%)	57 (58.8%)	56 (58.3%)	8 (8.3%)	31 (32.0%)
II,III	8 (2.0%)	3 (37.5%)	4 (50.0%)	5 (62.5%)	2 (25.0%)	5 (62.5%)
II,III,V	4 (0.8%)	2 (50.0%)	2 (50.0%)	4 (100%)	1 (25.0%)	1 (25.0%)
II,IV	10 (2.0%)	5 (50.0%)	5 (50.0%)	4 (40.0%)	2 (20.0%)	4 (40.0%)
II,IV,V	4 (0.8%)	1 (25.0%)	2 (50.0%)	4 (100%)	0 (0%)	1 (25.0%)
II,V	12 (2.4%)	7 (58.3%)	5 (41.7%)	9 (75.0%)	2 (16.7%)	6 (50.0%)
III,V	42 (8.4%)	13 (31.0%)	23 (54.8%)	24 (58.5%)	6 (14.3%)	11 (26.2%)
IV,V	36 (7.2%)	11 (30.6%)	21 (58.3%)	25 (73.5%)	17 (47.2%)	13 (36.1%)

503 patients were classified into 11 different groups based on the findings of the first biopsy. African-Americans were more likely to have Class V (P=0.044).

Conclusion: In lupus nephritis, the most common class was class IV. Class IV either as the sole class or as a mixed class had the greatest risk of renal failure. However, nephrotic syndrome and thrombosis were common regardless of ISN class. Reliance on renal failure as the only outcome would miss these other important longterm consequences of lupus nephritis.

623

Ultrasound Assessment of Erosive hand arthritis In Systemic Lupus Erythematosus. Elisabeth M.A Ball[1], Madeleine Rooney[2] and Aubrey Bell[3]. [1]Musgrave Park Hospital/Queens' University, Belfast, United Kingdom, [2]Arthritis Research Group, Queen's University, Belfast, United Kingdom, [3]Musgrave Park Hospital/Queens' University, Belfast, Ireland

Background/Purpose: Joint involvement in Systemic Lupus Erythematosus is common and affects up to 90% of patients at some stage in their disease and has a significant impact on quality of life. Despite this lupus arthritis remains largely understudied in comparison to the abundance of research that exists surrounding rheumatoid arthritis. The traditional idea that lupus patients develop a non-erosive arthropathy with reducible deformities is being challenged by newer imaging techniques which have the potential to provide a framework for a well-defined classification system.

Methods: 31 patients who fulfilled the ACR criteria for the diagnosis of SLE and who complained of painful hands for > 1 year were recruited and included in the study. 12 patients with rheumatoid arthritis were also recruited as a comparator group. Baseline immunological tests were performed; lupus disease activity was measured and clinical examination was carried out to assess joint deformities. All patients underwent ultrasonography by the same sonographer and the presence of synovitis, erosions, tenosynovitis and Doppler signal were noted and scored according to a recognised scoring system[1].

Results:

	SLE patients (n = 31)	RA patients (n = 12)
Clinical deformity	12 (38%)	8 (67%)
Wrist synovitis	15 (48%)	10 (83%)
Erosive disease (wrist or 2nd/3rd MCP joint)	9 (29%)	10 (83%)
Tenosynovitis (Extensor Carpi Ulnaris or 2nd/3rd finger flexor tendon)	9 (29%)	5 (41%)
Anti-CCP antibody	1 (3.2%)	11 (91%)
Rheumatoid factor	3 (9.6%)	12 (100%)
Anti- ds DNA antibody	18 (58%)	0 (0%)
CRP > 20mg/l	5 (16%)	2 (16%)

Conclusion: Arthritis with radiological erosion similar to the pattern in rheumatoid arthritis is thought to be less common in SLE and has been estimated to be < 5% of patients. Our small study has shown that ultrasound may reveal a higher percentage of erosions than previously thought. The role of the anti-CCP antibody in SLE arthritis remains controversial. Some studies have identified a link with erosive disease as in rheumatoid arthritis however our results are in keeping with other studies to date which have identified no link [2].

While data is accumulating gradually our current understanding of lupus arthritis remains incomplete and a well-defined classification system does not yet exist. It is clear that developments in imaging including MRI and ultrasound are reshaping our understanding of the processes of erosion and joint pathology in the spectrum of rheumatic diseases as a whole. Future continued application of these developments to SLE arthritis will continue to provide answers to several important questions.

Human CD8 regulatory T cells generated *Ex-Vivo* have Potent Protective Activity *In Vivo*. Qin Lan, Stephanie Pan, Dixon Gray, Julie Wang, Song G. Zheng and David A. Horwitz. USC Keck School of Medicine, Los Angeles, CA

Background/Purpose: In addition to CD4+ cells, CD8+ cells can also be induced to become regulatory/suppressor cells ex-vivo. Here we asked whether various CD8+ induced Treg subsets have potent protective activity *in vivo* in humanized mice.

Methods: Human blood CD8+ cells were stimulated with anti-CD3/28 coated beads and IL-2± TGF-β alone or with all-trans retinoic acid (atRA), rapamycin (rapa) or both for 3 to 9 days. Their phenotype and functional activity were assessed. *In vivo* Treg activity was assessed by protection of NOD SCID cγ chain $^{-/-}$ (NOG) mice from the xeno-GVHD induced by human PBMC (p values by log rank test).

Results: CD8+ cells activated with IL-2 only rapidly expressed CD25, GITR, CTLA-4, TNFR-2, PDL-1, Granzyme A, and 30±2% (mean ±SEM) expressed Foxp3. The addition of TGF-β significantly increased Foxp3 (48±2%), CD122, PD-1 and CD103, but decreased Granzyme A. The addition of atRA did not enhance TGF-β effects, but did enhance downregulation of CD127. Approximately 40% of control activated CD8+cells secreted IL-2 and this decreased only slightly with CD8+ cells activated with TGF-β ± atRA. TGF-β decreased IFN-γ production and adding atRA resulted en even less IFN-γ. All previously activated CD8 subsets tested proliferated poorly after restimulation, and had significant suppressive activity in vitro in ratios of 1 Treg per 10 responder cells. In assays without APC, suppression CD8 cells activated with TGF-β was greater than CD8 cells stimulated with IL-2 only. Studies with 7-ADD and annexin V indicated that none of the activated CD8 subsets killed CD4 responder cells or monocytes. Separation of the CD8 cell subsets into TNF-R2 and PDL-1 bright and dim cells revealed that suppressive activity was concentrated in the former. The *in vivo* studies revealed that all activated CD8+ cells added to human PBMC in a ratio of 1:4 significantly enhanced survival of NOG mice. Remarkably, unlike CD4+Foxp3+ Tregs we studied previously

which can double or triple survival, the CD8regs could increase survival five fold.

Conclusion: Similar to findings with CD4+ cells, polyclonal activation of CD8+ cells with IL-2 and TGF-β enhances Foxp3 expression. However, CD4+ cells require other agents for them to rapidly acquire protective suppressive activity. By contrast, CD8+ cells activated with IL-2 only that strongly expressed TNFR2 and PDL-1 had significant suppressive activity both *in vitro* and *in vivo*. Although TGF-β addition resulted in enhanced suppressive activity *in vitro*, to date TGF-β with or without atRA or rapa has not resulted in significant enhancement of protective activity *in vivo*. Consistent with recent reports of *in vivo* suppressive effects of CD8+ cells in mouse and human SLE, our studies suggest that CD8 regs induced ex-vivo deserve consideration in future clinical trials with Tregs in SLE.

625

Higher Frequency and Worse Outcome of Lupus Nephritis in Korean Male. Jiwon Hwang[1], Jaejoon Lee[1], Joong Kyong Ahn[2], Chan Hong Jeon[3], Hoon-Suk Cha[1] and Eun-Mi Koh[1]. [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Soonchunhyang University College of Medicine, Bucheon, South Korea

Background/Purpose: Female preponderance is a well-known characteristic of systemic lupus erythematosus (SLE), and gender may influence the clinical features and outcome of SLE patients. In this study, we investigated the clinical characteristics and outcome in Korean male SLE patients compared to female patients.

Methods: We performed a retrospective analysis using medical records at a single tertiary hospital between August 1994 and May 2010. Each male patient was matched with 3 female SLE patients for age and disease duration. Clinical and serologic features at the disease onset and during the course of disease were compared between the groups. SLE severity was assessed using the Severity of Disease Index (SDI). The assessment of organ damage was made using the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SLICC/ACR DI).

Results: Among total of 632 patients with SLE, 57 males were identified. The ratio of female to male was 11.6:1. The mean time to SLE diagnosis was 23.2 $\pm$ 43.3 months for males and 8.9 $\pm$ 10.5 months for females ($p = 0.001$). The mean age at diagnosis was 32.7 $\pm$ 12.1 years-old and the mean duration of follow-up was 55.3 $\pm$ 51.1 months for both groups. The 5- and 10- year survival rates of male lupus were 90% and 90% compared to 95.9% and 94.2% of female lupus ($p = 0.11$). Male lupus patients had less discoid rash ($p = 0.005$), alopecia ($p = 0.010$), leucopenia ($p < 0.001$) and anti-Ro ($p < 0.001$) at the onset of disease but renal disorder was more prevalent in male lupus ($p < 0.001$). The adjusted odds ratio (OR) demonstrated a significant gender difference for discoid rash (OR 0.34, 95% confidence interval (CI) 0.14 – 0.81) and renal disorder (OR 3.26, 95% CI 1.62 – 6.57). In male lupus, high-dose of corticosteroid and immunosuppressive agents for disease control were used more frequently compared to female (62.7% vs. 32.7, $p < 0.001$ and 74.5% vs. 46.7%, $p = 0.001$). Male lupus patients had a higher percentage of diffuse proliferative lupus nephritis ($p = 0.025$) and end-stage renal disease (ESRD) which required dialysis ($p < 0.001$) during the course and the risk for dialysis were significantly elevated (OR 4.02, 95% CI 1.07 – 15.06). There was no difference in the neuropsychiatric and cardiovascular damage between male and female lupus ($p = 0.62$ and $p = 0.52$). In male lupus, the mean SDI and SLICC/ACR DI were significantly higher (4.44 $\pm$ 2.69 vs. 3.45 $\pm$ 2.03, $p = 0.011$ and 1.55 $\pm$ 1.35 vs. 1.02 $\pm$ 1.57, $p = 0.028$).

Conclusion: Our data shows a significant gender effect in the clinical features and outcome of Korean male SLE. Delayed diagnosis was observed in male SLE patients and higher frequency of renal disorder including diffuse proliferative lupus nephritis and dialysis-required ESRD was demonstrated. Male SLE was more severe and more organ damage was present in male SLE.

626

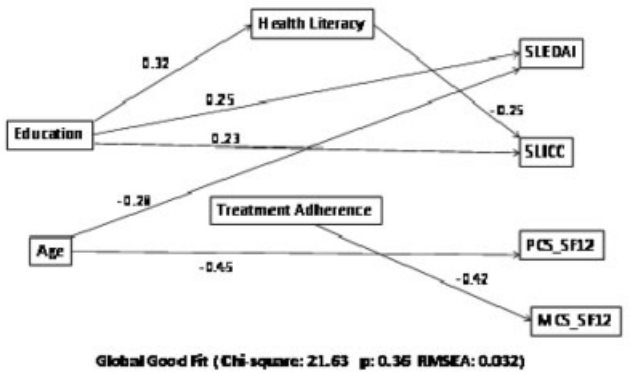
Impact of Health Literacy on Treatment Adherence and Clinical Outcomes in Patients with Systemic Lupus Erythematosus. Maria F. Marengo[1], Michael A. Kallen[1], Sofia De Achaval[2], Vanessa Cox[1], Araceli Garcia[3], Marsha Richardson[4] and Maria E. Suarez-Almazor[5]. [1]UT MD Anderson Cancer Center, Houston, TX, [2]U.T. MD Anderson Cancer Center, Houston, TX, [3]UT MD Anderson, Houston, [4]UT MD Anderson, Houston, TX, [5]University of Texas. M.D Anderson Cancer Center, Houston, TX

Background/Purpose: Limited Health Literacy (HL) has been associated with poorer health outcomes and higher cost; however, little is known about the effects of low health literacy among patients with rheumatic diseases.The objective of our study was to measure the level of HL among patients with Systemic Lupus Erythematosus (SLE) and evaluate its impact on treatment adherence and clinical outcomes.

Methods: This study was part of a 2– year prospective cohort study of 110 patients with SLE from 2 publicly-funded county hospitals; 85 SLE patients completed the HL assessment. HL was measured using the numeracy score (0–50) related to health care issues from the Test of Functional Health Literacy in Adults (TOFHLA) and the reading comprehension score (0–50) from TOFHLA-Short. A total score (0–100) was obtained (total TOFHLA), with 0 being the worst HL. Patients were categorized as having low or adequate HL using the traditional cutoff ($\geq$60). Patient information was collected at baseline, 12, and 24 months, including disease activity (SLEDAI), organ damage (SLICC), physical (PCS-SF12) and mental component scales (MCS-SF12) of quality of life and treatment adherence (AAGTG). 85% of patients completed the 2-years' follow-up. A conceptual casual model was developed, with demographic variables predicting HL and adherence, all of which predicted disease activity, organ chronic damage, and quality of life. Path analysis was conducted to test the model. Statistical analyses were carried out using STATA 11.1 and LISREL 8.8.

Results: 90% of patients were female, 38.2% Hispanic, and 55.4% African-American; mean age was 36.3y ($\pm$12), disease duration 5.8y ($\pm$5.1), SLEDAI 2.7 ($\pm$2.7), SLICC 1.1 ($\pm$1.3), PCS-SF12 36 ($\pm$9.9), MCS-SF12 42 ($\pm$9.7) and AACTG 0.67 ($\pm$ 0.48). Mean total TOFHLA was 85.2 ($\pm$14.5); mean numeracy was 40.4($\pm$7.6) and mean reading comprehension 44.4 ($\pm$9.1). Of 85 patients, 12 (14.1%) had low HL; these patients were more frequently Spanish-only speakers ($p=0.02$), with lower education ($p<0.01$) and higher SLEDAI ($p=<0.01$). In the path analysis (Graph1), age was found to have a significant negative direct effect on SLEDAI and PCS-SF12. Education had significant positive direct effects on HL, SLEDAI, and SLICC. HL had only a negative direct effect on SLICC and no effect on treatment adherence, SLEDAI, or SF-12. Treatment adherence had a negative direct effect on MCS-SF12. Overall, the path analytic model displayed good fit to the data (chi-square= 21.6, $p=0.36$, RMSEA= 0.032). No differences were obtained when this model was applied in subpopulations differing by gender or ethnicity.

Graph 1:Model in SLE patients



Conclusion: Low HL level was relatively frequent among SLE patients. In our population, higher education is associated with higher HL, which is related to lower chronic organ damage; however, this education effect is not mediated via disease activity or treatment adherence.

627

Risk Factors to Predict the Development of Chronic Kidney Disease In Patients with Lupus Nephritis. Dong-Jin Park[1], Sung-Ji Lee[1], Tae-Jong Kim[2], Yong-Wook Park[2] and Shin-Seok Lee[1]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Chonnam National University Medical School and Hospital, Gwangju, South Korea

Background/Purpose: Although the outcome in patients with lupus nephritis (LN) has improved with the availability of more effective and better tolerated immunosuppressive drugs, a significant proportion of patients still progress to chronic kidney disease (CKD) and end-stage renal disease. The consequences of CKD include not only progression to kidney failure but also increased risks for cardiovascular disease and premature death. It is important to identify risk factors capable of predicting progression to CKD in LN patients in order to develop strategies for its prevention, detection, and treatment. Here, we aimed to find prognostic factors for the development of CKD in ethnically homogeneous Korean patients with LN.

Methods: Eighty-nine LN patients were included in this study based on availability of kidney biopsy specimens. Sociodemographic, clinical, laboratory, and treatment-related data at the time of kidney biopsy and during follow-up were obtained by reviewing patients' charts. Renal biopsy specimens were reclassified according to the ISN-RPS classification, by a renal pathologist blinded to the previous classification. CKD was defined as a glomerular filtration rate <60 mL/min/1.73 m^2 for 3 or more months, as recommended by the Kidney Disease Quality Outcome Initiative. Univariate and multivariate analyses were performed using the Cox proportional hazard regression model to identify independent risk factors for CKD in LN patients.

Results: Eighteen of 89 patients (20%) developed CKD during a mean follow-up of 41.9 months (range: 12–86 months). Patients who developed CKD were older at onset of LN ($P = 0.010$), less educated ($P < 0.001$), and more likely to have hypertension ($P = 0.005$); they had a lower serum albumin level ($P = 0.019$), lower platelet level ($P = 0.008$), higher serum creatinine level ($P < 0.001$), lower estimated glomerular filtration rate (eGFR, $P < 0.001$), higher chronicity index ($P = 0.010$), lower frequency of anti-ribosomal P antibodies ($P = 0.012$), and they were less likely to be in complete remission (CR) in the 1st year ($P = 0.006$). The incidence of CKD was lower in patients treated with hydroxychloroquine at the onset of LN than in those not taking hydroxychloroquine ($P = 0.039$). In stepwise multivariable analyses, hypertension ($P = 0.004$), eGFR ($P = 0.017$), and failure to achieve CR in the 1st year of treatment ($P = 0.032$) were significant predictors of the development of CKD in LN patients.

Conclusion: These findings suggest that patients with hypertension and decreased kidney function at the onset of LN and showing a poor response to immunosuppressive drugs in the 1st year should be monitored carefully and managed aggressively to avoid deterioration of kidney function.

628

Emergency Room Visits and Hospitalizations in Systemic Lupus Erythematosus. Jie Xu, Hong Fang and Michelle Petri. Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: SLE has a profound effect on medical care costs (Clark et al.). We quantified the frequency and clinical associations of ER visits and hospitalizations.

Methods: A medical resource use questionnaire that covered the last 3 months was distributed to 386 SLE patients. They were 91% female, mean age 45.7±12.3, 55% Caucasian, 36% African American. Exclusion criteria were diagnosis with SLE less than 6 months, age younger than 18 or older than 75, pregnant at baseline, and active HIV patients.

Results: 9% were hospitalized and 13.5% had an ER visit during the 3 month period. Of the hospitalizations, 57% were due to SLE. Of the emergency visits, 52% were due to SLE.

Table 1. SLE Characteristics Associated with Hospitalizations

Variable	No hospitalizations (%, N=351)	Hospitalizations (%, N=35)	P-value
Age at visit (years)			
≤35	24.8	34.3	0.22
>35	75.2	65.7	
Race			
African-American	35.3	45.7	0.30
Caucasian	56.4	42.9	
Other	8.3	11.4	
Education (years)			
<12	31.6	25.7	1.47
≥12	68.4	74.3	
Income ($)			
≤50K	47.3	48.6	0.89
>50K	52.7	51.4	
Smoking	11.7	5.7	0.28
Physician Global Assessment of Activity >1 (0 to 3 VAS)	12.5	28.6	0.018
SLEDAI ≥ 4	22.2	34.3	0.11
Low C3	14.8	11.4	0.59
Low C4	14.3	11.4	0.65
Anti-dsDNA	21.4	28.6	0.33
Urine protein/cr ≥ 0.5	6.0	20.0	0.008
Prednisone	36.5	62.9	0.002
ESR > 20	42.9	67.7	0.006

Table 2. SLE Characteristics Associated with ER visits

Variable	No ER visits (%, N=334)	ER visits (%, N=52)	P-value
Age at visit (years)			
≤35	22.5	46.2	0.0003
>35	77.5	53.9	
Race			
African-American	35	44.2	0.44
Caucasian	56.3	48.1	
Other	8.7	7.7	
Education (years)			
<12	30.2	36.5	0.36
≥12	69.8	63.5	
Income ($)			
≤50K	45.5	59.6	0.058
>50K	54.5	40.4	
Smoking	9.3	23.1	0.003
Physician Global Assessment of Activity >1 (0 to 3 VAS)	11.1	32.7	<.0001
SLEDAI · 4	21.9	32.7	0.086
Low C3	15.3	9.6	0.28
Low C4	14.4	11.5	0.58
Anti-dsDNA	20.1	34.6	0.019
Urine protein/cr ≥ 0.5	5.7	17.3	0.007
Prednisone	35	63.5	<.0001
ESR > 20	43.3	56.9	0.071

Conclusion: Hospitalizations and ER visits were very frequent. Young age was associated with ER visits but not hospitalizations. Surprisingly, race, education, and income were not associated with hospitalizations or ER visits. Smoking was strongly associated with ER visits. The physician global assessment of disease activity (but not SLEDAI) was associated with both hospitalization risk and ER visits. Of individual organ systems, only lupus nephritis was associated with hospitalizations and ER visits. These data can be used to predict subsets with higher future costs and indicate that effective therapies for lupus nephritis will limit costs.

629

Eltrombopag As Steroid Sparing Therapy for Immune Thrombocytopenic Purpura (ITP) in Systemic Lupus Erythemathosus (SLE), Report of Three Cases. Marie Claire Maroun[1], Rosanne Ososki[2], Judith Andersen[1], Frank B. Vasey[1] and J. Patricia Dhar[1]. [1]Wayne State University, Detroit, MI, [2]Detroit Medical Center, Detroit, MI

Background/Purpose: To review the efficacy of eltrompobag, as a steroid sparing therapy for ITP associated with SLE.

Eltrobopag activates the thrombopoietin (TPO)surface receptor on the megakaryocyte, which increases the production of platelets, and rapidly improves circulating platelet numbers in patients with ITP. This allows for rapid tapering and/or cessation of corticosteroid therapy. Less is known about the platelet response to this drug in ITP associated with SLE.

Methods: Retrospective review was performed of the clinical course of 3 consecutive patients, each with SLE-associated ITP who were initially treated with corticosteroids or other immunomodulatory therapy. These patients were treated with eltrombopag at the DMC Center for Bleeding Disorders and Thrombosis. Eltrompopag was administered according the package insert, with an initial dose of 50 mg daily, with weekly, then monthly monitoring of platelet counts and dose adjustments. Some immunomodulatory agents (*e.g.* hydroxychloroquine) were continued to control non hematologic SLE manifestions..

Results: All 3 patients maintained acceptable platelet counts ($>$ 50,000/μL, (see graphs) for $>$ 6 months following tapering and cessation of corticosteroids. The drug was well-tolerated and there were no adverse events, and specifically no thrombotic events.

Conclusion: Eltrombopag is effective as a rapidly acting corticosteroid sparing therapy for patients with ITP associated with SLE. This is important in reducing corticosteroid related side effects and morbidities in treating SLE patients with ITP. Larger studies are needed to ascertain safety and efficacy of eltrombopag in SLE patients with ITP, particularly those with coexisting antiphospholipid antibodies.

How Does Cutaneous Lupus Disease Area and Severity Index (CLASI) Compare with Physician Assessments of Cutaneous Activity and Damage in Lupus? Meenakshi Jolly, Nazia Kazmi, Rachel A. Mikolaitis and Joel A. Block. Rush University Medical Center, Chicago, IL

Background/Purpose: The purpose of this study was to validate Cutaneous Lupus disease Area and Severity Index (CLASI) against physician assessments of itemized and total cutaneous disease activity and damage in patients with cutaneous manifestations of lupus (CLE) or Systemic Lupus Erythematosus (SLE). Additionally, we sought to determine its relationship with patient reported health assessments (LupusPRO, EQ5D and Body Image Quality of Life Index-BIQLI).

Methods: 29 consecutive SLE and CLE patients seen in our lupus clinic were self-administered demographics, LupusPRO, EQ5D VAS, and BIQLI. A physician then completed the CLASI, and assessed disease activity (SLEDAI) and damage (SLICC/SDI) during the study visit.

Results: Mean age (SD) was 42.4 (13.2) yrs. 25/29 had SLE. Ninety seven percent were women and 46% had a flare at the time of the study. Mean (SD) total scores were CLASI activity 8.8 (5.6), CLASI damage 9.6 (9.1), PGA 1.1 (0.8), SLEDAI 4.5 (4.1) and SDI 1.8 (2.2). Fifty-nine percent patients were on prednisone and 66% on hydroxy-chloroquine. Mean (SD) EQ5D VAS was 73 (15.1), and BIQLI 0.39 (1.5).

CLASI activity score correlated with SLEDAI-rash item (r 0.46, p=0.01), LupusPRO Lupus Symptom item on skin flare (r 0.37, p=0.05), EQ5D VAS (r −0.49, p=0.04), but not with PGA (r 0.35, p=0.08) or total SLEDAI (r 0.19, p=0.33). CLASI damage score correlated with age (r 0.45, p=0.02), SDI items on cutaneous skin scarring/alopecia (r 0.51, p=0.001), skin extensive scarring/panniculum (r 0.51, p=0.01) and skin ulceration (r 0.37, p=0.05) and total SDI score (r 0.53, p=0.001).

BIQLI was not associated with CLASI activity or damage score. However, CLASI face activity adversely affected patient's interactions with people of their own sex (r −0.53, p=0.001), interactions with people of opposite sex (r −0.49, p=0.01), experiences when they met new people (r −0.36, p=0.05), experiences at work/school (r −0.45, p=0.01), relationships with friends (r −0.40, p=0.03) and relationships with family members (r −0.39, p=0.04).

Conclusion: CLASI has good validity against physician assessed itemized cutaneous disease activity and damage, and overall damage in SLE. Furthermore, visible cutaneous activity adversely affects lupus patient's interactions, life experiences and relationships.

631

Clinical Outcomes In SLE Patients Since the introduction of the 2003 ISN/RPS Classification of Lupus Nephritis. Natasha Jordan, Shirish Sangle, Yousuf Karim, Fahim Tungekar, Ian Abbs and David P. D'Cruz. Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom

Background/Purpose: Lupus nephritis affects approximately 60% of Systemic Lupus Erythematosus (SLE) patients and is associated with significant morbidity and mortality. The 2003 International Society of Nephrology (ISN)/Renal Pathology Society (RPS) classification is currently used to histologically define lupus nephritis classes.

The objectives of this research were to determine the rate of progression to end-stage renal disease in lupus nephritis patients who have undergone renal biopsy since the introduction of the 2003 ISN/RPS classification and to identify risk factors associated with poor outcome.

Methods: We retrospectively reviewed the clinical data of 84 lupus nephritis patients who underwent renal biopsy since the introduction of 2003 ISN/RPS classification. Data collected included demographic details, autoantibody profiles, co-existence of Antiphospholipid Syn-

drome, activity and chronicity indices on renal biopsy and renal outcomes.

Results: 99 renal biopsies were performed in 84 SLE patients since the introduction of 2003 ISN/RPS classification. 83% of those biopsied were female (n=70) and 17% were male (n=14). The mean age at renal biopsy in female patients was 35 years (range 10–64 years) and 26 years in male patients (range 14–50 years). 41.6% of patients biopsied were of Caucasian origin (n=35), 32% were of Afro-Caribbean descent (n=27) and 21.4% of Asian extraction (n=18). 7% of our cohort progressed to advanced renal impairment requiring dialysis or renal transplantation.

Afro-Caribbean ancestry was associated with an increased likelihood of developing advanced renal disease (p=0.053). Younger age at renal biopsy was also associated with a worse outcome. Patients with class IV-G on biopsy were more likely to develop renal impairment (p=0.049). No particular autoantibody profile was associated with an adverse outcome. The presence of anti-cardiolipin antibodies, lupus anticoagulant or thrombotic microangiopathy on biopsy were not associated with disease progression in this cohort. High chronicity index on renal biopsy was significantly associated progression to end-stage renal impairment (p=0.001). High activity index on renal biopsy was not associated with the development of renal failure.

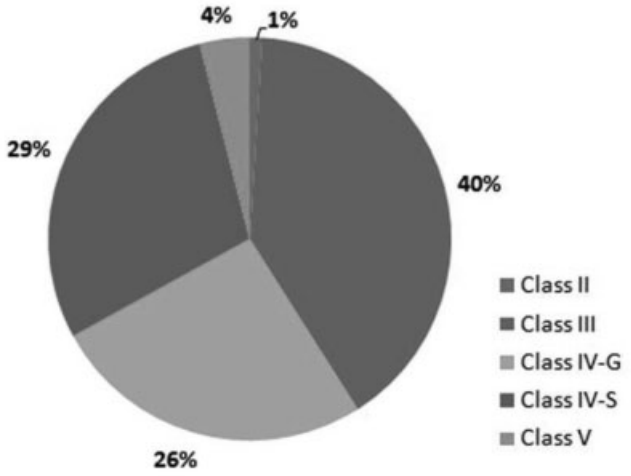

Figure 1. Frequency of lupus nephritis classes seen on renal biopsy

Degree of renal impairment	Class III	Class IV-G	Class IV-S	Class V	
Normal renal function GFR>90	12	5	7	2	37% (n=26)
GFR 60-89	9	4	11	1	35% (n=25)
GFR 30-59	7	7	1	0	21% (n=15)
GFR 15-29	1	0	0	0	1% (n=1)
GFR <15	0	3	1	O	6% (n=4)

Figure 2. Clinical outcomes in ISN/RPS lupus nephritis classes based on KDOQI (kidney disease outcomes quality initiative) stages of kidney disease. GFR (glomerular filtration rate)

Conclusion: Despite advances in the clinical management of lupus nephritis with earlier recognition of disease and improved immunosuppressive regimens, a proportion of patients still progress to end-stage renal failure. In our cohort 7% of patients progressed to advanced renal disease. In our cohort patients with proliferative nephritis were more likely to require renal replacement therapy particularly those with class IV-G nephritis. The association with high chronicity indices on biopsy and progression to renal impairment emphasizes the importance of prompt diagnosis and initiation of appropriate therapy.

ACR Poster Session A
Systemic Lupus Erythematosus - Human Etiology and Pathogenesis I: Susceptibility and Pathogenic Mechanisms
Sunday, November 6, 2011, 9:00 AM–6:00 PM

Background/Purpose: Systemic lupus erythematosus is a clinically-heterogeneous autoimmune disease characterized by antinuclear antibody production. A number of genetic loci that increase lupus susceptibility have been established. Herein, we examine if these genetic loci also contribute to the clinical heterogeneity in lupus.

Methods: A total of 4,001 European-derived, 1,547 Hispanic, 1,590 African-American, and 1,191 Asian lupus patients were genotyped for tag SNPs within 16 confirmed lupus susceptibility loci. Ancestry informative markers were genotyped to calculate and adjust for admixture proportions in each population. The association between the risk allele in each locus was determined and compared in patients with and without the various clinical manifestations included in the ACR criteria.

Results: Significant associations were found between clinical manifestations and the *FCGR2A*, *ITGAM*, *STAT4*, *TNSF4*, and *IL21* genes. Renal disorder was significantly correlated with the lupus risk allele in *ITGAM* ($P = 5.0 \times 10^{-6}$, OR= 1.25 95%CI 1.12–1.35) and in *TNFSF4* (P= 0.0013, OR= 1.14 95%CI 1.07–1.25). Other significant findings include the association between the risk alleles in *FCGR2A* and malar rash (P= 0.0031, OR= 1.11 95%CI 1.17–1.33), *ITGAM* and discoid rash (P= 0.0020, OR= 1.20 95%CI 1.06–1.33), *STAT4* and the protection from oral ulcers (P= 0.0027, OR= 0.89 95%CI 0.83–0.96), and *IL21* and hematologic disorder (P= 0.0027, OR= 1.13 95%CI 1.04–1.22). All

these associations are significant with a false discovery rate of <0.05 and pass the significance threshold using Bonferroni correction for multiple testing.

Conclusion: We analyzed the association between genetic risk loci and clinical manifestations in lupus using a large multi-ethnic cohort of lupus patients. Our findings suggest that genetic profiling might be a useful tool to predict disease manifestations in lupus patients in the future.

633

Genetic Associations with Serologic Autoimmunity in a Large Multi-Ancestral Systemic Lupus Erythematosus Cohort. Silvia Kariuki[1], Beverly S. Franek[1], Akaash A. Background/Purpose: Systemic lupus erythematosus (SLE) is a highly heterogeneous disorder characterized by production of autoantibodies directed at particular self-antigens in the cell nucleus. Similar to other autoimmune diseases, the genetic basis of SLE appears to vary in different serologic groups. We followed up loci from a case-only GWAS study which were associated with particular autoantibodies.

Methods: We genotyped 43 tag SNPs from 10 regions identified in the above GWAS in a multi-ancestral SLE cohort of over 8000 patients split between African-American, European, Hispanic, and Asian ancestral backgrounds. For each SNP and by ethnic group, we computed admixture adjusted logistic regression analyses among cases for association between the SNPs and the presence or absence of the autoantibodies. P-values less than 1.2×10^{-3} withstand Bonferroni correction for the number of SNPs tested.

Results: In African-Americans, the rs310230 SNP in JAK1 was strongly associated with anti-dsDNA and anti-RNP antibodies in an additive manner (OR=1.63, $p=6.20\times10^{-05}$). Additionally, a SNP in KLHL6 demonstrated evidence for association in the anti-RNP positive, anti-Sm negative group ($p=2.1\times10^{-3}$). In Asian ancestry, MAPK4 rs7242442 was associated with anti-Ro antibodies (OR=1.68, $p=4.49\times10^{-05}$). In Hispanic subjects, the strongest serologic association was also with the MAPK4 rs7242442 SNP, although it was associated with anti-RNP in this background (OR=1.47, $p=3.9\times10^{-3}$). In European ancestry, the strongest evidence for a SNP-antibody association was observed between a different MAPK4 tag SNP and anti-Ro antibodies (OR=1.23, $p=5.3\times10^{-3}$).

Conclusion: We demonstrate association of SNPs within the JAK1, KLHL6, and MAPK4 genes with SLE-specific autoantibodies. Serologic autoimmunity differs greatly by ancestral background in SLE, and different autoantibodies have been associated with important clinical differences in patients. This study begins to genetically map this aspect of SLE across multiple ancestral backgrounds.

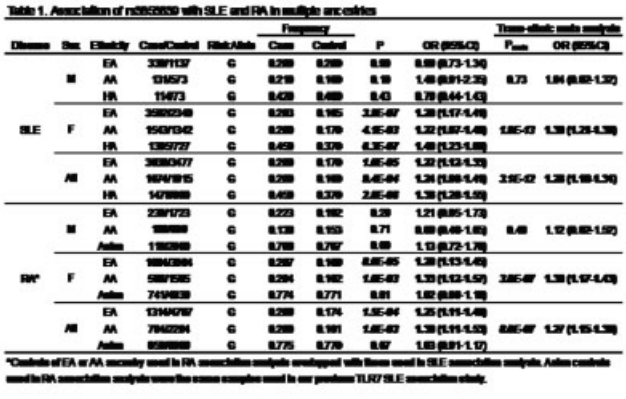
Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: We have established an X-linked *TLR7* 3'UTR SNP (rs3853839) as a risk locus for SLE in 9,274 Eastern Asians (OR = 1.27 [1.17–1.36], $p = 6.5\times10^{-10}$). The aim of this study was to seek replication of SLE-associated SNP(s) in 13,275 SLE case-control subjects including European Americans (EA), African Americans (AA), and Hispanics enriched for the Amerindian-European admixture (HS), to assess whether SLE-risk SNP(s) also predispose to RA in 2,877 RA subjects of EA, AA and Asian ancestries, and to explore functional consequences of disease-associated SNP(s).

Methods: We genotyped 47 SNPs and imputed genotypes for SNPs in the HapMap Phase III and Immunochip. Each SNP was assessed for the association with SLE. Then, identified SLE-risk SNPs were genotyped and assessed for the association with RA. We performed χ^2 testing to identify disease-associated SNPs, and Mantel-Haenszel testing to generate a trans-ancestral meta-analysis *P* value. We performed RT-PCR and reporter gene assay to measure gene expression level, pyrosequencing and mRNA stability assay to measure allelic variations in mRNA level and stability.

Results: The previously identified *TLR7* 3'UTR SNP (rs3853839) was the only independent variant across all 3 replication populations, exhibiting significant association with SLE below a Bonferroni-corrected $P < 4.17\times10^{-3}$ (Table 1). Trans-ancestral meta-analysis extended our previous finding to 13,275 subjects of EA, AA and HS ancestries ($P = 3.1\times10^{-12}$, OR [95%CI] =1.26 [1.18–1.34]). Additionally, the SLE-risk G allele of rs3853839 was associated with susceptibility of RA in EA and AA populations, but not in Asians ($P = 1.5\times10^{-4}$ in EA, 1.0×10^{-3} in

AA, and 0.67 in Asians). Compared to the C allele, disease-associated G allele conferred elevated expression of *TLR7* mRNA in PBMCs from healthy individuals of European ancestry ($P = 0.01$ and 0.02 for men and women respectively), and enhanced transcriptional activity in transfected HEK 293 cells ($P = 0.026$). Allelic specific expression confirmed a higher level of G allele-containing *TLR7* transcripts in PBMCs from European heterozygote women. PBMCs from heterozygote women exhibited a higher G/C allele ratio in *TLR7* transcripts after 4 hours of incubation with actinomycin D (transcriptional inhibitor) than with vehicle control ($P = 0.047$), suggesting a slower degradation of the G allele-containing transcripts.



Conclusion: The G allele of *TLR7* 3'UTR SNP that confers elevated mRNA level through a slower degradation predisposes to SLE and RA in multiple ancestries, highlighting the importance of TLR signaling pathway in the pathogenesis of autoimmune diseases.

The Association Between the TNFAIP3 Gene Polymorphisms and Systemic Lupus Erythematosus: A Meta-Analysis. Young Ho Lee[1], Sung Jae Choi[1], Jong Dae Ji[1] and Gwan Gyu Song[2]. [1]Korea University Medical Center, Seoul, South Korea, [2]Korea University Medical Center, Seoul

Background/Purpose: The tumor necrosis factor alpha inducible protein 3 (TNFAIP3) gene, located at 6q23 region, has been associated with susceptibility to multiple autoimmune diseases. The aim of this study was to determine whether tumor necrosis factor alpha inducible protein 3 (TNFAIP3) polymorphisms confer susceptibility to systemic lupus erythematosus (SLE) in ethnically different populations.

Methods: A meta-analysis was conducted on the TNFAIP3 polymorphisms across eight comparative studies that include 6,311 SLE subjects and 6,492 subjects. We examined the contrast of the allelic effect of 2 (the minor allele) versus 1 (the common allele). The random effects model was used in the presence of significant between-study heterogeneity. Otherwise, the fixed effects model was applied.

Results: Meta-analysis showed an association between the 2 allele of the rs2230926 and SLE in all subjects (OR [odds ratio] 1.848, 95% confidence interval [CI] 1.547, 2.208, $p < 1.0 \times 10^{-9}$). Analysis after stratification by ethnicity indicated that the 2 allele of the rs2230926 was significantly associated with SLE in Asians and Europeans (OR 1.821, 95% CI 1.495, 2.219, $p < 1.0 \times 10^{-9}$; OR 2.251, 95% CI 1.830, 2.768, $p < 1.0 \times 10^{-9}$). Meta-analysis revealed a significant association between the 2 allele of the rs5029939 polymorphism and the risk of developing SLE in overall group and Europeans (OR 1.804, 95% CI 1.255, 2.592, $p = 0.001$; OR 2.145, 95% CI 1.731, 2.658, $p < 1.0 \times 10^{-9}$). Meta-analysis revealed an association between the 2 allele of the rs3757173 and SLE in all subjects (OR 1.540, 95% CI 1.017, 2.331, $p = 0.041$). However, no association was found between SLE susceptibility and rs6922466 by meta-analysis (OR 0.953, 95% CI 0.812, 1.120, $p = 0.561$).

Conclusion: This meta-analysis confirms that the TNFAIP3 polymorphisms are associated with SLE susceptibility in different ethnic groups such as Asians and Europeans.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with diverse clinical manifestations characterized by the development of pathogenic autoantibodies and target tissue damage. Genome-wide association (GWA) studies have identified genetic variants in the *UBE2L3* region that are associated with SLE in subjects of European and Asian ancestry. *UBE2L3* encodes an ubiquitin-conjugating enzyme, UBcH7, involved in cell proliferation and immune function. In this study, we sought to further characterize the genetic association in the region of *UBE2L3* and use molecular methods to determine the functional effect of the risk haplotype.

Methods: The IlluminaiSelect platform was employed to genotype SNPs within the *UBE2L3* region in 8,922 cases and 8,077 controls, including: African-Americans (1,569 cases/1,893 controls), Asians (1,328 cases/1,348 controls), Europeans (4,248 cases/3,818 controls), Gullah (155 cases/131 controls), and Hispanics enriched for Amerindian-European admixture (1,622 cases/887 controls). Imputation was performed using IMPUTE2 and the 1000 Genomes Project reference panels. The single marker association analyses were calculated using the logistic regression function in PLINK adjusting for gender and global ancestry estimates. Haploview version 4.2 was used to generate probable haplotypes and calculate haplotypic association for all haplotypes formed by the associated markers. Eight EBV-transformed B cell lines with risk haplotype and 16 with non-risk haplotype were used to study the effect on *UBE2L3* mRNA and UBcH7 protein expression. Quantitative RT-PCR and western blotting was performed to compare the mRNA and protein expression level of *UBE2L3*, respectively.

Results: We identified strong associations between variants in *UBE2L3* and SLE in Europeans (86 SNPs with $P < 1 \times 10^{-4}$), Asians (71 SNPs with $P < 1 \times 10^{-3}$), and modest association in African-Americans (24 SNPs with $P < 0.01$), and Hispanics (17 SNPs with $P < 0.01$). A single risk haplotype was observed in subjects of European-ancestry ($P = 2.07 \times 10^{-7}$), and the other associated populations. However, due to strong LD across the region we were not able to narrow the risk interval using genetic methods ($r^2 > 0.8$). Previous studies suggested that variants in the region of *UBE2L3* influence *UBE2L3* transcript expression. To evaluate if the SLE risk haplotype carries variants that influence *UBE2L3* transcript or UBcH7 protein levels, we used quantitative-PCR and western blotting. Our results demonstrate that individuals harboring the risk haplotype display a significant increase in both mRNA expression ($P < 0.001$) and UBcH7 protein expression ($P = 0.001$). These results suggest

the variants carried on the SLE associated *UBE2L3* risk haplotype influence autoimmunity by modulating UBcH7 expression.

Conclusion: *UBE2L3* is an SLE risk locus present in multiple ethnic groups. Our data demonstrate a single risk haplotype with strong linkage disequilibrium that resists further genetic refinement. The *UBE2L3* risk haplotype results in increased expression of both *UBE2L3* mRNA and UBcH7 protein.

637

A Functional Haplotype in the Region of *TNIP1* Is Associated with Systemic Lupus Erythematosus in Multiple Populations. Indra Adrianto[1], Graham B. Wiley[1], Shaofeng Wang[1], Kenneth M. Kaufman[2], Juan-Manuel Anaya[3], Marta E. Alarcón-Riquelme on behalf of BIOLUPUS and GENLES networks[4], Sang-Cheol Bae[5], Elizabeth E. Brown for PROFILE[6], Barry I. Freedman[7], Gary S. Background/Purpose: Recent genome-wide association studies (GWAS) in Asian and European-ancestry (EA) populations have revealed genetic variants in the vicinity of *TNIP1* to be associated with systemic lupus erythematosus (SLE), an autoimmune disease characterized by loss of tolerance to self-antigens and dysregulated interferon responses. *TNIP1* encodes for the adapter protein ABIN1 that recruits A20 to polyubiquitinated NEMO (IKKγ) facilitating NEMO deubiquitination and restriction of NF-κB signaling. To fully characterize the variants in *TNIP1* responsible for association with SLE, we performed fine mapping, resequencing, and imputation using single-nucleotide polymorphisms (SNPs) within *TNIP1* on chromosome 5q33 in five ethnically diverse populations.

Methods: Genotyping was performed on the Illumina iSelect platform for 83 SNPs within *TNIP1* in the following cases and controls: African-American (AA) (1,569/1,893), Asian (1,328/1,348), EA (4,248/3,818), Gullah (155/131) and Hispanic (1,622/887) populations. Imputation was conducted using IMPUTE2 and the 1000 Genomes Project haplotypes. Imputation using targeted resequencing data from 187 EA and 46 AA individuals was also performed in order to improve ascertainment of causal alleles enriched in SLE patients. The single marker association analyses were performed using logistic regression in PLINK. Conditional analyses adjusting for each haplotype-tagging variant were done using logistic regression. Haplotypes were estimated followed by haplotypic association using Haploview. Western blotting was performed to compare the basal protein expression level of ABIN1 in the EBV-transformed B cell lines of 9 individuals with risk haplotypes and 7 individuals with non-risk haplotype.

Results: The peak associations of variants within *TNIP1* were observed in EA ($P = 2.24 \times 10^{-11}$), Hispanic ($P = 8.00 \times 10^{-7}$), and AA ($P = 1.15 \times 10^{-5}$) populations, respectively. We saw more modest association in Asians ($P = 2.53 \times 10^{-4}$), but no association in Gullah. In the EA population, we were able to dissect two independent risk haplotypes (H1 and H2) with $P = 1.54 \times 10^{-6}$ and $P = 7.49 \times 10^{-6}$ by conditional analyses. Interestingly, the H1 haplotype was also present in AAs and Hispanics, but we saw no evidence of the H2 haplotype in other populations. To determine if these risk haplotypes carry variants that influence the expression of ABIN1 protein, we used Western blotting in lysates from resting EBV transformed lymphocytes harboring either haplotype. We observed a significant decrease in ABIN1 protein expression ($P = 0.0029$) in 7 individuals with the H1 haplotype suggesting functional variants present on this haplotype influence susceptibility to autoimmunity by restricting ABIN1 expression.

Conclusion: We have comprehensively characterized the variants present within *TNIP1* in five populations. In the EA population, we observed two risk haplotypes one of which was also seen in AAs and Hispanics. Variants present on this haplotype result in decreased ABIN1 protein expression. Further functional studies to investigate the role of *TNIP1* in regulating autoimmunity are ongoing.

The Role of *Bsm*I and *Fok* I Vitamin D Receptor Gene Polymorphisms and Serum 25-Hydroxyvitamin D in Systemic Lupus Erythematosus. Odirlei A. Monticielo[1], Jose A. B. Chies[1], Guilherme G. Rucatti[2], Maria G. F. Longo[1], R. Scalco[3], João Carlos T. Brenol[1] and Ricardo M. Xavier[1]. [1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Universidade Federal do Rio Grande do Sul, Porto A legre, Brazil, [3]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

Background/Purpose: Vitamin D has pleiotropic actions on many chronic diseases. The expression of the VDR (vitamin D receptor) in various cells of the immune system strengthens the possible influence of vitamin D on systemic lupus erythematosus (SLE). Genetic polymorphisms located in *VDR* gene may determine changes in the mechanisms of action of vitamin D, but with results still unknown. The *Bsm*I *VDR* polymorphism was associated with SLE in Asian patients and more studies are needed to further clarification.

Methods: A case-control study with 195 SLE patients and 201 health controls was performed to investigate the influence of *Bsm*I and *Fok*I *VDR* gene polymorphisms on the susceptibility to SLE. Serum 25-hydroxyvitamin D [25(OH)D)] levels were measured in the cases. Genotyping was performed by Restriction Fragment Length Polymorphism-Polymerase Chain Reaction (RFLP-PCR), using primers and restriction enzymes specific for each polymorphism. The measurement of 25(OH)D was performed by chemiluminescence.

Results: There was no statistically significant difference in genotypic and allelic frequencies of *Bsm*I and *Fok*I polymorphisms among European-derived cases and controls. There was no association between clinical and laboratory features in SLE patients and the studied polymorphisms. The mean serum levels of 25(OH)D were 25.51±11.43 ng/ml in SLE patients. When patients were classified according to vitamin D status, the following distribution was observed: 55 (30.4%) had normal ($\geq$30 ng/ml), 63 (34.8%) insufficient (20–30 ng/ml), 52 (28.7%) deficient ($<$20 ng/ml) and 11 (6,1%) critically low serum levels ($<$10 ng/ml). Fifty six percent of patients with deficiency received at least 800 IU of vitamin D per day. Based on genotype distribution, 25(OH)D levels were significantly higher in patients carrying the f/f genotype, when compared to patients carrying the F/F genotype (31.6±14.1 ng/ml versus 23.0±9.2 ng/ml, p=0.004). Vitamin D levels were not associated with clinical and laboratory features of SLE.

Conclusion: The *Fok*I polymorphism showed significant influence on 25(OH)D levels, reinforcing its role in functional activity of VDR. This finding may be considered in future clinical and experimental studies involving vitamin D measurements. Serum concentrations of 25(OH)D required to maintain optimal musculoskeletal, cardiovascular and immune health should be individualized for each patient and new guidelines about vitamin D supplementation may have to take into consideration the individual genetic background. Genetic-specific definitions of ideal levels of vitamin D in SLE should therefore be established in future studies.

639

SLE-Risk Alleles of SNPs in the *NMNAT2*/*SMG7* Region Are Associated with Lower mRNA Levels of *SMG7*. Jian Zhao[1], Daisuke Sakurai[1], Yun Deng[1], Andrea L. Sestak[2], Carl D. [1]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Wake Forest University Health Sciences, Winston-Salem, NC, [4]US Department of Veterans Affairs Medical Center and Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK, [6]Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [7]Centro de Genómica e Investigación Oncológica Pfizer-Universidad de Granada-Junta de Andalucía (GENYO), Granada, Spain and Oklahoma Medical Research Foundation, Oklahoma City, OK, [8]Cincinnati Children's Hospital Medical Center and the US Department of Veterans Affairs Medical Center, Cincinnati, OH, [9]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [10]Divisions of Genetics and Molecular Medicine and Immunology, King's College London, London, United Kingdom, [11]Keck School of Medicine University of Southern California, Los Angeles, CA, [12]University of Alabama Birmingham, Birmingham, AL, [13]Rosalind Russell Medical Research Center for Arthritis, Department of Medicine, University of California San Francisco, San Francisco, CA, [14]Department of Medicine, University of Oklahoma Health Sciences Center and Oklahoma Medical Research Foundation, Oklahoma City, OK, [15]Division of Rheumatologyand Immunology, Medical University of South Carolina, Charleston, SC, [16]Universidad del Rosario-Corporacion para Investigaciones Biologicas, Bogota, Colombia, [17]National Defense Medical Center, Taipei, [18]Seoul National University, Seoul, [19]UCLA David Geffen School of Medicine, Los Angeles, CA, [20]University of California Los Angeles, Los Angeles, CA

Background/Purpose: Within the 1q25 region, rs2022013 located in *NMNAT2* (encoding a central enzyme of the NAD biosynthesis pathway expressed mainly in neurons) was associated with SLE in the SLEGEN genome-wide association study (GWAS) and a replication study conducted in subjects of European ancestry, which indicates the *NMNAT2* region is a risk locus for SLE. Here we sought to fine map the *NMNAT2* region to identify underlying causal variants predisposing to SLE.

Methods: We genotyped 34 *NMNAT2* SNPs and 347 ancestry informative markers (AIMs) in 15,292 case-control subjects including European Americans (EA, 3438 cases vs. 3417 controls not used in SLEGEN GWAS), African Americans (AA, 1679 vs. 1934), Asians (AS, 1265 vs. 1260) and Hispanics enriched for the Amerindian-European admixture (HS, 1492 vs. 807). AIMs were used to estimate global ancestry for each subject and eliminate genetic outliers. *NMNAT2* SNPs were assessed for the association with SLE under a logistic regression model adjusted for sex and global ancestry. We also imputed genotypes for SNPs in the 1000 Genomes Project and assessed them for the association with SLE. In addition, we performed conditional analysis to distinguish independent association signals, meta-analysis to calculate combined *P* value and RT-PCR to measure gene expression levels.

Results: We detected significant association signals (defined as $P<0.05/34=1.5\times10^{-3}$) in EA and HS but not in AA and AS. Previously reported association of rs2022013 with SLE was confirmed in EA ($P=3.9\times10^{-7}$, OR=0.83). After imputation, 163 SNPs in EA and 10 SNPs in HS, spanning 239 kb from *NMNAT2* to *SMG7*, were significantly associated with SLE, of which 68 SNPs showed consistent association in EA and HS ($P<0.05$). These association signals could be explained by 4 groups of SNPs (group 1: rs12146097, $P_{meta}=6.4\times10^{-13}$, OR=1.40; group 2: proxy SNP rs12410472, $P_{meta}=1.6\times10^{-6}$, OR=0.77; group 3: proxy SNP rs2702178, $P_{meta}=7.9\times10^{-10}$, OR=1.22; group 4: proxy SNP rs536586, $P_{meta}=1.5\times10^{-7}$, OR=1.18). Group 1, 2 and 4 SNPs are all located in intron 1 of *NMNAT2* long isoform, but multiple group 3 SNPs are located in the *SMG7* region. SMG7 is an ubiquitously expressed key component of the nonsense-mediated mRNA decay (NMD) pathway, which mainly functions in controlling mRNA quality and expression levels and is coupled with alternative splicing to regulate core spliceosomal proteins such as Sm and snRNP. In the Genevar eQTL database, SLE-risk alleles of group 1, 3 and 4 SNPs were associated with lower expression levels of *SMG7* rather than *NMNAT2* or other genes within 250 kb. We confirmed that the risk allele of group 3 SNPs showed dosage-dependent association with lower mRNA levels of *SMG7* in PBMCs of 34 SLE patients and 33 healthy controls of European ancestry ($P<1.0\times10^{-4}$), in which *SMG7* levels were negatively associated with known ANA titers of 26 of the 34 SLE patients ($r=-0.43$, $P=0.03$).

Conclusion: We identified SLE-associated SNPs, exceeding GWAS significance level of $P<5.0\times10^{-8}$, in the *NMNAT2*/*SMG7* region and showed that these SNPs might confer risk of SLE, at least in part, by influencing the expression of *SMG7*. These findings implicate a novel mechanism by which the NMD pathway may be involved in the pathogenesis of SLE.

Association of Androgen Receptor Gene Polymorphism with Damage in Systemic Lupus Erythematosus. Yun Deng[1], Jennifer M. Grossman[2], Qiong Fu[1], William Martin[1], Matthew Quirk[1], Ornella J. Rullo[3], Susan A. Boackle[4], Chaim Putterman[5], Jane E. Salmon[6], Vasileios C. Kyttaris[7], George C. Tsokos[7], Erika Magdangal[1], Lori Sahakian[2], Weiling Chen[1], Jennifer MP Woo[3], Deborah K. McCurdy[3], Chack-Yung Yu[8], Bevra H. Hahn[2], Maureen A. McMahon[1] and Betty P. Tsao[1]. [1]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [4]University of Colorado Denver School of Medicine, Aurora, CO, [5]Albert Einstein College of Medicine, Bronx, NY, [6]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [7]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [8]7Center for Molecular and Human Genetics, The Research Institute at Nationwide Children's Hospital and The Ohio State University, Columbus, OH

Background/Purpose: Organ damage predicts physical function and mortality of SLE. The exploration of genes contributing to risk for damage in SLE has been limited. Since men with SLE tend to accrue damage more rapidly, we investigated whether an X-linked androgen receptor (*AR*) polyGLN polymorphism that impacts androgen receptor transactivation activity correlated with damage assessed by the SLICC/ACR Damage Index (SDI) in SLE.

Methods: A retrospective chart review was performed to collect the clinical data. The damage score was calculated using SDI, a standardized, validated damage instrument. Length of CAG repeat in exon 1 of *AR* genotyped by PCR was assessed for association with SDI using the Spearman correlation test, Chi square test, and logistic regression analysis.

Results: Men with SLE (n = 129) had a shorter disease duration than 422 women with SLE (median [interquartile range] = 5.5 [2–11] vs. 8.5 [3–16] years, $p = 0.007$), but similar composition of ancestry background, age at onset and cumulative prednisone dose. The proportion of patients who had accrued any damage was higher among men than women in the first 5 years of disease (63.5% vs.39.5%, $p = 0.004$). Both genders had similar damage accrual in the general SDI categories, except for the renal and pulmonary system in which men were more likely to accrue damage ($p = 0.0002$ and 0.01, respectively). For AR analysis, CAG repeat length ranged from 12 to 31 in men and 11 to 26 in women with SLE. Combined both genders, the number of CAG repeats varied with ethnicity that the interquartile range was 17–21 in European or Hispanic, 16–19.5 in African, and 18.5–22 in Asian ancestry ($p < 0.0001$). The lowest quartile of CAG repeat length ($n \leq 17$) was significantly associated with more damage (SDI ≥ 2) in women (OR = 2.49 [1.57–3.94], $p = 0.0001$), but only in men within the top quartile of disease duration (>16 years) (OR = 3.71 [1.10–12.56], $p = 0.04$). Using logistic regression analysis, independent risk factors for increased damage (SDI ≥ 2) in the combined 551 SLE patients were short CAG repeat length ($n \leq 17$) (OR = 2.17 [1.36–3.47], $p = 0.001$), higher cumulative prednisone dosage (OR = 2.13 [1.62–2.79], $p<0.0001$), and longer disease duration (OR = 1.06 [1.04–1.09], $p<0.0001$), but not male gender, non-European ancestry and age at onset which were previously observed to be associated with more organ damage (Table 1).

Table 1. Independent risk factors for increased damage (SDI≥2) in SLE

Independent factors*	OR	95% CI	*p*
Short CAG repeat (≤17)	2.71	1.36–3.47	0.001
Cumulative prednisone dose	2.13	1.62–2.79	*<0.0001*
Disease duration (yrs)	1.06	1.04–1.09	*<0.0001*
Male gender	1.52	0.86–2.67	0.13
Non-European ancestry	1.52	0.97–2.40	0.15
Age at onset (yrs)	1.01	0.99–1.02	0.11

*In this logistic regression model, disease duration and age at onset were entered as a continuous variable, whereas others as categorical variables. Cumulative prednisone dose was defined as: 0=0–10 grams; 1=10–20 grams; 2=>20 grams.

Conclusion: Compared to women, men with SLE in this study had accelerated damage accrual particularly in the early course of disease and a higher risk of developing renal and pulmonary damage. The short CAG repeat (≤17), which confers an enhanced androgen transactivation activity resulting in a heightened response of testosterone and DHEA binding might be a prognostic marker for SLE damage in both genders, particularly during the second decade after disease onset. These data support a potential role for androgen signaling in the development of damage in SLE.

641

Association of Reactive Intermediate Genes with Systemic Lupus Erythematosus (SLE) Varies Across Populations with Different African Ancestries. Paula S. Ramos[1], James C. Oates[2], Diane L. Kamen[2], Patrick M. Gaffney[3], Carl D. Langefeld[1], Jennifer A. Kelly[3], Kenneth M. Kaufman[3], Robert P. Kimberly[4], Timothy B. Niewold[5], Chaim O. Jacob[6], Betty P. Background/Purpose: Very little is known about the genetic etiology of systemic lupus erythematosus (SLE) in individuals of African ancestry – in spite of its higher prevalence, incidence, disease severity, and mortality rates in African Americans (AA). Overproduction of nitric oxide (NO) has been implicated in its pathogenesis and correlated with disease severity, making NO synthases and other reactive intermediate genes biological candidates for disease susceptibility. Here, we report a comprehensive analysis of reactive intermediate genes for their association with SLE in populations of African ancestry. One such population is the Gullah of the Sea Islands of South Carolina: a population isolate with limited and well defined ancestral diversity. Such reduced genetic heterogeneity may increase the power to detect associations in this population. In addition, their higher familial disease prevalence might reflect a stronger genetic component to the disease.

Methods: We analyzed 279 SNPs from 55 regions in 133 Gullah cases and 112 Gullah controls, as well as in other 1432 AA cases and 1575 AA controls. These and approximately 300 additional ancestry informative markers were genotyped on an Illumina custom array; principal components analysis and admixture estimates were computed and adjusted for in association analyses.

Results: While the *glutathione reductase G*SR (rs2253409, P=0.0014, odds ratio (OR) [95% confidence interval (CI)]=1.26 [1.09–1.44]) and *paraoxonase PON3* (rs17879114, P=0.0016, OR [95%CI]=0.79 [0.68–0.91]) were the most significant single-SNP associations in AA, in the Gullah the *NADH dehydrogenase NDUFS4* (rs381575, P=0.0065, OR [95%CI]=2.10 [1.23–3.59]) and *nitric oxide synthase NOS1* (rs561712, P=0.0072, OR [95%CI]=0.62 [0.44–0.88]) were the most strongly associate with SLE. When analyzed together, *GSR* remained the most significant effect (rs2253409, P=0.00072, OR [95%CI]=1.26 [1.10–1.44]). Haplotype analyses revealed a significant 3-SNP haplotype in *NOS1* in AA (rs3741476-rs10774909, P=0.00029, OR=1.32), as well as in the joint cohorts together (P=0.00074, OR=1.28). Two-loci interaction analysis uncovered significant interactions between *NDUFS2* (rs4656993) and the *minichromosome maintenance complex component MCM5* (rs4645794) in AA (P=9.74E-05, OR [95%CI]=1.40 [1.32–1.48]), between the *ring finger protein RNF157* (rs11099897) and the *toll-like receptor TLR7* (rs5741880) in the Gullah (P=6.61E-05, OR [95%CI]=4.10 [1.54–10.91]), and between *PON3* (rs13226149) and *TLR7* (rs1731479) in the joint cohort (P=0.0003, OR [95%CI]=1.41 [1.32–1.50]).

Conclusion: These results suggest that different variants in reactive intermediate genes in different African ancestries may be associated with SLE.

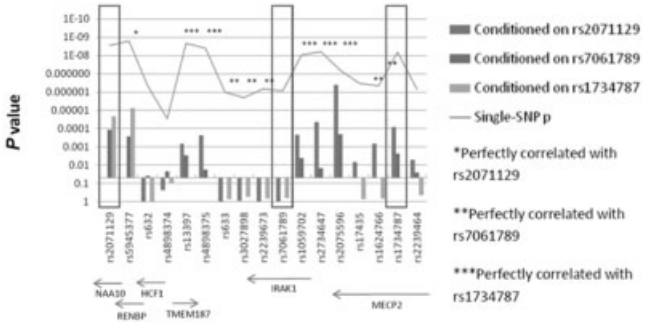
Objectives: Previous studies have identified genetic associations of SLE with *IRAK1* (interleukin-1 receptor associated kinase-1) and its adjacent gene, *MECP2* (Methyl-CpG-binding protein 2) located on chromosome Xq28. To further our understanding of Xq28, we assessed a 215 kb region, including *IRAK1, MECP2,* and 6 other genes, in a trans-ancestral approach using >15,000 case-control samples of European, African, Asian and Hispanic descent.

Methods: We genotyped 55 SNPs spanning 8 genes on Xq28 and 347 ancestry informative markers (AIMs) using a customized Illumina array on the iSCAN instrument. Association tests were calculated using logistic regression, as implemented in PLINK, while adjusting for the four admixture proportions (west African, Indigenous American, Asian and European) using AIMs. Standard haplotype analyses were performed using Haploview 4.2. A trans-ancestral meta-analysis was conducted on the 23 SNPs that produced clean data for the European, Asian and Hispanic samples using METAL. Conditional haplotype-based likelihood ratio test statistics were calculated to localize genetic effects observed at Xq28.

Results: Stratification based on gender identified association in Xq28 in both males and females, however the number of males analyzed was smaller due to lupus being a predominately female disease. Robust associations of SNPs located in genomic region containing *NAA10, RENBP, HCFC1, TMEM187, IRAK1*, and *MECP2* with SLE in samples of European (4248 cases vs. 3818 controls), Asian (1328 vs. 1348) and Hispanic (961 vs. 336) populations surpassing genome wide significance were detected ($p<5\times10^{-8}$;

n=7, 12, and 4 SNPs, respectively), but no association after adjustment for multiple testing was detected in African descent (1569 vs. 1893). Located ~70 kb upstream of the *IRAK1/MECP2* locus, the *NAA10* (N-alpha-acetyltransferase 10)/*RENBP* (rennin binding protein) locus also exhibited strong linkage disequilibrium between the two neighboring genes, and the strongest association was observed at rs5945377 of *RENBP* in the European samples ($p=1.58\times10^{-9}$, OR= 1.35) and supported in both Asian and Hispanic samples ($p=1.76\times10^{-5}$and 7.36×10^{-5}, OR=1.32 and 1.30, respectively). A trans-ancestral meta-analysis of European, Asian, and Hispanic derived samples showed $p_{meta}=5.85\times10^{-17}$, $p_{meta}=1.95\times10^{-22}$ and $=2.68\times10^{-21}$ at *NAA10/RENBP*, *MECP2* and *IRAK1,* respectively. In the largest dataset of Europeans, haplotype-based likelihood ratio test statistics showed that the *NAA10/RENBP* effect (proxy SNP rs2071129) appeared to be independent of *IRAK1* (rs7061789) and *MECP2* (rs1734787), and the *MECP2* association was stronger than that of *IRAK1* in lupus susceptibility (Figure 1).



Conclusion: We confirmed strong association of *MECP2* and *IRAK1* with SLE in European, Asian, and Hispanic ancestries, and identified the *NAA10/RENBP* region as a novel lupus susceptibility locus within Xq28.

Background/Purpose: Autoimmune diseases are a common cause of death among young women, but not men. Women are ~8 times more likely to have systemic lupus erythemstosus (SLE) and ~14 times more likely to have Sjögren's syndrome (SS). This gender bias has long been suspected to be caused by sex hormones. However, on the contrary, men who have an extra X chromosome (47,XXY Klinefelter's syndrome) are ~11 times more likely to have lupus, even though their circulating sex hormone profile is closer to a man's than a woman's. This observation lead to the hypothesis that the extra X chromosome may be the culprit behind female biased autoimmune diseases, instead of circulating sex hormones. In order to further test this hypothesis, here we looked to see if triple X syndrome (47,XXX), which has a hormone profile comparable to 46,XX females, is increased among lupus and Sjögren's patients.

Methods: All patients either met the 1997 ACR criteria for SLE or the 2002 revised European criteria for SS. Genotyping of at least 200k SNPs was performed on each DNA sample from 2,137 lupus women, 1,483 Sjögren's women, and 2,902 control women. Samples with abnormal SNP allele frequencies for chromosome X were confirmed by interphase FISH and/or quantitative PCR. The prevalence of Turner syndrome (45,X), triple X syndrome (47,XXX), mosaicism, and Down syndrome in the patients and controls were statistically compared using Fisher's exact test.

Results: Triple X syndrome (47,XXX) and its variants were found in 9 of 2,137 lupus patients and in 5 of 1,483 Sjögren's patients, but not in any of the 2,902 control women (RR=∞ (2.30-∞), P<0.001; and RR=∞ (1.69-∞), P=0.004; respectively). We estimate that there is 1 lupus and ~8 Sjögren's women among every ~453 women with 47,XXX. The average age of lupus onset in women with 47,XXX was 23.2yrs vs. 35.5yrs for the rest of the lupus cohort (P=0.044, Mann-Whitney U test). Classic Turner syndrome (45,X) was not found in any lupus or Sjögren's patient, but in one control (P=1.00). Down syndrome (47,XX,+21) was not found in anyone, contrary to case reports suggesting its association with lupus.

Conclusion: The prevalence of lupus and Sjögren's in triple X syndrome (47,XXX) was estimated to be ~3 and ~4 times higher than in 46,XX women and ~25 and ~52 times higher than in 46,XY men, respectively. Interestingly, the lupus patients with a 47,XXX genotype developed the disease on average ~13yrs earlier than the other patients in the cohort. Furthermore, no lupus or Sjögren's patient was found with a 45,X genotype. These results along with our results showing increased Klinefelter's (47,XXY) in SLE, imply that X chromosome number, independent of circulating sex hormone levels, explains the sex-bias of SLE and SS.

Effects of OAZ In Regulating B-Cell Proliferation by Mesenchymal Stem Cells From Patients with Systemic Lupus Erythematosus. Xuebing Feng[1], Yan Liu[1], Nan Che[1], Dandan Wang[1], Betty P. Tsao[2] and Lingyun Sun[1]. [1]Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [2]UCLA School of Medicine, Los Angeles, CA

Background/Purpose: Allogeneic mesenchymal stem cell transplantation (MSCT) has shown some benefits in patients with refractory systemic lupus erythematosus (SLE). However, the underlying mechanism is still unclear. Our data indicate that Olf1/EBF associated zinc finger protein (OAZ), a novel lupus susceptibility gene down-regulated after MSCT, is involved in the production of antinuclear antibody (ANA). Because this gene is highly expressed in MSCs, the role of OAZ in MSC-B cell regulation is explored.

Methods: Study protocol was approved by the hospital's Ethics Committee. MSCs isolated and expanded after culturing for 3 passages from bone marrow of 4 female SLE patients, were incubated with siRNAs targeting OAZ or non-targeting sequence. Three days later, cells were collected for measuring mRNA levels of OAZ and ID1–3, downstream genes of OAZ, using quantitative real-time polymerase chain reaction (qPCR) and levels of cytokines and chemokines in cultured supernatants were detected by ELISA. Splenic B cells from C57BL/6 mice were purified using anti-CD43 antibody, co-cultured with SLE MSCs at 10: 1 ratio in the presence or absence of OAZ siRNAs, and then harvested for the detection of proliferation by using BrdU assay.

Results: Silencing OAZ in SLE MSCs 1) significantly reduced mRNA levels of OAZ and its downstream ID1–3 by 67.9 ± 7.2% and ~50% respectively, 2) significantly increased expression levels of CCL2, a MSC-derived chemokine involved in plasmablast proliferation, in both mRNA and protein of cultured supernatants, and had no effects in IL-21 levels. Figure 1 showed LPS stimulated proliferation of mouse B cells was not affected by co-culturing with human MSCs at 1:10 ratio (28 ± 0.4% vs 31 ± 0.8%,n= 3 and $p > 0.05$), but was impaired (18 ± 1.6%, $p < 0.05$) by the addition of siRNAs targeting human OAZ gene in the co-cultures. Interestingly, when anti-CCL2 neutralizing antibody (1ng/ml) was added to MSC-B cell co-cultures, the ability of B cell proliferation was fully restored.

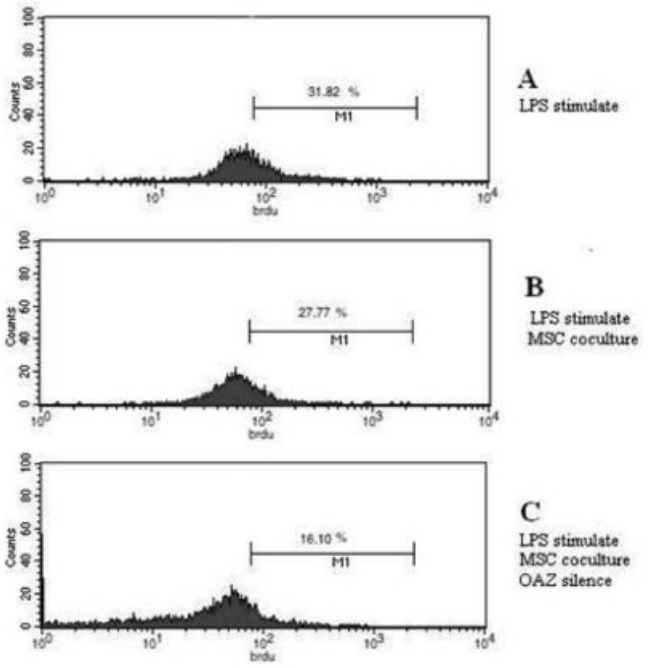

Figure 1. Representative result of proliferated B cells measured by BrdU. A, B cell cultured with LPS stimulation. B, B cell- MSC co-culture, with LPS stimulation. C, B cell-MSC co-culture in the presence of OAZ siRNAs, with LPS stimulation.

Conclusion: Down-regulating of OAZ in MSCs increases CCL2 levels and inhibits B cells proliferation in MSC-B cell co-cultures, implicating a role of OAZ in SLE MSCT.

Differential DNA Methylation Associated with Anti-dsDNA Autoantibody Production In Systemic Lupus Erythematosus. Sharon A. Chung[1], Kimberly E. Taylor[1], Hong L. Quach[2], Lisa F. Barcellos[2] and Lindsey A. Criswell[1]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California, Berkeley, Berkeley, CA

Background/Purpose: Aberrant DNA methylation has been implicated in the pathogenesis of systemic lupus erythematosus (SLE), with less DNA methylation observed in SLE patients compared to healthy controls. We conducted this study to identify differences in DNA methylation across the genome associated with anti-dsDNA autoantibody production, a clinically relevant autoantibody associated with kidney damage and more severe disease in SLE.

Methods: Genomic DNA from peripheral blood leukocytes was isolated from 104 pairs of SLE cases (n=208 cases total). All SLE cases were female, of European descent, and had never smoked. Case pairs were discordant for anti-dsDNA autoantibody production status (positive vs. negative), and were matched (within 5 years) on age at DNA sample collection and SLE disease duration. Using the Illumina HumanMethylation27 Beadchip, the methylation status of 27,568 CpG sites across the genome were interrogated in all SLE cases. Paired t-tests were used to identify site-specific methylation differences associated with anti-dsDNA autoantibody production. P-values less than 1.8×10^{-6} (Bonferroni corrected) were considered statistically significant.

Results: Overall, less methylation was observed in the anti-dsDNA positive group. Mean methylation levels were decreased in the anti-dsDNA positive cases when compared to anti-dsDNA negative cases for 63% of the CpG sites investigated (n=17,286). Increased methylation of two CpG sites in *PRIC285*, a transcriptional co-activator for nuclear receptors, was significantly associated with anti-dsDNA autoantibody production ($p=1.9 \times 10^{-7}$ and 3.4×10^{-7}). Decreased methylation of a CpG site near *SOCS2* ($p=3.5 \times 10^{-7}$), an inhibitor of the STAT family of transcription factors, was also associated with anti-dsDNA autoantibody production. No evidence of interaction ($p>0.05$) was found between methylation of the associated *SOCS2* CpG site and rs7574865 of *STAT4*, a known SLE susceptibility and anti-dsDNA propensity locus.

Conclusion: Similar to comparisons between SLE cases and controls, DNA from autoantibody positive SLE cases appears to be less methylated than autoantibody negative SLE cases. Abnormal methylation of specific genes such as *PRIC285* and *SOCS2* may contribute to autoantibody production in SLE. Lastly, studies of DNA methylation and other epigenetic modifications may identify additional biologic mechanisms involved in the pathogenesis of SLE.

Circulating T Helper Cells in Patients with Systemic Lupus Erythematosus Share the Phenotypic Property with Lymphoid T Follicular Helper Cells. Elvira Lindwall[1], Carl Gauthier[1], Anika Alarakhia[1], Gwendoline Menga[1], Jerald M. Zakem[1], William E. Davis[1], Tamika A. Webb-Detiege[1], Young Sung Choi[1], Robert Quinet[2] and Xin Zhang[1]. [1]Ochsner Medical Center, New Orleans, LA, [2]Ochsner Medical Center - New Orleans, New Orleans, LA

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by autoreactive B cells and autoantibody (autoAb) production. These autoAbs bind to self-antigens, leading to multi-system disease. T follicular helper (T_{FH}) cells, a T cell subset located in germinal center in secondary lymphoid organs, have emerged as a key participant that controls B cell peripheral tolerance and Ab production. Previously we have found that circulating T_{FH} (cT_{FH}) cells are expanded in SLE patients. To identify the origin and the role of cT_{FH} cells in SLE, we compared the phenotypic property of cTFH cells in SLE patients with lymphoid T_{FH} cells in the secondary lymphoid organ (tonsil), and correlated the percentage of cT_{FH} cells with autoAb production and disease activity in SLE patients.

Methods: Eighteen SLE patients diagnosed according to the ACR criteria were recruited. The disease activity was determined by SLEDAI. Blood from these lupus patients and eighteen age, gender-matched healthy controls was obtained. Mononuclear cells were isolated by Ficoll density-gradient centrifuge, and stained with fluorescent-conjugated Abs. T_{FH} cells were defined by their signature surface markers ($CD4^+CXCR5^+ICOS^+CD57^+$) via flow cytometry and analyzed using FlowJo software. The cT_{FH} cells, non- cT_{FH} cells from SLE patients, and lymphoid T_{FH} cells from tonsils were purified by MACS columns, and the purities were above 90%. The expression levels of cytokines of these cells were measured by RT-PCR and intracellular staining. Plasmablasts were identified by surface $CD20^{lo}CD38^{hi}$expression. Levels of anti-dsDNA Ab, anti-nuclear Ab (ANA), C3 and C4 were also collected. Statistical analysis was carried out using GraphPad Prism software and the significance was evaluated by *t* test. Correlation analysis was determined by Spearman's rank correlation test as *r* value.

Results: The frequency of cT_{FH} cells was significantly increased in SLE patients compared to healthy controls ($P<0.01$). This elevated frequency of cT_{FH} cells had a positive correlation with levels of circulating plasmablasts, serum anti-dsDNA Ab and ANA, but no correlation with serum C3 and C4. In addition, cT_{FH} cells from SLE patients shared similar phenotype and frequency with lymphoid T_{FH} cells, with less intense expression of co-stimulatory molecules CXCR5, CD57, and ICOS. Both the cT_{FH} cells from SLE patient and lymphoid T_{FH} cells expressed significant higher amounts of IL-21, IL-6 and IL-10 than non-T_{FH} cells in lupus patients and T helper cells from healthy donors. These cytokines are known to drive B cells to differentiate into IgG-secreting plasma cells *in vitro*.

Conclusion: The increased frequency of ectopically located cT_{FH} cells in SLE patients share a similar phenotype with lymphoid T_{FH}, and may derive from lymphoid organs. By secreting plasma cell driving cytokines (IL-21, IL-10, and IL-6), these accumulated cT_{FH} cells may ensure that self-reactive B cell clones further differentiate to plasmablasts producing autoAbs in the periphery, thus serve as perpetrators in the pathogenesis in SLE patients and a possible mechanism for treatment.

Microarray Analysis of the autologous Hematopoietic Stem Cell Transplantation Induced Remission Associated CD8 Treg Cells Gene Expression Profile. Li Zhang, Anne M. Bertucci, Richard K. Burt and Syamal K. Datta. Northwestern University FSM, Chicago, IL

Background/Purpose: Our previous work demonstrated that autologous hematopoietic stem cell transplantation (HSCT) can induce true Immunologic Remission in refractory lupus by generating a newly differentiated population of FoxP3+, $LAP^{high}CD103^{high}CD8^{TGF\text{-}beta}$ Treg cells, which is lacking in

patients with conventional drug treated "clinical remission" (SLEDAI = 0). With the unique opportunity provided by HSCT, here we begin to characterize the genes for generation and mechanism of action of the unusual CD8+ Treg subset of post-transplant lupus patients.

Methods: Microarray analysis was conducted with Illumina Human HT12 Chip. The RNA was isolated from the autologous CD8+ T cell lines which were derived from the **same lupus patients** pre- and post-transplantation. RNA from the healthy subjects' CD8 T cell lines were included to compare with genes expression of post-transplant CD8 Treg cells, since both showed potent suppressive function. The data was analyzed with functional gene networks and gene set enrichment analysis to select the interesting genes.

Results: There were marked differences in the gene expression profiles between autologous pre- and post- transplantation CD8 line T cells. At the level of a ≥ 2-fold change, there were **314** genes showing an increase or decrease in expression in common among all three patients on comparing pre-transplant with their autologous post-transplant CD8 T cells that were cultured with IL-2 for 6 hours before the RNA was isolated. Among these **314** genes, **136** showed a consistent increase, and **85** genes showed a consistent decrease in expression among all three **pre**-transplant CD8 T cell samples when compared with their autologous **post**-transplant CD8 T cell lines, and also when compared with three different **normal** CD8 T cells lines from unrelated subjects, at two different time points (cultured with IL-2 for 6 or 12 hours before RNA isolation). After confirming with real time PCR, we narrowed down interesting genes which belong to pathways of immune response, inflammatory cytokine/chemokine, immunomodulation, TGF-β signal transduction, apoptosis pathways, DNA replication, cell cycle, and mitochondrial energy metabolism.

Conclusion: Gene expression microarray analysis of the autologous pre- and post-transplant CD8 line T cells derived from **same lupus patients** reveal interesting candidate genes, which may provide insight into the mechanisms of *human* lupus development (including how the pre-transplant CD8 line T cells "help" CD4 T cell reactivity to autoantigens) and understanding how the post-transplant CD8 Treg cells maintain patients in true *immunological remission* and how they are generated by HSCT, as well as to identify new cell surface markers of CD8 Treg cells.

648

Peptides Inducing Potent Autoantigen-Specific Treg Cells in Human Lupus. Li Zhang[1], Anne M. Bertucci[1], Rosalind Ramsey-Goldman[2], Richard K. Burt[1] and Syamal K. Datta[1]. [1]Northwestern University FSM, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: To develop a natural, non-toxic therapy that generates potent Treg cells and devise a screening assay for therapeutic peptides to maintain lupus patients in remission.

Methods: PBMC from 15 lupus patients (5 active and 10 remission, 20–60 years), and 8 healthy subjects (23–57 years) were isolated and cultured with low doses of nucleosomal histone peptide autoepitopes: H1(22–42), H3(115–135), H3 (82–105), H4(16–32), and H4(71–94), as well as control peptides for 7 days, along with 50 U/ml of hIL-2. Then the percentage of *STABLE* CD4 and CD8 FoxP3+ Treg cells were analyzed by flow cytometry. The expression of TGFβ precursor-Latency Associated Peptide (LAP), CD103 and CD39 in T cells induced by peptides were also measured. The optimal culture conditions, and the effect of anti-inflammatory drugs on peptide induction of Treg cells, such as Dexamethasone (DEX), hydroxychloroquine (HCQ) and anti-IL6 were determined. The relation of FoxP3 expression with TGF-β/ALK-5/Smad signaling pathway in induced Treg cells was also explored.

Results: CD4+CD25highFoxP3+ cells, CD4+CD45RA+FoxP3low cells (induced Treg cells), CD8+CD25+FoxP3+ cells were all significantly increased in PBMCs when cells were cultured with very low dose histone peptide in vitro for 7 days, compared with control peptide pConA or with medium only ($P < 0.01$). These histone peptides can induce stable FoxP3 positive Treg cells in vitro in PBMC from active and remission lupus patients as well as healthy subjects. LAP expression on CD4 and CD8 T cells was also increased when cells were cultured with histone peptides, but CD103, CD39 expression did not increase significantly. Anti-inflammatory drugs DEX, HCQ could enhance the effect of peptides in inducing Treg cells, but anti-IL6 did not show such enhancing effects although it could increase CD25 expression on T cells remarkably. Interestingly, pSmad 2/3 expression in CD4 T cells was also induced by these low dose peptide epitopes and the number of peptide induced FoxP3 positive cells was significantly reduced when ALK-5 inhibitor (SB-431542), to block TGF-β signaling was added.

Conclusion: Very low dose histone peptide epitopes can induce stable CD4+ and CD8+ Treg cells in vitro in both active and remission lupus patients through TGF-β/ALK-5/Smad signaling pathway. In animal models, similar peptide-induced Treg cells can block accelerated lupus disease. This study would be useful for screening therapeutic peptides and developing approaches for maintaining lupus patients in remission by inducing autoantigen-specific Treg cells in vivo, or by adoptive transfer of in vitro generated Treg cells.

649

Genome-Wide Association Scan of Antigenic Epitopes of Lupus Specific Autoantibodies in European Americans. Chee Paul Lin[1], Indra Adrianto[1], Jessica J. Hale[1], Jennifer A. Kelly[1], Stuart B. Glenn[1], Jourdan Anderson[1], Kenneth M. Kaufman[2], John B. Harley[3], Tomothy J. Vyse[4], Robert P. Kimberly[5], Marta E. Alarcón-Riquelme[1], Carl D. Langefeld[6], Betty P. Tsao[7], Lindsey A. Criswell[8], Chaim O. Jacob[9], Patrick M. Gaffney[1], Kathy L. Moser[1], Judith A. James[1] and Courtney G. Montgomery[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Cincinnati, OK, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]King's College London, Guy's Hospital, London, United Kingdom, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Wake Forest University Health Sciences, Winston-Salem, NC, [7]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [8]Rosalind Russell Medical Research Center for Arthritis, Department of Medicine, University of California San Francisco, San Francisco, CA, [9]Keck School of Medicine University of Southern California, Los Angeles, CA

Background/Purpose: Systemic lupus erythematosus (SLE) is a prototypic systemic autoimmune disease characterized by multi-organ-system involvement and the production of autoantibodies that can lead to tissue inflammation, destruction of cells and even end-organ damage. Susceptibility to SLE is likely to arise from a complex network of gene-environment interactions. Several studies support these contributions of environmental exposure to the development of disease. A temporal sequence of specific immune targets of select autoantibodies is observed in patients prior to disease classification and in phases of early pathogenesis. Curiously these autoantibodies are closely related to the antibodies that emerge in some lupus patients in response to viral infection, specifically Epstein-Barr Virus (EBV). In this study, we conduct a genome-wide association study (GWAS) of the three initial humoral antigenic epitopes of Sm B' (PPPGMRPP), Sm D1 (a Gly-Arg repeat) and 60kD Ro (amino acids 169–180) to evaluate the genetic influence on the production of these early autoimmune antigenic structures in SLE cases.

Methods: A sample of 703 independent SLE patients of European descent was recruited from multiple institutions and their genotypes were obtained from several large-scale genetic studies. Sera of these patients were tested for antibodies directed against early humoral epitopes of Sm B' (PPPGMRPP), Sm D1 (GRGRGRGR) and 60kD Ro (TKYKQRNWSHK) constructed on poly-lysine backbones. We used enzyme-linked immunosorbent assays (ELISA) to quantify levels of autoantibody response directed against each epitope. Box and Cox transformation was applied to epitope variables that did not fulfill the normality assumption. Genome-wide imputation was performed using IMPUTE2 and the phase III Hapmap panel for 659,676 observed single-nucleotide polymorphisms (SNPs). After quality control, the final genotype sample comprised 581,509 SNPs. We tested for association between the epitopes as quantitative traits and the genetic variants using multiple linear regression under an additive model, adjusting for gender and global ancestry.

Results: After performing stringent quality control, no effects met the Bonferroni corrected threshold of $p < 8.60\times10^{-8}$. However, several regions were significant at a suggestive level ($p< 1\times10^{-4}$) in *RYR2* ($p=1.95\times10^{-6}$), *GTDC1* ($p=1.06\times10^{-5}$) and *NAALADL2* ($p=1.72\times10^{-6}$) for anti-Sm B', anti-Sm D1 and anti-60kD Ro epitopes, respectively. Genes previously shown to be associated with SLE were also evident in the study, particularly *JAZF1* ($p=0.000456$) for anti-Sm B', *KIAA1542* ($p=0.000204$) and *XKR6* ($p=0.0001$) for anti-Sm D1 and *PXK* ($p=0.00058$) for anti-60kD Ro epitopes.

Conclusion: Our results demonstrate the potential power gained by examining more precise phenotypes and refines the association of previously reported SLE genes to the production of these antigenic responses. Overall, our study presents the first evidence of genetic associations with early lupus autoimmunity. It also highlights the importance of examining sub-phenotypes of a complex disease and further supports the involvement of gene by environment interactions toward initiating specific lupus autoimmune responses.

Inhibited Expression of HPK1 Associated with Loss of JMJD3 Promoter Binding Contributes to Autoimmunity in Systemic Lupus Erythematosus. Qing Zhang, Hai Long, Jieyue Liao, Ming Zhao, Gongping Liang, Xiaoyan Wu, Peng Zhang, Shu Ding, Shuangyan Luo and Qianjin Lu. Second Xiangya Hospital, Central South University; Hunan Key Laboratory of Medical Epigenomics, Changsha, China

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by T cell overactivation and B cell hyperstimulation. Hematopoietic progenitor kinase 1 (HPK1, also called MAP4K1) negatively regulates T cell-mediated immune responses. However, the role of HPK1 in the development of SLE remains poorly understood. This study investigated whether HPK1 played roles in the pathogenesis of SLE and what regulated HPK1 expression.

Methods: HPK1 and JMJD3 mRNA and protein levels were determined by real-time RT-PCR and western blotting. Detection of IFN-α and IgG levels were performed by ELISA. Cell proliferations were evaluated with MTT assay. Amounts of histone H3 lysine 27 trimethylation (H3K27me3), JMJD3, and EZH2 within the HPK1 promoter were analyzed by chromatin immunoprecipitation (ChIP) and real-time PCR.

Results: We found that HPK1 mRNA and protein levels were significantly decreased in CD4+ T cells of patients with SLE, and that down-regulation of HPK1 in healthy CD4+ T cells significantly accelerated T cell proliferation and production of IFNα and IgG. Consistent with these findings, overexpressing HPK1 in SLE CD4+ T cells caused the opposite phenotypes. In addition, we found that H3K27me3 enrichment at the HPK1 promoter was significantly higher in SLE CD4+ T cells than in healthy controls. We also observed a decrease in JMJD3 binding, but no marked change in EZH2 binding at the HPK1 promoter region in SLE CD4+ T cells compared to healthy controls. Knocking down JMJD3 with siRNA in healthy CD4+ T cells led to decreased JMJD3 binding and increased H3K27me3 enrichment at the HPK1 promoter, thus inhibiting the expression of HPK1. Concordantly, plasmid-induced overexpression of JMJD3 in SLE CD4+ T cells had the opposite effect.

Conclusion: These findings indicate that inhibited HPK1 expression in SLE CD4+ T cells is associated with loss of JMJD3 binding and increased H3K27me3 enrichment at the HPK1 promoter, contributing to T cell overactivation and B cell overstimulation in SLE.

Increased IL-21R Expression and Signaling in B Cells From Patients with Systemic Lupus Erythematosus. Vinh Nguyen[1], Horea Rus[2] and Violeta Rus[2]. [1]Univ of Maryland Schl of Med, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD

Background/Purpose: IL-21 exerts an autocrine effect on T follicular B helper cells (TFH) cells and also stimulates B cell proliferation, plasma cell (PC) differentiation and germinal center (GC) expansion. Studies in murine models of lupus have indicated increased production of IL-21 and attenuation of autoimmune features following IL-21 blockade. Recent studies have also revealed a strong association between genetic polymorphisms in IL-21 and IL-21R and systemic lupus erythematosus (SLE), suggesting a role for IL-21 in human SLE. We have previously reported elevated serum levels of IL-21 and increased mRNA and intracellular expression of IL-21 in CD4+ T cells from patients with SLE. These data implicate IL-21 in disease pathogenesis and suggest that IL-21 blockade may be an attractive therapeutic option in SLE. However, there are limited data on the effect of IL-21/IL-21R interaction on B cells in patients with SLE. To address this issue we analyzed the expression and binding availability of IL-21R on subsets of B cells from lupus patients compared to controls as well as the response of lupus B cells to exogenous or endogenous IL-21 with respect to proliferation, STAT-3 phosphorylation and PC differentiation.

Methods: The expression of IL-21R in purified B cells was detected by flow cytometry and PCR. Levels of IL-21R available for binding were detected on naïve and memory B cells by flow cytometry using biotinylated rhIL-21. Phosphorylation of STAT-3, the major signaling molecule induced by IL-21, was detected by intracellular staining of purified B cells incubated for 30 minutes with 0.1, 1 or 10 ng/ml rhIL-21. In vitro proliferation and PC differentiation of purified B cells stimulated with anti-CD40 in the presence or absence of rhIL-21 or in coculture with purified CD4 T cells stimulated with anti-CD3 were detected by thymidine incorporation and flow cytometry, respectively.

Results: IL-21R mRNA expression was 1.5 fold higher in lupus patients vs. controls and displayed a trend toward increased surface expression, although the difference was not statistically significant. Similarly, the total available receptors for binding IL-21 were increased on both naive and memory B cells from lupus patients suggesting that increased serum levels of IL-21 and IL-21/IL-21R interactions do not alter the availability of IL-21R on B cells. Phosphorylation of STAT-3 was increased in lupus B cells vs. controls and reached statistical significance at the lowest dose ($p=0.03$). In concordance with the increased surface expression and enhanced signaling through IL-21R, lupus B cells exhibited higher proliferation rates in coculture with anti-CD3 stimulated CD4 T cells or in response to rhIL-21, ($p<0.05$). In addition, anti-CD40 induced PC differentiation was significantly higher in the presence of IL-21 in patients compared to controls ($p=0.02$).

Conclusion: These results suggest that the IL-21/IL-21R pathway is aberrantly expressed in patients with lupus through both increased production of IL-21 by CD4 cells and increased expression, availability and responsiveness of IL-21R by lupus B cells. These data suggest that IL-21 can be targeted therapeutically in SLE.

High Plasma Microparticle-IgG Burden Characterizes Systemic Lupus Erythematosus Patients and Is Associated with Autoantibodies Against DNA and C1q and Activation of the Complement System. Christoffer T. Nielsen[1], Ole Østergaard[2], Line Stener[1], Line V. Iversen[1], Lennart T. Truedsson[3], Søren Jacobsen[4] and Niels H.H. Heegaard[1]. [1]Statens Serum Institut, Copenhagen S, Denmark, [2]Statens Serum Institute, Copenhagen S, Denmark, [3]Dept of Clinical Sciences Lund, Section of Microbiology, Immunology and Glycobiology, Lund, Sweden, [4]Rigshospitalet - 4242, Copenhagen, Denmark

Background/Purpose: Circulating plasma microparticles (MPs), a heterogenous pool of submicron cell-derived membranous vesicles, is suspected as carriers of autoantigens and precursors of immune complexes (ICs) triggering the immune system in systemic lupus erythematosus (SLE). We wanted to characterize immunoglobulins and complement on circulating cell-derived microparticles (MPs) in systemic lupus erythematosus (SLE) and explore correlations between the MP-immunoglobulin burden and clinical and serological parameters.

Methods: IgG on MPs was characterized by flow cytometry in samples from 68 clinically well-characterized SLE patients and 38 healthy controls (HCs). MPs with IgG-, IgM- and C1q were analyzed using both flow cytometry and quantitative mass spectrometry in a subset of SLE and patients and in control samples from HCs, systemic sclerosis (SSc), and rheumatoid arthritis (RA) patients.

Results: SLE patients had significantly increased total and relative numbers of IgG-positive MPs ($p=0.0004$) with a much higher average IgG-load/MP ($p<0.0001$) than HCs. In subset analyses, IgG-positive MPs were also more numerous in SLE than in RA samples ($p=0.03$). In both RA and SSc the average IgG-load/MP was significantly lower than in SLE ($p=0.006$ and 0.05, respectively). Also the IgM and C1q-loads/MP were higher in SLE than in all the controls ($p<0.05$) except for IgM in the RA-group. Mass spectrometry confirmed increased MP-associated IgG, IgM and C1q in SLE. IgG-positive MPs were significantly associated with the presence of anti-dsDNA, with total IgG levels, and with decreased leukocyte levels. The average IgG-load/MP was associated with lower total concentrations of MPs, presence of anti-C1q, and highly significantly with the consumption of complement components.

Conclusion: Circulating cell-derived MPs in SLE carry significantly increased loads of IgG, IgM, and C1q. This is likely to be important for disease etiology and for the sustained systemic pro-inflammatory activities characteristic of SLE.

Enhanced Apoptosis and Senescence of Bone Marrow-Derived Mesenchymal Stem Cells From Patients with Systemic Lupus Erythematosus. Lei Liu, Defang Meng, Xia Li and Lingyun Sun. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background/Purpose: Previous studies have indicated that bone marrow mesenchymal stem cells (BMSCs) from patients with systemic lupus erythematosus (SLE) exhibit impaired capacities of proliferation, differentiation, secretion of cytokines and immune modulation. In this study, we aimed to investigate whether apoptosis and senescence of BMSCs from SLE patients were dysregulated.

Methods: BMSCs were isolated from bone marrow of SLE patients and healthy controls by density centrifugation and adhesive culture in vitro. TNF-a was added to detect its effect on the activation of apoptosis. The apoptosis of BMSCs was evaluated by TUNEL assay and Annexin

V-FITC/PI Apoptosis Detection. Real-time PCR technique was used to determine the gene expressions of Fas, Bcl-2, Bax, Bcl-w, Caspase 8 and TNFR or without with TNF-a. Cytochrome C was detected by immunocytochemistry. Western blot was used to detect the expressions of Fas, TNFR and Caspase 8. The expressions of Fas, Bcl-2 and the activity of Caspase 8 were detected by flow cytometry. Meanwhile, serum levels of FasL and TNF-a were measured by ELISA.

Results: The frequencies of apoptotic and ageing BMSCs from SLE patients were significantly increased in culture when compared with those of healthy controls. Notably, levels of Bcl-2 expression in BMSCs from SLE patients were markedly deceased both at mRNA and protein levels. When BMSCs were induced to apoptosis in vitro stimulated by TNF-a, the Bax and Caspase 8 expressions in BMSCs from SLE patients were significantly inceased at mRNA levels. The activity of Caspase 8 was enhanced in BMSCs from SLE patients. More cytochrome C positive pellets in the cytosolic fraction were detected in BMSCs from SLE patients compared with healthy controls. The expressions of Fas and TNFR1 on BMSCs from SLE patients were significantly upregulated compared to healthy controls as well as serum level of FasL and TNF-a. Moreover, intracellular ROS levels of BMSCs from SLE patients were higher than those of healthy controls characterized with the activation of PI3K/AKT/FoxO3 signaling pathway.

Conclusion: Our results have demonstrated increased apoptosis and senescence in BMSCs from SLE patients, which may be associated with the pathogenesis of SLE.

654

Activated NF-Kb in Mesenchymal Cells From SLE Patients Inhibits Osteogenic Differentiation Through Down-Regulating Smad Signaling. Yu Tang, Jiyun Zhang and Lingyun Sun. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background/Purpose: The osteoporosis of patients with systemic lupus erythematosus (SLE) is thought to be the results of over-osteoclastogenesis induced by pro-inflammatory cytokines such as TNF-a. However, the osteoblastogenesis in SLE patients is unclear. We investigated the (Bone morphogeneic protein) BMP-2-induced osteoblastic capacity of bone marrow-derived mesenchymal stem cells (BMMSCs) from SLE patients and the TNF signaling system in determining BMP-2-induced the regulatory pathways.

Methods: BMMSCs were differentiated into osteoblasts in vitro stimulated by BMP-2 and the osteogenic capacity was quantitated. cDNA microarray was performed between BMMSCs from four SLE patients and four healthy controls, and differentially expressed genes in BMP/TGF-β signaling pathway were analyzed. The activation of BMP/Smad and NF-κB signaling pathways in SLE-BMMSCs were evaluated by detecting the phosphorylated Smad1/5/8 (p Smad1/5/8) and I-κB. TNF-a was added and its effect on the activation of pSmad1/5/8 and BMP-2-induced osteogenic differentiation of normal BMMSCs was determined, while PDTC, a NF-κB inhibitor, was used to examine its effect on that of SLE-BMMSCs. Finally, BMP-2 level in the serum from SLE patients were detected by ELISA.

Results: The capacity of osteogenic differentiation of BMMSCs from SLE patients reduced as compared with that from healthy controls. The NF-κB signaling was active, while the BMP/Smad pathway was repressed in the BMMSCs from SLE patients. TNF-a activated NF-kB pathway and inhibited the phosphorylation of Smad 1/5/8 and BMP-2-induced osteoblastic differentiation in normal BMMSCs, while addition of PDTC to SLE-BMMSCs could partially restore them. The BMP-2 level was lower in the serum of SLE patients.

Conclusion: Our findings suggest that the activated NF-κB pathway in SLE-BMMSCs inhibits the BMP-2-induced osteoblastic differentiation through BMP/Smad signaling pathway. The inadequate osteoblastic differentiation may participate in the pathology of osteoporosis in SLE patients.

655

High Oxidation Status Induced the Rearrangement of F-Actin Cytoskeleton of Bone Marrow-Derived Mesenchymal Stem Cells in Patients with Systemic Lupus Erythematosus Via Downregulation of RhoA Signaling Pathway. Dongyan Shi, Xia Li and Lingyun Sun. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background/Purpose: Systemic lupus erythematosus (SLE) is described as a hematopoietic stem cell disorder and bone marrow-derived mesenchymal stem cells (BMMSCs) from SLE patients is proved to be abnormal in their functions. This study was undertaken to determine the effect of oxidation status on F-actin cytoskeleton and RhoA signaling pathway in BMMSCs from SLE patients

Methods: The F-actin cytoskeleton was observed by fluorescence microscopy after staining with Alexa Fluor 594 phalloidin. Transwell system was performed to determine the migration ratio of MSCs. RT-PCR and western blot were carried out to detect changes of RhoA signaling pathway. Serum level of SOD-1 was examined by ELISA and ROS level of MSCs was tested by flow cytometry. In order to investigate the effect of oxidation status on F-actin cytoskeleton of MSCs, 20mM H_2O_2 was added into the growth medium of normal MSCs 1h before testing and 0.2mM NAC, an antioxidant, was added into the growth medium of SLE MSCs.

Results: F-actin cytoskeleton of MSCs was rearranged in SLE patients. The percentage of abnormal MSCs was significantly higher in SLE patients than that of normal controls and increased as they were passaged. The migration capacity was also impaired as passaged. Both of the mRNA level and protein expressions of RhoA, which participates in a main regulatory signaling pathway of F-actin cytoskeleton and cell migration, were downregulated in SLE MSCs. Reduced serum SOD-1 level and higher intracellular ROS level suggested high oxidation status in SLE patients. H_2O_2, as an exogenous oxidant, induced upregulation of ROS level in normal MSCs. As a result, the F-actin cytoskeleton was rearranged and subsequently reduced migration ratio. While NAC, which downregulated ROS level, reversed the rearrangement of F-actin cytoskeleton and the impairment of migration capacity of SLE MSCs. RhoA expression was downregulated by H_2O_2 while upregulated by NAC.

Conclusion: These experimental findings suggest that the rearrangement of F-actin cytoskeleton of MSCs in SLE patients leads to the impairment of their migration capacity, which may result from the high oxidation status via downregulation of RhoA.

656

A Paradoxical Increase in Th17 Cells in Patients with High Interferon Activity in Systemic Lupus Erythematosus. Vivian V. Stone, Thomas H. Teal, Pradipta Ghosh, Jeffrey A. Ledbetter and Keith B. Elkon. University of Washington, Seattle, WA

Background/Purpose: Increased expression of type I interferons (IFN) is reported in ~60% of SLE patients and is strongly implicated in the pathogenesis of SLE. Recently, several groups have reported that some SLE patients, particularly those with nephritis, have increased numbers of Th17 cells in the blood and kidneys. An increase in the number of Th17 cells in SLE is surprising because type 1 IFN suppresses Th17 proliferation and differentiation *in vitro*. Furthermore, type 1 IFN is widely used for the treatment of multiple sclerosis where its mechanism of action is thought to be suppression of Th17 cells. Based on these findings, we tested the hypothesis that increased Th17 cells are predominantly observed in SLE patients with a low IFN score.

Methods: IFN activity was measured using real-time quantitative PCR to determine mRNA expression of three interferon stimulated genes (ISG)—MX1, CXCL10 and PKR—in peripheral blood mononuclear cells obtained from 68 lupus patients and 23 healthy controls. Interferon stimulated gene (ISG) scores were calculated as the number of standard deviations (SD) above the mean of the controls and total IFN score was calculated as the sum of the 3 ISG scores. A high IFN score is defined as >2 SDs above mean control score. Th1 and Th17 cells were quantified by intracellular staining for IFN-g and IL-17 by flow cytometry following PMA/Ionomycin stimulation in 50 SLE patients and 27 controls. A high %Th17 cells is defined as >2 SDs above the mean of the controls. Disease activity was assessed at the time of blood collection using the SELENA-SLEDAI disease activity index (active disease = SLEDAI>5).

Results: High IFN scores were found in 73% of lupus patients. Patients with high IFN scores trended to more active disease ($p=0.05$). A higher %Th17, but not Th1, T cells was also found in SLE patients compared to controls ($p<0.05$), and patients with high Th17 cells had more active disease ($p<0.05$). Higher %Th17 cells were found in patients with active disease ($p<0.01$), renal disease ($p<0.001$), and low complement ($p<0.01$) compared with controls. Contrary to expectations, higher %Th17 cells were found in lupus patients with high IFN scores compared to controls ($p<0.01$). To define more precisely the relationship between Th17 cells, IFN-a and their clinical correlates, patients were divided into 4 groups: 1) high IFN only (n=14), 2) high Th17 only (n=1), 3) high in both cytokines (n=9), and 4) low in both cytokines (n=9). Patients with elevations in both IFN and Th17 had the

highest percentage (45%) of renal disease; while patients with only high IFN had the highest percentages of skin and joint disease (30% in each group).

Conclusion: There are four main conclusions: 1) Increased %Th17 cells are more strongly associated with active disease than IFN scores. 2) The paradoxically higher percentages of Th17 cells in patients with high IFN scores suggests that in some SLE patients, type I IFN fails to suppress the Th17 pathway. 3) Evaluation of cytokine combinations is likely to be more powerful correlates and, perhaps, predictors of clinical subsets of disease. 4) SLE therapy may need to target more than one cytokine in individual patients, especially those with renal disease.

657

Abnormal Electron Transport Chain Activity in Mitochondria of Peripheral Blood Lymphocytes From Patients with Systemic Lupus Erythematosus. Edward Doherty[1] and Andras Perl[2]. [1]SUNY Upstate, Syracuse, NY, [2]Upstate Medical University, Syracuse, NY

Background/Purpose: T cells from patients with systemic lupus erythematosus (SLE) exhibit an elevation of the mitochondrial transmembrane potential ($\Delta\Psi_m$) or mitochondrial hyperpolarization (MHP) and increased mitochondrial mass which have been linked to increased production of nitric oxide (NO) and reactive oxygen intermediates (ROI). Here, we investigated the role of the electron transport chain (ETC) in MHP of patients with SLE.

Methods: We studied peripheral blood lymphocytes (PBL) from 17 SLE subjects and from 10 healthy subjects, matched for age within ten years, gender and ethnicity of the patients. Mitochondrial O_2 consumption was measured in 1) freshly isolated PBL, 2) PBL rested overnight, and 3) PBL stimulated overnight through CD3/CD28, using Clark-type O_2 electrode (Hansatech, Norfok, UK). Cell viability, mitochondrial mass, $\Delta\Psi_m$, NO, ROI, and Ca^{2+} were assessed by flow cytometry.

Results: Freshly isolated lupus PBL exhibit moderately decreased O_2 consumption through complex II (−18% ±0.30; p=0.011). However, after resting overnight in culture medium, lupus PBL show increased O_2 consumption through complex II (+38% ±0.31; p=0.015). Following overnight stimulation with anti-CD3, O_2 consumption is increased by lupus mitochondria through complexes I (2.26-fold ±0.27; p=0.001) and IV (+14% ±0.57; p=0.040). In accordance with our earlier findings, resting SLE T cells have increased $\Delta\Psi_m$ (DiOC6: 19% ±0.07; p=0.022), mass (NAO: +10% ±0.09; p=0.037), Ca^{2+} (Rhod-2: +10% ±0.06), NO (DAF-FM: +9% ±0.06), nitrite (DAR-4M: +10% ± 0.06), and H_2O_2 levels (DCF-DA: +10% ±0.04; p=0.035). There was a negative correlation between 1) NO production and O_2 consumption through Complex II (r= −0.559; p = 0.011) and 2) H_2O_2levels and O_2 consumption through Complex IV (r = −0.364; p = 0.035). O_2 consumption through complex I by CD3-stimulated PBL negatively correlated with increased NO (r = −0.143; p = 0.036). O_2 consumption through complex IV by CD3-stimulated PBL positively correlated with $\Delta\Psi_m$ (r = 0.591; p = 0.002) and mitochondrial mass (r = 0.267; p = 0.036). In vitro addition of 600μM NOC-18, an NO donor, directly inhibited O_2 consumption through complex I in healthy but not in lupus PBL.

Conclusion: The results suggest that MHP and increased mitochondrial mass are associated with increased ETC activity by mitochondria of SLE PBL. The negative correlation of O_2 consumption with increased NO production and H_2O_2levels indicate that these two metabolites may impair ETC activity and enhance mitochondrial biogenesis in lupus PBL. Along this line, blockade of ETC activity by NO in healthy but not by lupus mitochondria indicate pre-existing damage in patients with SLE. Such ETC defect may underlie the MHP and altered T cell activation in SLE.

658

The Monitoring of FoxP3 Expressing CD4+ T Cell Subsets May Be Helpful for the Prediction of Systemic Lupus Erythematosus Flares. Makoto Miyara[1], Alexis Mathian[1], Julien Haroche[1], Laurent Arnaud[2], Driss Chader[1], Lucile Musset[1], Guy Gorochov[1] and Zahir Amoura[1]. [1]CHU Pitié-Salpêtrière, Paris, France, [2]Paris, France

Background/Purpose: Based on the functional delineation of FoxP3 expressing $CD4^+$ T cell subsets that we defined recently, we have shown that perturbation in Treg cell homeostasis may participate in the immunopathogenic mechanisms that lead to SLE flares. Whether modifications in FoxP3 expressing $CD4^+$ T cell subsets are observed in patients before they develop SLE flares has not been determinde yet.

Methods: Patients with inactive SLE (SLEDAI <6, n=45) were included for a 6 month follow-up. Clinical and biological evaluation of SLE activity and analysis of the proportions of FoxP3 expressing subsets were performed every 2 months. Normal values of each FoxP3 expressing $CD4^+$ T cell subsets were defined in a cohort of 50 healthy donors as follows: naïve Treg cells (nTreg) defined as $CD4^+FoxP3^{low}CD45RA^+$ cells: 2.4% (1–4.5%), effector Treg cells (eTreg) as $CD4^+FoxP3^{high}CD45RA^-$ cells: 1.55% (1–3%) and FoxP3 non Treg cells ($FoxP3^+$nonTreg) defined as $CD4^+FoxP3^{low}CD45RA^-$: 3.05% (1.3–5.8%).

Results: 20 patients (44.4 %) had normal proportions of nTreg, eTreg and $FoxP3^+$nonTregs at inclusion. The most frequent anomaly was an isolated increase in the proportion of $FoxP3^+$nonTregs (n=11, 24.4%). Other anomalies were: decrease in eTreg (n=2, 4.4%), decrease in nTreg cells (n=2, 4.4%), increase in nTreg cells (n=2, 4.4%), increases in both $FoxP3^+$nonTreg and nTreg (n=4, 8.8%), combination of increase in FoxP3+nonTreg and decrease in nTreg, (n=3, 6.6%), decrease in both nTreg and in eTreg (n=1, 2.2%). Increase in $FoxP3^+$nonTreg was thus observed in 18 patients (40%), decrease in nTreg in 6 (13%), increase in nTreg in 6 (13%) and decrease in eTreg cells in 3 patients (6.7 %).

Only one patient among the patient that did not display anomalies in any FoxP3 expressing subset at inclusion developed a mild flare (arthritis, 5%) while, among those with anomalies, 5 patients developed SLE flares including 2 nephritis (20%). The most prevalent anomaly observed before flares was an increase in $FoxP3^+$nonTreg (n=4) while an increase in nTreg was observed in 3 patients, a decrease in nTreg in 2 and a decrease in eTreg cells in 3.

Among the 25 patients that had anomalies at inclusion, only 4 of them returned to normal proportions. None of them developped SLE flare. Among the 21 patients that kept anomalies, 5 of them developed SLE flares (25%). Most patients without anomalies at inclusion (n=20) developed a new anomaly 6 months later (n=12, 60%) that was mainly an increase in FoxP3+nonTreg (n=8, 75%). Of note, the last patient that developed a mild SLE flare belonged to this group. Thus, 8 patients kept normal proportions of FoxP3 expressing subsets and did not develop SLE flare.

Conclusion: Although phenotypically similar, inactive SLE patients have different patterns in the proportions of FoxP3 expressing $CD4^+$ T cell subsets. Most patients that developed SLE flares during the 6 month follow-up had anomalies in FoxP3 expressing $CD4^+$ T cells subset before flares while those who maintained the absence of anomaly did not develop flares. The monitoring of $FoxP3^+$ $CD4^+$ T cell subsets may be a novel efficient parameter for the prediction of SLE flares in SLE outpatients.

The study was supported by ARTHRITIS Fondation Courtin

Hypermethylation of CD3*Z* Promoter CpG Islands in Patients with Autoimmune Diseases Including Systemic Lupus Erythematosus. Kyeong-Man Hong[1], Hyun-Kyoung Kim[1], Seong-Yeol Park[1], Yong-Bock Choi[1], Mi-Kyeong Kim[1], Ji Ah Park[2], Eun Young Lee[2], Eun Bong Lee[2] and Yeong Wook Song[2]. [1]National Cancer Center, Goyang, South Korea, [2]Seoul National University Hospital, Seoul, South Korea

Background/Purpose: To assess the role of epigenetic factors in autoimmune disease, systemic lupus erythematosus (SLE) was used as a model system because lots of epigenetic importance has been demonstrated.

Methods: microarray analysis and quantitative measurements of methylated promoters in whole blood DNAs of patients with autoimmune disease including SLE, rheumatoid arthritis and systemic sclerosis

Results: A significantly increased *CD3Z* promoter methylation was found in SLE patients (n=114) compared to healthy control (n=105, p <0.0001 with OR = 20.6). Increased methylation levels were also observed in affected discordant monozygotic twins (4 pairs). Moreover, the level of methylation was significantly higher in active SLE patients (n=108) than inactive cases (n=6, p=0.0075). In patients with rheumatoid arthritis (n=19) or systemic sclerosis (n=18), increased *CD3Z* promoter methylation was also observed, suggesting increased *CD3Z* methylation is a common phenomenon in autoimmune disease. In addition to *CD3Z*, increased promoter methylations of two other genes, *ADA* and

VHL, were also found in blood cell DNAs from patients with autoimmune diseases.

Conclusion: Our results not only indicate that epigenetic components in blood cells might be fluctuating more profoundly and often especially in disease status, but also provide a model system to support the importance of epigenetic changes for the clinical manifestation of disease.

Comprehensive Screening for Primary Immunodeficiencies Shows Unexpectedly High Frequency of Selective IgM Deficiency in Systemic Lupus Erythematosus. Sandro F. Perazzio[1], Neusa P. Silva[2], Reinaldo Salomao[1] and Luis Eduardo C. Andrade[3]. [1]Federal University of Sao Paulo, Sao Paulo, Brazil, [2]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo and Fleury Health and Medicine Laboratories, Sao Paulo Brazil, Sao Paulo, Brazil

Background/Purpose: Systemic Lupus Erythematosus (SLE) is known to be associated with deficiency of C1q, C4, and C2. There is high frequency of discoid lesions (2.7%) and SLE (0.5%) in Chronic Granulomatosus Disease (CGD). Selective IgA Deficiency (SIgAD) has been associated with juvenile (5.2%) and adult (2.6%) SLE. About 25% of patients with Common Variable Immunodeficiency (CVID) develop autoimmune manifestation, including SLE. Although there are reports of individual primary immunodeficiency (PID) in SLE, there is no systematic study estimating the fraction of SLE patients presenting a comprehensive array of PID. We present preliminary results of an ongoing study aimed to estimate the prevalence of overall PID in a cohort of SLE patients and age- and gender-matched healthy controls, and to compare the clinical characteristics of the SLE patients with and without PID.

Methods: 265 SLE patients and 215 controls recruited among blood donors underwent clinical examination and were evaluated for C2, C3, mannose binding lectin (MBL), immunoglobulin isotypes, and quantification of the oxidative burst in neutrophils. Those who presented any laboratory indication of PID were submitted to a novel examination within 60 days for confirmation. Cases under disease activity were followed and submitted to novel examinations after the end of the flare or excluded if no remission was attained up to the end of the project. PID was established after confirmation of abnormal results in a second evaluation and after disease remission.

Results: Altogether there were 27 SLE patients and four controls with established diagnosis of PID ($p<0.01$). PIDs in SLE patients included Selective IgM Deficiency (SIgMD) (n=19), SIgAD (n=2), SIgGD (n=6, all due to lower IgG1 serum component). No patient presented evidence of Hyper-IgM Syndrome, MBL deficiency, CVID, and CGD. There was one female patient with neutrophil oxidative burst compatible with CGD gene carrier status. There was isolated reduction of C2 or C3 in eight patients but these were not classified as PID at this moment because these results must be confirmed by genotyping. As expected, there was higher frequency of hypergammaglobulinemia (high IgA and IgG levels) in SLE (40%) as compared to controls (6%) ($p<0.001$). SLE patients with and without evidence for PID did not differ with respect to clinical manifestations, immunosuppressant use, infection rate and severity, SLEDAI, and age at disease onset.

Conclusion: These preliminary findings demonstrate high frequency of overall PID in SLE, suggesting that an immunodeficient state PID might represent a risk factor for SLE development. The unexpected high frequency of SIgMD appears to indicate an intriguing aspect of SLE pathophysiology since IgM is important for immunocomplex and pathogen clearance. Therefore, low IgM levels might induce a state of frequent and persistent immunological stimulation, which may culminate in autoimmunity development.

661

Altered Selection Leads to Expansion of the Anergic IgM$^-$ B Cell Population in SLE. Julie Kim[1], Nan-Hua Chang[1], Murray B. Urowitz[2], Dafna D. Gladman[3], Paul R. Fortin[2] and Joan E. Wither[1]. [1]Toronto Western Research Institute, University Health Network, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Recently, the IgM$^-$IgD$^+$ naïve B cell population in healthy humans was identified as a naturally auto-reactive subset that is functionally anergic. Here, we examined this population in SLE patients and controls.

Methods: Patients (N=75) satisfying at least 4 ACR criteria for SLE and 37 healthy age-matched controls without a family history of systemic autoimmune disease were recruited. Naïve B cells (CD19$^+$CD27$^-$IgD$^+$) that were categorized to be mature (CD38$^+$, CD24$^+$ or CD10$^+$) or transitional (CD38^{++}, CD24^{++} or CD10^{++}) were identified by flow cytometry following staining of PBMC. Identification of IgM$^-$and CD86$^+$ populations was determined by FMO controls. The IgM$^+$ population was stratified into two groups (IgM^{lo} and IgM^{hi}) based on contour plots. B cell signaling was examined using Phosflow.

Results: There was an increased proportion of IgM$^-$cells within the mature naïve and transitional B cell compartments of SLE patients vs. controls (mature $p = 0.003$; transitional $p = 0.020$). In SLE patients and controls there was a significant trend to increased proportions of CD86$^+$ cells with decreasing levels of IgM ($p < 0.0001$). Although increased proportions of CD86$^+$cells were seen in SLE vs. controls for all IgM populations, this only achieved significance for the mature IgM^{lo} subset. Notably, a substantial (0–80%) proportion of IgM$^-$ mature B cells expressed CD86, suggesting that they had been recently activated. Consistent with this possibility, basal levels of pPLCγ2 were elevated in a significant proportion of these cells. To determine whether the IgM$^-$ cell population was anergic, cells were stimulated with anti-IgD. The proportion of cells that upregulated pPLCγ2$^+$ following anti-IgD stimulation was significantly reduced with decreased cell surface expression of IgM. Nevertheless, some upregulation of pPLCγ2 following anti-IgD stimulation was retained in IgM$^-$ cells, which was slightly reduced in SLE patients. To investigate whether the expanded IgM$^-$ population in SLE results from an altered B cell signaling threshold, the correlation between the proportion of IgM$^-$ cells and upregulation of pSYK$^+$ or pPLCγ2$^+$ with anti-IgM or -IgD stimulation was examined. No association was seen. However, comparison of the proportion of IgM$^-$ cells in the transitional vs. mature naïve subsets indicated that SLE patients with high proportions of IgM$^-$ cells within their transitional subset also had high proportions of IgM$^-$ cells in their mature subset, whereas for controls the proportion of IgM$^-$ cells in the mature B cell subset became normalized.

Conclusion: The IgM$^-$ naïve B cell population is equivalently refractory to activation in SLE patients and controls. Some of these cells appear to recently activated, rather than anergic cells. The expansion of the IgM$^-$ population in SLE patients may result from altered selection at the transitional to mature stage of B cell development.

Auto-Reactive IgEs and Basophils in Systemic Lupus Erythematosus. Barbara Dema[1], Sarfaraz A. Hasni[2], Chao Jiang[1], Donna F. Hardwick[3], Nicolas Charles[4], Gabor G. Illei[5] and Juan Rivera[1]. [1]Laboratory of Molecular Immunogenetics, NIAMS, NIH, Bethesda, MD, [2]National Institutes of Health, Bethesda, MD, [3]NIH MSC 1616, Bethesda, MD, [4]Institut national de la Sante et de la Reserche Medicale, Paris, France, [5]NIDCR/ NIH #10 1N110, Bethesda, MD

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disorder that can lead to kidney failure as a consequence of the deposition of immune complexes (ICs) in the glomeruli. Previous studies in mice deficient in the Src family protein tyrosine kinase Lyn, which develop a lupus nephritis-like phenotype, indicated an involvement of basophils in the development of this disease. IgE present in the circulating ICs of these mice promoted the activation of basophils, IL-4 production and thus, autoantibody production and disease amplification. Furthermore, the presence of circulating anti-dsDNA IgE in a small cohort of SLE patients was found to be associated with active lupus nephritis and with the presence of activated basophils in secondary lymphoid tissue. In the current study we first explore whether auto-reactive IgE is found in other mouse models of spontaneous lupus-like disease. We also investigate the role of auto-reactive IgE and basophils in a larger population of SLE patients. In addition, we investigate if IgE's with other antigen specificities play a role in disease development.

Methods: Blood samples from healthy blood donors (n=75) and patients that fulfilled the American College of Rheumatology classification criteria for SLE (n=99) were collected under a current NIH protocol after prior written informed consent. Disease activity was measured using SLE Disease Activity Index (SLEDAI) scores. Serum auto-reactive IgE antibodies were measured by ELISA and basophil markers were measured by flow cytometry (BD FACSCanto II, BDBioscience).

Results: Auto-reactive IgE and total IgE were significantly elevated in the *FcgRII*$^{-/-}$*.Yaa* mouse model of spontaneous lupus demonstrating the presence of auto-reactive IgE in this innate driven lupus model. In SLE patients, the levels of dsDNA and Sm/RNP specific IgE were significantly elevated when compared to healthy individuals. A stronger association was evident

with higher disease activity (SLEDAI≥4) when compared to patients with lower disease activity (SLEDAI <4). The levels of anti-dsDNA IgE correlated with the anti-dsDNA IgG, anti-Sm IgG and anti-Sm IgE in SLE patients. Moreover, we detected increased expression of the basophil activation marker (CD203c) and of the homing marker for secondary lymphoid tissues (CD62L or L-Selectin) on the surface of basophils from patients with modest to high disease activity (SLEDAI ≥4). This was consistent with a reduced proportion of circulating basophils in patients with modest to high disease activity.

Conclusion: Auto-reactive IgEs are present in a least two mouse models of spontaneous lupus; the previously reported *lyn*$^{-/-}$ mice and the herein reported *FcgRII*$^{-/-}$.*Yaa* mice. In patients, these IgE autoantibodies (dsDNA and Sm/RNP) are associated with increased disease activity. Other antigen specificities may also be important and this possibility is under investigation. Activated basophils may also amplify autoantibody production through their presence in secondary lymphoid organs and expression of markers that support T and B cell function. Our findings are consistent with a role for auto-reactive IgE and basophils in the development of lupus.

ZAS3 Is Overexpressed in Peripheral Blood Mononuclear Cells in Systemic Lupus Erythematosus Patients and Is Regulated by Estrogen: A Cause of the Dysreguated IL-2 Response? Nicholas Young, Alexandra Friedman, Francesca Madiai, Benjamin Kaffenberger, Lai-Chu Wu and Wael N. Jarjour. The Ohio State University Medical Center, Columbus, OH

Background/Purpose: Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease characterized by significant gender bias. Previous studies have demonstrated some of the contributions of hormones to SLE pathogenesis. Estrogen (E2) has been shown to regulate the expression of multiple genes by binding and activating estrogen receptors (ER) alpha and beta. While many ER-target genes have been previously described, recent evidence indicates that many others remain to be characterized. ZAS3 is a member of the Zas family of zinc-finger transcription factors. This subtype is rapidly degraded in primary lymphocytes ex vivo and thought to be involved in controlling cellular growth and inflammation. Studies have shown that ZAS3 expression inhibits nuclear translocation and DNA binding of NF-kB. Similarly, abnormal NF-kB activity has also been observed through cross-talk with hormone receptors and when SLE PBMCs are compared to healthy controls. Consequently, IL-2 production is decreased in SLE patients since NF-kB contributes to the transcriptional regulation of this promoter. To this accord, recent work has shown that transfection of p65 can restore IL-2 production in SLE T cells.

Methods: PBMCs of SLE patients and healthy controls were isolated to examine resting ZAS3 expression. ZAS3 was then measured with or without treatment with a physiological dose of E2 in these PBMCs and in cell lines. EMSA was performed with nuclear extracts to examine DNA-protein interactions in the ZAS3 genomic region. The *in vivo* effect on ZAS3 expression with E2 treatment was investigated through subcutaneous injections into wild-type B6 mice. Wild-type and ZAS3 −/− mice were challenged with LPS and IL-2 production was measured through cytokine assays of collected serum.

Results: Elevated ZAS3 mRNA levels were observed from PBMCs in whole blood samples of SLE patients when compared to healthy controls. In order to study the influence of E2 over ZAS3 expression, healthy human PBMCs were examined and displayed significantly induced ZAS3 expression with E2 treatment. This E2-induction was found to be dose dependent and endogenous ZAS3 was expressed primarily in T, B and breast cancer cell lines. In order to establish the validity of these *in vitro* observations, the *in vivo* E2-induced expression of ZAS3 was examined in B6 mice. Increased ZAS3 protein expression, by indirect immunofluorescence, was observed not only in lymph nodes and spleen but also the mammary gland. Mechanistic evidence of the direct role of E2 in the induction of ZAS3 expression was shown through EMSA analysis. Here, differential DNA binding in the ZAS3 region with the treatment of E2 was observed. LPS stimulation of wild-type and ZAS3 −/− mice illustrated the knockout of ZAS3 resulted in significantly elevated levels of IL-2.

Conclusion: ZAS3 expression is upregulated in resting PBMCs of SLE patients and is induced by E2. This was shown to be a direct E2 effect in a breast cancer cell line. Furthermore, a higher expression of ZAS3 was associated with a lower IL-2 production. Taken together, these data suggest that ZAS3 upregulation plays a significant role in SLE pathology by inhibiting NF-kB binding activity.

Elevated IgE Anti-Ds-DNA Levels Are Associated with Serological Disease Activity in Patients with SLE: Potential for a New Treatment Target. Sarfaraz A. Hasni[1], Barbara Dema[2], Donna F. Hardwick[3], Gema Souto-Adeva[4], Chao Jiang[5], Juan Rivera[2] and Gabor G. Illei[4]. [1]National Institutes of Health, Bethesda, MD, [2]Laboratory of Molecular Immunogenetics, NIAMS, NIH, Bethesda, MD, [3]NIH MSC 1616, Bethesda, MD, [4]NIDCR/ NIH #10 1N110, Bethesda, MD, [5]Laboratory of Immunogenetics, NIAMS, NIH, Bethesda, MD

Background/Purpose: Autoreactive IgE leads to activation of basophils and lupus-like nephritis in lyn −/− mice. Prior studies in subjects with Systemic Lupus Erythematosus (SLE) showed increased levels of IgE directed against ds-DNA. In this study we explored the correlation between IgE anti-ds-DNA levels and lupus disease activity.

Methods: We collected blood samples over a period of 8 months from patients followed under SLE natural history protocol. Demographic information, clinical manifestations, current medications and laboratory data were collected; disease activity was measured using SLE Disease Activity Index SELENA modification (SELENA/SLEDAI) scores. Serum IgE anti-ds-DNA was measured by our internally standardized ELISA. Statistical analysis was done using SAS Enterprise Guide 4.2 software (SAS Institute Inc. Cary, NC).

Results: In this cross-sectional study IgE anti-ds-DNA was measured on sera from 92 patients and 66 healthy controls. The average age of the patients was 41.5 yrs, 81/92 patients were females, 30 African-American, 31 white, 18 Hispanics and 13 were Asian. Mean SLEDAI score was 2 (min-max:0–37). Average serum IgE anti-ds-DNA level was 546.58 A.U. ±1760.32 (mean±SD) in patients and 22.71 A.U. ±93.32 (mean±SD) in healthy controls. Total serum IgE levels and IgE anti-ds-DNA levels did not correlate (Spearman Correlation Coefficient: 0.32) in a subset of 67 patients with available total serum IgE. IgE anti-ds-DNA levels correlated modestly with SLEDAI scores (Spearman correlation coefficient: 0.46). Median IgE anti-ds-DNA levels were higher (56.52 A.U.) in patients with SLEDAI≥4 (N=33) compared to those with SLEDAI<4 (0 A.U.)(N=59)(p value<.0001). In contrast to our previous findings, there was no difference in IgE anti-ds-DNA levels in patients with or without lupus nephritis (p-value 0.23). Levels of IgE-ds-DNA correlated modestly with IgG-ds-DNA (Spearman correlation coefficient:0.49). Complement proteins C3 and C4 trended inversely with IgE-ds-DNA levels(Spearman correlation coefficient:−0.44 and−0.42 respectively). Patients with hypocomplementemia (26/92) had a higher IgE anti-ds-DNA level (median 247.99 A.U.) compared to those with normal complement levels (median 1.19 A.U.) (p-value <0.0001).

Conclusion: Our results indicate that serologic activity in SLE includes increased production of IgE anti-ds-DNA antibodies. Levels of these autoreactive antibodies correlate with disease activity index and hypocomplementemia; suggestive of their role in disease pathogenesis. Based on this data we are planning a pilot treatment study using an anti-IgE monoclonal antibody.

SELF-Administered Systemic Sclerosis Questionnaire. Validation of A SPANISH Version (SYSQ) In Mexicans. Maria Pilar Cruz-Dominguez[1], Moises Casarrubias-Ramirez[1], Victor Gasca Martínez[1], Olga Lidia Vera Lastra[1], Luis J. Jara Quezada[2] and Daniel Hector Montes-Cortes[3]. [1]Hospital de Especialidades CMN La Raza, IMSS, Mexico, DF, Mexico, [2]Hospital de Especialidades CMN La Raza, IMSS, Mexico City, Mexico, [3]Hospital General CMN La Raza, IMSS, Mexico DF, Mexico

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease, characterized by systemic progressive fibrosis and frecuently severe functional alterations.

The purpose of this study was validate a Spanish version of The self-administered systemic sclerosis questionnaire (SySQ) to evaluate functional performance in patients with systemic sclerosis.

Methods: We conducted a trans-cultural and translation-retranslation validation of the original german version of the questionnaire. The second spanish version was submmitted to a panel of experts for face and content validity, and then used in a pilot test for final modifications. Type of study. Prospective, observational, cross-sectional and analytical study. We included patients with

diagnosis of scleroderma according to the criteria of The American College of Rheumatology, who signed informed consent and had complete clinical information to be evaluated with the severity scleroderma scale. We established a sample size of 50 subjects. Reliability analysis of SySQ, and severity index was done with Cronbach alpha (for each domain and the full questionnaire). The convergent construct validity was performed with a correlation analysis between SySQ and the severity scale for scleroderma. An $r \geq 0.4$ was considered good correlation with a significance level ≤ 0.05 (two-tailed).

Results: We included a total of 53 patients for the study. Age range was 17 to 81 years (mean ± SD.: 50.45 ± 14.05 years). α Cronbach's for the full questionnaire was 0.961. The Spearman's correlation coefficient was 0.526 between both instruments ($p<0.0001$)

Conclusion: The SySQ for scleroderma is a reliable and valid measure for functional performance in a Mexican sample of patients with scleroderma.

666

Marital Status in Systemic Sclerosis: Association with Pulmonary Function and Skin Involvement. Brock E. Harper[1], Shervin Assassi[2], Giovanni Geslani[3], Joanna Leung[3], Holly Bentz[1], Emilio B. Gonzalez[1], Hilda T. Draeger[4], Deepthi Nair[2] and Maureen D. Mayes[2]. [1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas Health Science Center at Houston, Houston, TX, [3]Galveston, TX, [4]Univ of TX Health Sci Ctr, San Antonio, TX

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disease associated with fatigue, depression, and work disability. Previous studies have shown that non-married SSc patients report more unmet psychosocial needs and feelings of disability compared to their married counterparts. Being married has been associated with less frequent work disability in other rheumatic diseases, including systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). No study to date has investigated the relationship between SSc and marital status. The goal of this study is to assess possible determinants of marital status in SSc.

Methods: Demographic data including age, gender, ethnicity, marital status (married, not married but living in a marriage-like relationship, divorced, separated, widowed and never married) and clinical data including extent of skin involvement as measured by modified Rodnan Skin Score (mRSS), forced vital capacity (FVC), disease type, and presence of anti-centromere and anti-topoisomerase I antibodies were collected at enrollment in the Genetics versus ENvironment In Scleroderma Outcome Study (GENISOS). Widowed patients were subsequently excluded from the analysis. Multivariate logistic regression analysis controlling for age, gender and ethnicity was performed comparing patients in a union (married or in a marriage-like relationship) to patients who were not in a union (separated, divorced, or never married.)

Results: Data from 303 patients with SSc were analyzed. Among women with scleroderma, 128 (50.6%) were married, 11 (4.4%) were living in a marriage-like relationship, 10 (4.0%) were separated, 59 (23.3%) were divorced, 14 (5.5%) were widowed and 31 (12.3%) were never married. Among men with scleroderma, 32 (65.3%) were married, 8 (16.3%) were separated, 1 (2.0%) was widowed and 8 (16.3%) were divorced. Multivariable logistic regression analysis revealed significant associations of FVC <50% and higher mRSS with lower likelihood of being in a union with patients with FVC <50% being 1/3 as likely of being in a union as patients with normal FVC.(Table 1) No other significant associations were identified.

Table 1. Correlation of Being In a Union with Clinical and Serologic Features of SSc

	Multivariable Logistic Regression OR (95% CI)	p
Limited Skin Involvement	1.1781 (0.7159, 1.9388)	0.519
Topo +/−	0.9792 (0.5003, 1.916)	0.951
Centromere +/−	0.9140 (0.4323, 1.9323)	0.814
mRSS	0.9787 (0.9582, 0.9995)	0.045
Disease duration	0.9935 (0.8485, 1.1634)	0.936
FVC < 50 % pred	0.3355 (0.1200, 0.9378)	0.037

Conclusion: At baseline, more severe skin involvement and interstitial lung disease were associated with lower likelihood of being married or in a marriage-like relationship. Further identification of factors contributing to loss of marital support may provide strategies for preserving these relationships and better overall quality of life and coping for patients with SSc.

667

Cancer in Systemic Sclerosis: Results From a Single Centre Cohort Report. Giuseppina Abignano, Hannah Lee Evans, Paul Emery, Francesco Del Galdo and Maya H. Buch. University of Leeds, Leeds, United Kingdom

Background/Purpose: Malignancy has been reported in 3.6–10.7 % of patients with systemic sclerosis (SSc) (1) with lung and breast being the most commonly reported types. The aim of this study was to determine the incidence of cancer in our SSc cohort, describe their demographic and clinical features and any cancer risk factors.

Methods: The medical records of 191 patients admitted to our centre and diagnosed with SSc between 1985 and 2010, all fulfilling the ACR classification criteria, were retrospectively reviewed. Patients with overlap syndrome and mixed connective tissue disease were excluded from the analysis. The epidemiological and clinical information and any risk factors of the patients with cancer history were compared to those of a gender-matched control group, randomly selected from our scleroderma database. Continuous variables were expressed as mean and standard deviation. Unpaired two-tailed t-test was used to compare groups. Qualitative variables were compared using Fisher's exact test. Data were analysed using GraphPad Prism software.

Results: Of 191 SSc patients, 18 (9.4%) were found to have a history of cancer. Twenty-one primary cancers were identified. Breast cancer was the most frequent (7 cases, 3.6 %), followed by non-melanoma skin cancer (4 cases, 2.1 %; 3 basal cell carcinoma, 1 squamous cell carcinoma), lung cancer (3 cases, 1.6%), non-Hodgkin's lymphoma (3 cases, 1.6 %), melanoma (1 case, 0.5 %), myeloma (1 case, 0.5.%), colon (1 case, 0.5 %) and parotid cancer (1 case, 0.5%). In 2 patients cancer preceded the SSc onset (1 breast cancer, 1 non-Hodgkin's lymphoma). One patient had 2 primary cancers, breast and colon, before and after the SSc onset, respectively. Comparing the 2 groups with gender-matched controls, we found that cancer diagnosis occurred at a younger age in patients that developed SSc after the malignancy ($p = 0.02$). Patients with cancer developed SSc at an older age compared to controls ($p = 0.0123$). No difference was found in any risk factors. The risk associated to the cyclophosphamide (CYC) therapy in SSc patients with cancer was nearly significant ($p = 0.075$) (table).

Parameters	Post-SSc cancer (n=15)	Pre-SSc cancer (n=2)	Post-SSc cancer vs pre-SSc cancer (p value)	Pre- and post SSc cancer (n=1)	SSc no cancer (n=18)	All SSc-cancer (n=18) vs control (p-value)
Gender (M/F)	2/13	0/2	1	0/1	2/16	–
Subset, L/D	12/3	2/0	1	1/0	13/5	0.69
ANA +	14 (93.3%)	2 (100%)	1	1 (100%)	17 (94.4%)	1.5
ACA +	7 (46.6%)	0 (0%)	0.48	1 (100%)	5 (27.7%)	0.49
AntiScl-70 +	3 (20%)	1 (50%)	0.43	0	6 (33.3%)	0.71
Age at SSc onset (mean ± sd)	52.9 ± 17	47.5 ± 3.5	0.67	65	37.9 ± 18.2	0.0123
Age at cancer dx (mean ± sd)	63.4 ± 11.3	42 ± 4.2	0.02	41, 78	–	–
Family malignancy history	1 (6.6%)	1 (50%)	0.23	0	3 (16.7%)	1
ILD	7 (46.6%)	0 (0%)	0.49	0	5 (27.7%)	0.72
tobacco	5 (33.3%)	1 (50%)	1	0	4 (22.2%)	0.71
alcohol	0 (0%)	0 (0%)	–	0	1 (5.55%)	1
CYC	8 (53.3%)	1 (50%)	1	0	3 (16.6%)	0.075
MMF	2 (13.3%)	1 (50%)	0.33	0	2 (11.1%)	1
AZA	0 (0%)	0 (0%)	–	0	0 (0%)	–
MTX	0 (0%)	1 (50%)	0.12	0	2 (11.1%)	1

Conclusion: In line with previous reports, we found breast and lung cancer among the most common types of malignancy in our SSc patients. High incidence of cases of non-Hodgkin's lymphoma cases was also observed. Although not mostly associated in SSc patients, a relatively high incidence of non-melanoma skin cancers was noted in in our cohort; the small studied population may underlie these findings. With the limitations of a case-control study, no risk factors were identified, except for the nearly significant risk associated to the CYC therapy.

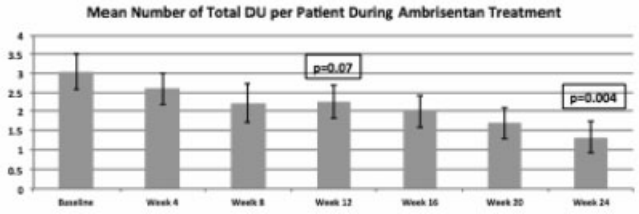
Effect of the ET_A Selective Endothelin Receptor Antagonist Ambrisentan on Digital Ulcers in Patients with Systemic Sclerosis: Results of a Prospective Pilot Study. Lorinda Chung[1], Kait Arefiev[2], Aaliya Yaqub[2], Deborah Strahs[2], Bharathi Lingala[2] and David Fiorentino[1]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]Stanford Univ Medical Center, Palo Alto

Background/Purpose: Previous studies have shown that the dual endothelin receptor antagonist (ETRA) bosentan is useful in the prevention of new digital

ulcers (DU) in patients with systemic sclerosis (SSc), but has no effect on the healing of existing DU. We sought to evaluate the effect of the relatively ET_A selective ETRA ambrisentan on the prevention and healing of DU.

Methods: This was a prospective open-label single-center study enrolling patients with limited or diffuse cutaneous SSc with at least one active DU located at or distal to the proximal interphalangeal joint. Patients with functional class III or IV pulmonary hypertension and those receiving phosphodiesterase-5 inhibitors, ETRAs, or prostacyclins within 4 weeks of screening were excluded. The primary endpoint was the difference in number of new DU that developed in the preceding 4 weeks after 24 weeks of therapy compared with baseline. Secondary endpoints included the % of patients who experienced complete healing of baseline DU; change in number and mean diameter of DU; change in physician global assessment of DU severity by visual analogue scale (VAS); and change in patient assessment of severity of DU and Raynaud's by VAS. A completers analysis was performed.

Results: 20 patients (80% female, mean age 49.3±13.8 years, 65% dcSSc) with a mean disease duration since first Raynaud symptom of 12.7±10.8 years were enrolled. 12 (60%) received stable doses of a calcium channel blocker and/or other vasodilator throughout the study. 16 patients completed 24 weeks of therapy. 2 withdrew due to lower extremity edema, 2 for scheduling conflicts. The mean number of new DU that developed 4 weeks prior to week 24 was not different from baseline (0.44±0.81 vs. 0.45±0.69). However, 14 (88%) patients had complete healing of all baseline DU at week 24. Of the 19 patients who completed 12 weeks of therapy, 7 (37%) had healed all baseline DU and 12 (63%) had healed at least 50% of baseline DU by week 12. The total number of DU decreased from 3.1±2.1 to 1.3±1.6 at week 24 ($p=0.004$) (Figure). For DU that did not heal, the mean diameter decreased from 3.3±1.6 mm to 1.6±1.5 mm ($p<0.0001$). Physician and patient assessments of DU severity were significantly improved at week 24 ($p=0.015$ for both), but patient assessment of Raynaud severity was not significantly different. The most common adverse events (AE) were lower extremity edema (50%), anemia (50%), and DU infection (40%). There were 3 serious AEs: 1 patient had a myocardial infarction and developed pulmonary edema; 1 patient was hospitalized for worsening of underlying SSc lung disease; and 1 patient had a severe Raynaud attack after an angiogram.



Conclusion: Ambrisentan may be useful in reducing ulcer burden and healing DU in SSc patients. A larger randomized double-blind placebo-controlled trial is warranted to further evaluate the efficacy of ambrisentan in the prevention and treatment of DU.

669

Successful Pregnancies but Higher Risk of Preterm Delivery in Systemic Sclerosis Women. IMPRESS: The Italian Multicentric Study on Pregnancy in Systemic Sclerosis.. A. Brucato[1], Mara Taraborelli[2], Véronique Ramoni[3] and Angela Tincani[4]. [1]Ospedali Riuniti, Bergamo, Italy, [2]University of Brescia and Spedali Civili, Brescia, Italy, [3]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [4]Rheumathology Unit, University of Brescia, Brescia, Italy, Brescia, Italy

Background/Purpose: To assess fetal and maternal outcomes in Systemic Sclerosis (SSc) women.

Methods: Prospective collected data were retrospectively analyzed according to an uniform protocol. 100 SSc women were observed in 25 Italian referral Centres during their 109 pregnancies (years 2000–2011) and compared to general obstetrical population (GOP, 3939 deliveries). Gestational outcomes and the course of the disease were recorded. Maternal mean age at conception was 31.8 (SD:5,3) years and median disease duration was 67 months (range 2–193).

Results: In SSc patients preterm deliveries (26% vs 12%) and severe (<34 weeks) preterm delivery (10% vs 5%), intrauterine growth restriction (6% vs 1%) and very low birth weight babies (5% vs 1%) were significantly more frequent than in GOP. Patients with a preterm delivery were taking folic acid supplementation in a smaller proportion (36%) than those who had a term delivery (68%) ($p< 0.01$). Antitopoisomerase and anticentromere antibodies were not significantly associated with different pregnancy outcomes, such as diffuse and limited disease. The disease remained stable in most SSc patients, but we observed 4 cases of disease evolution within 1 year from delivery, all in antitopoisomerase positive patients.

Conclusion: SSc patients can have successful pregnancies, but they have an increased risk of preterm delivery, intrauterine growth restriction and very low birth weight babies. A disease evolution during or after pregnancy is a rare but possible event. High-risk management should be standard in these patients and pregnancy should be avoided in cases of severe organ damage and postponed in early diffuse SSc.

Increased Risk of Osteoporosis and Fracture in Patients with Systemic Sclerosis. A Comparison to Rheumatoid Arthritis. Jérôme Avouac, Eugénie Koumakis, Emese Toth, Marine Meunier, Emilie Maury, Catherine Cormier, Andre Kahan and Yannick Allanore. Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France

Background/Purpose: To investigate whether patients with systemic sclerosis (SSc) have increased risk of osteoporosis (OP) and fractures compared to a "high risk" population with rheumatoid arthritis (RA)

Methods: Cross-sectional study with successive inclusion of SSc and RA patients matched for age and sex on a 12-month period. Risk factors for OP and fractures, including age, menopausal status, calcium/vitamin D intake, family history, comorbidity and steroid use, were collected for all patients. Bone mineral density (BMD) was assessed at AP lumbar spine (L1-L4), femoral neck, and total hip region with DXA Prodigy (GE-Lunar) or QDR4500 (Hologic). We included 75 successive patients with SSc (70 women, 93%) and 147 (139 women, 94%) with RA. The mean ± standard deviation, SD, age of SSc patients was 62±12 years; the mean ± SD disease duration was 10±9 years; 52 (69%) had the limited cutaneous subset and 23 (31%) the diffuse. The mean ± SD age of RA patients was 61±11 years and their mean ± SD disease duration was 18±13 years. RA Patients were more likely to receive corticosteroids than SSc patients (137 (93%) vs. 45 (60%), $p<0.0001$). Cumulative dose of corticosteroids and CRP were significantly higher in patients with RA than SSc (39554±29661 mg *vs.* 19392±19333 mg, $p<0.0001$ and 12±16 mg/l *vs.* 7±7.9 mg/l, $p=0.01$).

Results: The point prevalence of OP (T-score <−2.5) was 28% and 32% in SSc and RA, respectively (p=NS). Bone mineral density measured on lumbar spine, femoral neck and total hip was not different between SSc and RA patients. The point prevalence of fractures was 33% and 32% in SSc and RA, respectively (p=NS). The frequency of vertebral (24% vs. 17%) and non-vertebral fracture (23% vs. 21%) did not differ between the two groups. In multivariate logistic regression analysis, patients with SSc and OP (n=21) were more likely to have longer disease duration than patients without osteoporosis (odds ratio, OR: 1.11, 95% confidence interval, CI: 1.03–1.21). There was no association between OP and treatment with corticosteroid, systemic inflammation (CRP >10mg/l) or any SSc feature. In multivariate analysis, patients with SSc and fractures (n=25) were more likely to be older (OR: 1.10, 95% CI 1.03–1.18) and to have vitamin D deficiency (OR: 95% CI: 5.04 1.27–20.02). In comparison, patients with RA and OP (n=47) were more likely to be older (OR: 1.04, 95% CI: 1.01–1.09) and treated with corticosteroids than patients without OP (OR: 3.30, 95% CI: 1.02–10.70). Cumulative dose of corticosteroids negatively correlated with BMD measured at lumbar spine ($r=0.38$, $p=0.01$) and total hip ($r=0.49$, $p=0.008$) in RA patients. In addition, age (OR: 1.07, 95% CI: 1.02–1.12) and vitamin D

deficiency (OR: 4.97, 95% CI: 1.53–16.13) were associated with fractures in RA patients.

Conclusion: The prevalence of OP and fracture in SSc patients was comparable to those with RA, highlighting an increased risk of OP and fracture. Age and vitamin D deficiency were found to be important factors. Our results indicated that BMD in SSc was similar to patients with RA. Increasing the awareness to perform BMD measurements and supply vitamin D in patients with SSc may be warranted based on our results, especially for older patients.

Serum Estradiol and Estrone Levels in Patients with Systemic Sclerosis: Relationship to Disease Specific Clinical Manifestations. Christine Peoples[1], Mary Lucas[1], Yona Cloonan[2], Thomas A. Medsger Jr.[1] and Carol A. Feghali-Bostwick[1]. [1]University of Pittsburgh Scleroderma Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Systemic sclerosis (SSc) is a chronic, multisystem autoimmune disease which affects the connective tissues. The female to male ratio in SSc is 3:1, but the difference is accentuated during childbearing years with a ratio of 10:1, suggesting that female sex hormones such as estrogen may play a role in disease pathogenesis. There are three main estrogens: estradiol, estrone, and estriol. Estradiol and estrone are the estrogens found in non-pregnant women while estriol is the estrogen of pregnancy. Estrogens induce production of collagen, fibronectin, and a fibrotic phenotype. We propose that abnormal levels of estrogens may be a marker for, or participate in, the pathogenesis of fibrosis in SSc.

Methods: Serum levels of estradiol (68 patients) and estrone (50 patients) were measured by mass spectrometry in post-menopausal SSc patients with diffuse cutaneous (dc) involvement and disease duration less than 3 years who did not receive any hormone replacement therapy (HRT) and age-matched, healthy, post-menopausal controls who similarly did not receive HRT. The levels of estradiol and estrone were analyzed by SSc duration (early vs. late) at the time of the serum sample and by disease specific clinical manifestations occurring at any time during the illness, including severity of skin disease, frequency of internal organ involvement, and serum autoantibody profile. High levels of estradiol were defined as those 5+ pg/mL and high levels of estrone were defined as those 47+ pg/mL. Two separate sets of analyses were performed: case vs. control comparisons of estrone and estradiol and case-only comparisons of clinical manifestations based on high vs. low estrone and high vs. low estradiol among cases. For the comparisons, we utilized the Wilcoxon rank-sum test and Chi-square test of proportions where appropriate.

Results: 34% of SSc patients had high levels of estradiol compared to 21% of controls. Patients with higher estradiol levels had a shorter duration of disease from first symptom to first visit. 32% of patients with high estradiol levels had renal crisis compared to 18% of patients with low estradiol levels. Serum levels of estrone were significantly higher in SSc patients compared to controls (<0.01), with 40% of SSc patients having high estrone compared to 13% of controls. 42% of patients with high estrone had gastrointestinal (GI) involvement compared to 17% of patients with low estrone. 44% of SSc patients with high estrone levels had an anti-Scl 70 antibody as compared to 25% in the low estrone group.

Conclusion: Circulating estradiol and estrone levels are elevated in post-menopausal patients with dcSSc compared with healthy post-menopausal women, and these elevations are associated with renal crisis, GI involvement, and the presence of anti-Scl 70 antibodies. These estrogen compounds may participate in the production of the excessive fibrosis which occurs in the early phase of dcSSc.

Burden of Disease in Dutch Patients with Systemic Sclerosis and Digital Ulcers; Data From Thedata From the Dutch National Registry. Madelon C. Vonk[1], Alexandre E. Voskuyl[2], Michel Walravens[3], Pieter Paassen[4] and Annemie Schuerwegh[5]. [1]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]Maasstad hospital, Rotterdam, Netherlands, [4]University Medical Centre Maastricht, Maastricht, Netherlands, [5]Leids Univ Medisch Centrum, Leiden, Netherlands

Background/Purpose: Digital ulcers (DU) are a frequent complication of systemic sclerosis (SSc) with a negative impact on quality of life. The Dutch incidence, prevalence and natural history of DU in SSc patients are largely unknown. Furthermore, clinical management varies, as international guidelines for the management of DU are not available. RESIDU is a Dutch national observational study, designed to collect cross-sectional and longitudinal epidemiological data in SSc-DU patients. RESIDU aims to describe demographic data, clinical characteristics and Dutch management practice.

Methods: Known Dutch SSc-treating physicians were invited to participate in RESIDU. Upon EC approval in participating centres, all SSc-patient charts were screened for a history of DU and/or pitting scars (PS) and data were collected in an online disease registry.

Results: In June 2011, 28 Dutch hospitals participated in RESIDU. As most larger hospitals participated, RESIDU is estimated to represent approximately half of the Dutch SSc population. In total 1,304 patient charts were screened; 547 patients (42%) had a history of DU. Data of 439 patients were included in RESIDU. The actual number of patients is given for each item, to account for missing data.

Patient inclusion per site ranged from 6 to 301 SSc patients and the incidence of DU varied between 5% and 63%. Smaller sites showed a larger variation in incidence of DU, probably caused by different policies for patient referral to specialized sites.

The average age at first Raynaud phenomenon (RP) occurrence was 43 ± 15 years (n=378) and at first DU 49 ± 15 years (n=315). Time between first RP and DU was 4.4 years (n=287). Other SSc manifestations were gastro-intestinal involvement (57.1%, n=424), lung fibrosis (31.4%, n=424), PAH/PH (9.9%, n=424), heart involvement (6.4%, n=424) and kidney involvement (4.7%, n=424). The most important DU complications were gangrene (29.2%, n=432), soft tissue infection requiring antibiotics (19.3%, n=409), auto-amputation (6.7%, n=406) and osteomyelitis (3.7%, n=432). Hospitalization was needed in 41.5% of patients (n=427), mainly due to need for parenteral prostanoids (38.2%).

Conclusion: The RESIDU database represents half of the Dutch SSc-DU population and therefore gives a good estimate of Dutch DU epidemiology. Furthermore, it offers clear opportunities for evaluation of patient management practices. The current data show that DU patients suffer from a considerable burden of disease.

Background/Purpose: Systemic sclerosis (SSc) is associated with a significant reduction in life expectancy. The existing clinical prediction model developed in 1999 for 5 year survival in SSc underestimated survival in new patients. Therefore, the objective was to develop and

validate a new clinical prognostic model to predict 5-year survival in early systemic sclerosis (SSc).

Methods: A multi-centre cohort of SSc patients diagnosed before 2002 was established in EUSTAR centers. Patients were eligible if they were followed for five-years or shorter if they died. The sample (N=955) was split in a development sample (2/3 of deaths) and a validation sample (1/3 of deaths). In the development sample, univariate and multivariate logistic regression and a bootstrap procedure were used to develop a prognostic model to predict 5-year survival after diagnosis of SSc. Model performance (discrimination and calibration) was studied in the validation sample.

Results: The development sample consisted of n=700 patients of whom 59 (8.4%) died and the validation sample consisted of n=255 patients of whom 25 (9.8%) died. After univariate logistic regression, 14 clinical variables ($p<0.10$) entered the multivariate logistic regression model. Using a backward selection procedure, a combination of 6 variables ($p<0.20$) remained. The six items were: age >55 at diagnosis (OR 2.16), female gender (OR 1.73), dcSSc (OR 1.93), ECG abnormalities (OR 1.71), low FVC or low DLCO (OR 1.36) and presence of urine protein (OR 2.50). In the validation sample, the 1999 prediction model had an area under the ROC curve of 0.73. The area under the ROC curve of the new model was 0.85 and the predicted probabilities of 5-year survival appropriately ranged from 0.02 to 1.0.

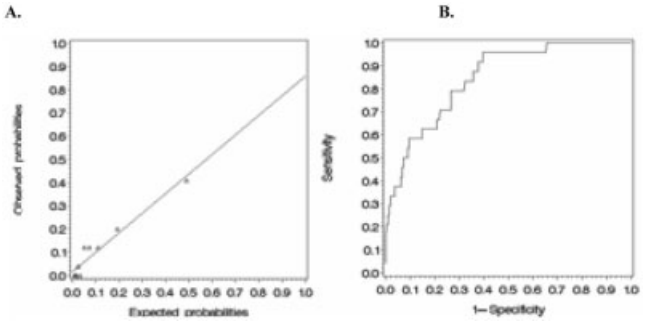

Figure 1. Figure A. Calibrations curves for the prognostic score; **B.** Receiver operating characteristics curve for the new prognostic model.

Conclusion: A new simple prognostic model using 6 disease factors to predict 5 year survival at diagnosis in SSc was developed. It showed good performance regarding calibration and discrimination in the external validation sample.

Periungueal Capillaroscopy Using Conventional Dermoscopy: Easily Available Method and Simple to Perform During the Regular Office Consult in Patients with Systemic Sclerosis. Nicolle Mazzotti[1], Claiton Brenol[1], Markus Bredemeier[2], João Carlos T. Brenol[1], Ricardo M. Xavier[1] and Tania Cestari[1]. [1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Hospital Nossa Senhora da Conceição, Porto Alegre, Brazil

Background/Purpose: Systemic sclerosis (SSc) patients present microvascular dysfunction which can be assessed by nailfold capillaroscopy.The aim of this study was to evaluate the accuracy of capillaroscopy using polarized light noncontact dermoscopy (PLD) and nonpolarized light contact dermoscopy (NPLD) compared to conventional stereomicroscope nailfold capillaroscopy (SNFC) in diagnosing SSc-related alterations.

Methods: Demographics and physical exam of 45 consecutive confirmed SSc patients. Standardized phographs were taken by the same observer, of 4 digits capillaroscopy using the 3 devices: PLD, NPLD and SNFC. Images were randomly analyzed by another blinded observer, considering the parameters: pattern analysis (normal, scleroderma, systemic lupus erythematosus, non specific and traumatic microangiopathy); structure analysis (presence of hemmorrages, ectasia, giant capillaries, bush-shaped and bizarre vessels); morphological variations and degree of devascularization. Statistical analysis to confirm sensitivity, specificity and intra-observer agreement.

Results: Scleroderma pattern was found in 83% of patients (82% women, average age 52yo). PLD and NPLD accuracy were highly sensitive in evaluating deletion (96% and 100%), presence of hemorrhages (96% and 92%) and highly specific for hemorrhage and enlarged loops. The intra-observer Kappa value for diagnosis of SD pattern was moderate to good (0.71, 0.60 and 0.60) for the 3 methods. Presence of hemorrhage showed high Kappa (0.77, 0.90 and 0.95). The average number of capillaries in the central 3 mm presented Pearson's index of 0.94 ($p<0.0$)and the Bland Altman graphic analysis confirmed the good agreement between the used devices.

Conclusion: Both polarized and nonpolarized light dermoscopy are reliable methods with good accuracy to evaluate the nailfold capillaroscopy when compared to the gold standard (stereomicroscopy). These results open a new possibility for conventional dermoscopy that is easily available and simple to perform during the regular office consult.

Increased Expression of NOX4 in Systemic Sclerosis Dermal Fibroblasts. Regulation by TFG-β, Protein Kinase C Delta and c-Abl Kinase. Sonsoles Piera-Velazquez, Alma Makul and Sergio A. Jimenez. Jefferson Insititute of Molecular Medicine, Thomas Jefferson University, Philadelphia, PA

Background/Purpose: Systemic sclerosis (SSc) is characterized by the excessive deposition of collagen and other connective tissue components in skin and multiple internal organs. Although transforming growth factor β (TGF-β) has been shown to play a crucial role in the development of tissue fibrosis in SSc, recently, other factors such as excessive oxidative stress have been implicated in the pathogenesis of the disease. Oxidative stress is caused by cellular overproduction of ROS (reactive oxygen species). One of the main ROS is superoxide anion radical which is generated by NADPH oxidases. NOX4 is one of seven NADPH isoforms which plays a crucial role in the generation of ROS. The purpose of these studies was to examine the role of NOX4 in the pathogenesis of tissue fibrosis in SSc.

Methods: Normal and SSc human dermal fibroblasts were isolated from skin biopsies. Normal dermal fibroblasts were expanded and treated with 10 ng/ml of human recombinant TGF-β in media containing 10% FBS for 24 h with or without previous treatment for 1h with 2.5 and 5 μM of rottlerin, an inhibitor of protein kinase Cδ (PKCδ) or 5 μM of imatinib mesylate an inhibitor of c-Abl kinase. Small interfering RNA (siRNA) was employed to confirm the PKCδ role in normal dermal fibroblasts. RNA and proteins were isolated and examined by Real Time PCR and Western blots using a NOX4 specific antibody.

Results: Immunofluorescence and Western blot analysis showed that NOX4 is constitutively expressed by human dermal fibroblasts and that its expression is upregulated in SSc fibroblasts compared to normal fibroblasts. TGFβ increased the protein and mRNA expression of NOX4 by 3-fold in normal human dermal fibroblasts. Inhibition of PKCδ with rottlerin and a specific PKCδ siRNA or with the c-Abl inhibitor, imatinib mesylate, abrogated the TGF-β-induced stimulation of NOX4.

Conclusion: NOX4 expression and production is constitutively elevated in SSc fibroblasts and its expression is stimulated by TGF-β. PKCδ and the c-Abl kinase are involved in the process. Thus, targeting NOX4 expression may be a novel therapeutic approach for the treatment of SSc and other systemic fibrotic disorders.

Construct Validity of the Saint George's Respiratory Questionnaire in An Observational Cohort of Patients with Early Diffuse Systemic Sclerosis. Dinesh Khanna[1], James R. Seibold[2], Peter A. Merkel[3], Maureen D. Mayes[4], Kristine Phillips[5], Robert W. Simms[6], Shervin Assassi[7], Philip J. Clements[8] and Daniel E. Furst[9]. [1]University of Michigan, Ann Arbor, MI, [2]Scleroderma Research Consultants LLC, Avon, CT, [3]Boston University School of Medicine, Boston, MA, [4]University of Texas Health Science Center at Houston, Houston, TX, [5]University of Michigan Medical School, Ann Arbor, MI, [6]Boston University School Medical, Boston, MA, [7]Univ of Texas Health Science, Houston, TX, [8]UCLA School of Medicine, Los Angeles, CA, [9]UCLA Medical School, Los Angeles, CA

Background/Purpose: The Saint George's Respiratory Questionnaire (SGRQ) is a self-administered questionnaire for measuring health-related quality of life () in respiratory diseases. It consists of 76 items, producing three sub-scores: Symptoms (SYM), Activity (ACT), and Impacts

(IMPACT), and Total (TOTAL). SYM scale assesses the patients' perception of their respiratory problems; the ACT scale measures he patients' current daily physical activity; the IMPACT scale evaluates the impact of the respiratory problems and the TOTAL scale is a weighted summation of the 3 scales. Scores for each scale can range from 0 (no impairment) to 100 (the worst impairment).

Methods: We recruited patients with early diffuse SSc (< 5 years from 1st non-Raynaud's sign or symptom) at four scleroderma centers in the United States. We hypothesized there would be at least moderate correlations (r>=0.30) between the 4 SGRQ scales vs. FVC% predicted, HAQ-DI, VAS breathing, and 6-minute walk test (6MWT). We also assessed the discriminatory validity to distinguish between i) FVC ≤ 70% vs. > 70% and ii) presence vs. absence of fibrosis as assessed by high-resolution CT.

Results: Of 200 patients, we had data on 177 patients with SGRQ. The mean (SD) age was 51 (12) years, disease duration (from 1st non-Raynaud's sign or symptom) 2.4 (1.6) years, modified Rodnan skin score (MRSS) 21 (10), HAQ-DI 1.1 (0.8), and VAS breathing of 20 (35 on a 0–150mm). The mean (SD) scores for SYM, ACT, IMPACT, and TOTAL scales were 25 (19), 41 (31), 15 (17), and 25 (19), respectively. The table summarizes correlations between SGRQ scores and other outcomes. ACT, IMPACT, and TOTAL scales had significant associations with FVC%, HAQ-DI, VAS breathing, and 6MWT except for SYM scale vs. HAQ-DI and 6 MWT (P> 0.05). Patients with low FVC% (≤ 70%; N=42) had higher (worse) scores for SYM, ACT, IMPACT, and TOTAL scales compared to FVC% >70% (N=135; P< 0.05 for all scales). Patients with evidence of fibrosis on HRCT (N=32) had numerically higher scores for SYM, ACT, IMPACT, and TOTAL scales, although only TOTAL score was statistically significant (p< 0.05).

Conclusion: The SGRQ has acceptable construct validity in early dcSSc. Ongoing longitudinal analysis will define the sensitivity to change and minimally clinically important differences of the SGRQ scales as well as the additive value of SGRQ to other outcome measures for dcSSc.

Table. Correlation coefficients between SGRQ scales and other measures

SGRQ	FVC% Predicted (N = 165)	HAQ-DI (N = 177)	VAS Breathing (N = 175)	6 MWT (N = 54)
SYM	−0.25*	0.12	0.52*	0.16
ACT	−0.36*	0.44*	0.62*	−0.52*
IMAPCT	−0.36*	0.33*	0.79*	−0.45*
TOTAL	−0.38*	0.38*	0.75*	−0.48*

* P value< 0.05

Progression of Isolated Raynaud's Phenomenon to Systemic Sclerosis: Impact of ANA Subtype and Disease Subset. Pia Moinzadeh[1], Kevin J. Howell[2], Voon Ong[3], Svetlana Nihtyanova[2] and Christopher D. Denton[2]. [1]Royal Free Hospital, Medical School, London, United Kingdom, [2]Royal Free Hospital, Medical School, London, England, [3]UCL Medical School, London, England

Background/Purpose: Raynaud's phenomenon often precedes the diagnosis of systemic sclerosis (SSc) and may be regarded as the first symptom of the disease in many cases. Conversely only a minority of cases of isolated Raynaud's phenomenon (RP) progress to defined connective tissue disease (CTD) including SSc. We have explored the predictive potential of ANA positivity and nailfold capillaroscopy for identifying cases of RP that may progress to CTD and explored the time between onset of RP and SSc-specific ANA pattern in a large patient cohort. This study has significant implications for strategies for earlier diagnosis of SSc that focus on RP.

Methods: To ascertain progression of Raynaud's to CTD patients with isolated RP (n=569) presenting to our centre were evaluated for antinuclear autoantibodies and for scleroderma-typical capillary changes using nailfold capillaroscopy. To explore the duration of isolated RP in cases evolving to SSc patients with definite SSc (n=2150) were evaluated from our clinical database, which was developed to determine and follow the current disease status of SSc patients.

Results: 569 patients with isolated RP were characterized by a mean age of 43 years (+13y), were predominantly female (85%) and had already a mean duration of Raynaud phenomenon features at presentation of 13 years (+13y). Further evaluation revealed that 7% showed antinuclear autoantibodies (ANAs) and 17% showed grade III abnormalities in nailfold capillaroscopy at their first visit. During our follow-up period of 1500 patient years (mean = 4.6 years) only 1.5% (8/569) of cases developed further clinical features of SSc (7/8 had positive capillaries and ANAs at first presentation) and 0.5% (3/569) developed autoantibodies (3/3 had positive capillaries at presentation).

Conversely, for those with definite SSc attending our centre the interval between the onset of the RP and definite SSc onset varied significantly between disease subsets and autoantibodies, being shortest for the dcSSc (2.3+6.5years) variant and longest for the lcSSc (8.4+11.5years) disease variant (p<0.0001) and regarding the antibody status being shortest for patients with anti RNA-Polymerase III (ARA) (1.7+6.4years) and longest for ACA antibodies (10.8+12.5years) (p<0.0001). The duration for other reactivities was 3.6+6.4years for patients with anti-topoisomerase antibodies (ATA), 4.2+6.1years for patients with anti-U1RNP antibodies, 3.9+7.9 years for patients with anti-U3RNP antibodies

Conclusion: Since classification criteria for earlier diagnosis of SSc are being developed the duration of pre-existing RP may be an important determinant of the profile of SSc cases identified through screening. Our analysis revealed that over 95% of patients with isolated Raynaud phenomenon, negative autoimmune serology on more than one visit and normal capillaroscopy score (less than grade 2) showed no progression to CTD. Duration of antecedent RP differs substantially between disease subsets and SSc-specific ANA patters and so a cohort of SSc cases that is selected based upon pre-existing RP may be less likely to include diffuse disease or ARA positive cases.

Efficacy and Safety of Intravenous Cyclophosphamide In the Treatment of Scleroderma Lung Disease: 7-Year Follow-up. Alexandra Balbir-Gurman[1], Ludmila Guralnik[2], Mordehai Yigla[3], Menahem A. Nahir[1], Alexander P. Rozin[4], Kohava Toledano[1], Doron Markovits[4] and Yolanda Braun-Moscovici[1]. [1]B. Shine Rheumatology Unit, Rambam Health Care Campus, The Bruce Rappaport Faculty of Medicine, Technion-Institute of Technology, Haifa, Israel, [2]Department of Diagnostic Imaging, Rambam Health Care Campus, The Bruce Rappaport Faculty of Medicine, Technion-Institute of Technology, Israel, [3]Division of Pulmonary Medicine, Rambam Health Care Campus, The Bruce Rappaport Faculty of Medicine, Technion-Institute of Technology, Haifa, Israel, [4]B. Shine Rheumatology Unit, Rambam Health Care Campus, Haifa, Israel

Background/Purpose: Interstitial lung disease (ILD) is a serious complication in the course of systemic sclerosis (SSc). Various efficacy of cyclophosphamide (CYC) for treatment of SSc-ILD was demonstrated with follow up for 2 years. We analyzed changes in lung function tests (LFTs), pulmonary artery pressure (PAP) estimated by ECHO, and skin changes measured by modified Rodnan skin score (mRSS) at 4 and 7-years after IV CYC monthly treatment of SSc-ILD.

Methods: Active ILD was defined as presence of ground glass and/or fibrosis on chest HRCT and reduction in FVC and/or DLCO for more than 10% during 2 consecutive visits. Patient's data was completed from EUSTAR database at our site. Student paired T-test, Mann-Whitney U-test and Wilcoxon Signed Ranks tests were used for statistical analysis.

Results: Among 170 SSc pts registered at our site 38 pts (21.8%) had active ILD. Data of 28 pts (female 78.6%) started CYC before 2007 and 17 pts started before 2004 were eligible. Age, disease duration, and follow-up period were 50.7 +/− 12.7 yrs, 16.3 +/− 17.9 months, 6.5 +/− 6 yrs. Eight pts (28.6%) died, 2 pts during first 4 yrs. Mean cumulative CYC dose was 8.96 +/− 3.8 G. Changes in FVC and DLCO from baseline and at the end of the first year were: 78.3% and 75.4% (p=NS); 65.6% and 54.7% (p<0.005). More than 20% reduction in FVC, DLCO, and mRSS during 4 and 7 years was registered in 34% vs 7% of pts; 68% vs 24% of pts; 80% vs 7% of pts; more than 20% elevation in PAP was observed in 25% vs 6% respectively. The rate of annual reduction in FVC, DLCO and mRSS different significantly in the first 4 years and next 4–7 years after CYC: 3.2 +/−2.9 and 0.4 +/−1.0 (p<0.004); 4.6 +/−2.9 and 0.9+/−1.6 (p<0.001); 1.8 +/−1.9 and 0.2 +/−0.2 (p<0.002) respectively. Among presenting features (cough, dyspnea, lung crepitus, weight loss, presence of specific antibodies, esophageal widening, CPK level, mRSS) only elevated CPK correlated with FVC, DLCO and PAP changes (p=0.04, p=0.026 and p=0.028 respectively). Reduction in mRSS was significant (p=0.023) at both total CYC doses (6 and 12 G). Adverse events were pneumonia, HBV reactivation, Kaposi sarcoma, premature menopause.

Conclusion: IV CYC stabilized FVC up to one year follow-up but did not prevent further reduction in LFT in the next 4 and 7 yrs. CYC rapidly improved mRSS. CYC doses more than 6G CYC had no additive contribution regarding LFT and mRSS. We suggest that CYC is effective for induction of SSc-ILD remission but should be followed by other less toxic disease-modified drugs for maintenance of LFT stability; more than 24 months of follow-up should be considered in judgment of treatment efficacy in SSc-ILD.

Preliminary Steps to a Health Index for Systemic Sclerosis Based on the World Health Organization's International Classification of Functioning, Disability and Health: A European League Against Rheumatism Scleroderma Trials and Research Initiative. Lesley Ann Saketkoo[1], Reuben Escorpizo[2], Kevin J. Keen[3] and Oliver Distler[4]. [1]LSU Health Science Center, New Orleans, LA, [2]ICF Research Branch in cooperation with the WHO Collaborating Centre for the Family of International Classifications Department of Health Sciences; and Health Policy, University of Lucerne, Switzerland, [3]University of Northern British Columbia, Prince George, BC, [4]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Systemic Sclerosis (SSc) affects multiple organ systems in varying combinations resulting in many types and degrees of disability in patients. Skin fibrosis, ischemic pain, ulceration, arthritis, contractures, myopathy as well as cardiopulmonary, renal and gastrointestinal manifestitations may carry significant burden on emotional, social and physical functioning.

International Classification of Disability, Health and Functioning (ICF) is a universal framework introduced by the World Health Organization (WHO) to describe and quantify the impact caused by health conditions on functioning which may lead to disability. The ICF uses a standardized alphanumerical language to describe health states in terms of the bio-psycho-social model. The ICF is accepted by national and international health care and policy-making systems to assess the impact of disease on personal, scientific, economic and service levels.

Methods: Comprehensive literature search in PubMed was performed with the following keywords: outcome measures, SSc, rehabilitation, function, quality of life, mental health, sexual health, pain and traditional measures of disease activity to identify 5 validated measures that represent the broadest range of manifestations (OD, LAS). Instruments were deconstructed to meaningful concepts according to ICF linkage rules and linked by 2 health professionals familiar with ICF updated linkage rules (RE, LAS). Inter-linker agreement was analyzed (KK).

Results: The 5 validated measures for this exercise were:
Hand Mobility in Scleroderma Test (HAMIS)
Modified Rodnan Skin Score (mRSS)
Raynaud Condition Score (RCS)
Scleroderma Health Assessment Questionnaire (SHAQ)
Systemic Sclerosis Gastrointestinal Tract Instrument (GIT).

Thirteen ICF Chapters and 65 ICF categories were linked to SSc (Table 1). Overall inter-linker agreement was 66% (95% CI: 57, 75) (Table 2).

Table 1. Linkages from the 5 Pilot Instruments

Domain	Chapter	Title	Number of Categories	Categories Shared Between Instruments	Contributing Instruments
Body Functions	Chapter 1:	Mental	3	0	GIT
	Chapter 2:	Sensory and Pain	4	3	GIT, RCS, SHAQ
	Chapter 4:	Cardiovascular and Respiratory	3	0	SHAQ
	Chapter 5:	Digestive, Metabolic and Endocrine	12	3	GIT, SHAQ
	Chapter 7:	Neuromuscular and Movement	1	0	HAMIS
	Chapter 8:	Skin	2	2	RCS, SHAQ
Body Structures	Chapter 7:	Movement	1	1	RCS
	Chapter 8:	Skin	4	0	mRSS
Activities & Participation	Chapter 4:	Mobility	21	2	GIT, mRSS, RCS, SHAQ
	Chapter 5:	Self-Care	8	0	SHAQ
	Chapter 6:	Domestic Life	3	0	SHAQ
	Chapter 7:	Interpersonal Interactions & Relationships	1	0	GIT
	Chapter 9:	Community, Social & Civic Life	2	0	GIT

Table 2. Instrument Comparison and Inter-Reviewer Agreement

Instrument	Number of Items Linked	Number of Categories Identified	Agreement (%)	Agreement 95% Confidence Interval
HAMIS	11	16	69	(41, 89)
mRSS	16	18	89	(65, 99)
RCS	11	21	52	(30, 74)
SHAQ	14	22	64	(41, 83)
SSc GIT	34	41	63	(47, 78)
(9 Items of the SSc GIT were not included in the agreement analysis.)				
Total	78	118	66	(57,75)

Conclusion: This exercise is the first attempt to establish an ICF language for SSc in terms of functioning, beyond the traditional biomedical aspect of the disease. A preliminary composite of all validated outcome measures in systemic sclerosis will soon be made available using this methodology for ICF engaged health systems and other entities with validation studies to follow. Thus, the global, regional and personal impact of SSc across cultures, age and socioeconomic status may be assessed fairly for use in policy making and provision of services and funding.

Evaluation of Nutritional Status and Dietary Intake in Women with Systemic Sclerosis. Thais F. Marighela[1], Ligia A. Martini[2], Vera Szejnfeld[1], Marcelo M. Pinheiro[1] and Cristiane Kayser[1]. [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: To evaluate nutritional status, body composition, and dietary intake in systemic sclerosis (SSc) women, as well as to compare these findings according to different disease subsets.

Methods: 61 SSc women (31 with limited and 30 with diffuse cutaneous form) and 67 age-matched healthy women were included in this transversal study. Body composition measurements were performed using dual energy X-ray absorptiometry (DXA) in order to evaluate fat mass, lean mass and appendicular lean mass. Body mass index (BMI) was measured and a validated 3-day food intake questionnaire was used in all patients and controls. Nutrient intakes were assessed using Nutrition Data System for Research software (University of Minnesota, 2007) and their adequacies according DRI's proposed values. Total energy (kcal/day), and total macronutrients and fiber intake were evaluated. In addition, all data were compared among diffuse (dcSSc) and limited cutaneous SSc (lcSSc) patients, and between patients with and without gastrointestinal involvement (oesophageal dysmotility or intestinal abnormalities). $P<0.05$ was set as significant.

Results: Women with SSc had significantly lower BMI, total fat mass, total and appendicular lean mass as compared to healthy controls ($p=0.02$; $p=0.009$; $p=0.04$; $p=0.01$, respectively). Women with lcSSc had no significant changes on body composition when compared to healthy controls. Besides, dcSSc women had significantly lower BMI, total fat mass, and total and appendicular lean mass than healthy women (Table 1). In addition, BMI and appendicular lean mass was also significantly lower in dcSSc in comparison to lcSSc women. There was no significant difference in DXA parameters or BMI values between patients with or without gastrointestinal involvement. The total energy and macronutrients intake was similar between SSc and controls, but there was a lower intake of fibers in SSc patients, with no significant difference between dcSSc and lcSSc patients or between patients with and without gastrointestinal involvement.

	dcSSc	lcSSc	Healthy controls	p
Age (years)	48.5 ± 11.5	53.4 ± 12.1	48.3 ± 14.6	0.12
Body mass index (kg/m$^{2)}$	22.6 ± 6.2***	26.3 ± 5.0**	26.6 ± 4.8*	0.002
Total fat mass (kg)	19.2 ± 11.5*	23.9 ± 10.5	26.3 ± 9.2*	0.007
Total lean mass (kg)	33.0 ± 4.5*	35.4 ± 6.4	36.1 ± 4.9*	0.03
Appendicular lean mass (kg)	13.8 ± 2.7***	15.7 ± 3.4**	16.0 ± 2.6*	0.002

Tukey's test, with $p<0.01$*; $p<0.05$**

Conclusion: An abnormal body composition, probably related to more severe disease, was found in dcSSc women, but not in those with lcSSc. Our data suggest some degree of malnutrition and cachexia in dcSSc patients, regardless dietary intake or previous gastrointestinal involvement. Thus, a more detailed screening, including medical history, nutritional approach and imaging, should be performed for better clinical management in SSc patients.

681

Evaluation of the Impact of Recurrent Ischemic Digital Ulcers on Hand Disability in Patients with Systemic Sclerosis (ECLIPSE). Report of the Cohort At the Time of Inclusion. Luc Mouthon[1], Patrick Carpentier[2], Catherine Lok[3], Eve Puzenat[4], Pierre Clerson[5], Virginie Gressin[6] and Marie-Aleth Richard[7]. [1]Hopital Cochin, Paris, France, [2]CHU Grenoble, Grenoble, France, [3]Amiens Hospital, France, [4]Besançon, Besançon, France, [5]Orgametrie, Roubaix, [6]Actelion France, Paris, France, [7]Marseille, Paris, France

Background/Purpose: Ischemic digital ulcers (DU) occur in the course of systemic sclerosis (SSc).

Methods: Prospective, longitudinal, observational study of 24 months evaluating the impact of recurrent DU on hand disability. Patients included fulfilled the American college of Rheumatology and/or Leroy & Medsger diagnosis criteria for SSc, experienced at least one DU during the previous year with or without active DU at the time of inclusion and were candidates to Bosentan therapy. Data were collected on SSc, characteristics of past and active DU, Rodnan skin score, factors influencing hand function and mobility, disability scores (Cochin hand function scale, health assessment questionnaire disability index (HAQ-DI)) and quality of life (SF36).

Results: 178 patients (124 women) were included between September 2009 and December 2010 in 49 centers. Mean age at inclusion and at the time of diagnosis of SSc were 53±15 and 43±14 years, respectively. SSc was diffuse in 44% of the cases, and Raynaud's phenomenon started 14±12 years before inclusion. 11% of patients had pulmonary arterial hypertension, 71% had oesophagus involvement. Mean Rodnan skin score was 14.5±8.9. Time elapsed since the first episode of DU was 8±8 years, 59% of patients had recurrent DU (first non Raynaud's sign for 52%), leading to sequellae including loss of substance (68%), auto-amputation (8%) and surgical amputation (10%). Complications occurred: infection 9%, gangrene 6%, osteitis 2%. 50% of patients had ≥ 1 active DU at the time of inclusion. In these patients, the mean number of DU was 2.4±1.9; 46% had more than one DU, 37% had both hands involved and 2.3±1.7 fingers involved. 23% of cases had ≥ 1 extended DU (>1cm). Concomitant mechanical DU were localized at the dorsal face of fingers (n=22) or bony reliefs (n=13). DU patients complained with more painful hands (visual analog scale 6.07±2.65 vs 2.42±2.5 without DU) and disabling, involving the dominant hand in 68% of the cases. DU increased hand disability (Cochin hand function scale: median 36 in patients with active DU vs 23 without, $p<0.0001$), HAQ-DI and altered the SF36. Other factors were independently participating to the alteration of hand function: diminution of proximal interphalangeal and distal interphalangeal joints mobility on more than one finger (66% and 57% of the cases, respectively), retraction of flexor tendons (46%).

Conclusion: DU represents an early complication of SSc. DU are significantly associated with hand disability in patients with SSc. Prospective follow up at two years will allow to determine the contribution of recurrent episodes to disability in patients with SSc.

682

Survival and Causes of Death of 312 Norwegian Patients with Systemic Sclerosis. Anna-Maria Hoffmann-Vold, Oyvind Midtvedt, Oyvind Molberg, Torhild Garen and Jan Tore Gran. Oslo University Hospital, Oslo, Norway

Background/Purpose: The purpose of this study was to determine the survival of systemic sclerosis (SSc) in Norway and to analyse the causes of death in SSc patients.

Methods: Multiple sources of case identification were used to collect all SSc patients in South East Norway with a population of 2 707 021 inhabitants at the time period 1999–2009. All 312 identified patients met either ACR criteria or the modified Medsger and LeRoy criteria for SSc. Vital status at 1 January 2010 was provided for all participants by the national population register. Kaplan-Meyer and Cox proportional hazard models were used to analyse survival in SSc subgroups. The causes of death were based on information obtained from death certificates and chart review.

Results: 43 of 312 patients (14%) died in the study period. Median observation time from disease onset to death, age at onset and age at death for limited cutaneous SSc (lcSSc) and diffuse cutaneous SSc (dcSSc) are summarized in table 1. The 5 and 10 years survival rates for lcSSc were estimated to 97.6% and 92.9%, and to 90.6% and 70.3% for dcSSc.

According to the death certificates, 58.1% of deaths were attributed directly to SSc. Among these, 28% to pulmonal arterial hypertension (PAH), 20% to interstitial lung disease (ILD) and 16% were attributed to kidney disease.

Of the non SSc-related deaths, 33.3% were assigned to malignancies, 16.6% to other lung diseases and 16.6% to left heart diseases.

Table 1. Demographic features of 43 patients with SSc

	Male		Female	
Type	lcSSc	dcSSc	lcSSc	dcSSc
Number (% of total)	6 (12)	9 (42.9)	20 (10)	8 (17)
Age at onset, yrs	48 (33–77)	57 (43–74)	55 (20–74)	48.5 (28–74)
Age at death, yrs	56 (45–79)	73 (49–81)	65 (51–87)	59.5 (39–76)
Disease duration	8.5 (2–13)	6 (1–28)	13 (1–33)	4 (1–29)

Conclusion: Survival is decreased in SSc patients in Norway. Outcome is worst among male patients with dcSSc. However, the 5 and 10 year survival rate was better than those reported in earlier studies. The main cause of death was PAH, followed by ILD and kidney affection.

683

Characteristics and Impact of Pain in Systemic Sclerosis: Comparison with Rheumatoid Arthritis. Serge Perrot[1], Philippe Dieude[2] and Yannick Allanore[3]. [1]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [2]APHP, Hopital Bichat, Paris, France, [3]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France

Background/Purpose: Pain has a major impact in chronic rheumatic diseases. Pain has been much less studied in systemic sclerosis (SSc) than in rheumatoid arthritis (RA), in which it is systematically assessed and is a major outcome measures both for trials and in routine care. Our objectives were to measure and characterise pain and its management in patients with (SSc), and to compare these aspects between SSc and RA patients.

Methods: A prospective study was carried out over a nine-month period in 3 universitary medical departments: consecutive inpatients with SSc or RA referred for routine assessment of disease activity were examined and asked to complete self-reported pain (MPQ, DN4, BPI), sleep, psychological (PCS, SOPA, Beck, HADs) and quality of life (SF12) questionnaires. Patients referred for severe or end-stage organ involvements were excluded.

Results: We included 159 patients: 82 SSc patients (85% women, 59±12 years of age, 56% with limited cutaneous and 44% with diffuse SSc, relatively severe as reflected by 45% of patients fulfilling Medsger's classes 3–4, SSc-HAQ 1.5±1.0) and 67 RA (68% women, 55±14 years of age, mean DAS 4.3±1.6, HAQ 1.9±1.0). Pain was significantly less frequent (55%) and less intense (VAS 3.9 ± 2.6) in SSc patients than in RA patients (75%, 5.3±2.1, $P<0.001$). Significant differences in type of pain were found between SSc and RA, with pain being more frequently generalised, (26% vs 20%, $p=0.01$), more frequently located in the skin (14% vs 1.3%, $p<0.001$) or muscle (9% vs 2.6, $p=0.03$) in SSc patients. A neuropathic pain component was observed in 40% of SSc vs 32.8% of RA patients ($p<0.01$), and pain related to synovitis and tenosynovitis was found in 25 % of SSc and in 78% of RA patients ($p<0.001$). Pain related to Raynaud's phenomenon was found only in SSc patients (N=25), with mild pain intensity. The MPQ questionnaire subscales demonstrated significant differences between SSc and RA respectively, for both sensory (6.8±6.6 vs 10.8±6.9) and affective dimensions (2.7±3.1 vs 5.4±4.3). Even with adjustment for pain level, pain had a lower impact in SSc than in RA (BPI questionnaire) on general activity ($p<0.001$), mood ($p<0.01$), walking capacity ($p<0.001$), usual work ($p<0.001$), relationships with others ($p<0.001$) and enjoyment of life ($p<0.05$). This was not related to a higher psychological distress since we found similar levels of anxiety and depression in SSc and RA, but was significantly correlated to the presence of joint pain. Pain coping strategies did not found differences in catastrophizing (PCS), but demonstrated higher scores for emotion and medication in RA patients (SOPA). No difference was observed between SSc and RA in analgesic prescriptions, regardless of the type of pain, except for acetaminophen (20% vs 27%, $p=0.02$)

Conclusion: In SSc, pain appears less intense, less frequent and more diffuse than in RA, with a limited impact, and does not represent a major severity symptom, conversely to RA. However, a neuropathic component can be more frequently found in SSc,. Furthermore, in SSc, when there is a joint component, sensory and affective pain dimensions are increased, with high impact and high medication demands, reaching the levels observed in RA patients.

684

Esophageal Involvement in Systemic Sclerosis and Rheumatoid Arthritis: Prevalence of Esophagitis and Barrett's Esophagus. Andrey E. Karateev, Mikael M. Movsisyan, Lidiya P. Ananieva and Stefka G. Radenska-Lopovok. Research Institute of Rheumatology RAMS, Moscow, Russia

Background/Purpose: Esophageal involvement is a typical visceral manifestation of systemic sclerosis (SSc). Life threatening complications of esophagitis

in scleroderma such as ulcers and Barrett's esophagus (BE) must be actively monitored and require long-term treatment.

Objectives: To assess prevalence of esophageal involvement in SSc and rheumatoid arthritis (RA) patients, to reveal connection between clinical manifestation and endoscopic findings in patients with scleroderma esophagitis. Also, to assess effectiveness of proton pump inhibitors (PPIs).

Methods: 356 patients with SSc (females 92,6%; males 7,4%, age 47,8 + 19,7 years) and 1018 patients with RA (females 89,0%, males 11,0%, age 44.1 + 16.3 years), among whom glucocorticoids (GC) were administered in 66,7% vs 52,6% of patients, respectively. 1,6% vs 82,9% of patients were treated with NSAIDs, 13,2% vs 0% - D-penicillamine, 15,7% vs 56,5% - cytotoxics, 23,7% vs 8,7% - PPIs. All patients underwent upper gastrointestinal endoscopy.

Results: Subjective symptoms of esophageal pathology were detected in 64,0% vs 33,9% of patients with SSc and RA ($p<0.001$). Dysphagia and substernal ache were revealed in 10,1% and 7,0% of SSc patients, and only in 1,7% of patients with RA. Accoding to endoscopy results musocal hyperemia was seen in 27,4% vs 1,5% of patients, erosive esophagitis in 21,9% vs 2,2%, ulcers of the esophagus in 4 (1,1%) vs 0 ($p=0,000$) patients. Esophageal mucosal biopsy was performed in 92 patients with SSc and we revealed BE (intestinal metaplasia) in 19 patients (20,1%). No cases of BE were detected in RA patients. There was reliable link between symptoms and development of erosive esophagitis ($p=0,001$). At the same time we didn't find correlation between esophagus involvement, age, disease type (limited or systemic) and drugs administration (NSAIDs, GC, cytotoxics). Against the background of regular administration of PPIs (90 SSc patients) erosive esophagitis was detected in 35,0%, BE in 36,8% of patients. All 4 patients with esophageal ulcers were treated with PPIs.

Conclusion: According to our study esophageal involvement was revealed in majority of SSc and only few in RA patients. BE a frequent complication of esophagitis in scleroderma patients, which requires regular endoscopy investigation in all patients with SSc. Erosive esophagitis is often accompanied by clear clinical presentation, however some cases remain asymptomatic. PPIs are not always effective enough, which defines the necessity of administration of these drugs in higher doses or combined treatment regimen usage.

685

Ultra Sensitive Troponin in Systemic Sclerosis. Christophe Meune[1], Jérôme Avouac[2], Camille Gobeaux[3], Marine Meunier[2], Andre Kahan[2] and Yannick Allanore[2]. [1]Paris Descartes University, Cardiology department, Cochin Hospital, Paris, France, [2]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [3]Paris Descartes University, Biochemistry A department, Cochin Hospital, Paris, France

Background/Purpose: Microangiopathy is a cardinal feature of SSc that has a critical role in the development of primary myocardial involvement and possibly pulmonary hypertension. Cardiac troponin (cTn) is the recommended biomarker to detect myocardial injury. The recently developed high sensitive assays of cTn (hs-cTn) allow the measurement of concentration 20-fold lower than previously. Numerous studies have reported the high prognostic significance of these new assays; moreover some studies reported that hs-cTnT may be elevated in other condition than acute myocardial infarction, including acute and chronic myocardial ischemia. Our aim was to measure hs-cTn in SSc patients and to examine associated factors with elevated hs-cTn concentrations (99^{th} percentile).

Methods: The plasma HScTnT concentrations were measured using an electrochemiluminescence immunoassay (Roche Diagnostic, Meylan, France) in consecutive stable SSc patients. The 99^{th} percentile, with a CV £10% is achieved for 14 ng/L.

Results: 90 consecutive SSc patients were included (male 19, age 59±13 years, diffuse cutaneous form 30, disease duration 10.3±8.9 years). A single patient had LEVF <55%; reduced LV/RV contractility, as assessed by Tissue-Doppler echocardiography was detected in 18 patients (36.7%). Hs-cTnT concentration ranged between 3ng/l (the limit of detection) and 53ng/l, with 17 patients (19.5%) having elevated hs-cTnT concentration above 14ng/l (99^{th} percentile). Hs-cTnT correlated with NT-proBNP ($r=0.52$, $p<0.001$). By univariate analysis, the following parameters were associated with increased hs-cTnT; age ($p= 0.046$), systolic pulmonary aterial pressure ($p=0.012$), the presence of anti-centromere antibodies ($p=0.03$), c-reactive protein ($p=0.037$), previous treatment with prednisone ($p=0.046$), and untreated hypertension ($p=0.050$). By bivariate analysis, after adjustment for age, the presence of elevated pulmonary artery pressure (sPAP>40mmHg) remained strongly associated with elevated versus normal hs-cTnT concentration ($p=0.031$).

Conclusion: Hs-cTnT, a strong prognosticator, might be elevated in SSc patient. It correlates with NT-proBNP, a marker of global myocardial involvement. The major determinants of SSc elevation were age, sPAP, ACA, and past prednisone treatment which may reflect the severity of the disease. Elevated pulmonary artery pressure remained the main associated factor with elevated versus normal hs-cTnT after adjustment for age. The capacity of hs-cTnT to predict pulmonary hypertension occurrence, as well as its prognostic significance, in the context of SSc remained to be established.

686

Hypergammaglobulinemia in Systemic Sclerosis. Nicole Saddic[1], Donna Rose Swistowski[2], Victoria K. Shanmugam[3] and Virginia D. Steen[4]. [1]Georgetown University Hospital, Washington DC, DC, [2]Martinsburg Veterans Affairs Medical Center, Martinsburg, WV, [3]Georgetown University Hospital, Washington, DC, [4]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Hypergammaglobulinemia (HGGB) is associated with active disease in systemic lupus erythematosus. Sedimentation rates have been shown to be a predictor of survival in systemic sclerosis (SSc), however hypergammaglobulinemia has not been evaluated as a prognostic marker. Altered B-cell homeostasis, HGGB and increased numbers of activated B-cells in SSc suggest that B-cell dysregulation may be important in the pathogenesis of SSc. The purpose of this study was to evaluate the clinical and antibody associations of HGGB in a cohort of SSc patients.

Methods: Using an ICD-9 search of the electronic medical record (Centricity, GE) 249 consecutive SSc patients evaluated in the Georgetown Scleroderma Clinic between June 2008 and June 2009 were identified. Data were collected on demographics, serum protein electorphoresis gammaglobulin levels (GGB), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), albumin, creatinine phosphokinase (CPK), albumin and hemoglobin. Antinuclear antibodies (ANA), scleroderma specific autoantibody profiles, and clinical findings were also recorded. Gammaglobulin results were available in 90 patients. Normal gammaglobulin levels (<1.6mg/dL, mean 1.11mg/dL) were found in 51 patients (56.6%) and hypergammaglobulinemia (≥1.6mg/dL mean 2.17 mg/dL) was found in 39 patients (43.3%). Chi-square and t-tests were used to compare the normal gammaglobulin (NGGB) and HGGB groups.

Results: Consistent with our scleroderma population, patients were predominantly female (91%). Of the 90 patients with GGB results, 47.7% were Caucasian and 43.3% African American. However, 60% of the patients with HGGB were African American, compared to only 48% of patients with NGGB ($p=0.0056$). Of the 39 African American patients in the study, 62% had HGGB. Patients with HGGB had significantly higher ESR (mean 39.45 mm/hr +/−5.918 compared to 17.15 mm/hr +/−4.235, $p=0.0032$) and lower hemoglobin (mean 11.52 g/dL +/−0.3163 compared to 12.42 +/−0.2848, $p=0.0391$) than those with NGGB.

SSA antibody was strongly correlated with HGGB ($p=0.0007$) and was positive in 44% (14/32) of African American patients compared to 17% of non-African Americans (5/25). In contrast, we did not find an association between HGGB and anticentromere, Scl-70, U1RNP, SSB antibodies or nucleolar pattern on the ANA. RNA polymerase III (Pol3) antibody (which is clinically associated with absence of myositis and interstitial lung disease) was associated with the NGGB group ($p=0.0271$).

HGGB was not associated with skin score, digital ulcers, tendon rubs, acid reflux, or death, but significant association was seen between HGGB and both pulmonary arterial hypertension ($p=0.038$) and pulmonary fibrosis ($p=0.0084$).

Conclusion: HGGB in SSc is associated with African American race, SSA antibody, ESR, pulmonary hypertension and pulmonary fibrosis. Since African American scleroderma patients often have more severe lung disease and worse outcomes further investigation of gammaglobulin profile as a prognostic indicator and marker of B-cell activation in scleroderma is warranted.

Mycophenolate Mofetil Is An Effective, Well-Tolerated, Steroid-Sparing Agent for a Diverse Spectrum of Connective Tissue Disease-Associated Interstitial Lung Disease. Aryeh Fischer, Mahalakshmi Krishnamoorthy, Amy L. Olson, Joshua J. Solomon, Evans R. Fernandez-Perez, Tristan J. Huie, Kevin K. Brown and Jeffery J. Swigris. National Jewish Health, Denver, CO

Background/Purpose: Interstitial lung disease (ILD) is a common and often devastating manifestation of connective tissue disease (CTD). Immunosuppressive medications are commonly used for the management of CTD-associated ILD (CTD-ILD). Small series have suggested that mycophenolate mofetil is well tolerated and may be effective for CTD-ILD. The purpose of this study was to describe a single provider's experience with MMF for CTD-ILD at a tertiary referral autoimmune lung center.

Methods: We performed a retrospective assessment of consecutive CTD-ILD patients treated by a rheumatologist (AF) with MMF for whom we had available pulmonary function testing (PFT) at time of MMF initiation and at 12 months from initiation. We also extracted demographic information, dosing of

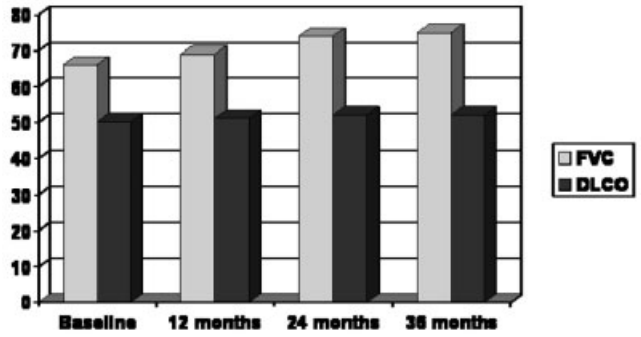
prednisone at baseline and at 12 months from MMF initiation, side effects associated with MMF, rate of discontinuation of MMF, and when available, subsequent PFT results at 24 and 36 months from MMF initiation.

Results: The cohort is comprised of 61 subjects with CTD-ILD; 25 (41%) with systemic sclerosis, 14 (23%) with anti-synthetase syndrome, 9 (15%) with "lung-dominant CTD", 6 (10%) with RA, 3 (5%) with primary Sjögren's syndrome, 2 (3%) with systemic lupus erythematosus, 1 (2%) each with mixed CTD and primary anti-phospholipid syndrome. The duration of MMF therapy was on average 3.5 years (median 4 years [range 1–10 years]), with a dose of 3000 mg/day in 38 (62%), 2000 mg/day in 21 (34%) and 1 each at 2500 mg/day and 1000 mg/day.

Clinical Features of CTD-ILD patients treated with MMF

Age	**55 (21–81)**
Female gender	39 (64%)
Ethnicity	54 (89%) White, 6 (10%) Hispanic, 1 (2%) Black
Past smokers	25 (41%)
Current smokers	0
MMF discontinuation	7 (11%), symptoms of intolerability (3), leukopenia (1) abnormal liver tests (1), lymphoma (1) ILD progression (1)
Prednisone dose @ MMF start	39 patients on prednisone; mean 14 mg / d (+/−16)
Prednisone dose @ 12 months	34 patients on prednisone; mean 4 mg / d (+/−5)
FVC% @ MMF start (n=61)	66 (+/−17)
FVC% @ 12 months (n=61)	69 (+/−16)
FVC% @ 24 months (n=42)	74 (+/−17)
FVC% @ 36 months (n=29)	75 (+/−16)
DLco% @ MMF start (n=61)	50 (+/−17)
DLco% @ 12 months (n=61)	51 (+/−17)
DLco% @ 24 months (n=42)	52 (+/−17)
DLco% @ 36 months (n=29)	52 (+/−16)
Survival @ 36 months	100%

Serial pulmonary function testing in CTD-ILD patients treated with MMF



Conclusion: Among a diverse spectrum of patients with CTD-ILD, MMF treatment appears to be well-tolerated, is associated with few side effects, and has a low rate of discontinuation. Furthermore, MMF treatment for CTD-ILD appears to serve as an effective steroid-sparing agent, and is associated with preservation of lung function. Prospective studies of MMF – such as with the Scleroderma Lung Study II – are indicated to further evaluate the efficacy of MMF in CTD-ILD.

688

Scleroderma Digital Ulcers Complicated by Infection with Fecal Pathogens. Dilia Giuggioli[1], Andreina Manfredi[1], Michele Colaci[1], Federica Lumetti[2], Marco Sebastiani[1] and Clodoveo Ferri[3]. [1]University of Modena and Reggio Emilia, Modena, Italy, [2]Universitu of Modena and Reggio Emilia, [3]Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy

Background/Purpose: Digital ulcers represent one of the most frequent complications in the course of systemic sclerosis (SSc); these lesions are very painful, scarcely responsive to treatment, and usually responsible for marked limitations on daily activities. Moreover, infectious complications may severely compromise the outcome of skin lesions in a significant percentage of patients. Therefore, the presence of pain and bandages, frequently used to promote the efficacy of contact medications, may limit the personal hygiene with an increased risk of local infection and difficult ulcer healing. A number of pathogens of different origin may be involved, including bacteria from patients' endogenous flora. We evaluated the possible involvement of faecal pathogens in SSc digital ulcers.

Methods: Among a series of 82 SSc patients with digital ulcers, we retrospectively analyzed 42 subjects with clinical signs of local bacterial infection. All digital ulcers with typical signs of infection (increase of yellow or green exudates, pain, perilesional erythema and swelling, bad odour) have been investigated by swabs.

Results: The table summarizes the main clinico-serological and microbiological features of the 42 SSc patients with digital ulcer infection. Bacterial infection was confirmed in all 42 patients investigated; in particular, Staphylococcus aureus was the most frequently found (50%). Interestingly, 11/42 (26%) patients showed digital ulcers infected by intestinal bacteria; namely, 7 subjects resulted positive for Escherichia coli and 4 for Enterococcus faecalis. A significantly higher percentage of diffuse cutaneous SSc was recorded in the subgroup of 11 patients with digital ulcers infected by faecal pathogens compared to the remaining 31 infected by other bacteria (6/11 vs. 5/31, respectively; Fisher's p=0.011).

Clinico-serological and microbiological data of 42 SSc patients with infected digital ulcers

Male/Female	5/37
Mean age±SD (yrs)	56.3±15.8
Mean disease duration±SD (yrs)	11.1±7.9
L/D	31/11
Scl70/ACA/others	19/15/8
Infections	
E. coli; E. faecalis	11/42 (26%)
P. aeruginosa;	5/42 (12%)
S. aureus	21/42 (50%)
*Others**	5/42 (12%)

L: limited, D: diffuse cutaneous subset;

Scl70: autoantibodies anti-Scl70; ACA: anti-centromere;

* Proteus mirabilis, Streptococcus agalactiae, Citrobacter koseri, Stenotrophomonas maltophilia

Conclusion: A number of effective measures, involving health care personnel and hospital environment, are essential in the management of digital ulcers and prevention of infectious complications. The prevalence of faecal pathogens in a quarter of cases has never been reported previously; it suggests an important role of patient's self-care limitations, generally more frequent in patients with diffuse cutaneous SSc, mainly during intercurrent home medications. Consequently, methodical patients' education on hand hygiene is mandatory to avoid such deleterious complications.

689

Lung and Breast Cancer in Systemic Sclerosis: Correlations with the Disease's Features. Michele Colaci, Dilia Giuggioli, Marco Sebastiani, Andreina Manfredi, Caterina Vacchi and Clodoveo Ferri. University of Modena and Reggio Emilia, Modena, Italy

Background/Purpose: Systemic sclerosis (SSc) shows an increased incidence of lung and cancer compared to general population. Chronic interstitial inflammation might have a causative role for lung cancer; while, it is very difficult to explain the breast cancer since mammalian glands are not involved in disease's processes. We aimed to investigate the possible correlations between SSc features and the development of lung or breast cancer in SSc.

Methods: We retrospectively evaluated 312 consecutive SSc patients (30/282 M/F, mean age 60.6 ± 13.7 SD years, mean disease duration 10.1 ± 6.8 SD years). Besides clinical features, individual cumulative radiation dosage (measured in mSv equivalents) for radiological examinations since SSc diagnosis was calculated.

Results: We found 14 cases of lung cancer (4.5%) and 12 cases of breast cancer (3.8%), which appeared 14.3 ± 6.7 SD years and a median period of 5 years (range 1–22) after the diseases onset, respectively. Statistical analysis evidenced significant correlations between pulmonary neoplasia and male sex (p=0.035), disease duration (p=0.019), presence of anti-Scl70 (p=0.001) and

absence of anticentromere ($p<0.0001$) antibodies, lung fibrosis ($p=0.011$), forced vital capacity (FVC) reduction ($p<0.0001$), and cyclophosphamide therapy ($p=0.005$). Logistic regression identified only FVC as significant independent factor (OR 1.08, 95% confidence interval 1.03–1.13; $p=0.02$) for lung cancer. On the contrary, breast cancer did not correlate with any SSc clinical parameters. Finally, cumulative radiation dosage did not affect the appearance of both lung and breast cancer. Interestingly, this latter was inversely related to radiation cumulative dosage ($p=0.022$).

Conclusion: The present findings suggest that a SSc patients' subset with more severe disease might have an increased risk to develop lung cancer. This malignancy mainly affects male patients, as well as subjects with longer disease duration and higher prevalence of lung fibrosis, presence of anti-Scl70 and absence of anticentromere autoantibodies. The correlation with previous cyclophosphamide therapy could be an indirect sign of severe lung involvement. Breast cancer did not show any significant correlations with SSc features; it involved women with significantly lower x-ray exposure, due to the medially shorter time interval between SSc diagnosis and the breast cancer onset, compared to SSc patients without this malignancy.

Incomplete Thymic Involution in Systemic Sclerosis and Rheumatoid Arthritis. Marine Meunier[1], Ramin Bazeli[2], Jerome Avouac[1], Antoine Feydy[2], jean-Luc Drape[2], Andre Kahan[1] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [2]Paris Descartes University, Radiology B department, Cochin Hospital, Paris, France

Background/Purpose: The thymus is a central lymphatic organ responsible for many immunological functions, including the production of mature functional T cells and the induction of self-tolerance. Several reports have suggested a potential association between thymus alterations and some immune-mediated rheumatic diseases, with radiological thymic alterations, such as incomplete thymic involution, thymic hyperplasia or thymoma., However, data regarding thymus alterations and systemic sclerosis (SSc) or rheumatoid arthritis (RA) are sparse. The aim of this study was to evaluate by chest CT scans the frequency and characteristics of incomplete thymic involution, in patients with SSc and RA, together with a non-autoimmune group of controls.

Methods: We performed a retrospective observational study between 2006 and 2009 including 161 patients who were at least 40 years old. These patients comprised 96 SSc patients (median age 59 years, 80% women) and 65 RA patients (median age 57 years, 88% women). All patients had a systematic chest CT-scan performed during the usual follow-up of their disease. SSc and RA patients were compared with 32 healthy controls (median age 63 years, 62% women) free of autoimmune disease. For the purpose of our study, *complete involution* of the thymus was defined as the absence of a residual thymus or a gland thickness, corresponding to the short axis on the axial slice, of less than 7 mm. We defined *incomplete involution* of the thymus as a residual thymic tissue more than 7 mm thick.

Results: The frequency of incomplete thymus involution was significantly higher in SSc and RA patients (respectively 15% and 14%) than in the control group (0%; $p<0.05$). SSc patients with incomplete thymic involution were younger than SSc patients with complete thymic involution (47 (39–80) years vs. 59 (39–87) years; $p=0.002$) and more likely to have pulmonary fibrosis with restrictive syndrome (24% vs. 0%, $p=0.03$). There was no correlation between incomplete thymic involution and other SSc-related disease characteristics, especially specific autoantibodies. In RA patients, incomplete thymic involution was more frequently associated with treatment with biologics (100% vs. 62%; $p=0.02$) and an absence of antinuclear antibodies (0% vs. 32%, $p=0.05$).

Conclusion: The prevalence of incomplete thymic involution to be higher in SSc and RA patients than in the control group. Our results suggest that incomplete thymic involution is linked to disease severity. Further larger studies are required to confirm this association and clarify the pathological significance of incomplete thymic involution in autoimmune diseases.

Shock Wave Therapy: A Novel Treatment for Systemic Sclerosis? Laura Belloli[1], Nicola Ughi[1], Maria-Cristina D'Agostino[1], Alberto Tedeschi[2], Marco Massarotti[1], Massimo Cugno[2] and Bianca Marasini[1]. [1]IRCCS Humanitas Clinical Institute, Rozzano (Milan), Italy, [2]Fondazione IRCCS Ca' Granda, University of Milan, Milan, Italy

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by microvascular involvement and widespread fibrosis, resulting in significant morbidity and mortality. No single effective treatment exists, and the current therapeutic options target only few aspects of the pathogenetic mechanisms. Since microangiopathy is the key feature of the disease, and extracorporeal shock wave treatment (ESWT) has been suggested to exert a vascular protective action and to enhance nitric oxide availability within the endothelium, we evaluated whether ESWT could reduce SSc endothelial damage and ameliorate skin involvement.

Methods: Eight SSc consecutive females fulfilling SSc validated criteria, aged 66 ± 12 yrs, were included in the study, after informed consent. Four consecutive ESW sessions (Dermagold–MTS Germany defocused lithotripter device, 10,000 shots/session applied at the energy level of 0.06 mJ/mmq) were weekly applied to both hands, including digits, and to one forearm, equally divided on volar and dorsal surfaces. The controlateral forearm served as control. Circulating vascular endothelial growth factor (VEGF), von Willebrand factor (vWf) and tissue plasminogen activator (tPA) were measured before treatment, immediately after the first session and at the end of the cycle. Skin involvement, assessed by Rodnan Skin Score (RSS) and durometer (digits and forearm) and nailfold capillaroscopy were performed at baseline and after the ESWT cycle.

Results: VEGF and vWf significantly decreased after the first session (500.8 ± 227.2 vs 411.0 ± 201.6 pg/ml, $p=0.007$ and 172.3 ± 64.8 vs 152.0 ± 67.6 % of normal, $p=0.004$, respectively), and remained stable at the end of treatment (417.0 ± 129.3 pg/ml and 167.1 ± 70.8 %,VEGF and vWf, respectively, p=ns). tPA did not change (data not shown). At the end of treatment, while total RSS did not change, RSS at fingers appeared significantly reduced (4.9 ± 1.2 vs 3.9 ± 1.7, $p=0.018$). Durometer measurement showed a significant decreased both at forearm (26.9 ± 5.4 vs 23.4 ± 4.3 U.I., $p=0.021$) and at finger-pad: (52.0 ± 9.8 vs 48.8 ± 10.4 U.I., $p<0.0001$). Among capillaroscopic parameters, only haemorrages (score:0–3) were significantly reduced at the end of treatment (-35 ± 15.6%, [mean±SE], $p=0.038$).A significant relationship was observed at baseline between vWf levels and finger RSS ($p=0.016$, $R=0.804$).

Conclusion: Our preliminary data suggest a possible role of ESWT in the therapeutic armamentarium of SSc. However, more studies on a larger series of patients are needed and timing and site of ESWT should better defined.

692

Clinical Associations of Elevated Acute Phase Response, Proteinuria and Low Dlco in Early Scleroderma Patients: A Report From the EULAR Scleroderma Trials and ReSearch Group (EUSTAR) Database. Patricia E. Carreira[1], Loreto Carmona[2], Beatriz E. Joven[3], Christopher D. Denton[4], Yannick Allanore[5], Ulrich A. Walker[6], Marco Matucci-Cerinic[7], Ulf Muller-Ladner[8] and EUSTAR coauthors[9]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Fundación Española de Reumatología, Madrid, Spain, [3]HOSPITAL UNIVERSITARIO 12 DE OCTUBRE, MADRID, Spain, [4]Royal Free Hospital, Medical School, London, England, [5]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [6]Dept. of Rheumatology at Basel University, Felix-Platter Spital, Basel, Switzerland, [7]University of Florence, Florence, Italy, [8]Justus-Liebig Universität Gieβen, Kerckhoff-Klinik GmbH, Bad Nauheim, Germany, [9]Florence

Background/Purpose: Elevated ESR, low DLCO and proteinuria are known risk factors for early mortality in systemic sclerosis (SSc). Although these factors are routinely collected by SSc experts, this is not the case in other settings, as general rheumatology clinics. The EUSTAR database allow us to analyze the clinical associations of these mortality risk factors in a large number of early SSc patients, which might help to improve scleroderma care in daily practice. The objective of this study is to identify the clinical associations of elevated ESR, proteinuria and low DLCO in a large group of recently diagnosed SSc patients

Methods: EUSTAR collects prospectively the Minimal Essential Data Set (MEDS), on all sequential SSc patients in participating centres. Patients with disease duration <3 years at the first EUSTAR entry were selected, and baseline data from the first visit were analyzed. Since ESR was not collected in MEDS, we used elevated acute response (ESR > 20 mmHg and/or CRP over normal) as a surrogate. Binary logistic regression, Chi square ant t test were used to analyze differences between groups with or without elevated acute response, proteinuria and low DLCO. Generalized lineal model was used to identify symptoms present in patients with none, one, two or three of these prognostic factors

Results: From 1180 patients (19% men), 482 had diffuse and 590 had limited disease. Mean age was 53 ± 14 years. Mean disease duration was 18 ± 6 months and time between Raynaud onset and first non Raynaud symptom was 3 ± 7 months. By multivariate logistic regression, elevated acute response was associated with older age (OR 1.02; 95%CI 1.009–1.04;

p=0.001), arthritis (OR 2.4; 95%CI 1.6–3.7; p<0.0001), male gender (OR 1.9; 95%CI 1.3–2.8; p=0.003), higher mRSS (OR 1.04; 95%CI 1.02–1.06; p<0.0001), Scl70 (OR 1.6; 95%CI 1.1–2.3; p=0.02), muscular atrophy (OR 1.9; 95%CI 1.1–3.3; p=0.02) and low FVC (OR 1.8; 95%CI 1.3–2.7; p=0.002). Proteinuria was associated with renal crisis (OR 8.1; 95%CI 2.7–24.5; p<0.0001), high blood pressure (OR 2.5; 95%CI 1.2–5.1; p=0.02), intestinal involvement (OR 2.3; 95%CI 1.1–4.8; p=0.02) and pulmonary hypertension (OR 2.5; 95%CI 1.2–5.1; p=0.02). Low DLCO was associated with lung fibrosis (OR 3.7; 95%CI 2.3–5.9; p<0.0001), low FVC (OR 4.5; 95%CI 2.6–7.5; p<0.0001) and pulmonary hypertension (OR 1.7; 95%CI 1–3.2; p=0.05). Generalized lineal model showed that the presence of lung fibrosis (p<0.0001), low FVC (p<0.0001), renal crisis (p<0.004), CK elevation (p=0.04), pulmonary hypertension (p=0.04) and arthritis (p=0.05) were more frequent in patients with increased number of poor prognostic factors

Conclusion: In early SSc patients, elevated acute phase response is associated with severe skin and visceral involvement, proteinuria with renal crisis, and low DLCO with lung disease and pulmonary hypertension. Patients with increased number of these 3 poor prognostic factors present with diffuse disease, renal crisis and lung, articular and muscular involvement. Our results support the importance of a careful evaluation, including acute phase response, DLCO and urine protein, in every SSc patient.

693

Correlation Between Exercise Echocardiography and Right Heart Catheterization in Scleroderma Patients At Risk for Pulmonary Hypertension. Ami A. Shah[1], Susan Mayer[1], Reda Girgis[1], James Mudd[2], Laura K. Hummers[1] and Fredrick M. Wigley[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Oregon Health & Science University, Portland, OR

Background/Purpose: Pulmonary hypertension (PH) is a major cause of morbidity and mortality in systemic sclerosis (SSc), and early detection may improve prognosis. Recent studies have utilized exercise provocation during echocardiography as a screening tool to identify patients at high risk for PH, and an increase in estimated right ventricular systolic pressure (RVSP) of 15–20mmHg with exercise has been utilized as a cutoff for a positive test. Among SSc patients who are suspected of PH by clinical or laboratory parameters, we sought to determine whether exercise induced changes in RVSP measured by echocardiography could identify patients with right heart catheterization (RHC) evidence of PH.

Methods: Scleroderma patients with RVSP ≥ 40mmHg and any dyspnea, RVSP ≥45 mmHg regardless of symptoms, isolated decline in diffusing capacity (DLCO) ≥10%, or new onset unexplained dyspnea (Hct>28 and no active ILD, COPD, or LVEF<50%) who underwent supine ergonometric exercise echocardiography (echo) and RHC as part of their routine clinical care were studied. Our outcome of interest was the presence of any PH as defined by a mean pulmonary artery (PA) pressure ≥ 25mmHg at rest or ≥ 30mmHg with peak exercise on right heart catheterization. Three exercise echo cutoffs were compared between patients with and without PH using the Fisher's exact test: 1) increase in RVSP ≥ 15mmHg with exercise, 2) increase in RVSP ≥ 20mmHg with exercise, and 3) peak RVSP ≥ 50mmHg regardless of baseline RVSP.

Results: Twelve SSc subjects met inclusion criteria in this pilot study. The median age was 61 years (range 41.6–77.2 years), 91.7% were female, and 58.3% had limited SSc. At baseline, the median RVSP, forced vital capacity, DLCO and NTproBNP were 40 mmHg (range 27–52 mmHg), 79.7% predicted (range 49.7–99.4%), 59.6% predicted (range 46.3–106.7%), and 207.5 pg/mL (range 20–981 pg/mL), respectively. Eight of 12 subjects (66.7%) met our RHC criteria for any PH. Five of 12 subjects had an increase in RVSP ≥ 15mmHg with exercise, 4 of 12 had an increase in RVSP ≥ 20mmHg with exercise, and 7 of 12 had a peak RVSP ≥ 50mmHg. Only a cutoff peak RVSP ≥ 50mmHg was statistically significantly associated with the presence of any PH on RHC (p=0.01). Neither threshold of increasing RVSP with exercise was statistically associated with the presence of any PH on RHC in this small sample (p=0.08 for 15mmHg cutoff, p=0.21 for 20mmHg cutoff).

Conclusion: Exercise echocardiography may be a useful noninvasive screening tool for the presence of any PH in high-risk SSc patients. These preliminary data suggest a peak RVSP of 50mmHg with exercise may be an important threshold that identifies a patient who needs an invasive hemodynamic assessment by RHC. These preliminary data need to be validated in a large prospective sample of SSc patients to examine the utility of exercise echo as a screening tool for PH and to understand the clinical relevance of abnormal exercise hemodynamics.

694

Positive Predictive Value of Anti-Centromere and Anti-Scl-70 Antibody Multiplex Assays in a Rheumatology Practice Setting. Svetlana Meier[1] and Ted R. Mikuls[2]. [1]Univ of Nebraska Med Center, Omaha, NE, [2]Omaha VA and University of Nebraska, Omaha, NE

Background/Purpose: Recent concerns have been raised regarding the sensitivity of multiplex ANA testing compared to 'gold-standard' methods involving Hep2A substrate by immunoflourence (IF). There has been less attention given to the predictive values of antibodies targeting specific nuclear antigens incorporated in the multiplex approach, specifically with regards to anti-centromere and anti-SCL-70 positivity that have had high specificity with conventional assays in the past. The aim of this study was to determine the positive predictive value (PPV) of anti-centromere and anti-SCL-70 antibody multiplex assays in a rheumatology practice setting and to characterize patients with false-positive results using this approach.

Methods: As part of a retrospective medical record review, we identified patients seen in an academic rheumatology practice between January 2008 and January 2010 and with positive test results for either anti-centromere or anti-Scl-70 antibody. As a gold-standard, we categorized patients based on the receipt of a formal connective tissue disease (CTD) diagnosis from a board certified rheumatologist or satisfaction of distinct ACR CTD classification criteria available (with a focus on classification criteria for systemic sclerosis – both limited and diffuse forms). Alternative CTD diagnoses, other health conditions and comorbid illnesses were documented.

Results: There were 73 patients seen over the two-year study period with positive tests for either anti-centromere (n = 47) or anti-SCL-70 (n = 23) (See Table). All patients were examined by a board certified academic rheumatologist. Of the 47 patients who had a positive anti-Scl-70 antibody and were evaluated by a rheumatologist, 2 patients had a diagnosis of diffuse systemic sclerosis and 1 patient had a diagnosis of CREST syndrome, yielding a PPV of only 6.4%. Among patients not meeting criteria for scleroderma and who were anti-SCL-70 positive, 4 were diagnosed with liver cirrhosis or autoimmune hepatitis, 5 had a positive Raynaud's phenomenon without any other CTD manifestations, 6 had SLE complicated by glomerulonephritis, and 2 were diagnosed with RA. Of the 26 patients who were positive for anti-centromere antibodies, 8 patients had a diagnosis of CREST syndrome, yielding a PPV of 30.7%. Additionally, 7 had liver disease, 2 had Raynaud's phenomenon in the absence of other CTD manifestations, 1 had an SLE, and 1 RA.

Test	Diffuse scleroderma	Limited scleroderma (CREST)	Liver disease	Raynaud's phenomenon	SLE	RA
Anti-Scl-70 (+), n = 47	2	1	4	5	6	2
Anti-centromere (+), n = 26	0	8	7	2	1	1

Conclusion: In contrast to prior reports examining the diagnostic characteristics of anti-centromere and anti-SCL-70 using conventional laboratory methods, false positive results are frequently observed using the newer solid-phase multiplex approach. Chronic liver disease, primary Raynaud's phenomenon, SLE, and RA emerged as frequent underlying conditions among rheumatology patients with false-positive results.

695

Severe Interstitial Lung Disease within the PHAROS Registry: Baseline Characteristics and Clinical Features. Aryeh Fischer[1], Jerry A. Molitor[2], Laura K. Hummers[3], Vivien M. Hsu[4], Monique E. Hinchcliff[5] and Virginia D. Steen[6]. [1]National Jewish Health, Denver, CO, [2]Univ of MN MMC108, Minneapolis, MN, [3]Johns Hopkins University, Baltimore, MD, [4]RWJ Med Schl Scleroderma Prog, New Brunswick, NJ, [5]Northwestern University, Chicago, IL, [6]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Pulmonary hypertension (PH) and interstitial lung disease (ILD) are the leading causes of mortality in scleroderma. A significant number of scleroderma patients have both PH and ILD and this combination is associated with a particularly poor prognosis. The multicenter **PHAROS** (**P**ulmonary **H**ypertension **A**ssessment and **R**ecognition of **O**utcomes in **S**cleroderma) registry is comprised of 434 subjects from 21 centers in the USA and Canada and prospectively follows scleroderma subjects at high-risk for, or with incident PH. In this study we sought to determine the prevalence and characteristics of subjects in PHAROS with severe ILD at study entry.

Methods: Pre-PH scleroderma subjects are enrolled if they have a FVC%/DLco% > 1.6, or echo-estimated RVSP > 40 mmHg. Subjects with right-heart

catheterization confirmed incident PH within the previous 6 months are classified into pulmonary arterial hypertension (PAH), pulmonary venous hypertension (PVH) or PH-associated with ILD (PH-ILD). Baseline and biannual demographic, clinical, and laboratory data as well as patient-reported health questionnaires are collected. In this study, we characterize and analyze only those subjects with severe ILD demonstrated by a severe restrictive defect on pulmonary function testing as defined by a FVC% < 60 at enrollment.

Results: Sixty-three (15%) subjects from 17 centers had a FVC% of < 60 at study entry. Gender and scleroderma subtype were more evenly distributed than expected for PAH. Most were Caucasian, the median age was 52 and disease duration from time of diagnosis was 5.8 years. Autoantibodies were recorded in 58 subjects. Positive anti-centromere was noted in 3 (5%), isolated-nucleolar ANA in 13 (22%), anti-Scl-70 in 15 (26%), and other antibody positivity in 17 (29%). Mild dyspnea (NYHA FC II) was noted in 32% and moderate dyspnea (NYHA FC III) in 49%. Median DLco was 28% and most (56%) had a FVC%/DLco > 1.6. Forty-nine (78%) had undergone RHC within 6 months of study entry and 41 (84%) of these had PH (median mPAP 29[17–60]). Among those with PH, 63% had PH-ILD and 27% had PVH.

Baseline characteristics of PHAROS subjects with FVC < 60% at study entry

Age	52.5 (26–81)
Female gender	49 (78%)
Ethnicity	40 W (63%), 15 B (24%), 7 H (11%)
SSc type	27 L (43%), 28 D (44%)
Rodnan skin score	8 (0–43)
UCSD Dyspnea Score	2.04 (0–4.33)
NYHA FC	8-I (13%), 20-II (32%), 31-III (49%), 3-IV (5%)
TLC (range)	55 (32–102)
FVC (range)	50 (27–59)
DLco (range)	28 (10–53)
FVC%/DLco%	1.73 (0.46–5.31)
FVC%/DLco% > 1.6	35 (56%)
Echo RVSP (range)	46 (17–100)
Pericardial Effusion	19 (30%)
Underwent RHC	49 (78%)
mPAP (range)	29 (17–60)
RHC mPAP > 25 mmHg	41 of 49 (84%)
mPCWP (range)	11 (2–35)
RHC mPCWP < 15	37 of 49 (59%)
PH type	31 PH-ILD (63%), 13 PVH (27%)

Conclusion: A sizeable cohort (15%) of PHAROS subjects has severe ILD at study entry. These subjects frequently have a positive anti-Scl-70 or isolated-nucleolar ANA, and are rarely anti-centromere positive. They have a severely reduced DLco, most have a FVC%/DLco% ratio > 1.6 and have PH at study entry. Prospective assessment of this subset within PHAROS will provide valuable information about the natural history of combined PH and ILD in scleroderma.

696

Clinical Significance of Antibodies to Ro52/TRIM21 in Systemic Sclerosis. Marie Hudson[1], Janet Pope[2], Solene Tatibouet[1], Russell Steele[1], Murray Baron[3] and Marvin J. Fritzler[4]. [1]McGill University, Montreal, QC, [2]Univ of Western Ontario, London, ON, [3]Jewish General Hospital, Montreal, QC, [4]University of Calgary, Calgary, AB

Background/Purpose: Ro52/TRIM21 antibodies have been identified in 20% of the Canadian Scleroderma Research Group cohort, making it the second most common autoantibody in this group of systemic sclerosis (SSc) patients. Given its high prevalence and the controversy in the literature surrounding its role in autoimmune diseases, we undertook this study to determine whether Ro52/TRIM21 antibodies in SSc are associated with distinct clinical manifestations in SSc.

Methods: Sera from 963 patients with SSc enrolled in a multi-centre cohort study were collected. Antibodies to Ro52/TRIM21 were assayed in a central laboratory by an addressable laser bead immunoassay using a commercially available kit (QUANTAPlex ENA 8, INOVA Diagnostics Inc., San Diego, CA). Associations between Ro52/TRIM21 and clinical and other serological manifestations of SSc were investigated using standard statistical methods.

Results: Mean age of the cohort was 55 (+ 12) years, 87% were female, 85% were White, mean disease duration (since the onset of the first non-Raynaud's disease manifestation) was 11 (+ 9) years, and 59% had limited, 37% had diffuse and 3% had no skin involvement. Ro52/TRIM21 antibodies were present in 194 (20.2%) patients, thus representing the second most common autoantibody in this cohort with anti-centromere, RNA polymerase III and topoisomerase I antibodies present in approximately 35%, 19% and 16% of the patients, respectively. Ro52/TRIM21 overlapped with many other autoantibodies, although the association differed according to antibody. Indeed, whereas 16% of the overall cohort had topoisomerase I antibodies, only 10% of Ro52/TRIM21 positive patients had topoisomerase I antibodies ($p = 0.0129$) and the titres of Ro52/TRIM21 were among the lowest measured (763.28 U/ml) in this subset of patients. On the other hand, whereas 6% of the overall cohort had Ro60 antibodies, 21% of Ro52/TRIM21 positive patients were Ro60 positive ($p < 0.0001$) and the titres of Ro52/TRIM21 were among the highest measured (5530.66 U/ml). Similar strong relationships between Ro52/TRIM21 and Ro60 were noted between Ro52/TRIM21 and U1 RNP ($p = 0.0066$, 2099.45 U/ml), SS-B/La ($p < 0.0001$, 6003.88 U/ml) and Jo-1 ($p = 0.0171$, 4412.83 U/ml), and to a lesser degree between Ro52/TRIM21 and CENP-B ($p = 0.0372$, 1098.86 U/ml) and Sm ($p = 0.0361$, 1482.09 U/ml). In univariate analyses, Ro52/TRIM21 antibodie were associated with interstitial lung disease and polyautoimmunity. In multivariate logistic regression analyses, there was a strong trend towards an association between Ro52/TRIM21 and interstitial lung disease (odds ratio (OR) 1.50; 95% confidence interval (CI): 0.99–2.27; $p = 0.0550$) and to a lesser extent between Ro52/TRIM21 and polyautoimmunity (OR 1.49; 95% CI: 0.89–2.50; $p = 0.1287$).

Conclusion: Ro52/TRIM21 autoantibodies were the second most common autoantibody in this large SSc cohort. In SSc, Ro52/TRIM21 antibodies may be a marker of interstitial lung disease and polyautoimmunity.

Elevated Pulmonary Vascular Resistance At Rest Is Associated with Exercise Pulmonary Arterial Hypertension in Systemic Sclerosis Patients without Pulmonary Hypertension Hemodynamics At Rest. Jonathan Kushi[1], Mary Ellen Csuka[1], Laura K. Hummers[2], Fredrick M. Wigley[2], Vivien M. Hsu[3], Dinesh Khanna[4], Jerry A. Molitor[5] and Virginia D. Steen[6]. [1]Medical College of Wisconsin, Milwaukee, WI, [2]Johns Hopkins University, Baltimore, MD, [3]RWJ Med Schl Scleroderma Prog, New Brunswick, NJ, [4]University of Michigan, Ann Arbor, MI, [5]Univ of MN MMC108, Minneapolis, MN, [6]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Pulmonary arterial hypertension occurs in 1 of 7 patients with systemic sclerosis (SSc), but is the leading cause of death. Patients who do not have pulmonary hypertension (PH) at rest have been shown to have elevated mean pulmonary arterial pressure (mPAP) with exercise. This population represents a group that may be at increased risk for PH, which could have implications on prognosis and treatment. This study analyzes the resting and exercise right heart catheterization (RHC) data in the PHAROS (Pulmonary Hypertension Assessment and Recognition of Scleroderma) registry.

Methods: PHAROS is a multicenter cohort of SSc patients designed to determine the outcomes of high risk SSc patients for the development of PH. Of 390 patients within the registry, 87 patients had RHC at rest and with exercise following local protocols. Analysis of the data was performed with focus on the parameters of mPAP, pulmonary capillary wedge pressure (PCWP), and pulmonary vascular resistance (PVR). The following definitions of pulmonary hypertension were used: pulmonary arterial hypertension (PAH) = mPAP ≥ 25mmHg, PCWP ≤ 15mmHg; pulmonary venous hypertension (PVH) = mPAP ≥ 25mmHg, PCWP > 15mmHg; exercise pulmonary arterial hypertension (ePAH) = mPAP with exercise > 30mmHg, PCWP ≤ 18mmHg; exercise pulmonary venous hypertension (ePVH) = mPAP with exercise > 30mmHg, PCWP > 18mmHg.

Results: There were 87 patients within the PHAROS registry that had an exercise RHC. Of these, 52 patients (60%) had no change between resting and exercise RHC, including patients that remained normal with exercise or had pulmonary hypertension with rest and exercise. Thirty-five patients (40%) had discrepant hemodynamic changes with exercise. Within this group of 35, 21 patients (60%) had normal resting RHC with ePAH, 8 patients (23%) had normal resting RHC with ePVH, and 6 patients (17%) had PAH with ePVH. In total, PAH was diagnosed in 22 patients (25%) and ePAH in an additional 21 (24%). Among patients with a normal resting RHC, a PVR >140 dyn·s/cm^5 was associated with ePAH, (positive predictive value 76%, negative predictive value 62%). A PCWP >10mmHg was associated with ePVH, (positive predictive value 62%, negative predictive value 100%).

Conclusion: In patients with SSc, an exercise RHC can reveal underlying pulmonary hypertension despite normal resting hemodynamics. Patients with normal mPAP at rest, but elevated PVR >140 dyn · s/cm^{5}or PCWP >10 mmHg may be at increased risk of ePAH or ePVH respectively. In these patients, pursing an exercise RHC may lead to earlier diagnosis and treatment.

698

A Panel of Serum Biomarkers Including Type I Interferon- Related Chemokines Distinguishes Clinical and Autoantibody Status of Patients with Systemic Sclerosis. Emily Baechler Gillespie[1], Jane Hoyt Buckner[2], Joseph C. Wilson[3] and Jerry A. Molitor[3]. [1]University of Minnesota, Minneapolis, MN, [2]Benaroya Research Institute, Seattle, WA, [3]Univ of MN MMC108, Minneapolis, MN

Background/Purpose: Systemic Sclerosis (SSc) is a clinically heterogeneous disorder with inflammatory, fibrotic, and vascular manifestations and a highly variable prognosis and response to therapies. Biomarkers that segregate with disease manifestations and which may predict prognosis or response to therapy are needed. SSc shares a type I interferon (IFN) mRNA signature with Systemic Lupus (SLE). We have previously developed a panel of chemokines which correlate with the IFN signature in SLE, and which predicts SLE disease course. We now report the initial testing of this chemokine panel, and additional potentially relevant biomarkers in SSc patients.

Methods: Serum samples from 57 SSc patients, 5 healthy controls, and 6 autoimmune controls were obtained from the Scleroderma biorepository at the Benaroya Research Institute. Autoantibody status and presence/absence of interstitial lung disease(ILD) was determined by initial chart review at time of sample acquisition. Four IFN-regulated chemokines(IP-10, I-TAC, MCP-1, and MIP-3β) were measured by Searchlight multiplexed immunoassays, and 14 additional cytokines, chemokines, and growth factors were measured by multiplexed bead-based immunoassays (Luminex). Samples were run in duplicate and recombinant proteins were used to generate standard curves. Due to non-normal distribution of analyte values, nonparametric Mann-Whitney tests were used for group comparisons with $p<0.05$ considered significant. Significant variables from the univariate analysis were tested in a stepwise multiple logistic regression model.

Results: In our initial study, IP-10 and MIP-3β were significantly elevated in SSc patients compared to healthy controls. These two chemokines and I-TAC were also significantly elevated in SSc compared to autoimmune controls. A chemokine score (calculated from summed levels of the four chemokines) was significantly higher in SSc compared to both control groups. MCP-1 levels were significantly higher in both anti-topoisomerase (topo) + patients (n=25) and topo-, CENP- patients (n=16) as compared to anti-centromere (CENP) + patients (n=15). Among 14 additional proteins, IL-1ra, VEGF, and Eotaxin were significantly increased in SSc vs. autoimmune controls, but none were found at altered levels in SSc patients compared to healthy controls. IL-1ra, VEGF, and IL-12p70 were elevated in SSc patients with ILD (n=34) compared to patients without ILD (n=18).IL-1ra and VEGF were also lower in CENP+ patients as compared to both Topo+ patients and Topo-, CENP- patients. In multivariate analysis of SSc vs. healthy controls, only IP-10 was retained in the model ($p=0.0047$); the model for SSc vs. autoimmune controls included both IP-10 and IL-1ra ($p=0.0006$). MCP-1 was the only significant variable retained in the model of ILD ($p=0.0004$).

Conclusion: Serum levels of IFN-regulated chemokines and other cytokines associate with specific autoantibodies and with important clinical manifestations of SSc. Further studies are needed to determine whether these putative biomarkers will predict disease course or response to therapy.

699

Myocardial Involvement in Systemic Sclerosis As Assessed by Ultrasonography and Scintigraphic Perfusion Imaging. Niki Tsifetaki[1], Charalampos Papagoras[2], Kersten Achenbach[3], Athanasia Georgiou[4], Spyridon Tsiouris[5], Andreas Fotopoulos[6] and Alexandros A. Drosos[7]. [1]Registrar in Rheumatology, Ioannina, Greece, [2]Fellow in Rheumatology, Ioannina, Greece, [3]Cardiologist, Ioannina, Greece, [4]Fellow in Nuclear Medicine, Ioannina, Greece, [5]Registrar of Nuclear Medicine, Greece, [6]Associate Professor of Nuclear Medicine, Greece, [7]Professor of Medicine/Rheumatology, Ioannina, Greece

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease with two cardinal features: vascular involvement with intense vasoconstriction and smooth muscle proliferation, resulting in increased vascular resistance and tissue ischemia, together with excessive extra-cellular collagen deposition resulting in fibrosis. Both features affect multiple organs such as the skin and the lung. However, limited data are available on heart involvement.

Methods: We conducted a cross-sectional study of subclinical heart involvement in patients with SSc followed in a single tertiary rheumatology department. Enrolled patients underwent transthoracic echocardiography (GE Vivid 7 equipment), which assessed left ventricular hypertrophy (LVH) (defined as LV wall thickness >11mm), LV diastolic dysfunction, LV ejection fraction (EF) and pulmonary systolic arterial pressure (PASP). Stress echocardiography with dobutamine was performed in some cases. We also performed stress-rest myocardial perfusion imaging (MPI) scintigraphy by ^{99m}Tc-tetrofosmin single-photon emission computed tomography (SPECT). LV wall was divided in 20 segments to quantify ischemia as follows: mild (1–2), medium (3–4) & significant (≥5).

Results: Thirty-seven patients with SSc were enrolled (33 females, 4 males; median age 56 years, range 30–75). Eighteen of them had limited and 19 diffuse SSc, with median disease duration 15 years (range 2–57). Eleven patients had a history of arterial hypertension (AH), 2 of pulmonary arterial hypertension (PAH), 1 of myocardial infarction and 1 of diabetes mellitus. Two patients were on endothelin receptor antagonists due to PAH, while 14 received bosentan alone or in combination with sildenafil for digital ulcers without PAH. Echocardiography revealed LVH in 9 cases (24.3%); diastolic dysfunction (up to grade 1) was found in 17 (45.9%), though only one had EF<55% (EF median 67%, range 50–80). After excluding patients with a history of AH, LVH was still found in 6 (23.1%) and diastolic dysfunction in 10 (38.5%). PASP>30 mmHg was found in 13 patients (35.1%), 11 of whom had no history of PAH, while 3 were already on bosentan for digital ulcers. Stress echocardiography was performed in 12 patients and was negative in all. MPI by ^{99m}Tc-tetrofosmin SPECT was performed in 35 patients. Twenty-one (60%) exhibited reversible LV perfusion defects consistent with ischemia. Their median age was 54 years (range 30–75); 4 patients were less than 40 years and 8 patients less than 50 years old. In the majority of cases (20) ischemia was graded as mild and in one it was moderate.

Conclusion: Subclinical heart involvement is common in SSc, even in patients in the younger age groups. Diastolic dysfunction without compromised systolic performance, increased PASP and ischemia on MPI SPECT are found in a significant proportion of SSc cases. Although the precise underlying pathology need be elucidated, careful screening of SSc patients for potential heart involvement and consultation by a cardiologist may often be warranted.

700

Prevalence of Celiac Antibodies in Patients with Systemic Sclerosis. Lindsy J. Forbess[1], Jessica K. Gordon[1], Kamini Doobay[2], Brian Bosworth[3], Morgana L. Davids[1] and Robert Spiera[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]New York Presbyterian Hospital, Weill Cornell Medical Center, New York, NY

Background/Purpose: Gastrointestinal (GI) manifestations of systemic sclerosis (SSc) are common and symptoms overlap with those of celiac disease. A high prevalence of celiac antibodies has been found in populations with autoimmune conditions. Two prior studies showed celiac antibody prevalence in SSc to be 7% and 10%, which is higher than the general population estimates of 1–2%. These studies were limited by small sample sizes, the lack of correlation of antibody status with symptoms, and the use of traditional celiac screening antibodies, where newer ones with potentially improved sensitivity and specificity have since emerged. We conducted a cross-sectional study to determine the prevalence of celiac antibodies in an SSc population using a registry cohort at a single academic medical center. We used both traditional and newer celiac antibody tests. We also investigated whether the presence of celiac antibodies correlated with GI symptoms in our patients.

Methods: Serum was available on 107 well-characterized SSc patients, and a random number generator was used to select 39 diffuse and 33 limited SSc patients. These 72 patient sera were tested using commercially available enzyme-linked immunosorbent assay kits (INOVA, San Diego, CA) for traditional anti-tissue transglutaminase (anti-TTG) IgA and IgG and newer anti-deamidated gliadin peptide (anti-DGP) IgA and IgG antibodies. If any of the above antibodies were positive, more specific anti-endomysial antibodies were tested on sera using immunofluorescence methods (Quest laboratories, NJ). Clinical data from registry forms was used to determine whether antibody status correlated with GI symptoms. Fischer's exact and Wilcoxon rank-sum tests were used to compare differences.

Results: Of 72 patients tested, 1 patient was positive for anti-TTG IgG and 2 patients were positive for anti-DGP IgA antibodies. Of these 3 patients, none was positive for anti-endomysial antibodies. The prevalence of celiac antibodies in our SSc patient population, therefore, was 3/72 or 4%. No significant differences with respect to GI symptoms, including abdominal pain, early satiety, post-prandial bloating, diarrhea, constipation, vomiting, reflux, or dysphagia, were seen in the celiac antibody positive compared with negative SSc patients. The table below describes baseline characteristics of the 72 patients tested.

Table. Baseline Characteristics of SSc Registry Patients

Characteristic	All patients	Antibody Positive	Antibody Negative	P value
Age, mean ± SD years	51 ± 13.1 (n = 72)	59 ± 9.8 (n = 3)	51 ± 13.2 (n = 69)	0.242
Female (%)	63/72 (87.5)	3/3 (100)	60/69 (87)	1.000
Caucasian (%)	57/72 (79.2)	3/3 (100)	54/69 (78.3)	1.000
Disease duration, mean ± SD years	6.1 ± 6.7 (n = 66)	5.3 ± 4.5 (n = 3)	6.1 ± 6.8 (n = 63)	0.853
Classification				
Diffuse (%)	39/72 (54.2)	2/3 (66.7)	37/69 (53.6)	1.000
Limited (%)	33/72 (45.8)	1/3 (33.3)	32/69 (46.4)	1.000
Modified Rodnan skin score (range 0–51), mean ± SD	13 ± 11.6 (n = 65)	18 ± 9.9 (n = 2)	13 ± 11.8 (n = 63)	0.351
Sicca (%)	30/63 (47.6)	3/3 (100)	27/60 (45)	0.102
Joint involvement (%)	56/67 (83.6)	3/3 (100)	53/64 (82.8)	1.000
Hemoglobin, mean +/− SD	12.4 +/− 1.63 (n = 53)	12.1 +/− 1.7 (n = 3)	12.4 +/− 1.64 (n = 50)	0.658

Conclusion: In the largest study to date, we demonstrate the presence of celiac disease associated antibodies to be 4% in our SSc population, which is lower than previously reported. In our study, there was no difference between celiac antibody positive and negative SSc patients with respect to GI symptoms, likely attributable to the high prevalence of GI involvement in our cohort and the small number of antibody positive patients. Our study does not suggest that concurrent celiac disease is a common cause of GI complaints in patients with SSc.

701

Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma: Racial Differences in Systemic Sclerosis-Related Pulmonary Hypertension. Christine Peoples[1], Robyn T. Domsic[1], Thomas A. Medsger Jr.[1], Virginia D. Steen[2] and PHAROS Investigators[3]. [1]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [2]Georgetown Univ Medical Center, Washington, DC, [3]Washington, DC

Background/Purpose: PHAROS is a multi-center, longitudinal study designed to assess risk factors and outcomes in patients with systemic sclerosis (SSc) who have definite pulmonary hypertension (PH) or are at high risk to develop PH (pre-PH). The objective of this study was to examine the racial differences in SSc-related and PH characteristics in the PHAROS population.

Methods: Entry criteria into PHAROS for SSc patients at high risk for PH included a diffusion capacity (DLCO) <55% predicted, a forced vital capacity (FVC) %/DLCO% ratio >1.6, or an estimated pulmonary arterial systolic pressure (PASP) on echocardiogram > 35mmHg. Patients complete questionnaires every 6 months and are seen yearly for physician evaluation. Information collected includes New York Heart Association (NYHA) functional classification, the World Health Organization class of PH, autoantibody profile, pulmonary function test results, and evidence of interstitial lung disease by radiographic imaging. Differences at baseline (first visit) between African American and Caucasian patients were compared by t-test, Wilcoxon, Fisher's exact, and chi-square where appropriate. With correction for multiple comparisons, a p-value of 0.01 was considered significant.

Results: There are 309 Caucasians and 70 African Americans (18%) enrolled in PHAROS. African Americans (mean age 50.5 ± 11.2 years) were significantly younger than Caucasians (59.3 ± 10.5 years, p < 0.0001), although there was no difference in gender (p=0.15).

Table 1. Systemic Sclerosis and Pulmonary Hypertension Characteristics at Time of PHAROS Enrollment in Caucasians and African Americans.

	Caucasians	African-Americans	p-value
SSc Type	–	–	0.01
limited	67%	49%	
diffuse	28%	47%	
unclassified	5%	4%	
Autoantibody Profile	–	–	0.02
anti-centromere	26%	13%	
anti-topoisomerase I	14%	14%	
anti-U1RNP	5%	7%	
nucleolar ANA	14%	30%	
anti-RNA polymerase III	3%	3%	
other antibody	23%	16%	
unidentified/missing	15%	17%	
PH Type	–	–	0.11
pre-PH	58%	67%	
pulmonary arterial hypertension	30%	16%	
pulmonary venous hypertension	5%	7%	
ILD-related PH	7%	10%	
Baseline NYHA Class	–	–	0.76
0	15%	18%	
I, II	58%	58%	
III, IV	27%	24%	

There was no difference in the frequency of pulmonary fibrosis (p=0.90). There was also no difference (p=0.29) between the mean FVC predicted in African Americans (80% ± 19) compared to Caucasians (74% ± 20), but African Americans had a significantly lower DLCO percent predicted (median 39%, IQR 34, 57) compared to Caucasians (44%, IQR 30, 46; p=0.008). There was no difference in the six minute walk distance (p=0.66).

Conclusion: In the PHAROS population of patients with or at high risk for PH, the overall proportion of African Americans is higher than generally seen in published SSc series. African Americans tend to be younger, have a significantly higher proportion of diffuse cutaneous SSc, and a lower DLCO than Caucasians. African Americans less often had anti-centromere antibody, but more frequently had one of the nucleolar ANAs. This suggests that African Americans with a nucleolar ANA should be monitored closely for the development of PH.

702

Effects and Safety of Rituximab in Systemic Sclerosis: An Analysis From the European Scleroderma Trial and Research Group. Suzana Jordan[1], Jorg HW Distler[2], Britta Maurer[1], Jacob M. Van Laar[3], Yannick Allanore[4], Oliver Distler[1] and EUSTAR Rituximab Group[5]. [1]University Hospital Zurich, Zurich, Switzerland, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Musculoskeletal Research Group, Newcastle, United Kingdom, [4]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [5]Florence, Italy

Background/Purpose: Preclinical studies and smaller case-series suggest potential effects of Rituximab (RTX) on skin fibrosis, interstitial lung disease and polyarthritis in patients with systemic sclerosis (SSc). Objective of this study was to analyze the effects and safety of RTX in a real-life clinical setting using the EUSTAR cohort.

Methods: Patients treated with RTX were captured from the EUSTAR cohort and centers were asked to provide additional data for this study. Primary outcomes were: modified Rodnan skin score (mRSS) for skin fibrosis, FVC for SSc-ILD, DAS 28 3v for SSc-associated polyarthritis, and CK levels for SSc-associated myositis. Effects on fibrosis were analyzed at the follow up closest to 12 months, and effects on polyarthritis and myositis at the follow up closest to 6 months. Normally distributed data are shown as mean ± SD and were analyzed by paired t-test. Nonparametric data are shown as median and interquartile range and were analyzed by Wilcoxon matched paired signed rank test.

Results: Seventy two SSc patients treated with RTX from 27 EUSTAR centers were available for analysis (52 diffuse SSc/19 limited SSc, disease duration 6 years (3–10 years)). The most frequent application scheme was 2 × 1000mg RTX given 2 weeks apart. Twenty-eight patients had co-treatment with other disease modifying drugs (most frequent methotrexate, n =14).

The mRSS as the primary outcome for skin fibrosis showed a statistically significant reduction compared to baseline (n=47, 18.2+10.9 vs. 14.5+9.9, p=0.0002). This effect became even more evident when the cohort was enriched for patients with extended skin fibrosis (diffuse SSc with mRSS >16 at baseline, n= 26: 26.5+6.8 vs. 20.4+8.9, p<0.0001). This was paralleled by an improvement of the European SSc activity score (n=10; 3.7 (2.6–6.4) vs. 1.7 (0.9–2.5), p=0.01).

There were no effects on FVC in patients with SSc-ILD (n=11, 57.7+9.1 vs. 56.2+16.0 %; p=0.5). Similarly, other lung function parameters including DLCO, TLC, and extent of fibrosis on HRCT did not change after RTX treatment.

In patients with SSc-associated polyarthritis, the DAS 28 score was reduced after RTX treatment (n=8; 4.8 (2.5–7.5) vs. 3.7 (2.6–6.6)), but did not reach statistical significance (p=0.3). Other arthritis outcomes including tender joint count, swollen joint count, VAS articular pain, CRP and ESR showed similar trends.

Levels of CK decreased significantly in patients with SSc-associated myositis after RTX treatment (n=12, 273+177 vs. 184+139, p=0.03). Other measures of myositis such as levels of myoglobin and VAS scores were available only for a limited number of patients and did not change significantly versus baseline.

During RTX treatment, infections occurred in 14 patients, 29 reported fatigue, 9 had nausea and 3 patients developed serum sickness. Four patients died, one of them possibly related to RTX (pneumonia and cardiac failure 1.5 months after RTX infusion).

Conclusion: In this large, observational multicenter EUSTAR study, positive signals for potential efficacy of RTX were obtained for skin fibrosis

and SSc-related myopathy. These results strongly emphasize the need for a randomized controlled trial with RTX in patients with SSc.

703

B Cell Depletion Therapy in Systemic Sclerosis: a Follow-up Study of 4 Years on Skin and Lung Involvement in Fourteen Patients. Silvia L. Bosello[1], Antonella Laria[1], Manuela Rucco[1], Mario Bocci[1], Giacomo De Luca[1], Annunziata Capacci[1], Matteo Falcione[2], Francesco Maria Danza[2] and Gianfranco Ferraccioli[1]. [1]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [2]Institute of Radiology, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: Experimental data show that B cells play important roles in fibrogenesis and vascular abnormalities, but discordant results on Rituximab's efficacy in skin and lung involvements in small cohorts of patients have been reported.

The objective of our study was to define the changes in skin score and lung parameters after Rituximab therapy in SSc patients with a long follow-up.

Methods: Fourteen patients with SSc with mean age 44.3±12.2 years were treated with anti-CD20, 1 g at time 0 and after 14 days. All patients presented a diffuse disease. Mean disease duration was 32.9±37.1 months, 8 presented an early disease, defined as a disease duration of less than 24 months. Skin score and presence of digital ulcers were assessed at baseline and at final follow-up. Pulmonary function tests to assess forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO) and lung high resolution computed tomography (HR-CT) were performed at baseline and at follow-up. A semiquantitative scores were used to assess the alveolar and interstitial lung involvement. An improvement or a decrease of more than 10% for FVC and 15% for DLCO was considered clinical significant.

Results: A mean follow-up of 41.0±14.8 months was reached. The mean skin score at baseline was 24.9±9.8, while at follow-up it decreased to 12.0±6.7, (p=0,001). All but one of the patients experienced an improvement of skin score higher than 10% with a median decrease of the skin score of 56.0% (range 11.0–85.1%). Six patients presented digital ulcers at baseline and two patients (33%) experienced healing of ulcers and did not present digital ulceration during follow-up.

Considering lung involvement, nine patients (64.3%) presented a stable FVC, 3 (21.4%) showed an improvement and 2 (14.3%) a decrease. None of the patients with an early disease presented a decrease of FVC, while 2 of 6 patients with a long disease showed a decrease of this functional parameter.

The HRCT alveolar score improved or remained stable in 10 patients (71.4%). Only one patient with an early disease presented an increase of alveolar score (12.5%), compared to 3 patients (50%) with a long disease duration.

One (7.2%) patient presented a decrease of interstitial score, 8 patients (57.1%) a stability, while five (35.7%) showed an increase of the interstitial score.

Conclusion: Our data confirm the efficacy of Rituximab on cutaneous involvement as revealed by the significant decrease in the skin score. AntiCD20 therapy seems to preserve the stability of lung involvement as supported by stable or improved FVC and alveolar score, over all in patients with early scleroderma. The long follow-up, considering the rapid progression of lung disease in the first phases of the diffuse scleroderma disease, supports a possible role of CD20 depletion as a disease modifying therapy (DMTSSc) in systemic sclerosis.

704

ELF Score: A Validated Serum Test Strongly Predictive of Fibrosis in Systemic Sclerosis. Giuseppina Abignano[1], Giovanna Cuomo[2], Maya H. Buch[1], William M. Rosenberg[3], Gabriele Valentini[4], Paul Emery[5] and Francesco Del Galdo[1]. [1]University of Leeds, Leeds, United Kingdom, [2]Second University of Naples, Naples, Italy, [3]Centre for Hepatology - UCL, London, United Kingdom, [4]Second Univ of Napoli, Napoli, Italy, [5]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom

Background/Purpose: The absence of a serum test predictive of activity or severity in Scleroderma (SSc) is a major burden both for clinical intervention studies and for clinical management. Recently, a large multicenter study has identified an algorithm of three serum biomarkers as predictive of severity and clinical outcome in Chronic Liver Disease.The algorithm,known as Enhanced Liver Fibrosis (ELF), includes the measurement of serum concentrations of hyaluronic acid, TIMP-1 and aminoterminal propeptide of procollagen type III. Objectives: To evaluate the predictive value of ELF test as surrogate outcome measure of fibrosis in SSc.

Methods: 210 patients with SSc, all satisfying the ACR criteria for the classification of the disease, were enrolled in the study. 260 sera were analysed of which 90 were longitudinal samples from 40 patients. All patients were investigated for clinical and serological subset, disease duration, vascular, skin, joint, tendon, muscle, esophago-gastrointestinal, lung, heart and kidney involvement, disease severity, disease activity and HAQ-DI. ELF score was determined blindly by an independent commercial service (iQur, London, UK). Correlations were calculated using Spearman's correlation test and an unpaired two-tailed T-test was used to perform comparison between groups. All the variables found to be correlated in univariate analysis were subsequently assessed by step-wise regression analysis. Data were analysed employing SPSS18 software.

Results: The mean ELF score in SSc patients sera was 8.75±1.05 (normal range < 5.97). ELF score correlated with many clinical and instrumental measures assessing fibrotic involvement including: mRSS ($r = 0.32; p < 0.0001$),DLCO ($r = -0.29; p < 0.0001$), FVC % ($r = -0.21; p = 0.038$), Ejection Fraction ($r = -0.21; p = 0.0009$). The other variables found to be correlated with ELF in univariate analysis were Age, ESR, CRP and FVC. Step-wise regression analysis indicated that the single measures independently associated with ELF score were mRSS, DLCO, EF and age whereas ESR, CRP and FVC were not. When compared to complex clinical indexes ELF score was also found to be correlated with EScSG-Activity Index ($r = 0.20; p = 0.0015$), total Medger's disease severity score ($r=0.35; p<0.0001$) and total HAQ-DI ($r=0.32; p<0.0001$).Most interestingly, in the longitudinal samples ELF test showed a strong sensitivity to change, keeping the correlation with mRSS ($r=0.34$ $p = 0.0009$), DLCO ($r=-0.029; p=0.029$). In the same cohort of longitudinal samples ELF test was again correlated with total Severity ($r=0.49; p< 0.0001$), EScSG-Activity index ($r = 0.21; p=0.046$), and HAQ-DI ($r= 0.42; p<0.0001$).

Conclusion: The ELF test is a simple serum test that strongly correlates with several measures of fibrosis in SSc. It has a clear face validity for measuring the concentration of molecules involved in extracellular matrix turnover and strongly correlates with fibrotic severity and activity in SSc. The profound sensitivity to change with changes in mRSS, severity, activity and lung function indicate a clear discriminant validity of ELF as biomarker in SSc fibrotic involvement. ELF test should be included in the algorithm of activity index in Scleroderma and considered as outcome in clinical trials.

705

Optical Coherence Tomography: A New Imaging Technique That Allows Detailed Visualization of Affected Scleroderma Skin. Giuseppina Abignano[1], Sibel Aydin[2], Concepcion Castillo-Gallego Jr.[3], Maya H. Buch[1], Paul Emery[4] and Francesco Del Galdo[1]. [1]University of Leeds, Leeds, United Kingdom, [2]Goztepe Training and Research Hospital, Istanbul, Turkey, [3]Hospital Universitario La Paz, Madrid, Spain, [4]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom

Background/Purpose: Skin involvement in scleroderma is a crucial clinical feature often considered primary outcome in clinical trials and yet orphan of a validated and reliable imaging technique. Optical Coherence Tomography (OCT) is an emerging imaging technology for clinical examination. OCT systems focus a low-intensity infra-red beam in tissue up to 2 mm below the surface. While Ophthalmic OCT has been in development since the early 1990s, advanced laser technology and recent MultiBeam developments have recently enabled the development of high-speed topical OCT providing high-contrast skin mages. The purpose of this study was to describe skin appearances as seen with OCT and to compare these findings clinical assessment of skin in patient affected by Scleroderma.

Methods: Dorsal aspect of fingers, hands and forearm were assessed in this study. A total of 66 skin regions from 22 patients (9 lcSSc, 13 dc-SSC) and 12 healthy controls (HC) were scanned by OCT with topical probe "VivoSight" (Michelson Diagnostics) and optics of Swept-source Fourier-Domain type with a laser wavelength of 1305+/− 15 nm. The investigator was blinded to the clinical details.

Signal changes within epidermis, dermal epidermal junction and

superficial dermis were documented. Clinical skin involvement of the regions examined was determined by an assessor blinded to the OCT findings using the mRSS scoring system.

Results: OCT provided real-time, pain free, video-rated images without any pretreatment or gels applied to the skin. Skin structure was imaged 2mm beneath the surface.showed remarkably high quality images of the skin. Images collected in healthy volunteers showed, consistently with published findings a regular hyperreflective border of the skin surface and a homogeneous hypo-reflective epidermal layer. The papillary dermis consistently showed hyper-reflective properties compared to the adjacent epidermis allowing the visualization of the dermal-epidermal junction. The deeper reticular dermis was imaged as less reflective than the adjacent papillary dermis. Blood and lymphatic vessels could be identified as hypreflective tube-like structures, often with tapering ends and visible both in the papillary and reticular dermis.

Average mRSS on the site of analysis was 2.5 for dcSSc and 1 for lcSSc. (0 for healthy volunteers).

The most striking finding of Scleroderma affected skin was the loss of the hyporeflective epidermal layer and consequently of the visualization of the dermal epidermal junction. Similarly there was no distinction of papillary and reticular dermis. Instead skin was visualized as a homogeneous textured layer. Blood vessels were less numerous than in normal skin or unaffected skin.

Conclusion: This is a proof of concept study determining the potential of OCT as imaging technique of Scleroderma Skin. Here we show that OCT is indeed a powerful harmless technique that allows a finely detailed visualization of the skin. The implementation of a OCT scoring system of the abnormalities we have identified in this initial study is warranted to determined whether OCT could be used as surrogate outcome measure in intervention studies or as predictive of skin involvement in Systemic Sclerosis.

706

Decreased Plasma Ghrelin Levels in Patients with Systemic Sclerosis. Yuko OTA, Yasushi Kawaguchi, Kae Takagi, Takahisa Gono, Masanori Hanaoka and Hisashi Yamanaka. Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Ghrelin, an endogenous ligand for the growth hormone secretagogue receptor, is a gastric hormone that plays a major role in the regulation of food intake. In 2008, it was reported that rikkunshito, an herbal medicine, had beneficial effects for anorexia in upregulating the secretion of acylated-ghrelin. In addition to energy homeostasis, ghrelin exerts an anti-inflammatory effect and inhibits pro-inflammatory cytokines such as IL-1beta and TNF-alpha. Recently, it was reported that ghrelin attenuated fibrosis progression in hepatocellular injury. The aim of the present study was to investigate the levels of plasma acylated-ghrelin and desacylated-ghrelin in patients with systemic sclerosis (SSc) and to determine the association between ghrelin levels and disease phenotypes. We also explored the effects of skin fibroblasts derived from patients with SSc on collagen production.

Methods: Forty five patients with SSc and 19 healthy controls (HCs) were enrolled in the study; 32 of the patients with SSc were complicated with interstitial lung disease (ILD-SSc). The plasma acylated-ghrelin and desacylated-ghrelin levels were determined by enzyme-linked immunosorbent assay (ELISA). Skin fibroblasts derived from 5 patients with SSc were cultured with various concentrations of recombinant ghrelin. After the skin fibroblasts were cultured for various times, the supernatants were collected and stored at −80°C. Procollagen type I C peptide was then measured using a commercial ELISA kit.

Results: The levels of plasma acylated-ghrelin were 13.2 ± 6.3 fmol/ml in the SSc patients and 21.9 ± 7.9 fmol/ml in the HCs, whereas the levels of plasma desacylated-ghrelin were 66.3 ± 35.1 fmol/ml in the SSc patients and 129.6 ± 50.3 fmol/ml in the HCs. Both the acylated-ghrelin and desacylated-ghrelin concentrations were significantly lower in the patients with SSc than in the HCs ($p < 0.0001$), as shown in Figure 1. In particular, the levels of acylated-ghrelin in patients with ILD-SSc were lower than those in patients with uncomplicated SSc ($p = 0.028$). In the experiments in vitro, procollagen type I C peptide production was suppressed by optimal concentrations of ghrelin in cultured SSc fibroblasts ($p < 0.05$).

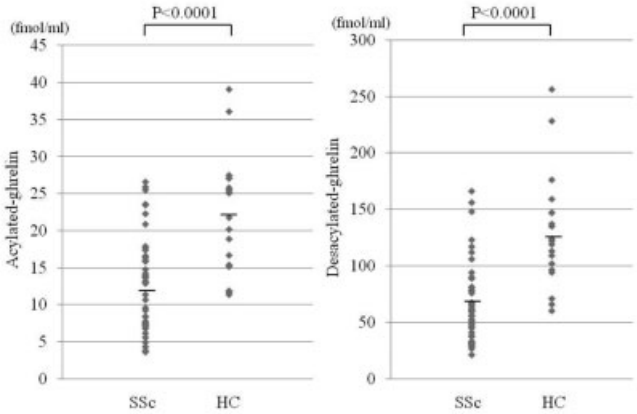

Figure 1. Plasma acylated-ghrelin and desacylated-ghrelin concentrations in patients with SSc and HCs.

Conclusion: The levels of plasma ghrelin were significantly lower in patients with SSc than in the HCs, and the levels of acylated-ghrelin in patients with ILD-SSc were significantly lower than those in patients without ILD. Our results also suggest that ghrelin exerts an anti-fibrotic effect in skin fibrosis, and its use may represent a novel strategy for anti-fibrotic therapy.

707

A Pilot Study of Abatacept for the Treatment of Patients with Diffuse Cutaneous Systemic Sclerosis. Eliza F. Chakravarty[1], David Fiorentino[2], Mihoko Bennett[3] and Lorinda Chung[4]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Stanford, Stanford, CA, [3]Stanford University, Palo Alto, CA, [4]Stanford Univ Medical Center, Palo Alto, CA

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disease characterized by progressive fibrosis of skin and internal organs, vascular damage, and autoantibody production. Several lines of evidence support a role for T-cells in initiating and perpetuating disease. We performed a randomized, double-blinded placebo controlled trial to evaluate the safety and efficacy of intravenous abatacept, an inhibitor of T-cell costimulation, or placebo in patients with diffuse cutaneous systemic sclerosis (dcSSc).

Methods: Adult subjects with dcSSc who had adequate cardiac, pulmonary (FVC>49% predicted, DLCO >39% predicted), and renal function (serum Cr <2.0) were recruited for this study. Prednisone >10 mg daily and other immunosuppressive therapies were not permitted. Subjects with active infection, history of malignancy, or infection with tuberculosis, hepatitis or HIV were also excluded. Subjects were randomized in a 2:1 double-blinded fashion to receive IV abatacept or placebo at weeks 0, 2, 4, and every 4 weeks for a total of 24 weeks. Primary outcomes were safety and the percent change in modified Rodnan Skin Score (mRSS, scale 0–51) from week 24 to baseline. Secondary clinical outcomes included change in Health Assessment Questionnaire-Disability Index (HAQ-DI), patient and physician global assessments by visual analogue scale (VAS), and pulmonary function tests (PFTs).

Results: 12 patients screened for the study: two were not eligible due to lack of peripheral venous access. 10 patients (8 women and 2 men, mean age 42.2 years) enrolled in the study. Mean disease duration from the time of the first non-Raynaud's manifestation was 4.4 (3.8) years. 7 patients were randomized to receive abatacept and 3 received placebo. At baseline, there were no significant differences in mRSS, HAQ-DI, VAS scales and PFTs between the two groups, although subjects randomized to abatacept had shorter disease duration (2.4 vs. 8.8 years, $p=0.004$). Compared with those receiving placebo, subjects treated with abatacept reported greater improvement in HAQ-DI and patient VAS. Numerically, patients receiving abatacept had larger improvements in absolute (−8.6 vs −2.3, $p=0.059$) and mean % change (−33% vs −6.2%, $p=0.31$) in MRSS than the placebo group (**Table**). No deaths or serious adverse events occurred during the study. 14 AEs (7 in each group) were reported in 9 patients: most were mild in nature. One patient, in the placebo arm, terminated the study at week 20 due to infection of a preexisting toe ulcer.

Variable	Abatacept (n = 7)	placebo (n = 3)	p-value
Baseline			
Age (year, SD)	39.8 (11.4)	48.6 (13.9)	0.32
% Male	28.6	0	1
% caucasian	57.1	66.7	1
Duration (raynauds)	3.9 (3.4)	9.2 (3.2)	0.05
Duration (1st non-raynauds)	2.4 (1.6)	8.8 (3.8)	0.0042
mRSS	23.6 (6.6)	30 (3)	0.15
HAQ-DI	0.6 (0.8)	1.5 (1.1)	0.18
Physician Global VAS	37.6 (13.8)	56.3 (5.5)	0.57
Patient Global VAS	53 (35.8)	61.7 (44.8)	0.75
Patient Pain VAS	42.7 (35.3)	53 (47.8)	0.71
FVC	77.3 (19)	73.3 (27.6)	0.79
DLCO	87 (17.5)	80.3 (24)	0.65
Outcomes			
Change in HAQ-DI	−0.04 (0.2)	0.25	0.56
Absolute change in mRSS	−8.6 (7.5)	−2.3 (15.0)	0.059
% change in mRSS	−33 (29.0)	−6.2 (52.3)	0.31
Change in Physician Global	−11.9 (18.1)	−17.3 (23.2)	0.048
Change in Patient Global	−8 (7.6)	−2.7 (6.7)	0.023
Change in Patient Pain	−11.4 (8.3)	−15.0 (25.1)	0.18
Change in FVC	1.3 (8.5)	0.3 (8.5)	0.72
Change in DLCO	2.0 (6.3)	−7.4 (10.7)	0.84
# Adverse events	7	7	

Conclusion: Blockade of T-cell costimulation with abatacept appears to be safe and may be a useful treatment for cutaneous sclerosis in patients with dcSSc. Larger, multi-center placebo-controlled studies limited to patients with early disease are necessary to further evaluate the utility of abatacept in the treatment of patients with dcSSc.

708

Clinical Correlates of CENP-A and CENP-B Antibodies in a Large Cohort of Systemic Sclerosis Patients. Marie Hudson[1], Michael Mahler[2], Janet Pope[3], Daniel You[4], Solene Tatibouet[1], Russell Steele[1], Murray Baron[5] and Marvin J. Fritzler[4]. [1]McGill University, Montreal, QC, [2]INOVA Diagnostics, Inc., San Diego, CA, [3]Univ of Western Ontario, London, ON, [4]University of Calgary, Calgary, AB, [5]Jewish General Hospital, Montreal, QC

Background/Purpose: To study the clinical phenotypes of CENP-A and B positive systemic sclerosis (SSc) patients and to compare them to anticentromere antibody (ACA) positive and negative SSc patients.

Methods: Sera from 802 patients with SSc enrolled in the Canadian Scleroderma Research Group multi-centre cohort study were collected. Indirect immunofluorescence was performed on HEp-2 substrate (HEp-2000; ImmunoConcepts, Sacramento, CA, USA) that included fluorescein-conjugated goat antibodies to human IgG (H+L) in Calgary (Mitogen Advanced Diagnostics). CENP-B ELISA (Dr. Fooke Laboratorien GmbH, Neuss, Germany) with recombinant full-length CENP-B expressed in insect cells was used and performed according to the manufacturer's instructions. The CENP-A ELISA (Dr. Fooke Laboratorien GmbH), a CE-certified peptide based assay, was performed according to the manufacturer's AI-Line instructions for use as previously described. Associations with clinical and other serological manifestations of SSc were investigated using standard statistical methods.

Results: CENP-A antibodies were detected in 276 (34%), CENP-B antibodies in 286 (36%) and ACA in 279 (35%) patients. ACA, CENP-A and/or CENP-B patients resembled each other and differed from the remainder of the cohort in many respects: older chronologically and at disease onset; more commonly women; more likely to have limited disease and lower skin scores; less likely to have finger ulcers, digital tuft resorption or finger contractures; more likely to have pulmonary hypertension; less likely to have interstitial lung disease, scleroderma renal crisis, inflammatory arthritis and inflammatory myositis; and lower overall disease severity. CENP-A and/or B status was predictive of the extent of skin involvement over time. Limited patients who were CENP-A *negative* at baseline were more likely to progress to diffuse disease compared to positive patients (odds ratio 2.55, 95% confidence interval 1.37, 4.85, p-value 0.004).

Conclusion: Our study contributes significantly to increase the knowledge concerning the clinical significance of CENP-A and B in SSc. This is the largest and most detailed analysis of the clinical correlates of CENP-A and B in a large SSc cohort with well-defined phenotypes. The clinical phenotypes of CENP-A and/or B patients are generally consistent with that associated with ACA positive patients. The data from this and from previous studies indicate that CENP-A and CENP-B assays can be used a) to identify patients with SSc with high sensitivity and specificity, and b) using optimized cut-off values, to identify the same clinical phenotypes as known for ACA. This data is of considerable clinical importance because clinical immunology labs are increasingly using high throughput ELISA tests to test for CENP antibodies, with or without ACA detected by IIF. Accordingly, it is imperative that clinicians should be informed that the phenotypes that they generally associate with ACA in SSc is similar to that which they should associate with CENP-A and/or B positive antibodies.

709

Influenza H1N1 Vaccination in Mixed Connective Tissue Disease: Effectiveness and Safety Independent of Disease or Therapy. Renata Miossi[1], Ricardo Fuller[1], Julio C. B. Moraes[1], Ana Cristina Medeiros[1], Carla G.S. Saad[1], Nadia E. Aikawa[1], Joao Miraglia[2], Maria A. Ishida[3], M.Teresa C. Caleiro[1] and Eloisa Bonfa[1]. [1]University of Sao Paulo, Sao Paulo, Brazil, [2]Fundação Butantan, São Paulo, Brazil, [3]Adolfo Lutz Institute, Sao Paulo, Brazil

Background/Purpose: There are specific recommendations for influenza vaccination in systemic autoimmune diseases and the WHO recently recommended that the 2010–2011 trivalent seasonal flu vaccine must contain the A/California/7/2009 (H1N1) virus. With regard to mixed connective tissue disease (MCTD) there is only one study in the literature from our group focusing solely in vaccine side-effects and the overall immunoresponse in large cohort of rheumatic diseases (Ann Rheum Dis. 70(6): 1068–73, 2011). We therefore evaluated herein the possibility of clinical and laboratorial disease exacerbation as well as the influence of disease manifestations and therapy in antibody response.

Methods: From March 22 to April 02, 2010, 69 subjects diagnosed with MCTD according to Kasukawa's classification criteria and 69 age and gender matched controls were vaccinated with non-adjuvanted influenza A/California/7/2009 (H1N1) virus-like strain. Patients were clinically evaluated and blood samples (inflammatory markers, muscle enzymes) were collected pre- and 21 days post-vaccination. Anti-H1N1 titers were determined by influenza hemagglutination inhibition assay. The percentage of seroprotection (SP), seroconversion (SC) and the factor increase in geometric mean titer (GMT) were calculated.

Results: Mean age (48.6 ±12.6 vs. 48±12, P=0.68) and female gender predominance (95.6%) were alike in patients and controls. The mean disease duration was 12.9±8.9 years. A comparable SP (10.1 vs. 10.1%, P=1), SC (66.7% vs. 65.2%, P=1) and factor increase GMT (10; 95%CI, 7.1–14.1 vs. 8; 95%CI, 6–10.6; P=0.33) was observed in patients and controls. The specific analysis of immunosuppressive therapy influence (prednisone≥7,5mg/day and/or cytotoxic drugs) revealed a similar SC rate in patients with and without these drugs (72.7% vs. 56.0%, P=0.19). Moreover, the SC rate in the only 7 patients with prednisone≥20mg/day were similar to controls (P=0.69). Patients, at entry, with and without current pulmonary disease (P=0.62), pulmonary arterial hypertension (P=0.75) had comparable SC rates. Laboratorial parameters remained stable pre- and post vaccine: CRP (P=0.55), CPK (P=0.31), aldolase (P=0.4). Of note, none of the patients presented deterioration of the clinical disease. No major severe side effects were reported.

Conclusion: The non-adjuvanted influenza A/H1N1 vaccination immunoresponse in MCTD patients is adequate and independent of disease manifestations and therapy. In addition, the observed overall disease clinical and laboratorial safety settles its recommendation.

710

How Do Physicians Make a Global Assessment of Raynaud's Phenomenon in a Clinical Trial? Richard W. Martin[1], Andrew J. Head[2], James D. Birmingham[1] and Aaron T. Eggebeen[1]. [1]Michigan State University College of Human Medicine, Grand Rapids, MI, [2]College of Human Medicine, Michigan State University, Grand Rapids, MI

Background/Purpose: To evaluate how physicians in a clinical trial integrate patient historical information to make a judgment of the global activity of Raynauds phenomenon (RP).

Methods: Patients were enrolled in a prospective double blind cross-over clinical trial of topical nitroglycerine for the prevention or treatment of RP. Brief structured interviews were conducted in the clinic weekly where physicians used a standardized template to evaluate and

semi-quantitatively score seven aspects of RP activity experienced by patients over the preceding week. Items assessed number and duration of RP attacks, severity of associated pain (0–5) and numbness (0–5), development of new finger ulcers (yes, no), the impact of RP in restricting activities (0–5) and importance of activity restrictions to patients (0–5). Physicians used the structured interview data to judge the MD global assessment of RP activity (RP MD-GA) (0–9). Physician judgment strategy was represented as a linear regression model, with standardized regression weights describing the relative importance of the 7 historical attributes of RP in determining the physician's global assessment.

Results: Data were analyzed from 100 patient visits of 15 patients. All patients were female, mean age was 38.5 (s =13.1), 91% white, 29% history of scleroderma, 9% had digital ulcers at baseline, 23% were taking concurrent medications to treat RP. Mean number of RP attacks was 2.3 per day (s=.62), mean minutes duration 25.7 (s=14.4). RP MD-GA was significantly correlated with daily # RP =.699 ($p<.001$), RP impact on life =.662 ($p<.001$), RP pain =.625 ($p<.001$), RP importance =.641 ($p<.001$), RP numbness =.436 ($p<.001$), duration RP =.381 ($p<.001$), but not patient age. Due to the exploratory nature of the study, all significantly correlated independent variables plus development of new or worse digital ulcers were included in a stepwise linear regression model with RP MD-GA as the dependent variable.

The most parsimonious model was: MD-GA RP = −1.495 +.472 daily # RP +.308 RP pain +.311 RP impact on life. This model had an overall R=.859 and adjusted R^2=.730. Addition of the other measured variables did not significantly add to the power to predict RP MD-GA.

Conclusion: When 7 RP historical clues were considered, only daily # RP, RP associated pain and RP impact on life significantly influenced physician decision models when they assigned a global assessment of RP. Duration of RP attacks, numbness, patient's view of the importance of the QOL impact, and development of new or worse ulcers did not significantly impact the RP MD-GA. In a RP clinical trial, a physician may only need to ask 3 questions to secure the data needed to assign a global assessment.

711

Tendon and Joint Involvement in Diffuse Systemic Sclerosis: An Ultrasound and Magnetic Resonance Imaging Study. Maria S. Stoenoiu[1], Frederic E. Lecouvet[1] and Frédéric. A. Houssiau[2]. [1]Cliniques Universitaires Saint-Luc, Brussels, Belgium, [2]Université catholique de Louvain, Brussels, Belgium

Background/Purpose: Musculoskeletal involvement is present in 40 to 80% of patients suffering from systemic sclerosis (SSc) and impacts their daily activities, thus decreasing their quality of life. Musculoskeletal ultrasonography (MSUS) has emerged as a new imaging modality, which allows detection of synovitis and tenosynovitis. In addition, using power-Doppler (PDUS) techniques, vessels can be detected inside the synovium.

The aim of the present study is (*i*) To report the frequency of tendon and joint involvement at wrists and ankles of patients suffering from diffuse SSc. (*ii*) to describe the morphological substrate of tendon friction rubs (TFR).

Methods: All patients had two MSUS of wrists and ankles performed by a radiologist and a rheumatologist. The first MSUS was performed on the day of the clinical examination. The second was performed on the day of MRI examination, at least 1 week later, in order to look for persistence of synovitis and/or tenosynovitis. MRI was performed at the most affected joint as detected by MSUS. In addition, all sites in which tendon friction rubs (TFR) were present, were imaged by MRI. OMERACT definitions were used to evaluate the presence of synovitis/ tensoynovitis on MSUS-PDUS.

Results: Fifteen consecutive patients suffering from diffuse SSc were included. Synovitis was detected by MSUS in 8/15 patients, tenosynovitis in 4/15 patients and tendon rupture in 2/15 patients. PDUS was positive in the majority of patients. Thickened retinacula were present in 4/15 patients. TFR at ankles were present in 5 patients (9 ankles). Synovitis was similarly distributed in the SSc patients with or without TFR. Tenosynovitis was more frequently observed in ankles in which TFR were present (3/9) than in ankles without TFR (3/21). Juxta-tendinous soft tissue infiltrates were present in all patients with TFR and only one patient without TFR.

Conclusion: Both MSUS/PDUS and MRI are useful to characterize tendon and joint involvement in SSc patients. Tenosynovitis, synovitis and thickened retinacula are not infrequently seen in these patients. Interestingly, our data suggest that juxta-tendinous soft tissue infiltrates are the morphological substrate of tendon friction rubs, which may thus be a misnomer for tissue friction rubs.

712

Iloprost Enhances Th17 and Th22 While Decreasing Th1 Cells Expansion in Healthy and Systemic Sclerosis Mononuclear Cells. Marie-Elise Truchetet[1], Yannick Allanore[2], Carlo Chizzolini[1] and Nicolò Costantino Brembilla[1]. [1]University hospital of Geneva, Geneva, Switzerland, [2]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France

Background/Purpose: In systemic sclerosis (SSc) inappropriate T cell responses are thought to participate in initiating events ultimately leading to excessive extracellular matrix deposition and fibrosis. Iloprost, a prostacyclin analog, is currently used as vasodilating agent to treat SSc-related vascular events. However, its immunomodulatory properties in humans remain unclear. Aim of this work was to assess whether Iloprost may influence the polarization and the cytokine-production capacity of T helper cells in healthy donors (HD) and SSc patients and to identify the receptors mediating its effects.

Methods: Peripheral blood mononuclear cells (PBMC) and clinical characteristics were obtained from 30 SSc and 29 age- and sex-matched HD upon informed consent and approval by the ethics committee. None of the patient was under immunosuppressant agents at the time of sampling. Frequencies of interleukin (IL)-17A, IL-22, interferon-gamma (IFN-gamma), and IL-4-producing CD4 T cells were assessed upon 7 days of polyclonal expansion in the presence or absence of Iloprost by multiparametric flow cytometry. The cytokines released in the supernatants were quantified by ELISA. Selective IP and EP receptor antagonists were used to identify the receptors mediating Iloprost effects. Differences between the means were assessed by the Student's t test. P values lower than 0.05 were considered as significant.

Results: Iloprost (Bayer Schering Pharma, Berlin, Germany) enhanced in a dose-dependent manner the CD4+ T cell production of IL-22 and IL-17A while decreasing the production of IFN-gamma. Analysis at single cell level confirmed these results and revealed that Iloprost treatment in vitro slightly but significantly favored the expansion of Th17 ($P<0.0001$) and Th22 cells ($P<0.0001$). Simultaneously, Iloprost induced a quantitatively more important decrease in Th1 cells ($P<0.0001$). No effects of Iloprost were observed on Th2 cells producing IL-4. Of interest, PBMC from SSc and HD responded to the same extent to Iloprost. Finally preliminary experiments indicated that the decreased production of IFN-gamma in the presence of iloprost was specifically reversed by CAY10449 (Cayman Chemical Co, Ann Arbor, MI), a peptide inhibitor specific for IP, while the enhanced production of IL-17A and IL-22 was partially inhibited by CAY10449, AH6809 (antagonist of EP1, EP2, and EP3), and AH23848 (antagonist of EP4) suggesting that the effect of Iloprost on cytokine production by PBMC was cooperatively mediated by several distinct receptors.

Conclusion: Our results show that Iloprost *in vitro* increases IL-17A and IL-22 while decreasing IFN-gamma production by CD4+ T cells, underlying new immunomodulatory proprieties of this compound distinct from its action on endothelial cells and fibroblasts. The capacity of Iloprost to modulate the production of cytokines by T cells should be taken into account in current Iloprost-based therapies and could be exploited for novel therapeutic approaches.

713

Evaluation of the Effect of Ambrisentan On Digital Microvascular Flow In Patients with Systemic Sclerosis Using Laser Doppler Perfusion Imaging. Nilanjana Bose[1], James Bena[1], Charles Trunick[1], John Petrich[2], Debora J. Bork[3], Geetha Krishnan[1] and Soumya Chatterjee[1]. [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic, Cleveland, [3]The Cleveland Clinic Found A50, Cleveland, OH

Background/Purpose: Conventional vasodilators such as calcium channel blockers may not be as helpful in Scleroderma (SSc) associated Raynaud's phenomenon (RP), as in primary RP, as they have little effect on the vascular fibro-proliferative changes that lead to chronic digital ischemia in SSc. Ambrisentan (Am) is a selective endothelin receptor type A (ET_A) antagonist FDA approved for the treatment of pulmonary hypertension. Am differs from bosentan in its ability to permit the vasodilatory effect of endothelin through its interaction with the endothelin-B receptor, while inhibiting its vasoconstrictive effect through its interaction with the ET_A receptor. Laser Doppler perfusion imaging (LDPI) is a non-invasive technique that involves perfusion mapping of areas of skin, rather than examination of blood flow at a single point. We hypothesized that Am would increase digital microvascular flow (as measured by LDPI) in patients with SSc-associated digital ischemia.

Methods: In this randomized, double-blinded, placebo controlled trial, we

enrolled 20 patients with limited SSc of duration < 7 years. Smokers and those with pulmonary hypertension or active digital ulcers were excluded. There were 3 visits: week 0 (baseline), week 1 and week 12. At each visit, 3 baseline blood flow readings of fingers of the non-dominant hand were obtained at room temperature (25°C) and after cold challenge (10°C) for 2 minutes. Raynaud's Condition Score (RCS), Scleroderma Health Assessment Questionnaire (S-HAQ) and Pain-Visual Analog Scale (P-VAS) were also completed at each visit. Fifteen patients received Am 5 mg tablets daily for one month and then increased to 10 mg daily for 2 months while 5 patients received placebo throughout. The primary outcome measure was the mean change of blood flow in selected regions of interest (ROI) of the fingers after 1 and 12 weeks of therapy. Secondary outcome measures included changes in RCS, S-HAQ, and P-VAS.

Results: There were 16 females (80%); mean age was 50 years (range: 20 to 70). All but 2 patients completed the study. The Am group showed a 0.11 unit mean increase in perfusion at 1 week and a 0.01 unit mean decrease at 12 weeks. In the placebo group, the corresponding numbers were a mean increase of 0.18 unit and a mean decrease of 0.06 unit. Changes were similar within ROI as well. None of these differences overall or within ROI reached statistical significance. However, patients in the Am group showed significant improvement in RCS ($p = 0.001$) and S-HAQ ($p = 0.005$) with minimal change in P-VAS ($p = 0.14$) scores. No adverse events occurred.

Conclusion: The final analysis for this pilot study did not support increase in digital microvascular blood flow in SSc patients over time; however, there was an improvement in S-HAQ score and RCS over 12 weeks. The study may have been underpowered to detect small differences over a short (3-month) duration of drug exposure. However, if that is not the case, then the results imply that Am does not augment digital blood flow by inducing vasodilation (1 week) and/or reversing remodeling (12 weeks) (as they do in the pulmonary circulation). This difference might be due to intrinsic differences in the vessel wall or in the local micro-environment of the digital arterioles.

714

Echo-Doppler Evaluation Does Not Show Abnormal Diastole In Scleroderma Patients with Pulmonary Venous Hypertension. Santhanam Lakshminarayanan[1], Nada Shaban[1], Diane Tran[2], Jason W. Ryan[2], Irina Collins[2], David Hager[1] and Naomi F. Rothfield[1]. [1]University of Connecticut School of Medicine, Farmington, CT, [2]University of Connecticut School of Medicine, Farmington,, CT

Background/Purpose: Systemic sclerosis (SS) is a multisystem disorder which may cause myocardial and pulmonary fibrosis and pulmonary vasculopathy. Pulmonary arterial hypertension (PAH) due to increased pulmonary vascular resistance (PVR) is a major cause of morbidity and mortality in this population. Exercise induced elevation of pulmonary pressures from PAH can identify patients at high risk for chronic PAH. SS patients may also develop elevated pulmonary pressures with exercise in the setting of normal PVR due to diastolic dysfunction and pulmonary venous hypertension (PVH). We report a case series of 19 scleroderma patients with exercise-induced PVH diagnosed with invasive hemodynamic studies. We assessed whether echocardiographic parameters of impaired relaxation could have predicted the presence of PVH.

Methods: The echocardiograms on 19 clinically dyspneic SS patients whose hemodynamic monitoring during exercise showed PVH were retrospectively analyzed for evidence of diastolic dysfunction.

Results: Data on eighteen female patients and one male patient was studied. The mean age was 54 years. Other than hypertension (47%), most did not have medical conditions predisposing to diastolic dysfunction. Hemodynamic testing confirming PVH as shown in Table 1.

Table. RIGHT HEART CATHETERIZATION DATA

MEAN VALUES	REST	EXERCISE
PAP mmHg	18 ± 5	34 ± 7
PCWP mmHg	11 ± 3	26 ± 6
Cardiac Output L/min	5.8 ± 1.4	9.2 ± 3.0
Mean arterial pressure mmHg	94 ± 12	132 ± 9
Systemic vascular resistance dyn·s/cm^5	1306 ± 445	1282 ± 638
PVR dyn·s/cm^5	111 ± 52	81 ± 46
Mixed venous oxygen saturation %	73 ± 6	64 ± 6
Heart rate bpm	79 ± 10	110 ± 18

Mean pulmonary artery pressure (MPAP) and pulmonary capillary wedge pressure (PCWP) increased by an average of 15mmHg with exercise indicating significant PVH. ECHO parameters associated with diastolic dysfunction are listed in Table 2.

Table. ECHO DATA

	Percent
LV Hypertrophy	
Interventricular septum >1.1cm	32
Left Ventricular posterior wall >1.1cm	11
Left ventricular mass index ≥100g/m^2	17
Dilated Left Atrium	
Antero posterior diam ≥4.0cm	32
Left atrial volume ≥28ml/m^2	22
Mitral Inflow Doppler	
Early diastolic mitral inflow velocity/mitral inflow velocity during atrial contraction ≤1	63
Early diastolic mitral inflow velocity/mitral inflow velocity during atrial contraction 1.1–1.4	32
Early diastolic mitral inflow velocity/mitral inflow velocity during atrial contraction ≥1.5	5
Deceleration time ≥200ms	76
Tissue Doppler	
Early diastolic mitral inflow velocity/early diastolic mitral annular tissue velocity ≤8	22
Early diastolic mitral inflow velocity/early diastolic mitral annular tissue velocity 8.1–14.9	61
Early diastolic mitral inflow velocity/early diastolic mitral annular tissue velocity ≥15	17

All patients had preserved ejection fraction. Most patients (>63%) did not have findings associated with diastolic dysfunction when parameters for left ventricular hypertrophy, left atrial (LA) size, mitral doppler inflow, or tissue doppler were analyzed.

Conclusion: Conventional echocardiography may not suggest underlying diastolic dysfunction in the majority of symptomatic SS patients with exercise induced pulmonary venous hypertension.

715

Nutrition In Systemic Sclerosis Patients. Maureen Murtaugh[1] and Tracy M. Frech[2]. [1]University of Utah, Salt Lake, [2]University of Utah School of Medicine, SLC, UT

Background/Purpose: The multiple gastrointestinal manifestations in systemic sclerosis (SSc) can potentially affect the nutritional status of patients through several mechanisms. We examine the association of gastrointestinal variables—captured by University of California Los Angeles Scleroderma Clinical Trials Consortium Gastrointestinal Tract 2.0 (GIT 2.0); weight loss and manifestations of malnutrition—captured by the Subjective Global Assessment (SGA); and possible laboratory markers of gastrointestinal health—albumin, vitamin D, and hematocrit values, with clinical features of SSc.

Methods: Patients were recruited from the University of Utah SSc Clinic and consented during their routine clinic visit (IRB number 00038705). A series of 24 SSc patients were assessed using the SGA and GIT 2.0 questionnaires. Weight was measured in the clinic on the day of study enrollment. Change in weight from a 2 week interval was obtained by patient recall as an increase, no change, or decrease. Change in weight at 6 months and one year was calculated using weights recorded on pulmonary function tests documented in the medical record. A single evaluator (TF) asked the patients questions regarding dietary intake change, gastrointestinal symptoms and functional capacity, and evaluated metabolic demand, physical signs of malnutrition and overall SGA score. Statistical analysis was conducted using SAS version 9.2 (Cary, NC). We used descriptive statistics including mean for continuous variables and frequency for categorical variables to describe the patient population, GIT and nutritional status (SGA). We used Fishers' exact to examine associations between two categorical variables. We used general linear models (PROC GLM) to assess differences in continuous variables across duration of disease or SGA nutritional status category. We assigned significance at $p < 0.05$.

Results: We have identified that although the Medsger severity index did correlate with SGA, no single GI etiology of malnutrition was identified in this study. Nutritional status was not associated with duration of disease and/or presence of reflux, distention/bloating, soilage, and/or constipation, diarrhea, but social and emotional well-being suffered as nutritional status became worse.

Conclusion: Although, malnutrition is important to identify in SSc, its mechanism(s) remains an area that requires further clarification.

716

Associations Between the UCLA SCTC GIT 2.0 Vs. Objective Tests of Upper Gastrointestinal Involvement in Systemic Sclerosis. Sangmee Bae[1], Yannick Allanore[2], Daniel E. Furst[3], Vijay Bodukam[4], Baptiste Coustet[5], Olga Morgaceva[6], Paul Maranian[3] and Dinesh Khanna[7]. [1]David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [3]UCLA Medical School, Los Angeles, CA, [4]Crozer Chester Medical Center, Upland, PA, [5]Université Paris Descartes, Hopital Cochin, Paris, France, [6]UCLA, Los Angeles, CA, [7]University of Michigan, Ann Arbor, MI

Background/Purpose: UCLA-SCTC-GIT 2.0 is a 34 item instrument designed to assess gastrointestinal (GI) symptoms in systemic sclerosis (SSc). The objective of our study was to assess the associations between the upper GI symptom scales of the instrument (Reflux and Distention/ Bloating (D/B) scales) vs. objective/ laboratory studies of upper GI involvement.

Methods: We enrolled 60 patients at 2 SSc centers (30 from the US, 30 from Europe) with SSc. Each patient filled out the GIT 2.0 and patients had barium swallow with small bowel follow through, gastric emptying study, lactulose breath test, endoscopy, esophageal manometry, HRCT of the chest, and laboratory tests (serum amylase, lipase, iron, 25 hydroxyvitamin D, vasoactive intestinal peptide, gastrin, carotene, methylmalonic acid, and celiac panel). We explored correlations between the Reflux scale scores vs. barium swallow, UGI endoscopic findings, and esophageal manometric abnormalities. We also explored correlations between the D/B scale scores vs. lactulose breath test, gastric emptying study, unplanned weight loss, and laboratory tests. Correlations were assessed using the Spearman's test. We calculated the average scores in patients with positive vs. negative tests and compared them using the T-test and Wilcoxon test.

Results: The mean (SD) age was 53.5 (11.7) yrs and participants were mostly women (90%); 50% had limited SSc. The mean (SD) Reflux score was 0.82 (0.64; moderate) and D/B score was 1.25 (0.85; moderate) The Reflux scale had statistically significant correlations with upper GI objective evaluations and was able to differentiate between patients with EGD proven esophagitis and manometric abnormalities (Table). There were no associations between the Reflux scores vs. HRCT findings for interstitial lung disease. D/B had non-significant associations with the objective tests (Table). Although D/B scores were higher in patients with positive tests, these were non-significant associated with objective measures. There were no significant correlations between laboratory values and GIT 2.0 scales.

Table. ECHO DATA

UCLA SCTC GIT 2.0	Test	Correlations	Positive test	Negative test	p value
Reflux scale	Esophagitis on upper endoscopy (n=32)	0.46*	1.38 (0.54) n=9	0.76 (0.58) n=23	0.01
	Manometry abnormalities (n=29)	0.51*	1.39 (0.70) n=15	0.69 (0.59) n=14	0.01
	Dysmotility on barium swallow (n=22)	0.26	0.93 (0.69) n=16	0.77 (0.46) n=6	0.58
	Presence of fibrosis on HRCT (n=53)	−0.26	0.62 (0.52) n=28	0.96 (0.69) n=25	0.06
	Presence of ground glass on HRCT(n=51)	−0.11	0.62 (0.37) n=16	0.88 (0.71) n=35	0.45
Distention/ Bloating scale	Abnormal lactulose breath test(n=38)	0.07	1.35 (0.94) n=21	1.12 (0.91) n=17	0.67
	Delayed gastric emptying(n=22)	0.13	1.48 (1.15) n=11	1.14 (0.73) n=11	0.55
	Unplanned wt loss (n=53)	0.16	>5% of wt 1.46 (0.71) n=10	<5% of wt 1.22 (0.90) n=43	0.24

*P< 0.05

Conclusion: The GIT 2.0 Reflux scale has significant correlations with esophagitis on the EGD and upper GI dysmotility on barium swallow and was able to differentiate between patients with positive vs. negative tests. Although D/B scale scores were higher in patients with positive vs. negative tests, D/B scale had poor correlations with objective tests. Reflux and D/B scale scores complement the objective tests for assessment of the upper GI involvement.

717

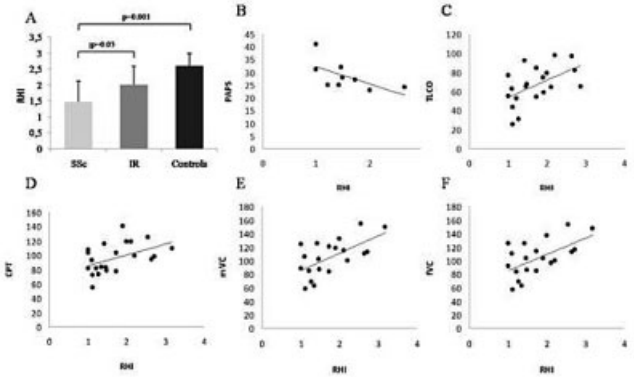
Reactive Hyperemia Index Is Associated with Macroangiopathy and Lung Involvement in Systemic Scleroderma. Alain Meyer[1], Bernard Geny[2], Emmanuel Chatelus[3], Olivier Rouyer[2], Arnaud Theulin[4], Christelle Sordet[4], Rose-Marie Javier[4], Jean Sibilia[5] and Jacques-Eric Gottenberg[6]. [1]Hautepierre Strasbourg university, Strasbourg, France, [2]Medicine faculty, Strasbourg university, Strasbourg, France, [3]Hopital Hautepierre, Strasbourg, France, [4]Hautepierre Strasbourg Hospital University, Strasbourg, France, [5]CHU Hautepierre, Strasbourg, France, [6]Strasbourg University Hospital, Strasbourg, France

Background/Purpose: Both rheumatoid arthritis (RA) and systemic scleroderma (SSc) patients have impaired brachial artery endothelial flow mediated dilatation (FMD) as compared with controls. FMD independently predicts adverse cardiovascular events in different populations and in SSc, it correlates with nailfold microvascular impairment. We compared reactive hyperhemia index (RHI), known to be related to FMD, in inflammatory arthritides (IA) and SSc and searched for correlations with cutaneous, articular, cardiac and pulmonary disease activity in these two groups.

Methods: RHI taken at the estimated maximal vasodilatation (1 min 30 s after release of occlusion) using digital pulse amplitude tonometry was performed on 21 patients with SSc, 14 patients with IR and 15 healthy subjects. In IR and SSc patients, DAS 28, Rodnan score, cardiac echography, spirometry, DLCO and 6 minute walk test were also performed.

The Mann-Withney U test was used to compare RHI values between the 3 groups. The Spearman test was performed to assess correlation between RHI value and the others measured parameters.

Results: *Characteristics of the 3 groups:* Mean age of SSc was 57 years (28–75), sex ratio (SR) was 5/1 and mean disease duration was 4.5 years (0–22). 11 patients had limited form and 7 had diffuse form. The mean Rodnan score in 13 of 18 SSc patients was 10.2 (4–28). IA patients had a mean age of 60 years (38–73) and SR was 6/1. 11 patients had RA, 1 spondylarthropathy, one antisynthetase syndrome and one myositis with SRP antibody. Mean IR duration was 16 years (0–31). Mean DAS 28 in 11 of 14 IR patients was 4.45 (2.03–6.66) and 8 patients were treated with biologic treatments. Controls were 57 years old (53–64) and SR was 6/1. Patients mean weight was comparable: 67 kg (45–106), 67 kg (54–79) and 64 kg (54–91) in SSc, PR and controls respectively. Mean blood pressure was also similar (SSc: 127/73mmHg, PR: 128/76mmHg and controls: 130/75mmHg in SSc). One IR patient suffered of diabetes mellitus and had history of heart infarct.



Results: Median RHI was significantly lower in SSc patients (median 1.45, range 1.00–3.18) compared with IA patients (median 2.01, range 1.35–3.02) ($p=0.03$) and was significantly lower in both SSc and IA patients compared with controls (median 2.60, range 1.40–3.05) ($p=0.001$ and $p=0.049$ respectively). In SSc patient but not in IA patients, RHI value significantly correlated with echocardiograhic PAPs (r:−0.75; $p=0.037$), DLCO (r:0.53; $p=0.017$), total pulmonary capacity (r:0.46; $p=0.032$), functional and maximal vital capacity (r:0.48; $p=0.032$ and r: 0.48; $p=0.033$ respectively).

Conclusion: RHI, an easy and non invasive test, is associated with macroangiopathy and lung involvement in SSc. Further studies are necessary to determine whether RHI may represent disease activity and therapeutic response marker.

Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor, in Combination with Methotrexate, in Patients with Active Rheumatoid Arthritis with An Inadequate Response to Tumor Necrosis Factor-Inhibitors: A 6-Month Phase 3 Study. Gerd-Rüdiger Burmester[1], R. Blanco[2], C. Charles-Schoeman[3], J. Wollenhaupt[4], C A. F. Zerbini[5], B. Benda[6], D. Gruben[7], G. Wallenstein[7], S. Krishnaswami[7], S. H. Zwillich[7], T. Koncz[8], J. D. Bradley[7], C. A. Mebus[7] and the ORAL Step investigators[9]. [1]Charité-University Medicine Berlin, Berlin, Germany, [2]Hospital Universitario Marques De Valdecilla, Santander, Spain, [3]University of California, Los Angeles, CA, [4]Schön Klinik, Hamburg, Germany, [5]Centro Paulista de Investigação Clinica, Sao Paulo, Brazil, [6]Pfizer Inc., Collegeville, PA, [7]Pfizer Inc., Groton, CT, [8]Pfizer Inc., New York, NY, [9]Groton

Background/Purpose: Tofacitinib (CP-690,550) is a novel, oral Janus kinase inhibitor investigated as a targeted immunomodulator for rheumatoid arthritis (RA). This study was designed to compare efficacy and safety of tofacitinib vs placebo (PBO) in pts with active RA with inadequate response to tumor necrosis factor (TNF)-inhibitors.

Methods: In this 6-month (Mo) study (NCT00960440), pts with inadequate response or lack of tolerance to ≥1 TNF inhibitor and on concomitant treatment with a stable (>6 weeks) dose of methotrexate (MTX; 7.5–25 mg/week) were randomized 2:2:1:1 to one of four sequences: tofacitinib 5 mg twice daily (BID); tofacitinib 10 mg BID; PBO advanced to 5 mg BID; PBO advanced to 10 mg BID (at Mo 3 all PBO patients were advanced to tofacitinib 5 or 10 mg according to randomization at baseline; for analyses PBO sequences were combined into one group). Primary endpoints included ACR20 responder rate, change from baseline in HAQ-DI, and rate of pts achieving a DAS28-4(ESR) <2.6, all at Mo 3.

Results: 399 pts were randomized and treated: 5 mg BID (n=133); 10 mg BID (n=134); PBO to 5 mg (n=66); PBO to 10 mg (n=66). Mean baseline values were comparable across treatment sequences: age, 54.3–55.4 years; disease duration, 11.3–13 years; HAQ-DI, 1.50–1.66; DAS28-4(ESR), 6.29–6.64; rheumatoid factor (RF) positive, 60.6–70.8%; anti-CCP positive, 68.5–77.8%; ≥2 prior anti-TNFs, 32.1–36.6%. Both doses of tofacitinib were statistically superior to PBO for all primary efficacy endpoints at Mo 3 and were maintained to Mo 6 (end of study) (Table). Onset of efficacy as measured by significant ACR20 responses vs PBO was seen by Week 2. Key safety endpoints are summarized in the table. Most AEs were mild; most frequently reported were infections and infestations. There was 1 death due to pulmonary emboli in the 10 mg BID dose group. No serious infectious events were reported in Mo 0–3, and 2 (5 mg BID), 2 (10 mg BID), and 1 (PBO to 5 mg) were reported in Mo 3–6. There were no opportunistic infections. Decreases in neutrophils, increases in LDL and HDL, and small increases in serum creatinine were seen with tofacitinib.

Table. Efficacy and safety endpoints

	Tofacitinib 5 mg BID (n=133)	Tofacitinib 10 mg BID (n=134)	PBO (n=132)	PBO to tofacitinib 5 mg BID (n=66)	PBO to tofacitinib 10 mg BID (n=66)
Efficacy

Primary endpoints employed a step-down procedure employed to protect Type I error. No protection employed for secondary comparisons
*p< 0.05; ***p< 0.0001 vs PBO (Mo 3) / vs baseline (Mo 6)
[F]Primary endpoints; [a]non-responder imputation; [§]mixed-effect longitudinal linear model
D/C, discontinuation; NA, not available; SAE, serious AE

Conclusion: This was the first Phase 3 study of tofacitinib in combination with MTX in pts with active RA with an inadequate response to TNF-inhibitors. In this treatment refractory patient population, tofacitinib demonstrated rapid, significant, and clinically meaningful improvements in the signs and symptoms of RA, physical function, and disease activity over 6 mo of study treatment. No new safety signals were detected.

719

Reduced Cardiovascular Risk with Use of Methotrexate and Tumor Necrosis Factor-α Inhibitors in Patients with Rheumatoid Arthritis. Rasa Bozaite-Gluosniene[1], Xiaoqin Tang[2], H. Lester Kirchner[2], Jana L. Antohe[3], Stephanie J. Morris[4], Mary Chester Wasko[5] and Androniki Bili[1]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Center for Health Research, Danville, PA, [3]Geisinger Health System, Danville, PA, [4]Rose Tree Medical Associates---Riddle Memorial Hos, Danville, PA, [5]West Penn Allegheny Health System, Pittsburgh, PA

Background/Purpose: Methotrexate (MTX) and tumor necrosis factor (TNF)-α inhibitors have been associated with a reduction of incident coronary artery disease (CAD) in rheumatoid arthritis (RA) patients. Here we examine the independent contribution of each medication on risk of CAD.

Methods: Using an inception cohort of 1829 RA patients without preexisting CAD, diagnosed between 1/1/2001–3/31/2008 were identified. Patients were classified as users (n=1119) or nonusers (n=710) of MTX and users (n=588) or nonusers (n=1241) of TNF-α inhibitors (etanercept, adalimumab, infliximab). Medication exposure was analyzed in time-varying fashion using medication start and stop dates, allowing patient

drug exposure status to change over time. Outcome was incident CAD (ICD-9 410. – 419.99 or cardiac revascularization procedure). Cox proportional hazard regression models were used to estimate the associations on developing incident CAD after adjusting for age, gender, hypertension, hyperlipidemia, diabetes, rheumatoid factor, BMI, blood pressure, LDL, ESR, hydroxychloroquine, MTX, corticosteroid and NSAID use. Exposure to MTX, TNF-α inhibitors and all other variables were treated as time-variant in models.

Results: In MTX nonusers and users groups, incidence rate (IR) for CAD was 37.5 vs.17.6 events per 1000 person-years (p-y), respectively. Among MTX users, the hazard for incident CAD was 0.54 (95% confidence interval (CI) 0.37, 0.77; p=0.001) compared to nonusers; among those taking MTX for more than 24 months the hazard was 0.33 (95% CI 0.22, 0.50; p<0.001). In TNF-α inhibitors nonusers and users groups, IR for CAD was 32.1 vs.11.8 events per 1000 p-y, respectively. Among TNF-α inhibitor users the hazard for incident CAD was 0.54 (CI 0.30, 0.95; p=0.03) compared to nonusers; among those taking TNF-α inhibitor for more than 24 months hazard was 0.24 (95% CI 0.12, 0.51; p<0.001).

Conclusion: In this inception RA cohort, the use of MTX or TNF-α inhibitors was independently associated with a 46% reduction in incident CAD compared to nonusers; for MTX or TNF-α inhibitor use for more than 24 months the risk was further decreased by 67% and 76% respectively, raising the possibility that TNF-α inhibitor use offers additional cardioprotective effect in RA patients.

Table. Characteristics of RA patients by methotrexate and TNF-α inhibitors use

		Methotrexate use*			TNF-α inhibitors use*

The Value of Periodic Echocardiography Screening to Detect Pulmonary Hypertension and Predict Mortality In Scleroderma. Ami A. Shah, Shang-En Chung, Fredrick M. Wigley and Laura K. Hummers. Johns Hopkins University, Baltimore, MD

Background/Purpose: Pulmonary hypertension (PH) is a leading cause of morbidity and mortality among patients with scleroderma, and early detection of disease may play a critical role in preventing or delaying disease progression. Although data suggest that right ventricular systolic pressure (RVSP) on echocardiography (echo) has a moderate positive correlation with mean pulmonary artery pressure on right heart catheterization (RHC), it is commonly debated whether echo has additional value beyond routine pulmonary function tests (PFTs) and whether serial, annual echo predicts development of PH.

Methods: Subjects in the Johns Hopkins Scleroderma Center database who had at least 3 echos over at least 1 year and had data on the date of SSc onset as defined by the first non-Raynaud's phenomenon symptom were included. The rate of change in RVSP per year was determined by regressing RVSP on years from first non-Raynaud's symptom for each subject. Survival analysis was performed to assess the association between PH and change in RVSP, adjusted for baseline RVSP, FVC%/DLCO% ever $\geq$ 1.4, age, race, gender, scleroderma subtype and smoking status. Similar analysis was performed with mortality as the outcome, and this model included RHC-confirmed PH as an additional explanatory variable. Survival analysis was also performed to identify the minimum rate of change in RVSP that associates with increased risk of death.

Results: 681 scleroderma patients with 3516 echos met inclusion criteria. 140 (20.6%) had RHC-confirmed PH, and 181 (26.7%) were deceased after a median survival of 11 years (mean 13.1; SD 8.32). The mean rate of change in RVSP was 1.82 mmHg/yr (SD 6.45). The hazard ratio for development of PH was 1.07 (95% CI 1.05, 1.08; p<0.0001) per 1mmHg increase in RVSP/yr after adjustment for the other covariates in the model. The hazard ratio for death was 1.06 (95% CI 1.04, 1.08; p<0.0001) per 1mmHg increase in RVSP/yr after adjusting for PH and the other covariates in the model. Relative to patients whose RVSP was stable over time (RVSP change $<$ 1mmHg/yr), the hazard ratio for development of PH was 1.52 (95% CI 0.80, 2.89), 3.22 (95% CI 1.70, 6.11), 4.24 (95% CI 2.14, 8.41), and 6.54 (95% CI 4.10, 10.4) for subjects whose RVSP increased at rates of 1–1.99, 2–2.99, 3–3.99, and 4+ mmHg/yr. Compared to the same reference group, the hazard ratio for death was 0.52 (95% CI 0.27, 0.99), 1.26 (95% CI 0.68, 2.32), 2.00 (95% CI 1.04, 3.84), and 4.27 (95% CI 2.81, 6.48) for subjects whose RVSP increased at rates of 1–1.99, 2–2.99, 3–3.99, and 4+ mmHg/yr. Kaplan-Meier survival curves demonstrate that patients with an increase in RVSP $\geq$ 3 mmHg/yr have a greater mortality risk than subjects with a change in RVSP $<$ 3 mmHg/yr.

Conclusion: Serial echo is an important screening tool for PH and adds additional information beyond that available from routine PFTs. An increase in RVSP $\geq$ 3 mmHg/yr is strongly associated with increased mortality risk.

Trial of Early Aggressive Therapy in Polyarticular Juvenile Idiopathic Arthritis. Carol Wallace[1], Edward H. Giannini[2], Steven J. Spalding[3], Philip Hashkes[4], Kathleen M. O'Neil[5], Andrew S. Zeft[6], Ilona S. Szer[7], Sarah Ringold[8], Hermine Brunner[9], Laura E. Schanberg[10], Robert P. Sundel[11], Diana Milojevic[12], Marilynn G. Punaro[13], Peter Chira[14], Beth S. Gottlieb[15], Gloria Higgins[16], Norman T. Ilowite[17], Yukiko Kimura[18], Anne Johnson[19], Stephanie Hamilton[1], Bin Huang[9] and Daniel J. Lovell[9]. [1]Childrens Hosp & Regional Med, Seattle, WA, [2]PRCSG-Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Cleveland Clinic, Cleveland, OH, [4]Shaare Zedek Medical Center, Tel Aviv, Israel, [5]Okla Univ Health Science Ctr, Oklahoma City, OK, [6]University of Utah, Salt Lake City, UT, [7]Rady Childrens Hosp San Diego, San Diego, CA, [8]Children's Hosp Regional Med, Seattle, WA, [9]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [10]Duke University Medical Center, Durham, NC, [11]Childrens Hosp Medical Center, Boston, MA, [12]UCSF, San Francisco, CA, [13]Texas Scottish Rite Hospital, Dallas, TX, [14]Stanford University, Palo Alto, CA, [15]Schneider Children's Hospital, New Hyde Park, NY, [16]PRCSG, Columbus, OH, [17]Children's Hospital Montefiore, Bronx, NY, [18]Hackensack Univ Medical Ctr, Hackensack, NJ, [19]Cincinnati Child Hosp Med Ctr, Cincinnati, OH

Background/Purpose: Early aggressive therapy produces superior outcomes in adults with RA, but evidence for a similar benefit has not been demonstrated in children with JIA.

Methods: The objectives of this study (abbrev TREAT) were to determine if aggressive treatment initiated early in the course of RF (+) or (−) polyarticular JIA (poly JIA) can induce *clinical inactive disease* (CID) within 6 mos (primary endpoint) and *clinical remission on medication* (CRM: CID for 6 continuous mos on medication; exploratory endpoint) within 1 yr of starting therapy. Other endpoints were changes in the ACR pediatric core variables.

TREAT was designed as a multi-center, prospective, double blind, randomized, placebo controlled trial in children aged 2–16 yrs with onset of poly JIA <12 mos in duration. Subjects were randomized 1:1 into 1 of 2 aggressive treatment arms: (Arm 1) MTX 0.5 mg/kg/wk SQ (40 mg max), plus etanercept (ETN) 0.8 mg/kg/wk (50 mg max), plus prednisolone (pred) 0.5 mg/kg/d (60 mg max) tapered to 0 by 17 wks or; (Arm 2) MTX (same dose as Arm 1) plus ETN placebo, plus pred placebo, then followed on protocol for up to 12 mos. After 4 mos on therapy subjects who failed to achieve at least an ACR Pediatric 70 received open label ETN, MTX, and pred in the same doses as Arm 1. At 6 mos, subjects who did not achieve CID received open label medication. Efficacy analyses focused on the intent-to-treat approach. Safety data were recorded for all subjects.

Results: 15 centers enrolled 85 subjects (64 [75%] female; median age 11.1 yrs; disease duration 4.1 mos). 69% were ANA+ and 36% were RF(+). Median values at baseline of ACR pediatric core variables were: physician's global assessment of disease activity 7.5; parent global assessment of well-being 5.5; ESR 33; number of joints with arthritis 19; number of joints with limited motion 11.5, C-HAQ 1.1.

At 4 mos, 30 of 42 (71%) subjects in Arm 1 and 19 of 43 (44%) in Arm 2 achieved an ACR Pediatric 70 ($X^2 = 6.5$; p=0.011). At 6 mos, 17 of 42 (40%) of subjects in Arm 1 achieved CID, compared to 10 of 43 (23%) in Arm 2 ($X^2 = 2.91$; $p = 0.088$). Logistic regression showed the only variable predictive of CID at 6 mos was disease duration at baseline. The odds of CID increased by 1.324 times for each month earlier treatment was started after onset of symptoms (p=0.011). Although all 6 ACR pediatric core variables showed highly significant improvement by 6 mos in both Arms (all p values <0.001), 5 showed statistically greater improvement in Arm 1 vs. Arm 2. By 12 mos, 12 (14%) subjects achieved CRM; 9 (21%) had remained in Arm 1, and 3 (6%) had remained in Arm 2 throughout the study (p=0.053).

There were no significant inter-arm differences in the incidence of Grade 3 or higher adverse events, including infections requiring systemic therapy. There were 3 SAEs: pneumonia (Arm 1), psychosis (open label), and bacteremia with septic arthritis (open label). All resolved without sequelae.

Conclusion: Although this trial did not reach its primary endpoint, early aggressive therapy in this cohort of children with severe JIA and a high rate of RF positivity resulted in substantial proportions of subjects achieving an ACR Pediatric 70 at 4 mos, CID at 6 mos, and CRM within 12 mos of treatment initiation.

The Intensive Diet and Exercise for Arthritis Trial: 18-Month Clinical Outcomes. Stephen P. Messier[1], Barbara J. Nicklas[2], Claudine Legault[3], Shannon Mihalko[1], Gary D. Miller[1], Paul DeVita[4], Mary Lyles[3], David J. Hunter[5], Felix Eckstein[6], Jeff D. Williamson[3], J. Jeffery Carr[3] and Richard F. Loeser[1]. [1]Wake Forest University, Winston-Salem, NC, [2]Winston-Salem, NC, [3]Wake Forest University School of Medicine, Winston-Salem, NC, [4]East Carolina University, Greenville, NC, [5]Royal North Shore Hospital, Sydney, Australia, [6]Paracelsus Medical University, Salzburg, Austria

Background/Purpose: Obesity is the most prevalent modifiable risk factor, and dietary induced weight loss potentially the best non-pharmacologic treatment for symptomatic knee osteoarthritis (OA) symptoms. We report the clinical outcomes of a long-term study designed to test the hypothesis that intensive weight loss, either with or without exercise, will reduce pain and improve function compared to an exercise only control group in older, overweight and obese adults with symptomatic knee OA.

Methods: The Intensive Diet and Exercise for Arthritis trial (IDEA) was a prospective, single-blind, randomized controlled trial that enrolled 454 overweight and obese (BMI = 27–42 kg/m^2) older (age ≥ 55 yrs) adults with pain and radiographic evidence of tibiofemoral OA (KL = 2–3). Participants were randomized to one of three 18-month interventions: intensive dietary restriction-only (D); intensive dietary restriction-plus-exercise (D+E); or exercise-only control (E). The weight loss goal for the two diet groups was ≥ 10% of baseline body weight, and the exercise intervention consisted of low to moderate intensity walking and resistance training 3 d/wk for 1 hr/d. We used an intention-to-treat analysis to compare changes between groups at 18 month follow-up (FU18) after adjusting for gender, baseline BMI, and baseline values of the dependent variable using repeated measures ANCOVA.

Results: Mean (SD) baseline descriptive characterisitics of the cohort included: age, 65.6 (6.2) yrs.; BMI, 33.6 (3.7) kg/m^2; %female, 72; %white, 81. Bilateral knee OA was evident in 85% of the participants. A total of 399 (88%) participants completed the study (returned for FU18 testing). Mean weight loss was: D+E, 10.6 kg (11.4%); D, 8.9 kg (9.5%); E, 2.0 kg (2.2%). WOMAC pain (baseline, FU 18, %change) was significantly less ($p < 0.0004$) at FU18 in the D+E group (6.7,3.3; 51%) compared to the D (6.6, 4.8; 27%) and E (6.1, 4.4; 29%) groups. Similarly, WOMAC function was significantly ($p = 0.003$) better in the D+E group (24.6,13.0; 47%) relative to the D (24.8,17.3; 30%) and E (23.1,17.5; 24%) groups. Walking speed (m/s), our measure of mobility, was significantly ($p = 0.004$) faster in the D+E group (1.20, 1.34; 12%) than in the D (1.18, 1.30; 10%) and E (1.23, 1.30; 6%) groups. There was no significant difference between the groups on the SF-36 physical or mental health scales.

Conclusion: The IDEA trial shows that intensive weight loss with excellent long-term retention is possible in this population and, when combined with low to moderate intensity exercise, results in an approximate 50% reduction in pain accompanied by significant improvements in function and mobility. These data provide evidence that the best recommendation for long-term symptom reduction in overweight and obese persons with knee OA is intensive weight loss combined with low to moderate intensity exercise.

ACR Concurrent Abstract Session
Antiphospholipid Syndrome

Involvement of TLR7 and TLR9 in the Production of Antiphospholipid Antibodies. Renan Aguilar-Valenzuela[1], Kevin Nickerson[2], Zurina Romay-Penabad[1], Mark J. Shlomchik[2], Gracie Vargas[1], Tuya Shilagard[1] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Yale University School of Medicine, New Haven, CT

Background/Purpose: Molecular mimicry and genetic factors have been shown to be involved in the production of antiphospholipid antibodies (aPL)

but a role of innate immunity has not been studied. Our aim was to elucidate the involvement of TLR7, TLR9 and molecular mimicry in aPL production by monitoring the production of pathogenic aPL in lupus mice ($MRL^{lpr/lpr}$) deficient in TLR7 and TLR9 and in autoimmune prone mice (PL/J) immunized with cytomegalovirus (CMV)-derived peptides (TIFI and VITT) in the presence of TLR7 and TLR9 agonists.

Methods: APL (anticardiolipin (aCL) and anti-β_2Glycoprotein I (aβ_2GPI) titers were determined in the sera of $MRL^{lpr/lpr}$ and their congenic *tlr9* and *tlr7* knockout mice (16 weeks old). Additionally, PL/J autoimmune-prone mice were challenged with 150 μg of CMV peptides (TIFI and VITT) in the presence or absence of TLR9 (ODN1585) and TLR7 (CL264) agonists. As negative controls two mouse groups were immunized with Egg Albumin (OVA) (150μg) in the presence or absence of TLR9 agonist (50μg). The aPL titers were followed for 9 weeks using solid phase ELISA. Levels of IL6, IL2, IL10, TNF-α and IL2 were measured using Multiplex Bioassay (Millipore™) and IFN-α was detected by ELISA. At week nine, aPL thrombogenic effects were evaluated using a model of induced thrombosis. Tissue factor (TF) expression in peritoneal macrophages was measured using specific immunostaining and dual photon laser microscopy and nanocrystal bioconjugates.

Results: $MRL^{lpr/lpr}$ mice had significantly higher titers of aCL and aβ_2GPI antibodies when compared to the TLR9 and TLR7 double knockouts ($p<0.05$) and $MRL^{lpr/lpr}$ tlr7 single knockouts had lower IgG or IgM aPL titers compared to $MRL^{lpr/lpr}$. The titers of aPL (aCL and aβ_2GPI) antibodies induced with TIFI and VITT were significantly higher in mice immunized with the TLR9 (ODN1585) or with TLR7 (CL264) agonists at the time of the surgical procedures to examine thrombus formation (Table). No significant titers of aPL were seen in mice receiving only TIFI + VITT. Importantly, increased aPL production correlated with larger thrombi in mice receiving TLR7 and TLR9 agonists, compared with those that did not ($p<0.05$). Increased TF expression was seen in mice treated with CMV peptides and the TLR9 agonist ($p<0.05$).

Treatment	aCL IgG (O.D.)	aCL IgM (O.D.)	aβ_2GPI IgG (O.D.)	aβ_2GPI IgM (O.D.)	Thrombus size (μm^2)
OVA	0.14 (±0.03)	0.2 (±0.05)	0.18 (±0.0007)	0.18 (±0.06)	683 (±88)
OVA+ODN1585	0.2 (±0)	0.3 (±0.17)	0.11 (±0.1)	0.11 (±0.0.6)	674 (±52)
TIFI+VITT	0.13 (±0.047)	0.22 (±0.08)	0.27 (±0.9)	0.27 (±0.04)	605 (±13)
VITT+VITT+ODN1585	0.22 (±0.065)	0.17 (±0.02)	0.79(±0.1)	0.79 (±0.13)	1051.5 (±123)
TIFI+VITT+CL264	0.29 (±0.08)	0.23 (±0.05)	0.91 (±0.28)	0.91 (±0.12)	1280.17 (±166.87)
TIFI+VITT+ ODN1585+CL264	0.3 (±0.06)	0.16 (±0.018)	1.7 (±0.85)	1.7 (±1.2)	1126.56 (±318.1)

Conclusion: Production of pathogenic aPL involves TLR7 in the $MRL^{lpr/lpr}$ mice. In the TIFI/VITT-challenged PL/J mice, the activation of TLR9 and TLR7 lead to the production of pathogenic aPL. Altogether, our data support the involvement of TLR7 and TLR9 in tolerance loss to β_2GPI and raises the possibility of using TLR9 and TLR7 inhibitors to prevent aPL production.

724

Endothelial Cell Injury and Activation Promote the Binding of Anti-Phospholipid Antibodies and Thrombus Formation. Patrick Laplante[1], Marc-Antoine Gillis[2], Rebecca Subang[1], David Salem[1], Jerrold S. Levine[3], Yahye Merhi[2] and Joyce Rauch[1]. [1]Research Institute of the McGill University Health Centre, Montreal, QC, [2]Montreal Heart Institute, Montreal, QC, [3]University of Illinois at Chicago, Chicago, IL

Background/Purpose: Anti-phospholipid antibodies (aPL) are found in 20–30% of patients with systemic lupus erythematosus and in all patients with anti-phospholipid syndrome (APS). APS is classified clinically by the combined presence of aPL and a clinical event (e.g., thrombosis and/or pregnancy loss). To date, the mechanisms responsible for both the initiation of aPL production and the development of clinical events are unclear. We propose that aPL alone are insufficient to cause thrombotic events in APS, and that a concomitant trigger of innate immunity (e.g., toll-like receptor [TLR] activation) is required.

Methods: To address this hypothesis, we studied the interactive effects of aPL and TLR ligand by two complementary approaches: (1) *in vitro* endothelial cell (ECs) studies, and (2) an *in vivo* model of thrombosis. aPL were produced by immunizing rabbits with murine β2-glycoprotein I (β2GPI). *In vitro* studies were performed on human umbilical vein (HUVECs) and murine (EOMA cell line) ECs. *In vivo* effects of aPL were evaluated using a ferric chloride ($FeCl_3$)-induced murine model of carotid artery injury; localized induction of thrombosis in this model permits both quantifiable monitoring of thrombus formation and use of the uninjured contralateral carotid artery as a control. Purified rabbit aPL (n=15) or control IgG (n=16) were injected intravenously into naive C57BL/6 mice 48 hours prior to $FeCl_3$-induced carotid artery injury.

Results: *In vitro*, aPL were reactive with murine and human β2GPI, and cardiolipin, and showed dose-dependent binding to HUVECs and EOMA cells by enzyme-linked immunoassay. Stimulation of HUVECs and EOMA cells with TLR4 ligand (lipopolysaccharide [LPS]) resulted in increased expression of E-selectin and von Willebrand factor (vWF), as well as increased binding of aPL to ECs. LPS also induced cultured ECs to produce pro-inflammatory cytokines such as IL-8. *In vivo*, thrombus formation was significantly faster in aPL-treated mice than in control IgG-treated mice ($p<0.05$). For example, aPL-treated mice achieved 50% occlusion of carotid arteries more rapidly than control IgG-treated mice (4.2+/−0.39 minutes versus 7.2+/−0.72 minutes, $p<0.001$), demonstrating that aPL promote thrombus generation in the context of endothelial injury. Furthermore, uninjured contralateral carotid arteries from mice treated with aPL, but not control IgG, showed increased expression of P-selectin and vWF by immunohistochemical staining.

Conclusion: aPL reactive with murine b2GPI bind to ECs *in vitro* and promote thrombus formation in an *in vivo* model of carotid artery injury. TLR4 stimulation of ECs *in vitro* results in enhanced aPL binding, increased E-selectin and vWF expression, and pro-inflammatory cytokine secretion. *In vivo*, aPL promote thrombus formation in injured arteries, and EC activation in uninjured arteries. These data suggest that aPL and TLR4 activation interact to promote thrombogenesis, and may explain why only certain individuals with aPL develop thrombotic events.

Mitochondrial Dysfunction in Monocytes From Antiphospholipid Syndrome Patients: Implications in the Pathogenesis of the Disease and Effects of Coenzyme Q Treatment. Chary Lopez-Pedrera[1], Carlos Perez-Sanchez[1], Patricia Ruiz-Limon[1], M[a] Angeles Aguirre[1], Rosario M[a] Carretero[1], Nuria Barbarroja[1], Antonio Rodriguez-Ariza[1], Eduardo Collantes-Estevez[1], Jose Antonio Gonzalez-Reyes[2], Jose Manuel Villalba[2], Francisco Velasco[1], Munther A. Khamashta[3], Maria Laura Bertolaccini[3] and M[a] Jose Cuadrado[4]. [1]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [2]University of Cordoba, Cordoba, Spain, [3]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [4]The Rayne Institute, London, United Kingdom

Background/Purpose: Recent studies have evidenced that oxidative stress may play a role in the pathophysiology of APS. However it is still not clear whether oxidative stress is the cause or the effect of the prothrombotic/proinflamatory status of APS. Furthermore, the precise role of mitochondria in the redox imbalance reported in APS remains unknown. Aim: We undertook this study to investigate the role of mitochondrial dysfunction and oxidative stress in aPL-induced prothrombotic status in APS patients, and to test the effects of supplementing cells with coenzyme Q_{10} (CoQ_{10}), a well established mitochondrial cofactor and antioxidant.

Methods: We studied 25 patients and 25 healthy controls. Mitochondrial function in monocytes was analyzed by measuring mitochondrial membrane potential (MMP) with flow cytometry. Oxidative stress was determined by quantifying peroxide and peroxynitrite generation, intracellular glutathione, nitric oxide (NO), and N-Tyr in monocytes and plasma. Various parameters related to thrombosis and inflammation, as well as the intracellular pathways involved were also tested. Mitochondrial function was evaluated through *in vitro* studies in which purified monocytes were preincubated with CoQ_{10}, followed by stimulation with purified IgG from 7 APS patients (aPL-IgG). We also studied mitochondrial dynamics in monocytes treated with aPL-IgG in the presence or in the absence of CoQ_{10}, by measuring cellular levels of proteins controlling mitochondrial fission (Drp-1, Fis1, and Opa-1) or fusion (Mfn-1 and Mfn-2). Mitochondrial alterations were also studied by electron microscopy.

Results: CoQ_{10} decreased significantly the percentage of cells with altered MMP as well as the production of ROS and aPL-IgG-induced production of peroxides. CoQ_{10} treatment also affected significantly the aPL-IgG induced expression of TF, VEGF and Flt1, as well as the intracellular signalling pathways regulating their expression. Treatment of monocytes with aPL-IgG consistently upregulated proteins involved in mitochondrial fission, and these alterations were reversed by pre-treatment with CoQ_{10}. Monocytes treated with aPL-IgG contained rounded mitochondria, and figures evidencing mitochondrial fission were readily observed. Monocytes pretreated with CoQ_{10} contained elongated mitochondria with significantly improved ultrastructure.

Conclusion: The binding of aPL-IgG to monocytes membrane elicites a redox-signalling pathway in which mitochondrial activity is compromised, and dynamics is altered towards enhanced rates of mitochondrial fission. The induced mitochondrial dysfunction, which is prevented by CoQ_{10}, seems to

be directly involved in the aPL-induced monocyte activation. Supported by JA0246/2009, P08CVI04234 and PS09/01809.

726

Effects of Fluvastatin on Pro-Inflammatory and Pro-Thrombotic Markers in Antiphospholipid Antibody (aPL)-Positive Patients: Preliminary Results from an Open-Label Prospective Pilot Study. Vijaya L. Murthy[1], Doruk Erkan[2], Praveen Jajoria[1], Rohan Willis[1], JoAnn Vega[2], Giuseppe Barilaro[1], Gurjot Basra[1], Elizabeth Hsu[1], Laura Aline Martinez-Martinez[1], Shraddha Jatwani[1], Elizabeth Papalardo[1], Emilio B. Gonzalez[1], Prashanth R. Sunkureddi[3] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Barbara Volcker Center for Women and Rheumatic Diseases, Hospital for Special Surgery, New York, NY, [3]The University of Texas Medical Branch, Nassau Bay, TX

Background/Purpose: Antiphospholipid antibodies (aPL) induce a pro-inflammatory and pro-thrombotic state by upregulating the production of various cytokines, chemokines, and tissue factor (TF). Fluvastatin reduces TF expression and decrease thrombogenic effects of aPL in vitro and in mice. The purpose of this prospective pilot study was to examine the effects of fluvastatin on pro-inflammatory and pro-thrombotic biomarkers in persistently aPL-positive patients.

Methods: Persistently aPL-positive patients received fluvastatin 40 mg daily for 3 months (m). At 3m, patients were instructed to stop fluvastatin and they were followed for another 3m. Persistent aPL positivity was defined as IgG/M aCL $\geq$ 40U, IgG/M aβ_2GPI $\geq$ 20U, and/or positive LA test on $\geq$2 occasions at least 12w apart. Selected exclusion criteria were pregnancy, statin use, prednisone >10 mg/day, and immunosuppressive use (except hydroxychloroquine) at the time of the screening. Serum samples were collected at baseline and monthly thereafter for 6m. IFNα2, IL1β, IL6, IL8, IP10, MCP1, TNFα, VEGF, and sCD40L levels were determined by the MILLIPLEXMAP human cytokine/chemokine assay (Millipore, Billerica, MA). Plasma samples were used to detect soluble tissue factor (sTF) using a chromogenic assay. CRP was evaluated by a nephelometric assay. aCL, aβ_2GPI, soluble ICAM-1, VCAM-1, and E-selectin were evaluated by ELISA. For the purpose of this preliminary analysis of baseline, 1m, 2m, and 3m samples, we: a) compared baseline biomarker levels of patients with serum samples from 30 healthy age/sex-matched controls (Kruskal-Wallis test); and b) analyzed the change in biomarker levels of patients between baseline and 1–3m samples (Spearman test).

Results: When we compared the baseline samples of 41 aPL-positive patients (74% female; mean age: 42 $\pm$ 25; Primary APS: 18; asymptomatic aPL positivity with no SLE:9; APS with SLE: 7; and asymptomatic aPL positivity with SLE:7) with controls, we found that the levels of IL6 (38 vs 0.7 pg/ml), VEGF (225 vs 114 pg/ml), IP10 (584 vs 107 pg/ml); sCD40L (2477 vs 24.7 pg/ml), INFα2 (213 vs 16 pg/ml), IL1β (4.7 vs 0.4 pg/ml), TNFα 30 vs 0.5 pg/ml), and sTF (134 vs 13 pg/ml) were significantly elevated, but not of MCP-1, IL8 or CRP. Based on the analysis of the available follow-up samples, fluvastatin significantly reduced IL6, IL1β, TNFα, sTF, sICAM-1, sVCAM, and sE-sel levels within 30–90 days of treatment (Table). There was no significant change in aCL or aβ_2GPI titers.

Biomarker	# of Patients with Biomarker Levels Above Cut-off Points @ Baseline	# of Patients with Decreased Biomarker Levels with Fluvastatin	% of Maximum Biomarker Level Reduction with Fluvastatin (+/− SD)	Mean Time (Days) to Maximum Biomarker Level Reduction with Fluvastatin
IL8	8/41 (20%)	3/8 (38%)	73.8 ± 31.0	70 ± 34
IL6	17/41 (42%)	14/17 (82%)*	72.9 ± 32.1	51 ± 24
VEGF	17/41 (42%)	6/17 (35%)	59.7 ± 23.4	30 ± 23
IP10	39/41 (95%)	8/39 (21%)	55.4 ± 23.9	45 ± 22
sCD40L	36/41 (88%)	6/36 (17%)	68.0 ± 21.0	30
INFα2	13/41 (32%)	6/13 (46%)	81.0 ± 25.6	30
IL1β	18/41 (44%)	11/18 (61%)*	70.3 ± 30.0	51 ± 28
TNFα	20/41 (49%)	10/20 (50%)*	53.3 ± 30.8	54 ± 28
sTF	39/41 (95%)	22/39 (56%)*	57.0 ± 29.9	56 ± 25
sICAM-1	18/41 (44%)	18/18 (100%)*	55.9 ± 35.9	68 ± 25
sVCAM-1	11/41 (27%)	11/11 (100%)*	49.9 ± 34.6	46 ± 32
E-selectin	11/41 (27%)	11/11 (100%)*	52.9 ± 26.1	33 ± 19

* $p<0.0001$, statistically significant reduction compared to baseline

Conclusion: Based on the preliminary analysis of our ongoing pilot study, fluvastatin 40 mg daily for 3 months significantly reduced the pro-inflammatory and prothrombotic biomarkers in persistently aPL-positive patients with or without SLE. These findings: a) underscore the importance of identifying aPL-related disease biomarkers; and b) provide further support for the potential beneficial effects of statins in aPL-positive patients justifying future controlled clinical studies.

727

Rituximab in Antiphospholipid Syndrome (RITAPS)—A Pilot Open-Label Phase II Prospective Trial for Non-Criteria Manifestations of Antiphospholipid Antibodies (aPL). Doruk Erkan[1], JoAnn Vega[2], Glendalee Ramon[2], Elizabeth Kozora[3] and Michael D. Lockshin[2]. [1]Barbara Volcker Center for Women and Rheumatic Diseases, Hospital for Special Surgery, New York, NY, [2]Barbara Volcker Center for Women and Rheumatic Diseases: Hospital for Special Surgery, New York, NY, [3]National Jewish Health, Denver, CO

Background/Purpose: Few studies address the treatment of non-criteria aPL manifestations. Given that B cell inhibition can be effective in APS mouse models and rituximab can result in depletion of peripheral B cells, we designed the "RITAPS" trial. The primary objective of this pilot, open-label, Phase II study was to evaluate the safety of rituximab in 20 aPL-positive patients, as assessed by serious and non-serious adverse events (AE) (up to 12 months [m]). The secondary objectives were to evaluate the effect of rituximab on aPL profile (up to 12m) and non-criteria aPL manifestations (up to 6m) as assessed by specific outcome measures (SOM).

Methods: aPL-positive patients (>18yo, no other systemic autoimmune diseases) with persistent thrombocytopenia, autoimmune hemolytic anemia, heart valve disease, skin ulcers, aPL-nephropathy, and/or cognitive dysfunction with/without white matter (WM) changes received two doses of IV rituximab (1000 mg) on Days 1 and 15. aPL-positivity was defined as: positive LA test; aCL IgG/M/A ($\geq$40U); and/or aβ_2GPI IgG/M/A ($\geq$40U), on $\geq$2 occasions including screening, and at least 12 weeks apart. The follow-up aPL profiles and SOMs were analyzed at preset time points only in patients with baseline positivity for that aPL test and SOM. These were categorized as: "complete response (CR)", "partial response (PR)", "no response (NR)", and "recurrence (RC, only for SOM)". Preliminary descriptive results are reported as the study is ongoing.

Results: Of 19 aPL-positive patients enrolled (mean age: 40.5$\pm$13.8), 11 were female and 11 fulfilled APS Criteria. Two patients developed infusion reactions resulting in early termination. There were 59 AEs (12 serious with hospitalizations [all "unlikely" to be related to rituximab]; 7 non-serious within 48h of infusion [all "likely"]; and 40 non-serious [35 "unlikely" and 5 "possibly"]. Table shows the number of patients with positive aPL tests at baseline and the percentage of patients who had follow-up aPL tests with CR (LA test [-] or aPL ELISA<20U), PR (aPL ELISA 20–39U), or NR (LA test [+] or aPL ELISA$\geq$40U) at week 4, 16, 24, and 52. Excluding early termination or pending follow-up, the CR/PR/NR/RC rates at 6m were: 25/25/50/0% for thrombocytopenia (n:4); 0/0/100/0% for heart valve disease (n:2); 60/20/0/20 for skin ulcers (n:5); 0/100/0/0% for aPL-nephropathy (n:1); and 40/20/40/0% for cognitive dysfunction (n:5) (with no improvement in WM changes [n:3]).

Baseline[1]	CR/PR/NR (4w)[2]	CR/PR/NR (16w)[2]	CR/PR/NR (24w)[2]	CR/PR/NR (52w)[2]
LA (n:17)	0/-/100	0/-/100	0/-/100	0/-/100
aCL IgG (n:13)	0/9/91	0/0/100	0/0/100	0/13/87
aCL IgM (n:5)	20/20/60	20/20/60	25/25/50	33/33/33
aCL IgA (n:2)	0/0/100	0/0/100	0/0/100	0/0/100
aβ_2GPI IgG (n:10)	0/0/100	0/29/71	0/33/67	0/33/67
aβ_2GPI IgM (n:5)	0/20/80	0/20/80	25/0/75	66/33/0
aβ_2GPI IgA (n:3)	0/0/100	50/0/50	50/0/50	0/50/50

[1] # of patients with positive aPL.
[2] % of patients with follow up aPL tests excluding early termination or pending follow-up.

Conclusion: Based on the preliminary analysis of our ongoing pilot study of rituximab-receiving aPL-positive patients with non-criteria aPL manifestations: a) safety appears to be consistent with rituximab's known safety profile although 11% of our patients could not complete the treatment protocol due to reactions; b) B cell depletion appears to be effective in controlling some aPL manifestations during 6m of follow-up; and c) no substantial change in aPL profiles was observed in patients who completed 12m of follow-up.

Background/Purpose: To describe the outcome and the immunological status of children born to mothers with antiphospholipid syndrome (APS), to determine the factors responsibles of children abnormalities, to correlate childrens immunological status to mother's antibodies.

Methods: A prospective follow up of a European multicentric cohort of 130 children born to mothers with APS. Both maternal (clinical features, history, pregnancy features, immunological status) and infant's data at birth were recorded. A clinical, developmental and immunological follow up of infants at 1 to 3, 9 to 12, 24 months and 5 years was performed.

Results: One hundred forty women with APS (Sapporo) (mean age 36±5 years) were included. Eighty one percent of the mothers (n=115) have primary APS and the purely obstetrical APS represents 79% of the cohort (n=111). During pregnancy, treatment with aspirin-low molecular weight heparin was present in 125 cases (90%), steroids in 25 cases (18%), and hydroxychloroquine in 15 cases (11%).

One hundred thirty children born to mothers with APS were analyzed (female sex in 61 cases, birth weight 3000±500 g, height 48±3 cm, cranial perimeter 34±3 cm). Seventeen percent have a premature birth (n=22), and fifteen percent presented birth weight <2500 g (n=19). Thrombopenia was noted in 2 children, without any case of lupus or thrombosis. Four percent of children have lupus anticoagulant and antibeta2GP1 IgG antibodies (n=4), fifteen percent have anticardiolipid IgG antibodies at birth (n=17) (table).

	Cordon (n=40)	First week (n=110)	3 months (n=35)	9 months (n=38)	24 months (n=49)
ACC	0	4 (4%)	1 (3%)	1 (3%)	0
Anticardiolipid IgG	7 (18%)	17 (15%)	3 (9%)	7 (18%)	11 (22%)
Anticardiolipid IgM	0	0	0	0	1 (2%)
AntiB2GP1 IgG	2 (5%)	4 (4%)	5 (14%)	7 (18%)	5 (10%)
AntiB2GP1 IgM	0	0	0	0	1 (2%)

During 5 year follow-up, four children displayed behavioural abnormalities between 3 months and three years of age (psychomotor development delay with axial hypertonia, autism, attention-deficit/hyperactive disorder and language delay, growth failure and language delay (n=1 each)). No thrombosis or lupus was noted during follow-up. Eighteen percent have anticardiolipid IgG and antibeta2GP1 IgG antibodies above 6 months (table). Among children with abnormal psychomotor development, one has persistent anticardiolipid IgG antibodies.

Anticardiolipid Ig G and antibeta2GP1 Ig G antibodies in children, even after 6 months, were correlated with the same antibodies in mother ($p<0.05$).

The presence of maternal lupus with odds ratio 4 [1.2; 15]) and anticardiolipid IgG (odds ratio 6 [1.1; 33]) were predictive of neonates complication, whereas the presence of previous placenta praevia and mother's anticardiolipid IgG antibody were predictive of complications in children at 3 and 9 months.

Conclusion: Despite a high rate of premature birth and persistent antiphospholipid antibodies, the children born to mothers with APS do not have significant abnormalities of psychomotor development, thrombosis or lupus. The significance of persistent antibodies in children is not actually established.

IL-7 Contributes to Monocyte Migration In Rheumatoid Arthritis. Nathan D. Chamberlain[1], Sarah R. Pickens[1], Richard M. Pope[2], Michael Volin[3] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Northwestern Univ Med School, Chicago, IL, [3]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL

Background/Purpose: The aim of the study was to characterize the expression of IL-7 and IL-7R in rheumatoid arthritis (RA) synovial tissue and to examine their regulation and pathogenic role in RA.

Methods: Expression and regulation of IL-7 and IL-7R was determined in RA and normal (NL) peripheral blood (PB) monocytes and in vitro differentiated macrophages by real-time RT-PCR and/or flow cytometry**.** Next the ability of IL-7 to induce monocyte migration was determined by in vitro chemotaxis.

Results: Since we have previously shown that expression levels of IL-7 and IL-7R were elevated in RA synovial lining and sublining macrophages, we asked whether expression of these factors was increased in RA PB and synovial fluid macrophages compared to NL PB monocytes and macrophages. Expression of IL-7 was elevated 17-fold in RA synovial fluid macrophages and 7-fold in RA PB macrophages compared to their counterpart NL cells by real-time RT-PCR. Levels of IL-7 were 4-fold greater in RA PB monocytes compared to NL monocytes. Further, concentrations of IL-7R were significantly higher in RA synovial fluid (45 fold) and RA PB (10 fold) macrophages compared to NL macrophages employing real-time RT-PCR. Also, RA PB monocytes expressed 8-fold greater levels of IL-7R compared to NL monocytes. Consistent with our mRNA results, flow cytometry experiments demonstrate that IL-7R is significantly elevated in RA monocytes and macrophages compared to NL counterparts. To determine which factors modulate expression of IL-7 and IL-7R in RA PB in vitro differentiated macrophages, cells were either untreated or treated with LPS, IL-1b, TNF-a, IL-17 or RA synovial fluid. Our results demonstrate that both IL-7 and IL-7R expression were greatly induced by LPS, TNF-a and IL-1b activation of RA PB macrophages compared to untreated cells. However only expression levels of IL-7 were upregulated (3.5-fold) by IL-17 stimulation, while RA synovial fluid activation of macrophages resulted in increased IL-7R expression compared to untreated cells. To determine whether IL-7 affects cell trafficking in the RA joint, IL-7-induced monocyte chemotaxis was examined. IL-7 was chemotactic for monocytes beginning at 0.1 ng/ml. Further, neutralization with anti-IL-7R antibody, but not control IgG, suppressed IL-7 mediated chemotaxis. Studies were performed to determine if the IL-7 identified in RA synovial fluid was chemotactic for monocytes. The mean concentration of IL-7 in the 18 RA synovial fluids analyzed was 138 + 19 pg/ml (up to 414 pg/ml), a value that was highly chemotactic. Next, experiments were performed to determine if the monocyte chemotaxis induced by RA synovial fluid was mediated by IL-7. Neutralization of IL-7 with a monoclonal antibody to IL-7, significantly reduced (40%; $p<0.05$) monocyte chemotaxis compared to control IgG-treated RA synovial fluids. Additionally, neutralization of IL-7R on monocytes was also effective in suppressing RA synovial fluid-mediated monocyte migration.

Conclusion: We identify, for the first time, regulators of IL-7 and IL-7R expression in RA PB in vitro differentiated macrophages and we document a novel role of IL-7 in RA monocyte migration.

CCL21 a Novel Proangiogenic Factor in Rheumatoid Arthritis. Sarah R. Pickens[1], Nathan D. Chamberlain[1], Michael Volin[2], Arthur M. Mandelin II[3] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: This study was performed to determine the role of CCL21 and its corresponding receptor, CCR7, in the pathogenesis of Rheumatoid Arthritis (RA).

Methods: Histological studies were performed to compare the expression of CCR7 in RA with normal (NL) synovial tissues. Next, the role of CCL21 and/or CCR7 in angiogenesis was examined by employing in vitro chemotaxis, tube formation and in vivo matrigel plug assays. Finally the

mechanism by which CCL21 mediates angiogenesis was determined by Western blot analysis, endothelial chemotaxis and tube formation.

Results: In this study, we document that CCR7 expression was significantly increased in RA synovial tissue lining and endothelial cells compared to NL synovial tissue. We next validated that CCR7 is expressed by RA synovial lining macrophages and sublining endothelial cells by co-localizing CCR7 expression on CD68+ and VWF+ cells. Interestingly, the CCR7 expression pattern in RA synovial tissue is similar to what was previously noted for its ligands, CCL19 and CCL21. Since the CCR7, CCL19, and CCL21 are all expressed by RA endothelium, their ability to mediate angiogenesis was examined. For this purpose, chemotaxis was performed in a Boyden chamber with varying concentrations of CCL19 and CCL21, as well as positive (VEGF, 10ng/ml) and negative (PBS) controls. While CCL21 was chemotactic for human microvascular endothelial cells (HMVEC)s at concentrations ranging from 1 to 100 ng/ml ($p<0.05$), CCL19 did not induce HMVEC migration. The mean concentration of CCL21 in the RA synovial fluids ($n=74$) and tissues ($n=11$) analyzed was 519 ± 38 pg/ml (up to 3.4 ng/ml) and 824 ± 104 pg/mg (up to 1.6 ng/mg) respectively, concentrations that were chemotactic for HMVECs. Further, incubation of HMVECs with a neutralizing antibody to CCR7 suppressed CCL21-induced HMVEC migration suggesting that the chemotactic effect was due to CCR7 ligation. We found that CCL21 activates the PI3K, ERK and JNK pathways in HMVECs. While inhibition of ERK and JNK was ineffective in suppressing CCL21-induced HMVEC chemotaxis and tube formation, suppression of PI3K reduced these processes starting at 1 mM by 35–40% ($p<0.05$). Neutralization of either CCL21 in RA synovial fluids or CCR7 on HMVECs significantly reduces the induction of HMVEC migration and/or tube formation by RA synovial fluid. The role of CCL21 on angiogenesis in vivo was assessed by determining its effect on blood vessel formation in matrigel plugs in mice by employing hemoglobin quantification. The hemoglobin content of the CCL21 treated group was 14 times greater ($p<0.05$) than the PBS control. The concentration of CCL21 quantified from day 10 matrigel plugs was 405 pg/ml ± 89 pg/ml which is within the range of CCL21 levels detected in RA synovial fluid and tissue.

Conclusion: These observations identify a novel function for CCL21 as an angiogenic mediator in RA, supporting CCL21/CCR7 as a therapeutic target in RA.

731

Evidence for CXCL16 As An Endothelial Progenitor Cell Chemotactic Factor. Jeffrey H. Ruth[1], Takeo Isozaki[1], M. Asif Amin[1], Charles A. Lesch[1], Ali S. Arbab[2] and Alisa E. Koch[3]. [1]University of Michigan, Ann Arbor, MI, [2]Henry Ford Hospital, Detroit, MI, [3]Department of Veteran's Affairs and University of Michigan, Ann Arbor, MI

Background/Purpose: We and others have previously shown that the transmembrane chemokine CXCL16 and its counterpart CXCR6 are important in the pathogenesis of rheumatoid arthritis (RA), predominantly via recruitment and stimulation of monocytes and T-cells. Here, we investigated the possibility that CXCR6 is expressed on human endothelial progenitor cells (EPCs), human dermal microvascular endothelial cells (HMVECs) and mouse lung endothelial cells (ECs). We also examined if CXCL16 recruits EPCs to developing neovasculature in rheumatoid arthritis (RA) synovium *in vivo,* and finally, if CXCR6 deficiency attenuates arthritis development and vascular formation in the K/BxN serum induced arthritis model.

Methods: We utilized the RA synovial tissue (ST) severe combined immunodeficient (SCID) mouse chimera system to examine EPC recruitment into engrafted human synovium injected intragraft with RA synovial fluid (SF) immunodepleted of CXCL16 or sham depleted with non-specific IgG. In addition, CXCR6 deficient ($CXCR6^{-/-}$) and wild-type (Wt) C57BL/6 mice were primed to develop K/BxN serum induced arthritis and evaluated for joint swelling. Joint tissue homogenates from these mice were examined for hemoglobin (Hb) content as a measure of total joint tissue vascularity, whereas OCT embedded joint tissue was examined for vascular formation and leukocyte migration by immunofluorescence histology. Lastly, EC populations including HMVECs, human EPCs from human cord blood and primary mouse ECs from lung tissue were all examined for CXCR6 expression by immunofluorescence.

Results: We show that CXCR6 is prominently expressed on the cell surface of human EPCs. CXCR6 is also expressed on HMVECs and mouse lung ECs and can be upregulated by interleuin-1β (IL-1β) or lipopolysaccharide (LPS) respectively. We also examined the recruitment of human EPCs in the RA ST SCID mouse chimera system and found that SCID mice injected intragraft with RA SF immunodepleted of CXCL16 showed a significant reduction in EPC recruitment compared to mice injected similarly with sham depleted RA SF. Finally, using the K/BxN serum induced inflammatory arthritis model, $CXCR6^{-/-}$ mice showed significantly reduced joint swelling compared to Wt mice at day 5 after serum induction. We measured Hb content in joint tissue homogenates from the K/BxN serum induced mice and discovered profound reductions in Hb levels, that correlated with reductions in monocyte and T-cell recruitment to arthritic joint tissue in $CXCR6^{-/-}$ compared to Wt mice. These findings indicate that CXCR6 deficiency reduces EPC migration to RA synovium, as well as vasculature formation and pro-inflammatory leukocyte recruitment in K/BxN serum induced arthritis.

Conclusion: We show that CXCR6 is expressed on mouse and human ECs and can be upregulated by pro-inflammatory stimuli. We also show that EPCs migrate into RA synovium towards soluble CXCL16 in RA SF. Additionally, K/BxN mice lacking CXCR6 have a reduced arthritic phenotype including reductions in Hb content, vasculature and leukocyte infiltration into inflamed ST. These results indicate that CXCL16 and its receptor CXCR6 may be a central ligand-receptor pair for inducing EPC recruitment and vascular formation in RA synovium.

732

Notch Signaling Pathways Mediate Synovial Angiogenesis in Response to Vascular Endothelial Growth Factor and Angiopoietin 2. Wei Gao, Catherine Sweeney, Ceara Walsh, Peadar Rooney, Jennifer McCormick, Douglas J. Veale and Ursula Fearon. Translation Rheumatology Research Group, Dublin, Ireland

Background/Purpose: Angiogenesis plays a crucial role in the formation and maintenance of the pannus in inflammatory arthritis. Endothelial cell (EC) activation and survival signaling pathways preserve synovial blood vessel integrity and facilitates leukocyte infiltration. The Notch signaling pathway is critical for vascular angiogenesis and EC cell fate; however, the mechanisms involved in regulating these processes in the inflamed joint remain to be elucidated. The aim of this study was to examine if Notch signaling pathways mediate Vascular Endothelial Growth Factor (VEGF) and Angiopoietin 2 (Ang2) induced angiogenesis and blood vessel invasion in the inflamed joint.

Methods: Whole tissue synovial explants obtained at arthroscopy and microvascular endothelial cell cultures (HDEC) were utilised. Notch 1IC and 4IC protein expression were measured using western blots, Notch ligand DLL-4 and downstream signaling components Hrt 1 and Hrt 2 were quantified by qRTPCR. Notch signaling was directly blocked by Notch 1 siRNA transfection and DAPT (γ-secretase inhibitor). Measurements of angiogenesis were assessed *in vitro* by matrigel tube formation, invasion assay and pro-MMP-2/9 expression was measured by zymography.

Results: Notch 1IC and 4IC expression were observed in RA and PsA synovial tissue lysates with undetectable levels in OA patients. VEGF and Ang2 alone induced Notch1 IC, and 4IC expression in HDEC and RA synovial explants cultures, with a synergistic increase in Notch 1IC expression in response to VEGF and Ang2 in combination ($p<0.05$). VEGF and Ang2 alone significantly induced Notch 1, its ligand DLL-4 and downstream target genes Hrt 1 and Hrt 2 mRNA expression, with synergistic effects observed when cells were stimulated with VEGF and Ang2 in combination ($p<0.05$). VEGF-induced Notch 1IC expression was completely blocked in the presence of siRNA ($p<0.05$). Furthermore VEGF/Ang2-induced angiogenesis, cell invasion and pro-MMP-2/9 expression, were inhibited in the presence of siRNA or DAPT ($p<0.05$).

Conclusion: These data demonstrate increased expression of Notch 1IC in RA and PsA synovial tissues. VEGF and Ang2 alone and in combination induce Notch1 IC signaling pathways, blockade of which inhibits VEGF/Ang2-induced EC function. Taken together, these results suggest that in the inflamed joint, VEGF/Ang2-induced angiogenesis is in part dependent on the Notch signaling pathways.

Active Non-Canonical NF-κB Signaling in Blood Vessels of Rheumatoid Arthritis Synovial Tissue May Enhance Inflammation by Stimulating Angiogenesis. Ae-Ri Noort, Katinka P.M. van Zoest, Paul P. Tak and Sander W. Tas. Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam The Netherlands, Amsterdam, Netherlands

Background/Purpose: In rheumatoid arthritis (RA) synovial tissue (ST), (pathological) angiogenesis can be observed already in the earliest phase of disease, and this may be critical in the switch from acute to chronic inflammation. The chemokine CXCL12, which is induced via non-canonical

nuclear factor-KB (NF-KB) signaling, plays an important role in angiogenesis, lymphocyte transendothelial migration, and the homing of endothelial progenitor cells. Therefore, the non-canonical NF-κB pathway, in which NF-κB inducing kinase (NIK) is a key mediator, may play an important role in pathological angiogenesis and the perpetuation of synovial inflammation in RA. Objectives: To study the role of non-canonical NF-κB signaling in pathological angiogenesis in RA.

Methods: ST was obtained via mini-arthroscopy from inflamed joints of RA patients with active disease. Expression of NIK, p52 and CXCL12 was evaluated using immunohistochemistry and immunofluorescence (IF) microscopy. NIK expression was also studied in Grawitz tumor and breast cancer tissues, in combination with vWF or CD31/CD34. The effects of non-canonical NF-κB signaling in endothelial cells (EC) were studied in vitro using angiogenesis/tube formation assays. In addition, VCAM-1 expression was measured by FACS analysis and $\alpha v\beta 5$ integrin levels by PCR.

Results: NIK was highly expressed in vascular structures in RA ST. IF microscopy demonstrated that NIK co-localized with the EC marker vWF in small vessels, but not with lymphatic vessel markers LYVE-1 and podoplanin. p52 and CXCL12 expression was observed in the same vascular structures. Furthermore, NIK was also expressed in EC in Grawitz tumor and breast cancer tissues, whereas normal skin EC did not exhibit increased NIK expression. In vitro, HUVEC treated with stimuli that induce non-canonical NF-KB signaling significantly enhanced tube formation 2,5-fold ($p<0.05$). FACS analysis of stimulated HUVEC showed a 2-fold increased VCAM-1 expression ($p<0.05$) and preliminary data also showed increased $\alpha v\beta 5$ levels.

Conclusion: NIK is preferentially expressed in EC in RA ST, and interestingly also by EC in tumor tissues. CXCL12 and p52 were also expressed in these blood vessels in RA ST, suggesting functional non-canonical NF-KB signaling. In vitro, stimulation of the non-canonical NF-KB pathway resulted in EC activation and enhanced angiogenesis. These findings point towards an important role of the non-canonical NF-KB pathway in (pathological) angiogenesis. This could be exploited for the development of new therapies that could not only be of benefit for RA patients, but also for a wide array of other diseases.

In Vivo Imaging of T Cell Motility in the Joint Draining Lymph Nodes of Genetically Unmanipulated Mice in a Model of Rheumatoid Arthritis.
Tamas Kobezda, Sheida Ghassemi-Nejad, Colt Egelston, Tibor T. Glant and Katalin Mikecz. Rush University Medical Center, Chicago, IL

Background/Purpose: Development of adaptive immunity relies on the recognition of antigens (Ags) by cognate T cells and subsequent signaling through the T cell receptor (TCR). The threshold of TCR activation is usually high, and co-stimulatory signals are required. Recent in vivo two-photon imaging studies on lymph nodes (LNs) have revealed that T cells exhibit random motility until they encounter an APC that presents cognate Ag and provides co-stimulation, both of which require prolonged cell-cell interaction. Because cognate T cells are thought to be rare, most in vivo imaging experiments employ genetically altered mice expressing a TCR transgene specific for a model Ag. The purpose of our study was to determine if changes in T cell motility (consistent with APC-T cell interaction) can be observed in genetically unmanipulated (wild type, WT) mice in a model of rheumatoid arthritis.

Methods: T cells were isolated from naïve BALB/c mice and from BALB/c mice with cartilage proteoglycan-induced arthritis (PGIA). Naïve T cells were labeled with a green fluorescent cell tracer dye, and Ag-experienced T cells (from PGIA mice) with a red fluorescent dye. The donor cells were then co-transferred (1:1 ratio) into either naïve or arthritic BALB/c recipients. Following cell transfer, proteoglycan (PG, as a cognate Ag) was injected into the ankle joints. The T cell recipient mice were then anesthetized, and the popliteal (ankle joint-draining) LNs were subjected to two-photon microscopy at defined time points between 2 and 72 h after Ag injection.

Results: At the earliest time point (2 h) after intra-articular Ag injection, the co-transferred naïve and Ag-experienced T cells both exhibited high motility ("random walk") in the LNs of naïve recipient mice. However, at 4 h, Ag-experienced, but not naïve, T cells showed significantly reduced motility, which was consistent with their engagement with APCs. At 8 h after Ag injection the Ag-experienced population became highly motile again, suggesting their disengagement from the APCs. When naïve and Ag-experienced T cells were co-transferred into arthritic recipients, both T cell populations exhibited reduced motility in the popliteal LNs 4 h after Ag injection, but naïve T cells disengaged soon afterwards. This prompted us to ask whether the access of naïve T cells to APCs was limited by occupancy of the APCs by Ag-experienced T cells. Indeed, when naïve T cells were transferred alone into arthritic hosts, they exhibited long-lasting interactions with APCs.

Conclusion: It this in vivo study we demonstrate that changes in T cell motility upon Ag presentation occur in genetically unaltered mice. Co-transfer of naïve and Ag-experienced T cells into naïve recipient mice results in preferential interaction of Ag-experienced T cells with APCs in the presence of Ag, as expected. However, naïve T cells also show evidence of cognate interaction with APCs following transfer into arthritic recipients. These results indicate that Ag-experienced T cells from WT mice recapitulate the motility patterns reported in TCR-transgenic mice upon Ag presentation. Our study also suggests that cognate T cells in naïve WT mice are not as rare as previously thought.

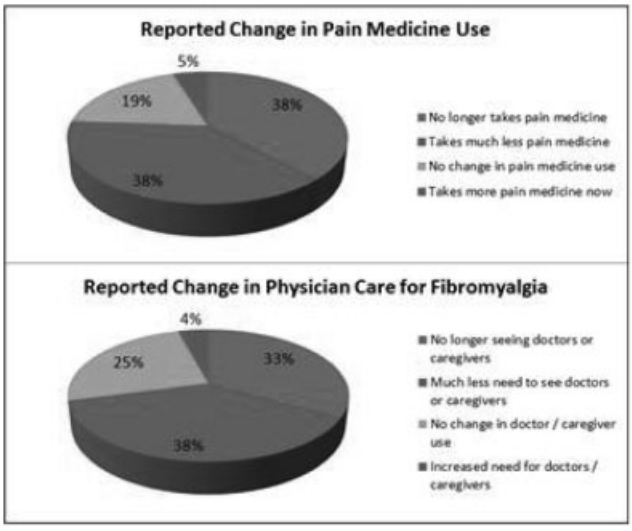
Long-Term Outcomes In Fibromyalgia Patients Treated with Cortical Electrostimulation.
Jeffrey B. Hargrove[1], Robert M. Bennett[2] and Daniel J. Clauw[3]. [1]Kettering University, Flint, MI, [2]Oregon Health & Science Univ, Portland, OR, [3]University of Michigan, Ann Arbor, MI

Background/Purpose: This study evaluated the long-term outcomes of Reduced Impedance Noninvasive Cortical Electrostimulation (RINCE) in fibromyalgia (FM) patients. These FM patients had been treated with RINCE twice weekly over a period of 11-weeks in 2006–2008, in a placebo controlled, double-blind study that targeted areas of the brain considered to be involved in central sensitization (Arthritis Rheum 2010;62(10 Suppl):269–70).

Methods: Under IRB-approval, subjects treated with RINCE were asked to complete an un-blinded follow-up survey that included the Fibromyalgia Impact Questionnaire (FIQ). Thirty-nine subjects were mailed surveys, 25 were returned (64%). In addition to the FIQ, survey responses provided patient self-reports on the duration of symptom improvement, incidence of side effects, and changes in pain medicine use and physician visits.

Results: The average respondent age was 59 years (range 39–71); the average time since completion of therapy was 45 months (range 31–60). The mean total FIQ score was 53 at baseline, 36 at end-of-study (EOS) and 32 at follow-up ($P<0.001$). The change from baseline in FIQ scores at EOS and follow-up were significantly correlated ($R=0.78$, $P<0.001$). Subjects reported symptom improvements lasting at least two-years in pain (68%) sleep (56%) and fatigue (60%). Some 76% of treated subjects reported that they had reduced or completely eliminated medicine use for pain, and 71% indicate reduced or eliminated need to see physicians for FM (see pie charts). No post-treatment side effects were reported.



Conclusion: A high percentage of FM patients, who had been treated with RINCE, continued to experience a worthwhile level of improvement in FM symptoms at a 45-month follow-up. These sustained benefits were

accompanied by significant reductions in pain medicine use and physician visits. Follow-up total FIQ scores demonstrated durability of treatment effect when compared to baseline and EOS. The strong correlation between total FIQ scores at EOS and follow-up suggests that the initial response to RINCE is predictive of a long lasting therapeutic benefit. Cortical electrostimulation is a non-pharmacological modality that shows some promise in the management of FM patients, and has the potential for future development.

Incidence and Predictors of Fibromyalgia in An Early Arthritis Cohort. Yvonne C. Lee[1], Daniel H. Solomon[1], Bing Lu[1], Gilles Boire[2], Boulos Haraoui[3], Carol A. Hitchon[4], Janet E. Pope[5], J. Carter Thorne[6], Edward Keystone[7], Diane S. Ferland[8] and Vivian Bykerk[9]. [1]Brigham and Women's Hospital, Boston, MA, [2]CHUS-Sherbrooke University, Sherbrooke, QC, [3]Institut de Rhumatologie, Montreal, QC, [4]University of Manitoba, Winnipeg, MB, [5]St. Joseph's Health Care, University of Western Ontario, London, ON, [6]Newmarket, ON, [7]Mount Sinai Hospital, Toronto, ON, [8]LaSalle, QC, [9]Brigham & Women's Hospital, Boston, MA

Background/Purpose: The prevalence of fibromyalgia (FM) is 20% among patients with established rheumatoid arthritis (RA) compared to 3% in the general population. However, little is known about the time course of FM in inflammatory arthritis and whether chronic pain and inflammation due to arthritis impact the risk for FM. We examined the development of FM in an early inflammatory arthritis cohort and assessed the association between baseline clinical variables and future diagnosis of FM.

Methods: Data were analyzed from 1198 patients in the Canadian Early Arthritis Cohort, a prospective, observational, multi-center cohort of early inflammatory arthritis patients. Diagnoses of FM were determined by the participants' rheumatologists. Cumulative incidence rates were calculated, and Cox regression models were used to determine hazard ratios for the development of FM.

Results: The cumulative incidence of FM rose from 0% at baseline (excluding 68 prevalent cases) to 5.9% at 12 months and 11.8% at 60 months (Figure). Female sex (HR 3.66, 95% CI 1.44–9.32), tender joint count (HR 1.06, 95% CI 1.04–1.09), depressed mood (HR 1.81, 95% CI 1.07–3.05) and poor memory (HR 2.05, 95% CI 1.21–3.49) were significantly associated with an increased risk for FM (Table). Swollen joint count (HR 0.96, 0.92–1.00) and erythrocyte sedimentation rate (ESR) (ESR 30–49: HR 0.42, 95% CI 0.20–0.92; ESR ≥ 50: HR 0.28, 95% CI 0.11–0.71) were negatively associated with the development of FM.

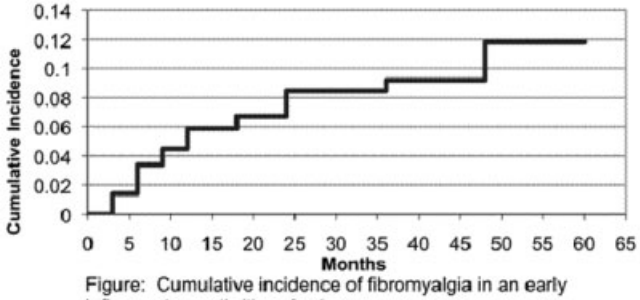

Figure: Cumulative incidence of fibromyalgia in an early inflammatory arthritis cohort.

Table. Multivariable Cox regression models for the development of fibromyalgia in an early inflammatory arthritis cohort (N = 1198).

Baseline Characteristics	Hazard Ratio	95% CI	*P*
Age, per year	1.00	0.98–1.02	0.75
Female	3.66	1.44–9.32	**0.006**
Non-Caucasian	1.38	0.78–2.43	0.27
Current smoker	0.53	0.25–1.14	0.10
68-tender joint count, per joint	1.06	1.04–1.09	**<.0001**
68-swollen joint count, per joint	0.96	0.92–1.00	**0.04**
ESR, per mm/hr	–	–	–
10–19 mm/hr	0.61	0.33–1.14	0.12
20–29 mm/hr	0.50	0.24–1.07	0.07
30–49 mm/hr	0.42	0.20–0.92	**0.03**
≥ 50 mm/hr	0.28	0.11–0.71	**0.008**
Depressed mood	1.81	1.07–3.05	**0.03**
Poor memory	2.05	1.21–3.49	**0.008**

Conclusion: The cumulative incidence of FM increased during the first 60 months after diagnosis of inflammatory arthritis, with the greatest increase occurring over the first 18 months. Although female sex, depression and poor memory were predictive of the development of FM, inflammatory measures were associated with a decreased risk for FM. These results may reflect physician decision-making processes when considering a diagnosis of FM in patients with inflammatory arthritis. Future studies are needed to better define the diagnosis of FM in patients with inflammatory arthritis and understand the role of inflammatory measures as a negative predictor of fibromyalgia.

Cortical Oscillatory Changes During Mechanical Brushing in Fibromyalgia Syndrome Patients. Nick Fallon, Yee Ho Chiu, Xiaoyun Li, Turo Nurmikko and Andrej Stancak. University of Liverpool, Liverpool, United Kingdom

Background/Purpose: Pain resulting from innocuous mechanical stimuli is common in Fibromyalgia syndrome (FMS) and is likely to be a key pathophsyiological component of FMS symtpomatology. This study aims to investigate the cortical oscillatory changes associated with tactile cutaneous stimuli in FMS patients.

Methods: Nineteen female FMS patients and 18 healthy, age matched, female controls underwent electroencephalographic (EEG) examination during 2 blocks of mechanical brush stimulation of the right arm (right lateral epicondyle). Blocks consisted of 20 cycles, containing 4 seconds of rest and 4 seconds of brushing with a soft bristled paintbrush. After each block participants rated any pain experienced on a 4-point Likert scale ranging from no pain to severe pain. Participants were also required to undergo a clinical manual tender point scale examination and to complete a variety of psychological and clinical questionnaires.

Results: Thirteen patients (no controls) reported discomfort or pain following brushing. A Student's independent t-test indicated a significant difference between the mean total pain score for patients (1.61 ± 1.42) and controls (0.00 ± 0.00); $t(35) = 4.79$, $P < 0.001$.

Surface EEG data was analysed to compare oscillatory changes related to the onset of brushing in each group. FMS patients demonstrated profound amplitude reductions in beta band (16–24Hz) frequencies during brushing (event related desynchronisation, ERD), over bilateral somatosensory areas and limited ERD over much of the scalp. This is indicative of a strong bilateral, widespread activation in response to brushing. Controls demonstrated a more focal ERD, primarily in electrodes over contralateral somatosensory cortex. An independent t-test comparison of beta amplitude changes during brushing revealed three significantly different clusters of electrodes over the medial occipital, ipsilateral prefrontal, and ipsilateral somatosensory cortices. Only the cluster over the ipsilateral primary somatosensory cortex demonstrated a robust unidirectional difference in ERD, patients exhibiting a strong mean ERD (16.87 %) compared to almost no ERD (0.01%) in healthy controls (Students independent T-test, $t(35) = 2.93$, $p = 0.006$).The remaining clusters demonstrated statistically significant amplitude changes due to small but opposing oscillatory alterations, with smaller ERD in the patient group contrasting with slight amplitude increases in the control group. Multiple regression analysis indicated that manual tender point score was a significant predictor of the ERD in the ipsilateral somatosensory cortical area during brushing.

Conclusion: Results point to the presence of cortical activation in the ipsilateral primary somatosensory cortex in FMS patients, but not healthy subjects, during dynamic tactile stimulation. The ipsilateral somatosensory cortex activation during brushing in FMS patients is associated with the manual tender point score suggesting that disinhibition of this area may contribute to clinical pain. Such disinhibition may potentially cause stronger recruitment of thalamic neurons in response to the stream of afferent somatosensory information manifesting in FMS pain.

738

Pain Variability Influences Recalled Pain Estimation. Steven E. Harte[1], Robert H. Palmer[2], R. Michael Gendreau[3], Daniel J. Clauw[1] and Richard E. Harris[1]. [1]University of Michigan, Ann Arbor, MI, [2]Forest Research Institute, Jersey City, NJ, [3]Cypress Bioscience, Inc., San Diego, CA

Background/Purpose: Pain variability refers to fluctuations in pain intensity that occur over time. Previous studies indicate that real-time assessment of clinical pain shows significant pain variability both within

and between subjects (Harris et al., Arthritis Rheum 52, 2005). Moreover the degree of variability is associated with analgesic response (Harte et al., Arthritis Rheum 60, S1, 2009). Here we investigated the relationship between pain variability (PVI: pain variability index) and recalled pain in fibromyalgia (FM) patients.

Methods: FM patients (n = 888) were enrolled in a randomized, double-blind, placebo-controlled trial of milnacipran (Mease et al., J Rhem, 2009). Patients entered their current and weekly recalled pain intensity into electronic diaries. Current pain was assessed several times a day by random prompts. Pain intensity was rated on a 0–100 VAS, anchored by "no pain" and "worst possible pain." PVI was calculated as the natural log of the standard deviation in current pain entries over a two-week baseline assessment period conducted before treatment with either milnacipran or placebo. Recall bias was calculated as the difference between average current pain and recalled pain over the same two-week assessment period.

Results: A significant recall bias was observed during the baseline assessment period. Patients reported higher recalled pain as compared to current pain (recalled VAS: 69.89 +/− 11.82 (SD); current VAS: 66.71 +/− 13.59; $p < 0.001$). PVI was significantly associated with pain recall bias ($r = -0.456$; $p < 0.001$) over the same period.

Conclusion: These data indicate that pain recall is influenced by the degree of pain variability experienced during the recall period, with greater variability being associated with greater recall error. These findings have relevance for clinical trials in chronic pain which rely solely on recalled pain.

739

Nocebo in Fibromyalgia: Meta-Analysis of Placebo-Controlled Clinical Trials and Implications for Practice. DD Mitsikostas[1], NG Chalarakis[1], LI Mantonakis[1], E. Delicha[2] and PP Sfikakis[2]. [1]Naval Hospital, Athens, Greece, Athens, Greece, [2]First Department of Propaedeutic and Internal Medicine, Laiko, Athens University Medical School, Greece, Athens, Greece

Background/Purpose: Poor medication adherence has long been observed in clinical practice in patients with fibromyalgia. This may result in treatment failure and/or increased total healthcare costs, and can be partly related to nocebo. Nocebo refers to adverse effects generated by patients' fear that medical treatment will likely harm instead of heal and can be assessed in placebo-controlled randomized clinical trials (RCTs). The present meta-analysis examined adverse effects following placebo administration in RCTs for fibromyalgia.

Methods: Following a systematic Medline search for RCTs for fibromyalgia pharmacologic monotherapy treatment published between 2001–2010, we assessed percentages of placebo-treated patients reporting at least one adverse effect or discontinuing due to placebo intolerance and searched for factors influencing nocebo's extent. Percentages were compared to those revealed by similarly performed meta-analyses of placebo-controlled RCT's for multiple sclerosis (Mult Scler, 2010;16:816–828) and primary headaches (Cephalalgia 2011;31:550–61)

Results: Data were extracted from 16 RCTs fulfilling search criteria. Of 2026 placebo-treated patients, 67.2% (95%CI:51.0%–81.5%) reported at least one adverse effect, and 9.5% (95%CI:8.3%–10.9%) discontinued placebo treatment due to intolerance. Adverse effects in placebo arms corresponded quantitatively and qualitatively to those in active drug arms ($\rho > 0.88$, $p < 0.0001$). Younger age and larger placebo arm size were associated with increased dropout rates. Patients with depression were more likely to withdraw from trials. Nocebo dropouts in fibromyalgia trials were 4-fold and 2-fold higher than in RCT's for multiple sclerosis treatment and migraine preventive treatment, respectively.

Conclusion: Nocebo is remarkably prevalent in fibromyalgia patients participating in RCTs probably being a serious confounding factor. Since nocebo contributes to drug intolerance and treatment failure in clinical practice, identification of predisposing factors and efforts to prevent nocebo by educating these patients appropriately seems to be important for fibromyalgia outcome.

740

The Performance of American College of Rheumatology 2010 Diagnostic Criteria for Fibromyalgia Among Fibromyalgia Patients Seen in a Rheumatology Clinic and Diagnosed by 1990 Classification Criteria. Muhammad B. Yunus and Jean C. Aldag. University of Illinois College of Medicine at Peoria, Peoria, IL

Background/Purpose: The 2010 American College of Rheumatology (ACR) Diagnostic Criteria for Fibromyalgia (FM) were developed to diagnose FM in the clinic without the need for performing tender point (TP) examination. The predominant purpose of our study was to assess the performance of the above 2010 criteria among FMS patients seen in our clinic. Further, we wished to assess correlations among important variables.

Methods: We selected 473 patients in our data base who fulfilled the 1990 ACR criteria for classification of fibromyalgia (widespread pain plus at least 11 TPs among 18). These patients did not have another condition that would explain the pain. According to the 2010 criteria, widespread pain index (WPI) was calculated by counting sites of pain symptom among 19 sites (possible WPI score 0–19). Symptom severity (SS) scale score was calculated by adding the severity (0–3 categories) of the following symptoms: fatigue, waking unrefreshed and cognitive symptoms, as well as number of total symptoms (0=none, 1= few, 2=moderate and 3= large number). Thus, possible score for SS scale was 0–12. To fulfill the 2010 diagnostic criteria a patient needed to have WPI score of 7 or greater and SS score of 5 or greater, OR WPI score of 3–6 and SS score of 9 or greater.

Results: The mean (SD) age in years was 46.7 (13.2), 95.7% Caucasian, 87.7% female. Mean (SD) duration of symptoms was 9.2 (9.7) years. Mean (SD) number of TPs among 18 sites was 15.7 (2.4). Of the 473 FM patients by 1990 ACR criteria, 408 (86.2%) fulfilled the new 2010 diagnostic criteria. Spearman correlations showed significant correlation of TPs with 19 pain sites (p=.0001), no. of symptoms (p=.0001), no. of subjective swollen sites (p=.0001), no. of subjective numbness sites (p=.003), and AM fatigue (p=.021). No correlation was found between TPs and self-assessed depression or anxiety. Anxiety correlated with depression (p=.0001). Sleep difficulties correlated with AM fatigue (p=.0001), depression (p=.0001), anxiety (p=.001) and AM stiffness (p=.001).

Conclusion: 86.2% of our FM patients diagnosed by 1990 ACR criteria fulfilled the 2010 FM diagnostic criteria. This figure is similar to 88.1% found in the multicenter 2010 criteria study. Since 76% of FM patients diagnosed by a physician in a clinic fulfilled the 1990 ACR criteria in the 2010 study, as many as 33–35% of physician diagnosed FM will be missed by the new 2010 criteria. Given the strong correlation between TPs and number of subjective swollen sites and no. of subjective numbness sites, these symptoms are likely to be part of central sensitization that characterizes FM. Further, TP was not correlated with self-assessed anxiety or depression in our study. However, poor sleep was correlated with both depression and anxiety.

ACR Concurrent Abstract Session
Orthopedics and Low Back Pain
Sunday, November 6, 2011, 2:30 PM–4:00 PM

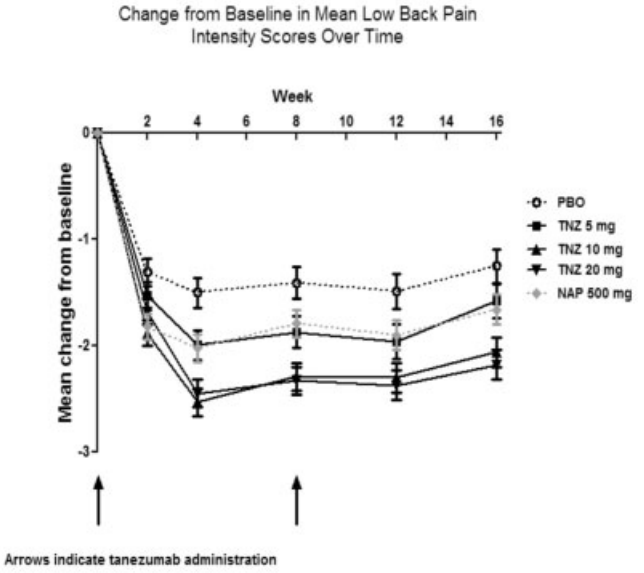
741

A Study of Tanezumab in Adults with Chronic Low Back Pain (NCT00876187). A. Kivitz[1], Joseph Gimbel[2], Candace Bramson[3], Mary Ann Nemeth[3], David Keller[4], Mark T. Brown[4], Christine R. West[5] and Kenneth M. Verburg[4]. [1]Altoona Center for Clinical Research, Duncansville, PA, [2]Arizona Research Center, Phoenix, AZ, [3]Pfizer, Groton, [4]Pfizer, Groton, CT, [5]Pfizer, Williamston, MI

Background/Purpose: A randomized, double-blind, placebo (PBO)- and active-controlled phase 2 study was conducted to investigate the efficacy and safety of tanezumab (TNZ), a humanized monoclonal antibody that specifically inhibits nerve growth factor vs. naproxen (NAP) and PBO as analgesic treatment for chronic low back pain (LBP).

Methods: Patients with moderate to severe, chronic, non radiculopathic LBP, received TNZ (20, 10, or 5 mg IV every 8 weeks, and oral PBO), NAP (500 mg BID starting at randomization and TNZ vehicle IV), or PBO (TNZ vehicle IV and oral PBO). Patients recorded daily pain scores for average LBP Intensity (aLBPI; an 11-point numeric rating scale). Mean Changes from Baseline (MCB) to Week 16 in the daily aLBPI for TNZ vs. PBO and vs. NAP were primary efficacy endpoints. Key secondary efficacy endpoints were change from Baseline to Week 16 in the Roland Morris Disability Questionnaire (RMDQ; a measure of function used for LBP) and change from Baseline to Week 16 in the Patient Global Assessment (PGA) of LBP. Adverse event (AE) incidence was also assessed.

Results: A total of 1347 patients were randomized and treated. TNZ 20 mg (MCB: −2.18; p<0.001), TNZ 10 mg (MCB: −2.06; p<0.001), and NAP (MCB: −1.66; p=0.037) but not TNZ 5 mg (MCB: −1.58; p=0.113) showed significant improvements in aLBPI versus PBO (MCB: −1.25) at Week 16. Improvements in aLBPI with TNZ 20 mg (p=0.006) and TNZ 10 mg (p=0.035) were also superior to NAP (Figure). Improvements in the RDMQ versus PBO (MCB: −1.75) were observed with TNZ 20 mg (MCB: −2.80; p=0.006) and TNZ 10 mg (MCB: −3.18; p<0.001) but not with TNZ 5 mg (MCB: −2.37; p=0.125) or NAP (MCB: −2.07; p=0.405). Improvements in the PGA versus PBO (MCB: −0.40) were seen with all TNZ treatments (MCB: −0.67, −0.65 and −0.58 by decreasing dose; p≤0.030), but not with NAP (MCB: −0.50; p=0.197). Additionally, both TNZ 20 mg and 10 mg treatment showed significant improvements in efficacy vs. NAP-treatment as measured by the RMDQ (p≤ 0.042) and PGA (p≤0.038).



The overall incidence of AEs was similar among the TNZ treatment groups (range: 58.0–64.4%) but higher than the NAP (48.1%) and PBO (52.2%) treatment groups. The most common AE was paresthesia (TNZ 20 mg, 12.9%; 10 mg, 7.1%; and 5 mg, 4.7%; NAP, 1.7%; and PBO, 2.2%). The incidence of serious AEs was highest in the PBO group and the rate of discontinuation across all treatments was low. There were no reported cases of osteonecrosis or total joint replacement. The AE profile for the TNZ, NAP and PBO treatment groups was comparable to that of previous TNZ studies in patients with osteoarthritis and other conditions of chronic pain.

Conclusion: Treatment with TNZ (20 mg and 10 mg) resulted in superior analgesic efficacy and improvements in pain, function and global assessment as measured by the aLBPI, RDMQ and PGA compared to PBO and NAP treatment. Results indicate that TNZ is efficacious in the treatment of chronic LBP. No new safety signals were identified.

742

Time-Course and Extent of Pain and Function Improvements Post-Knee Replacement: The Multicenter Osteoarthritis Study. Tuhina Neogi[1], Jingbo Niu[1], David T. Felson[1], Michael C. Nevitt[2], Yuqing Zhang[1], Laura Frey-Law[3], Jessica L. Maxwell[1] and Jasvinder Singh[4]. [1]Boston University School of Medicine, Boston, MA, [2]University of California-San Francisco, San Francisco, CA, [3]University of Iowa, Iowa City, IA, [4]University of Alabama at Birmingham and Birmingham VA Medical Center, Birmingham, AL

Background/Purpose: Prior studies have reported pain and function improvements post-knee replacement (KR) to be similar between 6 to 24-months post-KR. However, many studies relied on postal surveys, and often had incomplete follow-up. We examined the time-course and extent of pain and function changes post-KR, and whether these differed according to age, sex, and BMI in a comprehensively tracked cohort.

Methods: The Multicenter Osteoarthritis (MOST) Study is a longitudinal NIH-funded cohort of persons with or at high risk of knee OA. Pain and function by WOMAC were assessed at baseline, 30, and 60 months in those who had a KR during follow-up. Data from clinic visits immediately prior to and after the KR were used to evaluate the mean change in and proportion achieving the MCID (Escobar, 2007) for pain (WOMAC ↓ ≥5.6/20) and function (WOMAC ↓ ≥14.2/68), and proportion post-KR with moderate-to-severe pain (≥moderate pain on ≥1 of the 5 WOMAC pain questions) and poor function (≥28/68 (average function in those awaiting TKR)). We plotted the mean change in pain and function for the whole sample using local regression (LOESS). We also stratified changes in pain and function by age, sex, and BMI, additionally adjusting for other potential confounders (depressive symptoms, race/clinic, catastrophizing).

Results: During follow-up, 399 knees from 302 subjects had new KRs with ≥1 study visit post-KR (mean age 67±7.5, BMI 33±7, 72% female), with 97 having bilateral KRs. The median # of months between the pre-KR visit and KR was 16, and between the KR and post-KR visit was 20. Pain and function patterns did not differ by time between pre-KR visit and KR date. The median improvements in pain and function were 4/20 and 10.6/68, respectively. Only 64% and 49% achieved the MCID for pain and function, respectively. Moderate-severe pain in the replaced knee was present in 36% and 16% had poor function post-KR. There were no clinically meaningful differences in mean adjusted pain or function improvements among those age ≤65 vs. >65 (pain: −4.3 vs. −4.5; function: −11.0 vs. −12.0); males vs. females (pain: −4.0 vs. −4.8; function: −10.8 vs. −12.2); and those with BMI <30 vs. ≥30 (pain: −4.2 vs. −4.6; function: −10.8 vs. −12.3). Similar results were seen for VAS pain and performance-based function measures. Pain and function continued to improve between 6–12 months, 12–24 months, and beyond, potentially greater than the minimal perceptible clinical improvement threshold of ~10% (see Figures).

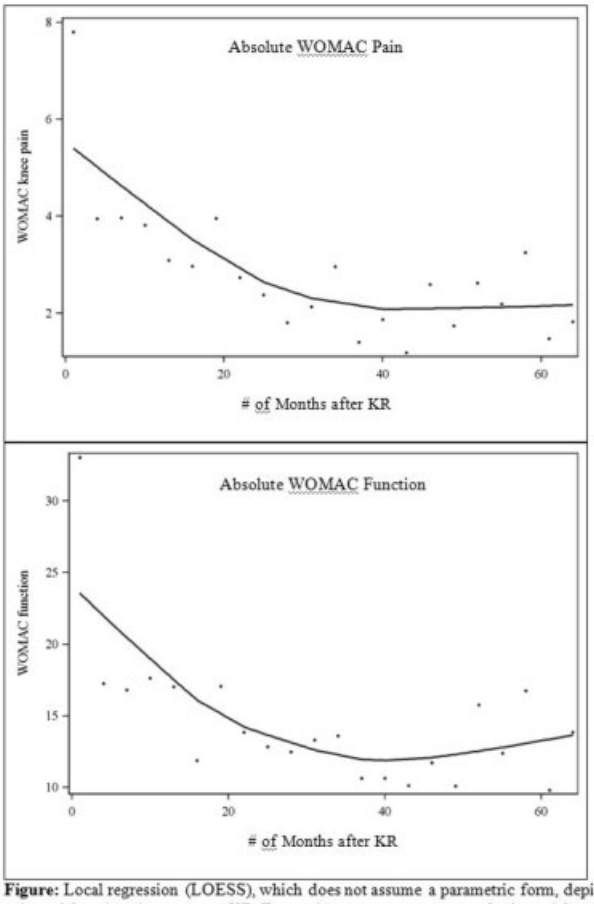


Figure: Local regression (LOESS), which does not assume a parametric form, depicting pain and function changes post-KR. Data points represent average of pain and function over 3-month intervals.

Conclusion: A substantial proportion had poor pain and function outcomes post-KR. In keeping with prior studies, no substantial differences in pain or function changes post-KR were noted based upon age, sex, or BMI. However, in contrast to other studies, pain and function continued to change post-KR between 6 to 24 months and beyond. Further study into factors contributing to poor post-KR outcomes and time-course for improvement is warranted.

743

Impact of a Patient Decision Aid with An Interactive Values Component On Decisional Conflict Associated with Total Knee Arthroplasty. Sofia De Achaval[1], Liana Fraenkel[2], Robert Volk[3], Vanessa Cox[3] and Maria E. Suarez-Almazor[4]. [1]U.T. MD Anderson Cancer Center, Houston, TX, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [3]UT MD Anderson Cancer Center, Houston, TX, [4]University of Texas. M.D Anderson Cancer Center, Houston, TX

Background/Purpose: Decision support tools that include information on risks and benefits, and help patients consider the importance of attributes of competing options, could help patients face difficult medical decisions, such as elective total knee arthroplasty (TKA), by reducing uncertainty. Our objective was to examine the impact of a videobooklet patient decision aid supplemented by an interactive values clarification exercise using adaptive conjoint analysis (ACA) on decisional conflict in patients with knee OA considering TKA.

Methods: 208 patients with knee OA who were considering undergoing TKA participated in the study (mean age 63 years; 68% female; 66% White). Participants were randomized to 1 of 3 groups: (1) Educational booklet about medical and surgical management of OA (control); (2) Videobooklet patient decision aid (DVD) on OA treatment choices; and (3) Videobooklet patient decision aid (DVD) + ACA tool regarding TKA. The ACA tool enables patients to consider competing attributes (i.e. specific risks and benefits) by asking them to rate a series of paired-comparison tasks. The primary outcome was the Decisional Conflict Scale (DCS) which has a possible range of 0 to 100. Differences between groups were analyzed using analysis of variance (ANOVA) and Tukey's honestly significant difference (HSD) post hoc tests.

Results: Overall, decisional conflict decreased significantly in all groups ($p<0.05$). The largest reduction in decision conflict was observed for participants in the DVD decision aid group (21 points). Post hoc analyses indicated statistically significant differences in pre vs. post-intervention DCS total score comparing the DVD decision aid-alone group to the control group (21 vs. 9.5 point reduction; $p<0.001$) and to the DVD + ACA group (21 vs. 14 point reduction; $p<0.001$). The changes in decision conflict for the control compared to the DVD decision aid + ACA group were not significantly different.

Conclusion: Patient decision aids appear to reduce decisional conflict in OA patients, and could be used at point of care to facilitate informed patient decision-making. In our study, an videobooklet patient decision aid (DVD) decreased decisional conflict more than printed material alone and the addition of a more complex computer-based ACA tool requiring more intense cognitive involvement, and explicit value choices.

744

Pain Catastrophizing, but Not Widespread Pain, Is Associated with Poor Pain Outcomes After Knee Replacement: An Analysis From the Multicenter Osteoarthritis Study (MOST). Jasvinder A. Singh[1], Cora E. Lewis[2], Ke Wang[3], David T. Felson[4], Michael C. Nevitt[5], James Torner[6], Laurence A. Bradley[7] and Tuhina Neogi[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama, Birmingham City, Birmingham, AL, [3]Boston University, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]University of California-San Francisco, San Francisco, CA, [6]University of Iowa, Iowa City, Iowa City, IA, [7]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Recent studies have suggested that pre-surgery mental and emotional health impact pain outcomes after knee replacement (KR). Little is known about the associations among pain catastrophizing, widespread pain, and pain outcomes post-KR.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a longitudinal cohort study of persons with or at high risk of knee OA. Western Ontario McMaster Osteoarthritis index (WOMAC) was used to assess pain and function at baseline, 30, and 60 months in entire cohort, including those who had a KR during follow-up. We used data from clinic visits immediately prior to and at least 3 months after KR to assess the proportion of patients with poor pain outcomes: (1) moderate-severe knee pain post-KR (maximal score of at least moderate pain on at least one of the 5 WOMAC pain questions); and (2) poor pain responder (failure to achieve clinically meaningful change in knee pain i.e., decrease of ≥5.6/20 on WOMAC pain in replaced knee after KR). Primary predictor variables of interest were: (1) pain catastrophizing assessed by the Coping Strategies Questionnaire; and (2) widespread pain assessed by a homunculus, categorized as present if there is pain reported above and below the waist, on both sides of the body, and axial pain. Multivariable-adjusted regression analyses adjusted for age, sex, BMI, ethnicity, clinic, contralateral knee OA or KR, comorbidity, lower back pain and pre-KR WOMAC pain.

Results: During follow-up, 297 subjects had 391 new KRs with ≥1 study visit post-KR to ≥3-months after KR. Mean age was 66±8, BMI 33±7, 71% female, median time after KR 20 months with 94 patients having bilateral KRs. 34% patients had moderate-severe knee pain post-KR and 31% patients were poor pain responders. In multivariable-adjusted analyses, pain catastrophizing was associated with significantly higher odds of poor pain outcome with an odds ratio of 2.3 (95% CI, 1.3, 3.9; $p=0.0025$), but widespread pain was not significantly associated, odds ratio of 1.2 (0.7, 2.1; $p=0.49$). Pain catastrophizing was significantly associated with poor pain responder status with odds ratio of 2.8 (95% CI, 1.5, 5.1; $p=0.0008$), but widespread pain was not significantly associated, odds ratio of 1.1 (0.6, 2.0; $p=0.71$).

Conclusion: This is the first evidence in a well-characterized longitudinal osteoarthritis cohort that pain catastrophizing is associated with worse pain outcomes post-KR. It is important to determine the cognitive, behavioral, and neurophysiologic pathways that may mediate this relationship as well as the efficacy of coping skills training prior to KR on catastrophizing and postsurgical outcomes.

745

Identifying Comorbid Conditions That Affect the 6 Month Recovery Pattern of Total Knee Arthroplasty. C. Allyson Jones[1], Lauren A. Beaupre[2], Gian S. Jhangri[3] and Maria E. Suarez-Almazor[4]. [1]Departments of Physical Therapy and School of Public Health, University of Alberta, Edmonton, AB, [2]Dept of Physical Therapy, University of Alberta, Edmonton, AB, [3]School of Public Health, University of Alberta, Edmonton, AB, [4]University of Texas. M.D Anderson Cancer Center, Houston, TX

Background/Purpose: Cormorbid conditions can affect the recovery of total knee arthroplasty (TKA), yet aside from counting the number of comorbid conditions, the identification of which conditions have the most impact on pain relief and functional recovery is not clearly understood. We looked at the pattern of recovery for pain and function of TKA to determine what comorbid conditions had the most impact on the recovery following TKA in terms of pain relief and functional improvement.

Methods: Longitudinal prospective inception cohort of 405 patients receiving elective primary TKA were followed within a month prior to surgery, and 1, 3, 6 months after surgery. The outcome measures, knee pain and function were measured using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Comorbid conditions were extracted from the chart and reported by the patient using a list generated from the Charlson Comorbidity Index and National Population Health Survey. The Center for Epidemiologic Studies-Depression (CES-D) was used to screen for depression. Measurements were repeated at each of the follow-up interviews. Linear mixed models were developed for pain and functional recovery to evaluate changes over time while adjusting for covariates.

Results: The mean age was 68 (SD10) yrs; 249(61.5%) were female. Mean pre-operative pain improved from 49.0 (SD 17.0) to 17.9 (SD 17.1) over the 6 months ($p<0.001$). The mean pre-operative function improved from 44.7 (SD 17.3) to 19.8 (SD 16.2) over this time ($p<0.001$). At baseline, mean depression score was 8.7 (SD 8.4), 90 (22%) had chronic respiratory disease, 156 (39%) back pain, 60 (15%) diabetes and 114 (28%) urinary incontinence. After controlling for age, sex, baseline pain and time, depression score (coeff 0.2, $p<0.001$), back pain (2.7, $p<0.01$), chronic respiratory disease (4.1, $p<0.001$), and diabetes (2.8, $p=0.03$) had a deleterious effect on pain relief. For instance, the coefficient of diabetes in this model implies diabetic patients have 2.8 units less pain relief over the 6 months than non-diabetic patients. Depression score (0.2, $p<0.01$), chronic respiratory disease (4.0, $p<0.001$), and urinary incontinence (2.1, $p=0.04$) affected functional improvement. No interactions were found between depression and diabetes, chronic respiratory disease or urinary incontinence.

Conclusion: Patients with higher depression scores or chronic respiratory disease are likely to have slower pain relief and functional improvement over a 6 month recovery. Active pain management and rehabilitation should target these patient subgroups given the slower recovery patterns seen. Managing these conditions before surgery may also help patients attain more favourable outcomes.

746

The Role of Pre-Operative Pain Sensitisation in Chronic Pain After Knee Joint Replacement. Vikki Wylde[1], Shea Palmer[2], Ian Learmonth[1] and Paul A. Dieppe[3]. [1]University of Bristol, Bristol, United Kingdom, [2]University of the West of England, Bristol, United Kingdom, [3]University of Exeter, Plymouth, United Kingdom

Background/Purpose: Although total knee replacement (TKR) is a successful intervention for most patients with knee OA, approximately 20% of patients

continue to experience chronic pain in their replaced knee. The reasons for this are unknown. The aim of this study was to use Quantitative Sensory Testing (QST) to explore whether pain sensitisation could be one factor contributing to this phenomenon.

Methods: Pressure pain thresholds (PPTs) were measured in 107 knee OA patients listed for TKR, and a subgroup of 47 of these patients were followed-up for a year after TKR using the WOMAC Pain scale (0–100; worst to best). To provide normative data, PPTs were also measured in 50 age- and gender-matched healthy participants without knee pain. QST was performed on the knee listed for surgery (or the right knee of healthy participants) to identify localised pain sensitisation and the pain-free forearm to identify widespread hyperalgesia. PPTs were measured 3 times at each body site using a digital Algometer, and the mean of the last 2 reading was used as the PPT.

Results: The mean age of the 107 OA patients was 69 years, which was not significantly different from the mean age of 68 years for the healthy participants ($p=0.524$). The gender distribution between the two groups was similar with 52% of OA patients being male, compared to 42% of healthy participants.

Pre-operatively, the 107 OA patients had significant lower median PPTs than healthy participants at the knee ($p<0.001$) and the forearm ($p<0.001$), indicating localised and distant pressure hyperalgesia. Of the 47 patients followed up after surgery, 13 had chronic pain in their replaced knee at 1-year post-operative (defined as WOMAC Pain score ≤ 75 at 3-months and 1-year). There was a trend for approximately twice as many patients with chronic pain after TKR to have had pre-operative localised hyperalgesia (62% vs 29%) or widespread hyperalgesia (38% vs 18%), compared to patients with no chronic pain after TKR. Although this trend did not reach statistical significance for widespread hyperalgesia ($p=0.132$), it was significant for localised hyperalgesia ($p=0.043$).

Conclusion: We found that patients with knee OA have evidence of localised and widespread hyperalgesia to pressure stimuli, suggesting changes in the central nervous system resulting from chronic nociceptive input. This pain sensitisation appears to be associated with the development of chronic pain after TKR. If confirmed in a larger study, this finding suggests that some patients may experience chronic pain after TKR because of abnormal pain processing, and that they could benefit from a pre or post-operative interventions to reduce this pain sensitisation.

The Childhood Arthritis & Rheumatology Research Alliance Network Registry: Demographics and Characteristics of the Initial One Year Cohort.

Marc D. Natter[1], Jane R. Winsor[2], Kathleen A. Fox[2], Norman T. Ilowite[3], Kenneth D. Mandl[1], Kelly L. Mieszkalski[4], Christy I. Sandborg[5], John S. Sundy[4], Carol A. Wallace[6], Laura E. Schanberg[4] and CARRAnet Investigators[7]. [1]Children's Hospital Boston, Boston, MA, [2]Duke Clinical Research Institute, Durham, NC, [3]Children's Hospital Montefiore, Bronx, NY, [4]Duke University Medical Center, Durham, NC, [5]Stanford University, Palo Alto, CA, [6]Childrens Hosp & Regional Med, Seattle, WA, [7]Durham, NC

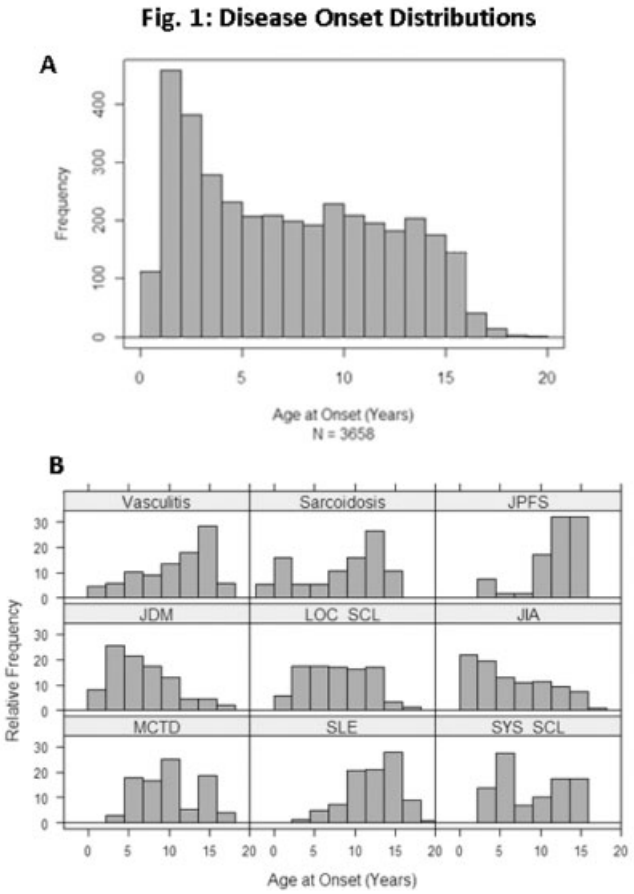
Background/Purpose: In 2009, the Childhood Arthritis and Rheumatology Research Alliance (CARRA) established a longitudinal multicenter, multiple disease U.S. national registry (CARRAnet) for pediatric rheumatology with the intent of providing 60 participating clinical sites a new framework to drive observational clinical research and evidence-based care. CARRAnet seeks to enroll up to 20,000 subjects with childhood-onset rheumatic disease and twice yearly follow-up. We report baseline characteristics of the initial one year enrollment cohort; disease-specific results are reported separately.

Methods: Enrollment commenced 5/29/2010 with data available through 6/10/2011. Inclusion criteria comprised 1 of 8 categories of defined rheumatic disease with pediatric onset (e.g. prior to the 16th birthday) in subjects <=21 years (localized scleroderma, juvenile dermatomyositis, juvenile idiopathic arthritis, juvenile primary fibromyalgia syndrome, SLE or mixed connective tissue disease, sarcoidosis, systemic sclerosis, and vasculitis). A common baseline data set and one disease-specific data set was completed on each participant by interview and chart review. Data cleaning and analysis employed Microsoft Excel and Access (Microsoft Corp), SAS (SAS Institute), and R (R Foundation for Statistical Computing).

Results: The analysis cohort reflected 3860 subjects, predominantly with JIA, enrolled from 51 centers throughout the US; 63 variables were collected for the shared baseline form with summary statistics presented in the table and figures. The population reported overall good to excellent health by patient and physician report: 95% with mean HRQOL good to excellent; physician mean global assessment of disease activity (PGAS) 1.7 on 0–10 scale. PGAS correlated with subject reports (CHAQ, subject global, subject pain scores—Pearson corr. 0.30, 0.40, 0.42 respectively). Medication use was prevalent, including 71% ever on steroids, 40% ever on biologics, and 31% currently on biologics. A wide range, however, was seen on both objective and subjective measures, identifying probable subpopulations with high disease activities.

Table 1. Summary characteristics

Demographic Measures	**N (%)**
Total Participants Studied	3860
Female Gender	2851 (74%)
White/Caucasian	3266 (85%)
Age at onset of symptoms, mean in years	7.3
Age at baseline visit, mean in years	12.1
Black or African American	393 (11%)
Asian	148 (4%)
American Indian or Alaska Native	60 (2%)
Native Hawaiian or Pacific Islander	29 (<1%)
Hispanic Ethnicity	150 (12%)
Primary Rheumatic Diagnosis	
Juvenile Idiopathic Arthritis	2850 (74%)
Juvenile Dermatomyositis	290 (8%)
Systemic Lupus Erythematosus	388 (10%)
Localized Scleroderma	130 (3%)
Mixed Connective Tissue Disease	69 (2%)
Vasculitis	67 (2%)
Systemic Sclerosis	26 (<1%)
Sarcoidosis	19 (<1%)
Juvenile Primary Fibromyalgia Syndrome	41 (1%)
Assessments (scale: best -> worst)	**Mean & (Range)**
Physician Global Assess Disease Activity (0–10)	1.7 (0–10)
Subject Global Assess Disease Activity (0–10)	2.3 (0–10)
Subject Pain Score (0–10)	2.4 (0–10)
CHAQ (0–3)	0.3 (0–3)
HRQOL – Good, Very Good, Excellent (%)	95%
HRQOL – Very Poor, Poor (%)	4%
Family History (First Degree Relative) of	**N (%)**
Psoriasis	246 (6%)
Rheumatoid Arthritis	236 (6%)
Autoimmune Thyroiditis	190 (5%)
Fibromyalgia	154 (4%)
Juvenile Idiopathic Arthritis	136 (4%)
Diabetes Type 1	118 (3%)
Systemic Lupus Erythematosus	88 (2%)
Inflammatory Bowel Disease	82 (2%)
Spondyloarthritis or Ankyl. Spondylitis	56 (1%)
Multiple Sclerosis	35 (1%)
Celiac Disease	28 (<1%)
Uveitis	10 (<1%)
Medication Use	N (%)
Steroids (ever)	2734 (71%)
Steroids (longterm daily, ever)	1862 (48%)
Steroids (IV pulse, ever)	611 (16%)
Steroids (IA, ever)	1301 (34%)
Biologics (ever)	1528 (40%)
Biologics (current)	1184 (31%)
TNF-a Blockers (current)	979 (25%)
DMARDs (ever)	3072 (80%)
DMARDs (current)	2340 (61%)
Methotrexate (current)	1704 (44%)
NSAIDs (current)	1578 (41%)
Opioids (current)	31 (<1%)



Conclusion: The initial CARRAnet cohort reflects predominantly low disease activity with favorable self-reports. This is not a population study and issues of enrollment bias require further investigation. Despite the overall well-being of the population, the high use of steroids, biologics, and DMARDs, along with significant subpopulations concerning for high disease activity, are important areas of future focus.

748

Distinct Phenotypical Clusters In Childhood Inflammatory Brain Diseases: Implications for Diagnostic Evaluation. Tania Cellucci, Pascal N. Tyrrell, Marinka Twilt, Gordon S. Soon, Ivanna Yau, Shehla Sheikh and Susanne M. Benseler. The Hospital for Sick Children, Toronto, ON

Background/Purpose: The spectrum of childhood Inflammatory Brain Diseases (IBrainD) is rapidly expanding. Overlapping clinical presentations lead to significant diagnostic uncertainty. However, early diagnosis and treatment are critical to prevent brain damage. The aim of this study was to identify distinct clusters of childhood IBrainD based on clinical, laboratory and imaging features at presentation in order to guide the diagnostic approach.

Methods: A single centre cohort study was performed with consecutive children up to 18 years of age who were diagnosed with an IBrainD from June 1989 to December 2010 and were enrolled in the BrainWorks cohort at The Hospital for Sick Children. Demographic, clinical, laboratory, neuroimaging and histologic data at diagnosis were collected. K-means cluster analysis was performed to identify clusters of patients based on key presenting features. Associations between the clusters and variables including demographic characteristics, diagnostic tests and diagnosis were determined.

Results: A total of 165 children (51% females, median age 8.3 years) with IBrainD were identified: 123 primary angiitis of the CNS (cPACNS), 11 secondary CNS vasculitis, 7 neuronal antibody syndromes, 6 post-infectious IBrainD and 18 other IBrainD (e.g. neurosarcoidosis). Three distinct clusters of children with IBrainD were identified based on key clinical and imaging features at diagnosis. Children in cluster 1 were significantly more likely to present with seizures, behaviour changes and cognitive dysfunction ($p<0.01$), while those in cluster 2 experienced vision abnormalities and ataxia ($p<0.01$). Paresis was the most common presenting feature in cluster 3 ($p<0.01$). Predominant MRI findings in clusters 1 and 2 were bilateral T2/FLAIR lesions ($p<0.01$) and in cluster 3 were unilateral ischemic lesions ($p<0.01$). The clusters were associated with specific diagnoses and diagnostic test results: for example, children in cluster 3 were likely to have positive findings on angiography.

Conclusion: Children with IBrainD presented with distinct phenotypical patterns that are associated with specific diagnoses. This information should inform the development of a diagnostic classification for childhood IBrainD in the future. Based on the identified clusters, specific pathways of diagnostic evaluation are warranted.

749

Whole Body Magnetic Resonance Imaging in Juvenile Spondyloarthritis: Will It Provide Vital Information Compared to Clinical Exam Alone? Alisa C. Rachlis[1], Paul S. Babyn[2], Edrise Lobo-Mueller[3], Susanne M. Benseler[1], Jennifer Stimec[4], Michelle Anderson[1], Margaret Reaume[1], Kristi J. Whitney-Mahoney[1], JoAnne Marcuz[1] and Shirley Tse[3]. [1]The Hospital for Sick Children, Toronto, ON, [2]Saskatoon Health Region, Saskatoon, SK, [3]Hospital for Sick Children, Toronto, ON, [4]Hospital For Sick Children, Toronto, ON

Background/Purpose: Juvenile-onset spondyloarthritis (JSpAs), referred to as enthesitis-related arthritis (ERA) sub-type under the International League of Associations for Rheumatology (ILAR) classification are characterized by arthritis and enthesitis largely affecting the lower limbs. Clinical exam can be inconclusive and decisions for therapy become difficult. Whole body MRI (WB-MRI) can assess several body regions within a reasonable scan time. The purpose of this study was to evaluate if WB-MRI identifies areas of inflammation seen with JSpAs and agrees with positive findings on clinical exam.

Methods: Patients diagnosed with ERA (ILAR criteria) followed in the JSpA Clinic at The Hospital for Sick Children (Aug 2008 – Jan 2010) who received a WB-MRI within 3 months of their last clinic visit were included. WB-MRIs consisted of multiple evaluations of 13 regions and were reviewed and scored by consensus of 3 radiologists (PB, ELM, JS). WB-MRIs were correlated to joint and entheseal clinical exam. Arthritis was defined as the presence of synovitis, effusion, or bony erosions (sacroiliac joints (SIs)) and enthesitis as edema in the tendon and bone attachment site. Data were described using means, standard deviations and proportions. MRI results were expressed as detecting more, less or similar findings to clinical exam. Kappa statistics measured agreement.

Results: There were 23 patients (83% male) with a mean age at diagnosis of 12.6 ± 2.1 years. Time between last clinic visit and WB-MRI was 0.87 ± 0.68 months. A total of 42 active joints and 16 entheses were observed on WB-MRI. Bone marrow edema (BME) like signal changes were most common (83%) with the majority in lower extremities. Arthritis was seen in 70% of patients (SIs most common, 48%), bony erosions in 35% (SIs most common, 22%), synovitis in 22% (ankles most common, 17%), and enthesitis in 26% (hip region most common, 17%). Clinical exam revealed 65% of patients had arthritis and 52% had enthesitis. By all joint sites, WB-MRI detected more findings in keeping with enthesitis in 5%, similar results in 82%, and less in 13% in comparison to clinical exam. WB-MRI detected more arthritis in 7%, similar results in 79% and less in 14% by all joint sites in comparison to clinical exam. While 70% of regions on WB-MRI that reported a positive finding had an associated BME like signal change, 40% of BME sites correlated to either clinical arthritis (88%) or enthesitis (39%). Good agreement (Kappa coefficient > 0.4) was demonstrated for knee, ankle and foot arthritis, and hip region enthesitis.

Conclusion: The current study demonstrates that WB-MRI identified characteristic lesions expected in our JSpA population. For arthritis, while there was good agreement for peripheral arthritis, WB-MRI was superior to clinical exam for the hips, SIs and spine. For enthesitis, clinical exam over-estimated disease activity in the periphery making WB-MRI an important tool to evaluate entheseal disease. The results of this study illustrate that WB-MRI may become an objective addition to the diagnostic work-up of JSpAs, allowing for assessment of disease presence and severity, monitoring of treatment outcomes and detection of early and subtle inflammatory changes.

Decreased Expression of Nicotinamide Phosphoribosyltransferase (NAMPT) in Active Juvenile Idiopathic Arthritis Patients Receiving Methotrexate. E.J. Fox, M. Gibson, L.Q. Zhang, J.S. Leeder, S.Q. Ye and M.L. Becker. Children's Mercy Hospital, Kansas City, MO

Background/Purpose: Nicotinamide phosphoribosyltransferase (NAMPT) also termed Pre-B cell colony-enhancing factor (PBEF) or Visfatin, is an adipocytokine that has been identified as a pro-inflammatory mediator in cardiovascular disease, pulmonary inflammation and sepsis. Most recently, its effects have been studied in rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis and ankylosing spondylitis. In RA, NAMPT has been shown to

activate human leukocytes and induce proinflammatory cytokines, including IL-1, IL-6, and TNF-α. However, the role of NAMPT has not been studied in pediatric rheumatic diseases, particularly Juvenile Idiopathic Arthritis (JIA). Our study assesses the variability of NAMPT in a cross sectional JIA cohort and the association with treatment modality, disease severity and subtype.

Methods: This single center cross-sectional study at a tertiary care children's hospital evaluated 115 JIA patients on stable doses of methotrexate (MTX) and 80 JIA patients who were not currently on MTX. After obtaining informed consent, blood was obtained from patients during routine screening labs. Clinical data were collected by chart review. Plasma concentrations of NAMPT were measured using a human NAMPT-specific carboxy-terminal enzyme immunoassay kit, and genotyping was performed for two SNPs (T-1001G and C-1535T) in the NAMPT promoter region using a 5'-nuclease based assay.

Results: A total of 195 JIA patients were included in the analysis. Median (quartile) NAMPT concentrations were 19.8 (15.4, 25.8) ng/ml, (range 7.4– 56.2). Higher concentrations of NAMPT were found in subjects with active arthritis at the time of the visit (p=0.041), specifically in subjects not receiving anti-TNF-α therapies (p=0.026). Lower concentrations of NAMPT were observed in subjects receiving MTX (p=0.018). The use of MTX remained a significant predictor of NAMPT concentrations (p=0.023) in a multivariable linear regression model controlling for the presence of active arthritis and anti-TNF-α use. There was no association between NAMPT concentrations and age, ESR, number of active, swollen, tender, or limited joints, or BMI. There were no statistically significant differences in NAMPT concentrations between JIA subtypes, in subjects receiving anti-TNF-α therapies, or with different genotypes in the SNPs analyzed

Conclusion: NAMPT or PBEF/Visfatin is a pro-inflammatory adipocytokine that inhibits neutrophil apoptosis and has been a new investigational therapeutic target in RA. In our cohort of JIA patients, we have shown higher concentrations of NAMPT in children with active arthritis, specifically in children not being treated with anti-TNF-α therapy. Interestingly, NAMPT concentrations in patients receiving MTX therapy were lower, an effect seen despite controlling for the use of anti-TNF-α therapy. This may suggest additional unknown mechanisms in which MTX affects the innate immune system and complex pathways of cytokine induction. These data also support the potential further study of novel anti-NAMPT therapeutics in children with JIA.

751

Brain Morphometric Changes Associated with Childhood-Onset Systemic Lupus Erythematosus and Neurocognitive Deficit. Marisa Klein-Gitelman[1], Adlin Cedeno[1], Aimee Baker[2], Frank Zelko[1], Dean Beebe[2], Blair Dina[1], Anna Carmela P. Sagcal-Gironella[2], Darren Gitelman[3], Hermine Brunner[2], Mark Difrancesco[2] and Travis Beckwith[2]. [1]Children's Memorial Hospital, Chicago, IL, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Northwestern University, Chicago, IL

Background/Purpose: 1) To use structural magnetic resonance imaging (MRI) to characterize gray matter (GM) and white matter (WM) volumetric differences between cSLE patients and matched best-friend controls. 2) To ascertain whether the presence of neurocognitive deficits (NCD), as measured by formal neuropsychological (NP) testing, correlates with these volumetric differences.

Methods: As part of a MRI study protocol, high-resolution (1 mm isotropic), 3-dimensional, T1-weighted structural MRI data were acquired for 44 subjects (F:M=36:8; age 10–17 yrs; 59% African-American, 41% Caucasian; 11% Hispanic), 22 with cSLE and 22 controls matched for age, sex, and race. All subjects underwent NP testing allowing categorization according to NCD status, as defined previously by our group (Arthritis Care Res. 2010; 62: 1029–33). Image data were pre-processed and analyzed in SPM8 (www.fil.ion.ucl.ac.uk/spm) using VBM8, a toolbox for implementing voxel-based morphometry (VBM) analysis (dbm.neuro.uni-jena.de/vbm). Probability density maps for GM and WM tissue types were calculated for each subject and compared according to disease status and NCD status by random effects analysis.

Results: For GM, several regions showed prominent differences in volume between the control and cSLE group (Fig 1). Most notably, a region comprising parts of anterior cingulate cortex, Brodmann area (BA) 32, the frontal eye fields (BA8), and premotor cortex (BA6) had greater volume for controls vs. cSLE. This outcome was also found in left inferior/dorsolateral prefrontal cortex and in right visual association areas (BA19 and BA37). Controls also tended to have greater WM volume than cSLE subjects in the right anterior corona radiate, adjacent to the cingulate regions with GM differences, and in the left superior longitudinal bundle (Fig 1). No WM or GM regions had volume differences with cSLE > controls. ANOVA that considered both disease and NCD status suggested that the anterior cingulate GM volume differences noted above were particularly evident for subjects with neurocognitive dysfunction.

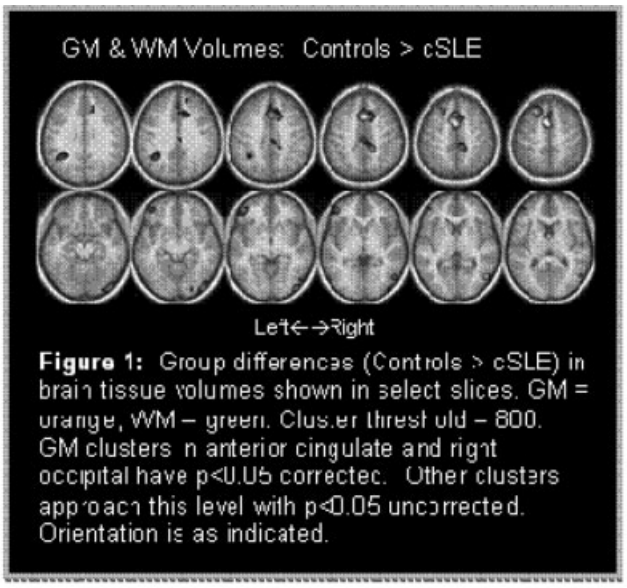

Figure 1: Group differences (Controls > cSLE) in brain tissue volumes shown in select slices. GM = orange, WM = green. Cluster threshold = 800. GM clusters in anterior cingulate and right occipital have p<0.05 corrected. Other clusters approach this level with p<0.05 uncorrected. Orientation is as indicated.

Conclusion: cSLE patients were found to have less GM cortical volume than their best-friend controls in anterior cingulate, prefrontal, and visual association regions that are pertinent to cognitive domains that have been previously shown to have deficits for this disease, including attention, working memory, and visuo-constructional ability. Concordance was observed between volume differences associated with disease state and NCD in the cingulate region. Relationships between these volumetric findings and functional connectivity are also being assessed in pursuit of a comprehensive network-based characterization of cSLE impact on the brain.

752

Frequency and Levels of Maternal Antibodies Reactive with Full Length Ro52 and p200 in Umbilical Cord Blood and Risk of Cardiac Neonatal Lupus. Joanne H. Reed, Robert M. Clancy and Jill P. Buyon. New York University School of Medicine, New York, NY

Background/Purpose: Women with anti-SSA/Ro antibodies face a 2% risk of having a child with cardiac manifestations of neonatal lupus (cardiac NL). Serial echocardiograms of all anti-Ro exposed fetuses are generally recommended to detect potentially reversible incomplete blocks. Identification of a more specific marker of cardiac NL would channel intense monitoring to those fetuses at greatest risk of disease. Antibodies against Ro52 amino acids 200–239 (p200) have received international attention with inconsistencies regarding their utility in high risk assessment relative to the pregnancy exposure. Accordingly, evaluation of umbilical cord blood from affected and unaffected pregnancies was used to determine whether p200 antibodies confer added risk of cardiac NL over antibodies to full length Ro52.

Methods: Pregnancies resulting in cardiac or non-cardiac NL were identified from the Research Registry for Neonatal Lupus and the PR Interval and Dexamethasone Evaluation (PRIDE) study. Umbilical cord blood from anti-Ro exposed (mother tested positive for reactivity to native Ro60) neonates with cardiac NL, unaffected siblings, or unaffected neonates without any affected siblings (unaffected non siblings) were evaluated for reactivity with p200 peptide and full length recombinant Ro52 by ELISA. Serum from anti-Ro-positive mothers during the last 6 months of pregnancy was also evaluated. Reactivity (IgG isotype) was expressed as binding units based on a positive calibrator; a positive defined as mean +3 SD > 28 anti-Ro-negative controls.

Results: 122 umbilical cord blood samples were studied, 59 cardiac NL, 35 unaffected siblings, and 28 unaffected non siblings. All were positive for anti-Ro60 and 118 (97%) were positive for full length Ro52 antibodies. The frequency of anti-p200 was equivalent among cardiac NL (81%), unaffected siblings (91%), and unaffected non siblings (79%). Titers of anti-Ro52 were highest in cardiac NL (104.5±11.5) and their unaffected siblings (125.7±17.2) compared to unaffected non siblings (73.4±15.1), p = 0.026 and p=0.007, respectively and independent of gestational age. In contrast, anti-p200 titers were not significantly different among cardiac NL (45.7±3.7), unaffected siblings (59.8±9.3), or unaffected non siblings (50.7±18.1). Serum from 77 pregnant mothers (35 had a child with cardiac NL, 18 with an unaffected child but a prior cardiac NL child, 24 with only unaffected children) were tested. The frequencies and titers of anti-Ro52 and p200 antibodies were not significantly different among

the groups. Serum samples were available from multiple pregnancies in 10 mothers. Titers of anti-Ro52 and p200 antibodies were not significantly different between cardiac NL (Ro52: 69.1±23.5, p200: 49.2±34.1) or unaffected pregnancy (Ro52: 81.1±24.3, p200: 63.9±29.2) in the same mother.

Conclusion: Maternal p200 antibodies do not confer an added risk to fetal conduction defects over full length Ro52 antibodies. Titers of Ro52 or p200 antibodies do not vary over time or between cardiac NL and unaffected pregnancies in the same mother. However, higher titers of full length Ro52 antibodies are associated with neonates with cardiac NL and their unaffected siblings.

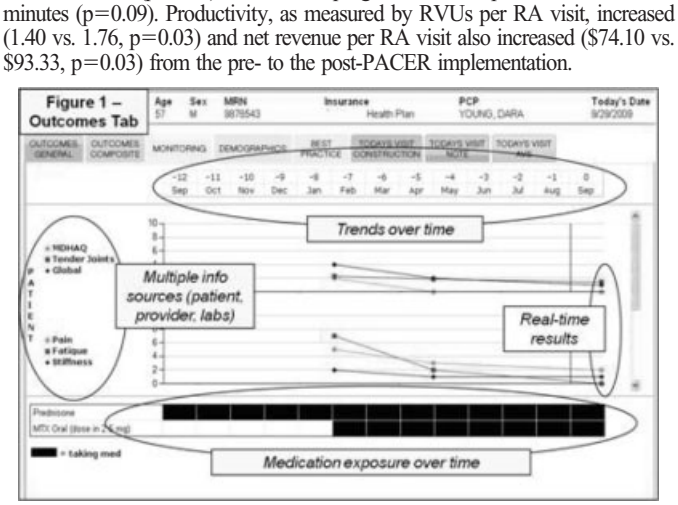
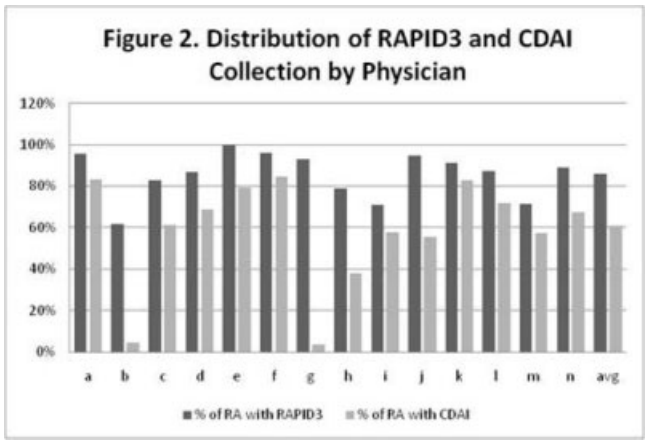
Rheum-PACER—Design, Implementation, and Adoption of Innovative Visual Display Software. Eric D. Newman[1], Virginia Lerch[2], J. B. Jones[2], William T. Ayoub[3], Thomas P. Olenginski[1], Thomas M. Harrington[1], Androniki Bili[1], Brian DelVecchio[1], Alfred E. Denio[1], Brian P. Oppermann[3], Sorina Dancea[1], Jana Antohe[1], Chad Walker[1], Rasa Bozaite-Gluosniene[1] and Walter Stewart[2]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Danville, PA, [3]Geisinger Medical Group, State College, PA

Background/Purpose: Electronic health records (EHRs) do not provide the information needed for optimal rheumatic disease care. Accordingly, we developed Rheum-PACER (Patient-Centric Electronic Redesign). PACER efficiently collects information from patients (touchscreen questionnaire) and effectively displays information from multiple sources (patient, nurse, physician, EHR) into a series of actionable views.

Methods: PACER is web-based but easily invoked using an EHR hyperlink. Functions include 1) demographics: diagnoses, treatments, social history, rheumatic tests; 2) outcomes: trends over time in simple measures (MDHAQ, pain, fatigue, stiffness, patient and physician global, joint counts—Figure 1) and complex measures (DAS28, CDAI, GAS, RAPID3), in the context of treatment given and in real time; and 3) documentation: auto-generation of a clinic note and patient summary. Implementation involved ownership by key team members, training of staff, and aligning incentives. PDSA (Plan-Do-Study-Act) redesign methodology was used to integrate PACER into 2 Rheumatology Clinics (academic and multispecialty). A pre vs. post-PACER implementation analysis was done for efficiency (physician time for chart review and progress note completion, n=107) and productivity (physician work effort [RVUs], notes reviewed by a certified coder, n=100).

Results: Over a 2 year period, 6,275 return patients completed 19,876 touchscreen questionnaires (TQs). 1,431 unique rheumatoid arthritis (RA) patients completed 6,781 TQs. For disease activity measures, 86% of RA patients had a completed RAPID3 (patient-derived composite measure) and 61% had a completed CDAI (patient and provider derived composite measure). PACER was well adopted by 12/14 physicians (Figure 2). Median chart review time fell from 5 to 4 minutes (p=0.39) and median progress note completion from 7 to 5.5 minutes (p=0.09). Productivity, as measured by RVUs per RA visit, increased (1.40 vs. 1.76, p=0.03) and net revenue per RA visit also increased ($74.10 vs. $93.33, p=0.03) from the pre- to the post-PACER implementation.





Conclusion: Rheum-PACER is innovative software that allows for the collection of objective information vital to optimal patient care delivery in real-time. Adoption of use was seen in 86% of physicians, and productivity improved significantly with no reduction in efficiency. Rheum-PACER has allowed the rapid development of a large objective rheumatic database—next steps include development of quality and task management functions to improve population management of patients with rheumatic diseases.

754

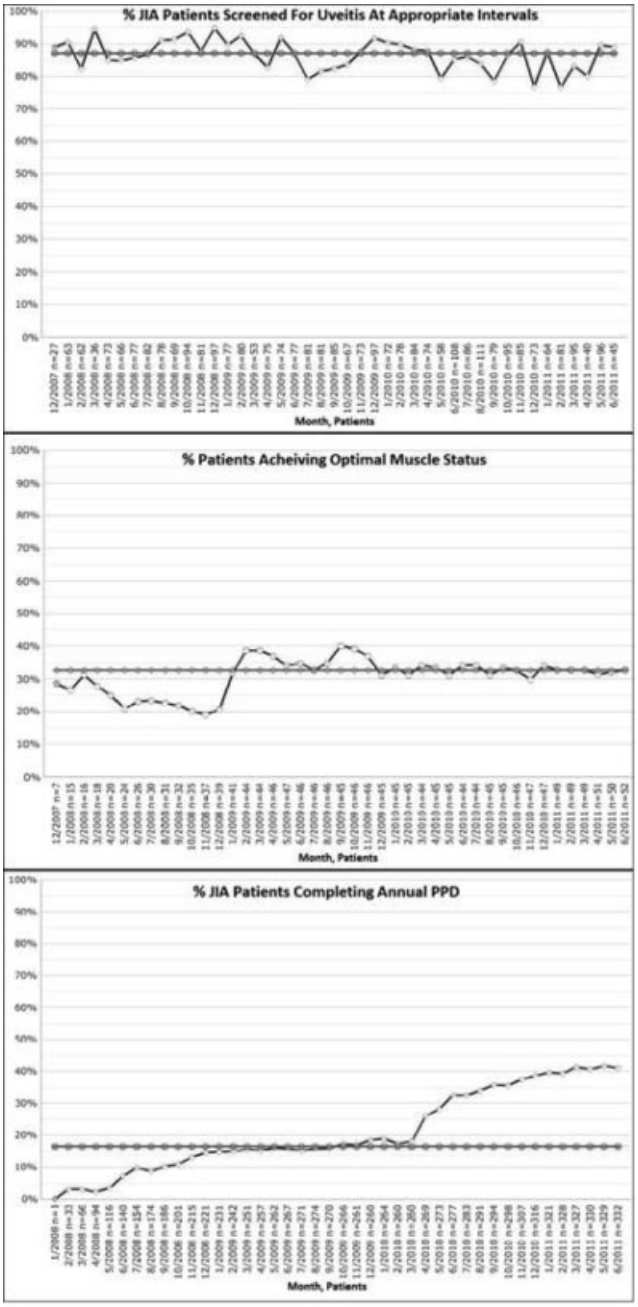
Generating Run Charts for Quality Improvement Using the Electronic Health Record. David W. Moser, Tracy V. Ting, Janalee Taylor, Daniel J. Lovell, Hermine Brunner, Jennifer L. Huggins and Esi M. Morgan DeWitt. Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: The American College of Rheumatology has focused on improving the quality of care. Quality improvement (QI) methodology employs plan-do-study-act cycles as a way of testing change with interventions. Run charts are considered effective analytic tools for studying quality measures over time and are a first step in developing statistical process control charts. The use of run charts allows for: 1) displaying data to make process performance visible; 2) determining if changes tested resulted in improvement; 3) determining if gains are being held; and 4) allowing for a temporal versus static view of data. We discuss how the electronic health record (EHR), specifically Epic, has been leveraged to generate run charts for our QI work.

Methods: An operational definition was created to describe the process being measured. Patients included in the run chart were defined using inclusion and exclusion criteria. Multiple criteria were used for complete ascertainment of the desired population. These data were obtained from problem lists, ICD-9 codes and flowsheets within the EHR. Flowsheets are a structured data capture tool that allow discrete variables to be extracted; free text data in clinic visits is not discrete data and thus not extractable. Data were graphically represented as proportions. The numerator was defined as the number of eligible patients meeting the desired outcome. The denominator was the total number of patients belonging to the process being measured. Data was visualized using a web-based reporting system

Results: We monitor run charts updated at monthly intervals from January 2008 in three rheumatologic conditions. For juvenile idiopathic arthritis we follow the percentage of patients achieving complete clinical remission by Wallace criteria, patients on biologic response modifiers screened for tuberculosis prior to first use and annually, and screening for uveitis at appropriate time intervals. Domains measured in systemic lupus erythematosus include the percentage of patients with controlled disease activity (SLEDAI<5) and hydroxychloroquine prescription rate. For the juvenile dermatomyositis patient population, the percent of patients with optimal muscle strength assessed by the childhood myositis assessment scale is measured. For all conditions we monitor completion of a self-management assessment tool and the percentage of patients with pain scores ≤ 3 (scale 0–10, 0 equals no pain). Examples of disease specific run charts are displayed in the accompanying figure.

Conclusion: The EHR can be designed and specifically modified to readily implement and integrate QI into clinical care. Repurposing clinical data has been a valuable tool in our QI efforts as we can now easily measure our performance in treating multiple diseases.



755

Rheumatoid Arthritis Quality Measure Bundle—Development and Implementation. Chad P. Walker[1], Eric D. Newman[1], William T. Ayoub[2], David M. Pugliese[3], Jeffrey M. Barrett[1], Shea Mealia[1] and Androniki Bili[1]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Medical Group, State College, PA, [3]Geisinger Specialty Clinic, Wilkes-Barre, PA

Background/Purpose: Rheumatoid arthritis (RA) is associated with significant morbidity and mortality. The main cause of death is cardiovascular disease (CVD). We developed an RA quality measure bundle to identify care gaps that will allow improvement in population management.

Methods: Using American College of Rheumatology published guidelines, pertinent literature, and team meetings with primary care and Rheumatology, we reached consensus on a core bundle of quality measures for which our Rheumatology group would be attributable. The RA bundle has three areas of focus: disease activity, medication safety and comorbidity measures (Table 1). LDL was chosen as the comorbidity measure due to association of hyperlipidemia with CVD. The US Preventive Services Task Force recommendations for the general population were used (LDL level <130 mg/dl unless indications for lower levels for secondary CVD prevention). Data were extracted from the electronic medical record and specifically developed software that allows routine electronic capture of a composite disease activity measure (CDAI - Clinical Disease Activity Index). CDAI >10 was defined as active and ≤10 as not active RA.

Results: The baseline RA bundle results are displayed in Table 2. As expected, high percentages were noted in RA on DMARD (85%) – even higher when the measure was limited to active RA on DMARD (90%). However, lower scores were seen with % of RA patients with low disease activity–61% in patients where a CDAI was available, and 28% with the most conservative measure (no CDAI available = low disease activity not achieved). Safety measures showed some opportunity (54–73%). Comorbidity measures showed excellent baseline measurement (91% had LDL checked) but opportunity for improvement in the actual measurement goal (76% had LDL within goal).

Table 1. Measure Definitions

Disease Activity Measures	
RA* on DMARD	DMARD on active drug list
Active RA on DMARD	CDAI done and >10, then on DMARD
RA at low disease activity**	CDAI done and ≤ 10
Medication Safety Measures	
PPD if on Biologic	If on biologic, PPD ever done?
Influenza Vaccine per Recommendations	Yearly unless contraindications
Pneumococcal Vaccine per Recommendations	Per 2008 ACR recommendations
Comorbidity Measures	
LDL checked	Checked within 5 years if age > 45
LDL < 130	LDL < 130 within 5 years

RA = Rheumatoid Arthritis, DMARD = Disease Modifying Anti Rheumatic Drug, CDAI = Clinical Disease Activity Index, PPD = Purified Protein Derivative, ACR = American College or Rheumatology, LDL = Low Density Lipoprotein
* RA population defined as 714.0 encounter diagnosis and at least 1 visit to a rheumatology department over the past 12 months
** CDAI ≤ 10

Table 2. Baseline Measure Achievements

	Population (n)	Applicable	% Meeting Metric
Disease Activity Measures			
RA* on DMARD	1409	1663	85
Active RA on DMARD	260	288	90
RA at low disease activity**	460	1663	28
(RA with CDAI measured)		(749)	(61)
Medication Safety Measures			
PPD if on Biologic	414	565	73
Flu Vaccine Yearly	1080	1663	65
Pneumococcal Vaccine if applicable	903	1663	54
Comorbidity Measures* **			
LDL checked	641	705	91
LDL < 130	537	705	76

RA = Rheumatoid Arthritis, DMARD = Disease Modifying Anti Rheumatic Drug, CDAI = Clinical Disease Activity Index, PPD = Purified Protein Derivative, CDC = Center for Disease Control and Prevention, LDL = Low Density Lipoprotein
* RA population defined as 714.0 encounter diagnosis and at least 1 visit to a rheumatology department over the past 12 months
** CDAI ≤ 10
*** Population limited to patients with providers within the health system

Conclusion: This is the first report of a RA quality measure bundle for which a Rheumatology department has agreed to be held accountable. We have developed the ability to capture these measures electronically, including measures which are more difficult to measure and achieve, yet far more important to achieve better outcomes (i.e. % of RA at low disease activity, not just % on DMARD). Opportunities were found to improve data measurement gaps (e.g. greater capture of a CDAI value) and quality

care gaps (e.g. e.g. vaccine rate). Capturing patient and physician data systematically allows identification of care gaps in RA population management. Next steps include internal discussion of the bundle results and focusing on care process redesign to improve these gaps.

756

Improving Adherence to Glucocorticoid Induced Osteoporosis Guidelines. Minna J. Kohler[1], Matxalen Amezega[2], James Drozd[3], Susan Crowley[1], Barbara Gulanski[1], Daren Anderson[4] and Liana Fraenkel[5]. [1]Yale University School of Medicine, New Haven, CT, [2]Griffin Hospital, Derby, CT, [3]VA Connecticut Healthcare System, West Haven, CT, [4]Community Health Center, Inc., Middletown, CT, [5]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT

Background/Purpose: ACR guidelines recommend that patients receiving glucocorticoids (GCs) take calcium (Ca) and vitamin D (Vit D) supplements for any duration of GC use. However, adherence to these recommendations is poor. The purpose of this study was to examine whether use of an automated prescription order set increases the number of co-prescriptions for Ca and Vit D for patients on GCs.

Methods: We designed an automated prescription order set such that Ca and Vit D supplements were automatically ordered each time a prednisone electronic prescription was placed for 2 or more weeks. Physicians had the option of not ordering supplements by unchecking a box. The order set was not generated for patients with hypercalcemia. We used a pre-post design to examine the effectiveness of the intervention. A database search was performed for all patients who had one or more orders of GCs. The first GC order was chosen for those with multiple prescriptions. Clinical data were collected over 12 months before (T1) and after (T2) the intervention. We compared the proportion of patients prescribed GCs who were co-prescribed Ca and Vit D supplements or who purchased supplements over the counter. Associations between patient and provider characteristics were examined using logistic regression. Reasons for physician non-adherence were collected after T2.

Results: 1041 patients had a GC prescription of at least 2 weeks duration: 535 during T1 and 506 during T2 respectively. The most frequent prescribers were internal medicine/primary care 480 (46%), rheumatology 179 (17%), and pulmonary 63 (6%) physicians. The percent of co-prescriptions for Ca (37% to 49%) and Vit D (38% to 53%) increased significantly after the new order set was implemented ($p<0.0001$). Patient demographic and clinical characteristics did not differ across time periods. One patient with hypercalcemia was precluded from co-prescription during T1 and 2 were precluded in T2. Older age, female sex, duration on GCs, bisphosphonate use, and being a fellow or resident versus an attending, were also significantly associated with prescription of Ca and Vit D. Bi-and multivariate analyses are presented in the table below. Previous fracture history and physician specialty were not related to ordering supplements. Physicians stated that they were unaware of any evidence supporting the ACR recommendation of Ca and Vit D co-prescription "for any duration of GC use". This reason explained the strong association between duration of GC use and prescribing supplements and the reason many patients did not receive supplements.

Table. Predictors of Ca and Vit D Co-Prescriptions

	Calcium		Vitamin D	
Variable	Unadjusted Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)	Unadjusted Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)
Older age	1.26 (0.95–1.66)	1.06 (0.78–1.45)	1.33 (1.01–1.76)	1.20 (0.88–1.63)
White	1.02 (0.71–1.48)	0.97 (0.65–1.46)	0.68 (0.47–0.97)	0.60 (0.40–0.90)
Female	2.62 (1.43–4.78)	2.78 (1.43–5.41)	2.16 (1.19–3.91)	2.22 (1.16–4.26)
GCs for 3 months or more	2.97 (2.29–3.85)	2.92 (2.18–3.00)	2.81 (2.20–3.67)	2.78 (2.09–3.69)
Current bisphosphonate use	5.09 (3.43–7.52)	3.90 (2.50–6.08)	4.04 (2.75–5.94)	3.09 (2.00–4.77)
Diagnosis of osteoporosis	2.60 (1.68–4.04)	1.24 (0.72–2.11)	2.47 (1.59–3.84)	1.30 (0.77–2.20)
Level of provider	0.82 (0.70–0.96)	0.64 (0.54–0.77)	0.84 (0.72–0.98)	0.67 (0.56–0.79)
T2 versus T1	1.68 (1.31–2.15)	1.78 (1.36–2.33)	1.81 (1.42–2.32)	1.90 (1.50–2.48)

Conclusion: Implementation of an automatic prescription for Ca and Vit D supplementation significantly improves adherence to ACR guidelines. Hypercalcemia is not a limiting factor in co-prescription. The lack of data supporting supplements for any duration of GC use is a significant barrier to adherence.

757

Use of Quality Improvement Methodology to Improve the Safety of Intravenous Infusions in a Pediatric Rheumatology Practice At a Tertiary Care Children's Hospital. Pai-Yue Lu, Janalee Taylor, Moussa El-hallak, Keith A. Sikora, David W. Moser, Terry M. Moore, Julie V. Ranz, Judy Thomas, Grace McIntyre-Patton, Jennifer L. Huggins and Tracy V. Ting Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: Medication safety remains at the forefront of patient care. The 2006 Institute of Medicine report, "Preventing Medication Errors," urged hospitals to take action to reduce the potential for errors. Regulatory agencies require institutions to identify, evaluate, reduce, respond, and prevent harm related to medical care. Safe administration of intravenous (IV) infusions in pediatric patients is a complex process. The development of new IV biologics for the treatment of pediatric rheumatologic conditions has led to an increase in our hospital administered infusions. The overall aim of this project was to improve the safe delivery of our IV infusions.

Methods: Key members of the pediatric rheumatology division formed a multidisciplinary improvement team led by clinical fellows. First, process flow mapping of the IV infusion system was performed, including scheduling, communication among staff and providers, and order entry. Next, Failure Mode Effect Analysis (FMEA) was conducted, providing the team with a systematic method to identify steps where system failures may occur. Time to an event and order errors were monitored. Lastly, Plan-Do-Study-Act (PDSA) cycles were performed, which focused on 4 areas of change concepts: a) improved work flow, b) improved communication, c) process standardization, and d) building reliability.

Level 1 and Level 2 reliability concepts guided interventions and testing. Level 1 (80–90% reliability) interventions included order training and education. Also, 3 process changes were implemented: delegation of nursing tasks to review upcoming infusions, weekly automated email reminders to providers for sign-off, and weekly order entry by fellows. Level 2 reliability (95% reliability) concepts included standardization of evidence-based order sets and a provider checklist for infusions. Medication errors were categorized using the hospital's coding system of "near miss event", "precursor event", and "serious safety event".

Results: IV infusions are prescribed for 82 patients, with an average of 65 (79%) occurring monthly. Order entry errors occurred 37% of the time. System analysis revealed several problems: 1) discrepancy of prescribed dosages among providers, 2) irregular completion of order entry, 3) untimely provider sign-off on orders, 4) absence of expiration date for electronic orders, and 5) accidental delivery of incorrect medication to a patient, which was our one precursor event – an event that reached the patient but resulted in minimal or temporary harm—that was identified during the process of change.

Conclusion: Quality improvement methods allow for ready identification of problems (order errors, time to event) and solutions for testing and adoption. In performing only a few PDSAs, we were able to implement reliable systems changes, with the goal to prevent future errors. While only one precursor event was identified, this event resulted in institutional policy change for standardizing order expiration. Continued monitoring of the process is important to identify and reduce both unnecessary variability and deviations from clinical guidelines and best practices.

758

Improving the Influenza Vaccination Rate in Patients Visiting Pediatric Rheumatology Clinics Using Automatic Best Practice Alert in Electronic Patient Records. Anjali Patwardhan[1], Kelly Kelleher[1], Dennise Cuningham[2] and Charles H. Spencer[1]. [1]Nationwide Childrens Hospital, Columbus, OH, [2]Nationwide Childrens Hospital, Columbus

Background/Purpose: Children with rheumatic disease who are infected with influenza have increased rates of complications. Influenza-related morbidity and mortality can be reduced by improving the flu vaccination rate. We used a single prong best practice alert to increase the influenza vaccination rate in a high risk population of patients with rheumatic diseases.

Methods: Institutional Review Board approval was obtained for retrospective chart review. We examined three yearly cohorts (2007, 2008, and 2009 for baseline status) of rheumatology clinic patients from a large pediatric hospital for evidence of influenza vaccination in the electronic health record. We introduced an electronic health record (EHR) intervention best practice alert reminder in our patients' records from October 2009 until the end of January 2010. We compared claims-based records of receipt over 3 years. Using Clarity Report Write for EPIC, each chart was examined for evidence of influenza vaccination in order to test for vaccination rate difference amongst the cohorts. We revaluated our intervention after the flu season in 2010, through Delphi survey of the stakeholders. Delphi Questionnaire of Stakeholders resulted in the several changes to the EHR intervention. It was reprogrammed to trigger upon initial entry into the EHR and, remained until all questions were answered & the reminder was utilized from 15 Sept 2010 – 15 April 2011. This second EHR best practice alert was made non-negotiable with better blocking power. It was in effect in the flu season for long enough to be able to change a provider's behavior. We re-evaluated the vaccination rate for flu after the flu season in 2011 for improvement. We employed logistic regression equations to control for possible confounders (age, sex, ethnicity, insurance status, distance from clinic and attending physician) using SAS 9.1.3

Results: There was a significant difference in the probability of being vaccinated before and after intervention (p value <0.0001). With the rate increased from 5.9 % in 2007 and 7.8% in 2008 to 25.5 % in 2009. Refinement of the pop-up (2^{nd} intervention) in 2010–2011 resulted in increase of influenza immunization to 43.9%. In all three years, individual attending's contribution and ethnicity of patients had significant effects on vaccination rate

Conclusion: EHR-embedded information in past studies has been only modestly effective in improving care for many chronic conditions. Our automatic best practice alert reminder for flu-vaccine appears to be effective in changing behaviors and improving the vaccination rate in rheumatology clinics

Differential Predictors of Mixed and Fully Calcified Coronary Plaques in Coronary Artery Disease-Naïve Patients with Rheumatoid Arthritis. George A. Karpouzas[1], Jennifer Malpeso[2], Dong Li[2], Panteja Razaeian[2], Maria V. Peralta[2], Silvia Munoz[1] and Matthew Budoff[2]. [1]Harbor-UCLA, Torrance, CA, [2]Harbor-UCLA Medical Center, Torrance, CA

Background/Purpose: Vulnerable coronary plaques are characterized by a large lipid core, a thin fibrous cap, spotty calcification, and positive remodeling. Multi-detector Computed Tomography Angiography (MDCTA) accurately distinguishes these morphologic features and classifies plaques as Non-Calcified (NCP), Mixed (MP), and fully Calcified (CP). MP commonly combine all the aforementioned vulnerability characteristics, and have been associated with significant risk of future events. By contrast, fully CP are considered more stable plaques with lower such risk. In this report we evaluated potential predictors of MP and CP in coronary artery disease (CAD)- naïve subjects with Rheumatoid Arthritis (RA).

Methods: One hundred and fifty subjects with RA underwent MDCTA for coronary plaque evaluation and assessments of epicardial adipose tissue (EAT) and thoracic adipose tissue (TAT) volumes. The standard 15-segment American Heart Association (AHA) model was used for plaque evaluation, and plaque burden was reported as total plaque segment score for different plaque types as previously described. Disease activity scores (DAS28-3v-CRP), serologic, laboratory, radiographic parameters and treatments were captured. Irreversible articular damage (IAD) defined as subluxation, and/ or fusion, ankylosis, or arthrodesis, as well as joint replacement surgeries were tracked. Determinants of MP and CP were explored in multivariable crude and fully adjusted models for age, gender, hypertension, diabetes, dyslipidemia, smoking, and family history of CAD.

Results: Patients were largely middle aged females, with long standing and robustly seropositive disease. The presence of at least moderate disease activity (DAS28-3v$\geq$3.2), high C- reactive protein (CRP), and the highest quartiles of TAT were significantly associated with a higher adjusted likelihood ratio (LR) of MP prevalence (4.1, 3.9, and 12.7 respectively, all with $p<0.05$- table 1). By contrast, treatment with tumor necrosis factor-a inhibitors (TNFi), even in the absence of good clinical response (DAS28-3v$<$3.2), was associated with a 70% lower risk for MP presence ($p=0.027$). None of the aforementioned parameters predicted the risk for presence of CP; increasing patient age was the only determinant of such plaque (LR=1.1, $p=0.016$).

Conclusion: The presence of high risk mixed plaques was positively predicted by parameters of ongoing inflammation, and TAT, and was inversely related to treatment with TNFi, even in the presence of active disease. Conversely, calcified plaque prevalence was only associated with higher subject age.

Table 1.

	Crude		Adjusted μ	
Mixed Plaque (MP)	***LR (95% CI)***	***p-value***	***LR (95% CI)***	***p-value***

Outward Carotid Arterial Wall Remodelling in Rheumatoid Arthritis: A Case-Control Study. Alper M. van Sijl[1], Katja van der Hurk[2], Mike J.L. Peters[3], Vokko P. van Halm[4], Giel Nijpels[2], Coen D.A. Stehouwer[5], Yvo M. Smulders[3], A.E. Voskuyl[6], Jacqueline M. Dekker[2] and Michael T. Nurmohamed[7]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]EMGO institute, VU university medical centre, Amsterdam, Netherlands, [3]VU University medical center, Amsterdam, Netherlands, [4]Academic Medical Centre, Amsterdam, Netherlands, [5]Maastricht University, Maastricht, Netherlands, [6]VU Medical Center, Amsterdam, Netherlands, [7]Reade, Centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased cardiovascular (CV) risk, but mechanisms explaining this increased risk have not been fully elucidated. To maintain circumferential wall stress, arteries react on hemodynamic changes by arterial remodelling. So far arterial remodelling has not been studied in RA.

Methods: 96 RA-patients and 274 healthy controls were investigated in a case-control study. B-mode carotid ultrasonography was used to investigate arterial wall parameters, including intima-media thickness (IMT), inter-adventitial diameter (IAD), lumen diameter (LD), calculated as IAD $-$ (2 $\times$ IMT). Linear regression analyses were used to assess the association between presence of RA and arterial wall parameters.

Results: RA was associated with a significantly greater LD as compared to control subjects: 6.43 mm vs. 6.13 mm.($p=0.02$) IAD was also higher in RA-patients: 8.04 mm vs. 7.79 mm.($p=0.07$) As IMT did not differ between RA patients and control subjects, RA patients had 6.3% ($p=0.02$) greater wall-to-lumen ratio (ratio of IAD to IMT, an indicator of wall thinness or outward remodelling). Associations remained similar after exclusion of patients with prior CV disease and after adjustment for demographic factors and CV risk factors (including mean arterial pressure). Inflammatory markers (C-reactive protein, erythrocyte sedimentation rate, disease activity score of 28 joints and rheumatoid factor positivity) were not associated with arterial wall parameters.

Conclusion: RA is associated with outward remodelling. This is relevant in view of the association between outward remodelling and plaque instability and rupture.

Abnormal Concentric Ventricular Remodeling in Rheumatoid Arthritis. John M. Davis III, Veronique L. Roger, Cynthia S. Crowson, Terry M. Therneau, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk for heart failure (HF). Pre-clinical left ventricular (LV) diastolic dysfunction is more frequent in RA patients than the general population, suggesting a distinct pathogenesis of HF in these patients. The purpose of this study was to provide new insights into myocardial disease in RA by evaluating LV geometry in RA and non-RA subjects without HF.

Methods: A cross-sectional, community-based study was conducted among adult subjects (age ≥50 yrs) without HF, 210 with RA and 1446 without RA (non-RA). Participants had an echocardiogram and completed a questionnaire. Data collection included demographics, cardiovascular (CV) risk factors, and RA disease characteristics. Two-dimensional & Doppler echocardiography was performed by a registered diagnostic cardiac sonographer and interpreted by an expert cardiologist. LV geometry was classified into four categories based on relative wall thickness (RWT) and sex-specific cutoffs for LV mass index (LVMI): concentric remodeling, concentric hypertrophy, eccentric hypertrophy, or normal geometry. Sex-specific proportions of subjects with RA vs. non-RA in each category of LV geometry were compared. Logistic regression models were used to identify predictors of abnormal LV geometry (concentric remodeling, concentric hypertrophy, or eccentric hypertrophy) as compared to normal geometry, and separately among patients with abnormal LV geometry, to identify predictors of concentric remodeling as compared to concentric or eccentric hypertrophy. Candidate predictors included RA, disease characteristics, and CV risk factors.

Results: The mean ages of the 210 RA and 1446 non-RA subjects without HF were similar among the females (64.2 ± 10.1 and 65.2 ± 9.5 yrs for RA and non-RA, respectively; p=0.13) whereas male RA subjects were slightly older (67.6 ± 9.3 vs. 64.7 ± 9.4 yrs; p=0.018). Systolic blood pressure was higher in RA women (130 ± 17 vs. 125 ± 20 mm Hg) and RA men (136 ± 19 vs. 127 ± 17 mm Hg) than their non-RA counterparts. LVMI was lower in RA women (80.9 ± 13.9 vs. 87.8 ± 20.0; p=0.001); a trend to lower LVMI was also seen in RA men (94.3 ± 15.7 vs. 99.4 ± 21.6; p=0.26). RWT was higher in both RA females (0.43 ± 0.07 vs. 0.39 ± 0.09; p<0.001) and RA males (0.44 ± 0.07 vs. 0.39 ± 0.06; p<0.001). RA subjects were 26% more likely to have abnormal LV geometry though this was not statistically significant (OR 1.26; 95% CI: 0.89, 1.76; p=0.18). Among those with abnormal LV geometry, RA subjects were 6.5 times more likely to have concentric LV remodeling (OR: 6.5; 95% CI: 3.7, 11.5; p<0.001). After adjusting for age, sex, CV risk factors, and RA characteristics; higher disability (OR: 1.74; 0.97, 3.12; p=0.062) and methotrexate use (OR 2.17; 95% CI 1.11, 4.23; p=0.023) were associated with abnormal LV geometry. RA characteristics were not significantly associated with concentric LV remodeling.

Conclusion: RA is strongly associated with abnormal concentric LV remodeling. These findings suggest that RA disease-related factors promote myocardial injury, remodeling, and ultimately myocardial dysfunction. The biological mechanisms underlying these changes warrant further investigation.

Expansion of Intra-Thoracic Adipose Tissue Depots Associate with Prevalence and Burden of Mixed (Vulnerable) Plaques in Coronary Artery Disease-Naïve Patients with Rheumatoid Arthritis. George A. Karpouzas[1], Panteja Razaeian[2], Jennifer Malpeso[2], Dong Li[2], Maria V. Peralta[2], Silvia Munoz[1] and Matthew Budoff[2]. [1]Harbor-UCLA, Torrance, CA, [2]Harbor-UCLA Medical Center, Torrance, CA

Background/Purpose: Expansion of intrathoracic adipose tissue (AT) depots were reported to associate with the risk of myocardial infarction and fatal coronary artery disease (CAD) in the general population. Similarly, such AT increase was correlated with higher prevalence and severity of coronary plaque. Multidetector Computed Tomography Angiography (MDCTA) accurately classifies coronary plaque as non-calcified (NCP), mixed (MP), or fully calcified (CP), and readily recognizes features of plaque vulnerability such as a large lipid core, spotty calcification, and positive remodeling, often expressed in MP. In this report we explored the associations of different coronary plaque types with intrathoracic AT volume status, as well as the ability of such volumes to predict the presence of a specific plaque type in CAD-naïve subjects with RA.

Methods: One hundred and fifty patients underwent MDCTA for plaque evaluation and assessment of epicardial adipose tissue (EAT) and thoracic adipose tissue (TAT) volumes. The standard 15-segment American Heart Association (AHA) model was used, and plaque burden was reported as total plaque segment score (TPSS) for different plaque types as previously described. Risk regression analysis models adjusted for age, gender, and all cardiac risk factors were constructed to assess the incremental change of EAT or TAT volumes for different plaque types per standard deviation (SD) of such change in subjects without plaque. Subsequent modeling for evaluation of risk for MP prevalence was attempted by quartile of EAT and TAT.

Results: Subjects with any prevalent coronary plaque (TPSS-all>0) displayed higher EAT and TAT volumes compared to those without (TPSS-all=0- table 1). Of the different plaque types, only the presence of MP was associated with significant expansion of EAT and TAT; for each SD of change in subjects without plaque, there was a 2.5-fold and 3.5-fold change in EAT and TAT in patients with prevalent MP (p<0.05 and <0.01 respectively). The highest TAT quartile was significantly associated with MP prevalence; 29% of patients with TAT in the 4th quartile had MP compared to 2.9% in those with TAT in 1st quartile (p=0.012). In an

adjusted model, patients on the highest TAT quartile had 13-fold higher risk for MP prevalence compared to those in the lowest quartile.

Table 1.

	Plaque (−) TPSS-all=0	Plaque (+) TPSS-all>0	TPSS-NCP>0 & TPSS-MP=0 & TPSS-CP=0	TPSS-MP>0 & TPSS-CP=0	TPSS-CP>0 & TPSS-MP=0 & TPSS-NCP=0
EAT (cc)	100.2±30.2	120.6±45.3	110.1±42.73	130.1±42.1	135±47.1
TAT (cc)	153.9±74.3	193.7±83.8	171.5±78.55	224.7±87.7	214±64.3

* p<0.05,**p<0.01

MP prevalence by Quartiles of EAT and TAT

	Quartile 1 N (%)	Quartile 2 N (%)	Quartile 3 N (%)	Quartile 4 N (%)	p-value
EAT					
MP (−)	32(94.1)	28(82.4)	30(85.7)	26(76.5)	0.234
MP (+)	2(5.9)	6(17.6)	5(14.3)	8(23.5)	
TAT					
MP (−)	33(97.1)	31(91.2)	28(80.0)	24(70.6)	*0.012*
MP (+)	1(2.9)	3(8.8)	7(20.0)	10(29.4)	

Association between MP burden and quartiles of EAT and TAT

	Crude			*Adjusted μ*		
	OR	95% CI	p-value	OR	95% CI	p
EAT-Q1	1.0 (Ref)			1.0 (Ref)		
EAT-Q2	3.4	0.6,18.4	0.15	3.7	0.6,23.2	0.17
EAT-Q3	2.7	0.5,14.8	0.26	2.2	0.4,14.3	0.39
EAT-Q4	4.9	1.0,25.2	0.06	4.8	0.8,27.7	0.08
TAT-Q1	1.0 (Ref)			1.0 (Ref)		
TAT-Q2	3.2	0.3,32.4	0.33	3.6	0.3,39.0	0.29
TAT-Q3	8.2	1.0,71.2	0.06	6.5	0.7,61.0	0.10
TAT-Q4	13.7	1.6,114.8	*0.02*	12.9	1.4,121.1	*0.03*

μ adjusted for age, gender, all cardiac risk factors, RA duration, presence of TNF-inhibitors

Conclusion: Coronary plaque presence is associated with a 30% expansion in EAT and 50% expansion in TAT compared to absence of plaque. Of all plaque types, only MP- that commonly harbors vulnerable features-associates with significantly higher EAT and TAT volumes, and highest quartiles of TAT independently predict the presence of MP.

763

Oxidation Products of Arachidonic Acid and Linoleic Acid Are Increased in High Density Lipoprotein and Low Density Lipoprotein From Patients with Active Rheumatoid Arthritis. Christina Charles-Schoeman[1], David Meriwether[2], Yuen Yin Lee[2] and Srinivasa T. Reddy[3]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]UCLA, Los Angeles, CA, [3]UCLA, Los Angeles

Background/Purpose: Oxidation products of arachidonic acid and linoleic acid including hydroxyeicosatetraenoic acids (HETES) and hydroxyoctadecadienoic acids (HODES), respectively, play an important role in the pathogenesis of atherosclerosis. These fatty acids contribute to the oxidation of low density lipoprotein (LDL) and their accumulation in high density lipoprotein (HDL) has been proposed to inhibit HDL function, increasing atherosclerotic risk. The current work evaluated the levels of HETES and HODES in HDL and LDL isolated from patients with active rheumatoid arthritis (RA) compared to healthy controls.

Methods: HDL and LDL were isolated from plasma using fast protein liquid chromatography for 10 RA patients and 8 age and sex matched healthy controls. 5-HETE, 12-HETE, 15-HETE, 9-HODE, and 13-HODE levels in HDL and LDL fractions were measured by mass spectrometry as described previously (Imaizumi et al. *Drug Metab Lett.* 2010; 4(3):139–48). HDL's anti-inflammatory function was measured by a cell free assay as described previously (Charles-Schoeman et al. *Arthritis Rheum.* 2009; 60(10):2870–9). Lipoprotein cholesterol levels were determined by standard methods.

Results: 5-HETE, 15-HETE, 9-HODE and 13-HODE levels were significantly increased in both HDL and LDL isolated from patients with active RA compared to healthy controls (see Table). The levels of oxidized fatty acids in HDL correlated significantly with measures of systemic inflammation; ESR and hs-CRP (r values= 0.70–0.80, [ESR]; 0.65–0.74 [hs-CRP]; p values <0.004). Similar correlations were also noted for oxidized fatty acids in LDL (r values= 0.30–0.48, [ESR]; 0.34–0.62 [HSCRP]; p values 0.006–0.25). Moreover, 5-HETE, 15-HETE, 9-HODE and 13-HODE levels in HDL significantly correlated with impaired HDL function as measured by the HDL inflammatory index (HII), r= 0.54–0.58; p values <0.03). No differences in lipoprotein cholesterol levels or traditional cardiovascular risk factors were noted between the two groups.

Conclusions: Oxidation products of arachidonic acid and linoleic acid are increased in HDL and LDL from patients with active rheumatoid arthritis compared to healthy controls, and are strongly correlated with levels of systemic inflammation, particularly in HDL. Elevations of 5-HETE, 15-HETE, 9-HODE and 13-HODE in HDL are also significantly associated with impaired HDL anti-oxidant function. These results suggest a potential mechanism by which active inflammation from RA increases oxidized fatty acids in circulating lipoproteins, promoting LDL oxidation and HDL dysfunction, thereby increasing atherosclerotic risk. Further investigation of therapeutic agents such as apoA-1 mimetic peptides which bind oxidized fatty acids and reduce atherosclerosis in animal models may be warranted in patients with RA.

Cholesterol Efflux by High Density Lipoproteins Is Impaired in Patients with Active Rheumatoid Arthritis. Christina Charles-Schoeman[1], Yuen Yin Lee[2], Victor Grijalva[3], John D. FitzGerald[2], Veena K. Ranganath[4], Mihaela Taylor[2], Maureen A. McMahon[2], Harold E. Paulus[4] and Srinivasa T. Reddy[3]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]UCLA, Los Angeles, CA, [3]UCLA, Los Angeles, [4]University of California, Los Angeles, Los Angeles, CA

Background/Purpose: Reverse cholesterol transport (RCT) and prevention of oxidative stress are two major anti-atherogenic functions of high density lipoprotein (HDL). We previously showed that the anti-oxidant function of HDL in patients with rheumatoid arthritis (RA) is abnormal and associated with high levels of systemic inflammation. Since inflammation has been proposed to impair RCT, in the current work, we evaluated whether the RCT capacity of HDL from RA patients is impaired when compared to healthy controls.

Methods: HDL was isolated from 40 patients with RA and 40 age and sex matched healthy controls. Cholesterol efflux experiments were performed as described previously (Navab et al. Circulation 2004; 109(25):3215–3220). HDL's anti-oxidant function was assessed by cell free assay as described previously (Charles-Schoeman et al. Arthritis Rheum 2009; 60(10):2870–2879), which assesses the ability of patient HDL to inhibit oxidation of a stock LDL. Lipoprotein cholesterol levels were determined by standard methods.

Results: Mean cholesterol efflux capacity of HDL was not significantly different between RA patients (40.2% ± 11.1%) and controls (39.5% ± 8.9%); p=0.75. However, HDL from RA patients with high disease activity measured by a disease activity score using 28 joint count (DAS28 > 5.1), had significantly decreased ability to promote cholesterol efflux compared to HDL from patients with low disease activity (DAS28 < 2.6). In addition, a significant correlation was noted between cholesterol efflux and disease activity measured by the DAS28 (r= −0.39, p=0.01). Higher RA disease activity was associated with decreased efflux by HDL. A similar correlation was observed with ESR, (r= −0.41, p=0.0009), and a trend noted with HS-CRP (r= −0.29, p=0.08). HDL's ability to promote cholesterol efflux

was modestly but significantly correlated with its anti-oxidant function ($r = -0.34$, $p = 0.03$).

Conclusion: Cholesterol efflux capacity of HDL is impaired in RA patients with high disease activity and is correlated with systemic inflammation and HDL's anti-oxidant capacity. Attenuation of HDL function, independent of HDL cholesterol levels, may suggest a mechanism by which active RA contributes to increased CV risk.

Familial Clustering of the Serum Cytokine Profile: Comparison Between the Asymptomatic First-Degree Relatives of Rheumatoid Arthritis Patients and Controls with No Family History of Autoimmune Disease. Hani S. El-Gabalawy[1], David B. Robinson[1], Donna M. Hart[2], Irene Smolik[3], Charles N. Bernstein[1], Marianna M. Newkirk[4] and Marvin J. Fritzler[5]. [1]University of Manitoba, Winnipeg, MB, [2]Health Sciences Centre, Winnipeg, MB, [3]University of Manitoba, Winnipeg, [4]McGill University Health Centr, Montreal, QC, [5]University of Calgary, Calgary, AB

Background/Purpose: Seropositive RA is prevalent in North American Native (NAN) populations, with a high frequency of multi-case families. We studied the first-degree relatives (FDR) of NAN RA probands to evaluate risk factors for disease development. Data from studies of other pre-clinical RA cohorts suggest that many serum cytokines are elevated prior to the onset of clinically detectable disease. We sought to determine whether the serum cytokine profile of the FDR at risk for future disease development differed from that of individuals with no family history of autoimmunity.

Methods: We studied NAN RA patients (n=105), FDR (n=273), healthy NAN (NC) (n=200) and Caucasian controls (CC) (n=150) with no family history of autoimmune disease. Rheumatoid factor (RF) and anti-CCP2 antibodies (CCP) were tested by nephelometry and ELISA, respectively. We used a cytokine/chemokine 42-plex array to test a range of serum cytokines. Confirmation of specific cytokine levels and hsCRP were tested by ELISA. Raw cytokine data were normalized and differences between groups were analyzed by ANOVA. Discriminant analysis was used to classify individuals based on canonical functions generated from transformed cytokine data.

Results: The NAN FDR and NC groups were well matched for age and gender, while the RA and CC groups were older. The prevalence of RF (>50 IU) was RA= 88%, FDR=34%, NC=9% and CC=5%, and CCP (>40 units) was RA= 81%, FDR=9%, NC=4% and CC=0%. Levels of almost all cytokines tested were markedly higher in RA patients compared to the other groups. Of the cytokines tested, 17/40 (43%) were significantly higher in the FDR compared to both NC and CC, in particular IL-1β, IL-6, TNFα, IL-12, IL-8, MCP-1, MIP-1α, and VEGF. Discriminant analysis showed a remarkable distinction between RA, FDR, and controls based on the canonical function centroids, with 85% classification accuracy. Centroids from NC and CC were similar indicating no major ethnic differences in the absence of a family history of RA. Comparison of the FDR and NC groups using a logistic regression model suggested that MCP-1 levels were the strongest single discriminator between these two groups, and results from an MCP-1 ELISA confirmed this finding. There were minimal differences in the cytokine profile of autoantibody positive and negative FDR, indicating that the elevated cytokine levels in the FDR were not explained on the basis of the high prevalence of RF and/or CCP. Moreover, technical effects of RF seropositivity did not appear to impact of the differences in cytokine levels between FDR and NC. Mean hsCRP levels (mg/l) were RA=9.1±5.6, FDR=4.9±4.7, NC=1.6±1.6, CC=4.2±2.2 indicating significantly higher levels in FDR compared to both control groups.

Conclusion: Both pro and anti-inflammatory cytokines are elevated in RA. Surprisingly, levels of these biomarkers, as well as hsCRP, are significantly higher in disease-free FDR of NAN RA patients compared to individuals from families with no autoimmune disease. These data suggest that elevated basal cytokine levels, potentially based on genetic or epigenetic factors, may be part of the risk profile for developing RA in families at risk for this autoimmune disease. Confirmation of these findings in other non-NAN populations is needed.

***Porphyromonas Gingivalis (P. gingivalis)* is Associated with the Presence of Disease-Specific Autoantibodies in Individuals At Increased Risk for the Future Development of Rheumatoid Arthritis.** Ted R. Mikuls[1], Kevin D. Deane[2], Jeffrey Payne[3], Geoffrey M. Thiele[4], James R. O'Dell[4], Lezlie A. Derber[5], William H. Robinson[6], V. Michael Holers[7] and Jill M. Norris[8]. [1]Omaha VA and University of Nebraska, Omaha, NE, [2]University of Colorado School of Medicine, Aurora, CO, [3]University of Nebraska Medical Center, Lincoln, NE, [4]Univ of Nebraska Med Ctr, Omaha, NE, [5]University of Colorado AMC, Aurora, CO, [6]Stanford University, Stanford, CA, [7]Univ of Colorado School of Med, Aurora, CO, [8]University of Colorado Denver, Aurora, CO

Background/Purpose: *P. gingivalis* (*Pg*) leading to periodontal disease has emerged as a potential environmental risk factor in rheumatoid arthritis (RA). *Pg* is the only prokaryote known to express peptidyl-arginine deiminase (PAD) as a virulence factor, suggesting that this oral pathogen could play a direct role in tolerance loss in RA. Our group has previously shown that patients with established RA are more likely to exhibit antibody to *Pg,* with additional significant correlations between anti-*Pg* and anti-citrullinated protein antibody (ACPA) levels. We sought to examine the relationship of antibody to *Pg* with the presence of RA-related autoantibodies in first-degree relatives (FDRs) of RA probands.

Methods: FDRs (n = 185), none of whom met 1987 ACR criteria for RA, were categorized as being 'high-risk' for developing future classifiable RA (positive anti-CCP or ≥ 2 RF isotypes; n = 38), cases (≥ 1 positive RA-related autoantibody; n = 97), or controls (no positive autoantibody; n = 88). An additional 99 unaffected individuals from an *HLA-DRB1* 'enriched' cohort were included as controls. IgG antibody concentrations (μg/ml) to *Pg* and *P. intermedia* (*Pi;* a common oral pathogen that does not express PAD) were measured using ELISA with bacterial whole cell lysates serving as the coating antigen. Intra-assay coefficients of variation for the ELISAs ranged from 11 to 13%. There were no significant changes in measured anti-bacterial antibody concentrations following RF depletion. Following log-transformation, associations of antibody concentrations with group status (high risk and case vs. control) were examined using logistic regression, adjusting for age, gender, race, educational status, diabetes, ever smoking, and *HLA-DRB1 shared epitope (SE)*.

Results: Log-transformed Anti-*Pg* concentrations were significantly higher in both the high-risk ($p = 0.0043$) and case group ($p = 0.0054$) as compared to the controls. There were no significant group differences for anti-*Pi*. Univariate and multivariable associations of bacterial antibody concentrations with group status are shown:

Bacterial IgG Ab (μg/ml, log-transformed)	Case vs. Control OR (95% CI)		High Risk vs. Control OR (95% CI)	
	Univariate	Multivariable	Univariate	Multivariable
Anti-*Pg*	1.50 (1.12 to 2.00) p = 0.006	1.46 (1.08 to1.98) p = 0.014	1.86 (1.20 to 2.89) p = 0.005	1.99 (1.25 to 3.17) p = 0.004
Anti-*Pi*	1.06 (0.71 to 1.58) p = 0.480	1.11 (0.72 to 1.71) p = 0.631	1.25 (0.68 to 2.30) p = 0.480	1.49 (0.74 to 2.99) p = 0.260

Conclusion: Immunity to *Pg*, but not *Pi*, is significantly associated with the presence of RA-related autoantibodies in FDRs, including those at highest risk for future RA. This association is independent of other factors associated with both RA and PD risk. These results support the hypothesis that infection with Pg may play a central role in the early loss of tolerance to self antigens and may explain prior reported associations of periodontitis with risk for established RA.

767

Analysis of Twin Concordance for ACPA Positivity and ACPA fine specificities in a Large Swedish Twin Cohort (TwinGene). Aase Haj Hensvold[1], Patrik KE Magnusson[2], Monika Hansson[1], Lena Israelsson[1], Cecilia Carlens[1], Rikard Holmdahl[3], Per-Johan Jakobsson[1], Johan Askling[4], Vivianne Malmström[1], Lars Klareskog[1] and Anca Irinel Catrina[1]. [1]Rheumatology unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [2]Swedish Twin Registry Karolinska Institutet, Stockholm, Sweden, [3]Medical Biochemistry and Biophysics Karolinska Institutet, Stockholm, Sweden, [4]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Both genetic and environmental factors are established risk factors for Anti Citrulline Peptide Antibodies (ACPA) positive rheumatoid arthritis (RA). As ACPA appear before disease onset and are highly specific for RA we aimed to investigate the influence of genetic and environmental factors in ACPA positivity, using a twin study approach.

Methods: We used a subset of the Swedish twin registry, which includes 12 594 monozygotic (MZ) and dizygotic (DZ) twins born 1958 or earlier. All

blood samples were analyzed for ACPA using a commercial ELISA. All available paired samples (n=312 twin pairs) in which at least one twin was ACPA positive were further investigated for presence of ACPA fine specificities against native and citrullinated forms of alpha-enolase (aa5–21; cep1), collagen type II (aa359–369; citC1), fibrinogen (aa566–580; citfib573) and vimentin (aa60–75; citvim60) peptides, using a cut off set at the 98 percentile, based on analysis of sera from healthy controls. RA or other rheumatic joint diseases were verified by, data from register linkage to national care registers or by reviewing medical records.

Concordance for ACPA positivity was estimated by casewise concordance and tetrachoric correlation. Odds ratios (OR) to develop ACPA were calculated according to self-reported smoking status and cumulative dose of smoking estimated by pack years. Twins were defined as smokers (n=6252) if they were or had been smoking regularly or occasionally.

Results: 387 out of 12 594 tested individuals (3.1%) were positive for ACPA. Smokers had an increased risk of developing ACPA as compared with non-smokers (OR 1.33, 95% CI 1.08–1.63) and the risk was highest among those smoking more than 10 pack years (OR 1.49, 95% CI 1.18–1.88).

Among the ACPA positive, 312 twin complete pairs were available, 7 concordant and 305 ACPA discordant pairs. Casewise concordance for ACPA was 6.8% among MZ and 6.2% among DZ twins, with no significant tetrachoric correlation (r MZ twins 0.17, 95% CI −0.10–0.44, and r DZ twins 0.14, 95% CI −0.10–0.36).

Her analysis of ACPA fine specificities was performed in the same subgroup of twins. The most common of the analyzed fine specificities was against Cit-enolase (19% of the 624 tested samples). The casewise concordance rate for Cit-enolase was 19% among MZ and 10% among DZ twins, with no significant tetrachoric correlation (r MZ twins 0.17, 95% CI −0.35–0.69 and r DZ twins −0.32, 95% CI −0.58—0.07). A majority of ACPA positive twins with a RA diagnosis at the time of inclusion, 77%, were positive for one or more of the tested ACPA fine specificities as opposed to ACPA positive twins without any rheumatic joint disease where only 26% were positive for one or more of the tested ACPA fine specificities.

Conclusion: In this large population-based cohort of middle-aged twins, we found a low concordance rate for ACPA in both MZ and DZ twins. Our results indicate that environment, life style and stochastic factors may be more important than genetics in determining which individuals will develop ACPA, whereas genetic factors may have a larger impact in determining which ACPA-positive individuals that will ultimately develop arthritis.

768

Prevalence of Periodontitis, Anti-*P. Gingivalis* antibodies, and Rheumatoid Arthritis Autoantibodies in a Community Sample of North American Natives with Prevalent Rheumatoid Arthritis. Isanne Schacter[1], David B. Robinson[1], Donna M. Hart[2], Mary Bertone[1], Christine A. Peschken[1], Irene Smolik[3], Carol A. Hitchon[1] and Hani S. El-Gabalawy[1]. [1]University of Manitoba, Winnipeg, MB, [2]Health Sciences Centre, Winnipeg, MB, [3]University of Manitoba, Winnipeg

Background/Purpose: RA is prevalent and severe in North American Native (NAN) populations. We have studied risk factors for disease development in the Cree-Ojibway population of Central Canada and have previously shown that this population has an excessive burden of genetic risk factors for RA, particularly a high frequency of shared epitope (SE) encoding alleles. Environmental risk factors that have been shown to be associated with RA risk include smoking and the presence of periodontal disease, possibly in association with the oral pathogen *P. gingivalis.* We therefore sought to determine the prevalence of these risk factors in this population, and whether they are associated with the presence of RA autoantibodies and SE alleles.

Methods: We randomly surveyed two isolated NAN communities, Norway House (NH) (n=130) and St Theresa Point (STP) (n=172) Manitoba, for the prevalence of periodontal disease and RA autoantibodies. A dental hygienist performed an examination of the oral cavity in each study subject and quantified the degree of periodontitis using the standardized periodontal screening record (PSR) instrument having a scale ranging from 0 (no periodontitis) to 4 (severe periodontitis). Oral health symptoms, RA-like symptoms, and smoking history were captured using a questionnaire. Serum samples were tested for anti-*P. gingivalis* antibodies, anti-CCP2, and rheumatoid factor (RF). HLA-DRB1 testing was available for 100 study subjects in STP.

Results: The demographic characteristics of the two study populations were comparable age (mean age 35.2 in NH, 34.7 in STP), as well as gender (55.2% female in NH, and 52.9% in STP). The mean PSR score in both communities was comparable (2.94 in NH, and 3.00 in STP, p=NS). Because of this, data from both communities was aggregated. Males had significantly worse PSR scores than females (3.17 versus 2.82, p<0.001). The only self-report symptom that correlated with PSR scores was the presence of bleeding gums (correlation = 0.130, p = 0.026). There was no correlation between the PSR scores and levels of anti-*P. gingivalis* (PSR>2 = 56 vs. PSR<3 = 58 ELISA units, p=NS). Anti-CCP2 and RF were detectable in (2.3% and 4.6%, respectively). Individuals who were anti-CCP2 or RF positive had comparable PSR scores. Although anti-*P. gingivalis* titres were comparable in CCP2+ and CCP2- individuals, RF+ individuals had significantly higher titres than RF negative individuals (66±19 vs 55±19, p=0.02). The prevalence of ever-smokers was very high in all groups (86.6%). PSR scores and anti-*P. gingivalis* titres did not differ between SE+ (91%) and SE- (9%) individuals, but all autoantibody positive individuals were also SE+

Conclusion: In a random sample of two NAN communities known to have a high prevalence of RA we demonstrated a high frequency of the known risk factors for the disease including SE, smoking, and periodontitis. Despite this, the frequency of RA autoantibodies in this community based sample was low, and there was no clear association with the study risk factors, including immune responses to anti-*P. gingivalis*. Thus, the interaction between these risk factors in predisposing to RA does not appear to be preceded by an increased overall frequency of anti-CCP or RF in this population.

769

Lung Abnormalities in Subjects with Elevations of Rheumatoid Arthritis-Related Autoantibodies without Arthritis by Examination and Imaging Suggest the Lung Is An Early and Perhaps Initiating Site of Inflammation in Rheumatoid Arthritis. M. Kristen Demoruelle[1], Michael H. Weisman[2], Lezlie A. Derber[3], Jason R. Kolfenbach[4], Chris Striebich[1], Isabel Pedraza[5], Annie Harrington[5], David Lynch[6], Peter Sachs[1], Brian Petersen[1], Colin Strickland[1], Jill Norris[7], V. Michael Holers[4] and Kevin D. Deane[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Cedars Sinai Med Ctr, Los Angeles, CA, [3]University of Colorado AMC, Aurora, CO, [4]Univ of Colorado School of Med, Aurora, CO, [5]Cedars Sinai Med Ctr, Los Angeles, [6]National Jewish Health, Denver, CO, [7]University of Colorado Denver, Aurora, CO

Background/Purpose: Elevations of serum autoantibodies (Abs) prior to joint symptoms suggest that rheumatoid arthritis (RA) may be initiated outside of the joints. This site is unknown, although several factors suggest that it may be the lungs including the association of inhaled factors such as smoking with RA. Our purpose herein was to evaluate a hypothesis that the lung is a site of initiation of RA-related autoimmunity by comparing lung findings in RA-related Ab+ subjects at risk for future RA but without current inflammatory arthritis (IA) to Ab- controls and patients with established early RA.

Methods: 45 Ab+ cases without IA on 68 joint exam were identified from the Studies of the Etiology of RA (SERA) project, a prospective study of preclinical RA. These cases were positive for Abs >96% specific for future RA: anti-CCP2 (Axis-Shield) or CCP3.1 (INOVA), and/or ≥2 rheumatoid factor (RF) isotypes (IgA, M, G) (INOVA) [N=9 CCP2+; N=25 CCP3.1+; N=11 RFs+ only]. Additionally, 16 Ab- SERA controls (frequency matched to Ab+ cases on age, sex and smoking) and 12 patients with early RF/aCCP2+ RA (<1 year) were selected. All subjects underwent high-resolution computed tomography (HRCT) of the lungs, interpreted in a blinded fashion by 2 chest radiologists according to established criteria (Fleischner Society; Hansell et al 2008). To evaluate for synovitis not detected on joint exam, a subset of Ab+ cases underwent contrasted magnetic resonance imaging (MRI) of the MCPs, wrists and MTPs, scored for synovitis by 2 joint radiologists using the OMERACT/RAMRIS protocols.

Results: 45 Ab+ cases were a mean age of 54, 56% female and 33% smokers (no significant differences from Ab- controls). 77% of Ab+ cases had airways disease on HRCT including bronchial wall thickening, bronchiectasis, centrilobular opacities and air trapping, compared to 31% of Ab- controls (p<0.01). Of the 30 Ab+ cases that were never smokers, 70% had airways disease compared to 3/12 (25%) of never smoking controls (p=0.01). No Ab+ case had evidence of IA on joint exam at time of lung evaluation, and additionally, 15 Ab+ cases with abnormal lungs that underwent joint MRI had no synovitis by imaging. One Ab+ subject with airways disease developed RA by 1987 criteria (Arnett et al 1988) ~13 mos. after lung study. Finally, 9/12 (75%) of early RA subjects (mean age 50, 58% female, 42% smokers) studied in parallel had radiographically indistinguishable airways abnormalities when compared to the Ab+ cases (p>0.5).

Conclusion: Airways abnormalities are present in a high proportion of RA-specific Ab+ cases without IA (examination or MRI), and these lung

abnormalities are similar to those in patients diagnosed with early RA. This suggests that there is a continuum of lung injury during the development of RA, and that lungs are either a site of RA-related autoimmune-mediated injury during the pre-symptomatic phase of disease, or more likely a site of initiation of RA-related autoimmunity perhaps due to external factors beyond smoking that generate local inflammation, especially since the airways interact substantially with the environment. Prospective studies are ongoing to evaluate the generation of RA-specific in the lungs, and to follow the evolution of autoimmunity and IA in these subjects.

Synovial Inflammation and Expression of Mediators of Pain in Preclinical Rheumatoid Arthritis Subjects with Arthralgia. Maria J. H. de Hair[1], Patrick Leclerc[2], Britt N. Sotthewes[1], Marleen G. H. van de Sande[1], Tamara H. Ramwadhdoebe[1], Christiaan van der Leij[3], Wouter Bos[4], Mario Maas[1], Dirkjan van Schaardenburg[5], Danielle M. Gerlag[1], Marina Korotkova[2], Per Johan Jakobsson[6] and Paul P. Tak[7]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Karolinska Institute, Stockholm, Sweden, [3]Academic Medical Center / University of Amsterdam, [4]Reade, Amsterdam, Netherlands, [5]Jan van Breemen Research Institute / Reade, Amsterdam, Netherlands, [6]Rheumatology Unit, Karolinska Institutet; Karolinska University hospital, Stockholm, Sweden, [7]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam The Netherlands, Amsterdam, Netherlands

Background/Purpose: We have previously shown in a small pilot study that there are no signs of synovial inflammation in preclinical rheumatoid arthritis (RA) subjects with arthralgia when synovial biopsies are obtained at least several months before the development of arthritis. Here, we examined the synovium in a markedly larger group of individuals and evaluated the prostaglandin (PG) pathway, one of the main mechanisms involved in pain perception.

Methods: Forty-nine individuals without any evidence of arthritis upon physical examination who were positive for IgM-rheumatoid factor and/or anti citrullinated protein antibodies were included in the study. All participants underwent MRI and arthroscopic synovial biopsy sampling of a knee joint at inclusion and were prospectively followed to assess arthritis development. Biopsies were analysed by immunohistochemistry for expression of several inflammatory markers and evaluated by semiquantitative analysis. Results were compared with knee MRI and synovial biopsy data of 6 and 7 healthy controls, respectively, and 5 early RA patients. Nineteen individuals were additionally analyzed for the expression of the PGE_2 synthesizing enzymes microsomal prostaglandin E synthase-1 (MPGES-1) and cyclooxygenase (COX) 1 and 2, and its degrading enzyme 15-prostaglandin dehydrogenase (15-PGDH). Four of these individuals did not have joint complaints whereas 15 suffered from arthralgia (arthralgia biopsied knee n=7). Five individuals developed RA after follow up. Stained sections were quantitatively evaluated by digital image analysis.

Results: MRI findings (presence of synovitis, bone marrow edema, erosions and cartilage degeneration) were similar in the autoantibody positive individuals compared to healthy controls. Consistent with these findings, expression of T cells, B cells, intimal macrophages, sublining macrophages, fibroblast-like synoviocytes, plasma cells, and von Willebrand factor was comparable to healthy controls, and significantly low compared to early RA patients. During follow-up of a median of 12 (range 0–47) months, 9 of the 49 individuals (18%) developed RA. In these patients baseline synovium was completely comparable with that of healthy controls and of the individuals who did not develop arthritis. Also, no differences could be observed in the expression of MPGES-1, COX-1 and -2, and 15-PGDH when comparing individuals who did or did not suffer from arthralgia in general or in the biopsied knee joint specifically. Moreover, expression of these enzymes was comparable between individuals who did and who did not develop arthritis over time.

Conclusion: Subclinical inflammation of the synovium does not coincide with the appearance of serum autoantibodies during the preclinical RA stage. Thus, systemic autoimmunity precedes the development of synovitis, suggesting that a 'second hit' is involved. Even though autoantibody positive individuals may suffer from arthralgia, local expression of PGs does not seem to be involved in pain sensation in this preclinical phase. Pain perception in these individuals may be regulated more centrally by PGs or other pain mediators may be involved.

771

Preferential Transmission of Genetic Risk Variants of Candidate Loci At 6p21 From Asymptomatic Grandparents to Anti-SSA/Ro Positive Mothers of Children with Neonatal Lupus. Amit Saxena[1], Erin McDonnell[1], Paula S. Ramos[2], Satria Sajuthi[2], Miranda C. Marion[2], Carl D. Langefeld[2], Jill P. Buyon[1] and Robert M. Clancy[1]. [1]New York University School of Medicine, New York, NY, [2]Wake Forest School of Medicine, Winston-Salem, NC

Background/Purpose: Neonatal lupus (NL) occurs in fetuses exposed to maternal anti-SSA/Ro-SSB/La antibodies, and associates with significant morbidity and mortality if manifested by cardiac disease. Although NL mothers may be asymptomatic when the affected child is born, their autoantibodies and susceptibility to having an NL child represent a unique autoimmune phenotype. To evaluate transmission of risk factors for autoantibody aggregation and genetic susceptibility in families, two variant alleles at 6p21 associated with NL in children, rs1800629 (*TNFα-308* promoter) and rs7775397 (*C6orf10*), were evaluated in NL mothers and grandparents.

Methods: 51 mothers of NL children, 48 maternal grandmothers and 35 maternal grandfathers in the Research Registry for Neonatal Lupus (RRNL) were interrogated for clinical symptoms and laboratory assessments including anti-Ro60, Ro52, La48 recombinant proteins and genotype at rs1800629 (*TNFα*-308) and rs7775397 (*C6orf10*). The transmission disequilibrium test (TDT) was computed to evaluate nonrandom transmission from grandparents to the NL mothers.

Results: 92% of the families were Caucasian and 82% had children with cardiac NL. 14 (27%) of the NL mothers had Sjogren's Syndrome (SS), 7 (14%) SLE, 7 (14%) SS and SLE, and 23 (45%) were asymptomatic or had an Undifferentiated Autoimmune Syndrome (UAS). In contrast, only 1 (2%) grandmother had SS, 1 (2%) SLE, 1 (2%) Rheumatoid Arthritis and 1 (2%) Ankylosing Spondylitis, while 44 (92%) were asymptomatic or had UAS. 1 (3%) grandfather had SS and SLE, 1 (3%) SLE, and 33 (94%) were asymptomatic or had UAS. All NL mothers had anti-SSA/Ro antibodies. However, only 2 (5%) of 41 grandmothers had autoantibodies (1 anti-Ro60/Ro52/La48, 1 anti-Ro52) and 1 (4%) of 27 grandfathers had anti-Ro60/Ro52. NL mothers were enriched in variant allelic frequencies at both *TNFα-308* (A allele, 38% vs. 22% in HapMap controls) and *C6orf10* (G allele, 32% vs. 9% in HapMap controls). In contrast, the grandmothers were not enriched in the risk alleles, and their profile was significantly different from NL mothers (21% for *TNFα-308, P=0.02*; 12% for *C6orf10, P*=0.0065). Grandfathers had lower frequencies of risk alleles compared to NL mothers, but were not significantly different (32% for *TNFα-308*, *P*=0.59*;* 23% for *C6orf10, P*=0.35). The TDT analysis showed significant excess transmission of the risk alleles at both *TNFα-308* ($P=3.93\times10^{-4}$, OR=6.67) and *C6orf10* ($P=3.74\times10^{-5}$, OR=35) from maternal grandparents to the NL mothers (see Table).

Table.

Transmission of risk allele (A) for *TNFα-308* promoter SNP (rs1800629) in neonatal lupus (NL) trio cohort (TDT Test)

	Mothers with NL Child			
			Nontransmitted	
	Allele	A	G	
Transmitted	A	3	20	23
	G	3	24	27
		6	44	50

Number of Complete Trios = 25
OR=6.67 CI=(1.98–35.03)
$P_{TDT}=3.93\times10^{-4}$

Transmission of risk allele (G) for *C6orf10* SNP (rs7775397) in neonatal lupus (NL) trio cohort (TDT Test)

	Mothers with NL Child			
			Nontransmitted	
	Allele	G	T	
Transmitted	G	1	17	18
	T	0	34	34
		1	51	52

Number of Complete Trios = 26
OR=35.0 CI=(4.12-infinity)
$P_{TDT}=3.74\times10^{-5}$

Conclusion: Anti-SSA/Ro positive NL mothers are enriched for the *TNFα-308* and *C6orf10* variant alleles, which are preferentially inherited from asymptomatic, serologically silent maternal grandparents with a suggestive skewed pattern from the grandfather. These findings from the largest documented cohort of NL maternal grandparents support the hypothesis that the development of NL and genetic etiology are multigenerational.

772

A Point Mutation in the SSA/Ro60 Autoantigen Which Prevents Y RNA Binding Attenuates a Requisite Signal for Cell Surface Expression and TLR-Dependent Inflammation. Joanne H. Reed[1], Soyeong Sim[2], Sandra L. Wolin[2], Jill P. Buyon[1] and Robert M. Clancy[1]. [1]New York University School of Medicine, New York, NY, [2]Yale University School of Medicine, New Haven, CT

Background/Purpose: The Ro/SSA ribonucleoprotein particle is a major autoantigen in Sjögren's syndrome, Systemic Lupus Erythematosus, and asymptomatic mothers of children with heart block. The particle comprises a 60kD Ro protein (Ro60) that binds misfolded RNAs in the nuclei and noncoding RNAs, Y RNAs, in the cytoplasm. During apoptosis, Ro60 translocates to the cell surface where it is available to bind extracellular antibody. Previous studies have demonstrated that the immune complex of RNA and Ro60 bound by anti-Ro60 antibody gains access to the macrophage endosome via FcγR uptake with subsequent ligation of Toll-like receptors (TLR) and secretion of proinflammatory cytokines. This study employed cells expressing novel Ro60 mutants that influence RNA binding to address the dependency of Ro60 associated RNA in translocation of Ro60 during apoptosis and activation of macrophages.

Methods: Murine fibroblast cell lines were obtained in which constitutively transfected constructs of FLAG-tagged forms of mutated Ro60 were introduced into Ro60 knockout cells. Ro60 K170A, R174A (170/4) does not bind misfolded pre5S RNA but binds Y RNA. Ro60 H187S does not bind Y RNA. Evaluations included the capacity of fibroblasts either permeabilized or rendered apoptotic by staurosporine or loss of anchorage signals, to form immune complexes with anti-Ro60 antibody (flow cytometry). Function was assessed by TNFα secretion (ELISA) by macrophages obtained from human peripheral blood mononuclear cells and PMA-differentiated THP-1.

Results: Early apoptotic fibroblasts (Annexin V-positive, PI-negative) transfected with Ro60 170/4 (binds pre5S but not Y RNA) were bound by anti-Ro60, affinity purified from the serum of a mother with a child effected by heart block, but not control IgG (190 ±108 vs 10±9, p=0.027). Cell surface expression of this Ro60 mutant was similar to wild type Ro60 (348±158, p=0.49 vs Ro60 170/4). In contrast, apoptotic fibroblasts transfected with Ro60 H187S (does not bind Y RNA) were not bound by anti-Ro60 (14±8 vs 170/4, p=0.029, vs wild type, p=0.029). Despite differences in cell surface translocation and RNA content, both Ro60 mutants, H187S and 170/4 showed equivalent intracellular binding of anti-Ro60 (1345±738 and 1384±282). The functional consequences of surface bound Ro60-anti-Ro60 complexes were subsequently addressed. Macrophages cultured with Ro60 170/4 apoptotic fibroblasts preincubated with anti-Ro60, secreted significantly higher levels of TNFα compared to macrophages incubated with Ro60 H187S apoptotic fibroblasts also preincubated with anti-Ro60 (146±32 pg/ml vs 46±14 pg/ml respectively, p=0.04). The TNFα secretion induced after macrophages were cultured with Ro60 170/4 apoptotic fibroblasts and anti-Ro60 was inhibited by 45% ± 13% in the presence of the TLR7 inhibitor, IRS661.

Conclusion: These data suggest that an alteration of the Ro60 domain which prevents Y RNA binding attenuates a permissive signal that is required for its participation as an antigen to form immune complexes in apoptotic cells and generate a TLR dependent proinflammatory cascade. Accordingly, the Y RNA moiety of the Ro/SSA ribonucleoprotein imparts a critical role in the pathogenicity of anti-Ro60 autoantibodies.

Background/Purpose: Sjögrens syndrome (SS) is a chronic, inflammatory autoimmune condition characterized by exocrine gland dysfunction and dysregulation of interferon responses. The etiology of SS is largely unknown, but current hypotheses suggest roles for environmental and genetic factors. To date, the identification of SS risk loci has been confined to candidate gene studies. In this study, we sought to evaluate a collection of European-derived SS cases for association with regions previously reported in other related inflammatory conditions (e.g. rheumatoid arthritis, etc).

Methods: We have established the Sjögrens Genetics Network (SGENE) to assemble a sizable cohort for large-scale genetic studies. We used the ImmunoChip, an Illumina iSelect custom array designed with ~196,000 single nucleotide polymorphisms (SNPs) from 12 inflammatory phenotypes. Stringent quality control measures were applied and principal component (PC) analysis was used to determine genetic outliers. After quality control, ~130,000 variants were available to test for association with 1051 SS cases and 1727 controls. Replication was performed in an independent collection of 268 SS cases and 380 controls. SNP-SS association was tested using logistic regression under an additive genetic model in PLINK while adjusting for the first three PCs and gender. Meta-analysis was conducted using weighted Z-scores in METAP.

Results: We identified a novel association unique to SS within the 3′-UTR of the gene protein kinase, interferon-inducible double-stranded RNA-dependent activator (*PRKRA*; $P=6.44\times10\text{E-}24$, OR=0.47, 95%CI=0.40–0.54). This result replicated in the independent case-control cohort ($P=1.04\times10\text{E-}6$ OR=0.43, 95%CI=0.31–0.61) yielding a *Pmeta*=1.3×10E-27. *PRKRA* encodes a double-stranded RNA-activated protein kinase that modulates the interferon cascade upon infection by viruses. Approximately 220 SNPs in the region of interferon regulator factor 5 (*IRF5*) were typed on this array including variants in genes centromeric (*KCP*) and telomeric (*TNPO3*) of this locus. A total of 12 SNPs had $P<5\times10\text{E-}8$, with the most significant SNP resulting in a $P=4.12\times10\text{E-}12$ (OR=1.52, 95%CI=1.35–1.71). *IRF5* encodes a transcription factor involved in the activation of interferon, cell growth and differentiation, apoptosis, and other immunologic-related functions. A SNP in the gene B lymphoid kinase (*BLK*) was found to be significantly associated with SS ($P=4.07\times10\text{E-}8$, OR=1.40, 95%CI=1.24–1.58). *BLK* encodes for a non-receptor protein kinase involved in B cell receptor signaling and B cell development. The strongest overall association identified was within the major histocompatibility complex (MHC) with 1467 SNPs resulting in $P<5\times10\text{E-}8$. Peak association was observed in HLA-DRB1 with $P=1.55\times10\text{E-}52$ (OR=3.675, 95%CI=3.10–4.34).

Conclusion: We have discovered and independently confirmed a novel association unique to SS in *PRKRA*, and report, for the first time, *IRF5* and *BLK* exceeding the genome-wide significance threshold. In addition, we replicate association with the *MHC*. Collectively these genes illustrate the importance of both the innate and adaptive immune responses in the etiology of SS.

774

Salivary Gland Epithelial Cells Are Capable to Directly Induce the Differentiation of IL-21-Secreting Follicular Helper CD4 T Cells in Primary Sjögren's Syndrome. Yazhuo Gong[1], Ghada Alsaleh[2], Emmanuel Chatelus[3], Christelle Sordet[4], Jean Sibilia[5], Dominique Wachsmann[1] and Jacques-Eric Gottenberg[2]. [1]EA 44 38, Strasbourg, France, [2]Strasbourg University Hospital, Strasbourg, France, [3]Hopital Hautepierre, Strasbourg, France, [4]Hautepierre Strasbourg Hospital University, Strasbourg, France, [5]CHU Hautepierre, Strasbourg, France

Background/Purpose: Follicular helper CD4 T lymphocytes (Tfh) play a pivotal role in the activation of B lymphocytes, notably through IL-21 secretion. An increase in blood proportion of Tfh was recently reported in primary Sjögren's syndrome (pSS). Salivary gland epithelial cells (SGEC) of patients with pSS express various molecules implicated in innate and acquired immune responses and can act as antigen-presenting cells. We therefore investigated whether SGECs were capable to differentiate naïve T cells into follicular helper T cells.

Methods: Primary culture of salivary epithelial cells was derived from minor salivary gland biopsies isolated from patients with SS or controls (subjects complaining from dry symptoms without any feature of autoimmunity).

Expression of ICOSL by SGECs after stimulation with poly I:C was assessed using qPCR. Naïve T cells were cocultured with SGECs and activated by anti-CD2, anti-CD3 and anti-CD28. Expression of ICOS and CXCR5 was analyzed using flow cytometry. Levels of IL-21, Il-6 and IL-17 were assessed in culture supernatants.

Results: SGECs of patients pSS (n=4) or controls (n=4) both up-regulated the expression of ICOSL when stimulated with poly I:C, but did not secrete IL-21. Coculture between T cells and non stimulated SGECs (1 pSS, 2 SS and 3 controls) induced the increased expression of CXCR5 (MFI 6.5 *versus* 5.2, p=0.09) and ICOS (MFI 41.25±14.8 *versus* 15.75±1.26, p=0.005). 3.76±2.05% on average (n=6) $CXCR5^+ICOS^+$ T cells were differentiated by coculture with SGECs. Secretion of IL-21 was also significantly increased after coculture (671.8±394.6 *versus* 17.8±19.5 pg/ml in CD4 T cells alone and 0 pg/ml in SGECs alone, p=0.0004). Secretion of IL-17, a cytokine that can be secreted by Tfh, was detected in the supernatant of cocultures (57±49.2 pg/ml) but not in the supernatant of SGEC or in T naive alone (p=0.0004). No significant change was observed in ICOS or CXCR5 expression using or not a transwell for cocultures.. However, coculture with a transwell partly inhibited IL-21(198.6±83.3 pg/ml with a transwell *versus* 591.4±308.9 pg/ml without, p=0.0286) and completely inhibited IL-17 secretion.

Conclusion: We demonstrated that SGEC are capable to directly induce the differentiation of IL-21 secreting follicular helper T cells, which might contribute to the marked activation of B lymphocytes in salivary glands. Further analyses are ongoing to determine the pathways implicated in this differentiation, which may involve IL-12. These results emphasize the pivotal role of salivary gland epithelial cells in this autoimmune epithelitis and suggest that follicular helper T cells and IL-21 might represent relevant therapeutic targets in pSS.

Functional Delivery of EBV-Mir-BART13 by exosomes in Human Salivary Gland Cells Affects Calcium Signaling. Alessia Gallo[1], Mayank Tandon[1], Shyh-Ing Jang[1], Hwei Ling Ong[1], Indu Ambudkar[1], Gabor G. Illei[2] and Ilias Alevizos[1]. [1]NIDCR, Bethesda, MD, [2]NIDCR/NIH #10 1N110, Bethesda, MD

Background/Purpose: Loss of secretory function of salivary glands is one of the most important functional effects of Sjögren's syndrome (SS), a chronic systemic autoimmune disease. We have shown that an EBV microRNA (ebv-mir-BART13) is significantly over-expressed in minor salivary gland biopsies of SS patients, when compared to the healthy volunteers. We have also shown that the over-expression of EBV-mir-BART13 in human salivary gland cell line is responsible of the down regulation of STIM1, an ER-Ca2+ sensor protein regulating store-operated calcium entry. Previous works have also shown that EBV miRNAs can be transferred from B-cells to other cells. Objective of this work is to establish if this mechanism can occur in SS and can explain how EBV-mir-BART13 is delivered into epithelial cells.

Methods: To investigate how the viral microRNA is transferred into epithelial cells from the B we used transwell system where we co-cultured the EBV stably transfected X50-7 B-cell line with a human salivary gland cell line (HSG) or a primary salivary epithelial cells line derived from human minor salivary gland. RT-PCR was performed on HSG cells and primary salivary epithelial cells RNA to assess the uptake of EBV-mir-BART13.

Results: In a transwell system, we co-cultured EBV stably transfected X50-7 B-cell line with a human salivary gland cell line (HSG) or primary salivary epithelial cells line. This system allows the passage of soluble molecules and small microvescicles but not cells. After 7 days of co-culture, we demonstrated by RT-PCR that EBV-miR-BART13 was released from X50-7 B-cell line in the medium and was successfully transferred and taken up by both co-cultured HSG cells and primary salivary epithelial cells. The functional effects EBV-mir-BART13 on these two cell lines was assessed by measuring STIM1 protein level and functional Ca^{2+} assays through thapsigargin-mediated depletion of the endoplasmic reticulum calcium. Cells co-cultured with EBV-miR-BART13 producing B cells showed a decrease in STIM1 expression and a significant delay in the influx of calcium consistent with a functional blockade of STIM1.

Conclusion: Together, these finding suggest that EBV-miR-BART13 can be transferred from the X50-7 B-cell line to human salivary gland cells and primary salivary epithelial cells *via* exosomes. The delivery of this miRNA has also a functional effect by reducing STIM1 expression and affecting the Ca^{2+} signaling. Exosomal delivery of viral microRNAs from lymphocytes to epithelial cells may represent a mechanism by which viruses may contribute to salivary gland dysfunction in Sjogren's syndrome.

Matriptase Dificency and Primary Sjogren Syndrome Induction: From Patients to Mice. Hongen Yin, Peter Kosa, Xibao Liu, Bill Swaim, Javier Cabrera-Perez, Zhennan Lai, Indu Ambudka, Thomas Bugge and John A. Chiorini NIH/NIDCR, Bethesda, MD

Background/Purpose: The role of epithelial cells in salivary gland function has long been recognized as central to gland activity. However changes in the epithelia of the salivary gland are poorly understood. We previously reported that mice with a ductal cell-specific deletion of the serine protease matriptase display a decrease saliva production following pilocarpine stimulation. This would suggest that matriptase could have a role in the development or maintenance of salivary gland function. The purpose of this study is to determine the role of matriptase in salivary gland function and to investigate its link to salivary gland dysfunction in Sjögren's syndrome.

Methods: Matriptase expression was detected in minor salivary gland biopsy (MSG) of health volunteer (HV) and primary Sjögren's syndrome (pSS) patients by microarray and quantitative PCR (qPCR). The role of matriptase in salivary and lacrimal gland function was studied by using tissue-specific conditional knockout mice ($MMTV\text{-}Cre^{+/0};St14^{LoxP/-}$) mice and salivary gland-specific matriptase knock out [local delivery of adeno-associated virus vector serotype 2 (AAV2) encoding the Cre gene in the submandibular gland (SMG) of $St14^{LoxP/LoxP}$ mice]. SMG and LG from matriptase-ablated and control mice were assessed for inflammation and activity changes by identifying lymphocytic foci (LF) (H&E), pilocarpine stimulated salivary flow rate (SFR) and tear flow rate (TFR) respectively. Autoantibody development was detected by ELISA. Alteration of T cells and cytokine productions were accessed by flow cytometry and multiplex ELISA assay respectively in SMG draining lymph nodes (DLN), spleen and serum. Immunofluorescent staining was used to identify SMG tight junction and ion transport channels. Ductal and acinar cell function was also assayed by regulatory volume decrease (RVD) following hypotonic swelling.

Results: A significant decrease in matriptase expression was found in the MSGs from pSS patients. Furthermore, mice with reduced matriptase expression develop a number of characteristics associated with pSS, including decreased salivary and lacrimal gland function. This decrease in function correlated with a decrease in electrical potential across the epithelial membrane of the gland. In matriptase KO mice, anti-Ro, anti-La and anti-nuclear antibodies (ANA) were detected in serum and a significant increase in LF was detected in LG but not SMG. Altered T cell regulation and cytokines production was found in local and peripheral immune systems. TJ proteins and ion/water channels changes were found in the SMG of matriptase-deficient mice compared to controls. A loss of volume regulation was observed in both ductal and acinar cells after matriptase local depletion in SMG.

Conclusion: Our data suggest that matriptase deficiency is associated with primary Sjögren's syndrome and can induce a pSS-like phenotype in mice. The induction of pSS by matriptase depletion is correlated with a change in epithelial barrier function and subsequent impairment of immune homeostasis in natural and adaptive immunity, resulting in a systemic autoimmune condition similar to pSS.

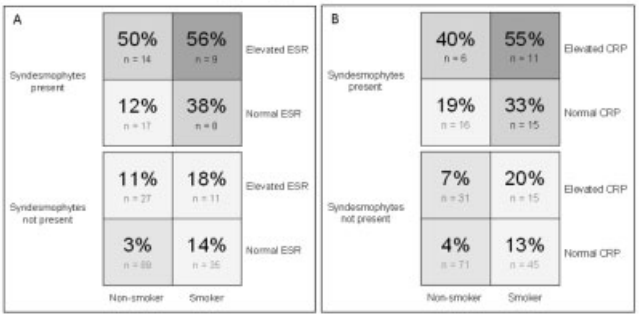
Baseline Radiographic Damage, Elevated Acute Phase Reactants and Cigarette Smoking Status Predict Radiographic Progression in the Spine in Early Axial Spondyloarthritis. Denis Poddubnyy[1], Hildrun Haibel[2], Joachim Listing[3], Elisabeth Märker-Hermann[4], Henning Zeidler[5], Jürgen Braun[6], Joachim Sieper[2] and Martin Rudwaleit[7]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Charité – Campus Benjamin Franklin, Berlin, Germany, [3]German Rheumatism Research Centre, Berlin, Germany, [4]Dr. Horst Schmidt Kliniken, Wiesbaden, Germany, [5]Medizinische Hochschule, Hannover, Germany, [6]Rheumazentrum Ruhrgebiet, Herne, Germany, [7]Ev. Krankenhaus Hagen-Haspe, Hagen, Germany

Background/Purpose: There are some data available on the frequency of structural damage in the spine in patients with ankylosing spondylitis (AS) and about potential risk factors for the development of syndesmophytes, but these data refer exclusively to patients with long-standing AS. Nearly no data exist regarding rates and predictors of radiographic spinal progression in early axial spondyloarthritis (SpA). The objective of the study was to investigate rates and predictors of structural damage development in the spine in patients with early axial SpA (AS with symptoms duration of <10 years and non-radiographic axial SpA (nrSpA) with symptoms duration of <5 years).

Methods: 210 patients with axial SpA (115 with AS according to the modified New York criteria and 95 with nrSpA) from the German Spondyloarthritis Inception Cohort (GESPIC) were selected for this analysis based on availability of radiographs (sacroiliac joints, lumbar and cervical spine lateral views) at baseline and after 2 years of follow-up. Images were centrally collected, digitized, and subsequently scored independently by two trained readers. Spinal radiographs were scored according to the mSASSS scoring system. The readers scored both time points simultaneously but were blinded for the time point and for all clinical data. Significant radiographic spinal progression was defined as a worsening of the mean mSASSS score by ≥ 2 units over two years

Results: Altogether, 14.3% of the patients in the whole SpA group showed spinal radiographic progression according to this definition. This rate was higher in the group of patients with AS (20%) in comparison to non-radiographic axial SpA (7.4%). The following parameters were independently associated with radiographic spinal progression: presence of syndesmophytes at baseline (odds ratio (OR)=6.29, $p<0.001$), elevated markers of systemic inflammation (erythrocyte sedimentation rate: OR=4.04, p=0.001, C-reactive protein: OR=3.81, p=0.001), and cigarette smoking (OR=2.75, p=0.012), that was confirmed in the multivariate logistic regression analysis. No clear association with radiographic spinal progression was found for HLA-B27 status, sex, age, disease duration, BASDAI, BASFI, presence of peripheral arthritis, enthesitis or psoriasis. Based on the obtained data two prediction matrix models were constructed incorporating the following variables: baseline syndesmophytes, smoking status and an elevated acute phase reactant (either ESR or CRP)—figure.

Figure. Matrix model of association of syndesmophytes, elevated acute phase reactants (A - ESR >20 mm/h, B - CRP >6 mg/l at baseline) and smoking (as present at baseline) with spinal radiographic progression over two years in patients with axial SpA (n = 210). Percentages refer to patients with spinal radiographic progression (≥2 mSASSS units over two years), n – number of patients with combination of the respective parameters.



Conclusion: The presence of radiographic damage in the spine (syndesmophytes), elevated acute phase reactants and cigarette smoking status predict spinal radiographic progression in early axial SpA.

Multivariate Analysis Indicates That Fat Lesions Dominate Over Inflammatory Lesions in Predicting New Bone Formation in the Spine of Patients with Ankylosing Spondylitis. Walter P. Maksymowych, Nathalie Morency, Barbara Conner-Spady and Robert GW Lambert. University of Alberta, Edmonton, AB

Background/Purpose: Recent prospective data indicates that as inflammatory lesions mature, they undergo a process of transformation into fat in the spine of patients with ankylosing spondylitis (AS)[1]. It has been proposed that bone formation becomes uncoupled from inflammation in these complex inflammatory lesions characterized by: 1. Inflammation that has receded from the vertebral corner (VC) on STIR MRI 2.Fat infiltration at the same VC location on T1W MRI. Early inflammatory lesion may resolve completely without sequelae while resolution of complex inflammatory lesion may be accompanied by new bone formation[2]. Consequently, the appearance of fat lesions may indicate an even greater propensity to new bone formation than inflammatory lesions. We tested this hypothesis in this prospective study.

Methods: MRI scans were performed at baseline, 12, and 52 weeks while radiographs were done at baseline and 104 weeks in 76 AS patients randomized to receive either adalimumab (ADA) 40 mg every other week or placebo for 24 weeks in a, double-blind, Phase III study of active AS. After the week 12 assessment, patients were eligible for early escape therapy and after 24 weeks all patients received ADA. The anterior VC of the cervical and lumbar spine were examined for new syndesmophytes and ankylosis (baseline, 104 weeks) on lateral radiographs of the spine. Anonymized MR scans were read independently by 2 readers who recorded the presence/absence of inflammatory and fat lesions at the same anterior VC that were assessed by radiography. We used Generalized Linear Latent and Mixed Models (GLLAMM) multivariate analysis to adjust for within patient dependence in the *total number* of vertebral corners with syndesmophytes/ankylosis at baseline to determine which lesions were independently predictive of new bone.

Results: At the patient level, the mean (SD) number of VC inflammatory or fat lesions was significantly higher on baseline MRI in those who developed new bone compared to those who did not ($p = 0.002$ and 0.0003, respectively). New bone developed significantly more frequently from VC that demonstrated inflammatory lesions (13 of 220 (5.9%)) or fat lesions (20 of 179 (11.2%) on baseline MRI as compared to VC with neither (29 of 1138 (2.5%)) ($p= 0.002$ and <0.0001, respectively). New bone also developed significantly more frequently from VC with ***both*** inflammation and fat (7 of 52 (13.5%)) compared to VC with ***only*** inflammation (6 of 168 (3.6%), $p = 0.015$). GLAMM multivariate analysis that included inflammation, fat, and syndesmophytes/ankylosis showed that fat dominated over inflammation in predicting new bone.

	OR (95%CI)	P value
Inflammation	1.11 (0.48–2.59)	NS
Fat	4.39 (2.08–9.26)	P<0.0001
Syndesmophyte/ankylosis	1.18 (1.10–1.27)	P<0.0001

Conclusion: Our data supports the hypothesis that new bone formation is more likely in complex inflammatory lesions characterized by fat metaplasia where it may be uncoupled from inflammation.

Anti-Interleukin 17A Monoclonal Antibody Secukinumab Reduces Signs and Symptoms of Psoriatic Arthritis in a 24-Week Multicenter, Double-Blind, Randomized, Placebo-Controlled Trial. I. McInnes[1], J. Sieper[2], J. Braun[3], Paul Emery[4], D. van der Heijde[5], J. Isaacs[6], G. Dahmen[7], J. Wollenhaupt[8], H. Schulze-Koops[9], S. Gsteiger[10], A. Bertolino[11], W. Hueber[11] and P. P. Tak[12]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Charitè Campus Benjamin Franklin, Berlin, Germany, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]NIHR-Leeds Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Newcastle University and the Freeman Hospital, Newcastle-upon-Tyne, United Kingdom, [7]Praxis fuer klinische Studien, Hamburg, Germany, [8]Eilbeck Hospital, Hamburg, Germany, [9]Klinikum Innenstadt der Ludwig-Maximilians-Universität, Munich, Germany, [10]Novartis Pharma AG, Basel, Switzerland, [11]Novartis Institutes for BioMedical Research, Basel, Switzerland, [12]University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Interleukin 17A (IL-17A) is a novel target for the treatment of psoriatic arthritis (PsA). We assessed the safety and preliminary efficacy of secukinumab, an anti-IL-17A monoclonal antibody, in PsA.

Methods: 42 patients with active PsA fulfilling CASPAR criteria were assigned 2:1 to receive two injections with secukinumab (10mg/kg) or placebo, given three weeks apart. The primary efficacy endpoint was the proportion of ACR20 responders at Week 6 in active compared with placebo recipients (one-sided p-value <0.1). As per protocol, no imputation was made for missing data (drop-outs were treated as missing).

Results: 25 (89%) patients on secukinumab and 10 (71%) on placebo completed the study. Five patients (4 secukinumab and 1 placebo) were excluded from the efficacy analysis due to protocol violations. Three (11%) of patients on secukinumab and 4 (29%) on placebo discontinued prematurely for lack of efficacy or withdrawal of consent. Demographics and baseline characteristics were balanced between groups for age, sex and parameters including mean (SD) SJC (secukinumab *vs*. placebo): 8.3 (5.6) *vs*. 9.5 (5.4); TJC 23.5 (19.4) *vs.* 22.6 (11.0); DAS28 4.8 (1.2) *vs.* 4.8 (1.2); MASES 3.0 (4.1) *vs.* 3.4 (2.3). Co-existing psoriasis, prior TNFi exposure and co-medication with DMARDS were present in 23 (98%), 11 (46%) and 21 (88%) patients on secukinumab and in 11 (89%), 5 (38%) and 10 (70%) on placebo, respectively. The ACR20 response rate at week 6 was 39% (9/23) on secukinumab *vs.* 23% (3/13) on placebo (*P = 0.27*). ACR20 response rates were 39% (9/23) *vs*. 15% (2/13) at week 12, and 43% (10/23) *vs*. 18% (2/11) at week 28 with secukinumab *versus* placebo, respectively. ACR50 and ACR70 response rates at week 6 on secukinumab *vs*. placebo were 17% *vs*. 8 % and 9% *vs*. 0%, respectively. CRP reductions at week 6 compared to baseline were observed on secukinumab (median [range] of 5.0 [0.3, 43.0] at baseline *vs*. 3.0 [0.2, 15.2] at week 6, but not on placebo (3.9 [1.3, 39.7] at baseline *vs*. 5.0 [0.8, 29.6] at week 6). Similar reductions were seen for ESR, and reductions in acute phase parameters were maintained up to week 28. The overall rate of adverse events (AEs) was comparable in secukinumab *versus* placebo: 26 (94%) *vs.* 11 (79%). One severe adverse event (cellulitis hand) occurred on secukinumab, and was not suspected by the investigator to be study drug-related. 7 serious AEs were reported in 4 secukinumab patients (tendon rupture/carpal tunnel syndrome/cellulitis, obesity, fall, breast cancer [diagnosed prior to dosing and inclusion constituting a protocol violation]) and 1 with placebo (polyarthritis). Infections were reported in 16 (57%) patients on secukinumab and 7 (50%) patients on placebo.

Conclusion: The safety profile of secukinumab was favorable overall. Although the primary endpoint was not met, a substantial proportion of patients showed rapid and sustained improvements of clinical scores and acute phase parameters up to week 28. Trends towards a beneficial clinical effect support the rationale for larger clinical trials designed to assess clinical effectiveness.

Oral Apremilast Is Effective with and without Concomitant Methotrexate Therapy in the Treatment of Subjects with Active Psoriatic Arthritis. Georg A. Schett[1], Angela Hu[2] and Randall Stevens[2]. [1]University Erlangen-Nuremberg, Erlangen, Germany, [2]Celgene Corporation, Warren, NJ

Background/Purpose: Phosphodiesterase 4 (PDE4) is expressed in cells mediating immune response. Apremilast (APR) is a novel, orally available small molecule that specifically targets PDE4, thereby increasing cellular cyclic adenosine monophosphate, which modulates multiple pro- and anti-inflammatory mediators. Because a large proportion of psoriatic arthritis (PsA) subjects are treated with methotrexate (MTX), the comparable efficacy and tolerability of APR as monotherapy and in combination with MTX is of interest. *We evaluated the effectiveness of APR for the treatment of* active PsA in subjects taking and not taking concomitant MTX.

Methods: In a phase 2 randomized, double-blind, placebo (PBO)-controlled, multicenter study, subjects with active PsA (joint involvement ≥6 mo; ≥3 tender joints; ≥3 swollen joints) were randomized to PBO, APR 20mg BID (APR20), or APR 40mg QD (APR40) and treated for 12 wks. Stable doses of NSAIDs, corticosteroids, and MTX (≥56 days before screening; dose range 1.5–30mg/wk) were allowed; randomization was stratified by baseline MTX use. Last observation carried forward was used for missing data. The Breslow-Day statistic was used to test the null hypothesis of homogenous odds ratio (OR; APR vs PBO) among subjects treated and not treated with MTX.

Results: Of 204 subjects enrolled (mean PsA duration 7.8 yrs), at baseline 89 subjects were taking MTX (PBO: 29 [42.6%]; APR20: 30 [43.5%]; APR40: 30 [44.8%]) and 115 were not taking MTX (PBO: 39 [57.4%]; APR20: 39 [56.5%]; APR40: 37 [55.2%]). Use of APR20 and APR40 resulted in more subjects achieving an ACR20 vs PBO (OR 3.68–7.58) at wk 12 regardless of concomitant MTX use. No differences were noted in ACR20 in subjects taking MTX vs not taking MTX in any group: PBO, 10.3% vs 12.8%; APR20, 46.7% vs 41.0%; and APR40, 36.7% vs 35.1%. There was no evidence that the APR treatment response (APR vs PBO) differed among subjects treated and not treated with MTX (treatment by MTX interaction: p=0.606 [APR20]; p=0.739 [APR40]). Adverse events (AEs) were reported by 78/89 (87.6%) subjects taking MTX vs 94/115 (81.7%) subjects not taking MTX regardless of randomization assignment. The most commonly reported AEs were diarrhea, headache, nausea, fatigue, and nasopharyngitis. Gastrointestinal AEs, particularly diarrhea and vomiting, tended to occur in more subjects treated with MTX vs without MTX regardless of randomization assignment (Table). Overall, there was no strong evidence for increasing AEs with concomitant APR/MTX treatment vs APR monotherapy.

	Placebo		Apremilast 20 mg BID		Apremilast 40 mg QD		Total

Fatigue	2 (6.9)	4 (10.3)	2 (6.7)	3 (7.7)	7 (23.3)	4 (10.8)	11 (12.4)	11 (9.6)
Respiratory, thoracic, and mediastinal disorders	4 (13.8)	5 (12.8)	3 (10.0)	1 (2.6)	4 (13.3)	1 (2.7)	11 (12.4)	7 (6.1)
Pharyngolaryn-geal pain	3 (10.0)	1 (2.6)	1 (3.3)	0	1 (3.3)	0	5 (5.6)	1 (0.9)

Conclusion: APR was previously shown to be effective in the treatment of active PsA. The current analysis demonstrates the efficacy and safety of APR in PsA subjects with and without concomitant MTX therapy. There was no additional benefit or risk associated with combination APR/MTX therapy. Phase 3 studies are ongoing to further explore APR efficacy for the treatment of PsA and psoriasis.

781

The Association Between Human Leukocyte Antigen and Killer-Cell Immunoglobulin-Like Receptor Gene Variants and Progression of Peripheral Joint Damage in Psoriatic Arthritis. Vinod Chandran[1], Arane Thavaneswaran[2], Fawnda Pellett[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Genetic factors may influence peripheral joint damage progression in psoriatic arthritis (PsA). We therefore conducted a case-only study to identify *HLA* and *KIR* polymorphisms associated with progression of peripheral joint damage in PsA.

Methods: Data on the number of clinically damaged joints at each clinic visit 6 months apart was obtained on a cohort of 649 Caucasian subjects with PsA satisfying CASPAR criteria. Peripheral joint damage was defined by the presence of limitation of range of movement of > 20% of the range not related to the presence of joint effusion, the presence of joint deformities, subluxation, flail joints or ankylosis. HLA typing was performed by PCR-SSO, and KIR typing by PCR-SSP with appropriate quality control. The principal outcome was the change in the number of clinically damaged joints between clinic visits. A negative binomial model best fit the distribution of the outcome variable and was used for all analyses. The predictor variables included age at diagnosis, sex and genetic variables (HLA, KIR). To allow for any remaining, unadjusted, within-patient correlation, a generalised estimating equation analysis was used to provide robust estimated standard errors when fitting primary multivariate models.

Results: The 649 subjects [373 (57.5%) males, mean age at diagnosis 36 years, mean age at first visit 43 years, mean duration of PsA 7 years, mean tender joint count 8.6, mean swollen joint count 5.1, mean number of damage joints at first visit 8.7] had a median number of 7 visits during a median follow up of 6 years. Univariate analyses of HLA associations showed that the alleles A*02, C*01, B*27 and B*39 increased risk of joint damage progression whereas the alleles A*11, A*29, C*04, B*35, B*44, B*50, DRB1*13 and DQB1*0604 decreased risk. Multivariate analysis confirmed that HLA- B*39 (OR 1.87, 95% CI 1.38, 2.54, p <0.0001), B*27 (OR 1.51, 95% CI 1.15, 1.97, p =< 0.01) and A*02 (OR 1.30, 95% CI 1.03, 1.63 p = 0.03) independently increase the odds of joint damage progression between clinic visits, whereas HLA DQB1*0604 (OR 0.52, 95% CI 0.35, 0.78 p < 0.01), C*04 (OR 0.69, 95% CI 0.49, 0.97, p = 0.03) and B*50 (OR 0.51, 95% CI 0.27, 0.98, p = 0.04) decreases risk. Of the KIR genes only *KIR3DS1* (OR 1.33, 95% CI 1.07, 1.66, P = 0.01) was associated with joint damage progression. Neither HLA-C C group 1, HLA-C C group 2, HLA-C alleles with high cell-surface expression, HLA-B Bw4, Bw4 80ile, Bw4 80thr or HLA-Bw6 alleles were associated. There was no evidence of an association between KIR genes and joint damage progression in the presence/absence corresponding HLA ligands.

Conclusion: Genetic markers play a role in the progression of clinical joint damage in patients with PsA. HLA alleles HLA-B*39, B*27 and A*02 and the KIR gene *KIR3DS1* are independently associated with increased peripheral joint damage progression between clinic visits in PsA, whereas the alleles DQB1*0604, C*04 and B*50 decreases risk.

The Impact of Psoriasis Extent On Prevalence of Psoriatic Arthritis. Alexis Ogdie[1], Nicole Seminara[2], Sinead Langan[3] and Joel Gelfand[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania., Philadelphia, PA, [3]London School of Hygiene and Tropical Medicine, United Kingdom

Background/Purpose: Psoriatic arthritis (PsA) is a chronic, inflammatory arthritis associated with psoriasis with prevalence in the general population of approximately 0.25% making it a difficult disease to study from a population-based perspective. The Health Improvement Network (THIN) is a medical record database in the United Kingdom with 7 million patients and an average length of follow up of 7 years that can be used to perform high quality, population-based epidemiology studies. With more than 7,000 patients with at least one code for PsA, this database could be a tremendous resource for the study of PsA. In this study, we aimed to assess the impact of extent of skin psoriasis on the prevalence of PsA.

Methods: 4,900 patients ages 45–65 with a code for psoriasis were randomly selected and a questionnaire was sent to their GP to confirm the diagnosis of psoriasis and disease severity. Among patients with a diagnosis of psoriasis confirmed by the GP, the lifetime prevalence of PsA and prevalence stratified by severity of psoriasis (%BSA) were evaluated. Using logistic regression, we then assessed whether psoriasis severity was an independent predictor for prevalent psoriatic arthritis.

Results: 4,634 surveys have been returned (response rate 95%). Prevalence of psoriasis in THIN is 1.9% overall, consistent with other population based estimates. The psoriasis diagnosis was confirmed in 90% (95%CI: 89–91) of patients. %BSA was obtained for 3,896. Of 4,586 patients with psoriasis between age 45–65, 349 or 8.6% (95%CI: 7.7–9.5) had at least one diagnostic code for psoriatic arthritis. Additionally, patients with more extensive skin psoriasis had a significantly higher prevalence of PsA (Table) which increased in a dose-dependent manner. A multivariable logistic regression model included psoriasis extent (mild, moderate, severe), body mass index category, duration of psoriasis category, age and sex. Age and sex were not significant in the model. Independent predictors of prevalent PsA among psoriasis patients after adjusting for all factors in the model included severe psoriasis or >10% BSA (OR 3.37; 95%CI: 2.39–4.6), BMI (OR 1.80; 95%CI: 1.31–2.4), and duration of psoriasis for 10 or more years (OR 6.36; 95%CI: 3.86–14.25).

	Psoriasis	PsA	% PsA of Total (95%CI)
≤2%	1951	92	4.7 (3.8–5.8)
3–10%	1249	128	10.2 (8.6–12.1)
>10%	370	105	28.4 (23.8–33.3)

Conclusion: The prevalence of PsA among patients with psoriasis is consistent with previous population based estimates in both the US and UK. The prevalence of PsA increases dramatically with increasing severity of skin psoriasis, even after adjusting for BMI, length of disease, age and sex, confirming our findings from a previous US population-based study that was much smaller and relied on patient self-report.

The Protective Effect of Antimalarials On Thrombovascular Events In Latin American Systemic Lupus Erythematosus Patients. Guillermo J. Pons-Estel[1], Graciela S. Alarcón[2], Daniel Wojdyla[3], Ana I. Marcos[4], Alejandro J. Alvarellos[5], Antonio A. Iglesias-Gamarra[6], Maria H. Esteva-Spinetti[7], Lilian Costallat[8], Nilzio A. Silva[9], Gloria Vázquez[10], Maria Loreto Massardo[11], Marlene Guibert-Toledano[12], Guillermo F. Huerta-Yáñez[13], Mariano Cucho-Venegas[14] and Bernardo Pons-Estel[15]. [1]Servicio de Enfermedades Autoinmunes, Hospital Clínic Barcelona, Barcelona, Spain, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Universidad Nacional de Rosario, Argentina, Rosario, Argentina, [4]Hospital Interzonal General de Agudos "General San Martin, La Plata, La Plata, Argentina, [5]Hospital Privado, Cordoba, Argentina, [6]Universidad Nacional, Bogota, Colombia, [7]Centro Clinico San Cristobal, San Cristobal, Venezuela, [8]Faculdade de Ciencias Medicas, Universidade Estadual de Campinas, Campinas, Brazil, [9]Faculdade de Medicina, Universidade Federal de Goias, Goiania, Brazil, [10]Universidad de Antioquia, Hospital Universitario "San Vicente de Paul", Medellín, Colombia, [11]Catholic University of Chile, Santiago, Chile, [12]Centro de Investigaciones Médico Quirúrgicas, Habana, La Habana, Cuba, [13]Hospital de Especialidades Miguel Hidalgo, Aguascalientes, Mexico, [14]Almenara Hospital IPSs, Lima, Peru, [15]Hospital Provincial de Rosario, Rosario, Argentina

Background/Purpose: Antimalarials (AMs) have shown to exert a thromboprotective effect in systemic lupus erythematosus (SLE), but studies thus far have been limited to North American and European

patients. This study was conducted to assess whether a similar effect is observed in Latin American patients with SLE.

Methods: SLE patients with a recent diagnosis (≤2 years) recruited and followed longitudinally as part of the GLADEL cohort were examined to establish risk factors for thrombotic events (TEs) and the possible preventive role of AMs. The outcome variable was defined as the presence of an arterial or venous thrombotic event during follow up. AM use was considered present (ever used) or absent (never used). After controlling for possible confounding variables identified in univariable analysis, the use of AM drugs was assessed for its effects on the development of TEs in cohort patients and by Cox proportional hazards regression analyses.

Results: Of the 1,480 patients included in the GLADEL cohort, 1,213 (82%) were considered AMs users. Thrombosis occurred in 87 (5.9%) of the patients during a median follow up time of 64 (range 12–98) months. After adjustment for potential confounders in the Cox proportional hazards regression model, AM use was associated with a 39% reduction in the rate of TEs (hazard ratio 0.61, 95% CI 0.40–0.95). Other variables significantly associated with TEs are depicted in Table 1.

Table 1. Effects of AMs drugs on the development of TEs in SLE patients from the GLADEL cohort by multivariable Cox proportional hazards regression analysis.

Parameter	HR	95% CI		P Value
Antimalarial use	0.612	0.40	0.95	0.0288
Female sex	0.486	0.28	0.84	0.0096
Antiphospholipid antibodies	1.689	1.01	2.82	0.0443
Any Hospitalization	2.200	1.39	3.48	0.0008
Aspirin/Anticoagulant use	2.156	1.14	4.07	0.0181
Thrombosis Previous to SLE Diagnosis	3.688	1.85	7.35	0.0002

Conclusion: After adjusting for possible confounding factors related to AM use, a clear protective effect of AM in the development of TEs in SLE patients from this Latin American cohort was observed.

784

Non-Calcified Coronary Plaque in Systemic Lupus Erythematosus Quantitative Analysis. Adnan Kiani[1], Jens Vogel-Claussen[2], Armin Zadeh[2], Margaret Yew[2], Laurence S. Magder[3], Joao Lima[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University of Maryland, Baltimore, MD

Background/Purpose: Atherosclerosis is accelerated in SLE. Inflammation is a risk factor for both plaque instability and atherosclerosis. New technology (CTA) can measure non-calcified plaque (NCP), which is highly unstable and has a high degree of inflammation compared to calcified plaque. We report on a large quantified study of NCP in SLE.

Methods: 64 (n=106) and 320 (n=41) slice coronary multidetector computed tomography (MDCT) was performed in 147 patients with SLE. The MDCT scans were evaluated quantitatively by a radiologist, using dedicated software.

Results: The 147 SLE pts were 86% female, 70% Caucasian, 27% African-American, 3% other; mean age 51 years. Table 1 shows the mean NCP score, by demographics, traditional cardiovascular risk factors and history of ever positive lupus serologies. Table 2 shows the mean NCP score by current lupus serologies and current medications. Table 3 shows the multivariate regression model.

Table 1. Association of NCP with Demographics and Past History

	Group	Mean Noncalcified Plaque Score	p-value	p-value when age is controlled
Demographics			0.007	–
Age				
	<45 (n=50)	0.14 (0.20)

	No (n=91)	0.25		
	Yes (n=55)	0.21		

Table 3. Multiple Variable Model to predict mean Noncalcified Plaque

Variable	Effect on mean noncalcified plaque score (95% confidence Interval)	P-value
Age (per 10 years)	0.08 (0.04, 0.12)	<0.0001
Low BMI (vs. normal)	−0.09 (−0.20, 0.02)	0.11
High BMI (vs. normal)	0.03 (−0.08, 0.14)	0.61
Hypertension	0.08 (−0.02, 0.18)	0.12
History of ant-dsDNA	0.12 (0.02, 0.21)	0.019
Male sex	0.08 (−0.04,0.21)	0.20
Methotrexate ever	0.07 (−0.05, 0.19)	0.23
Methotrexate current	0.34 (0.15, 0.53)	0.0005

Conclusion: NCP is a marker of more immediate atherosclerotic risk and contributes to overall atherosclerotic burden. In our univariate analysis, age, weight, methotrexate (MTX) use, anti-dsDNA, hypertension, anticardiolipin IgG and BMI were associated with NCP. It is not explained by homocysteine. In summary, traditional cardiovascular risk factors, anticardiolipin IgG and anti-dsDNA are associated with quantified NCP in SLE. This highlights the multifactorial etiology of accelerated atherosclerosis in SLE, and the potential role of SLE autoantibodies in the process. Confirmation of the harmful association with MTX is necessary before any recommendations can be made on limiting its use.

Development of Atherosclerotic Vascular Events in Systemic Lupus Erythematosus: How Important Are Race/Ethnicity and Geography?

Murray B. Urowitz[1], D. D. Gladman[1], Dominique Ibanez[1], Nicole Anderson[1] and Systemic Lupus International Collaborating Clinics (SLICC)[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto, ON

Background/Purpose: We have previously demonstrated that there are differences at inception in the atherosclerotic disease related risk factors for the development of AVE in SLE when studied by geographic and race/ethnicity origins. In this study we examined the influences of race/ethnicity and geography on the development of AVEs attributed to atherosclerosis (AS) in patients with SLE followed from inception.

Methods: An international research network comprising 27 centres from 11 countries has followed an inception cohort of SLE patients yearly according to a standardized protocol between 2000 and 2011. Patients enter the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Clinical and laboratory features of SLE and comorbidities are gathered in a standardized protocol at yearly intervals. Vascular events are described and attributed on a specialized form. Events recorded include myocardial infarction (MI), angina, congestive heart failure (CHF), intermittent claudication (PVD), stroke, transient ischemic attack (TIA). Diagnosis of an event was confirmed using standard clinical criteria, relevant laboratory data and imaging where appropriate. Attribution to AS was made on the basis of lupus disease being inactive at the time of the event, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Predictor factors for AVE at enrolment included age, sex, SLEDAI-2K, hypercholesterolemia, hypertension, diabetes, metabolic syndrome (MetS), geography, and race/ethnicity. Univariate and multivariate analyses were performed.

Results: 1332 patients have been entered into the inception cohort with at least 1 year followup. Of those 24 had AVEs attributed to AS (angina 10, MI 3, claudication 4, TIA 3, pace maker 2 congestive heart failure 1, stroke 1). In univariate analyses older age at diagnosis, male sex, hypertension, hypercholesterolemia, diabetes, metabolic syndrome at inception were predictive for AVE. Neither individual geographic regions, nor individual race/ethnicities were predictive in univariate analyses. However, AVEs occurred more commonly among Caucasians when compared to other race/ethnicities combined (log rank $p=0.002$). Caucasians were significantly older then non-Caucasians at SLE diagnosis (38.3 ± 14.5 compared to 31.0 ± 11.2, $p<0.0001$) On multivariate regression analysis adjusting for age at diagnosis, sex, SLEDAI-2K, hypercholesterolemia, hypertension and diabetes, only older age at SLE diagnosis (HR = 1.06, 95% CI (1.03, 1.10), $p=0.0002$) and Male Sex (HR=3.58 95% CI (1.40, 9.17), $p=0.008$) remained statistically significantly associated with AVE.

Conclusion: These analyses were unable to establish important influences of geographic region and individual race/ethnicities with respect to AVEs in patients with SLE.

786

Vitamin D Insufficiency and Deficiency in Systemic Lupus Erythematosus.

Michelle Petri[1], Kayode J. Bello[1], Hong Fang[1], Caroline D'Souza[1] and Laurence S. Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Vitamin D insufficiency/deficiency is common in SLE patients. The evidence linking various SLE manifestations with vitamin D insufficiency/deficiency is inconclusive. We investigated clinical and laboratory associates of vitamin D insufficiency and deficiency in SLE.

Methods: 922 SLE patients were enrolled in a prospective observational study from 7/2009 to 12/ 2010. Vitamin D status was assessed by measuring serum 25-hydroxyvitamin D levels by chemiluminescence immunoassay. Data were analyzed using univariate, multivariate linear regression and multivariate logistic regression analyses (SAS Institute, Cary, NC, USA). Vitamin D insufficiency was 15–32 ng/mL and deficiency <15 ng/mL.

Results: The 922 SLE patients were 91% female, mean age 44.8 ± 13.0 years, 55% Caucasian, 37% African-American, 8% other ethnicity. The mean 25-OH vitamin D level in Caucasians was 33.0 ± 13.2 ng/mL, African-Americans 24.2 ± 14.6 ng/mL and other ethnicity 32.1 ± 16.0 ng/mL. The mean 25-OH vitamin D level for all 922 patients was 29.7 ± 14.6 ng/mL.

Table 1. Association between various factors and vitamin D deficiency/insufficiency in SLE based on a multivariate logistic regression model

		OR (95% CI) Vit D Deficiency	P-Value	OR (95% CI) Vit D Insufficiency	P-Value
Age	18–30	1.00 (reference)		1.00 (reference)	
	31–49	0.77 (0.45; 1.31)	0.33	1.17 (0.78; 1.75)	0.44
	50+	0.40 (0.22; 0.75)	0.0042	0.59 (0.39; 0.91)	0.018
Ethnicity	Caucasian	1.00 (reference)		1.00 (reference)	
	African-American	6.28 (4.05; 9.74)	<.0001	2.09 (1.53; 2.86)	<.0001
	Other	2.13 (0.93; 4.85)	0.073	1.01 (0.59; 1.73)	0.97
Urine Protein/Cr Ratio	<0.5	1.00 (reference)		1.00 (reference)	
	>=0.5	0.94 (0.53; 1.68)	0.85	1.85 (1.04; 3.30)	0.036
Body Mass Index	<=30	1.00 (reference)		1.00 (reference)	
	>30	2.00 (1.35; 2.95)	0.0005	2.64 (1.91; 3.64)	<.0001
Cholesterol	<=200	1.00 (reference)		1.00 (reference)	
	>200	1.44 (0.95; 2.19)	0.08	1.72 (1.23; 2.40)	0.0015
Systolic BP	No	1.00 (reference)		1.00 (reference)	
	Yes	1.60 (0.99; 2.57)	0.056	1.60 (1.04; 2.45)	0.03
Diabetes Mellitus	No	1.00 (reference)		1.00 (reference)	
	Yes	2.08 (1.21; 3.57)	0.0078	1.53 (0.92; 2.56)	0.10

Table 2. Association between various factors and 25-OH vitamin D levels in SLE based on a multivariate linear regression model

	Effect on Mean Vitamin D (ng/mL)	P-value
Age (per year)	0.11 ± 0.04	0.005
Ethnicity (African-American vs Caucasian)	−6.64 ± 0.97	<0.0001
Systolic BP (per mmHg)	−0.09 ± 0.03	0.0015
Diabetes	−1.92 ± 1.58	0.22
Urine Pr/Cr Ratio	−1.65 ± 0.68	0.015
Body Mass Index	−0.31 ± 0.06	<0.0001
Cholesterol (per mg/dL)	−0.04 ± 0.01	0.0002

Table 3. Percentage of patients with organ damage among those with and without Vitamin D insufficiency

	Percent with Condition			
Condition	Vit D insufficiency (N=381)	Normal Vit D (N=378)	P-value	Adjusted P-value for Race
GFR<50%	5.5	2.4	0.027	0.034
End-stage renal disease	3.9	1.1	0.011	0.0072
Cardiomyopathy	3.9	1.3	0.025	0.047

Conclusion: Younger age, African-American ethnicity, higher systolic blood pressure, higher cholesterol, higher urine protein/creatinine ratio and obesity were associated with low 25-OH vitamin D level in multiple variable models. SLE patients with vitamin D insufficiency were more likely to suffer from renal and cardiovascular damage. Studies of vitamin D supplementation in SLE are clearly indicated, but would have to be long-term to show prevention of organ damage.

787

Predictors of Risk for Progression of Subclinical Atherosclerosis in Women with Systemic Lupus Erythematosus.

Apinya Lertratanakul[1], Peggy W. Wu[1], Alan Dyer[1], William Pearce[1], Kim Sutton-Tyrrell[2], George Kondos[3], Daniel Edmundowicz[2], James Carr[4] and Rosalind Ramsey-Goldman[5]. [1]Northwestern University, Chicago, IL, [2]University of Pittsburgh, [3]University of Illinois at Chicago, Chicago, IL, [4]James, Chicago, IL, [5]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: Women with systemic lupus erythematosus (SLE) have increased rates of subclinical atherosclerosis and cardiovascular events. We sought to determine which cardiovascular (CV) and SLE-related risk factors may be significant in the rate of subclinical atherosclerosis progression in the carotid artery, as measured by the change in intima-media thickness (IMT). We also investigated risk factors for subclinical atherosclerosis progression, as measured by progression in plaque index (PI), coronary artery calcium score (CAC), and aorta calcium score (AS).

Methods: Data were collected on 147 women with SLE including demographics, self-reported and measured traditional CV risk factors. SLE factors collected included the SLE disease activity index (SLEDAI), modified SLICC/ACR-DI Damage Index (SDI) (excluding coronary artery bypass grafting, myocardial infarction, stroke, and angina), disease duration, and corticosteroid and immunosuppressant use. PI and IMT were measured by carotid B-mode ultrasound, and CAC and AS were measured by electron beam or multidimensional computed tomography at baseline and at one follow-up visit in the Study of Lupus Vascular and Bone Long-Term Endpoints (SOLVABLE). An abnormal PI, CAC, and AS was defined as PI≥1, CAC>10 and AS>100. Progression in PI at follow-up was defined as any increase in PI compared to baseline. Progression in CAC at follow-up was defined as a CAC>10 and an increase of >10% compared to baseline. Progression in AS at follow-up was defined as an AS>100 and an increase of >10% compared to baseline. Univariate regression models of PI, CAC, AS, and change in IMT per year with risk factors were examined. These models were further adjusted for follow-up time, age, and body mass index (BMI).

Results: In 147 women with SLE, mean age was 43.6 ± 10.1 yrs, disease duration was 11.8 ± 8.7 yrs, SLEDAI was 3.8 ± 3.5, SDI was 1.6 ± 1.7 (mean ± SD). Imaging data at baseline and follow-up were available on 147 women for IMT and PI, 123 with CAC, and 88 with AS. Mean follow-up time was 3.25 ± 0.36 yrs (mean ± SD).

Change in IMT per year was not significantly associated with any risk factors. PI progression was associated with presence of hypertension, hyperlipidemia, older age, and higher total cholesterol, fasting glucose, low-density lipoprotein, fibrinogen, BMI, waist circumference, disease duration, and SDI. After adjustment for follow-up time, BMI, and age, only higher fasting glucose (p=0.005, OR=3.36, 95% CI 1.55–8.55) and higher SDI (p=0.007, OR=1.40, 95% CI 1.10–1.80) remained significant.

CAC progression was associated with older age, higher fibrinogen, and higher SDI. After adjustment for follow-up time, BMI, and age, only SDI remained significant (p=0.002, OR=1.55, 95% CI 1.18–2.07).

AS progression was associated with older age, increased SDI and disease duration. After adjusting for follow-up time, age, and BMI, only SDI remained a significant factor (p=0.01, OR=1.48, 95% CI 1.10–2.03).

Conclusion: In this group of women with SLE, the progression of PI, CAC, and AS was not significantly associated with most traditional CV risk factors after adjustment for age, BMI, and follow-up time. However, progression in PI, CAC, and AS was associated with higher SLE damage as assessed by the SDI.

788

Plasma Tumor Necrosis Factor-Like Weak Inducer of Apoptosis (sTWEAK) Levels Are Associated with Carotid Plaque Progression in Women with SLE. Maureen A. McMahon[1], E. Lorenco[1], Jennifer M. Grossman[1], Lori Sahakian[1], John D. FitzGerald[1], Nagesh Ragavendra[1], Christina Charles-Schoeman[1], Alan H. Gorn[1], Michael H. Weisman[2], Daniel Wallace[3], Bevra H. Hahn[1] and Brian Skaggs[1]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Cedars Sinai Med Ctr, Los Angeles, CA, [3]Cedars-Sinai/UCLA, Los Angeles, CA

Background/Purpose: Women with SLE have increased risk of coronary artery disease (CAD) that is not adequately explained by traditional risk factors**.** We previously reported that pro-inflammatory HDL (piHDL) and elevated leptin independently confer increased risk for the concurrent presence of carotid artery plaque (ATH). It is unknown, however, whether these or other biomarkers predict future progression of ATH in SLE. Soluble tumor necrosis factor-like weak inducer of apoptosis (sTWEAK) is a cytokine and member of the TNF superfamily. Although sTWEAK levels have been inversely correlated with ATH in the general population, higher levels have been positively associated with acute MI and increased mortality in end stage renal disase patients with high levels of inflammation. In addition, higher sTWEAK levels have been associated with both synovitis in RA and with lupus nephritis, and urinary TWEAK levels have been proposed as a biomarker for lupus nephritis. Here we hypothesize that sTWEAK, piHDL, and other traditional and novel biomarkers in SLE are associated the progression of subclinical ATH in SLE. To determine this, we measured plasma biomarkers and the progression of plaque using carotid ultrasound in a cohort of SLE patients.

Methods: Female SLE and healthy age-and gender- matched subjects not taking statins at baseline were studied. B-mode and Doppler scanning of carotid arteries was performed at baseline and at 24– 36 months. Antioxidant function of HDL was measured as the change in fluorescence intensity caused by oxidation of DCFH by LDL in the presence or absence of test HDL. Fluorescence in the absence of HDL was normalized to 1.0. Values greater than 1.0 after the addition of HDL indicated piHDL. Plasma Leptin and soluble TWEAK levels were measured in the baseline blood samples using ELISA (R&D Biosystems).

Results: Repeat carotid ultrasounds were completed on 200 women with SLE. The mean age of the SLE group was 43.7 ± 12.5 years. Plaque progression (defined as new or increased plaque) was seen in 40 subjects (20%). Mean baseline plasma sTWEAK levels were significantly increased in SLE patients with plaque progression compared to those without: 4093.7 ± 7901.0 vs. 1654.3 ± 3090.1 pg/mL in controls (p<0.02). Similar to factors associated with baseline plaque, piHDL (p<0.001), leptin in the highest quartile (>34ng/mL) (p=0.02), age >48 (p<0.001), diabetes (p=0.001), and plaque on the baseline ultrasound (p<0.001) were also associated with plaque progression. Using logistic regression to control for traditional cardiac risk factors, the factors still significantly associated with plaque progression in SLE included sTWEAK in the highest quartile (>1740 pg/mL) (OR 2.8, p=0.04), piHDL (OR 4.4, p=0.008), age >48 (OR 2.7, p=0.04), and DMII (OR 26.0, p=0.001).

Conclusion: In conclusion, plasma TWEAK and piHDL levels are significantly and independently associated with plaque progression on carotid ultrasound in patients with SLE. A panel of novel and traditional biomarkers may be useful for prediction of which SLE patients are at risk for accelerated progression of ATH in SLE.

Immunoglobulin Concentrations and Infection Risk Among Patients with ANCA-Associated Vasculitis Treated with Rituximab or Cyclophosphamide. Ulrich Specks[1], Peter A. Merkel[2], Philip Seo[3], Robert F. Spiera[4], Carol A. Langford[5], Gary S. Hoffman[5], Cees G.M. Kallenberg[6], E. William St. Clair[7], Swati Tole[8], Paul Brunetta[9], Shuyi Shen[8], Nadia Tchao[10], Barri J. Fessler[11], Lisa Webber[12], Linna Ding[13], Lourdes P. Sejismundo[14], Kathleen Mieras[1], Deborah J. Phippard[10], Adam Asare[10], Noha Lim[10], David Ikle[15], Brett Jepson[15], Alice Lail[15] and Mark Mueller[16]. [1]Mayo Clinic, Rochester, MN, [2]Boston University School of Medicine, Boston, MA, [3]Johns Hopkins Vasculitis Center, Baltimore, MD, [4]Hospital for Special Surgery, New York, NY, [5]Cleveland Clinic, Cleveland, OH, [6]University Medical Center Groningen, Groningen, Netherlands, [7]Duke University Medical Center, Durham, [8]Genentech, Inc., South San Francisco, CA, [9]Genentech, So San Francisco, CA, [10]Immune Tolerance Network, Bethesda, MD, [11]Univ of Alabama-Birmingham, Birmingham, AL, [12]National Institute of Allergy and Infectious Diseases, [13]NIAID, Bethesda, MD, [14]Johns Hopkins University, Baltimore, MD, [15]Rho, Chapel Hill, NC, [16]Food & Drug Administration, Bethesda, MD

Background/Purpose: Patients (pts) with ANCA-associated vasculitis (AAV) are treated with immunosuppression and are at increased risk of infection. The incidence of low immunoglobulin (Ig) concentrations observed with rituximab (RTX) and cyclophosphamide (CYC) is therefore a potential concern. Limited data exist on the incidence and risk for infection of low Ig concentrations in AAV. We evaluated changes in Ig concentrations among patients (pts) treated with either RTX or CYC followed by azathioprine (CYC/AZA) in the RAVE trial (*NEJM* 2010), and investigated the impact of these changes on infection.

Methods: Post hoc analysis of RAVE, a trial of 197 pts with severe AAV randomized and treated with RTX followed by placebo (n=99) or CYC followed by AZA (n=98). Quantitative assays for IgM, IgG, and IgA were performed at baseline, 6 months (M), and 18M. Proportions of pts with low Ig (<lower limit of normal (LLN)) at each time point and the median changes in Ig at 6M and 18M were assessed, along with the rates of overall and serious infections.

Results: Of the 56 pts who had low Ig of any isotype at baseline, 36 (64%) entered with relapsing disease. Pts in both treatment groups had low Ig at baseline and the proportions with low Ig increased at 6M and 18M (Table 1). Median changes from baseline in Ig concentrations were similar in the RTX and CYC/AZA groups. In the RTX group, pts with low Ig levels at any time had received numerically higher quantities of glucocorticoids (GC) at baseline compared to those who did not have low Ig (IgM: 1.51 g prednisone or equivalent vs 1.03; IgG: 1.31 vs 1.27; IgA 1.73 vs 1.11; p=0.07, 0.45, 0.32, respectively). Rates of overall and serious infections were similar in pts with low Ig at any time compared to those with normal Ig levels (Table 2).

Table 1. Change from Baseline and Proportion of Patients with Low Ig (< LLN[&]) by Visit

	RTX	CYC/AZA
Baseline (n*)	99	94
IgM < LLN	16 (16.2%)	6 (6.4%)
IgG < LLN	18 (18.2%)	20 (21.3%)
IgA < LLN	5 (5.1%)	10 (10.6%)
6M (n*)	83	77
IgM		
Median Change from baseline (mg/dL)	−42.0	−42.5
< LLN	49 (59.0%)	36 (46.8%)
IgG		
Median change from baseline (mg/dL)	−259	−252
< LLN	54 (65.1%)	43 (55.8%)
IgA		
Median change from baseline (mg/dL)	−48	−59
< LLN	25 (30.1%)	24 (31.2%)
18M (n*)	69	60
IgM		
Median Change from baseline (mg/dL)	−38.0	−23.5
< LLN	27 (39.1%)	17 (28.3%)
IgG		
Median Change from baseline (mg/dL)	−185	−131
< LLN	31 (44.9%)	19 (31.7%)
IgA		
Median Change from baseline (mg/dL)	−44	−42
< LLN	19 (27.5%)	16 (26.7%)

[&] LLN: IgM 23 mg/dL (16 – 19 yrs), 40 mg/dL (≥20 yrs); IgG 549 mg/dL, 700 mg/dL; IgA 61 mg/dL, 70 mg/dL
* n indicates number of subjects with available data at the corresponding visits.

Table 2. Rates of overall and serious infectious events (SIE) in patients with low and normal Ig levels

	RTX		CYC/AZA	
	Normal IgM	**IgM < LLN at any time**	**Normal IgM**	**IgM < LLN at any time**
N (pt-year)	45 (51.5)	54 (74.7)	57 (66.5)	39 (51.2)
rate of infection per patient year	1.61	1.28	1.08	1.56
rate of SIE per patient year	0.17	0.08	0.17	0.18
	Normal IgG	**IgG < LLN at anytime**	**Normal IgG**	**IgG < LLN at anytime**
N (pt-year)	36 (37.1)	63 (89.1)	43 (48.4)	53 (69.3)
rate of infection per patient year	1.86	1.23	1.16	1.38
rate of SIE per patient year	0.22	0.08	0.19	0.16
	Normal IgA	**IgA < LLN at anytime**	**Normal IgA**	**IgA < LLN at any time**
N (pt-year)	70 (86.3)	29 (39.9)	66 (77.4)	30 (40.3)
rate of infection per patient year	1.30	1.68	1.24	1.39
rate of SIE per patient year	0.14	0.08	0.18	0.15

Conclusion: A substantial proportion of pts with AAV receiving either RTX or CYC/AZA had low Ig concentrations at baseline, perhaps resulting from immunosuppression prior to trial entry. The proportions of pts with low Ig increased at 6M and 18M in both groups, and median changes in Ig levels were similar in both groups. Low Ig was not associated with increased rates of infections.

Association of Ferritin Antibodies with GCA/PMR: New Biomarker for Diagnosis. Niklas T. Baerlecken[1], Anna Linnemann[2], Wolfgang L. Gross[3], Frank Moosig[4], T.R. Vazquez-Rodriguez[5], Miguel Gonzalez-Gay[6], Javier Martin[7], Ina Kötter[8], Joerg C. Henes[9], Inga Melchers[10], Peter Vaith[11], Reinhold E. Schmidt[12] and Torsten Witte[13]. [1]MD, Hannover, Germany, [2]Student, Hannover, Germany, [3]Medical University at Lubeck, Lubeck, Germany, [4]Stormarnzing 156, Bad Bramstedt, Germany, [5]MD, Spain, [6]Hospital Marques De Valdecilla, Santander, Spain, [7]Instituto de Parasitologia y Biomedicina Lopez-Neyra (CSIC), Granada, Spain, [8]MD, Tübingen, Germany, [9]University Hospital Tuebingen, Tuebingen, Germany, [10]PhD, Freiburg, Germany, [11]Medizinische Uni Klinik, Freiburg, Germany, [12]Hannover Medical School, Hannover, Germany, [13]MD, Hanover, Germany

Background/Purpose: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are relatively common inflammatory disorders. Establishing the diagnosis however may be difficult, since so far no specific markers of the disorders have been described.

The goal of our study was to find new antibodies as markers of PMR and/or GCA.

Methods: As a screening procedure, we used protein array technology for detection of possible new antigens in GCA and PMR. 6 different GCA sera were screened for the presence of antibodies. In the second step, the results of the protein array were confirmed by an ELISA for the detection of antibodies against human ferritin heavy chain and a second ELISA for the detection of antibodies against N-terminal 27 amino acids of the human ferritin heavy chain. Sera of patients with only GCA (n=85) and only PMR (n=47) and both PMR and GCA (n=31) were collected in Hannover (n=56), Lugo (n=35), Bad Bramstedt (n=22) and Tübingen (n= 14). Sera from patients with SLE (n=40), RA (n=36), *fever above 38.5°C* caused by different infections (n=70) and blood donors (n=180) were obtained in Hannover. The study was approved by our local ethical committee (project number 4928), and the patients provided informed consent.

Results: We could detect antibodies against human ferritin heavy chain in 12/71 (17%) of the sera obtained from patients (treated and untreated patients combined) with both GCA and PMR and in 4/28 (14%) of the patients with isolated GCA and in 8/43 (19%) of the patients with isolated PMR. The presence of IgG antibodies against ferritin was 22% in the 37 patients with GCA and/or PMR, from whom sera were obtained before steroid treatment was initiated. In SLE, the prevalence of autoantibodies against ferritin was 1/32 (3%). 0/36 (0%) patients with RA were positive. In the further control groups, the prevalence of autoantibodies against ferritin was 4/34 (12%) in fever above 38.5°C and 0/50 (0%) in blood donors.

In the ELISA for antibodies against N-terminal 27 amino acids of the human ferritin heavy chain 64/117 (55%) of the sera obtained from all patients (treated and untreated patients combined) with isolated GCA, isolated PMR and combined GCA and PMR were positive. The prevalence of IgG antibodies against the ferritin peptide was 92% in the 36 GCA and/or PMR patients, from whom sera were obtained before steroid treatment was initiated. In the sera of GCA and PMR patients drawn in remission, the prevalence of antibodies was only 13%. 22/32 (69%) of the patients with disease flares of GCA and PMR had antibodies. In other autoimmune disorders, the prevalence was 11/38 (29%) in active SLE and 1/36 (3%) in RA. In *blood donors*, the prevalence was 1/100 (1%).

Conclusion: In conclusion, antibodies against the human ferritin peptide were present in up to 92% of untreated GCA and PMR patients at disease onset. They can be useful as a diagnostic and activity marker of PMR and GCA.

Immunological Signature Discriminates Active and Inactive Patients with Takayasu Arteritis. David Saadoun[1], Benjamin Terrier[2], Guillaume Geri[3], Wahiba Chaara[4], Michelle Rosenzwajg[5], Nathalie Costedoat-Chalumeau[3], Pierre Fourret[6], Lucile Musset[3], Adrien Six[4], David Klatzmann[5] and Patrice Cacoub[3]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]Pitié-Salpêtrière Hospital, Paris, France, [3]CHU Pitié-Salpêtrière, Paris, France, [4]Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Paris, France, [5]Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Paris, France, [6]Anatomopathology, Groupe Hospitalier Pitié-Salpetrière, Paris, France

Background/Purpose: Takayasu arteritis (TA) is a large-vessel vasculitis of unknown origin. Data on predictive criteria of TA activity are lacking. Objective: To identify an immunological signature that help to discriminate active and inactive patients with TA.

Methods: Thirty TA patients (11 active untreated [aTA] and 19 treated and inactive [iTA]) fulfilling the American College of Rheumatology criteria and 20 healthy donors (HD) were included. We measured levels of 26 cytokines in culture supernatants using Luminex and ELISA. We used a multivariate analysis in order to identify a signature that discriminate active and inactive TA patients. Flow cytometric analysis of peripheral blood mononuclear cells was performed for cell surface markers, intracellular production of cytokines and FoxP3 expression. Artery biopsies from 3 TA patients and 3 controls were tested by immunohistochemistry.

Results: Multivariate analysis identified a cytokine signature discriminating active and inactive TA patients with positive and negative predictive values of 100% and 95%, respectively. Using FACS analysis, we observed the expansion of Th17 cells in peripheral blood of aTA compared with iTA and HD (3.0 vs. 1.3

and 0.6 %, P=0.0005 and P<0.0001, respectively), as well as Th1 cells (24.2 vs. 10.7 and 18.3 %, P<0.0001 and P=0.02, respectively) and IFN-g producing CD8+ T cells (51.0 vs. 36.9 and 36.0 %, P=0.02 and P=0.01, respectively). Immunohistochemical analysis revealed an expression of IL-17A, IFN-g, IL-6, CCL20 and TLR5 within large-vessel inflammatory infiltrates of TA patients,

Expansion of IL-21-producing CD4+ T cells was also observed in peripheral blood of aTA compared with iTA and HD (7.9 vs. 4.1 and 1.7%, P=0.001 and P<0.0001, respectively), that correlated with Th17cells (r=0.68; P<0.0001) and Th1 cells (r=0.56; P=0.002) expansion. Stimulation of purified CD4+ T cells from TA patients with human recombinant IL-21 increased Th17 cells and decreased FoxP3 expression. In contrast, the blockade of IL-21 using IL-21R/Fc chimera markedly decreased production of IL-17A and increased FoxP3 expression.

Conclusion: We identified an immunological signature that discriminate active and inactive Takayasu arteritis patients with high sensitivity and specificity. Cytokine measurement, FACS and immunochemistry analyses suggest the major role of Th1, Th17 and IL-21 in the pathogenesis of TA. IL-21 exerts a critical role in modulating Th1 and Th17 responses and regulatory T cells in TA, and might represent a potential target for novel therapy.

Serum Proteins Reflecting Inflammation, Injury, and Repair As Biomarkers of Disease Activity in ANCA-Associated Vasculitis. Paul A. Monach[1], Roscoe L. Warner[2], Gunnar Tomasson[3], Ulrich Specks[4], John H. Stone[5], Linna Ding[6], Fernando Fervenza[4], Barri J. Fessler[7], Gary S. Hoffman[8], David Ikle[9], Cees GM Kallenberg[10], Jeffrey Krischer[11], Carol A. Langford[12], Mark Mueller[13], Philip Seo[14], E. William St Clair[15], Robert Spiera[16], Nadia Tchao[17], Steven R. Ytterberg[4], Kent J. Johnson[2] and Peter A. Merkel[3]. [1]Boston University, Boston, MA, [2]University of Michigan, Ann Arbor, MI, [3]Boston University School of Medicine, Boston, MA, [4]Mayo Clinic, Rochester, MN, [5]Massachusetts General Hospital, Boston, MA, [6]NIAID, Bethesda, MD, [7]Univ of Alabama-Birmingham, Birmingham, AL, [8]Cleveland Clinic Found A50, Cleveland, OH, [9]Rho, Chapel Hill, NC, [10]University Medical Center Groningen, Groningen, Netherlands, [11]University of South Florida, Tampa, FL, [12]Cleveland Clinic, Cleveland, OH, [13]Food & Drug Administration, Bethesda, MD, [14]Johns Hopkins Vasculitis Center, Baltimore, MD, [15]Duke University Medical Center, Durham, NC, [16]Hospital for Special Surgery, New York, NY, [17]Immune Tolerance Network, Bethesda, MD

Background/Purpose: To identify biomarkers that distinguish between active ANCA-associated vasculitis (AAV) and remission.

Methods: Twenty-eight serum markers representing diverse aspects of the biology of AAV were measured before and 6 months after treatment in a large clinical trial in AAV. 186 subjects enrolled in the Rituximab in ANCA-Associated Vasculitis (RAVE) trial were studied. ESR and CRP levels were available for comparison. The primary outcome was the ability of markers to distinguish severe AAV (BVAS/WG ≥ 3 at screening) from remission (BVAS/WG = 0 at month 6) in the same patients (n=137), using areas under receiver operating characteristic (ROC) curves (AUC). Secondary outcomes included distinction of severe AAV (n=186) from healthy controls (n=68), and distinction of mild AAV (n=25) from remission (n=137) at month 6.

Results: All subjects had severe active vasculitis (median BVAS/WG score 8) at screening. Among 137 subjects in remission at month 6, 24 of 28 markers showed significant declines (see **Table**). ROC analysis indicated that levels of CXCL13 (BCA-1), MMP3, and TIMP-1 best discriminated between active AAV and remission, with AUC > 0.8 (P < 0.05 vs. AUC = 0.76 for ESR, see **Figure**). Comparing active AAV to remission: CXCL13 > 70 pg/ml was 77% sensitive and 85% specific; MMP3 > 38 ng/ml was 82% sensitive and 88% specific; and TIMP-1 > 270 ng/ml was 78% sensitive and 82% specific. These three markers were also among the best (AUC > 0.9) in distinguishing active AAV from healthy controls. Multivariable modeling showed that a combination of 5 markers (ACE, GM-CSF, MMP3, TIMP-1, and ESR) distinguished severe AAV from remission quite well (AUC 0.96), but had only modest ability to distinguish mild AAV (median BVAS/WG score 1) from remission (AUC 0.78).

Table. Marker levels in severe active AAV (screening) and in remission 6 months later, in the same patients.

Marker*	Units	Screening Median (25%; 75%) N = 137	Month 6 Remission Median (25%; 75%) N = 137

* P<0.0001 by Signed Rank test. † P=0.0001–0.001. ‡ P=0.001–0.05.

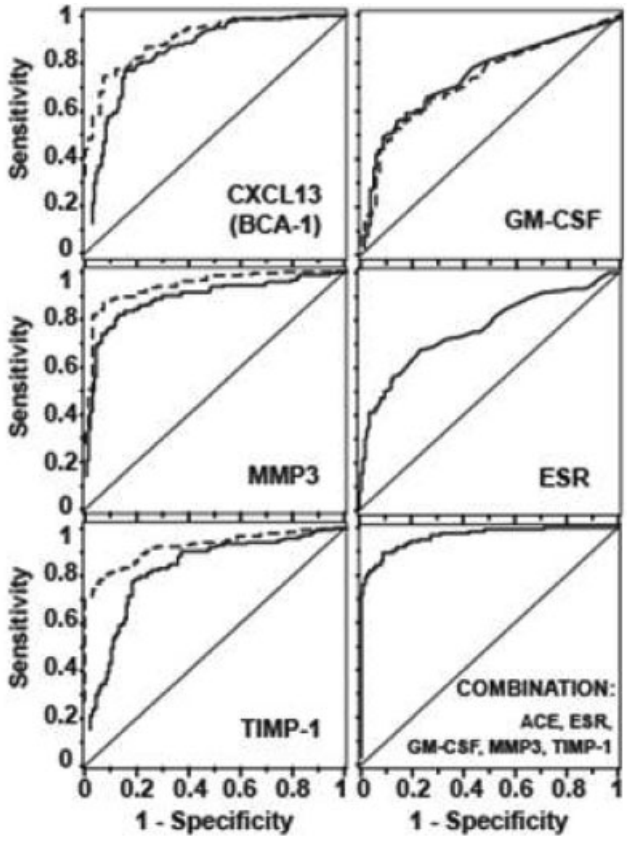

Figure. Receiver operating characteristic (ROC) curves for 5 individual markers and for a combination of 5 markers, comparing active vasculitis to remission (solid curves) or to healthy controls (dashed curves, not done for ESR or the combination of markers).

Conclusion: Many markers are elevated in severe active AAV and decline with treatment, but CXCL13, MMP3, and TIMP-1 distinguish between active AAV and either remission or healthy controls better than the other markers studied, and ACE, GM-CSF, and ESR provide additional information. These markers have potential clinical utility for measuring disease activity in AAV. Finally, the finding that levels of CXCL13—a chemokine specific for B cells—correlate well with disease activity may provide insight into the pathophysiology of AAV.

In Situ Immune Complex (MPO-anti MPO antibody) and Complement 3 cause Glomerular Capillary Injury in Human MPO-ANCA Associated Glomerulonephritis. Soko Kawashima, Yoshihiro Arimura, Yoshinori Komagata, Shinya Kaname and Akira Yamada. Kyorin University School of Medicine, Tokyo, Japan

Background/Purpose: Pauci-immune necrotizing glomerulonephritis(NCGN) is often seen in a patient of myeloperoxidase anti-neutrophil

cytoplasmic antibody (MPO-ANCA) associated vasculitis. MPO-ANCA has been thought to be involved in the activation of neutrophils in the pathogenesis of NCGN. Recent studies suggest that immunoglobulins precipitated on the glomerular capillaries might play some role in the pathogenesis of MPO-ANCA associated GN. Here, we investigated a possible role of MPO, IgG, complements and MPO-positive cells in the pathogenesis of MPO-ANCA associated GN.

Methods: Renal specimen including 317 glomeruli obtained from 20 patients with MPO-ANCA associated GN were analyzed. Glomerular infiltration of MPO-positive cells, deposition of extracellular MPO and endothelial cell injury were analyzed and the number of infiltrating MPO-positive cells was scored in each glomerulus, especially in early stage of the disease. Colocalization of MPO, IgG, C3 and CD34 deposition was analyzed. Immunofluorescence staining for triple staining (MPO, IgG and CD34) were performed for samples of renal biopsies.

Results: All of 20 patients showed a weak but significant staining for IgG (pauci-immune GN), which was often accompanied by MPO deposition along the glomerular capillary walls. Double positive (MPO & IgG) deposition was detected in 45 glomeruli (14%) mainly with low activity and chronicity. Double positive (MPO & C3) deposition was detected in 41glomeruli (13%) mainly with low activity and chronicity. Triple positive (MPO, IgG & C3) deposition was detected in 15 glomeruli (5%) mainly with low activity and chronicity. CD34 staining was lost around the area where MPO and IgG were detected, suggesting the endothelial injury may be induced by MPO- and IgG-associated pathogenic mechanism. Deposition of MPO, IgG and C3 was observed along the glomerular capillary walls predominantly in the early stage of MPO-ANCA associated GN.

Conclusion: These results indicate that not only the activation of neutrophils, but also MPO and the immune complexes composed of MPO-anti MPO antibody may play some direct roles in the pathogenesis of glomerular capillary injury in the early phase of human MPO-ANCA associated GN.

794

Increased Frequency of Circulating Follicular Helper T-Cells (T_{FH}) in Patients with Granulomatosis with Polyangiitis. Wayel H. Abdulahad[1], Nikola Lepse[1], Henko Tadema[1], Minke G. Huitema[1], Berber Doornbos-van der Meer[1], Coen Stegeman[1], Pieter C. Limburg[1], Peter Heeringa[2] and Cees GM Kallenberg[1]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Netherlands

Background/Purpose: Follicular helper T cells (T_{FH}) are a newly distinguishable subset of Th *cells* characterized by IL-21 production that influences B-cell differentiation and antibody production. Recent studies support the concept that T_{FH} cells are an important player in antibody-mediated *autoimmune* diseases. In the present study, we aimed to explore a possible role for T_{FH} cells in the immunopathogenesis of granulomatosis with polyangiitis *(GPA).*

Methods: Peripheral blood from 33 GPA-patients in remission and 22 age-matched healthy controls (HCs) were stimulated in vitro with Phorbol-Myristate-Acetate and Calcium-Ionophore in the presence of Brefeldin-A. Intracellular IL-21 was used as a marker for T_{FH} cells. Since Th-17 cells produce a low level of IL-21, IL-17 was also included in the analysis to discriminate between T_{FH} cells ($IL\text{-}17^{-}IL\text{-}21^{+}$) and Th-17 cells ($IL\text{-}17^{+}IL\text{-}21^{+/-}$). The frequencies of T_{FH} cells were determined by 4-color cytometric detection of CD4 (negatively gated as $CD3^{+}CD8^{-}$ cells), and intracellular cytokine expression of IL-21 and IL-17. The mRNA expression level of transcription factors Bcl-6 (for T_{FH}) and RoRgc (for Th17) were evaluated in lysed cell from GPA-patients and HCs. To investigate the effect of IL-21 on antibody-production, PBMCs from GPA-patients were stimulated in vitro with BAFF/IL-21 for 12 days and total IgG was measured in supernatants by ELISA. In addition, the expression level of IL-21-receptor on B-cells was analyzed in GPA-patients and HCs.

Results: Percentages of circulating T_{FH} cells were significantly elevated in GPA-patients compared to HCs ($P = 0.001$). The expression level of Bcl-6 was significantly higher in GPA-patients, whereas no difference was found in RoRgc between GPA-patients and HCs. The hallmark cytokine for T_{FH}, IL-21, enhance the production of IgG *in vitro* in stimulated PBMCs from GPA-patients. Moreover, frequencies of T_{FH} cells were significantly increased in ANCA-positive patients (n=21) in comparison to HCs (P= 0.0009), whereas no such difference was found between ANCA-negative patients (n=12) and HCs.

Conclusion: Increased frequencies of circulating T_{FH} cells producing IL-21 suggest a role for these cells in the immunopathogenesis of GPA. Blockade of IL-21 could constitute a new therapeutic strategy for GPA.

Musculoskeletal Conditions Are the Most Common Causes of Work Limitation in U.S. Adults. Kristina A. Theis[1], Charles G. Helmick[1] and Jennifer M. Hootman[2]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]Centers for Disease Control and Prevention, Kennesaw, GA

Background/Purpose: People with work limitations are less likely to be employed, contribute to payroll taxes, or add to national productivity than those without work limitations, and chronic diseases are among the major causes of work limitation. However, there are existing interventions that can decrease, delay, or mitigate work limitations that may be especially effective if targeted to appropriate populations. We estimated the most common causes of work limitation among U.S. adults overall and among those with 7 common chronic diseases.

Methods: The data source was the 2009 National Health Interview Survey, an annual survey designed to be nationally representative of civilian, non-institutionalized U.S. adults (age ≥18 years) conducted by in-person interview (n = 27,731; response rate = 65%). Work limitation was identified by self-report of being "unable to work" or "limited in work." Respondents with limitations were shown a flashcard of 18 health conditions plus an "other" category and asked to identify all health problems causing their difficulties. All respondents were separately asked about the presence of 7 chronic conditions. Arthritis was identified by "Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" The same question wording was used for hypertension, stroke, asthma, cancer, diabetes, and heart conditions (coronary heart disease, angina, heart attack, and any other kind of heart condition or disease). Diagnoses were not mutually exclusive. Weighted proportions and 95% confidence intervals (CI) were calculated, accounting for the complex sample design (SAS 9.2).

Results: Overall, 28.4 million (12.5%, 95% CI = 12.0–13.1) U.S. adults reported work limitation. The most commonly reported causes of work limitation were back/neck problems (25.8%, 95% CI = 24.0–27.6) and arthritis/rheumatism (19.4%, 95% CI = 17.7–21.2), followed by depression/anxiety/emotional problems (15.1%, 95% CI = 13.6–16.6), heart problems (14.6%, 95% CI = 13.2–16.0), and musculoskeletal/connective tissue problems (13.1%, 95% CI = 11.6–14.7). Among those with 7 common chronic diseases and work limitation, arthritis/rheumatism and/or back/neck problems were among the top 3 causes for each (Table).

Table. Most Common Causes of Work Limitation by Chronic Condition, weighted prevalence estimates and proportions with 95% confidence intervals (CI), NHIS, 2009

Chronic condition	Causes of work limitation	Prevalence (in 1,000s)	Proportion in % (95% CI)
Hypertension	Back/neck problems	4,077	26.4 (24.0–28.7)
	Arthritis/rheumatism	3,892	25.2 (22.7–27.7)
	Hypertension	3,295	21.3 (19.0–23.6)
Stroke	Stroke	1,146	39.3 (34.6–44.0)
	Heart problems	742	25.4 (22.3–28.5)
	Arthritis/rheumatism	690	23.7 (19.9–27.4)
Asthma	Lung/breath problems	2,130	33.5 (29.9–37.0)
	Back/neck problems	1,753	27.6 (24.0–31.1)
	Arthritis/rheumatism	1,398	22.0 (18.9–25.0)
Cancer	Cancer	1,193	26.5 (23.1–29.8)
	Back/neck problems	1,108	24.6 (21.1–28.1)
	Arthritis/rheumatism	1,099	24.4 (20.7–28.0)
Diabetes	Diabetes	3,446	51.8 (48.0–55.6)
	Arthritis/rheumatism	1,745	26.2 (22.6–29.9)
	Back/neck problems	1,653	24.9 (21.3–28.4)
Heart conditions	Heart problems	184	41.9 (38.8–45.1)
	Arthritis/rheumatism	2,171	23.5 (20.7–26.3)
	Back/neck problems	2,152	23.3 (20.5–26.1)
Arthritis	Arthritis/rheumatism	5,175	33.5 (30.7–36.3)
	Back/neck problems	4,997	32.4 (29.8–34.9)
	Musculoskeletal/ connective tissue problems	2,300	19.4 (17.3–21.6)

Conclusion: In addition to being the most common causes of work limitation overall, arthritis/rheumatism and/or back/neck problems were among the top 3 causes of work limitation regardless of chronic condition, suggesting that addressing work limitation caused by musculoskeletal conditions is important no matter what other chronic conditions are present.

Evidence-based public health interventions (e.g., the Chronic Disease Self-Management Program) and vocational rehabilitation may delay or reverse disability among adults with chronic conditions experiencing work limitations.

A Population-Based Approach to Establishing the National Burden of Severe Hip and Knee Osteoarthritis In Australia. Ilana N. Ackerman[1] and Richard H. Osborne[2]. [1]The University of Melbourne, Melbourne, Australia, [2]Deakin University, Melbourne, Australia

Background/Purpose: Severe hip and knee osteoarthritis (OA) is an ongoing public health problem in Australia, as evidenced by the growing demand for joint replacement surgery. However, the burden of these conditions has not been evaluated using a national, population-based approach. Rising rates of obesity are also of great concern, similar to many developed countries. This study aimed to investigate the prevalence and impact of severe hip and knee OA in Australia and examine the relationship between obesity and wellbeing in OA.

Methods: Five thousand Australians were randomly selected from the federal government electoral roll and invited to participate. Participants completed a questionnaire to identify doctor-diagnosed hip and knee OA and evaluate the severity and burden of these conditions. Pain, stiffness and function were assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) (range 0–100; scored best-worst). Total WOMAC score was used to classify OA severity (<7 = asymptomatic, 7–38 = mild-moderate, ≥39 = severe). Health-Related Quality of Life (HRQoL) was assessed using the Assessment of Quality of Life (AQoL) instrument (range −0.04–1.00; scored worst to best; minimal important difference 0.06 AQoL units). Body Mass Index (BMI) was used to classify underweight/normal weight (BMI ≤24.99 kg/m^2), overweight (BMI 25–29.99) and obesity (BMI ≥30). Analysis of covariance was used to determine the effect of OA severity on HRQoL and the effect of obesity on HRQoL, pain, stiffness and function, after adjusting for age and gender.

Results: Data for analysis were available from 1153 participants (23%). The prevalence of hip OA was 4.9% (n=56) and prevalence of knee OA was 8.2% (n=95). The specific prevalence of severe hip and knee OA was 2.3% (n=27) and 3.2% (n=37), respectively. Reduced HRQoL was seen with increasing OA severity ($F=59.02$, $p<0.01$ for hip OA; $F=67.40$, $p<0.01$ for knee OA); participants with severe OA had extremely low HRQoL (mean AQoL 0.34 for hip OA, 0.39 for knee OA), compared to those with mild-moderate OA (mean AQoL 0.75 for hip OA, 0.72 for knee OA), those who were asymptomatic (mean AQoL 0.77 for hip OA, 0.81 for knee OA) and those without OA (mean AQoL 0.82 without hip OA, 0.83 without knee OA).

Obesity was strongly associated with poorer wellbeing in OA, even after adjusting for age and gender. Of those with hip OA, participants who were obese had the highest pain (mean WOMAC pain 50.3 vs 24.4 for underweight/normal weight; $F=3.69$, $p=0.03$) and lowest HRQoL (mean AQoL 0.33 vs 0.59 for underweight/normal weight; $F=3.88$, $p=0.03$). In knee OA, those who were obese had the highest pain (mean WOMAC pain 40.0 vs 27.4 for underweight/normal weight; $F=3.99$, $p=0.02$), greatest stiffness (mean WOMAC stiffness 44.3 vs 29.9 for underweight/normal weight; $F=3.86$, $p=0.03$) and poorest function (mean WOMAC function 40.6 vs 23.7 for underweight/normal weight; $F=5.07$, $p=0.01$).

Conclusion: This study provides the first Australian data on the prevalence of severe hip and knee OA and clearly shows that severe OA is associated with markedly reduced HRQoL. The relationship between obesity and poorer wellbeing in OA highlights the importance of targeted interventions for this patient group.

Does Physical Performance Mediate the Effect of Knee Osteoarthritis and Risk of Indoor and Outdoor Falls in Older Men and Women? Uyen Sa D. Nguyen[1], Yuqing Zhang[1], Tyler J. VanderWeele[2], Jingbo Niu[1], Robert H. Shmerling[3], Douglas P. Kiel[4], Suzanne G. Leveille[5], Carol A. Oatis[6] and Marian T. Hannan[7]. [1]Boston University School of Medicine, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Beth Israel Deaconess Med Ctr, Boston, MA, [4]Hebrew Senior Life/Harvard Medical School, Boston, MA, [5]University of Massachusetts-Boston, Boston, MA, [6]Arcadia University, Glenside, PA, [7]Hebrew SeniorLife & Harvard Med Sch, Boston, MA

Background/Purpose: Knee osteoarthritis (OA) and falls are common in older adults and limit mobility. Research has shown that having knee OA increases the risk of indoor falls for men and outdoor falls for women. It is possible that men and women with OA differ in physical performance (PP) ability, which could potentially explain the differences in the effect of knee OA on the risk of indoor and outdoor falls by gender. We explored to what extent the effect of knee OA on the risk of indoor and outdoor falls may possibly be mediated by PP and whether such a mediating effect varied by gender.

Methods: This study included 764 participants from the MOBILIZE Boston Study, a population-based cohort of older adults. Knee OA was assessed at baseline using the ACR clinical criteria. Falls data were prospectively collected using monthly calendars, with phone follow-up to assess location of falls. PP was measured at baseline using the Short Physical Performance Battery (SPPB, range 0–12, with a higher score indicating better performance). Using negative binomial regression, we examined the sex-specific association of knee OA with the risk of indoor falls and with outdoor falls adjusting for confounders. We assessed the extent such associations were mediated by SPPB using linear and negative binomial regressions, and a counterfactual approach of mediation analysis to estimate the direct and indirect effect, controlling for potential confounders.

Results: Of 764 participants (486 women and 278 men, mean age: 78 years, mean BMI: 27.3), 25% had ACR-defined clinical knee OA. Over an average of 2.2 years, 60% of participants had ≥ 1 fall, 318 (42%) had ≥ 1 indoor fall, and 300 (39%) had ≥ 1 outdoor fall. Mean SPPB (SD) scores for people with and without knee OA were 9.1 (2.6) and 9.7 (2.3) in men, and 8.6 (2.8) and 9.3 (2.5) in women. Having a higher SPPB *decreased* the risk of *indoor* falls in men and *increased* the risk of *outdoor* falls in women. Also, men and women with knee OA had lower SPPB scores than their counterparts without OA (Table 1). In men, the rate ratio (RR) for the total effect of knee OA compared with no OA (Table 2) on risk of *indoor* falls in men was 1.6 (95%CI: 1.0, 2.5). Adjusting for SPPB decreased the RR for the direct effect of knee OA on risk of indoor falls in men by 16%. For women, the RR for the total effect of OA on risk of *outdoor* falls in women was 1.7 (95%CI: 1.2, 2.4). Adjusting for SPPB increased the RR for the direct effect of OA on risk of outdoor falls by 13%.

Table 1. Associations among Knee OA, SPPB, and Risk of Indoor and Outdoor Falls in Men and Women: The MOBILIZE Boston Study

		Each 1 Unit Increase in SPPB and Risk of Falls[1]		SPPB Scores in OA vs. No OA[2]	
	Falls	RR (95% CI)	P-Value	Mean Difference	P-Value
Men	Indoor	0.91 (0.83, 1.01)	0.07	−0.67	0.025
Women	Outdoor	1.11 (1.03, 1.21)	0.01	−0.50	0.03

[1]From negative binomial regression model with falls as outcome and SPPB, knee OA, age, BMI, use of medications (anti-depressants, anti-psychotics, anti-hypertensives, and sedatives), no. of co-morbidities (high blood pressure, stroke, heart disease, diabetes, ulcer/stomach disease, kidney disease, anemia, cancer/skin cancer, rheumatoid arthritis), and history of falls as predictors.
[2]From linear regression with baseline SPPB as outcome and knee OA, age, BMI, use of medications (anti-depressants, anti-psychotics, anti-hypertensives, and sedatives), no. of co-morbidities (high blood pressure, stroke, heart disease, diabetes, ulcer/stomach disease, kidney disease, anemia, cancer/skin cancer, rheumatoid arthritis), and history of falls as predictors, irrespective of falls.

Table 2. Rate Ratio for the Association between Knee OA and Rate of Indoor and Outdoor Falls

		Rate Ratio (95% CI)					
				Adjusted[2] with SPPB			
	Falls	Unadjusted	Adjusted[1] w/o SPPB	Direct Effect	Indirect Effect	Total Effect	Δ in RR
Men	Indoor	1.39 (0.83, 2.32)	1.58 (0.99, 2.52)	1.48 (0.93, 2.37)	1.06 (0.98, 1.16)	1.58 (0.99, 2.52)	16%
Women	Outdoor	1.64 (1.15, 2.34)	1.70 (1.21, 2.40)	1.81 (1.28, 2.55)	0.95 (0.89, 1.01)	1.71 (1.22, 2.42)	−13%

[1]Adjusted for age, BMI, use of medications (anti-depressants, anti-psychotics, anti-hypertensives, and sedatives), no. of co-morbidities (high blood pressure, stroke, heart disease, diabetes, ulcer/stomach disease, kidney disease, anemia, cancer/skin cancer, rheumatoid arthritis), and history of falls.
[2]Adjusted for above covariates and SPPB: (a) Direct Effect (DE) is the effect of knee OA on risk of falls adjusting for covariates including SPPB; (b) Indirect Effect (IE) is the effect of OA mediated by SPPB on risk of falls; (c) Total Effect (TE) is the product of the estimates for Direct and Indirect effect, e.g., RR(DE)*RR(IE); (d) Δ in RR is % change in estimates before and after adjusting for SPPB, e.g., [RR(TE)-RR(DE)]/[RR(TE)-1].

Conclusion: Among older individuals with knee OA, the increased risk of indoor falls in men and outdoor falls in women may be partially explained by differences in physical performance, but in opposite directions. It is possible that women with higher SPPB may be more mobile when outdoors, thus may be more likely to fall. Future studies should examine specific mechanisms why physical performance affect risk of indoor and outdoor falls differently for men and women.

798

Trajectory of Weight Associated with Arthritis: A Population-Based Longitudinal Cohort Analysis. Orit Schieir[1], S. Hogg-Johnson[2] and E. M. Badley[3]. [1]University of Toronto, Toronto, ON, [2]Institute for Work and Health, and Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [3]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON

Background/Purpose: While it is known that both overweight and obesity are more prevalent in arthritis populations, the potential role of arthritis on trajectories of weight change has not been explored. The objective was to estimate associations between arthritis with and without activity limitation, on trajectories of weight in the adult Canadian general population over a 16-year period.

Methods: The present study was a longitudinal analysis of 8 cycles of the longitudinal Canadian National Population Health Survey (NPHS - 1994/95 to 2008/09). Every 2 years, NPHS participants completed a standardized questionnaire including self-reported diagnosed chronic conditions present for at least 6 months, socio-demographic variables and lifestyle/health behaviours, administered by trained interviewers. Descriptive statistics and time-lagged linear multi-level regression models were used to estimate the association between arthritis and the trajectory of weight over time, adjusting for both time-invariant (sex, baseline physical activity, activity limitation, and weight) and time-varying (age, income, smoking, alcohol) covariates. Time-varying joint effects of arthritis and activity limitation were examined with interaction terms.

Results: The NPHS included 14 117 participants aged 18+ years that were eligible for analysis. The mean age of the sample was 45 years, 54% were female, and 18% reported having arthritis at baseline. Results of linear multi-level regression analysis with time (measured as NPHS cycle) as the only predictor showed that overall, weight increased over time in the Canadian population with an average rate of change of 1.12 lbs (95% CI: −4.57, 6.82 lbs) every 2 years. The covariance between initial weight status and rate of change in weight was negative indicating that individuals with higher initial weights changed less over time (and vice versa). Results from analyses that included arthritis and interactions for arthritis with time as predictors, showed that persons with arthritis had a higher average starting weight (+3.61 lbs, 95% CI: 2.95 – 4.26 lbs) and a smaller but still positive rate of change of 0.4 lbs every 2 years relative to Canadians without arthritis. Analyses that included interactions for arthritis with activity limitation and with time, showed that persons with arthritis but without activity limitation, and persons with arthritis and activity limitation, had higher average starting weights (+3.24, and +4.34 lbs, respectively) and smaller but still positive rates of change relative to Canadians without arthritis and no activity limitation. Results were unchanged after adjusting for time-invariant and time-varying predictors.

Conclusion: Persons with arthritis, and persons with arthritis and activity limitation in particular, had higher average starting weights and, lower but nevertheless positive increases in weight over time suggesting that primary prevention initiatives providing reinforcement about the benefits of weight control for persons with arthritis is warranted.

799

Identifying Obesity in Rheumatoid Arthritis: Current BMI Definition of Obesity Does Not Accurately Reflect Body Composition. Patricia P. Katz[1], Mary E. Margaretten[2], Steven Gregorich[3], Sandi Kaplan[4], Holly Wing[4], Edward Yelin[5] and Lindsey A. Criswell[5]. [1]Univercity of California San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA, [3]University of California, San Francisco, San Francisco, CA, [4]University of California, San Francisco, CA, [5]University of California San Francisco, San Francisco, CA

Background/Purpose: There is evidence that body mass index (BMI), the most commonly used measure of body composition or obesity, is not an accurate reflection of body composition among individuals with rheumatoid arthritis (RA). The purpose of these analyses was to determine the prevalence of obesity and evaluate how accurately the standard BMI definition identified obesity in RA.

Methods: Data were collected from an in-person visit conducted at the Clinical and Translational Science Institute's Clinical Research Center (CRC). Subjects (n=141, 85 women 56 men) were drawn from participants in a longitudinal cohort study of RA, who lived in proximity to the clinical site. Body composition was measured with dual-energy x-ray absorptiometry (DXA), and obesity defined using % body fat criteria based on age, sex, and race/ethnicity. Height and weight were also collected to calculate body mass index (BMI; obesity defined as BMI ≥30 kg/m^2). Correspondence between obesity measures was assessed with Cohen's kappa. Receiver operating characteristic (ROC) curves determined optimal cut-points for BMI, relative to DXA.

Results: Overall, 58% were classified as obese by DXA, and 27% by BMI. A greater proportion of men were obese according to DXA (80% of men, 44% of women); sex differences in the prevalence of obesity defined by BMI were small (29% men, 26% women). Correspondence between anthropometric and DEXA-based measures was weak to moderate (total: kappa=0.39, 67% correctly classified; men: kappa=0.16, 54% correctly classified; women: kappa=0.49, 77% correctly classified). Individuals misclassified by anthropometric measures had significantly more truncal fat and significantly less appendicular fat mass; men also had significantly less appendicular lean mass. Cut-points were identified for BMI that better approximated obesity estimated from DXA-obtained percent body fat: ≥24.7 kg/m^2 for men, and ≥ 25.7 for women. With the revised cut-points, 73% of men and 80% of women were correctly classified as obese by BMI.

Conclusion: A large percentage of this sample with RA was obese, but substantial portions were misclassified by BMI. DXA-defined obesity was more common in men than women, and fewer women than men were misclassified by BMI. Misclassification may be at least partially attributable to appendicular muscle wasting. Revised cut-points permit better estimation of obesity with BMI, although the utility of these new cut-points in terms of health outcomes remains to be investigated.

Does Hallux Valgus and Foot Pain Affect Self-Reported Lower Extremity Limitations in Men and Women? the Framingham Study. Alyssa B. Dufour[1], Virginia A. Casey[2], Patricia P. Katz[3], Robert R. McLean[4] and Marian T. Hannan[4]. [1]Hebrew SeniorLife & Boston Univ, Boston, MA, [2]Hebrew Senior Life, Boston, MA, [3]Univercity of California San Francisco, San Francisco, CA, [4]Hebrew SeniorLife & Harvard Med Sch, Boston, MA

Background/Purpose: Hallux valgus (HV) may affect the base of support in older adults, and thus could affect lower extremity physical abilities. It is unknown whether foot pain contributes to lower extremity physical limitation along with, or separately from, HV. This study investigated HV and foot pain and their relations with self-reported lower extremity physical limitation in community-dwelling older adults.

Methods: This cross-sectional study included 2208 ambulatory adults, contributing 4414 feet, from the population-based Framingham Study. We used a validated foot exam done by trained examiners with criteria to assess HV and foot pain. HV was present if the angle of the hallux toward the lesser toes was observed to be >15°. Foot pain (y/n) was queried: "On most days, do you have pain, aching or stiffness in either foot?" Each foot was categorized into four groups based on foot pain and HV status: 1) foot pain and no HV, 2) no foot pain and HV, 3) foot pain and HV, and 4) no foot pain, no HV. Lower extremity physical limitation was assessed using the subject's ability to climb stairs and to stand for 15 minutes. Self-reported difficulty, inability, or instruction from a physician to avoid was considered to be a limitation (y/n). Age, sex, and body mass index (BMI, kg/m^2) were also collected. Sex-specific generalized estimation equations, to account for within-person correlation of feet, adjusting for age and BMI, were performed to determine the odds ratios (and 95% confidence intervals) for limitations in climbing stairs and standing for 15 minutes among feet with 1) foot pain and no HV, 2) no foot pain and HV, and 3) foot pain and HV, versus feet with neither foot pain nor HV.

Results: 956 men and 1252 women had mean age of 66 ± 11.4 y (range 36–100 y). 7%, 9% and 2% of men had foot pain, HV, or both. In women, 8%, 14% and 6% had foot pain, HV, or both. Limitation in standing was seen in 17% of men and 19% of women. Limitation in walking up and down stairs was present in 13% of men and 19% of women. Among men, although foot pain only was not associated with limitation, those with HV only had 20–40% increased risk of limitation (see Table). Furthermore, men with foot pain and HV had almost 30% increased risk of limitation in standing, and 70% increased risk of being limited in climbing stairs. In women, while foot pain only and foot pain and HV were associated with limitations in both stairs and standing, those with HV only were not at increased risk of being limited in either outcome.

Conclusion: The combination of foot pain and HV had consistently

higher risks of physical limitation in climbing stairs in both men and women. Additionally, the risk of lower extremity limitation was only elevated in women with foot pain (and no HV), whereas in men, the risk was elevated in those with HV (and no foot pain). This study suggests that foot pain is important in evaluating the relation between structural foot disorders and lower extremity physical limitations in older adults and is different for men and women.

Table. Odds ratios and 95% confidence intervals for the association between lower extremity physical limitation and foot pain and hallux valgus.

	Men		Women	
	% limited	OR (95% CI)	% limited	OR (95% CI)
Up and down stairs				
Neither (referent)	6.4	1.00	6.8	1.00
Foot pain only	2.8	0.90 (0.45, 1.77)	4.4	1.73 (1.28, 2.35)
Hallux valgus only	2.2	1.38 (1.07, 1.77)	4.7	1.19 (0.90, 1.57)
Foot pain and hallux valgus	1.4	1.69 (1.07, 2.66)	3.0	1.83 (1.27, 2.64)
Standing 15 minutes				
Neither (referent)	9.2	1.00	6.0	1.00
Foot pain only	3.6	0.92 (0.53, 1.62)	5.2	1.74 (1.28, 2.36)
Hallux valgus only	2.8	1.21 (0.88, 1.65)	4.6	1.06 (0.78, 1.42)
Foot pain and hallux valgus	1.1	1.26 (0.61, 2.58)	3.2	1.26 (0.95, 1.69)

Initiation of Biologic DMARDs and the Risk of Hospitalization for Infection in Patients with Autoimmune Diseases. Carlos Grijalva[1], Lang Chen[2], Elizabeth S. Delzell[2], John Baddley[2], Timothy Beukelman[3], Kevin L. Winthrop[4], Marie Griffin[5], Lisa Herrinton[6], Liyan Liu[6], Parivash Nourjah[7], Nivedita M. Patkar[3], Daniel H. Solomon[8], James Lewis[9], Fenglong Xie[2], Kenneth G. Saag[2] and Jeffrey R. Curtis[2]. [1]Vanderbilt University, Nashville, TN, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Univ of Alabama-Birmingham, Birmingham, AL, [4]Oregon Health Science Univ, Portland, OR, [5]Vanderbilt, [6]Oakland, CA, [7]Rockville, MD, [8]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [9]University of Pennsylvania

Background/Purpose: Although TNF-alpha(α) antagonists are increasingly used in place of other non-biologic disease modifying antirheumatic drugs (DMARDs), their safety profile remains debatable. The objective of this study was to determine whether initiation of TNF-α antagonists increases the risk of serious infections compared with non-biologic DMARDs in patients with autoimmune diseases.

Methods: We combined data from Kaiser Permanente Northern California, Pharmaceutical Assistance Contract for the Elderly, Tennessee Medicaid and National Medicaid/Medicare, in a retrospective cohort (1998–2007). We identified patients with rheumatoid arthritis (RA); inflammatory bowel disease (IBD); and psoriasis (PsO), psoriatic arthritis (PsA) or ankylosing spondylitis (PsO-PsA-AS). The incidence of hospitalizations for serious infections was compared between initiators of TNF-α antagonists and alternate non-biologic DMARD regimens in disease specific-propensity score (PS) - matched cohorts using Cox regression models with non-biologics as reference. Baseline glucocorticoid use was categorized according to the estimated average daily dose of prednisone equivalents (none, >0-<5 (low dose), 5–10 (medium dose) and >10 mg (high dose)), and evaluated as a separate covariate.

Results: Among RA, IBD and PsO-PsA-AS patients, we identified 10602, 3219 and 1323 PS-matched pairs of episodes of TNF-α antagonist and alternate regimen use, respectively. Among RA patients, hospitalization rates of serious infections were 8.17 and 7.66 per 100 person-years, respectively (adjusted hazard ratio [aHR]: 1.09 (95% CI: 0.94–1.25)). Among IBD patients, the respective rates were 10.91 and 9.49 per 100 person-years (aHR: 1.14, (0.86–1.52)) whereas among PsO-PsA-AS patients, the respective rates were 5.41 and 5.19 per 100 person-years (aHR: 1.10, (0.80–1.53)). Among RA patients, infliximab was associated with a significant increase in the risk of serious infections compared with etanercept and adalimumab (aHRs: 1.26 (1.08–1.49) and 1.23 (1.02–1.48), respectively). For RA and PsO-PsA-AS, baseline glucocorticoid use was associated with a dose-dependent increase in risk of infections compared with no glucocorticoid use (for RA, aHRs: 1.39, 1.76 and 2.73; and for PsO-PsA-AS, aHRs: 1.36, 2.24 and 2.28 for low, medium and high doses, respectively).

Conclusion: In this large study consisting predominantly of older and low income patients with autoimmune diseases, initiation of TNF-α antagonists (as a group) was not associated with a significant increase in the risk of hospitalization for infections compared with alternate non-biologic regimens. Glucocorticoid use was associated with a dose-dependent increase in risk.

802

Short Periods of Glucocorticoid Use Are Associated with a Prolonged Risk of Osteonecrosis. Steven C. Vlad[1], Donald R. Miller[2], Yuqing Zhang[1] and David T. Felson[1]. [1]Boston University School of Medicine, Boston, MA, [2]Edith Nourse Rogers Memorial VA Hospital, Bedford, MA

Background/Purpose: Chronic glucocorticoid (GC) use has long been known to be a risk factor for osteonecrosis (ON). What is less clear is whether short periods of GC use instill an elevated risk of ON, and how long the risk persists.

Methods: We conducted a case-control study using national Veterans Affairs healthcare data, including linked outpatient/inpatient administrative and outpatient pharmacy records. Based on a published case-finding algorithm (Vlad, 2009) we found 6206 potential ON cases from fiscal years 1999 through 2006. These persons were free of GC use and ON in the first year of their enrollment and had never received inpatient GCs. Of these, we randomly reviewed 1112 medical records to confirm the ON diagnosis. Confirmed cases had ON (X-ray, MRI, CT, or bone scan by the criteria of Sugano, et al. (1999)) according to radiology reports, and had symptom onset within 1 year of the first ON code according to clinical notes. Each case was matched by sex, race, age (10 year windows from 20 to 90), year of 1st VA visit, VA location, and VA priority rating (a combined measure of need and service related disability) to up to 10 randomly selected controls by risk-set sampling. We defined GC exposure (oral and IV, ignoring inhaled and topical) relative to an index date one year prior to the 1st ON code as 1) current, or last used 1–90, 91–180, 181–365, 366–730, or > 730 days previously; and 2) cumulative number of days used (1–30, 31–90, 91–180, 181–365, > 365). We also looked at cumulative dose in those who last used GCs > 365 days before the index date (remote users). No use was the for reference all analyses. We used conditional logistic regression adjusted for (ever) bisphosphonate use, heavy alcohol use, and osteoporosis; fracture within the prior year; and new cancer diagnosis within the 2 prior years to calculate odds ratios for ON.

Results: We identified 172 ON cases (164 men) and 1581 controls (1553 men). Mean age was 60.3 years (std 10.7). 43 cases (25.0%) and 82 controls (5.2%) had at least one GC prescription. Compared to no GC use, the risk of ON was elevated in all strata regardless of recency of use (though there were few current users). Compared to no GC use, the risk of ON was elevated for all categories of cumulative use, even for those using =< 30 days (OR 3.8, 95% CI 2.1–6.8). Even in remote GC users, =< 30 days use carried an elevated risk for ON (OR 3.4, 95% CI 1.7–6.8).

Conclusion: We found that even a short period of GC use (=< 30 days) puts patients at risk for ON, even after 1 year of drug discontinuation. Potential limitations of this study include small numbers of GC users in some strata (generating wide CIs), not taking GC dosing into account, and residual confounding, e.g. by indication.

Table. Association of glucocorticoid use with osteonecrosis

Glucocorticoid use	Cases N (%) (N = 172)	Controls N (%) (N = 1581)	OR	(95% CI)
Never used (reference)	129 (75.0)	1499 (94.8)	1	–
Recency of use (prior to an index date one year prior to 1st ON code)				
Use at index date	1 (0.6)	1 (0.1)	13.3	(0.8, 220.1)
1–90 days prior	4 (2.3)	9 (0.6)	5.8	(1.6, 21.2)
91–180 days prior	4 (2.3)	6 (0.4)	9.7	(2.5, 38.4)
181–365 days prior	5 (2.9)	8 (0.5)	8.9	(2.5, 32.5)
366–730 days prior	13 (7.6)	23 (1.5)	5.6	(2.5, 12.4)
>730 days prior	16 (9.3)	35 (2.2)	4.3	(2.0, 9.0)
Cumulative duration of use				
1–30 days	22 (12.8)	68 (4.3)	3.8	(2.1, 6.8)
31–90 days	6 (3.5)	8 (0.5)	11.5	(3.5, 38.1)
90–180 days	6 (3.5)	3 (0.2)	12.8	(2.7, 60.1)
181–365 days	2 (1.2)	2 (0.1)	12.6	(1.1, 150.0)
>365 days	7 (4.1)	1 (0.1)	212.2	(8.9, >999.9)
Duration of use in remote users (>365 days prior to index date)				
1–30 days	16 (9.3)	45 (2.9)	3.4	(1.7, 6.8)
31–90 days	4 (2.3)	8 (0.5)	9.3	(2.5, 34.9)
90–180 days	2 (1.2)	2 (0.1)	4.1	(0.4, 47.9)
181–365 days	1 (0.6)	2 (0.1)	3.0	(0.2, 60.7)
>365 days	6 (3.5)	1 (0.6)	165.4	(7.0, >999.9)

Odds ratios (ORs) adjusted for bisphosphonate use, heavy alcohol use, fracture within prior year, osteoporosis, and recent cancer diagnosis. Duration of use in remote users also adjusted for recent use.

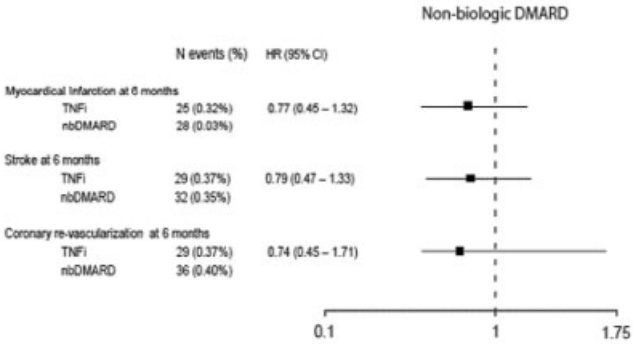
803

Cardiovascular Risk Reduction Associated with TNF Blockade: Results From a Large Multi-Site Observational Study. Daniel H. Solomon[1], Leslie R. Harrold[2], Jeremy Rassen[1], Huichuan Lii[3], Lang Chen[4], David Graham[5], Marie Griffin[6], Mary Kowal[3], Bindee Kuriya[7], James Lewis[8], Liyan Liu[9], Kenneth G. Saag[10] and Jeffrey R. Curtis[10]. [1]Brigham & Womens Hospital, Boston, MA, [2]UMass Medical School, Worcester, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Food and Drug Administration, [6]Vanderbilt, [7]University of Toronto, Toronto, ON, [8]University of Pennsylvania, [9]Kaiser Permanente, [10]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: The risk of cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA) and is a major source of morbidity and mortality. Inflammation mediated by TNF may increase CV risk. Prior studies suggest that TNF blockade (TNFi) may reduce the risk of ischemic CV events. However, little is known about the timing, pattern and patient populations at risk, or the specific types of CV events.

Methods: Administrative data from 1998–2007 for patients with ≥ 2 RA diagnoses who had previously used methotrexate (MTX) were aggregated across a large US health maintenance organization, Medicare and Medicaid. Follow-up began when another non-biologic disease modifying antirheumatic drug (nbDMARD) or a TNFi was added to or substituted for MTX, creating two groups of new users. We matched these groups (n:1) based on a propensity score (PS) that included cardiovascular risk factors, relevant medications, sociodemographic variables, and health care utilization data. Cox proportional hazard regression models were fit, with a composite CV endpoint including MI, stroke and coronary revascularization. One analysis used an "intention to treat" approach carrying the first exposure forward and another used an "as-treated" approach, censoring individuals 30 days after exposure ended.

Results: From a total source population of 139,611 we found 22,907 potentially eligible individuals with RA using MTX. Among this group, 9,034 new users of a nbDMARD were PS-matched with 7,780 new users of a TNFi. The baseline covariates were well matched. Incidence rates per 100 person-years for the composite CV endpoint were 2.99 (95% CI 2.41–3.71) for nbDMARDs and 2.26 (95% CI 1.78–2.87) for TNFi. The glucocorticoid adjusted PS-matched hazard ratio (HR) for the intention to treat result at 6 months was 0.79 (95% CI 0.60–1.04), while the as-treated analysis at 6 months was 0.72 (95% CI 0.62–0.99). At 12 months in the as-treated analysis, the HR was 0.86 (95% CI 0.66–1.13). In as-treated analyses at 6 months, similar effects were seen across MI, stroke, and coronary re-vascularization (see **Figure**). The potential cardiovascular benefits of TNFi were only seen among persons ≥ 65 years of age (HR 0.51, 95% CI 0.33– 0.78) versus < 65 (HR 1.20, 95% CI 0.72–2.01).



Conclusion: In this large observational study of RA, we found a trend towards reduced CV risk among new users of TNFi compared with nbDMARDs, but this effect seems to wane after the first six months. The effect of TNFi on CV risk in the first 6 months includes all types of CV events and may be most pronounced in older adults. Randomized controlled trials would help clarify these relationships.

804

Use of Bisphosphonates for the Prevention of Glucocorticoid-Induced Osteoporosis in Rheumatoid Arthritis—a Population Based Study. Diane Lacaille[1], Mushfiqur Rahman[1] and John Esdaile[2]. [1]Arthritis Research Centre; University of British Columbia, Vancouver, BC, [2]University of Calgary, Calgary, AB

Background/Purpose: Osteoporosis is a common co-morbidity in rheumatoid arthritis (RA). The increased osteoporosis in RA is felt to be due to the inflammatory process itself, decreased mobility from physical impairment, as well as treatment with glucocorticoids (GC). Glucocorticoid-induced osteoporosis (GIOP) is a preventable cause of osteoporosis in RA, since bisphosphonates (BPPs) have been shown to prevent bone loss associated with GC and to reduce fracture risk. American and Canadian guidelines recommend BPPs as primary prevention in all cases starting prednisone at a dose >5 mg/d and >7.5 mg/d, respectively, for an expected duration > 3 mos. The purpose of this study was to evaluate the compliance with these guidelines in a population-based cohort of RA and to determine if compliance has improved over time.

Methods: Using administrative billing data from the Ministry of Health, we have assembled a population-based cohort of all RA cases who received care by a physician for RA between 01/1996 and 03/2006. Previously published RA criteria included: at least 2 MD visits, at least 2 mos apart, where ICD-9 code for RA was used for reimbursement of MD visits. Cases were excluded if they had at least 2 subsequent visits for another type of inflammatory arthritis, if assessment by a rheumatologist did not confirm the diagnosis of RA made by another physician, or if no subsequent RA visits occurred over > 5 years. Our population-based cohort includes 37,151 RA cases, yielding an RA prevalence of 0.82%. For this study, all RA cases in the population-based cohort who were prescribed GC at doses >5 mg/d (prednisone equivalent) for >= 3 months were included (N = 10,153). Data on all medications were obtained for all RA cases. The use of BPP during courses of GC was evaluated and compared before and after the year 2000.

Results: Of our population-based cohort, 10,153 RA cases (27%) received GC for >3 mos at a mean daily dose > 5mg, with a total number of GC courses of 21,547. BPP were prescribed for 8,692 of the GC courses (8,692/21,547 or 40.3%) in 4,669 RA cases (4,669/10,153 or 46%). In 4,215 GC courses (2,473 RA cases) the BPP preceded the GC; in 1673 GC courses (1,499 RA cases) BPP and GC were started simultaneously, and in 2,804 GC courses (2,448 RA cases) the BPP were started after the GC, with a median delay of 4.3 months (IQR = 2.3;9.3 mos). Of the 8,692 GC courses with BPP prophylaxis, BPP were used for 55% (95% CI:54%;56%) of the time of the duration of the GC courses. The use of BPP prophylaxis for GIOP prevention improved after the year 2000. BPP were used in 33.0% of GC courses before 2000 vs 46.7% after 2000, and were used for 46% (95% CI: 44%;48%) vs 63% (95% CI:62%;64%) of the duration of the GC courses.

Conclusion: Despite the burden of osteoporosis in RA and the evidence supporting the use of BPP as prophylaxis to prevent GIOP, concomitant use of BPP during courses of glucocorticoids was infrequent in our population-based study. Although use of BPP improved after the year 2000, it still remains suboptimal both in terms of frequency and duration of its use.

805

Switching From Oral Bisphosphonates to Intravenous Zoledronic Acid Is Associated with A Reduction In the Incidence Rates of Morphometric Vertebral Fractures Among Patients with Postmenopausal Osteoporosis?—A Real-World Time-Series Study. Peter Sun[1], Jean Lian[2], Chris Recknor[3] and Julie Recknor[3]. [1]Kailo Research Group, Indianapolis, IN, [2]Novartis Pharmaceuticals Corp., East Hanover, NJ, [3]United Osteoporosis Centers, Gainesville, GA

Background/Purpose: Once-yearly intravenous zoledronic acid is a potent third-generation amino-bisphosphonate approved by Food and Drug Administration (FDA) for postmenopausal osteoporosis in 2007. This real-world study examines the impact of switching from oral bisphosphonates to intravenous zoledronic acid (with assured annual compliance) on the incidence rates of morphometric vertebral fractures among patients with postmenopausal osteoporosis in a clinical practice setting.

Methods: We used a retrospective time-series study design, and electronic medical records databases from a large US osteoporosis treatment center, where a systematic clinical protocol change to convert oral bisphosphonate patients to zoledronic acid occurred in 2007. Patients with postmenopausal osteoporosis and a switch from oral bisphosphonates to once-yearly intravenous zoledronic acid after the protocol change met the criteria for the study if they had 24 months of oral bisphosphonates prescriptions before the switch and 24 months of zoledronic acid treatment after the switch, and were continuously observed by the center throughout the 48-month study period. Based on electronic medical records, the monthly incidence rates of morphometric vertebral fractures were calculated. Eight interrupted time-series analysis models were developed to examine whether the switch was associated with any changes in the monthly incidence rates of morphometric vertebral fractures. To ensure the robustness of these interrupted time-series

models, both conditional least square method and maximum likelihood method were used.

Results: We identified 897 patients who received once-yearly intravenous zoledronic acid, had once-yearly spine X-rays and frequent fracture history inquiry during the study period. Of these 897 patients, 144 patients met our selection criteria. These patients had a mean age of 70 years at switch, were 99% white. The average incidence rates of morphometric vertebral fractures were 7.13 per 1,000 patients per month in the last two pre-switch years, and 1.93 per 1,000 patients per month in the first 2 post-switch years. The eight interrupted time-series models suggested that the switch was associated with a reduction in morphometric vertebral fracture rates by 5.15~5.25 per 1,000 patients per month in the first 2 post-switch years (all $p<0.05$).

Conclusion: In a large osteoporosis treatment center, switching from oral bisphosphonates to once-yearly intravenous zoledronic acid therapy was associated with a significant reduction in the monthly incidence rates of morphometric vertebral fractures.

806

Safety of Zoster Vaccine in Individuals with Rheumatoid Arthritis, Psoriatic Arthritis, Ankylosing Spondylitis, and Inflammatory Bowel Disease. Jie Zhang[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Lang Chen[1], Kenneth G. Saag[1], Kevin L. Winthrop[2] and Jeffrey R. Curtis[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Oregon Health Science Univ, Portland, OR, [3]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: The live zoster vaccine is approved in the US for individuals ages 50 and older to reduce risk and severity of Herpes zoster infection, also known as shingles. Based upon limited data, the vaccine is currently considered to be contraindicated in individuals taking biologics. The objective of the study is to examine whether the administration of zoster vaccine is associated with an increased risk of Herpes zoster shortly following vaccination among persons treated with biologics for autoimmune and inflammatory diseases.

Methods: From 2006 through 2009, we identified from the 100% Medicare fee for service population individuals who were 60 years of age or older; had rheumatoid arthritis, psoriasis, psoriatic arthritis, ankylosing spondylitis, or inflammatory bowel disease; and received zoster vaccine. We classified these individuals according to their concomitant medications (biologics; non-biologic DMARDs, including methotrexate, leflunomide, hydroxychloroquine, and sulfasalazine; oral glucocorticoids) within 60 days prior to or after vaccination. The cumulative incidence of Herpes zoster infection within 42 days following vaccination (the typically-used risk window in zoster vaccine trials) was calculated according to drug exposure.

Results: A total of 6793 subjects were vaccinated; among these, 76 had ankylosing spondylitis, 1,260 had inflammatory bowel disease, 161 had psoriatic arthritis, 1,745 had psoriasis, 3,246 had rheumatoid arthritis, and 305 had two or more diseases; 580 were on biologics, 1825 on non-biologic DMARRDs, and 1432 were on glucocorticoids at the time of or immediately prior (+- 60 days) to vaccination. The mean ± standard deviation (SD) age of vaccinated patients was 74.5 ± 6.3, 72% were women, and 96% were Caucasians.

Within 42 days following vaccination, the overall cumulative incidence of Herpes zoster infection was 2.2 per 1,000 persons. The cumulative incidence of zoster infection was not significantly different between those who were using biologics (1.7 per 1,000) or only non-biologic DMARDs (2.7 per 1,000). Irrespective of biologic or DMARD use, the short term risk of zoster infection was higher for patients receiving oral glucocorticoids compared to those not ($p = 0.07$) (Table).

Drug Exposure Within 60 days of Vaccination	Number of patients vaccinated	Cumulative Incidence of Zoster within 42 days, per 1000 persons (95% CI)
Biologics with oral glucocorticoids	193	5.2 (0.0–15.3)
Biologics without oral glucocorticoids	387	0.0 (0.0–9.5)
DMARDs with oral glucocorticoids	550	5.5 (0.0–11.6)
DMARDs without oral glucocorticoids	1275	1.6 (0.0–3.7)

Conclusion: Zoster vaccine in current biologic users does not appear to be associated with a short term risk of Herpes zoster infection following vaccination compared to those using only non-biologic DMARDs. In addition, the risks were not different than the rates observed in the general population participating in a large zoster vaccine trial of 38,546 individuals in which the cumulative incidence of Herpes zoster infection within 42 days 1.2 per 1,000 among those who receiving placebo. Vaccination with the live zoster vaccine may be reasonable to consider for patients currently using biologics.

807

Can Ultrasound (PDUS) Easily Detect Erosions? Evaluation of Physiological and Abnormal Cortical Breaks of Small Joints in Healthy Individuals (HI) and Rheumatoid Arthritis (RA) Patients by PDUS Comparison with Micro Computed Tomography (μCT) Scan. Stephanie Finzel[1], Philippe Aegerter[2], Georg Schett[1], Maria-Antonietta D'Agostino[2] and OMERACT Ultrasound Task Force[3]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Versailles-Saint Quentin en Yvelines University- APHP, Ambroise-Paré Hospital, Boulogne-Billancourt, Paris, France, Paris, France, [3]Paris, France

Background/Purpose: The correct detection of bone erosions in RA by ultrasound is sometimes delicate due to the presence of pitfalls such as physiological vessel channels, grooves, sesamoids and osteophytes. Thus, ultrasound needs further standardization. Objective: To evaluate by PDUS the size and location of physiological and abnormal cortical breaks in HI and RA patients by using μCT as gold standard.

Methods: Metacarpophalangeal joints (MCPJ) of both hands of 43 HI (without history of inflammatory joint disease) and 40 RA patients (disease duration > 6 months; fulfilling the new ACR/EULAR classification criteria) were examined by PDUS using a palmar, dorsal and, where possible, a lateral approach. All accessible joint facets were assessed in longitudinal and transversal planes. PDUS was performed by using an ESAOTE MyLab 70 (Genoa Italy) both in B- (linear array probe of 18 MHz) and PD-mode (10.2 MHz; PRF of 500). Cortical break was defined as a break in cortical lining detectable in two perpendicular planes. For each plane the width and the depth were recorded. Physiological and abnormal breaks were defined according to the opinion of ultrasonographer. Additionally, a μCT scan of MCPJ (2 to 5) was performed at a resolution of $82\times82\times82$ μm voxel size of the clinically more affected hands of 26 RA patients and of the dominant hands of 17 HI. The prevalence, sensitivity and specificity of breaks as determined by PDUS and μCT were recorded and compared.

Results: A total of 430 and 390 MCPJ were scanned by PDUS in HI and RA respectively. 48 and 81 MCPJ were additionally evaluated by μCT in HI and RA respectively. In HI, among the 1118 performed scans 226 breaks (20%) were recorded, 222 (98%) physiological (61% in the palmar side) and 4 (2%) pathological (3 in the lateral side). In RA patients 255 breaks were detected out of 1014 scans performed (25%). 143 (14%) were considered physiological (64% in the palmar side) and 112 (11%) as abnormal – erosions (51% in the lateral side). All physiological breaks were considered as vessel channels, despite the absence of PD signal. Overall there was an excellent agreement between PDUS and μCT regarding the specificity of detection of physiological and abnormal breaks in HI and RA (Sp of 1 for HI and 0.95 for RA) except for the dorsal side of MCP 2 (κ values of 0 for HI and 0.1 for RA). Sensitivity was difficult to assess due to low sample size in both groups. Table 1 shows the mean (mm) cortical physiological and abnormal breaks by PDUS and μCT in HI and RA.

Table 1.

	PDUS (mean in mm)				μCT (mean in mm)			
	longitudinal		transversal		longitudinal		transversal	
	Width	Depth	Width	Depth	Width	Depth	Width	Depth
HI (physiological breaks)	1.85	2.2	1.77	2.18	0.66	1.41	0.61	1.51
RA (physiological breaks)	0.48	0.63	0.66	0.8	1.03	1.24	1.02	1.27
HI (abnomal breaks)	2.5	3.2	1.8	2.3	0.67	1.74	0.84	1.59
RA (abnormal breaks)	1.43	1.35	1.53	1.43	1.83	1.79	1.79	1.79

Conclusion: Ultrasound is a valuable method for the detection of and the discrimination between abnormal (i.e. erosions) and physiological breaks in cortical bone. Predilection sides for nutritive vessels could be identified in both ultrasound and μCT. This study could work as a map for the correct detection of bone erosions in rheumatoid arthritis allowing for the discrimination between pathological and physiological breaks.

808

Imaging As An Outcome Measure in Early Inflammatory Arthritis: Monitoring Disease Activity and Patients' Response to Therapy Using Ultrasonography. Yasser M. El Miedany[1], Maha El Gaafary[2], Deborah Palmer[1] and Sally Youssef[2]. [1]Darent Valley Hospital, Dartford, United Kingdom, [2]Ain Shams University, Cairo, Egypt

Background/Purpose: 1. To compare grey scale (GS) and PD US with clinical and biological findings in early arthritis patients treated with DMARDs/Biologic therapy and fulfill clinical remission criteria. 2. To assess US imaging as an outcome measure in monitoring the RA patients' response to therapy and its impact on the patients' management. 3. To identify which joints should be US scanned in the standard clinical practice.

Methods: Inclusion criteria: (1) Inflammatory arthritis diagnosed according to ACR/EULAR criteria (2) clinical remission (DAS28 <2.6) (3) no flares of disease in past 6 months. Each patient completed a copy of the PROMs including patients self-reportded joint tenderness. Clinical examination of tender and swollen joints was recorded and US assessment was carried out for every patient for: Hands: 1–5th MCP and 2–5 PIP joints, both wrists, both knee joints, feet: 1–5 MTP and 2–5 PIP joints in addition to any other painful/tender or swollen joint. Individual joints were scored for GS synovial hypertrophy and PD using a validated semi-quantitative method (0–3). Correlation between the clinical findings and US activity score was carried out. Patients who had active synovitis as proved by US were treated aiming at achieving US remission. Post-treatment correlation with clinical outcome measures was assessed.

Results: 121 patients receiving either DMARDs (n=65) or anti-TNF (n=56) were included. Over 1-year period of 3 monthly monitoring, 38/484 (7.9%) US scans showed active inflammatory arthritis. In comparison to clinical examination, US showed significantly more joints with effusion (mean 14.2) and synovitis (mean 16.1) than clinical examination (mean 10.2, $p < 0.05$). A significant correlation was found between patient self-reported joint tenderness and both US-PD as well as total US scores ($p< 0.0001$). US findings correlated significantly with pain score and CRP ($p< 0.01$), ESR ($p< 0.05$) whereas it did not correlated with patient global assessment, nor functional disability score. US findings had an impact on the patients' management where following: 16/38 (42.1%) scans the DMARDs dose was increased, 16/38 (42.1%) scans the DMARDs agent was changed, 12/38 (31.6%) scans the biologic therapy frequency was increased whereas an intra-articular injection was given following 20/38 (52.6%) scans. In the follow up visits, US was sensitive to change as improvement in US and PD scores were associated with clinical and laboratory changes ($p< 0.01$) in response to treatment. Therapeutic intervention based on US findings maintained the DAS-28 score at the same range (< 2.6) over the 1-year follow up period.

Conclusion: The combination of GS US and PD joint assessment is a sensitive and reliable outcome measure that should be a component of RA remission criteria. Despite DAS-28 score < 2.6, US imaging-detected subclinical active joint inflammation that warranted change of the current patient's management. In the standard clinical practice, patient self-reported joint tenderness is the best marker to identify joints need to be US scanned. Therapeutic intervention based on US findings has helped to achieve disease remission state that is of importance for subsequent clinical and radiographic progression.

809

Ultrasonography Is a Potent Tool for Prediction of Ongoing Joint Destruction During Clinical Remission of Rheumatoid Arthritis. Ryusuke Yoshimi, Kaoru Takase, Maasa Hama, Daiga Kishimoto, Kayo Terauchi, Reikou Watanabe, Takeaki Uehara, Darisuren Tsolmon, Sei Samukawa, Atsushi Ihata, Atsuhisa Ueda, Mitsuhiro Takeno and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background/Purpose: Although "clinical remission" has been a realistic goal of treatment in rheumatoid arthritis (RA), there is evidence that subclinical synovitis is associated with progression of structural damage even after achieving clinical remission. Here we assessed whether ultrasonography (US) can predict progressive joint destruction in RA patients who are evaluated as clinical remission.

Methods: Twenty-seven RA patients who were in clinical remission (DAS28-ESR < 2.6 or DAS28-CRP < 2.3) were recruited. Bilateral wrists, and all of MCPs and PIPs were examined by power Doppler (PD) US. Gray scale (GS) and PD signals were scored in each joint from 0 to 3, respectively. Total PD score and total GS score were calculated by summing up the score of individual joints. Hand X-ray was performed at the entry and at 2 years. Patients were defined as radiographically progressing cases when the change of the van der Heijde-modified total Sharp score exceeded 0.5 units per year and the others were as non-progressing cases. In principle, therapy was not modified during the study, unless the patients had clinical flare-up.

Results: Twenty-two patients maintained clinical remission during the 2-year follow-up, while 5 patients had clinical flare-up. The remission-maintaining group was further divided into 7 progressing cases (32%) and 15 non-progressing cases (68%) based on radiographic findings. There was no significant difference in age (51.4 ± 7.74 years vs 59.2 ± 12.1 years, $p = 0.15$) and disease duration (7.3 ± 3.9 years vs 6.7 ± 3.7 years, $p = 0.74$) at the entry between the two groups. Progressive radiographic destruction was strongly associated with total PD score at the entry, but not with total GS score (*Table 1*). Progressive radiological destruction in any joints was found in 7 of 11 patients (64%) having more than 2 of total PD score in US at the entry, but none of the other 11 patients having PD score, one or zero. There was no significant association of particular therapeutic agents with progressing cases or non-progressing cases.

Table 1. Correlation between radiographic change and baseline variables during clinical remission

Baseline variable	No radiographic progression ($n = 15$)	Radiographic progression ($n = 7$)	p
Total PD score	0.87 ± 1.15	6.00 ± 6.44	0.0099**
Total GS score	8.80 ± 5.78	12.6 ± 12.4	0.36
Swollen joint count	0.33 ± 0.79	1.29 ± 0.70	0.017*
Tender joint count	0.13 ± 0.34	0.57 ± 0.49	0.032*
Global VAS (mm)	9.40 ± 9.58	12.7 ± 4.40	0.41
ESR (mm/h)	10.2 ± 5.94	18.6 ± 16.2	0.11
CRP (mg/dl)	0.12 ± 0.15	0.08 ± 0.12	0.60
MMP-3 (ng/ml)	96.8 ± 110	62.1 ± 19.7	0.44
RF (U/ml)	73.8 ± 89.5	86.8 ± 68.1	0.77

* $p < 0.05$,** $p < 0.01$

Conclusion: PDUS detects latent synovitis which causes joint destruction even in the clinical remission of RA patients, irrespective of therapeutic agents. Thus, imaging remission in US is essential to reach "true remission" of RA.

810

Does Rheumatoid Synovitis Activity Vary During the Day? A Sonographic and Doppler Evaluation. Agnes Lhoste, Bruno Pereira, Marion Couderc Sr. and Martin Soubrier. CHU Clermont-Ferrand, Clermont-Ferrand, France

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory disease, and patients' symptoms often decrease during the day. Sonography and Doppler have been shown to reliably depict activity of the synovitis, but may possibly decrease as well. The aim of this study is to determine whether Doppler activity of rheumatoid synovitis is the same in the morning and in the afternoon.

Methods: 27 patients (23 women and 4 men) with definite (1987 ACR criteria) and active RA (DAS28 4.66 ± 1.32) were included in the study.

Sonographic evaluation with B-mode and Color Doppler was performed twice for each patient, before 9 am and at 4 pm on the same day, using the same unit, with the same transducer and settings, by a single experienced radiologist (ALT). 22 synovial areas were scanned on each wrist, hand and forefoot, including 15 joints and 7 tendon sheaths. "Synovitis" was noted as defined by the OMERACT group as abnormal hypoechoic synovial hypertrophy. Synovial was considered as "normal" if thin and hardly visible. Synovial vascularization was visualized by color Doppler and scored as follow: "inactive synovitis" = S0 if no flow; "mild active synovitis" = S1 if color flow was detected in less than 1/3 of the hypertrophic synovial area; "moderate active synovitis" = S2 if flow was detected in more than 1/3 but less than 2/3 of the hypertrophic synovial area; "marked active synovitis" = S3 if flow was detected in more than 2/3 of the hypertrophic synovial area.

Results: 1) Number of detected synovitis: of the 1188 imaged joints and sheaths, 328 showed synovitis in the morning, 381 in the afternoon

(p = 0.05). This number increased in 20 patients, was the same in 6, and decreased in one. Statistical analysis of each localisation showed that right forth PIP modified significatively (p = 0.02), and right second MCP had a tendency to modify (p = 0.08), whether tenosynovitis did not modify (p = 1).

2) Activity of synovitis modified in 26 patients. this change concerned several joints in 21 patients, and only one in five. Activity significantly increased in left second MCP (p = 0.02) and right fifth MCP (p = 0.04) and had a tendency to increase in the third and forth right PIP and in the left radio-carpal joint (p = 0.08). Some inactive or mild synovitis (S0 and S1) may turn to moderate or marked (S2 or S3): This was significant in the second right MCP (p = 0.013) and in the combination of all explored hand and wrist joints of the right side (p = 0.002) and of the left side (p = 0.026)

Conclusion: These data suggest that synovitis activity changes during the day, surprisingly more often increasing than decreasing, and not uniformly in each patient. Only mild changes seem to be linked to the subjective scoring method. Daily physical activity may also be considered, as suggested by more significant variations on several dominant hand joints of these patients. Further data are needed to confirm with a larger cohort including patients in clinical remission, evaluating the risk of underestimating disease activity in this population. Our results, if confirmed, may have a direct impact on the patients' follow-up, as ultrasound performed for remission evaluation should not concern dominant side only, and should be repeated if necessary at the same hour of the day: but when?

811

Sonoelastography Detects Rigidity of Salivary Glands in Primary Sjögren's Syndrome. Christian Dejaco[1], Tobias DeZordo[2], Daniel Heber[1], Rainer Lipp[1], Andre Lutfi[1], Marton Magyar[1], Saelde Baumgartner[1], Dorothea Zauner[1], Winfried B. Graninger[1] and Josef Hermann[1]. [1]Medical University Graz, Graz, Austria, [2]Innsbruck Medical University, Innsbruck, Austria

Background/Purpose: To investigate the value of sonoelastography (SElasto) in patients with primary Sjögren's syndrome (pSS).

Methods: Prospective study on 38 pSS patients fulfilling the American-European consensus group criteria [mean age 58 years; 92% female; median duration of sicca symptoms 6 years, 65% histological sialadenitis] and 11 healthy controls. B-mode sonography and SElasto of parotid and submandibular glands was performed using a GE Logiq E9 ultrasound device. Parenchymal homogenicity, echogenicity, hypoechogenic areals, hyperechoic reflections and clearness of glandular borders were semiquantitatively scored (total score ranging from 0–48) [Hocevar A et al, 2005]. SElasto was used to examine the elasticity of glandular parenchyma and a semiquantitative rating was performed with 0=no, 1=up to 25%, 2=up to 50%, 3=up to 75% and 4=more than 75% hardened areas within the salivary gland. The total score ranged from 0 to 16. Clinical assessments were performed at the same day of sonographic evaluation and included: Saxon test, Schirmer test, Xerostomia inventory (XI), and the Ocular Surface Disease Index (OSDI). Statistical analysis was performed using SPSS program (v18.0) and the Mann-Whitney-U and Spearman rank correlation test were performed as appropriate. Interobserver variability of sonography was tested in 30% of pSS patients by intraclass correlation coefficient (ICC).

Results: pSS patients had higher B-mode scores [median 25 (range 2.0–44.0) vs. 2.0 (0–8.0), p<0.001] and SElasto scores [6.0 (2.0–12.0) vs. 3.0 (1.0–4.0), p<0.001] than healthy controls.

pSS patients showed a median salivary flow rate of 1.69 g/2min (range 0.31–3.79), a median moisture on the filter paper (Schirmer test) of 4.0mm/5min (0–50.0), a median XI of 27.5 (8.0–43.9) and an median OSDI of 43.8 (0–77.1). In pSS patients, an inverse correlation was found between the result of the Saxon test and SElasto score ($corr_{coeff}$ −0.426, p=0.009), whereas B-mode ultrasound results were not associated with saliva production. No correlation was found between SElasto scores and Schirmer test as well as subjective ratings of dryness according to the XI and OSDI. In addition, neither disease duration nor duration of sicca symptoms influenced ultrasound results.

A good reproducibility of B-mode and SElasto results was found as indicated by an ICC of 0.926 (95%CI 0.565–0.983) and 0.934 (0.787–0.981), respectively.

Conclusion: Increased rigidity of major salivary glands as demonstrated by sonoelastography in patients with pSS correlates with the impairment of saliva secretion.

812

Vertebral Fracture Assessment (VFA): A Valid Tool to Detect Vertebral Fractures in Community-Dwelling Older Individuals. Diogo S. Domiciano[1], Jaqueline B. Lopes[1], Liliam Takayama[2], Camille Figueiredo[1], Valéria Caparbo[1], Eloisa Bonfa[3] and Rosa M.R. Pereira[4]. [1]University of São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]University of Sao Paulo, Sao Paulo, Brazil, [4]Disciplina de Reumatologia da FMUSP, Sao Paulo, Brazil

Background/Purpose: Vertebral fractures (VFx) are associated with higher morbidity and mortality in the general population. Since 70% of the VFx are clinically silent, radiologic image of spine has to be acquired for the diagnosis. Vertebral Fracture Assessment (VFA) has emerged as possible alternative for the gold standard radiographic image to detect prevalent VFx. Previous studies evaluating this method are hampered by the limited sample size, selection of women with specific indication for spine X-ray and inclusion of patients under 70 years. Thus, the aim of this study was to compare the performance of VFA with X-ray to identify VFx in healthy community-dwelling older men and women.

Methods: 429 non-institutionalized subjects (60% women), aged over 65 years, from community, were enrolled in this cohort. VFA by DXA measurements was evaluated by two expert rheumatologists by consensus and spine X-ray (T4 to L4) were analyzed according to semiquantitative method (Genant HK, 1993) by an expert radiologist. The correlation between VFA and spine X-ray to identify VFx was analyzed by kappa (k) scores. P<0.05 was set as significant.

Results: The average age of subjects was 73.1 ± 5.1 years. The prevalences of VFx in VFA and X-ray were 30.1 and 28.6% in women (P=0.68), and 28.2 and 30.6% in men (P=0.78), respectively. The frequency of unavailable vertebrae was significantly lower in spine X-ray than VFA (1% and 5.5%, respectively, P<0.001), particularly along with T4-T6. According to VFA, 5013 (96%) vertebrae were identified as normal, 144 (2.7%) had grade 1 fractures, 58 (1.1%) grade 2 fractures and 12 (0.2) grade 3 fractures. The sensitivity of VFA was 73% and the specificity was 99.1% to identify VFx. The sensitivity increased to 93% and specificity to 99.6% excluding deformities grade 1. A good correlation between VFA and X-ray (k=0.74) was observed and the exclusion of grade 1 resulted in an even better agreement (k=0.84). The correlation vertebrae by vertebrae between VFA and spine X-ray was lower for T5-T7 (k=0.60). Correlations between the two methods were comparable in both gender (k=0.72 in men, k=0.75 in women).

Conclusion: In elderly community, VFA and X-ray had comparable performances to identify VFx, particularly if mild deformities are excluded. Thus, this methodology is an easy and feasible promising alternative to improve the identification and management of patients with high risk of osteoporotic fractures.

Circulating Mitochondrial DNA Copy Numbers As a Disease and Activity Marker in ANCA-Associated Vasculitis. Ulrich A. Walker[1], Nora M. Effelsberg[2], Nils Venhoff[3], Chingching Foocharoen[1], Jens Thiel[3], Paul Hasler[4] and Dirk Lebrecht[3]. [1]University of Basel, Basel, Switzerland, [2]Dept. of Rheumatology and Centre of Chronic Immunodeficiency, University of Freiburg, Freiburg, Germany, Freiburg, Germany, [3]Dpt. of Rheumatology and Center of Chronic Immunodeficiency, University of Freiburg, Freiburg, Germany, Freiburg, Germany, [4]Dept. of Rheumatology, Kantonsspital Aarau, Aarau, Switzerland, Aarau, Switzerland

Background/Purpose: Polymorphonuclear neutrophils and eosinophils may play an important role in the pathogenesis of ANCA-associated vasculitis (AAV) by releasing DNA in the process of extracellular trap generation after priming by endothelial cells, anti-proteinase 3 (PR3) autoantibodies, or S. aureus. Extracellular traps may contain mitochondrial DNA (mtDNA), which by binding to toll-like receptor 9, contributes to systemic inflammation and organ damage. The purpose of this study was to determine the characteristics of circulating cell free mtDNA in AAV and to examine if mtDNA quantification could be useful in the diagnosis and monitoring of AAV.

Methods: 54 consecutive subjects with AAV and 31 controls (healthy volunteers, and persons hospitalized for osteoarthritis or herniated intervertebral disks) were included in this crossectional study. mtDNA and nuclear DNA (nDNA) copy numbers were measured by quantitative PCR in plasma. AAV activity was measured with the Birmingham Vasculitis Activity Score (BVAS vs. 3). Anti-PR3 autoantibody titers, S. aureus nasal carriage and routine lab parameters were determined simultaneously.

Results: The intra-run coefficient of variation of the assay was 2.8% for the mtDNA and 5.3% for the nDNA amplicon. The inter-run coefficient of variation was 5.4 for both assays.

In control plasma, the median mtDNA copy number was 15,400/ml (interquartile range, IQR 10,992–31,233) and 449,683/ml (IQR 257,500–1,120,000) in AAV. On multivariate analysis, only BVAS ($p<0.001$) and CRP ($p=0.001$) remained predictive for circulating mtDNA-levels. CRP however contributed only little to the goodness of fit, indicating that BVAS is the major predictor of mtDNA plasma levels.

Conversely BVAS was only predicted by circulating mtDNA copy numbers ($p<0.001$) and neutrophil counts ($p=0.03$), generating an adjusted R^2 value of 0.635. Notably PR3-ANCA levels, and CRP levels were not predictive of BVAS. Cell free nDNA copies in control plasma were low (median 5,747 copies/ml), similar in AAV patients (5,125 copies/ml, $p=0.93$), and not correlated with BVAS.

In our patient population, the receiver operating characteristic curve determined an area under the curve of 0.968 with a cut-off of 178,000 mtDNA copies/ml plasma. The same cut-off would result in a sensitivity of 87.5%, a specificity of 100%, and a positive likelihood ratio of 27.1.

Conclusion: Circulating mtDNA, unlike nDNA, is markedly increased in patients with AAV compared to non-inflammatory controls. Elevated cell free mtDNA-levels distinguish most patients with AAV from healthy persons irrespective of disease activity. Within AAV subjects, circulating mtDNA copy numbers may contribute to systemic inflammation and are valid predictors of disease activity.

Soluble CD14 in Synovial Fluid From Patients with Early-Stage Osteoarthritis Augments Synoviocyte Responses to TLR-2 and TLR-4 Ligands. Anjali Nair[1], Veero Kanda[1], Charles Bush-Joseph[1], Nikhil Verma[1], Susanna Chubinskaya[1], Katalin Mikecz[1], Tibor T. Glant[1], Anne-Marie Malfait[1], Mary K. Crow[2], Greg Spear[1], Alison Finnegan[1] and Carla R. Scanzello[1]. [1]Rush University Medical Center, Chicago, IL, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: Low-grade synovitis is a variable feature of osteoarthritis (OA) that is associated with symptoms and is detectable even at early stages of disease. This inflammation is hypothesized to be triggered in part via stimulation of Toll-like receptors (TLRs) by products released from cartilage matrix degradation, we tested whether a TLR-2 or TLR-4 stimulating factor in synovial fluid (SF) from these early-stage knee OA patients with meniscal injury could lead to inflammatory activation of synoviocytes.

Methods: SF was obtained from patients undergoing arthroscopic meniscal procedures. Given the well described association between meniscal lesions and OA, these patients serve as a model population of patients with early-stage knee OA cartilage lesions. Cartilage damage was confirmed by intra-operative inspection and the extent graded according to the Outerbridge scoring system. X-rays were also evaluated using the Kellgren-Lawrence scoring system. Synovial tissue specimens for establishment of fibroblast-like synoviocyte (FLS) lines were obtained from asymptomatic organ donors with no documented history of joint disease via IRB approved protocols. SF from the patients was used to stimulate primary FLS, as well as HEK-293 cell lines transfected with TLR-2 or TLR-4. SF was used alone and in combination with a known TLR-2 stimulus (Pam_3Cysk_4) or TLR-4 stimulus (LPS). Stimulation was measured by IL-6 and IL-8 release into the culture media measured by ELISA, and by real-time quantitative PCR measurement of IL-6 and IL-8 mRNA expression levels in stimulated cell lysates. Levels of soluble CD14 were measured in SF by ELISA. A monoclonal anti-CD14 antibody was used to block the effects of CD14 in the stimulation assays.

Results: SF from these patients did not in general stimulate IL-8 release from the TLR transfectants. However, compared with SF on its own, SF (0.09–25%) in combination with TLR-2 or TLR-4 ligands resulted in significant augmentation of IL-8 release from the transfectants (greater than 100-fold), and significantly augmented release of both IL-8 and IL-6 from the primary FLS ($p<0.01$ to $p<0.001$ compared with SF or ligands alone). Augmentation of IL-6 and IL-8 mRNA expression was also demonstrated by real-time PCR. Soluble CD14 (sCD14), a co-receptor for TLRs, was measured in early OA SF at levels comparable to advanced OA and rheumatoid arthritis (RA) but significantly higher than in asymptomatic organ donors. Blockade with anti-CD14 antibody abolished the ability of SF to augment IL-8 production in response to LPS, and diminished Pam_3CysK_4 responses.

Conclusion: SF from patient with early stage OA augments FLS IL-6 and IL-8 production in response to TLR-2 and TLR-4 ligands. This effect appeared to be largely due to sCD14 in the fluid specimens. Our results demonstrate that sCD14 in the setting of OA and meniscal injury can sensitize FLS to respond more robustly to inflammatory stimuli such as TLR ligands. It suggests similarities between RA and OA at the level of innate immune activation in the joint. As synoviocytes are expected to be in contact with SF *in vivo*, we speculate that this priming of FLS inflammatory responses may have relevance to symptomatic "flares" seen clinically in OA patients.

817

Abatacept (CTLA-4Ig) Treatment Reduces Adhesion and Migratory Capacity of Monocytes in Patients with Rheumatoid Arthritis (RA). Michael Bonelli[1], Elisabeth Ferner[1], Anastasiya Hladik[1], Lisa Goeschl[1], Thomas Karonitsch[1], Hans Peter Kiener[1], Stefan Bluemel[1], Carl-Walter Steiner[1], Michael Bergmann[1], Josef Smolen[2] and Clemens Scheinecker[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Abatacept (CTLA-4Ig) inhibits the binding of CD28 to the B7 ligands CD80/CD86 and thereby effector T cell activation. In addition, binding of CTLA-4Ig and reverse signalling via CD80/CD86 potentially exerts effects on antigen presenting cells (APC) and might therefore contribute to the therapeutic effect. In order to further elucidate the mechanism of CTLA-4Ig we performed phenotypic and functional analysis of APC in rheumatoid arthritis (RA) patients before and after the initiation of CTLA-4Ig therapy.

Methods: Peripheral blood mononuclear cells (PBMC) from RA patients (n=12) were analyzed before and 2 and 4 weeks after the initiation of CTLA-4Ig therapy. Proportions of $CD14^+$ monocytes, $CD19^+$ B cells, $CD1c^+$ myeloid dendritic cells (DC) and $CD303^+$ plasmacytoid DC were determined by flow cytometry. Monocytes were further analyzed for the expression of costimulatory and adhesion molecules and for their transendothelial migratory capacity in vitro. Further, $CD14^+$ cells from healthy controls (HC) were isolated by fluorescence activated cell sorting (FACS) and magnetic cell sorting (MACS), incubated with CTLA-4Ig and analyzed for their migratory and spreading capacity.

Results: Proportions of $CD14^+$ monocytes were significantly increased in RA patients treated with CTLA-4Ig. Phenotypic analysis revealed no significant differences in the expression of costimulatory molecules whereas the expression of several adhesion molecules was found to be significantly diminished. In addition isolated monocytes displayed a significant reduction in their adhesion and transendothelial migratory capacity upon treatment with CTLA-4Ig. Likewise, isolated monocytes from HC displayed a significant reduction in their migratory capacity after pre-incubation with CTLA-4Ig in a dose dependent manner. In line with these findings, spreading assays also revealed a profound impact of CTLA-4Ig on actin cytoskeletal and focal adhesion reorganization in $CD14^+$ monocytes.

Conclusion: Our data suggest that CTLA-4Ig directly affects phenotypic and functional characteristics of monocytes, which might decrease monocyte migration to the synovium. These findings represent an additional mechanism of CTLA-4Ig therapy in RA.

818

A Novel Autoinflammatory Syndrome Presenting with Chronic Atypical Neutrophilic Dermatitis, Lipodystrophy and Elevated Temperatures (CANDLE syndrome) Caused by Mutation in the Immunoproteasome. Yin Liu[1], Yongqing Chen[1], Yuval Ramot[2], Damaris Garcia[1], Antonio Torrelo[3], Afzal Sheikh[4], Amy Paller[5], Adam Reinhardt[6], Deborah Stone[1], Massimo Gadina[7], Plass1 Plass[1], Dawn Chapelle[1], Zlotogorski Zlotogorski[2] and Raphaela T. Goldbach-Mansky[8]. [1]Translational Autoinflammatory Disease Section, Office of the Clinical Director NIAMS, Bethesda, MD, [2]Department of Dermatology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel., Jerusalem, Israel, [3]Departments of Pediatric Dermatology, Hospital Niño Jesús, Madrid, Spain, Madrid, Spain, [4]Medical Genetics Branch, NHGRI, Bethesda, MD, [5]Departments of Dermatology and Pediatrics, Feinberg School of Medicine, Northwestern University, Chicago, IL, USA;, Chicago, IL, [6]Faculty of Physicians of the University of Nebraska Medical Center, College of Medicine, Nebraska, [7]NIAMS, Bethesda, MD, [8]NIH Building 10 Room 6D47B, Bethesda, MD

Background/Purpose: Chronic atypical neutrophilic dermatitis, lipodystrophy and elevated temperature (CANDLE) syndrome is a novel autoinflammatory syndrome in the pediatric population. We investigated the clinical phenotype, the genetic cause and characterize the immune-dysregulation in 9 clinically defined CANDLE syndrome patients. PSMB8 is a critical subunit of the immunoproteasome, a multi-protein complex which degrades poly-ubiquitinated proteins in the cells.

Methods: Homozygosity analysis and genomic DNA sequencing were performed. Bio-rad multiplex cytokine assay was used to analyze the cytokine profile in patient serum or supernatant from stimulated PBMC. Blood microarray profile (n=4) and stat-1 phosphorylation were assessed and skin biopsies were evaluated immunohistochemically.

Results: Genomic DNA sequencing showed that one patient was homozygous for a nonsense mutation in *PSMB8* (c.405C>A encoding p. C135Z) leading to a protein trunctation, 5 patients were homozygous and 2 were heterozygous for a missense mutation (c.224C>T encoding p.T75M) recently reported to cause joint contractures, muscle atrophy, and panniculitis-induced lipodystrophy (JMP) syndrome in adults; 1 patient was mutation negative. Analysis of skin biopsy showed heavy infiltration of myeloperoxidase and leder stain positive immature granulocytes and activated, macrophages positive for CD68/CD163 and Myeloperoxidase staining. *PSMB8* mutation positive and negative patients expressed high serum levels of the IFN induced cytokine IP-10. Other elevated cytokines included MCP-1, IL-6, and IL-1Ra. Whole blood microarray analysis on four patients showed a strong IFN signaling signature that distinguishes it from other autoinflammatory syndromes. IFN stimulated stat-1 phsophorylation in patient monocytes was stronger than in healthy controls. Both STAT1 phosphorylation and IP-10 production in patients can be blocked by a JAK kinase inhibitor, as in healthy controls.

Conclusion: CANDLE is caused by mutations in *PSMB8,* a gene encoding a component of the immunoproteasome. Our data extend the clinical and pathogenic description of this novel autoinflammatory syndrome and suggest a novel mechanism of immunedysregulation involving IFN. The prominent IFN signature raises questions of pathways linking proteasome dysfunction to the interferon signaling and IFN signaling may be a key mediator of the inflammatory response that can be targeted therapeutically in patients with *PSMB8* associated disorders

Micrornas Mir-15b and Mir-206 Are Key Factors in the Regulation of Impaired Angiogenesis in Muscle of Children with Untreated Juvenile Dermatomyositis. Simone Treiger Sredni[1], Peter Hendrickson[2], Erin Kim[3], Gabrielle Morgan[3], Sheela Shrestha[3], Yi-Wen Chen[4], Chiang-Ching Huang[5] and Lauren M. Pachman[1]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Children's Memorial Research Center, Chicago, IL, [3]Children's Memorial Hospital, Chicago, IL, [4]George Washington University, Washington, [5]Northwestern Univ Med School, Chicago, IL

Background/Purpose: Juvenile dermatomyositis (JDM), the most common pediatric inflammatory myopathy, is an autoimmune vasculopathy. The hallmark of JDM, damaged small blood vessels, is associated with local hypoxia and tissue apoptosis. MicroRNAs are non-coding RNAs that regulate several messenger RNAs simultaneously by mechanisms such as translational repression or cleavage of target messages, offering a new prototype for therapeutic intervention.

Objectives: To compare the microRNA expression profile in muscle from untreated children with active symptoms of JDM and healthy pediatric controls in order to investigate the pathophysiology of JDM.

Methods: All diagnostic muscle biopsies were MRI directed, and approved consent was obtained from JDM and controls (IRB# 2008–13457, IRB# 2001–11715 respectively). For microRNA expression, 6 children with definite/probable JDM (Bohan and Peter criteria) and two age/gender-matched orthopedic control muscles were profiled. MicroRNA array experiments were conducted in triplicate on Exiqon's miRCURY LNA microRNA Array, v.11.0. For gene expression, 25 JDM and 4 healthy age-matched orthopedic control muscles were profiled using Affymetrix U133A arrays. After normalization, fold change and t-tests assessed the mean difference of GE and microRNA expression between JDM and controls. MicroRNAs and protein-coding genes with FC $\geq$1.5 or FC$\leq$ $-$1.5 and p-value $\leq$0.05 were evaluated. Selected protein-coding genes and miRNAs were validated by qRT-PCR.

Results: A total of 19 microRNAs were differentially expressed in JDM: Seven were up regulated and 12 were down regulated. MicroRNAs miR-15b (FC= 1.92, p-value=0.028) and miR-206 (FC=2.57, p-value=0.03) were among the top miRNAs that were up regulated. Both of these microRNAs target the angiogenesis regulator, EGFR, down regulated (FC=$-$1.8, p-value=0.008) in the JDM samples. Besides regulating EGFR, miR-15b targets the Bcl2 gene (FC=$-$2, p$<$0.0003) that together with EGFR, controls expression of NF-kB2 (FC=$-$1.6, p-value=0.02). NF-kB and EGFR regulate MAPK1 (FC=$-$2, p-value 0.03) that contributes to angiogenesis by controlling VEGF (VEGFA FC=$-$2, p-value= 0.009 and VEGFB FC=$-$1.6, p-value=0.01) through JUN (FC=$-$3.2, p-value=0.008). These results suggest that the down regulation of a network of pro-angiogenic genes by miR-15b and miR-206 does not allow recovery of the impaired vascular network, thus sustaining the hypoxic conditions at a tissue level. Thus, miRNA activity in JDM muscle impairs recovery of angiogenesis, contributing to disease chronicity. In addition, an inhibitor of angiogenesis, TIMP-1, is up-regulated (FC=3.5, p-value=0.004), compounding this inhibitory process. No association with duration of untreated disease was observed.

Conclusion: The data suggest that neoangiogenesis, normally stimulated by tissue hypoxia, is impaired in untreated JDM muscle, and that this impairment is regulated by the microRNAs—miR-15b and miR-206. These findings add to the current knowledge of JDM pathophysiology and might potentially lead to new forms of therapeutic intervention.

Type I Interferon-Related Biomarkers Predict Clinical Disease Activity in Inflammatory Myositis. Ann M. Reed[1], Cynthia S. Crowson[1], Hatice Bilgic[2], Emily Baechler Gillespie[2], Molly Hein[1], Steven R. Ytterberg[1], Shreyasee Amin[1] and Erik J. Peterson[2]. [1]Mayo Clinic, Rochester, MN, [2]University of Minnesota, Minneapolis, MN

Background/Purpose: Biomarkers are needed that are sensitive to disease activity during treatment for juvenile and adult dermatomyositis (DM). DM subjects carry distinct immune Type I interferon (IFN)-inducible gene and chemokine signatures in peripheral blood, which are correlated cross-sectionally with disease activity. We evaluated whether changes in peripheral blood IFN-inducible gene and chemokine scores may serve as novel biomarkers for treatment-independent change in DM disease activity.

Methods: We followed 51 patients with juvenile (mean age 8 yrs; n=21) and adult (mean age 45 yrs; n=30) DM prospectively for 2 study visits separated by 3–6 months. At each visit, peripheral blood was collected, and clinical data were recorded regarding medication use and disease activity (global, muscle, and extra-muscular) each assessed using a 10 cm visual analog scale (VAS). The whole-blood Type I IFN gene score was defined by expression levels of 3 IFN-regulated genes (IFIT1, G1P2, IRF7) measured by quantitative real-time RT-PCR. Multiplexed immunoassays were used to quantify serum levels of pro-inflammatory cytokines including IL-6, and of Type I IFN-regulated chemokines (I-TAC, IP-10, MCP-1; together yielding a derived IFN chemokine score). Spearman partial correlation methods were used to correlate changes in disease activity with changes in analytes adjusting for medication use.

Results: The median global disease activity for the total DM cohort at visit 1 was 26 (range 0–80) and median change in global disease activity (visit 2-visit 1) was −13 (range −69, 45). We found strong positive correlations between change in global and muscle disease activity and change in Type 1 IFN chemokine scores (see Table). These measures were correlated both before and after adjustment for medication use. Furthermore, decreasing levels of cytokines and chemokines were highly correlated with a decrease in disease activity, even after medication adjustment ($p<0.001$–0.009). No differences in results were seen between juvenile and adult DM subgroups.

Cytokine or Chemokine	N	Spearman Partial Correlation Coefficient After Adjustment for Medication Use (p-value) Global VAS	Muscle VAS	Extra-muscular VAS
IL-6	51	**0.39 (0.009)**	**0.49 (0.001)**	**0.31 (0.049)**
IP-10	51	**0.48 (0.001)**	**0.45 (0.003)**	**0.48 (0.002)**
ITAC	51	**0.42 (0.004)**	**0.53 (<0.001)**	**0.45 (0.003)**
MCP-1	51	**0.32 (0.032)**	**0.46 (0.002)**	**0.33 (0.036)**
IFNγ	50	−0.11 (0.48)	−0.26 (0.10)	−0.06 (0.72)
IL-1β	50	−0.22 (0.16)	−0.12 (0.47)	−0.14 (0.38)
IL-8	50	**0.37 (0.016)**	**0.50 (<0.001)**	0.31 (0.055)
TNFα	50	**0.32 (0.040)**	**0.48 (0.001)**	0.28 (0.085)
MCP-2	41	0.29 (0.095)	**0.51 (0.002)**	0.16 (0.39)
IFN gene score	49	0.26 (0.096)	**0.41 (0.007)**	0.19 (0.25)
IFN chemokine Score*	51	**0.50 (<0.001)**	**0.55 (<0.001)**	**0.52 (<0.001)**

* IFN chemokine score contains: IP-10, I-TAC and MCP-1.

Conclusion: Changes in whole blood Type I IFN gene and chemokine signatures, as well as in levels of T-cell cytokines IL-6, IL-8 and TNFa, are highly correlated with changing DM disease activity irrespective of medication use.

821

Pandemic Unadjuvanted Influenza A 2009 Vaccine in Adult Dermatomyositis and Polymyositis: Immunogenicity Independent of Therapy and No Harmful Effect in Disease. Samuel K. Shinjo[1], Maurício Levy Neto[1], Clovis A. Silva[1], Julio C. B. Moraes[1], Ana C. M. Ribeiro[1], Carla G.S. Saad[1], Nadia E. Aikawa[1], Alexander R. Precioso[2], Maria C.S. Timenetsky[3] and Eloisa Bonfa[1]. [1]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, [2]Butantan Institute, Sao Paulo, Brazil, [3]Instituto Adolfo Lutz, São Paulo, Brazil

Background/Purpose: There are specific recommendations for influenza vaccination in systemic autoimmune diseases and the WHO recently recommended that the 2010–2011 trivalent seasonal flu vaccine must contain the A/California/7/2009 (H1N1) virus. The vaccine potential deleterious effect in adult dermatomyosisits (DM) and polymyositis (PM) and the influence of therapy in antibody response in these diseases has not been explored in our previous report (*Ann Rheum Dis*, 2011).

Methods: Fifty-eight patients (37 DM and 21 PM - Bohan and Peter's criteria, 1975) were gender and age-matched to 116 healthy controls. All subjects were vaccinated with a unadjuvanted influenza A/California/7/2009 (H1N1) strain and evaluated pre- and 21 days post-vaccination. Patients with fever, egg allergy, and autoimmune neurological diseases were not included. Antibody titers were evaluated by hemagglutination inhibition (HAI) assay. Percentage of seroprotection (titer ≥1:40) before and after immunization, and seroconversion (pre-vaccination titer <1:10 and a post vaccination HIA titer ≥1:40 or pre-vaccination titers ≥1:10 and a ≥ 4-fold rise post-vaccination) were calculated. Adverse events of vaccination were also analyzed. DM/PM muscle enzyme and scores (patient's visual analog scale (VAS), physician's VAS and MMT-8 (manual muscle strength score)) were evaluated before and after vaccination.

Results: Mean age (43.1±9.9 *vs*. 43.8±8.4 years, $P=0.607$) and frequency of female gender ($P=1.000$) were comparable in patients and controls with a mean DM/PM duration of 7.3±3.0 years. Seroprotection (72.4% *vs*. 84.5%, $P=0.058$) and seroconversion rates (72.4% *vs*. 78.5%, $P=0.377$) were similar in both groups. Of note, patients under glucocorticoids and/or immunosupressors (72.4%) also reached an adequate seroconversion rate (69.8% *vs*. 78.5%, $P=0.254$), including those 9 patients under prednisone ≥0.5mg/kg/day (88.9% *vs*. 78.5%, $P=0.254$). Disease activity and muscle parameters remained stable during the protocol (pre and post-vaccination): CK 224.1±209.0 *vs*. 242.1±256.9U/L, aldolase 5.8±5.9 *vs*. 5.8±5.4U/L, MMT-8 77.7±5.3 *vs*. 77.8±5.2, patient's VAS 9.5±0.9 *vs*. 9.5±0.9, physician's VAS 9.3±0.8 *vs*. 9.6±0.7 (all $P>0.05$) and seroconversion rate was similar to controls in eight patients with active disease (75.0 *vs*. 78.5%, $P=0.819$). The frequencies of minor local reactions (8.6 *vs*. 11.2%, $P=0.597$) and of mild systemic reactions (15.5 vs. 25.7%, $P=0.123$) were alike in patients and controls, without any report of severe side effects.

Conclusion: This prospective study of pandemic influenza A H1N1/2009 vaccination in DM/PM patients emphasizes its recommendation supported by novel evidence of its adequate immunogenicity in spite of therapy with no short-term harmful effect in disease itself (ClinicalTrials.gov number, NCT01151644).

822

CD28null T Cells From Myositis Patients Are Cytotoxic to Autologous Muscle Cells in Vitro. Paulius Venalis, Jayesh Pandya, Vanessa Stache, Gustavo Nader, Vivianne Malmström, Ingrid E. Lundberg and Andreas Fasth. Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are chronic, rheumatic disorders characterized by muscle weakness, leading to disability. T cells have been implicated in the disease pathogenesis, but precise phenotype, function and specificity of these cells remain unclear. We have previously demonstrated that CD28null T cells dominate both in the affected muscle and peripheral blood of patients with myositis. These cells are apoptosis resistant, pro-inflammatory and potentially cytolytic. Here we have investigated whether CD28null T cells are directly cytotoxic to autologous muscle cells.

Methods: An autologous co-culture system was developed with peripheral blood cells and myotubes derived from three patients with definite DM or PM and with >10% of $CD4^+$ $CD28^{null}$ T cells in peripheral blood. Biopsy specimens were obtained from tibialis anterior muscle. Enzymatic digestion was performed for myoblast collection. Myoblasts cultures, showing 90% N-CAM positivity, were further differentiated into myotubes. PBMC were isolated by ficoll separation, and further into $CD4^+CD28^{null}$, $CD4^+CD28^+$, $CD8^+CD28^{null}$ and $CD8^+CD28^+$ T cell populations by flow cytometry. Before co culturing, myotubes were labeled with calcein and the autologous T cell subsets were stimulated with PHA. Co cultures were set at varying effector-target ratios. Supernatants were harvested after 24 hours, and calcein release was measured. The results are expressed as percentage of maximal lysis and were confirmed by morphological changes.

Results: We have assessed the potential of autologous CD28null T cells from both the CD4+ and CD8+ lineage to kill myotubes by cell mediated cytotoxicity. We have previously demonstrated that CD4+CD28null T cells from myositis patients contain perforin. Here, we investigated whether such T cells had direct cytolytic capability. Indeed CD4+28null showed 30.5±3.5% myocytotoxicity (in 2 out of 3 tested patients) in autologous 24h coculture (at effector-target ratio 10:1), whereas no significant cytotoxicity was observed in CD4+CD28+ population. We have also shown that CD8+CD28null T cells contain more perforin than CD8+CD28+ T cells and here we compared the

cytolytic capability of these populations. Myocytotoxicity was higher in CD8+CD28null than in CD8+CD28+ T cells, 15±5.3% versus 0.1±1.6% respectively (at 5:1 effector-target ratio, n=3). When increasing the effector-target ratio to 15:1 and 30:1 in CD8+CD28null compartment, the myocytotoxicity was further increased to 37% and 60% respectively.

Conclusion: Although we need to analyze more patients, we could demonstrate that CD28null T cells of both the CD4 and CD8 lineage can make use of their cytolytic granules and kill autologous myotubes derived from muscle biopsies of myositis patients. These T cells may contribute to loss of muscle fiber and as they are apoptosis resistant they may contribute to the chronicity of PM/DM disease.

823

Role of MyD88-Dependent Toll-Like Receptor Signaling in a Murine Model of Histidyl-tRNA Synthetase-Induced Myositis. Lisa Harlow[1], Irina Fernandez[1], Yunjuan Zang[1], Makoto Soejima[2], Eric L. Greidinger[3] and Dana P. Ascherman[3]. [1]University of Miami Miller School of Medicine, Miami, FL, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Miami, Miami, FL

Background/Purpose: In previous work, we have demonstrated that IM immunization with Jo-1 induces exuberant muscle inflammation in multiple strains of mice. This phenotype does not require Jo-1-specific TCR recognition and can also occur in the absence of functional TLR4 signaling, suggesting the contribution of other non-TLR4-mediated signaling pathways of the innate immune system.

Objectives: To determine the contribution of toll-like receptor signaling in a murine model of myositis induced by intramuscular immunization with histidyl-tRNA synthetase (Jo-1)

Methods: To examine the potential role of innate signaling pathways beyond TLR4, we immunized B6.MyD88$^{-/-}$ and B6.TLR2$^{-/-}$ mice with a recombinant amino terminal fragment of murine Jo-1 fused to maltose binding protein (MA/MBP=amino acids 1–151 of murine Jo-1 linked to maltose binding protein) in the absence of exogenous adjuvant. At Day 17, we obtained quadriceps and hamstring muscle from euthanized mice for subsequent analysis of lymphocytic infiltrates in hematoxylin/eosin stained specimens. As a complement to this in vivo modeling, we assessed the capacity of our recombinant murine Jo-1 fragment and appropriate control proteins to activate TLR2 and TLR4 signaling through in vitro stimulation of TLR2 transfected 293 cells and Limulus Amebocyte Lysate testing, respectively.

Results: MA/MBP immunization of B6.MyD88$^{-/-}$ mice (n=7) failed to replicate the muscle inflammation previously demonstrated in parental C57BL/6 mice, implicating MyD88-dependent TLR signaling in this model system of Jo-1-induced myositis. In vitro assessment of Limulus Amebocyte Lysate activation demonstrated that recombinant Jo-1 proteins/fragments possess endotoxin-like activity (log order greater activity than MBP or the control autoantigen, 70 kDa RNP) capable of activating TLR4. At the same time, in vitro stimulation of TLR2 transfected 293 cells with different versions of recombinant Jo-1 revealed antigen-specific induction of IL-8 secretion relative to MBP and other recombinant autoantigens, supporting a potential role for this alternative MyD88-dependent signaling pathway in modulating the muscle inflammation detectable in the setting of functional TLR4 deficiency. Strikingly, however, IM immunization of B6.TLR2$^{-/-}$ mice (n=10) with MA/MBP yielded robust lymphocytic infiltration of muscle tissue relative to that generated in C57BL/6 WT mice—findings that paralleled the relationship between muscle inflammation induced in TLR4-deficient C3H/HeJ and WT C3H/HeOuJ mice.

Conclusion: Collectively, these results demonstrate that our model of Jo-1-induced myositis requires the TLR adaptor molecule MyD88, but is not absolutely dependent on either TLR2- or TLR4-mediated signaling cascades. Future assessment of TLR2$^{-/-}$/TLR4$^{-/-}$ double knockout mice will further clarify the apparent functional redundancy of these TLR systems (suggested by in vitro stimulation assays) and allow us to rule out the involvement of other, less likely MyD88-dependent TLR signaling pathways.

824

Clinical and Autoantibody Associations in Myositis Patients with Anti p155/140kDa Autoantibodies—a Multicenter European Study. Herman F. Mann[1], Lenka Plestilova[2], Hector Chinoy[3], Robert G. Cooper[4], Lara Dani[5], Ingrid E. Lundberg[5], Zoe Betteridge[6], Neil J. McHugh[7] and Jiri Vencovsky[2]. [1]Institute of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague 2, Czech Republic, [2]Institute of Rheumatology, Prague 2, Czech Republic, [3]The University of Manchester, Manchester, United Kingdom, [4]Hope Hospital, Salford, United Kingdom, [5]Karolinska Institutet, Stockholm, Sweden, [6]Royal National Hospital, Bath, United Kingdom, [7]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom

Background/Purpose: Malignancy is common among patients with dermatomyositis (DM). A novel myositis specific autoantibody (autoAb) directed against a 155/140 kDa (p155/140) protein has been reported in association with cancer associated DM. This study investigated anti-p155/140 antibodies in patients with idiopathic inflammatory myopathies from 3 European centers and the association with malignancy types and with the presence of other concurrent autoantibodies.

Methods: A multi-center cross sectional study of adult patients with IIM was performed as a part of ongoing collaboration within the EuMyoNet project. All patients fulfilled probable/definite criteria for IIM diagnosis according to the Bohan & Peter criteria. Six hundred and forty seven sera were tested for presence of various myositis specific and myositis associated autoAbs by immunoprecipitation using ^{35}S methionine labeled extracts from K562 leukemia cell line in a single facility (Bath, UK). Clinical data regarding IIM and malignancies were collected by treating physicians at the 3 participating sites (UK, S, CZ). Cancer associated myositis (CAM) was defined as cancer occurring in IIM patients within 3 years of disease onset.

Results: 40 patients (6.2%) (37 DM, 2 polymyositis and 1 with IIM/CTD□overlap syndrome) tested positive for p155/140. Patients were predominantly Caucasian (39) and mostly women (32/40). 17/40 p155/140 positive patients (all DM) developed cancer (6 breast, 3 ovarian, 2 bladder, 2 lymphatic tissue, 1 each in esophagus, gallbladder, uterus and unknown primary localization) within 3 years of IIM onset (4 prior, 8 after and 5 concurrent with IIM). In addition one patient had a history of colon cancer 10 years prior to first IIM symptoms. The subgroup of p155/140 positive CAM patients were compared to 16 p155/140 negative CAM patients (4PM, 12DM) from 2 participating sites (S, CZ). There was no difference in mean age at the onset of IIM (56.8±9.8 and 54.9±10.8 years, p=0.6), diagnosis of cancer (57.1±9.7 and 56.1±10.6 years; p=0.78) or sex (76% vs. 73% women) between p155/140 positive and negative groups. The type of malignancies did not differ between the two cancer groups.

Seventy-five percent of the p155/140 negative CAM patients had another myositis specific or associated autoAb (SAE 3x, Mi-2 2x, Jo-1 2x, p140 2x, SRP 1x, U1 RNP 1x, Ro 2x) whereas only 17.5 % of the p155/140 had another autoantibody (Ro 4x, U1RNP 2x, KS 1x, SRP 1x).

Conclusion: Prevalence of CAM in our p155/140 cohort (43%) was similar to that reported previously. Presence of the p155/140 autoantibody is not restricted to DM patients only, but the increased risk of cancer associated with p155/140 seems to be confined to the DM population. We were not able to identify any difference in terms of age of IIM or clinical presentations between p155/140 positive and negative CAM patients. In addition the p155/140 autoAb is not exclusive as some patients may have other, even myositis specific autoAb, at the same time.

Heritability and Linkage of Radiographic Progression of Hip and Knee Osteoarthritis: Results From the Longitudinal Component of the Genetics of Generalized Osteoarthritis Study. Michelle S. Yau[1], Laura Yerges-Armstrong[1], Michael Doherty[2], Marc Hochberg[1], Joanne M. Jordan[3], Virginia Byers Kraus[4], Braxton Mitchell[1], A. G. Wilson[5] and GOGO Investigators[6]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]City Hospital, Nottingham, United Kingdom, [3]UNC Thurston ARC, Chapel Hill, NC, [4]Duke University Medical Center, Durham, NC, [5]Sheffield Uni /Medical School, Sheffield, United Kingdom, [6]Durham

Background/Purpose: Understanding the role of genetics in the progression of osteoarthritis (OA) may help identify biological mechanisms, potential treatments, and individuals at risk for rapid progression of OA. Using data from the Genetics of Generalized Osteoarthritis (GOGO) study, we 1) assessed heritability of radiographic progression of OA and 2) used genome-wide linkage analysis to identify susceptibility loci for progression of OA.

Methods: OA of the hip and knee were analyzed separately for progression. Progression was defined as an increase in Kellgren-Lawrence

(KL) grade, osteophyte score or joint space narrowing (JSN) score, or decline in minimum joint space width (mJSW) >= 0.1 mm/year. We assessed heritability of baseline mJSW and rate of change in mJSW (mm/year) in the lateral and medial compartments of the left and right knees, and left and right hip, using a variance components approach as implemented in SOLAR. Age, gender, and their interaction were included as covariates in the models. We used MERLIN for the non-parametric linkage analysis of hip and knee OA progression based on 1115 microsatellite markers. Prior to linkage analysis, Mendelian inconsistencies and unlikely recombinations were detected and corrected using PedCheck and MERLIN.

Results: A total of 1374 and 1381 individuals with a mean follow-up of 3 years were included in the hip and knee OA progression analyses, respectively. There was significant heritability ($P < 0.01$) of baseline mJSW at the hip (40–42%) and medial knee compartment (27–31%), but not the lateral knee compartment. Heritability of the rate of change in mJSW was significant at the hip (25–26%) but not in either knee compartment. There was significant evidence for linkage to progression of hip and knee OA on the X chromosome (hip: peak LOD=2.71 at 92cM; knee: peak LOD=5.52 at 110cM). Potential candidate genes in this region include *DIAPH2*, which may play a role in the development and function of ovaries; *IL1RAPL2*, an interleukin-1 signaling accessory receptor; *CHRDL1*, an antagonist of bone morphogenic protein 4; *PAK3*, which may be involved in focal adhesion and T cell receptor signaling pathways; *CAPN6*, which may regulate microtubule dynamics and cytoskeletal organization; *AMOT*, which may play a role in tight junction maintenance via a complex formed with ARHGAP1; *PGRMC1*, a putative membrane-associated progesterone steroid receptor; *IL13RA1* and *IL13RA2*, interleukin-13 receptors that may mediate activation of JAK1, STAT3, and STAT6; *NKAP*, an NF$\kappa\beta$ activating protein; *NKRF*, an NF$\kappa\beta$ repressing factor; and *SLC6A14*, an amino acid carrier that may be associated with X-linked obesity.

Conclusion: Heritability analyses show that mJSW at both the hip and knee and change in mJSW at the hip have a genetic component. However, hip mJSW and its rate of change are more heritable than knee mJSW, suggesting that progression of knee OA may be more susceptible to environmental factors than hip OA. Linkage analyses revealed several susceptibility loci present on chromosome X, suggesting involvement of bone morphology, sex hormones, inflammation and obesity in OA progression. Further work will interrogate susceptibility regions and determine how various pathways may interact to cause OA progression.

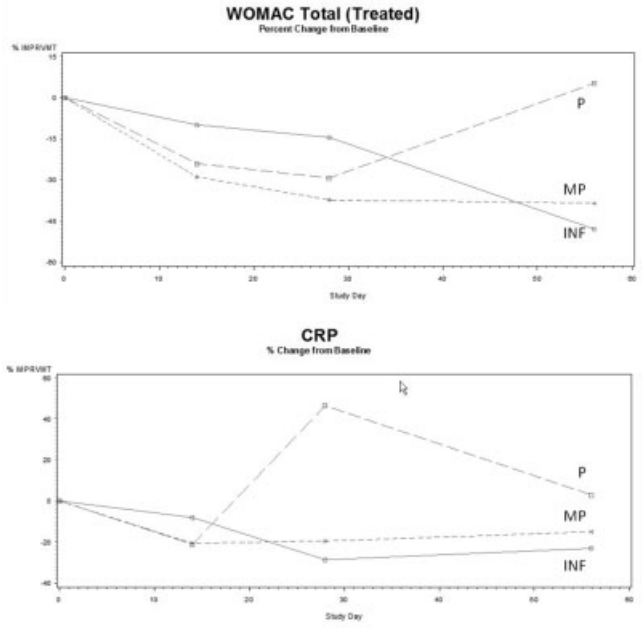
826

Treatment of Knee Osteoarthritis with Intraarticular Infliximab May Improve Knee Function and Reduce Synovial Infiltration by Macrophages. Jeremy R. Schue[1], Ossama Tawfik[1], Donald D. Smith[1], Gary Hinson, Rebecca Bolce[3], Jo A. Wick and Herbert B. Lindsley[1]. [1]Kansas University Med Ctr, Kansas City, KS, [2]Janssen Services, LLC, Horsham, PA

Background/Purpose: Synovial tissue from patients with early osteoarthritis (OA) demonstrated higher levels of inflammation than from late OA (Benito et al. Ann Rheum Dis 2005). We hypothesized that a single intraarticular (IA) injection of an anti-TNF drug would result in decreased inflammatory cell infiltration and ultimately reduce articular injury.

Methods: This study was single center, 2:1:1 [INF:MP:P] randomization, double-blind, placebo-controlled treatment of knee OA with IA treatments of infliximab (INF) 100 mg, methylprednisolone (MP) 80 mg or saline (P) on Day 0. Subjects (n=16) had to have knee pain and show minimal to moderate osteoarthritic change on plain radiographs. Closed needle synovial biopsies (Bx) were taken from the suprapatellar pouch on Days 0 and 28 and assessed for reduction in inflammation. Changes in categorical variables (scored 0 to 3) were calculated and the proportions of observed decreases were compared between groups using Fisher's Exact tests. Differences in continuous measures between groups were assessed using Wilcoxon tests.

Results: The median Total WOMAC score improved between Day 0 and 28 in all three groups and then declined in the P group (Fig 1). The INF and MP groups trended better than the P group, with MP showing more improvement initially and INF delayed benefit. The median CRP (Fig 2; baseline values = 0.57–1.21 mg/dl) for MP and P declined by Day 14; MP reached a plateau Days 14– 56, whereas Group P exceeded baseline (Days 28, 56). INF reached a plateau by Day 28. Of the 3 groups INF had the greatest % improvement at Day 56 for WOMAC and CRP. Synovial tissue showed reduction in two markers: CD68 macrophages (3 of 7 Bx INF) and CD54 ICAM-1 (2 of 4 Bx MP). Otherwise there was no reduction in inflammation for the remaining markers in any group; these included fibrosis, TNFα, IL-1β, IL-6, IL-17, CD56, CD68, CD3, and CD25. Flow cytometric studies of PBMCs at Days 0 and 28 showed reduced numbers of INF subjects with TNF-expressing CD20 B cells and high-MFI CD14 monocytes; likewise total low-MFI monocytes were reduced (p=0.07) in INF.



Conclusion: In this pilot study the Total WOMAC score showed early persisting improvement in MP and delayed improvement in INF, compared to transient improvement seen in P. The two anti-inflammatory treatments reduced CRP levels mildly. There was no statistical difference between baseline and post-treatment values in WOMAC, CRP or synovial tissue scoring. However, both INF and MP showed a trend in improvement both in knee function (WOMAC) and in CRP reduction.

827

Prolonged Improvement of Clinical Status and Structural Cartilage Tissue Repair by Joint Distraction in Treatment of End-Stage Knee Osteoarthritis; The 2 Years Follow-up Data. Karen Wiegant[1], Femke Intema[1], Peter van Roermund[1], Anne C. A. Marijnissen[2], Sebastian Cotofana[3], Felix Eckstein[3], SC Mastbergen[2] and Floris Lafeber[1]. [1]University Medical Centre Utrecht, Utrecht, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]Paracelsus Medical University, Salzburg, Austria

Background/Purpose: Knee joint distraction (KJD) is a new treatment for end-stage osteoarthritis (OA) of the knee that temporarily unloads the femorotibial cartilage and subchondral bone. This technique was previously shown to be clinically effective at 1 year follow-up. Clinical improvement coincided with the significant increase of joint space width. The current study provides 2 year follow-up results on the effect of KJD.

Methods: The open, uncontrolled study included 20 patients (age 49±6 years; 11 females) with knee OA, considered for total knee replacement. Patients were treated with KJD for 2 months. The study was approved by the medical ethical committee (METC) of the University of Utrecht and all patients gave written informed consent. Two monotubes with internal coil springs were placed parallel, bridging the knee joint, creating a distance between both cartilage surfaces of 5 mm, confirmed by X-ray. Patients were encouraged to load the knee during distraction, in order to attain intermittent intra-articular fluid pressures.

The primary clinical outcome parameter was pain and function by use of the 'Western Ontario McMasters University Index' (WOMAC) questionnaire, with a visual analoge pain score (VAS) as secondary outcome. The primary structural outcome was minimal joint space width (JSW) on semi-flexed, anterior-posterior, weight bearing radiographs analyzed by digital interactive computer analysis (KIDA). Secondary structural outcomes were quantitative MRI parameters of cartilage morphology, analyzed by Chondrometrics Gmbh (Ainring, Germany). Additionally, biomarkers for

synthesis (sPIIANP) and breakdown (uCTXII) of collagen type II were evaluated.

Results: Total WOMAC score increased from 45%±3.6 at baseline to 78%±4.8 ($p<0.000$) and the VAS pain score decreased from 73±2.1 at baseline to 28±6.0 mm ($p<0.000$). The clinical improvement coincided with structural tissue changes: the minimum JSW increased from 1.0±0.3 to 1.8±0.3 mm ($p<0.03$) and quantitative MRI analysis showed an increase in cartilage thickness over total subchondral bone area (ThCtAB) of the most affected compartment (from 2.4±0.1 at baseline to 2.8±0.1 mm; $p<0.05$) and a decrease of the percentage of subchondral bone area that was denuded (dABp: change from 22±5 at baseline to 8±2%; $p<0.004$). MRI and X-ray changes were moderately correlated ($r=0.67$ $p<0.000$). Biomarker analysis shows that from 6 months post-treatment to 2 years follow-up, the average change in the ratio of PIIANP / CTXII changed in favor of collagen type II synthesis ($p<0.003$).

Conclusion: Joint distraction results in significant improvement in the clinical (pain, already 1 month after treatment) and structural (cartilage) status in end-stage knee OA which is sustained for at least 2 years. MRIs suggest an increase in cartilage thickness and covering of denuded areas in comparison with baseline values. The mechanical competence of the formed tissue is suggested by increased JSW of weight-bearing X-ray, and the hyaline nature by collagen type II biomarker analysis. At present, distraction therapy appears to be the first treatment that can reverse cartilage damage in end-stage knee osteoarthritis accompanied by significant clinical improvement.

828

Efficacy of Tanezumab Compared with Non-Steroidal Anti-Inflammatory Drugs in Patients with Knee or Hip Osteoarthritis (NCT00809354). Yusuf Yazici[1], Evan F. Ekman[2], H. Scott Greenberg[3], Michael D. Smith[3], Mark T. Brown[3], Christine R. West[4] and Kenneth M. Verburg[3]. [1]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY, [2]Southern Orthopaedic Sports Medicine, Columbia, SC, [3]Pfizer, Groton, CT, [4]Pfizer, Williamston, MI

Background/Purpose: A phase III study evaluated efficacy & reported on safety events of intravenous (IV) tanezumab (Tzb), a monoclonal antibody that inhibits nerve growth factor & reduces osteoarthritis (OA) pain, alone or combined with non-steroidal anti-inflammatory drugs (NSAID) versus NSAID alone.

Methods: Patients with moderate to severe knee or hip OA experiencing only partial symptomatic relief with NSAID received oral naproxen 500 mg BID, oral celecoxib 100 mg BID, Tzb (5 or 10 mg, IV every 8 weeks), or Tzb (5 or 10 mg, IV every 8 weeks) combined with naproxen 500 mg BID or celecoxib 100 mg BID. Co-primary efficacy endpoints (Western Ontario & McMaster Universities OA Index [WOMAC] Pain subscale, WOMAC Physical Function subscale, & Patient Global Assessment [PGA] of OA) were assessed at Week 16 versus naproxen or celecoxib. Long-term safety of Tzb alone & in combination with NSAID was evaluated up to Week 56.

Results: Tzb alone or with NSAID provided significantly greater improvement in WOMAC Pain & Physical Function subscales than naproxen & celecoxib alone ($p\leq0.015$; Table). For PGA, Tzb 10mg + naproxen, Tzb 10mg + celecoxib & Tzb 5mg + celecoxib provided significantly greater improvement versus NSAID alone, but improvements with Tzb alone & Tzb 5mg + naproxen were not statistically significant. The general safety profile was similar to previous Tzb trials, although incidence of adverse events (AEs) was higher likely due to longer treatment. Overall incidence of AEs & withdrawals due to AEs were higher with Tzb alone (ranges 74–75% & 12–16%, respectively) or Tzb with NSAID (ranges 73–74% & 14–18%) than NSAID alone (68% & 9%). Overall incidence of serious AEs was higher in Tzb + NSAID (range 10–12%) than either Tzb (8–9%) or NSAID alone (9%), which had similar rates. Differences in crude incidence of reported osteonecrosis or all-cause total joint replacement were not statistically significant for Tzb groups versus NSAID. Statistically significant risk increases for rapidly progressive OA were observed with Tzb (Tzb alone: 0.94–1.69/100 patient-years; Tzb + NSAID: 2.13–3.12/100 patient-years) versus NSAID alone (0.24/100 patient-years). Mean reduction in medial joint space was greater with Tzb versus NSAID alone; differences vs. NSAID alone were statistically significant for Tzb alone in knee patients and for Tzb 5 mg + NSAID for hip patients. A higher proportion of Tzb-treated patients reported AEs of abnormal peripheral sensation than with NSAID alone, but the majority of patients had no new or worsened abnormalities at final neurologic examination.

Table

LS Mean, least squares mean; PGA, Patient Global Assessment; SD, standard deviation; SE, standard error; WOMAC, Western Ontario & McMaster Universities Osteoarthritis Index; *WOMAC subscales were assessed on a 0-10 numerical rating scale & PGA was assessed on a 5-point Likert scale; baseline observation carried forward imputation was used for missing data.

Conclusion: Tzb alone or combined with NSAID resulted in greater improvement in pain & physical function than NSAID alone. An increased risk of rapidly progressive OA, particularly for Tzb combined with NSAIDs was noted. No other new safety signals emerged when Tzb was combined with naproxen or celecoxib; however a false negative result cannot be ruled out.

Osteoarthritis Is Related to An Increased Risk of Falls and Fractures: A Prospective Multinational Cohort Study (the GLOW study). Daniel Prieto-Alhambra[1], Xavier Nogués[2], M. Kassim Javaid[3], Nigel K. Arden[3], Cyrus Cooper[4], Allison Wyman[5], Adolfo Díez-Pérez[6] and GLOW Investigators. [1]URFOA-IMIM, Parc de Salut Mar; Idiap Jordi Gol i Gurina-Institut Català de la Salut; Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, UK, Barcelona, Spain, [2]Hospital del Mar-IMIM, Universitat Autònoma de Barcelona, Barcelona; and RETICEF, ISCIII Madrid; Spain, Barcelona, United Kingdom, [3]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, UK, Oxford, United Kingdom, [4]Southampton General Hospital, Southampton, United Kingdom, [5]Center for Outcomes Research, UMass Medical School, Worcester, MA, [6]Hospital del Mar-IMIM, Universitat Autònoma de Barcelona, Barcelona; and RETICEF, ISCIII Madrid; Spain, Barcelona, Spain

Background/Purpose: Although patients with osteoarthritis (OA) have increased bone mass, no corresponding decrease in fractures has been observed. We therefore studied the association between OA and incident falls and fractures in postmenopausal women.

Methods: The Global Longitudinal Study of Osteoporosis in Women (GLOW) is a prospective, multinational, observational cohort study. Practices that were typical of each region were identified through primary care networks organized for administrative, research, or educational purposes. Non-institutionalized women aged ≥55 years who visited a practice within the previous 2 years were eligible. A total of 60,393 women agreed to participate. Participants were mailed a self-administered questionnaire at baseline; follow-up questionnaires were sent at 12-month intervals for 3 years. Patients were classified as having OA or not according to their answer to the following question in the baseline survey: "Has a doctor or other health provider ever said that you had osteoarthritis or degenerative joint disease?" Information on incident falls and fractures, and potential confounders were self-reported by participants. For this analysis, women with missing baseline OA or fracture information, as well as those with celiac disease or rheumatoid arthritis, were excluded. The cumulative fracture incidence was calculated by the Kaplan-Meier method. Unadjusted and multivariable Cox models for incident fractures and falls were used to compute hazard ratios (HRs) according to baseline OA status. A Kaplan-Meier curve was computed on the subset of women with complete follow-up data.

Results: Of 51,386 women who were followed up for a median time of 1072 days (interquartile range 772 to 1095 days), 20,409 (39.7%) were classified as having OA. The unadjusted HR for fracture among OA patients was 1.40 (95% CI 1.32–1.48; $p<0.0001$), and this remained significant after multivariable adjustment (HR 1.21; 95% CI 1.13–1.30; $p<0.0001$; Figure). Falls were also more likely in women with OA (adjusted HR 1.27; 95% CI 1.23–1.30; $p<0.0001$). The association between OA and fracture remained significant even after adjusting for baseline falls (HR 1.16; 95% CI 1.08–1.25; $p<0.0001$).

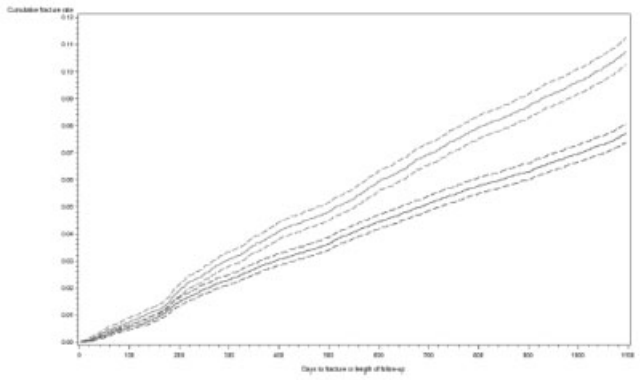

Figure 1. Kaplan-Meier curve predicting fracture by year 3, by baseline OA status, with 95% CIs (women with all 4 years of survey data only, n = 40132).

Conclusion: Postmenopausal women with OA have a 20% higher risk of fracture and experience almost 30% more falls than those without OA. Although incident falls may partially explain the increased risk of fracture observed in women with OA, our data suggest that the association between OA and fracture is independent of the number of falls.

Association of Candidate Single Nucleotide Polymorphisms with Radiographic Knee Osteoarthritis in African-Americans: Data From the Genetic Components of Knee Osteoarthritis Study. Rebecca Jackson[1], Changwan (Larry) Lu[2], Laura Yerges-Armstrong[2], David Duggen[3], Marc Hochberg[2], Braxton Mitchell[2] and OAI Investigators[4]. [1]Ohio State University, Columbus, OH, [2]University of Maryland School of Medicine, Baltimore, MD, [3]TGen, Pheonix, AZ, [4]San Francisco

Background/Purpose: Most genetic epidemiology studies in osteoarthritis (OA) have been conducted in either Asian or Caucasian populations. To our knowledge, no data from extension of these genetic association studies to African-American populations have been published. We used data from the African American subjects enrolled in the Genetic Components of Knee Osteoarthritis (GeCKO) Study to examine associations between radiographic knee OA (RKOA) and 13 single nucleotide polymorphisms (SNPs) previously reported to be associated with RKOA with odds ratios (OR) ranging from 1.15 to 6.6 (see Valdes AM, Spector TD: Nat Rev Rheumatol 2011;7:23–32).

Methods: 666 African American participants from the GeCKO Study, a genome wide association study (GWAS) using biospecimens from participants enrolled in the Osteoarthritis Initiative (OAI), with complete genotype and phenotype information were included in this analysis. Cases (n=446) had at least one knee with definite RKOA, defined as the presence of definite osteophytes (OARSI grade $\geq$1) regardless of the presence of joint space narrowing. Controls (n=220) were free of RKOA in both knees (i.e., both osteophyte and joint space narrowing grade = 0). Genotyping was completed on the Illumina 2.5M platform as part of the larger GWAS of OAI participants. Nine of the 13 previously reported SNPs were available on this platform for extension analysis. Association results for these individual SNPs were calculated using logistic regression with adjustment for age and sex; results were considered nominally significant with a p-value $<$ 0.05.

Results: Cases were slightly older (mean age 60.4 vs. 56.9 years) and more often female (69.9% vs. 64.5% women) than controls. Assuming a nominal α of 0.05, we estimated that our sample had 80% power to detect an OR of at least 1.22 for a SNP with a minor allele frequency (MAF) of 40% or an OR of at least 1.46 for a SNP with a MAF of 5%. Of the nine previously reported SNPs available for extension analyses, only one SNP, rs419598, was nominally associated with RKOA (P = 0.02). This is a synonymous coding variant in the Interleukin 1 Receptor Antagonist (*IL1RN*) gene that has been reported previously as associated with RKOA severity in Caucasian populations. The OR for association with RKOA in African Americans in the GeCKO study was 0.59 compared to an observed OR of 0.22 for severe knee OA, defined as KL grade 3–4, in 130 Caucasian individuals (Attur M, et al: Ann Rheum Dis 2010;69:856–61).

Conclusion: This preliminary extension study in African American subjects participating in the OAI GWAS provides evidence of genetic association of RKOA in the IL1RN gene region, but was unable to replicate many other previously reported genetic associations. The lack of association with many previously reported SNPs may be due to low power or to differences in allele frequency and/or linkage disequilibrium structure between African Americans and Asians/Caucasians. Future work in larger, ethnically diverse populations to extend previous findings and refine association signals is still needed, as is study of novel association patterns detectable only in African Americans.

Nanoparticle Encapsulated STAT1 siRNAs Induce Regression of Established Collagen Arthritis In Mice. Robert I. Scheinman, Ruchit Trivedi and Uday Kompella. University of Colorado Denver, Aurora, CO

Background/Purpose: Disease progression in Rheumatoid Arthritis (RA) is driven by a network of cytokines promoting the interactions between synovial cells and infiltrating immune cells. Macrophages represent a key cell type within the arthritic joint space, against which, no therapeutic has specifically been targeted. This cell is attractive in that it serves as a major source of cytokines such as TNFα and also functions as a source of antigen for the activation of lymphocytes. Nano-carrier systems such as functionalized polymeric nanoparticles are being explored for the targeted delivery of therapeutics to specific tissues. Here we attempted to design a functionalized nanoparticle with increased uptake properties in diseased joints. Hypothesizing that these nanoparticles would be preferentially taken up by phagocytic cells, we loaded them with an siRNA pool targeting STAT1 and explored the consequences of administration of this therapeutic to mice with developing or established disease. Knockdown of STAT1 in macrophages would be predicted to decrease IFNγ mediated events such as priming.

Methods: The FDA approved polymer; poly(lactic-co-glycolytic acid) (PLGA) was used to encapsulate either a pool of STAT1 targeted siRNAs, a non-targeting siRNA, or one of several tracking molecules using the water/oil/water emulsion method. Nanoparticles were functionalized by conjugating some of the polymers to a peptide containing an RGD domain which binds to $\alpha_v b_3$ integrins. Mice were made arthritic by either the Collagen Induced Arthritis (CIA) protocol or the Collagen Antibody Induced Arthritis (CAIA) protocol. Nanoparticles were introduced by weekly tail vein injections. Mice were assessed for disease. Upon sacrifice, tissues were obtained and assessed for nanoparticle uptake, disease measures, flow cytometry, and mRNA levels.

Results: Nanoparticles containing siRNA or Nile Red were 100 – 200 nm in diameter as measured by transmission electron microscopy. The RGD peptide was present at the surface of the nanoparticles as measured by changes in the zeta (surface) potential. Inclusion of the RGD integrin binding domain increased uptake in arthritic paw tissues by 10 – 20 fold. Nanoparticles were taken up by macrophages as measured by flow cytometry and by immunohistochemistry. STAT1 siRNA containing nanoparticles were effective in decreasing disease while empty nanoparticles and non-targeting siRNA loaded nanoparticles had no effect on disease progression. Remarkably, even when administered after disease was well established, STAT1 siRNAs effected a regression of swelling and redness. Analysis of mRNA levels demonstrated a reduction in STAT1 mRNA in tissues and suggested an increase in IL-10 signaling.

Conclusion: We have successfully delivered siRNAs to arthritic joint tissue using functionalized nanoparticles. Knock down of STAT1 stops disease progression and in some instances promotes disease regression. The data suggests that the mechanism is via the modulation of the activation state of macrophages, and possibly, dendritic cells.

Identification of Microrna-221, −222 and −323-3p Association with Rheumatoid Arthritis Via Predictions Using the Human TNF Transgenic Mouse Model. Ioannis Pandis[1], Caroline Ospelt[2], Niki Karagianni[3], Maria C. Denis[4], Martin Reczko[5], Artemis Hatzigeorgiou[5], Jiannis Ragoussis[6], Steffen Gay[2] and George Kollias[1]. [1]Institute of Immunology, Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece, [2]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [3]Institute of Immunology, Biomedical Sciences Research Center 'Alexander Fleming' and Biomedcode Hellas SA, Vari, Greece, [4]Biomed-Code Hellas SA, Vari, Greece, [5]Institute of Molecular Oncology, Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece, [6]Institute of Molecular Biology & Genetics, Biomedical Sciences Research Center 'Alexander Fleming' and Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom

Background/Purpose: Molecular alignment of animal models to their corresponding human disease is essential for basic understanding of biological mechanisms, the identification and validation of novel pathogenic pathways and the evaluation of diagnostic and therapeutic agents. MicroRNAs (miRs) have been found dysregulated and functionally involved in many inflammatory diseases, including rheumatoid arthritis (RA). In this study we sought to discover novel miRs associated with RA pathogenesis exploiting the predictive value of the human TNF transgenic (TghuTNF, Tg197) mouse model.

Methods: Mouse synovial fibroblasts (SFs) were isolated from fully diseased 8-week-old TghuTNF and wild type (WT) littermate mice and human SFs from RA and osteoarthritis (OA) patients. Total SF RNA was isolated using the mirVana™ miR Isolation Kit (Ambion). TghuTNF SF miR expression was determined via small RNA sequencing using an Illumina platform. Individual microRNA quantitation in human and mouse SFs was achieved via qRT-PCR based TaqMan microRNA assays.

Results: miR sequencing showed that TghuTNF SFs, a key cell type mediating RA pathogenesis, exhibit a significantly distinct miR expression profile with 12 upregulated and 16 downregulated miRs, compared to WT SFs. miRs 223, 146a, 221, 222, 155 and 323-3p were upregulated and miRs 322 and 335 downregulated in TghuTNF SFs in qRT-PCR validation assays. These results showed a high degree of correlation with sequence-based measurements ($R^2=0.954$, $p<0.0001$), indicating that the profile is highly quantitative. Several miRs have been reported in the literature to be dysregulated in human RA patient SFs, namely miR-124 (downregulated) and miRs 203, 155, 146a (upregulated) compared to OA SFs. miRs 155 and 146a have also been found to be induced by TNF in human RA SFs. Markedly, both TNF induced miRs 146a and 155 are also found upregulated in the TghuTNF mouse, suggesting that TghuTNF SFs align well with human RA SFs. Most notably, of the remaining validated miRs of the mouse profile, miR-221, miR-222 and miR-323-3p were also found to be significantly upregulated in RA SFs vs OA SFs, indicating that the TghuTNF model can be used effectively to predict previously unidentified miR dysregulations in human RA SFs.

Conclusion: Our comparative analysis of the TghuTNF miR profile with human patient data identified three novel miRs (miR-221, miR-222 and miR-323-3p) to be associated with human RA. Moreover, our results confirm that the TghuTNF model is a valuable predictive tool to study TNF-driven biology in RA SFs and propose novel modifiers and biomarkers with relevance to human disease.

Why p38 Inhibitors Are Ineffective in Rheumatoid Arthritis (RA): Increased Pro-Inflammatory Macrophage Function. Monica Guma, Deepa Hammaker, Meghan Edgar, Katharyn Topolewski, Mary Corr and Gary S. Firestein. UCSD School of Medicine, La Jolla, CA

Background/Purpose: p38 inhibitors have limited benefit in RA. One explanationfor this unexpected observation could be related to anti-inflammatory functionsof p38a in macrophages. For example, p38a inhibitors suppressexpression of IL-10 and the phosphatase DUSP1. Low DUSP1 expression couldprolong activation of other MAP kinases. Therefore, we determined if selective deletionof p38a in macrophages affectsseverity of arthritis in the passive K/BxN mouse model of arthritis. Wealso determined whether blocking upstream kinases in the p38 pathway mightavoid the limitations of traditional p38a inhibitors.

Methods: Wildtype (WT) and mice with selective deletion of p38ain macrophages ($p38a^{dM}$; p38adeletion using Cre/lysozyme M promoter) were injected with K/BxN sera once orweekly to induce acute or chronic arthritis, respectively. Joint extracts wereevaluated by ELISA, qPCR, and Western blot (WB). WT, MKK3, and MKK6-deficientbone marrow derived macrophages (BMDM) were stimulated with LPS and evaluatedby ELISA, qPCR, and WB.

Results: $p38a^{dM}$ mice had higher clinical scores and a delay inarthritis resolution compared with WT mice. In the acute model, day 8 scoreswere 6.8 ± 1.2 and 9.75 ± 0.1 andday 14 scores were 1.1 ± 0.3 and 3 ± 0.3($p=0.01$) for WT and $p38a^{dM}$ mice, respectively. In the chronic model (Fig 1), scores were persistently higher in $p38a^{dM}$mice (day 28 5.2 ± 1.6 and 10.2 ± 1.1,$p=0.05$, for WT and $p38a^{dM}$ mice, respectively). On day 5, DUSP1 mRNAexpression was lower and ERK phosphorylation was higher in inflamed $p38a^{dM}$ joints. On day 28 in the chronicmodel, IL-1b protein levels were 1.5 fold higherin inflamed $p38a^{dM}$ joints compared with WT joints ($p=0.02$). For in vitro experiments,LPS-stimulated IL-10 and IL-6 expression in p38inhibitor (SB203580)-treated BMDM was decreased by 80% and 50%, respectively.DUSP1 expression was also decreased by 50%, which was accompanied by persistentJNK and ERK phosphorylation. LPS stimulated MKK6 and MKK3-deficient BMDMalso had suppressed IL-6 expression but surprisingly, had normal IL-10production, DUSP1 expression, and JNK and ERKphosphorylation. In contrast to $p38a^{dM}$ mice, WTchimeric mice with either MKK6 or MKK3-deficient bone marrow had markedlydecreased severity of passive K/BxN arthritis.

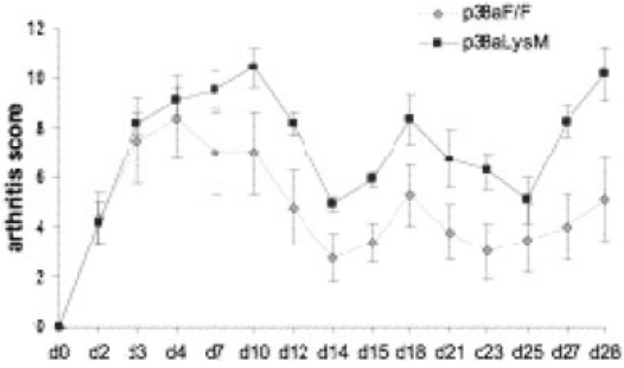

Figure 1. Chronicpassive K/BxN model in WT (p38aF/F)and $p38a^{dM}$mice

Conclusion: Selective deletion of p38a in macrophages increases inflammatory arthritis in mice bysuppressing anti-inflammatory feedback loops like IL-10 and DUSP1 expression.Targeting p38 in a disease like RA dominated by macrophage cytokines couldparadoxically interfere with anti-inflammatory pathways and lead to increaseddisease severity. Alternatively, targeting an upstream kinase that regulatesp38 could be more effective by suppressing pro-inflammatory cytokineswhile sparing IL-10 expression and preventing increased ERK/JNK activation.

834

Superior Efficacy of Ozoralizumab, An Anti-Human TNF Nanobody in a Transgenic Mouse Model of Polyarthritis. Martin Hegen[1], Els Beirnaert[2], Guy Hermans[2], Peter Casteels[2], Marina Shen[1], Julie Lee[1], Lori Fitz[1], Nilufer Seth[1], Yulia Vugmeyster[1], Christopher Wrocklage[1], Kyri Dunussi-Joannopoulos[1], Cheryl L. Nickerson-Nutter[1] and Mary Collins[1]. [1]Pfizer, Cambridge, MA, [2]Ablynx nv, Zwijnaarde, Belgium

Background/Purpose: Tumor necrosis factor (TNF) is expressed as a trimeric transmembrane protein that can be proteolytically cleaved by TNF converting enzyme to release its soluble form. Both forms of TNF interact with TNF receptor (TNFR) 1 and TNFR 2. Inhibition of TNF has been shown

to be an effective treatment of Rheumatoid Arthritis (RA). Nanobodies are antibody-derived single domain antigen binding therapeutic proteins that contain the unique structural and functional properties of naturally-occurring heavy-chain antibodies derived from camelids. They have a high degree of sequence and structural homology to human immunoglobulin variant heavy chain domains. The aim was to develop a new protein-based TNF therapeutic using novel protein moieties that has the potential to maximize efficacy while optimizing the product for ease of delivery.

Methods: Nanobodies that were high affinity binders of human TNF were selected. The strategy was to humanize and optimize a lead molecule for potency and *in vivo* half-life extension. Binding kinetics to human and rhesus monkey TNF and to human and rhesus monkey albumin were determined using surface plasmon resonance. Potent neutralizers of human TNF were identified in an *in vitro* bioassay and the *in vivo* efficacy of the lead molecule was subsequently evaluated in a human TNF transgenic mouse model of RA.

Results: Ozoralizumab (ATN-103) is a humanized, trivalent, bispecific Nanobody containing two human TNF-binding domains linked to a human serum albumin-binding domain. Human and rhesus monkey TNF had very similar on and off-rates, resulting in nearly identical equilibrium dissociation constants. In addition, Ozoralizumab demonstrated identical equilibrium dissociation constants based on binding to human and rhesus monkey albumin. In an *in vitro* bioassay, Ozoralizumab was as potent or more potent than currently marketed TNF inhibitor agents, as measured by the ability to neutralize the *in vitro* cell cytotoxicity of human and rhesus monkey TNF. Ozoralizumab does not have an antibody Fc region and is therefore unable to mediate any antibody-dependent cellular cytotoxicity or complement-dependent cytotoxicity. Pharmacokinetic analysis in mice and in non-human primates confirmed the long *in vivo* half-life of Ozoralizumab, adopting the half-life of serum albumin. Ozoralizumab further demonstrated efficacy by inhibiting infiltration of neutrophils induced by human TNF in a mouse air pouch model. In comparison with Infliximab, Ozoralizumab demonstrated superior efficacy in a therapeutic treatment protocol in a TNF transgenic mouse model of RA. Ozoralizumab was able to decrease the clinical scores and reverse the pathology.

Conclusion: The data presented show that Ozoralizumab combines high potency with long *in vivo* half-life. Ozoralizumab is considered to be a more effective anti-TNF therapeutic with less frequent and more convenient dosing for RA.

835

CXCL5 An Important IL-17 Mediated Proangiogenic Factor in Rheumatoid Arthritis and Experimental Arthritis Model. Nathan D. Chamberlain[1], Michael Volin[2] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL

Background/Purpose: These studies were performed to identify IL-17 down stream proangiogenic mediators in rheumatoid arthritis (RA) and IL-17-induced arthritis.

Methods: IL-17-induced proangiogenic factors were determined in RA synovial tissue explants and IL-17-induced arthritis joints employing ELISA. Next, the mechanism of proangiogenic factor induction by IL-17 was examined in macrophages and RA fibroblasts using ELISA. To determine whether angiogenesis is differentially modulated by the identified proangiogenic factors compared to IL-17, signaling pathways contributing to *in vitro* endothelial migration were determined.

Results: To determine IL-17 mediated proangiogenic factors in RA explants, tissues were activated with IL-17 or PBS and results were demonstrated as fold increase above the PBS value. We found that IL-17 significantly increases levels of CXCL1 (8 fold), CXCL5 (12 fold) and FGF2 (3 fold) compared to control, however VEGF levels were not affected in this process. To examine proangiogenic mediators in the IL-17-induced arthritis model, C57BL/6 mice were injected intra-articularly with 10^7 PFU adenoviral (Ad)-IL-17 or Ad-control. Ankles were harvested on day 10 post injection, and joint proangiogenic factors were quantified. We found that similar to RA synovial tissue explants, local expression of IL-17 significantly upregulates production of CXCL1 (40 fold), CXCL5 (10 fold) and FGF2 (2 fold) without affecting VEGF levels compared to control treatment. As CXCL1 and CXCL5 were the most prominent proangiogenic factors their mechanism of production was examined in macrophages and RA fibroblasts. To determine the mechanism by which IL-17 induces CXCL1 and CXCL5 production, signaling pathways were suppressed in IL-17-activated cells. Inhibition of PI3K or ERK pathways suppress production of CXCL1 in macrophages and CXCL5 in both cell types, however, in RA fibroblasts only inhibition of PI3K was capable of reducing IL-17-mediated CXCL1 levels. Our earlier studies demonstrate that IL-17-mediated arthritis severity and vascularization was significantly reduced in the anti-CXCL5 treatment group whereas, anti-CXCL1 treatment had no effect on these processes. To address the different efficacy of blocking CXCL1 and CXCL5 in IL-17 arthritis model we examined the mechanism by which these chemokines induce endothelial migration. We found that in HMVECs CXCL1 signals through PI3K and ERK, however this chemokine was unable to activate NF-kB or p38 signaling pathways. CXCL5 stimulation of HMVECs results in activation of the NF-kB pathway only. To demonstrate the mechanism by which CXCL1 and CXCL5 mediate HMVEC migration, inhibitors to these pathways were employed in *in vitro* chemotaxis. In agreement with our signaling results, inhibition of PI3K suppresses CXCL1-induced HMVEC migration, while chemotaxis mediated by CXCL5 was reduced through NF-kB inhibition.

Conclusion: Our results demonstrate that inhibition of CXCL1 is ineffective in reducing joint inflammation because IL-17 is present in the mouse ankles and can induce angiogenesis through PI3K pathway whereas CXCL5 mediates angiogenesis through a non-overlapping IL-17 mechanism.

Novel Small Molecule Inhibitors of Interleukin-1 Receptor Associated Kinase-4 Are Effective in a Preclinical Model of Arthritis. Eric G. Vajda, Tsung H. Lin, Bojing Wang, Koc-Kan Ho, Arjan van Oeveren, Brian McGuinness, Jeffrey Letourneau, Yong-Hee Lee, Deepa Rungta, Lin Zhi and Keith B. Marschke. Ligand Pharmaceuticals, La Jolla, CA

Background/Purpose: Interleukin-1 Receptor Associated Kinase-4 (IRAK4) is a serine/threonine protein kinase that activates NF-kappaB in both the toll-like receptor (TLR) and interleukin-1 (IL-1) signaling pathways. IRAK4 plays a critical role in innate immunity and recent evidence suggests it may play an important role in multiple autoimmune conditions including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), inflammatory bowel disease (IBD), and gout. We have discovered potent small molecule inhibitors of IRAK4 which may provide a novel therapeutic approach for the treatment of a range of inflammatory conditions.

Methods: Kinase inhibition was measured by IMAP technology or radioisotope filtration binding assays. Cell-based activity was determined in human and mouse cell lines, as well as human PBMCs. Cells were stimulated with either IL-1β or LPS and IL-6 secretion was measured by ELISA. Pathway selectivity was determined by flow cytometry measurements of NF-kappaB or STAT1 phosphorylation after stimulation with TNF or interferon-γ, respectively. Acute measurements of IL-1 pathway suppression *in vivo* were determined in mice orally administered IRAK4 inhibitors and injected i.p. with IL-1β. Serum IL-6 and TNF levels were determined by ELISA. Chronic assessment of IRAK4 suppression was determined in the mouse collagen induced arthritis (CIA) model.

Results: We have identified a lead series of compounds that bind to the ATP pocket of IRAK4 and inhibit kinase activity with potencies <10 nM. Compounds are selective inhibitors of IRAK4, with reduced inhibition versus a panel of off-target kinases. IL-1β-induced IL-6 secretion was inhibited in cell based assays with potencies <100 nM. In primary human PBMCs, both IL-1β and LPS induced IL-6 secretion were inhibited, indicating suppression of both IL-1 receptor and TLR-4 receptor signaling activity. Compounds had minimal activity in the TNF or interferon-γ pathways. The lead compound, LG0224912, inhibited IL-1 cytokine signaling after oral administration to mice. Suppression of TNF and IL-6 in mice tracked closely with exposure levels, demonstrating a clear pharmacodynamic-pharmacokinetic relationship. Oral administration of LG0224912 to mice with established CIA resulted in significant suppression of inflammation comparable to etanercept, and is the first demonstration of efficacy of an IRAK4 inhibitor in a disease model.

Conclusion: We have identified novel IRAK4 inhibitors that suppress both IL-1 receptor and TLR-4 receptor signaling. The compounds are active in an animal model of arthritis and have the potential to treat a range of inflammatory conditions including RA, SLE, IBD, and gout.

ACR Concurrent Abstract Session
Rheumatoid Arthritis Treatment - Small Molecules, Biologics, Therapy: Biomarkers

Sunday, November 6, 2011, 4:30 PM–6:00 PM

837

A Plasmablast Molecular Biomarker for Reduced Clinical Benefit From Anti-CD20 Therapy in Rheumatoid Arthritis. Kasia Owczarczyk[1], Preeti Lal[2], Alexander R. Abbas[1], Kristen Wolslegel[1], Cecile TJ Holweg[1], Wolfgang Dummer[2], Ariella Kelman[2], Paul Brunetta[2], Nicholas Lewin-Koh[2], Marco Sorani[1], Diane Leong[2], Paul Fielder[1], David E. Yocum[2], Carole Ho[2], Ward Ortmann[2], Michael J. Townsend[1] and Timothy W. Behrens[2]. [1]Genentech Research and Early Development, South San Francisco, CA, [2]Genentech, South San Francisco, CA

Background/Purpose: An important goal for personalized health care is the identification of biomarkers that predict the likelihood of treatment responses. Here, we tested the hypothesis that quantitative mRNA assays for B lineage cells in blood could serve as baseline predictors of therapeutic response to anti CD20-mediated B cell depletion therapy in subjects with rheumatoid arthritis (RA).

Methods: A reverse transcription-quantitative PCR panel comprising B cell-specific genes was developed to establish levels of B lineage cells using messenger RNA from whole blood of patients. *IgJ* gene expression was established as a marker of plasmablasts and plasma cells, while a B cell-specific splice variant of *FcRL5 (IRTA2c)* was established as a marker of mature B cells. Whole blood RNA samples from 3 large placebo-controlled trials of rituximab as well as a large placebo-controlled trial of ocrelizumab in RA patients were assessed for association of baseline B cell lineage status with clinical outcome. P values and confidence intervals for odds ratios were calculated using two-tailed Fisher's exact test.

Results: In samples from the REFLEX trial of rituximab in anti-TNF inadequate responders (118 rituximab, 23 placebo), a 25% subgroup of treated subjects with elevated baseline mRNA levels of *IgJ*, a marker for antibody-secreting plasmablasts, showed reduced clinical response rates (9% ACR50 response in IgJ^{hi}, 31% ACR50 in IgJ^{lo}). There were no significant efficacy differences in the placebo arm subjects stratified by this marker. Prospective testing of the *IgJ* biomarker in the DANCER and SERENE rituximab clinical trial cohorts (total n=200 rituximab, 93 placebo) and the SCRIPT ocrelizumab cohort (275 ocrelizumab, 137 placebo) confirmed the utility of this marker to predict lesser clinical benefit to anti-CD20 therapy ($P_{REPLICATION}$=0.006; OR = 2.4, 95% c.i. (1.2, 5.0). A combination mRNA biomarker, $IgJ^{hi}FCRL5^{lo}$, showed improved test performance over IgJ^{hi} alone by removing all ACR50 responders in the REFLEX trial. Prospective testing of the $IgJ^{hi}FCRL5^{lo}$ profile, representing a 17% subgroup in the replication cohorts, confirmed its utility ($P_{REPLICATION}$=0.008; OR = 2.7, 95% c.i. (1.3, 6.3).

Conclusion: This study demonstrates that baseline blood levels of molecular markers for late B lineage stage plasmablasts identify a ~20% subgroup of active RA subjects who are unlikely to gain significant clinical benefit from anti-CD20 B cell depletion therapy compared with placebo. Additional investigation into alternate dosing regimens and monitoring of plasmablast biomarkers may be warranted for these patients.

838

Development of a Multi-Biomarker Structural Damage Score in Rheumatoid Arthritis to Predict Radiographic Progression in the Leiden Early Arthritis Cohort. Annette H.M. van der Helm-van Mil[1], Rachel Knevel[1], William C. Manning[2], Lyndal K. Hesterberg[2], Guy Cavet[2], T.W.J. Huizinga[3] and Yijing Shen[2]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Crescendo Bioscience, Inc., South San Francisco, CA, [3]Leiden University Medical Centre, Leiden, Netherlands

Background/Purpose: The ability to predict progressive structural damage has the potential to improve disease management in rheumatoid arthritis (RA) patients. We aimed to develop a Multi-Biomarker Structural Damage (MBSD) score to predict the risk and quantity of joint damage in an individual patient over 12 months.

Methods: 28 serum biomarkers representing diverse biological pathways were previously selected from 93 candidates in a series of studies based on their performance at predicting joint damage. Biomarker concentrations were determined in 307 serum samples from 187 patients followed in the Leiden Early Arthritis Cohort. The concentrations of individual biomarkers were assessed for their association with change in total van der Heijde Sharp Scores (SHS) over 12 month intervals by Spearman correlation.. Multivariate statistical models were built using linear regression to predict both the rate of change in SHS (ΔSHS) and risk of progression (RP) using combinations of biomarkers and conventional variables. Independent contributions of variables to modeling were assessed in ordinary least squares (OLS) regression. Model performance for ΔSHS was evaluated in Leave One Out cross-validation by the area under the receiver operating characteristic curve (AUROC). Model performance for RP models was evaluated by specificity, sensitivity, total classification error and AUROC for classifying ≤ 0 versus > 0 ΔSHS.

Results: At False Discovery Rate (FDR) < 0.05, 15 biomarkers were correlated with ΔSHS. Prototype MBSD models using serum markers had the highest observed performance among clinical measures with an AUROC of 0.73.The performance values of clinical measures that were significantly correlated with ΔSHS were: initial erosion score (AUROC=0.70), initial SHS (AUROC=0.67), ESR (AUROC=0.62), initial joint space narrowing score (AUROC=0.6), SJC44 (AUROC=0.58), CRP (AUROC=0.59) and DAS44 (AUROC=0.57). MBSD had higher observed performance than a combination of clinically available variables (CRP, ESR, SJC44, CCP, Presence of Erosions, Ritchie Articular Index (RAI), Patient Global (PG) and RF; AUROC=0.64). The combination of serum biomarkers and initial erosion score gave slightly higher performance than either alone (AUROC=0.74). RF and CCP titers, PG, age, and RAI were not significantly correlated with ΔSHS. In OLS multivariate regression (with JSN and erosion scores included separately), only two measures were significant independent predictors of ΔSHS: initial erosion score ($p<0.001$) and MBSD ($p=0.002$). The sensitivity, specificity and total classification error of MBSD for risk of progression were 0.63, 0.73 and 0.32, respectively.

Conclusion: Combinations of serum biomarkers had independent predictive value and higher observed performance than conventional clinical measures at predicting progressive structural damage in RA. An MBSD score generated by serum biomarkers has the potential to improve prediction of radiographic change in clinical practice.

839

New Assay Generation for Antibodies Against Modified and Citrullinated Peptides Predicts Poor Response to TNF Inhibitor Therapy. Lotta Ljung[1], Karl Egerer[2], Holger Bang[3], Eugen Feist[4], Gerd R. Burmester[5] and Solbritt Rantapää Dahlqvist[1]. [1]Umeå University Hospital, Umeå, Sweden, [2]Labor Berlin - Charité Vivantes GmbH, Berlin, Germany, [3]Orgentec Diagnostika GmbH, Mainz, Germany, [4]Charité Medical School, Berlin, Germany, [5]Charité - Universitätsmedizin Berlin, Berlin, Germany

Background/Purpose: Current perception of the therapy for rheumatoid arthritis (RA) suggests that response to treatment is only partially predictable by autoantibodies against citrullinated proteins (ACPAs). These antibodies precede the debut of RA and are associated with a more aggressive course of the disease. Our aim in this study was to analyse several new ACPAs against antigens with additional post-translational modifications and to evaluate their predictive value for response to therapy using tumour necrosis factor (TNF) inhibitors.

Methods: The study included 118 patients (mean age at inclusion 52.9±12.6 years) with polyarthritis, who started on treatment with their first TNF-inhibitor (etanercept n=23, 19.5%, adalimumab n=6, 5.1%, infliximab n=89, 75.4%). Of these patients (pts), 109 (92.4%) fulfilled the ACR 1987 RA criteria, 4 (3.4%) had undifferentiated polyarthritis, 4 (3.4%) juvenile idiopathic arthritis and one (0.8%) psoriatic polyarthritis. Disease activity score for 28 joint count (DAS28) was evaluated at start of treatment and after three months. The mean DAS28 at start of therapy was 5.64±1.24, without significant difference between smokers (n=22, 18.6%) and non-smokers. Poor response was defined as a DAS28 ≥3.2 at three months. Blood samples for analyses of ACPAs were drawn before treatment started. Antibodies (abs) against cyclic citrullinated peptid (a-CCP) and mutated citrullinated vimentin (a-MCV) were analysed by commercial assays; modified MCV (a-modMCV), sialinized MCV (a-sialMCV) and anti-modified vimentin (a-modvim) were analysed by research assays. Cut-off for all research assays was 20 U/ml. Test for anti-vimentin (a-vim) abs was used as negative control. Odds ratios for poor response were calculated by logistic regression analyses using SPSS 19.0.

Results: Positivity for a-CCP abs was found in 100 pts (84.7%), for a-MCV abs in 99 pts (83.9%), for a-modMCV abs in 65 pts (55.1%) and for

a-modvim abs in 37 pts (31.4%). All pts except one had a-sialMCV ab concentrations above cut-off level (n=117, 99.2%) and none had a-vim abs above cut-off. The mean DAS28 after 3 months of treatment was 3.68±1.23, with 78 pts (66.1%) not achieving remission or low disease activity. In simple logistic regression models, poor response to therapy was significantly associated with smoking (OR 4.0, 95%CI 1.1–14.4) and a positive test for a-modMCV abs (OR 3.0, 1.4–6.6), but not with positivity for the other ACPAs, age, sex or disease duration. The combination of smoking and positivity for abs against a-modMCV or a-MCV, significantly predicted poor response to the TNF-inhibitor (OR 14.7, 1.8–120.0 and OR 7.0, 1.5–32.0, respectively) compared with not having these factors. Similar patterns, although not significant, were also seen for a-CCP abs and a-modvim abs in combination with smoking.

Conclusion: Antibodies against modified MCV, or smoking in combination with a-MCV abs or a-modMCV abs, respectively, significantly predicted a poor response to TNF inhibitor after 3 months of therapy. Thus, the individual ACPA status could represent a negative predictive factor for response to TNF inhibitors, particularly in conjunction with smoking habits.

Protein Array Screening Reveals Autoantigenicity Patterns Predicting Anti-TNF Alpha Therapy Response in Rheumatoid Arthritis Patients. Zoltan Konthur[1], Katja Köpke[2], Hans Lehrach[1], Gerd R. Burmester[2] and Karl Skriner[2]. [1]Max Planck Institute for Molecular Genetics, Berlin, Germany, [2]Charité - Universitätsmedizin Berlin, Berlin, Germany

Background/Purpose: One third of rheumatoid arthritis patients treated with biologicals targeting TNFα are therapy non-responders. We investigated the differences in seroreactivity of patients responding and not responding toanti-TNF alpha therapies prior and after therapy to deduce diagnostically applicable autoantigenicity patterns

Methods: Screening with patient sera were conducted on protein macroarrays consisting of 37.830 unique putative expression clones. Response patterns of different immunoglobulin classes were recorded and bioinformatically evaluated enabling us to deduce a set of proteins, which allow to distinguish between therapy responders and non-responders. Next, selected candidates were expressed recombinantly in *E. coli*, purified and further stratified with larger patient cohort in ELISA.

Results: Comparative analysis of macroarray results with sera from responders and non-responders to anti TNF drug revealed a more than 30-fold higher number of autoantigens targeted by high titers of IgA autoantibodies in non-responders compared to responders (221 versus 6).More detailed analyses suggest that with 5 autoantigens found to be common in all individual non-responders to anti-TNFα treatment, a reduced number of antigens might be sufficient to predict non-responsiveness. Pretreatment sera from patients with diagnosis of RA based on the ACR classification criteria who were initiated on therapy with TNF inhibitors were analyzed with three markers from the biomarker set of highest priority (RAB11B, PPP2R1A, KPNB1) using an ELISAs assay. In total, analyses of 69 patients were carried out, of which 13 were clearly defined as responder and 8 were clearly defined as non-responder. Of these, already 5 (62,5%) Non-responders could clearly be identified with already three markers from biomarker set of highest priority (RAB11B, PPP2R1A, KPNB1). None of the Responder or Intermediate Responder gave any signal on said markers on IgA-level. The remaining 48 patient samples are derived prior treatment with anti-TNFalpha inhibitors and were blinded. According to published studies, 20–25% of RA patients treated with TNFalpha inhibitors are Non-responders: Hence we expect ~10 patients to be non-responder. Within this set, 5 patients (50%) showed clear IgA response to three markers from biomarker set of highest priority (RAB11B, PPP2R1A, KPNB1).

Conclusion: These data suggest that non-response to anti-TNFα biologicals might be predicted based on frequency and magnitude of autoantibodies of the IgA class. Furthermore, 5 IgA autoantigens common in all individual non-responders may be sufficient to predict non-responsiveness.

841

Gene-Gene Interactions in Folate Pathway Contribute to Methotrexate Adverse Events in Rheumatoid Arthritis. Thierry Dervieux[1], Judith Wessels[2], J. M. Kremer[3], Tom W.J. Huizinga[2] and Henk-Jan Guchelaar[2]. [1]Exagen Diagnostics, Albuquerque, NM, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: To determine whether gene-gene interactions (epistasis) in folate, purine and pyrimidine gene pathways contribute to adverse events following methotrexate (MTX) therapy in rheumatoid arthritis (RA).

Methods: The discovery cohort consisted of 186 patients (93% Caucasians) with early RA enrolled in the monotherapy arm of the BeSt study. MTX therapy was started at 7.5 mg/week and increased to 25 mg/week to control disease activity. MTX related adverse events were evaluated after 6-months therapy. A total of 12 SNPs in folate (RFC-1, MTHFR, MTHFD1, MS, GGH, SHMT1), purine (ATIC, AMPD1, ITPA) and pyrimidine (TYMS) pathways were measured using standard molecular methods. Haplotypes in Methylenetetrahydrofolate Reductase (MTHFR 677C/T-1298A/C) were inferred using expectation-maximization algorithms. Data analysis consisted of multifactor dimensionality reduction technique (MDR). MDR detects non-linear gene-gene interactions by combining predisposing genotypes of adverse events (predisposing genetic attribute) into two separate groups depending on whether they are more common in patients presenting with adverse events or not. The robustness and significance of the model was tested through internal cross validation consistency (CVC, 10-fold) and 1000-fold permutation testing. The predictive value of the predisposing genetic attribute of adverse events was further tested independently in a validation cohort consisting of 47 RA patients from the United States (92% Caucasians) starting MTX (7.5 mg/week) with adverse events evaluated after 4-months MTX therapy.

Results: After 6-months MTX therapy, the incidence of MTX related adverse events was 29% in patients enrolled in the BeSt study (median MTX dose received was 25 mg/week). MDR analysis revealed a non linear pattern of interactions between MTHFR 677C/T-1298A/C haplotypes and variants in GGH [C16T] and MTHFD1 [G1958A] (Table I). The stepwise addition of the three genetic components increased the testing accuracy from 0.49 to 0.64. The constructed predisposing genetic attribute pooling higher and lower likelihood of adverse events in two separate groups revealed a 6.1 fold (CI 95%: 2.9–12.9, $p<0.001$) greater likelihood of adverse events in carriers (50%) versus non carriers ($p<0.001$). Sensitivity was 79.6% and specificity was 60.1%. In the validation cohort, the incidence of MTX adverse event was 51% after 4 months therapy (median MTX dose received was 15 mg/week). A total 66% patients carried the genetic attribute predisposing to MTX adverse events. These patients were 5.4 fold (CI 95%: 1.4–21.3, $p<0.001$) more likely to develop adverse events than those without the predisposing genetic attribute. Sensitivity was 83% and specificity was 52%.

Table. Multifactor dimensionality reduction analysis

Model	Training accuracy	Testing accuracy	CVC	P value
GGH C16T	0.553	0.490	6/10	0.838
GGH C16T + MTHFR 677C/T-1298A/C haplotype	0.621	0.610	10/10	0.081
GGH C16T + MTHFR 677C/T-1298A/C haplotype + MTHFD1 G1958A	0.706	0.639	10/10	0.016

CVC: cross validation consistency; GGH: Gamma-glutamyl-Hydrolase; MTHFD1: Methylene tetrahydrofolate dehydrogenase.

Conclusion: These hypothesis generating data indicate that gene-gene interactions contribute to MTX-induced adverse events in RA.

842

Patterns of Interaction Between Genetic and Non-Genetic Attributes and Methotrexate Efficacy in Rheumatoid Arthritis. Thierry Dervieux[1], Judith Wessels[2], J. M. Kremer[3], Leonid Padyukov[4], Maria Seddighzadeh[4], Saedis Saevarsdottir[4], R.F. van Vollenhoven[4], Lars Klareskog[4], T. Huizinga[2] and Henk-Jan Guchelaar[2]. [1]Exagen Diagnostics, Albuquerque, NM, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Albany Medical College and The Center for Rheumatology, Albany, NY, [4]Karolinska Institutet, Stockholm, Sweden

Background/Purpose: The contribution of low-penetrance single nucleotide polymorphisms to methotrexate (MTX) efficacy in rheumatoid arthritis (RA) is inconsistent between studies. We sought to elucidate an architecture of MTX response in three cohorts of RA patients treated with MTX.

Methods: SNP frequencies in genes from folate, purine and pyrimi-

dine pathways were measured to develop a model of gene-gene interactions (epistasis). The cohorts consisted of 439 patients who received MTX in the United States (n=255) and The Netherlands (n=184). A third cohort of 530 RA patients from Sweden was used to replicate the findings. MTX efficacy was assessed using the European League Against Rheumatism criteria in the majority of patients. Gene-gene interactions were detected and a predisposing genetic attribute of response was constructed using multifactor dimensionality technique (MDR). Meta-analysis was conducted and Cochran's Q test was used to detect heterogeneity.

Results: Non-linear patterns of gene-gene interactions between variants in Amino-Imidazole Carboxamide Ribonucleotide Transformylase (C347G), Reduced Folate Carrier (G80A) and Inosine Triphosphate Pyrophosphatase (C94A) revealed a predisposing genetic attribute significantly associated with MTX response in the US and Dutch cohorts (OR=2.9, CI95%:1.9–4.2; p<0.001), a finding that did not replicate in the Swedish cohort (OR=0.9; CI95%: 0.64–1.37; p=0.74). A meta-analysis combining the three cohorts revealed significant heterogeneity (Q=15.3; p=0.005) with random effects odd ratio of 1.8 (OR=1.79 CI95%: 0.80–4.02). We reasoned that difference in population structure and, hence, heterogeneity may explain the lack of replication in the Swedish cohort. Therefore, we conducted an additional MDR analysis by superimposing patient age, gender and anti-citrullinated peptide antibodies (ACPA) status on the constructed predisposing genetic attribute. MDR revealed that the stepwise addition of these genetic and non genetic components increased the testing accuracy from 0.518 (genetic attribute only) to 0.585 (genetic attribute with gender, age and ACPA status). This new attribute resulted into a 2.2-fold (OR=2.2, CI95%: 1.6–2.9; p<0.01) higher likelihood of response and significance was achieved in the three cohorts. The selective advantage toward response in the presence of the predisposing genetic attribute was not observed in females and ACPA positive patients, while older and male ACPA negative patients tended to exhibit a greater likelihood of response in the absence of the predisposing genetic attribute. No significant heterogeneity was detected (Q=3.67; p=0.160) and random effects OR was 2.3 (OR=2.31 CI95%: 1.53–3.49).

Conclusion: Gene-gene interactions together with non-genetic attributes may contribute to MTX efficacy in RA. Apparent inconsistencies between studies on MTX responsiveness were reconciled using MDR, by demonstrating that complex gene-gene interactions together with non-genetic attributes predict MTX efficacy in RA.

Survival and Predictors of Mortality In Australian Patients with Connective Tissue Disease-Associated Pulmonary Arterial Hypertension. Gene-Siew Ngian[1], Wendy Stevens[2], Jill Byron[2], Ai Tran[3], Janet E. Roddy[3], Robert Minson[4], Catherine L. Hill[5], Ken Chow[6], Joanne Sahhar[7], Susanna Proudman[6] and Mandana Nikpour[1]. [1]The University of Melbourne, Melbourne, Australia, [2]St Vincent's Hospital, Melbourne, Australia, [3]Royal Perth Hospital, Perth, Australia, [4]Flinders Medical Centre, Adelaide, Australia, [5]The Queen Elizabeth Hospital, Woodville, Australia, [6]Royal Adelaide Hospital, Adelaide, Australia, [7]Monash Medical Centre, Melbourne, Australia

Background/Purpose: We sought to determine predictors of mortality in connective tissue disease-associated pulmonary arterial hypertension (CTD-PAH).

Methods: This was a retrospective cohort study of patients with CTD-PAH recruited from six tertiary hospitals. In addition to data prospectively collected as part of the Australian Scleroderma Cohort Study, physician records were reviewed. PAH was defined on right heart catheterization. All patients had systemic sclerosis (SSc) or another underlying CTD. Records were censored at 31/12/09. Survival was determined using Kaplan-Meier estimates. Univariate and multivariable predictors of survival were determined using log-rank / Wilcoxon tests, and proportional hazards regression modelling.

Results: Amongst 117 patients (105 female) there were 32 deaths. Mean age at PAH diagnosis was 61.5 ± 11.4 years. SSc was the most common underlying CTD, accounting for 104 patients (88.9%). Forty-eight patients (41.0%) had coexistent interstitial lung disease (ILD). At baseline, mean six-minute walk distance was 325 ± 127 m and 88 patients (75.2%) were in WHO functional class III. Average duration of follow-up from PAH diagnosis was 2.6 ± 1.8 years. Seventy patients (59.8%) received monotherapy, 12 (10.3%) sequential monotherapy and 34 (29.0%) combination pulmonary vasodilator therapy. Bosentan was the most commonly prescribed medication, used in 102 patients (87.2%). Sildenafil was the next most common, followed by inhaled iloprost and sitaxentan. One-, two- and three-year survival was 94%, 89% and 73%, respectively (see Figure 1). On univariate analysis, predictors of mortality were WHO functional class IV at baseline, male sex, ILD, right ventricular dysfunction, pericardial effusion, absence of warfarin therapy, absence of combination therapy and higher mean right atrial pressure (mRAP) at PAH diagnosis. On multiple regression analysis, WHO functional class IV at baseline, higher mRAP at PAH diagnosis, coexistent ILD and absence of warfarin therapy remained independent predictors of mortality (see Table 1).

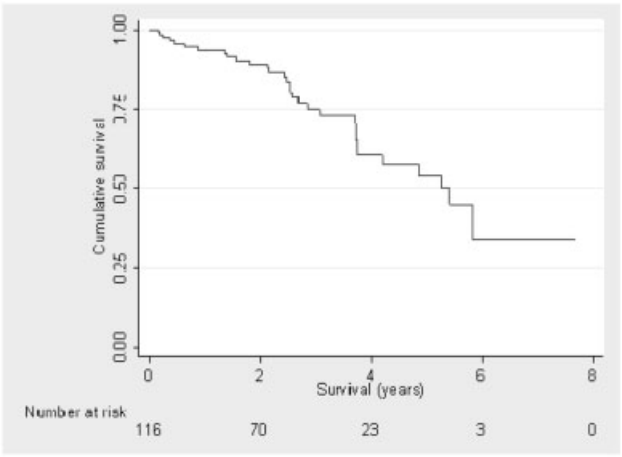

Figure 1. Survival from PAH diagnosis.

Table 1. Predictors of mortality on multivariable analysis

Variable	Adjusted HR (95% CI)	*p* value
Male sex	8.23 (0.59–114.98)	0.117
WHO class at baseline	7.45 (1.18–47.13)	0.033
Warfarin therapy ever	0.07 (0.01–0.88)	0.040
ILD	9.81 (1.07–89.92)	0.043
Pericardial effusion	3.83 (0.67–21.79)	0.130
mRAP	1.19 (1.01–1.40)	0.037
Baseline 6-minute walk distance	0.995 (0.987–1.003)	0.199
Combination therapy	0.43 (0.14–1.33)	0.145

Conclusion: Among patients in this study, three-year survival is 73%; this is better than that reported in several studies of CTD-PAH in the current treatment era. Predictors of survival include lower WHO functional class at baseline, lower mRAP at PAH diagnosis and warfarin therapy, suggesting that earlier diagnosis of PAH and treatment with warfarin in addition to advanced pulmonary vasodilator therapy may improve survival in these patients.

844

Prognostic and Diagnostic Significance of Autoantibodies to Citrullinated Proteins (ACPA) in Patients with a Scleroderma-Rheumatoid Arthritis (SSc-RA) Overlap Syndrome. Makoto Soejima[1], Zhou Zhijie[2], Donald M. Jones[1], Danielle Goudeau[1], Christine L. Amity[1], Lynne M. Frydrych[1], Robyn T. Domsic[1], Aarat M. Patel[1], Larry W. Moreland[3], David M. Lee[4], Thomas A. Medsger[1] and Marc C. Levesque[1]. [1]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [2]Aurora Health Care Oshkosh, Oshkosh, WI, [3]University of Pittsburgh, Pittsburgh, PA, [4]Brigham and Womens Hospital, Boston, MA

Background/Purpose: In clinical practice, the anti-CCP test is used to detect ACPA and is used as a diagnostic test for RA. However, approximately 3–5% of patients with SSc are anti-CCP positive. It is uncertain whether anti-CCP tests are only positive in patients with SSc-RA overlap syndromes or are also positive in patients with SSc only. It is also not clear whether the ACPA antigens recognized by anti-CCP antibodies from anti-CCP positive SSc patients differ from those of RA patients.

Methods: We performed a chart review of new sequential patients with a

diagnosis of SSc enrolled in a University of Pittsburgh Medical Center (UPMC) SSc registry in the calendar years from 2004 to 2007 (N = 300). We also reviewed the records of 16 other SSc patients seen prior to 2004 who had symptoms suggestive of both SSc and RA. Finally, we reviewed the records of 143 patients from the UPMC RA Comparative Effectiveness Research (RACER) registry. We used the 1987 and 2010 ACR/EULAR RA criteria to determine the number of patients in each group with RA only, with a SSc-RA overlap syndrome or with SSc only. We determined the frequency of interstitial lung disease (ILD) and other clinical features in each group of subjects. Serum samples were analyzed for anti-CCP by ELISA (anti-CCP2; Axis-Shield, UK). A panel of linear and cyclic citrullinated and non-citrullinated peptides derived from fibrinogen, vimentin, enolase and filaggrin were examined by ELISA for reactivity with the same serum samples.

Results: Among the 300 sequential SSc patients seen initially between 2004 and 2007, we identified 8 (2.7%) subjects with RA. The 16 SSc patients seen prior to 2004 also met criteria for a diagnosis of RA. Among the SSc only subjects, 1 was anti-CCP positive and among the SSc-RA overlap subjects, 14 of 24 were anti-CCP positive ($p < 0.0001$; Fisher's exact test; 99% specificity; 58% sensitivity). 116 of 143 (81%) RA only subjects were anti-CCP positive. Among the anti-CCP positive subjects, the pattern of ACPA peptide reactivity was essentially identical in the SSc-RA overlap subjects as compared to the RA only subjects. There was an increased frequency of ILD, but not other clinical features, among SSc-RA subjects as compared to SSc only subjects (63% vs. 29%, respectively; $p=0.0008$, Fisher's exact test). Among SSc-RA patients, 63% of anti-CCP positive patients had ILD, while 63% of anti-CCP negative SSc-RA patients had ILD ($p=1.0000$), suggesting that anti-CCP positivity is not specifically associated with ILD in SSc-RA.

Conclusion: These studies indicate that among patients with SSc, a positive anti-CCP test is highly specific for a SSc-RA overlap syndrome. Furthermore, the ACPA peptide reactivity pattern by ELISA in SSc-RA patients suggests that these patients have RA that is indistinguishable from RA patients without SSc. SSc-RA overlap patients have a higher frequency of ILD suggesting that an overlap of these disorders may promote development of ILD. Taken together, these studies provide a better understanding of the test characteristics of the anti-CCP ELISA and a better understanding of rheumatic overlap syndromes.

Detection of Autoantibodies to RNA-Protein Complex in Scleroderma by Quantitative-PCR of RNA Components of the Antigens. Angela Ceribelli, Minoru Satoh and Edward K.L. Chan. University of Florida, Gainesville, FL

Background/Purpose: Autoantibody tests in scleroderma (SSc) are useful to help diagnosis, predict organ involvement, and prognosis. SSc autoantibodies recognizing RNA-protein complex, anti-Th/To (7-2RNA, 8-2RNA-protein complex) and anti-fibrillarin/U3-snoRNP (U3RNA-protein complex), have been known for over 20 years. However, they are usually detected by immunoprecipitation (IP) and validated commercial assays are not available. Quantitative PCR (qPCR) has become a standard technique to quantify mRNA levels of specific genes in cells or tissues, but qPCR of the RNA component of autoantigens has not been applied to identify autoantibodies. Our aim is to establish a novel method for anti-Th/To and U3-snoRNP antibodies, using qPCR to detect the RNA component of the autoantigens.

Methods: Standard IP was performed using K562 cell extract. cDNA was made from RNA extracted from immunoprecipitate, and qPCR was performed using primers for the 7-2 RNA (Th) and U3 RNA. Ct (cycle threshold) values were compared in a titration experiment, serially diluting the cell lysate, RNA and cDNA up to 1:4096, to test the efficacy and sensitivity of the assay. Evaluation was based on 22 anti-Th/To (+), 12 anti-U3 (+) sera and 39 controls (normal controls and SSc with other autoantibodies).

Results: When cell extract was serially diluted for IP, linear dose response curves showed that with every 1:8 dilution, Ct value changed by ~3, which reflects the 8 fold difference as expected. Difference of Ct between antibody positive and negative samples was 8–10 and it was similar throughout the dilutions. Similar results were obtained when serial dilutions were made at the level of RNA purified after IP or cDNA after RT, indicating that reliable range of Ct numbers can be obtained even with very small amount of cell extract, RNA and cDNA. In the screening of anti-Th and anti-U3 samples using cell extract from one million cells, the mean Ct value is 15.28 (SD 0.7) for anti-Th/To (+) and 20.37 (SD 1.83) for anti-U3 (+). These values were significantly lower compared with the control group, with a difference of 8 Ct values for anti-Th/To (+) and 5 Ct values for anti-U3 ($p<0.05$).Sensitivity of our method is 100% for anti-Th/To and 92% for anti-U3 antibodies, while specificity is 97% and 94%, respectively, compared with IP followed by urea-PAGE/silver staining of the RNAs.

Conclusion: This new method offers highly reliable identification of antibodies to Th/To and U3 compared with the gold standard IP assay. Making tests for these autoantibodies widely available to clinicians should be helpful in the diagnosis and follow-up of SSc patients.

846

The Significance of Tendon Friction Rubs in Early Diffuse Systemic Sclerosis Patients. Adam Doré[1], Thomas A. Medsger Jr.[2], Mary Lucas[3], Dana Ivanco[3] and Robyn T. Domsic[2]. [1]UPMC Presbyterian Shadyside Hospital, Pittsburgh, PA, [2]University of Pittsburgh Med Ctr, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Palpable tendon friction rubs (TFR) in systemic sclerosis (SSc) have been associated with diffuse cutaneous (dc) skin disease and increased disability index scores, but little information on patient outcomes has been published. The objective of this study was to determine the relationship of TFR in early dcSSc to the development of new internal organ system involvement and survival.

Methods: From our prospectively enrolled institutional scleroderma databank we identified a group of early dcSSc patients (disease duration < 2 years from the first symptom attributable to SSc) who were first evaluated during 1980–2005 and found to have one or more palpable TFRs on exam. The next consecutive early dcSSc patient seen without TFR was matched (1:1) as the control. All cases and controls had at least two clinic visits and five years of follow-up from the time of their first visit. Survival was obtained through the Social Security Death Index. Cases and controls not seen in the last year were contacted via mail questionnaire. Testing results were located in those who responded and organ system involvement determined. Descriptive statistics were used for baseline data, and conditional logistic regression to assess risk of new internal organ involvement. Cox proportional hazards was used to identify factors associated with survival.

Results: 287 early dcSSc patients with TFRs were matched to 287 early dcSSc controls. There was no difference in age or gender between the groups. Patients with TFR had a higher median modified Rodnan skin thickness score, compared to controls (26 vs 21, $p <.0001$). Patients with TFRs had a shorter median disease duration (0.83 years, IQR 0.61, 1.13) compared to controls (1.03 years, IQR 0.70,1.48, $p < 0.0001$). The TFR group had a higher proportion of Caucasians (94%) compared to controls (89%, $p=0.02$)

The five year cumulative survival rate in TFR patients was 32% compared to 19% in controls ($p=0.006$). After adjustment for age and gender, patients with TFR were 83% more likely to die within five years after their initial evaluation (OR 1.83, 95% CI 1.25 – 2.67, $p=0.002$).

Patients with TFRs were significantly more likely to later develop new renal crisis or cardiac involvement, as displayed in Table 1. There was no increased risk in patients with TFR to develop new pulmonary or gastrointestinal involvement.

Table 1. Risk of new internal organ involvement in early dcSSc patients with tendon friction rubs

	Odds Ratio	95% Confidence Interval	p-value
Renal Crisis	4.00	2.00 – 8.00	<.0001
Cardiac	3.72	1.96 – 7.05	<.0001
Interstitial Lung Disease	1.32	0.88 – 1.97	0.18
Gastrointestinal	1.16	0.78 – 1.73	0.46
Pulmonary Hypertension	2.33	0.60 – 9.02	0.22

Conclusion: Early dcSSc patients with a TFR on exam are at increased risk for five year mortality compared to early dcSSc patients without a TFR. Patients with TFR have a four-fold increased risk of later developing renal crisis, and a 3.7-fold risk of later developing cardiac system involvement. The TFR is an important prognostic physical exam finding in early dcSSc patients.

847

Long-Term Follow-up of Limited Cutaneous Systemic Sclerosis Patients with Anti-Th/to Antibody. Erin Snell[1], Mary Lucas[1], Dana Ivanco[1], Thomas A. Medsger[2] and Robyn T. Domsic[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh, Pittsburgh, PA

Background/Purpose: Anti-Th/To antibody occurs in 5–10% of limited cutaneous Systemic Sclerosis (lcSSc) patients. Anti-Th/To testing is not commercially available, thus only small case series have been described. The objective of this study was to assess the clinical features and long-term outcomes of lcSSc patients with anti-Th/To.

Methods: From our prospectively enrolled scleroderma databank we identified lcSSc patients first seen from 1980 – 2005 who were anti-Th/To positive. 3:1 matched controls were the next three consecutive lcSSc patients seen after each case. Survival and death cause were obtained from the National Death Index. Cases and controls not seen in the last year were contacted via mail questionnaire. Testing results were located in responders and organ system involvement determined. Descriptive statistics were used for baseline data and conditional logistic regression to assess risk of internal organ involvement. Cox proportional hazards was used to identify factors associated with survival.

Results: 175 anti-Th/To positive lcSSc patients were matched to 525 lcSSc controls. The mean ages were 52.2 and 53.5 years, respectively (p=0.29). There was no significant difference in female gender (82% cases, 84% controls; p=0.49) or Caucasian race (94% cases, 92% controls; p=0.43). Median duration of follow-up after first visit was 8.0 years in both groups (p=0.57). Five year cumulative survival was 66% in cases and 71% in controls (p= 0.98), with no difference in risk after adjustment for age and gender.

Patients with anti-Th/To were 47% more likely to develop interstitial lung disease (ILD), although 37% less likely to have esophageal involvement (Table 1). Anti-Th/To patients were 65% more likely to have pulmonary hypertension (PH), either primary or secondary, when verified by clinical data. This difference persisted when we included those with PH listed as the cause of death without available medical record confirmation. Anti-Th/To patients with ILD were twice as likely (OR 2.09, 95% CI 1.03–4.22, p=0.04) to also have PH compared to controls with ILD, with no difference in risk of associated PH in those without ILD (p=0.63). Overall 32% of anti-Th/To patients and 25% of controls had PH when using cause of death or verified clinical information. Thus long-term follow-up identifies a greater proportion of lcSSc patients ultimately developing PH than previously reported.

Table 1. Risk of patients with anti-Th/To having internal organ complications

	Odds Ratio	95% Confidence Interval	p-value
Interstital Lung Disease (ILD)	1.47	1.04 – 2.10	0.03
Pulmonary Hypertension (PH)	1.65	1.11 – 2.44	0.01
Esophageal Involvement	0.63	0.44 – 0.91	0.01
Cardiac Involvement	1.48	0.98 – 2.25	0.06
Renal Crisis	1.30	0.49 – 3.44	0.60
Muscle Involvement	0.41	0.14 – 1.17	0.09

Conclusion: This is the first and largest cohort of anti-Th/To positive SSc patients for whom there is long-term follow-up. Anti-Th/To patients with lcSSc are more likely to have ILD and PH than other patients with lcSSc, with significantly increased risk of having both PH and ILD. Anti-Th/To patients are less likely to develop esophageal involvement. Patients with anti-Th/To should be carefully screened for ILD and PH as part of their initial and follow-up evaluations.

A Prospective Observational Study of Mycophenolate Mofetil Treatment in Rapidly Progressive Diffuse Cutaneous Systemic Sclerosis of Recent Onset. Fabian A. Mendoza[1], Sarah J. Nagle[2], Jason B. Lee[3] and Sergio A. Jimenez[4]. [1]Jefferson Institute of Molecular Medicine and Scleroderma Center, Rheumatology Division, Department of Medicine, Thomas Jefferson University, Philadelphia, PA, [2]Jefferson Medical College, Thomas Jefferson University, Philadelphia, PA, [3]Dermopathology Division, Department of Dermatology and Cutaneous Biology, Thomas Jefferson University, Philadelphia, PA, [4]Jefferson Institute of Molecular Medicine, Thomas Jefferson University, Philadelphia, PA

Background/Purpose: The introduction of target organ specific therapies has substantially decreased Systemic Sclerosis (SSc) morbidity and mortality. In contrast, most studies of potential disease-modifying agents have shown negative results and currently there is no generally accepted SSc disease modifying therapy. The purpose of this study was to perform a prospective observational study to examine the effects of mycophenolate mofetil (MMF) treatment on skin and pulmonary involvement in patients with rapidly progressive diffuse cutaneous systemic sclerosis (SSc) of recent onset. The clinical observations were validated by skin histopathology and assessment of fibrosis-related gene expression.

Methods: Twenty five consecutive patients with early (<24 months) rapidly progressive diffuse cutaneous systemic sclerosis who had not received immunosuppressive or anti-fibrotic treatment received MMF as the only disease-modifying therapy. A modified Rodnan skin score (mRSS), assessment of affected body surface area (BSA), and a modified SSc severity scale were compared from initiation of MMF to the end of study. Histopathology and real time PCR assessment of fibrosis-related gene expression were performed before and after treatment in skin biopsies from 3 patients.

Results: At a mean+/−SD of 18.2 ± 8.73 months duration of MMF therapy and at a median dose of 2000 mg per day the mRSS decreased significantly from 24.56 ± 8.62 to 14.52± 10.9 (p=0.0004) and the BSA improved from 36 ±16% to 14 ±13.3% (p=0.00001). MMF therapy also prevented pulmonary function deterioration as total lung capacity and diffusion capacity remained stable without statistically significant differences between the pre- and post-treatment values. Histopathology showed a remarkable reduction in fibrotic tissue accumulation. Real time PCR showed a marked decrease in the expression of fibrosis-related genes. Adverse events were mild and most of the patients tolerated well the medication. One patient had a fatal outcome from dilated cardiomyopathy of unknown origin but not likely related to MMF treatment.

Conclusion: Treatment of previously untreated patients with diffuse cutaneous SSc of recent onset and rapid progression with MMF as the only disease modifying therapy resulted in marked clinical improvement in the extent and severity of skin involvement and caused an improvement of skin histopathological abnormalities and decreased expression of fibrosis-related genes. MMF also prevented pulmonary function deterioration in these patients.

ACR Concurrent Abstract Session

T-cell Biology and Targets in Autoimmune Disease: Lymphocyte Biology and Targets in Autoimmune Disease

Sunday, November 6, 2011, 4:30 PM–6:00 PM

849

Therapeutic Effects of TGF-β-Induced Regulatory T Cells on the Established Autoimmune Diseases. Song G. Zheng[1], Qin Lan[2], Julie Wang[2], David Brand[3], David A. Horwitz[4], Zhong-Min Liu[5] and Hejian Zou[6]. [1]USC Keck School of Medicine, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]VA Medical Center, Memphis, TN, [4]USC School of Medicine, Los Angeles, CA, [5]Shanghai East Hospital, Tonji University, Shanghai, China, [6]Huashan Hospital, Shanghai, China

Background/Purpose: While it has been well recognized that both natural Foxp3+ regulatory T (nTreg) cells and TGF-β-induced Treg (iTreg) cells can prevent autoimmune diseases in animal models, recent studies reveled that injection of nTregs has less therapeutic effects on established autoimmune diseases. It is less clear if iTregs can treat the established autoimmune diseases. We now provide evidence that unlike nTregs, injection of iTreg cells can markedly ameliorate the established autoimmune arthritis and lupus.

Methods: iTregs induction was developed as previously described. Collagen-induced arthritis (CIA) was induced in DBA/1J mice after immunized with CII/CFA. 80×10^6 DBA/2 spleens were transferred into D2B6F1 mice to induce chronic GVHD with a typical lupus syndrome. Cytokine levels were examined by FACS and ELISA. Bone erosion was determined by micro-CT and osteoclast differentiation was analyzed by TRAP staining.

Results: Both antigen-specific and polyclonally induced iTregs suppressed the established CIA although antigen-specific iTregs had a superior therapeutic effect. CIA mice given iTregs have a significantly lower incidence of disease and lower clinic scores than mice given nTregs, Teff cells or no cells. We found while nTregs were converted into Th1/Th17 cells *in vitro* and *in vivo* in the inflammatory milieu, iTregs were resistant to T effector cell conversion in the similar condition. Injection of iTregs to naïve mice and

immune deficient mice displayed similar levels of Foxp3 stability as comparing with nTregs. Of note, the stability of Foxp3 expression was only found in iTreg cells during established CIA. iTregs suppressed Th17 cell and osteoclast differentiation that paralleled with improved clinical scores, CII-specific IgG production and bone erosion. Injection of iTregs to the established lupus mice significantly decreased the levels of anti-dsDNA and proteinuria, and markedly prolonged the survival of lupus. Blocking of TGF-β/TGF-βR pathway using anti-TGF-β antibody or TGF-βRI (ALK5) inhibitor, or anti-IL-10R antibody almost completely abolished the therapeutic effects of iTregs on lupus, suggesting that TGF-β and/or IL-10 secreted by iTregs play a crucial role in the cell therapy. We further observed that DC isolated from lupus mice received iTregs but not control cells expressed lower levels of CD80 and CD86 and adoptive transfer of these DCs to another lupus mouse can suppress the disease development. Interestingly, blockade of TGF-β but not IL-10 signal abolished the suppressive effects of tolerogenic DC on the lupus in mice.

Conclusion: We therefore suggest that iTregs are stable and able to target DC in the inflammatory milieu, these DC then have become tolerogenic DC and further suppress disease progression through its direct or indirect effect (inducing new iTregs) in autoimmune disease settings. Manipulation of iTregs might have a therapeutic value in patients with RA and SLE.

850

p53 Regulates Th17-Mediated Autoimmune Arthritis. Jin-Sil Park[1], Mi-La Cho[1], Mi-Ae Lim[1], Young-Mee Moon[1], Hye-Jwa Oh[1], Joo-Yeon Jhun[1], Jun-Geol Ryu[1], Jae-Kyeong Byun[1], Eun-Joo Jeon[1], Hye-Rin Jeong[1], Sang-Heon Lee[2] and Ho-Youn Kim[1]. [1]Catholic University of Korea, Seoul, South Korea, [2]Konkuk University School of Medicine, Seoul, South Korea

Background/Purpose: A great deal of effort has focused on the role of the p53 tumor suppressor in cancer. Recently, previous observations indicated that p53 can play a protective role in several immune and inflammatory diseases. To identify the role of p53 in autoimmune disorders, we examined whether p53 could regulate the *in vivo* effects of rheumatoid arthritis (RA).

Methods: Arthritis severity of wild type or p53 knockout (KO) mice with CIA was assessed by clinical and histologic scoring. p53 agonist or antagonist was administered via intraperitoneal injection in C57BL/6 mice and the *in vivo* effects were determined by assessing joint swelling, histological changes. The proliferation was determined by [^{3}H] thymidine incorporation and concentrations of CII-specific IgG2a, IL-17, and TNF-α were determined by ELISA. The expression of Th17 and Treg cells was analyzed by flow cytometry. Adoptive transfer of CD4+ T cells from WT or p53KO mice, respectively, to IL-17KO mice was performed. In human, CD4+ T cells from human peripheral blood mononuclear cells were differentiated into Th17 cells with p53 agonist and proportion of Th17/Treg was determined by flow cytometry.

Results: p53 inhibits Th17 differentiation of CD4+ T cells, while p53 promotes expression of Foxp3 *in vitro*. We observed that p53 mediated the suppression of Th17 differentiation by physically interacting with STAT3 or STAT5, which is major transcription factor for Th17 and Treg, respectively. p53 deficiency in mice exacerbated disease in collagen-induced arthritis (CIA) model, whereas p53 activation ameliorated the severity of arthritis through regulation of the balance between Th17 and Treg cells. Adoptive transfers of CD4+ T cells from p53 KO mice with CIA into IL-17 KO with CIA, which is resistant to CIA, induced severe autoimmune arthritis. p53 could regulate the differentiation of Th17 more effectively in patients with RA, when compare to healthy controls.

Conclusion: These results demonstrated that p53 serves as a novel regulator of Th17-Treg mediated autoimmunity and could be a new therapeutic target for rheumatoid arthritis.

Citrullinated Fibrinogen-Specific CD4$^+$ T Cells Display Memory and Regulatory Phenotypes. Laura Su and Mark M. Davis. Stanford University School of Medicine, Stanford, CA

Background/Purpose: Rheumatoid arthritis (RA) is a common, highly debilitating systemic inflammatory condition. To date, little is known about which autoantigens are involved in RA and how T cells which recognize self-proteins may become pathogenic in disease. Fibrinogen is a common target of autoantibodies in RA patients, and a putative T cell autoantigen involved in disease development. The goal of this study is to identify and characterize fibrinogen-specific CD4$^+$ T cells.

Methods: Autoantigen-specific T cells were identified directly *ex vivo* using peptide-MHC tetramers. To identify individuals carrying the HLA-DRB1*0401 (DR4) allele, HLA typing was performed on healthy blood donors and RA patients using sequence-specific primer PCR. To identify antigen-specific T cells, tetramer staining was performed at room temperature for 1 hour using tetramers loaded with peptides from hemagglutinin (HA), citrullinated fibrinogen (cit-Fib), melanosomal matrix protein gp100, or the human immunodeficiency virus (HIV). Memory phenotyping was performed using antibodies against CD45RO and CCR7. Regulatory T cells (Tregs) were identified by Foxp3, CD25, and CTLA4 staining. Tetramer tagged cells were magnetically enriched and analyzed by flow cytometry.

Results: We demonstrated that the frequency of cit-Fib-specific CD4$^+$ T cells ranges from 0.5 to 22 per million CD4$^+$ T cells in healthy individuals. Surprisingly though, on average, 66% of cells display an antigen-experienced phenotype. This finding suggests prior TCR stimulation by cit- Fib or cross-reactive ligand(s) and brings up the question of why these fibrinogen-specific T cells do not cause autoimmunity in healthy individuals. Cell lineage analysis demonstrated that many cit-Fib-specific lymphocytes are Tregs that express Foxp3. Compared to other antigen-specific populations, the frequency of Tregs among cit-Fib-specific T cells is similar to that of another self-antigen specific population which recognizes gp100. Cit-Fib-specific Treg frequency is also similar to cells that recognize naïve epitopes from HIV. In contrast, Tregs are nearly undetectable among highly expanded populations of influenza-specific T cells. These results indicate that a significant response to foreign antigens correlates with a smaller, to nearly absent Treg population in the peripheral blood, and suggests that this may be a precondition for a robust T cell response against microbial challenges. Preliminary analysis using peripheral blood from RA patients demonstrates that cit-Fib-specific T cells can be identified and are present at higher frequency in comparison to healthy people. Further investigation is current ongoing to evaluate whether these cells are deficient in Foxp3 expression. A deficiency in cit-Fib-specific Tregs may contribute to exaggerated effector activity against citrullinated fibrinogen in RA patients.

Conclusion: T cells that recognize citrullinated fibrinogen can be detected in the peripheral blood of healthy individuals. These Cit-fib-specific populations contain large numbers of antigen-experienced T cells, many of which exhibit a Treg phenotype.

Characterization of the Expanded Populations of TH17 and T Follicular Helper Cells in New Zealand Black (NZB) Chromosome 1 Congenic Mice. Nafiseh Talaei[1], Carolina Landolt-Marticorena[2], Babak Noamani[1], Evelyn Pau[1], Nan-Hua Chang[3] and Joan E. Wither[1]. [1]Toronto Western Research Institute, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Toronto Western Research Institute, University Health Network, Toronto, ON

Background/Purpose: We have previously shown that B6 mice with an introgressed homozygous NZB chromosome (c) 1 interval (70 to 100 cM) develop high titres of antinuclear antibodies and severe renal disease, with approximately 40% of the mice dying by 8 months age. Using subcongenic mice with shorter intervals in this region we found that expansion of T follicular helper (T_{FH}) and IL-17-producing T (T_H17) populations was closely associated with the severity of renal disease. In this report, we have characterized the nature and origin of these two cell populations.

Methods: To assess the cytokine profile of T_{FH} and T_H17 cells, splenocytes from c1(70–100), c1(88–100), c1(96–100), and B6 four month old mice were stimulated with PMA/Ionomycin for 4h in presence of GolgiStop, and analyzed by flow cytometry after cell surface (anti -CD3, -CD4, -PD1, and –CXCR5) and intracellular staining for IL-4, IL-17, IL-21 and IFN-g. Naïve T cells were differentiated in-vitro by stimulation with a-CD3 and -CD28 under T_H0 (a-IFN-g, a-IL-4), T_H17 (rIL-6, rIL-23 and rTGF-b and a-IFN-g, a-IL-4) and T_{FH} (rIL-6 and a-IFN-g, a-IL-4) cell conditions for 5 days before measuring intracellular cytokine production by flow cytometry.

Results: A significant proportion of the T_{FH} ($CD3^+CD4^+PD1^{hi}CXCR5^{hi}$) cells in c1 congenic mice secreted IL-21 alone or together with IFN-g. Very few T_{FH} cells secreted IL-17 and the proportion of these cells was not increased in c1 congenic mice. An increased proportion of IL-21-secreting cells was also seen in the conventional (T_{CON}, gated as non-T_{FH}) T cell subset. In contrast, the majority of IL-17 secreting cells were seen in the T_{CON} population and, consistent with previous reports, low levels of IL-21 but not IFN-g were also secreted by these cells. c1(88–100) and c1(70–100) mice demonstrated an equivalent enhanced tendency to differentiate towards T_H17 cells in-vitro as compared to B6 and c1(96–100) mice. However, differentiation of naive T cells to T_H0 and T_{FH} cells

was similar for all strains. We have previously shown that T cells from pre-autoimmune 8 wk old c1 congenic mice demonstrate enhanced differentiation to T_{FH} and T_H17 cells following immunization with an exogenous antigen stimulus (OVA/CFA i.p.). Preliminary adoptive transfer experiments where OVA-specific T cells, obtained from B6 or c1(70–100) OT-II TCR transgenic mice, were injected into B6 or c1(70–100) mice and subsequently immunized with OVA/CFA, confirmed that the enhanced T_H17 but not T_{FH} differentiation arises in part from an intrinsic T cell defect.

Conclusion: The findings suggest that a genetic polymorphism on NZB c1, located in the 88–96 cM interval, is associated with an intrinsic T cell functional defect that leads to enhanced differentiation of auto-reactive and antigen-primed T cells to IL-17 producing cells and that this polymorphism is associated with increased renal disease.

Contribution of a Kidney-Infiltrating CD4$^+$ T Cell Clone to Nephritis in Lupus-Prone Mice. Akiko Okamoto[1], Keishi Fujio[1] and Kazuhiko Yamamoto[2]. [1]Graduate school of Medicine, The University of Tokyo, Tokyo, Japan, [2]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Background/Purpose: In systemic lupus erythematosus (SLE), CD4$^+$ T cells play key roles in the initiation and promotion of autoantigen-specific humoral immunity.Although autoantibody-associated T cells are supposed to exacerbate lupus-nephritis by enhancing autoantibody production, whether organ-infiltrating T cells directly contribute to kidney inflammation is unclear because it is difficult to directly analyze organ infiltrating T cells. In this study, we attempted to examine the pathogenic roles of autoreactive cytokine-expressing CD4$^+$ T cells from the kidney of early nephritic MRL/lpr mice. We focused on IFN-γ as a pathogenic cytokine because previous studies demonstrated the role of IFN-γ in the pathogenesis of lupus nephritis. And we hypothesized that the autoreactive T cells that responded to self-antigens in the early inflamed kidney would exhibit increased CD5 expression levels, because previous reports of TCR transgenic mice revealed that high CD5 and TCR expression are reflective of high avidity interactions with self-peptide:MHC complex and can be used to predict the survival/homeostatic expansion capacity of CD4$^+$ T cells.

Methods: We examined surface CD5 expression and cytokine secretion of CD4$^+$ T cells with flow cytometry. We performed single-cell analyses of CD5^{high}TCR^{high}CD4$^+$ T cells in the kidneys of early nephritic mice. We have retrovirally reconstituted TCR α/β genes of IFN-γ expressing cells in CD4$^+$ T cells.

Results: In the early nephritic MRL/lpr mice, the kidney CD4$^+$ T cells exhibited increased CD5 levels. We observed that IFN-γ secreting cells were enriched among CD5^{high}CD4$^+$ T cells from early inflamed kidney. Using single cell analyses of the TCR^{high}CD5^{high}CD4$^+$ T cells from the kidney of early nephritic MRL/lpr mice, two IFN-γ-expressing CD4$^+$ T cell clones, MLK2 and MLK3, were identified. TCR genes from MLK2- and MLK3-transduced CD4$^+$ T cells respond to splenic dendritic cells in an MHC class II dependent manner, but not to B cells or macrophages. MLK3-transduced CD4$^+$ T cells proliferated in the spleens of pre-nephritic mice and promoted nephritis progression upon adoptive transfer. Interestingly, MLK3-transduced CD4$^+$ T cells enhanced the deposition of C3 without promoting anti-dsDNA antibody production.

Conclusion: Our results suggest that CD4$^+$ T cells in the inflamed kidney of MRL/lpr mice contribute to nephritis progression without enhancing production of anti-dsDNA antibody. Although it is difficult to isolate and culture cytokine expressing clones that have infiltrated a parenchymatous organ, a combination of single cell sorting and TCR reconstitution enabled us to verify the pathological role of kidney infiltrating CD4$^+$ T cells in lupus-prone mice.

Deficient Ubiquitin Ligase Casitas B-Lineage Lymphoma b Expression and Abnormal Peripheral Tolerance in CD4$^+$ T Cells From Systemic Lupus Erythematosus Patients. Diana Gomez-Martin, Maria J., Ibarra-Sanchez, Jose Cruz-Ruiz, Jorge Romo-Tena, Jose Esparza-Lopez, Mariana Diaz-Zamudio and Jorge Alcocer-Varela. Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico city, Mexico

Background/Purpose: A resistant to anergy phenotype has been evidenced in T cells from SLE patients. This might be related to intrinsic defects associated to abnormalities in the anergy induced genetic program, particularly ubiquitin ligases such as Casitas B-lineage lymphoma b (Cbl-b), which have not been fully addressed in SLE. The aim of this study was to analyze the expression of Cbl-b in CD4$^+$ T cells from SLE patients upon anergy induction and the associated proliferative and effector response.

Methods: Twenty patients with SLE (11 in clinical remission and 9 with active untreated disease) and 20 healthy controls were included. PBMC were isolated and CD4$^+$ T cells were negatively selected. Four experimental conditions were defined as followed: ex vivo, activation (anti-CD3 +anti-CD28), anergy (ionomycin) and rest. Cellular proliferation was addressed by CFSE dilution method. Cbl-b expression was assessed by real time PCR and western blot. Cytokine production was measured in the supernatants from cell cultures by luminometry. Surface expression of activation and costimulatory molecules were analyzed by flow cytometry. Mean and standard deviation or median and interquartilar range were used for descriptive statistics. Comparison between groups was made by means of Student's T test and Mann Whitney test.

Results: Upon anergy induction, Cbl-b normalized mRNA (0.21 vs 0.47, $p=0.015$) and protein expression (0.73 vs 0.90, $p=0.038$) in CD4$^+$ cells from SLE patients was decreased in comparison to controls. No differences were found between active and remission patients. CD4$^+$ cells from SLE patients shown multiple abnormalities regarding the proliferative response, particularly, resistance to anergy was evidenced by a decreased anergy index in patients vs controls (237 vs 558, $p<0.05$), as well as higher IL-2 production (43.4 vs 17.1 pg/mL) after ionomycin treatment. Moreover, the proliferative response to activation protocol was lower for SLE patients vs controls. Among SLE patients, after anergy induction, the synthesis of pro-inflammatory cytokines was diminished in comparison to activation protocol, being this difference significant only for IFN-' (130.30 pg/mL vs 23.72 pg/mL, $p<0.05$).After ionomycin treatment, a dichotomy between suppressive cytokines was displayed, as IL-4 production was increased and IL-10 was decreased in SLE patients vs controls (IL-4: 33 vs 24.2 pg/mL; IL-10: 159.5 vs 1166.7 pg/mL). In terms of activation surface markers, after anergy induction, increased expression of CD69 (20.1 vs 2.1, $p<0.001$), CD83 (30.7 vs 10.1, $p=0.001$) and CD40L (33.6 vs 15.1, $p<0.001$) was found in SLE patients vs healthy controls.

Conclusion: CD4$^+$ T cells from SLE patients display a vast array of abnormalities regarding proliferative and effector responses to activation and anergy induction. Our data suggest that resistance to anergy in CD4$^+$ cells from SLE patients, without regarding disease activity, is related to decreased Cbl-b expression as well as overexpression of activation and costimulatory molecules. These might be related to persistent proliferation of autoreactive T cells even under the absence of appropriate costimulation.

Prednisone Versus Tamoxifen for Idiopathic Retroperitoneal Fibrosis. Augusto Vaglio[1], Alessandra Palmisano[1], Stefania Ferretti[1], Rocco Cobelli[1], Luigi Boiardi[2], Carlo Buzio[1] and Carlo Salvarani[2]. [1]University of Parma, Parma, Italy, [2]Arcispedale S Maria Nuova, Reggio Emilia, Italy

Background/Purpose: Glucocorticoids are the mainstay of therapy for idiopathic retroperitoneal fibrosis (IRF), but they often have considerable toxicity. Several reports have suggested that tamoxifen may be a valid alternative to glucocorticoids. In this open-label, randomised controlled trial, we compared the efficacy of prednisone and tamoxifen in patients with IRF.

Methods: Forty patients with newly diagnosed IRF received induction therapy with 1 mg/kg/day of prednisone for 1 month, at the end of which those who achieved remission were randomly assigned to receive tapering prednisone (initial dose, 0.5 mg/kg/day) for 8 months or tamoxifen (fixed dose, 0.5 mg/kg/day) for 8 months. After the end of treatment, the patients were followed up for an additional 18 months (overall, 26 months). The primary end-point was the relapse rate by the end of treatment (month 8). Secondary end-points included 8-month change in IRF size and renal function. This trial is registered with ClinicalTrials.gov, number NCT00440349.

Results: Thirty-six of the 40 enrolled patients achieved remission following induction therapy and were randomised to receive prednisone or tamoxifen (18 per group). One patient (6%) in the prednisone group and seven patients (39%) in the tamoxifen group developed relapses by the end of treatment (difference −33% [95% confidence interval −58% to −8%, P=0.04]). The difference in relapse rates between the groups was sustained after the additional 18-month follow-up (26-month estimated cumulative relapse probability 17% with prednisone and 50% with

tamoxifen, P=0.04). Prednisone also induced a greater reduction in size of IRF (P=0.03), whereas no differences were found in renal function improvement.

Conclusion: Prednisone is more effective than tamoxifen in preventing relapses in IRF patients, and induces a greater shrinkage of the retroperitoneal mass.

856

The Relationship Between Systemic Vasculitis and Retinal Vasculitis. James T. Rosenbaum[1], Jennifer Ku[2], Amro Ali[2], Dongseok Choi[2] and Eric B. Suhler[2]. [1]Oregon Health & Science University, Portland, OR, [2]Oregon Health & Science Univ, Portland, OR

Background/Purpose: Systemic vasculitis is often assumed to be a common cause of retinal vasculitis. We sought to determine the relationship between retinal vasculitis and systemic vasculitis as diagnosed in a tertiary referral clinic for patients with uveitis.

Methods: A selected review was performed on 1390 charts of patients attending the uveitis clinic at the Oregon Health & Science University, Casey Eye Institute, between 1985 and 2010. Included in the review were all patients with diagnoses commonly associated with retinal vasculitis and all patients who were diagnosed with a systemic vasculitis. Retinal vasculitis was identified by perivascular exudates, intraretinal hemorrhage, or cotton wool spots as seen on clinical examination or by vascular occlusion or leakage as identified by fluorescein angiogram.

Results: Of the 1390 charts reviewed, 207 or 14.9% had retinal vasculitis as a component of the intraocular inflammation. Thirty-five patients had retinal vasculitis which was primary, i.e. not associated with a systemic disease, and the dominant manifestation of the uveitis. Fourteen of the patients with retinal vasculitis had Behcet's disease. Only 11 of the 1390 patients with uveitis had a systemic vasculitis, 3 with granulomatosis with polyangiitis (formerly Wegener's granulomatosis), 4 with primary central nervous system vasculitis, 2 with Churg-Strauss syndrome, 1 with leukocytoclastic vasculitis, and one with pulmonary vasculitis. Of these 11, four had retinal vasculitis including one secondary to a CMV retinitis. Thus, systemic vasculitis was directly responsible for 1.4% or 3 of 207 cases of retinal vasculitis. In comparison to systemic vasculitides, non-vasculitic systemic diseases such as sarcoidosis (n=13), immune-mediated syndromes confined to the eye such as birdshot retinochoroidopathy (n=9) or pars planitis (n=36), and intraocular infections (n=29) were far more common causes of retinal vasculitis.

Conclusion: Retinal vasculitis is not defined by vessel wall destruction, a hallmark of systemic vasculitis. Retinal vasculitis is a relatively common feature of uveitis, but it is an extremely uncommon manifestation of the classical systemic vasculitides.

857

Efficacy and Tolerance of Treatments in Patients with Non-Infectious Mixed Cryoglobulinemia Vasculitis: Results From the French Nationwide CryoVas Survey. Benjamin Terrier[1], Evguenia Krastinova[2], Isabelle Marie[3], Adeline Lacraz[4], David Launay[5], Emmanuelle Plaisier[6], Luc de Saint-Martin[7], Fabrice Bonnet[8], Pauline Belenotti[9], Jean-Emmanuel Kahn[10], Olivier Hinschberger[11], Patricia Rullier[12] and Patrice Cacoub[13]. [1]Pitié-Salpêtrière Hospital, Paris, France, [2]INSERM U707, Paris, France, [3]Service de médecine interne, CHU de Rouen, Rouen, France., Rouen, France, [4]Nephrology, CHU Bordeaux, Bordeaux, France, [5]Internal Medicine, CHRU Claude Huriez, Lille, France, [6]Nephrology, Tenon Hospital, Paris, France, [7]Internal Medicine, CHU Brest, Brest, France, [8]Internal Medicine, CHU Bordeaux, Bordeaux, France, [9]Internal Medicine, CHU Marseille, Marseille, France, [10]Internal Medicine, Foch Hospital, Suresnes, France, [11]Internal Medicine, CH Mulhouse, Mulhouse, France, [12]Internal Medicine, CHU Montpellier, Montpellier, France, [13]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: Data on efficacy and tolerance of treatments in non-infectious mixed cryoglobulinemia vasculitis (CryoVas) in the era of hepatitis C virus screening are lacking. The CryoVas survey was set up to describe presentation and evaluate efficacy and tolerance of treatments in patients with non-infectious CryoVas, in the absence of large series and therapeutic guidelines. Objective: To analyze the efficacy and the tolerance of treatments in patients with non-infectious mixed CryoVas.

Methods: Eighty-one French centers from Universitary and general hospitals have included 242 patients with non-infectious mixed CryoVas diagnosed between January, 1995 and July, 2010. We compared the efficacy and tolerance of corticosteroids alone versus corticosteroids plus immunosuppressive agents. In order to analyze the impact of treatments in the presence of time-dependent confounders, we used Cox Marginal Structural Models (Cox-MSM). We created a pseudo-population using the inverse probability of treatment weighting. Baseline covariates (age, gender, GFR, cause of CryoVas) and time-dependant covariates (i.e., clinical manifestations of vasculitis) were included in the model.

Results: Data on 209 patients (86%) who received therapy and had at least 6 months of follow-up were analyzed for efficacy and tolerance. Treatments used during follow-up were: corticosteroids (n=209 patients), alkylating agents (n=95), rituximab (n=80), plasmapheresis (n=43), azathioprine/mycophenolate mofetil (n=31).

Regarding efficacy, rituximab plus corticosteroids was more effective than corticosteroids alone for achieving a complete clinical response (HR 3.7, P=0.01), a prednisone dosage <10 mg/d at month 6 (HR 2.5, P<0.0001), a renal response (HR 31.6, P=0.03) and an immunological response (HR 33.8, P=0.001). In contrast, alkylating agents plus corticosteroids was more effective than corticosteroids alone only for achieving a prednisone dosage < 10 mg/d at month 6 (HR 1.5, P=0.004) and an immunological response (HR 5.7, P=0.001).

Regarding tolerance, rituximab plus corticosteroids was more frequently associated with serious infections than corticosteroids alone (HR 9.0, P<0.0001), while death rates did not differ between therapy groups. Among patients who received rituximab, a daily dose of corticosteroids >50 mg/d was more frequent in those who experienced a serious infection (71% vs. 39%, P=0.008). In contrast, alkylating agents plus corticosteroids was less frequently associated with serious infections than corticosteroids alone (HR 0.2, P=0.002), while death rates did not differ between therapy groups.

Conclusion: Data from this large survey show that in patients with non-infectious mixed cryoglobulinemia vasculitis, rituximab plus corticosteroids showed the greater efficacy. This regimen was also associated with serious infections, particularly when higher dose of corticosteroids were used. The place of each therapeutic strategies remains to be defined in well-designed randomized controlled trials.

Background/Purpose: Earlier studies on Churg–Strauss syndrome (CSS, recently renamed eosinophilic granulomatosis with polyangiitis/EGPA), including each less than 120 patients, demonstrated that ANCA+ and ANCA– patients differed clinically at diagnosis but not in their outcomes. However, their mean follow-up durations were limited (< 3 years). Our aims were to describe the main characteristics of a larger cohort of patients and their

long-term outcomes and to determine potential predictors of death and relapse.

Methods: We conducted a retrospective study of the patients diagnosed with CSS, satisfying the American College of Rheumatology and/or Chapel Hill criteria, entered in the FVSG database since its creation in 1983. Their characteristics and outcomes were compared according to their ANCA status at diagnosis and year of diagnosis (≤ or >1996, when the FFS was devised). ANCA were tested either on fresh or, for those patients diagnosed before ANCA testing became routinely available, on stored frozen serum samples, when available. Vasculitis relapse was defined as the recurrence or worsening of a clinical manifestation of CSS, following a period of remission of ≥3 months. Isolated asthma flares, which might have required transient increase of corticosteroid dose, sinusitis (or rhinitis) and/or increases in eosinophil count without any other clinical CSS manifestations were recorded, but not considered as vasculitis relapse per se, and were analyzed separately.

Results: We identified 383 patients diagnosed with CSS between 1957 and June 2009 (128 (33.4%) ≤ 1996) and followed for 66.8 ± 62.5 months. At diagnosis, their mean age was 50.3 ± 15.7 years and 91.1% had asthma (since 9.3 ± 10.8 years). Main disease manifestations were peripheral neuropathy (51.4%), ENT manifestations (48.0%), skin lesions (39.7%), lung infiltrate (38.6%), gastrointestinal signs (23.2%), renal disease (21.7%) and/or cardiomyopathy (16.5%). Among the 348 patients tested for ANCA, 108 were positive (31.0%) and had significantly ($P < 0.05$) more frequent ENT manifestations (59.3% vs. 44.2%), peripheral neuropathy (63.0% vs. 44.2%) or renal involvement (26.9% vs. 16.3%), but less frequent clinical cardiomyopathy (19.2% vs. 8.3%) than ANCA– patients. Vasculitis relapses occurred in 35.2% of ANCA+ vs 22.5% of ANCA– patients ($P = 0.01$) and deaths in 5.6% vs 12.5%, respectively ($P < 0.05$). Relapse-free survival at 5 years was 58.1% [95% CI; 45.6–68.6] for ANCA+ and 67.8% [95% CI; 59.8–74.5] for ANCA– patients ($P = 0.35$). Both original and revised FFS were predictive of mortality. Multivariable analysis on individual parameters identified cardiomyopathy, older age and a diagnosis ≤1996 as risk factors for death. The sole independent predictors of relapse were a lower eosinophil count at diagnosis (< 7,065/mm3) and, if excluding eosinophil count from the model, ANCA positivity.

Conclusion: CSS patients differ according to their ANCA status, in their clinical presentation at diagnosis but also in their long-term outcomes. Even though CSS mortality has declined over the past decades, at least since 1996, relapses remain frequent, especially in the ANCA+ patients.

859

Surgery Versus Endovascular Repair in Takayasu Arteritis: A Multicenter Study of 166 Procedures. David Saadoun[1], Marc Lambert[2], Tristan Mirault[3], Yoland Shoindre[1], Zahir Amoura[4], Mathieu Resche Rigon[1], Pierre yves Hatron[5], Joseph Emmerich[3] and Patrice P. Cacoub[6]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]Service de médecine interne, Hôpital Claude Huriez, Université Lille II, Lille, France, Lille, France, [3]Service de Médecine Vasculaire HEGP, Paris, France, [4]CHU Pitié-Salpêtrière, Paris, France, [5]Service de médecine interne, Hôpital Claude Huriez, Université Lille II, Lille, France, Paris, France, [6]Hopital La Pitie, Paris, France

Background/Purpose: With recent advances in endovascular treatment, percutaneous endoluminal angioplasty (PTA) has become particularly attractive for arterial lesions of Takayasu arteritis (TA). However, data provided from cases reports or small series and the long term outcome has not been reported. The incidence of potential vascular complications after surgery or endovascular treatment is still to be determined.

Methods: Retrospective multicenter study comparing the results and outcome of 79 consecutive patients with TA [median (IQR) age 39 (25–50) years, with 63 (79.7%) females)] who underwent 166 vascular procedures [104 (62.7%) surgery and 62 (37.3%) PTA] for the management of arterial complications.

Results: After a time of follow-up of 6.5 (2.2–11.5) years, 74 complications were observed including restenosis (n=42), thrombosis (n=7), renal insufficiency (n=7), bleeding (n=6), sepsis (n=4), stroke (n=4) and hypertension (n=4). The 5- and 10-years arterial complication free survival rates were 60% and 57% versus 49% and 29% ($P<0.05$) in the surgery group versus PTA group, respectively. In multivariate analysis, PTA [OR (95%CI) 3.61 (1.3–10.3); $P=0.021$] was independently associated with the occurence of arterial complications. Patients who experienced complications had higher erythrocyte sedimentation rate ($P<0.001$), C-reactive protein ($P<0.001$) and fibrinogen ($P<0.005$) serum levels compared to those without complications.

Conclusion: Our study is the first to show in TA that PTA increase by 4 times the likelihood of complications compared to surgery. Biological inflammation at the time of revascularisation is associated with an increase odds of arterial complications.

860

Causes and Prognostic Factors of Mortality in Patients with Non-Infectious Mixed Cryoglobulinemia Vasculitis: Results From the French Nationwide CryoVas Survey. Benjamin Terrier[1], Evguenia Krastinova[2], Isabelle Marie[3], Adeline Lacraz[4], David Launay[5], Emmanuelle Plaisier[6], Luc de Saint-Martin[7], Fabrice Bonnet[8], Pauline Belenotti[9], Jean-Emmanuel Kahn[10], Olivier Hinschberger[11], Patricia Rullier[12] and Patrice Cacoub[13]. [1]Pitié-Salpêtrière Hospital, Paris, France, [2]INSERM U707, Paris, France, [3]Service de médecine interne, CHU de Rouen, Rouen, France., Rouen, France, [4]Nephrology, CHU Bordeaux, Bordeaux, France, [5]Internal Medicine, CHRU Claude Huriez, Lille, France, [6]Nephrology, Tenon Hospital, Paris, France, [7]Internal Medicine, CHU Brest, Brest, France, [8]Internal Medicine, CHU Bordeaux, Bordeaux, France, [9]Internal Medicine, CHU Marseille, Marseille, France, [10]Internal Medicine, Foch Hospital, Suresnes, France, [11]Internal Medicine, CH Mulhouse, Mulhouse, France, [12]Internal Medicine, CHU Montpellier, Montpellier, France, [13]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: Data on prognosis in non-infectious mixed cryoglobulinemia vasculitis (CryoVas) in the era of hepatitis C virus screening are lacking. Objective: To analyze causes of death and prognostic factors in patients with non-infectious mixed CryoVas.

Methods: Eighty-one French centers of Internal Medicine, Nephrology, Rheumatology, Hematology, Dermatology and Neurology from Universitary and general hospitals have included 242 patients with non-infectious mixed CryoVas diagnosed between January, 1995 and July, 2010. Causes of death and prognostic factors were assessed. We included all variables with p value >0.2 in the univariate anlysis in a multivariate Cox proportional hazard ratio model.

Results: 166 women and 76 men (sex ratio W/M 2,2), mean age 62.6±14.5 years, were included. Baseline manifestations were: purpura (75%), peripheral neuropathy (52%), arthralgia (44%), glomerulonephritis (35%), Raynaud phenomenon (26%), cutaneous ulcers (16%), necrosis (14%), myalgia (10%), gastrointestinal involvement (5%), central nervous system (2%) and pulmonary (2%) involvement.

After a median follow-up of 54 months (IQR 9–77), 42 patients (17%) died. Causes of death were: infections (n=21), vasculitis (n=8), cardiovascular disease (n=5), deterioration of the general health status (n=2), unknown (n=7). One-year, 2-year, 5-year and 10-year overall survival were 91, 89, 79 and 65%, respectively.

In multivariate analysis, factors significantly associated with death were: age > 65 years [Hazard Ratio (HR) 1.04 (95% IC 1.02–1.08); P=0.001], gastrointestinal involvement [HR 2.29 (0.99–5.31); P=0.05], male gender [HR 2.13 (1.01–4.11); P=0.02] and a glomerular filtration rate < 60 mL/min [HR 1.90 (1.01–3.56); P=0.04].

A prognostic score (CryoVas score, CVS) including these factors was significantly associated with survival (P<0.0001, with HR for death of 1, 8.2 and 26.8 for a score of 0, 1 and ≥ 2, respectively). The Five Factor Score 2009 (FFS) was also significantly associated with survival (P<0,0001, with HR for death of 1, 3.8 and 10.2 for a score of 0, 1 and ≥ 2, respectively). Comparison between CVS and FFS showed a better but not significant performance of the CVS.

Conclusion: In patients with non-infectious mixed cryoglobulinemia vasculitis, main prognostic factors are age >65 years, gastrointestinal involvement, male gender and renal failure. A score including these variables is significantly associated with survival.

The Development of a New Service for the Management of Non-Inflammatory Musculoskeletal Pain. Susan Maillard, Swati Bhagat, Charmaine Bernie, Alice Morgan, David Adkins, Ellie Haggart and Clarissa Pilkington. Great Ormond Street Hospital, London, United Kingdom

Background/Purpose: Great Ormond Street Hospital Rheumatology Department recognised that 50% of the referrals that were received were for

young people with non-inflammatory musculoskeletal pain (NIMP) but that the service was not able to provide adequate treatment after diagnosis. A business plan was proposed to the hospital management board and a new service was developed and subsequently reviewed.

Methods: The business plan was developed by senior multidisciplinary members of the Rheumatology team. The new service was set up and then specific outcome measures were followed after 1 year to monitor the success and effectiveness of the treatments and service.

Results: The service was funded to employ a full time Physiotherapist (PT), Occupational Therapist (OT), Psychologist (Psych) and administrator. Out-patient appointments were established and patients were placed into the new service. The initial appointment was in a new-patient clinic and they were assessed by a Consultant paediatric Rheumatologist and a specialist physiotherapist. This initial assessment ensured that there was no other diagnosis other than a non-inflammatory condition such as hypermobility syndrome; the patient was then referred to PT, OT and Psych as appropriate. The treatments included individualised home muscle strength training programmes, life style advice, group patient and parent education programmes and individualised pain management interventions. Specific Outcome measures (OCM) were used to monitor the success of the treatments provided. The most significant OCM's were:

School attendance which increased from 75% missing at least 1 day a week due to pain to only 7%.

Loss of muscle strength was present in 98% of children and this was resolved in 100% of those who completed the programme given.

Participation in PE increased from only 25% participating to 75% joining in sport at school.

The cost of providing the staff and facilities was less than 50% of the revenue the service brought into the hospital and so the service made a significant profit.

Conclusion: The establishment of a dedicated service to the management of NIMPS has been shown to be both clinically and cost effective and has worked extremely well as an AHP led service enabling the medical staff to focus upon inflammatory diseases.

862

Development of a Questionnaire for Early Detection of Factors Associated to the Adherence to Treatment of Children and Adolescents with Chronic Rheumatic Diseases—"the Pediatric Rheumatology Adherence Questionnaire (PRAQ)". Vanessa M. Bugni[1], Karine Y. K. Okamoto[1], Luciana S. Ozaki[1], Fernanda M. Teles[1], Juliana Molina[1], Vanessa C. Bueno[1], Maria Odete E. Hilário[1], Claudio A. Len[1] and Maria Teresa Terreri[2]. [1]Universidade Federal de São Paulo/UNIFESP, São Paulo, Brazil, [2]Universidade Federal de São Paulo/UNIFESP, Sao Paulo, Brazil

Background/Purpose: Over the last three decades the interest in studying adherence to treatment in children and adolescents with chronic rheumatic diseases has substantially increased. This is of particular importance since harmful and irreversible effects may arise due to poor treatment adherence. Our objective is to develop a questionnaire that would allow an early identification of factors related to the adherence to medical and non-medical treatments of children and adolescents with chronic rheumatic diseases.

Methods: First step: a preliminary questionnaire composed of 46 questions directed at parents was created by a group of experts in the treatment of children with chronic rheumatic diseases (4 pediatric rheumatologists, 2 physical therapists, 1 psychologist) and by a group of 3 parents from our patient population. 2nd step: a panel of 4 pediatric rheumatologists prepared a questionnaire with the following parameters: socioeconomic status, relationship with the health care team and system, diagnoses, therapy and relationship between patient and caregiver. 3rd step: the questionnaire was tested in a group of parents of low socioeconomic status, who accompanied their children to the Pediatric Rheumatology Outpatient clinic at the beginning of their treatment. After six months, a different questionnaire was administered to identify good or poor adherence to treatment. Poor adherence was defined as adherence to less than 80% or more than 120% of the medical treatments and/or appointments and exams. We applied the Cronbach's alpha coefficient for reliability evaluation, the Kappa coefficient for agreement between the questions in each block and Spearman correlation to test the correlation between the parameters and the percentages of adherence.

Results: Thirty three patient's parents answered the questionnaires. The average age in the initial evaluation was 10.3 years. Thirteen patients presented idiopathic juvenile arthritis, 10 had systemic lupus erythematosus, 7 had juvenile dermatomyositis and 3 had localized scleroderma. We observed poor adherence to the medical and/or non-medical treatment in 25% of the patients. After statistical analysis to evaluate for internal consistency, 27/46 questions were retained and included in the PRAQ. We observed a tendency for correlation within the socioeconomic block (distance to the hospital, type of transportation, number of children and parent's work) and poor adherence to the medical treatment ($p=0.087$). No significant correlations among the other parameters and adherence to the medical treatment and/or appointments and exams were observed.

Conclusion: The development of tools which identify indicators for poor treatment adherence is important in order to make better therapeutic decisions and better monitoring of patients with chronic rheumatic diseases. The administration of the PRAQ must be conducted in a larger number of patients in order to reach the proposed objectives.

Characterization of Active Joint Count Trajectories in Juvenile Idiopathic Arthritis. Roberta A. Berard[1], George A. Tomlinson[2], Xiuying Li[3], Kiem Oen[4], Alan M. Rosenberg[5], Brian M. Feldman[6], Rae SM Yeung[7] and Claire Bombardier[8]. [1]Children's Hospital of Western Ontario, London, ON, [2]University of Toronto, Toronto, ON, [3]University Health Network, Toronto, ON, [4]University of Manitoba, Winnipeg, MB, [5]Royal University Hospital, Saskatoon, SK, [6]The Hospital for Sick Children, Toronto, ON, [7]Hospital for Sick Children, Toronto, ON, [8]Institute for Work & Health, Toronto, ON

Background/Purpose: To describe the patterns of longitudinal disease activity (active joint count (tender and swollen joints) in juvenile idiopathic arthritis (JIA) and to examine the association of clinical and laboratory characteristics with these patterns.

Methods: A retrospective cohort study at two Canadian centres was performed. The longitudinal patterns of active joint counts were described using latent curve growth analysis. This method is ideally suited to a population whereby the underlying hypothesis is that the population is comprised of (unobserved) subpopulations. Latent curve growth analysis aims to classify individuals into statistically distinct groups based on individual response patterns so that individuals within a group are more similar than individuals between groups. The trajectory classes are each defined by a longitudinal growth curve. The association of baseline characteristics with class membership was performed by conducting a test of mean difference across classes for continuous variables and by comparing proportions for categorical variables.

Results: Data were analyzed on 659 children diagnosed with JIA between 1990/03–2009/09. The median age at diagnosis was 10.00 (IQR 3.67–13.39), 61% (402/659) were female and 45% (286/629) were ANA positive. The distribution of the ILAR diagnoses were as follows: systemic (7%), oligoarthritis (36%), polyarthritis (RF negative) (13%), polyarthritis (RF positive) (4%), psoriatic arthritis (8%), enthesitis-related arthritis (20%) and undifferentiated (12%). A maximum of 10 years of follow-up data was included in the longitudinal analysis. The 659 patients were classified into 5 statistically different patterns of longitudinal active joint count (AJC) profiles using a latent curve growth analysis. 44% of patients were in group 1 characterized by a low initial AJC (mean 0.9) following by a decrease in joint count, 18% in group 2—minimal to no active joint disease throughout course (mean 0.3), 19% in group 3—moderate persistent AJC (mean 3.8), 10% in group 4—initial mean AJC 4.9 followed by an increase in AJC at 5 years (mean 9.7) and finally 10% in group 5 characterized by an initial polyarthritis (mean 14) followed by a decline in AJC. The baseline characteristics of participants stratified by trajectory were statistically significantly different for all variables considered (age, sex, diagnostic delay, ANA positive, HLA-B27 positive, systemic fever, lumbosacral back pain, family history of HLA-B27 associated disease).

Conclusion: This study was a successful application of a novel approach to longitudinal growth curve modeling to identify distinct trajectories of disease activity in JIA. The trajectories identified were statistically and clinically distinct from the ILAR subtypes. Identification of patterns of disease course is important in working towards the development of an outcome-based classification system in JIA.

Predictors of Health-Related Quality of Life in Children and Adolescents with Juvenile Idiopathic Arthritis: Results From a Web-Based Survey.
Lotte Haverman[1], Martha A. Grootenhuis[2], J. Merlijn Van den Berg[3], Mira van Veenendaal[1], Koert M. Dolman[4], Joost F. Swart[5], Taco W. Kuijpers[1] and Marion A.J. Van Rossum[3]. [1]Emma Children's Hospital/Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Emma Children's Hospital/Academic Medical Center (AMC), Amsterdam, Netherlands, [3]Emma Children's Hospital/Academic Medical Center (AMC) and Reade, Amsterdam, Netherlands, [4]St. Lucas Andreas Hospital and Reade, Amsterdam, Netherlands, [5]VU medical center and Reade, Utrecht, Netherlands

Background/Purpose: Children with Juvenile Idiopathic Arthritis (JIA) experience functional impairment due to joint manifestations of the disease. Based on previous studies, children with JIA have lower Health Related Quality Of Life (HRQoL) scores compared to their healthy peers. However, comparison between studies is hampered because of e.g. heterogeneity of age cohorts and recruitment protocols. The aim of our present study was to assess Health Related Quality of Life (HRQoL) by the use of Patient Reported Outcomes (PROs) and its predictors in a group of children and adolescents with JIA.

Methods: This study is part of the 'KLIK study', which assesses the effect of identifying and discussing HRQOL problems using PROs. The study sample includes all JIA patients (6–18 years) visiting four pediatric rheumatology outpatient clinics in Amsterdam in the period February 2009 until March 2010. Patients or parents (of children 6–7 years) are invited to complete questionnaires online before visiting the rheumatologist. The outcome (PROfile) is presented to the paediatricians to help identify and discuss HRQoL issues. HRQoL is measured using the Pediatric Quality of Life Inventory 4.0 (Pedsql 4.0). Functional ability is measured using the Child Health Assessment Questionnaire (CHAQ). Data concerning disease characteristics, disease activity parameters, joint counts and medication use were collected at consultation. The study sample was compared to healthy peers and to peers with other chronic illnesses using a two sample t-test. The proportion of children with JIA with an impaired HRQoL was evaluated and multivariate regression analyses were performed to predict HRQoL outcome. Effect sizes (d) were calculated.

Results: Approximately 70% of the eligible JIA patients participated (n=157). Data of 14 children aged 6–7 years (M=7.22), 63 children aged 8–12 years (M=11.20) and 78 adolescents aged 13–18 years (M=15.95) were available for analysis. At consultation, 40% of the patients had inactive, 38% mild and 22% moderate to severe disease activity; the mean CHAQ score was 0.79; 90% of the patients used DMARDS including biologicals. Children and adolescents with JIA differed on almost all domains significantly with healthy controls and a chronic health condition. Effect sizes were moderate to large, with the exception of emotional functioning (table 1). Approximately half of the children with JIA have an impaired HRQoL. The main predictors of HRQoL were physical functioning, subjective burden of medication use and school absence.

Glucocorticoid: Major Factor for Reduced Immunogenicity of 2009 Influenza A (H1N1) Vaccine in Juvenile Autoimmune Rheumatic Diseases Patients.
Nadia E. Aikawa[1], Lucia M.A. Campos[1], Clovis A. Silva[1], Carla G.S. Saad[1], Jozelio F. Carvalho[1], Guilherme Trudes[1], Alberto J.S. Duarte[1], Joao Miraglia[2], Maria C.S. Timenetsky[3], Vilma S.T. Viana[1], Ivan L.A. França[1], Eloisa Bonfa[4] and Rosa M.R. Pereira[5]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Fundação Butantan, São Paulo, Brazil, [3]Instituto Adolfo Lutz, São Paulo, Brazil, [4]University of Sao Paulo, São Paulo, Brazil, [5]Disciplina de Reumatologia da FMUSP, Sao Paulo, Brazil

Background/Purpose: In 2010 the Advisory Committee on Immunization Practices from the Center for Disease Control and Prevention recommended that all children and adolescents should receive the trivalent seasonal influenza vaccine containing the A/California/7/2009(H1N1)-like virus. There are, however, no data evaluating the immunogenicity and safety of the non-adjuvanted influenza A H1N1/2009 vaccine in a large cohort of juvenile autoimmune rheumatic diseases (ARD) patients.

Methods: 237 juvenile ARD patients [juvenile systemic lupus erythematosus (JSLE), juvenile idiopathic arthritis (JIA), juvenile dermatomyositis (JDM), juvenile scleroderma and primary vasculitis] and 91 age-matched healthy controls were vaccinated with a non-adjuvanted preparation of influenza A/California/7/2009 (H1N1) virus-like vaccine. Subjects were ≥ 9 and ≤ 21 years old. All participants were evaluated pre- and 21 days post-vaccination and serology for anti-H1N1 antibody was performed by hemagglutination inhibition (HI) assay. Seroprotection (percentage of subjects with HI antibody titer ≥ 1:40), seroconversion (percentage of subjects with either a pre-vaccination HI titer < 1:10 and a post vaccination HI titer ≥ 1:40 or a pre-vaccination HI titer > 1:10 and a minimum four-fold rise in post-vaccination HI antibody titer) rates, geometric mean titres (GMT) and factor increase (FI) in GMT (ratio of the GMT after vaccination to the GMT before vaccination) were calculated. Adverse events were also evaluated.

Results: Age was comparable in juvenile ARD patients and controls (14.8 ± 3.0 vs. 14.6 ± 3.7 years, p=0.47). Three weeks after immunization, seroprotection rates (81.4 vs. 95.6%; p=0.0007), seroconversion rates (74.3 vs. 95.6%; p<0.0001) and the factor increase in GMT (12.9 vs. 20.3; p=0.012) were significantly lower in juvenile ARD patients *versus* controls. Subgroup analysis comparing with controls revealed reduced seroconversion rates in JSLE (p<0.0001), JIA (p=0.008), JDM (p=0.025) and primary vasculitis (p=0.017). Additionally, seroprotection (p<0.0001) and GMT (p<0.0001) were decreased solely in JSLE. Glucocorticoid use and lymphopenia were associated with lower seroconversion rate (60.4 vs. 82.9%, p=0.0001 and 55.6 vs. 77.2%, p=0.012), compared to patients without these conditions. Multivariate logistic regression including each disease (JSLE, JIA, JDM, primary vasculitis), lymphopenia, glucocorticoid and immunosuppressants use revealed that only glucocorticoid use remained significant (OR 0.20, 95%CI 0.06–0.70, p=0.012).

Conclusion: This is the largest study to demonstrate a reduced immune response to 2009 influenza A (H1N1) vaccine in juvenile ARD patients and it identified current glucocorticoid use as the major factor for this deleterious effect. The short-term safety supports its routine recommendation for juvenile ARD patients and the indication of a second boost in patients under this therapy. (ClinicalTrials.gov, #NCT01151644)

Silent Arthritis Progression in Children with Juvenile Idiopathic Arthritis Detected by Magnetic Resonance Imaging.
Nikolay Tzaribachev[1], Marius Horger[2] and Jan Fritz[3]. [1]Center for Rheumatic Diseases, Bad Bramstedt, Germany, [2]M.D., Tuebingen, Germany, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: The aim of the study was to detect silent (subclinical) arthritis (SA) progression in patients with juvenile idiopathic arthritis (JIA) and inactive disease using MRI.

Methods: Patients with JIA according to Durban criteria presenting

with inactive disease according to the Wallace criteria underwent clinical examination (active joints, joints with limited range of motion) and laboratory tests (CRP, ESR). CHAQ, physician global assessment (PGA) and patient's visual analogue scale (VAS) for pain were recorded. Minimally swollen joints were not considered inactive. A standardized MRI-protocol was applied to examine the same target joint in the same patient during disease course. The protocol included: coronal/axial T1 weighted images [T1WI], coronal fluid sensitive images (STIR) and coronal/axial fat saturated Gadolinium enhanced T1WI. Target joints were: wrists, knees, ankles. MRI criteria for inflammation were: effusion, synovitis, synovial hypertrophy, bone marrow edema (BME), osteitis, erosions, tenosynovitis. SA was defined as isolated pain on end grade of motion with VAS pain < 2 (no other symptoms), limited range of motion $< 5°$ (no other symptoms), normal lab results, normal CHAQ (0,00). Silent progression was considered if bone marrow edema/osteitis and or erosions occurred.

Results: 21 consecutive patients with JIA on medication (methotrexate, NSAIDs, TNF α antagonists) with a median age at inclusion of 10.2 years (7.0 – 16.8) were evaluated in the study. JIA subtype distribution was: 5 oligo persistent, 4 oligo extended, 6 polyarthritis, 5 psoriatic arthritis, 1 undifferentiated arthritis. Median follow up time was 2.5 years (1.2 – 5.6). All patients had at all MRI examinations synovitis and synovial hypertrophy. Seven of the patients progressed silently developing BME/osteitis and erosions. One patient developed BME/osteitis without having erosions. One patient developed erosions without preceding BME/osteitis. Tenosynovitis was a frequent finding.

Conclusion: Despite clinically inactive disease patients with JIA may have a silent progressive course leading to joint destruction. Gadolinium enhanced MRI is capable in detecting early changes (BME/osteitis) which precede the development of erosions. MRI appears to be an indispensable tool for monitoring disease activity and drug treatment in order to prevent from joint damage.

ARHP Concurrent Abstract Session
ARHP Clinical Practice/Patient Care I
Sunday, November 6, 2011, 4:30 PM–6:00 PM

Factors That Influence Appointment Compliance Rates In a Multi-Disciplinary Specialized Lupus Clinic. Pretima G. Persad[1], Su Jin Kim[2], Kyriakos A. Kirou[1] and Doruk Erkan[1]. [1]Mary Kirkland Center for Lupus Care- Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: Missed patient appointments can interfere with treatment adherence and lead to poor health outcomes. The primary objective of this two-phase study was to analyze the demographic and clinical characteristics of a select cohort of "low-income" lupus patients in our clinic who missed a significant number of appointments over one year. The secondary objective was to determine the effectiveness of a "telephone intervention" on appointment compliance.

Methods: *During phase one*, "low income" patients receiving public health insurance benefits (Medicaid and Medicare) who had appointments scheduled between October 2009 and October 2010 were identified from our lupus clinic database. Patient demographics, lupus manifestations (based on the American College of Rheumatology Criteria), and appointment compliance rates (1%–30% [poor compliance], 31%–70% [average compliance], 71–100% [good compliance]) were retrospectively analyzed. Clinic patients who had never scheduled a follow-up appointment within the year's time were designated as having zero compliance and were excluded from the analysis. *During phase two* (January 2011 to June 2011), a "telephone intervention" was implemented. This consisted of: a) reminder phone calls for all patients one day before their appointments; and b) follow-up phone calls either the same or following day for patients who missed their appointments (for re-scheduling and identifying reasons for their missed appointments). A Chi-square test was used to compare categorical variables.

Results: *During phase one*, we identified 143 patients with an average compliance rate of 67%. Patients with poor, average, and good compliance rates were 7 (4%), 66 (46%), and 70 (50%), respectively. The seven patients with poor compliance were excluded from the analysis due to small sample size. When patients with average compliance (n: 66; 89% female; mean age: 38.5 +/− 13.9; number of total appointments: 6.2 +/− 3.3, and number of missed appointments: 3.1 +/− 2.0) and good compliance (n: 70; 83% female; mean age: 40.9 +/− 15.7; number of total appointments: 5.0 +/− 3.5, and number of missed appointments: 0.7 +/− 0.9) were compared, there were no statistical differences in demographics or cumulative lupus manifestations. *During phase two*, the overall compliance rate was 69%. Based on the missed appointment follow-up phone survey, the top three reasons patients missed their appointments were: transportation problems (44%) (e.g., ambulette cancelling or not picking patients up on time, patients not having funds for public transportation); no child care available (19%); and job-related conflicts (12%). Only 5% of the patients missed their appointments due to forgetfulness.

Conclusion: In a multi-disciplinary specialized lupus clinic serving patients who receive public health insurance benefits, we found that appointment compliance is more likely related to socioeconomic factors rather than to demographics, lupus manifestations, or appointment confirmations. Our data suggests that improving transportation services and providing access to temporary childcare for medical appointments may aid in increasing appointment compliance rates.

868

Identifying Predictors of Medication Adherence In Patients with Rheumatoid Arthritis. Elizabeth G. Salt and Susan K. Frazier. University of Kentucky, Lexington, KY

Background/Purpose: Despite the many effective disease modifying anti-rheumatic drugs (DMARDs) available to treat rheumatoid arthritis (RA), medication adherence is a significant problem. Inconsistencies in reported research have resulted in a lack of predictors of medication adherence in patients with RA. The purpose of this study was to: 1) describe self-reported medication adherence to DMARDs; 2) compare demographic (age, residence, marital status, employment status, years of education, and race) and clinical (duration of disease and number of medications) factors of adherent and nonadherent individuals; and 3) determine the predictive power of demographic and clinical factors for DMARD adherence.

Methods: This study will use a cross-sectional descriptive, predictive design in a sample of 108 patients with RA. A validated, self-report scale using various cut-points (used in prior research, mean, and median) will be used to determine medication adherence. Logistic regression modeling, independent samples t-tests, and Chi square analyses were used to analyze these data.

Results: Ninety percent of the individuals (mean age 52 ± 13 years, 76% female) reported adherence with their prescribed DMARD prescriptions using a cut-point of 39 for the Medication Adherence Report Scale (Horne and Weinman, 2002). Race was the only demographic or clinical difference between the adherent and nonadherent group ($p=0.04$); white individuals reported significantly more adherence with their prescribed DMARDs when compared to non-white individuals (Table 1). Similarly, race (OR= 3.34–10.1; $p< 0.05$) and the number of medications taken (OR=1.7; $p< 0.05$) were predictors of medication nonadherence using logistic regression models with 3 cut-points (Table 2).

Table 1. Characteristics of Participants.

Variable	Total sample (n = 108)	Adherent group (n = 98)	Nonadherent group (n = 10)	p value
Age in years	52 ± 13	52 ± 14	53 ± 9	0.77
Gender female	82 (76%)	75 (76%)	6 (68%)	0.69
Ethnicity	89 (83%)	84 (86%)	5 (56%)	
Caucasian	14 (13%)	11 (11%)	3 (33%)	
African American/Other	4 (4%)	3 (3%)	1 (11%)	0.04
Education in years	13 ± 3	13 ± 3	12 ± 3	0.81
Marital status				
Married/cohabit	62 (58%)	56 (57%)	6 (67%)	0.74
Widowed	7 (7%)	7 (7%)	0	
Divorced/Separated	20 (19%)	19 (19%)	1 (11%)	
Single/ Never Married	18 (17%)	16 (16%)	2 (22%)	
Employment				
Employed full-time	27 (26%)	25 (26%)	2 (22%)	0.72
Employed part-time	7 (7%)	7 (7%)	1 (11%)	
Unemployed	10 (9%)	10 (10%)	0	
Sick leave/disability	35 (33%)	33 (34%)	2 (22%)	
Homemaker	7 (7%)	6 (6%)	1 (11%)	
Retired	20 (19%)	17 (17%)	3 (33%)	

Residence location				
Urban	55 (51%)	48 (53%)	7 (78%)	0.18
Rural	45 (42%)	43 (47%)	2 (22%)	
Years since diagnosis	10 ± 10	10 ± 10	11 ± 8	0.73
Total number of RA medications	2 ± 1	2 ± 1	3 ± 2	0.43

Values are mean + SD or frequency (%), May not total to 100% due to some missing data points
Variables compared with independent t tests or Chi square analyses based on level of measurement
For those variables with no cases in a cell, categories were collapsed to ensure the assumptions of Chi square were met prior to analysis

Table 2. Predictors of Adherence to DMARDs.

Using the cut point from a prior research study

Factor	Odds Ratio	Significance	95% Confidence Interval	
			lower	upper
Race (white versus nonwhite)	10.10	0.01	1.66	61.40
Residence (rural versus urban)	7.52	0.10	83.33	0.70
Duration of disease	1.00	0.83	1.01	1.00
Years of education	1.09	0.61	1.50	0.79
Total number of medications taken for RA	1.26	0.51	2.53	0.63
Marital status (married versus not married)	1.44	0.75	0.151	13.68
Employment (full time versus not full-time)	2.19	0.52	21.3	0.21
Age	1.01	0.80	0.94	1.08

Using the median cut point

Factor	Odds Ratio	Significance	95% Confidence Interval	
			lower	upper
Race (white versus nonwhite)	2.67	0.12	0.78	9.17
Residence (rural versus urban)	1.54	0.38	0.58	4.08
Duration of disease	1.00	0.18	1.01	0.99
Years of education	1.03	0.73	0.89	1.19
Total number of medications taken for RA	1.69	0.02	2.63	1.09
Marital status (married versus not married)	2.76	0.17	11.63	0.66
Employment (full time versus not full-time)	2.71	0.20	0.59	12.40
Age	0.99	0.71	1.04	0.97

Using the mean cut point

Factor	Odds Ratio	Significance	95% Confidence Interval	
			lower	upper
Race (white versus nonwhite)	3.34	0.05	1.02	10.95
Residence (rural versus urban)	1.87	0.22	0.70	5.05
Duration of disease	1.00	0.11	1.01	0.99
Years of education	1.04	0.59	1.21	0.89
Total number of medications taken for RA	1.37	0.16	2.11	0.89
Marital status (married versus not married)	2.11	0.30	8.62	0.51
Employment (full time versus not full-time)	2.62	0.21	0.58	11.79
Age	1.00	0.88	1.04	0.97

Conclusion: Race and taking an increased number of medications for RA were independent predictors of medication adherence in this sample of patients with RA. These findings further define a health disparity. Future research is needed to develop a full understanding of this problem and thus, to improve patient outcomes.

869

Clinical Decision Support System Improves Bone Mineral Density Screening Rates in 65 Year Old Women. Kori A. Dewing[1], Basia Belza[2], Brenda Zierler[2] and Andrea LaCroix[3]. [1]Virginia Mason Medical Center, Seattle, WA, [2]University of Washington, Seattle, WA, [3]Fred Hutchinson Cancer Research Center, Seattle, WA

Background/Purpose: Clinical decision support systems can improve efficiency and standardization in patient care by flagging electronic medical records of patients due for recommended health maintenance screening. Bone mineral density testing is an important tool in identifying who is at risk for osteoporotic fracture. Despite the staggering numbers of people affected by osteoporosis and the economic and medical consequences of suffering a preventable osteoporotic fracture, rates of screening by bone mineral density testing by dual-emission x-ray absorptiometry (DXA) remain low.

The purpose of this quality improvement project was to evaluate the effectiveness of a clinical decision support tool (health maintenance module or HMM) in improving rates of bone mineral density testing in women age 65 within the Virginia Mason Medical Center health system.

Methods: The implementation date for the HMM was September 30, 2008. The study periods chosen for data analysis were October 1, 2006 to September 30, 2007 (pre HMM), October 1, 2007 to September 30, 2008 (pre HMM), October 1, 2008 to September 30, 2009 (post HMM), and October 1, 2009 to September 30, 2010 (post HMM). The population cohort included women turning 65 in the year prior to each study period, who were seen twice by primary care during the study period. There was no subject overlap between study periods. Subjects who died or were in hospice care were excluded. Information on BMD testing, and diagnosis of osteoporosis was collected using administrative data. A systematic review using the electronic medical records was performed on the remaining subjects to determine DXA results, documentation of previous DXA in chart notes, diagnosis of osteoporosis, or documentation of bisphosphonate use during the study period.

Percent rate differences were calculated by comparing each post-HMM study period to the mean of the two pre-HMM study periods. The odds ratios were also calculated by comparing each post-HMM study period to the mean of the two pre-HMM study periods.

Results: Rates of bone mineral density testing by DXA increased significantly from 84.3% and 81.2% in the two years prior to implementation of the HMM to 97.3% (OR 7.7, 14.5% rate increase) in the first year post-implementation of the HMM, and 99.6% (OR 70.5, 16.8% rate increase) in the second year post-implementation of the HMM. See Table 1 below.

Table 1. Performance of HMM in improving rates of BMD testing in 65 year old women

Study Period	Number of women screened/number of women eligible for screening	% of eligible women screened		Odds Ratio	% Rate Difference	95% Confidence Interval
10/1/06–9/30/07	364/432	84.3	Mean 82.8			
10/1/07–9/30/08	302/372	81.2				
10/1/08–9/30/09	360/370	97.3		7.7	+14.5	13.5–15.1
10/1/09–9/30/10	330/331	99.6		70.5	+16.8	15.8–17.8

Conclusion: In conclusion, this quality improvement project found an improvement in bone mineral density testing rates in 65 year old women in the two years following implementation of a clinical decision support system. The clinical decision support tool (HMM) provided standardization of health maintenance screening and helped to better identify those patients at risk of osteoporotic fracture.

870

Assessment and Treatment of Osteoporosis After Hip-Fracture: An Observational Study. Maria Antonelli, Douglas Einstadter and Marina N. Magrey. Case Western Reserve University/MetroHealth Medical Center, Cleveland, OH

Background/Purpose: Most patients with osteoporosis (OP) are untreated and remain so even after hip fracture. Outcomes following osteoporotic hip fractures are worse among men and non-Caucasians compared to Caucasian women. We hypothesized that screening and treatment of OP after hip fracture remains low in men and non-Caucasian women.

Methods: We identified all patients aged ≥ 65 years old with a primary diagnosis of hip fracture (ICD9-DM code 820.xx) discharged form an urban public hospital between Jan 1, 2000 and Dec. 31, 2010. Patients with active malignancy (one year before or after the fracture), and Paget's disease were excluded. Also, patients were excluded if they had less than two encounters for post-event care at the hospital. Patient charts were reviewed to obtain information on demographics, post- fracture osteoporosis screening status (Dual-energy x-ray absorptiometry (DXA) ordered or resulted), osteoporosis treatment status (prescription for oral bisphosphonates, raloxifene, zoledronic acid, calcitonin or teriparatide), and referral to rheumatology clinic. Data were captured using Research Electronic Data Capture (REDCap). Differences in frequency of patients who had been evaluated by DXA and/or prescribed anti-osteoporotic therapy after hip fractures overall and stratified by sex and race were evaluated using Chi-square tests. The study was approved by our hospital IRB.

Results: There were a total of 597 patients discharged with a primary diagnosis of hip fracture during the study period. After exclusions, 420 patients

remained and were included in the analyses. The median age was 80 years (range 65– 95), 113 (27%) were men, and 243 were White women (57.9%). Overall, 13.8% of patients were ordered DXA after their hospital discharge, 8.9% of men and 15.6% of women (p = 0.43). A total of 19% received treatment for osteoporosis, and women were nearly 3 times more likely to receive treatment than men (23.1% vs. 8%, p = 0.004). Less than 1% of patients were referred to a Rheumatologist. The rates of DXA, treatment and referral to Rheumatology did not differ by race.

Conclusion: The frequency of osteoporosis screening using DXA scan, and the initiation of osteoporosis treatment was low in all patients after fragility fractures of hip. Women were more likely than men to receive DXA and significantly more likely to receive osteoporosis treatment. While representative of only one hospital, these data suggest that more attention should be paid to possible osteoporosis among elderly patients hospitalized for hip fracture, and especially among men.

The Association of Symptomatic Osteoarthritis At Multiple Time Points with Functional Limitation Over 5 Years: The Multicenter Osteoarthritis Study. Daniel K. White[1], Yuqing Zhang[1], Jingbo Niu[1], Michael C. Nevitt[2], C.E. Lewis[3], James Torner[4] and Tuhina Neogi[5]. [1]Boston University School of Medicine, Boston, MA, [2]University of California-San Francisco, San Francisco, CA, [3]University of Alabama, Birmingham City, AL, [4]University of Iowa, Iowa City, Iowa City, IA, [5]Boston University, Boston, MA

Background/Purpose: Knee pain associated with knee osteoarthritis (OA) is a complex phenomenon that can come and go over time. While pain over the short-term is associated with functional limitation, it is not known if pain over the long-term confers greater risk for functional limitation, with few studies examining this association beyond 3 years. It may be that people learn to cope with their pain over time, and therefore have sufficient adaptation as to lessen the impact on functional limitation. Thus, we examined the association of the presence of symptomatic OA at different time points during the course of 5 years of follow-up with the incidence of functional limitation, as well as with decreased recovery from functional limitation.

Methods: The Multicenter Osteoarthritis Study (MOST) is an NIH funded longitudinal study of people who have or are at high risk for knee OA. We included people who had symptomatic radiographic knee OA at the baseline visit, with symptomatic defined as reporting pain at two time points: a telephone screen and a clinic visit occurring approximately one month later. We classified the presence of symptomatic OA at different time points as follows: i) at baseline only; ii) baseline and 30 months; iii) baseline and 60 months; and iv) baseline, 30 and 60 months. We examined the incidence of functional limitation with self report and performance outcomes at 60 months using WOMAC physical function ≥ 28/68 (risk factor for total joint replacement) and gait speed <1.22 m/s (minimal speed needed to walk in the community) among subjects without these outcomes at baseline using logistic regression adjusting for potential confounders. We also examined recovery at 60 months among subjects with functional limitation at baseline.

Results: Of the 797 subjects (Age 64 ± 8 yrs, BMI 33 ± 7 kg/m^2, female 64%), 12% had symptomatic knee OA at baseline only, 20% at baseline and 30 mo, 13% at baseline and 60 mo, and 45% at baseline, 30, and 60 mo. Of those without functional limitation at baseline, 20% of 348 and 36% of 192 subjects developed functional limitation at 60 mo by self-report and performance, respectively. We found an increasing odds of functional limitation for the presence of symptomatic OA at more time points (adj OR 1.2–8.1). Of those with functional limitation at baseline, 68% of 327 and 8% of 547 subjects recovered from poor function at 60 mo by self-report and performance, respectively. We found a deceasing odds of recovery from functional limitation for presence of symptomatic OA at more time points (adj OR 0.1–0.9).

Conclusion: The presence of symptomatic OA over multiple time points during the course of 5 years contributed to greater risk of functional limitation and less recovery from functional limitation. It therefore seems unlikely that adaptation to pain related to knee OA limits pain's impact on functioning.

Table.

	Incidence of Functional Limitation*	
SxOA	**(%) n/N**	**Adjusted** OR [95% CI]**
Self Report (WOMAC Physical Function)		
0m only	7.7 (5/64)	1.0 [Reference]
0m and 30 m	16 (8/49)	2.0 [0.6, 6.8]
0m and 60 m	18 (8/45)	3.0 [0.9, 10.3]
0m, 30 m, and 60 m	37.9 (44/116)	8.1 [2.9, 22.9]
Performance (Walking Speed)		
0m only	25.0 (10/40)	1.0 [Reference]
0m and 30 m	34.6 (9/26)	1.2 [0.4, 3.9]
0m and 60 m	37.5 (9/24)	1.5 [0.5, 5.0]
0m, 30 m, and 60 m	45.8 (33/72)	3.0 [1.1, 7.8]
Recovery from Functional Limitation***		
SxOA	**(%) n/N**	**Adjusted** OR [95% CI]**
Self Report (WOMAC Physical Function)		
0m only	80.0 (24/30)	1.0 [Reference]
0m and 30 m	70.6 (24/34)	0.6 [0.2, 1.9]
0m and 60 m	40.0 (6/15)	0.2 [0.1, 0.9]
0m, 30 m, and 60 m	32.6 (30/92)	0.1 [0.0, 0.3]
Performance (Walking Speed)		
0m only	19.9 (11/58)	1.0 [Reference]
0m and 30 m	14.0 (9/64)	0.6 [0.2, 1.5]
0m and 60 m	23.7 (9/38)	0.9 [0.3, 2.7]
0m, 30 m, and 60 m	5.7 (8/140)	0.2 [0.1, 0.5]

*Functional Limitation incidence was defined as developing a score of ≥28/68 for the WOMAC physical function or developing a walking speed <1.22 m/s at the 60 month visit. Higher OR indicate a higher odds of developing functional limitation at 60 months.
**Adjusted for age, sex, BMI, knee pain severity, and disease severity (KL grade) at baseline.
***Functional Limitation recovery was defined as recovering from a score of ≥28/68 at baseline to <28/68 at the 60 month visit for the WOMAC physical function or walking <1.22 m/s at baseline and ≥1.22 m/s at the 60 month visit. Lower OR indicate a lower odds of recovery from functional limitation at 60 months.

872

Continued Tocilizumab Infusion for Rheumatoid Arthritis Is Well Tolerated and Safe At An Accelerated Infusion Rate.. Gunhild Bukh, Michael Sejer Hansen, Sussi Larsen and Susse Skalsted Rasmussen. Gentofte Hospital, Hellerup, Denmark

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic disease related to progressive disability and an increased mortality compared to the general population. New therapies are needed and one promising candidate is Tocilizumab ® that binds specifically to the IL-6 receptor. This treatment is given every four week over one hour, and is quit time-consuming over time. No serious infusion-reactions have been reported after the 5th infusion. The purpose of our study was to evaluate if an accelerated infusion-rate of Tocilizumab after the 5th infusion would be as safe and tolerable for RA patients as the conventional infusion regiment. The reduced infusion-time is comparable with the reduced time used for infliximab ® infusion at our department after the 10th infusion.

Methods: The present study was conducted consecutively for RA patients allocated to treatment with Tocilizumab. Fifty RA patients have received Tocilizumab-infusion at our Department since 2005.

21 have stopped Tocilizumab treatment. 9 due to lack of efficacy, 5 patients due to adverse events, 4 due to remission and 3 lost to follow-up. Twenty-nine patients are still successfully treated with Tocilizumab; 4 with the recommending Tocilizumab-infusion procedure (1 hour/infusion) and 3 patients in a RCT (ActRay) study. The study population is thereafter comprised of 22 patients and was treated with Tocilizumab at an accelerated infusion rate (30 minutes/infusion). These patients are characterized as: 17 F/ 5 M, median age 55 years (range 27–77), disease duration 11 years (2–45), positive IgM-RF or anti-CCP: 18 (85%), DAS28CRP 5.5 (2.7–7.2), HAQ-score 1.5 (0.0–2.375), number of previous DMARDs 2.3 (0–8), number of previous biologics 2.3 (0–5). 18 patients were on concomitant DMARDs (15 Methotrexate, 2 Azathioprine) and 1 Sulfasalazin. Tocilizumab was given at a dose of 8 mg/kg/100 ml isot NaCl during one hour for infusion number 1 – 5, and from infusion 6 and thereafter at the same dosage during 30 minutes.

During the infusion period, the patients were monitored with blood pressure, pulse, temperature, respiration and registration of any kind of side effects according to the CTC grading system.

Results: 321 Tocilizumab infusions at an accelerated infusion rate of 30 minutes/infusion were given to 22 patients (median 5 (range 1–27) infusions/ patient) with only a small number of side-effects. One patient had had a serious adverse event after the 23rd ½-hour infusion and has been treated for septicaemia. Result unresolved. One patient got dizzy and nausea after the 31st ½-hour infusion. This side effect was resolved by increasing the infusion time to one hour. No long term side effects were found for any of the treatment regimens.

Conclusion: The patients with RA were satisfied and comfortable with an accelerated time-sparing infusion regimen as well as the health professionals. No unexpected adverse events were recorded. These results have led to a change in our routine management of Tocilizumab infusions.

Osteoarthritis Severity Is Associated with Increased Risk for Diabetes and Heart Disease. Gillian A. Hawker, Andrew Warner and Taryn Simms. Women's College Hospital, Toronto, ON

Background/Purpose: Prior studies have documented increased rates of diabetes and heart disease in individuals with osteoarthritis (OA). However, there is a paucity of research that has examined if OA severity contributes independently to these relationships. Our study aim was to evaluate the relationship between OA severity and prevalence of heart disease and diabetes and the extent to which these relationships, if found, were explained by common risk factors.

Methods: In a population cohort with hip and knee OA, sociodemographics, OA severity (WOMAC subscale and summary scores), body mass index (BMI) general health status (SF36) and comorbidity (list of 13 non-musculoskeletal, MSK, conditions) were assessed. Diabetes and heart disease were defined as present if the participant reported having 'ever' received a diagnosis or received treatment in the past year. Logistic regression was used to examine the association of OA severity with each of diabetes and heart disease, first unadjusted, then controlling for potential confounders (age, sex, education, income, BMI and diabetes). We assessed for potential interactions between OA severity and age, sex, education, and income, and between OA severity and diabetes on heart disease. Statistical significance was considered at a 2-tailed level of 0.05.

Results: Mean age of the 2225 participants was 70.7 years, 72.0% were female and 96.1% Caucasian; 81.1% reported ≤ high school education and 63.9% reported an annual income < $20,000. WOMAC scores indicated moderate to severe OA pain and disability. Mean BMI was 27.9 kg/m^2; 38.8% were overweight and 30.9% were obese. Three-quarters (73.1%) reported receiving treatment for at least one other non-MSK chronic condition; 22.5% reported 3 or more comorbid conditions; 30.4% reported heart disease and 16.8% reported diabetes. Unadjusted for other factors, a 10-point increase in WOMAC summary scores was associated with a 10% increase in the odds of self-reporting diabetes (odds ratio 1.10; 95% confidence interval 1.04–1.16). This relationship was attenuated, becoming non-significant, after controlling for BMI. Unadjusted for other factors, a 10-point increase in WOMAC summary scores was associated with a 12% increase in the odds of reporting heart disease (odds ratio 1.12; 95% confidence interval 1.06–1.17). In adjusted analyses, self-reported heart disease was significantly and independently associated with male sex, lower income, and interactions between OA severity and each of age ($p = 0.015$) and self-reported diabetes ($p = 0.02$); the effect of a 10-point increase in WOMAC summary scores on the odds of self-reporting heart disease decreased with increasing age, but was significantly greater at all ages among those with comorbid diabetes.

Conclusion: In a population cohort with moderately severe hip and knee OA, the prevalence of comorbid diabetes and heart disease was substantial and positively linked to increasing symptomatic OA severity. For diabetes, this relationship was explained by a common risk factor, obesity. For heart disease, this relationship remained significant even after controlling for common risk factors, and was stronger among those with comorbid DM.

876

Serum 25 Hydroxy Vitamin D (25OHD) and Incident or Worsening Knee Pain In Older Adults: A Five Year Longitudinal Study. Laura Laslett[1], Chang-Hai Ding[2], Stephen Quinn[3], John Burgess[4], Venkat Parameswaran[4], Tania Winzenberg[1] and Graeme Jones[1]. [1]University of Tasmania, Hobart, Australia, [2]University of Tasmania & Monash University, Hobart, Australia, [3]Flinders University, Australia, [4]Royal Hobart Hospital, Hobart, Australia

Background/Purpose: Vitamin D is important for bone, cartilage and muscle function. However, there is little data on its association with pain. The aim of this study was to describe the association between serum 250HD and change in knee pain over five years.

Methods: Longitudinal population-based study of randomly selected older adults (n=766). Serum 25OHD was assessed by radioimmunoassay and knee pain using the WOMAC questionnaire at baseline and again after five years. We used linear regression with adjustment for season, age, sex and BMI. We also examined potential structural mechanisms for any effect by additionally adjusting for radiographic osteoarthritis, bone marrow lesions, chondral defects and muscle strength.

Results: Participants were aged 50–80 years (mean 62 years), 50% were male with a mean WOMAC score of 3.2 (range 0–39). Mean serum vitamin D was 53.8 nmol/l (range 13–166 nmol/l), with 4.2% of participants having moderate deficiency (<25 nmol/l). Knee pain (total WOMAC score) was stable in participants with vitamin D 25–50 and ≥50 nmol/l but worsened over five years in persons with vitamin D <25 nmol/l (b −1.02, p=0.002), with consistent results within each of the pain subscales. This association persisted after adjustment for covariates. When vitamin D was analysed as a continuous measure, there were no associations between vitamin D and change in WOMAC score (b −0.12, p=0.2). This effect was largely independent of structural factors.

Conclusion: Serum vitamin D level in the osteomalacic range (<25 nmol/l) is an independent predictor of worsening or incident knee pain over five years suggesting a lag time between the development of low levels and pain. This suggests supplementing levels below this will prevent worsening knee pain.

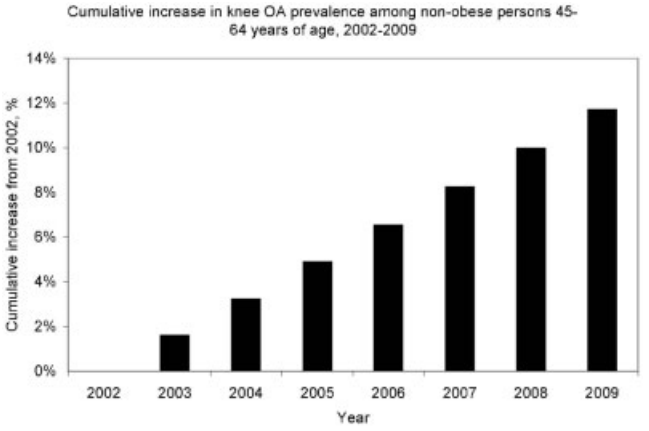
877

Trends in the Prevalence of Symptomatic Knee Osteoarthritis From 2002 to 2009. William M. Reichmann[1], Jeffrey N. Katz[2], Sara A. Burbine[3], Meghan E. Daigle[3], Benjamin N. Rome[3], Alexander M. Weinstein[3] and Elena Losina[3]. [1]Brigham and Womens Hospital, Boston, MA, [2]Brigham & Womens Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

Background/Purpose: A growing body of evidence suggests that the prevalence of symptomatic knee OA has increased over time from the 1980s to early 2000s. The goal of this study is to describe temporal trends in the prevalence of symptomatic knee OA from 2002 through 2009 and to determine whether increases in knee OA prevalence occur across all age groups and for obese and non-obese persons.

Methods: We used data from the National Health Interview Survey (NHIS) from 2002 to 2009. The NHIS is an annual survey of the non-institutionalized United States population with approximately 30,000 respondents during each year. We defined persons with symptomatic knee OA as those who stated that a physician diagnosed arthritis and that they had right or left knee pain, aching, or stiffness in the last 30 days. We used logistic regression to obtain prevalence estimates by obesity status for the overall population and by age groups (25–44, 45–64, and 65+) adjusting for sex and age within the age group. We defined obesity as BMI 30+. To assess the temporal trends in the prevalence of symptomatic knee OA, we included survey year in the model as a continuous variable. We accounted for the complex multi-stage sampling design of NHIS to derive prevalence estimates that were representative of the US.

Results: In the overall population we did not find evidence of increased prevalence of symptomatic knee OA between 2002 and 2009, adjusting for age and sex among obese and non-obese persons. Among obese persons, the age- and sex-adjusted prevalence of knee OA was 15.2%, vs. 6.6% among non-obese. When we further stratified by age group, we found the prevalence of symptomatic knee OA ranged from 2.8% in non-obese persons aged 25–44 to 34.8% among obese aged 65+. We found a statistically significant increase in prevalence of symptomatic knee OA over time for those that were non-obese and in the 45–64 age group (p for linear trend = 0.04; Figure). We estimated that the prevalence of symptomatic knee OA increased from 9.2% in 2002 to 10.3% in 2009 in these persons.



Conclusion: From 2002 to 2009, we found a consistent increase in prevalence of symptomatic knee OA in non-obese persons ages 45–64. One possible explanation for the increase among non-obese persons ages 45–64 is that an increase in knee injuries has led to an increase in symptomatic knee OA. These data are helpful in understanding the burden of symptomatic knee OA in US.

878

Impact of Psychosocial Determinants on Total Knee Replacement Costs: Results From the Patient Expectations about Knee Surgery Cohort. Christian A. Waimann[1], Rodrigo J. Fernandez-Mazarambroz[1], Scott B. Cantor[1], Maria Lopez-Olivo[1], Hong Zhang[1], Glenn C. Landon[2], Sherwin J. Siff[2] and Maria E. Suarez-Almazor[1]. [1]University of Texas, M.D Anderson Cancer Center, Houston, TX, [2]St. Luke's Episcopal Health System, Houston, TX

Background/Purpose: Psychosocial factors have been associated with clinical outcomes after total knee replacement (TKR) in patients with osteoarthritis (OA). We hypothesized that poor baseline psychosocial determinants and skills would increase TKR-related costs during the initial 6 months of follow up.

Methods: PEAKS is a prospective cohort of patients with OA who underwent TKR. Patients were followed for 6 months after surgery, and we collected sociodemographic data, TKR-related costs, clinical outcomes (Western Ontario McMaster (WOMAC) pain and function) and psychosocial determinants (Medical Outcomes Study Social Support Scale (MOS-SSS); Health Locus of Control (MHLC); Brief COPE Inventory; Depression, Anxiety, and Stress Scale (DASS); Arthritis Self-Efficacy Scale (ASES); and Life Orientation Test-Revised (LOT-R)). The economic analysis was conducted using a societal perspective based on 2007 US dollars. Direct medical costs were estimated using the Medicare Reimbursement Prospective Payment System and hospital billing was adjusted by cost-to-charge ratios reported to Medicare. Average wholesale price was used for drugs costs. Productivity losses (patient and relatives) were calculated using time lost multiplied by estimated wage per occupation reported by the Bureau Labor of Statistics for Texas. We also estimated each patient's OA-related costs in the 2 months prior to surgery. Bivariate analysis and stepwise multiple regression were performed to identify the impact of psychosocial outcomes on total TKR-related costs adjusted by gender, age, body mass index, ethnicity, baseline WOMAC and patient OA-related costs prior to surgery.

Results: 218 patients were included; 65% were female, 69% were white, mean age was 65±9 years. Baseline WOMAC pain was 55±19 and function was 54±20. Mean total costs were ≈$24,000±10,000 USD. Bivariate analysis showed that younger patients and those with less social support (emotional, tangible, positive), more anxiety, more depression, stronger belief that their health is related to events given by chance and less optimism, were more likely to have higher TKR-related costs. Stepwise regression analyses (Figure 1) indicated that more anxiety, lower stress, and less emotional/information support were significantly associated with higher TKR-related costs (R^2=0.35).

Stepwise regression using TKR-related total costs as dependent variable

Baseline variables	b	SE	B	p
Intercept	21457	5508.2	0	<0.01
Age	−53.8	52.7	−0.06	>0.20
Female	−1603.3	1012.6	−0.10	0.12
Non-white race	2892.1	975.7	0.18	<0.01
Body mass index	311.5	72.1	0.29	<0.01
WOMAC function	−14.6	24.2	−0.04	>0.20
Patient usual expenses prior to surgery	0.3	0.2	0.11	0.07
DASS anxiety subscale	483.6	119.0	0.34	<0.01
DASS stress subscale	−160.0	82.7	−0.16	0.05
MOS emotionalscale	−1777.3	550.2	−0.19	<0.01
MHLC powerful to others subscale	142.8	80.1	0.11	0.08

Score direction: WOMAC, higher scores indicating greater discomfort; MOS-SSS, higher scores indicate more support; DASS, higher scores indicating worse emotional states; MHLC, higher scores indicating stronger beliefs that others persons are the determinants of his health.

Conclusion: Patients' level of stress, anxiety and emotional support are associated with total costs following TKR. A perioperative psychosocial evaluation and intervention may reduce TKR-related costs.

879

Incidence of Hip Symptoms and Radiographic and Symptomatic Hip Osteoarthritis in African Americans and Caucasians: The Johnston County Osteoarthritis Project. Barbara T. Do[1], Louise Murphy[1], Charles G. Helmick[1], Kamil E. Barbour[1], Yiling J. Cheng[1] and Joanne M. Jordan[2]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]UNC Thurston Arthritis Center, Chapel Hill, NC

Background/Purpose: Estimate the population-based incidence of 4 hip osteoarthritis (hOA)-related outcomes.

Methods: We analyzed baseline (1991–1997) and first follow up (1999–2005) data from Johnston County Osteoarthritis Project participants (n=1,423; aged > 45 years). The 4 outcomes were: 1) hip symptoms (pain, aching, and/or stiffness on most days in their hip and/or groin); 2 & 3) radiographic and severe radiographic hOA (Kellgren-Lawrence [K-L] radiographic grade of >2 and >3, respectively); and 4) symptomatic hOA (K-L radiographic grade of >2 and hip symptoms in the radiographically affected hip). Incidence rates were calculated overall and stratified (age; sex; race; highest education attainment; body mass index [BMI] at age 18 and at baseline; and history of hip injury in affected hip) for each outcome among those who did not have the outcome at baseline.

Results: The overall incidence rates (people per 100 person-years) were 5.5 for hip symptoms, 2.2 for radiographic hOA, 1.7 for symptomatic hOA, and 0.3 for severe radiographic hOA. The subgroup analysis indicated that incidence rates generally rose with increasing age, self-reported BMI at age 18, and clinically measured BMI at baseline and were higher among women and those with a history of hip injury. The largest absolute difference in incidence for any characteristic was for hip symptoms among those with and without a history of hip injury (9.2 and 5.3, respectively). Across all subgroups, incidence was generally higher among African Americans than Caucasians.

Conclusion: The incidence of 4 hip OA-related outcomes in this >45 year old population ranged from 0.3 to 5.5% each year. For each outcome, older age, being female, and having a history of hip injury were all predictors of increased incidence. Our findings indicate that greater intervention efforts (self-management education, physical activity, weight management, joint injury prevention) may reduce the onset and effects of these outcomes.

880

Back Pain. Gary J. Macfarlane[1], Marcus Beasley[1], Elizabeth A. Jones[1], Karina Lovell[2], Gordon J. Prescott[1], Philip Keeley[2], John McBeth[2], Gareth T. Jones[1] and MUSICIAN study team[1]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]University of Manchester, Manchester, United Kingdom

Background/Purpose: Relatively little is known about back pain at older ages although it has been claimed to be under-assessed and managed in this age group. The aim of the current study was to determine: the prevalence of back pain and associated disability across the whole adult

age range; the frequency of consultations to general practice; whether there are differences in management by age of the person consulting with back pain.

Methods: We conducted a cross-sectional population-based study in Aberdeen city and Cheshire county, UK. Participants were 15,272 persons aged 25 years and older, randomly selected from participating GP registers and who returned a completed postal questionnaire. The outcomes of interest were the reporting of back pain on a body manikin (with or without disability as measured by the Chronic Pain Grade); consultation to general practice amongst persons with back pain; the management recommended as a result of consultation, by patient self-report.

Results: The one-month period prevalence of low back pain was 28.5 %. It peaked at age 41– 50 years and decreased thereafter, but at ages over 80 years 1 in 4 persons still reported back pain. However the impact of pain is greater at older ages: the prevalence of more severe pain (Chronic Pain Grade III/IV) continued to increase with age and low back pain in the elderly leads to a greater likelihood of consultation. Management by GPs differed by age of the patient. Older persons (over 70 years v. 40 years or less) were significantly more likely to only have only been prescribed painkillers (Odds ratio (OR) 1.74 95% Confidence Interval (CI) (1.28,2.35)) or only pain killers with other medications (OR 1.45 95% CI (1.07, 1.98)). They were significantly less likely to receive a prescription for physiotherapy or exercise (OR 0.63, 95% CI (0.46, 0.85), or to be referred to a specialist (OR 0.77, 95% CI 0.57, 1.04). Older persons were more likely to have previously received exercise therapy for pain, they were less likely to be enthusiastic about receiving it ($p < 0.0001$)and if they were to receive it they were less likely to think it would result in improved symptoms ($p < 0.0001$).

Conclusion: In order to achieve optimal outcome from episodes of back pain it is important that older persons, who have the highest prevalence of back pain with disability and are most likely to consult, are receiving both pharmacological and non-pharmacological management. Future studies should investigate why pharmacological management predominates and is likely to have to address patient attitudes and beliefs as well as ensuring that GPs are using the full range of treatment shown to be efficacious.

881

Association of Lumbar Spine Individual Radiographic Features with Serum C-Propeptide (sCPII) and Serum Collagen Neoepitope (sC2C) of Type II Collagen: The Johnston County Osteoarthritis Project. Adam P. Goode[1], Virginia B. Kraus[1], Yvonne M. Golightly[2], Stephen W. Marshall[3], Debra E. Irwin[3] and Joanne M. Jordan[2]. [1]Duke University Medical Center, Durham, NC, [2]University of North Carolina Thurston Arthritis Center, Chapel Hill, NC, [3]University of North Carolina, Chapel Hill, NC

Background/Purpose: Serum levels of C-propeptide (sCPII), a biomarker of type II collagen synthesis, and serum collagen neoepitope (sC2C), a biomarker of type II collagen degradation, have been associated with radiographic knee osteoarthritis (OA). Whether these biomarkers are associated with joint metabolism changes in the lumbar spine has not been reported previously. We sought to: 1) determine if elevated levels of sCPII and sC2C reflect the presence and severity of the lumbar spine individual radiographic features (IRF) of disc space narrowing (DSN) and vertebral osteophytes (OST), controlling for the presence of knee OA, and 2) determine if these associations differ significantly by gender or race.

Methods: Of the 1,015 participants enrolled in the Johnston County OA Project from 2003–2004, lumbar spine IRF (DSN and OST) were available for 547 participants with complete sCPII and sC2C data (mean age 62.3 (SD 9.9), 61.8% female, 37.8% African American, mean [body mass index (BMI) 30.1 (SD 6.2)], 29.2% knee OA). Both sC2C and sCPII were natural log transformed to meet model assumptions due to a right skewed distribution. Each lumbar spine level was graded in a semi-quantitative fashion (0–3) according to the Burnett Atlas. A summary score was developed, separately for each IRF (DSN and OST), by adding the severity grade from each participant's five lumbar levels. Analysis of variance was used to determine differences in geometric mean levels of sCPII and sC2C across severity of both DSN and OST. Proportional odds models were used to determine associations of DSN and OST severity with sCPII and sC2C. All analyses were adjusted for age, gender, race, BMI and concomitant radiographic knee OA (defined as Kellgren-Lawrence score of 2–4). Interactions were tested with likelihood ratio tests to determine if associations differed significantly ($p<0.10$) by gender or race.

Results: No significant differences in mean levels of sCPII across severity of DSN ($p=0.074$) or OST ($p=0.863$) were observed. After adjustment, a one-unit change in sCPII was associated with 64% higher odds of DSN [adjusted odds ratio (aOR) = 1.64 (95% CI 1.07, 2.40)], but there was no association between sCPII and OST severity (aOR = 1.03 (95% CI 0.67, 1.60).

In contrast, significant differences in mean levels of sC2C were found across severity of DSN ($p=0.007$), but not for OST ($p=0.503$). After adjustment, a one unit change in sC2C was associated with an 89% higher odds of DSN (aOR=1.89 (95% CI 1.04, 3.46). The association with OST was moderate but not statistically significant (aOR=1.32 (95% CI 0.73, 2.39).

No significant interactions were found across gender or race.

Conclusion: Moderate to strong significant associations were found for sC2C and sCPII separately with DSN, above and beyond associations of each biomarker with radiographic knee OA, whereas no significant associations were found with OST. These findings suggest active collagen turnover in the lumbar spine intervertebral disc and underscore the importance of analyzing IRF separately for revealing biological insights through OA biomarker studies.

To What Degree Is the Rise in US Total Knee Replacement Rates Attributable to Aging of the Population? Louise Murphy[1], Gillian A. Hawker[2], Erica Odom[1] and Charles G. Helmick[1]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]Women's College Hospital, Toronto, ON

Background/Purpose: In the past decade, total knee replacement (TKR) rates have increased resulting from multiple factors including the aging of the US population, rising prevalence of obesity and increased access to and demand for TKRs. To quantify the degree to which aging accounts for the observed increase in TKRs, we examined TKR rates, annual percent change (APC) and standardized incidence ratio (SIR) over 13 years among US adults aged ≥18 years.

Methods: Using 1997–2009 US Nationwide Inpatient Sample data – hospital discharge data for 44 states comprising 95% of all US hospital discharges -- we estimated overall and age-specific (18–44, 45–64, 65–84, and ≥85 years) annual hospital discharge rates, and APC for TKRs (ICD-9-CM procedure=81.54 [excludes revisions]). Also, we calculated overall and age-specific SIRs with 1997 and 2009 data to examine whether the rise in TKR rates from 1997 to 2009 was attributable solely to changes in the age distribution of the US population. Expected 2009 values, based on estimated 1997 TKR rates (# of TKR in 2007/# of people in 2000 US Census Population) were applied to population estimates from the 2010 US Census. SIRs were the ratio of observed to expected number of TKRs in 2009.

Results: Among all US adults aged ≥ 18 years, approximately 1 and 3 per 1000 people had a TKR discharge in 1997 and 2009 respectively. TKR rates (per 1000 people) in 2009 were higher than 1997 for all age groups: 18–44=0.04 and 0.1; 45–64=1.1 and 3.1; 65–84=5.9 and 9.7; and ≥85 years=2.2 and 3.1. The APC was 10% among all US adults (from 264,331[1997] to 620,192 [2009]); across age groups the largest APC was among those 45–64 years (21%) (18–44=11%; 65–84=7%; ≥85=6%). The overall SIR was 2.1; age-specific SIRs were 2.4, 2.9, 1.6 and 1.4 for adults aged 18–44, 45–64, 65–84, and ≥85 years respectively.

Conclusion: From 1997 to 2009, overall TKR rates tripled representing an APC of 10%. Although TKR rates rose most rapidly among people aged 45–64 years (APC=21%), observed rates in both 1997 and 2009 were highest among those aged 65–84 years (5.9 and 9.7). SIRs indicated that rates were between approximately 1.5 to 3 times higher than would be expected if the rise was attributable to aging alone. In this analysis, we were unable to quantify the effect of increased prevalence of obesity, a major risk factor for knee osteoarthritis and subsequent TKRs, and increased access to and demand for TKRs on this increase but it is likely substantial.

883

Patterns of Population Use of Total Joint Arthroplasty: Focus on Outcomes Following a *Single* primary TJA Is Too Narrow. Ruth Croxford[1] and Gillian A. Hawker[2]. [1]Institute for Clinical and Evaluative Science, Toronto, ON, [2]Women's College Hospital, Toronto, ON

Background/Purpose: Many studies have evaluated outcomes following total joint arthroplasty (TJA) for hip and knee osteoarthritis (OA) and, on average, outcomes are good to excellent. However, these studies have focused on

recipients of a single hip or knee replacement procedure, excluding those with bilateral or consecutive TJAs. The extent to which this reduces the generalizability of these studies to all patients receiving TJA is unknown. To address this gap, we evaluated patterns of use of TJA following an index primary TJA over an 8-year period.

Methods: Primary and revision TJA procedures performed on Ontario, Canada, residents aged 55+ years between April 2002 (baseline) and March 2010 were identified from hospital discharge abstracts using specific ICD-10-CA/CCI procedure and diagnosis codes. The records of individuals who underwent TJA prior to April 1, 2002 (i.e. pre-baseline) or before age 55 years were excluded as were non-elective TJAs and those performed for cancer, fractures or trauma. We examined the proportions with repeat hospitalizations for TJA, and the associated TJA type (elective versus non-elective, hip versus knee, primary versus revision).

Results: Excluding those with a pre-baseline TJA, 164,330 index TJA procedures were identified. Of these, 129,937 were eligible for inclusion (90.4% of TJAs performed in people aged 55+ years). Bilateral knee replacements in the same hospitalization were more frequent (n=4,460, 3.44%) than were bilateral hip replacements (n=228, 0.18%). Further, knee replacements as the first TJA were almost twice as common as hip replacements (65.85% vs. 34.15%). A total of 33,474 (25.76%) second TJA hospitalizations occurred. Of 85,565 index primary knee replacements (4,460 bilateral), 23,984 (28.03%) experienced a second TJA hospitalization, with a median duration (IQR) from the index procedure of 1.37 years (0.63–2.93 years). Of these, 83.68% were for primary TJA of the contra-lateral knee, 1,802 (7.51%) were single or bilateral primary hip replacements, and 2,087 (8.7%) were for revision of one or both index knees. Of 44,372 index primary hip replacements (228 bilateral), 9,490 (21.39%) experienced a second TJA hospitalization with a median duration of 1.21 years (0.64–2.58 years) from the index procedure. Of these, 69.52% were for primary TJA of the contra-lateral hip, 2,193 (23.11%) were single or bilateral primary knee replacements, and 700 (7.38%) were for revision or one or both index hips. Of those who experienced a second TJA hospitalization, 2,561 (1.97% of the cohort) went on to receive a third within a median duration of 2.8 years (IQR 1.1–4.1 years) from the index procedure; the majority (89.54%) of these were elective TJAs.

Conclusion: In a population cohort undergoing primary hip or knee TJA, repeat TJA hospitalizations are frequent; approximately one-quarter experienced a second TJA hospitalization, which was most often for primary TJA of the contra-lateral hip or knee. Most repeat hospitalizations occurred within 3 years of the index TJA. Together, these data suggest that exclusion of such individuals from TJA cohort studies reduces the generalizability of results to all patients undergoing primary TJA.

884

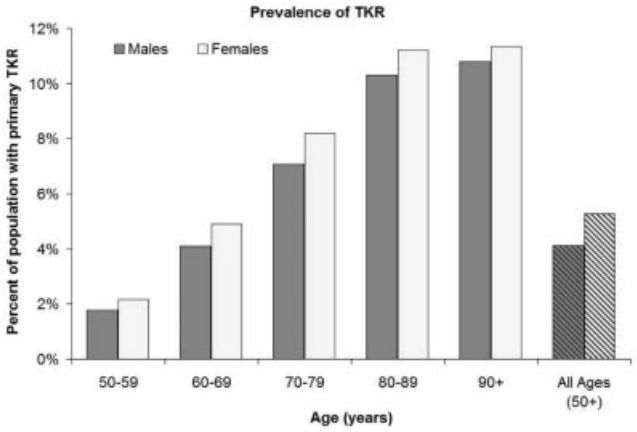
How Many Americans Are Currently Living with Total Knee Replacement?

Alexander M. Weinstein, Benjamin N. Rome, William M. Reichmann, Jamie E. Collins, Sara A. Burbine, Thomas S. Thornhill, John Wright, Jeffrey N. Katz and Elena Losina. Brigham and Women's Hospital, Boston, MA

Background/Purpose: In the last decade, the number of total knee replacements (TKRs) performed in the US doubled, exceeding 600,000 in 2009. The vast majority are done for osteoarthritis (OA). The growth in TKR use has been greatest among younger individuals, and as a result the average age at which patients receive TKR has decreased over time. The rapid growth in TKR utilization among younger individuals, coupled with increased life expectancy, may lead to increased health care costs due to periprosthetic fractures, prosthetic infections, and symptomatic loosening, with the need for revision TKR. While changes in annual rates of TKR over time have been described, estimates of the number of persons in the US living with knee implants have not been reported.

Methods: We used the OAPol Model, a state-transition, computer-simulation model, to estimate the prevalence of primary TKR stratified by age and sex. We combined these prevalence estimates with 2009 US Census data to calculate the number of Americans currently living with an intact primary TKR. The incidence and prevalence of symptomatic knee OA were derived using data from the National Health Interview Survey. The annual incidence of TKR among persons with advanced knee OA (Kellgren-Lawrence grade 3 or 4) was derived using the data from two national longitudinal studies of persons with knee OA (Multicenter Osteoarthritis Study and Osteoarthritis Initiative). Input parameters related to mortality, obesity, comorbidities, non-surgical OA treatments, and prosthesis failure were obtained from national survey data and published literature.

Results: Over 4.5 million Americans currently have an intact primary TKR, representing 4.7% of the population aged 50 years or older. The prevalence of TKR is higher in females (5.3%) than males (4.1%). Among persons 60–69 years of age, 4.1% of men and 4.9% of women have had at least one knee replaced. Among those 70–79 years of age, 7.1% of men and 8.2% of women have had at least one knee replaced. Approximately 10% of those older than 80 years have had at least one knee replaced. (Figure).



Conclusion: Five percent (5%) of females and 4% of males older than 50 years are living with TKR. Among persons older than 50 years of age, TKR has become considerably more prevalent than rheumatoid arthritis or congestive heart failure. Knowledge of TKR prevalence is useful in planning health services specific to the population living with TKR. This includes the prevention and management of periprosthetic fractures and infections, as well as planning for adequate capacity for revision TKR.

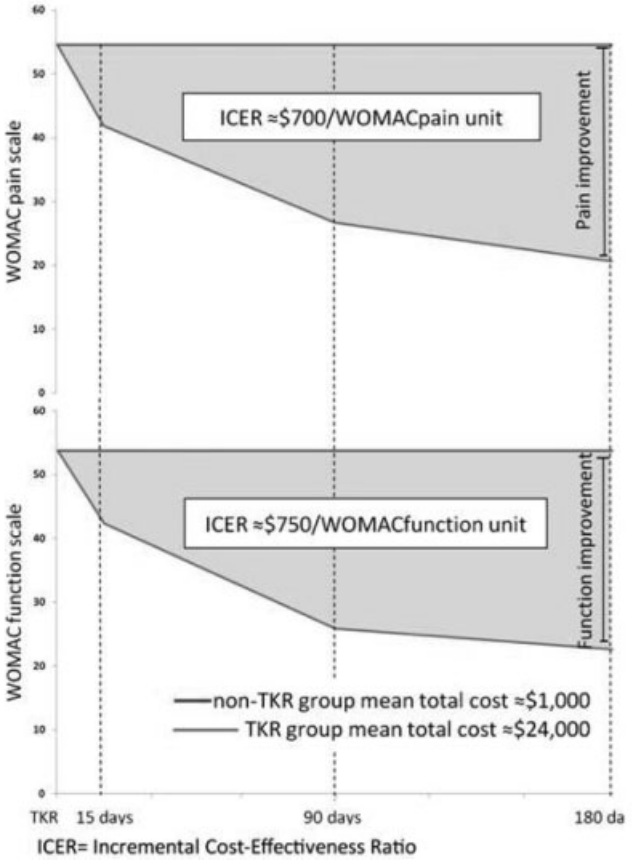
Impact of Slow Recovery and Poor Functional Outcomes on Direct and Indirect Costs After Total Knee Replacement in Osteoarthritis Patients.

Christian A. Waimann[1], Rodrigo J. Fernandez-Mazarambroz[1], Scott B. Cantor[1], Maria Lopez-Olivo[1], Hong Zhang[1], Glenn C. Landon[2], Sherwin J. Siff[2] and Maria E. Suarez-Almazor[1]. [1]University of Texas. M.D Anderson Cancer Center, Houston, TX, [2]St. Luke's Episcopal Health System, Houston, TX

Background/Purpose: About 15–30% of patients with osteoarthritis (OA) who undergo total knee replacement (TKR) have little or no improvement after the surgery. The aim of our study is to determine the impact of slow recovery and poor functional outcomes on TKR-related costs.

Methods: PEAKS (Patient Expectations About Knee Surgery Study) is a prospective cohort of patients with OA who underwent TKR. We followed patients for 6 months after surgery, and collected sociodemographic data, TKR-related costs, and clinical outcomes (the Western Ontario McMaster (WOMAC) pain and function scale). The economic analysis was conducted using a societal perspective based on 2007 US dollars. Direct medical costs were estimated using the Medicare Reimbursement Prospective Payment System; hospital bills were adjusted by cost-to-charge ratios reported to Medicare. Average wholesale price was used for drugs costs. Productivity losses (patients and relatives) were calculated using time lost from work multiplied by estimated wage per occupation reported by the Bureau Labor of Statistics for Texas. We defined improvement as either absolute (minimal clinically important difference (MCID), 20-point change), or relative (20%, 50% or 70% improvement in WOMAC (WOMAC20, 50 and 70)). Incremental cost-effectiveness ratios (ICERs) for each level were calculated, assuming a hypothetical non-TKR cohort where WOMAC scales and OA-related costs prior to surgery remained stable. We stratified WOMAC in four severity levels: none-to-mild (0 to ≤25), mild-to-moderate (>25 to ≤50), moderate-to-severe (>50 to ≤75), and severe-to-extreme (>75 to ≤100). TKR-related costs were calculated for each level at 3 and 6 months post-surgery.

Results: 218 patients were included; 65% were female, 69% were white, mean age was 65±9 years. Mean total costs were ≈$24,000±10,000. At 6 months 91% of patients improved, 61% showed a MCID and 80% WOMAC20 response. Figure 1 shows ICERs for WOMAC at 6 months. The ICERs for MCID, WOMAC20, WOMAC50, WOMAC70 were ≈$39000, ≈$30000, ≈$41000 and ≈$67000, respectively. TKR-related costs were higher in patients with poor function and worse pain (moderate-to-extreme level, WOMAC score >50 points) at 3 and 6 months, in comparison to better levels of function and pain.



Conclusion: TKR remains a cost-effective intervention at low and high levels of improvement. Patients with worse pain and function outcomes had higher TKR-related costs, suggesting that peri-operative interventions that can lead to a fast recovery and improve TKR outcomes might be cost-effective by decreasing subsequent costs.

886

Predictors of Suboptimal Patient Outcome Following Total Joint Arthroplasty. Gillian A. Hawker[1], Ruth Croxford[2], A. M. Davis[3], Sheila Dunn[1], Joy G. Elkayam[1], Melissa R. French[1], M. A. Gignac[4], Susan B. Jaglal[5] and Joanna Sale[5]. [1]Women's College Hospital, Toronto, ON, [2]Institute for Clinical and Evaluative Science, Toronto, ON, [3]Health Care and Outcomes Research, Toronto Western Research Institute; Departments of Rehabilitation Science and Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, [4]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [5]University of Toronto, Toronto, ON

Background/Purpose: Total Joint Arthroplasty (TJA) on average shows good to excellent outcomes for patients that have failed medical management, but significant variability has been observed. The determinants of suboptimal TJA outcome have not been well studied; thus our aim was to evaluate the determinants of suboptimal TJA outcome at a patient level.

Methods: Participants were members of a population cohort with hip/knee arthritis, recruited from 1996–98 through screening 100% aged 55+ years in two regions, one rural and one urban (n=2,411). Annual interviews assessed socio-demographics, arthritis type (OA versus inflammatory arthritis, IA); arthritis severity (WOMAC), other MSK complaints (presence of other troublesome hips/knees, low back pain), joint replaced (hip versus knee), health status (SF36 mental health and general health scores) and comorbidity (0, 1, 2, 3+ conditions). Survey data were linked with health administrative databases to examine receipt of primary, elective TJA from 1988 to 2008. Suboptimal outcome was defined as a pre-post change in WOMAC summary score less than a Minimal Important Difference (MID) (MID = 0.5 SD change of the mean difference in scores). Pre- and post-surgery WOMAC scores were those obtained at the interview closest in date and prior to the index TJA date, and closest in date to the end of the 6 month post-operative period, respectively. Logistic regression was used to model predictors of sub-optimal outcome. Akaike's Information Criterion (AIC) was used to determine the size of the best predictive model, and then all possible subset regression was used to identify the final model of the selected size.

Results: 166 cohort members received a TJA following their baseline interview and completed a post-TJA assessment. Mean age at TJA was 71 years; most recipients were female and had a knee replaced. Almost half the TJA recipients (48.7%) met the criterion for sub-optimal outcome (reduction in WOMAC score of < 9/100 points; 49.5% knees versus 42.4% hips, p=0.42). In univariate analyses, only pre-surgery WOMAC score distinguished those with versus without a suboptimal outcome, with a lower (better) score associated with suboptimal outcome. The multivariable predictive model found that the probability of a suboptimal outcome following TJA increased with lower pre-surgery pain and disability (WOMAC summary score) and poorer pre-surgery mental health, and increased if the patient had another troublesome hip/knee and/or a diagnosis of IA (Table 1) (c-statistic 0.79).

Predictor variables	Odds Ratio	Confidence Interval	p-value
Pre-surgery WOMAC score, per 10-point increase*	0.43	0.32 to 0.58	<0.0001
Pre-surgery SF-36 mental health score, per 10-point increase†	0.79	0.64 to 0.98	0.031
Presence of 1+ other troublesome hip/knee at surgery	3.06	1.02 to 9.17	0.046
Inflammatory arthritis	8.47	1.70 to 41.7	0.009

*Increasing values indicate increasing pain and disability
† Increasing SF36 values indicate improved health

Conclusion: Suboptimal outcome, observed in almost half of participants, was associated with lower levels of arthritis severity, poor mental health status, and the presence of other troublesome hips/knees or IA diagnosis pre-surgery. These results may help prospective patients and their health care providers make an informed cost-benefit decision on the expected outcomes of TJA.

887

Alcohol Intake Is Associated with Incident Gout Among Black and White, Men and Women in the Atherosclerosis Risk in Communities Study. Mara McAdams DeMarco[1], Janet W. Maynard[2], Alan N. Baer[2] and Josef Coresh[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

Background/Purpose: Alcohol increases gout risk in white men. We sought to quantify the association of alcohol intake and incident gout in a biracial population-based cohort.

Methods: The Atherosclerosis Risk in Communities study (ARIC) is a prospective cohort study of 15,792 individuals from 4 US communities, consisting of 4 visits administered 3 years apart. At visit 4, participants reported their gout status. We excluded those who did not attend visit 4 or had gout prior to visit 1. The % daily calories from alcohol intake was categorized into quintiles (≤1.5, 1.5–3.1, 3.1–5.3, 5.3–9.8, >9.8) as well as no alcohol intake. We tested the association of categorical alcohol intake and incident gout using a Cox Proportional Hazards model with age as the time scale (adjusted for sex, race, BMI, diuretics, eGFR, hypertension, calories, and intake of specific foods). We adjusted for serum urate and tested for sex, race, BMI and serum urate level interactions.

Results: This study contains 10,799 participants; 6,495 (60%) abstained from alcohol and 275 (2.5%) developed gout. The study population was 57% female and 22% African American. Results are presented in the table. Compared with no alcohol intake (reference), the adjusted hazard ratio (HR) and 95% CI for quintiles of alcohol intake were 1.00 (0.60, 1.70); 0.93 (0.54, 1.63); 0.92 (0.53, 1.61); 2.26 (1.54, 2.29); 2.31 (1.57, 3.40), respectively (p-value for trend <0.001). The increased HR for gout in the higher quintiles of alcohol intake was not changed significantly when adjusted for serum urate level. There was no interaction of alcohol intake with sex (p-value=0.8), race (p-value=0.2) or BMI (p-value=0.3). However, there was a statistical interaction between baseline serum urate level and alcohol intake (p-value=0.029).

Hazard rate ratio (HR) of incident gout by categorical baseline alcohol intake in the ARIC cohort (n=10,799)

Model	No alcohol intake	Quintile 1 (≤1.5%)	Quintile 2 (1.5%–3.1%)	Quintile 3 (3.1%–5.3%)	Quintile 4 (5.3%–9.8%)	Quintile 5 (>9.8%)	p-value for the trend
		HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)	
Sex adjusted	–	0.76 (0.46, 1.28)	0.64 (0.37, 1.11)	0.64 (0.37, 1.01)	1.64 (1.15, 2.36)	1.53 (1.06, 2.21)	0.02
Model 1	–	0.98 (0.58, 1.65)	0.88 (0.51, 1.54)	0.86 (0.50, 1.51)	2.16 (1.48, 3.14)	2.26 (1.54, 3.30)	<0.0001
Model 2	–	1.00 (0.60, 1.70)	0.93 (0.54, 1.63)	0.92 (0.53, 1.61)	2.26 (1.54, 2.29)	2.31 (1.57, 3.40)	<0.0001
Model 3	–	0.85 (0.50, 1.43)	0.91 (0.52, 1.59)	0.84 (0.48, 1.46)	1.71 (1.17, 2.48)	1.81 (1.29, 2.66)	0.001

Model 1: Adjusted for sex, race, and baseline BMI, diuretic use, categorical eGFR, hypertension, and total calories.
Model 2: Model 1 additionally adjusted for fructose intake, caffeine intake, and vitamin c intake.
Model 3: Model 2 additionally adjusted for serum urate at baseline
Age was used as the time-scale.

Conclusion: Participants in the 2 highest quintiles of alcohol intake had more than a 2-fold risk of gout, independent of confounders. Additionally, this is the first study to detect an interaction of serum urate level and alcohol intake such that patients with higher serum urate levels and high alcohol intake are at the highest risk of developing gout.

888

Gout Treatment Gaps and Factors Associated with Incident Patients Having Uric Acid Goal Attainment: A Retrospective Cohort Study in An Integrated Healthcare System. Nazia Rashid[1], T. Craig Cheetham[1], Jeffery R. Curtis[2], Gerald D. Levy[3], Kenneth G. Saag[2] and Ted R. Mikuls[4]. [1]Kaiser Permanente Pharmacy Analytic Services, Downey, CA, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Southern California Permanente Medical Group, Downey, CA, [4]Omaha VA and University of Nebraska, Omaha, NE

Background/Purpose: Gout affects approximately 1 to 2% of the US population and is the most common form of inflammatory arthritis in men. Urate lowering therapy is effective; however is often characterized by inadequate dose adjustment to achieve goal-directed urate lowering. This study was undertaken to characterize the gaps in gout care leading to suboptimal outcomes in an integrated healthcare delivery system.

Methods: This was a retrospective cohort study of gout patients in Kaiser Permanente Southern California. Patients aged 18 years and older with a diagnosis of gout (ICD9 274.xx) and allopurinol prescription from January 1, 2007 to June 31, 2010 were included. Incident allopurinol users were defined as patients that had no allopurinol prescription within 12 months prior of the 1st gout diagnosis. Patients were followed from the 1st gout diagnosis until disenrollment or end of study period.

Primary outcome of interest was attainment of serum uric acid (sUA) level <6mg/dl, and secondary outcome of interest was sUA monitoring. Descriptive statistics were calculated comparing incident patients at sUA goal or not at sUA goal (>=6mg/dl) at the end of observation (at least 12 months after treatment initiation). Logistic regression was used to evaluate characteristics such as age, gender, race, co-morbid conditions, concomitant medications, adherence, care by a rheumatologist, and allopurinol dose adjustment associated with sUA goal attainment.

Results: 15,596 patients were identified as incident gout patients (mean age 60 years, men 81%). Overall, all patients had at least one comorbid condition: hypertension (73%), chronic kidney disease (30%), and diabetes (25%) being the most common; hydrochlorothiazide (20%) and furosemide (15%) were the most commonly utilized concomitant medications. Only 9,287 patients (60%) had follow up uric acid lab levels after the 1st allopurinol prescription. At the end of observation, 2,917 patients (30%) were at sUA goal (mean age 63 years, men 71%) versus 6,538 patients not at goal (mean age 59 years, men 81%). Patients whom saw a Rheumatologist within 6 months of their 1st allopurinol prescription and preceding their 1st sUA level were more likely at goal (Odds Ratio [OR] = 1.21, 95% CI 1.02 – 1.43). Older patients (OR = 1.02, 95% CI 1.01–1.02) and those who were at least 80% adherent (OR = 2.82, 95% CI 2.56–3.11) were more likely to achieve goal sUA. Overall, male patients were 37% less likely to be at goal. CHF and CKD were significantly associated with not achieving target sUA.

Conclusion: A total of 40% of incident allopurinol users did not have a follow up sUA level after their 1st prescription of allopurinol. Factors such as age, care by a rheumatologist, and adherence were key factors associated with achieving goal serum urate levels.

889

Evaluation of Healthcare Costs for Patients with Gout by Serum Uric Acid. Karen Rascati[1], Karim Prasla[2], Haesuk Park[1] and Tyrone McBayne[3]. [1]University of Texas at Austin College of Pharmacy, Austin, TX, [2]Scott and White Health Plan, Temple, TX, [3]Takeda Pharmaceuticals America, Inc., Deerfield, IL

Background/Purpose: The objective of this study was to assess the costs and utilization patterns of medical and pharmacy services, categorized into 3 cohorts based on serum uric acid (sUA) levels.

Methods: Retrospective analysis was conducted using lab, pharmacy, and medical service claims data (January 1, 2005-June 30, 2010) for patients 18 years and older enrolled in a regional staff model health plan. Inclusion criteria were at least 2 sUA levels and at least 1 primary gout diagnosis (ICD-9: 274.xx), and at least 1 prescription for one of the following gout-specific medications: allopurinol, colchicine, probenecid, probenecid/colchicine, or febuxostat. Costs, healthcare resource utilization, and medication utilization patterns were assessed for 1 year post-index and summarized for the 3 cohorts based on sUA: 1) <6 mg/dL; 2) 6–8.99 mg/dL; and 3) ≥9 mg/dL. Costs were defined as total allowed amount, including allowable plan costs plus patient costs. Cost components were compared using either a generalized linear model (GLM) or a 2-part model that controlled for baseline clinical and demographic parameters. Medication adherence, including medication possession ratio and proportion of days covered, persistence, and treatment patterns were measured for 1 year post-index.

Results: 352 patients met inclusion criteria: Cohort 1 (sUA <6 mg/dL) n=38, mean age 59 yrs, 71% male; Cohort 2 (sUA 6–8.99 mg/dL) n=231, mean age 61 yrs, 77% male; Cohort 3 (sUA ≥ 9 mg/dL) n=83, mean age 62 yrs, 61% male. Mean adjusted gout-related healthcare costs were $332, $353, and $663, respectively ($P<0.05$); mean adjusted all-cause healthcare costs were $11,365, $11,551, and $14,474, respectively, for the 3 cohorts ($P<0.05$). The difference in the mean number of all-cause hospitalizations claims and all-cause emergency department (ER) visits was statistically significant. The mean number of all-cause hospitalizations claims were 0.84, 0.94, and 1.67, respectively ($P=0.019$); mean number of all-cause emergency department visits were 0.39, 0.51, and 0.86, respectively, for the 3 cohorts ($P=0.026$). Gout medication adherence and persistence were significantly associated with sUA levels. Significantly more patients with sUA <6 mg/dL (56.0%) achieved adherence rates of 80% or better relative to patients with sUA between 6 and 8.99 mg/dL (28.5%) or patients with sUA ≥9 mg/dL (30.5%) ($P<0.05$). Patients with sUA <6.0 mg/dL had a longer mean duration of continuous treatment before 60-day discontinuation (255 days) than the other 2 cohorts (164 days for patients with sUA 6–8.99 mg/dL and 178 days for patients with sUA ≥9.0 mg/dL, respectively: $P<0.05$).

Conclusion: Patients with higher sUA levels have higher gout-related and all-cause healthcare costs, increased all-cause medical, hospital, and ER utilization, while also exhibiting poorer adherence and persistence.

890

Total Health-Care Costs Among Gout Patients On Allopurinol or Febuxostat. Brett W. Pinsky[1], Bhavik J. Pandya[2], Gabriel Gomez Rey[3] and Jasvinder A. Singh[4]. [1]Innovus, O'Fallon, MO, [2]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [3]Innovus, Eden Prairie, MN, [4]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: The goal of the study was to identify the total health-care (HC) costs for gout patients receiving allopurinol (ALLO) or febuxostat (FEB).

Methods: This retrospective study in adult patients (pts) used 2009–10 medical and pharmacy claims linked with laboratory data from a large US managed-care population. All pts had at least 1 fill for ALLO or FEB; any pt prescribed FEB was placed in the FEB cohort. The ALLO cohort included only pts with no FEB use. The index date was the date of first fill during the study period. Pts were required to have at least 1 serum uric acid (sUA) measurement ≥14 days post index date. Pts had 6 months of continuous enrollment prior to their index date (baseline period) and were followed for ≥90 days post treatment start (follow-up). Total HC costs were calculated as per member per month (PMPM) to adjust for variable follow-up. The change in cost (baseline vs follow-up) was examined. HC costs were also divided into subcategories: pharmacy and total medical (all non-pharmacy) costs; medical costs were further broken down into inpatient, ER, and office/outpatient costs. A multivariate log-linked regression using a gamma distribution was conducted to further examine HC costs.

Results: The study sample included 451 FEB pts and 5,880 ALLO pts. Prior to starting therapy, FEB pts had a higher Quan-Charlson score (1.4 vs 1.0; $p<0.01$). Baseline PMPM total HC costs were higher for FEB pts vs ALLO pts ($p=0.02$) (Table). Following initiation of index medication, total PMPM HC costs decreased $97 ($p=0.65$) from the baseline period in FEB pts, compared to an increase of $204 ($p<0.01$) in ALLO pts. The change was mainly due to medical costs. Medical costs decreased 18% in the FEB pts and

increased 23% in ALLO pts. After controlling for comorbidities (hypertension, peripheral artery disease, heart failure, rheumatoid arthritis, osteoarthritis, hyperlipidemia, kidney failure); presence of tophi; baseline sUA; baseline utilization (ER visits, inpatient, and office/outpatient visits); geographic region; gender; age; and insurance type, pharmacy costs were higher in FEB patients ($p<0.01$); however, no difference in follow-up total HC costs was observed between ALLO and FEB pts ($p=0.89$).

Table. Total Health-Care Costs in the Baseline and Follow-Up Periods

PMPM HC costs (SUS)	Baseline			Unadjusted Follow-up			Adjusted Follow-up		
	FEB†	ALLO‡	p-value	FEB	ALLO	p-value	FEB	ALLO	p-value*
Total Healthcare	1,294	817	**0.02**	1,196	1,022	0.14	1,074	1,096	0.89
Medical	1,040	634	**0.04**	857	818	0.72	762	884	0.42
Inpatient	483	241	0.16	381	385	0.95	409	524	0.55
ER	21	18	0.32	28	19	0.08	29	21	**0.04**
Office/outpatient	447	326	**0.04**	379	356	0.51	341	362	0.57
Pharmacy	255	182	0.05	339	204	**<0.01**	331	205	**<0.01**

† 451 FEB patients
‡ 5,880 ALLO patients
* Adjusted p-value based on the regression model parameter estimate.
Note: p-values in boldface are significant ($p<0.05$).

Conclusion: At baseline, total HC costs for FEB pts were higher compared to pts on ALLO; however, the follow-up total HC costs of the 2 cohorts were similar. Total HC costs increased between baseline and follow-up for ALLO-treated patients, while there was a decreased trend for FEB-treated patients during the same time period.

891

Serum Urate−Lowering Effectiveness of Febuxostat Compared with Allopurinol and Switching to Febuxostat From Allopurinol In the Real-World Setting. Bhavik J. Pandya[1], Brett W. Pinsky[2], Gabriel Gomez Rey[3] and Jasvinder A. Singh[4]. [1]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [2]Innovus, O'Fallon, MO, [3]Innovus, Eden Prairie, MN, [4]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: The study goal was to examine the changes in serum uric acid (sUA) level for gout patients (pts) new to sUA-lowering medication vs patients with prior allopurinol (ALLO) use, who did or did not switch to febuxostat (FEB).

Methods: This retrospective study in adult pts used 2009–10 medical and pharmacy claims linked with laboratory data from a large US managed-care population. All pts had at least 1 fill for ALLO or FEB. The ALLO cohorts included only pts with no FEB use. The index date was the date of first fill during the study period. Pts were categorized into 4 cohorts based on their index medication and prior ALLO use. Pts were required to have at least 1 sUA measurement ≥14 days post index date. Pts had 6 months of continuous enrollment prior to their index date (baseline period) and were followed for ≥90 days post treatment start (follow-up). Follow-up sUA and change in sUA was examined using a t-test and linear regression; likelihood to attain sUA goal was examined using logistic regression.

Results: The study sample included 264 new FEB pts without prior ALLO (FEB-N), 187 FEB switch pts (FEB-S; switched from ALLO to FEB), 2,552 new ALLO pts (ALLO-N), and 3,328 ALLO continuation pts (ALLO-C). Prior to starting therapy, FEB-S pts had the highest Quan-Charlson score (1.8 vs 1.2 [FEB-N], 1.1 [ALLO-N], and 1.0 [ALLO-C]; $p<0.01$). Baseline sUA was higher for FEB-N (9.1 mg/dL pts vs FEB-S (8.2 mg/dL; $p<0.01$) and ALLO-C pts (6.6; $p<0.01$) (Table). There was no difference in baseline sUA value between ALLO-N and FEB-N patients. FEB-N pts had the highest average decrease in sUA of 2.5 mg/dL (t-test; $p<0.01$ compared with FEB-S, ALLO-N and ALLO-C). Over 80% of both FEB-N and FEB-S pts received an index dose of 40 mg. and over33% of ALLO-N and ALLO-C pts had an index dose <300mg. Over 45% of ALLO-N and ALLO-C pts had an index dose of 300mg. After controlling for comorbidities (hypertension, peripheral artery disease, heart failure, rheumatoid arthritis, osteoarthritis, hyperlipidemia, kidney failure), presence of tophi, baseline sUA, geographic region, gender, age, and insurance type, FEB-N pts had 93% higher odds ratio of attaining sUA goal at ≤6 mg/dL ($p<0.01$) and 168% higher odds of attaining sUA of ≤5 mg/dL (OR 2.68; $p<0.01$) compared with ALLO-N. FEB-S pts had 60% higher odds ratio of attaining sUA goal at ≤6 mg/dL ($p<0.01$) and 74% higher odds ratio of attaining sUA of ≤5 mg/dL (OR 1.74; $p<0.01$) compared with ALLO-C. The mean dose at time of goal attainment was slightly higher in pts achieving an sUA goal of <5 mg/dL(FEB-N=52.9 mg; FEB-S=59.1mg; ALLO-N=305.7mg; ALLO-C=309. mg) than <6 mg/dL (FEB-N=54.0mg; FEB-S=54.9mg; ALLO-N=280mg; ALLO-C=292mg).

Table. Unadjusted sUA Values and sUA Goal Attainment

Parameter	Baseline sUA*	Follow-up sUA	Change in sUA*	% of Patients Attaining Goal (<6.0 mg/dL)	% of Patients Attaining Goal (<5.0 mg/dL)
FEB-N Pts	9.1	6.4	2.5	53.8%	32.2%
FEB-S Pts	8.2	6.5	1.6	59.4%	33.2%
ALLO-N Pts	9.0	6.9	2.0	38.7%	16.0%
ALLO-C Pts	6.6	6.1	0.3	55.9%	28.2%
p-value FEB-N vs FEB-S	<0.01	0.90	<0.01	0.24	0.83
p-value FEB-N vs ALLO-N	0.37	<0.01	<0.01	<0.01	<0.01
p-value FEB-S vs ALLO-C	<0.01	0.06	<0.01	0.35	0.15

* Baseline sUA and Change in sUA only available for subset of the population: FEB-N=176, FEB-S=136, ALLO-N=1,284, and ALLO-C=1,161.

Conclusion: Pts newly started on urate-lowering therapy had the largest decrease in sUA. FEB-N pts had the largest drop in sUA, while ALLO-C pts had the smallest drop. ALLO-N pts were the least likely to attain sUA goal, and FEB-S pts were the most likely to attain sUA goal.

892

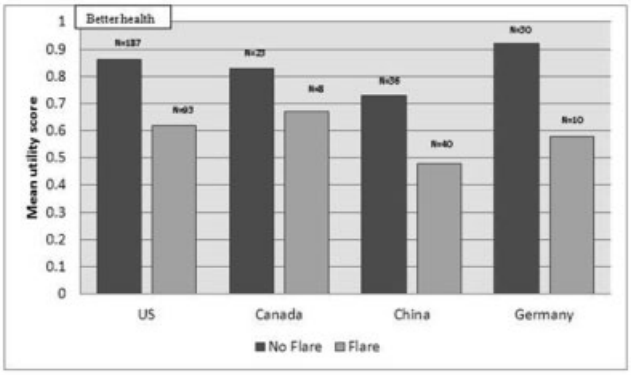
Multinational, Prospective, Observational Study to Characterize and Assess the Burden of Refractory Gouty Arthritis on Patients Over One Year: Global Baseline Results. Pascal Lecomte[1], Louis Bessette[2], Alberto Ferreira[1], Hans-Peter Goertz[1], Paula Jones[3] and Jasvinder A. Singh[4]. [1]Novartis Pharma AG, Basel, Switzerland, [2]CHUL, Quebec, [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [4]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Gouty arthritis (GA) is the most prevalent form of inflammatory arthritis. Refractory (or difficult to treat) GA occurs when therapies are ineffective, not tolerated, or contraindicated, leading to frequent attacks. The objective of this study is to characterize the humanistic and economic burden of refractory GA on patients in selected countries.

Methods: The MOTION study is an ongoing multinational, non-interventional, prospective, observational study of patients with GA who experienced at least 3 gout attacks in the previous year. Enrolled patients were refractory to at least one anti-inflammatory therapy (NSAIDs, colchicine or corticosteroids) or to urate lowering therapies. The study is being conducted in six countries (Canada; China; France; Germany; Spain; US). The primary objective of this study is to assess patient health utility during a GA attack and the intercritical period (between attacks), using the EuroQol Health Status Questionnaire 5D (EQ-5D). This instrument consists of the EQ-5D descriptive system which enables calculation of a utility score (ranging from 0.0 (dead) to 1.0 (perfect health)) and the EQ-5D visual analog scale (VAS) (ranging from 0 (worst imaginable health state) to 100 (best imaginable health state)). Secondary objectives are to evaluate patient quality of life; patient and physician satisfaction with treatment and quantify health care resource utilization; assess lost work productivity; and characterize pain during GA attack and the intercritical period. Data are being collected monthly over 12 months. We report baseline characteristics of all enrolled patients.

Results: Among the 454 patients enrolled in 57 sites, most were men (86%), and the mean age was 56 years. Nearly all (84%) suffered from polyarticular gout with 51% of patients having 4 or more joints affected in an acute GA attack. The mean disease duration was 11 years with a mean number of attacks of 6.9 in the year prior to enrollment. Tophi were documented in 30% of the patients and those that presented with tophi had a mean of 5.4 tophi. More than 80% of patients suffered from at least one comorbidity. During the baseline GA attack,

mean EQ-5D utility score was 0.57 and VAS score 60. During the baseline intercritical period, mean EQ-5D utility score was 0.85 and VAS score 76.



Conclusion: MOTION study population consisted mostly of men, frequently flaring, who suffered from polyarticular gout and comorbidities. Impact of GA attack on patient health utility as assessed with the EQ-5D, was marked. Among countries participating, the smallest mean drop in utility due to GA attack was 0.16. Monthly assessments of health utility in the MOTION study will help to better quantify the impact of GA attacks on patients.

893

Frequency of Gouty Arthritis Attacks and Presence of Comorbid Conditions Have An Impact on Gout-Related Healthcare Resource Utilization and Costs. Joseph J. Saseen[1], Neetu Agashivala[2], Richard R. Allen[3], Vahram Ghushchyan[1] and Kavita V. Nair[1]. [1]University of Colorado, Aurora, CO, [2]Novartis Pharmaceutical Corporation, East Hanover, NJ, [3]Peakstat Statistical Services, Evergreen, CO

Background/Purpose: Gouty arthritis attacks cause significant pain and inflammation, and typically require medical intervention and pharmacotherapy for proper resolution. Although prior retrospective analyses have estimated health care costs associated with gouty arthritis attacks, predictors of patients with higher healthcare costs and the effect of comorbidities have not been completely assessed. We examined the impact of the cumulative number of attacks and comorbidities on healthcare expenditures.

Methods: We used the MarketScan database to identify patients > 18 years and above with an ICD9 code for gout (274.xx) or at least 1 prescription claim for specific gout-related medication (allopurinol, febuxostat, probenecid or colchicine) between July 1, 2005–June 30, 2010. The date of the first diagnosis or prescription claim was the index date. Patients were required to have a minimum of 12 months pre and post enrollment data from the index date. Patients were categorized as having frequent gouty arthritis (≥3 attacks in the 1-year post index period) using a claims-based algorithm and were compared to patients with infrequent gouty arthritis (<3 attacks) who were matched in a 1:2 ratio on age, sex and geographic region. All costs were inflation adjusted to 2011 dollars.

Results: A total of 5,222 patients with ≥3 (frequent) and 10,444 patients <3 (infrequent) gouty arthritis attacks were identified. The mean age was 58 years and 77.3% were men. Patients with frequent gouty arthritis had a higher prevalence of comorbid conditions: chronic kidney disease, 12.2% vs. 7.2%; hypertension, 59.1% vs. 50.8%; heart failure, 10.1% vs. 6.8%; rheumatoid arthritis, 8.8% vs. 3.2% and osteoarthritis, 32.3% vs. 17.5% (all $p<0.001$). Mean number of all-cause and gout-related outpatient visits were 23.9 and 5.4 for patients with frequent gouty arthritis versus 17.3 and 1.2 for patients with infrequent gouty arthritis (between groups, both $p<0.001$). Mean gout-related medical costs and total costs expressed in 2011 dollars were $834 and $889 for patients with frequent gouty arthritis versus $176 and $210 for infrequent gouty arthritis (between groups, both $p<0.001$). Mean all-cause outpatient visits in patients with comorbid conditions compared with patients with only gouty arthritis were 25.8 vs. 11.8 in the frequent gouty arthritis group, and 19.8 vs. 8.5 in the infrequent gouty arthritis group (between groups, both $p<0.001$). Mean number of gout-related outpatient visits were higher in patients with comorbid conditions in the frequent gouty arthritis group (5.5 vs. 4.9, $p<0.001$), and in patient with infrequent gouty arthritis (1.2 vs. 1.1, $p<0.001$). However, mean gout related medical costs were higher in the frequent gouty arthritis group in patients with comorbid conditions ($886 vs. $513, $p=0.03$), but was similar in the infrequent gouty arthritis group in patients with comorbid conditions ($180 vs. $156, $p=0.25$).

Conclusion: Frequency of gouty arthritis attacks and presence of comorbid conditions are associated with higher health care costs. Severity of gouty arthritis and other health conditions should be considered when projecting health care costs in this population.

894

Multinational, Prospective, Observational Study to Characterize and Assess the Burden of Refractory Gouty Arthritis on Patients Over One Year: US Baseline Results. Pascal Lecomte[1], Louis Bessette[2], Alberto Ferreira[1], Hans-Peter Goertz[1], Paula Jones[3] and Jasvinder Singh[4]. [1]Novartis Pharma AG, Basel, Switzerland, [2]CHUL, Quebec, [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [4]University of Alabama and VA Medical Center, Birmingham, AL

Background/Purpose: Gouty arthritis (GA) is the most prevalent form of inflammatory arthritis. Refractory (or difficult to treat) GA occurs when therapies are ineffective, not tolerated, or contraindicated, leading to frequent attacks. The objective of this study is to characterize the humanistic and economic burden of refractory GA on patients in selected countries.

Methods: The MOTION study is an ongoing multinational, non-interventional, prospective, observational study of patients with GA who experienced at least 3 gout attacks in the previous year. Enrolled patients were refractory to at least one anti-inflammatory therapy (NSAIDs, colchicine or corticosteroids) or to urate lowering therapies. The study is being conducted in six countries (Canada; China; France; Germany; Spain; US). The primary objective of this study is to assess patient health utility during a GA attack and the intercritical period (between attacks), using the EuroQol Health Status Questionnaire 5D (EQ-5D). This instrument consists of the EQ-5D descriptive system which enables calculation of a utility score and the EQ-5D visual analog scale (VAS). For each item, a higher value indicates better health. Secondary objectives are to evaluate patient quality of life; patient and physician satisfaction with treatment; quantify health care resource utilization; assess lost work productivity; and characterize pain during GA attack and the intercritical period. Data are being collected monthly over 12 months. We report baseline characteristics of the subgroup of US patients.

Results: In total, 284 US patients were enrolled from 35 sites. Patients were predominately male (82%); mean age was 57 years; 50% were employed; mean BMI was 34 Kg/m^2. Polyarticular gout was reported in 84% of patients; mean disease duration was 11 years; mean number of attacks in the year prior to enrollment was 6.6. Tophi were documented in 23% of patients. More than 85% of patients suffered from at least one comorbidity: 69% from cardiovascular disease or hypertension; 42% from lipid disorder; 25% from diabetes; 19% from gastrointestinal disorders; and 6% from chronic kidney disease. At baseline, mean EQ-5D utility score for patients during a GA attack and during the intercritical period was 0.62 and 0.86, respectively. In the last month, 5% of patients had visited the emergency unit; 2% had been admitted to the hospital; 40% visited a physician; and 22% required help at home due to GA.

Table. Patients contra-indicated or intolerant or with lack of efficacy to the following treatments

	N=284	% Overall
MONOTHERAPY		
NSAIDs	242	85.2%
Colchicine	122	43.0%
Corticosteroids	64	22.5%
DUALTHERAPY		
NSAIDs and colchicine	98	34.5%
NSAIDs and corticosteroids	50	17.6%
Colchicine and corticosteroids	30	10.6%
TRIPLETHERAPY		
NSAIDs and colchicine and corticosteroids	27	9.5%

Conclusion: Refractory GA patients suffer from many comorbidities and are frequently flaring, which yields to additional, and sometimes very costly, health care utilization. Contra-indication, intolerance, lack of efficacy to current treatments leave a lot of patients without options. Patients experiencing a GA attack show a sharp decrease in their health utility as assessed with the EQ-5D.

895

Gout Characteristics, Health-Related Quality of Life and Health Care Utilization: Caucasians Vs. Non-Caucasians In An Observational Cohort of Patients with Gout. Puja Khanna[1], Jan Hirsch[2], Susan J. Lee[3], Robert Terkeltaub[4], Jasvinder Singh[5], Arthur F. Kavanaugh[6], Andrew Sarkin[7] and Dinesh Khanna[1]. [1]University of Michigan, Ann Arbor, MI, [2]Skaggs School of Pharmacy & Pharmaceutical Sciences, University of California San Diego, San Diego, CA, [3]Univ of California San Diego, La Jolla, CA, [4]VA Medical Ctr, San Diego, CA, [5]University of Alabama and VA Medical Center, Birmingham, AL, [6]University of California San Diego, San Diego, CA, [7]Health Services Research, University of California San Diego, San Diego, CA

Background/Purpose: Ethnic differences are well documented in patients with arthritis; however, there are no such studies in patients with gout. We sought to compare gout characteristics, health-related quality of life (HRQOL), and health care utilization (HCU) between Caucasian (Cau) and Non-Caucasian (Non-Cau) patients with gout in a cross-sectional US observational study.

Methods: Data were obtained from patients who participated in a cross-sectional validation study of a gout-specific HRQOL instrument. Patients completed the SF-36 v2 and the Gout Impact Scale (GIS), which assesses impact of gout during an attack and overall (each scale 0 to 100 [greater gout impact]), and reported gout characteristics, comorbidities, demographics, and gout-related HCU over past year. Differences were evaluated using Student t-test and chi-square analyses.

Results: Of the 308 patients, 220 (71%) were Caucasian, 37 (12%) were African American, 16 (5%) were Asian, 17 (6%) indicated Other, and 18 (6%) did not specify. The Cau vs. Non-Cau sample was older (63 vs.58, $p=0.01$), and had a greater proportion of males (92% vs. 83%, $p=0.02$) and longer duration of gout (15 vs. 11 years, $p=0.05$). Non-Cau appeared to have poorer gout control—higher sUA level, greater percentage of subjects experiencing attack in past 3 months, and higher pain rating for worst attack (all $p<0.05$). No significant difference in SF-36 or HCU was observed. However, non-Cau had significantly higher (worse, $p<0.05$) scores for 3 of the 5 GIS scales.

Variable [mean(SD) unless noted]	Caucasian (n=220)	Non-Caucasian (n=70)
GOUT CHARACTERISTICS		
Physician has prescribed medication (prevention &/or acute), %	94	88
Latest sUA, mg/dl	6.9 (1.9)	7.6 (1.7)*
Presence of tophi, %	24	29
Gout attack in the last 3 months, %	53.3	69.6*
Pain during (0–100 VAS)		
typical attack	64.9 (26.5)	71.1 (23.4)
worst attack	75.5 (25.4)	86.3 (16.7)*
HRQOL		
SF-36 PCS†	38.8 (8.5)	40.3 (7.7)
SF-36 MCS†	44.1 (7.2)	42.9 (6.5)
GIS: Gout concern	58.9 (28.2)	75.8 (22.6)*
GIS Medication side effects	45.4 (24.7)	57.9 (26.6)*
GAQ Unmet treatment need	37.2 (22.0)	41.4 (19.3)
GAQ Well-being during attack	54.6 (26.2)	60.9 (25.1)
GAQ Concern during attack	47.7 (23.1)	57.2 (26.2)*
HEALTH CARE UTILIZATION		
Physician or Nurse	2.2 (3.9)	3.2 (3.9)
Rheumatologist	1.6 (4.6)	2.5 (3.7)
ER or Urgent Care	0.7 (1.7)	1.2 (2.5)

* $p<0.05$, † US Normal population score mean = 50 and SD = 10. VAS=visual analogue scale. PCS=physical component summary. MCS=mental component summary. GAQ=gout assessment questionnaire.
For GAQ: higher scores denotes poor HRQOL; for SF-36: higher score denotes better HRQOL.

Conclusion: In this cohort, Non-Cau appeared to have poorer gout control and experienced greater impact of gout on their HRQOL. Future studies should explore possible ethnic differences and explanatory factors.

Ambulatory Resource Utilization for Gouty Arthritis and Gouty Arthritis Attacks. Chenghui Li[1], Bradley C. Martin[1], Dosha F. Cummins[1], L.M. Andrews[2], Feride Frech-Tamas[2] and Anthony Yadao[2]. [1]University of Arkansas for Medical Sciences College of Pharmacy, Little Rock, AR, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ

Background/Purpose: Gouty arthritis (GA) is increasingly prevalent worldwide and is associated with significant economic burden. The objectives of this study are: 1) to describe ambulatory medical care resource utilization and prescribing patterns for patients with GA and GA attacks as well as the associated costs; and 2) to determine the patient characteristics associated with visits for GA and GA attacks.

Methods: Data from the 2002–2008 National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey were used to provide national estimates of office-based visits, hospital outpatient department (OPD) visits, and emergency department (ED) visits in the U.S. Visits associated with GA and GA attacks were identified based on physician diagnosis codes, reason for visit codes, and supplemented with medication mentions for antigout and antihyperuricemic agents during the visits. Rates of visits per 1,000 persons per year in the U.S. population stratified by age, gender, race, ethnicity, and geographic region were estimated using U.S. census data. Unit costs for visits and drug prescribing obtained from a commercial administrative claims database were used to estimate U.S. costs expressed in 2009 dollars. Logistic regression was used to examine patient characteristics associated with ambulatory visits for GA or GA attacks. Data were analyzed using STATA 9.2, accounting for complex survey design, and weights were applied to generate national estimates.

Results: An estimated 7 million ambulatory visits annually were associated with GA, with 2 million (28%) of them attributable to GA attacks. Eighty-nine percent of GA-related visits and 80% of visits for GA attacks occurred in physician offices; 5% and 13% occurred in the EDs, with the remainder in OPDs. The rates were 23.81 and 6.68 visits per 1000 persons per year for GA and GA attacks, respectively, and more than doubled from 2002 to 2008. The rates increased with age and were higher in males (33.85 vs. 13.46 visits per 1000 persons per year in females). Among patients who had an ambulatory visit, the likelihood of GA-related visits increased with the diagnosis of renal disease (OR: 5.38; 95% CI: 3.80–7.63), hypertension (OR: 2.23; 95% CI: 1.79–2.77), diabetes (OR: 1.46; 95% CI: 1.15–1.85), heart failure (OR: 1.81; 95% CI: 1.21–2.69), and non-GA arthritis (OR: 1.54; 95% CI: 1.02–2.33). Allopurinol (63%), NSAIDS (20%), and colchicine (17%) were the most frequently recorded drugs during GA-related visits. For visits associated with GA attacks, NSAIDS (44%), colchicine (28%), and allopurinol (26%) were most frequently recorded. The total ambulatory care costs associated with GA were estimated at $923 million per year, with 32% of the costs attributed to GA attacks. Drug costs accounted for 61% of the total costs.

Conclusion: The annual ambulatory care costs associated with GA were near $1 billion with 32% of the costs attributed to GA attacks. Drug expenditures accounted for 61% of the total costs during the period 2002–2008. Annual rates of GA and GA attack-related ambulatory visits more than doubled from 2002 to 2008 and varied across demographic groups and by patient comorbid conditions.

897

Health Care Resource Utilization Is Associated with Attack Frequency in Patients with Gouty Arthritis. Prakash Navaratnam[1], Carl deMoor[1], Michael Shaffer[2], Paula Chakravarti[3], L.M. Andrews[3] and Anthony Yadao[3]. [1]DataMed Solutions LLC, Hilliard, OH, [2]BioTrends Research Group LLC, Exton, PA, [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ

Background/Purpose: The objective of this analysis was to evaluate the extent to which frequency of gouty arthritis attacks is associated with disease progression and health care resource utilization.

Methods: 226 primary care physicians and rheumatologists who treated ≥50 gouty arthritis patients in the last year were asked to complete a cross-sectional, retrospective chart review for patients with gouty arthritis. Patients were stratified by number of gouty arthritis attacks in the last year (<3 and ≥3). Multivariate regression analysis was conducted to assess health-related outcomes during a 12-month observation period, to

evaluate demographic and clinical characteristics, as well as to identify factors associated with attacks that resulted in an ER visit, urgent care utilization, or hospitalization. Variables included gouty arthritis severity, serum uric acid (sUA) level, prescription use, age, gender, duration of disease, presence of tophi, organ/joint damage, and comorbidities. SAS version 9.1 was used to conduct analyses.

Results: 1,039 gouty arthritis patients were identified for the analysis. 39.1% of patients were 50–64 yrs of age and 81.9% were male. Time since diagnosis was 52.5±67.0 (mean±SD) months. The most frequently reported comorbidities were hypertension (51.2%), hyperlipidemia (37.9%), obesity (26.4%), osteoarthritis (22.9%), and diabetes (20.1%). 19.8% of patients had cardiovascular disease, while 16.9% of patients had chronic kidney disease. 14% of the patient population had organ/joint damage, and 17% had tophi at the most recent visit. Nearly 74% of patients were prescribed uric acid lowering therapy at the time of the survey. NSAIDs (46.0%), steroids (44.4%), and colchicine (32.1%) were therapies most commonly used for treatment of attacks. Patients in the ≥3 attacks group (n = 195) were more likely to have physician-reported alcohol use (21% vs 10.8%, p<0.001), chronic kidney disease (25.6% vs 14.5%, p<0.001), obesity (32.3% vs 25%, p=0.040), and organ/joint damage (18.5% vs. 13%, p=0.056) compared to the <3 attacks group (n=844). sUA levels were 8.4±2.4 mg/dL in the ≥3 attacks group and 7.0±2.1 mg/dL in the <3 attacks group. Patients with ≥3 attacks were more likely to be seen primarily by rheumatologists (58% vs. 47.9%, p=0.011) and be reported as having severe gouty arthritis (24.1% vs. 12.0%, p<0.0001). These patients were also nearly twice as likely to use narcotics for treatment of gouty arthritis attacks compared with patients who had <3 attacks (22.6% vs. 12.3%, p=0.001). In the multivariate regression analysis, gouty arthritis attack frequency was the strongest predictor of having an ER visit (OR=4.00, 95% CI 2.56–6.25), urgent care visit (OR=5.59, 95% CI 2.37–13.19), or hospitalization (OR=2.59, 95% CI 1.80–3.72), p<0.05 in all cases.

Conclusion: Patients with ≥3 gouty arthritis attacks were more likely to have attacks result in ER visits, urgent care center visits, and overnight hospitalizations, compared with the <3 attacks group. Greater attack frequency was also associated with alcohol use, CKD, obesity, organ/joint damage, increased gouty arthritis severity, higher prevalence of tophi, and use of narcotics.

898

Hypertension, but Not Pre-Hypertension, Is Associated with Incident Gout in White and Black, Men and Women From the Atherosclerosis Risk in Communities Study. Mara McAdams DeMarco[1], Janet W. Maynard[2], Alan N. Baer[2] and Josef Coresh[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

Background/Purpose: Hypertension as a known risk factor for gout. The role of hypertension on the development of gout in a population of African American and white, men and women as well as the association of pre-hypertension and gout has never been quantified.

Methods: Atherosclerosis Risk in Communities Study (ARIC) is a prospective population-based cohort recruited in 1987–1989 from 4 US communities, consisting of 4 visits over 9-years. Participants were included in this analysis if they answered the gout query and were free of gout at baseline. Incident gout was defined as self-reported onset after baseline. Using a time-dependent Cox Proportional Hazards model, we estimated the hazard rate ratio (HR) of incident gout by time-varying hypertension (self-report of medication to treat hypertension, or a measured blood pressure ≥ 140/90 mmHg) and time-varying pre-hypertension (no hypertension treatment and blood pressure ≥ 120/80 but < 140/90 mmHg) adjusted for confounders, and tested for mediation by serum urate level.

Results: There were 10,872 participants among whom 45% had pre-hypertension and 44% had hypertension at baseline or during follow-up. Over 9 years of follow-up, 274 participants developed gout; 1.8% of women and 3.5% of men. The results are presented in the table. The unadjusted HR of incident gout was 3 times (95% CI: 2.20, 3.97) greater for those with hypertension compared to those without hypertension. Adjusting for confounders resulted in an attenuated but still significant association between hypertension and the development of gout (HR= 1.92; 95% CI: 1.41, 2.62). Serum urate level mediated the association between hypertension and incident gout (HR=1.19, 95% CI: 0.86, 1.64). Pre-hypertension was not associated with the development of gout except in the adjusted models, where a weak protective effect was noted (HR=0.65, 95% CI: 0.43, 0.98) after accounting for serum urate level. There was no evidence of effect modification of the association of hypertension and gout by sex (p-value=0.39), race (p-value=0.89) or obesity at baseline (p-value=0.90). Results were similar when the study was limited to those without diuretic use.

Hazard rate ratio and 95% confidence intervals of incident gout by time-varying hypertension and pre-hypertension status in ARIC (N=10,872)

	Hypertension	Pre-hypertension
Unadjusted	2.95 (2.20, 3.97)	0.94 (0.63, 1.41)
Sex and race adjusted	2.47 (1.82, 3.34)	0.86 (0.57, 1.28)
Confounder adjusted	1.92 (1.41, 2.62)	0.75 (0.50, 1.12)
Confounder and serum urate adjusted	1.19 (0.86, 1.64)	0.65 (0.43, 0.98)

Confounders: Sex, race, BMI, estimated glomerular filtration rate and alcohol intake.

Conclusion: In a cohort of men and women of both African American and white race, participants with hypertension had a two-fold increased risk of gout; this is the first study to show that the association was mediated by hyperuricemia. Participants with pre-hypertension did not have an elevated risk. These results confirmed that hypertension is a risk factor for gout. This is the first study to suggest that the risk of gout may not increase until a patient transitions from having pre-hypertension to the development of hypertension.

899

Prevalence and Risk Factors of Sarcopenia Among Community-Dwelling Older Women with High Frequency of Overweight/Obesity. Diogo S. Domiciano[1], Camille Figueiredo[1], Jaqueline B. Lopes[1], Valéria Caparbo[1], Liliam Takayama[2], Eloisa Bonfa[3] and Rosa M.R. Pereira[4]. [1]University of São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo (FMUSP), Sao Paulo, Brazil, [4]Disciplina de Reumatologia da FMUSP, Sao Paulo, Brazil

Background/Purpose: Sarcopenia is a syndrome characterized by progressive loss of skeletal muscle mass, which results in decreased muscle strength, impairment of physical and functional capacity and increased risk of death. The most widely used criteria for sarcopenia (Baumgartner *et al*.) has the disadvantage to underestimate the prevalence in overweight/obese people, whereas the Newman *et al*. definition considers appendicular muscle mass adjusted to total fat mass. Since prevalence of overweight/obesity is a growing public health issue in the world population, including older people, the aim of this study was to evaluate the prevalence and risk factors associated with sarcopenia, according to these two criteria in older women.

Methods: A total of 611 community-dwelling women, aged over 65 years, were included. Anthropometric data, lifestyle and medical history were assessed by a specific questionnaire. Body composition and bone mineral density were evaluated by DXA measurements (Hologic QDR 4500A). Laboratory tests were also performed (25-hydroxyvitamin D, intact parathormone, calcium, phosphorus, creatinine, glucose and lipid profile). Logistic regression models were used to identify risk factors related to sarcopenia in each criteria used.

Results: The prevalence of overweight/obesity (BMI > 24.9 kg/ m^2) in this community-dwelling older women was high (74.3%). The frequency of sarcopenia was significantly lower (3.7%) using Baumgartner than Newman's (19.9%) criteria (P<0.0001). Of note, less than 5% (1/23) of those classified as sarcopenic by Baumgartner's criteria had overweight/obesity, whereas 60% (74/122) of sarcopenic women by Newman's definition had this complication. Risk factors, after adjustments for age, were identified to be distinct in these two groups of individuals. Using Baumgartner's definition, the only risk factor observed in logistic regression models was T-score on femoral neck (OR=0.45; IC95% 0.27–0.76; *P*=0.003). In contrast, we have identified that creatinine (OR=0.24; IC95% 0.08–0.71; *P*=0.01) and ethnicity (non-Caucasian race: OR=0.48; IC95% 0.30–0.77; *P*=0.003) had a significant association with sarcopenia in the group defined by Newman's criteria.

Conclusion: In women with overweight/obesity, Newman′s definition seems to be more appropriate for sarcopenia diagnosis. This finding has relevant public health implications taking into consideration the distinct risk

factors identified herein and the high prevalence of overweight/obesity in older women.

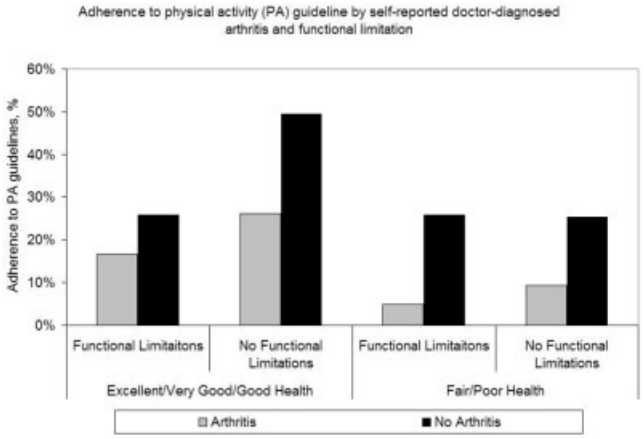
Adherence to Physical Activity Guidelines and Its Relationship with Self-Rated Health Among Persons with Doctor-Diagnosed Arthritis. William M. Reichmann[1], Jeffrey N. Katz[2], Sara A. Burbine[3], Meghan E. Daigle[3], Benjamin N. Rome[3], Alexander M. Weinstein[3] and Elena Losina[3]. [1]Brigham and Womens Hospital, Boston, MA, [2]Brigham & Womens Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

Background/Purpose: Adherence to physical activity (PA) guidelines set forth by the US Department of Health and Human Services has been linked to higher quality of life for persons with and without arthritis. The goal of this study is to describe the degree of adherence to PA guidelines in the US among persons with and without arthritis.

Methods: We used data from two cycles (2003–2004 and 2005–2006) of the National Health and Nutrition Examination Survey (NHANES). PA was assessed using an accelerometer, which counted the amount of PA the subject engaged in every minute for seven consecutive days. We defined adherence to PA guidelines as having at least 150 minutes of moderate/vigorous activity during the week. We also considered data on self-rated health (SRH), doctor-diagnosed arthritis, age, sex, race/ethnicity, body mass index (BMI), comorbidities, and functional limitation. SRH was defined as fair/poor (FP) versus excellent/very good/good (EVGG). Obesity was defined by BMI = 30. We used logistic regression models to estimate the level of adherence to PA guidelines for those with and without arthritis by SRH and functional limitation, adjusting for age, sex, race/ethnicity, obesity and comorbidities. All analyses accounted for the sampling design and used sampling weights to obtain estimates representative of the US population.

Results: 5,938 participants aged 25+ were included in the analysis. No groups had >50% adherence to PA guidelines. Among those with arthritis, the adherence to PA guidelines ranged from 4% among those with functional limitations and FP health to 27% among those without functional limitations and in EVGG health (Figure). Older age and female sex were associated with lower adherence to PA guidelines for all combinations of SRH, arthritis diagnosis and functional limitations.



Conclusion: Despite growing evidence that PA promotes good health among those with arthritis, adherence to PA guidelines is poor, especially among persons with arthritis who are in worse health, older, female, and obese. Further efforts to promote adherence to PA are urgently needed.

901

Do Climatological Changes Affect Arthritic Pain Severity in Patients with Rheumatic Diseases? K. Deftereou[1], B. Haidich[2], A. Benos[2], M. Trachana[3] and A. Garyfallos[1]. [1]4th Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]Department of Hygiene, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece, [3]1st Department of Paediatrics, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background/Purpose: Literature reports and clinical practice evidence support that patients with rheumatic diseases demonstrate exacerbation of arthritic pain in relation with changes in weather conditions. The aim of the study was to assess the effect of day by day weather condition changes on the frequency and severity of incidents of increased arthritic pain in patients with Rheumatoid Arthritis (RA), Osteoarthritis (OA) and Juvenile Rheumatoid Arthritis (JRA).

Methods: All participants (118 in total, 40 with RA, 26 with OA, 25 with JRA and 27 healthy volunteers) were asked to record all incidents of increased arthritic pain and mark their severity according to the Visual Analogue Scale (VAS) within an 11 weeks period of time. ESR and CPR were measured to exclude possible disease flare. Weather data [mean temperature (T), relative humidity (RH) and atmospheric pressure (AP)] on the day of the incidence and five days before and after were retrieved from the official archives of the National Institute of Meteorology of Greece.

Results: At least one incident of increased arthritic pain was reported by 58% of the RA patients, 100% of the OA and 44% of the JRA patients (280 incidents in total). No increase in ESR or CRP was found. No incidents were reported in the control group. VAS scores were higher in RA and OA groups than in the JRA group ($P<0.001$ and $P=0.003$ respectively) whereas there was no difference between the RA and OA groups ($P=0.776$). Incidents were also more frequent in the OA group than in the JRA group ($P<0.001$), whereas there was no difference between the RA and JRA groups ($P=0.328$). Women with RA demonstrated higher frequency of incidents ($P=0.011$) and higher VAS score ($P=0.002$) than men. Women with JRA demonstrated higher frequency of incidents ($P<0.001$) but no difference in VAS score ($P=0.455$) whereas within the OA group there was no difference in frequency ($P=0.05$) or VAS score ($P=0.250$) between women and men. In the RA group it was found that higher VAS scores were associated with changes in RH ($\beta=-0.265$ $P=0.014$) and T ($\beta=-1.778$ $P=0.026$) 24h before the incident and with changes in AP 48h before ($\beta=-0.280$ $P=0.045$) and 24h after ($\beta=0.485$ $P=0.041$) the incident. In the JRA group, pain severity was found to correlate with RH ($r=0.397$ $P=0.022$) and AP ($r=0.361$ $P=0.039$). Higher AP was associated with higher VAS scores ($\beta=0.075$ $P=0.017$). In the OA group pain severity was found to correlate with RH ($r=0.218$ $P=0.01$), T ($r=-0.190$ $P=0.024$) and RH change 24h ($r=0.208$ $P=0.014$) and 48h ($r=0.189$ $P=0.03$) before the incident. Higher RH ($\beta=0.213$ $P=0.004$) and lower T ($\beta=-0.409$ $P=0.012$) the day of incidence and RH raise 24h before ($\beta=0.173$ $P=0.011$) were associated with higher VAS scores.

Conclusion: Weather conditions and their changes are associated with severity and frequency of arthritic pain in patients with rheumatic diseases in a way that is not related to disease activity. This association does not seem to be uniform across different disease groups and sexes, a fact that reflects the perplexity of the condition and possible different mechanisms.

902

Economic Burden of Fibromyalgia: A Systematic Review and Meta-Analysis. John B. Wong, Marcia P. Griffith and Chenchen Wang. Tufts Medical Center, Boston, MA

Background/Purpose: Despite the 2% prevalence of fibromyalgia and its associated morbidity, the economic costs of fibromyalgia remains understudied, and to date, no systematic quantification of its financial consequences exists, so our aim was to determine the economic costs associated with fibromyalgia.

Methods: A systematic review of Medline from inception to 2011 for economic studies regarding fibromyalgia resulted in 483 titles when using recommended search terms for identifying health economic studies. Of these 483 titles, 19 studies contributed to the base case analysis. We calculated annual direct medical care costs. Using the United States (US) Consumer Price Index (CPI) for medical care services, we inflated annual cost data to 2010 US dollars, and we used World Health Organization (WHO) purchasing power parity data from 2005 to convert foreign currencies to US dollars. Data were pooled using the DerSimonian and Laird random effects model with weighting by the inverse variance.

Results: Based on 19 studies from 1996–2010, annual direct medical care costs were $3700 (95% CI $3682–3718). Sensitivity analysis considering 4 additional studies without reported standard deviations did not alter the results. Among 4 studies estimating the ratio of indirect to direct medical care costs, 3 of them yielded ratios of 1.7 to 2.2 and a fourth outlier estimated a ratio of 0.4. Based on 5 studies, patients with fibromyalgia had annual costs that were 1.7 to 2.9 times population controls. Not surprisingly, pain medication costs were higher in patients diagnosed with fibromyalgia versus controls. One study found that the co-existence of fibromyalgia and depression raised annual cost by 2.3 fold versus fibromyalgia alone and 1.5 fold

versus depression alone. Another study showed that annual fibromyalgia costs were about 0.75 times that for patients with osteoarthritis. Data were conflicting with regard to the effect of the diagnosis of fibromyalgia on costs with 3 studies suggesting annual savings post- versus pre-diagnosis of $146-$1711 and 2 studies suggesting increased annual costs of $2577-$6276 following fibromyalgia diagnosis. One study identified a non-statistically significant increase in annual costs for 2 higher Fibromyalgia Impact Questionnaire (FIQ) categories versus the lowest one.

Conclusion: Fibromyalgia is associated with substantial annual direct medical costs and indirect costs, exceeding that for population controls and approximating those for patients with osteoarthritis. Effective interventions may reduce fibromyalgia costs, and cost-effectiveness analyses of these interventions are needed.

903

Bone Mineral Density Across Age and Gender in Navajo People Compared to the National Health and Nutrition Examination Surveys III: the Education and Research Toward Health Study. Karla L. Miller, Tracy M. Frech, Tom Greene, Khe-ni Ma, Molly McFadden, Lillian Tom-Orme, Laurie J. Moyer-Mileur, Martha Slattery and Maureen Murtaugh. University of Utah School of Medicine, SLC, UT

Background/Purpose: To compare bone mineral density (BMD) as defined by bone mineral content (BMC) and measured bone area (BA) by age and gender in an adult Navajo population to those reported in other ethnicities by the National Health and Nutrition Examination Surveys (NHANES) III.

Methods: Study participants (N=1100) were randomly selected from the Education and Research Toward Health (EARTH) study to fill age and gender groups between November 2007 and January 2010. Dual energy x-ray absorptiometry (DXA) measurements of bone mineral density (BMD) were obtained at the left femoral neck, total hip, and lumbar spine (L1–4) by a certified DXA technician using standard protocol on a Hologic Discovery W machine. SAS version 9.2 (SAS Institute, Carey, NC) was utilized for data analysis. NHANES III data were analyzed using weights for design effects of clustering (SDPPSU6), stratification (SDPSTR6), and exam (WTPFEX6) for the unequal probability of sampling and non-response. Age and gender specific (6853 men and 7207 women) means from NHANES III data were created using proc survey means which adjusts for the unequal probability of sampling and non-response. Comparison of the age and gender specific means for large independent samples with normal approximation was used to assess difference.

Results: In general, BMD and BMC in Navajo men were similar to that of Non-Hispanic white (NH-white) and Mexican American men. BMD and BMC were lower among Navajo men compared to Non-Hispanic black (NH-black) men in all age groups. BA in Navajo men was lower than in NH-white and NH-black men, but similar to that of Mexican American men. BMD and BMC in Navajo women over 30 were higher than in NH-white women of similar age. BMD and BMC in Navajo women were lower than in NH-black women, and similar to Mexican American women in all age groups. BA in Navajo women over the age of 30 was lower than in NH-white women, and similar to NH-black women. BA in Navajo women was similar to Mexican American women between the ages of 40 and 70, but higher among those at the extremes of age. These differences were statistically significant.

Conclusion: In Navajo men compared to NH-black men, differences in BMD may be accounted for by lower BMC. Differences in BMD in Navajo women compared to NH-white women may be accounted for by higher BMC in the former, and higher BA in the latter. In general, BMD was similar in Navajo men and women compared to Mexican American men and women. Few data exist that address BMD among Native American populations, especially in men. Future studies are needed to determine the clinical implications posed by differences in BMC and BA among ethnicities, and the significance of our findings with respect to fragility fracture risk.

904

Prevalence of Anti-Osteoporotic Medication Use in a Cohort of Older Women with Both Rheumatoid Arthritis and Postmenopausal Osteoporosis. Gregory Cherkowski, Cynthia O'Malley and Primal P. Kaur. Amgen, Inc., Thousand Oaks, CA

Background/Purpose: With the known increased risk of fracture among women with RA (Gabrile, *Arthritis Rheum* 2009), the treatment of postmenopausal osteoporosis (PMO) should be considered in the management of RA. We examined overlapping use of pharmacologic osteoporosis therapy in a population of older women with both RA and PMO, across a selection of pharmacologic RA therapies.

Methods: Using administrative claims data from the 2005–2009 MarketScan Database, we identified a cohort of women aged ≥55 with both RA and PMO. RA and PMO were identified through ICD-9 diagnosis codes. The cohort was restricted to those treated with an anti-tumor necrosis factor alpha (anti-TNF-α) (etanercept, infliximab, and adalimumab), or a disease-modifying antirheumatic drug (DMARD) (hydroxychloroquine, leflunomide, methotrexate, and sulfasalazine). Medication exposure was identified through procedure J codes, HCPCS codes and outpatient prescription drug claims. Given that subjects are treated with overlapping combinations of therapy classes, we distributed subjects as follows: those who received DMARD and no anti-TNF-α were entered into the DMARD treatment group, and those who received anti-TNF-α, with or without DMARD, were assigned into the anti-TNF-α treatment group. Stratified by RA treatment groups, frequencies describing subject demographics, co-morbidities and osteoporosis medication use during the study period were collected.

Results: We identified 3,719 women aged ≥55 with RA, PMO, and the specified RA treatment. Among the study cohort, 2,287 (61.5%) received DMARD but no anti-TNF-α and 1,432 (38.5%) women were treated with anti-TNF-α. Anti-TNF users were slightly younger than nonusers. Both treatment arms received similar administration of PMO medication: 1,773 (77.5%) of the DMARD only group and 1,080 (75.4%) of the anti-TNF-α users received at least one class of PMO medication. Oral bisphosphonate use was highest across both treatment groups compared to all other PMO treatments. IV bisphosphonate and teriparatide use was lower in the DMARD group.

Demographic, co-morbidity and medication use characteristics of women aged ≥55 with both postmenopausal osteoporosis (PMO) and rheumatoid arthritis (RA), stratified by RA treatment in the MarketScan Database

	DMARD† n=2,287		Anti-TNF-α‡ n=1,432		Total n=3,719

† Treated with hydroxychloroquine, leflunomide, methotrexate, or sulfasalazine with no TNF-α inhibitor use
‡ Treated with etanercept, infliximab, or adalimumab
μ Metropolitan statistical area measured by zip code
*p <0.05
**p <0.01

Conclusion: Data indicate that over 75% of older women with RA and PMO receiving RA pharmacotherapy are also receiving pharmacologic osteoporosis therapies. DMARD use was greater than anti-TNF-α use; anti-PMO medication use was similar among DMARD and anti-TNF-α user groups.

905

Prevalence of Low Bone Mass and Osteoporosis in Navajo People Older Than 50 Across Age, Gender, and Body Mass Index. Karla L. Miller, Tracy M. Frech, Tom Greene, Khe-ni Ma, Molly McFadden, Lillian Tom-Orme, Laurie J. Moyer-Mileur, Martha Slattery and Maureen Murtaugh. University of Utah School of Medicine, SLC, UT

Background/Purpose: To describe the prevalence of low bone mass (osteopenia) and osteoporosis in in Navajo men and women over the age

of 50 as defined by the World Health Organization (WHO) classification criteria for densitometric diagnosis.

Methods: Study participants were randomly selected from the Education and Research Toward Health (EARTH) study to fill age and gender groups between November 2007 and January 2010. Dual energy x-ray absorptiometry (DXA) measurements of bone mineral density (BMD) were obtained at the left femoral neck, total hip, and lumbar spine (L1–4) by a certified DXA technician using standard protocol on a Hologic Discovery W machine. WHO classification criteria were applied to BMD measurements for densitometric diagnosis of low bone mass (T-score between −1 and −2.5) and osteoporosis (T-score ≤ −2.5). Health history was assessed by the Health, Lifestyle, and Physical Activity questionnaire. Dietary intake was assessed by questionnaire adapted from the CARDIA diet history to include foods common to the diet of the select population. SAS version 9.1 (SAS Institute, Carey, NC) was utilized for data analysis. A Chi-square test p value of less than 0.05 was used to note statistically significant differences. Age and body mass index (BMI) were assessed categorically. Femoral neck BMD was adjusted for age, hormone use, and education in women, and for age and education in men.

Results: Prevalence of low bone mass by femoral neck T-scores in men over 50 was 42.5%, and osteoporosis was 1.5%. Prevalence of low bone mass by femoral neck T-scores in women over the age of 50 was 47.9% and osteoporosis was 6%. There were no significant differences in the prevalence of low bone mass and osteoporosis by femoral neck T-score when compared to the overall prevalence reported in NHANES III for women over the age of 50. Prevalence of low bone mass and osteoporosis in men and women over the age of 50 increased significantly using BMD measurements obtained at the lumbar spine (L1–4) with osteoporosis and low bone mass diagnosed in 14% and 41% of women, respectively, and 4.5% and 22% of men, respectively. Bone mineral density measurements increased significantly among both men and women across BMI groups.

Conclusion: Overall prevalence of low bone mass and osteoporosis by bone densitometry in this Navajo population was low, but increased among men and women over the age of 50. Prevalence of low bone mass and osteoporosis by T-score in women over the age of 50 is similar to that reported by NHANES III. This is the first report to our knowledge describing prevalence of low bone mass and osteoporosis in an American Indian male population. Previously reported increases in BMD across BMI have been reported in American Indian and other populations. This observation was substantiated by this study.

906

Health-Related Quality of Life Among Patients with Osteoporotic Fractures In Mexico. Patricia Clark[1], Fernando Carlos[2], Gabriela Chico[1], Oskar Ström[3], Ingrid Lekander[3] and Fredrik Borgström[3]. [1]Hospital Infantil de México Federico Gómez, Mexico City, Mexico, [2]RAC Salud Consultores, S.A. de C.V., Mexico, Mexico, [3]Innovus, Sweden

Background/Purpose: To evaluate the change in health-related quality of life (HRQoL) among patients with osteoporotic fractures in Mexico.

Methods: A cohort of 261 patients 50 years and over, both sexes, that had sustained a low energy fracture, was recruited as part of the ICUROS study in three different centers in Mexico City. Patients were interviewed about their health status at three different times: before fracture (recollected), within 14 days after fracture, and 4 months after the fracture. HRQoL was assessedby using the EQ-5D instrument (including VAS scale) and a time-trade-off (TTO) questionnaire with a maximum of ten years life horizon. The UK algorithm was used to transform each EQ-5D profile to an EQ-5D utility value, censored to zero. Differences in means were calculated with a one-way Kruskal-Wallis analysis of variances.

Results: Mean age was 71.43±1.61 years and 85.8% were women. Hip fractures (61.7%) were the most frequent type of fracture, followed by ankle (14.2%), wrist (9.2%), humeral (8.0%) and vertebral (3.4%).

Baseline mean (±SD) scores of EQ-5D utility, EQ-5D VAS and TTO were 0.64±0.31, 0.79±0.19 and 0.78±0.26 respectively.

After sustaining an osteoporotic fracture, HRQoL decreased dramatically. Mean differences between HRQoL immediately after fracture and the HRQoL prior the fracture were: −0.58 (95%CI: −0.54 to −0.62; p<0.001) for EQ-5D; −25.8 (95%CI: −0.22 to −0.30; p<0.001) for EQ-5D VAS and −0.13 (95%CI: −0.10 to −0.16; p<0.001) for TTO.

Four months after the patients had sustained an osteoporotic fracture, their HRQoL was better than it was immediately after the fracture had occurred, but significant lower in comparison with pre-fracture health state using EQ-5D utility index. Mean gain from immediately after the fracture were: 0.44 (95%CI: 0.38–0.49; p<0.001) for EQ-5D index; 0.22 (95%CI: 0.16–0.27; p<0.001) for EQ-5D VAS and 0.22 (95%CI: 0.13–0.30; p<0.001) for TTO.

32 patients were withdrawn of the study, almost half of them (n=14) died during the 4 months period after fracture, and all of them had a hip fracture.

Conclusion: HRQoL decreases in all osteoporosis-related fractures immediately after fracture but has increased significantly after a period of 4 months.

907

Disparities in the Prevention/Treatment of Glucocorticoid-Induced Osteoporosis. Florina M. Constantinescu[1], Primal Bhatia[2], Lenore M. Buckley[3], Paul Falzer[4] and Liana Fraenkel[5]. [1]Washington Hospital Ctr/Georgetown University, Washington, DC, [2]Washington Hospital Center, Washington, DC, [3]VCU School of Medicine, Richmond, VA, [4]VA Connecticut Healthcare System, New Haven, CT, [5]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT

Background/Purpose: Significant efforts have been made to improve the quality of care delivered to women on glucocorticoids to prevent/treat glucocorticoid (GC)-induced osteoporosis (GIOP). The objectives of this study were 1) to examine current trends in the quality of care of women on at least 90 days of consecutive GCs under the care of a rheumatologist, and 2) to determine if differences in care exist between specific sociodemographic groups.

Methods: Women identifying themselves as either African American (AA) or White, with at least 90-days exposure to prednisone, and able to read and write English, completed a survey after their appointments in outpatient rheumatology clinics. Women were classified into 3 groups: 1) AA women with annual household income levels less than $20,000, 2) AA women with annual household income levels of $20,000 or more, and 3) White women. We examined the relationship between group membership and: 1) the likelihood of having had a bone densitometry exam, 2) the likelihood of having had a physician recommend that they take treatment to prevent GIOP or fractures, and 3) the likelihood of currently taking both calcium and vitamin D. Multivariate logistic regression was used to adjust for age, fracture history and previous bone densitometry results. The same analyses were repeated for 3 groups classified based on race and education level: 1) AA women with no college education, 2) AA women with at least some college education, and 3) White.

Results: 186 women were interviewed: mean age (SD) = 49 (16); 60% were AA; 26% reported incomes less than $20,000; 32% did not have any college education; 28% of the subjects had not undergone bone densitometry. The relationship between sociodemographic group (based on race and income as well as race and education level) and care for GIOP is provided in the Table. In each case, White women are treated as the referent group.

Conclusion: Despite the presence of well-established risk factors for osteoporosis, the likelihood of reporting 1) having undergone a bone densitometry, 2) receiving a doctor recommendation to initiate treatment for prevention/treatment of GIOP, and 3) currently using daily calcium and vitamin D was significantly less among AA women with low income and less education than White women. In contrast, no significant differences were found between AA with higher incomes and education levels compared to White women. These results have important clinical implications and indicate that further efforts are warranted to improve GIOP-related care among AA disadvantaged women.

Table. Associations between Sociodemographic Group and Care to Prevent/Treat GIOP

	Odds Ratio (95% CI): Having Undergone Bone Densitometry		Odds Ratio (95% CI): Reporting a Physician Recommendation		Odds Ratio (95% CI): Current Use of Calcium and Vitamin D

Obesity Increases the Risk of Adhesive Capsulitis. Yuqing Zhang[1], Christine Peloquin[1], Daniel K. White[1], Yanyan Zhu[1], Young Hee Rho[2] and Hyon K. Choi[1]. [1]Boston University School of Medicine, Boston, MA, [2]Vanderbilt Medical Center, Nashville, TN

Background/Purpose: Adhesive capsulitis (AC) is a painful and disabling shoulder disorder, with an incidence rate of 3 per 1000 person-years among individuals >=40 years. Previous studies have shown that AC occurs more frequently among individuals with diabetes and cardiovascular diseases; however, to date, no study has examined the relation of obesity, a strong risk factor for diabetes and cardiovascular diseases, to the risk of AC.

Methods: We conducted a case-control study to examine the association between obesity and the risk of AC using The Health Improvement Network (THIN), an electronic medical record database of 7.3 million patients from general practices across the United Kingdom from 1990 to 2010. An incident case of AC was defined as a first diagnosis of AC by a general practitioner in a subject aged >=40 years, following at least four years of enrollment in the database. For each AC case, we identified a control who did not have AC at the time of case diagnosis (i.e., index date), matched by sex, age, and year of enrollment in THIN. Body Mass Index (BMI, kg/m^2) prior to the index date was divided into 4 categories: < 25, 25-<30, 30-<35, and >=35. Potential confounders, including diabetes, cardiovascular disease, hypertension, and hypothyroidism, were all assessed prior to BMI assessment. We examined the association between BMI categories and risk of AC using the conditional logistic regression, adjusted for confounders. Finally, we evaluated the effect of obesity on the risk of AC across strata of age (<65 vs. >=65) and sex and assessed whether the effect of obesity on the risk of AC was modified by each of these factors.

Results: We identified 21,303 cases of AC (mean age: 63 years, 39% male). Higher BMI was associated with a higher risk of AC. Compared with those with BMI < 25, the odds ratios were 1.06, 1.27, and 1.31 for individuals with BMIs of 25-<30, 30-<35, and >=35, respectively (p for trend < 0.001). The association was consistent across age categories but was stronger in women than in men (Table).

		Adhesive Capsulitis			
Variable	BMI (kg/m^2)	Cases	Controls	OR (95% CI)	P for interaction
Men	<25	2117	2220	1.0	0.007
	25-<30	3615	3797	0.99 (0.91, 1.06)	
	>30	2568	2283	1.15 (1.06, 1.25)	
Women	<25	4133	4752	1.0	
	25-<30	4422	4568	1.11 (1.04, 1.18)	
	>30	4448	3683	1.36 (1.28, 1.45)	
<65 years	<25	3813	3418	1.0	0.98
	25-<30	4576	4344	1.05 (0.98, 1.11)	
	>30	3695	4322	1.25 (1.17, 1.34)	
>=65 years	<25	3159	2832	1.0	
	25-<30	3789	3693	1.09 (1.01, 1.16)	
	>30	2271	2694	1.32 (1.22, 1.43)	

Conclusion: This general population study provides the first epidemiologic evidence that obesity is associated with an increased risk of AC. Future studies to understand the biological mechanisms linking obesity to the risk of AC are warranted.

909

Prevalence and Impact of Extreme Obesity (Class III) Among US Adults with Arthritis. Jennifer M. Hootman[1], Charles G. Helmick[2] and Casey Hannan[2]. [1]Centers for Disease Control and Prevention, Kennesaw, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA

Background/Purpose: Obesity is highly prevalent among adults with arthritis. Extreme obesity (Class III) is specifically associated with poor quality-of-life, worse WOMAC pain scores, intra-operative difficulties and post-surgical complications after total joint replacement surgery. The purpose of this study was to assess the prevalence and personal impact of extreme obesity among adults with arthritis.

Methods: Data were from the 2009 Behavioral Risk Factor Surveillance System, an annual telephone health survey conducted in all 50 states and the District of Columbia (n = 424,592 adults). Arthritis was defined as a 'yes' response to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?". Body mass index (BMI = weight kg/ height m^2) was calculated from self-reported height and weight. BMI was categorized as underweight (<18.5), normal (18.5–24.9), overweight (25.0–29.9), obese class I (30.0 – 34.9), obese class II (35.0–39.9), and extreme obese class III (>40.0). Seven impact measures included three arthritis-related and general health measures [arthritis-attributable activity limitation, severe pain (>7 on a 0–10 scale), and fair/poor self-rated health] and four unhealthy days measures (14+ days in the past 30) [frequent mental distress, frequent physical distress, frequent activity limitation days, and frequent sleep insufficiency]. Prevalence (percent), odds ratios (OR) and 95% confidence intervals (CI) were calculated using statistical weights to account for the complex sample design. BMI categorical distributions were compared between adults with and without arthritis using Wald Chi Square tests ($p < 0.05$). Among adults with arthritis, logistic regression was used to estimate the association between extreme obesity (referent = normal weight) and the 7 impact measures adjusting for age, sex, and race/ethnicity.

Results: The prevalence of obesity was significantly higher among adults with arthritis compared with adults without arthritis (Class I: 20.4% vs. 15.2%; Class II: 8.5% vs. 5.3%; Extreme Class III: 6.2% vs. 2.9%). Adults with arthritis were 2.2 (CI 2.2 – 2.3) times more likely to be extremely obese than adults without arthritis. Compared to normal weight adults with arthritis and adjusting for age, sex, and race/ethnicity, extremely obese adults with arthritis were significantly more likely to report activity limitation (OR 3.3, CI 3.1–3.4), severe pain (OR 3.0, CI 2.8–3.2), fair/poor self-rated health (OR 3.8, CI 3.6–4.0), frequent mental distress (OR 1.8, CI 1.7–2.0), frequent physical distress (OR 2.5, CI 2.4–2.7), frequent activity limitation days (OR 2.6, CI 2.4–2.7), and frequent sleep insufficiency (OR 1.7, CI 1.6–1.8). Results for analyses using Class I obesity as the referent group were similar, all associations were statistically significant but smaller in magnitude.

Conclusion: Extreme obesity is relatively common [6%, 3.4 million] among adults with arthritis and severely affects all seven personal impact measures. Aggressively screening, counseling, and treating obese patients with arthritis may improve these outcomes.

910

A Patient Reported Frailty Index That Can Predict Mortality Outcomes Among Patients with Arthritis. Eswar Krishnan[1], James F. Fries[2] and Bharathi Lingala[3]. [1]Stanford University, Stanford, CA, [2]Stanford Univ Medical Center, Palo Alto, CA, [3]Stanford

Background/Purpose: Physical Frailty, conceptually defined as loss of functional reserves at organ and organism level, is increasingly recognized as a state that is distinct from functional disability and contributes to adverse patient outcomes. There have been few studies that have examined the predictive power of Frailty in patients with arthritis.

Methods: Utilizing the domain framework of physical Frailty from published literature, we constructed a simple five-item Patient reported (PRO)-Frailty Index using the following components- fatigue, poor balance, grip strength, anorexia and memory loss. Using Cox regressions, we analyzed the utility of this Index to predict all-cause mortality in a cohort of 3,185 (78% women, mean age 64 years) patients with rheumatoid arthritis and osteoarthritis followed for a mean 4.3 years. Receiver Operating Curve (ROC) analyses were performed to identify the optimal cutoff that can be used to dichotomize the Frailty Index.

Results: The PRO-Frailty Index (range 0–5) had a near-normal distribution in the population studied with a mean (SD) of 1.3(1.1) overall. The PRO-Frailty Index predicted mortality in age-sex adjusted analyses with a hazard ratio of 1.15 (1.01–1.31) for each unit increase in PRO-frailty index. In multivariable analyses where the effect of age, gender, disease duration and education level were accounted for, each unit increase in PRO-Frailty Index was associated with 17% increased mor-

tality risk (1.17; 1.02–1.34). ROC analyses suggested that dichotomizing the index at 0 and >0 offered the best model fit. The frailty-mortality association was observed in both the arthritis categories although the confidence interval was too wide for statistical significance individually.

Conclusion: PRO-Frailty Index can predict mortality among patients with arthritis.

911

Unintended Consequences; Increased Prescription of Narcotic Analgesics for Osteoarthritis in the Elderly Is Associated with Increased Falls and Fractures in the Post-Vioxx Era. Lydia Rolita[1], Adele Spegman[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]Geisinger Health System, Danville, PA, [3]New York Univ Medical Center, New York, NY

Background/Purpose: Narcotic analgesics (NA) have long been used to treat pain although a number of alternatives have been developed, including selective COX-2 inhibitors. In 2004 Merck withdrew Rofecoxib from the market due to cardiovascular events and subsequent guidelines for treating chronic pain by the AHA and AGS recommend short-term narcotic analgesic use as the first step in managing chronic pain. Falls in the elderly are common and because NA contribute to falls in the elderly we determined whether prescriptions for NA for elderly patients were increased after COX-2 inhibitors were taken off the market and whether the incidence of falls/fractures changed in these patients.

Methods: Records of all patients >65yo with a diagnosis of OA (>10,000 patients) over the years 2001–2009 were identified in the Geisinger EMR data warehouse for analysis. Diagnoses of falls and fractures were identified by ICD 9 codes. Three analgesic prescription groups were identified: NA with or without other analgesics, COX-2 alone or with other analgesics, and NSAIDS, others and none. Other factors analyzed were age, gender, and Charlson Index Score of comorbidities (CI).

Results: From 2001–2004, patients receiving only NA prescriptions increased from 8% to 20% of the population and doubled again to 40% by 2009. COX-2 usage was low in this population (8%). The incidence of falls/fractures increased from less than 1% of all patients in 2001 to 4% in 2009 (Fig 2) and appears to be associated with the increased use of narcotic analgesics (Figure 1). Across all groups, patients with falls were older (78.1±6.6 v 73.8±6.3), yet in the NA group only, patients with falls had higher CI. The influence of age and comorbidities on falls were examined using conditional logistic regression; *no fall patients* were matched 3:1 to *fall patients* according to age and CI at time of fall. Falls risk increased with NA use in both study periods. In 2005–2009 when compared with: COX-2, NA use was associated with a 3.7 OR (2.6, 5.4; p <.001) and with NSAID a 4.4 OR for falls (3.9, 4.9; p <.001).

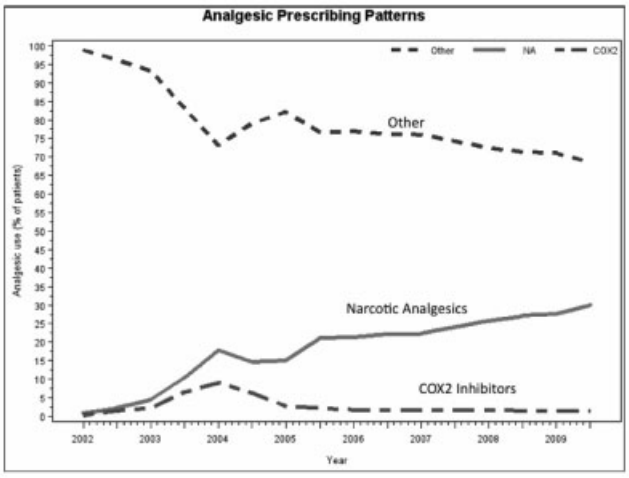

Figure 1.

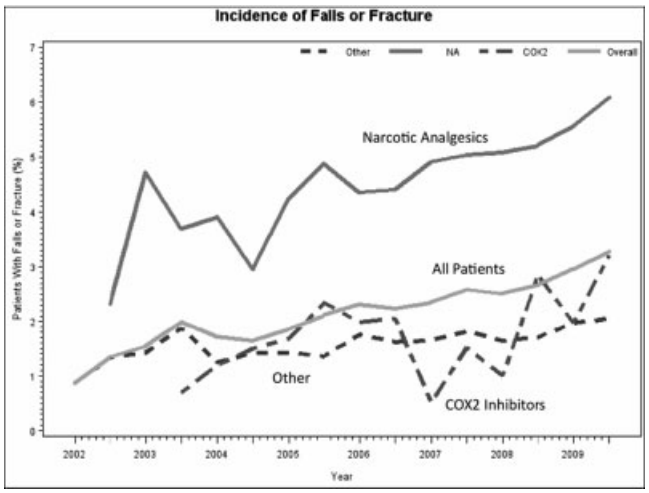

Figure 2.

Conclusion: After Vioxx was taken off the market there was a marked increase in the prescription of narcotic analgesics. Falls and fractures in this elderly population with OA increased markedly and all of the increase in falls were in patients prescribed narcotic analgesics. These findings strongly indicate that recommendations for the treatment of chronic pain be re-evaluated.

912

The Impact of Biologics for the Treatment of Rheumatoid Arthritis: The Case of Total Hip and Knee Replacement Surgery. Neeta Tandon[1], Guy David[2], Arthur Kavanaugh[3] and Candace Gunnarsson[4]. [1]Janssen Services, LLC, Horsham, PA, [2]University of Pennsylvania Wharton School of Business, Philadelphia, PA, [3]University of California San Diego, San Diego, CA, [4]S2 Statistical Solutions, Inc, Cincinnati, OH

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, progressive systemic inflammatory disease that can be associated with severe long-term disability caused by joint destruction. Important sequelae of joint damage include joint replacement (e.g. total knee replacement [TKR] and total hip replacement [THR]). While effective, such surgeries are expensive and can pose risks for patients. A notable proportion of patients with uncontrolled RA may require TKR and/or THR. Since the late 1990's, the availability of highly effective biologic therapies has helped change the treatment paradigm in RA, and led to improved outcomes. One way of studying the impact of biologics is by examining RA patients' need for procedures due to RA-related damage, such as TKR and THR.

Methods: We performed a retrospective analysis of patient hospital discharges data between 1993 and 2008 in the United States from the Nationwide Inpatient Sample (NIS) of the Healthcare Cost and Utilization Project (HCUP). We used a coding algorithm to identify all 1,742,935 patients having THR or TKR procedures, 58,036 of which had a diagnosis of RA. Difference-in-differences methodology was utilized to examine the potential effect of the introduction of biologic agents on the likelihood that RA is the primary reason for receiving THR or TKR by comparing RA patients after the time these drugs were introduced with RA patients before their introduction, and to patients' without a diagnosis of RA in order to capture general trends for THR and TKR. All models controlled for patient demographics and co-morbidities.

Results: The number of annual THR procedures more than doubled between 1993 and 2008 (25,987 to 56,478), and the number of annual TKR procedures more than tripled over this period (38,136 to 125,881). However, patients with RA (as a primary or secondary diagnosis), had a statistically significant (p<.01) 28% decrease in the likelihood of RA being the primary reason for receiving THR or TKR after the time that biologic agents (In particular the TNF inhibitors etanercept, infliximab and then adalimumab) were introduced.

Conclusion: Since the time of the introduction of biologics for the treatment of RA, there has been a reduction in THR and TKR surgeries among patients with a primary diagnosis of RA. This consistent and significant finding suggests that the availability of biologic agents, as well as other changes in the therapeutic approach to RA, may confer long term benefits to both RA patients and health care systems.

913

Costs and Absences Associated with Rheumatoid Arthritis On Work Productivity: A Comparison Between Employees with and without Rheumatoid Arthritis In a United States Population. Nathan L. Kleinman[1], Richard A. Brook[2], Stephanie E. Kirbach[3] and Mary A. Cifaldi[3]. [1]HCMS Group, Cheyenne, WY, [2]The JeSTARx Group, Newfoundland, NJ, [3]Abbott Laboratories, Abbott Park, IL

Background/Purpose: Rheumatoid Arthritis (RA) was recently reported to have societal costs in the US of $19.3 billion and $39.2 billion (in 2005 dollars) without and with intangible costs, respectively. (Birnbaum 2010) However, most indirect components were subjectively imputed. This research was designed to use objective data to quantify the incremental work absence and indirect costs associated with RA in an employed population and compare these absences and costs to controls.

Methods: Employee records from multiple large employers in the US providing data about demographic, job-related information, and health care use in the HCMS database were assessed from 1/1/01 to 6/30/10. Patients with RA were identified by claims with primary, secondary, or tertiary ICD-9 codes of 714.xx, and the date of the first claim was considered the index date. Controls were employees without claims for RA, and their index date was defined as the average index date (by employer) among RA patients. All subjects were required tohave 12 months continuous health plan enrollment. Absences and indirect costs were measured for the 12 months following each employee's index date. All costs were adjusted to June 2010 US$. Regression modeling was used to separately compare days absent and indirect costs using two-part models controlling for demographics, job-related variables, location, and modified Charlson Comorbidity Index.

Results: Out of more than 800,000 employees in the HCMS database, 2705 (0.79% of employees) had RA and 338,035 were controls (Table 1).

Table 1. Descriptive Statistics for Employees with and without RA

Variable	Employees with RA (N=2,705) Mean (Standard Error) or %	Employees without RA (N=338,035) Mean (Standard Error) or %	P-Value
Age, at index date (N, controls=338,017)	45.13 (0.19)	40.37 (0.02)	<0.0001
Female	61.4%	40.9%	<0.0001
Married	42.5%	45.1%	0.0065
Not Married	31.1%	32.9%	0.0436
Missing Marital Status	26.4%	22.0%	<0.0001
White	44.1%	41.3%	0.0036
Black	8.6%	11.6%	<0.0001
Hispanic	10.8%	6.6%	<0.0001
Other Race	2.4%	3.6%	0.0007
Missing Race	34.1%	36.8%	0.0036
Annual Salary (N, RA=2686; N, controls=332,333)	$53,499 ($771)	$53,655 ($300)	0.9629
Tenure, at index date	9.60 (0.17)	8.92 (0.01)	<0.0001
Exempt	31.3%	33.0%	0.0614
Full Time	94.6%	89.7%	<0.0001
Modified Charlson Index	0.477 (0.021)	0.129 (0.001)	<0.0001

The incremental indirect costs (RA minus controls, Table 2) were: Sick Leave $145; Short-term Disability $249; Long-term Disability $41 (P=0.0505); Workers' Compensation $90; and Total $525. Incremental absence days (Table 2) were: Sick Leave 1.2; Short-term Disability 1.91; Long-term Disability 0.47 (P>0.05); Workers' Compensation −0.01 (P>0.05), and Total 3.58. All comparisons P<0.01 except where noted.

Table 2. Annual Indirect Costs and Absences for Employees with and without RA (†Adjusted Mean, ‡difference due to rounding)

Component	Employees with RA			Employees without RA			P-Value	
	N	Cost†	Days†	N	Cost†	Days†	Cost†	Days†
Sick Leave	1,106	$470	3.25	145,354	$325	2.05	**<0.0001**	**<0.0001**
Short-term Disability	1,562	$466	3.74	188,103	$218	1.83	**<0.0001**	**<0.0001**
Long-term Disability	2,153	$55	0.74	247,497	$14	0.26	0.0505	0.1136
Workers' Compensation	2,440	$271	0.18	312,226	$181	0.19	**0.0093**	0.8715
Total (sum above)		$1,262	7.92		‡$737	4.34		

Conclusion: Employees with RA incur 71% more indirect costs than those without RA and utilize 82% more lost time.

914

A Simple Model That Suggests Possible Cost Savings When Modified-Release Prednisone 5mg/Day Is Added to Current Treatment In Patients with Active Rheumatoid Arthritis. Maarten Boers[1] and Frank Buttgereit[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Charité University Medicine, Berlin, Germany

Background/Purpose: The prognosis of rheumatoid arthritis (RA) has improved through the application of early treat-to-target strategies with innovative combinations of traditional antirheumatic drugs and rapid switch to biological agents. However, the high cost of biologic agents is straining health care budgets; consequently reimbursement is restricted.

Increasing evidence suggests glucocorticoids have a good benefit/harm ratio when used at low doses. Recently, a modified-release prednisone preparation has become available (MR-pred) that promises an even better benefit/harm ratio.

Methods: We used data from a 12-week placebo-controlled study to model the economical benefits of starting MR-pred in patients that have a reimbursable indication for biologic treatment. In the Netherlands, this indication is persistent disease activity (Disease Activity Score threshold, DAS28 > 3.2) despite treatment with at least two antirheumatic drugs. In Belgium and UK the threshold is DAS28 > 3.7 and > 5.1, respectively.

Results: The CAPRA-2 study randomized 350 RA patients with active disease (mean DAS28: 5.2; SD 0.8) despite disease-modifying antirheumatic therapy to MR-pred 5mg/day (n=231) or placebo (n=119). After 12 weeks DAS28 was reduced by mean 1.2 in the MR-pred group compared to 0.6 in the placebo group. Analysis according to last observation carried forward suggests that 28% of patients in the MR-pred group and 15% in the placebo group had a DAS28 ≤ 3.2 at the end of the study, a difference of 13% (95% CI: 4–21%; Mundipharma: CAPRA-2 study report; submitted for publication). Thus, starting MR-pred would have delayed initiation of biologics by at least 3 months in 28% of these patients: a net effect of 13% against the wait-and-see policy (or placebo), increasing to 28% when biologics are started immediately.

For Belgium and UK 97 resp. 55% of patients had an indication for reimbursement. The Table shows that the effect of MR-pred is similar at different thresholds (difference between treatment groups: 13% resp. 11%).

Without any further extrapolation beyond 3 months the conservative net estimate of 13% results in 3.25% (i.e., 13/4) less biologics prescriptions on a yearly basis. Assuming € 15,000 as mean drug cost of one year of biologics treatment and € 1.- as daily cost for MR-pred, net drug cost savings can be calculated to be € 396, i.e.: Costs savings in biologics: €487,50 (=3,25% * 15.000); minus Costs of 3 months MR-pred: € 91,25.

Table. Proportion of patients dropping below reimbursement thresholds of disease activity during the trial.

% of patients at or below threshold	*DAS28 threshold for reimbursement* *UK: 5.1* MR pred	Plac	*Belgium: 3.7* MR pred	Plac	*NL: 3.2* MR pred	Plac
Baseline	45	45	3	3	0	0
12 weeks	79	68	42	29	28	15
Improvement	*34*	*23*	*39*	*26*	*28*	*15*
Difference (MR pred–placebo)	**11**		**13**		**13**	

Conclusion: Despite a considerably higher cost price than conventional prednisone, MR-pred is a cost-effective option for patients not on glucocorticoids that are eligible for therapy with biologic agents.

915

Costs of Tumor Necrosis Factor Blockers Per Treated Rheumatoid Arthritis Patient Using Real-World Drug Data in US Commercially-Insured Population. Vernon F. Schabert[1], Shravanthi R. Gandra[2], Crystal Watson[2], Jason Yeaw[1], Seth Goodman[1], Kathy M. Fox[3], Sandra Milev[4] and David J. Harrison[2]. [1]IMS Consulting Group, Alexandria, VA, [2]Amgen Inc, Thousand Oaks, CA, [3]Strategic Healthcare Solutions, LLC, Monkton, MD, [4]IMS Brogan, Ottawa, ON

Background/Purpose: Etanercept (ETN), adalimumab (ADA), and infliximab (INF) are FDA-approved tumor necrosis factor (TNF)-blocker treatments for moderate to severe rheumatoid arthritis (RA). However, they

differ in their mode of administration, dosing ranges and dosing frequency. These differences can lead to cost fluctuations that can be captured using real world data. This study describes the annual costs of ETN, ADA and INF per treated RA patient using real-world drug data in a US commercially-insured population.

Methods: IMS LifeLink™ Health Plan Claims database was used to identify adult patients (≥18y) with ≥1 claim for ETN, ADA or INF between January 1, 2005 and March 31, 2009 (first claim in study period is index claim); including patients new to TNF-blocker treatment (i.e., with no claims for a TNF blocker during the 180 days prior to index claim) and those continuing TNF-blocker treatment. Patients had to have 360 days continuous plan enrollment following index claim (follow-up) and 180 days prior to index claim (pre-index period).

In the pre-index period, patients had to have a RA diagnosis, but were excluded if they had a diagnosis of psoriasis, psoriatic arthritis, ankylosing spondylitis, Crohn's disease, ulcerative colitis or juvenile idiopathic arthritis. Patients were followed for 1-year or until end of study period (March 31, 2010).

Mean monthly dose was computed for patients on therapy; 2011 wholesale acquisition costs were applied to mean monthly dose and 2011 Medicare Physician Fee Schedule was applied to related drug administrations. Costs from restarting index TNF blocker therapy after discontinuation and costs from switching to a different TNF blocker were included and attributed to patients' index TNF-blocker therapy.

Results: Overall, 18,094 patients with RA (8,840 ETN, 4,578 ADA, 4,676 INF) were identified. Mean age was 50 years old, with 76% female. The 1-year mean TNF-blocker cost per treated patient for all RA patients was lowest for patients on ETN, $13,482, followed by ADA, $17,652 then INF, $19,824. For biologic-naïve patients, mean TNF-blocker cost per treated patient was $12,863 for ETN, $16,402 ADA, and $17,276 INF. For patients continuing biologic therapy, TNF-blocker cost per treated patient was $13,939 ETN, $18,920 ADA, and $21,217 INF.

Conclusion: When evaluating the TNF-blocker cost per treated RA patient across commonly used TNF-blockers with different modes of administration and dosing frequencies, patients on ETN had the lowest annual TNF-blocker cost for RA patients using real-world drug utilization data from US commercially-insured population.

916

Direct Costs in Newly Diagnosed and Established Rheumatoid Arthritis Patients, and Comparison with Non-Rheumatoid Arthritis Controls in An Insurance Claims Database. Martin M. Crane[1], Stephanie Manson[2], Maneesh Juneja[3], Jeffery Allen[1], Regina H. Kurrasch[4], Myron E. Chu[5], Emilia Quattrocchi[2] and David J. Chang[5]. [1]GlaxoSmithKline, Research Triangle, NC, [2]London, United Kingdom, [3]GlaxoSmithKline, Stockley Park, United Kingdom, [4]Medicines Development, GlaxoSmithKline, King of Prussia, PA, [5]Medicines Development GlaxoSmithKline, King of Prussia, PA

Background/Purpose: Although DMARDs (disease modifying antirheumatic drugs) remain a mainstay of rheumatoid arthritis (RA) therapy, the cost structure of treating these patients has significantly changed, often with higher direct medical costs, since introduction of biologics. We sought to quantify these costs in different RA populations.

Methods: An incident (newly diagnosed in 2006) and a prevalent RA (end of 2005) cohort based on two Outpatient(OP)/Inpatient (IP) visits >30 days apart were identified by ICD9 codes from the Pharmetrics Choice administrative claims database and followed through 9/2008. An "aggressive" subset of incident patients was defined based on >8 OP/IP visits in the first 12 months. Annualized direct costs per patient were determined for medication, OP (includes laboratory and imaging), and IP (includes ER), based on actual amounts reimbursed to providers; co-pays were also available. Costs are presented as mean (SD), adjusted for inflation. A non-RA cohort, matched by age, gender and duration in the database was selected for comparison.

Results: There were 2,136 incident (265 in the aggressive subset) and 19,805 established patients (incidence 0.07%; prevalence 0.65%). Between years 1 and 2, total annualized costs per incident patient increased from $4,703 ($8,339) to $5,137 ($9,273). Medications, OP and IP costs comprised 66%, 24% and 10% respectively of the total in Year 1 and 78%, 14% and 8% in Year 2. For the aggressive subgroup, the total cost per patient in Year 1 was $8,804 ($9,268) and $10,803 ($12,557) inYear 2 due more rapid and extensive uptake of biologics (50% by end of Year 2 vs 22% in the non-aggressive group); co-pays in the aggressive patients averaged $1,200/year vs $600 in the non-aggressive patients. During the total study period (median follow-up 2.3 yrs), 71.5% of incident patients were not prescribed an anti-TNF and the total cost over follow-up was $1,573 ($3,389); of those who were prescribed an anti-TNF, 66.7% continued with the original prescription, 21.0% switched to a second, and 4.9% switched to a third with total costs of $13,224 ($9,066), $17,059 ($10,891), and $18,691 ($9,330), respectively. In established patients,total annualized costs increased with duration of documented RA up to four years after first known date of diagnosis: in 2006, costs increased from $5,508 ($9,299) in patients with duration up to one year to $8,653 ($14,423) for patients with duration up to four years. Prevalent RA patients compared to the non-RA group had higher rates of cardiovascular disease (20% vs 14%), anemia (29% vs 15%) and infections (91% vs 84%) and greater total medical costs from 2005-Sept/2008 ($15,276 ($18,683) vs $5,753 ($10,642)); costs in all categories (medications, OP, IP, ER, lab, imaging) were greater in the RA cohort, especially medication [$7,128 ($9,633) vs $1,499 ($3,299)].

Conclusion: Medications accounted for the highest proportion of direct costs in incident RA patients and costs for those prescribed biologics were an order of magnitude higher than those receiving conventional DMARDs. Total direct costs increased with duration of disease in established RA patients up to at least four years post-diagnosis. RA is an expensive disease due, in large part, to medication costs.

917

Healthcare Utilization of Patients with Systemic Lupus Erythematosus In a U.S. Medicaid Population. Xue Song[1], Hong Kan[2], Barbara H. Johnson[3], Benno Bechtel[4], Donna O'Sullivan[3] and Charles T. Molta[5]. [1]Thomson Reuters, Cambridge, MA, [2]GlaxoSmithKline, Research Triangle Park, NC, [3]Thomson Reuters, Washington, DC, [4]GlaxoSmithKline, Munich, Germany, [5]GlaxoSmithKline, Philadelphia, PA

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that requires extensive medical treatment and healthcare utilization. This study examines healthcare utilization associated with SLE in a Medicaid population in the U.S.

Methods: Patients ≥18 years old who had ≥1 inpatient or ≥2 outpatient diagnostic codes for SLE (ICD-9-CM 710.0x) ≥30 days apart but within 2 years were extracted from the Thomson Reuters MarketScan® Medicaid Multi-State Database 2002–2009. Proportion of Medicaid enrollees with SLE diagnosis in 2005 was estimated. For the healthcare utilization analysis, index date was the date of the first SLE diagnosis. Patients without SLE were matched to patients with SLE separately in each Medicaid state using demographic (age, gender, race, Medicare dual eligibility, Medicaid basis of eligiblity, health plan type, index year) and clinical chracteristics (Charlson comorbidity index, comorbidities) as matching factors. All patients had at least 6-month continuous enrollment prior to (baseline) and 12-month continuous enrollment post (follow up period) the index date. Patients were followed from index date to inpatient death, end of continuous enrollment, or end of study period (12/31/2009), whichever came first. Annualized healthcare utilization was assessed during the follow up period. Logistic and generalized linear models (GLM) were used to adjust for any remaining inbalances on patient demographic and clinical characteristics between the matched SLE and non-SLE cohorts to estimate incremental healthcare utilization associated with SLE.

Results: In 2005, 251 per 100,000 Medicaid enrollees had SLE diagnosis, with the highest rates in women aged 35–64 and African Americans. For the healthcare utilization analysis, a total of 14,777 SLE patients met the study criteria, and 14,262 were matched to non-SLE patients, with a mean age of 45 years, 92.6% women and 36.1% African Americans. Compared with matched controls, SLE patients were more likely to have inpatient admissions (59.3% vs. 39.6%) and emergency room (ER) visits (78.5% vs. 67.5%), had more physician office visits (9.8 vs. 6.4), more hospital outpatient visits (3.3 vs. 2.2), and more outpatient other services (69.7 vs. 56.8) per year ($p<0.001$ in all cases). Logistic regressions estimated an odds ratio of 2.6 for having at least one inpatient admission and 2.0 for having at least one ER visit per year for SLE patients relative to their controls. After GLM model adjustment, SLE patients had 0.3 more inpatient admissions, 0.7 more ER visits, 3.5 more physician office visits, 1.2 more hospital outpatient visits, and 15.9 more outpatient other services per year than their matched controls ($p<0.001$ in all cases). Multivariate adjusted healthcare utiliza-

tion varied significantly across the different Medicaid states included in the database.

Conclusion: This study estimated that SLE patients had significantly higher healthcare resource utilization than their matched non-SLE controls. Further research is needed to understand the potential impact of SLE treatment on healthcare resource use in the Medicaid population.

Economic Burden of Psoriatic Arthritis and Diabetes in Patients with Psoriatic Arthritis in the United States. Annie Guerin[1], Genevieve Gauthier[1], Robert Day[2], Zeba Khan[2] and Frank Zhang[2]. [1]Analysis Group, Inc., Montreal, QC, [2]Celgene Corporation, Summit, NJ

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthropathy characterized by arthritis and psoriasis. Recently, PsA was reported has a disease with a high prevalence of diabetes. This retrospective study aimed to estimate the incremental costs of having both PsA and diabetes.

Methods: Adult patients with PsA (i.e., ≥2 claims with a diagnosis for PsA ICD-9 codes: 696.0) were selected from a US administrative claims database (2004–2008). PsA-free controls (i.e., no PsA or psoriasis (ICD-9 code 696.1) during the observation period) were matched to each PsA patient by age and gender in a 1:1 ratio. To capture patients at all stages of PsA, the index date was selected from all the dates of health services coded with a diagnosis of PsA in the database. Claims histories were followed for one year after the index date to assess healthcare resource utilization and to estimate associated costs (USD 2010) from a third-party payer perspective. Annual incidence rate (IR) differences and incremental total direct costs associated with both PsA and diabetes (ICD-9 codes 250.xx) versus each condition individually were estimated using multivariate Poisson regression models and generalized linear models, respectively.

Results: A total of 21,332 matched pairs were studied. Among PsA patients, 19% had diabetes compared to 13% of the PsA-free controls ($p<.01$). Among PsA patients, diabetic patients had on average 32 more urgent care visits (i.e., hospitalization and emergency room visits) per 100 patient-years than patients without diabetes (unadjusted IR: 78 vs. 40; $p<.01$). Among PsA-free patients, diabetic patients had on average 25 more urgent care visits per 100 patient-years than non-diabetic patients (unadjusted IR: 56 vs. 26; $p<.01$). Thus, patients with both PsA and diabetes had on average 7 more urgent care visits per 100 patient-years (unadjusted IR: 32 vs. 25; $p<.04$) when compared to patients with diabetes only. Among PsA patients, diabetes presented a $8,118 adjusted incremental cost when compared to the non-diabetic patients ($28,137 vs. $18,309; $p<.01$). Among PsA-free patients, diabetes presented a $6,441 adjusted incremental cost when compared to the non-diabetic patients ($13,350 vs. $5,280; $p<.01$). Thus, having both PsA and diabetes resulted in a higher $1,677 adjusted incremental cost ($8,118 vs. $6,441; $p<.03$) compared to diabetes only.

Conclusion: The incremental economic burden of patients having both PsA and diabetes is significantly higher than each condition individually. This could potentially be explained by the complexity of managing both conditions at the same time, however further investigations are warranted to confirm this assumption.

920

Economic Burden of Psoriatic Arthritis and Obesity in Patients with Psoriatic Arthritis in the United States. Frank Zhang[1], Annie Guerin[2], Dominick Latremouille-Viau[2], Robert Day[1] and Zeba Khan[1]. [1]Celgene Corporation, Summit,, NJ, [2]Analysis Group, Inc., Montreal, QC

Background/Purpose: Psoriatic arthritis (PsA), a chronic inflammatory arthropathy characterized by arthritis and psoriasis, has been associated with a high prevalence of obesity. This retrospective study aimed to estimate the incremental costs of having both PsA and obesity versus each condition individually.

Methods: Adult patients with PsA (i.e., ≥2 claims with a diagnosis for PsA ICD-9 codes: 696.0) were identified in a large US administrative claims database (2004–2008). One PsA-free control (i.e., no claims with a diagnosis of PsA or psoriasis (ICD-9 code 696.1) from 2004 to 2008) was matched to each PsA patient on the basis of age and gender. Obesity was defined based on patients' reported body mass index (BMI≥30). To capture patients at all stages of PsA, the index date was selected from all the dates of health services coded with a diagnosis of PsA in the database Claims histories were followed for one year after the index date to assess their healthcare costs (USD 2010), measured from a third-party payer perspective. Annual incremental total direct costs associated with both psoriasis and obesity versus each condition individually were estimated using multivariate generalized linear models (GLM) with random effect to account for matched pairs.

Results: A total of 426 matched pairs with reported BMI were studied. Among PsA patients, 41% were obese compared to 29% of the PsA-free controls ($p<0.01$). Among obese patients, PsA presented a $15,891 adjusted

incremental cost when compared to the PsA-free patients ($22,772 vs. $6,660; p<0.01). In the group of non-obese patients, PsA presented a $12,883 adjusted incremental cost when compared to the non-diabetic patients ($17,784 vs. $4,403; p<0.01). Among PsA patients, obesity was associated with a $4,361 adjusted incremental cost when compared to the non-obese patients ($22,772 vs. $17,784; p<0.02). In the group of PsA-free patients, obesity was associated with a $1,353 adjusted incremental cost when compared to the non-obese patients ($6,660 vs. $4,403; p<0.01). The difference associated with having both PsA and obesity versus each condition individually ($15,891 vs. $12,883 and $4,361 vs. $1,353; p=0.17) was not statistically significant.

Conclusion: PsA patients have a higher prevalence of obesity when compared to PsA-free patients. Both PsA and obesity were associated with significant incremental healthcare costs. Consequently, there may be some benefits of closely managing patients with both PsA and obesity.

921

Musculoskeletal Corticosteroid and Local Anesthetic Injections; A Survey of Practice Patterns Among Members of the American College of Rheumatology. Leah Alon[1], Nina Ramessar[1], Jenny Cabas-Vargas[2], Dimitre Stefanov[1] and Deana M. Lazaro[3]. [1]SUNY Downstate Medical Center, Brooklyn, NY, [2]SUNY Downstate, Brooklyn, NY, [3]Brooklyn VA, Brooklyn, NY

Background/Purpose: Corticosteroid and lidocaine injections into joints, bursae, tendon sheaths and trigger points are performed by rheumatologists and other practitioners. There is little evidence-based medicine for guidance on techniques, choice of injectable medications and on possible adverse effects. Most practice is based upon local standards of care. We undertook a descriptive study on the current practice patterns among members of the American College of Rheumatology (ACR). We hypothesized that corticosteroid and local anesthetic injection techniques will depend upon experience of the physician and type of practice.

Methods: We conducted an email survey of members of the ACR regarding corticosteroid and local anesthetic injection techniques. An email list was compiled from the 2010 ACR Directory. All members were included and all names in the first five pages of each alphabetical letter from the directory were chosen for the survey. Surveys were sent to 2616 members of the ACR with 275 responses (10.5% response rate). Respondents were asked about consent, frequency of injections, types and amounts of medication used, and complications experienced.

Results: Physicians who answered the survey included 64% males, 46% in private practice, and 41% in academic medicine. Forty-five percent indicated that they perform 2–15 injections per month, and 46% perform >15 injections monthly. The most common indications for the injections were rheumatoid arthritis, osteoarthritis, bursitis, tendonitis, gout, pseudogout and trigger finger. Most respondents use aseptic technique to prepare the area of injection. Written consent rate was 22% higher in academic/government practice group when compared to private practice (p<.001). Fifty-two percent perform a time out procedure and this was also more common in academic practice (p=.03). The most commonly used corticosteroid medications were methylprednisolone (47%), triamcinolone acetonide (26%) and triamcinolone hexacetonide (23%). Most respondents reported that they use an equivalent of 40mg prednisone to inject large joints, 20mg prednisone equivalent dose for intermediate structures, and 10mg for smaller structures. When injection technique was analyzed by years in practice (<5 years of practice, 5–20 years, >20 years) more experienced clinicians tend to use lower doses of corticosteroids for shoulder injections (p=0.003) and knee injections (p=0.02). Most respondents indicated that they wait 2–4 months before repeating an injection to the same anatomic structure, with a frequency of 3–4 injections per year for large joints and 1–2 injections per year for smaller structures. The most common adverse effects, reported in 1–10% of cases, were painful injection (45%) and elevated serum glucose (37%). In <1% of cases, fat atrophy (58% reported), skin discoloration (57%), bruising (43%), and infection (19%) were noted.

Conclusion: Corticosteroid injections were considered safe and well-tolerated by the physicians we surveyed. Although there are no official guidelines for corticosteroid injection, we found good agreement on the dose of steroid used and frequency of injections. There are some differences in practice based upon experience and practice type.

922

Cost Per Placebo Adjusted Response of Golimumab, Adalimumab, and Etanercept in Patients with Active Ankylosing Spondylitis. Atul Deodhar[1], J. Braun[2], R. D. Inman[3], Désirée van der Heijde[4], Benjamin Hsu[5], Neeta Tandon[6] and Chenglong Han[7]. [1]Oregon Health & Science University, Portland, OR, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]The Arthritis Program, Toronto Western Hospital and Division of Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, [4]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [5]Centocor R&D, a division of J&J Pharmaceutical R& D, LLC/Univ. of Pennsylvania, Malvern/Philadelphia, PA, [6]Janssen Services, LLC, Horsham, PA, [7]Janssen Services, LLC, Malvern, PA

Background/Purpose: Golimumab (GLM) is a once monthly subcutaneous (SC) human anti-tumor necrosis factor treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA). This study compares cost-per-placebo adjusted response of 3 SC anti-TNF biologic therapies: GLM, adalimumab (ADA), and etanercept (ETN) in pts with active AS.

Methods: Proportion of pts achieving at least 20% improvement in the Assessment in Ankylosing Spondylitis (ASAS) response criteria (ASAS20) were obtained from pivotal phase III clinical trials for GLM[1], ADA[2] and ETN[3]. The pt populations were similar at baseline in these clinical studies in terms of inclusion criteria, disease severity and treatment histories. Wk24 was the common time point for all three trials. In addition, efficacy at wk12 in studies of ADA and ETN, and at wk14 in the GLM study were used for the wk14 cost-efficacy analysis. Dosing was assumed to be per labeled indication in AS (GLM 50mg, monthly; ADA 40mg every other week and ETN 50mg weekly). US wholesale acquisition cost (WAC) as of May 2011 was used for calculating drug costs.

Results: At wk12–14, the placebo adjusted ASAS20 response rate (active treatment minus placebo) was 38%, 37% and 31% for GLM, ADA and ETN, respectively. The cost-per-placebo adjusted ASAS20 responder for 14-wks of therapy was $15,442, $16,958 and $19,295, for GLM, ADA and ETN, respectively. At wk24, the placebo adjusted ASAS20 response rate was 33%, 32% and 35%, and the cost-per-placebo adjusted ASAS20 responder for 24-wks therapy was $30,484, $33,613 and $29,296 for GLM, ADA and ETN, respectively.

Conclusion: The cost-per-placebo adjusted response analysis from 3 SC anti-TNF biologics for AS across three different trials demonstrated similar results. This must be interpreted given the limitations of cross-study comparisons and of potential inter-study differences. The cost-effectiveness in clinical practice will depend on the actual dose used, and actual effectiveness achieved; which may also depend on other factors such as compliance persistency, convenience, dose intervals and tolerability.

The "Table-1 p Value" Issue; Baseline Group Comparison Is Inappropriately Omitted in Non-Randomized Studies. Koray Tascilar, Emine Atac, Fehim Esen and Hasan Yazici. Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background/Purpose: Guidelines on reporting randomized controlled trials advise against performing baseline comparison in randomized groups (1). Such comparison is considered futile as any difference will be by chance by definition (2). In non-randomized studies, on the contrary, the baseline characteristics of the study groups should be compared because the differences may have direct implications on the results. The aim of this study was to determine the frequency of inappropriate commission or omission of baseline comparisons in randomized and non-randomized studies, respectively.

Methods: A PubMed search was conducted to identify clinical studies among human, designed to test the effect of a treatment or an observation

in more than one group Annals of the Rheumatic Diseases, Arthritis and Rheumatism and Rheumatology (Oxford) from January 2010 to June 2011 were searched. Studies were grouped as either randomized or non-randomized. We evaluated each study as to how the baseline characteristics were presented. Also the frequencies of inappropriate commission or omission of statistical comparisons were tabulated.

Results: 205 studies were found, 107 were included. There were 60 randomized trials and 47 non-randomized studies. Among the randomized studies, 6/60 (10%) reported inappropriate baseline statistical comparisons. On the other hand among the non-randomized studies, 27/47 (57%) omitted baseline statistical comparison. In 10 of these 27 studies, there was no table presenting the characteristics of the groups subject to comparison. 17 studies on the other hand presented baseline groups in a table 1 but did no statistical comparisons although necessary.

Conclusion: The CONSORT statement seems to be better adhered to when reporting randomized controlled trials. On the other hand there is common and inappropriate omission of the necessary statistical comparisons at baseline in non-randomized studies. In this line there's an obvious need to improve adherence to the TREND statement (3).

Seasonal Variation in Mortality of Six Rheumatic Diseases in Hong Kong, China: An Analysis of 2772 Deaths. Chi Hung To, Ka Lung Yu and Chi Chiu Mok. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To examine the seasonal variation in the mortality of 6 groups of patients with different rheumatic diseases in Hong Kong and its relationship with weather parameters.

Methods: All patients with a diagnosis of systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), systemic vasculitis (SV), or systemic sclerosis (SSc) who died between 2000 and 2008 in public hospitals in Hong Kong were studied. The date of death was retrieved by using the Clinical Data Analysis and Reporting System (CDARS) in public hospitals. The monthly death rates in each calendar month from 2000 to 2008 were calculated for patients with each of these rheumatic diseases by using the total number of patients registered in the CDARS with the corresponding rheumatic disease in each calendar year, inclusive of those who attended our out-patient clinics and all hospital admissions. The monthly death rates of all and individual rheumatic disease were correlated by Pearson's correlation method with a number of weather parameters which included mean maximum temperature, relative humidity, rainfall, duration of sunshine and mean ultraviolet light intensity index in the corresponding month (data retrieved from the web page of the Royal Observatory of Hong Kong).

Results: Between 2000 and 2008, a total of 2772 deaths (493 SLE, 1620 RA, 186 AS, 50 PsA, 314 SV, 109 SSc) were recorded in our system. For all these deaths with different rheumatic diseases, the mean monthly mortality rates varied between 9.88 ± 4.3 and 15.61 ± 6.1 per 1000 patient-month from January to December. The monthly mortality rate was higher in winter and spring seasons (ranged from 13.28 ± 5.1 to 15.61 ± 6.1 per 1000 patient-month from November to April) compared to summer and autumn seasons (ranged from 9.88 ± 4.3 to 12.87 ± 2.8 per 1000 patient-month from May to October), and the difference was statistically significant when the death rate of October was compared to March and November ($p=0.035$ and $p=0.034$ respectively). There was a significant negative correlation between the monthly death rates of patients with all these rheumatic diseases and the mean monthly temperature ($r=-0.022$, $p=0.02$) but no significant correlation could be found with other weather parameters. In the analysis of individual rheumatic disease, only the mortality rate of RA had a significant correlation to weather parameters, but not the other rheumatic diseases (SLE, AS, PsA, SV, SSc). The monthly death rate of RA was negatively correlated to the mean monthly maximum temperature ($r=-0.25$, $p=0.01$), total monthly rainfall ($r=-0.21$, $p=0.33$), and mean ultraviolet light intensity index ($r=-0.19$, $p=0.04$) but not correlated to the mean monthly relative humidity ($r=-0.06$, $p=0.51$) and total duration of sunshine ($r=-0.108$, $p=0.26$).

Conclusion: Seasonal variation of mortality of the 6 rheumatic diseases exists. Deaths were more common in the seasons of winter and spring compared to summer and autumn. Particularly for patients with RA, an increase in infection and cardiovascular diseases might have been contributed to increased mortality in winter months but which remains to be confirmed in further studies.

Milnacipran Improves Health Outcomes in Fibromyalgia Patients Who Have Had An Inadequate Response to Duloxetine Treatment As Measured by PROMIS Computer Adaptive Testing. Steven I. Blum, Stavros Tourkodimitris and Allan Spera. Forest Research Institute, Jersey City, NJ

Background/Purpose: This study sought to evaluate whether fibromyalgia (FM) patients who failed to achieve adequate treatment response to duloxetine (DLX) for FM would show improvement in health outcomes following a direct switch to milnacipran (MLN) treatment. Outcomes were measured using four different PROMIS® computer adaptive testing (CAT) instruments. PROMIS is a National Institutes of Health (NIH) funded initiative to develop new self-reported health measures using modern measurement tools like item response theory, item banking and CAT. PROMIS instruments can be used across a wide variety of chronic diseases/conditions and in the general population.

Methods: Patients with FM were eligible for this study if they were currently receiving a stable dosage of DLX (60 mg/d) for ≥4 weeks prior to screening. Following 2 additional weeks of open-label treatment with DLX 60 mg/d, patients that were not fully satisfied with DLX and had a 1-week recall VAS pain score ≥40 (range, 0–100 mm) were randomized 4:1 to receive double-blind MLN 100 mg/d (n=86) or placebo (PBO, n=21) treatment for 10 weeks. The purpose of the small PBO group was to minimize expectation bias rather than provide a comparator arm, since patients would be discontinuing a treatment that may have been partially efficacious. PROMIS CAT assessments, based on version 1.0 Item Banks (www.nihpromis.org) for Fatigue (F), Physical Function (PF), Satisfaction with Discretionary Social Activity (DSA), and Wake Disturbance (WD) were administered via Assessment Center™, an online system developed by PROMIS. The PROMIS CAT T-Score metric has a population norm of 50 and each 10 points in either direction represents 1 standard deviation (SD). Higher scores for F and WD and lower scores for PF and DSA indicate greater impairment. Mean change (using LOCF) from baseline in each domain T-Score was evaluated by a one-sample two-sided t-test comparing the difference to zero.

Results: For patients who were switched from DLX to MLN, baseline PROMIS CAT mean T-Scores were more than 1 SD from the population norm for F (mean=65.5; SD=5.8; range=[46.0,77.7]), PF (36.5 ± 4.7; [23.5,54.3]) and WD (63.6 ± 7.1; [37.2,76.0]), and within 1 SD for DSA (41.3 ± 7.6; [26.8,68.9]), despite at least 6 weeks of DLX treatment. Following a direct switch from DLX to MLN, patients demonstrated improvements at week 10 in each PROMIS CAT domain. MLN patients had significant reductions in F (-3.2 ± 9.8, $p=0.0067$) and WD (-2.8 ± 9.2, $p=0.0106$) and nonsignificant gains in PF (1.2 ± 6.2) and DSA (1.0 ± 10.8). Patients who discontinued active treatment with DLX and switched to PBO, had nonsignificant reductions in F (-0.4 ± 9.0), PF (-0.1 ± 4.7) and DSA (-1.5 ± 6.8), and increases in WD (0.5 ± 6.3).

Conclusion: Among patients who received an inadequate response to DLX treatment for FM, switching to MLN may improve health outcomes as measured by PROMIS CAT. Patients switched to MLN experienced improvements in each PROMIS domain (fatigue, physical function, social satisfaction, and sleep-related impairment) measured. To our knowledge, this is one of the first clinical trials to have used PROMIS CAT in assessing drug efficacy. Additional research is needed to further validate the use of PROMIS CAT and assess the clinical relevance of these results.

The Frequency of Fibromyalgia Syndrome and the Quality of Life in Patients with Periton Dialysis. Muyesser Okumus, Hulya Parpucu, Seher Kocaoglu, Esma Ceceli, Pinar Borman and Murat Duranay. Ministry of Health Ankara Education and Training Hospital, Ankara, Turkey

Background/Purpose: Fibromyalgia syndrome (FMS) is characterized by chronic widespread pain, fatigue, and sleep disturbances. As musculoskeletal pain is regarded as the most prevalent form of chronic pain in chronic kidney diseases, a differential diagnosis of FMS should be considered in that group of patients. The aim of this study was to determine the frequency of FMS in patients on periton dialysis (PD) and to investigate its impact on the quality of life of that population.

Methods: A hundred and twenty four patients with end stage renal disease who had undergone PD 4 or 5 times daily, and a control group of 54 age and sex-matched healthy volunteers were included to the study. Demographic characteristics of the subjects including age, sex, disease and dialysis durations were recorded. The associated symptoms including fatigue, morning stiffness, headache, irritable bowel syndrome, sleep disturbance, depression, anxiety, raynaud phenomen, restless leg syndrome, and paraesthesia of subjects were evaluated. Fibromyalgia Impact Questionnaire (FIQ) was used to measure the components of health status of the PD patients and controls. The quality of life of all subjects was assessed by Nottingham Health Profile (NHP).

Results: The mean age of the patients (68 female, 56 male) and control subjects (36 female 18 male) were 43.5±13.4 and 41.2±9.2 years respectively. The mean duration of PD was 34.3±29.8 months. The prevalence of FMS in the PD patients and controls were determined as 9.7% (12 patients) and 11.1% (6 controls) respectively and were found to be similar ($p=0.983$). The frequency of restless leg syndrome, anxiety and paraesthesia were found to be more common in PD patients with FMS, than in the control group with FMS. The mean FIQ and social subgroup of NHP scores in the PD group with FMS were significantly higher than, in the control group with FMS ($p<0.000$ and $p=0.043$ respectively). Except the social subgroup of NHP, the scores of all the subgroups and the mean FIQ levels were significantly higher than in PD patients with FMS than those without FMS. FMS related clinical features such as fatigue, morning stiffness, headache and restless leg syndrome were found to be significantly more common in the PD patients with FMS than in those without FMS.

Conclusion: In conclusion although the prevalence of FMS appears to be similar in PD patients and control subjects, the frequencies of associated symptoms are higher in PD patients. The functional disability is common and quality of life is worse in PD patients with FM than in patients without FMS. Fibromyalgia symptoms are suggested to be evaluated in patients receiving dialysis, in order to increase the quality of life of the patients suffering from this chronic condition.

927

Correlates of Word Finding Deficits in Fibromyalgia. Robert S. Katz and Frank Leavitt. Rush University Medical Center, Chicago, IL

Background/Purpose: Fibromyalgia (FMS) is associated with deficits in three different language retrieval skills; word finding ability, word naming speed, and letter-cued word generation proficiency. The purpose of this study is to determine if difficulty retrieving the appropriate words to convey the intended message in a natural manner is related to language retrieval skills involving word naming speed and letter-cued word generation.

Methods: A word naming speed measure (Stroop Color and Word Test) and a letter-cued word generation measure (Controlled Oral Word Association Test) were administered to 120 patients with fibromyalgia, 80 with word finding problems and 40 without. The FMS patients were female, met ACR criteria for FMS and had memory problems for a duration of at least six months.

Results: The fibromyalgia samples with and without word finding difficulty did not differ in age (46.3±11.6 versus 47.7±11.5), education (14.6 ±2.2 versus 14.8±2.4), vocabulary subscale score (11.1±2.5 versus 10.9±2.4) or Beck Depression score (16.2±8.1 versus 16.0 ± 7.4). Naming speed was significantly slower in the FMS group reporting word finding difficulty. The word finding sample read 86.5 words in 45 seconds or 520 milliseconds per word. The FMS sample without word finding difficulty read 97.2 words in 45 seconds or 463 milliseconds. The word finding sample was 57 milliseconds slower. Letter cued word generation did not differ for the two groups (word finding: 35.9±11.3 versus 38.0±11.1 for letters F, A and S over 180 seconds).

Conclusion: The findings support a role for naming speed deficiency in discourse fluency, but not for letter fluency. People with word finding difficulty name words at a slower speed than those without word finding difficulty. Slow naming speed likely reflects time delays in accessing the mental lexicon. Lags in speed in the magnitude of 57 milliseconds may disrupt the normal flow of information along connecting routes of the language retrieval network.

928

Carpal Tunnel Syndrome in Fibromyalgia: Evidence of a Subclinical Neuropathy? Robert S. Katz[1] and Bhagwan Shahani[2]. [1]Rush University Medical Center, Chicago, IL, [2]University of Chicago Hospital, Chicago

Background/Purpose: Fibromyalgia may be associated with central pain processing abnormalities, including central sensitization. However, peripheral mechanisms in muscles and nerves have not been excluded as possible sources of pain in fibromyalgia. We describe 22 patients who on EMG testing were found to have unilateral or bilateral carpal tunnel syndrome.

Methods: Sixty-seven patients with fibromyalgia who complained of paresthesias, as well as widespread pain, were assessed by EMG testing for peripheral neuropathy, entrapment neuropathy, and radiculopathy. Detailed electrphysiological studies including motor and sensory nerve conduction as well as late response studies were performed using a TECA EMG machine.

Results: 67 fibromyalgia syndrome patients had an EMG because of pain and paresthesias. 22 patients with fibromyalgia were found to have carpal tunnel syndrome. 13 had bilateral carpal tunnel and 9 had unilateral carpal tunnel syndrome based on electrophysiological studies.

Conclusion: Almost one third of the fibromyalgia patients tested were found to have carpal tunnel syndrome. Frequently, carpal tunnel syndrome was bilateral in these patients. Carpal tunnel syndrome in patients with fibromyalgia could represent a subclinical peripheral neuropathy, thereby possibly implicating peripheral nerves in addition to central pain processing as causes for the pain and paresthesias in patients with the fibromyalgia syndrome.

Designing a Fibromyalgia Screening Questionnaire for Primary Care Settings. Robert S. Katz[1], Alexandra Small[2], Lauren Kwan[3], Patricia Kuenzi[1] and Jessica L. Polyak[3]. [1]Rush University Medical Center, Chicago, IL, [2]University of Illinois Medical School, [3]Rheumatology Associates, Chicago, IL

Background/Purpose: The diagnosis of fibromyalgia can be complicated for non-rheumatologists.The purpose of this study is to develop a screening tool that can be employed in the primary care setting.

Methods: 125 patients with various rheumatic diseases answered a rheumatology office questionnaire that included questions about pain location, pain words, and a human-figure diagram. Pain words, based on the McGill Pain Questionnaire, were divided into those that were thought to be more likely associated with FMS, and included stabbing, exhausting, unbearable, squeezing, gnawing, numb, shooting, pricking, burning, penetrating, miserable, and radiating. Words associated with arthritis, but not with FMS, were thought to be aching and dull. Words that might be associated with either condition were sharp, nagging, throbbing, tender, tiring, cramping, and deep. An assumption was made that patients circling wide areas on a pain diagram or checking both many peripheral joints and spine locations on a list of pain regions were more likely to have FMS. An attempt was made to determine whether pain words alone, pain location alone, the pain diagram, or a combination of these, was most helpful in the diagnosis of FMS.

Results: A rheumatology health care professional was able to diagnosis FMS correctly in 118 of 125 (94%) patients using pain words, pain location, and the human diagram together. 52 of 61 (85%) fibromyalgia patients could be identified correctly using only fibromyalgia pain words. The diagnosis of FMS was made in 47 of 61 (77%) patients evaluating the human-figure diagram alone...A non-rheumatology health care professionals was able to correctly identify 52 of 61 (85%) of FMS patients when using all three components of this screening tool. Using only using pain words, they were able to diagnosis 45 of 61 (74%) FMS patients correctly.

The most effective method for the diagnosis of FMS was combining these three assessments: pain location from a checklist, pain word descriptors, and a human diagram.

Conclusion: A screening questionnaire can be devised using specific pain words, pain locations and a human figure diagram that could be used in population studies and screening in primary care offices and also in schools, health fairs, pharmacies and other locations to identify patients who need further evaluation for possible FMS.

The Effectiveness of Long-Term and Short-Term Interdisciplinary Treatment Approaches in Female Patients with Fibromyalgia. Ilknur Saral[1], Dilsad Sindel[1], Ozlem S. Berk[2] and Sina Esmaeilzadeh[1]. [1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Istanbul University, Faculty of Letters, Istanbul, Turkey

Background/Purpose: The aim of this study is to determine the effectiveness of long-term and short-term interdisciplinary treatment approaches on reducing the symptoms, improving the quality of life and physical functioning in patients with Fibromyalgia (FM) in comparison to control

group, as well as to evaluate the advantage of each interdisciplinary treatment over another.

Methods: We conducted a prospective, randomized and controlled trial involving 66 female patients with FM and randomized to long-term interdisciplinary treatment group (UDG, n=22) which consisted of ten sessions of cognitive-behavioral treatment (CBT) and all-day of exercise and educational programs, short-term interdisciplinary treatment group (KDG, n=19) which consisted of educational, exercise and CBT programs in two days and control group (KG, n=19). Patients were evaluated by the Visual Analogue Scale (pain, fatigue and sleep), Fibromyalgia Impact Questionnaire, Beck Depression Inventory, Short Form-36 Questionnaire, total tender point score and a pressure algometer at baseline, 3 and 6-month follow up after the treatment. Statistical tests were conducted at the 0.05 significance level for all outcome measures.

Results: The mean age of the patients was 41.66±10.25 years. We found that the long-term and short-term treatments were effective on reducing the severity of pain and the number of tender points, increasing the level of pain threshold ($p<0.001$) and improving the physical functioning ($p<0.05$). There was no evidence that the approaches have efficacy on decreasing the level of depression, reducing the fatigue and improving the quality of sleep and quality of life ($p>0.05$). When the efficacy of the long-term and short-term interdisciplinary treatments was compared to each other, there was no significant difference between two groups.

Conclusion: The long-term and short-term interdisciplinary treatments were determined to be effective on reducing the severity of symptoms and activity of disease in patients with FM. Further research should include studies with more participants, longer follow up durations and interventions that intend to decrease the level of depression and improve the quality of sleep.

931

Continuing Efficacy of Milnacipran Demonstrated After Long-Term Treatment of Fibromyalgia. Daniel J. Clauw[1], Philip J. Mease[2], Yimin Ma[3], Arlene Baldecchi[3], Robert H. Palmer[3] and Joel M. Trugman[3]. [1]University of Michigan, Ann Arbor, MI, [2]Seattle Rheumatology Associates and Swedish Medical Center, Seattle, WA, [3]Forest Research Institute, Jersey City, NJ

Background/Purpose: The efficacy of milnacipran for the management of pain, fatigue, and other fibromyalgia (FM) symptoms has been demonstrated in several 3- to 6-month double-blind (DB), placebo-controlled trials and in 6- to 9-month DB dose-controlled extension studies. Patients from these studies who were enrolled in a long-term open-label (OL) study of milnacipran (up to 3.25 years) were eligible for participation in this 17-week, multicenter, DB, placebo-controlled discontinuation study. This study was designed to evaluate the effect of discontinuation of long-term milnacipran treatment on the symptoms of FM.

Methods: Patients were enrolled and treated with OL milnacipran (up to 200 mg/day) for 4 weeks at the same dose as in the prior OL study. At the end of this 4 week period, patients taking milnacipran ≥100 mg/day and achieving a ≥50% reduction in visual analog scale (VAS) pain score from pre-milnacipran exposure to current status were randomized 2:1 to DB treatment with milnacipran (ie, milnacipran continued) or placebo (ie, milnacipran withdrawn) for 12 weeks. The primary efficacy parameter was the time to loss of therapeutic response (LTR), defined as an increase in VAS pain score to <30% reduction from pre-milnacipran exposure or a worsening of FM requiring an alternative treatment. Time to LTR was analyzed using Kaplan-Meier estimates and the log-rank test. Additional efficacy parameters included changes from baseline (randomization visit) in VAS pain and Brief Pain Inventory (BPI) scores.

Results: Time to LTR was significantly shorter for patients treated with placebo (ie, milnacipran withdrawn, n=50) than with milnacipran (ie, milnacipran continued, n=100, $P=.0004$). The median time to LTR was 56 days (95% CI, 28–85) for patients in whom milnacipran was withdrawn and not calculable for patients in whom milnacipran was continued, since half of these patients had not lost therapeutic response by study end. At the end of DB treatment, 64% of patients in whom milnacipran was withdrawn met LTR criteria vs 35% of patients in whom milnacipran was continued. Mean changes from baseline in VAS pain and BPI average pain scores indicated significant worsening at each postbaseline visit ($P<.05$) in patients in whom milnacipran was withdrawn as compared with patients in whom milnacipran was continued. Discontinuation due to treatment-emergent adverse events occurred in 2 milnacipran-treated patients (2.0%) and no placebo-treated patients.

Conclusion: In patients treated with milnacipran for up to 3.25 years, the loss of therapeutic response upon discontinuation of long-term treatment provides evidence of the continuing efficacy of milnacipran as a treatment for FM.

932

The Care Gap in Management of Fibromyalgia: A Needs Assessment Prompting the Development of Clinically Relevant Guidelines for the Diagnosis, Management and Follow-up of Patients. Peter A. Ste-Marie[1], Mary-Ann Fitzcharles[2], Pantelis Panopalis[2], John Pereira[3] and Yoram Shir[2]. [1]University of Montreal, Montreal, QC, [2]McGill University, Montreal, QC, [3]University of Calgary, Calgary, AB

Background/Purpose: Clinicians remain challenged regarding the clinical care of fibromyalgia (FM) patients. Uncertainty may even have been fuelled by publication of the 2010 diagnostic criteria recognizing symptoms beyond pain. The elimination of the tender point examination, a physical finding previously entrenched in this clinical concept, but with uncertain value, the absence of a positive diagnostic test and lack of an ideal treatment further nurtures insecurity. There is understandably a clear need for direction in the diagnosis and care of FM patients. Our objective was to perform a needs assessment for healthcare professionals regarding challenges in the management of these patients, formulate these needs into a battery of questions that could drive a literature search as the first step towards development of clinically useful and applicable guidelines.

Methods: 139 healthcare professionals treating patients with FM from various disciplines including physicians (rheumatologists, family physicians, pain specialists, neurologists, psychiatrists and physiatrists), pharmacists, nurses, and psychologists convened in workshop settings in eight regions of Canada. Following a formal presentation of current concepts in FM, open discussion followed with recording of commentary. Following review of all recorded discussions, a needs assessment was formulated as a series of questions and is presented as a descriptive analysis.

Results: The 4 major domains of clinical challenge were identified: 1. Diagnosis; 2. Knowledge gap; 3. Treatment; 4. Outcome. Highlights of discussions within each group are presented. 1. There is insecurity in making and confirming a diagnosis, often with need for confirmation by a specialist, which might be patient or payer driven. Concerns exist regarding misdiagnosis with resulting excessive investigation. 2. There is generally a poor understanding of pain mechanisms and a perception of a considerable knowledge gap especially for the primary care physician. 3. Treatment choices are confusing in the context of multiple symptoms, and with the perception that pharmacologic treatment recommendations may be largely industry driven. The large volume of often anecdotal literature of treatments options further adds to uncertainty. Non-pharmacologic treatments, although recommended, are often poorly accessible and costly, with limited direction regarding treatment combinations. 4. Ideal follow-up is unknown without guidance regarding monitoring of symptoms, ideal outcome measures and frequency of follow-up visits. Physician biases are emphasized with the perception that FM patients are "difficult", requiring prolonged clinical time, and often demonstrating suboptimal treatment responses.

Conclusion: There exists considerable uncertainty and an important care gap in the understanding, diagnosis and management of FM. Updated clinically applicable and comprehensive guidelines that address these issues are required in order to provide better care for patients with FM.

933

Supporting Evidence for the Clinical Utility of the Pain Subscale of the American College of Rheumatology 2010 Preliminary Diagnostic Criteria for Fibromyalgia. Peter A. Ste-Marie[1], Marc-Olivier Martel[2], Mary-Ann Fitzcharles[2] and Yoram Shir[2]. [1]University of Montreal, Montreal, QC, [2]McGill University, Montreal, QC

Background/Purpose: Understanding and recording the patient's experience of chronic pain is challenging, with no single measurement accepted as the standard. The clinical evaluation of pain may be by narrative report, measurement by pain scales or completion of pain drawings. As persons understand pain differently, specific measures may be subject to variable interpretation and may evaluate different components of pain such as location, intensity or emotional value. Our objective was to examine the agreement between the pain subscale of the ACR 2010

preliminary diagnostic criteria for fibromyalgia (FM), the Widespread Pain Index (WPI), completed as a checkbox, and the Body Map (BM), a drawn report of pain on a manikin, in FM patients. The WPI was also correlated with other measures of pain.

Methods: FM patients currently in a cohort study at a tertiary care multidisciplinary pain centre completed the WPI (total score 19), the BM (total score 50) and other measures of pain including: pain intensity Visual Analog Scale (VAS), McGill Pain Questionnaire (MPQ), Pain Disability Index (PDI) and Pain Catastrophizing Scale (PCS). The manikin was rescored to correspond to the 19 regions used in the WPI. Correlations between the WPI and the newly scored manikin, termed manikin WPI (manWPI), were calculated. Comparisons were made for the total scores as well as for each of the 19 individual regions for the WPI and the manWPI, and both the WPI and manWPI were compared to other pain instruments using Pearson's correlation coefficient.

Results: One hundred and three patients, 97 (94%) females, with a mean age 50±10 yrs and mean Fibromyalgia Impact Questionnaire 60±21 completed all pain instruments at a single routine clinic visit. The correlation coefficients for the WPI vs BM, WPI vs manWPI and manWPI vs. BM were.73,.72 and.90 respectively ($p<0.001$ for all values). Correlation coefficients for each of the 19 individual areas ranged between 0.27 and 0.60, showing overall moderate correlations, with strongest for low back pain and weakest for jaw pain. Other measures of pain similarly showed good correlation with both the WPI and manWPI, with lowest values recorded for PCS (Table 1).

Table 1. Correlation coefficients between the WPI and other pain measures

	WPI	manWPI
Pain VAS	.54**	.46**
MPQ	.50**	.46*
PDI	.57**	.52*
PCS	.36**	.23*

P<0.05*, P<0.001**

Conclusion: The WPI component of the ACR 2010 preliminary diagnostic criteria for FM correlates well with a visual representation of pain as portrayed in a manikin drawing, irrespective of the scoring method, as well as with other measures of pain. In view of this good correlation and taking into account the simplicity of the checkbox format, the WPI can be recommended as a reliable pain measurement for FM.

934

Fibromyalgia Syndrome in the General Population of Israel: A Prevalence Study. Jacob N. Ablin[1], Anat Oren[2], Sarit Cohen[3], Valerie Aloush[1], Ori Elkayam[4], Yonatan Wolman[1] and Mark Berman[1]. [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Tel Aviv University, Tel Aviv, Israel, [3]Carmel Medical Center, Haifa, Israel, [4]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background/Purpose: Fibromyalgia (FMS), a condition traditionally defined by the presence of chronic widespread pain and tenderness, represents the tip of the iceberg of chronic pain in the general population. Estimating the prevalence of FMS is challenging, as many cases go undiagnosed.

We have attempted to estimate the prevalence of FMS in the Israeli population, using the London Fibromyalgia Epidemiology Study Screening Questionnaire (LFESSQ), an instrument previously utilized in several European countries.

Methods: The London Fibromyalgia Epidemiology Study Screening Questionnaire (LFESSQ) is an epidemiological tool recently implemented in a number of European countries for evaluating the prevalence of FMS. The questionnaire includes two components, the LFESSQ-4, screening for widespread pain, and the LFESSQ-6, which screens for both widespread pain and chronic fatigue. The pain criteria include 4 questions regarding musculo – skeletal pain in the upper or lower limbs or in the spine. The LFESSQ-6 adds two fatigue criteria (fatigue and limitation of activity due to fatigue).

The LFESSQ was administered via telephone to a representative sample of 1019 individuals selected by the quota method. A positive screen was defined as: (1) meeting the 4-pain criteria alone (LFESSQ-4), or (2) meeting both the 4-pain and 2-fatigue criteria (LFESSQ-6). To estimate the positive predictive value (PPV) of LFESSQ-4 and LFESSQ-6, this questionnaire was submitted to a sample of consecutive rheumatology outpatients (n=64, 17 males), who were then examined to confirm the diagnosis of FMS according to the 1990 ACR criteria. The prevalence of FMS in the general population was estimated by applying the PPV to eligible community subjects (i.e. positive screens).

Results: In the community survey 5.1% and 3.92% screened positive for LFESSQ-4 and LFESSQ-6, respectively. Among males interviewed, 3.0% and 2.2% screened positive for the LFESSQ-4 and LFESSQ-6, respectively, while among females 7.1% and 5.6% screened positive for the LFESSQ-4 and LFESSQ-6, respectively.

Among rheumatology outpatients, 41.5% screened positive for LFESSQ-4 and 33.8% for LFESSQ-6, whereas 21.5% were confirmed FMS cases. Based on positive screens for LFESSQ-4, the prevalence of FMS was estimated at 2.64% in the Israeli general population. The corresponding figure was 2.49 % if positive screens for LFESSQ-6 were considered. Among males, the prevalence of FMS based on the LFESSQ-4 was 1.55%; based on the LFESSQ-6 the prevalence was 1.4%.

Among females the prevalence based on the LFESSQ-4 was 3.68% and based on the LFESSQ-6 it was 3.56%.

Conclusion: The prevalence of FMS in the Israeli population is considerable, as estimated by the use of the LFESSQ, and constitutes a significant health care issue. The prevalence is similar to that observed in other western populations.

Using the LFESSQ-4 and the LFESSQ-6 yields similar results, but the LEFSSQ-6 appears more accurate, having a higher PPV for an individual meeting ACR criteria for FMS. The LEFSSQ-6 also addresses fatigue, recognized as a central clinical feature of FMS. Based on this tool, over 25% of FMS cases appear to be males, a proportion higher than generally appreciated.

935

Concordance Between Subjective Dry Eye Symptoms and Objective Findings in Fibromyalgia Patients. Marco Antivalle, Michele Battellino, Alberto Batticciotto, Maria Chiara Ditto, Alessandra Mutti. Gabriella Santalena, Valentina Varisco and Piercarlo Sarzi-Puttini, L. Sacco University Hospital, Milano, Italy

Background/Purpose: Dry eye symptoms and signs have been frequently reported in fibromyalgia patients (1,2). However, no study so far has addressed the concordance between subjective symptoms and objective findings in this population. Aim of this study was to assess the concordance between subjective symptoms of dry eye and objective findings in fibromyalgia.

Methods: 52 patients were studied, 23 with fibromyalgia (FM: 20 F, 3 M, mean age 41.57 years, range 20–57) and 29 control subjects affected by miscellaneous rheumatic diseases (Controls: 26 F, 3 M, mean age 42.17 years, range 18–59). All patients completed the questionnaire used in the diagnosis of Sjögren's syndrome (3), and the McMonnies dry eye questionnaire, a 14-item validated questionnaire (4). In all patients Schirmer's I test (ST) was performed, and a result < 5 mm after 5 minutes was defined as positive. The impact of FM was assessed by the Widespread Pain Index (WPI), and by the Symptom Severity score (SS) (5). Statistical methods included chi-square statistic, and non-parametric ANOVA. The relatioship of selected variables on dry eye symptoms was assessed by binary logistic regression.

Results: Antinuclear antibodies (ANA) were positive in 15/52 (28.8%) patients (1 FM, 14 Controls). Schirmer's test was positive in 7/52 (13.5%) patients (FM 2/23 (8.7%); Controls 5/29 (17.2%)). 30/52 (57.7%) patients answered affirmatively to at least one of the three questions related to dry eye of the Sjögren's questionnaire (FM 18/23 (78.3%); Controls 12/29 (41.4%)), including 28 (53.8%) patients with negative ST (FM 16/21 (76.2%); Controls 12/24 (50.0%)) (fig 1). By McMonnies questionnaire, 32/52 (61.5%) patients (FM: 18/23 (78.3%); Controls 14/29 (48.3%)) were classified as having dry eye, including 27 with negative ST (FM 16/21 (76.2%); Controls 11/24 (45.8%)). Logistic regression results showed that for both the Sjogren's questionnaire and the McMonnies questionnaire, dry eye symptoms were correlated to age ($p = 0.003$) and to the presence of FM ($p = 0.004$ and $p = 0.040$ respectively), but not to age, to actual ST result, nor to ANA-positivity. Among FM patients, dry eye symptoms were correlated to higher SS scores (fig 2).

Fig. 1 - Number of affirmative answers to dry eye questionnaire

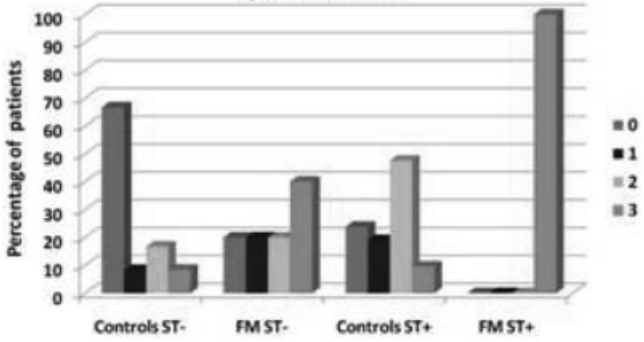

Fig. 2 - Mean WPI and SS score in patients with and without dry eye symptoms

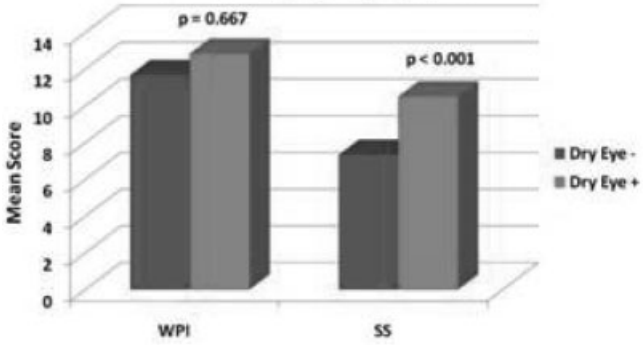

Conclusion: To our knowledge, this is the first study addressing the concordance between subjective symptoms and objective findings in the assessment of dry eye in fibromyalgia. Our results show that in this population, dry eye symptoms are extremely frequent, but are related to the severity of FM symptoms rather than to the results of Schirmer's test.

High Prevalence of Fibromyalgia Symptoms Among Healthy Full Term Pregnant. Sharon Saad, Ariel Many, Giris Jacob and Jacob N. Ablin. Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background/Purpose: Fibromyalgia (FMS), a syndrome characterized by centrally mediated pain, tenderness and fatigue, is more prevalent among females compared with males. The impact of fibromyalgia on the course of pregnancy is not clearly defined. In the current stud we have evaluated the frequency of FMS symptoms among full term healthy pregnant women and the impact of such symptoms on the course of delivery.

Methods: After signing informed consent, participants (N=57) were interviewed and filled out questionnaires. The 2011 modification of the ACR 2010 criteria for the diagnosis of fibromyalgia was used. In addition, participants filled out the Fibromyalgia Impact Questionnaire (FIQ) and the SF-36 and the AIMS questionnaires. Manual dolorimetry was performed using a standard manual dolorimeter, in order to document the 1990 ACR criteria. After delivery, data was collected from the obstetric files relating to the course of the delivery. This data Included documenting the implementation of induction, the length (In minutes) of stage 1,2 and 3 of delivery, the implementation of epidural anesthesia, the need for artificial rupture of membranes (AROM), instrumental delivery and cesarean section. A VAS scale recording pain intensity during delivery was also documented. The study was conducted as an open label, observational research. The setting of the study was the Obstetric clinic of the Tel Aviv Sourasky medical center. Participants were pregnant women attending the obstetric clinic for routine evaluation before birth. This evaluation is generally conducted at week 38 of pregnancy. High risk pregnancies were excluded.

Results: Out of 57 women recruited, 14 (24.6%) fulfilled Modified FMS criteria. This result did not correlate with the 1990 criteria, since none of these individuals fulfilled ACR 1990 criteria. The mean FIQ was 38.5 (SD- 14.5) and the men SF-36 (general health) was 82.3 (SD- 14.2). The mean SF-36 pain was 63.2 (SD- 22.8). A significant negative correlation was observed between the length of stage 3 of delivery and the SF-36 for social functioning (Pearson correlation −0.36, $p<0.05$). The VAS scale of pain during delivery was significantly positively correlated with the SF-36 pain recorded on the examination before delivery (Pearson correlation 0.482, $p=0.05$). Among women not fulfilling FMS criteria, 69.8% required epidural anesthesia. The corresponding figure among individuals fulfilling FMS criteria was 100%.

Conclusion: FMS symptoms were found to be highly prevalent among healthy pregnant women at term. The presence of such symptoms on evaluation before delivery correlated with the severity of pain during delivery and may have an impact on the course of delivery and the need for anesthesia. Evaluating for features of centrally mediated pain may be of clinical relevance for physicians involved in the treatment of pregnant women as well as for obstetricians.

937

Fibromyalgia: Can Online Cognitive Behavioral Therapy Help? Gwendoline Menga[1], Bobby J. Dupre[2], Carl Gauthier[3], William E. Davis[4], Tamika A. Webb-Detiege[5], Eve Scopelitis[3], Jerald M. Zakem[4] and Robert Quinet[6]. [1]Ochsner Clinic Center, New Orleans, LA, [2]Ochsner Health System, Baton Rouge, LA, [3]Ochsner Clinic Foundation, New Orleans, LA, [4]Ochsner Clinic, New Orleans, LA, [5]Ochsner Medical Ctr, New Orleans, LA, [6]Ochsner Medical Center - New Orleans, New Orleans, LA

Background/Purpose: Cognitive behavioral therapy (CBT) has proven useful in the treatment of fibromyalgia, depression, and anxiety. Access to such therapy, though, can be limited. Computerized delivery of cognitive behavioral therapy allows for increased access in a comfortable, worry free environment. The purpose of this study was to assess the effect of Internet- based online CBT on fibromyalgia impact questionnaire composite (FIQ) score and tender point (TP) assessment.

Methods: We conducted a 12 week randomized controlled trial including patients, 18 years of age or older, with ACR criteria for fibromyalgia and mild to moderate depression and anxiety. A total of 56 subjects were randomized into either a 6-week Internet-based CBT program (MoodGYM), or control group (usual care). Patients in both groups were evaluated at baseline and 6 and 12 week follow-up. The primary outcome measure was change in Fibromyalgia Impact Questionnaire composite (FIQ) score. A secondary outcome measure was change in tender point (TP) assessment.

Results: The mean age of study participants was 55 years, 88% female. There were no significant changes in the serial FIQ scores across the 3 time points in either group. However, mean FIQ scores were significantly lower in the MoodGYM group compared to the control. ($p<0.05$ for group differences at 6 and 12 weeks respectively). Mean TP scores were also significantly lower in the MoodGYM group ($p<0.0001$ for group differences at 6 and 12 weeks respectively).

Conclusion: Patients in the Internet-based MoodGYM CBT program had lower FIQ and TP scores at 6 and 12 week follow-ups. Internet-based CBT could be beneficial therapy in the treatment of mild to moderate symptoms of depression and anxiety in patients with fibromyalgia, by allowing for increased access to CBT.

The 2010 American College of Rheumatology Fibromyalgia Survey Diagnostic Criteria and Symptom Severity Scale Is Valid and Reliable in a French Speaking Fibromyalgia Cohort. Peter A. Ste-Marie[1], Pantelis Panopalis[2], Mary-Ann Fitzcharles[2], Henri A. Menard[3], Yoram Shir[2] and Frederick Wolfe[4]. [1]University of Montreal, Montreal, QC, [2]McGill University, Montreal, QC, [3]Montreal General Hospital, Montreal, QC, [4]National Data Bank for Rheumatic Diseases, Wichita, KS

Background/Purpose: There is currently no consensus regarding the ideal measurement to assess symptom severity in fibromyalgia (FM), or to follow patients regarding change in symptoms or outcome. The Fibromyalgia Survey Diagnostic Criteria and Severity Scale (FSDC) is a patient administered questionnaire that assesses both the diagnosis of FM as well as symptom

severity (Wolfe, Clauw et al. 2011). The FSDC assesses the locations of body pain measured by the Widespread Pain Index (WPI), and associated symptom severity (SS) of fatigue, unrefreshed sleep, cognitive complaints and somatic symptoms. The sum of WPI and SS provides a score (0–31), a composite measurement of symptoms termed the fibromyalgianess scale. We have evaluated the reliability and validity of the translated French version of the FSDC in patients with an established diagnosis of fibromyalgia in a tertiary care setting.

Methods: After translation of the FSDC into French, the questionnaire was administered on two occasions within a 1 week period to persons with FM, and the FSDC was correlated with the following commonly used measures of symptom status to test construct validity: the Fibromyalgia Impact Questionnaire (FIQ), Health Assessment Questionnaire (HAQ), McGill Pain Questionnaire (MPQ), and a visual analogue scale (VAS) for global severity and pain. Test-retest reliability was assessed with Pearson's correlation coefficients and internal consistency was evaluated using Cronbach's alpha coefficient. Construct validity was evaluated using the Spearman correlation coefficient.

Results: The study sample consisted of 73 patients, mean age 52±9 years, 67(92%) female, and mean disease duration 12±12 years. Test-retest reliability was between .600 and .888 for the 31 single items of the FSDC, and .912 for the total FSDC, with all correlations significant ($p<0.0001$). Cronbach's alpha was .846 for FSDC assessment 1, and .867 for FSDC assessment 2 indicating good internal consistency. Construct validity showed significant correlations between the FSDC and the FIQ 0.670, HAQ 0.413, MPQ 0.562, global VAS 0.591 and pain VAS 0.663 ($p<0.001$).

Conclusion: The French FSDC is a valid instrument for measuring symptom severity in French patients with FM and showed reliability as well as construct validity with other measures of symptom status in FM. This new scoring questionnaire, which is easily completed by patients and simple to score, has the potential to become the standard for measurement of symptom severity in FM.

The Michigan Body Map and Its Use in Assessing the American College of Rheumatology Survey Criteria for Fibromyalgia. Chad M. Brummett[1], Afton L. Hassett[2], Katherine A. Brummett[1], Daniel J. Clauw[3] and David A. Williams[4]. [1]University of Michigan Health System, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]Univ of MI Hlth System-Lobby M, Ann Arbor, MI

Background/Purpose: Body maps have been used for many years to assess the locations of pain complaints; however, quantifying and analyzing these data have been challenging. The ACR Survey Criteria for Fibromyalgia (FM) includes the assessment of pain in 19 selected body areas associated with rheumatologic complaints. To facilitate collection of the survey-based pain data, we created the Michigan Body Map (MBM). The MBM contains the 19 areas from the Widespread Pain Index (WPI) used to evaluate the FM clinical criteria, plus 16 additional areas for more general use. We present preliminary data using the MBM in combination with the ACR Symptom Severity (SS) scale to create a fibromyalgianess score. The MBM was also correlated with other measures of pain, mood and function and scored either with all 35 sites or those from the WPI.

Methods: 497 new patients presenting to the pain clinic were prospectively phenotyped using validated self-report measures, including the Brief Pain Inventory (BPI), PainDETECT, Hospital Anxiety and Depression Scale (HADS), PROMIS Physical Function Short Form (PROMIS SF1), and SS scale from the ACR Survey Criteria for FM. In addition, patients completed the MBM, which asks patients to check all of the 35 potential body areas in which they have experienced persistent or recurrent pain for 3 months or more on a one sided body image. Included in the MBM are the body regions included in WPI from the ACR FM survey criteria. Data were entered into the APOLO Electronic Data Capture system and analyzed using PASW 18.

Results: Correlations between the ACR Survey Criteria for FM, MBM and WPI are noted in Table 1. Fibromyalgianess correlated well with pain severity, pain interference, neuropathic pain descriptors, depression, and anxiety. It also showed an inverse correlation with positive affect and physical function. Fibromyalgianess was more highly correlated for all measurements when compared with a measure of widespread body pain alone using either the MBM or the WPI from the ACR FM Survey Criteria. The 35-item MBM demonstrated similar or stronger relationships in all measures, except for pain intensity, when compared with the WPI from the ACR FM Survey Criteria.

Table 1.

	ACR Survey Criteria for FM ("Fibromyalgianess")	Michigan Body Map (MBM)	WPI from ACR FM Criteria
BPI Pain Severity	0.363	0.216	0.272
BPI Pain Interference	0.477	0.309	0.283
PainDETECT	0.472	0.417	0.388
HADS Depression	0.436	0.274	0.241
HADS Anxiety	0.510	0.329	0.325
HADS Positive Affect	−0.442	−0.277	−0.248
PROMIS SF1	−0.356	−0.288	−0.256

Pearson Correlation. $p < 0.0001$ for all noted correlations in Table 1.

Conclusion: The MBM allows patients to note areas of chronic pain on a body map in a quantifiable manner. The selection of the body areas noted in the ACR Survey Criteria for FM along with the SS scale can be used to calculate a fibromyalgianess score. Future studies will determine the impact of the additional body areas in the MBM when combined with a symptom assessment.

940

Longitudinal Assessment of Fibromyalgia in Young Adults Previously Diagnosed with Juvenile Fibromyalgia. Tracy V. Ting[1], Daniel Strotman[1], Emily Verkamp[1], Anjali Desai[1], Anne Lynch-Jordan[1], Lesley M. Arnold[2] and Susmita Kashikar-Zuck[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH

Background/Purpose: At present, little is known about the prognosis for children and adolescents diagnosed with Juvenile Fibromyalgia (JFM). As part of a longitudinal assessment of outcomes in adolescents with JFM compared with healthy controls, we are collecting data about fibromyalgia (FM) symptoms as they transition into the young adult years. The objective of this study was to determine how many of the JFM patients and controls meet criteria for FM over time using 3 approaches to the diagnosis of FM: the 1990 American College of Rheumatology (ACR) criteria [Wolfe F et al. *Arthritis Rheum* 1990], the 2010 ACR criteria [Wolfe F et al. *Arthritis Rheum* 2010], and a questionnaire for FM developed by Pope and Hudson [Pope HG, Hudson JI. *Int J Psychiatry* Med 1991]. Another goal was to assess the sensitivity and specificity of the 2010 ACR criteria and the Pope-Hudson questionnaire in this population using the 1990 ACR criteria as the gold standard.

Methods: Participants were recruited approximately 4 years from initial participation and asked to complete a survey that contained the 2010 ACR criteria self-report questionnaire and the Pope-Hudson questionnaire. The 1990 ACR criteria were determined by an in-person evaluation by a trained research staff member. Demographic information, chi-square analysis and sensitivity and specificity calculations were performed.

Results: Forty-two young adults with a previous diagnosis of JFM and 20 healthy controls were recruited. The group included 98.4% females, average age = 22.6 years, 87.1% Caucasian. The JFM group was more likely to have FM based on all 3 criteria. FM was identified in 69% (N=29), 71.4% (N=30), and 88.1% (N=37) of the JFM group according to the 2010 ACR, Pope-Hudson and 1990 ACR criteria respectively. Only the Pope-Hudson questionnaire revealed FM among 20% (N=4) of controls, while neither the 2010 nor 1990 ACR criteria identified FM among controls. Using the 1990 ACR Criteria as the gold standard for the diagnosis of FM, the sensitivity and specificity of the 2010 ACR criteria was 76% and 96% respectively and Pope-Hudson questionnaire was 76% for both.

Conclusion: This study reports ongoing findings from the first controlled longitudinal study to explore the persistence of FM symptoms in a cohort of JFM patients and their healthy counterparts. The results indicate that a substantial number of JFM patients have persistence of FM through the transitional young adult years; therefore continued close follow-up and treatment may be warranted. In addition, both the 2010 ACR criteria and the Pope-Hudson questionnaire demonstrated good sensitivity and specificity in identifying FM using the 1990 ACR criteria as the gold standard, with greater specificity using the 2010 ACR criteria.

941

Prevalence of Physician-Diagnosed Fibromyalgia and Fibromyalgia-Related Fatigue in Olmsted County. Ann Vincent[1], Debra L. Barton[2], Daniel J. Clauw[3], Mary Whipple[1], Brian Lahr[4], Eric Hawkins[1], Terry H. Oh[2], Connie Luedtke[1] and Jennifer St.Sauver[4]. [1]Mayo Clinic, Rochester, MN, Rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]University of Michigan, Ann Arbor, MI, [4]Mayo Clinic, Rochester

Background/Purpose: Our primary objective was to estimate the prevalence of physician-diagnosed fibromyalgia (FM) in Olmsted County, MN in 2009. In addition, we sought to: a) determine the percentage of patients in this group who met the ACR 2010 criteria for FM, b) determine the percentage of patients in this group who reported any fatigue and c) describe the distribution of fatigue severity in this group.

Methods: Patients who carried an ICD-9 code for FM (729.1) in Olmsted County were identified using the Rochester Epidemiology Project. In doing so, we identified 3685 potential cases. We then conducted a medical record review to confirm that each potential case carried a diagnosis of FM (ACR 1990 criteria). Only 1509 (40.9%) of the 3685 patients were confirmed as having a physician diagnosis of FM, of whom 947 were prevalence cases between the ages of 18 to 70. All 1509 patients were sent a survey that included the 2010 ACR criteria for FM, along with the first three questions of the Multidimensional Assessment of Fatigue (MAF) questionnaire. Non-responders received a second survey at 4 weeks. The prevalence of physician-diagnosed FM in Olmsted County was estimated assuming the entire population with an age between 18–70 years was at risk.

Results: The overall prevalence of FM was 1.03% (0.13% in males and 1.88% in females). Additional follow-up of all 1509 patients by mailed questionnaire yielded a 42.1% response rate. Among responders, 516 (81.3%) met the ACR 2010 criteria for fibromyalgia and 616 (97.0%) reported fatigue. On the ACR fatigue question, 99 respondents (15.7%) reported slight or mild fatigue, 354 (56.1%) reported moderate fatigue, and 163 (25.8%) reported severe fatigue. Similarly, on the fatigue severity question on the MAF, 96 patients (15.3%) reported no fatigue to mild fatigue (score 0–4), 260 (41.5%) reported moderate fatigue (score 5–7), and 270 (43.1%) severe fatigue (score 8+). Correlation of fatigue severity between the ACR 2010 fatigue question and the MAF fatigue severity question demonstrated good correlation (Spearman correlation coefficient=0.72, P <0.0001).

Conclusion: The prevalence of physician-diagnosed FM in Olmsted County is 1.03%, much lower than known FM prevalence rates of 4%. This may be related to poor recognition and under diagnosis of FM among health care providers. Our study also demonstrates that moderate to severe fatigue is a significant problem in a vast majority of patients with FM.

942

What Does Affect the Sexual Behaviour in Fibromyalgic Patients? Laura Bazzichi[1], Alessandra Rossi[2], Ciro Conversano[2], Camillo Giacomelli[2], Claudia Ferrari[1], Francesca De Feo[2], Francesca Sernissi[2], Marica Doveri[2], Linda Carli[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]University of Pisa, Pisa, Italy

Background/Purpose: Sexuality is an important aspect of life. The prevalence of sexual difficulties in patients with chronic pain is high (Ambler et al., 2001). The aim of our study was to compare the sexual behavior of patients with fibromyalgia (FM) with patients affected by rheumatoid arthritis (RA).

FM is a chronic disease characterized by widespread pain and symptoms associated with several neurovegetative disorders. RA is a chronic, systemic and inflammatory condition characterized by pain, disability and joint deformations. Both FM and RA affect all domains of life, with a severe impairment in terms of quality, involving also the sexual behavior.

Methods: We enrolled 100 patients with FM, 20 patients with RA and 25 healthy subjects (all females of comparable age).

All subjects were administered the questionnaires "Index of Sexual Satisfaction" (ISS) and "Female Sexual Function Index" (FSFI). The ISS assesses, using 25 items, sexual functioning as a natural part of a relationship; the patients with an overall score higher than 30 points (cut-off point) were considered to have sexual dysfunction.

The FSFI assesses sexual satisfaction and includes the domain of sexual desire, arousal, lubrication, orgasm, satisfaction, and pain during sexual intercourse. The maximum score for total FSFI is 36, a good sexual function is associated with higher scores, the total score of less than 22.7 is indicative of sexual dysfunction.

Results: The mean age of FM patients was 47 years (± 8), the mean number of TP was 16.95 (± 2.80), VAS pain 6.3 (± 2.6) and FIQ total score 59.7 (± 18.7). The mean age of RA patients was 48.6 years (± 9), the mean HAQ values was 0.65 ± 045, DAS28 was 3.80 ± 1.91 and VAS 5 ± 2.7. The mean age of the healthy controls was 40.5 (± 10). The percentage of postmenopausal patients was 41% in FM and in RA and 23% in healthy controls.

The mean ISS score is significantly greater in FM patients (34.25 ± 9.58) than that for healthy controls (24.39 ± 14.00), and did not differ between FM and RA (28.87 ± 16.70) and between RA and controls. Fifty-seven % of patients with FM had ISS> 30, indicative of sexual dysfunction versus 36% of healthy controls (p=0.005). No differences were found between ISS values of healthy controls vs RA patients (42%) and between RA vs FM patients.

The mean total FSFI score did not differ between the 3 groups of subjects (FM=21.33±8.04, RA=22.52±6.66, controls=23.84±4.84).

When the subscores of each domain were evaluated, the most common sexual problem was diminished arousal, lubrication, satisfaction in FM patients and diminished pain during intercourse and orgasm in RA patients.

The percentage of patients with FSFI<22.7, indicative of sexual dysfunction, is significantly greater in FM and RA patients compared with controls (48%, 39%, 10.5%, p = 0.0001).

Conclusion: The sexual behavior of both FM and RA patients is affected by rheumatic disease, but probably in different ways; the couple's relationship of FM patients (as indicated by greater ISS values) appears to have considerable weight with respect to sexual dysfunction, suggesting that in FM patients emotions may play a crucial role in sexual behavior, perhaps deeper than that played by pain and physical disability.

943

Functional MRI (fMRI) in Patients with Cognitive Dysfunction Related to Fibromyalgia (Fibrofog). Robert S. Katz[1], Vy T. Dinh[1], Glen Stebbins[2] and Frank Leavitt[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago

Background/Purpose: Patients with fibromyalgia cognitive problems perform poorly on several neuropsychological tests, including the auditory consonant trigram. To date, fMRI activation differences in patients with fibromyalgia and control RA patients during the auditory consonant trigram (ACT) tasks have not been investigated.

Methods: In the present pilot study, we examined fMRI activation during an analog of the ACT task in 2 patients with fibromyalgia (FIBRO) (ages 46 and 54) and 2 patients with RA (ages 37 and 47). These participants completed an event-related fMRI protocol while performing the ACT task. Individual consonants were presented for 1000ms, followed by a distracter task of either a blank screen, or a forced choice between names of colors and anagrams of color names. The target during the distracter task was to choose the color name using MRI compatible responses devices. The duration of the distracter task was 15000ms. Following the distracter task, the participants were presented to two consonant trigrams, one of which was the trigram seen at the beginning of the event. Their task was to choose the matching trigram. These events were repeated for a total of 40 trials. fMRI data were processed in SPM 8, and examined activation contrast between distractors with blanks and words, and recognition of the trigrams following distraction with blanks or words.

Results: Behavioral results indicated that the FIBRO patients were slightly slower in reaction time compared to RA patients during recognition (Fibro = 1967ms; RA = 1222ms) and distracter tasks (FIBRO = 1914ms; RA = 1167ms) and correctly recognized fewer trigrams after distraction (FIBRO = 92% correct: RA = 98% correct).Using a statistical threshold of p = 0.01, imaging results revealed similar activation patters during recognition of the trigrams following the blank distracter task. Both FIRBO and RA subjects demonstrated activation in orbital frontal, inferior frontal, medialtemporal, cingulate and parietal lobes. Different patterns of activation were found between the FIBRO and RA patients during recognition following the color-name distracter task, however. RA patients demonstrated activation in middle frontal, inferior frontal, cingulate and insular lobes during recognition following the color-name distracter task, but FIBRO patients did not show any frontal lobe activation, but instead activated inferior temporal lobes and fusiform gyrus.

Conclusion: Behavioral differences in ACT performance has been noted in patients with FIBRO, but the underlying neural substrates involved in this deficit performance has not been explored. In this pilot study, we found that FIBRO patients demonstrate similar activation patterns to RA patients during ACT recognition following a non-demanding distraction task (blank screen). However, when the distraction task was difficult (color-name distraction), the FIBRO activation pattern of the FIBRO patients differed from that seen in the RA patients during recognition. These pilot data may provide insights into the underlying neural substrates supporting ACT performance and behavioral differences observed in FIBRO patients.

MRI Synovitis Is Prevalent in ACPA Positive Patients with Musculoskeletal Symptoms. Jackie L. Nam[1], Edith Villeneuve[1], Sudipto Das[1], Dennis McGonagle[1], Richard Hodgson[1], Andrew Grainger[1], Richard J. Wakefield[1], Philip G. Conaghan[1] and Paul Emery[2]. [1]University of Leeds and Leeds Teaching Hospitals, Leeds, United Kingdom, [2]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) associated autoantibodies including anti-cyclic citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF) may be present years before clinical presentation. Modern imaging modalities have proven their sensitivity for subclinical synovitis detection. The aim of this study was to explore whether the preclinical phase of RA was associated with clinically occult small joint synovitis as determined by MRI.

Methods: 21 patients identified from primary care and rheumatology clinics who were ACPA positive with musculoskeletal symptoms but without clinical synovitis, underwent MRI scans. MRI of one hand and wrist and both forefeet was performed using a 3T MRI scanner employing pre- and post-contrast sequences. Images were scored blindly by two musculoskeletal radiologists.

Results: 91% (19/21) patients were female, median age was 51 years and median duration of early morning stiffness (EMS) 12.5 min (range 0 to 240 min). All were ACPA+ and 57% (12/21) were RF+. Median ESR at study entry was 14.5 mm/h (range 1–40 mm/h) and median CRP using a high sensitivity CRP (hs-CRP) test was 2.7 mg/L (range <0.01 to 29 mg/L). CRP levels for 14/21 (66.7%) patients fell within the normal range (<10mg/L). X- rays of the hands and feet reported by experienced musculoskeletal radiologists showed no erosions or other radiographic features of RA.

All 21 cases had MRI determined synovitis. Synovitis was most frequently detected in the wrist (90.5% (19/21)). MCP synovitis reported in 52.4% (11/21) and involvement of one or both forefeet in 66.7% (14/21). MRI determined bone oedema was evident in 52.4% (11/21) cases with 23.8% (5/21) documented in the wrists, 14.3% (3/21) in the MCPs and 33.3% (7/21) in the forefeet. There was erosive change in 13/21 (61.9%) of patients on MRI–28.6% (6/21) in the wrists, 14.3% (3/21) in the MCPs and 42.9% (9/21) in the forefeet.

Similar proportions of MRI changes were documented in patients who had (1) elevated CRP levels (>10mg/L) and (2) normal CRP levels (<10mg/L), including the subgroup with (3) low CRP levels detected only using a high sensitivity test (hs-CRP 0.1–5 mg/L). Synovitis was documented in each of the 3 subgroups in 7/7(100%), 14/14 (100%) and 11/11 (100%) patients, bone oedema in 3/7(42.9%), 8/14(57.1%) and 5/11(45.5%) patients and erosions in 5/7(71.4%), 8/14(57.1%) and 6/11 (64.5%) patients respectively.

Conclusion: This MRI imaging study of small joints in ACPA positive patients who do not have clinical evidence of joint inflammation showed that patients already have MRI determined small joint synovitis, irrespective of CRP levels. In ACPA positive patients, musculoskeletal symptoms may be an early indicator of the presence of clinical synovitis. The study is ongoing to determine the specificity of these findings.

945

Comparison of High-Resolution Multi-Pinhole SPECT and MRI for Monitoring Early Arthritis Patients Under Methotrexat Therapy: First Results. Christian Buchbender[1], Philipp Sewerin[1], Axel Scherer[1], Falk Miese[1], Oliver Sander[1], Katalin Mattes-György[1], Hans-Jörg Wittsack[1], Christof Specker[2], Gerald Antoch[1], Matthias Schneider[1] and Ben Ostendorf[1]. [1]Heinrich-Heine-University, Düsseldorf, Germany, [2]Kliniken Essen Süd, Essen, Germany

Background/Purpose: To compare Magnetic Resonance Imaging (MRI) and Multi-pinhole Single-Photon-Emission Computed Tomography (MPH-SPECT) for the detection of joint inflammation in early rheumatoid arthritis (ERA) after six months Methotrexate therapy.

Methods: The clinically dominant hand of five consecutive ERA patients (4 f, 1 m, disease duration < 6 months, therapy-naive for DMARD, mean-values: CRP 15 mg/l, DAS 28 4.9, CCP 115.6 U/l, Rheumatoid factor 628 U/l) and involvement of the metacarpophalangeal (MCP) joints was imaged with a MPH-SPECT system at baseline (T0) and six months (T1) after initiation of methotrexate (MTX) therapy (15 mg/weekly p.o. or s.c.). SPECT (Picker PRISM 2000 S camera (Philips Medical Systems), MPH pyramidal collimator reaching a spatial resolution < 1 mm)) imaging was performed with 550 megabequerel (MBq) of technetium-99m dicarboxy propane disphosphonate (Tc99m-DPD). SPECT FoV was 110 × 100 mm covering the MCP, proximal and distal interphalangeal joints. Ratios of Tc99m-DPD uptake in MPH-SPECT were calculated intra-individually for MCP joints in relation to a non-involved joint in each patient. MR imaging of the same hand was contemporaneously performed on a 3T system (Magnetom Trio; Siemens Healthcare, Germany) using a 4 channel flex coil (imaging protocol: coronal STIR, coronal T1-TSE, dynamic T1 contrast enhanced, contrastenhanced coronal T1-TSE, axial contrast-enhanced T1-FS SE. MRI was evaluated based on the RAMRIS subset scores for synovitis, bone marrow edema (BME), and erosions. MPH-SPECT and MRI data of the two time points were compared (T0 and T1). Mann-Whitney-U test was used to test for differences in Tc99m-DPD uptake between the two time points.

Results: Clinically all patients respond to MTX (mean values (T1) DAS 28 1.4, CRP 2 mg/l). MPH-SPECT at T0 revealed increased bone metabolism in 12 out of 20 MCP joints. The mean Tc99m-DPD uptake ratio at baseline was 2.1 ± 1.2 (Range 1.2 –5.7). All 12 joints showed synovitis on baseline MRI scans. BME and erosions were found in one MCP joint. 10/12 showed a decreased bone metabolism after six month compared to baseline SPECT. The mean Tc99m-DPD uptake ratio of the follow up SPECT was 1.5 ± 0.46 (Range 1.1–2.7). We found that bone metabolism on follow-up was significantly decreased compared to baseline ($p = 0.013$). Bone metabolism showed an average decrease of 35%. The follow-up MRI scans revealed improvement of synovitis in 10/12 MCP joints. Despite improvement, synovitis was still present in 6/12 joints. No change or progression of erosions—detected on baseline MRI—was found at T1. No change of BME (1 MCP) was seen.

Conclusion: In comparison to MRI, MPH-SPECT more frequently reveals early inflammatory involvement of the bone (potentially prior to BME). In ERA, therapy monitoring using MRI was limited to soft tissue inflammation. Thus MPH-SPECT might represent an additional tool for monitoring initial bony alterations in inflammatory joints diseases, such as ERA. Further studies are needed to support this hypothesis.

Construct Validity and Responsiveness of Dynamic Contrast-Enhanced Magnetic Resonance Imaging in Early Rheumatoid Arthritis – A Comparison with Conventional Magnetic Resonance Imaging and Clinical Measures of Disease Activity. Mette Bjørndal Axelsen[1], Bo J. Ejbjerg[2], Merete L. Hetland[1], Kim Hørslev-Petersen[3], Mikael Boesen[4], Olga Kubassova[5], Ulrik B. Lauridsen[1], Ole Majgaard[2], Henning Bliddal[4], Niels Steen Krogh[6] and Mikkel Østergaard[1]. [1]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [2]Copenhagen University Hospital at Slagelse, Slagelse, Denmark, [3]University of Southern Denmark, Graasten, Denmark, [4]The Parker Institute, Copenhagen University Hospital at Frederiksberg, Frederiksberg, Denmark, [5]Image Analysis Ltd., Leeds, United Kingdom, [6]ZiteLab ApS, Copenhagen, Denmark

Background/Purpose: The aim of the study was to assess the responsiveness and construct validity of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) parameters during aggressive treatment of early rheumatoid arthritis (RA), by comparison with conventional MRI and clinical measures of disease activity.

Methods: DCE-MRI and conventional contrast-enhanced MRI of the non-dominant hand (wrist and 2.−5. metacarpophalangeal joints (MCP)) and clinical assessment were performed at months 0, 6 and 12 in 14 patients with early RA treated with disease modifying antirheumatic drugs (DMARDs) (methotrexate +/− cyclosporine) and intra-articular glucocorticoid in an investigator initiated clinical trial [1]. Conventional MRI was evaluated using the Rheumatoid Arthritis MRI score (RAMRIS). DCE-MRI (one coronal slice) was analysed using a computer-aided approach by which the temporal contrast uptake is characterized by parameters such as the Initial Rate of Enhancement (IRE), Maximal Enhancement (ME) and number of enhancing voxels (N_{voxel}) [2]. The analysis was performed for 2 manually outlined Regions of Interest

(ROIs) covering the wrist and 2.–5. MCP, respectively, and for the sum of wrist and MCP ROIs, ('Wrist+MCP').

Results: All DCE-MRI parameters in the 'Wrist+MCP' declined significantly from month 0 to 12 (see table for separate wrist and MCP values and SRMs). The SRMs for RAMRIS synovitis was −0.67 to −1.05 from month 0–6 and 0–12. DAS28, and tender and swollen joint counts declined similarly (SRMs −0.51 to −1.11). Correlations with RAMRIS synovitis were high for ME (rho 0.56–0.87, $p<0.04$), N_{voxel} (rho 0.76–0.80, $p\leq0.002$) and $IRExN_{voxel}$ (rho 0.73–0.81, $p\leq0.003$), and low–moderate for IRE (0.09–0.56, $p \leq 0.04$–0.76).

Table 1. Responsiveness of DCE-MRI, Conventional MRI and Clinical Parameters

	Baseline Median (range)	6 months Median (range)	12 months Median (range)	Change 0–6 months Median (range)	Change 0–12 months Median (range)	SRM 0–6 months	SRM 0–12 months

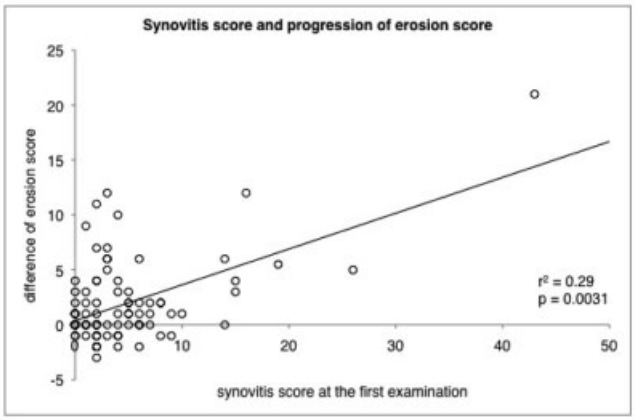
Evaluation of Activity, Making Diagnosis and Prediction of Future Bone Destruction by Using Low Field Compact Magnetic Resonance Imaging Machine in Patients with Rheumatoid Arthritis. Makoto Sugihara[1], Takeshi Suzuki[1], Yoshikazu Okamoto[2], Masanobu Horikoshi[1], Masahiro Yokosawa[1], Shinya Hagiwara[1], Tomoya Hirota[1], Yohei Takano[1], Naoto Umeda[1], Yuya Kondo[1], Hiroto Tsuboi[1], Hiroshi Ogishima[1], Taichi Hayashi[1], Yusuke Chino[1], Daisuke Goto[1], Isao Matsumoto[1] and Takayuki Sumida[1]. [1]Division of Clinical Immunology, Doctoral Program in Clinical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, [2]Division of Radiology, Doctoral Program in Clinical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan

Background/Purpose: The aim of this study was designed to evaluate activity of rheumatoid arthritis (RA), to make a diagnosis of RA using a new low field compact magnetic resonance imaging (cMRI), and to predict future bone destruction in individual RA patients.

Methods: We have developed cMRI with 0.3tesla magnetic field and set it in outpatient booth of Tsukuba University Hospital. We took hand images of coronal T1 weighted image and coronal short tau inversion recovery image without gadolinium enhancement. (1) Five hundreds and sixty four hands of 283 patients were included and evaluated by cMRI. Sixty eight hands of 84 patients were RA treated with biologic agents (infliximab 37 patients, etenercept 23, tocilizumab 13, adalimumab 6 and abatacept 5), 209 hands of 105 patients were RA treated without biologic agent, 54 hands of 27 patients had arthralgia caused by other connective tissue diseases (CTD) and 133 hands of 67 patients were unclassified arthritis (UA). Bone erosion, bone marrow edema and synovitis were scored by cMRI scoring system. In cMRI scoring system, 32 sites of bone erosion, 32 sites of bone marrow edema and 11 sites of synovitis were evaluated. Bone erosion, bone marrow edema and synovitis are graded on a scale from 0 to 3 by imaging, respectively. The total cMRI score (cMRIS) is calculated by the sum of total bone erosion score multiplied by 1.5, total bone marrow edema multiplied by 1.25 and total synovitis score. (2) One hundred and three hands of 53 RA patients were evaluated by cMRI at first time and 6 to 12 months later, scored by cMRI scoring system. We analyzed the correlation between synovitis score at first time and the difference of erosion score between two examinations.

Results: (1) Total cMRIS were 37.17 points ± 26.94 for RA treated with biologics ($p<0.0001$ versus RA treated without biologics, $p<0.0001$ versus patients with other CTD and $p<0.0001$ versus UA patients), 21.94 ± 21.19 for RA patients treated without biologics ($p<0.0001$ versus patients with other CTD and $p<0.0001$ versus UA patients), 10.45 ± 16.57 for patients with other CTD ($p=0.0056$ versus UA patients) and 3.83 ± 5.32 for UA (t test). (2) Mean synovitis score at first examination was 3.95 ± 5.99. Erosion score of the second examination (14.60 ± 12.60 was significantly higher than score of the first (12.93 ± 11.43, $p < 0.0001$, t test). Synovitis score at the first evaluation by cMRI is significantly correlated with progression of erosion score 6 to 12 months later ($r^2=0.29$, $p=0.0031$, Spearman correlation rate).



Conclusion: cMRI might be a useful tool to prospect disease activity of RA and distinguish RA from the other diseases. Synovitis observed by cMRI would predict future bone destruction in individual RA patients.

Is Experience Necessary to Accurately Score Low-Field Non-Contrast Magnetic Resonance Imaging of Rheumatoid Arthritis Joints? Comparison of Readings by Inexperienced Rheumatology Fellow to Scores of Experienced Musculoskeletal Radiologist. Fahed Hamadeh[1] and Ewa Olech[2]. [1]University of Oklahoma, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Radiography is a standard imaging technique for assessing destructive joint lesions in rheumatoid arthritis (RA). Magnetic Resonance Imaging (MRI) is more sensitive than conventional x-ray for the detection of RA joint pathology and it is increasingly being used for detecting and monitoring of this disease. It is not known if interpretation and scoring of small joints MRI requires more training and experience than reading x-rays. In this study we compare results of MRI scoring between inexperienced and experienced readers.

Methods: MR images of bilateral hand and wrist of 16 randomly selected RA patients were performed using 0.2 Tesla extremity unit (C-Scan) on two occasions, 1 year apart. The imaging protocol included coronal T1-weighted 3-dimensional gradient echo and coronal fat-suppressed short tau inversion recovery of the wrist and hand. Subsequently, the images were independently scored by inexperienced rheumatology fellow (IR) and experienced musculoskeletal radiologist (ER), according to RAMRIS system for erosions, osteitis and synovitis. IR had experience in evaluating RA x-rays. He was familiarized with RAMRIS definitions and scoring by reviewing the EULAR–OMERACT RA MRI reference image atlas[1]. He also reviewed several normal hand and wrist MRI studies. Agreement between the two readers was calculated as intraclass correlation coefficient (ICC) per patient per MRI.

Results: The patients' characteristics at baseline were as follows: mean age–49 years old, 31% male, mean disease duration–7 years, 81% RF-positive, 62.5% anti-CCP-positive, mean DAS28-ESR–4.96, DAS28–CRP–4.7. A total of 2944 bones were evaluated. IR reported lower number of erosions and erosion scores, but higher osteitis and synovitis scores than ER (Table 1). However, cross-sectionally, the ICCs between the 2 readers were high for erosions and osteitis (both wrists and metacarpophalangeal (MCP) joints), and moderate for synovitis (Table 2). There was no correlation between the readers for erosion, osteitis and synovitis scores change over time.

Table 1. Total erosion number and erosion, osteitis and synovitis scores per visit by ER and IR.

		Number of Erosions	Erosion Score	Osteitis Score	Synovitis Score
Baseline MRI	**ER**	127	342	45	76
	IR	58	161	120	149
MRI at 1 year	**ER**	126	345	36	74
	IR	53	184	114	104

Table 2. ICCs between the two readers' scores for MCP, wrist, and total joints.

	MCP joints	Wrist joints	Total joints
Erosions	0.95**	0.91**	0.95**
Bone edema	0.82**	0.94**	0.94**
Synovitis	0.49*	0.56*	0.73**

*p<0.05, **P<0.005

Conclusion: Despite high intraclass correlation coefficient values, the inexperienced reader underscored erosions and overestimated osteitis and synovitis. In order to accurately evaluate hand and wrist MRI of RA patients, experience is required.

Stability of Automated Quantitation of Dynamic Contrast Enhanced (DCE) 3T Wrist Magnetic Resonance Imaging (MRI) in Healthy Volunteers; A Year Long Longitudinal Study. A. Rastogi[1], Olga Kubassova[2], Mikael Boesen[3], J.V. Hajnal[4] and Peter Taylor[5]. [1]Barts and the London NHS Trust, London, United Kingdom, [2]Image Analysis Ltd., Leeds, United Kingdom, [3]The Parker Institute, Copenhagen University Hospital at Frederiksberg, Copenhagen, Denmark, [4]Imperial College, London, United Kingdom, [5]Kennedy Institute of Rheumatology, London, United Kingdom

Background/Purpose: A desirable property of new therapeutics is to arrest progression of joint damage at early stages of rheumatoid arthritis (RA). Dynamic Contrast Enhanced (DCE)-MRI has recently been recognized as a promising biomarker of disease modification in early phase inflammatory arthritis as it permits quantitative assessment of perfusion. To recommend DCE-MRI for quantification of treatment effect in patients, thorough validation should be conducted using the data from healthy volunteers where no disease related changes are expected over the course of imaging. This study is concerned with validation of variability inherent in newer automated DCE-MRI methods by testing software performance in healthy cohorts over a year.

Methods: Dominant wrists of 7 healthy volunteers (3 males:4 females, age range:24–40 years) were imaged by 3T MR at baseline, week 12, 24 and 52 using T2w TSE, pre and post contrast T1wFFE, DCE-MRI sequences with the following parameters: TR/TE/FA: 3.8 ms/2.1 ms/20°, slices: 127, 40 frames (scan mode: 3D) and T1wFFE Proset. DCE-MRI data were analysed using Dynamika, Image Analysis, UK. Using the software, parameters of maximum enhancement (ME), initial rate of enhancement (IRE) and the number of pixels (e.g. volume of enhancing synovium) with persistent and wash-out pattern of enhancement were measured using pixel-by pixel model based approach in the entire image and within regions of interest (ROI) drawn around the wrist and placed precisely around enhancing synovium.

Results: The average ± standard deviation for baseline parameters and change over time is shown in Table 1. In wrist ROI analysis and precise ROI analysis, ME and IRE change are consistently low and less then 0.1. The number of pixels with persistent, plateau and washout pattern of enhancement, reflecting the volume of synovium become more accurate as a % of the ROI size and are low too (normalised persistent voxel change over 12 weeks: 0.2±1.1%(wrist ROI) & −0.2±2.1% (precise ROI), normalised plateau voxel change over 52 weeks: 3.7±3.4% (wrist ROI) & 1.0±10.9% (precise ROI) and normalised washout voxel change over 52 weeks: 1.9±0.9% (wrist ROI) & 5.8±7.4% (precise ROI)).

Table 1. Shows baseline values of parameters and their change over time.

$ME_{st.\ dev.}$	0.106076	0.0798	0.006590	0.0694	0.034757	0.1100	0.041333	0.0382
IRE_{mean}	0.001761	0.0008	0.000285	0.0011	0.000809	0.0019	0.0008	0.0009
$IRE_{st.\ dev.}$	0.000952	0.0004	0.001142	0.0021	0.001809	0.0021	0.0013	0.0009
Normalised Persistent: (%)	1.578668	1.6659	−0.209247	2.1411	−0.540966	2.3994	−0.824105	1.5893
Normalised Plateau: (%)	22.432640	21.2280	−4.270537	13.8230	−3.060829	11.9250	1.078427	10.9669
Normalised Wash-out (%)	1.728650	1.5729	1.475777	1.8877	−0.619386	1.8319	5.819983	7.4759

Conclusion: This study shows that in healthy subjects, we can expect DCE-MRI parameters remain stable for as long as a year. The absence of variability associated with analysis methodology give confidence that these parameters can be used as imaging biomarkers in patients with inflammatory arthritis where early and sensitive quantification of change due to therapeutic intervention is desirable. Both wrist and precise ROI give similar results in healthy volunteers over a year and thus either could be used alone as part of the analysis.

Importance of Field Strength, Coil Type and Image Resolution for Visualization of Bone Marrow Edema in Magnetic Resonance Imaging (MRI)—a Comparison of Contrast-to-Noise Ratio, Signal-to-Noise Ratio and Contrast on 0.23 T, 0.6 T, 1.5 T and 3 T MRI Units. Simon Krabbe[1], Susanne Juhl Pedersen[2], Pernille Bøyesen[3], J.M. Møller[4], Flemming R. Therkildsen[5], Ole Rintek Madsen[2] and Mikkel Østergaard[1]. [1]Copenhagen University Hospital in Glostrup, Glostrup, Denmark, [2]Copenhagen University Hospital in Gentofte, Copenhagen, Denmark, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Copenhagen University Hospital in Herlev, Copenhagen, Denmark, [5]Copenhagen, Denmark

Background/Purpose: MRI bone marrow edema (BME) represents inflammatory infiltrates in trabecular bone and is an important predictor of joint damage in patients with RA. Earlier studies of BME at different MRI units did not measure parameters of image quality. The objective of this study was to compare three parameters of image quality (contrast-to-noise ratio (CNR), signal-to-noise ratio (SNR), and contrast) between: (1) 4 MRI scanners with different field strength and the same coil type and voxel size, (2) different coil types (flex coils versus dedicated hand-wrist coils), and (3) two different image resolutions (voxel sizes).

Methods: Coronal STIR (short tau inversion recovery) and T1-weighted images of wrist and 2^{nd}–5^{th} MCP joints were obtained in 40 RA patients with ≥1 swollen joint and 12 healthy controls on 4 Philips MRI

units with different field strengths (0.23 T, 0.6 T, 1.5 T (TR: 4000, TE: 26–30; TI: 85, 110 and 150 (all ms)) and 3 T (TR: 6000, TE: 30, TI: 100 (all ms))) within 24 hours. Voxel size was 1×1×3 mm in all 4 MRI units, and in addition a smaller voxel size (0.5×0.5×2 mm) was applied at the 1.5 T MRI unit. BME was identified and manually delineated on the 1.5 T images. Afterwards the area was copied onto the other STIR sequences as close as possible to the original anatomical position. The signal intensities (S) of BME and normal fatty marrow (FM) and the noise were measured. CNR = $(S_{BME}-S_{FM})$/noise, SNR = S_{BME}/noise, and contrast = $(S_{BME}- S_{FM})/(S_{BME}+ S_{FM})$ were compared with 30 predefined paired t-tests. The intra-observer reliability was assessed on the MRIs of 10 patients.

Results: BME was identified in 140 out of 920 assessed bones in the patients, and in 1 out of 276 assessed bones in the controls. CNR was highest at 0.6 T (CNR = 23.6), lower at 1.5 T (20.7), still lower at 3 T (17.0) and lowest at 0.23 T (8.6). SNR was higher at 1.5 T (SNR = 36.3), 0.6 T (33.3) and 3 T (30.4) in pairwise comparisons with 0.23 T (14.7). Contrast was highest at 0.6 T (contrast = 0.53) in pairwise comparison with 1.5 T (0.39), 0.23 T (0.40) and 3 T (0.37). A dedicated hand-wrist coil was superior to a flex coil at 1.5 T (CNR 37.2 vs. 20.7 and SNR 68.9 vs. 36.3), but not at 0.6 T. Smaller voxel size gave lower CNR (11.1 vs. 20.7), SNR (22.6 vs. 36.3) and contrast (0.32 vs. 0.37) than the larger voxel size (each of these results was statistically significant, $p<0.05$). The intra-observer reliability was κ (kappa) = 0.81 for BME/no BME, and ICCs for CNR, SNR, and contrast were good (0.72–0.79).

Contrast-to-noise ratios (CNRs)	N	Mean difference	Paired t-test, p-values
Field strength (all with flex coils):			
0.23 T - 0.6 T	28	−15.3	<0.001*
0.23 T - 1,5 T	33	−12.0	<0.001*
0.23 T - 3 T	28	−8.3	<0.001*
0.6 T - 1.5 T	27	3.9	0.020*
0.6 T - 3 T	23	4.9	0.015*
1.5 T - 3 T	27	4.3	0.014*
Coil type:			
Flex coil (0.6 T) - Wrist coil (0.6 T)	26	−1.6	0.43
Flex coil (1.5 T) - Hand-wrist coil (1.5 T)	33	−17.0	<0.001*
Voxel size (at 1.5 T):			
Large voxel (flex coil) - Small voxel (hand-wrist coil)	29	10.4	<0.001*
Large voxel (hand-wrist coil) - Small voxel (hand-wrist coil)	30	28.0	<0.001*

N = number of observations. Positive mean values indicate a higher CNR for the first mentioned field strength/coil/voxel size.

Conclusion: The 0.6 T MRI unit provided better CNR and contrast than the other MRI units, and similar SNR. As expected, a smaller voxel size resulted in lower CNR, SNR and contrast. It is important to appreciate these advantages and disadvantages of different field strengths, coils and image resolutions, when optimizing the MRI acquisition strategy in RA.

Tocilizumab Improves in Rheumatoid Arthritis Patients with Longstanding but Still Active Disease the Clinical Disease Activity (DAS28) and Ameliorates MRI Findings within the First Three Months of Therapy. Herbert Kellner[1] and Wolfgang Kellner[2]. [1]Centre for Inflammatory Joint Diseases, Munich, Germany, [2]Radiologische Praxis im Josephinum, Munich, Germany

Background/Purpose: Longstanding, but still active rheumatoid arthritis (RA) is often a therapeutic challenge. Tocilizumab (TCZ) has shown to be an effective biologic agent in mono as well as combination therapy. To assess therapeutic response in RA, the clinical disease activity score DAS 28 as well as MRI have shown to be value diagnostic tools. In the present study the therapeutic effect of TCZ in treatment experienced RA patients with active disease was examined.

Methods: 12 RA patients (m/f=1/11, age 53,8 y (41 –72), RF + n=8, CCP + n=7) with a disease duration of > 5 years (range 5–34 y) underwent tocilizumab mono (n=5) or combination therapy (n=7) over a 12 months period (8 mg/kg every 4 weeks). RA was active in all patients (DAS28 > 5). Pretreatment included DMARDs (average 3, range 2–5) and biologics (average 1,75, range 1–3). DAS28 and MRI (low-field, 0,2 T) was performed at baseline, week 12 and 52. The images were evaluated semiquantitatively using the RAMRIS scoring system and correlated with clinical results.

Results: DAS 28 at baseline was 6,0 (range 5,1 – 8,2) and decreased to 3,8 (3,2–51) in week 12 and 3,4 (2,8 –4,1) in week 52 respectively. The RAMRIS score improved from baseline values of a mean of 110 (range 64–188) to 58 (range 30–156) at week 12 and continued to stay there until week 52 (mean 58, range 26–140). During the first 12 weeks of therapy synovitis and bone edema improved significantly whereas erosions due to longstanding disease persited but did not impair.

Conclusion: Tocilzumab can even in treatment experienced patients with longstanding RA disease improve the clinical condition. DAS28 decreased within 12 weeks of therapy and there was no significant difference in therapeutic efficacy between mono and combination treatment. Low-field MRI could demonstrate improvement of especially synovitis and bone edema already within the first 3 months of therapy and progression of already established joint erosions could be prevented.

952

Early Response to Tocilizumab in Patients with Treatment Resistant Rheumatoid Arthritis—Assessment Using 3 Tesla MRI. Joerg C. Henes[1], Marius Horger[1], Florian Haas[1], Gunther Zeh[1], Daniel Spira[1] and Ina Kötter[2]. [1]University Hospital Tuebingen, Tuebingen, Germany, [2]University Hospital Tuebingen, Tübingen, Germany

Background/Purpose: The monoclonal interleukin (IL)-6-antibody tocilizumab (TCZ) has been proven to be effective in rheumatoid arthritis (RA). Magnetic resonance imaging (MRI) is a very exact measurement in assessing inflammation as well as cartilage or bone damage in RA patients.

Methods: In this prospective trial we included 10 patients with RA refractory to at least 1 non-biological and 1 biological disease modifying antirheumatic drug (DMARD). TCZ was given in a standard dosing of 8mg/kg bodyweight every 4 weeks. C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), disease activity score 28 (DAS28) as well as the clinical disease activity score (CDAI) were assessed at baseline, week 4 and 12. MRIs were performed on a 3 T whole-body MRI unit (Magnetom Trio, Siemens Healthcare). One trained musculoskeletal radiologist performed the procedure by using MRI definitions for erosion, edema, and synovitis, in accordance with the OMERACT RAMRIS recommendations. In order to achieve maximal image quality we consciously modified the RAMRIS criteria by reducing the examination area to the clinically leading affected joints and added 2 additional scores: Bone marrow hyperemia is considered to be a very early marker of inflammation. Its presence correlates with increased levels of acute phase reactants (ESR, CRP) and scales for the clinical evaluation of disease activity analogous to bone edema. Tenosynovitis includes fluid in the tendon sheath, increased thickness or contrast enhancement of the tendon sheath synovium, or a combination thereof. Normal fluid in the tendon sheaths has a thickness of less than 1mm. As with the joint synovium, contrast enhancement of the tendon sheath synovium is considered a specific sign of tenosynovitis. We scored this sign similarly with articular synovitis (0–3).

Results: Two male and 8 female patients with a median age of 49 years were included. Patients had inadequate response to a median of 3 (range 1–6) DMARDs and 1.5 (1–5) biologicals. At baseline the median DAS28 was 4.8 (range 2.1–6.7) and the median CDAI 22 (12–40). Using Wilcoxan test a significant reduction of DAS28 ($p=0.007$), ESR ($p=0.005$) and CRP ($p=0.005$) was documented at week 4 and 12. CDAI reduction from 22 to 15.5 missed significance ($p=0.06$). 3 patients showed progressive erosions during the 12 weeks, all other had stable erosive manifestations. Synovitits, tenosynovitis, bone marrow edema and hyperemia all were reduced at week 12, but only synovitis reached significance ($p=0.042$). Six patients experienced a DAS28 remission with a score <2.8 at week 12. Two patients did not respond to treatment. No serious adverse events occurred.

Conclusion: Even in this negative selection treatment with TCZ significantly reduced disease activity. The fast response is one of the leading characteristics of TCZ, this could be demonstrated with a significant reduction of ESR, CRP and DAS28 after only 1 infusion. As these clinical measurements are known to be overestimated when using TCZ we added very early MRI for the evaluation. Using this sensitive method the effectiveness of TCZ was confirmed, but after 12 weeks at the earliest with a significant improvement of synovitis.

953

Reduction In MRI Inflammation During Adalimumab Therapy In Patients with Psoriatic Arthritis – Implementation of the OMERACT PsAMRIS Scoring Method In a Follow-up Study.

René Panduro Poggenborg[1], Pernille Bøyesen[2], Charlotte Wiell[3], Susanne Juhl Pedersen[3], Inge Juul Sørensen[1], Ole Rintek Madsen[3], Ole Slot[1], Jakob M. Møller[4], Maria Hasselquist[4] and MikkelØstergaard[1]. [1]Copenhagen University Hospital in Glostrup, Copenhagen, Denmark, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Copenhagen University Hospital in Gentofte, Copenhagen, Denmark, [4]Copenhagen University Hospital in Herlev, Copenhagen, Denmark

Background/Purpose: To evaluate the changes in magnetic resonance imaging (MRI) parameters of disease activity and structural damage in patients with psoriatic arthritis (PsA) during 48 weeks of adalimumab therapy.

Methods: Patients were included if they had 1) PsA according to Moll and Wright's criteria; 2) ≥3 tender and ≥3 swollen joints; 3) ≥1 swollen finger joint and/or ≥1 dactylitis and 4) clinical indication for TNFα inhibitor. MRI (0.6 T) was performed at weeks 0 (at initiation of adalimumab 40 mg sc eow), 6, 24 and 48, of the 2nd-5th fingers (metacarpophalangeal, and proximal and distal interphalangeal joints) of the hand with the highest clinical disease activity at inclusion. MRIs were scored according to PsAMRIS (1) by a trained reader. MRI total inflammation score was calculated by adding the components of the synovitis, flexor tenosynovitis, periarticular inflammation and bone marrow oedema. Clinically, patients were evaluated according to PsARC-response at week 24. Responders continued treatment with adalimumab, whereas non-responders changed therapy at the discretion of the treating rheumatologist.

Results: Patient (n=41) characteristics were: 18 (44%) males, median (interquartile range) age 49 (39–60) years, disease duration 9 (5–15) years, skin disease duration 23 (12–35) years, CRP 7 (4–14) mg/L, SJC 8 (5–16), TJC 21 (11–39), VAS pain 62 (49–73) mm, VAS global 65 (49–77) mm, VAS physician 50 (39–64) mm, HAQ-score 0.9 (0.4–1.4), MASES 13-enthesitis score 1 (0–2), dactylitis count 0 (0–2) and body surface area affected by psoriasis (BSA) 2 (1–5) %. SJC and TJC decreased significantly from baseline to week 6, 24 and 48 for clinical responders, whereas no decreases were seen in non-responders.

The table shows the PsAMRIS scores during 48 weeks of treatment with adalimumab.

Time (week)	0	6	24	48
All patients/PsARC-responders (n)	41/-	37/29	34/30	33/29
Synovitis (0–36)	9(6–14)	9(5–12)*; [10(5–12)]	8(4–12); [8(4–12)]	6(3–9)*; [7(4–9)]*
Flexor tenosynovitis (0–36)	2(0–6)	1(0–5)**; [2(0–5]**	1(0–4)*; [1(0–4)]*	1(0–3)**; [1(0–3]**
Periarticular inflammation (0–24)	0(0–1)	0(0–1); [0(0–2)]	0(0–1); [0(0–2)]	0(0–1); [0(0–1)]
Bone oedema (0–72)	0(0–2)	0 (0–2); [0(0–2)]	0(0–1); [0(0–0)]*	0(0–1); [0(0–1)]
Bone erosion (0–240)	2(1–6)	2(1–4); [3(1–4)]	2(0–6); [3(0–6)]	3(0–5); [3(0–5)]
Bone proliferation (0–12)	0(0–1)	0(0–1); [0(0–2)]	0(0–2); [0(0–2)]	0(0–1); [0(0–1)]
Total MRI inflammation (0–168)	16(8–22)	14(9–19)*; [15(9–19)]*	13(7–19)*; [13(8–18]	9(6–14)**; [9(7–14)]**

Values are medians (IQR). *p<0.05, **p<0.005, Wilcoxon signed-rank test. Values are for all examined patients at weeks 0, 6, 24 and 48 weeks, with values for PsARC responders given in squared brackets.

The baseline MRI very frequently showed synovitis (40 patient (98%)), whereas bone oedema was less common (18 patients (44%)). After 6 weeks, there was a significant decrease in synovitis, flexor tenosynovitis and total MRI inflammation scores. Flexor tenosynovitisand total MRI inflammation significantly had improved in the PsARC-responders (table). After 48 weeks both the pooled patient group and the responder group (but not non-responders) showed significantly decreased synovitis, flexor tenosynovitis and total MRI inflammation scores. Scores of periarticular inflammation, bone proliferation and bone erosion did not change significantly.

Conclusion: Treatment with adalimumab in patients with active PsA reduces MRI signs of inflammation as assessed by the PsAMRIS method.

Diffusion Tensor and Perfusion Magnetic Resonance Imaging Delineates Microstructural Changes of Inflammation and Differentiates Between Tuberculosis and Chronic Inflammatory Arthritis.

Vikas Agarwal[1], Rishi Awasthi[2], Deepak Tripathi[3], Vinita Agrawal[3], Ram Kishore Singh Rathore[4], Prativa Sahoo[4], Kusum Sharma[5], CM Pandey[3] and Rakesh K. Gupta[3]. [1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Lucknow, India, [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India,, Lucknow, India, [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Lucknow, India, [4]Indian Institute of Technology, Kanpur, India, [5]Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background/Purpose: Conventional MRI does not differentiate between infective and non-infective chronic inflammatory arthritis. Synovial histology and culture are the only means to differentiate between these two. Chronic inflammation is characterized by cellular infiltration and increased vascularity. We hypothesize that Diffusion tensor imaging (DTI), a non-contrast MRI technique, delineates synovial inflammation. DTI derived metrics [fractional anisotropy (FA), mean diffusivity (MD), linear anisotropy (CL), planar anisotropy (CP) and cylindrical isotropy (CS)] and perfusion parameters [blood flow (BF) and blood volume (BV)] assess cellular infiltration and vascularity, respectively, in inflamed synovium. Also, increased inflammation during infection should lead to greater variation in DTI and perfusion parameters that should differentiate between the two conditions.

Methods: Patients with knee arthritis (>3 months duration) underwent conventional and DTI (3T scanner) followed by arthroscopic biopsy. Synovial tissue was subjected to histopathology, immunohistochemistry (IHC), and culture and multiplex PCR for Mycobacterium tuberculosis. In-house developed software was used to process DTI and perfusion data. Pearson correlation coefficient was used to evaluate correlation between DTI and perfusion and IHC parameters. Independent samples t-test was used to compare parameters between tubercular and non-tubercular patients. Discriminant analysis was done to ascertain imaging parameters discriminant of tuberculosis.

Results: There were 41 patients (mean age 38 years, [range 18–75], 27 male). Ten patients had tuberculosis and rest had; chronic monoarthritis (n=11), undifferentiated spondyloarthropathy (n=12), osteoarthritis (n=3), reactive (n=2) and rheumatoid, juvenile idiopathic and lepra reaction one each. There was significant correlation between the DTI, perfusion and IHC parameters (Table-1). DTI, perfusion and IHC parameters were significantly different in the tubercular as compared to the non-tubercular group (Table-2). FA and blood volume were 100% sensitive and specific in discriminating and predicting tuberculosis.

Table 1. Correlation coefficient (R) between DTI, Perfusion and IHC markers (n=41)

Erosions on MRI of the Sacroiliac Joints in Patients with Ankylosing Spondylitis: Can They Be Reliably Detected? Ulrich Weber[1], Susanne Juhl Pedersen[2], Mikkel Ostergaard[3], Kaspar Rufibach[4], Robert GW Lambert[1] and Walter P. Maksymowych[1]. [1]University of Alberta, Edmonton, AB, [2]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [3]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [4]University of Zurich, Zurich, Switzerland

Background/Purpose: Erosions of the sacroiliac joints (SIJ) on pelvic radiographs of patients with ankylosing spondylitis (AS) are the most important feature of the modified New York classification criteria (mNYc). Assessment of SIJ erosions by computed tomography (CT) in clinical practice is limited given recent reports indicating an association of malignancy with pelvic CT. Recent studies have shown that erosions can be detected also on magnetic resonance imaging (MRI) of the SIJ early in the disease course before they can be seen on radiography [1]. Erosions may extend across major portions of the iliac and sacral subchondral bone (extended erosion (EE)). We have also recently observed a novel appearance of erosions on MRI where tissue metaplasia re-fills the excavated erosion and have termed this phenomenon "backfilling" (BP). However, data on the reliability of detection of erosions and these related features on MRI are scarce.

Objectives: To assess the reproducibility of erosions, EE and BP in the SIJ detected by MRI in 30 AS patients and in 30 controls using the Spondyloarthritis Research Consortium of Canada (SPARCC) MRI standardized methodology.

Methods: 30 patients with AS meeting the mNYc (15 patients each with symptom duration of ≤5 and ≥5/≤10 years) and 30 controls (15 healthy volunteers and 15 patients with mechanical back pain (MBP)) underwent an MRI with STIR and T1 spin echo sequences of the SIJ. A standardized erosion definition was applied and lesion reference images served to calibrate the 4 readers. Erosions in all 8 quadrants on each slice of the SIJ, EE and BP were scored on an internet-based reading program of the SPARCC method. The frequency of erosions was analyzed descriptively by concordant observations of the 6 possible reader pairs. Kappa statistics (erosions as binary variable on a patient level) and intraclass correlation coefficients (ICC) (erosion sum scores per patient) for all readers jointly were used to assess the reproducibility of erosions.

Results: Erosions on SIJ MRI were detected in all 30 AS patients by ≥2 readers, whereas 5 MBP patients and 1 healthy control also showed lesions meeting the definition of erosion. EE and BP were recorded in 22 (73.3%) and 19 (63.3%) AS patients, respectively. The median frequency of erosions recorded by 4 readers jointly in 30 AS patients was 4.3 in the ilium and 1.1 in the sacrum ($p < 0.0001$). The kappa value for all 60 subjects showed an agreement for erosions between the 4 readers of 0.70 (95% CI 0.56–0.81), for EE of 0.73 (CI 0.59–0.85) and for BP of 0.63 (CI 0.47–0.77). For all 4 observers, the ICC values for the erosion score were 0.76, for EE 0.72, and for BP 0.55, respectively. For comparison, the kappa and ICC values for bone marrow edema (BME) were 0.61 and 0.89, respectively.

Conclusion: Erosions were detected significantly more frequently in the iliac portion of the SIJ. The agreement between 4 readers regarding erosions on SIJ MRI was substantial and comparable to BME.

The Reliability of a New Juvenile Arthritis MRI Scoring System for the Knee; JAMRIS. Robert Hemke[1], Marion A.J. Van Rossum[2], Mira van Veenendaal[2], J. Merlijn van den Berg[2], Koert M. Dolman[3], Taco W. Kuijpers[2] and Mario Maas[4]. [1]Academic Medical Center (AMC)/Emma Children's Hospital, Amsterdam, Netherlands, [2]Emma Children's Hospital/ Academic Medical Center (AMC), Amsterdam, Netherlands, [3]St. Lucas Andreas Hospital and Reade Institute, Amsterdam, Netherlands, [4]Department of Radiology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: MRI provides unequalled visualization of all the anatomical structures involved in Juvenile Idiopathic Arthritis (JIA). The increasing evidence that early therapeutic intervention improves long-term outcome and the development of highly effective treatments highlight the need for reliable and accurate measures in the quantification of disease activity. Therefore, the aim of our study is to assess the reliability of a new composed Juvenile Arthritis MRI Scoring (JAMRIS) system for evaluating JIA activity of the knee.

Methods: A collaborative program between two tertiary pediatric rheumatology centers in the Netherlands was established, incorporating rheumatologists and radiologists with experiences in the research field of imaging in JIA. After an extensive search of all relevant literature a MRI grading score was developed. After a training session, the initial scoring system was re-evaluated. The scoring development exercise was focused to refine the MRI features, to remove redundant items, and to develop a more reader-friendly assessment score. After tailoring the initial grading score, four MRI features were included in the Juvenile Arthritis MRI Scoring system.

The JAMRIS method assesses synovial hypertrophy at six anatomical regions, scaling from 0–2. Bone marrow edema, cartilage lesions and bone erosions are scored at eight sites of the joint, scaling from 0–3.

Results: A MRI dataset from 40 JIA patients (mean age 12.8 years [SD 2.3]) was scored by two experienced readers using the JAMRIS method. The interreader agreement (ICC) for the different JAMRIS key features ranged from 0.85 for bone erosions up to 0.92 for synovial hypertrophy scores. The reliability for bone marrow edema was 0.91 and for cartilage lesions 0.86.

Conclusion: Our newly developed scoring system for the evaluation of inflammatory and destructive changes in knees of JIA patients (JAMRIS) shows good reliability for the evaluated variables. The score's sensitivity to change and its correlation with clinical assessment is topic of ongoing research.

957

Non-Invasive MRI by Omitting Intravenous Contrast Injection; Does It Change the Radiologic Assessment of Knee Joint Pathologies in JIA? Robert Hemke[1], Taco W. Kuijpers[2], Mira van Veenendaal[2], J. Merlijn van den Berg[2], Koert M. Dolman[3], Marion A. J. van Rossum[2] and Mario Maas[4]. [1]Academic Medical Center (AMC)/Emma Children's Hospital, Amsterdam, Netherlands, [2]Emma Children's Hospital/Academic Medical Center (AMC), Amsterdam, Netherlands, [3]St. Lucas Andreas Hospital and Reade Institute, Amsterdam, Netherlands, [4]Department of Radiology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: MRI is the most preferred imaging modality in detecting joint pathologies in Juvenile Idiopathic Arthritis (JIA), despite practical limitations such as the risk of allergic reactions when intravenous (IV) contrast is administered, and the evaluation of one joint because of time constraints. IV Gadolinium (Gd) contrast use prolongs examination time, increases invasiveness and patient discomfort, and thereby reduces feasibility of MRI in JIA patients. Therefore, our objective is to evaluate if JIA joint pathologies can be reliably assessed by MRI without Gd injection compared with Gd-enhanced MRI as the reference.

Methods: MRI data-sets (open-bore, 1.0T) of 46 JIA patients (mean age 12 years [range 4–18]) were prospectively scored twice by two experienced readers for the presence of knee joint pathologies. MRI features were evaluated using a literature-based assessment score, comprising synovial hypertrophy, bone marrow edema (BME), cartilage lesions and bone erosions. The first reading included unenhanced images (−Gd), whereas complete image sets were available for the second reading (+Gd).

Results: Using +Gd MRI as the reference, sensitivity and specificity of -Gd MRI in the detection of BME (89%, 99%), cartilage lesions (73%, 100%) and erosions (100%, 99%) were high. Good -Gd and +Gd interreader agreements (ICC) were found regarding BME (0.87, 0.88), cartilage lesion (1.00, 0.97) and bone erosion scores (0.90, 0.93).

Regarding the assessment of synovial hypertrophy the specificity of −Gd MRI was 98%, though the sensitivity was 60%. ICC for +Gd MRI was 0.88, however omitting post-Gd acquisitions increased interreader variation (ICC=0.76).

Conclusion: Omitting intravenous contrast injection is unimportant in the assessment of presence of bone marrow edema, cartilage lesions or bone erosions in knees of JIA patients, but decreases the reliability of the evaluation of synovial hypertrophy.

958

Patients with Juvenile Idiopathic Arthritis and Rheumatoid Arthritis in "Physician Determined Clinical Remission" Have Evidence of Persistent Inflammation Revealed by 3T MRI. Amanda G. Brown[1], Raphael Hirsch[2], Tal Laor[3], Kimberly A. Francis[4], Michael J. Hannon[5] and C. Kent Kwoh[6]. [1]Children's Hospital Pittsburgh of UPMC, Pittsburgh, PA, [2]Children's Hospital Pittsburgh, Pittsburgh, PA, [3]Cincinnati Children's Hospital Medical Center and University of Cincinnati College of Medicine, Cincinnati, OH, [4]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [5]University of Pittsburgh School of Medicine, Pittsburgh, PA, [6]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA

Background/Purpose: It has been reported that up to 90% of adults with RA who are in clinical remission have persistent synovitis and/or bone marrow lesion (BMLs) on MRI. Similar MRI abnormalities have been observed in unaffected joints in JIA patients with active oligoarthritis, but MRI findings in JIA patients in clinical remission have not been well described. In order to determine whether JIA patients in clinical remission have evidence of subclinical inflammation, we utilized 3T MRI with contrast enhancement to examine individuals with a history of JIA involving the hand and/or wrist who were in clinical remission. We compared this JIA cohort with a cohort of adult RA patients.

Methods: Eleven JIA patients and ten RA patients with hand and/or wrist involvement were included due to physician determined clinical remission. Physician determined clinical remission was defined as the absence of signs or symptoms of active arthritis, and no medication changes for at least 6 months. For the JIA cohort there could be no sign or symptom of systemic disease activity. A study rheumatologist performed an evaluation of hands and wrists for tenderness, swelling, and limitation of motion. Study participants self-reported tender joint counts. The participants under went MRI with contrast enhancement of one currently asymptomatic hand and wrist that had a history of arthritis symptoms and exam findings. A single musculoskeletal radiologist, blinded to the clinical data, scored the MRIs for the presence of synovitis, tenosynovitis, and/or BMLs. Synovitis and tenosynovitis in the hand and wrist were recorded as none, mild, moderate, or severe. BMLs were recorded as none, focal or diffuse. Wilcoxon-Mann-Whitney test was used to compare the disease activity scores, and Fisher's exact test to compare the MRI scores between cohorts.

Results: Sixty-three percent of the JIA cohort and 70% of the RA cohort had MRI findings of synovitis, BMLs, and/or tenosynovitis. Eighty-two percent of the JIA cohort met the recent JIA remission criteria, while 56% of RA patient met the revised ACR remission criteria. All pediatric patients with MRI abnormalities had normal physician tender and swollen joint counts. Patients' self-report of painful joint counts did not predict MRI abnormalities. Three of the JIA patients were in clinical remission without any therapy. The RA cohort trend was higher pain scores and more affected joints on physician joint count. The JIA cohort trended toward lower CHAQ compared to adult HAQ scores. The DAS28 tended to be higher in the RA cohort compared to the JIA cohort. In the RA cohort, there was a trend towards more synovitis and more BMLs when compared to the JIA cohort.

Conclusion: In this study, over half of the patients with a history of JIA in clinical remission had MRI evidence of persistent inflammation, as defined by the presence of synovitis, tenosynovitis, or BMLs. This suggests that, as in RA, a substantial proportion of patients with JIA who are in clinical remission may have persistent subclinical disease activity. Additional longitudinal studies are needed to determine whether this subclinical inflammation results in progression of joint destruction and/or impacts long-term outcomes in JIA.

959

Identification of Magnetic Resonance Imaging Morphologic Features Associated with Different Knee Pain Patterns. C. Kent Kwoh[1], Ali Guermazi[2], Michael J. Hannon[3], Robert M. Boudreau[4], Stephanie M. Green[4], John M. Jakicic[5] and Frank Roemer[6]. [1]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA, [2]Boston Medical Center, Boston, MA, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Pittsburgh, PA, [6]Boston University, Boston, MA

Background/Purpose: Knee pain (KP) is the main reason for patients to seek care for knee osteoarthritis, but the cause for KP is unclear. The Knee Pain Map is a validated measure to assess different KP patterns in regard to specific joint locations. The aim of the study was to examine the association of joint morphologic features on MRI with KP in specific locations, regions or global pain patterns.

Methods: The Joints on Glucosamine (JOG) study includes 177 subjects aged 35–65 (95 men and 82 women) with chronic, frequent KP in at least one knee. 3T magnetic resonance imaging (MRI) of both knees was performed at baseline on a Siemens Trio using the same pulse sequence protocol as in the Osteoarthritis Initiative (OAI). All MRI features were scored semi-quantitatively using a modified WORMS system. All MR features were divided into two categories: present (score $\geq$1) and absent (score=0). Knees were characterized into localized, regional or global pain patterns using the Knee Pain Map, an interviewer-administered assessment of location-specific KP patterns based on the presence of pain in the past 30 days. Associations of MRI abnormalities in any subregion of the medial and lateral compartments with pain localized in that joint line and with regional or global pain patterns in each respective compartment were evaluated. Multinomial logistic regression was used to compare the KP patterns, controlling for clustering by person.

Results: A total of 46 knees had no KP, 83 had localized medial joint line KP, 36 had medial regional KP, 68 had localized lateral joint line KP, 31 had lateral regional KP, and 27 had global KP. The medial and lateral joint lines were the most common localized KP patterns. The association of KP patterns with a separate model for each individual MRI abnormality is shown in the table below. Compared to those with no KP in the past 30 days, individuals with local medial joint line KP, medial regional KP or global KP were more likely to have MRI abnormalities such as cartilage damage, bone marrow lesions, or meniscal extrusion. Those with the medial regional KP were also more likely to have meniscal damage (Table 1).

Table 1.

	Local Medial Joint Line Pain (n = 83)			Regional Medial Pain (n = 36)			Global Pain (n = 27)		
Compartment-specific MRI features*	RRR	[95%CI]		RRR	[95% CI]		RRR	[95% CI]	
Cartilage damage	2.52	1.07	5.92	3.97	1.28	12.35	4.65	1.37	15.81
Bone marrow lesions	9.89	2.04	47.99	12.10	2.27	64.60	12.44	2.24	69.05
Synovitis/effusion**	0.99	0.46	2.14	1.62	0.61	4.28	0.94	0.31	2.79
Meniscal damage	1.46	0.56	3.77	3.72	1.10	12.60	2.65	0.77	9.11
Meniscal extrusion	1.08	0.47	2.49	8.77	2.18	35.23	3.46	1.00	12.05

* adjusted for age, sex and BMI and compared to knees with pain in the past 30 days;
RRR=relative risk ratio, CI=confidence interval
** Synovitis/effusion was read for the whole knee

Conclusion: The presence of MRI-detected pathology was associated with medial localized joint line, medial regional and global pain patterns. These findings may help to identify more homogenous populations for targeted knee OA interventions.

960

Progression of the MRI-Detected Osteoarthritis Features in Radiographic 'End-Stage' Knee Osteoarthritis (Kellgren-Lawrence grade 4) - the Multicenter Osteoarthritis Study. Ali Guermazi[1], Daichi Hayashi[1], Frank Roemer[1], David T. Felson[1], Ke Wang[1], John Lynch[2], Shreyasee Amin[3], James Torner[4], C.E. Lewis[5] and Michael C. Nevitt[6]. [1]Boston University, Boston, MA, [2]UCSF, San Francisco, CA, [3]Mayo Clinic, Rochester, MN, [4]University of Iowa, Iowa City, Iowa City, IA, [5]University of Alabama, Birmingham City, AL, [6]University of California-San Francisco, San Francisco, CA

Background/Purpose: Kellgren-Lawrence grade 4 (KL4) knees are considered radiographic 'end-stage' knee OA (bone-on-bone appearance) which theoretically does not progress further. We evaluated what proportion of KL 4 knees at baseline demonstrate further progression longitudinally in regard to features only detectable by MRI, i.e. cartilage, bone marrow lesion (BML), meniscus, Hoffa-synovitis, and effusion-synovitis.

Methods: We studied subjects from the Multicenter Osteoarthritis Study who had KL4 knees at baseline and had baseline and 30-month MRI. Cartilage, BML, meniscus, Hoffa-synovitis, and effusion-synovitis were semiquantitatively scored using the WORMS system in the 5 subregions of the medial and lateral tibiofemoral (TF) compartments of the knee: central and posterior femoral, anterior, central and posterior tibial subregions. WORMS cartilage grading ranges from 0 – 6 where 6 represents full-thickness cartilage loss in >75% of the subregion. Analysis was performed for the compartment showing bone-on-bone appearance ("index") on radiograph and also for the other TF compartment of the same knee. Hoffa-synovitis and effusion-synovitis were assessed for the whole knee. Changes in

scores at follow-up were noted for each feature. For cartilage and BML, within-grade changes were also recorded.

Results: 63 subjects (67 knees) were included (51% women, 84% White, mean age 65.1±8.6 years, mean BMI 30.2±5.2 kg/m^2). At baseline, in the index TF compartment, all knees showed severe cartilage loss (max WORMS score from 5 subregions was 5 in 1 knee and 6 in 66 knees), 54 knees (80%) showed moderate to large BMLs (max WORMS score 2 or 3), and 62 knees (94%) had severe meniscal lesions (i.e. displaced tear or maceration). In the other TF compartment, 12 knees (18%) had severe cartilage loss, but 47 (71%) had no BML and 57 (97%) had no meniscal damage. 39 knees (58%) had moderate to severe effusion-synovitis, 56 knees (86%) had mild or moderate Hoffa-synovitis. Longitudinally, 22 index compartments (35%) showed an increase in the sum of cartilage scores from all subregions, and 2 (3%) showed increase in the maximum cartilage score. In the other TF compartment, 22% showed an increase in the sum score for cartilage damage, while 15% showed increase in maximum score. For BMLs in the index TF compartment, 19 knees (31%) showed an increase in maximum score and 11 (18%) showed a decrease. Fluctuation of BMLs was also seen in the other TF compartment, but to a lesser extent. Meniscal status mostly remained the same in the index (98%) and other TF (95%) compartments. Effusion-synovitis worsened in 15 knees (27%) and improved in 2 knees (4%). Hoffa-synovitis worsened in 6 knees (11%) and improved in 2 knees (4%).

Conclusion: In KL4 knees, MRI detected progression of cartilage loss, and fluctuation of effusion-synovitis, Hoffa-synovitis and BMLs was observed over a 30-month period. Meniscal damage remained stable. Our findings support the idea that disease progression still occurs in KL4 knees. KL4 knees can be a potential target for assessing therapeutic interventions and should not necessarily be excluded from clinical trials.

961

The Association Between Bone Marrow Lesion Detected by Magnetic Resonance Imaging and Knee Pain in the Community Residents in Korea. Inje Kim[1], Yeong Wook Song[2], Hyun Ah Kim[3] and Ali Guermazi[4]. [1]Hallym University Kangdong Sacred Heart hospital, Seoul, South Korea, [2]Seoul National University College of Medicine, Seoul, South Korea, [3]Hallym University Sacred Heart Hospital, Kyunggi, South Korea, [4]Boston Medical Center, Boston, MA

Background/Purpose: The presence of bone marrow lesion (BML) detected by magnetic resonance imaging (MRI) has been associated with knee pain among patients with osteoarthritis (OA). The purpose of this study was to investigate the prevalence of BML and its association with knee pain in community residents in Korea.

Methods: Participants (n=346) were randomly chosen regardless of knee OA or knee pain from the population-based Hallym Aging Study. Demographic data were obtained by questionnaire including knee pain and the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) index. Radiographic evaluations consisted of weight-bearing knee anteroposterior radiographs and 1.5-tesla MRI scans. We assessed the BML in the dominant knee or in the more symptomatic knee, and scored BML using Whole-Organ MRI score in the medial femorotibial, lateral femorotibial and patellofemoral compartment. The association between BML and knee pain was examined by logistic regression analysis after adjustment of age, sex, body mass index and radiographic knee OA.

Results: Radiographic knee OA in either knee was present in 33.4% of subjects. The prevalence of BML and large BML in any compartment of the knee were 80.3% and 40.4%, respectively. BML was more common in women and was most common in the patellofemoral compartment. The prevalence of BML in any compartment was 98.3% and 70.6% in subjects with and without knee OA, respectively. BML in any compartment and in medial compartment were found in 46.2% and 57.6% of subjects with knee pain, and in 53.8% and 42.4% of subjects without knee pain, respectively. After multivariate analysis, BML was found to be significantly associated with radiographic knee OA (OR 18.58, 95% CI [4.31–80.09]). After adjusting for age, sex and radiographic knee OA, knee pain was significantly associated with BML in medial compartment (OR 2.18, 95% CI [1.29–3.66]).

Conclusion: Incidental BML on MRI of the knee are very common in the middle- aged and elderly community residents in Korea. BML in the medial compartment of knee is related with knee pain.

962

Correlation of Bony Enlargements with Radiological Findings in Hand Osteoarthritis. Niveditha Mohan[1], Michael J. Hannon[2] and C. Kent Kwoh[3]. [1]Univ of Pittsburgh Arth Inst, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA

Background/Purpose: A strong association between the presence of bony enlargement (BE) and x-ray evidence of hand osteoarthritis (HOA) has been reported. We assessed the validity of this relationship and attempted to delineate the association between BE on clinical exam and different grades of osteophytes (OST) and joint space narrowing (JSN).

Methods: The study utilized data from the Osteoarthritis Initiative (OAI), a community based cohort aged 49–75 years with symptomatic knee OA or with risk factors for developing knee OA. The dominant hand films of 400 women were read using the ICRS/OARSI Atlas. The 1st CMC, 2nd–5th DIP and PIP joints were read for JSN and OST on a 0–3 scale. Only the presence of Heberden's nodes was assessed by trained OAI clinic staff at enrollment. The relationship between BE and JSN and OST was evaluated using the four DIP joints in a logistic regression model adjusted for age, race, BMI, smoking history, and family history of arthritis. The model was controlled for clustering by person.

Results: The sample was 84% white with a mean age of 61.6 (SD 9.3). 33% were overweight and 39.5% obese. 47% were current or former smokers. 26% were premenopausal with 26% reporting a family history of arthritis.

A total of 1586 DIP joints were read, 589 (37.1%) with BE on exam. Of these joints, 285 (48.4%) had OST, 142, 80 and 63 of which were grade 1, 2, and 3 OST, respectively. Of the 997 without BE, only 93 (9.7%) had x-ray evidence of OST and 80, 10 and only 3 were grade 1, 2 and 3 respectively. 427(72.5%) had JSN, 258, 87, 82 of which were grade 1, 2 and 3 respectively. Of the 997 without BE, only 303 (30.4%) had x-ray evidence of JSN and 296, 37 and 4 were grade 1, 2 and 3 JSN respectively.

Odds ratios were calculated for the association of BE with JSN and OST (Table 1). When JSN and OST were combined, of the 589 joints with BE, 445 (75.6%) had an x-ray finding of some problem while only 352 (35.3%) of those with no BE had such a finding. The presence of any x-ray findings was associated with a large increase in risk of BE (adjusted OR 4.9, 95% CI of 3.6–6.7).

Table 1. Adjusted OR for BE and presence of JSN and OST

BE	Odds ratio	95% CI
Grade 1 JSN	2.29	1.62–3.24
Grade 2 JSN	3.75	2.07–6.81
Grade 3 JSN	10.83	3.03–38.74
Grade 1 OST	3.17	2.16–4.66
Grade 2 OST	9.04	4.38–18.65
Grade 3 OST	9.71	1.62–58.29
Age	1.46	1.02–2.07
Race (Caucasian)	1.19	0.76–1.89
BMI overweight	0.67	0.44–1.03
BMI obese	0.78	0.52–1.17
Family history	1.81	1.21–2.70
Smoking history	0.98	0.71–1.37

Conclusion: The presence of BE strongly associated with x-ray evidence of HOA, and the strength of the association increases as the grade of OST and JSN increases. The interaction between OST and JSN was not significant. This association is validated at the earliest radiological changes as well as when OST and JSN are adjusted for OA risk factors. However, having a BE clinically does not always indicate having x-ray findings. This suggests that x-ray changes may be preceded by soft tissue changes that may be clinically consistent with a BE. Further prospective studies may provide us with pathophysiological insights into characteristics that predispose to HOA and may provide an ideal therapeutic window for intervention, prior to onset of irreversible x-ray changes.

963

Correlation of Hand Pain and Radiological Findings in Hand Osteoarthritis. Niveditha Mohan[1], Michael J. Hannon[2] and C. Kent Kwoh[3]. [1]Univ of Pittsburgh Arth Inst, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA

Background/Purpose: Symptomatic hand osteoarthritis (HOA) affects 20% of patients above the age of 55 years. We assessed the association between hand pain as reported on a homunculus by patients with the presence of HOA based on x-ray findings.

Methods: The study utilized data from the Osteoarthritis Initiative (a community based cohort aged 49–75 years with symptomatic knee OA or with risk factors for developing knee OA). The dominant hand films of 400 women were read using the ICRS/OARSI Atlas. The 1st CMC, 2nd–5th DIP and PIP joints were read for Joint Space Narrowing (JSN) and Osteophytes (OST) on a scale of 0–3 and the presence of central erosions (CE) and lateral deviation (LD>15 degrees). Hand pain was self-reported by participants using a whole body homunculus as part of a general pain assessment (individual hand joints were not delineated). The relationship between hand pain and radiological findings was evaluated using logistic regression adjusted for age, race, BMI, smoking history, and family history of arthritis.

Results: The sample was 84% white with a mean age of 61.6 (SD9.3). In the sample 33% of the women were overweight and 39.5% obese. 47% were current or former smokers. 26% were premenopausal, with 26 % reporting a family history of arthritis. 140 of 400 patients (35%) reported hand pain within the past 30 days in any/either hand. Of these, 126 (31.5%) reported pain in the dominant hand (which was the hand x-ray that was read in our study). All measures of radiological HOA changes were highly intercorrelated (α=0.92). We formed a hand scale for measuring presence or absence of x-ray features of HOA (OST>1, JSN>1, CE or LD). X-ray features of HOA associated strongly with hand pain after adjusting for multiple factors (Table 1). The strength of the association increased with increase in number of joints involved (Table 2).

Table 1. Association of hand pain and x-ray changes adjusted for multiple factors (age, race, obesity, family history of OA and menopausal status)

Joint	Odds ratio	95% CI
1st CMC joint	1.89	1.15–3.10
2nd DIP joint	3.53	1.96–6.34
3rd DIP joint	3.14	1.69–5.84
4th DIP joint	3.45	1.86–6.42
5th DIP joint	4.11	2.26–7.49
2nd PIP joint	3.16	1.36–7.3
3rd PIP joint	2.93	1.38–6.21
4th PIP joint	2.04	0.96–4.30
5th PIP joint	2.23	1.06–4.71

Table 2. Association of hand pain with number of joints with x-ray changes of HOA adjusted for multiple factors (age, race, obesity, family history of OA and menopausal status)

Number of joints affected	Odds ratio	95% CI
1	2.08	1.07–4.05
2–3	3.11	1.54–6.29
4–6	3.90	1.65–9.19
7 or more	12.96	4.58–36.67

Conclusion: There is a strong association between overall hand pain and radiological evidence of HOA with increasing strength of the association with increase in the number of joints involved. The association of hand pain with x-ray changes at the CMC joint was not significantly stronger than that noted at other joints, which is in contrast to previously published data.

964

Biomarkers of Bone Resorption and Bone Formation Are Specifically Linked to Catabolic and Anabolic Skeletal Changes Assessed by High Resolution CT Scans in Patients with Rheumatoid Arthritis. Sophie Aschenberg, Stephanie Finzel, Sarah Schmidt, Matthias Englbrecht, Juergen Rech and Georg Schett. University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Biomarkers of bone metabolism may emerge as powerful tool to monitor and predict structural joint damage in patients with rheumatoid arthritis (RA). Based on rather large patients cohort, several bone biomarkers, i.e. biomarkers for bone resorption have been successfully correlated to bone damage visualized in conventional radiographs. We hypothesized that improvement of sensitivity for detection of joint damage by high resolution micro computed tomography (μCT) may allow to better correlate bone biomarkers and structural bone damage and allow to proof this link even in small cohorts of RA patients.

Methods: Forty RA patients received a simultaneous μCT scan and analysis of serum markers of bone resorption (collagen type1 crosslaps: CTX1, tartrate resistant acid phosphatase 5b:TRAP5b) and formation (bone alkaline phosphatase: BAP, osteocalcin) at baseline and one year follow up. Erosions (erosion count and score) as well as osteophytes (osteophyte count and score) detected by μCT in the metacarpophalangeal (MCP) joints 2–4 of the dominantly affected hand were recorded. Bone biomarkers were related to the imaging data by partial correlations including age, sex, disease duration, DAS 28 and autoantibody status.

Results: All erosions and osteophytes detected at baseline were also visible at follow up with a slight progression in both numbers of erosions and of osteophytes (mean erosion count 5.112 ±7.120 at baseline versus 5.432 ±7.338 at follow up; mean osteophyte count 3.233 ±2.498 vs. 3.294 ±2.150respectively). Erosion score did not change (5.001 ±7.452 vs. 5.002 ±6.907) whereas osteophyte score did increase (4.094 ±3.815 vs. 4.343 ±3.412). The mean levels (±SD) of bone metabolism parameters were as follows: CTX1 at baseline 0.354 ng/ml ±0.205 and 0.351 ng/ml ±0.220 at follow-up, tartat-resistent acid phosphatase 5b (±Trap5b) at baseline 2.464 U/l ±1.294, at follow-up 2.537 U/l ±1.134, BAP at baseline 19.360 E/l ±6.299, follow-up 19.731 E/l ±5,945 and osteocalcin 12.577 ng/ml ±7.791 vs. 11.600 ng/ml ±6,209. Bone erosions in the MCP joints detected by μCT were strongly correlated with the serum level of the osteoclast-specific protease TRAP5b, a marker for bone resorption and osteoclast activity at both baseline and 1-year follow-up (baseline: p=0.030, r= 0.426, follow-up: p=0.004, r=0.493). In contrast, osteophytes detected by μCT were strongly correlated to bone alkaline phosphatase being a marker for bone formation (baseline: p=0.022, r= 0.447, follow-up: p=0.004, r=0.499).

Conclusion: These data suggest that specific biomarkers of bone formation and bone resorption can be correlated to different forms of structural joint damage, such as bone erosions and osteophytes formation in patients with RA. Detailed assessment of structural bone changed in the joints by μCT allows a validation of bone biomarkers in patients with RA. Moreover, these data are stimulating for small proof-of-concepts studies with novel therapeutics, by suggesting that biomarkers can be related to structural bone damage even in small patient cohorts.

965

High Resolution Peripheral Quantitative Computed Tomography Bone Health Outcomes in the Metacarpal Head and Ultra-Ultra Distal Radius: A Precision Study Using Novel Scan Acquisition and Custom Semi-Automatic Contour and Evaluation Protocols. Lynne M. Feehan[1], Helen R. Buie[2], Eric C. Sayre[3], Steve K. Boyd[2], Heather A. McKay[4] and Linda C. Li[1]. [1]Arthritis Research Centre of Canada and University of British Columbia, Vancouver, BC, [2]University of Calgary, Calgary, AB, [3]Arthritis Research Centre of Canada, Vancouver, BC, [4]University of British Columbia, Vancouver, BC

Background/Purpose: High Resolution Peripheral Quantitative CT (HR-pQCT) imaging can assess early changes in microstructural bone health in the metacarpal head (MH) and ultra-ultra distal radius (DR); two sites commonly affected in early inflammatory arthritis. The purpose of this study was to determine the precision of HR-pQCT measures of density and microstructure in these two regions using novel scan acquisition and custom semi-automatic contour and evaluation protocols. The advantages of these new protocols include: 1) more stable and comfortable positioning of the upper body and arm for scanning; 2) more consistent positioning of hand and forearm alignment and joint angles; and 3) more efficient image analyses with low risk of operator bias.

Methods: The MH and DR in 12 healthy adults were scanned using HR-pQCT (XtremeCT, Scanco Medical AG), with 2 repeat scans at 3–7 days. Participants sat facing the scanner, leaning forward with their upper body and head supported by pillows. The dominant arm was scanned in a custom-made positioning device that held the wrist and metacarpal joints in a neutral joint angle. Scans were done using standard parameters (82 μm, 60kVp, 900 μA,100 ms). DR scans were 110 slices starting 1 mm proximal to the distal-medial end of the radius and MH scans were 220 slices starting 1 mm distal to the 3rd MH. A previously described semi-automated contouring and evaluation method for standard DR scans was adapted for the MH and ultra-ultra DR and applied to 110 slices at each site. Analyses included Total (ToD), Cortical (CtD) and Trabecular (TbD) bone density; Cortical thickness (CtTh) and Trabecular bone volume fraction (BV/TV), thickness (TbTh) and number (TbN). Reliability was assessed with an intraclass correlation coefficient (ICC) of up to 3 repeated measures. Coefficient of variation (CV) was calculated as the standard deviation of up to 3 repeated measurements divided by the mean.

Short-term precision errors (PE) were calculated as the root mean square coefficient of variation (RMSCV) of at least 2 paired images.

Results: *Participants:* 8 females and 4 males, mean age 44 (range 23–71) *Findings:* Our novel scan acquisition and custom semi-automated analyses protocols demonstrate excellent precision for repeated measurement of both microstructure and density in the ultra-ultra DR and 3rd MH sites; with ICCs ranging from 0.894 to.994, CVs ranging from 1 to 6% and PEs ranging from 1 to 7%. DR measures were slightly less precise than MH measures and measures of cortical thickness were less precise than other parameters, See Table 1.

Table. Summary of Results

	ICC (0.000–1.000)		Mean CV (%)		PE (RMSCV%)	
	DR	MH3	DR	MH3	DR	MH3
ToD (mgHA/cm3)	0.986	0.994	2.33	1.07	3.19	1.40
CtD (mg/HA/cm3)	0.962	0.963	3.48	1.98	3.75	2.82
TbD (mgHA/cm3)	0.993	0.993	1.31	1.03	1.61	1.44
CtTh (mm)	0.959	0.937	5.92	4.85	7.29	6.21
TbBV/TV (%)	0.990	0.981	1.66	1.23	2.04	1.60
TbTh (mm)	0.956	0.981	0.79	0.76	1.07	1.08
TbN (1/mm)	0.908	0.894	3.09	1.99	4.35	2.39

Conclusion: Our findings using novel HR-pQCT scan acquisition and analyses protocols for the evaluation of the ultra-ultra DR and MH are consistent with previously published estimates for precision of bone microstructure and density measures using microCT in the ultra-ultra DR in cadavers [Mueller et al,2009; DR region 1] and in the MH in humans using HR-pQCT [Fouque-Aubert et al, 2010; MH3 – 71 slices].

966

Correlation of [18f]FDG PET Assessments with Disease Activity and Markers of Inflammation in Patients with Early Rheumatoid Arthritis Following Initiation of Antirheumatic Therapy. Anne M. Roivainen[1], Sannamari Hautaniemi[1], Timo Möttönen[1], Pirjo Nuutila[1], Vesa Oikonen[1], Riitta Parkkola[1], Luminita Pricop[2], Rudyard Ress[2], Nicholas Seneca[3], Marko Seppänen[1] and Timo Yli-Kerttula[1]. [1]Turku University Hospital, Turku, Finland, [2]Hoffmann-La Roche Inc, Nutley, NJ, [3]F. Hoffmann-La Roche Ltd., Switzerland

Background/Purpose: In patients with early rheumatoid arthritis (RA), the quantitative assessment of disease activity is still challenging. Identification of patients who are likely to respond to therapy early in a course of the disease should be the valuable key for the successful treatment. This observational, single center, imaging study evaluated the potential for advanced functional imaging techniques to monitor disease activity and the efficacy of treatment in patients with early, DMARD naïve RA.

Methods: Functional imaging focused on two important pathological features of RA, e.g. synovial metabolism was evaluated by [^{18}F]FDG PET/CT, and tissue perfusion and vascular permeability was evaluated by Gd-DOTA enhanced MRI. Seventeen RA patients with active disease, committed to initiate combination oral therapy with hydroxychloroquine 5 mg/kg per day, sulfasalazine 2.0 g per day, and methotrexate 7.5–15 mg per week plus low dose prednisolone, were enrolled in this study. Clinical disease activity was assessed by using disease activity scoring (DAS), numbers of tender and swelling joints (TJC, SJC) and measuring erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) at screening, baseline and after 2, 4, 8, and 12 weeks of the therapy. Whole-body [^{18}F]FDG PET/CT and Gd-DOTA MRI of the most affected joints (wrist, knee or ankle) were performed at baseline and at weeks 2 and 4. Quantification of [^{18}F]FDG uptake was performed by the calculation of the standardized uptake value (SUV), fractional uptake rate (FUR) and glucose uptake rate (GU). Positive enhancement integral and maximum slope of increase at the site of inflamed synovium were determined from Gd-DOTA MRI. The mean PET and MRI imaging measures of all regions of interest per patient were calculated and used for statistical analysis. For PET analysis, only the DAS-28 joints with detectable [^{18}F]FDG uptake were taken into account.

Results: Based on [^{18}F]FDG PET/CT evaluation, 76% of patients had reduction in SUV_{max} from baseline to week 2 (mean±SD reduction 22±13%) and 81% from baseline to week 4 (mean±SD reduction 29±13%), respectively. The percentual decrease in SUV_{max}, FUR_{max} and GU_{max} from baseline to week 2 predicted clinical outcome as measured by DAS-28 (ESR) and DAS-28 (CRP) at week 12. In addition, changes in CRP and ESR levelswere positively associated with changes in all PET imaging measures-.Interestingly, the PET measures at baseline showed a positive correlation with CRP and TJC measured at week 12. Although the maximum slope of increase of MRI correlated with SUV_{mean}, FUR_{mean} and GU_{mean}, none of the MRI measures up to week 4 correlated with clinical outcome measures in this patient population.

Conclusion: Our results suggest that [^{18}F]FDG PET/CT but not Gd-DOTA MRI findings at weeks 2 and 4 predicted treatment efficacy and clinical outcome in patients with early active RA treated with combination hydroxychloroquine-sulfasalazine-methotrexate therapy. Future studies utilizing these methods may aide in predicting therapeutic response using novel drug treatments.

Fluorine-18 Fluorodeoxyglucose Positron Emission Tomography Is Useful for the Visualization of Reticulo-Endotheliao System and Prediction of Steroid-Resistant Cases in Adult Onset of Still's Disease. Tomohiro Kameda[1], Kentaro Susaki[1], Yuka Yamamoto[2], Miharu Izumikawa[3], Junichi Danjo[1], Shusaku Nakashima[1], Hiromi Shimada[1], Yohei Takeuchi[1], Yoshihiro Nishiyama[2], Hiroaki Dobashi[1] and Takuya Matsunaga[1]. [1]Kagawa University, Kagawa, Japan, [2]Kagawa University, Kita-gun, Japan, [3]Kagawa University, Kita-Gun, Japan

Background/Purpose: Adult onset of Still's disease (AOSD) is rare inflammatory disease characterized by the fever, rash, polyarthritis, sore throat, splenomegaly, lymphadenopathy, and serological examination as follows; increasing the level of CRP or ESR, hyperferritinemia and leukocytosis. Among these serological markers, serum ferritin level is associated with disease activity of AOSD relatively, but not be specific. Furthermore, though AOSD is considered as autoimmune disorder, autoantibody such as anti-nuclear antibodies or rheumatoid factor are commonly negative. Additionally, there are no reports to analyze the activity of AOSD visually. These are reason why the diagnosis of AOSD is difficult for us. On the other hand, fluorine-18 fluorodeoxyglucose positron emission tomography (^{18}F-FDG PET) has been an established in a field of oncology. Recently, the indications for ^{18}F-FDG PET are expanding rapidly. ^{18}F-FDG PET is used as diagnostic tool for inflammatory disorder such as infection or collagen vascular disease. As for treatment, AOSD patients are treated with corticosteroid mostly. However, we encounter the cases that are difficult to taper corticosteroid. These cases are needed salvage therapy such as immunosuppressant or biologics. If we can predict a refractory AOSD cases before treatment, the disease activity of AOSD can be controlled earlier. We investigate the features and the usefulness of ^{18}F-FDG PET in the diagnosis of AOSD. Additionally, we examine the predictive marker of refractory AOSD patients.

Methods: Eleven patients with the diagnosis of AOSD were treated in our hospital. Ten patients with AOSD had undergone ^{18}F-FDG PET, and the inflammatory lesion was evaluated by using the standardized uptake value (SUV). Laboratory data showing disease activity of AOSD such as CRP, WBC counts, LDH, sIL-2R and ferritin was measured in all patients. We examined the correlation of FDG accumulation and serological markers such as CRP, WBC, LDH, sIL-2R or ferritin. In addition, all patients were treated with only corticosteroid (responder group) or combined with immunosuppressant (non-responder group). We investigated the difference between two groups by using serological markers or FDG accumulation.

Results: ^{18}F-FDG PET revealed hepatosplenomegaly and FDG accumulation in the bone marrow, lymph node or spleen with AOSD patients. Two serological markers (sIL-2R, ferritin) showed close correlation with FDG accumulation. Additionally, SUV levels and the titer of ferritin were significantly high in non-responder group.

Conclusion: In AOSD patients, ^{18}F-FDG PET is useful for the diagnosis of AOSD with the serological markers equally. Furthermore, FDG accumulation can visually reveal a disease activity. Additionally, we suggest the possibility that high level of SUV and high titer of ferritin become predictive factor of refractory AOSD cases.

968

PET-CT, Interleukins and Metalloproteinases to Assess Disease Activity in Takayasu Arteritis Patients. Anne E.D. Arraes[1], Alexandre W.S. Souza[1], Eduardo N.P. Lima[2] and Emilia I. Sato[1]. [1]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Hospital AC Camargo, São Paulo, Brazil

Background/Purpose: Takayau arteritis (TA) is a large vessel arteritis affecting mainly aorta and its branches. One of the great difficulties to treat TA patients is a lack of reliable criteria to assess disease activity. There is study showing that even in TA patients with no complaints and no abnormal acute phase reactants (classified as inactive disease), at surgical procedure it was found an inflammatory process at vessel wall, characterizing a histologically active disease. The aim of this study was to quantify 18F-fluorodeoxyglucose (FDG) uptake on PET-CT and measure serum levels of IL-2, IL-6, IL-8, IL-12, IL-18, TNF-alfa, MMP-3 and MMP-9 to assess disease activity in TA patients. We also evaluate correlation between FDG uptake on PET-CT and level of these serum biomarker.

Methods: Thirty-six TA patients (≥3 ACR criteria, 1990) followed at Vasculitis unitis of a University hospital and 36 age-and-sex matched controls participated in the study. The serum level of IL-2, IL-6, IL-8, IL-12 and TNF-alfa were measured by LUMINEX (HSCYTO-60SK-05 Milliplex, Millipore, USA). IL-18 (Med & Biol Lab CO, Japan), MMP-3 and MMP-9 (R&D System, EUA) were measured by ELISA assay. Maximum standard uptake value (SUVmax) in arterial walls was registered by PET-CT (Gemini, Phylips, EUA). The TA activity was evaluated using NIH criteria

Results: The mean age of patients and controls was respectively 36.2 and 37.0 years and 92% of them were female. The serum level of IL-6 [13.3 pg/ml (95% CI 7.0–19.6) vs 3.4 pg/ml (95%CI 1.9–4.8) $P<0.001$] and of MMP-3 [647.8 pg/ml (95%CI 494.7–800.8) vs 563.7pg/ml (95%CI 439.4–688.0); $P<0.001$] were higher in TA patients than in controls. Comparing the serum level of these interleukins and metalloproteinases between patients classified as active vs inactive disease, only IL-6 was significantly higher in patients with active disease (22.5 pg/ml vs 7.5 pg/ml; $P=0.027$). Regarding SUVmax on PET-CT, patients with active disease had higher SUVmax values than those with inactive disease ($P=0.042$). ROC curve analysis showed that the value of SUVmax as a predictor of clinical activity ($P=0.043$; AUC=0.703; IC 95%=0.534–0.832). SUVmax ≥ 1.3 was associated with clinical activity ($P=0.039$). TNF-alfa levels were higher in patients with SUVmax ≥ 1.3, when compared to those <1.3 ($P=0.045$) and to controls ($P=0.012$). IL-6 and MMP3 levels were higher in patients with SUVmax ≥ 1.3 than in controls ($P<0.001$ and $P=0.006$, respectively). There was no significant difference regarding others serum biomarkers comparing TA patients and controls.

Conclusion: This is the first study evaluating various interleukins and metalloproteinase to assess disease activity in TA patients. The serum level of IL-6 was associated with disease activity. This study also finds a correlation between 18F-FDG uptake in PET-CT and disease activity. Therefore PET-CT and serum level of IL-6 appear to be promising tools to assess Takayasu arteritis disease activity.

969

The Value of Positron Emission Tomography – Computed tomography in Patients with Large Vessel Vasculitis. Man Wai Tang, Danielle Marie Gerlag, A. Elisabeth Hak, Berthe L.F. van Eck-Smit and Paul-Peter Tak. Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Positron emission tomography - computed tomography (PET-CT) scan has become a promising, noninvasive diagnostic test in various diseases, such as large vessel vasculitis. It is currently unknown what the influence of corticosteroids on the outcome of this technique is in this disease. The purpose of this research is to study the correlation between the inflammatory markers, erythrocyte sedimentation rate and C-reactive protein (respectively ESR and CRP) and outcome of PET-CT. Furthermore, the influence of corticosteroids on the outcome of PET-CT in large vessel vasculitis will be studied.

Methods: 24 patients with a suspicion of large vessel vasculitis were evaluated between November 2007 – January 2010 using PET-CT. Levels of ESR and CRP were measured and correlated to vascular FDG-uptake. The levels of ESR and CRP were categorized in both normal values, elevated ESR or CRP and both elevated levels. The use of corticosteroids at the time the PET-CT was performed, was also evaluated. Clinical outcome was also studied, which was defined as starting with corticosteroids in patients with and with no pathological vascular FDG-uptake.

Results: Patients with the suspicion of vasculitis who showed pathological vascular FDG-uptake in the large vessels on PET-CT had a higher level of ESR compared to patients without vascular FDG-uptake, respecitively mean ± SD: 72 ± 45 versus 30 ± 20 mm/hr (p=0,011). Similar results were found for the CRP levels with positive and negative FDG-uptake, respectively median 43 (4,2–220) versus 6,2 (1–221) mg/L (p=0,053). Using the three categories, 90% of the patients who have both elevated markers showed pathological vascular FDG-uptake, compared to 50% of patients with elevated ESR or CRP level and only 20% of patients with normal levels (p=0.011), see figure 1. Overall, the area under the curve (ROC) of the three groups of normal and/or high ESR and/or CRP increased from 0.731 (p=0,063) to 0.804 (p=0,014) after addition of the PET-CT scan.

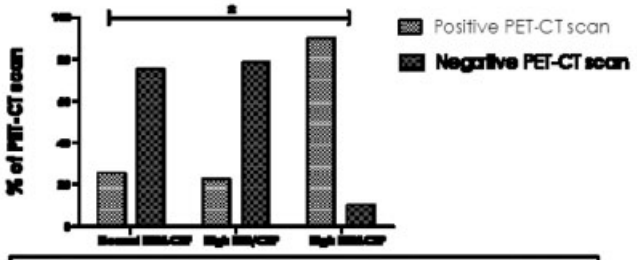

Fig. 1 Elevated levels of ESR and CRP were significantly more correlated with a positive PET-CT scan.

As expected, lower ESR levels were measured in the group of patients who used corticosteroids compared to patients who did not use corticosteroids, respectively 35 ± 30 versus 78 ± 45 mm/hr (p=0.016). Use of corticosteroids was not related to FDG-uptake itself (p=0.680).

Conclusion: The PET-CT scan seems to have more additional value in patients suspected of vasculitis who have normal ESR or CRP levels compared to patients who have elevated levels of ESR and CRP. Corticosteroids decrease inflammatory markers in the peripheral blood, but do not seem to have a direct effect on FDG-uptake.

Reduced Insular Gamma-Aminobutyric Acid in Fibromyalgia. Bradley Foerster[1], Myria Petrou[1], Richard Edden[2], Pia Sundgren[1], Tobias Schmidt-Wilcke[1], Suzan E. Lowe[1], Steven Harte[1], Daniel J. Clauw[1] and Richard E. Harris[1]. [1]University of Michigan, Ann Arbor, MI, [2]Johns Hopkins, Baltimore, MD

Background/Purpose: Recent findings indicate that chronic pain patients diagnosed with fibromyalgia (FM) display elevated levels of glutamate, a major excitatory neurotransmitter, within the insula and other brain regions. This has led our group and others to suggest that some individuals with FM have augmented central glutamatergic neurotransmission and that this may play a role the pathology of this disorder. Here we quantified the level of γ-aminobutyric acid (GABA), the brain's major inhibitory neurotransmitter, in individuals with FM. We hypothesized that decreased inhibitory neurotransmission may also play a role in the pathology of FM.

Methods: 16 female FM patients (mean±SD age in years: 37.2±12.8) and 17 age- and sex-matched healthy controls (36.1±11.7; p-value = 0.79) underwent a single 3 Tesla proton magnetic resonance spectroscopy (H-MRS) session. Single voxels were placed in the right anterior insula, the right posterior insula, the anterior cingulate and the occipital cortex. The insula cortex was chosen based on our previous findings of elevated glutamate, whereas the cingulate and occipital cortex were selected as exploratory and negative control regions respectively. For voxel placement, each subject underwent a 3D-MPRAGE sequence with 0.9 mm^3 isotropic voxel resolution. MR spectra were acquired from using 3.0 cm × 2.0 cm × 3.0 cm^3 volumes. Single-voxel point resolved spectroscopy (PRESS) spectra (TR/TE=2000/35 ms) were acquired from each region of interest. GABA was isolated using MEGA-PRESS with the following parameters: TE = 68 ms (TE1 = 15ms, TE2 = 53 ms); TR= 1.8s; 256 transients of 2k datapoints; spectral width= 2 kHz; frequency selective editing pulses (14 ms) applied at 1.9 ppm (ON) and 7.46 ppm (OFF). Refocusing was performed using amplitude-modulated pulse 'GTST1203' (length = 7 ms, bandwidth = 1.2 kHz). MEGA-PRESS spectroscopy was analyzed using in-house post-processing software in Matlab with Gaussian curve fitting to the GABA and inverted N-acetylaspartate

(NAA) peaks. The concentration of GABA (in arbitrary institutional units, AIU) was then calculated by multiplying the ratio of GABA:NAA by the absolute NAA concentration determined from LCModel analysis of PRESS data.

Results: Compared to healthy pain free controls, FM patients had significantly lower levels of GABA within the right anterior insula (AIU mean ± SD 1.02 ± 0.21 versus 1.24 ± 0.28; p=0.015). There was a trend towards increased GABA in the anterior cingulate of FM patients (p=0.06). No significant differences between groups were detected in the posterior insula or occipital cortex (all $p > 0.05$). Within the right posterior insula, higher levels of GABA were positively correlated with pressure pain thresholds for the FM patients (r=0.70; p=0.008).

Conclusion: Diminished inhibitory neurotransmission resulting from lower concentrations of GABA within the insula may play a role in the pathophysiology of FM. Moreover, reduced GABA may partially explain the efficacy of GABA receptor agonists such as sodium oxybate in this condition.

971

Pregabalin Reduces Posterior Insula Combined Glutamate and Glutamine in Fibromyalgia. Richard E. Harris[1], John P. Huggins[2], Lynne Pauer[2], Pia Sundgren[1], Craig Urwin[1], Kathy Scott[1] and Daniel J. Clauw[1]. [1]University of Michigan, Ann Arbor, MI, [2]Pfizer Inc., Sandwich, United Kingdom

Background/Purpose: Pregabalin has been shown to reduce pain in fibromyalgia (FM) however its clinical mechanism of action is unknown. Preclinical studies *in vitro* and *in vivo* both indicate that pregabalin binds to the $\alpha 2\delta$-subunit of voltage gated calcium channels thereby potentially down regulating glutamate (Glu) release at the synapse as well as inhibiting glutamatergic synapse formation. Recently our group has demonstrated that patients diagnosed with FM display elevated levels of Glu and combined Glu + glutamine (Glx) within the posterior insula, suggesting augmented glutamatergic neurotransmission in this disorder. Here we quantify the levels of insular Glu and Glx in individuals with FM before and after treatment with pregabalin and placebo. We hypothesized that pregabalin, as compared to placebo, would decrease the amount of Glu and/or Glx within the posterior insula.

Methods: 17 female FM patients (mean±SD age in years: 38.0±10.9), with complete data, completed a randomized double-blind two-period cross-over study of pregabalin versus placebo. During the pregabalin period, drug concentration was dose escalated to 450mg/day over the course of 14 days. During the placebo period, sugar pills were taken over the course of 14 days to match the pregabalin period. Prior to and following each period (pregabalin or placebo), patients underwent proton magnetic resonance spectroscopy (H-MRS) imaging at 3 Tesla at rest. Single voxels were placed in the right anterior insula and the right posterior insula. The insula cortex was chosen based on our previous findings of elevated Glu and Glx in this structure. Single-voxel point resolved spectroscopy (PRESS) spectra were acquired from each region of interest with the following parameters:TR 3000ms/TE 30ms, 90 degree flip angle, NEX 8, FOV 16, with a voxel size of 2×2×3cm. Spectra were analyzed offline with LCModel. Values for Glu and Glx were calculated as ratios to the internal standard creatine (Cr; eg. Glu/Cr). Data were analyzed with SPSS v.19.

Results: FM patients displayed a significant reduction in Glx/Cr within the posterior insula following pregabalin treatment (post minus pre; mean difference ± SD: 0.116 ± 0.177; p=0.016) but not placebo (post minus pre; mean difference ± SD: −0.028 ± 0.308; p=0.71). There was a trend towards decreased Glu/Cr in the posterior insula following pregabalin (post minus pre; mean difference ± SD: 0.070 ± 0.157; p=0.08) but not placebo (p=0.44). No significant changes following either pregabalin or placebo were detected for Glx/Cr and Glu/Cr in the anterior insula (all $p>0.05$). No significant changes were detected for any of the other H-MRS detected metabolites within the anterior and posterior insula (all $p>0.10$).

Conclusion: Consistent with preclinical data, pregabalin reduces combined glutamate and glutamine within the posterior insula of individuals with FM. This may be related to the clinical efficacy of this drug.

972

Feasibility of Bone Density Evaluation Using Plain Digital Radiography. Margot B. Kinds, Anne C. A. Marijnissen, Koen L. Vincken, Lambertus W. Bartels, Max A. Viergever, Hugo WAM de Jong and Floris P.J.G. Lafeber, University Medical Center Utrecht, Utrecht, Netherlands

Background/Purpose: For the evaluation of subchondral bone density (BD) changes due to OA, Dual Energy X-ray Absorptiometry (DEXA) is the most validated method. The need for DEXA might be reduced if the quantitative measurement of clinically relevant BD changes on radiographs is proved feasible, since radiographs are commonly acquired to evaluate structural changes due to OA. Precision of BD evaluation might be influenced by variations in acquisition settings that commonly occur in clinical practice and by post-processing (PP) that was introduced with the transition from conventional film-screen radiography to digital radiography. The objective of this study was to evaluate the effects of PP and acquisition settings on the precision and with that feasibility of BD measurement using plain digital radiography.

Methods: A bone density standard (BDS) was created consisting of eight cups with hydroxyapatite (HA: range 1.0–5.75 g/cm^2). Digital radiographs of the BDS were taken (Philips Digital Diagnost), with variations in the acquisition and PP settings. Tube voltage (in kilovolt: kV), exposure (in milliampere seconds: mAs), tube added filtering, and BDS position in the field-of-view were systematically varied and the default clinical PP was compared with minimal PP (at minimal strength). An aluminum step wedge served as an internal reference to express gray values of the BDS in mm aluminum equivalents (mmAl), by use of custom made software. In all cases a human (cadaver) knee joint was added to simulate clinical conditions. The relation (R^2) between the BD values normalized to the reference wedge (in mmAl equivalents) and actual BD (HA in g/cm^2), with variations in acquisition and PP settings was evaluated with linear regression analyses. Precision of BD measurement of the BDS was calculated in early OA (Cohort Hip & Cohort Knee: CHECK) to evaluate the relevance for clinical (research) practice.

Results: The BDS was validated by DEXA scanning and the relation between actual HA (g/cm^2) and DEXA values was strongly linear: $R^2=0.99$. In general for digital radiographs a strong correlation between actual BD and BD in mmAl was found for all settings. The correlation improved by changing PP from clinical ($R^2=0.96$) to minimal ($R^2=0.98$). Higher kV improved the correlation further. Even, for clinical PP mean SD was 0.97 mmAl, much smaller than the change of 2.51 mmAl clinically observed during two-year follow-up in early OA which implies the feasibility of BD measurements using plain digital radiography.

Conclusion: Accurate bone density measurement using digital radiography is feasible in a clinically relevant range, which removes the need for additional DEXA scans since plain radiographs are acquired for to evaluate structural changes due to osteoarthritis. Care should be taken in changing post-processing and acquisition settings, which can have profound effect on outcome.

973

Alterations of Bone Geometry, Volumetric Density and Microarchitecture in Women with Systemic Lupus Erythematosus on Chronic Corticosteroids: A Case-Control Study Using High Resolution-Peripheral Quantitative Computed Tomography. Xiao Lin Tang, Tracy Y. Zhu, Lai Shan Tam and Edmund K. Li. The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background/Purpose: To assess the alterations of bone geometry, volumetric bone mineral density (vBMD) and microarchitecture and areal BMD (aBMD) in women with systemic lupus erythematosus (SLE) on chronic corticosteroid.

Methods: One hundred and twenty-one Chinese women with SLE taking chronic corticosteroid with mean (SD) age of 44.78 (8.47) and 121 age- and sex-matched healthy controls with mean (SD) age of 45.19 (8.31) were recruited. Bone geometry, vBMD and microarchitecture were measured by high resolution peripheral quantitative computed tomography (HR-pQCT) at the non-dominant distal radius. aBMD was measured by dual-energy x-ray absorptiometry at femoral neck, total hip, lumbar spine and non-dominant distal radius

Results: At all 3 sites, aBMD was not significantly different between patients with SLE and controls. Prevalence of osteoporosis was significantly higher in patients with SLE than controls (8.3% vs. 2.5%, p=0.046). Using HR-pQCT, average bone density (p=0.02) and cortical bone density (p=0.002) were lower in patients than controls. Patients with SLE developed more deterioration in cortical area (p=0.014) and cortical thickness (p=0.002). After adjusting for body mass index and menopausal status, cortical area and cortical thickness remained significantly lower in patients than controls. There was a trend toward deterioration in trabecular bone quality, including trabecular bone density, trabecular bone volume fraction

and trabecular number in patients with SLE, although not statistically significant.

aBMD and geometry, volumetric density, microarchitecture measured by DXA and HR-pQCT in SLE women and age-matched controls

	Patients (n=121)	Controls (n=121)	p
aBMD (g/cm^2)			
Femoral neck	0.72±0.15	0.74±0.11	0.197
Total hip	0.85±0.12	0.88±0.11	0.053
L1-L4 spine	1.02±0.93	0.99±0.15	0.744
Distal radius	0.56±0.05	0.56±0.07	0.457
Geometry			
Total bone area (cm^2)	209.18±32.42	203.94±34.86	0.227
Cortical area (cm^2)	54.43±9.63	57.28±8.26	0.014
Trabecular area (cm^2)	151.80±31.72	144.49±33.64	0.083
Volumetric BMD			
D100 (mg HA/cm^3)	365.70±73.42	386.63±65.14	0.020
Dcomp (mg HA/ cm^3)	940.19±51.91	958.30±39.03	0.002
Dtrab (mg HA/cm^3)	140.48±43.11	142.17±38.15	0.747
Dmeta (mg HA/cm^3)	198.45±40.89	204.23±36.11	0.245
Dinn (mg HA/cm^3)	100.16±45.91	98.90±40.46	0.821
Microarchitecture			
Ct.Th (mm)	0.91±0.17	0.97±0.15	0.002
Ct.Pm (mm)	60.30±4.95	59.34±4.99	0.135
BV/TV	0.12±0.04	0.12±0.03	0.748
Tb.N (1/mm)	1.54±0.28	1.55±0.26	0.759
Tb.Th (mm)	0.08±0.02	0.08±0.01	0.615
Tb.Sp (mm)	0.60±0.15	0.59±0.15	0.669
Tb.1/N.SD (mm)	0.26±0.10	0.26±0.10	0.944

Conclusion: Patients with SLE on chronic corticosteroid developed lower vBMD and deterioration of bone microarchitectural that can be assessed noninvasively by HR-pQCT. HR-pQCT appears sensitive to detect bone loss, especially cortical bone loss, in patients with SLE.

974

Disease Damage Has Deleterious Effect on Trabecualr Bone Microarchitecture in Female Patients with Systemic Lupus Erythematosus On Chronic Corticosteroids. Xiao Lin Tang, Tracy Y. Zhu, Lai Shan Tam and Edmund K. Li. The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease. It can affect almost all the organs of the body, for example the musculoskeletal system. Patients have higher risk of osteoporosis and fracture than general population. Recently, with advances in high resolution imaging techniques, such as high-resolution peripheral quantitative computed tomography (HR-pQCT), interest in investigating bone microarchitecture as an important role in the development of osteoporosis has increased. We aimed to investigate the effect of various clinical parameters on bone geometry, volumetric density and microarchitecture in female SLE patients on chronic corticosteroids using HR-pQCT.

Methods: One hundred and twenty Chinese females with SLE on long-term corticosteroids, with mean age (SD) of 42 (9) and 37.5% being post-menopausal, were selected to participate in a cross-sectional study. Areal bone mineral density (aBMD) at the total hip, lumbar spine and non-dominant distal radius was measured by dual-energy X-ray absorptiometry (DXA). Bone geometry, volumetric density and microarchitecture at the non-dominant distal radius were measured by HR-pQCT. Clinical parameters of interest included disease activity, disease damage, major organ involvement (lupus nephritis and neuropsychiatric damage), and use of corticosteroids and cyclophosphomade were recorded.

Results: Disease damage measured by the Systemic Lupus International Collaborative Clinics/American College of Rheumatology Damage Index (SDI) was the only variable constantly associated with bone loss in patients with SLE. Other clinical parameters had minimal effect on bone quality. The median SDI score of the cohort was 0 (interquartile range: 0–1, range 0–4), among which 51 (42.5%) had a SDI score ≥ 1. Ocular (12.5%), neuropsychiatric (10%) and cardiovascular damage (5%) were the most common damages. Forty-two (35%) patients were osteopenic or osteoporotic at total hip, 43 (36%) at lumbar spine, 25 (21%) at radius and 60 (50%) at either 1 site. Strong correlations were found between aBMD and all volumetric/architecture parameters. More organ damage were significantly correlated with more deterioration in trabecular bone quality, including trabecular bone density, trabecular bone volume fraction, trabecular thickness, trabecular separation and standard deviation of 1/trabecular number. After adjusting for age, body mass index, menopausal status and trabecular area, significant correlations still remained between higher SDI score and all the above trabecular bone parameters.

Conclusion: Disease damage has deleterious effect on trabecular bone microarchitecture in female SLE patients on chronic corticosteroids. Preventing disease damage may be effective in preserving bone quality, especially trabecular bone quality in SLE.

A Toll-Like Receptor 1 Polymorphism Is Associated with Heightened T Helper 1 Responses and Antibiotic-Refractory Lyme Arthritis. Klemen Strle, Junghee J. Shin, Lisa Glickstein and Allen C. Steere. Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Single nucleotide polymorphisms (SNPs) have been identified in several genes encoding Toll-like receptors (TLRs) that lead to modified cellular immune responses, decreased cytokine production, and altered disease susceptibility. The TLR SNPs with the best evidence for affecting immune function are TLR1 (1805GG), TLR2 (2258GA) and TLR5 (1174CT). We studied the frequency and functional outcome of these polymorphisms in patients with various manifestations of Lyme disease.

Methods: PCR amplification-restriction fragment length polymorphism assays were used to determine the genotypes of TLR1 at position 1805, TLR2 at position 2258, and TLR5 at position 1174 in 71 patients with erythema migrans (EM) an early disease manifestation, and in 76 patients with antibiotic-responsive and 101 patients with antibiotic-refractory Lyme arthritis, a late disease manifestation. To assess the functional outcome of the polymorphisms, protein levels of 12 cytokines and chemokines were determined in serum of EM patients, and in joint fluid of Lyme arthritis patients using bead-based multiplex assays. In addition, the protein levels of these mediators were assessed in supernatants of *Borrelia burgdorferi*-stimulated PBMC from 43 patients with Lyme arthritis.

Results: The frequency of TLR1 polymorphism (1805GG) was greater in patients with antibiotic-refractory arthritis compared to patients with EM (62% vs, 49%, odds ratio = 1.7, P = 0.1) or antibiotic-responsive arthritis (62% vs. 47%, odds ratio = 1.9, P=0.05). Early in the illness, patients with EM who had 1805GG, primarily those infected with *B. burgdorferi* RST1 strains, had higher serum levels of IFNγ, CXCL9 and CXCL10, and more severe infection than patients with 1805TG/TT. These inflammatory responses were amplified in patients with Lyme arthritis, and the highest responses were observed in patients with antibiotic-refractory arthritis who had 1805GG and had been infected with RST1 strains. When PBMC from Lyme arthritis patients were stimulated with a *B. burgdorferi* RST1 strain, the 1805GG group had significantly larger fold changes in the levels of IFNγ, CCL2, CXCL9 and CXCL10, than those with 1805TG/TT (P<0.001). In contrast, the frequencies of TLR2 (2258GA) and TLR5 (1174CT) were not significantly different among the groups, and cytokine and chemokine values were similar in those with or without the polymorphism.

Conclusion: We concluded that the TLR1 1805GG polymorphism in *B. burgdorferi* RST1-infected patients was associated with stronger T_H1-like immune responses, more symptomatic infection, and antibiotic-refractory arthritis. This is the first innate immune factor identified associated with antibiotic-refractory arthritis.

Toll Like Receptor-2 Activation Prevents Cartilage Damage in Osteoarthritis Models That Display Synovial Activation. Arjen Blom, Peter van Lent, Shahla Abdollahi-Roodsaz, Peter M. van der Kraan and Wim B. van den Berg. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: There has been a huge interest in the role of Toll-Like Receptors (TLR) in human and experimental arthritis. Several endogenous ligands for TLR2 are present in osteoarthritic joints. However, the involvement of TLR2 in osteoarthritis (OA) has not been studied extensively. This study was performed to evaluate the role of TLR2 in experimental OA pathology.

Methods: Three models for OA were used, collagenase induced OA (CIOA), destabilization of the medial meniscus (DMM) and spontaneous OA in IL-1ra$^{-/-}$ murine knee joints. CIOA was induced by injection of collagenase into murine knee joints. Due to instability, OA-like pathology develops within 42 days. DMM

was induced by transsecting the medial meniscotibial ligament, which results in OA-like pathology within 56 days. The role of TLR2 was studied by induction of CIOA and DMM OA in TLR2$^{-/-}$ mice (n=16) and C57BL/6 controls (n=15), and by backcrossing of TLR2$^{-/-}$ mice to IL-1ra$^{-/-}$ mice. At end point, knee joints were isolated and OA-like changes in the cartilage were scored. At several time points after induction, synovial tissue was isolated to study TLR2 expression in the wild type (WT) mice by Q-PCR.

Results: In CIOA and to a lesser extent in the IL-1ra$^{-/-}$ mice, synovial activation, indicated by thickening of the synovial lining layer, was clearly present during the whole course of the disease. However, no synovial activation was observed in the DMM model. At day 7 after induction of CIOA in WT mice, synovial TLR2 levels were upregulated up to 56 fold, probably reflecting cellular influx at this time point. At day 21 TLR2 levels were up 2-fold and 42 days after induction, TLR2 levels in the synovium were down to baseline levels. In the DMM model, TLR2 was not regulated at any of these time points.

During CIOA in TLR2$^{-/-}$ mice, OA cartilage pathology increased from 10,0 in the WT controls to 15,5 ($p<0,02$). Changes were observed in both medial and lateral joint compartment. Incidence of severe cartilage damage was increased in the medial femur, medial tibia, lateral femur and lateral tibia respectively from 13% to 44%, from 27% to 69%, from 60% to 81% and from 53% to 81%. In knee joints of IL-1ra$^{-/-}$ mice, damage was mild compared to CIOA WT mice with a mean score of 2,2 and showed an increase in the IL-1ra$^{-/-}$/TLR2$^{-/-}$ up to a score of 4,1. In contrast, cartilage pathology during DMM OA in TLR2$^{-/-}$ was not changed in the medial compartment of the joints, compared to WT mice, respectively 13,7 and 14,7. Severe cartilage damage did not differ between WT and TLR2$^{-/-}$. In all models, synovitis in TLR-2$^{-/-}$ mice was comparable to the WT, indicating no direct role for TLR2 in synovitis.

Conclusion: Unexpectedly, this study indicates that in TLR2 deficient mice OA pathology is more severe in experimental OA that involves synovial activation. This suggests a protective role for this receptor in OA. This protective role was abolished in the absence of synovial activation, as was found in the DMM model. Stimulation of TLR2 by endogenous ligands such as biglycan, hyaluronan or HMGB-1 has been shown to induce IL-10, TGFb and HGF, which are protective mediators for OA. Although further research is needed, these results indicate that the TLR2 pathway protects cartilage from developing OA and that this effect is mediated by the synovium.

977

NI-0101, a Therapeutic TLR4 Monoclonal Antibody for Rheumatoid Arthritis. Greg Elson[1], Theresa Page[2], Vanessa Buatois[1], Bruno Daubeuf[1], Laurence Chatel[1], Laura Cons[1], Carla Lippens[1], Susana Salgado-Pires[1], Walter Ferlin[1], Marie Kosco-Vilbois[1], Kim Midwood[2] and Limin Shang[1]. [1]NovImmune S.A., Plan-Les-Ouates, Geneva, Switzerland, [2]Kennedy Institute of Rheumatology, Imperial College of Science, Technology and Medicine, London, United Kingdom

Background/Purpose: Toll-like receptor 4 (TLR4) is a powerful sensor of inflammation bridging mechanisms that give rise to both innate and adaptive immunity. Dysregulation of TLR4 signaling via endogenous ligands created during chronic inflammatory processes appears to play an underlying role in the pathogenesis of autoimmune diseases. The aim of this study was to evaluate the full potential of TLR4 blockade for the treatment of rheumatoid arthritis (RA) using a novel therapeutic monoclonal antibody (mAb), NI-0101.

Methods: The anti-human TLR4 mAb, NI-0101, was generated and shown to efficiently block TLR4 activation in vitro by exploiting a mechanism involving both Fv and Fc portions. Using exogenous, endogenous or chemical ligands, the capacity to block TLR4 activation was evaluated. Subsequently, NI-0101 was tested in synovial explant cultures obtained from RA patients. Furthermore, the corresponding mouse surrogate antibody was tested in a laboratory model of RA.

Results: Due to inhibition of TLR4 dimerization, NI-0101 efficiently blocked the activation of TLR4 by different ligands, including tenascin C, the endogenous ligand of TLR4 upregulated in synovial fluid from RA patients. Consistent with this result, NI-0101 reduced the spontaneous production of TNFα and IL-6 in synovial explant cultures from RA patients. To determine the effects of NI-0101 *in vivo*, we used the mouse surrogate antibody of NI-0101, 5E3. Therapeutic administration of 5E3 efficiently ameliorated disease progression in the he IL-1Rn−/− model of RA.

Conclusion: The therapeutic anti-human TLR4 mAb, NI-0101, has the capacity to interfere with not only LPS but also signaling of TLR4 through endogenous and chemical ligands. When used in *in vitro* models with tissue from RA patients, NI-0101 reduces spontaneous pro-inflammatory cytokine production. We demonstrated that anti-TLR4 mAb therapy is efficient in abolishing disease progression in arthritic mice. Taken together, these data promote NI-0101 as a promising treatment in RA. Moreover, by targeting a central upstream mediator in the inflammatory cascade, NI-0101 may have broad effects on RA pathogenesis and promote remission.

978

MiR-20a Regulates Negatively TLR4 Signalling Pathway by Targeting ASK1 in Rheumatoid Synoviocytes. Lucas Philippe[1], Ghada Alsaleh[1], Sébastien Pfeffer[2], Jacques-Eric Gottenberg[1], Jean Sibilia[1], Dominique Wachsmann[1] and Philippe Georgel[3]. [1]EA4438 Laboratoire Physiopathologie des Arthrites, Illkirch-Strasbourg, France, [2]Architecture et Réactivité de l'ARN, Université de Strasbourg, Strasbourg, France, [3]Laboratoire d'ImmunoGénétique Moléculaire Humaine, Strasbourg, France

Background/Purpose: In rheumatoid arthritis (RA), the fibroblast-like synoviocytes (FLS), resident cells of the joint space, show an aggressive phenotype. They release a broad range of cytokines and enzymes which contribute to destruction. Extrinsic factors such as microbial components (PAMPs) or damage associated molecular patterns (DAMPs) activate FLS by interacting with Pattern Recognition Receptors (PRRs) such as Toll like receptors (TLRs). But it becomes more and more evident that epigenetic factors such as miRNAs play an important regulatory role in the development of the inflammatory response in RA. Our group identified in LPS-activated RA FLS a miRNA, miR-346 which functioned as a negative regulator of IL-18 and TNF-α release by activated FLS. We also demonstrated that miR-19 (miR-17–92 cluster) controlled directly TLR2 expression in RA FLS. An online search of the miRBase target database, demonstrated that one miRNA: miR-20a belonging to the downregulated miR 17–92 cluster was predicted to potentially target the 3'-UTR region of a mitogen-activated protein 3-kinase (ASK1) selectively required for LPS-induced activation. In this study, we aimed to evaluate the role of miR-20a in the regulation of this TLR signalling component.

Methods: RA FLS were isolated from synovial tissues and stimulated with TLR2 (BLP) and TLR4 (LPS) ligands. QRT-PCR was performed to evaluate miRNA and mRNA expression. Transient transfection of FLS with mimic 20a was performed using the Human Dermal Fibroblast Nucleofector™ kit from Amaxa. All assays were performed 48 h post transfection. Transfection of HEK293 cells with reporter constructs and miR-20a mimic or antagomir was performed using Lipofectamine. Luciferase activity was determined using the dual-luciferase reporter assay system. IL-6 release was measured in culture supernatants by ELISA.

Results: We first showed by qRT-PCR that RA FLS expressed constitutively ASK1 and that ASK1 expression is significantly enhanced in response to LPS and BLP. Consistent with the downregulation of miR-17-92 cluster expression, miR-20a was strongly down regulated in RA FLS activated by LPS and BLP. As *in silico* analysis predicted that miR-20a might possibly bind to the 3'-UTR of human ASK1 transcript, we transiently transfected into HEK-293 cells, a reporter construct that contain the firefly luciferase gene fused to the ASK1 3'-UTR containing the putative miR-20a interactor site along with miR-20a. We observed a downregulation of the luciferase activity, indicating that the 3'-UTR of ASK1 mRNA is directly targeted by miR-20a. Finally, to examine the consequence of a decrease of ASK1 expression by miR-20a, we tested by transfection, whether expression of miR-20a affected IL-6 release in LPS-activated RA FLS. As compared to the control, we observed that transfection of the mimics induced a strong downregulation of IL-6 release in response to LPS and not to BLP.

Conclusion: These results illustrate a negative feedback loop that control TLR4 response. Our data strongly suggest a critical role of miR-20a in the regulation of the expression of ASK1 in response to TLR4 activation which could play an important role in the regulation of the inflammatory response in RA.

979

TIR-Domain-Containing Adaptor-Inducing Interferon-β (TRIF)-Dependent Toll-Like Receptor 4 Signaling Mediates Antibody Class Switching in a Mouse Model of Histidyl-tRNA Synthetase-Induced Myositis. Lisa Harlow[1], Makoto Soejima[2] and Dana P. Ascherman[3]. [1]University of Miami Miller School of Medicine, Miami, FL, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Miami, Miami, FL

Background/Purpose: In our previously published model of myositis generated by intramuscular (IM) immunization with a recombinant fragment of murine Jo-1 fused to Maltose Binding Protein (MA/MBP), we determined that induction of IgG anti-Jo-1 autoantibodies does not require the addition of exogenous adjuvant, but is dependent on TLR4 signaling. While this observation highlighted the potential role of innate immune pathways in directing the

production of IgG autoantibodies, the relative contribution of TLR4 signaling to antibody formation versus class switching remained undefined.

Objectives: To determine the role of toll-like receptor (TLR) signaling in histidyl-tRNA synthetase (Jo-1)-induced autoantibody formation and class switching.

Methods: We used standard solid phase ELISA to determine IgM and/or IgG anti-Jo-1 antibody responses at various time points following IM immunization of different mouse strains with a recombinant amino-terminal fragment of murine Jo-1 fused to Maltose Binding Protein (MA/MBP). Mouse strains used for this analysis included C3H/HeOuJ (WT), C3H/HeJ (TLR4 loss of function mutation), C57BL/6 (B6), B6.MyD88$^{-/-}$, and B6.Ticam1 (TRIF loss of function mutation).

Results: Relative to post-immunization sera derived from C3H/HeOuJ (WT) mice, sera obtained from C3H/HeJ (functional TLR4 knockout) mice following IM immunization with MA/MBP demonstrated markedly reduced titers (5–40 fold) of IgG anti-Jo-1 autoantibodies. Although this finding implicated TLR4 signaling in anti-Jo-1 autoantibody formation/class switching, MA/MBP-immunized B6.MyD88$^{-/-}$ mice surprisingly demonstrated equivalent levels of anti-IgG Jo-1 autoantibodies relative to their WT counterparts, C57BL/6 (with some differences in the ratio of IgG_1/IgG_{2a}). In contrast, IM immunization of B6.Ticam1 (deficient TRIF signaling) mice with MA/MBP yielded markedly reduced titers of IgG anti-Jo-1 autoantibodies (similar to C3H/HeJ mice), implicating the TRIF-dependent arm of TLR4 signaling in the generation of IgG anti-Jo-1 autoantibodies. To clarify the role of TRIF-mediated TLR4 signaling in autoantibody formation versus class switching, we assessed the induction of IgM and IgG anti-Jo-1 antibodies at Days 4, 7, and 11 following IM immunization of C3H/HeJ and C3H/HeOuJ mice. These experiments demonstrated that C3H/HeJ mice produced equivalent levels of anti-Jo-1 IgM compared to C3H/HeOuJ mice at early time points following MA/MBP immunization, but failed to generate significant titers of class switched anti-Jo-1 autoantibodies.

Conclusion: IM immunization with recombinant murine Jo-1 in the absence of exogenous adjuvant induces antigen-specific, class switched autoantibodies. This humoral immune response is dependent on TRIF-mediated TLR4 signals regulating IgG class switching rather than IgM antibody formation. With relevance to the study of autoimmunity as well as vaccine biology, these findings provide insight regarding the contribution of innate immune signaling pathways to the generation of adaptive humoral immune responses.

Presence of Fas Associated Death Domain Protein in the Synovial Fluids and Sera (ESPOIR Cohort) of Rheumatoid Arthritis Patients Mirrors the Inflammatory Attribute of the Disease. Léa Tourneur[1], Sylvie Mistou[1], Valérie Vilmont[1], Nicolas Cagnard[2], Jacques-Eric Gottenberg[3], Valerie Devauchelle[4] and Gilles Chiocchia[2]. [1]Institut Cochin, Paris, France, [2]Institut Cochin, 75014 Paris, France, [3]Strasbourg University Hospital, Strasbourg, France, [4]Brest university medical school, EA 2216, UBO and CHU de la Cavale Blanche,, Brest, France

Background/Purpose: Fas-associated Death Domain (FADD) is the pivotal adaptor of the apoptotic signal mediated by death receptors. In rheumatoid arthritis (RA), ligands of IL-1R/TLR4 are present in the synovial fluid (SF), and FADD can act as an anti-inflammatory molecule by sequestering MyD88, the adaptor of IL-1R/TLR4 signaling. Thus, absence of FADD in synovial cells can potentially contribute to the establishment of inflammation. Recently, we identified adenosine receptors as the main regulators of a new mechanism of FADD regulation of expression by shedding of microvesicles. As adenosine is abundant in the SF of RA patients, we investigated whether FADD could be detectable in the SF and sera of RA patients compared to non-RA patients.

Methods: Detection of intracellular FADD in patients affected with RA and osteoarthritis (OA) was investigated by western blot followed by densitometry in synovial tissues (RA n=11, OA n=14) and cultured synoviocytes (RA n=7, OA n=7). A homemade protocol was used for quantification of FADD expression by ELISA. FADD was assessed in Synovial fluid (SF) from two independent cohorts (n=26 and 67) and in the sera of patients from the ESPOIR cohort (n=551 RA and 67 non-RA patients), [a French multi-centric cohort of patients having early arthritis lasting less than 6 months], and from healthy individuals (n=20). Student's *t* tests were conducted to verify statistical significance of our data.

Results: Densitometry analysis (Arbitrary Unit = AU) showed a higher concentration of cytoplasmic FADD in OA tissues and synoviocytes compared to RA tissues and synoviocytes: 0.809±0.06 vs 0.592±0.06 AU and 0.532±0.212 vs 0.317±0.143 AU respectively. Similarly nuclear FADD was higher in OA tissues and synoviocytes: 0.621±0.08 vs 0.320±0.09 and 0.247±0.05 vs 0.138±0.042AU. We detected more FADD in SF of RA patients compared to OA patients in the two cohorts: 249.4 ±72.7 vs 55 ng/ml±17 (P=0.017) and 140.2±28.5 vs 5.8±1.4 ng/ml (P=0.0015) respectively. Also FADD concentration was higher in sera of RA patients than in non-RA and healthy patients: 33.5± 5.2 vs 10.7±1.7 (P=0.00004) and vs 5.6±2.5 ng/ml (P=0.000002). The presence of FADD in RA sera at inclusion correlated with the presence of anti-CCP antibodies (P=0.035), rheumatoid factor (P=0.03) and the DAS28 (P=0.0002). Conversely no link could be made between FADD concentration and joint erosion at inclusion (P=0.2) or at 2 years post-inclusion (p=0.39).

Conclusion: This is the first demonstration that human FADD could be detected specifically during the course of an inflammatory disease. These results raised the hypothesis that low expression of FADD in joint cells could occur through a release of the protein in SF and could contribute to the development of RA.

981

TLR4 on Resident Cells and Bone Marrow Derived Cells Contribute Equally to Arthritis. Ben T. van Den Brand[1], Shahla Abdollahi-Roodsaz[1], Miranda B. Bennink[2], Onno J. Arntz[2], Wim van den Berg[1] and Fons A. van de Loo[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Nijmegen, Netherlands

Background/Purpose: The IL-1 receptor antagonist (IL-1Ra) knockout mice spontaneously develop a Th17 driven arthritis. When cross bred with TLR4 knock out (TLR4−/−) these animals showed reduced inflammation, joint destruction, and diminished IL-17 levels.

Methods: An age-matched (4–5 weeks), sex-mismatched reciprocal bone marrow transplantation was performed with TLR4−/− and TLR4+/+ mice in the IL-1Ra−/− background by 7.5 Gy irradiation and intravenous injection of freshly harvested bone marrow cells. Bone marrow was stained for Y-chromosome. Peritoneal macrophages were stimulated with lipopolysaccharide. Clinical manifestation of disease was monitored macroscopically (0 to 2 per joint). Animals were sacrificed at the age of 25 weeks. Bone erosion was scored on Safranin-O stained histological slides (0–5). T cell analysis was performed on cells from spleen and draining lymph nodes using flow cytometry.

Results: Reconstitution of bone marrow was successful as determined by Y-chromosome staining. Peritoneal macrophages from animals engrafted with TLR4+/+ bone marrow showed normal IL-6 mRNA up regulation after LPS challenge, whereas IL-6 mRNA up regulation was significantly reduced by 90% in animals that received TLR4−/− bone marrow. Lack of TLR4 on either the engrafted bone marrow cells or the radio-resistant cells did not affect disease incidence, ranging from 55 to 90% between all groups and comparable to previous experiments. However, animals that lacked TLR4 on the engrafted bone marrow derived cells, radio-resistant cells, or both showed a reduced macroscopic arthritis score (mean 1.0, 0.9, and 0.9, respectively) compared to animals expressing Tlr4 on all cells (mean 1.6). This was also reflected in bone erosion scores of the joints. T-cell analysis showed no differences in Th1 or Th17 in the spleen. However, the percentage of IL-17 positive cells was reduced in the draining lymph nodes of animals lacking TLR4 on the bone marrow derived cells, resident cells, or both, averaging 0.7%, 0.7%, and 0.57% respectively, whereas lymph nodes of complete TLR4+/+ animals contained 1.1% IL-17 cells.

Conclusion: These data suggest that TLR4 plays an equally important role on both the bone marrow derived and local resident cells in Th17 development and in aggravating experimental arthritis. TLR4 could play a local role by creating a cytokine environment favouring Th17. On the other hand, TLR4 activation on the bone marrow derived antigen presenting cells might promote a more aggressive Th17 phenotype.

982

Toll-Like Receptor-9 Activation Regulates Macrophage Triggering Receptor Expressed on Myeloid Cells-1 Expression and shedding. Yair Molad[1], Elisheva Shapira[2] and Vered Carmon[3]. [1]Felsenstein Medical Reseach Center, Sackler Faculty of Medicine, Tel Aviv University, and Beilinson Hospital, Rabin Medical Center, Petah Tikva, Israel, [2]Beilinson Hospital, Rabin Medical Center, Petah Tikva, Israel, [3]Laboratory of Inflammation Research, Felsenstein Medical Research Center, Tel Aviv University, Petah Tikva, Israel

Background/Purpose: Toll-like receptor (TLR)-4-mediated immune response plays a pivotal role in the initiation and progression of the chronic and destructive stages of arthritis in both human disease and rodent models of

rheumatoid arthritis (RA). In-addition, previous studies suggested TLR-9 plays a role in the pathogenesis of RA. For example, TLR-9 K.O. mice suffered of worse arthritis. Triggering receptor expressed on myeloid cells-1 (TREM-1) is a DAP12-associated receptor which its up-regulation is TLR-4-mediated and plays an essential role in innate immune response by augmenting the production of proinflammatory chemokines and cytokines. Monocyte TREM-1 expression is increased in human and mouse synovium as well as its soluble form (sTREM-1) serum level. Moreover, sTREM-1 was shown to exert anti-inflammatory effects in animal models of RA. We hypothesize that anti-inflammatory effects of CpG-oligonucleotide (ODN), an inducer of TLR-9 activation, are mediated by regulating membrane TREM-1 expression and sTREM-1 shedding. Thus, the purpose of our study was to determine the *in vitro* effects of CpG-ODN-induced TLR-9 activation on macrophage TREM-1 expression and shedding.

Methods: Membrane TREM-1 expression was assayed by FACS and sTREM-1 level was assayed by ELISA. Zymography was used to determine metalloproteinase (MMP)-9 activity.

Results: We sought to determine whether CpG-ODN-mediated TLR-9 activation affects TREM-1 expression and sTREM-1 level using mouse peritoneal macrophages and mouse macrophage cell line RAW 264.7. We found that the expression of TREM-1 is not significantly altered by CpG-ODN alone whereas lipopolysaccharide (LPS) up-regulates TREM-1 as was previously shown. However, macrophage stimulation with both LPS and CpG-ODN significantly abrogated TREM-1 LPS-induced up-regulation (For peritoneal cells MFI= 86.03 $\pm$ 8.6 vs. 229 $\pm$ 19.4, $p<0.005$; and for RAW cells MFI= 55.7 $\pm$ 5.6. vs. 97.6 $\pm$ 7.5, $p<0.05$). Moreover, supernatant soluble TREM-1 level of CpG-ODN as well as LPS-stimulated cells was increased and sTREM-1 level as result of both LPS-and CpG-ODN macrophage stimulation was significantly higher compared with LPS or CpG-ODN alone (56.4 $\pm$ 5.36 pg/ml vs. 16.2 $\pm$ 2.74pg/ml, $p = 0.05$). The release of sTREM-1 was found to be positively correlated with MMP-9 activity ($r=0.914$, $p<0.005$) and was inhibited by chloroquine (a TLR-9 and MMP-9 inhibitor).

Conclusion: Our novel results suggest that CpG-ODN-induced TLR-9 activation abrogates the effect of LPS on macrophage TREM-1 up-regulation and induces either by itself or in conjunction with LPS a significant increase of sTREM-1 level through a mechanism that involves MMP-9-mediated TREM-1 shedding. Our results suggest that the anti-inflammatory effects of CpG-ODN might be mediated through decreased membrane TREM-1 expression and increased MMP-9-mediated TREM-1 shedding. Since both CpG-ODN and sTREM-1 were found to exert anti-inflammatory effects in mouse models of RA, we suggest a novel pathway for CpG-ODN-mediated up-regulation of sTREM-1 that can be used to treat inflammatory arthritis.

983

A TLR 9 Antagonist Diminishes Arthritis Severity and Inhibits Bone Erosion in a Rat Model of Rheumatoid arthritis. Sonja Herman[1], Anita Fischer[1], Markus Hoffmann[2] and Gunter Steiner[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Karolinska Institutet, Stockholm, Sweden

Background/Purpose: There is increasing evidence that release of endogenous nucleic acids may trigger autoimmune reactions crucially involved in the induction of systemic autoimmune diseases such as SLE or rheumatoid arthritis (RA). In recent years, endosomal Toll-like receptors (TLRs, i.e. TLR3, TLR7, TLR8 and TLR9) have been implicated in autoimmune processes due to their ability to recognize these nucleic acids.

To study the role of TLR7 and TLR9 in the pathogenesis of erosive arthritis by antagonizing these TLRs in rats with pristane-induced arthritis (PIA).

Methods: First, the inhibitory capacity of immunoregulatory sequences (IRS) known to antagonize TLR7 and/or TLR9 activation was investigated in cultured rat splenocytes by measuring production of pro-inflammatory cytokines. Subsequently, using the PIA model, these IRS were also tested for their efficiency to inhibit arthritis development in rats with PIA. The IRS' were applied twice a week subcutaneously at the base of the tail, a non-inhibitory IRS and PBS served as control substances. Weight changes were measured during the experiment and arthritis was assessed using an established scoring system. Expression of TLRs was analyzed in paws, lymph nodes and spleen by Western blotting, RT-PCR and immunohistochemistry. Further, the impact of antagonizing TLR7/9 in osteoclastogenesis was analyzed by performing *in vitro* osteoclast assays.

Results: IRS specific for TLR7, TLR9 or TLR7/9 inhibited in a dose-dependent manner production of pro-inflammatory cytokines in rat splenocytes pre-activated by TLR specific stimulators. However, neither the TLR7 specific inhibitor nor the inhibitor targeting both TLR7 and TLR9 showed an effect on incidence and severity of PIA. Remarkably however, antagonizing TLR9 solely led to delayed disease onset and reduced arthritis severity, which was accompanied by diminished TLR9 protein expression levels in paws and lymph nodes compared to placebo-treated control animals. Moreover, bone erosion was largely reduced in animals treated with the TLR9 antagonist. Furthermore, inhibition of TLR9 but not of TLR7 in an in vitro osteoclast formation assay diminished osteoclastogenesis significantly in a dose-dependent manner.

Conclusion: Our *in-vitro* and *in-vivo* results indicate a potential involvement of TLR9 not only in the initiation of inflammatory arthritis but also in the later phase of inflammatory bone loss pointing toward a hitherto unknown role for TLR9 in the regulation of osteoclast activity.

Upregulated High Mobility Group Box One Acts in Synergy with Danger Signals Through the Activation of of p38 Mitogen-Activated Protein Kinases to Promote Inflammation in Patients with Lupus Nephritis. Shui-Lian Yu, Chun-Kwok Wong, Da-Peng Chen, cheuk-Chun Szeto, Edmund K. Li and Lai-Shan Tam. The Chinese University of Hong Kong, Hong Kong, China

Background/Purpose: The chromatin DNA binding protein high mobility group box one (HMGB1) has previously been demonstrated to act as an "alarm" prototypical damage associated molecular pattern (DAMP) to contribute to the pathogenesis of SLE via breaking the immunological tolerance against nucleosomes/dsDNA, yet its mode of action is still not well defined. To assess the balance between the levels of receptor for advanced glycation end products (RAGE), RAGE ligand (HMGB1) and soluble RAGE in active lupus patients (systemic lupus erythematosus disease activity index, SLEDAI > 4), and subsequently explore the modulating and synergy effects of HMGB1 with endogenous and exogenous danger signals on its downstream cytokine in lupus patients.

Methods: Plasma HMGB1 and soluble RAGE were detected in lupus patients and healthy controls (HCs) by enzyme-linked immunosorbent assay. Monocyte cell surface RAGE expression was assessed using flow cytometry. *Ex vivo* production of inflammatory cytokines (IL-1β, IL-6, IL-8, IL-10, TNF-α and IL-12p70) from monocytes of lupus patients and HCs upon 24 hours HMGB1 stimulation was assessed using human inflammatory cytokine Cytometric Bead Array with flow cytometry.

Results: Elevated plasma levels of HMGB1 in lupus patients were positively correlated with SLEDAI (both $p < 0.05$). Significantly lower concentrations of soluble RAGE were found in lupus plasma, albeit higher protein expression on monocytes than HCs. Recombinant HMGB1 (rHMGB1) could significantly induce the *ex vivo* production of IL-6 from monocytes of lupus patients. Moreover, there was an observable elevated release of proinflammatory (IL-6 and IL-12p70) from monocyte in lupus patients upon the stimulation with TLR9 ligand (CpG-ODNs) or nuclear extract alone than that of HCs. Strong enhancing effects on induction of IL-6 and IL-12p70 occurred when HMGB1 in combination with CpG-ODNs, which subsequently promoted the phosphorylation of p38 mitogen-activated protein kinases (MAPK) in monocytes.

Conclusion: Upregulated alarmin HMGB1 may act in synergy with TLR9 ligand (CpG-ODNs) through the activation of p38 MAPK to promote the production of proinflammatory (IL-6 and IL-12) in monocytes of patients with Lupus Nephritis.

985

The Anti-Inflammatory Action of Nerve Growth Factor Is Mediated by Trka Signalling: Modification in Trka Expression in Juvenile Idiopathic Arthritis Mononuclear Cells Create An Unbalance Between Inflammatory and Anti-Inflammatory Pathways? Gaetana Minnone[1], Giusi Prencipe[1], Raffaele Strippoli[1], Loredana De Pasquale[1], Ivan Caiello[1], Fabrizio De Benedetti[1] and Luisa Bracci-Laudiero[2]. [1]Children Hospital Bambino Gesù, Rome, Italy, [2]Institure of Translational Pharmacology-CNR, Rome, Italy

Background/Purpose: Nerve Growth Factor (NGF) production in the organism is a strictly regulated process. Inflammation increases NGF expression and indeed high NGF levels are a feature of synovial fluid and tissue in patients with chronic arthritis. Although all mononuclear cells express NGF receptors, it is, however, unclear what are the biological effects of these high NGF levels on immune cell activity. In order to evaluate the ability of mononuclear cells to respond to NGF in vivo, we analyzed the expression of TrkA and p75-NTR in mononuclear cells of patients with juvenile idiopathic arthritis (JIA). For better understanding the possible effect of NGF during the

inflammatory response we studied how intracellular signalling pathways induced by NGF affect TLR downstream signalling in monocytes, which are key players in inflammation and a critical link between innate and adaptive immunity.

Methods: Mononuclear cells were isolated from synovial fluid and peripheral blood samples of 25 children with JIA and age matched controls by Ficoll-Hypaque density centrifugation. Healthy donor monocytes, purified using Percoll discontinuous density gradients, were stimulated with TLR ligands with or without NGF addition. The expression of TrkA and p75NTR and the effects of TrkA activation or inhibition on TLR signalling and cytokine release were evaluated using real-time PCR, western blot and ELISA.

Results: We found that mononuclear cells of JIA patients from both peripheral blood and synovial fluid are characterized by a significant decrease in TrkA expression, while p75-NTR expression remains stable. In normal monocytes, phosphorylation of TrkA after NGF binding activated intracellular pathways that interfered with TLR signalling. Indeed NGF addition increased Akt phosphorylation, inactivated GSK3 and reduced IkB phosphorylation. Blocking TrkA enhanced inflammatory cytokine production, while reducing IL-10 synthesis and resulted in a greater activation of the NF-kB pathway and in inhibition of the PI3K pathway.

Conclusion: Our results imply that NGF is a relevant component of the endogenous mechanisms limiting excessive inflammatory response. Indeed, through TrkA NGF potentiates anti-inflammatory responses usually activated after TLR stimulation. The well-known increase in NGF in chronic arthritis patients may be *de facto* not efficacious in controlling inflammation because of the decrease of TrkA expression observed in JIA patients. This down-regulation of TrkA expression may influence the balance between inflammatory and anti-inflammatory pathways.

986

Dysregulation of Pyrin, the Familial Mediterranean Fever Protein, Exacerbates Endotoxin-Induced Uveitis in Mice. Holly L. Rosenzweig[1], Jenna S. Clowers[2], Jordan Allensworth[1], Emily E. Vance[1], Stephen R. Planck[1], Michael P. Davey[2], Jae Jin Chae[3], Daniel L. Kastner[4] and James T. Rosenbaum[1]. [1]Oregon Health & Science University, Portland, OR, [2]Veterans Affairs Medical Center, Portland, OR, [3]Medical Genetics Branch, National Human Genome Research Institute, MD, [4]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD

Background/Purpose: Mutation of pyrin (encoded by the gene *MEFV*) is the cause of the recessively inherited autoinflammatory disorder, familial Mediterranean fever (FMF). Pyrin is involved in regulation of inflammasome activation and IL-1β production. Given the importance of IL-1β in disease and the association of uveitis with systemic autoinflammatory disorders linked with pyrin, we sought to elucidate the functional consequences of the pathogenic, variant V726A, on the onset and severity of uveitis in mice.

Methods: Knock-in (KI) mice containing the V726A mutation or littermate controls (S129SV background) were observed without intervention or were administered an intravitreal injection of 250 ng lipopolysaccharide (LPS) in one eye and saline in the contralateral eye. Ocular inflammation was assessed histologically using a scoring system. Granulocyte populations in the blood and uveitic eye tissue were quantified by flow cytometry and immunofluorescence. Arthritis was assessed histologically and by whole body, near-infrared fluorescence imaging of inflamed regions labeled by with ProSense. Multi-plex ELISA was performed to quantify cytokine levels in uveitic eye tissue.

Results: Akin to patients with FMF, carriers with 2 copies of the mutation (i.e. KI mice) exhibit granulocytosis and arthritis that coincided with conjunctivitis. While the *MEFV* mutation did not predispose to spontaneous onset of uveitis, it did render KI mice markedly sensitive to LPS-induced uveitis as these mice developed an extensive pan-uveitis that was significantly worse that litter-mate controls. Interestingly, a pathergy response was observed in saline-injected KI controls. Ocular inflammation was characterized by infiltration predominantly of neutrophils and eosinophils that coincided with dilated blood vessels and hemorrhaging within the retina. Analysis of cytokine levels in uveitic eye tissue homogenates revealed a significant increase in IL-1β production compared to litter-mate controls.

Conclusion: Our data provide insight into how dysregulation of pyrin might influence intraocular inflammatory responses, and thereby result in more severe uveitis following an environmental trigger such as LPS.

987

Expression and Function of the NALP3 Inflammasome in Behçet's Disease. En Hyung Kim[1], Jae Young Shin[2], Mi-Jin Park[2], Sun Park[2] and Eun-So Lee[2]. [1]Kwan Dong University, Cheil General Hospital and Women's Healthcare Center, Seoul, South Korea, [2]Ajou University School of Medicine, Suwon, South Korea

Background/Purpose: NOD-like receptors (NLRs) are pattern recognition receptors that sense intracellular microbial products. Some NLRs sense danger signals and form large complexes called inflammasomes that link the sensing of microbial products and metabolic stress to the proteolytic activation of the proinflammatory cytokines. NALP3 and NOD2 belong to the NLR family. After activation, the NALP3 inflammasome subsequently releases pro-inflammatory cytokines such as interleukin-1β (IL-1β).There is strong evidence for pro-inflammatory role of IL-1β in Behçet's disesase (BD). Therefore we explored the expression of the different components of the NALP3 inflammasome and NOD2 in tissue and serum samples from patients with BD. We also evaluated altered function of inflammasomes in BD patients.

Methods: The expression of NALP3, apoptosis-associated speck-like protein containing CARD domain (ASC) and NOD2 in erythema nodosum lesions of 25 BD patients and 25 non-BD patients were examined by immunohistochemistry. The mRNA expression of NALP3 and NOD2 were examined by RT-PCR in 20 patients with BD and as control, 10 patients with psoriasis and 10 healthy adults were studied. The altered function of inflammasomes in 20 BD patients was evaluated by measuring the release of IL-1β and TNF-α from PBMCs and monocytes after stimulation using ELISA.

Results: The immunohistochemistry results showed that the expression of NALP3 and ASC was significantly higher in BD patients. Also RT-PCR results showed similar results. However, neither immunohistochemistry nor RT-PCR results showed any difference in NOD2 expression between the groups. When PBMCs from BD patients were stimulated with LPS, IL-1β secretion significantly increased by 58 times. And with ATP, IL-1β release was even more increased by 1.6 times compared to LPS stimulation alone. Caspase-1 inhibitor decreased IL-1β release caused by LPS, however the decrease was less dramatic when ATP was added as a second stimulus. So in PBMCs, LPS stimulation caused large IL-1β release in BD patients but not in healthy controls. But with ATP, IL-1β release increase significantly in healthy controls but not in BD patients. When monocytes from BD patients were stimulated with LPS, IL-1β secretion was increased by 5 times And with ATP, IL-1β release was even more increased by 14 times compared to LPS stimulation alone. So, in BD patients, monocytes secrete impressively greater amounts of mature IL-1β following LPS stimulation, comparable to that of healthy individuals, but fail to increase IL-1β secretion in response to ATP. However, when TNF-α release was measured in a similar way, the result was independent of crosstalk between toll like receptors and NALP3 in BD patients.

Conclusion: This study reveals a role for the NALP3 inflammasome complex in BD. In normal monocytes, 2 signals are required to activate the inflammasome, thus tightly controlling IL-1β secretion but in patients, a single stimulus, which would be unable to trigger IL-1β secretion in healthy individuals, is sufficient to drive a dramatic inflammatory cascade. Modulation of the NALP3 inflammasome activity may delay the inflammatory process and chronic morbidities noticed in patients with BD.

Gaslini, Genova, Italy, [6]Charite, Berlin, Germany, [7]Policlinico le Scotte, Sienna, Italy, [8]Hopital Femme Mere Enfant, Groupement Hospitalier Est, Lyon, France, [9]University Medical Center Utrecht, Utrecht, Netherlands, [10]CHU Le Kremlin Bicetre, Paris, France, [11]P. A. Kyriakou Childrens Hospital of Athens University, Athens, Greece, [12]Hospital de Cruces, Barakaldo, Spain, [13]Paediatric Rheumatology International Trials Organisation – IRCCS [PRINTO], Genova, Italy, [14]G Gaslini Institute, Genoa, Italy

Background/Purpose: The TNF receptor associated periodic syndrome (TRAPS) is an autosomal dominant autoinflammatory syndrome due to muta-

tions in the TNFRSF1A gene. It is associated with severe morbidity and increased mortality due a high risk of AA amyloidosis. The estimated prevalence is 1 per million and experience has previously been limited to small series.

Methods: The Eurofever/Eurotraps consortia (funded by the European Union) have developed a common web-based registry for all autoinflammatory diseases. The registry is accessed from the member area of the PRINTO web-site (www.printo.it/eurofever) and is available to all interested specialists physicians.

Results: 178 patients with clinical disease and a TNFRSF1A mutation were identified from 11 countries. The series included cases with 66 different mutations and 2 low penetrance mutations/polymorphisms, R92Q and P46L. Of the 66 mutations 8 (12%) were reported in more than 1 unrelated individual or kindred; 19 (29%) mutations affected a cysteine residue and of these 5 (26%) were seen in at least 2 unrelated patients. The T50M mutation was the most widespread and was found in 5 families originating from 5 different European countries. More than 1 disease associated mutation was identified at 7 sites, including 5 cysteine residues. In total of the 122 patients with a TNFRSF1A mutation: 68 (60.7%) reported a family history of similar symptoms; 58 (51.8%) were male; 105 (93.8%) were of Caucasian ethnicity and the mean age at symptom onset was 7.6 yrs (range: neonatal to 49 yrs). Of note in 10 patients (9%) the first symptoms developed after the age of 30 yrs. The 59 patients with R92Q polymorphism were 98% Caucasian, 45.8% male and 17% gave a family history of similar inflammatory disease. They presented at an average age of 10 yrs (range: neonatal to 52.6 yrs). The 7 patients with the P46L polymorphism included 2 patients of African ancestry, 1 Turk and a Gulf Arab, they presented at an average age of 16.6 yrs (range: 2.5 to 66.3 yrs) and 2 of them reported that other family members had similar disease.

Conclusion: The EUROFEVERS/EUROTRAPS consortia have collected data on 178 mutation positive TRAPS patients from 11 countries constituting the most extensive clinical series to date. The patients were largely contributed by European centres which may explain the dominance of Caucasian ethnicity. It confirms that TRAPS usually presents in childhood with a median age at presentation of less than 5 yrs but 9% of patients present well into adult life. 60% of patients report a family history of disease and most reported kindreds are small and mutations are family specific. Mutations affecting cysteine residues in extracellular domains are over represented but the most widespread disease causing mutation is T50M. Symptomatic patients with the well recognised polymorphism of R92Q and P46L make up 38% of the patients and appear to have a later onset of disease symptoms with lower penetrance. The availability of a large patient cohort will facilitates interpretation of the significance of TNFRSF1A mutations/polymorphism and understanding of genotype phenotype correlations.

989

The Pattern-Recognition Receptor NOD1 Promotes Production of Inflammatory Mediators in Different Cell Types of the Synovium in Rheumatoid Arthritis. Kazuhiro Yokota[1], Toshihide Mimura[2], Renate E. Gay[1], Steffen Gay[1], Christoph Kolling[3] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Saitama Medical University, Saitama, Japan, [3]Schultess Clinic, Zurich, Switzerland

Background/Purpose: We previously reported that the functional pattern-recognition receptor NOD1 is significantly increased in rheumatoid arthritis (RA) compared to osteoarthritis (OA) synovial tissues and that stimulation of RA synovial fibroblasts (SFs) with the NOD1 ligand induces expression of pro-inflammatory cytokines. Now, we looked at the expression and regulation of NOD1 in RASFs, OASFs, monocyte-derived macrophages (MDMs) and peripheral blood mononuclear cells (PBMCs) and analyzed its interaction with TLR pathways.

Methods: Expression of NOD1 mRNA and protein in RASFs, OASFs, healthy control PBMCs and MDMs was analyzed by real-time PCR and flow cytometry. RASFs, MDMs and PBMCs were stimulated with TNF, IL-1β, NOD1 ligand, TLR2 ligand, TLR3 ligand and TLR4 ligand. ELISA was used to quantitate protein levels of IL-6 and IL-1β. Silencing of NOD1 was performed with transfection of RASFs siRNA targeting NOD1 mRNA by Amaxa Nucleofector Technology. Phosphorylation levels of interleukin-1 receptor-associated kinase 1 (IRAK1) were measured by western blotting.

Results: Basal expression levels of NOD1 mRNA (n=4–5) and protein (n=5–6) were not different in RASFs, OASFs, healthy control PBMCs and MDMs. Only stimulation with TLR3 induced the expression of NOD1 mRNA (2.67±0.29-fold, $p<0.05$) and protein (2.30±0.59-fold, $p<0.05$) in RASFs, but not in PBMCs or MDMs. Thus, NOD1 is constitutively similarly expressed among different cell types of the RA synovium, but is upregulated by TLR3 stimulation only in RASFs. Even though PBMCs (n=6) and MDMs (n=6) did not produce IL-6 or IL-1β by NOD1 stimulation alone, there was a strong synergistic effect of NOD1 with TLR2 as well as TLR4 in the production of IL-1β and IL-6 in these cells. Similar synergisms were found in the production of IL-6 by RASFs (n=6), showing that NOD1 and TLRs strongly synergize in the induction of pro-inflammatory effects in RASFs, MDMs and PBMCs. Most interestingly, IL-6 production induced by TLR2 ligand or IL-1β stimulation was significantly decreased by silencing of NOD1 compared with that of controls in RASFs (n=6). Silencing of NOD1 significantly reduced the phosphorylation of IRAK1 induced by TLR2 stimulation (n=9).

Conclusion: In the current study we show a strong interaction of NOD1 with other pattern recognition receptors in different synovial cells. In addition to a synergistic response of the parallel activation of these receptors, our data indicate a role of NOD1 in the promotion of TLR2 and IL-1β signaling pathways in RA.

990

Innate Immune Stimulation Triggers Early-Onset Spondyloarthritis in HLA-B27/Human beta2 Microglobulin Transgenic Rats. Leonie M. van Duivenvoorde[1], Gleb M. Slobodin[2], Nimman Satumtira[2], Martha L. Dorris[2], Paul P. Tak[3], Dominique L. Baeten[1] and Joel D. Taurog[2]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]UT Southwestern Medical Center, Dallas, TX, [3]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam The Netherlands, Amsterdam, Netherlands

Background/Purpose: We recently proposed that spondyloarthritis (SpA) is driven by altered innate immune responses rather than by autoantigen-specific T or B cell responses[1].

The objective of this study aimed to test directly the hypothesis that stimulation of the innate immune system triggers experimental SpA.

Methods: Rats were injected subcutaneously with *Mtb* in oil or IFA with doses of 30 – 100 μg *Mtb*, which is lower than doses typically used to trigger arthritis adjuvant arthritis in non-tg LEW rats. In the first experiments, HLA-B27/hb2m rats from several different tg lines[2], HLA-B7/hb2m tg rats[2] and non-tg LEW control rats were injected with 30, 60 or 100 mg *Mtb* in IFA. The second set of experiments, used (21-3×283-2)F1 HLA-B27/hb2m tg and (120-4×283-2)F1 HLA-B7/hb2m control rats, both with high copy hb2m, and non-tg LEW controls. These rats were immunized with 30, 60 or 90 mg *Mtb* in IFA at 6 wk of age. Arthritis and spondylitis were monitored clinically.

Results: In the first set of experiments, arthritis was induced in both HLA-B27/hb2m and HLA-B7/hb2m tg rats at doses of ≤60 μg of *Mycobacterium tuberculosis* (*Mtb)* (B27/hb2m: 10/22; B7/hb2m: 8/17 vs. 1/24 non-tg controls). To test whether this effect was more specifically related to HLA-B27 and to assess the effect on spondylitis, which only occurs spontaneously in (21-3×283-2)F1 males, the second set of experiment was carried out as described in Methods. In the spontaneous SpA of (21-3×283-2)F1 rats, the males develop arthritis and spondylitis beginning at 110 d of age, reaching an incidence of 70% and 40% respectively. The female (21-3×283-2)F1 and both sexes of the (120-4×283-2)F1 B7/hb2m rats remain healthy. Data obtained in these rats are depicted in the table.

	Mycobacterium tuberculosis/IFA					
	90 μg Arthritis	Spondylitis	60 μg Arthritis	Spondylitis	30 μg Arthritis	Spondylitis
Males						
HLA-B27/hβ2m	2/2 (100%)	2/2 (100%)	2/2 (100%)	2/2 (100%)	5/6 (83.3%)	6/6 (100%)
HLA-B7/hβ2m	2/3 (66.6%)	2/3 (66.6%)	2/3 (66.6%)	2/3 (66.6%)	0/3 (0%)	0/3 (0%)
Females						
HLA-B27/hβ2m	3/3 (100%)	3/3 (100%)	3/3 (100%)	3/3 (100%)	1/3 (33.3%)	0/3 (0%)
HLA-B7/hβ2m	0/3 (0%)	0/3 (0%)	0/3 (0%)	0/3 (0%)	0/3 (0%)	0/3 (0%)

In males, 30 mg *Mtb* induced arthritis and/or spondylitis in 6/6 HLA-B27/hb2m rats, but not in the HLA-B7/hb2m controls. In females, 60 or 90 mg *Mtb* induced both arthritis and spondylitis in 6/6 of the HLA-B27/hb2m tg rats, but in none of the HLA-B7/hb2m controls. Arthritis and spondylitis appeared 2–3 weeks after immunization in both genders, over 40 d before the age of earliest onset of spontaneous arthritis in males.

Conclusion: These data indicate that low dose *Mtb*, an innate immune stimulus, triggers SpA in HLA-B27/hb2m tg rats. Moreover, it induces SpA in females, increases incidence in males, and accelerates and synchronizes disease onset, all of which will facilitate use of this model for experimental and preclinical research.

Dual Signaling Pathways Dependent Upon the Adaptor Protein SLP-76 Lead to Distinct Natural Killer Cell Effector Functions. Rebecca May[1], Chih-Jung Hsu[1], Mariko Okumura[1], Gary A. Koretzky[2] and Taku Kambayashi[1]. [1]University of Pennsylvania, Philadelphia, PA, [2]University Pennsylvania, Philadelphia, PA

Background/Purpose: Natural killer (NK) cells are innate immune cells that provide a defense against intracellular pathogens and tumors by displaying cytotoxicity and producing immune-activating cytokines. NK activation is regulated by the expression of activating receptors that are finely counterbalanced by inhibitory receptors. Although mechanisms by which activating signals are blocked by inhibitory receptors are well defined, the proximal signaling pathways that lead to NK effector function are incompletely understood. Thus, we aimed to dissect the proximal signaling pathways downstream of the Ly49D activating receptor and focused our studies on SLP-76, an adaptor molecule which is important in mediating signals downstream of activating receptors in many hematopoietic cell types.

Methods: To investigate the involvement of SLP-76 in Ly49D signal transduction, SLP-76 phosphorylation and clustering at the plasma membrane was examined in Ly49D-activated NK cells. Furthermore, the role of SLP-76 in NK cell signal transduction, activation, and development was assessed in SLP-76-knockout (KO) compared to wildtype (WT) NK cells.

Results: When NK cells were activated through Ly49D, SLP-76 was phosphorylated and recruited to the plasma membrane. Furthermore, SLP-76 was required for optimal signal transduction through Ly49D as SLP-76 KO NK cells exhibited diminished ERK and Akt phosphorylation compared to WT NK cells. This correlated with decreased IFNg production and granule exocytosis by SLP-76 KO NK cells. Although NK cells from SLP-76 KO mice appeared developmentally mature based on expression of late maturation markers, we noted a selective defect in the acquisition of Ly49 family member inhibitory and activating receptors in SLP-76 KO NK cells. Since the defective function of SLP-76 KO NK cells might be related to perturbed development, SLP-76 was inducibly deleted in NK cells after maturation. Despite normal Ly49 receptor expression, NK cells inducibly deleted of SLP-76 still displayed defective IFNg production and granule exocytosis, suggesting that SLP-76 plays an important role in Ly49D-mediated NK cell function.

We next explored the mechanisms by which SLP-76 relocalizes from the cytosol to the plasma membrane. As this process depends on membrane-resident adaptor molecules LAT and NTAL in T cells and mast cells, we tested whether LAT and NTAL were similarly crucial for SLP-76 function in NK cells. Like SLP-76 KO NK cells, LAT/NTAL double KO (DKO) NK cells displayed significant functional defects, suggesting that LAT/NTAL may be required for SLP-76 activation. Surprisingly, membrane recruitment and phosphorylation of SLP-76 were intact in LAT/NTAL DKO NK cells following Ly49D stimulation. Cellular proliferation was also independent of LAT/NTAL, but dependent on SLP-76 expression.

Conclusion: These data suggest that NK cells use a novel LAT/NTAL-independent pathway leading to SLP-76 phosphorylation and membrane recruitment. This novel pathway leads to distinct NK cell effector functions. Together, these results demonstrate a critical role of SLP-76 in NK cell activation downstream of multiple signaling pathways emanating from the Ly49D activating receptor.

Untreated Juvenile Dermatomyositis: Altered Peripheral Blood Natural Killer Cell Receptors Associated with Increased Natural Killer Cell Localization in Inflamed Muscle. Sheela Shrestha[1], Maurice O'Gorman[2], Jordan Orange[3], Chelsea Tessler-Verville[1], Katelin Snow[1], Gabrielle Morgan[1], Deli Wang[4] and Lauren M. Pachman[2]. [1]Children's Memorial Hospital, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Children's Hospital of Philadelphia, Philadelphia, [4]Northwestern University's Feinberg School of Medicine, Chicago, IL

Background/Purpose: We have observed decreased levels of circulating $CD3^{-}CD56^{+}$ natural killer (cNK) cells in children with untreated JDM (Arthritis Rheum 58:S225, 2008).

Objectives: 1) To further characterize specific surface and intracellular receptors on cNK cells in untreated JDM with: a) low, or b) normal cNK (age-normed) at diagnosis and after clinical response to therapy, compared with healthy pediatric controls; 2) Evaluate NK localization in inflamed, untreated JDM muscle.

Methods: Definite/probable JDM and healthy pediatric controls (IRB# 2008–13457) were enrolled. We tested frozen peripheral blood mononuclear cells (PBMCs) from untreated white JDM females with low (Group 1, n=6) and normal cNK (Group 2, n=5) at diagnosis; in both groups the cNK normalized after institution of immunosuppressive therapy (19.92 ± 11.46 mo after diagnosis). Controls for the two groups (n= 7 and 8 respectively) were age matched. Marker expressions on viable $CD3^{-}CD56^{+}$ NK cell was measured by flow cytometry using FlowJo software. **Results:** were expressed as the percentage (%) NK positive for a specific marker and median fluorescence intensity (MFI) of the specific marker. Results were analyzed using the paired t-test for the two JDM groups and the student's t-test for comparing the JDM patients and controls ($p<0.05$ as significant). Using dual stain immunohistochemistry, NK cells were identified in 27 untreated JDM muscle tissue as $CD16^{+}/CD56^{+}$ cells (n=16, low cNK; n=11, normal cNK; n=7, controls) Wilcoxon Rank Sum test was used for comparisons ($p<0.05$ as significant).

Results: In Group 1 JDM (low cNK at diagnosis), 7 out of 17 NK receptors analyzed at diagnosis were significantly reduced compared to the levels observed when the cNK normalized, and to controls. The density (MFI) of 5 of these receptors (CD16, CD2, NKG2D, CD11b, and CD94) was also significantly reduced, ($p<0.05$). After cNK levels normalized following therapy, the % of NK cells expressing NKp46 increased, but % of NK cells expressing CD158b was significantly lower than controls, ($p<0.05$). The DNAM1+ cNK cells were decreased to 50% normal range at diagnosis, and remained depressed (78% of normal) after response to therapy. In contrast, in Group 2 JDM children (normal cNK at diagnosis), only CD2 was below the healthy control group (both % and MFI), but increased to normal ranges after therapy. This group also had a higher % of cNK cells expressing perforin at diagnosis (92.06 ± 5.81 vs 84.90 ± 4.16, $p=<0.05$) compared to the control group. In the diagnostic muscle biopsies, the NK cell counts from JDM with either low or normal cNKs were significantly higher than controls ($p=0.012$, $p=0.044$) respectively.

Conclusion: At diagnosis, the percentage of NK cells expressing specific receptors and the density of these receptors expressed on the cell surface differed from levels observed post therapy and from healthy control age-matched children. Irrespective of the absolute count of cNK cells, we found a significant increase in NK cells localized in inflamed muscle tissue of untreated children with JDM compared to healthy controls. These data suggest NK cells may be involved in the pathogenesis of muscle damage and disease in JDM.

Antigen Cross-Presentation Is Essentially Required for the Pathogenesis of Lupus Nephritis: Essential Role of Endosomal Trafficking. Ken Tsumiyama[1], Mai Takimoto[1] and Shunichi Shiozawa[2]. [1]Kobe University Graduate School of Health Science, Kobe, Japan, [2]Kobe University Graduate School of Health Science and Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Background/Purpose: We repeatedly immunized mice normally not prone to autoimmune diseases with the same antigen to show that repeated immunization reproducibly led to the development of systemic lupus erythematosus (SLE). Importantly, autoantibodies are induced *via de novo* T cell receptor (TCR) revision at periphery, giving rise to a novel T cell type we term an autoantibody-inducing CD4 T (*ai* CD4 T) cell. The *ai* CD4 T cell not only stimulated B cells to generate varieties of autoantibodies including rheumatoid factor, anti-Sm and anti-dsDNA antibodies but also helped full maturation of CD8 T cell into cytotoxic T lymphocyte (CTL) *via* antigen cross-presentation to produce lupus nephritis. Here we examine the molecular detail of antigen cross-presentation in relation to lupus nephritis.

Methods: Bone marrow-derived dendritic cell (BMDC) from BALB/c mice was cultured with fluorescent-labeled ovalbumin (OVA). Early endosome antigen 1 (EEA1) and calnexin were detected to identify endosome and endoplasmic reticulum (ER), respectively, by using immunofluorescent staining. To examine whether or not engulfed antigen is exported from endosome to cytoplasm, translocon Sec61 was also detected. Localization of OVA, endosome, ER and Sec61 was examined under confocal laser scanning microscopy. For *in vivo* study, BALB/c mice were repeatedly immunized with OVA to induce tissue injuries. MG132 was co-immunized with OVA to inhibit proteasomal degradation of antigen. To investigate whether or not antigen peptide-MHC class I complex is transported from endosome to cell surface, mice were immunized with OVA in the presence of primaquine (PQ), an inhibitor of endosomal trafficking to cell surface. We also inhibited Sec61 *in vivo* by treating with exotoxin A. Proteinuria and histopathology of kidney

were assessed. IFNγ-producing CD8 T cell in spleen was detected under flow cytometry.

Results: In BMDC, OVA was first co-localized with an endosomal marker EEA1, and then gradually separated from EEA1. OVA was never co-localized with an ER marker calnexin. Instead, translocon Sec61 did co-localize with OVA, the findings indicated that OVA was exported from endosome to cytoplasm *via* Sec61. The *in vivo* treatment with MG132, an inhibitor of proteasomal degradation, inhibited the generation of fully mature CTL and lupus nephritis. Proteinuria and renal damage were not observed in the mice treated with PQ. Full maturation of CD8 T cell to IFNγ-producing CTL was also inhibited. Since PQ inhibits transport from endosome to cell surface, the finding indicates that antigen peptide-MHC class I complex is directly transported from endosome to cell surface for antigen cross-presentation. Further, the treatment with exotoxin A, an inhibitor of Sec61, also inhibited the maturation of effector CTL and the development of lupus nephritis, indicating that export of antigen from endosome to cytoplasm *via* Sec61 is indispensable for antigen cross-presentation.

Conclusion: Endosomal trafficking, bypassing ER, is required for antigen cross-presentation. Inhibition of this pathway resulted in inhibition of lupus nephritis. Thus, export of antigen from endosome to cytoplasm *via* Sec61 is essential for antigen cross-presentation and induction of lupus tissue injuries.

994

Immune-Complex Induced Inflammation Is Augmented in the Absence Nicotinic Acetylcholine Receptors in Mice. Milena Vukelic[1], Gloria Koo[1], Patricia M. Redecha[1] and Jane E. Salmon[2]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY

Background/Purpose: Integrated neural networks influence immune responses. We reported that activation of the "cholinergic antiinflammatory pathway" by stimulation of nicotinic acetylcholine receptors (nAchR) expressed on immune cells, neutrophils and monocytes, attentuates activation triggered by innate C5a and Fcγ receptors in human phagocytes. In vitro ligation of nAchR decreased markers of activation related to tissue damage: reactive oxygen species production, phagocytosis, TNFα production and expression of adhesion molecules. Here, our goal was to analyze the role of α7 cholinergic receptors on early phase of immune complex- mediated injury in vivo by using mice deficient in a7 subunit of nAchR ($\alpha7nAchR^{-/-}$) and their wild type littermates.

Methods: Mouse (WT (C57/Bl6) or $\alpha7nAchR^{-/-}$) or human neutrophils (PMNs) were incubated with C5a (100nM) in a presence or absence of cholinergic agonists, GTS21 (specific α7nAChR agonist) (1μM) or control medium. TNFα concentrations were analyzed by ELISA. IkB phosphorylation was detected by western blot. Peritoneal reverse passive Arthus reaction was initiated by injecting OVA i.v. and anti-OVA IgG i.p. After 1.5hrs PMN recruitment in peritoneal lavage fluid was assessed by FACS.

Results: Compared to WT mice, naïve $\alpha7nAchR^{-/-}$ mice had a greater number of neutrophils, macrophages and mast cells in peritoneal cavity ($0.58\pm0.2\times10^4$ vs. $7.4\pm4.1\times10^4$ $p<0.05$; $96\pm5\times10^4$ vs $144\pm13\times10^4$ $p<0.05$; $35\pm5\times10^4$ vs $58\pm8\times10^4$) with later two expressing higher levels of C5aR and FcγR on their surface, although bone marrow granulopoesis was comparable in both strains. Bone marrow derived $\alpha7^{-/-}$ macrophages spontaneously produced higher TNFα in culture medium than WT macrophages (33±6 vs 82±23 pg/ml) and TNFα levels were higher in the peritoneal cavity of naïve $\alpha7nAchR^{-/-}$ animals (120±20 vs 197±43 pg/ml). When $\alpha7nAchR^{-/-}$ mice were challenged with the reverse passive Arthus reaction, early neutrophil accumulation was enhanced to approximately 245% of wild type levels ($51\pm12\times10^6$ vs. $124\pm27\times10^6$cell/ml; p=0.024) and TNFα in peritoneal lavage fluid was also markedly increased (243±60 vs. 439±96 pg/ml; p=0.023). To examine the basis of the suppressive effect of ligation nAchR, we stimulated PMNs with C5a in the presence and absence of specific α7nAChR agonist, GTS21. C5a mediated NFkB activation was markedly decreased by GTS21 in association with blockade of phosphorylation of its inhibitor IKB; GST21 did not alter phosphorylation of IKB in unstimulated cells.

Conclusion: These results indicate that α7nAchR expressed on innate immune cells play critical role in suppressing inflammation at sites of immune complex deposition and suggest that tonic stimulation of α7nAchR attenuates the FcγR- and C5aR-mediated activation of the NFkB-proinflammatory cytokine axis, a pathway that activates resident and newly recruited leukocytes. Our findings have implications for tissue injury in SLE and RA and suggest new strategies to reduce damage at the sites of immune complex deposition.

Association of Functional *Fcgammariic* (*FCGR2C*) Polymorphisms with Rheumatoid Arthritis in African Americans. Jianming Wu[1], Xinrui Li[2], Rui Lin[3], Howard Wiener[4], Hemant Tiwari[4], Cunren Liu[4], Travis Ptacek[2], Jeffrey C. Edberg[5], S. Louis Bridges Jr.[6] and Robert P. Kimberly[4]. [1]University of minnesota, St. Paul, MN, [2]University of Alabama at Birmingham, Brimingham, AL, [3]University of Minnesota, St. Paul, MN, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, [6]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Functional polymorphisms in human Fcg receptor (FcgR) genes play important roles in the pathogenesis of various autoimmune diseases. *FcgRIIC* (*FCGR2C* or CD32C), an activating Fcg receptor gene, contains a stop codon/open-reading frame polymorphism (SNP 202T>C, rs10917661) and two novel SNPs at the intron 6 splicing junctions. The current study was intended to investigate whether *FcgRIIC* polymorphisms (SNPs) are associated with rheumatoid arthritis (RA) and to examine biological functions of the *FcgRIIC* SNPs.

Methods: *FcgRIIC* SNP 202T>C and the intron 6 SNPs (SNP6L-A>G and SNP6R-C>G) were genotyped in 833 African American (AA) healthy controls and 764 AA RA patients using Pyrosequecing methodology. SNP allele, genotype, and haplotype distributions were compared between RA and healthy controls. The functions of the *FcgRIIC* SNP were investigated in mini-gene and transfected cell systems.

Results: Our genotyping data demonstrated that the SNP 202C (open-reading frame allele) is significantly associated with RA susceptibility ($P = 0.0002$, Odds Ratio 1.584; 95% CI: 1.238–2.027) in AA. In addition, the frequency of the SNP-6L G allele (which forms a canonical splicing donor motif) is significantly increased in AA RA patients compared to controls ($P = 0.0007$, OR = 1.923, 95% CI 1.312–2.819). No association of SNP-6R alleles with RA susceptibility was observed in AA ($P = 0.9400$, OR = 1.005, CI = 0.874–1.156). The haplotype 202C/6L-G/6R-G is a major risk factor for RA in African Americans ($P = 0.015$, OR 3.533; 95% CI: 1.278–9.772). Functionally, the expression of SNP 202T allele enhanced the inhibitory FcgRIIB expression in human B cells. Furthermore, the intron 6 SNPs are the main origin of the various FcgRIIC mRNA species and the 202C/6L-G/6R-G is the sole FcgRIIC SNP haplotype capable of producing an activating receptor.

Conclusion: The functional *FcgRIIC* SNP haplotype 202C/6L-G/6R-G is a genetic marker for RA in AA and may have important biological consequences.

996

Low Copy Number of Fcgamma Receptor 3B Gene Is a Disease Susceptibility and Severity Factor in Primary Sjøgren's Syndrome. Johannes C. Nossent[1], Maureen Rischmueller[2], Andrea Becker-Merok[1] and Sue Lester[2]. [1]University of Tromsø, Tromso, Norway, [2]Queen Elizabeth Hospital, Adelaide, Australia

Background/Purpose: Cross linking of immune-complexes (IC) with the neutrophil specific Fc-gamma receptor 3b (Fcgr3b) initiates IC clearance. IC contribute to the complications of and primary Sjøgren's syndrome (pSS) and Systemic Lupus Erythematosus (SLE). Copy number (CN) variation of the Fcgr3b gene alters the Fcgr3b function on the cell membrane and thus influence the clearance of IC. We investigated whether FcgR3b CNV is associated with disease susceptibility and severity in adult patients with pSS.

Methods: Cross sectional study of patients with established pSS (n= 174), SLE (n=107) and healthy controls (n= 162). FcGr3b CNV was determined by three different RT-PCR parameter estimations (Ct-, Cy0 and CpD1) and confirmed by the Fcgr2c/Fcgr2a paralog ratio test. Clinical and serological data were analyzed for their association with FcGr3b CN.

Results: Low FcGr3b CN was significantly more frequent in SLE (OR 4.15, p=0.003) and pSS (OR 2.67, p=0.013) patients than in controls. In pSS patients, low FcGr3b CN was associated with daytime sleepiness, absence of anti-Ro/La and lower levels of RF and IgG. In contrast, low FcGr3b CN was associated with increased levels of antibodies against dsDNA, C1q and ribosomal P and nephritis in SLE patients. FcGr3b CN did not associate with serum levels of B-cell activating factor in either disease.

Conclusion: Low FcGr3b CN is a susceptibility factor for both pSS and SLE and associates with more severe disease and pathogenic autoantibodies in SLE and extraglandular features in pSS. The contrasting findings for low FCGr3B CN and levels of anti-dsDNA and anti-Ro/La antibodies indicates selective handling of autoantibodies by Fcgr3b on neutrophils in autoimmune diseases.

997

C1q Diverts Lupus Immune Complexes Away From CD14^{dim}CD16+ "Patrolling" Monocytes. Pradipta Ghosh*, Alice Wiedeman*, Deanna M. Santer, Vivian E. Vlamakis and Keith B. Elkon. University of Washington, Seattle, WA

Background/Purpose: Immune-complexes (IC) cause inflammation in systemic lupus erythematosus (SLE) in significant part by engagement of FcγR on neutrophils, monocyte/macrophages and plasmacytoid dendritic cells (pDCs). We previously observed that in the absence of C1q, IC bind to FcγRII on pDCs and potently stimulate IFN-α production; whereas IC containing C1q bind predominantly to monocytes leading to a reduction in IFN-α production by pDCs. Heterogeneity of human peripheral blood monocytes is known, but recently 3 subpopulations have been defined based on surface expression of CD14 and CD16. Both the CD14+CD16- and the CD14+CD16+ monocytes were described in mice as having "inflammatory" properties while the CD14^{dim}CD16+ population is thought to be a "patrolling" monocyte that responds to invading pathogens as well as to circulating ICs. Given the differing profiles of these newly defined monocyte subsets, we asked whether SLE-IC show preferential binding to the different monocyte subsets, how this binding is altered in the presence of C1q and what are the functional consequences in regards to inflammatory cytokine signaling.

Methods: IC were formed with diluted SLE serum (1:2000) and 0.5% U937 necrotic cell extract as a source of antigen or diluted SLE serum (1:1000) and Alexa Fluor 647 labeled RNP. Monocyte subsets were purified by flow sorting (FACSAria). IC were added to peripheral blood mononuclear cells (PBMCs) or purified monocyte subsets (> 95% pure) prepared from healthy donors in the presence or absence of C1q for 30 minutes on ice (binding studies) or 20 hours (ELISA and flow cytometry). Cytokines in culture supernatants were quantified by ELISA and expression of cell surface markers and the monocyte activation marker CD86 were determined by flow cytometry.

Results: When monocytes subsets were flow sorted according to cell surface markers, CD14 and CD16, and incubated with SLE-IC in the absence of C1q, the IC bound to all monocyte subsets. Similar to one published study, CD14^{dim}CD16+ monocytes (but not the CD14+CD16+ or CD14+CD16- populations) uniquely responded to SLE-IC stimulation by producing TNF-α. In addition, these IC induced strongest up-regulation of CD86 on the CD14^{dim} subset (two-fold increase of MFI). Whereas the addition of C1q enhanced SLE-IC binding to all monocyte subsets as determined by MFI of the labeled RNP antigen, the distribution of binding changed to favor the CD14+CD16+ monocytes (fold increase = 6.13±0.93) and the CD14+CD16- monocytes (fold increase =7.17±0.91) compared to the pro-inflammatory CD14^{dim} (fold increase = 3.00±0.48, $p<0.05$ compared to the other subsets).

Conclusion: Under steady state conditions SLE immune complexes bind to all of the presently described monocyte subsets, but induce CD86 up-regulation most strongly on the CD14^{dim} population. The presence of C1q diverts the IC away from the TNF-α producing CD14^{dim} "patrolling" monocytes and towards the less inflammatory CD14+CD16+ and CD14+CD16- monocyte subsets. Our findings point to a novel mechanism by which C1q may protect against inflammation in SLE.

Functional Effects Attributable to the R77H Lupus Susceptibility Variant Encoded by *ITGAM*. Benjamin Rhodes[1], Barbara G. Fürnrohr[1] and Timothy J. Vyse[2]. [1]King's College London, London, United Kingdom, [2]Divisions of Genetics and Molecular Medicine and Immunology, King's College London, London, United Kingdom

Background/Purpose: Variation at *ITGAM* (CD11b – the alpha chain of complement receptor 3 (CR3)) is among the strongest genetic susceptibility effects identified in human lupus, with rs1143679, encoding an R77H amino acid change, implicated by genetic analysis as the functional variant.

Methods: We studied COS7 cells transiently transfected with wild-type (WT) and 77H variant *ITGAM* alongside the invariant beta chain to reconstitute CR3. Transfected cells were used for a static adhesion assay in 96-well plates coated with various protein ligands and for a phagocytic assay using iC3b opsonised sheep erythrocytes (sRBC). Assays were replicated using *ex-vivo* monocytes (adhesion) and monocyte-derived macrophages (phagocytosis) from healthy genotyped volunteers.

Results: Phagocytosis of iC3b coated sRBC by COS cells was significantly impaired for cells expressing the 77H mutant compared with WT (mean at 30 minutes 0.48 sRBC/phagocyte vs. 0.87sRBC/phagocyte, $P<0.001$). The adhesion of sRBCs to the transfected cells was not impaired. Transfected cells bound specifically to 96-well plates coated with known CR3 ligands, most strongly iC3b and DC-SIGN in this static adhesion assay. However, the binding of the 77H transfects to protein coated wells was 39% lower than WT transfects to iC3b and 19% lower to DC-SIGN. Only 1% of the healthy European population are homozygous for the rs1143679, making the recruitment of healthy human participants for study difficult. Nonetheless we also have preliminary data in *ex-vivo* monocytes that demonstrates functional differences in adhesion and phagocytosis consistent with those found in our cell line model.

Conclusion: We demonstrate functional consequences of the R77H variation in a cell line model and extend this to provide preliminary evidence that these effects are also observed in *ex-vivo* myeloid cells from healthy individuals. Although further work is required it is apparent that the functional consequences of the rs1143679 mutation may fit within existing theories of lupus pathogenesis that include complement mediated clearance of apoptotic cells and immune complexes.

Anti-Inflammatory Profile of AS2444697, A Novel Interleukin-1 Receptor-Associated Kinase-4 Inhibitor. Junko Imanishi, Takeshi Ishikawa, Emiko Imamura, Hidekazu Mizuhara, Haruna Iwaoka, Ball Evelyn, Hiroshi Inami, Tsuyoshi Mizutani, Junko Watanabe, Hiroyuki Usuda, Shinya Nagashima, Tomonori Ito, Toru Kontani, Yasuaki Shimizu and Seitaro Mutoh. Astellas Pharma Inc., Tsukuba, Japan

Background/Purpose: Toll-like receptors (TLRs) function in the innate immune response by recognizing pathogen-associated molecular patterns or host-derived "danger signals" produced during tissue injury or inflammation. Interleukin-1 (IL-1) receptor-associated kinase-4 (IRAK-4) is known to be a pivotal mediator on the TLR/IL-1R signaling pathway, as both IRAK-4-knockout mice and IRAK-4-deficient human patients exhibit functional defects in this pathway. Observations of increased expression of TLRs and TLR ligands in patients with rheumatoid arthritis (RA) suggest that these receptors may contribute to RA pathogenesis. Here, we report the pharmacological profile of AS2444697, a novel IRAK-4 inhibitor.

Methods: In vitro IRAK-4 inhibitory activities of AS2444697 were evaluated using recombinant human and rat IRAK-4 enzymes and synthetic substrates (FGL ARF SRF AGS SPS QSS MVA RTQ TVR GTL A). IL-1β-mediated IRAK-1 degradation in A549 (human alveolar basal epithelial cell line) was assessed with western blot analyses using anti-IRAK-1 antibody (Cell Signaling Technology). The effect of AS2444697 on IL-1β-, TNF-α- and TLR ligands- (LPS for TLR-4, peptidoglycan for TLR-2, imiquimod for TLR-7) stimulated cytokine production were examined using A549 and two primary cells, PBMCs (Peripheral Blood Mononuclear Cells from healthy volunteers) and HFLS-RA (Human Fibroblast-Like Synoviocytes-Rheumatoid Arthritis from RA patient). In vivo anti-inflammatory activity was evaluated using lipopolysaccharide (LPS) induced cytokine production and adjuvant-induced arthritis (AIA) in rats.

Results: AS2444697 inhibited human and rat IRAK-4 with the same IC_{50} values of 21 nM. It also suppressed IL-1β-mediated IRAK-1 degradation in A549 in a concentration-dependent manner with a range of 10 nM–10 μM. It also inhibited IL-1 (1 ng/mL) and TNFα (3 ng/mL) stimulated IL-6 production from A549 with IC_{50} of 250 nM and 3900 nM, respectively. AS2444697 inhibited LPS- (0.01 ng/mL) induced TNF and IL-6 production from PBMCs, with IC_{50} values of 47 and 59 nM, respectively. In addition, AS2444697 was also effective on IL-6 production from HFLS-RA stimulated with IL-1β 1 pg/mL and TNFα 10 pg/mL (IC_{50}: 170 and 380 nM respectively). AS2444697 inhibited TNFα production from LPS (3 ng /animal) injected rat dose dependently with an ED_{50} of 3.4 mg/kg. Further, prophylactic administration of AS2444697 ameliorated paw swelling in AIA rats with an ED_{50} of 4.5 mg/kg (p.o. b.i.d).

Conclusion: AS2444697 inhibited not only TLR, IL-1β but also TNFα pathway. These results suggest that AS2444697 will an attractive agent for the treatment of RA.

MicroRNA-15a Regulates Etk/BMX Expression and IL-6 Release In Activated Rheumatoid Synoviocytes. Ghada Alsaleh[1], Lucas Philippe[1], Angélique Pichot[1], Sébastien Pfeffer[2], Jacques-Eric Gottenberg[1], Jean Sibilia[1], Philippe Georgel[3] and Dominique Wachsmann[1]. [1]EA4438 Laboratoire Physiopathologie des Arthrites, Illkirch-Strasbourg, France, [2]Architecture et Réactivité de l'ARN, Université de Strasbourg, Strasbourg, France, [3]Laboratoire d'ImmunoGénétique Moléculaire Humaine, Strasbourg, France

Background/Purpose: The Toll like receptor family is the best characterized group of innate immune receptors in term of known ligands, signaling pathways and functional relevance. TLRs are expressed by immune cells and also by resident cells of the joint such as fibroblast-like synoviocytes (FLS) which play a crucial role in RA. Etk/BMX, a Btk Family Tyrosine Kinase, is a key adaptor involved in signaling downstream of TLR2, TLR4, and integrin $\alpha 5\beta 1$, linking pathogen-associated molecule detection to the initiation of proinflammatory response by activated rheumatoid fibroblast-like synoviocytes (RA FLS). We previously demonstrated that the inhibition of Etk impaired IL-6 release by LPS activated-FLS. Many data indicate that miRNA can exert negative effects in inflammatory pathways and this prompted us to look for miRNA which could target directly TLRs signaling and control negatively cytokine release in response to TLRs stimulation, such as Etk.

Methods: RA FLS were isolated from synovial tissues from different patients. Cells were stimulated with TLR2 (BLP) and TLR4 (LPS) ligands and quantitative RT-PCR was performed to evaluate miRNA and mRNA expression in RA FLS. Transient transfection of FLS with mimic 15a was performed using the Human Dermal Fibroblast NucleofectorTM kit from Amaxa. All assays were performed 48 h post transfection. Transfection of HEK293 cells with reporter constructs and miR-15a mimic or antagomir was performed using Lipofectamine. Luciferase activity were determined using the dual-luciferase reporter assay system. IL-6 release was measured in culture supernatants by ELISA according to the manufacturer's instructions.

Results: We first showed that RA FLS expressed constitutively Etk, and that its expression is up-regulated in response to LPS and BLP. To identify miRNA targeting Etk mRNA, RA FLS were activated with LPS for six hours and a miRNA microarray analysis was performed. Among the down-regulated miRNAs, miR-15a was predicted to target Etk. This down regulation was confirmed by quantitative RT-PCR. As *in silico* analysis predicted that miR-15a might possibly bind to the 3'-UTR of human Etk transcript, we transiently transfected into HEK-293 cells a reporter construct that contain the firefly luciferase gene fused to the Etk 3'-UTR containing the putative miR-15a interactor site along with miR-15a. We observed a downregulation of the luciferase activity, indicating that the 3'-UTR of Etk mRNA is directly targeted by miR-15a. Moreover transfection of RA FLS using miR-15a mimics decreased IL-6 release in response to LPS and BLP.

Conclusion: These results suggest an important role of miR-15a in the control of Etk expression and IL-6 synthesis and indicate that its expression may be critical to prevent an excessive inflammatory response.

1002

Knock-Down of Galectin-3 Inhibits Spontaneous and Lipopolysaccharide -Induced IL-6 Secretion In Fibroblast-Like Synoviocytes. Uri Arad, Avital Angel-Korman, Sharon Amir, Sharon Tzadok, Ortal Seagal, Ori Elkayam and Dan Caspi. Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background/Purpose: Galectin-3 is a β-galactoside-binding lectin that plays an important role in the modulation of immune responses. Galectin-3 levels are increased in rheumatoid arthritis (RA) synovial tissue, synovial fluid and peripheral blood. Recombinant exogenous galectin-3 stimulates proinflammatory cytokine secretion by fibroblast-like synoviocytes (FLS). Our objective was to examine the effect of galectin-3 knock-down on spontaneous and lipopolysaccharide (LPS)-induced secretion of IL-6 in FLS from RA and osteoarthritis (OA) patients.

Methods: FLS from RA and OA patients were harvested from synovial fluid aspirates or directly from synovial tissue obtained during orthopedic surgery. The expression of galectin-3 was knocked-down by transfection of siRNAGal3 vs. siRNACtrl. The XTT test was used to evaluate cell viability, and galectin-3 knock-down was confirmed by western blotting. IL-6 secretion with and without lipopolysacharide (LPS)-stimulation was determined by ELISA.

Results: Maximal knock-down of galectin-3 expression was observed on the 3rd day post transfection, in both RA and OA FLS (50–75% knock-down). Galectin-3 knock-down caused a significant decrease in IL-6 secretion in both cell types (OA – 46%, RA – 21.5%, $p<0.05$). The inhibition of IL-6 secretion was not caused by decreased cell viability. LPS-stimulation caused a 35-fold increase in IL-6 secretion, and galectin-3 knock-down substantially inhibited LPS-induced IL-6 secretion (OA- 74%, RA- 33%, $p<0.05$).

Conclusion: siRNA-transfection is an effective means of suppressing galectin-3 expression in FLS. Knock-down of galectin-3 inhibited both spontaneous and LPS-induced IL-6 secretion. It appears that galectin-3 is an important component in the regulation of IL-6 secretion in FLS and may be targeted for suppressing joint inflammation.

1003

Vimentin Suppresses the Production of Reactive Oxygen Species and the Antimicrobial Response Via p47phox. Nirit Mor-Vaknin, Maureen Legendre, Yue Yu, Carlos H.C. Serezani, Sanjay Garg, Anna Jatzek, Michael D. Swanson, Seagal Teitz-Tennenbaum, Antonello Punturieri, N. Cary Engleberg, Ruma Banerjee, Marc Peters-Golden and David Markovitz. University of Michigan, Ann Arbor, MI

Background/Purpose: Vimentin, a widely expressed intermediate filament, is considered to function mainly as a structural protein that stabilizes the intracellular architecture. However, vimentin is particularly abundant in macrophages and is secreted in response to inflammatory cytokines and apoptosis. It was recently reported that mutation and citrullination of vimentin can trigger autoantibodies responses in arthritis patients. Susceptibility to mutations and general instability of the genome found in the RA synovium is thought to be the cause of DNA damage induced by persistent oxidative stress. Here we report that vimentin impedes production of reactive oxygen species (ROS) by interfering with the assembly and function of the NADPH oxidase complex. Remarkably, the absence of vimentin conferred significant resistance to death by bacterial septicemia *in vivo*.

Methods: Peritoneal and bone marrow macrophages were obtained from vimentin knockout and wild-type controls. Cells were analyzed for bacterial phagocytosis, bacterial killing and production of reactive oxygen species by chemiluminescence, H2O2 and NADPH production measurements. Redox was measured by high-performance liquid chromatography. Immunopreceipitation and Western blot analysis were performed to show the interaction between the p47 phox subunit of the NADPH oxidase complex with vimentin at the plasma membrane. Co-localization of p47phox and vimentin at the plasma membrane was confirmed via confocal fluorescence microscopy analysis.

Results: Here we report that peritoneal and bone marrow-derived macrophages of vimentin knockout (Vim KO) mice generated higher levels ROS upon activation compared with wild-type (WT) controls leading to reduced intracellular redox potential. This enhanced production of ROS by Vim KO phagocytes correlated with an improved capacity to mediate *in vitro* bacterial killing. Lack of vimentin accelerated the p47phox subunit of the NADPH oxidase complex from the cytosol to the plasma membrane via its interaction with the trans-located p47phox subunit at the plasma membrane. Challenging Vim KO and WT mice with a lethal dose of *Escherichia coli* (*E. coli*) demonstrated that lack of vimentin improved bacterial clearance and prolonged mouse survival.

Conclusion: These findings suggest that vimentin impedes production of ROS by interfering with the assembly and function of the NADPH oxidase complex. Remarkably, the absence of vimentin conferred significant resistance to death by bacterial septicemia. Based on our results, we propose that vimentin modulates the intensity of the innate immune response by attenuating ROS production, a surprising role for this highly abundant but poorly understood intermediate filament protein that has been recently implicated in the pathogenicity of arthritis.

SNAPIN Is Overexpressed in Rheumatoid Arthritis Synovial Tissue and Involved in Endosomal Lysosomal Pathway. Bo Shi[1], Qi Quan Huang[1], Andrea Dorfleutner[1], Christian Stehlik[1], Paul P. Tak[2] and Richard M. Pope[1]. [1]Northwestern University, Feinberg School of Medicine, Chicago, IL, [2]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: We identified Snapin, a SNARE complex protein required for synaptic vesicle docking and fusion, as a TLR2 binding molecule

in yeast two-hybrid system in screening cDNA library constructed from synovial tissue of RA patients. We further confirmed Snapin is a TLR2 agonist. Besides, Snapin was also reported to play a critical role in late endosome trafficking and endosome-lysosome fusion. In this study, we examined Snapin expression in synovial tissue of RA patients by immunohistochemistry. Further, we explored the Snapin's role in endosome-lysosomal pathway in macrophages.

Methods: Snapin expression in synovial tissue was examined by histology, and single and two-color immunohistochemistry. Snapin knock down in macrophages were performed using siRNA technique. Snapin, Lamp1, 2 and Lac3 protein levels were checked by Western blot analysis. The localization and co-localization of Snapin with Rab7 in macrophages were studied with confocal immunofluorescence microscopy.

Results: Snapin was significantly increased in RA synovial tissue compared to control synovial tissues from arthritis-free controls. The percentage of Snapin positive cells (lining: 21 vs 60%, sublining: 18 vs 54%; $p < 0.01$) and the Snapin expression score (lining: 18 vs 124, sublining: 10 vs 144; $p < 0.05$), reflecting the percent positive and intensity of staining, were both significantly increased in the synovial lining and in the sublining of the RA synovial tissues compared to the controls. Snapin expression level was correlated with inflammation. Two color immunohistochemistry showed that CD68 positive macrophages, especially those in the sublining region, strongly expressed Snapin in RA synovial tissue. Additionally, within lymphoid aggregates some CD3 positive T cells also expressed Snapin. Therefore, studies were performed to determine the homeostatic function of Snapin in macrophages. Employing in-vitro differentiated macrophages, Snapin was present in a diffuse granular pattern and it co-localized with Rab7, a marker for late endosomes. The forced reduction of Snapin by siRNA in macrophages resulted in increased Lamp-1, Lamp-2, two lysosomal markers, and LC3-II, a marker of autophagosomes, suggesting that Snapin might be functionally involved in endosome to lysosome fusion in macrophages. Studies are underway to determine the potential role of Snapin in the autophagy-lysosomal pathway, which may contribute to the pathogenesis of RA.

Conclusion: Snapin was highly expressed in RA synovial tissue, especially in sublining macrophages. Snapin was localized in the late endosomes and may play an important role in endosome to lysosome fusion in macrophages.

Mechanisms of Human Monocytes and Macrophages to Adapt to Hypoxia. Monique Fangradt[1], Timo Gaber[1], Martin Hahne[1], Paula Hoff[1], Manuela Jakstadt[1], Cindy Strehl[1], Gerd-Rüdiger Burmester[2] and Frank Buttgereit[1]. [1]Charité University Medicine, Berlin, Germany, [2]Charité University Hospital, Berlin, Germany

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease of diarthrodial joints, characterized by infiltration of immune cells and local tissue hypoxia. Migrating monocytes and differentiated macrophages are forced to adapt their energy metabolism to hypoxia. Hypoxia-inducible factor (HIF)-1a is known to act as key regulator for the adaptation of migrating cells into hypoxic areas. The aim of this study was to investigate the mechanisms used by human monocytes and macrophages to adapt to hypoxia.

Methods: Isolated human $CD14^+$ monocytes were incubated for 5h under normoxic and hypoxic conditions with or without PMA stimulation, respectively. Cell survival rates were measured by 7-AAD staining and subsequent FACS analyses. Using a Nuclear Extract Kit (Actife Motiv), nuclear and cytosolic fractions were prepared in order to detect HIF-1a and NFkB by immunoblot. For the experiments with macrophages, primary human monocytes were differentiated into monocyte derived macrophages (hMDM) using M-CSF. The effects of normoxia and hypoxia on gene expression were compared between monocytes and hMDMs using quantitative PCR.

Results: Hypoxia was found to improve the survival of primary human monocytes. Furthermore, monocytes stabilize HIF-1a under hypoxic conditions in a time dependent manner. Interestingly HIF-1a was detected exclusively in the cytoplasm, but not in the nucleus of unstimulated cells. PMA stimulation, however, resulted in the translocation of HIF-1a into the nucleus with PKC-a/b_1 being an essential regulator of this process. Also differentiation of monocytes into macrophages was found to be accompanied by the translocation of HIF-1a into the nucleus. In monocytes, hypoxia does induce the expression of glycolytic genes despite the absence of HIF-1a in the nucleus. NFkB1 turned out to be the transcription factor which mediates the regulatory effect under these conditions.

Conclusion: Monocytes migrate into inflamed and non-inflamed tissues where they differentiate into macrophages. During this differentiation process, HIF-1a translocates from the cytoplasm (monocytes) into the nucleus (macrophages). Therefore, while in macrophages HIF-1a seems to serve as key regulator for the adaptation to hypoxia, this function is fulfilled by NFkB1 in monocytes.

1006

The Key Apoptotic Cell Receptor Mer and Its Ligand Gas6 Are Differentially Regulated in M2 Macrophage Subsets. Gaetano Zizzo, Brendan A. Hilliard, Marc Monestier and Philip L. Cohen. Temple University School of Medicine, Philadelphia, PA

Background/Purpose: Mer is a receptor tyrosine kinase that binds to apoptotic cells via protein S and Gas6. Ligation of Mer leads to profound macrophage functional changes, with diminished production of inflammatory cytokines. Because little is known about the control of Mer expression in humans, we aimed to identify immunological mechanisms regulating Mer expression and Gas6 release in human monocytes and in macrophage subsets.

Methods: Expression of Mer and other surface markers in normal human monocytes and monocyte-derived macrophages was assessed by flow cytometry and Western blot. Gas6 and soluble Mer levels were measured by ELISA.

Results: Among fresh circulating monocytes, Mer was detectable in a small population of CD16+CD14dimHLA-DR+SR-A1+ cells. Macrophages differentiated in the presence of M-CSF (M2 conditions) showed enhanced Mer expression, yet GM-CSF (M1 conditions) was inhibitory. Other M1 stimuli, such as IFNγ, also caused Mer down-regulation, and LPS exposure led to generation of soluble Mer in supernatants. Among M2 macrophages, Mer was overexpressed in CD14brightCD163+SR-A1+CD206brightCD209-CD16+ "M2c" cells, and was driven by dexamethasone and by M-CSF (in the presence of serum) or M-CSF+IL-10 (in serum-free conditions). TGFβ had a negative effect on Mer and CD163 expression, although it up-regulated CD16 and CD206. Except for rare cells, prototypical M2 macrophages driven by IL-4 ("M2a"), defined as CD14dim/nullCD209+CD206+CD163-CD16-, did not express Mer. Mer's ligand Gas6 was released by IL-10- and glucocorticoid-differentiated "M2c" macrophages, though the highest levels were found in supernatants of IL-4-treated cells. In contrast, TGFβ inhibited Gas6 release. Down-regulation of Mer was dependent on PPARγ activation: in fact, GW9662 (PPARγ-antagonist) up-regulated Mer and CD163 in M1 and "M2a" cells; conversely, Rosiglitazone (PPARγ-agonist) suppressed Mer and CD163 expression in otherwise untreated macrophages.

Conclusion: The expression pattern of Mer and Gas6 in macrophages, sustained by anti-inflammatory cytokines and associated with other receptors involved in phagocytosis of apoptotic cells (SR-A1, CD14) and IL-10 production (CD163, FcγRs), reinforces the importance of Mer as a key regulator of inflammation and localizes its role mostly to "M2c" macrophages. In particular, the induction of Mer by glucocorticoids and cytokines may be of importance in the control of inflammation and has therapeutic implications. The role of PPARγ in Mer regulation may also be of clinical significance.

1007

Ly-6C^{high} Monocytes Are Key Cells in Pathogenesis of Autoimmune Arthritis and May Be An Interesting Target for Immunotherapy. Jessy Presumey[1], Gabriel Courties[1], Virginie Escriou[2], Daniel Scherman[2], Diego Kyburz[3], Steffen Gay[4], Yves-Marie Pers[5], Christian Jorgensen[5] and Florence Apparailly[1]. [1]Inserm, Montpellier, France, [2]Inserm, Paris, France, [3]University hospital of Zurich, Zurich, Switzerland, [4]University Hospital of Zürich, Zürich, Switzerland, [5]CHU Lapeyronie, Montpellier, France

Background/Purpose: Monocytes are important players in immunity and their heterogeneity reveals multiple functions. Recent publications suggest that the mouse Ly6C^{high} monocyte subset and its human counterpart $CD14^+/CD16^{low}$ may represent a valuable target for innovative immunotherapeutic strategies against immune-mediated inflammatory disorders. The present work aims at evaluating such hypothesis in vivo in a preclinical model of rheumatoid arthritis (RA) and in vitro in human $CD14^+/CD16^{low}$ primary monocytes. PBEF (Pre-B cell colony-enhancing factor/Visfatin), a pro-inflammatory adipokine described as a new marker of inflammation in RA, is expressed by monocytes and induces IL-6 production. Using RNAi-mediated gene silencing of PBEF, we investigated the therapeutic potential of the

targeting of the mouse Ly6C^{high} and the human CD14^{+}/CD16^{low} monocyte subsets for immuno-intervention in RA.

Methods: Collagen-induced arthritis (CIA) was induced in male DBA/1 mice. We first provided an in-depth characterization of the monocyte subsets in CIA mice using multiparametric analysis by flow cytometry. Small interfering (si)RNAs against mouse PBEF (siPBEF) or non targeting siRNAs (siCT) sequences were formulated with the cationic liposome RPR209120/DOPE and injected intravenously from arthritis onset (0,5 mg/kg). Clinical and biological features of the disease were investigated. In vitro, human CD14^{+}/CD16^{low} monocytes were transfected with human siPBEF or siCT formulated with the cationic liposome. Inhibition of PBEF expression and impact on pro-inflammatory cytokines was quantified.

Results: CIA mice present Ly-6C^{high} monocytosis that infiltrate into the arthritic joints and highly express TNFα. The lipoplex formulation used is preferentially uptaken by the Ly-6C^{high} monocytes from the blood, spleen and joints of CIA mice and by human CD14^{+}/CD16^{low} monocytes from PBMCs in vitro. Weekly systemic injection of siPBEF lipoplexes significantly decreased clinical disease activity scores compared with siCT treated animals as evidenced by paw swelling measures. The anti-PBEF siRNA lipoplexes efficiently triggered in vivo the inhibition of PBEF protein expression within Ly-6C^{high} monocytes/macrophages from blood and inflamed joints. Importantly, PBEF silencing significantly decreased several pro-inflammatory mediators including TNF-α, IL-6, IFN-γ and IL-17A, while increasing anti-inflammatory IL-10 cytokine production in the spleen. Finally, inhibition of PBEF expression in human primary CD14^{+}/CD16^{low} monocytes leads to a decreased IL-6 production.

Conclusion: These results provide novel evidence that silencing of PBEF within Ly-6C^{high} monocytes efficiently reduces experimental arthritis, and within CD14^{+}/CD16^{low} monocytes decreases their pro-inflammatory profile, emphasizing the therapeutic potential of Ly-6C^{high} / CD14^{+}/CD16^{low} monocytes targeting for anti-inflammatory intervention in RA.

Myeloid-Derived Suppressor Cells Present in the Synovial Fluid of Mice with Proteoglycan-Induced Arthritis Are Potent Suppressors of Dendritic Cell Maturation and T Cell Proliferation. Julia Kurko, Colt Egelston, Timea Besenyei, Beata Tryniszewska, Tamas Kobezda, Tibor A. Rauch, Tibor T. Glant and Katalin Mikecz. Rush University Medical Center, Chicago, IL

Background/Purpose: Innate immune cells with a myeloid phenotype and suppressor activity towards T cells have been recently described in cancer patients. Similar myeloid-derived suppressor cells (MDSCs) have been also found in transplant recipients. While such suppressor cells can weaken anti-tumor T cell responses with detrimental consequences in cancer, they have the potential to suppress transplant rejection or autoimmunity. If MDSCs were present in patients with autoimmune diseases such as rheumatoid arthritis (RA), their suppressor activity could be exploited to curtail the expansion of autoreactive T cells. The goal of the present study was to identify potential MDSCs in mice with cartilage proteoglycan-induced arthritis (PGIA), an autoimmune model of RA.

Methods: Various organs of naïve BALB/c mice and BALB/c mice with PGIA were screened for the expression of MDSC-related genes and phenotypic markers using RT-PCR, Western blot, and flow cytometry. MDSCs (which were found predominantly in the synovial fluid and spleen of arthritic mice) were then isolated and tested for suppressor activity towards proteoglycan (PG)-specific T cells using PG-loaded bone marrow-derived dendritic cells (DCs) and T cells from naïve PG-specific T cell receptor transgenic (PG-TCR-Tg) mice. The effect of MDSCs on DC maturation (expression of MHC-II and the co-stimulatory molecule CD86) was also examined. The mechanisms of MDSC-mediated suppression were investigated using inhibitors of MDSC-produced effector molecules such as arginase-1 (arg-1), nitric oxide (NO), and reactive oxygen species (ROS).

Results: We identified cells expressing a myeloid phenotype (CD11b+ Gr-1+) and co-expressing MDSC-specific molecules including arg-1 and inducible NO synthase (iNOS) in the synovial fluid (SF) of arthritic joints and spleens of mice with PGIA. Such MDSC-like cells were detectable at much lower numbers in the blood and bone marrow of the same animals, and were virtually absent in naïve mice. Upon co-culture with PG-TCR-Tg T cells in the presence of PG-loaded DCs, SF MDSCs profoundly inhibited the proliferation of T cells, thereby confirming their suppressor activity. Phenotypically similar CD11b+ cells isolated from the spleens of arthritic mice were much less potent suppressors of T cell proliferation. Intriguingly, SF MDSCs also significantly inhibited the maturation of DCs through down-regulation of MHC-II and CD86 expression. SF-MDSCs did not suppress the PG/DC-independent proliferation of anti-CD3/CD28-stimulated T cells, suggesting that they exhibited suppressor activity, at least in part, via inhibition of DC activation and antigen presentation. Experiments with inhibitors of arg-1, iNOS, and ROS reveled that the primary mechanisms of suppression of both DC maturation and T cell proliferation involved NO and ROS production by SF MDSCs.

Conclusion: Our study is the first to identify MDSCs in the SF of arthritic joints and spleen in an animal model of RA. As potent suppressors of DC maturation and antigen-specific T cell proliferation, MDSCs have a potential to down-regulate autoimmunity, and by doing so, prevent further inflammatory attacks on the joints in RA.

1009

Analysis of the Expression of Interferon Regulatory Factors on Dendritic Cells From Systemic Lupus Erythematosus Patients. Karina Santana-de Anda, Adriana Elizabeth Monsivais-Urenda, Diana Gomez-Martin, Jose Cruz-Ruiz and Jorge Alcocer-Varela. Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico city, Mexico

Background/Purpose: Dendritic cells (DC) are a key element between the innate and the adaptative immune responses, they are considered professional antigen presenting cells, and the main source (plasmacytoid DC) of type-I interferon (IFN-I). Elevated levels of IFN- I have been detected in many autoinmune diseases in humans. The genomic and proteomic studies have shown that elevated serum levels of IFN-I and the interferon related genes overexpression are the molecular signature of systemic lupus erythematosus (SLE). The interferon regulatory factors (IRF) are among these upregulated genes. These transcription factors are induced by many different receptors, mainly toll-like receptors and interferon receptors. Diverse genetic association studies have found relationship between many IRF-5 polymorphisms and increased susceptibility to SLE in different ethnic groups. However these studies have been done with total mononuclear cells, which may not reflect specific DC alterations. It is not known if there are alterations in the expression of IRF on DC from SLE patients. The aim of this study was to evaluate the expression of IRF-3 and IRF-5 on DC from SLE patients.

Methods: We included 10 SLE patients (4 with SLEDAI=0, 6 with SLEDAI>6) as well as 10 healthy controls. Peripheral blood mononuclear cells were isolated by Ficoll-Hypaque centrifugation. Monocytes were purified by positive selection with anti-CD14 mAb coated microbeads. DC were generated by culturing monocytes for 6 days in presence of GM-CSF, IL-4 and for 2 additional days in presence of LPS to induce maturation. In vitro generated DC as well as peripheral blood DC defined by the following phenotype, Lin^{-}HLA-DR^{+}CD11c^{-}BDCA-4^{+}, were analyzed for HLA-DR, CD40, IRF3, and IRF5 expression by flow cytometry and Western Blot.

Results: We found that immature DC from SLE patients shown significantly diminished levels of the CD40 molecule (percentage of CD40+ DC: control median= 48.8, SLE median= 28, p=0.03). In addition, we observed that expression of IRF-3 and IRF-5 on mature DC from SLE tended to be higher compared with controls (IRF3 MFI mean= 17.7 in controls versus 32.5 in SLE; IRF5 MFI mean=22.1 in controls versus 30.01 in SLE). Furthermore, we found that the expression of these molecules was increased in peripheral blood Lin^{-}HLA-DR^{+}CD11c^{-}BDCA-4^{+} DC from SLE patients compared with healthy controls (percentage of IRF3 positive cells= 29 in controls versus 76 in SLE; percentage of IRF5 positive cells= 3.6 in controls versus 34.6 in SLE). We found no differences on IRF expression on DC from active SLE and those with inactive disease.

Conclusion: Our results suggest that the previously reported elevated levels of IFN-I observed in SLE might be explained by the altered expression of IRF on DC from SLE patients. Furthermore, the impaired expression of these factors might be considered as an intrinsic defect in SLE.

1010

Expression of Caspase 8 in Dendritic Cells Is More Potent Than in Myeloid Cells in the Prevention of SLE-Like Disease Onset. Carla M. Cuda[1], Jaime Chowaniec[1], Jack Hutcheson[2], G. Kenneth Haines III[3], Chandra Mohan[2] and Harris R. Perlman[4]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]Yale University, New Harven, CT, [4]Northwestern University, Chicago, IL

Background/Purpose: Caspase 8 has been referred to as the initiator caspase of the death receptor mediated extrinsic apoptotic pathway. The death receptor Fas can trigger the extrinsic apoptotic pathway, and loss of Fas in macrophages and dendritic cells (DCs) results in autoimmunity. Deletion of caspase 8 revealed non-apoptotic roles for this molecule in regulating embryonic development,

lymphocyte activation and proliferation, and NFκB activation, though its effect on non-proliferating immune cells such as macrophages or DCs remains unknown. Due to caspase 8's involvement in the activation of apoptosis triggered by multiple death receptors as well as signaling via non-apoptotic pathways, it was of interest to assess how loss of caspase 8 in either macrophages or DCs would affect development of systemic autoimmunity.

Methods: Mice with caspase 8 flanked by *loxP* sites ($Casp8^{flox/flox}$) were crossed with mice expressing Cre under control of either the lysozyme M gene promoter (Cre^{LysM}), which functions in mature lysozyme-expressing cells of the myelomonocytic lineage, or the CD11c gene promoter (Cre^{CD11c}), which is expressed by dendritic cells. Both $Cre^{LysM}Casp8^{flox/flox}$ and $Cre^{CD11c}Casp8^{flox/flox}$ mice were verified by RT-PCR. Flow cytometric analysis was employed to characterize both myeloid and lymphoid cell distribution and activation in bone marrow, blood, lymph node, and spleen. Luminex-based assays and ELISAs were used to detect serum cytokine and Ig levels. Immunohistochemical staining revealed kidney pathology.

Results: With age, both $Cre^{CD11c}Casp8^{flox/flox}$ and $Cre^{LysM}Casp8^{flox/flox}$ mice presented with a break in tolerance, as indicated by splenomegaly, lymphadenopathy, and autoantibody production, though these phenotypes were more exaggerated in $Cre^{CD11c}Casp8^{flox/flox}$ mice. While central and peripheral lymphoid organ analysis revealed that this break occurs via peripheral mechanisms, it also strikes early in development. Peripherally, both myeloid cell and DC-specific loss of caspase 8 not only increased circulating granulocytes and $Gr\text{-}1^+$ monocytes, as well as splenic and lymph node antigen presenting cells. Additionally, increased peripheral effector T cells coincided with decreased peripheral naïve T cell populations. Moreover, not only did loss of caspase 8 in DCs and myeloid cells intrinsically amplified DC and macrophage activation, respectively, while affecting activation of other immune cells in a paracrine fashion. In an *in vitro* antigen-specific MLR, $Cre^{CD11c}Casp8^{flox/flox}$ DCs induced T cell proliferation, while $Cre^{LysM}Casp8^{flox/flox}$ macrophages inhibited proliferation. Elevated serum IL-12, TNFα, sRANKL levels were common to both strains, though $Cre^{CD11c}Casp8^{flox/flox}$ mice presented with heightened IgG2b levels and more severe kidney pathology.

Conclusion: These results demonstrate that while loss of caspase 8 in both DCs or myeloid cells initiates inflammatory phenotypes, intact caspase 8 signaling appears to be more crucial in DCs than in myeloid cells to prevent systemic autoimmunity. These data have implications for autoimmunity by elucidating previously unknown functions of a potentially useful target for therapy.

Analysis of the Bioactive Molecules That Promote the Induction of Human Tolerogenic Dendritic Cells. Takuya Matsumoto, Hitoshi Hasegawa, Jin Lei, Koichiro Suemori, Sachiko Onishi and Masaki Yasukawa. Ehime University Graduate School of Medicine, Toon, Japan

Background/Purpose: Tolerogenic dendritic cells (DCs) and regulatory T cells (Treg) play a critical role in immune tolerance and are involved in the pathogenesis of autoimmune diseases such as rheumatoid arthritis. Suppression by tolerogenic DCs is primarily mediated via the induction of Treg cells. Tolerogenic DCs and Treg cells are induced or differentiated in the presence of specific biological agents, but little is known about harmless, potent inducers, especially in humans. Previously we isolated some agents that induced human Treg cells and reported that peroxisome proliferator-activated receptor (PPAR) agonist together with TGF-beta induced functional human Treg cells. Therefore, in this study, we screened the molecules that enhanced induction of tolerogenic DCs and analyzed the mechanism of these molecules in induction of tolerogenic DCs.

Methods: DCs were prepared from human monocytes by treatment of GM-CSF and IL-4 for 5 days, and then cultured with TNF-alpha for 48h, in the presence of the molecule. From the libraries of lipids, nuclear receptor ligands, and kinase inhibitors, we screened the molecules that suppressed the expression of CD80, CD83, and CD86 for immature DCs and that induced the production of IL-10 for IL-10-producing DCs. Furthermore, we examined the effects of these molecules on stability and plasticity of DCs, antigen presenting, allogenic T cell response, and induction of cytokines and Treg cells.

Results: We screened 24 kinds of lipids, nuclear receptor ligands, and kinase inhibitors that suppressed the expression of CD80, CD83, and CD86 similar to the phenotype of immature DCs. DCs treated with PPAR-gamma, dexamethazone, and indirubin remained phagocytosis, suppressed allogenic T cell responses and production of IL-12, and enhanced induction of Treg cells. On the other hand, we screened 10 kinds of the molecules that produced IL-10 from DCs. DCs treated with prostaglandin and GSk 3-beta inhibitor such as kenpaullone decreased allogenic T cell responses and enhanced induction of Tregs through IL-10 production. Moreover, induction of tolerogenic DCs was enhanced by combination with two molecules. We show the details of mechanism and other molecules in congress.

Conclusion: We identified some bioactive molecules that promoted the induction of tolerogenic DCs. We aim at the development of efficient induction of both human tolerogenic DCs and Treg cells using these molecules.

1012

Active involvement of "alarmins" S100A8 and A9 in regulation of Synovial Activation and Joint Destruction During Mouse and Human Osteoarthritis. Peter Van Lent[1], Arjen Blom[1], Rik Schelbergen[1], Annet Sloetjes[1], Thomas Vogl[2], Johannes Roth[2], Wim B. Van Den Berg[1] and and The NOAC study group[3]. [1]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [2]University of Munster, Munster, Germany, [3]Maartens Clinic, Nijmegen, Netherlands

Background/Purpose: Prominent proteins released by activated macrophages are the "alarmins" S100 A8 and A9. There is increasing belief that synovial tissue activation contributes to OA cartilage pathology. The aim was to explore active involvement of S100A8/A9 in cartilage destruction in experimental osteoarthritis models that differ in degree of synovial activation and to evaluate the presence of S100A8/S100A9 in sera and synovia of patients with early symptomatic OA.

Methods: Experimental OA was either induced by transection of the medial anterior meniscotibial ligament which leads to destabilisation of the medial meniscus (DMM) or by injection of collagenase into murine knee joints, which causes overall ligament damage and broad instability. Collagenase-induced-osteoarthritis involves chronic synovial activation in contrast to DMM. Synovial expression of S100A8 and S100A9 was measured using immunolocalisation. Both models were induced in $S100A9^{-/-}$ deficient mice (myeloid cells also lack S100A8 at the protein level). Primary chondrocytes were stimulated with S100A8 and A9 and MMP levels were measured using RT-PCR.

Arthroscopic biopsies (30) and sera (200) were taken from patients with early symptomatic OA (CHECK cohort, The Netherlands). Protein levels of S100A8 and A9 was determined using immunolocalisation or ELISA and related to joint destruction (Kellgren Lawrence score) at year two.

Results: In collagenase-induced osteoarthritis, showing marked synovial activation S100A8 and S100A9 was strongly upregulated in synovium at day 7 and remained high at days 14, 28 and 42. In contrast IL-1β was expressed in early stages only. Using $S100A9^{-/-}$ mice, we found a major impact of s100A8 and A9 on synovial activation and OA cartilage destruction. Synovial activation was 62% lower at day 42. Cartilage destruction was significantly lower in all surfaces and ranged from a 45% reduction in the lateral tibia to 73% reduction in the medial femur. When primary mouse chondrocytes were stimulated with S100A8 or S100A9, a strong upregulation of particularly MMP-3 mRNA level was found indicating a direct role of S100A8/A9 in cartilage destruction. In contrast, in the DMM model in which synovial involvement is scant no role of S100A8/A9 was found for the focal OA cartilage destruction.

Arthroscopic synovial biopsies taken from patients in the early symptomatic OA CHECK cohort identified substantial S100A8 and A9 mRNA and protein expression and levels correlated with synovial lining thickness, cellularity in subintima and joint destruction. Serum S100A8/A9 protein levels were significantly enhanced at base line in patients showing pronounced progression of joint destruction in 2 years.

Conclusion: Alarmins S100A8/S100A9 are crucial proteins involved in synovial activation and cartilage destruction during OA and high levels may predict joint destruction in human OA.

1013

Rilonacept for Gout Flare Prevention in Patients on Uric Acid-Lowering Therapy: Results of a Double-Blind, Placebo-Controlled, Phase 3, International Safety Study. John S. Sundy[1], H. Ralph Schumacher[2], Judith Kirstein[3], Essack Mitha[4], Steven P. Weinstein[5], Jian Wang[5], Shirletta King-Davis[5] and Robert R. Evans[5]. [1]Duke University Medical Center, Durham, NC, [2]VA Medical Center and University of Pennsylvania, Philadelphia, PA, [3]Advanced Clinical Research, West Jordan, UT, [4]Newtown Clinical Research, Johannesburg, Gauteng, South Africa, [5]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Background/Purpose: Previous studies with rilonacept, an interleukin (IL)-1 antagonist, have confirmed that IL-1 plays an essential role in initiation of gout flares and is an appropriate target for flare prevention. RE-SURGE was a large double-blind, placebo-controlled, phase 3 study evaluating the safety and efficacy of rilonacept in patients with gout at risk of a gout flare (GF).

Methods: This phase 3 study was conducted in the US, South Africa, Europe, and parts of Asia. Adults (N=1315; 18–80 years of age) with gout at risk of a GF due to initiation of uric acid-lowering therapy (ULT) or continuation of ULT in the setting of high uric acid body stores were randomized in a 3:1 ratio to treatment with weekly subcutaneous injections of rilonacept 160mg (R160) or placebo (PBO) for 16 weeks. On day 1 a loading dose of rilonacept 320mg or PBO was administered. The primary endpoint was safety, assessed by type and incidence of adverse events (AEs) and changes in lab values over the 20-week study period. Secondary efficacy endpoints included the mean number of GFs per patient, and proportions of patients with ≥1 and ≥2 GFs.

Results: 985 patients were treated with R160 and 330 with PBO. Most patients were male (87.8%) and white (66%); median age was 53 years, and median weight was 95 kg. Tophi were present in 29% of patients. Baseline comorbidities included hypertension (53%), hypercholesterolemia (17%), renal and urinary disorders (14%) and cardiac disorders (11.5%); a history of polypharmacy was common. Through week 20, AEs were reported in 67% of R160 vs 59% of PBO patients. AEs reported in ≥5% of R160 patients are shown below:

Adverse Event	PBO (n=330)	R160 (n=985)
Infections	19.1%	20.1%
Injection site reactions	3.3%	15.2%
Headache	7.9%	9.1%
Arthralgia	6.1%	6.6%
Pain in extremity	4.5%	5.3%

Withdrawals due to treatment emergent AEs were seen in 4.7% and 3.0% of patients in R160 and placebo, respectively. Injection site reactions were the most common reason for withdrawal in the R160 group with 1.2% of rilonacept-treated patients experiencing an injection site reaction leading to withdrawal. Treatment emergent serious AEs were observed in 3.1% of R160 and 3.9% of PBO patients. Serious infections were uncommon, occurring in 0.5% of patients in the R160 group and 0.9% of patients in the PBO group. Six deaths occurred, 3 (0.3%) in R160 (none assessed as related to study drug) and 3 (0.9%) in PBO. For secondary efficacy endpoints, R160 resulted in a 70.3% reduction in mean number of total GFs per patient relative to PBO (0.51 vs 1.73; $P<0.0001$) at week 16. Treatment with R160 also resulted in a 49.6% reduction in patients experiencing 1 or more GFs (25.7% vs 51.1%; $P<0.0001$); 11.7% of patients in R160 vs 34.7% in PBO experienced 2 or more GFs ($P<0.0001$; 66.4% reduction).

Conclusion: Rilonacept demonstrated an acceptable safety and tolerability profile in gout patients with typical comorbid conditions. The rate of serious infections was low. Rilonacept resulted in a substantial reduction in gout flares in patients at high risk of flaring.

1014

Rilonacept Efficacy for Gout Flare Prevention in Patients with Tophi and/or Polyarticular Disease Who Initiate Uric Acid-Lowering Therapy. Robert Terkeltaub[1], H. Ralph Schumacher[2], A. Kivitz[3], Steven P. Weinstein[4], Richard Wu[4], Rebecca Gall[4] and Robert R. Evans[4]. [1]VA Medical Ctr, San Diego, CA, [2]VA Medical Center and University of Pennsylvania, Philadelphia, PA, [3]Altoona Center for Clinical Research, Duncansville, PA, [4]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Background/Purpose: Patients (pts) with greater disease burden, those with tophi and/or polyarticular disease, may be at greater risk of gout flares (GFs) when initiating uric acid-lowering therapy (ULT). This analysis used data from three Phase 3 clinical trials of the IL-1 antagonist rilonacept to evaluate the risk of these clinical features for occurrence of GFs during initiation of ULT, and to determine the efficacy of rilonacept in these pts.

Methods: PRE-SURGE 1, PRE-SURGE 2, and RE-SURGE were randomized, double-blind, placebo (PBO)-controlled trials evaluating safety and efficacy of weekly subcutaneous doses of rilonacept 80mg (R80) and 160mg (R160) for prevention of GFs during initiation of ULT. Treatment duration was 16 wks and pts analyzed had baseline serum urate ≥7.5 mg/dL and >2 GFs in the past year and were initiating allopurinol. GF rate ratios were calculated in the PBO group for each study by comparing pts with tophi and/or polyarticular disease vs pts without these features. GFs per pt and proportion of pts with ≥1 GF were estimated for pts within each study as well as pooled from the 3 studies. GFs were defined as pt-reported acute articular pain typical of a gout attack that required anti-inflammatory treatment.

Results: Pts with tophi and/or polyarticular disease had significantly higher rates of GFs than those with monoarticular, non-tophaceous disease: GF rate ratios (95% confidence intervals) were 1.97 (1.02, 3.79), 3.69 (1.51, 9.02), and 1.93 (1.30, 2.86), in PRE-SURGE 1, PRE-SURGE 2, and RE-SURGE, respectively. Among pts with these risk factors, rilonacept significantly reduced the mean number of GFs per pt (Table). These reductions were generally similar to those observed for the total population of all pts with serum urate ≥7.5 mg/dL, ≥2 GFs in the past year, and initiating allopurinol. Pooling the data within treatment groups showed that for pts with these risk factors, R80 resulted in a 69.5% reduction in mean number of GFs per pt versus PBO (from 1.81±2.52 (PB0) to 0.55±1.20 (R80); P≤0.0001); the reduction with R160 was 67.7% (to 0.59±1.19; P≤0.0001). The proportion of pts with ≥1GF in the pooled population of pts with risk factors was 59.4%, 29.8%, and 30.7% for PBO, R80, and R160, respectively, representing almost a 50% reduction with rilonacept.

Study	Treatment	GFs per patient, mean±SD	
		Total population (n)	Patients with tophi/polyarticular disease (n)
PRE-SURGE 1	PBO	1.19±1.75 (79)	1.31±1.83 (64)
	R80	0.40±0.91 (80)*	0.39±0.85 (56)†
	R160	0.28±0.62 (81)†	0.35±0.70 (56)†
PRE-SURGE 2	PBO	1.51±1.87 (82)*	1.68±1.92 (71)
	R80	0.62±1.32 (82)*	0.69±1.44 (65)*
	R160	0.48±0.99 (84)*	0.58±1.08 (68)*
RE-SURGE	PBO	1.99±2.89 (145)	2.17±3.05 (121)
	R160	0.55±1.20 (420)*	0.63±1.27 (340)*

* P≤0.0001 vs PBO; †P<0.005 vs PBO.
Subgroup = Pts with baseline serum urate ≥7.5 mg/dL and ≥2 GFs in the past year and initiating allopurinol; SD = standard deviation.

For the total study population in these 3 studies, the most commonly reported adverse event (AE), infections, was balanced among treatment groups; the most frequently reported treatment-related AE was injection site reaction.

Conclusion: The presence of tophi and/or polyarticular disease represents a risk factor for gout flares in patients initiating uric acid-lowering therapy. Among patients with these risk factors, rilonacept demonstrated efficacy for gout flare prevention that was generally similar to that observed for the overall population.

1015

Integrated Safety Analysis of Four Trials of Interleukin-1 Blockade with Rilonacept for Gout Flare Prevention in Patients Taking Uric Acid-Lowering Therapy. Robert Terkeltaub[1], H. Ralph Schumacher[2], Essack Mitha[3], John S. Sundy[4], Kenneth G. Saag[5], Steven P. Weinstein[6], Jian Wang[6] and Robert R. Evans[6]. [1]VA Medical Ctr, San Diego, CA, [2]VA Medical Center and University of Pennsylvania, Philadelphia, PA, [3]Newtown Clinical Research, Johannesburg, Gauteng, South Africa, [4]Duke University Medical Center, Durham, NC, [5]Univ of Alabama-Birmingham, Birmingham, AL, [6]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Background/Purpose: The IL-1 antagonist rilonacept has demonstrated efficacy for gout flare prevention in a phase 2 and three phase 3 clinical trials. This pooled analysis of the 4 trials provides an integrated summary of safety.

Methods: The phase 2 and phase 3 studies (PRE-SURGE 1, PRE-SURGE 2, RE-SURGE) were randomized, double-blind, placebo (PBO)-controlled trials evaluating the safety and efficacy of weekly subcutaneous doses of rilonacept 80mg (R80) and 160mg (R160) for the prevention of gout flares in patients at risk for flares while initiating or continuing uric acid-lowering therapy (ULT). Treatment duration was 16 weeks in all studies. Safety assessments in patients taking at least 1 dose of study drug included the incidence, type, severity and seriousness of adverse events (AEs), and changes in clinical lab values. Data from the 4 studies were pooled for the R80 (n=162), R160 (n=1191), and PBO (n=533) groups.

Results: Demographic characteristics were generally well-balanced across the pooled treatment groups. Most patients were male (89.5%) and white (67.2%), with a mean age of 52.3±11.5 years. AEs were reported in 59.7%, 64.8%, and 66.0% of PBO, R80, and R160 patients, respectively (Table), and were generally of mild or moderate severity. The incidences of serious AEs and AEs leading to withdrawal were similar among the groups (Table). Although AEs leading to withdrawal were infrequent, the main cause in the rilonacept groups was injection site reactions (1.0%). Six deaths occurred, 3 in PBO (0.56%) and 3 in R160 (0.25%); none of the deaths in the R160 group were assessed as related to study drug. Infections were the most commonly reported category of AEs and were similar among the treatment groups (Table). Serious infections were infrequent with 1 event, which occurred in the PBO group, considered treatment-related (Table). Injection site reactions, headache, and arthralgia were the most frequently reported individual AEs (Table); injection site reactions were dose-related, with 7 patients (0.6%) reporting severe injection site reactions, all in the R160 group. Changes in lab analytes were consistent with IL-1 inhibition with potentially clinically significant laboratory values for a given analyte generally <1.0% in any treatment group.

Treatment-Emergent AEs	Percent (number) of patients			
	PBO (n=533)	R80 (n=162)	R160 (n=1191)	All rilonacept doses (n=1353)
Any AE	59.7 (318)	64.8 (105)	66.0 (786)	65.9 (891)
Serious AEs	4.1 (22)	4.9 (8)	3.2 (38)	3.4 (46)
AEs leading to withdrawal	3.2 (17)	4.3 (7)	4.2 (50)	4.2 (57)
Infection AEs	20.8 (111)	23.5 (38)	20.2 (241)	20.6 (279)
Serious infections	0.6 (3)	1.9 (3)	0.4 (5)	0.6 (8)
Individual AEs in '5% patients in any treatment group				
Joint related signs and symptoms	6.8 (36)	4.9 (8)	7.0 (83)	6.7 (91)
Arthralgia	5.4 (29)	3.7 (6)	6.1 (73)	5.8 (79)
Injection site reactions	2.6 (14)	10.5 (17)	15.5 (185)	14.9 (202)
Injection site erythema	0.2 (1)	6.2 (10)	6.0 (72)	6.1 (82)
Headaches NEC	6.4 (34)	6.2 (10)	8.2 (98)	8.0 (108)
Headache	5.6 (30)	6.2 (10)	7.8 (93)	7.6 (103)
Individual treatment-related AEs in ≥5% of patients in any treatment group				
Any treatment-related AE	12.6 (67)	24.7 (40)	27.6 (329)	27.3 (369)
Injection site reactions	2.1 (11)	10.5 (17)	14.8 (176)	14.3 (193)
Injection site erythema	0.2 (1)	6.2 (10)	5.9 (70)	5.9 (80)

Conclusion: An integrated safety analysis of 4 trials indicates that a 16-week course of weekly 80mg or 160mg rilonacept for gout flare prevention in patients initiating or continuing uric acid-lowering therapy has a generally acceptable safety and tolerability profile. The rate of serious infections was low, and injection site reactions were the most common adverse event leading to discontinuation in only 1.0% of rilonacept patients.

Long-Term Efficacy and Safety of Canakinumab Versus Triamcinolone Acetonide in Acute Gouty Arthritis Patients. J.P. Brown[1], A. So[2], A. Dikranian[3], R. Alten[4], T. Bardin[5], H. R. Schumacher[6], A. Gimona[7], G. Krammer[7], A. Karpov[7] and N. Schlesinger[8]. [1]CHUQ-CHUL Research Centre, Laval University, Quebec City, QC, [2]CHUV, Lausanne, Switzerland, [3]San Diego Arthritis Medical Clinic, San Diego, CA, [4]Charité Teaching Hospital–Schlosspark-Klinik, Berlin, Germany, [5]Hôpital Lariboisière, Paris, France, [6]University of Pennsylvania and VA Medical Center, Philadelphia, PA, [7]Novartis Pharma AG, Basel, Switzerland, [8]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ

Background/Purpose: Gouty arthritis (GA) is a painful, progressive, destructive, chronic inflammatory disease. Targeting the inflammatory pathway through IL-1β inhibition with canakinumab, a fully human anti-IL-1β monoclonal antibody, is a novel therapeutic approach that may provide significant long-term benefits in this patient group. In 2 pivotal 12-week controlled trials (β-RELIEVED and β-RELIEVED-II), canakinumab showed superiority to triamcinolone acetonide (TA) in relieving pain, inflammation and delaying risk of new flares in GA patients with limited treatment options. We report the results of two extension studies that assessed long-term efficacy, safety and tolerability.

Methods: In two 12-week, multicenter, active-controlled trials, acute GA patients (meeting preliminary ACR-1977 criteria for acute GA and unresponsive, intolerant or contraindicated to NSAIDs and/or colchicine) were randomized to receive canakinumab 150mg sc or TA 40mg im, followed by two 12-week extension studies. Patients received canakinumab 150mg sc or TA 40mg im for the baseline flare and only "on demand" for any new flare. Time to first new flare, mean number of flares, physician's and patient's global assessment of treatment response (Likert scale) and safety over 24 weeks are assessed.

Results: 416 patients completed the core studies (β-RELIEVED: 214; β-RELIEVED-II: 202). 335 patients (β-RELIEVED: 175; β-RELIEVED-II: 160) entered the extension studies and 317 completed (β-RELIEVED E1: 167; β-RELIEVED-II E1: 150). Over 24-weeks following randomization, canakinumab delayed the time to first new flare vs TA with a statistically significant relative risk reduction of 52% in β-RELIEVED E1 and 60% in β-RELIEVED-II E1 (Table). The mean number of flares per patient was significantly reduced with canakinumab. At Week 24, a higher percentage of patients taking canakinumab achieved a better assessment of treatment response from physicians and patients. Incidence of AEs for canakinumab and TA in both studies was: β-RELIEVED E1: 62.8% vs 48.7%; β-RELIEVED-II E1: 69.6% vs 57%, respectively. Most AEs were mild to moderate in severity. No discontinuations due to AEs were observed in β-RELIEVED E1. 2 (1.8%) patients treated with canakinumab in β-RELIEVED-II E1 discontinued. SAEs [β-RELIEVED E1: canakinumab, n =11; TA n=6; β-RELIEVED-II E1: canakinumab n=7; TA n=2] were not considered to be related to study medication by the investigators. Most patients had no injection site reactions [β-RELIEVED E1: canakinumab, n=0; TA n=0; β-RELIEVED-II E1: canakinumab n=2; TA n=1].

Table. Efficacy assessments over 24 weeks: β-RELIEVED E1 and β-RELIEVED-II E1

	β-RELIEVED E1		β-RELIEVED-II E1	
Efficacy	Canakinumab N=113	TA N=115	Canakinumab N=112	TA N=114
Probability of new gout flare (Kaplan-Meier estimates) (%)	35.5	57.5	29.1	54.3
Hazard ratio to TA 40 mg im	0.48		0.40	
95% CI	(0.32–0.73)		(0.25–0.64)	
One sided p-value	0.0003		<0.0001	
Mean number of flares per patient	0.40	0.87	0.35	0.80
Estimated rate ratio (p-value)	0.45 (0.0001)		0.42 (0.0001)	
Assessment of response to treatment at Week 24				
Patient's global assessment, %				
Excellent	31.0	17.9	59.5	40.3
Good	46.0	44.9	26.6	44.4
Physician's global assessment, %				
Very Good	43.7	27.8	77.2	66.2
Good	50.6	50.6	16.5	29.6

Conclusion: In frequently flaring patients with limited treatment options, canakinumab demonstrated superior 24 week efficacy against TA with comparable safety and tolerability to 12-week data.

1017

No Dosing Adjustments Are Required for Colchicine in Patients Over Age 60 Years Compared to Younger Adults on the Basis of Age and Mild Renal Impairment. Suman Wason[1], Robert D. Faulkner[1], Darin B. Brimhall[2] and Matthew W. Davis[1]. [1]URL Pharma, Philadelphia, PA, [2]Novum Pharmaceutical Research Services Clinical Studies Inc., Pittsburgh, PA

Background/Purpose: Gout affects 4% of adults in the United States. Patients ≥65 yrs of age experience higher prevalence (~8%-12%). The objective of this study was to evaluate the pharmacokinetics (PK) of colchicine in subjects aged 18–30 yrs compared to ≥60 yrs to determine if older subjects require dose adjustments when prescribed colchicine.

Methods: Thirty-eight subjects (ages 18–30 [n=20], and ≥60 [n=18] yrs of age) received a single, oral 0.6-mg dose of colchicine after a 10-hr fast. Plasma samples for PK analyses were collected pre-dose and up to 72 hrs post-dose and analyzed for colchicine by a validated liquid chromatographic-tandem mass spectrometry method.

Results: Plasma samples from all subjects were included in the analyses. As seen in the Table, creatinine clearance (CrCl) at baseline was significantly lower ($P<0.0001$) in subjects ≥60 yrs of age compared with subjects 18–30 yrs of age. Mean colchicine maximum concentrations (C_{max}) were similar in both groups. There was marginally higher exposure (AUC) to colchicine in the older group; however, this difference was not significant ($P>0.05$). The mean $T_{1/2}$ (elimination half-life) was slightly longer in subjects aged ≥60 yrs than those 18–30 yrs of age; however, this was not significant ($P=0.0944$). Further, there were no differences between oral clearance (CL/F; $P=0.987$) or apparent volume of distribution (V/F; $P=0.785$) of colchicine between groups.

Table. Creatinine Clearance and Pharmacokinetic Parameters in Young Versus Older Subjects (N=38) Following a Single Dose of Colchicine Tablets USP, 0.6 mg

	Young Adults 18–30 years	Older Adults 60–70 years
Creatinine Clearance (mL/min)		
Mean (Range)	132.56 (99.2 – 182.6)	87.02 (56.8 – 119.9)
Pharmacokinetic Parameter (Units)	**Arithmetic mean ± SD (% CV)**	
AUC $_{0\text{-}t}$ (ng·hr/mL)	20.1362 ± 5.8576 (29.0897)	21.8804 ± 6.2248 (28.4490)
AUC $_{0\text{-}\infty}$ (ng·hr/mL)	22.3852 ± 6.9451 (31.0254)	25.0134 ± 6.922 (27.6743)
C_{max} (ng/mL)	2.6071 ± 0.707 (27.1332)	2.5559 ± 0.9701 (37.9553)
T_{max} (hr)	1.3824 ± 0.4157 (30.0708)	1.2500 ± 0.4287 (28.7140)
$T_{1/2}$ (hr)	24.9178 ± 5.3389 (21.4259)	30.0580 ± 10.779 (24.2464)
CL (mL/min)	0.0321 ± 0.0091 (28.2270)	0.0292 ± 0.0071 (24.1464)
Vd	1.1296 ± 0.3336 (29.5315)	1.2725 ± 0.5745 (45.1482)

There were 16 females and 22 males enrolled. Subgroup analysis showed that there was a difference ($P<0.05$) in AUCs; however, the mean ratios for female to male was 1.21, indicating this difference was not clinically significant. There were no significant differences between males and females in Tmax, T1/2, or body-weight adjusted CL/F, V/F, and CrCl. There were 14 African Americans, 15 Caucasians, and 9 "other" enrolled. There were no significant differences in the aforementioned PK parameters between the racial groups.

Adverse events (AEs) were reported in 15 subjects. The most commonly reported AEs were increased blood pressure and somnolence. All AEs were considered mild, were not related to colchicine, and resolved spontaneously prior to study completion.

Conclusion: Following administration of a single 0.6-mg dose of colchicine, there were no significant differences in PK parameters between young and older adults (including those with mild decreases in renal function estimated by creatinine clearance), suggesting there is no need to modify the dose of colchicine based on age alone.

BCX4208 Synergistically Lowers Serum Uric Acid (sUA) Levels When Combined with Allopurinol in Patients with Gout: Results of a Phase 2 Dose-Ranging Trial. Alan S. Hollister[1], Michael A. Becker[2], Robert Terkeltaub[3], Anita Waugh[1], Scott Lyman[1], Amy Flynt[4] and David Fitz-Patrick[5]. [1]BioCryst Pharmaceuticals, Inc., Durham, NC, [2]University of Chicago Medical Center, Chicago, IL, [3]VA Medical Ctr, San Diego, CA, [4]PharPoint Research, Inc., Chapel Hill, NC, [5]East-West Medical Research Institute, Honolulu, HI

Background/Purpose: BCX4208 is an oral, once-daily, novel purine nucleoside phosphorylase inhibitor in clinical development for the chronic management of gout. Because BCX4208 blocks production of uric acid earlier in the metabolic pathway than xanthine oxidase inhibitors, there is a strong mechanistic rationale for expecting synergistic reduction of sUA when combined with xanthine oxidase inhibition. This is important because >50% of gout patients fail to meet the therapeutic goal of sUA <6.0 mg/dL during treatment with 300 mg allopurinol daily. This study assessed the dose-response relationship of BCX4208 on sUA when administered as monotherapy and in combination with allopurinol.

Methods: Adults (n=87) with gout and sUA ≥8.0 mg/dL were randomized to placebo (Plc) or 20, 40, or 80 mg/d BCX4208 in combination with Plc or with 100, 200, or 300 mg/d allopurinol using a 4 × 4 factorial study design. Drugs were administered in a double-blind manner for 3 weeks with weekly assessments of sUA and adverse events (AEs). The key efficacy endpoints were the change in sUA from baseline on Day 22 and the percentage of patients achieving the goal (sUA <6.0 mg/dL).

Results: When BCX4208 was combined with allopurinol, there was a synergistic reduction in sUA (by Combination Index test). BCX4208 produced a significant reduction in sUA compared with Plc when administered as monotherapy and in combination with allopurinol. Both BCX4208 and allopurinol demonstrated dose-related reductions in sUA and increases in the proportion of patients achieving goal sUA (Table).

		BCX4208		
Cotreatment	**Placebo**	**20 mg**	**40 mg**	**80 mg**
Placebo	(n=5) 0%	(n=4) 0%	(n=6) 17%	(n=5) 40%
Allopurinol 100 mg	(n=5) 0%	(n=4) 0%	(n=5) 60%	(n=5) 40%
Allopurinol 200 mg	(n=4) 0%	(n=5) 20%	(n=5) 80%	(n=5) 80%
Allopurinol 300 mg	(n=5) 40%	(n=4) 75%	(n=4) 100%	(n=5) 100%

Seventy-five percent to 100% of patients achieved sUA <6.0 mg/dL with BCX4208 in combination with 200 mg allopurinol (>20 mg BCX4208) or 300 mg allopurinol (≥20 mg BCX4208) daily. Patients in the 300 mg allopurinol monotherapy group had a 1.8 mg/dL reduction in sUA, whereas the addition of 20 mg BCX4208 to 300 mg allopurinol decreased sUA by 3.9 mg/dL. AE frequency and severity were comparable across dose groups. Common AEs in the BCX4208 group included diarrhea (12% vs 5% in Plc) and headache (6% vs 5% in Plc). No serious AEs were reported. Lymphocyte counts and subsets (CD4+, CD8+, CD20+ and CD56+) were reduced, with both baseline counts and dose of BCX4208 significant factors in multivariate models for all subsets. One patient on BCX4208 experienced a reduction in lymphocytes (grade 0 at baseline to grade 2, 500–599 cells/μL, at Day 22). No severe or opportunistic infections were observed.

Conclusion: BCX4208 combined with allopurinol produces synergistic reductions in sUA in patients with gout and permitted substantially higher achievement of goal sUA compared with commonly prescribed doses of allopurinol alone. BCX4208 once-daily dosing is well tolerated when used in combination. Positive results of this trial have led to the initiation of a 6-month add-on study of BCX4208 in patients who did not achieve goal sUA with 300 mg allopurinol daily.

Inflammation Suppression Over 24 Weeks in Patients with Gouty Arthritis: Results From Two Phase-III Core and Extension Studies Comparing Canakinumab with Triamcinolone Acetonide. A. So[1], R. Alten[2], H. R. Schumacher[3], T. Bardin[4], M. Bloch[5], D. Richard[6], A. Karpov[6], T. Kiechle[6] and N. Schlesinger[7]. [1]CHUV, Lausanne, Switzerland, [2]Charité Teaching Hospital–Schlosspark-Klinik, Berlin, Germany, [3]University of Pennsylvania and VA Medical Center, Philadelphia, PA, [4]Hôpital Lariboisière, Paris, France, [5]Holdsworth House Medical Practice, Sydney, Australia, [6]Novartis Pharma AG, Basel, Switzerland, [7]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ

Background/Purpose: Gouty arthritis (GA) is a chronic inflammatory arthritis, mainly driven by IL-1β—a proinflammatory cytokine. Canakinumab, a fully human monoclonal anti-IL-1β antibody, offers a new therapeutic option for GA that may provide significant long-term benefits.

Methods: In two, pivotal 12-week, multicenter, double blind, double dummy, active-controlled studies (β-RELIEVED and β-RELIEVED-II), GA patients (meeting preliminary ACR-1977 criteria) with flare duration ≤5 days and unresponsive, intolerant or contraindicated to NSAIDs and / or colchicine were randomized to receive a single dose of canakinumab 150mg sc or triamcinolone acetonide (TA) 40mg im and were re-dosed "on demand" on each new flare. Patients completing the core studies were enrolled into 12-week extension studies

to further investigate "on demand" use of canakinumab 150 mg sc or TA 40 mg im on new flare. Inflammatory markers (CRP, SAA), tenderness and swelling were assessed at baseline, 72h and 7 days post dose, 12, and 24 weeks, where as IL-6 and TNF-α was assessed at baseline, 12 and 24 weeks.

Results: In both core studies, 454 patients received treatment and 416 completed the studies. Of these, 335 patients entered and 317 completed the extension studies. At baseline in β-RELIEVED and β-RELIEVED-II, 17.1% and 16.8% had polyarticular GA and the mean number of flares in the previous year was 6.8 and 6.2, respectively. A large proportion (60.5%; 60.2%) of patients had a history of GA >5 years. Median CRP and SAA levels were elevated at baseline (Table). Following treatment with canakinumab, CRP decreased rapidly and normalized by 7 days post dose and SAA normalized by 3 days post dose. Both remained below upper limit of normal (ULN) over 24 weeks. Following treatment with TA, CRP remained above ULN at all post-dose time points except 24 weeks and SAA remained above ULN until Week 12. IL-6 was more effectively suppressed with canakinumab than TA over 24 weeks. No major changes in levels of TNF-α were observed, demonstrating its lack of involvement in this inflammatory cascade.

Table. Changes from baseline in inflammatory markers at 72 h, 7 days, 12 and 24 weeks post dose by treatment group

	Canakinumab N=113					TA=115

* denotes p <0.0001; ULN: upper normal limit, **24 weeks (EOS) in case patient discontinued prior to 24 weeks, levels for IL6 measured at discontinuation visit was included
# baseline statistics in patients who had both baseline and 12 week values
^ baseline statistics in patients who had both baseline and 24 wk (EOS) values

Patients in the canakinumab group had less tenderness and swelling (β-RELIEVED OR: 2.00, 2.25; 1.72, 2.02 at 72 h and 7 days; β-RELIEVED-II OR: 2.34, 2.07; 1.76, 1.21, at 72 h and 7 days post dose) compared to the TA group.

Conclusion: IL-1β blockade with canakinumab provided significant and sustained anti-inflammatory benefit over 24 weeks that was consistent with the clinical improvement in pain and significant delay in subsequent flares. Longer persistence of higher levels of inflammatory markers in the TA group suggests less control of ongoing inflammation.

1020

Effect of IL-1β Inhibition with Canakinumab Compared to Triamcinolone Acetonide on Pain Intensity and New Flares in Gouty Arthritis Patients with Chronic Kidney Disease Stage 2–5. P. Sunkureddi[1], T. Bardin[2], R. Alten[3], N. Schlesinger[4], M. Bloch[5], T. Kiechle[6], G. Krammer[6], A. Shpilsky[7] and A. So[8]. [1]Clear Lake Rheumatology Center, Nassau Bay, TX, [2]Hôpital Lariboisière, Paris, France, [3]Charité Teaching Hospital–Schlosspark-Klinik, Berlin, Germany, [4]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [5]Holdsworth House Medical Practice, Sydney, Australia, [6]Novartis Pharma AG, Basel, Switzerland, [7]Novartis Pharmaceutical Corporation, East Hanover, NJ, [8]CHUV, Lausanne, Switzerland

Background/Purpose: Most gouty arthritis (GA) patients have pre-existing comorbidities. Chronic kidney disease (CKD) is common and can limit treatment options due to intolerance and contraindications to available therapies. Canakinumab, a fully human monoclonal anti-IL-1β antibody, is a potential new therapeutic option for treating acute GA pain and delaying new flares in this difficult to treat GA patient population. Here, we report a post-hoc efficacy and safety analysis of pooled 24-week data from two pivotal Phase III studies (β-RELIEVED and β-RELIEVED-II) for a subgroup of GA patients with renal impairment.

Methods: In two 12-week multicenter, double-blind, double-dummy, active controlled studies (β-RELIEVED, N=228; β-RELIEVED-II, N=226), patients aged ≥18-≤85 yrs meeting ACR 1977 criteria for acute GA and contraindicated, intolerant or unresponsive to NSAIDs and/or colchicine received one single dose of canakinumab 150 mg sc or triamcinolone acetonide (TA) 40 mg im and were re-dosed "on demand" on each new flare, followed by a 12-week extension where study completers received canakinumab 150 mg sc or TA 40 mg im only "on demand" upon a new flare. Here, we report 24-week data in this renal impaired cohort for time to first new flare, pain intensity on visual analog scale (VAS) in most affected joint and safety.

Results: A total of 380 (83.7%) patients had renal impairment (baseline estimated Glomerular Filtration Rate (eGFR) <90mL/min/1.73m^2; corresponding to CKD stages 2–5): 188 (83.6%) in the canakinumab group and 192 (83.8%) in the TA group. At 24 weeks, significantly fewer patients on canakinumab experienced new flares vs those on TA (25.5% vs 47.4%, OR 0.38, 95% CI 0.25–0.59, p<0.0001). Mean VAS scores for the canakinumab group and TA group were 73.9mm vs 73.8mm at baseline, and 38.5mm vs 49.9mm 72 hours post dose (Diff: −10.9 mm; 95% CI: −16.1, −5.8, p<0.0001). This significant difference in pain relief was sustained up to 7 days (Table). 66.5% of patients had adverse events (AEs) with canakinumab vs 52.6% with TA. The most frequent canakinumab AEs were back pain and hypertension (n=10, 5.3% each), headache (n=9, 4.8%); whereas for TA they were hypertension (n=11, 5.7%), arthralgia (n=9, 4.7%), pain in the extremity and worsening of gout (n=8, 4.2 % each). Incidence of infections and infestations were comparable between canakinumab group (14, 7.4%) and TA group (14, 7.3%). There were no opportunistic infections. Serious AEs (canakinumab: n=15, 8%; TA: n=6, 3.1%) were not considered to be related to treatment by the investigator.

Table. Pooled analysis of pain intensity over 7 days post-dose in the CKD stages 2–5 patients

Time		***BL**	**6 hours**	**12 hours**	**24 hours**	**48 hours**	**72 hours**	**4 days**	**5 days**	**6 days**	**7 days**
Pain intensity (0–100 mm VAS)	Canakinumab 150mg sc	73.9 (12.73)	57.4 (1.40)	50.1 (1.58)	39.5 (1.78)	30.6 (1.86)	24.4 (1.84)	21.9 (1.78)	19.1 (1.76)	17.2 (1.79)	15.6 (1.72)
LS Mean (SE)	TA 40mg im	73.8 (12.64)	61.3 (1.41)	54.9 (1.60)	48.1 (1.80)	41.7 (1.88)	35.3 (1.86)	31.1 (1.80)	28.4 (1.78)	26.3 (1.81)	21.8 (1.73)
LS Mean difference canakinumab vs TA, (mm)			−4*	−4.7*	−8.7*	−11.1*	−10.9*	−9.2*	−9.3*	−9.1*	−6.2*
95% confidence intervals			−7.9, −0.0	−9.2, −0.3	−13.6, −3.7	−16.3, −5.9	−16.1, −5.8	−14.2, −4.2	−14.3, −4.4	−14.1, −4.1	−11.0, −1.4

* Baseline pain scores are presented as mean±SD; TA, triamcinolone acetonide; *p value≤0.05, LS Mean difference, least square mean. difference; SE, standard error

Conclusion: Renal impairment is a common comorbidity in GA patients. This post-hoc analysis of these two large clinical trials demonstrated that renal impairment (CKD stages 2–5) did not compromise the therapeutic efficacy and safety of canakinumab in this difficult to treat population.

Efficacy and Safety of Lesinurad (RDEA594), A Novel Uricosuric Agent, Given In Combination with Allopurinol in Allopurinol-Refractory Gout Patients: Preliminary Results from the Randomized, Double-Blind, Placebo-Controlled, Phase 2B Extension Study. John Sundy[1], Fernando Perez-Ruiz[2], Eswar Krishnan[3], Vijay Hingorani[4], Jody Welp[4], Matt Suster[4], Kimberly Manhard[4], Matt Cravets[4], David Hagerty[4] and Barry Quart[4]. [1]Duke University Medical Center, Durham, NC, [2]Hospital De Cruces, Baracaldo, Spain, [3]Stanford University, Stanford, CA, [4]Ardea Biosciences, Inc., San Diego, CA

Background/Purpose: Lesinurad (RDEA594) is an oral investigational URAT1 inhibitor for the treatment of gout. A Phase 2B study in 208 gout patients (estimated creatinine clearance >60 mL/min) with an inadequate response to a stable dose of ALLO (200–600 mg/day for 6 weeks) confirmed the greater efficacy of the lesinurad/allopurinol combination. The lesinurad + ALLO groups showed superior reductions in sUA with 79%, 74%, and 63% of patients achieving sUA < 6 mg/dL after 28 days of dosing with 600 mg, 400 mg and 200 mg lesinurad + ALLO, respectively, compared to 25% with ALLO+placebo (p < 0.0001 with ITT analysis for all comparisons). Subjects completing the Phase 2B study could enter a long term extension, the preliminary results of which are presented here.

Objectives: To assess the ongoing efficacy and safety of lesinurad in combination with ALLO vs. ALLO and placebo (PBO) in patients with an inadequate response to standard doses of ALLO.

Methods: All subjects completing the double-blind 28-day dosing period washed out of lesinurad or PBO before entering the extension, but remained on a stable dose of ALLO. Subjects then restarted their original blinded treatment of lesinurad or PBO. All lesinurad-treated subjects started on the 200 mg dose and were to have the dose titrated stepwise to 400 or 600 mg if the sUA was not <6 mg/dL (<5 mg/dL in some regions). Formal statistical testing was not performed since this is an ongoing extension study and too few patients at this time have reached 6 months of dosing.

Results: 126 subjects enrolled into the extension study; 113 currently are continuing. Forty-one subjects completed 28 weeks and 8 subjects completed 1 year. Efficacy results are presented for all 41 subjects who completed extension week 28. Combination treated subjects continued to respond with 80% (4/5), 82% (9/11) and 92% (12/13) of ALLO + lesinurad 600 mg, 400 mg, and 200 mg, respectively, maintaining sUA < 6 mg/dL at 28 weeks, compared to 33% (4/12) of ALLO+PBO subjects; 40% (2/5), 64% (7/11) and 46% (6/13) of subjects receiving ALLO + lesinurad 600, 400 and 200 mg, respectively, also achieved sUA<5 mg/dL, compared to 17% (2/12) of ALLO+PBO subjects. 13 subjects (7 PBO/6 lesinurad) withdrew from the study for any reason before or after week 28. Two lesinurad subjects reported SAEs (angina, infected elbow) considered unrelated to lesinurad. CK elevations at baseline were common (24% of all subjects) and post-baseline elevations were also common, but rates were similar between the PBO (29%) and lesinurad (30%) groups. Transient serum creatinine elevations (increase to at least 1.5 × ULN) were observed with long term dosing in the lesinurad group (3.6%), which resolved to within the normal range at the next visit; no such elevations were observed with placebo.

Conclusion: Addition of lesinurad produced consistent, sustained reductions in sUA levels in patients not adequately responding to standard doses of ALLO. Most subjects achieved target sUA levels of <6 mg/dL on either the 200 or 400 mg lesinurad dose. Lesinurad was well-tolerated and no dose-related side effects were observed with combination treatment. Lesinurad is a promising investigational drug for the treatment of hyperuricemia in gout patients.

Febuxostat (vs. Allopurinol) In Treating the Hyperuricemia of Gout In Diabetic Patients. Michael A. Becker[1], Patricia A. MacDonald[2], Barbara Hunt[2] and Robert L. Jackson[2]. [1]University of Chicago Medical Center, Chicago, IL, [2]Takeda Global Research & Development Center, Inc., Deerfield, IL

Background/Purpose: Patients with gout have substantially greater incidences of metabolic, cardiovascular and renal comorbidities than nongouty individuals. Diabetes mellitus is one of the disorders commonly associated with gout, but data about baseline characteristics and the efficacy and safety of urate-lowering (UL) therapy in diabetic gout patients are limited.

Methods: To report on the baseline characteristics and the efficacy and safety of UL therapy in diabetic gout subjects, we examined 312 subjects with gout and diabetes (among 2,269 with gout and baseline serum urate [sUA] ≥8.0 mg/dL) in the 6 month CONFIRMS trial. Diabetes was identified at baseline by history, with 72% (225 subjects) receiving either insulin or oral hypoglycemic agents. Subjects were randomized to daily febuxostat (FEB) 40mg or 80mg (both in subjects with eCLcr ≥30ml/min) or allopurinol (ALLO: 300mg if eCLcr ≥60 ml/min; 200 mg if eCLcr 30–59 ml/min). UL efficacy was defined as the proportion of subjects in each group achieving final visit sUA <6.0 mg/dL. Safety was evaluated by physical/lab examination and reported adverse events (AEs).

Results: Comorbidities in diabetic subjects were very prevalent: CVD (86%, including: hypertension [83%], coronary artery disease [22%], arrhythmias [18%] and MI [10%]); impaired renal function (eCLcr <90 ml/min [79%], <59 ml/min [36%]); hyperlipidemia (65%); and mean BMI of 36 kg/m^2. Serum urate levels (mean 9.6 mg/dL), a history of years with gout (mean 13 years), and tophi (18%) were similar across groups. In diabetic subjects, UL efficacy (final visit sUA <6.0 mg/dL) was comparable between FEB 40mg (38%) and ALLO (32%), but efficacy of FEB 80 mg (75%) was superior to both ($p<0.001$), a finding also seen in mild and moderate CKD (defined as eCLcr 60–89 ml/min and 30–59 ml/min, respectively). Higher serum urate levels and the presence of tophi at baseline were associated with low UL efficacy response rate in all treatment groups. Non-fasting blood glucose levels remained stable throughout the study. Regarding safety, at least 1 AE was reported in 46%, 62%, and 66% of FEB 40mg, FEB 80mg, and ALLO-treated diabetic gout subjects. Self-limiting diarrhea and upper respiratory infections were the most common AEs across treatment groups. Serious AEs occurred in 1, 8, and 8 subjects in FEB 40mg, FEB 80mg, and ALLO groups, respectively.

Conclusion: Despite very high rates of CV, renal, and additional metabolic co-morbidities, diabetic gouty subjects tolerated UL therapy with either FEB or ALLO, but FEB 80mg treatment achieved sUA <6.0 mg/dL more often than ALLO treatment at commonly prescribed doses.

Rilonacept for Gout Flare Prevention: Subgroup Analysis of Patients Initiating or Continuing Uric Acid-Lowering Therapy in a Randomized, Placebo-Controlled Trial. John S. Sundy[1], H. Ralph Schumacher[2], Roy M. Fleischmann[3], Johannes M. Engelbrecht[4], Steven P. Weinstein[5], Jian Wang[5], Shirletta King-Davis[5] and Robert R. Evans[5]. [1]Duke University Medical Center, Durham, NC, [2]VA Medical Center and University of Pennsylvania, Philadelphia, PA, [3]MCRC, University of Texas, Dallas, TX, [4]Vergelegan Medi-Clinic, West Cape, South Africa, [5]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Background/Purpose: Studies with the IL-1 antagonist rilonacept have established that IL-1 plays a key role in gout flare (GF) initiation.

Results from RE-SURGE, a large international, double-blind, placebo-controlled, phase 3 study demonstrated that rilonacept has a favorable safety and tolerability profile and resulted in substantial reduction in GFs in patients at high risk of flaring. A subgroup analysis was performed to evaluate efficacy in different subpopulations of RE-SURGE patients.

Methods: RE-SURGE included adults 18–80 years of age with gout who were initiating or currently on uric acid-lowering therapy (ULT). Patients were randomized in a 3:1 ratio to weekly subcutaneous injections of rilonacept 160mg (R160; n=985) or placebo (PBO; n=330) for 16 weeks; a loading dose of rilonacept 320mg or PBO was administered on Day 1. ULT was titrated to achieve uric acid <6 mg/dL. Efficacy endpoints included the mean number of GFs per patient, the mean number of GF days per patient, and proportions of patients with ≥1 and ≥2 GFs. GFs were defined as subject-reported acute articular pain typical of a gout attack and deemed by patient or investigator to require anti-inflammatory treatment. This subgroup analysis evaluated patients initiating ULT; continuing ULT; those using liquid pre-filled syringes (others used lyophilized drug in vials requiring reconstitution); and those meeting additional inclusion criteria of previous phase 3 confirmatory efficacy studies: serum uric acid concentration ≥7.5 mg/dL, ≥2 GFs within the past year, and initiating allopurinol treatment. There was no adjustment for multiple comparisons in this exploratory analysis.

Results: At 16 weeks (end of treatment), statistically significant reductions from baseline were observed with R160 relative to PBO for all efficacy endpoints in all subgroups (Table). Efficacy in all subgroups was also similar to that observed in the total population. Across subgroups, reductions ranged from 67.8%-72.3% for GFs per patient; 58.7%-69.4% for GF days per patient; 44.7%-52.4% for the proportion of patients with ≥1 GFs; and 60.4%-84.3% for the proportion of patients with ≥2 GFs.

	GFs per patient, mean (SD)	GF days per patient, mean (SD)	≥1 GFs, %	≥2 GFs, %
Total population	0.51 (1.17)*	2.66 (7.69)*	25.7*	11.7*
R160 (n=985)	1.73 (2.69)	7.66 (11.79)	51.1	34.7
PBO (n=330)				
Initiating ULT	0.50 (1.18)*	2.34 (6.67)*	24.7*	11.0*
R160 (n=614)	1.75 (2.70)	7.62 (11.55)	51.9	36.1
PBO (n=212)				
Continuing ULT	0.55 (1.15)*	3.19 (9.10)*	27.4*	12.7*
R160 (n=371)	1.70 (2.68)	7.72 (12.26)	49.6	32.2
PBO (n=118)				
Pre-filled syringe	0.46 (1.03)*	2.28 (5.49)†	29.2†	6.2*
R160 (n=120)	1.66 (1.99)	7.42 (9.73)	57.9	39.5
PBO (n=40)				
Additional inclusion criteria	0.55 (1.20)*	2.67 (7.22)*	27.9*	12.4*
R160 (n=420)	1.99 (2.89)	8.69 (12.37)	56.6	39.9
PBO (n=145)				

* P<0.0001 versus PBO; † P <0.005 versus PBO; SD = standard deviation.

Infections were reported in 20.1% of R160 patients (0.5% serious) and 19.1% of PBO patients (0.9% serious). Other AEs reported in ≥5% of R160 patients were injection site reactions (leading to withdrawal in 1.2%), headache, arthralgia, and pain in extremity. Six deaths occurred, 3 (0.3%) in R160 (none assessed as related to study drug) and 3 (0.9%) in PBO.

Conclusion: Weekly treatment with rilonacept 160mg resulted in similar efficacy in patients initiating or continuing uric acid-lowering therapy who were at risk of gout flares. Pre-filled syringes demonstrated efficacy similar to lyophilized drug in vials. Efficacy was also consistent in patients meeting the additional inclusion criteria from previous phase 3 studies. No new safety signals were observed.

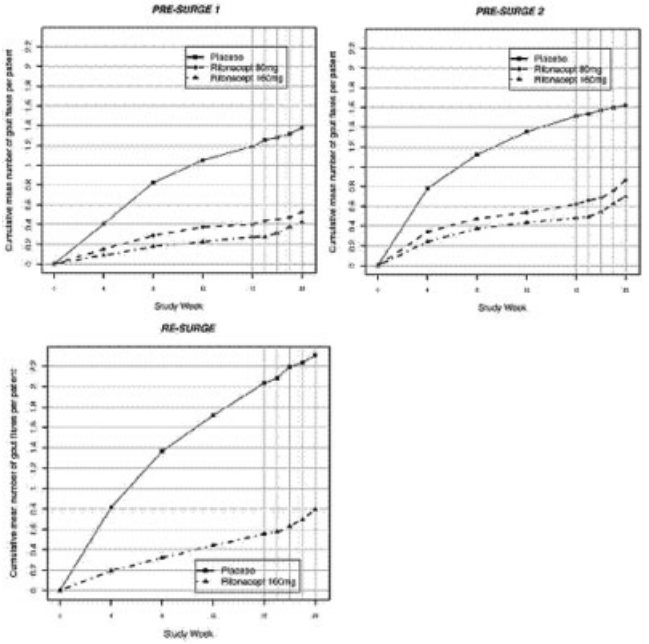
Rilonacept for Prevention of Gout Flares Associated with Uric Acid-Lowering Therapy: Response Rate Across Three Phase 3 Clinical Trials.
H. Ralph Schumacher[1], Robert R. Evans[2], Charles A. Birbara[3], Leon Fouche[4], Steven P. Weinstein[2], Jian Wang[2] and Robert Terkeltaub[5]. [1]VA Medical Center and University of Pennsylvania, Philadelphia, PA, [2]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [3]Univ Mass City Campus, Worcester, MA, [4]Limpopo Clinical Research Initiative, Thabazimbi, South Africa, [5]VA Medical Ctr, San Diego, CA

Background/Purpose: The efficacy of the interleukin (IL)-1 antagonist rilonacept for prevention of gout flares (GFs) associated with uric acid-lowering therapy (ULT) has been demonstrated in three phase 3 trials. While the 3 trials were of double-blind, placebo (PBO)-controlled design, they displayed some heterogeneity with regard to study populations and GF definition. This analysis evaluates the efficacy response across the 3 trials using the same GF definition (see **Methods**) for patients having similar inclusion criteria.

Methods: PRE-SURGE 1, PRE-SURGE 2, and RE-SURGE evaluated the safety and efficacy of weekly subcutaneous doses of rilonacept 80mg (R80; PRE-SURGE 1 and 2) and 160mg (R160; all 3 studies) for the prevention of GFs associated with ULT. PRE-SURGE 1 was conducted in North America, and the other two studies were conducted internationally. Double-blind treatment duration was 16 weeks (to Day 113) in all studies with a subsequent 4-week safety follow-up period. This analysis includes those patients who had baseline serum urate levels ≥7.5 mg/dL, ≥2 GFs in the past year, and were initiating treatment with allopurinol. GF rates were plotted for the individual studies and the percent reduction was estimated for the 16-week time point. GFs were defined as a subject-reported acute articular pain typical of a gout attack and deemed by patient or investigator to require anti-inflammatory treatment.



Results: Differences among the 3 studies in the GF rate curves over the 16-week treatment period manifested mainly as differences in the PBO GF rate (Figure). However, at the 16-week time point, the relative efficacy with R160 was similar across the 3 trials for reductions in GFs per patient. The mean reductions in flare rate with R160 were 76.9%, 68.1%, and 70.3%, for PRE-SURGE 1, PRE-SURGE 2, and RE-SURGE, respectively, providing an overall reduction of 69.2%. The mean reductions in flare rate with R80 were 66.4% and 58.9% for PRE-SURGE 1 and PRE-SURGE 2, respectively, providing an overall reduction of 62.3%. For the total population in the 3 studies,, infections were balanced among treatment groups. The most frequently reported treatment-related AE was injection site reaction, which led to patient withdrawal rates of 0% to 1.3% across rilonacept treatment groups. The rate of serious infections was low, ranging from 0% to 0.9% for PBO, 1.3% to 2.4% for R80, and 0% to 0.5% for R160.

Conclusion: In analyses employing the same gout flare definition in similar patient populations, the relative efficacy of rilonacept was consistent across three Phase 3 clinical trials. Rilonacept 160mg resulted in a 69.2% reduction in rate of gout flares and rilonacept 80mg resulted in a 62.3% reduction in rate of gout flares. Rilonacept demonstrated an acceptable safety and tolerability profile.

1025

Pharmacological Treatment of Acute Gout: A Systematic Review.
Puja Khanna[1], Manjit K. Singh[2], John D. FitzGerald[3], Sangmee Bae[2], Shraddha Prakash[3], Marian Kaldas[3], Maneesh Gogia[3], Paul Maranian[4], Robert Terkeltaub[5] and Dinesh Khanna[6]. [1]University of Michigan, Ann Harbor, MI, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]UCLA, Los Angeles, CA, [4]UCLA Medical School, Los Angeles, CA, [5]VA Medical Ctr, San Diego, CA, [6]University of Michigan, Ann Arbor, MI

Background/Purpose: Acute gout flares are commonly treated with non steroidal anti-inflammatory agents (NSAIDS), colchicine, or corticosteroids. We systematically reviewed the published data on the pharmacological agents used for the treatment of acute gouty arthritis.

Methods: PubMed and CENTRAL databases were searched to find articles on gout till March 2011. From 5830 titles, 3729 titles excluded as these were duplicate, non-English, or met our exclusion criteria—leaving 1827 abstracts. Abstracts were reviewed by 2 reviewers leading to a total 128 manuscripts. We also reviewed the ACR and EULAR abstracts for last 3 years. A total of 26 manuscripts and 3 abstracts were selected for the systematic review.

Results: 27 of the 29 studies were active comparator studies, while the remaining two studies had a placebo control group. 23 studies were randomized controlled trials and 6 open pilot studies. The pooled mean (SD) age in the trials was 55 (12) years and 88% were males. 21% of studies treated patients within 24 hours of an acute gout attack, 27.5% within 48 hours, and 27.5% within 5 days; in 24% studies the duration of acute gout attack was not reported.

NSAIDs are the most frequently studied agents for the treatment of acute gout attacks. Indomethacin (INDO) has been extensively studied at doses of 50mg TID. INDO is comparable in efficacy to oral or IM NSAIDs when started within 48 hours. When compared to COX-2 selective inhibitors, indomethacin is associated with greater adverse events. Naproxen has been used at 500mg BID up to 1500mg daily for the treatment of acute gout. Naproxen is as efficacious as other NSAIDs, but has not been compared to COX-2 inhibitors. Etorocoxib and lumiracoxib (COX-2 inhibitors) has similar efficacy to NSAIDs but greater tolerability profile. High dose celecoxib (800/400mg on day 1) has similar efficacy to INDO. 2 studies showed that oral colchicine had greater efficacy in treating pain compared to placebo within first 12 hours of an acute attack. Although low dose (1.2 mg, followed by 0.6 mg) and high dose colchicine (4.8mg total over 6 hours) have comparable efficacy, low-dose colchicine has a significantly greater tolerability profile. Corticosteroids and IM ACTH have similar efficacy to therapeutic doses of NSAIDs in treating an acute gout attack. Adverse events were generally lower in patients on corticosteroids and ACTH compared to NSAIDs. Subcutaneous single-dose canakinumamb 150mg is more efficacious than single-dose 40mg IM triamcinolone acetonide for acute gout attack whose disease is refractory to or who have contraindications to NSAIDs and/or colchicine. Rilonacept was not more efficacious than indomethacin in a RCT. Topical ice was effective in reducing pain, when used with corticosteroids and colchicine. 8 studies of NSAIDs reported pain as an outcome measure. NSAIDs treatment started within 24 hours of acute onset was associated with an average weighted percent improvement of 76% vs. 61% for 48 hours (P=0.16).

Conclusion: NSAIDs and colchicine are effective in treating acute gout attack. Corticosteroid, ACTH, and canakinumamb can be used in patients who have contraindications to NSAIDs and colchicine.

1026

Nonclinical Drug-Drug Interaction Profile of BCX4208, An Oral, Once-Daily, Novel Nonmetabolized Enzyme Inhibitor for Chronic Management of Gout.
Paul G. Pearson[1], Shanta Bantia[2] and Leigh Harman[2]. [1]Pearson Pharma Partners, Westlake Village, CA, [2]BioCryst Pharmaceuticals, Inc., Birmingham, AL

Background/Purpose: Common comorbidities associated with gout, including obesity, hypertension, diabetes, and chronic kidney disease, may confer a greater risk of drug-drug interaction (DDI) through both polypharmacy and disease-associated alterations in drug absorption, distribution, metabolism, or excretion. Currently available antiinflammatory and urate-lowering therapies (such as colchicine, allopurinol, and probenecid) used for management of gout are

associated with significant DDIs. BCX4208 is an oral, once-daily, novel enzyme inhibitor in clinical development for the chronic management of gout. In Phase 1 pharmacokinetic (PK) studies of BCX4208, a dose-dependent reduction in serum uric acid was related to inhibition of purine nucleoside phosphorylase. In this study, we characterized the potential for BCX4208 to (1) interact with cytochrome P450 enzymes, (2) interact with drug transporters, and (3) induce or act as a substrate of metabolizing enzymes.

Methods: BCX4208 was incubated in gender-pooled human liver microsomes with marker substrates for CYP1A2, CYP2A6, CYP2C9, CYP2C19, CYP2D6, CYP2E1, or CYP3A4/5, and the catalytic activity of these isoforms was determined. BCX4208 was incubated with human primary hepatocytes from three donors, and induction of CYP1A2, CYP2B6, CYP2C9, CYP3A4/5, MDR1 (P-glycoprotein [P-gp]), and MRP2 was assessed.

Results: CYP isoforms: No significant inhibition of catalytic activity by BCX4208 was observed for CYP1A2, CYP2A6, CYP2C9, CYP2C19, CYP2D6, CYP2E1, or CYP3A4/5 using gender-pooled human liver microsomal incubations. Additionally, BCX4208 was not shown to be a time-dependent inhibitor of CYP3A4/5. BCX4208 did not induce protein synthesis or enzyme activity for CYP1A2, CYP2B6, CYP2C9, and CYP3A4 in primary hepatocyte cultures from human donors. Drug transporters: BCX4208 did not induce protein synthesis of MDR1 or MRP2 in primary human hepatocytes, nor did the drug significantly inhibit OAT1 (kidney transport)–mediated uptake of p-aminohippuric acid, a substrate for OAT1. In addition, BCX4208 was not a substrate for the OAT1 transporter. BCX4208 was demonstrated to be a weak inhibitor of the kidney transporter OCT2 (11%-24% inhibition at 200 mM in CHP-OCT2 cells); however, BCX4208 is unlikely to mediate a DDI with compounds that are cleared by OCT2.

Conclusion: In summary, there is a low risk of DDIs between BCX4208 and coadministered medications. The potential for hepatic and/or renal DDIs is low given that BCX4208 does not induce or inhibit cytochrome P450 isoforms, has low potential as a P-gp substrate or inducer, and is not a substrate or inhibitor of renal organic anion and cation transporters. Furthermore, BCX4208 undergoes renal elimination and is not metabolized extensively; therefore, the clinical PK of BCX4208 will not be altered by inhibitors of drug metabolizing enzymes. These results provide good assurance in the clinical setting that drug interactions are not expected with BCX4208 in a chronic gout patient population. Indeed, in a Phase 2 trial of BCX4208 administered in combination with allopurinol, a first-dose PK assessment revealed no DDI with allopurinol or its active metabolite oxypurinol.

1027

Efficacy of Combined Treatment with Allopurinol and Benzbromarone in Gout Patients with Chronic Renal Impairment. Ji Seon Oh[1], Seung Won Choi[1], Bon San Koo[2], Min Wook So[2], Yong-Gil Kim[2], Chang-Keun Lee[2] and Bin Yoo[2]. [1]University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, South Korea, [2]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea

Background/Purpose: The management of hyperuricemia in gout patients with chronic renal impairment is difficult because of relatively high uric acid levels in such patients and a limitation in increasing doses of urate-lowering agents such as allopurinol. At the reduced doses proposed in the recommendations in such conditions, allopurinol alone may not decrease the serum urate concentration sufficiently to allow regression of tophi. Currently, the role of combination therapy with urate-lowering agents in such patients has not been well established. The purpose of this study is to evaluate the efficacy and safety of combined treatment with allopurinol and benzbromarone in hyperuricemic patients with moderate to severe renal impairment.

Methods: We retrospectively reviewed medial records of twenty gout patients with moderate to severe renal impairment (glomerular filtration rate (GFR) 15–59 mL/min/1.73m^2) who has been treated with both allopurinol and benzbromarone in our outpatient clinic between 2003 to 2011. We measured uric acid levels and GFR at baseline and during treatment with allopurinol before and after addition of benzbromarone. GFR was calculated by the Modification of Diet in Renal Disease (MDRD) equation. For statistical analysis, Wilcoxon test was used.

Results: Mean age of patients was 61.0 ± 11.2. Mean uric acid levels and GFR at baseline was 10.4 ± 1.3 mg/dL and 38.4 ± 8.3 mL/min/1.73m^2, respectively. Mean doses of allopurinol and benzbromarone were 197.5 ± 86.6 mg (range 100–400 mg) and 47.5 ± 29.1 mg (range 25–100 mg), respectively. Uric acid levels decreased from a mean of 10.4 ± 1.3 mg/dL to 5.6 ± 1.7 mg/dL ($p<0.001$). Of fourteen patients who treated with allopurinol alone at average doses of 193 mg/day before addition of benzbromarone, none had achieved the desired uric acid level (mean uric acid levels, 8.7 ± 1.4 mg/dL; mean reduction of uric acid levels, 1.9 ± 1.4 mg/dL, $p<0.001$). Fourteen (70%) of twenty patients with combination treatment reached the uric acid levels of ≤ 6.0 mg/dL. There was no serious adverse event including hepatic dysfunction during combination treatment. Benzbromarone was discontinued in one patient due to diarrhea. There were no significant changes in GFR during treatment with benzbromarone (mean changes in GFR, 1.1 ± 4.5 mL/min/1.73m^2, $p=0.298$).

Conclusion: This study results suggest that combined treatment with allopurinol and benzbromarone may be an effective strategy for achieving the goal of uric acid levels in gout patients with moderate to severe renal impairment.

1028

Comparison of Pain Intensity, Incidence of New Flares, Safety and Tolerability of Canakinumab Vs Triamcinolone Acetonide in Gouty Arthritis Patients with Cardiovascular Diseases or with Cardiovascular Risk Factors. N. Schlesinger[1], J. P. Brown[2], T. Bardin[3], T. Kiechle[4], A. Shpilsky[5], R. Alten[6] and A. So[7]. [1]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [2]CHUQ (CHUL) Research Centre, Laval University, Quebec City, QC, [3]Hôpital Lariboisière, Paris, France, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharmaceutical Corporation, East Hanover, NJ, [6]Charité Teaching Hospital–Schlosspark-Klinik, Berlin, Germany, [7]CHUV, Lausanne, Switzerland

Background/Purpose: Patients with gouty arthritis (GA) are at a higher risk of cardiovascular disease (CVD) than the general population and CVD comorbidities limit treatment options for acute flares. Acute flares are associated with an increase in inflammatory markers such as hsCRP, which is a risk factor for CVD. We report a post-hoc efficacy and safety analysis of canakinumab (a fully human, anti-IL-1β monoclonal antibody) vs triamcinolone acetonide (TA) in GA patients with CVD comorbidities.

Methods: In two, 12-week multi-center, double-blind, double-dummy, active controlled studies, patients ≥18−≤85 yrs meeting ACR 1977 preliminary criteria for GA and contraindicated, intolerant or unresponsive to NSAIDs and/or colchicine, with an onset of flares ≤5 days were randomized to receive a single dose CAN 150mg sc or TA 40mg im, and were re-dosed "on demand" on each new flare. Patients completing the core studies were enrolled into 12-week extension studies to further investigate "on demand" use of canakinumab 150 mg sc or TA 40 mg im on new flare. We report a post hoc analysis in CVD population including patients with a history of heart failure, coronary artery disease, cardiac arrhythmia, ischemic heart disease, and cerebrovascular disease and/or at least one CVD risk factor (stable hypertension, diabetes mellitus, hypercholesterolemia) at baseline. Evaluations included number of patients with new flares over 24 weeks; pain intensity in the most affected joint (0–100 mm VAS) at 72h post dose; effect on hsCRP and SAA and safety.

Results: 454 GA patients received treatment (β-RELIEVED, N=228; β-RELIEVED-II, N=226), 225 received CAN and 229 received TA. 319 (70.2%) had either a history of CVD and/or at least one CVD risk factor at baseline, 151 (67.1%) received CAN and 168 (73.4%) received TA. Pain intensity was comparable at baseline (mean±SD CAN: 74.4 mm ±12.37 mm; TA: 73.7±12.28 mm). A significantly lower pain score was reported for CAN vs TA at 72h post dose (LS mean: 25.3 mm vs 35.0 mm, Diff: −9.7 mm; 95% CI: −15.2, −4.3, $p=0.0005$). Incidence of new flares over 24 weeks was significantly lower for CAN vs TA (24.5% vs 46.4%, odds ratio = 0.37, 95% CI 0.23–0.60, $p<0.0001$). CRP levels were 39% lower in CAN vs TA 72h post dose (ratio=0.61, 95% CI: 0.50, 0.73, $p<0.0001$) and 52% lower at 7 days (ratio=0.48, 95% CI: 0.39. 0.59, $p<0.0001$). SAA levels were 59% lower in CAN vs TA 72h post dose (ratio=0.41; 95% CI: 0.32, 0.53, $p<0.0001$) and 62% lower at 7 days (ratio=0.38; 95% CI: 0.29, 0.49, $p<0.0001$). Decrease in blood pressure was observed over 24 weeks in CAN vs TA (mean±SD SBP: −5.1±17.26 mmHg vs −3.4±14.81 mmHg, DBP: −1.4±11.51 mmHg vs −0.4±9.61 mmHg). CAN had more AEs and SAEs (102 [67.5%], 12 [7.9%]) vs TA group (86 [51.2%], 5 [3.0%]). angina pectoris, arrhythmia, myocardial ischemia (1 each) was reported in canakinumab group and aortic valve incompetence and cardiac myopathy (1 each) were reported in TA group. None of the SAEs were reported by investigators as related to study drug. Infections were mostly mild to moderate.

Conclusion: CAN provided superior pain relief, reduced the risk of a new flare and lowered the level of inflammatory markers vs TA in GA patients with CVD or CVD risk factors.

1029

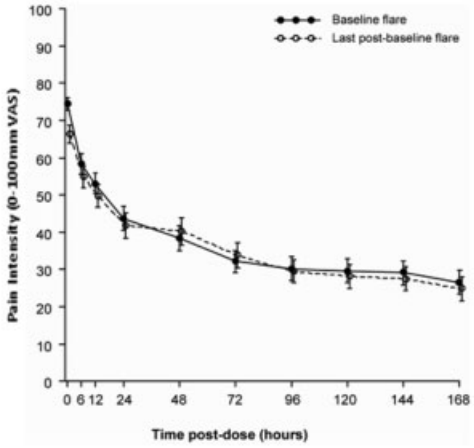
Efficacy of Canakinumab on Re-Treatment in Gouty Arthritis Patients with Limited Treatment Options: 24-Week Results From β-RELIEVED and β-RELIEVED-II Studies. R. Alten[1], A. So[2], A. Kivitz[3], T. Bardin[4], M. Bloch[5], A. Gimona[6], A. Widmer[6], G. Krammer[6], N. Schlesinger[7] and H. R. Schumacher[8]. [1]Charité Teaching Hospital–Schlosspark-Klinik, Berlin, Germany, [2]CHUV, Lausanne, Switzerland, [3]Altoona Center for Clinical Research, Duncansville, PA, [4]Hôpital Lariboisière, Paris, France, [5]Holdsworth House Medical Practice, Sydney, Australia, [6]Novartis Pharma AG, Basel, Switzerland, [7]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [8]University of Pennsylvania and VA Medical Center, Philadelphia, PA

Background/Purpose: Gouty arthritis (GA) is a chronic, recurrent, inflammatory arthritis affecting 1–4% of the population. A subset of patients experiencing acute flares may have limited anti-inflammatory treatment options due to contraindications, intolerance or unsatisfactory therapeutic response with current therapies. Canakinumab, a fully human anti-IL-1β monoclonal antibody, selectively targets the inflammatory cascade and is a novel therapeutic approach to treat acute GA. Here we report pooled results from two studies on time to first new flare and pain response to treatment of first and last flare.

Methods: In two, 12-week multicenter, active-controlled trials (β-RELIEVED and β-RELIEVED-II), GA patients (18–85 yrs) meeting preliminary ACR-1977 criteria and unresponsive, intolerant, or contraindicated to NSAIDs and/or colchicine were enrolled to receive one single dose canakinumab 150mg sc or triamcinolone acetonide (TA) 40mg im and were re-dosed "on demand" on each new flare. Patients completing the core studies were enrolled into 12-week extension studies to further investigate "on demand" use of canakinumab 150 mg sc or TA 40 mg im on new flare. Pooled data from 24-weeks treatment were analyzed for time to first new gout flare (Cox proportional Hazard regression model) and pain intensity in most affected joints (0–100mm VAS).

Results: 454 patients received study drug and 335 patients entered the extension studies. A total of 317 patients (95% of those entering the extension) completed 24-weeks. Over the entire 24-week period 64 patients on canakinumab and 112 patients on TA experienced ≥1 new flare and 17 patients on canakinumab and 50 patients on TA experienced ≥2 new flares. The probability of a new gout flare was lower with canakinumab (32.4%) vs TA (56.0%) corresponding to a statistically significant risk reduction of 56% (Hazard Ratio: 0.44; 95% CI 0.32–0.60; p<0.0001) over 24 weeks. The median time to first new flare per patient treated with canakinumab was >168 days (i.e. not reached within the 24 week study duration) vs 131 days with TA. For new flares in the canakinumab patients, pain was less intense than during first flare. With canakinumab, there was a good correlation between pain response during first flare and subsequent flares (r=0.60) vs TA (r=0.28). Treatment of the last new flare was as effective as treatment of the first flare (Figure).

Figure: Treatment response: Pain intensity (0-100mm VAS) during the 7 days post-dose in canakinumab patients for last new flare vs first flare



VAS Score on Y-axis displayed as Mean±Standard error

Conclusion: By targeting IL-1β, canakinumab provided effective pain-relief in all flares and reduced the risk of new flares compared to TA. Canakinumab may represent an important advance in the treatment of GA in patients whose disease cannot be appropriately managed with currently available treatments.

Pharmacokinetics, Efficacy and SAFETY of Lesinurad, a Novel URAT1 Inhibitor, In Individuals with Mild to Moderate Renal Impairment. David Hagerty, Brad Kerr, Zangong Shen, Li-tain Yeh, Vijay Hingorani, Matt Cravets, Jody Welp, Jeffrey N. Miner, Kimberly Manhard and Barry Quart. Ardea Biosciences, Inc., San Diego, CA

Background/Purpose: Lesinurad is novel URAT1 inhibitor that blocks reabsorption of uric acid in the proximal tubule of the kidney. Because many gout patients exhibit varying degrees of renal insufficiency, serum urate (sUA) lowering effect, pharmacokinetics (PK), safety, and tolerability of lesinurad were examined in subjects with normal and impaired renal function in 3 clinical trials.

Methods: In 2 double-blind, placebo-controlled, Phase 2b studies, 331 gout patients were randomized to receive a 28-day once-daily course of placebo or lesinurad from 200 to 600 mg as monotherapy or in combination with allopurinol (ALLO). In a phase 1 study, 24 subjects with varying degrees of renal function were given a single oral dose of lesinurad 200 mg. Full PK profiles were obtained in the phase 1 study and in a sub-study of the Phase 2b ALLO-combination study and predose trough concentrations were measured weekly in both phase 2b studies. Urinary lesinurad concentrations and sUA levels were also evaluated.

Results: Degrees of renal insufficiency for data analysis was based on Chronic Kidney Disease staging guidelines using measured 24-hr creatinine clearance (CrCL) in the phase 1 study and estimated CrCL by Cockcroft-Gault (ideal body weight) in the Phase 2b studies. Lesinurad C_{max} increased ≤30% in the various renal impairment categories compared to subjects with normal renal function. Lesinurad AUC increased ~33% in subjects with mild renal impairment and approximately doubled in subjects with moderate renal impairment. Renal clearance of lesinurad was similar between subjects with normal renal function and with mild renal impairment, but appeared to decrease as the creatinine clearance declined below around 40 ml/min. In the phase 2b studies, there was no meaningful difference in trough plasma concentrations of lesinurad. Median sUA reduction with the 400 mg dose in patients with normal, and mild to moderate renal impairment was 32%and 28% for monotherapy and 21%and 25% for combination with ALLO, respectively. Across the 3 studies, the tolerability and safety of lesinurad was similar in patients with normal and impaired renal function.

Conclusion: In Phase 2B clinical trials, there were no meaningful differences in lesinurad exposure in patients with mild-to-moderate renal impairment. Similar urate reductions were observed in these patients compared to patients with normal renal function. The efficacy and safety profile of lesinurad was similar in patients with normal and impaired renal function

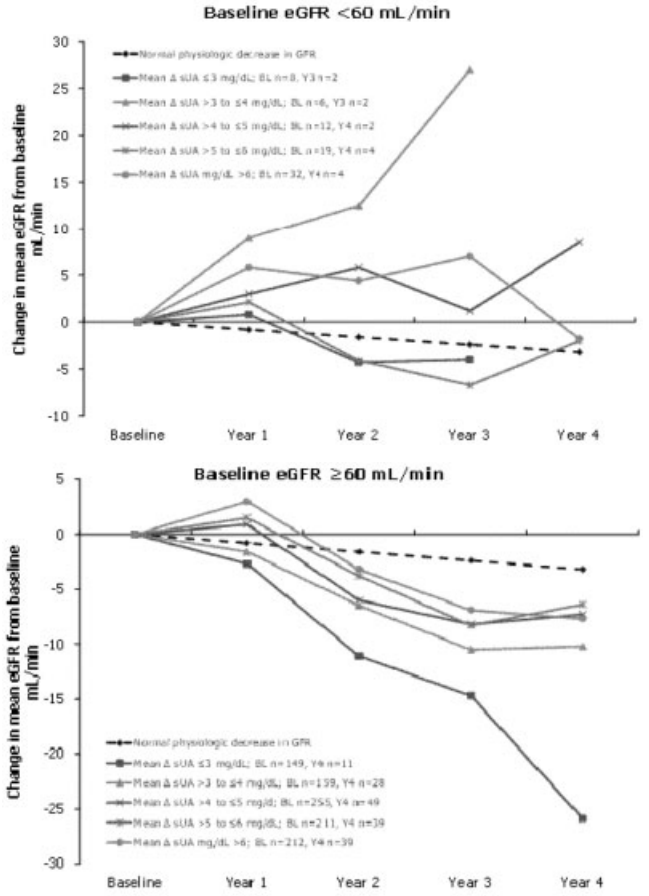
The Impact On Renal Function of Quantitative Serum Urate Reduction In Gout Patients. Andrew Whelton[1], Patricia A. MacDonald[2], Barbara Hunt[2] and Lhanoo Gunawardhana[2]. [1]The Johns Hopkins University and Universal Clinical Research Center, Inc., Baltimore, MD, [2]Takeda Global Research & Development Center, Inc., Deerfield, IL

Background/Purpose: Gout may lead to deterioration of renal function beyond that which can be attributed to aging. This analysis evaluated the effects of urate-lowering therapy (ULT) on renal function in hyperuricemic gout subjects with baseline (BL) estimated glomerular filtration rates (eGFR) of < or ≥60 mL/min.

Methods: Subjects (1086) completing 2 phase 3 trials (FACT and APEX) were enrolled in the long-term EXCEL study and received daily ULT (febuxostat 80 or 120 mg or allopurinol 300 mg) for ≤4 years. eGFR was calculated using the Modification of Diet in Renal Disease (MDRD) equation. A repeated-measures linear model was used to assess the relationship between eGFR change and sUA change, with factors for year of treatment and BL renal function (eGFR <60 vs ≥60 mL/min).

Results: Among this mostly male (96%), Caucasian (79%), and obese (63%) cohort, 7% (n=77) had BL eGFR <60 mL/min. Long-term ULT appeared to provide greater stabilization of renal function in subjects with BL eGFR <60 (Figure 1) than for those with BL eGFR ≥60 (Figure 2). Overall, greater sustained sUA decreases were associated with less renal function deterioration (p<0.001). The model projects that, overall, every 1 mg/dL sUA reduction from BL will yield 1.25 mL/min less of a decrease in eGFR compared with no sUA reduction. The impact of BL renal impairment was significant (p<0.05): given the same treatment duration and sUA change, subjects with renal impairment (BL eGFR <60 mL/min) had 4.7 mL/min less of an eGFR decrease compared to those with BL eGFR >60 mL/min.



Conclusion: In treated gout subjects, the magnitude of treatment-induced persistent decreases in sUA is correlated with reduced deterioration of renal function, especially in patients with baseline eGFR <60 mL/min. These findings have important clinical implications in the management of gout in patients with renal impairment.

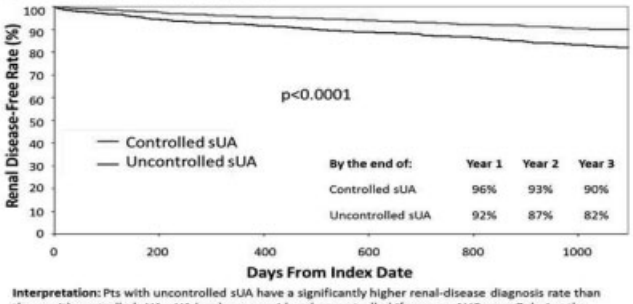
Uncontrolled Serum Uric Acid Is Associated with An Increased Risk of Developing Renal Disease In Veterans with Gout. Eswar Krishnan[1], Hari Sharma[2], Bhavik J. Pandya[3], Maryna Marynchenko[2], Andrew Yu[2], Eric Wu[2], Jinan Liu[4] and Lizheng Shi[4]. [1]Stanford University, Stanford, CA, [2]Analysis Group, Inc., Boston, MA, [3]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [4]Tulane University, New Orleans, LA

Background/Purpose: Increases in serum uric acid (sUA) levels are associated with renal function deterioration. This study aims to estimate the impact of uncontrolled sUA on the risk of developing renal disease in veterans with gout.

Methods: Adult male patients (pts) (age ≥18 yrs) with at least 2 gout diagnoses (ICD-9 CM: 274.xx) and 2 sUA measurements between 1/1/2002 and 1/1/2011 were identified from the Veterans Integrated Services Network 16 (VISN 16) data warehouse. The first sUA measurement date was assigned as the index date. Pts were required to be continuously eligible for at least 6 months prior to and 12 months following the index date and were excluded if they had history of inflammatory diseases (rheumatoid arthritis, lupus, scleroderma, vasculitis, psoriatic arthritis, autoimmune diseases, pseudogout, and other inflammatory arthritis). Renal disease was identified using ICD-9-CM codes (580–588, 250.4, 590, 593, and 791.0) and dialysis procedure codes (CPT: 90935, 90937, 90945, and 90947). Pts with history of renal disease prior to the index date were excluded. A longitudinal design was used with 6-month cycles from the index date until the end of eligibility. sUA levels were assessed for each cycle. Cycles with sUA levels >7/≤7 mg/dL were considered uncontrolled/controlled. Time to first renal disease diagnosis was compared between patients with uncontrolled vs. controlled sUAs using Kaplan-Meier (K-M) analysis and a Cox proportional hazard model. For K-M analysis, average area under the curve (AUC) for sUA measurements during the entire study period was used to classify pts into uncontrolled vs. controlled sUA cohorts. Cox proportional hazard model was used to estimate relative risk of renal disease associated with uncontrolled sUA level as a time-varying risk factor, controlling for: age at index date; year of index date; race; region; body mass index (BMI); and baseline tobacco use, hypertension, hyperlipidemia, and diabetes.

Results: 2,116 pts were selected. The majority of pts (53%) were white, with average age 62.6 yrs. Pts were generally obese (mean BMI 31.2). Average follow-up time was approximately 80 months. Major comorbidities at baseline included hypertension (93%), hyperlipidemia (67%), diabetes (20%), and smoking (8%). K-M analysis (Figure 1) showed that pts with controlled sUA had significantly higher renal disease-free rates at year 1, 2, and 3 compared to pts with uncontrolled sUAs (96% vs 92%; 93% vs 87%; and 90% vs 82%, respectively; p<0.0001). Cox proportional hazard model confirmed that the uncontrolled sUA was associated with a significantly higher risk of renal disease (hazard ratio: 1.43, 95% confidence interval: [1.20–1.70]).

Figure 1. Kaplan-Meier Survival Curve for Time to First Renal-Disease Diagnosis: Controlled sUA vs Uncontrolled sUA



By the end of:	Year 1	Year 2	Year 3
Controlled sUA	96%	93%	90%
Uncontrolled sUA	92%	87%	82%

Interpretation: Pts with uncontrolled sUA have a significantly higher renal-disease diagnosis rate than those with controlled sUA. sUA level was considered uncontrolled if average AUC was >7 during the study period.

Notes: Time to renal disease was measured from index date until: a) renal-disease diagnosis; b) death; or c) the end of data, whichever comes earlier. Pts with renal disease prior to index date were excluded.

Sample size at the end of:	Baseline	Year 1	Year 2	Year 3
Controlled sUA	912	873	805	741
Uncontrolled sUA	1,204	1,111	988	856

Conclusion: Compared to controlled sUA levels, uncontrolled sUA levels are associated with increased risk of a new diagnosis of renal disease among veterans with gout.

1033

Clinical Characteristics of Difficult-to-Treat Gout Patients: a Principal Components Analysis. Elizaveta Vaysbrot[1], Yoojin Lee[1], Sarah McLaughlin[1], Neetu Agashivala[2], Anthony Yadao[3], Timothy E. McAlindon[1] and William F. Harvey[1]. [1]Tufts Medical Center, Boston, MA, [2]Novartis Pharmaceutical Corporation, East Hanover, NJ, [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ

Background/Purpose: Difficult-to-treat gout patients have unmet medical need in symptom control due to limited treatment options and may require additional healthcare services, including ER visits and hospitalization. Understanding which clinical characteristics of this population are significant and how they are intercorrelated is vital for future research but limited at this point. Our objective was to uncover the correlation between the clinical characteristics of difficult-to-treat gout patients to identify key variables for future research.

Methods: Tufts Medical Center charts were reviewed for fiscal years 2008–2010. As no definition of difficult-to-treat gout exists, we chose inclusion criteria based on ease of electronic searching and on the principle that poor control of gout symptoms results in frequent visits/admissions. Inpatients with difficult-to-treat gout were defined as persons with ≥2 inpatient consultations in one year by a rheumatologist for gout (ICD9 274.xx) regardless of admission diagnosis. Outpatients were selected on the basis of a new rheumatologic outpatient consult and ≥5 outpatient rheumatology visits for gout in a year. From each of these two criteria sets, 75 inpatients and 75 outpatients with the highest billing codes were selected. Data were extracted on patient demographics, referral data, disease characteristics, comorbidities, and medication history over a 12 months period. Nominal dichotomous (Yes/No) variables such as "diuretics use" and comorbid conditions data were selected to perform a principal components analysis (PCA) using an orthogonal rotation (SAS version 9.2. Cary, NC. SAS Institute Inc.). Factors were selected based on the Kaiser criterion (eigenvalue >1), and components were included if their loading value was >0.4.

Results: Mean age was 63±13.7 years, 71% were male, and 67% were white. The most common referral source was primary care (43.2%). 9.3% had ≥3 attacks in the previous year. 72% were on ≥5 concomitant medications, excluding those for gout. Approximately 20% had an emergency room visit and 17% were hospitalized specifically for a gout attack. Five factors were identified in PCA (see table).

Factors (Eigenvalues) and principal components (loading values)	Patient Records (n=150)
Factor 1 (3.37): Chronic Heart Failure (0.81), Coronary Heart Disease (0.73), Cerebrovascular Disease (0.64), Diuretic Use (0.53), Dyslipidemia (0.52)	
Patients with 5 components (%(n))	5.3% (8)
Patients with 4 components (% (n))	10.7% (16)
Patients with 3 components (% (n))	4% (6)
Patients with 2 components (% (n))	19.3% (29)
Patients with 1 component (% (n))	31.3% (47)
Patients with 0 components (% (n))	29.3% (44)
Factor 2 (2.55): Cirrhosis (0.87), Chronic Liver Disease (0.86), Upper GI Ulcer (0.66), GI Bleeding history (0.48)	
Patients with 4 components (% (n))	1.3% (2)
Patients with 3 components (% (n))	0
Patients with 2 components (% (n))	4% (6)
Patients with 1 component (% (n))	8% (12)
Patients with 0 components (% (n))	86.7% (130)
Factor 3 (1.80): Hypertension (0.66), Metabolic Syndrome (0.61), Diabetes Mellitus (0.54), Chronic Kidney Disease (0.53), Arthritis other than gout (0.50)	
Patients with 5 components (% (n))	6% (9)
Patients with 4 components (% (n))	8% (12)
Patients with 3 components (% (n))	18.7% (28)
Patients with 2 components (% (n))	24.7% (37)
Patients with 1 component (% (n))	27.3% (41)
Patients with 0 components (% (n))	15.3% (23)
Factor 4 (1.37): Obesity (0.56), Alcohol Use (−0.55), Peripheral Vascular Disease (−0.51)	
Patients with 3 components (% (n))	0
Patients with 2 components (% (n))	3.3% (5)
Patients with 1 component (% (n))	52.% (79)
Patients with 0 components (% (n))	44% (66)
Factor 5 (1.14): Renal Stones (0.56), Tophi (−0.42)	
Patients with 2 components (% (n))	1.3% (2)
Patients with 1 components (% (n))	26.7% (40)
Patients with 0 components (% (n))	72% (108)

* negative loading values indicate that absence of that component is correlated with the other components.

Conclusion: The four out of five factors had components with clinical relationships: cardiovascular diseases, gastrointestinal disorders, metabolic syndrome and features of advanced gout. The components in factor 4 did not have a clear clinical relationship. The study was limited by its retrospective nature, small sample size, and an inexact, exploratory nature of PCA method. Characteristics of this population may vary if using different definitions of difficult-to-treat. Despite the limitations, our results confirm the clinical intuition that the above conditions are linked to difficult-to-treat gout and may help design future research.

1034

Predictors of Outcomes in Gout with Comorbid Chronic Kidney Disease. Ankoor Shah and John S. Sundy. Duke University Medical Center, Durham, NC

Background/Purpose: Gout in the setting of chronic kidney disease (CKD) poses particular challenges in disease management. Impaired renal function leads to reduced excretion of urate. CKD poses a challenge in terms of treatment of gout. Non-steroidal anti-inflammatory drugs and colchicine are contraindicated in the setting of CKD. The appropriate dosing of allopurinol in the setting of CKD remains controversial. We characterized the disease and treatment features of gout patients with CKD compared to gout patients without CKD in an integrated academic health system

Methods: Adult gout patients were identified by searching an institutional outpatient database for ICD-9 codes associated with gout (274.xx) in the past five years. Charts were further reviewed for conformity with the American College of Rheumatology's preliminary criteria for gout diagnosis. CKD was ascertained and staged based on the patient's estimated glomerular filtration rate from laboratory studies. The primary endpoint was the proportion of patients reaching a target serum uric acid (SUA) of less than 6.0 mg/dL. Statistical analysis was performed using JMP v9 (SAS Cary, NC).

Results: 1791 patients were identified with an ICD-9 code associated with gout, 500 of which were randomly selected for chart review. Of these, 240 met criteria for the diagnosis of gout. 130 patients had gout alone, while 110 patients had gout and comorbid CKD. The mean age at diagnosis in the gout alone group was 57 years and 67 years in the gout/CKD group ($p<0.0001$). Women represented 20% of the gout alone group compared to 47% of the gout/CKD group ($p<0.0001$). There were no significant racial differences.

45% of patients with gout alone reached a target SUA of <6.0 compared to 40% of those with CKD ($p = 0.40$). Patients with CKD had a higher baseline SUA (9.8 mg/dL v. 8.29 mg/dL, $p < 0.0001$), however there was no significant difference between their most recent treated SUA (6.49 mg/dL v. 6.96 mg/dL $p = 0.097$).

73% with gout alone and 75% of gout/CKD patients were on uric acid lowering therapy ($p = 0.675$). The mean allopurinol dose in patients with CKD was significantly less than in patients with gout alone (256 mg v. 208 mg; $p=0.01$).

30% of patients with gout alone had a rheumatologist involved in care compared to 43.7% of those in the gout/CKD group ($p = 0.029$). Among all patients, involvement of a rheumatologist led to significantly greater liklihood of reaching target SUA (54.02% v. 36.6%, $p = 0.009$). "A logistic regression model using multiple predictors found only rheumatologist involvement significantly predicted reaching a target SUA goal ($p = 0.007$).

Conclusion: Patients with comorbid gout and CKD were older at diagnosis, had a higher baseline SUA and had a greater proportion of females compared to patients with gout alone. A minority of patients in both groups reach target uric acid goals of less than 6.0 mg/dl regardless of comorbid CKD. Treatment by a rheumatologist was the only statistically significant predictor of improved outcomes. Our results indicate that the demographic features of comorbid gout and CKD are distinct from that of patients with gout alone. The presence of gout and CKD may serve as a marker of the need for referral to a rheumatologist in order to optimize care.

1035

Patient Management/Treatment and Outcomes of Gout Between Primary Care Physicians and Rheumatologists: A Chart Review of 1,039 Patients with Gout In the United States. Dinesh Khanna[1], Anna Forsythe[2] and Puja Khanna[1]. [1]University of Michigan, Ann Arbor, MI, [2]Savient Pharmaceuticals, Inc., East Brunswick, NJ

Background/Purpose: The prevalence of gout has doubled over the last two decades and estimated currently at 8.3 million patients in the U.S. (Hyon Choi NHANES IV abstract) [1]. Only 4% of patients with gout are cared for by rheumatologists (Rheums) whereas the majority are managed by primary care physicians (PCPs). Despite the availability of urate-lowering therapies (ULT), there still remains a subset of chronic gout patients whose serum urate (SUA) levels and gout symptoms are not controlled. However, the differences in treatment and management of these gout patients as well as the outcomes of therapy have not been compared between PCPs and Rheums. The purpose of this abstract is to identify the current ULT practice patterns among the PCP and Rheums in the US, understand the clinical burden of gout patients treated with ULT, and assess the differences in patient outcomes between PCPs and Rheums.

Methods: A retrospective chart audit of 1,039 US pts with gout was conducted during August and September, 2010 by BioTrends Research Group, Inc.[2] A panel of board-certified practice-based Rheums (119) and PCPs (122) who treated > 50 gout patients in US were selected. Each included chart records of the last 3–5 consecutive gout patients who had a physician-confirmed diagnosis of gout. A structured case report form was completed by each physician that included patient demographics, burden of illness (SUA levels, flare, tophi, swollen joints and presence of radiographic damage), co-morbidities, treatment and resource utilization. The data from Rheums and PCPs were compared using independent unpaired t-test for means (equal variances) and independent z-test for percentages. A difference of $p=0.05$ was considered statistically significant.

Results: Of 1,039 gout pts, 82% were male, 74% were Caucasian, mean age was 58 years and 30% had a BMI > 30. Pts under the care of Rheums had higher disease burden and co-morbidities compared to pts under care of PCPs. Burden of illness, co-morbidities, ULT treatment, and resource utilization are presented in Table.

Table.

	PCP's pts (n=522)	Rheum's pts (n=517)	P value
Burden of Illness (% total pts)			
Chronic tophaceous gout	3.1	22.5	<0.05
Tophi	14.2	37.5	<0.05
3 to 5 Annual Flares	10.7	15.9	<0.05
>6 Annual Flares	5.0	6.0	NS
High to extreme severity of recent flare	17.7	39.6	<0.05
sUA <6 mg/dl	30.3	36.0	NS
sUA >6 to <8 mg/dL	42.1	34.6	<0.05
sUA >8 mg/dL	27.6	29.4	NS
Co-Morbidities (% total pts)			
Cardiovascular disease	14.8	25.0	<0.05
Hyperlipidemia	41	34.8	<0.05
Chronic kidney Disease	11.1	22.1	<0.05
Currently on ULTs (% total pts)	63.2	84.5	<0.05
Allopurinol	49.0	59.7	<0.05
Febuxostat	12.6	23.4	<0.05
Probenecid	1.5	1.4	NS
% Allopurinol pts on >300 mg	20.7	24.0	NS
Resource Utilization over the last 12 months			
SUA labs (mean N per pt)	1.7	2.5	<0.05
Radiographic tests (mean N per pt)	14.4	35.0	<0.05
% Radiograph indicating joint damage	49.3	57.5	NS
% Flares resulting in ER visits	11.2	11.4	NS
% Flares resulting in hospitalization	1.6	2.9	NS

Conclusion: Pts under the care of Rheums had higher disease burden and co-morbidities compared to pts under care of PCPs. PCP's and Rheum's pts had similar resource utilization. Despite the availability of ULTs, 64 – 70% of patients had SUA > 6 mg/dL, 37.5% in Rheum practices have tophi, and 16% have 3–5 flares. Only 21–24% were on allopurinol > 300 mg/day. There continues to be a disconnect between the treatment guidelines for gout[3] and current practices in US.

Adverse Reactions to Allopurinol Are Not Increased In Patients Exposed to Doses Higher Than Recommended for Creatinine Clearance: A Retrospective Study of A Large Urban Multispecialty Group. Tawatchai Paisansinsup[1] and John T. Schousboe[2]. [1]Park Nicollet Health Services, St. Louis Park, MN, [2]Park Nicollet Health Services, Minneapolis, MN

Background/Purpose: Reported recommendations of allopurinol dose adjustment based on creatinine clearance to reduce adverse reactions in patients with renal insufficiency were based on case reports[1]. The efficacy of this strategy is unproved with unintended consequences of suboptimal uric acid level and poor control of gout.

Methods: We identified 551 patients who had allopurinol prescribed between 1/1/2004 and 12/31/2010 who had their serum creatinine measured while on allopurinol and who had complete covariate data. Adverse drug reactions (ADRs) to allopurinol were defined as listing of allopurinol in the ADR list of the medical record or as a physician's attribution of an adverse event to allopurinol combined with discontinuation of the drug. Patient charts were individually reviewed to adjudicate the accuracy of the reported ADRs and the reasons for prescription discontinuation. ADRs were categorized as major (severe cutaneous reactions and/or resulted in death) or minor. Each person's exposure to allopurinol was estimated to be above or below that recommended by Hande*, et al*[1] according to their creatinine clearance. The association of minor or major ADRs to allopurinol with use of allopurinol in doses above recommendation was estimated with logistic regression models.

Results: Prescribed allopurinol doses ranged from an average of 50 mg/day to 750 mg/day (mean and median, respectively, 227 and 300 mg/day). Mean creatinine clearance (Cockcroft-Gault) was 57 ml/min (range 8.5 to 125 ml/min). Three hundred forty two patients (61.5%) were prescribed doses that exceeded those recommended for their levels of renal function; 65 patients (11.7%) had a minor ADR and none had a major ADR to allopurinol. The odds ratio of an allopurinol ADR in those exposed to allopurinol doses higher than recommended for their levels of renal function compared to those treated with doses within or below the recommended dose was 0.84 (95% C.I. 0.49 to 1.46) adjusted for age, sex, diabetes mellitus, ischemic heart disease, hypertension, use of diuretics, and use of aspirin.

Conclusion: The risk of having ADRs to allopurinol is not increased in patients exposed to allopurinol doses higher than those recommended by Hande*, et al*[1]. These results support the strategy of titrating doses of allopurinol to attain a therapeutic goal of uric acid below 6 mg/dl to achieve adequate clinical control of gout.

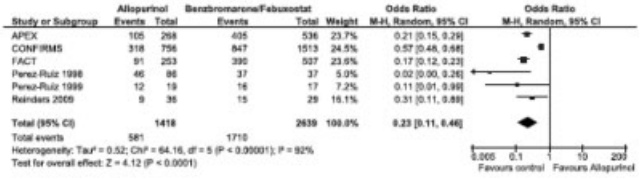
1037

Oral Urate Lowering Therapies in Chronic Gout: A Systematic Review and Meta-Analysis. Puja Khanna[1], Manjit K. Singh[2], Sangmee Bae[2], John D. FitzGerald[3], Shraddha Prakash[4], Marian Kaldas[4], Maneesh Gogia[4], Paul Maranian[5], Robert Terkeltaub[6] and Dinesh Khanna[1]. [1]University of Michigan, Ann Arbor, MI, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]UCLA David Geffen School of Medicine, Los Angeles, CA, [4]UCLA, Los Angeles, CA, [5]University of California, Los Angeles, [6]VA Medical Ctr, San Diego, CA

Background/Purpose: Urate-lowering therapy (ULT) is considered key to the optimal management of hyperuricemia in gout. We systematically reviewed the published data on the pharmacological ULT agents in gout.

Methods: PubMed and CENTRAL databases were searched to find published English language articles on gout up to March 2011. A total of 21 manuscripts were selected for this systematic review. A meta-analysis was carried out to assess the average effect size for the proportion achieving target SUA <6.0 mg/dl across studies between allopurinol (ALLO≤300mg/day) and the comparator drugs (benzbromarone [100– 200 mg/day] or febuxostat [40–120mg/day]). Mantel-Haenszel method of weighting was employed using a random-effects model. The average effect size is reported as an odds ratio (OR).

Results: The pooled mean (SD) age in the trials was 52.6 (12.0), 93.7% were males, and the disease duration 11.5 (9.2) years. ALLO at dose of 300 mg/day is largely ineffective in reaching the target goal of SUA< 6 mg/dl (24% to 53% achieved SUA< 6 mg/dl). The meta-analysis showed that the odds of achieving SUA < 6.0 mg/dl with ALLO (≤300mg/day) is 76% lower than with comparator drugs OR 0.23 [95%0.11–0.46; Figure]. Upwards dose titration every 4 weeks of ALLO, starting from 50–100 mg/day (to higher than 300 mg/day) is associated with achieving SUA < 6 mg/dl in 63% –100%. ALLO AEs in large RCTs included 2% with AST and ALT elevation> 3 ULN and 1.6% with rash. Renal impairment is associated with a significantly higher risk of severe cutaneous drug reaction with ALLO. Febuxostat (FEB) 80mg and 120 mg daily (not approved in USA) is more effective than ALLO 300 mg/day in achieving SUA< 6 mg/dl. There is lack of robust data in patients with CKD stage 4 or worse, including patients on dialysis. Rare skin hypersensitivity events also have been reported with FEB. Combination of 200–300 mg ALLO daily and probenecid 500 mg to 1 gram bid is effective in those with CrCl> 50 ml/min, at achieving SUA of <5 mg/dl. Fenofibrate and losartan also have been shown, in investigator-initiated trials, to be effective "add-on" uricosuric therapy for patients who have not achieved the target on ALLO that is not titrated above 300 mg daily.



Conclusion: Our systematic review established that ALLO ≤300mg/day fails to achieve a target SUA <6.0 mg/dl in the majority (>50%) of subjects with gout. The meta-analysis showed odds of achieving target SUA with ALLO (≤300mg/day) is 76% lower than with the comparator drugs benzbromarone and FEB. FEB at 80 and 120 mg/day is more effective than ALLO ≤300mg/day at achieving target SUA. Addition to ALLO of probenecid, or other weaker uricosurics (fenofibrate, losartan) with ALLO and probenecid is effective in patients with adequate renal function.

1038

A Case Series of HLA B27 Patients with a Behçet's Like Syndrome in a UK Population. Nicola Ambrose[1] and Dorian O. Haskard[2]. [1]Imperial College London, London, United Kingdom, [2]Imperial College, London, United Kingdom

Background/Purpose: This review focuses on patients referred to a UK Behçet's Syndrome (BS) Specialist Clinic who were found to be HLA B27 positive.

Methods: Patient demographics, symptoms, signs, treatments and HLA markers were recorded for the 598 patients seen in clinic from 1999 to 2011. Updates to the datasheet were made at subsequent visits.

Results: 597 patients were seen between 1999 and 2011. Of these, 319 were classified as having definite BS (DBS), 184 of having possible BS, 59 were definitely not BS and 36 were found to be HLA B27 positive and were classified as B27 BS-like syndrome (B27 group). We compared the DBS (ie B27 negative) group with the B27 group. Age and male sex were comparable (median age 36 and 38, male sex 44% and 58%, respectively). In the DBS group, 97% fulfilled ISG criteria, versus 69% of the B27 Group ($p<0.001$). Oral ulcers were found >99% of the DBS group versus 81% of the B27 group ($p=<0.001$). Genital ulcers were found in 89% of the DBS group versus 58% of the B27 group ($p<0.001$). Fewer patients in the HLA B27 group had the combination of oral and genital ulceration (B27 58% versus BS 89%, $p<0.001$). Similar numbers in both groups had inflammatory eye lesions (BS 46%, B27 56%, ($p=0.22$). Similar numbers also had skin lesions (BS 80%, B27 70%, $p=0.23$), Only a minority in either group had a positive pathergy test (BS 12%, B27 11%, $p=0.9$). While some of this B27 group present with features clinically identical to DBS, most had features that led us to suspect their B27 positivity. Thus, anterior uveitis was the predominant ocular manifestation in B27 group (85% of all), whereas posterior or panuveitis is more typical of DBS. Only 9% of our non-B27 DBS group had a history of joint swelling at any stage in their illness versus 61% of the B27 group ($p=0.001$). The latter patients also had findings which are not usual features of DBS such as psoriasis, enthesitis or plantar fasciitis. Interestingly, neurological and vascular BS manifestations were equally common in the two groups, with neurological involvement in 12% of the DBS group and in 22% of the B27 group ($p=0.06$). Neurological involvement in the B27 group included meningoencephalitis, trigeminal neuralgia, hemiparesis, intracranial hypertension and seizures. Secondly, vascular involvement was found in 18% of DBS and 25% of B27 groups respectively ($p=0.23$). In the B27 group, findings included deep vein thrombosis, subclavian vein thrombosis, superficial thrombophlebitis, dural sinus thrombosis, pulmonary embolism, development of an ischaemic digit and a radial artery aneurysm.

Conclusion: Of the 598 patients seen in this clinic, 36 have been found to be HLA B27 positive. While some of this cohort present with features identical to a classical BS, most have features that led us to clinically suspect their B27 positivity. This group may represent an extreme end of the spondyloarthropathy spectrum of disease. Importantly, they experience serious neurological and vascular BS-like manifestations to a similar extent as their classic BS counterparts.

Dual Effects of Testosterone in Behcet's Disease: Implications for a Role in Disease Pathogenesis. Sule Yavuz[1], Tugba Akdeniz[2], Muge Bicakcigil[2], Haner Direskeneli[1] and Gulderen Yanikkaya Demir[2]. [1]Marmara University, Istanbul, Turkey, [2]Yeditepe University, Istanbul, Turkey

Background/Purpose: Behçet's Disease (BD) is a systemic inflammatory disorder characterized by vasculitis that is usually accompanied by oral and genital ulcers, skin lesions, uveitis and arthritis. Increased neutrophil activity and hyperresponsiveness to streptococci have been considered to play a role in Behçet's disease (BD) pathogenesis. We previously showed that testosterone (T) may also play a role in BD pathogenesis via increasing neutrophil activity and decreasing neutrophil apoptosis. Here we aimed further to define the effects of testosterone in detail.

Methods: Twelve BD patients who were in remission at least 6 months were included in this study. Peripheral blood from patient and 20 controls (10 ankylosing spondylitis /10 healthy donors) groups were drawn into heparinized Vacutainer tubes (BD BioSciences, USA). None of the patients were on any immunosuppressive treatment other than colchicum dispert 1.5gr/d. Neutrophils were incubated with testosterone, CpG DNA (5'-TCG ATC GGG GCG GGG CGA GC-3', XX IDT) and lipoteichoic acid (LTA) and in combinations of Ts + LTA and Ts + CpG DNA. Activation degree of neutrophils after a 2 hour incubation were analyzed by Dihydrorhodamine 123 conversion to rhodamine as a result of mitochondria activation. Culture supernatants were collected for cytokine measurements. FC500 flow cytometer and CXP software were used for analysis. IL-1, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12, INF-gamma, TNF-alpha were assessed by using Th1/Th2 11plex RTU FlowCytomix Kit (BenderMed/e-Bioscience, Austria) on FC500 cytometry.

Results: Testosterone caused neutrophil activation in all groups, however, LTA and CpGDNA activated neutrophils in combination with T exclusively in BD (LTA vs LTA/T 66.2 ± 23.7 vs82.3 ± 22.5 $p<0.05$; CpGDNA vs CpGDNA/T 62.2 ± 23.6 vs 84.7 ± 13.4 $p<0.02$)When we further analyze the effect of T onto cytokines in different conditions, we observed that T induce IL-10 secretion (unstimulated vs stimulated 9.6 ± 1.01 vs 15.9 ± 4.3 $p<0.003$)in HC. Whereas, T led to elevated IL-12 levels (BD: 15.1 ± 4.6 vs 21.4 ± 5.4 $p<0.002$; AS:14.1 ± 2.4 vs20.5 ± 5.9 $p<0.006$) in both BD and AS and increased INFg only in AS. Interestingly, TNF-a levels were increased with LTA in both BD (18.5 ± 7.0 vs 28.4 ± 16.0 $p<0.01$) and AS (16.5 ± 1.7 vs 31.6 ± 25.3 $p<0.03$) compared to HC but significantly elevated IL-4 levels were observed in BD patients (103.2 ± 42.5) compared to AS (19.5 ± 2.8) and HC (17.6 ± 3.4) when stimulation occurred with LTA+T ($p<0.0001$). Similarly, CpGDNA+T induced significant upregulation of TNF-a (18.5 ± 7.0 vs 57.4 ± 52.1 $p<0.02$) in BD patients but also led to increase in IL-4 levels in BD (93.1 ± 37.2) compared to AS (18.3 ± 3.5,$p<0.0001$) and HC (20.1 ± 2.4,$p<0.01$).

Conclusion: Despite immunosuppressive behavior in healthy subjects, T causes T_H1 type immune alterations in BD patients and AS patients. The higher amount of IL-4 stimulation seen with uniquely in BD patients might be related to IL-4 gene polymorphism which is suggested to be a susceptibility factor to BD.

Major Arterial Involvement in Behçet's Disease: Results From a Single Centre about 29 Cases. Z. Tazi Mezalek, W. Ammouri, H. Harmouche, M. Maamar, M. Bourkia, M. Adnaoui and M. Aouni. Ibn Sina Hospital, Rabat, Morocco

Background/Purpose: Behçet's disease is a multisystem pathology, and survival is closely related to vascular involvement. We analyse the clinical findings, treatment, outcome, and prevalence of arterial disease in a cohort of patients with BD from single tertiary referral medical center.

Methods: Medical records of consecutive patients with arterial involvement were reviewed to determine the clinical characteristics of BD, the sites, laboratory test results, and response to treatment. The diagnosis of BD was made according to the international criteria of BD. Statistical analysis was performed to define factors that affect prognosis.

Results: Among a cohort of 292 patients with BD, arterial involvement was present in 29 patients (10%) The over age at diagnosis was $33.9+9.6$ years, with a large predominance of males (25 cases). In 16 patients (55%), arterial involvement leads to the BD diagnosis. In the other cases, patients presented with ocular symptoms in 13, venous thrombosis in 10 and fever in 1 case. Arterial involvement was present at the initial presentation of the disease. Symptomatic lesions presented in 15 patients (55%), and asymptomatic lesions were incidentally detected in 13 (45%). There were 28 aneurysms and pseudo aneurysms: 14 in pulmonary territory, 4 infrarenal abdominal aorta, 3 cases of each superficial femoral and carotid arteries, 2 subclavian and one of each thoracic aorta and coronary artery. Were reported 2 cases of stenosis: one of the abdominal aorta and of coronary artery. Compared with BD patients without arterial involvement, those with arterial disease had higher rate of venous thrombosis ($p=0.02$), of ocular disease ($p=0.03$), were mostly man ($p= 0.003$) and had higher rate of biological inflammation ($p=0.004$). All patients were treated with corticosteroids, and 25 received immunosuppressive therapy. Surgical treatment was possible in 8 patients. For pulmonary aneurysm, an embolisation was made in 3 cases. Four patients died from pulmonary aneurysms. Recurrence was observed in 4 patients (14%) after treatment with stent graft ($n = 1$), as venous thrombosis in 2 case and as a new pulmonary aneurysm in one. The other cases remain stables.

Conclusion: The rate of arterial involvement is high in our series, probably in relation with the recruitment of a tertiary referral center. Therefore, we suggest that routine examination of symptoms and signs of arterial disease is necessary in male BD patients with venous thrombosis and/or ocular disease and/or inflammatory syndrome.

1041

Treatment with Infliximab Is Effective and Safty in BD Patients with Uveitis. Kayo Terauchi, Mitsuhiro Takeno, Takeaki Uehara, Atsuhisa Ueda, Nobuhisa Mizuki, Etsuko Shibuya and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background/Purpose: Infliximab (IFX) is highly effective for uveitis in Behcet's disease (BD), but the therapy does not completely suppress ocular manifestations. This study determined what factors are associated with ocular attacks during the IFX therapy.

Methods: We retrospectively examined clinical courses of 18 BD patients (female 2, male 16, age 42 + 13.7 yo) who received IFX due to uveitis. In the original regimen, IFX (5mg/kg) was given at 0, 2, 6 week, and thereafter every 8 weeks, but the intervals were shortened after major ocular attacks occurred.

Results: Mean duration was 6.4 + 5.8 years from the disease onset to initiation of infliximab therapy. Before the infiliximab therapy, 15 patients had received colchicines and 7 patients had cyclosporine A. Duration of IFX was 29 + 15.6 months (7 to 60 months, 5 to 51 times). No patients discontinued the therapy, though the infusions were suspended one or two week in 2 patients because of infection including infectious mononucleosis by cytomegalovirus. Visual acuity were improved in 17 eyes, unchanged in 10 eyes, and deteriorated in 5 eyes, except blind eyes. Frequency of ocular attacks was 2.4 + 0.6 / 6 month before and during the IFX therapy, while that was reduced to 0.34 + 0.38 / 6 months. During the therapy, total 29 ocular attacks occurred at 6.87 + 1.12 weeks after the last infusion, 1.43 + 1.53 weeks before the next expected infusion. After ocular attacks, the infusion interval was shortened from 5 to 7 weeks in 8 patients. In the other 10 patients who had no major ocular attack, visual acuity was more frequently improved. However, there was no significant difference in clinical features before initiation of IFX between two groups. Surgical ocular operations were performed in 8 and 3 eyes for cataract and glaucoma, respectively, without operation-related ocular attacks. There was no major adverse event which required hospitalization.

Conclusion: Treatment with IFX is effective, safety and tolerable in BD patients with uveitis. Ocular attacks were significantly suppressed, resulting in improvement of visual acuity. However, the attacks were accumulated in the last 2 weeks of infusion interval. It is hard to predict responsiveness to IFX therapy based on the pre-therapeutic clinical features.

1042

Adverse Events of Immunosuppressive Therapy in Autoimmune Uveitis Patients. Zulema Rosales, Ana B. Rodríguez-Cambrón, Oscar Fontsere, Leticia León, Pedro Arriola, Lydia Abásolo, Cristina Martínez, Cristina Lajas and Esperanza Pato. Hospital Clínico San Carlos, Madrid, Spain

Background/Purpose: Uveitis is the inflammation of the uveal tract. An immune-mediated inflammatory mechanism is the main cause of the uveitis. Non infectious autoimmune uveitis might develop a severe course with poor visual prognosis if an adequate control of the disease is not achieved. Corticosteroids (CE) are central to control acute and severe ocular inflammation and immunosuppressive drugs (IS) are used when CE are insufficient. There are no published large series and long follow-up on the effects of IS in uveitis.

Our purpose was to analyze the incidence of side effects and the withdrawal rate of the IS in a cohort of patients with autoimmune uveitis attended at the uveitis unit in our hospital.

Methods: A retrospective study from January 1992 to October 2010 was performed. Study was approved by the Ethic Committee of our hospital.

The inclusion criteria were diagnosis of chronic anterior uveitis, intermediate uveitis, posterior uveitis and panuveitis who received one of the following IS: cyclosporine A (CSA), methotrexate (MTX), azathioprine (AZA), cyclophosphamide, mycophenolate mofetil, Infliximab, Adalimumab (ADA) and/or Etanercept. We analyze IS cycles used, survival time after treatment, adverse events (AE) during the follow-up and visual acuity (VA) at baseline and last ophthalmological assessment. Survival techniques were used to estimate the incidence rate (IR) and 95% confidence interval [95% IC] of adverse events and discontinuation by drug exposure. Descriptive and bivariate analyses were also performed with Stata package.

Results: 1535 patients were evaluated in the uveitis unit during the follow up (18.9 years). 75 patients met the inclusion criteria, 41 were women (54.7%) and the mean age at diagnosis of uveitis was 42 ± 19.7 years. 23 patients had any AE. A total of 38 AE were collected during follow-up (14 digestive intolerance, 11 increase of creatinine level, 5 liver toxicity, 5 hypertension, 2 cytopenias and 1 bronchospasm) with an incidence of 6.42% (95% CI 4.67 to 8.82) during follow-up. There were no differences between men and women in the development of AE ($p = 0.43$). The risk of an AE increased with increasing age of patients ($p = 0.02$). Table 1 shows the IR per 100 patients-years (95% IC) of AE and drug discontinuation by drug exposure. There was an improvement in VA in both eyes in the follow-up: mean change (±SD) right eye 0.11 ± 0.35 and left eye 0.10 ± 0.51.

Drug	N° of patients with the drug	N° of patients with AE	IR of AE by drug exposure	N° of withdrawals	IR of discontinuation by drug exposure
MTX	37	6	2.9 (1.3–6.5)	3	1.5 (0.5–4.5)
CSA	46	22	9.3 (6.1–14.1)	8	3.3 (1.7–6.7)
AZA	29	9	6.3 (3.3–12.2)	7	4.9 (2.3–10.3)
ADA	3	1	33.3 (4.7–236.2)	1	33.3 (4.7–236.2)

Conclusion: The use of IS for the treatment of ocular inflammatory disease, particularly uveitis refractory to CE, is an effective and necessary alternative treatment. In our series, the incidence rate of AE of IS and the rate of discontinuation are low. Although the safety profile of IS used is good, it is essential to maintain a continuous monitoring during treatment. The VA in this group of patients is maintained during the follow-up.

1043

Relationship Between Patterns of Clinical Presentation Uveitis and Final Inmunologic Diagnosis. Esperanza Pato[1], Zulema Rosales[1], Esther Toledano[1], Pilar Macarron[1], Cristina Vadillo[1], Rosalía Mendez[1], Miguel A. Descalzo[2] and Estíbaliz Loza[2]. [1]Hospital Clínico San Carlos, Madrid, Spain, [2]Spanish Society of Rheumatology, Madrid, Spain

Background/Purpose: In our multidisciplinary uveitis unit, coordinated by ophthalmologists and rheumatologists, a predefined set of 12 clinical patterns of uveitis presentation is used to help diagnose since 1992. The routinely use of these clinical patterns leads to a decrease in the number of diagnostic test to confirm the final diagnosis.

The purpose of this study was to analyze the association between these clinical patterns and the final immunologic diagnosis and its discriminative value.

Methods: A prospective cohort study was performed. The study was approved by the ethic committee of our hospital. All patients attended in our multidisciplinary uveitis unit from January 1992 to December 2009 who were diagnosed with uveitis were selected. In all of them the following data were collected: the clinical patterns of uveitis presentation, the initial diagnosis, the medical history, the diagnostic test results and the final diagnosis. The 12 clinical patterns of uveitis presentation are: a) anterior uveitis (AU) including 1) acute recurrent unilateral AU, 2) acute nonrecurrent unilateral AU, 3) acute bilateral AU, 4) chronic AU, 5) intermediate uveitis, b) posterior uveitis as 6) unilateral chorioretinitis, 7) bilateral chorioretinitis, 8) retinal vasculitis, 9) chorioretinitis panuveitis, 10) vitritis panuveitis, 11) retinal vasculitis panuveitis and 12) exudative retinal detachment panuveitis. To measure the association between uveitis and immunologic diagnosis a correspondence analysis was performed with every pattern. According to the model coordinates, 3 different levels of association were established -mild, high and very high-, based on the distance and magnitude of the coordinates. The highest absolute number and the smallest distance, the strongest association.

Results: A total of 1,465 patients were evaluated of whom 783 were women (53 %) with a mean age at the uveitis diagnosis of 45 years ± 18 years. The most frequent final diagnoses were idiopathic anterior uveitis (29%), spondyloarthropathy (13%) ophthalmologic uveitis (10%), toxoplasmosis (9%) and herpes (8%). Table 1 shows the association of the final diagnoses with a clinical pattern of uveitis presentation.

Uveitis Pattern	Major Diagnosis	Association
Acute recurrent unilateral AU	Spondyloarthropaty	Mild
Acute nonrecurrent unilateral AU	Ophthalmologic AU	Mild
Acute bilateral AU	Idiopathic AU	Mild
Chronic AU	Juvenile Idiopathic Arthritis	Mild
Unilateral chorioretinitis	Toxoplasmosis	High
Bilateral chorioretinitis	Ophthalmological chorioretinitis	High
Vasculitis	Idiopathic retinal vasculitis	High
Intermediate uveitis	Idiopathic intermediate uveitis	High
Chorioretintis panuvelitis	Toxoplasmosis	Mild
Vitritis panuveitis	Idiopathic panuveitis	High
Vasculitis panuveitis	Behçet	High
Exudative retinal detachment panuveitis	Vogt-Koyanagi-Harada	VeryHigh

Conclusion: Our data show the central diagnostic value of the clinical patterns of uveitis presentation. The use of these patterns in daily practice could definitively be a useful tool in order to diagnose, reducing therefore he number diagnostic tests, but could also help prescribe the most appropriate treatment.

1044

High Dose Intravenous Methylprednisolone Induces Rapid Improvement In Severe Uveitis: A Multicenter Study. Carmen Bejerano[1], Ricardo Blanco[1], Emma Beltrán[2], Alejandro Fonollosa[3], Olga Maiz[4], Ana Blanco-Esteban[4], Miguel Cordero[5], Inés Pérez-Martín[6], Joaquín Cañal[6], Juan Ventosa[6] and Miguel Angel González-Gay[6]. [1]Hospital Universitario Marqués de Valdecilla-IFIMAV, Santander, Spain, [2]Hospital Peset, Valencia, Spain, [3]Hospital de Cruces, Barakaldo-Bilbao, Spain, [4]Hospital Donostia, San Sebastian, Spain, [5]Hospital León, León, Spain, [6]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain

Background/Purpose: Since ocular inflammation may lead to early and irreversible structural and functional damage, remission induction therapy is required in severe uveitis. High-dose intravenous methylprednisolone (IVMP) may induce rapid improvement in a broad spectrum of severe inflammatory conditions including uveitis.

Methods: We reviewed 28 patients (47 eyes) with severe ocular inflammation, attended at the Uveitis Unit from 4 tertiary Hospitals, who received IVMP. The underlying diseases were: Idiopathic uveitis (n=11, 39%), Vogt Koyanagy Harada syndrome (n=9, 32%), Behçet disease (n=2), Ankylosing Spondylitis (n=1), Eales Disease (n=1), Sympathetic Ophthalmia (n=1), Multiple Sclerosis (n=1), Relapsing Polychondritis (n=1), Varicella-Zoster-associated acute retinal necrosis (n=1). The inflammatory ocular patterns were: posterior uveitis (n=12, 43%), panuveitis (n=11, 39%), anterior uveitis (n=1), scleritis (n= 2), sclero-uveitis (n=1), and intermediate uveitis (n=1). Bilateral ocular involvement was observed in 19 patients (68%). Patients were assessed at day 2–3, 7, 14 and 30 after IVMP treatment.

Results: We studied 17 women/11 men with mean age 41.7±15.2 years. IVMP dose ranged from 0.25–1 g/day for 3–5 consecutive days. All of them had active intraocular inflammation at baseline. Following IVMP therapy patients with anterior uveitis experienced rapid improvement. However, improvement of retinal vasculitis was more slowly achieved **(TABLE).** Retinal detachment occurred in 10 patients (19 eyes) showing partial improvement of affected eyes in 11% at day 2–3 and a complete recovery in 74% at day 30. Optical coherence tomography showed impairment ($> 200\mu$) in 14 patients (26 eyes) at baseline, partial improvement in 46% of affected eyes at day 2–3 and a complete normalization ($< 200\mu$) in 54% at day 30. Visual acuity was reduced in 27 patients (44 eyes) at baseline. Thirty-five eyes (80%) improved in visual acuity, 5 eyes (11%) remained stable and 4 eyes (9%) had worsened at day 30. The patient with acute retinal necrosis presented progressive improvement and inactive lesions at day 30. One of 2 patients with scleritis showed progressive improvement with complete normalization at day 30. IVMP therapy was well tolerated and no important side-effects were observed.

	patients (affected eyes)	complete inactivity (% of eyes) after high-dose intravenous methylprednisolone		
	baseline	Day 2–3	Day 7	Day 30
anterior inflammation	15 (24)	72%	72%	96%
vitritis	13 (20)	25%	40%	75%
retinal vasculitis	7 (11)	0	0	73%
choroiditis/ chorioretinitis	8 (14)	14%	14%	57%

Conclusion: IVMP is an effective and safe remission induction therapy in severe ocular inflammation.

1045

Adalimumab in 107 Refractory Uveitis: A Multicenter Study. Orlando Pompei[1], Ricardo Blanco[2], Manuel Diaz-llopis[3], David Salom[3], Carmen Garcia-Vicuña[4], Miguel Cordero-Coma[5], Gabriela Ortega-Larrocea[6], Norberto Ortego-Centeno[7], Marta Suarez-de-Figueroa[8], J. Carlos Fernandez-Cid[9], Alejandro Fonollosa[10], Angel M. Garcia-Aparicio[11], Jose M. Benítez-del-Castillo[12], Jose L. Olea[13] and J. Fernando Arevalo[14]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla-IFIMAV, Santander, Spain, [3]La Fe University Hospital of Valencia, Valencia, Spain, [4]Hospital Sant Joan de Déu, Barcelona, Spain, [5]Hospital de León, León, Spain, [6]National Institute of Rehabilitation, D.F Mexico, Mexico, [7]Hospital Clínico San Cecilio, Granada, Spain, [8]Hospital Ramon y Cajal, Madrid, Spain, [9]Hospital de Pontevedra, Pontevedra, Spain, [10]Hospital de Cruces, Bilbao, Spain, [11]Hospital Virgen de la Salud, Toledo, Spain, [12]Hospital Clínico San Carlos, Madrid, [13]Hospital Son Dureta, Palma de Mallorca, Spain, [14]Ophthalmology Clinic Center of Caracas, Caracas, Venezuela

Background/Purpose: To assess the efficacy and safety of adalimumab therapy in refractory autoimmune uveitis.

Methods: Retrospective, multicenter study on 107 patients. All of them had a failure or intolerance of prednisone therapy and ≥1 other systemic immunosuppressive therapy. Different etiologies were diagnosed: Juvenile Idiopathic Arthritis (40 cases, 37%), uveitis of Idiopathic origin (20 cases, 19%), Pars Planitis (14 cases, 13%), Behçet Disease (11 cases, 10%), Vogt Koyanagy Harada syndrome (7 cases, 7%), Ankylosing Spondylitis (5 cases, 5%), Inflammatory Bowel Disease (2 cases, 2%), Birdshot Coriorretinopathy (1 case, 1%), Rheumatoid Arthritis (1 case, 1%), Multifocal choroiditis with panuveitis (1 case, 1%), Sarcoidosis (1 case, 1%), Sympathetic Ophthalmia (1 case, 1%), and others (2%). Adalimumab (40 mg subcutaneously) every-other-week was maintained during 6 months. If uveitis was inadequately controlled, the Adalimumab dosage was increased up to 40 mg/wk. All patients underwent an outcome assessment at month 6.

Results: 107 patients (45 males, 62 females), mean age 25.23±17.68 years (range: 4 to 65 years), with active intraocular inflammation at baseline were studied. Thirty-eight had inflammation in the anterior camera, and following Adalimumab therapy achieved significant improvement (mean tyndall improved from 1.43±0.9 to 0.2±0.4; $p<0.0001$. Also, 54 patients had inflammation in the posterior camera. Significant improvement of optic coherence tomography (OCT) was achieved: baseline; 332.35±137.62 microns; and after 6 months of Adalimumab treatment 244.56±34.17 microns; $p<0.0005$. Also, 16 patients had cystoid macular edema (CME): at baseline mean OCT 432.81±144.21 microns, and after Adalimumab 256.25±37.36 microns; $p<0.0003$. Most of the remaining patients with intermediate uveitis (15 cases) had improvement. Also, most patients were able to reduce at least 50% of the dose of the concomitant immunosuppressive drugs at the end of follow-up. Adalimumab was usually well tolerated, and only local minor side effects at the injection site were observed. Nevertheless, 11 patients (10%) had moderate to severe relapses during the follow-up period, and 28 patients (26%) had minor relapses during the follow-up that were controlled with 1 periocular steroid injection.

Conclusion: Adalimumab appears to be an effective and safe treatment for refractory uveitis and may reduce steroid requirement. However, further controlled studies of adalimumab for uveitis are warranted.

1046

Recalcitrant Orbital Inflammatory Disease Responsive to Infliximab. Mary Bach and Gregory C. Gardner. University of Washington, Seattle, WA

Background/Purpose: Orbital inflammatory disease (OID) is a general descriptor for inflammatory syndromes affecting various orbital structures such as nerves, muscle and surrounding tissues. OID can be idiopathic or associated with inflammatory diseases such as ANCA-associated vasculitis, Behcet's disease, or Crohn's disease. OID is often responsive to corticosteroids. However, many cases are not fully responsive to steroids or are resistant to steroid tapering. Agents such as methotrexate, azathioprine, cyclosporine, and even cyclophosphamide have been tried as steroid-sparing medications. Several previously reported cases of idiopathic OID have been dramatically responsive to infliximab. We present three recalcitrant cases of OID that responded to therapy with infliximab.

Methods: Chart review and literature search

Results: The three cases included 2 females and 1 male with age range 28–59 years. All three cases had imaging studies demonstrating orbital inflammation and tissue biopsies showing chronic inflammation including one case that qualified for the diagnosis of Tolosa-Hunt syndrome with granulomatous changes on biopsy and cranial neuropathies. Two patients had initial response to high dose prednisone (1 complete, 1 partial) but were unable to taper without recurrence of symptoms. The third patient had persistent symptoms in spite of up to 100 mg per day of prednisone. Other steroid sparing agents used included methotrexate in all three and azathioprine in one with no or partial benefit. The addition of infliximab 3–5 mg/kg IV every 8 weeks resulted in prompt and dramatic improvement in symptoms and signs of disease and subsequent imaging studies in all patients. All three patients were able to taper prednisone completely (2 patients) or to low dose therapy. One patient developed drug–induced lupus after infliximab-induced remission but continued in remission on methotrexate and low dose prednisone. The patient with Tolosa-Hunt syndrome has been on methotrexate 7.5 mg per week and infliximab 3 mg/kg every 12 weeks in complete remission for 3 years.

There have been 10 previous cases of resistant idiopathic orbital inflammatory disease treated with infliximab reported in the English literature since 2004. Prior to infliximab, patients had been treated with one or more of the following; high dose prednisone, methotrexate, azathioprine, cyclo-

phosphamide, 6-mercaptopurine, cyclosporine, colchicine, steroid injections, and irradiation. Two of the 10 received methotrexate plus infliximab while 8 patients received infliximab alone. Infliximab dosing range was 3–5 mg/kg every 6–8 weeks. Six of the 10 went into remission while 4 patients had residual visual changes but were reported improved and inflammatory symptoms controlled.

Conclusion: Rheumatologists are often called on to provide immunotherapy for patients with inflammatory conditions such as OID. Recognizing the benefit of infliximab in patients with OID and early introduction in recalcitrant cases will hopefully help reduce morbidity and prevent excessive steroid side effects. Presentation of these three cases reports and review of previous cases will hopefully provide useful case background for rheumatologists treating patients with OID.

1047

Giant Cell Tumor of Synovial Sheath: Of Two Cases Treated with Intra-Articular Infiltration of Infliximab. Emanuela Praino, Crescenzio Scioscia, Maria Grazia Anelli, Laura Coladonato, Michele Covelli, Florenzo Iannone and Giovanni Lapadula. D.I.M.I.M.P, Rheumatology Unit - University of Bari, Bari, Italy

Background/Purpose: The giant cell tumor of the synovial membrane, formerly called pigmented villonodular synovitis, is a rare disease, often resistant to conventional therapy and with frequent recurrence after synovectomy.

Methods: We report the case of two women aged 47 and 51 years, both with a diagnosis of giant cell tumor of the synovial membrane of the left knee, resistant to therapy with methotrexate and/or surgery. Infliximab was administered to both, by intra-articular injection with in-line filter, at a dose of 100 mg (diluted in 10 cc of saline) at time 0, 4 and 12 weeks. At each visit blood tests, clinimetric and Power Doppler ultrasound evaluations were performed. MRI was performed at baseline and four weeks after the last Infliximab injection.

Results: At baseline, hyperplastic synovitis was noted by ultrasound for both patients, with power-Doppler signal of grade 2 and grade 3, these findings correlated with MRI results. At 4 weeks after the third administration, complete remission was noted with reduction of the thickening of the synovial membrane and a complete absence of power-Doppler signal. These findings were also confirmed by MRI. Both patients, therefore, were referred to an orthopedic specialist for a radical synovectomy. Two months after surgery, the patients had no recurrence of the tumor. No adverse events were noted.

Conclusion: The giant cell tumor of the synovial membrane, if untreated, can lead to disability. Synovectomy, possibly followed by radiosynovectomy, is the usual treatment of choice. Nevertheless, the recurrence of the tumor in approximately 50% of patients treated surgically indicates that surgery is not always sufficient. Our study confirms previous literature data reporting the effectiveness of infliximab, given intra articularly, in the treatment of giant cell tumor and showing a significant reduction In the number of macrophages and TNF-alpha expression in synovial tissue. Thus, this treatement is particularly effective in reducing inflammation and hyperplasia of the synovial membrane and prepare the joint for radical synovectomy surgery. Further studies are warranted to evaluate the long term efficacy and safety of infliximab in treatement of the giant cell tumor of the synovial membrane and whether this terapy may replace synovectomy.

1048

Distinct Rheumatological Features Induced by Aromatase Inhibitors in Breast Cancer Patients: A Prospective Multicenter Cohort Study of 138 Women with Breast Cancer. Serge Perrot[1], Paul Cottu[2], Xavier Decleves[1], Laure Chauvenet[1], Christophe Tournigand[3], Jean-Yves Pierga[2], Didier Bouhassira[4] and Francoise Laroche[3]. [1]Hopital Hotel Dieu, Paris, France, [2]Curie Institute, Paris, France, [3]Saint Antoine Hospital, Paris, France, [4]Ambroise Paré Hospital, Boulogne, France

Background/Purpose: Aromatase inhibitors (AI) are prescribed to postmenopausal women with breast cancer, to decrease estrogen production and thus, prevent cancer recurrence. Musculoskeletal pain was the most frequently reported adverse effect. We carried out a cohort study on women treated with AI, to define the types of AI-induced rheumatological disorders observed, their incidence and putative risk factors.

Methods: We carried out a prospective multicenter cohort study of women with breast cancer requiring long-term AI treatment. Women with breast cancer who gave informed consent were included just before the start of AI treatment. They were followed at 1, 3, 6 and 12 months of AI treatment. At each visit, patients were examined by a rheumatologist and asked to complete self-reported pain (BPI, MPQ) and psychological questionnaires. Laboratory tests were carried out for (1) two genetic polymorphisms potentially conferring a predisposition to chronic pain (COMT (cathecol-O-methyl transferase) and mu opioid receptor (OPRM1)), (2) inflammatory markers (CRP, ESR), (3) autoimmune disorders (ANA, ACPA, RF), (4) calcium metabolism abnormalities (vitamin D, calcium). Patients referred for severe or end-stage organ involvement and those with concomitant pain syndromes were excluded.

Results: In total, 138 women with breast cancer, from four cancer centers, were enrolled. Significant pain symptoms were observed at 1 month in 15% of the patients, at 3 months in 35%, at 6 months in 31% patients, and at 1 year in 22% of patients. Most of the patients (82%) that developed pain presented early pain symptoms (1–3 months), with pain in the hand associated with tenosynovitis and flare-ups of osteoarthritis, with no biological inflammatory disorder. A few patients (18%) developed late pain symptoms (6–12 months) with widespread pain, hot flushes, fatigue and sleep disorders, resembling fibromyalgia syndrome. All these patients had the typical 18 tender points and diffuse spontaneous pain and fulfilled the ACR1990 fibromyalgia classification criteria. One patient developed typical rheumatoid arthritis at 3 month of follow-up. Two patients displayed a significant increase in rheumatoid factor and ACPA levels, with no significant pain symptoms, at 1 year of follow-up. Six patients (4.3%) had to stop AI treatment between 3 and 8 months, due to pain intensity. Neither of the two genetic polymorphisms (COMT and OPRM1) tested was associated with musculoskeletal pain symptoms.

Conclusion: Pain is frequent in women treated with AI, occurring in up to a third of cases during the first year of treatment. Two major types of pain are observed. The most frequent consists of osteoarthritis symptoms in the first three months, mostly in the hands and wrists. The second resembles fibromyalgia syndrome and may occur at a late stage, probably through different mechanisms. The adverse effects of AI treatment constitute a clinical condition in which analyses of patients developing late diffuse pain syndrome may improve our understanding of the links between hormonal dysfunction and chronic widespread pain (e.g. fibromyalgia syndrome).

Treatment of Chemotherapy-Related Arthropathy with Disease Modifying Antirheumatic Drugs: Results of An Open-Labeled Multicenter Pilot Study. Hyoun Ah Kim[1], Hyo-Jin Choi[2], Hanjoo Baek[2], Mie Jin Lim[3], Won Park[3], Jisoo Lee[4], Sung Jae Choi[5], Bo Young Yoon[6], Sang Tae Choi[7], Jung-Soo Song[7], Sung Soo Kim[8] and Chang-Hee Suh[1]. [1]Ajou University School of Med, Suwon, South Korea, [2]Gachon University Gil Hospital, Incheon, South Korea, [3]Center for Rheumatism, Inha University Hospital, Incheon, South Korea, [4]Ewha Womans University Mokdong Hospital, Seoul, South Korea, [5]Korea University Medical Center, Ansan, South Korea, [6]Inje University Ilsan Paik Hospital, Goyang, South Korea, [7]Chung-Ang University College of Medicine, Seoul, South Korea, [8]Ulsan Univ Med Sch Gangneung, Gangneung

Background/Purpose: Various musculoskeletal manifestations can develop in a patient during chemotherapy for malignancy. We previously reported 18 patients who developed chemotherapy-related arthropathy (CRA). In this study, we evaluated whether hydroxychloroquine (HCQ) modify the disease activity in CRA.

Methods: In order to compare the efficacy of HCQ and nonsteroidal anti-inflammatory drugs (NSAIDs) to NSAIDs only for the treatment of CRA, an open-labeled clinical trial was carried out at 8 tertiary hospitals. A total of 80 patients were enrolled in this study. CRA activity was clinically assessed in tender joint count (TJC), swollen joint count (SJC), visual analogue pain score (VAPS), morning stiffness (MS), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP).

Results: Patients comprised 65 women (81.3%) and 15 men with mean age 51.43 ± 9.2 years. Forty two patients had breast cancer, 11 had lymphoma, and 7 had stomach cancer. The most commonly used drugs were cyclophosphamide, adriamycin, 5-fluorouracil and aromatase inhibitor. Joint symptoms usually began 8.54 ± 13.32 months after the first session of chemotherapy. Patients had an average of 6 tender joints and 4.5 hours of morning stiffness. Eleven patients were positive for antinuclear antibody and 8 for rheumatoid factor. Among 80 patients, 46 patients were withdrawn during the screening and follow-up. Of the 34 patients who were followed up for 3 months, 14 received HCQ and NSAIDs and 20 received NSAIDs only. If the patients did not show improvement, they could be given low-dose oral corticosteroids, acetaminophen or tramadol. There were no significant differences between baseline characteristics of two groups except ESR (30.86 ±

23.35 mm/hr in HCQ and NSAIDs group vs. 13.16 ± 9.31 mm/hr in NSAIDs only, p=0.003). After 3 months, statistically significant reduction of TJC and VAPS were observed in both groups. Also, a statistically significant reduction of ESR was observed in the HCQ and NSAIDs group.

Conclusion: The results indicate that both HCQ and NSAIDs are effective for CRA. HCQ could be used for CRA patients with elevated ESR. This pilot study encourages future randomized controlled clinical trial for treatment of CRA.

1050

Characterization of Non-Hodgkin Lymphomas in Rheumatic Diseases. Vladimir I. Vasilyev. Research Institute of Rheumatology of RAMS, Moscow, Russia

Background/Purpose: Non-Hodgkin lymphomas (NHL) are 3 to 45 times more common in rheumatic diseases (RD) than in the general population. The spectrum of NHL varies in different studies.

To describe the most common types of NHL diagnosed in rheumatic patients from 2008 to 2010 in the Institute of Rheumatology of RAMS, Moscow.

Methods: One hundred and eighty five patients (female-148, male-27) aged 19 to 80 years (median-52 years) with various RD and predictors of NHL development (massive enlargement of lacrimal and salivary glands, cytopenia, lymphadenopathy, splenomegaly, monoclonal secretion) were conducted an oncohematological survey, including incisional biopsies with subsequent immunomorphological study, trephine biopsies and myelograms, T-and B-cell clonality determination by PCR in peripheral blood and tissue samples.

Results: One hundred and ten (65.5%) patients (primary Sjögren's syndrome (pSS)–58, rheumatoid arthritis (RA)–25, systemic scleroderma (SSD)-4 and chronic hepatobiliary diseases (CHD)-6) were diagnosed with NHL. The diagnosis of RD was withdrawn with subsequent identification of primary NHL in 8 cases, myeloproliferative diseases in 5 cases and primary AL-amyloidosis in 4 patients. B-cell NHL were found in 97 (88%) and T-cell in 13 (12%) patients respectively. Immunoglobulin-secreting variant of lymphoma was observed in 30 (29.7%) patients with NHL. In RA B-cell (48 %) and T-cell (52%) lymphomas were represented in equal proportions. Marginal zone lymphoma (MZL) was most frequently detected in pSS, SSD and CHD, whereas T-cell leukemia of large granular lymphocytes was more often diagnosed in RA (n=9). Plasma cell dyscrasia (PD) ranked second more frequent in pSS (n=5) and RA (n=5). T-cell splenic lymphoma (RA–4), chronic lymphocytic leukemia (pSS–1, RA–2) and diffuse large B-cell lymphoma (RA-1, pSS-2) were diagnosed less frequently. Seventeen (76.5%) of the 22 examined patients with RA, SSD and CHD had associated Sjögren's syndrome. Three patients simultaneously developed two types of NHL.

Conclusion: A prospective study has shown that low-grade MZL, PD, T-cell leukemia of large granular lymphocytes and γδ-T-cell splenic lymphoma are the most common in RD. Primary NHL, PD, AL-amyloidosis and myeloproliferative disorders often have clinical features similar to rheumatic diseases.

1051

Colchicine Halves, but Does Not Eliminate Recurrences in Pericarditis: Colchicine for Recurrent Pericarditis. A Randomized, Controlled Trial. A. Brucato[1], S. Maestroni[1], D. Cumetti[1], R. Cemin[2], S. Ferrua[3], R. Belli[4], D. H. Spodick[5], Y. Adler[6], R. Trinchero[4] and M. Imazio[4]. [1]Ospedali Riuniti, Bergamo, Italy, [2]San Maurizio Regional Hospital, Bolzano, Italy, [3]Savigliano Hospital, Rivoli, Italy, [4]Maria Vittoria Hospital, Torino, Italy, [5]St. Vincent Hospital, Massachusetts, [6]Sackler Faculty of Medicine, Tel-Aviv, Israel

Background/Purpose: Recurrences are the most common complication of acute pericarditis (20 to 50% of cases). Aim of this study is to evaluate the efficacy and safety of colchicine for the secondary prevention of recurrent pericarditis.

Methods: This is a prospective, randomized, double-blind, placebo-controlled, multicentric trial; 120 Italian patients with a first episode of recurrent pericarditis were enrolled. Patients were randomized to receive placebo or colchicine on top of a conventional treatment (aspirin, NSAIDs and/or corticosteroids). Colchicine was given at the dose of 1.0 to 2.0 mg for the first day followed by a maintenance dose of 0.5 to 1.0 mg daily for 6 months. The primary study end point was the recurrence rate at 18 months. The secondary end points were symptom persistence at 72 hours, remission rate at 1 week, number of recurrences, time to first recurrence, disease-related hospitalization, cardiac tamponade, and constrictive pericarditis rates.

Results: Colchicine significantly reduced the actuarial incidence of recurrences at 18 months compared to placebo (23.9% vs. 55.3%; p<0.001; number needed to treat-NNT 3). Colchicine also significantly reduced the symptoms persistence at 72 hours (23.3% vs. 53.3%; p=0.001), and the mean number of recurrences. Colchicine increased the remission rate at 1 week (81.7% vs. 48.3%; p<0.001) and prolonged the time to a subsequent recurrence. The rate of side effects and drug withdrawal were similar in the colchicine and placebo groups (respectively, 6.7% vs. 6.7% for side effects, 8.3% vs. 5.0% for drug withdrawal).

Conclusion: Colchicine is safe and efficacious for the secondary prevention of recurrent pericarditis. It halves recurrences, but does not eliminate them.

1052

EDTA Resistant S100A12 Complexes (ERAC) In Serum of Patients with Coronary Artery Disease (CAD) with and without Inflammatory Rheumatic Disease (IRD). Ivana Hollan[1], Anita Kåss[2], Torstein Lyberg[3], Sven M. Almdahl[4], Øystein T. Førre[3], Knut Mikkelsen[5] and Magne Fagerhol[3]. [1]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [2]Betanien Hospital, Skien, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]University Hospital of North Norway, Tromsø, Norway, [5]Lillehammer Hosp for Rheumatic Diseases, Lillehammer, Norway

Background/Purpose: ERAC is a recently discovered high molecular weight protein fraction containing the leukocyte derived protein S100A12. In contrast to most S100A12 complexes, these complexes do not dissociate after addition of EDTA. The purpose of this study was to compare the occurrence of serum ERAC positivity in patients with CAD with and without IRD, in IRD patients without CAD, and in healthy controls (HC).

Methods: We examined 4 groups involved in Feiring Heart Biopsy Study: patients with IRD referred to coronary artery bypass graft (CABG) (CAD+IRD), patients without IRD, referred to CABG (CAD-nonIRD), patients with IRD without CAD (IRD-nonCAD), and HC. ERAC was examined in serum by a quantitative rapid test based on monoclonal antibodies and lateral flow principle. ERAC positivity was defined as ERAC>4μg/L.

Results: There were no significant relationships between ERAC positivity and traditional cardiovascular risk factors, CRP and acute coronary syndromes. The relationship between ERAC and CAD-IRD remained statistically significant after the adjustment for group, age and gender (OR=3.9, 95%CI:1.2–12.9, p=0.024). In age- and sex- adjusted analysis of all patients with IRD, ERAC positivity was related to CAD (OR=9.9, 95%CI:2.4–41.0, p=0.002). Similar relationship, independent of RA activity and duration, was observed also within the RA subgroup. The HC patient with ERAC highly positive (49 years old, ERAC=10000) was diagnosed with CAD (requiring CABG) within 1 year.

Table 1.

	CAD+IRD (n=56)*	CAD-nonIRD (n=46)	IRD-nonCAD (n=29)**	HC (n=26)	p
Male sex, no. (%)	35 (63)	30 (65)	8 (28)	16 (62)	0.006
Age, mean±SD	67.7±10.0	67.5±8.7	58.2±9.9	57.3±9.6	<0.0005
ERAC positive, no. (%)^	27 (48)	5 (11)	4 (14)	5 (19)	<0.0005

* Patients with RA (n=21), giant cell arteritis/polymyalgia rheumatica (17), spondyloarthritis (14), connective tissue diseases (4). There was no significant difference in ERAC positivity between these IRD subgroups. ** Patients with RA. ^ ERAC>100 μg/L occurred in three (5.4%) CAD-IRD patients, in no CAD+IRD patients, and in 1(3.8%)HC.

Conclusion: Patients with CAD and IRD had higher occurrence of ERAC than patients with CAD or IRD only, and than HC. Within IRD patients, the occurrence of ERAC was related to CAD. Thus, ERAC might be a biomarker of CAD in IRD. Further studies on ERAC may increase insights into the pathogenesis of accelerated CAD in IRD.

1053

The Baseline Characteristics and Survival of Chinese Patients with Connective Tissue Disease Associated Pulmonary Arterial Hypertension. YanJie Hao[1], Wei Zhou[1], Xin Jiang[2], Yu Wang[1], Lan Gao[1], GuangTao Li[1], Tao Hong[1], Yong Wang[3], ZhiCheng Jing[2] and ZhuoLi Zhang[1]. [1]Peking University First Hospital, Beijing, China, [2]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China, [3]Beijing Shijitan Hospital, Capital Medical University, Beijing, China

Background/Purpose: Pulmonary arterial hypertension (PAH) is a severe complication of connective tissue disease (CTD) with a poor prognosis. There have been sporadic reports with respect to the clinical features and survival of CTD associated PAH (CPAH), however, those in Chinese with CPAH are unknown yet. The purpose of this study is to investigate the baseline characteristics, survival and risk factors of mortality in Chinese with CPAH.

Methods: All consecutive adult patients who visited the three medical centers with confirmed diagnosis of CPAH between July 2006 and May 2011 were enrolled into the study. For all these patients, PAH was confirmed by right heart catheterization.

Results: A total of 144 patients (40.6±12.6 years old) were included in the study and 44% of them were associated with SLE. The other underlying CTDs, in the descending rank order, are pSS (15%), Takayasu arteritis (12%), MCTD (10%), SSc (8%) and some others(RA 3%, PM/DM 2%, adult onset Still'disease 2%, UCTD 2%, primary APS 1%, and ANCA associated small vasculitis 1%).

The median duration between symptom onset and diagnostic catheterization was 16.5 months. At diagnosis, 57.6% of patients were in WHO functional class III/IV. The six-minute walk distance was 377.0±99.7m. Mean pulmonary artery pressure was 49.7±14.4mmHg. Eighty five percent of patients received vascular-targeted therapy.

One hundred and twenty-nine patients were followed up with a median duration of 15.8 months (ranged 1.1–55.1 months). The survival rates of these patients at 1 and 3 years were 87.8% and 53.8%. The survival rates of patients with SLE associated PAH at 1 and 3 years were 90.0% and 57.1%.

Univariate Cox analysis showed shorter 6-min walk distance, lower cardiac output, cardiac index and mixed venous oxygen saturation, higher pulmonary vascular resistance (PVR), alkaline phosphatase (ALP), total bilirubin and direct bilirubin, lower total cholesterol and low-density lipoprotein were associated with high risk of death (all $p<0.05$). Multivariate Cox analysis showed higher PVR and ALP were independent predictors of mortality [HR were 1.10 (1.01–1.20) and 1.01(1.00–1.02) respectively, both $p<0.05$]. K-M analysis demonstrated the survival rate in PVR<15 wood unit group was higher significantly than that in ≥15 wood unit group (p=0.009), and the survival rate in ALP<150U/L group higher than that in ≥150 U/L group (p=0.012).

Conclusion: SLE was the most common underlying disease of CPAH in China; however, SSc-associated PAH was fewer in Chinese patients, which were much different from Caucasians. The survival of Chinese patients with CPAH at 1 and 3 years were 87.8% and 53.8%. Furthermore, elevated PVR and ALP were independent risk factors of bad outcomes.

1054

Overrepresentation of Lifestyle Associated Risk Factors Along the Spectrum of Rheumatic Disease. Inger L. Meek[1], H.S.J. Picavet[2], Harald E. Vonkeman[1] and Mart AF van de Laar[3]. [1]Rheumatology Center Twente, Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [2]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [3]Medisch Spectrum Twente & Twente University, Enschede, Netherlands

Background/Purpose: Over the past decades many reports have shown an association between rheumatoid arthritis (RA) and increased cardiovascular morbidity and mortality. This association is thought to be due to clustering of lifestyle associated cardiovascular risk factors in patients with RA, the chronic inflammatory disease process itself, as well as the use of medication such as non steroidal anti-inflammatory drugs (NSAIDs) and disease modifying anti-rheumatic drugs (DMARDs). Information on cardiovascular risks in patients with other chronic rheumatic diseases is lacking, although they might be exposed to similar pathofysiological processes.The aim of this study was to compare the prevalence of lifestyle associated cardiovascular risk factors among the three major disease categories attending a rheumatology outpatient clinic; RA, gout and osteoarthritis (OA), and the general population.

Methods: Comparison of individual lifestyle associated cardiovascular risk factors, i.e. hypertension, hypercholesterolemia, low HDL cholesterol, overweight (BMI > 25 kg/m^2), obesity (BMI > 30 kg/m^2) and smoking habits between the three major disease categories; RA (n=546), gout (n=129), and OA (n=168) in a cohort of all consecutive patients between 36 and 75 years of age attending the Arthritis Center Twente (ACT), a large rheumatology outpatient department in The Netherlands (n=1233), and a sample of the general population (GP) from the same geographic region (n=4523). Data were collected by direct measurements in 2009 (ACT), and from 2003 to 2007 (GP) respectively. Analyses were sex-specific and standardised by age.

Results: Compared to the GP, rheumatology outpatients have a relative higher prevalence of hypertension (P_{ACT}=68%, $P_{general}$=53%), overweight (P_{ACT}=72%, $P_{general}$=62%), obesity (P_{ACT}=30%, $P_{general}$=17%) and smoking (P_{ACT}=26%, $P_{general}$=21%) ($p<0.05$). Hypertension, overweight and obesity were overrepresented in all three major chronic disease categories, with a strong association between overweight and obesity and gout (overweight OR_{gout}8.6, OR_{RA}1.2, OR_{OA}2.1; obesity OR_{gout}4.2, OR_{RA}1.4, OR_{OA}2.5). There were specific associations between RA and smoking (OR 1.5; 95%CI 1.2–1.6), gout and hypercholesterolemia (OR 2.2; 95%CI 1.6–3.3) and lowered HDL cholesterol (OR 2.9; 95%CI 1.8–4.5), and OA and hypercholesterolemia (OR 2.3; 95%CI 1.7–3.2).

Conclusion: lifestyle associated cardiovascular risk factors are overrepresented along the whole spectrum of chronic rheumatic diseases. Risk factor patterns appear to be disease specific.

Subclinical Atherosclerosis In Inflammatory Rheumatic Diseases. Dan Nemes[1], Mihai Dragoi[1], Liliana Catan[1], Elena Amaricai[1], Daniel Popa[1], Roxana Onofrei[1], Dan Surducan[1], George Puenea[1], Elena Sarbu[2], Andreea Iana[2], Mihaela Muntean[2], Rodica Mihaescu[2], Rares Olariu[2] and Camelia Nemes[2]. [1]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [2]City Universitary and Emergency Hospital, Timisoara, Romania

Background/Purpose: Increased cardiovascular morbidity and mortality in rheumatic patients cannot be entirely explained by traditional cardiovascular risk factors, suggesting that the systemic inflammation may accelerate atherosclerosis. The aim of the present study is to link chronic inflammation with atherosclerosis in patients with systemic rheumatic diseases.

Methods: The cohort study was performed during an eighteen-month period (between November 2009 and April 2011) and enrolled 200 patients with systemic rheumatic disorders. Patients' mean age was 55.4 ± 8.18 years. 67 patients from this cohort group were selected. Subclinical atherosclerosis was assessed by the common carotid intima-media thickness (IMT) and flow mediated vasodilatation (FMD) of the brachial artery on B-mode ultrasound images, with the use of a 10 MHz linear-array transducer.

Results: Mean value of IMT at the right common carotid was 0.9 ± 0.19mm and at the left common carotid 0.9 ± 0.34mm. FMD was 8.0 ± 5.77%. ESR (Erythrocyte sedimentation rate) was increased in 80% patients, while CRP (C-reactive protein) was increased in 50% of the studied patients. We found a negative correlation between FMD and ESR (r= −0,397) or CRP (r= −0,628). Mean values of IMT was associated with ESR (r= 0,276) and CRP (r= 0,613). Disease activity was correlated with endothelial dysfunction as measured by intima-media thickness or by flow-mediated dilatation.

Conclusion: In our study we found an increased endothelial dysfunction as measured by intima-media thickness or by flow-mediated dilatation. Endothelial dysfunction was correlated with elevated levels of ESR and CRP suggesting that chronic inflammatory status promotes atherosclerosis. Disease activity was correlated with endothelial dysfunction as measured by intima-media thickness or by flow-mediated dilatation.

1056

Nontuberculous Mycobacterial Infections In Rheumatological Diseases. Vivek Nagaraja[1], Joel A. Terriquez[2], Susan E. Hoover[2] and Jeffrey R. Lisse[2]. [1]University of Arizona/University Physicians Healthcare at Kino Campus, Tucson, AZ, [2]University of Arizona, Tucson, AZ

Background/Purpose: Non-tuberculous mycobacterial (NTM) infections are frequently identified in patients with rheumatologic disease, and management of these infections can be challenging. The aim of this study was to describe the management and outcomes of cases of NTM infections in patients with any form of rheumatologic disease at two healthcare facilities.

Methods: We performed a retrospective chart review of inpatient and outpatient records at two health-care facilities. ICD-9 diagnostic codes were used to identify patients with NTM infection, and patients with any pre-existent rheumatologic disease were included in the study. Chart review focused on rheumatologic disease and its treatment, other co-morbidities, the NTM infection and its treatment, and impact of the infection on the rheumatologic disease management and outcome.

Results: Of 339 patients with NTM infection, 11 with rheumatologic disease were identified. Ten were females, with a median age of 67 years at the time of diagnosis of the infection. Eight cases were pulmonary and 3 were extrapulmonary. 5/11 patients had radiologically pre-existent bronchiectasis. There were five patients with rheumatoid arthritis, two patients with systemic

lupus erythematosus and one patient each with polymyalgia rheumatica, scleroderma, polymyositis, and sarcoidosis. Patients were on the following immunosuppressive medications for a significant period of time (3–5 years): prednisone (7/11), methotrexate (4/11), and anti-tumor necrosis factor (TNF) agents (3/11). Two patients were not on any immunosuppressive medications. In 4/9 cases who were on immunosuppressive therapy, the implicated medication was discontinued. In 3/9 it was continued, and in 2/9 it was restarted after a brief discontinuation. *Mycobacterium avium* complex was the commonest species isolated. Treatment for NTM infection was started in 8/11 patients based on severity and patient's choice. 2/8 patients had recurrence of the NTM infection after completion of antibiotic therapy, both while receiving concomitant immunosuppressive therapy. 3/11 patients died, with no death directly related to NTM infection.

Conclusion: This is the first study to describe the natural history of NTM infections in a rheumatologic disease population. As in the general population with NTM infection, patients tended to be female and have pre-existing bronchiectasis. The infection could often be successfully treated, but there appears to be some risk of recurrence in patients who are continued on immunosuppressive therapy. Because NTM infection and rheumatologic disease may have a predilection for the same patient population, such cases will likely continue to be identified and more study of the optimal management is needed.

A Meta-Analysis: Diagnostic Accuracy of Serum Procalcitonin Concentrations for Detecting Systemic Bacterial Infection In Patients with Rheumatic Diseases. Yoshinori Kogata, Daisuke Sugiyama, Akira Onishi, Ikuko Naka, Kosaku Tsuda, Keisuke Nishimura, Kenta Misaki, Goichi Kageyama and Akio Morinobu. Kobe university graduate school of medicine, Kobe, Japan

Background/Purpose: Procalcitonin (PCT) is reported as a useful serum marker for detection of systemic bacterial infection in variety of clinical settings. We previously reported diagnostic accuracy of PCT for systemic bacterial infections in patients with rheumatic diseases in the annual scientific meeting of American College of Rheumatology in 2006. In our study, sensitivity and specificity was 50.0% and 94.1%, respectively. And the area under the curve (AUC) of summary receiver-operating characteristic (sROC) curve for PCT was 0.861.

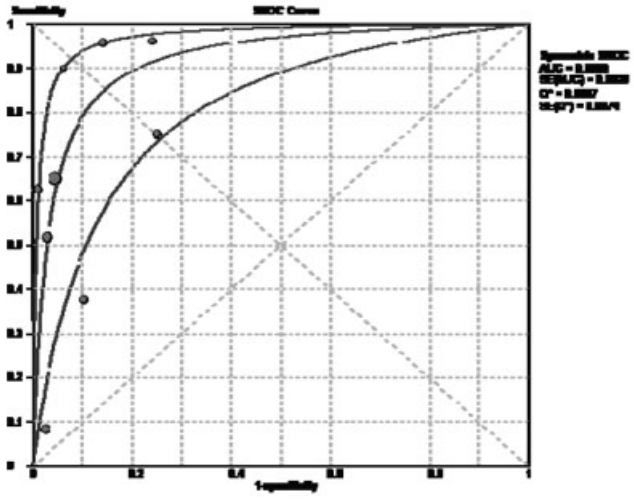
However, it is still controversial that clinical use of PCT for systemic bacterial infection in patients with rheumatic diseases. The reported diagnostic accuracy of PCT varies from study to study and their usefulness remains uncertain among the patients with rheumatic diseases. The relative rareness of rheumatic diseases has resulted in the samples for all studies being small so that no quantitative comparisons have been made of PCT for bacterial infection in patients with rheumatic diseases. We therefore systematically conducted this meta-analysis for PCT to quantitatively clarify its diagnostic accuracy of PCT.

Methods: Literature search were performed by MEDLINE (through March 7th, 2011), reference lists of retrieved studies and review articles. Included were studies in any language that examined the role of PCT in the diagnosis of adult patients with rheumatic diseases and that provided enough data to permit the calculation of sensitivity and specificity for diagnosing systemic bacterial infection. Two reviewers independently evaluated studies for inclusion, rated methodological quality, and extracted relevant data. Weighted sensitivity and specificity and an AUC of sROC curve were calculated. Meta-regression was used to identify the source of heterogeneity.

Results: We used a meta-analytic method to construct a sROC curve. Nine studies met the inclusion criteria and they involving 551 patients were relevant for the diagnostic accuracy of PCT. The diagnostic accuracy of the PCT was high, with an AUC from sROC of 0.920 (95% CI, 0.918–0.922) for patients with systemic infection. The pooled sensitivity, specificity and diagnostic odds ratio were 0.66(95% CI, 0.58–0.74), 0.94(95% CI, 0.91–0.96), and 25.1(95% CI, 11.3–55.9), respectively.

There was no heterogeneity among studies. (Cochran Q=10.9, P=0.2, I-square=26.6%)

Conclusion: Serum procalcitonin concentration showed good diagnostic capability for systemic bacterial infection among the patients with rheumatic diseases.



1058

Nutritional Deficiencies Linked to Nonspecific Complaints of Joints, Skin, and Nervous System in a University-Based Rheumatology Clinic; A Retrospective Chart Review. Shawn Macalester. University of Virginia, Charlottesville, VA; Authors: Shawn Macalester, Shikha Sarebahi, Donald L Kimpel

Background/Purpose: Nutritional and immune disorders in the context of gastrointestinal bypass surgeries and bacterial overgrowth have been linked to a variety of arthritic, dermal, and neurologic manifestations, potentially via an immune mediated process. It has been suggested that this complication of weight loss surgery was eliminated by the performance of gastric bypass procedures in place of small intestinal bypass. We carried out a two-step approach to assess 1) nutritional deficiencies, and 2) the prevalence of gastric bypass surgeries and bacterial overgrowth in this group.

Methods: A retrospective chart review was performed in individuals referred to the UVA Rheumatology clinic for nonspecific complaints including arthralgias, diffuse pain, and fatigue in order to evaluate for an enteropathic etiology and define potential areas for future intervention. Seventy three patients were evaluated in the clinic who had arthritic symptoms, and also complained of additional symptoms that could be related to gastrointestinal disorders or to malabsorption, including diarrhea, abdominal bloating and pain, Raynaud's phenomenon, sicca symptoms, muscle weakness, numbness, and tingling. These symptoms are relatively common in rheumatologic diseases as well as fibromyalgia, and symptoms could be attributed to diagnoses such as Celiac Sprue, Whipples disease, inflammatory bowel disease and post gastric bypass syndrome. We analyzed the patient results for common nutritional deficiencies, and where appropriate, for underlying gastrointestinal disorders. This group of 73 patients were tested for vitamin B1, B6, B12, 25-hydroxy-Vitamin D (D2+D3), and Serum Folate levels.

Results: Of the individuals tested, 60.3% were found to have vitamin B1 deficiency, 46.6% had B6 deficiency, 8.2% vitamin B12 deficiency, 6.8% folate deficiency, and 67.1% vitamin D deficiency. Strikingly, 30% of those evaluated had Roux-en-Y gastric bypass surgery and of those, 11 individuals underwent hydrogen breath testing for bacterial overgrowth and 9 of the 11 (81%) tested positive consistent with small intestine bacterial overgrowth (SIBO).

Conclusion: This study brought attention to common nutritional deficiencies which may lead to consultation in a rheumatology clinic, and the potential contribution of gastric bypass surgery. Further evaluation for causes of these deficiencies is indicated to evaluate for other causes such as celiac sprue. Patients with documented bacterial overgrowth, in this case associated with gastric bypass, are at risk for development of immune and nutritional disorders previously described in patients with jejunoileal small bowel bypass performed for weight loss. Our understanding of the role of gastric flora and gut-associated lymphoid tissue (GALT) on health, nutrition, and the immune system, is in its infancy. Further study to evaluate the effects of vitamin replacement, probiotics, or antibiotic treatment for bacterial overgrowth will be important.

Vitamin D Deficiency in Patients with Systemic Lupus Erythematosus and Rheumatoid Artrhitis in a Tropical Country. Claudia D.L. Marques, Thiago Sotero Fragoso, Andrea Tavares Dantas, Aline Jurema G. Costa, Henrique A. Mariz, Aline Ranzolin and Angela Luzia B. P. Duarte. Hospital das Clínicas - Universidade Federal de Pernambuco, Recife - PE, Brazil

Background/Purpose: In recent years, vitamin D has been target of an increasing number of studies which have shown that, besides its role in calcium metabolism and bone formation, it interacts with the immune system through its action on the regulation and differentiation of immune cells. Current studies have linked vitamin D deficiency with multiple autoimmune diseases, emphasizing its participation in the pathogenesis, treatment and activity of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). In Brazil, a tropical country, studies on vitamin D deficiency in patients with RA and SLE are limited, and previous studies have shown that in our country the vitamin D deficiency occurs even in normal individuals, despite the high rate of solar incidence. The objectives of this study was to determine serum levels of 25-hydroxyvitamin D_3 (25(OH)D) in RA and SLE patients and verify the association of insufficiency/deficiency of 25(OH)D with clinical parameters and laboratory tests.

Methods: A cross-sectional and prospective study, between April 2009 and March 2010. Recife, capital city of Pernambuco's state – Brazil, where the study was performed, has a tropical climate, hot and humid, with average annual temperature of 25.2 ° C. The city is located at latitude 8° 04 '03''S and longitude 34° 55' 00''O, with high rates of insolation throughout the year. We included 78 patients with SLE, 58 with RA and 79 health volunteers (comparison group).

Results: It was found insufficiency/deficiency 25(OH)D (<30 ng/mL) in 43/78 (55.1%) patients with SLE, in 21/58 patients with RA(36.2%) and 32/79 (40.5%) in the comparison group. The mean serum levels of 25(OH)D were 29.8 ng/mL in patients with SLE, 33.9 ng/mL in AR group and 33.40ng/mL in comparison group. The difference between the LES group was statistically significant when compared with both group AR ($p=0.11$) and comparison group ($p=0.026$). There was no statistically significant difference in the mean vitamin D serum levels of the RA and comparison group, and there were no statistically significant association between the time of diagnosis, the clinical parameters of activity or treatment in the LES or AR group.

Conclusion: There was a high prevalence of insufficiency/deficiency of 25(OH)D in patients with SLE (55.1%) who had significantly lower serum levels of 25(OH)D than in the AR or comparison group. Thus, taking into account the multiple "roles" of vitamin D, we emphasize the importance of determination of serum 25 (OH) D in all patients with SLE regardless where they live and the time of diagnosis.

Predictors of Outcomes of Total Knee Replacement Surgery. Andrew Judge[1], Nigel K. Arden[2], Cyrus Cooper[3], M. Kassim Javaid[2], Andrew Carr[1], Richard E. Field[4] and Paul A. Dieppe[5]. [1]Oxford University, Oxford, United Kingdom, [2]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, UK, Oxford, United Kingdom, [3]Southampton General Hospital, Southampton, United Kingdom, [4]Elective Orthopaedic Cnetre, Epsom, United Kingdom, [5]University of Exeter, Plymouth, United Kingdom

Background/Purpose: Total knee replacement (TKR) is, on average, an effective and cost-effective intervention for severe arthritis. However, a significant minority of patients are dissatisfied with the outcome and have persistent joint pain and disability.

The aim of this study was to identify pre-operative predictors of those who have poor outcomes after a TKR.

Methods: We analysed data from a large prospective cohort of patients undergoing a TKR in the UK. Pre-operative data was available on: age, gender, BMI, diagnosis, Oxford Knee Score (OKS), EQ-5D, ASA status as a proxy for general health, and socio-economic status. The primary outcome measure was the 6-month post-operative OKS. We calculated a patient-acceptable symptom state (PASS) by relating OKS outcomes to patient satisfaction with the surgery. Regression modelling was used to identify predictors of outcome.

Results: Full data were available from 1991 patients (mean age 71.7 years, 61% female). The majority improved after surgery, but in some there was either no change or worsening of the OKS score. Using a cut-point of a post-operative OKS of 30 points or more, we identified that 71.7% had achieved an acceptable PASS.

The strongest determinant of outcome was pre-operative pain and function (less severe patients had the best outcomes, multivariate ANCOVA 1.70, 95% confidence intervals 1.43–1.96)). Other significant predictive factors included diagnosis (those with RA did better than those with OA), socio-economic status (poor status associated with a poor outcome), anxiety and depression, age and sex. BMI was not an important predictor of outcome. Differences were observed between predictors of pain relief and functional gain. Those with OA and anxiety or depression were most likely to have post-operative pain; women, older people were most likely to have a poor functional outcome. However, less than 20% of the variance in outcome was explained by the variables in the model.

Conclusion: Predictors of the pain response to a TKR maybe different from those predicting functional improvement. Although significant predictors of poor pain or functional outcomes were detected in this study, the majority of the variance remained unexplained; other predictive factors need to be identified to improve our ability to select the patients who are most likely to improve.

Pain After Hip or Knee Joint Replacement for Osteoarthritis: A Systematic Review. Andrew Beswick[1], Vikki Wylde[2], Ashley Blom[2], Rachael Gooberman-Hill[1] and Paul A. Dieppe[3]. [1]University of Bristol, Bristol, [2]University of Bristol, Bristol, United Kingdom, [3]University of Exeter, Plymouth, United Kingdom

Background/Purpose: The view of the public, encouraged by orthopaedic surgeons, is that total hip or knee joint replacement (TJR) nearly always relieves the pain of osteoarthritis (OA). TJR is indeed highly successful when judged by prosthesis related outcomes, such as the radiographic appearance of the prosthesis, implant survival, or surgeon assessed outcomes. Nevertheless, registry data show that many people are dissatisfied with the outcome, and it is clear that some patients continue to experience severe pain.

The aim of this study was to establish the frequency of moderate or severe pain in the operated joint after TJR.

Methods: We conducted a systematic literature review to identify longitudinal studies reporting the proportion of people with significant long-term pain after total hip or knee replacement. To reduce the biases of loss to follow-up or highly selected patient groups, the only reports included were those that were prospective studies of consecutive or generally unselected osteoarthritis patients with total hip or knee arthroplasty followed for 3 months to 5 years that reported a patient-centred pain outcome. MEDLINE and EMBASE databases were searched from inception to January 2011. Citations of key articles in ISI Web of Science, and reference lists were checked. Two authors screened titles and abstracts. One author extracted data and this was checked independently against original articles by a second. We summarised the proportions of people with different severities of pain in the operated hip or knee.

Results: Searches identified 1308 articles of which only 119 reported patient-centred pain outcomes in representative populations followed for 3 months to 5 years. Fourteen articles describing 17 cohorts (6 in hip and 11 in knee patients) presented appropriate results, but the diversity of outcome measures reported and their interpretation precluded meta-analysis. Studies excluded from analysis mainly presented outcomes as mean values only. Applying the conservative assumption that patients in whom the outcome was unclear had a similar distribution of pain, an unfavourable pain outcome (moderate or severe pain in the operated joint) was reported in 7 to 23% of hip and 10 to 34% of knee arthroplasty patients.

Conclusion: For many people, total hip or knee arthroplasty is an effective treatment for OA pain. However a significant proportion of people continue to have painful joints after surgery. There is an urgent need to improve general awareness of this, and to address the determinants of good and bad outcomes.

1062

Efficacy of Total Arthroplasty Combined with Anti-Tumor Necrosis Factor Agents on Systemic Disease Activity in Patients with Rheumatoid Arthritis. Masatoshi Hayashi[1], Toshihisa Kojima[2] and Naoki Ishiguro[3]. [1]Nagoya University Graduate School, Nagoya, Japan, [2]Nagoya Univeristy, School of Medicine, Nagoya, Japan, [3]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan

Background/Purpose: To assess the effect of total large-joint arthroplasty combined with anti-tumor necrosis factor (TNF) therapy for rheumatoid arthritis (RA).

Methods: We studied 45 RA patients (age: 57.91 ± 12.74 years, RA duration: 13.43 ± 8.28 years) who underwent 58 total arthroplasties (35 knees, 19 hips, 3 elbows, and 1 ankle) between August 2002 and November 2009. All received anti-TNF agents during their operative periods (infliximab, 22; etanercept, 33; adalimumab, 3). Changes in clinical variables in 58 cases were investigated at baseline (just before operation), and at 4, 12, and 52 weeks after operation. We assessed means of DAS28-ESR in all patients and divided all into 2 equal groups (n = 29, each) based on the median of CRP and MMP-3 at baseline.

Results: Means of DAS28 in all patients significantly improved from baseline (4.32 ± 0.99) to 1 year after operation (3.35 ± 0.93) in contrast with the fact that the average values of DAS28 remained unchanged from 1 year before the operation to the baseline. Average values of CRP, ESR, and MMP-3 in all operations improved relative to baseline in a time-dependent manner, and were lowest 1 year after the operation (Table 1). Improvement of CRP was statistically significant ($P = 0.016$). Compared with high value groups, those with low CRP and MMP-3 values gained better results and reached low disease activity on an average (Table 2).

Table 1. Values of CRP, ESR and MMP-3 in all TNF blockers (n=58 operations) at baseline, 4w, 12w and 52w after operations

	Baseline		4w		12w		52w	
	Mean	SD	Mean	SD	Mean	SD	Mean	SD
CRP (mg/dl)	1.71	2.48	1.72	2.35	1.28	2.03	0.90*	1.08
ESR (mm/h)	40.34	28.81	44.81	25.85	39.13	25.74	34.43	23.02
MMP-3 (ng/ml)	230.79	242.32	181.13	174.51	197.55	209.61	165.98	145.75

* denotes significant difference from baseline. $P < 0.05$.
CRP C-reactive protein, *ESR* erythrocyte sedimentation rate, *MMP-3* matrix metalloproteinase-3, *TNF* tumor necrosis factor, *SD* standard deviation

Table 2. DAS28 of low and high groups devided by median of each CRP and MMP-3 at baseline

	Median	Group	Baseline DAS		DAS+1Y		DAS+1Y*f*3.2 (%)
			Mean	SD	Mean	SD	
CRP	0.52 (mg/dl)	low	3.93	0.87	3.00**	0.74	70.0##
		high	4.96	0.84	3.83*	0.99	11.1
MMP-3	136 (ng/ml)	low	3.97	0.92	2.95**	0.72	60.0
		high	4.65	0.97	3.80*	0.96	22.2

*,** denotes significant difference from baseline. *: $P < 0.05$. **: $P < 0.01$.
denotes significant difference from high group. $P < 0.01$.
DAS disease activity score, *DAS+1Y* DAS28 1 year after operation

Conclusion: Overall, the DAS28 of both the groups improved 1 year after operation. Large joint arthroplasty may be beneficial in RA patients using anti-TNF agents not only for pain relief from destructive joints but also for systemic improvement in RA activity.

1063

Peptic Ulcer Disease Is Associated with Periprosthetic Fractures After Total Hip Replacement. Jasvinder A. Singh[1] and David Lewallen[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Mayo Clinic College of Medicine, Rochester, MN

Background/Purpose: To assess if medical comorbidity is associated with risk of periprosthetic fractures after total hip replacement (THR).

Methods: We used the prospectively collected data from 1989–2008 in the Mayo Clinic total joint registry for two cohorts, primary THR and revision THR. Main variables of interest were Deyo-Charlson comorbidities at the time of the surgery. Outcome of interest was postoperative periprosthetic fracture at postoperative day one onwards. Multivariable Cox regression models additionally adjusted for gender, age, body mass index, American Society of Anesthesiology (ASA) class and operative diagnosis.

Results: We identified 14,065 primary THRs and 6,281 revision THRs with mean follow-up of 6.3 and 5.6 years respectively. There were 305 postoperative periprosthetic fractures in primary THR and 330 in revision THR cohort. In patients who underwent primary THR, two comorbidities were associated with higher risk of periprosthetic fracture: peptic ulcer disease with adjusted hazard ratios of 1.68 (95% confidence interval (CI): 1.16, 2.42; p=0.006); and cardiac disease with adjusted hazard ratio of 1.51 (95% CI: 1.07, 2.15; p=0.02). In patients with revision THR, peptic ulcer disease was associated with higher adjusted hazard of periprosthetic fracture, 1.58 (95% CI: 1.10, 2.29; p=0.015).

Conclusion: Peptic ulcer disease and cardiac disease in primary THR and peptic ulcer disease in revision THR patients were significantly associated with higher postoperative periprosthetic fracture risk. Further studies are needed to understand whether disease severity or specific medications used for treatment or both are responsible for this association. This may allow identification of modifiable factors amenable to interventions.

1064

Prognostic Factors for Surgical Intervention After Steroid Induced Avascular Necrosis of the Femoral Head. Ryo Hiroshima[1], Katsunori Ikari[1], Ikuko Masuda[2] and Shigeki Momohara[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]International University of Health and Welfare, Sanno Hospital, Tokyo, Japan

Background/Purpose: The MR imaging classification system of osteonecrosis proposed and revised in 2001 by the Japanese Investigation Committee characterizes osteonecrosis of the femoral head with respect to the size and location on T1-w imaging. We evaluated the prognostic value of the MR imaging classification in patients undergoing surgical intervention after avascular necrosis of the femoral head associated with connective tissue disease in Japanese patients.

Methods: We applied the MR imaging classification in 146 hips (104 patients; 87 % of the patients were female, 40% had bilateral AVN, the mean age of the patients at the diagnosis was 37.9 years and the mean observational period was 6.25 years) with connective tissue disease diagnosed with avascular necrosis of the femoral head (AVN). The classification is based on the extent of the lesion of low-signal-intensity or normal fat signal intensity demarcated by a low-signal-intensity band in the central coronal section of the femoral head as observed on T1-w images. The image consists of four types (A, B, C1, and C2): Type A, lesions occupying the medial one-third or less of the weight-bearing portion; Type B, lesions occupying the medial one-third to two-thirds; Type C1 and C2, lesions occupying more than two-thirds, in which type C2 lesions extend laterally to the acetabular edge while type C1 lesions do not. To define the prognostic factors for future surgical intervention after AVN, Cochran-Armitage trend test and multivariate logistic regression analysis (dependent variables: MRI classification, gender, age at diagnosis, unilateral or bilateral AVN, history of steroid pulse therapy and arthrodynia on the diseased hips) were performed.

Results: Regarding lesion volume and location, 12 hips were type A, 36 hips were type B, 56 hips were type C1, and 42 hips were type C2. Among them, 0/12 hips, 2/36 hips, 16/56 hips and 22/42 hips had future surgical intervention, respectively for type A, B, C1 and C2 ($P=5.0^{-7}$ by trend test). The results of the multivariate logistic regression analysis indicate that types C1 and C2 of the MRI classification (P=0.001, OR=11.6 [95%CI 2.6–52.7]) and bilateral cases (P=0.049, OR=2.7 [95%CI 1.0–7.1]) were associated with future surgical intervention after AVN.

Conclusion: Type C (C1 and C2) on the MR imaging classification at the time of diagnosis of AVN and bilateral AVN cases are the risks for future surgical intervention after diagnosis of AVN.

1065

Relationship Between Synovitis and Two-Year Post-Surgical Outcomes in Patients Undergoing Arthroscopic Partial meniscectomy. Carla R. Scanzello[1], Edward F. DiCarlo[2], Veero Kanda[1], Anthony Albert[3], Steven R. Goldring[2], John C. Richmond[3] and Brian McKeon[4]. [1]Rush University Medical Center, Chicago, IL, [2]Hospital for Special Surgery, New York, NY, [3]New England Baptist Hospital, MA, [4]New England Baptist Hospital, Boston, MA

Background/Purpose: In established OA, the presence of synovitis is associated with pain and progression of disease. We previously demonstrated that synovitis is also associated with worse pre-operative symptoms in patients undergoing arthroscopic partial meniscectomy, even in the absence of radiographic OA. Synovial inflammation in these patients was associated with expression of CCL19 and CCR7. Despite no radiographically evident disease,

the majority (80%) of these patients had intra-operative evidence of early-stage OA. The present study is the longitudinal follow-up of these patients to test whether synovial inflammation predicts progressive knee symptoms up to 2 years post-operatively.

Methods: Thirty-three patients undergoing athroscopic partial meniscectomy were recruited from Orthopedic practices at the New England Baptist Hospital. Synovial biopsies were taken at the time of surgery, and inflammation was previously scored on H&E stained sections using our published histologic scale based on the extent of perivascular lymphocytic infiltration. Symptoms were measured by the Lysholm score (a questionnaire measuring knee-specific symptoms and dysfunction) pre-operatively, at 16 weeks, 1 year and 2 years post-arthroscopy. Synovial chemokine expression was determined by quantitative real-time pcr.

Results: There were significant improvements from the pre-operative baseline Lysholm scores at all three post-operative time points (Kruskal-Wallis $p<0.0001$), with a mean (+/−SD) improvement at 2 years of 27 (+/−16) points. Despite having worse pre-operative Lysholm scores (Mann Whitney $p= 0.0008$), patients with synovial inflammation did not generally have worse Lysholm scores compared to patients without inflammation in follow-up ($p>0.05$). Patients with synovitis showed greater mean improvement in Lysholm scores at 16 week and 1 year ($p = 0.02$ and $p=0.03$), but only a trend by 2 years ($p=0.054$) compared to patients without synovial inflammation. mRNA relative expression levels of CCL19 and CCR7 were also associated with greater improvements in Lysholm scores at the 16 week (CCL19: Spearman $r=0.71$, $p = 0.049$; CCR7: $r = 0.71$, $p = 0.02$), and 2 year timepoints (CCL19: $r= 0.85$, $p = 0.004$; CCR7: $r = 0.79$, $p = 0.002$).

Conclusion: In this cohort of patients with meniscal tears and pre-radiographic OA undergoing arthroscopic partial meniscectomy, synovitis identified histologically did not predict worse Lysholm scores up to 2 years post-operatively. Patients with inflammation, measured both histologically and by expression of CCL19 and CCR7, demonstrated greater symptom improvement which was significant at multiple follow-up time points, indicating that these patients may be more responsive to surgical intervention. Radiographic evidence of OA at the time of arthroscopy has been associated with poorer outcomes. It is possible that in this radiographically normal population, longer follow-up is needed to identify patients who develop progressive knee symptoms after surgical intervention for meniscal tears.

Ultrasound Guided Hip Joint Injection, Its Safety and Efficacy. Srijana Pandit[1], Charles H. Pritchard[2], Elana Eisner[2] and Mary Naglak[1]. [1]Abington Memorial Hospital, Abington, PA, [2]Rheumatic Disease Associates, Willow Grove, PA

Background/Purpose: Osteoarthritis (OA) is a leading cause of disability and the most common joint disorder in United States. Intra-articular hip injections is one of the treatment modalities for OA which is challenging because the joint lines are not palpable and the femoral nerve, artery and veins lie in the close proximity to the anterior hip joint. For many years intra-articular hip injection has been done under fluoroscopic guidance for direct visualization and confirmation may requires iodized contrast. Disadvantages to this include frequent radiologic referral, the need for the patient to transfer to another facility, use of ionizing radiation and cost. The literature has documented the safety and effectiveness of this procedure in the outpatient setting using ultrasound (US). US visualize the hip joint well and can perform accurate and safe musculo-skeletal fluid aspiration and injection.

Methods: We evaluated 85 patients who underwent US guided arthrocentesis in one rheumatology center during the period of January 2009 to August 2010. Most patients received triamcinolone 40 mg and 2–4 cc of lidocaine. The time frame of a pain relief and the presence of adverse reaction were evaluated by subsequent chart review. Several patients had multiple hip joint injections; each injection was counted. There were 120 total numbers of injections. Patients with chronic pain syndrome, patients with trochanteric bursitis and patients with low back pain were excluded from the study. Data was summarized using descriptive statistics including means and frequencies. US machine used was a GE Logiq e with a LA 5–13 MHz probe.

Results: We had 85 patients with 120 injections, 72.9 % (n=62) were female with mean age of 67.44 years and mean BMI of 31.1. 64.2 % (n=77) were right hip injections compare to 32.5% (n=39) on the left and only 3.3 % (n=4) were both hip joint injections. 87.05 % (n=74) of the patients were on pain medication with NSAIDS being the most common followed by tramadol and others were on combination of the NSAIDS, tramadol, fentanyl patch or oral opoids. Out of 120 injections 73.3 % (n=88) had a pain relief, 16.7 % (n=20) had no relief, 10 % (n=12) were lost in follow up. 20 patients who had no pain relief were later found to have other causes e.g. trochanteric bursitis or back pain. A total of 42 %(n= 37) had pain relief period of 1 –3 months, 26 % (n= 23) had pain relief period of 3–6 months, 12.5 % (n= 11) for 6–12 months, 16 %(n= 14) for >1 year, 3.5 % (n=3) patient had a pain relief of <1 month. 31% (n=26) of 85 patient underwent joint replacement. Only one patient complained of difficulty managing her blood sugar. No signs of infection, bleeding, increase in blood pressure or OA flare were noted.

Conclusion: We evaluated the safety and efficacy of the US guided hip joint injection on 85 patients (120 injections**)**. This retrospective study concludes that the US guided hip joint injection is safe and efficacious. There was no complication documented except for one patient complaining of elevated blood sugars. Two third of the patient had a pain relief period of 1–6 months and those who did not have pain relief were found to have some other source of pain mainly trochanteric bursitis and back pain. Most of the patient was female and most of the injection was done in the right side.

Pilates to Treat Chronic Non-specific Low Back Pain. Jamil Natour, Andreia S. Baptista, Luciana A. Cazotti, Luiza H. C. Ribeiro and Anamaria Jones. Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Background/Purpose: Low back pain (LBP) is a common problem among adults. Approximately 70–85% of the adult population experiences this painful complaint at some point in their lives, making LBP the second most common reason for a visit to a clinician. Despite the frequency of this diagnosis, conventional treatment does not always provide patients the desired results of reduced pain and return of normal function. For these patients, alternative modalities are available to assist in the control of pain. These options include chiropractic care, physical therapy, massage therapy, and modalities that fall under the auspices of complementary and alternative medicine, such as acupuncture. Unfortunately, Clinical trials evaluating the efficacy of a variety of interventions for chronic non-specific low back pain indicate limited effectiveness for most commonly applied interventions and approaches. Our purpose were to evaluate the effectiveness of a mat and studio Pilates program on pain, function, quality of life and NHAI consumption for chronic non-specific low back pain patients.

Methods: Eligible patient include: chronic non-specific low back pain; age between 18 and 65 years; pain ranging from 4 to 8 in a numerical pain scale. Patients with previous surgery, other causes of low back pain, fibromyalgia, regular physical activity (three or more times per week for at least three months); labor lawsuit and body mass index more than 30 were excluded. Sixty patients were randomized to the Experimental Group (EG) or Control Group (CG). Patients in EG participated in 90 days of mat and studio Pilates program twice a week (50 minutes per class) and the CG remained with their usual medicament treatment and were included in a waiting list for physiotherapy. Assessment for pain (VAS), function (Roland Morris questionnaire), quality of life (SF-36) and NHAI consumption were done at baseline, after 45 days (T45), after 90 days (T90 - end of the program), after 90 days (T180 – follow up) by a blinded assessor.

Results: The groups were homogenous for all evaluated parameters at baseline. The EG patients show improve in pain score ($p<0.001$), Roland Morris score ($p<0.001$) and some domains of SF-36 (functional capacity $p=0,046$, pain $p=0,010$ and vitality $p=0,029$) and NHAI consumption ($p<0,001$) when compared with CG.

Conclusion: A mat and studio Pilates program is effective in reducing pain and NHAI consumption and improving function and some domains of quality of life in patients with chronic non-specific low back pain.

Some Clinical Features Are Associated with MODIC I Changes in Patient with Chronic Low Back pain; Results of a Case Control Study. Florian Bailly[1], Jean-Yves Maigne[2], Stéphane Genevay[3], Marc Marty[4], Frédérique Gandjbakhch[1], Sylvie Rozenberg[5] and Violaine Foltz[6]. [1]Hopital Pitié Salpétrière, Paris, France, [2]Hôpital Hôtel Dieu, Paris, France, [3]Hospital-Beau-Sejour, Geneva, Switzerland, [4]Hôpital Henri Mondor, Créteil, France, [5]Hopital La Pitie, Paris, France, [6]Hôpital Pitié Salpétrière, Paris, France

Background/Purpose: Modic 1 signal changes on lumbar MRI have been associated with chronic low back pain. However, it is still not clear whether specific clinical features are associated with these MRI changes in vertebral body marrow adjacent to the endplates of degenerative discs.

Purpose. To compare the clinical characteristics of low back pain (LBP) patients with and without Modic 1 changes on MRI

Methods: A case control study in which patients with Modic I and patients without Modic I were prospectively included, after informed consent, if they had a chronic LBP, no significant leg radiating pain and had a MRI taken in the previously 6 months.

Patients with Modic I and those without were matched for sex and age.

Demographic data (sedentary work, sick leaves), pain characteristics (including a standardized functional scale: Dallas Pain Questionnaire (DPQ), efficiency of NSAID or oral steroids and physical examination were recorded.

Inflammatory pain pattern was defined by the presence of at least one of the 3 characteristics: maximal pain when waking up, awakening at night because of pain, morning stiffness superior to 60mn.

Wilcoxon and Fisher tests were performed for ordinal and categorial variables respectively. Multivariate analysis (logistic regression, stepwise, backfit) were also performed.

The number of subjects included to achieve statistical significance were 60 patients per group.

Results: Table 1 summarizes the characteristics of the 2 groups. On multivariate analysis for clinical characteristics, sedentary work (OR=0.22 [0.05–0.93]), Pain in extension (OR=11.2 [3.1–40.4]) and inflammatory pain (OR=4.5 [1.2–16.9]) were significantly associated with Modic I changes.

Table 1. Characteristics of patients

	Patients with Modic I (n=60)	Patients without Modic 1 (n=60)	p
Number of years since the first episode, med(IQR)	6 (4–18)	4 (2–14)	**0.03**
Sedentary work, n(%)	32 (57)	40 (68)	0.25
Morning stiffness superior to 60 mn, n(%)	16 (27)	8(14)	0.1
Awakening at night because of LBP, n(%)	25 (42)	15(26)	0.08
Maximal pain intensity when waking up, n(%)	35 (58)	24 (40)	0.07
Inflammatory type of pain, n(%)	48 (80)	33 (55)	**0.006**
Scoliotic list, n(%)	8(14)	8(14)	1.00
Presence of morning stiffness, n(%)	36 (64)	26 (49)	0.12
Worst pain in lumbar flexion, n(%)	32 (55)	29 (54)	0.99
Worst pain in lumbar extension, n(%)	47 (80)	25 (46)	**<0.005**
Lumbar pain at straight leg raising test, n(%)	16 (27)	15 (28)	0.99
Radiculalgia, n(%)	8(14)	6(19)	0.55
DPQ impact on Daily Activities, %(SD)	62 (+/−18)	55 (+/−19)	0.053
DPQ impact on Work/Leisure, %(SD)	53 (+/−28)	53 (+/−26)	0.88
DPQ impact on Anxiety/Depression,%(SD)	35 (+/−28)	38 (+/−27)	0.56
DPQ impact on Social Activities, %(SD)	29 (+/−27)	31 (+/−23)	0.38
NSAID prescription n(%)	53 (88)	53 (88)	1.00
Good clinical response to NSAID, n(%)	18/53 (35)	14/54 (33)	0.83
Oral corticosteroids prescription, n(%)	34/58 (59)	15/50 (30)	**0.0037**
Good clinical response to oral corticosteroids, n(%)	17/34 (50)	1/15 (7)	**0.0039**

Conclusion: In this comparative cross sectionnal study, patients with Modic I changes on MRI complained more often from inflammatory pain pattern and felt the worst pain during back extension.

1069

The Efficacy of ThermaCare Heat Wraps on Relieving Lower Back Pain and Reducing Muscle Stiffness. Jerrold Petrofsky[1], Lee Berk[1], Gurinder Bains[1], Benny Hau[1], Geraldine Doyle[2], Shijie Chen[2] and Jill Stark[2]. [1]Loma Linda University, Loma Linda, CA, [2]Pfizer Consumer Healthcare, Madison, NJ

Background/Purpose: Lower back pain (LBP) is among the most common and costly healthcare problems throughout the world. Even when back injuries appear to resolve, they typically reoccur later in life on a continuous basis. The purpose of the present investigation was to assess the effect of ThermaCare heat wraps on relieving pain and reducing stiffness in a population with LBP.

Methods: The subjects' age range was 18–55 with primary muscular LBP which was atraumatic (e.g., no traumatic injury within 48 hrs of enrollment) and not caused by, or related to, any clinically significant medical diseases (e.g., multiple myeloma, metastatic carcinoma, spinal arthritis, etc.). Subjects were randomized into one of 2 primary efficacy groups: a heat wrap group (n=26) and an oral placebo group (n=25). For blinding purposes only, a small number of subjects were randomized to an unheated sham wrap group and an oral ibuprofen group, and are not included in the analysis. Two measures were assessed: pain (TOTPAR 0–8: sum of pain relief (PR) scores) hourly for 8 hrs and muscle stiffness (rating from 0, no muscle stiffness to 100, most stiffness).

Results: As shown in Figures 1 and 2, there was a statistically significant increase in pain relief in the ThermaCare heat wrap group over the entire 8 hrs compared to the oral placebo group (Fig. 1); furthermore, the mean back stiffness improvement from baseline was also significant, except at the 4th hr, with the ThermaCare heat wrap group compared to the oral placebo control (Fig. 2).

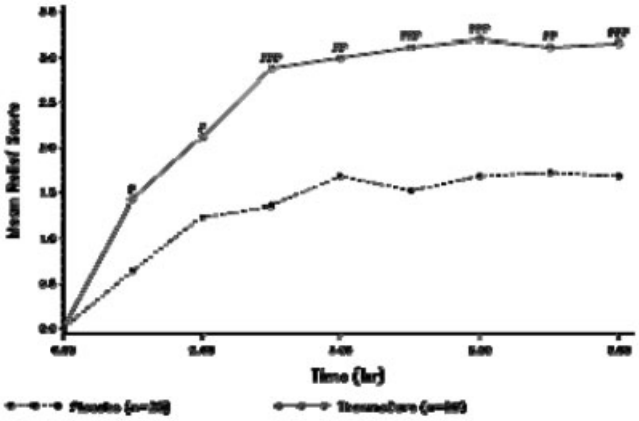

Figure 1. Mean pain relief over time. PPP: Significant compared to placebo at 0.001 level; PP: at 0.01 level; P: at 0.05 level.

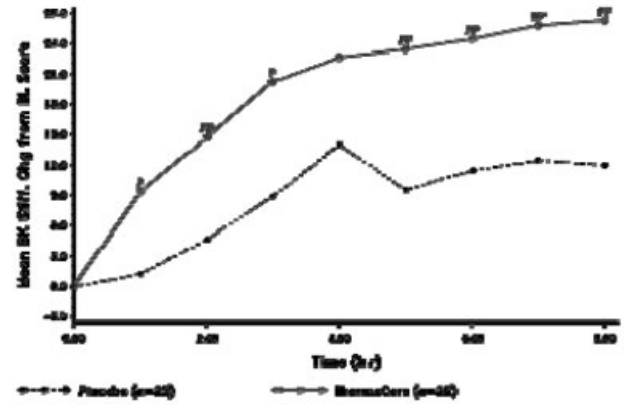

Figure 2. Mean back stiffness – change from baseline over time. PPP: Significant compared to placebo at 0.001 level; PP: at 0.01 level; P: at 0.05 level.

Conclusion: ThermaCare heat wraps provide significant back pain relief and reduce back stiffness in a measurable and sustained way over the 8 hrs of the application period. Additionally, there was no loss of pain relief at the end of the 8 hrs.

Hand Osteoarthritis: A Predictor of Accelerated Progression in Knee OA? Jonathan Samuels[1], Catherine Petchprapa[2], Elizabeth Carpenter[2], Mukundan Attur[1], Leon Rybak[2], Svetlana Krasnokutsky[3], Cheongeun Oh[4] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]NYU Langone Medical Center, New York, NY, [3]NYU Hospital for Joint Disease, New York, NY, [4]New York University, New York, NY

Background/Purpose: There is insufficient understanding regarding how generalized OA involving the hand and knee differs from isolated knee OA, which may result from other factors such as obesity or trauma. The purpose of these studies is to determine whether the presence of hand OA involving interphalangeal (IP) and first carpometacarpal (CMC) joints, alone or in combination, predicts progression of patients with symptomatic knee OA.

Methods: Hand radiographs were obtained on 146 patients at NYUHJD who met ACR criteria for symptomatic knee OA, and who were enrolled in a two-year NIH-sponsored prospective study. The patients completed standardized fixed-flexion knee radiographs at baseline and 24 months, with progression of the signal (more painful) knee OA determined by ≥ 30% decrease change in joint space width (JSW) or ≥1 grade increase in KL score. For each set of hand x-rays, 2 radiologists evaluated 18 IP joints and 2 CMC joints for joint space narrowing and/or osteophytes, and whether or not there was erosive change at the IP joints; we averaged the scores from the two readers whose scores provided excellent Kappa values.

Results: We identified 79 percent of the knee OA patients to have at least 2.0 IP joints with OA (5% with erosive OA), and 53% with at least 1.0 1st CMC OA joint - both consistent with other studies in the literature. While the overall mean IP score was 5.6 and 1st CMC score was 0.9, Caucasians had significantly higher scores for IP and CMC ($p=0.0019$ and 0.0037). Knee progressors by JSW had higher IP scores approaching significance, 7.0 vs. 4.6 ($p=0.11$). Since the IP scores were not normally distributed, we further analyzed data by dichotomizing the study populations into two groups using 2 IP joints with OA as the cutoff point. When so analyzed, the presence of "hand OA" increased the odds ratio of knee OA progression to 2.5 ($p=0.1797$). This burden of IP OA also associated with a trend towards knee progression by delta KL increase. Conversely, knee progressors defined by a KL increase to a score of 3 or 4 over 24 months were 3.5 times as likely to have ≥2 IP joints with OA ($p=0.008$) The 7 knee OA patients with radiographic evidence of *erosive* IP disease, as compared with the rest of the non-erosive IP OA patients and those without IP OA, had a higher percentage of knee OA progression ≥ 30% JSN (57% vs. 22% vs. 19%) approaching significance. None of the permutations involving the 1st CMC revealed significant differences in knee OA progression. In addition, while we had hypothesized that OA patients with prior knee trauma or surgery would have less hand OA given the external causation, we instead found no significant differences in hand OA prevalence in either of those analyses.

Conclusion: In our completed pilot cohort, the quantitative "burden" of hand OA at the IP joint associates with the radiographic severity of knee OA and a trend towards more rapid progression of knee OA, by either JSN or increased KL grade. Erosive IP disease may be an even stronger predictor than non-erosive IP disease of accelerated progression of knee OA.

Funding: This study is funded by NIAMS (R01- AR052873).

Erosive Osteoarthritis Is Associated with Preclinical Atherosclerosis. Athanasios Koutroumpas, Athanasios Giannoukas, Aikaterini Exarchou, Aristeidis Baliakos, Konstantinos Makaritsis and Lazaros I. Sakkas. Thessaly University School of Medicine, Larissa, Greece

Background/Purpose: Chronic inflammatory disorders have been associated with accelerated atherosclerosis and increased cardiovascular risk. Recent evidence suggests that erosive osteoarthritis (EOA) has considerable inflammation; therefore, we examined the presence of subclinical atherosclerosis and endothelial dysfunction in EOA

Methods: Twenty-four patients with EOA and 24 age and sex-matched healthy individuals without clinical OA were included in the study. No subject had a history of cardiovascular disease. Intima media thickness (IMT) and atheromatous plaques in the common carotid and common femoral arteries were measured by Doppler ultrasonography. The endothelium-dependent, flow-mediated vasodilatation was assessed by measuring the diameter of brachial arteries at baseline and after compression of the forearm with a sphygmomanometer at pressure above 30 mmHg of the individual's systolic blood pressure. The endothelium-independent vasodilatation was assessed after administration of 0.4 mg glyceryl trinitrate.

Results: The two groups were comparable for all demographic characteristics. The EOA patients had significantly elevated systolic and diastolic blood pressure ($p<0.001$ for both). IMT of both common carotid and common femoral artery was increased in EOA ($p=0.012$ and $p<0.01$, respectively). There was no difference in endothelium-dependent and independent vasodilatation, and the prevalence of atherosclerotic plaques between the two groups. The mean 10-year risk of general cardiovascular disease, as predicted with the Framingham Risk Score, was similar in patients and controls ($p=0.18$).

Table. Patients characteristics and results.

Parameter	EOA (n=24)	Controls (n=24)	p
Age (mean. SD)	62.5 (6.6)	60.7 (5.8)	0.33
Sex (Female)	22	22	1
Hypertension, n (%)	16 (66.6)	12 (50)	0.38
Hyperlipidemia, n (%)	7 (29.2)	13 (54.2)	0.14
Diabetes Melitus, n (%)	0 (0)	2 (8.3)	0.49
Smoking, n (%)	3 (12.5)	4 (16.7)	0.99
Statin use, n (%)	4 (16.7)	8 (33.3)	0.32
ACE inhibitor, n (%)	6 (25)	3 (12.5)	0.46
B blocker. n (%)	2 (8.3)	6 (25)	0.24
Angiotensin II receptor antagonist, n (%)	5 (20.8)	3 (12.5)	0.46
Diuretics, n (%)	6 (25)	5 (20.8)	0.74
Cholesterol, mean (SD) (mg/dl)	237.6 (49.5)	230 (35.4)	0.55
HDL, mean (SD) (mg/dl)	59.4 (14.3)	59.1 (13.1)	0.94
LDL, mean (SD) (mg/dl)	157.5 (48.8)	147 (33.3)	0.37
Triglycerides, mean (SD) (mg/dl)	141.8 (75.2)	124.4 (56)	0.63
Systolic Blood Pressure, mean (SD) (mmHg)	160 (32.9)	143.4 (32.1)	<0.001
Diastolic Blood Pressure, mean (SD) (mmHg)	99.9 (20.4)	83.4 (11.9)	<0.001
Intima media thickness, common carotid artery, mean (SD) (mm)	0.91 (0.17)	0.82 (0.19)	0.012
Intima media thickness, common femoral artery, mean (SD) (mm)	0.7 (0.19)	0.6 (0.2)	<0.01
Ultrasound Biopsy Score, mean (SD)	14 (3.3)	12 (2.8)	0.03
Patients with carotid and femoral artery plaques, n (%)	15 (62.5)	13 (54.2)	0.77
Δ brachial artery diameter- reactive hyperemia, mean (SD) (mm)	0.36 (0.39)	0.36 (0.44)	0.92
Δ brachial artery diameter after glyceryl trinitrare administration, mean (SD) (mm)	0.62 (0.49)	0.45 (0.48)	0.057
Framingham Risk Score (10-year risk of general cardiovascular disease), mean % (SD)	23.9 (14.7)	18.8 (11.2)	0.18

Conclusion: In this cross-sectional, controlled study, we found an association between EOA and subclinical atherosclerosis that cannot be fully attributed to traditional cardiovascular risk factors, as assessed by the Framingham score. These results suggest that chronic, low-grade inflammation could be implicated in the process of atherosclerosis in EOA.

1072

More Inflammatory Signs on Ultrasound in Interphalangeal Joints in Erosive Hand Osteoarthritis. Marion C. Kortekaas[1], Wing-Yee Kwok[1], M. Reijnierse[1], T.W.J. Huizinga[2] and Margreet Kloppenburg[3]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leiden University Medical Centre, Leiden, Netherlands, [3]Department Rheumatology and Department of Clinical Epidemiology, Leiden University Medical Centre, Leiden, The Netherlands, Netherlands

Background/Purpose: Erosive hand osteoarthritis (EOA) is a subset of hand osteoarthritis (HOA) associated with a higher clinical burden than non-erosive disease. The aetiology of erosive evolution is still unknown. Based on observations that underlying systemic processes may be involved and that during the clinical course inflammatory signs are often seen in EOA, we hypothesized that inflammatory signs are implicated in erosive evolution. We therefore investigated the presence of inflammatory signs assessed by US in erosive and non-erosive interphalangeal joints in patients with EOA in comparison to interphalangeal joints from patients with non-erosive HOA.

Methods: Consecutive patients with HOA (fulfilling ACR criteria) were included. Eighteen interphalangeal joints were scored on radiographs using the Verbruggen-Veys anatomical phase score; E and R-phases were defined as erosive. Effusion, synovial thickening, greyscale (GS) synovitis and power Doppler signal (PDS) were scored with US on a 4-point scale. Generalized estimated equation (GEE) analyses were used to study the association between erosiveness and anatomical phases with US features. Odds ratios (OR) with 95% confidence intervals were calculated with adjustments for patients effects and confounders.

Results: Of 55 HOA patients (mean age 61 years, 86 % females) 51% showed at least one erosive joint. In 94 erosive joints GS synovitis, synovial thickening, effusion and PDS were found in 57%, 13%, 50% and 15%, respectively; in 896 non-erosive joints in 29%, 10%, 26% and 8%, respectively. Summated scores of PDS, GS synovitis and effusion were higher in EOA than in non-erosive HOA. GS synovitis was more frequent in S, J, E and R-phases compared to N-phases. PDS was only associated with E-phase (5.3 (1.3–20.5)) not with other phases. Non-erosive joints in EOA demonstrated more PDS (3.2 (1.6–6.4)), GS synovitis (2.2 (1.3–3.7)) and effusion (2.2 (1.2–3.8)) in comparison to joints in non-erosive HOA.

Conclusion: Inflammatory signs are more frequent in EOA than in non-erosive HOA, not only in erosive joints but also in non-erosive joints, suggesting an underlying systemic cause for erosive evolution.

1073

The Association Between Erosive Hand Osteoarthritis and Systemic Bone Mineral Density. Ida K. Haugen[1], David T. Felson[2], Martin Englund[3], Ke Wang[2], Piran Aliabadi[4], Ali Guermazi[2], Frank Roemer[2] and Tuhina Neogi[2]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Boston University, Boston, MA, [3]Lund University, Lund, Sweden, [4]Brigham and Women's Hospital, Boston

Background/Purpose: Erosive hand osteoarthritis (OA) is characterized by attrition of the joint plate, which could be due to inadequate bone quality. However, the knowledge about bone mineral density (BMD) in erosive hand OA is scarce. Thus, our aim was to examine the association between erosive hand OA and systemic BMD.

Methods: We included 2236 participants from the Framingham OA study with hand radiographs and femoral neck BMD (DEXA). The bilateral distal (DIP) and proximal interphalangeal (PIP), metacarpophalangeal (MCP), thumb base and wrist joints were scored for radiographic hand OA (Kellgren-Lawrence grade (KLG)≥2) and central erosions. Central erosions were present in DIP/PIP joints only. Thus, we defined erosive OA as ≥1 DIP/PIP joint with KLG≥2 and central erosion in the same joint, and non-erosive OA as ≥1 DIP/PIP joint with KLG≥2 and no central erosions. The unexposed group included those with no DIP/PIP OA (i.e., no OA or isolated MCP/thumb base/wrist OA). We used logistic regression to explore whether BMD (as continuous variable or age- and sex-specific BMD tertiles) was associated with presence of any DIP/PIP OA. We also performed linear regression with presence of erosive or non-erosive OA as independent variable and BMD as continuous outcome variable (one model). The analyses were repeated with the number of erosive and non-erosive joints as independent variables (one model). All analyses were adjusted for age, sex and BMI.

Results: The 2236 participants (1281 women) had a mean (SD) age of 64.5 (9.0) years and a mean (SD) BMI of 28.6 (5.5) kg/m^2. Erosive and non-erosive OA were present in 221 (9.9%) and 761 (34.0%) persons respectively. In those with erosive OA, the median (IQR) numbers of erosive and non-erosive joints were 3 (1–5) and 5 (3–8) respectively. In those with non-erosive OA, the median (IQR) number of OA joints was 2 (1–5).

In adjusted analyses, higher BMD was associated with higher odds of any OA (OR=1.90, 95%CI 0.91–3.98; p=0.09). The odds of any OA was significantly higher in those with the highest BMD tertile (OR=1.37, 95%CI 1.08–1.73; p=0.01), while not significant for those in the middle tertile (OR=1.21, 95%CI 0.96–1.53; p=0.11) compared to those in the lowest tertile.

There were small differences in BMD between the unexposed, erosive and non-erosive OA participants: The adjusted LS-mean (SD) BMD was 0.92 (0.01), 0.93 (0.02) and 0.93 (0.01), respectively. There was a trend towards higher BMD in participants with erosive and non-erosive DIP/PIP OA compared to the unexposed group (table).

Table. The association between erosive and non-erosive hand OA and BMD of the femoral neck (linear regression adj. for age, sex and BMI).

	Adjusted beta (95% CI); p-value
Presence of erosive and non-erosive DIP/PIP OA vs. no DIP/PIP OA as reference (one model)	
No DIP/PIP OA (reference)	0.00
Erosive DIP/PIP OA	0.01 (−0.01, 0.03); p=0.33
Non-erosive DIP/PIP OA	0.01 (0.00, 0.02); p=0.08
Number of erosive and non-erosive DIP/PIP joints (one model) among all participants:	
Number of erosive joints	−0.001 (−0.005, 0.003); p=0.65
Number of non-erosive joints	0.002 (−0.001, 0.004); p=0.15

Analyses with exclusion of those with isolated MCP/thumb base/wrist OA from the unexposed group did not appreciably change the results.

Conclusion: There was a trend towards higher BMD in participants with DIP/PIP OA. Erosive hand OA was not associated with lower systemic BMD, suggesting that local structural impairment of periarticular bone quality may play a role in erosive hand OA not sufficiently covered by systemic BMD measurements.

1074

Magnetic Resonance Imaging in Hand Osteoarthritis: Validation of the Oslo Hand Osteoarthritis MRI-Scoring Method and Association with Pain, Radiographs and Ultrasound. Wing-Yee Kwok[1], Marion C. Kortekaas[1], M. Reijnierse[1], Desirée van der Heijde[1], J.L Bloem[1] and Margreet Kloppenburg[2]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Department Rheumatology and Department of Clinical Epidemiology, Leiden University Medical Centre, Leiden, The Netherlands, Netherlands

Background/Purpose: Magnetic Resonance Imaging (MRI) is able to visualise abnormalities in cartilage, subchondral bone and synovium at once in osteoarthritis (OA). We investigated the reproducibility of the newly developed Oslo Hand Osteoarthritis (OHOA)-MRI scoring method and validated it against other imaging modalities in hand OA patients. Furthermore, we associated MRI features in hand OA with pain and investigated the presence of MRI features in different stages of hand OA.

Methods: Sixteen patients (median age 57 years (range 42–71), 62% female) were recruited from the Rheumatology department of the LUMC. Pain per joint (yes/no) was assessed for the distal and proximal interphalangeal joints (DIPJs, PIPJs). MRI scans of 2nd–5th DIPJs and PIPJs of the right hand were made, using a 3.0T MRI unit. Coronal and sagittal T1-weigthed images pre-and post gadolinium contrast and fat-suppressed T2-weigthed images were obtained. MRI features were scored according to the OHOA-MRI scoring method (based on 1.0T images) for synovitis, erosions, osteophytes (OP) and bone marrow lesions (BML) (grade 0–3). Ultrasound was performed with a 10–14 MHZ linear array transducer and scored for greyscale synovitis and OP. Hand radiographs were scored following the Verbruggen-Veys scoring method. An pre-erosive joint was defined as J-phase (loss of joint space), erosive joint as E-phase and remodeled joint as R-phase (irregular, sclerotic subchondral plate).

To validate the OHOA-MRI scoring method, intra-reader reliability was assessed on 6 MRI scans, measured with single measurements (ICC, 95% confidence interval (CI)). Validity of MRI features versus US was tested with Spearman's rank correlation coefficients, ρ (p-value). With Generalized Estimated Equations associations between MRI features and pain per joint were calculated to account for within-patient effects, age, sex and BMI. Results were given in odds ratios (OR) with 95% CI.

Results: Thirteen patients (81%) had erosive OA (EOA). The ICCs for synovitis, erosions, OP and BML ranged from 0.66–1.00. Any/moderate-severe synovitis was seen in 98%/43% of joints on MRI, respectively, compared to 39% greyscale synovitis on US. BML was seen in 27% of the joints, OP in 77% and 99% of the joints on MRI and US, respectively. MRI was not correlated with US grayscale synovitis (Spearman's ρ 0.02, p=0.79) and only weakly with US OP (ρ 0.16, p=0.07). The correlation of MRI with radiographs was weak for OP and erosions (Spearman's ρ 0.35 (p<0.001) and 0.33 (p<0.001), respectively).

Pain was associated with the presence of moderate/severe synovitis (OR 2.4 (95%CI 0.1–3.2)), BML (OR 3.5 (95%CI 1.6–7.7)), erosions (OR 4.5 (95%CI 1.7–11.9)) and OP (OR 2.4 (95%CI 1.1–5.3)). Having BML on MRI is associated with J- or E-phase presence in that joint (ORs 5.0 (2.2–11.4) and 36.4 (5.1–260.3), respectively).

Conclusion: The OHOA-MRI scoring system is reproducible and valid. MRI detects more synovitis ompared to US, but less osteophytes. Presence of moderate/severe synovitis, BML, erosions and osteophytes are associated with pain per joint. BML is associated with having an (pre)erosive joint, suggesting that BML could be part of the process in EOA.

1075

MRI and Histologic Evidence for the Role of Synovitis in Bone Erosions in Erosive Osteoarthritis. Allen P. Anandarajah[1], Laura A. Paxton[2], Ellen Giampoli[3], Kenneth Badillo[3], Johnny Monu[3] and Christopher T. Ritchlin[4]. [1]Univ of Rochester Medical Ctr, Rochester, NY, [2]University of Rochester Strong Hospital, Rochester, NY, [3]University of Rochester Medical Ctr, Rochester, NY, [4]University of Rochester School of Medicine and Dentistry, Rochester, NY

Background/Purpose: Patients with erosive osteoarthritis (EOA) often develop disfiguring deformities and decline in hand function. Approximately 15% of patients with symptomatic hand OA have radiographic erosions but the relative contribution of synovitis, bone marrow edema (BME) and cartilage degradation in the development of EOA is poorly understood. To examine the role of synovitis in this disease we reviewed magnetic resonance images (MRI) and histologic data in a cohort of EOA patients.

Methods: The medical records from a cohort of 107 EOA patients were reviewed for MRI of hands and for synovial biopsies regardless of the joint or presence of erosions. The MRIs were assessed for the presence of synovitis, BME, osteophytes, erosions, joint effusions and subchondral cysts in all proximal (PIP) (5) and the second to fourth distal (DIP) (4) joints, by 2 musculoskeletal radiologists. Tissue specimens were examined for the presence of synovitis, inflammatory cells, new bone formation and cartilage pathology.

Results: A total of 11 patients had MRI of hands and 4 had biopsies (2 finger and 2 knees). The 11 MRIs were performed on 8 females and 3 males with a median age of 59 ± 13. All patients with MRI had evidence for progressive erosive disease on plain radiographs. A total of 54 PIPs and 44 DIPs were assessed for erosions, BME, osteophytes and subchondral cysts and 49 PIPs and 40 DIPs were assessed for synovitis and effusion. Erosions were noted in 29 PIP (54%) and 23 (53%) DIP joints, synovitis in 31 PIP (63%) and 14 DIP joints (35%), BME in 15 PIP (27%) and 11 DIP (25%) joints, osteophytes in 31 PIP (57%) and 25 DIP (57%), subchondral cysts in 25 PIP (46%) and 22 DIP (50%) joints and effusion in 4 PIP (8%) and none of the DIP joints. Erosions, synovitis and osteophytes were most frequently seen in the 3rd PIP and 5th DIP joints. Positive correlations were noted between the presence of synovitis and erosions (0.3) and the presence of BME and erosions (0.3). BME was noted more frequently near the central erosions.

A total of 4 biopsies, stained with haematoxylin and eosin, were retrieved. To date, 2 of the 4 biopsies, one from a finger with erosive disease and one from a knee joint have been analyzed and were compared with synovial biopsies from patients with rheumatoid arthritis (RA), by a pathologist. Histology revealed synovitis and new bone formation in both EOA specimens and increased inflammatory infiltrate. The frequency of inflammatory cells was however less than in patients with RA. A predominance of lymphocytes with few plasma cells were observed in EOA compared with abundant lymphoplasmacytic cell infiltrate in RA. The cartilage in EOA demonstrated central ossification, a finding not seen in RA.

Conclusion: Synovitis was a common finding on MRI and histology in patients with EOA and along with BME was associated with the presence of erosions on MRI. Osteophytes were also seen in most of the joints in patients with EOA and along with histologic new bone formation helped distinguish EOA from RA. Synovial inflammation was associated with bone erosions in EOA and was mainly lymphocytic. Future studies will determine if synovitis precedes bone erosions or is secondary to cartilage loss.

1076

Cartilage Damage in the Tibio-Femoral and Patello-Femoral Joints and Risk of Progression: Role of Prevalent Damage Severity – the MOST Study. Frank Roemer[1], David T. Felson[2], Ke Wang[1], Michel Crema[1], Monica D. Marra[1], Michael C. Nevitt[3], Yuqing Zhang[4], Cora E. Lewis[5], James Torner[6] and Ali Guermazi[7]. [1]Boston University, Boston, MA, [2]Department of Clinical Epidemiology, Boston University School of Public Health, Boston, MA, USA, Boston, MA, [3]University of California-San Francisco, San Francisco, CA, [4]Boston University School of Medicine, Boston, MA, [5]University of Alabama, Birmingham City, Birmingham, AL, [6]University of Iowa, Iowa City, Iowa City, IA, [7]Boston Medical Center, Boston, MA

Background/Purpose: Several studies suggest that one of the strongest predictors of subsequent cartilage loss seems to be prevalent cartilage damage. However, it is unknown if prevalent cartilage damage is only an intermediate for more severe subsequent damage or an independent predictor. Aims were to assess the risk of progressive cartilage loss for subregions with different grades of baseline cartilage damage severity in the tibio-femoral and patello-femoral joint and also to define baseline damage severity grade at highest risk for progression.

Methods: The Multicenter Osteoarthritis (MOST) Study is a longitudinal observational study of subjects with knee OA or at risk of OA. The MRI protocol included axial and sagittal proton density-weighted fat-suppressed and a coronal STIR sequence (1.0 T extremity system). MRIs were assessed semiquantitatively according to the modified WORMS scoring system, where cartilage is assessed on a scale from 0 to 6. Included were all knees with available baseline and 30 months MRIs. Ordinal logistic regression was used to estimate the risk of cartilage los in the same subregion at 30 months. Analyses were performed separately for the different baseline severity grades. Subregions without any associated articular pathology were assessed separately from subregions with associated pathology (i.e. bone marrow lesions, meniscal damage and meniscal extrusion). Analyses were performed on a whole knee basis, and for the tibio-femoral and patello-femoral joints separately. Additional adjustment was performed for possible confounders of cartilage loss.

Results: Altogether 18825 subregions of 1367 knees were included. Of these 786 (4.2 %) showed small focal superficial defects (=grade 2), 213 (1.1%) exhibited small focal full thickness defects (=grade 2.5), 3244 (17.2%) showed widespread superficial damage < 75% of subregion (=grade 3), 114 (6.1%) exhibited diffuse superficial damage >75% of subregion (=grade 4) and 1772 (9.4%) showed diffuse full thickness cartilage loss (grades 5 and 6). 6120 (32.5%) subregions exhibited adjacent pathology. Altogether 1508 (8.0%) subregions showed progressive cartilage loss at follow-up. Risk of progressive cartilage loss was markedly increased for subregions with any grade of prevalent cartilage damage (Figure 1). Focal superficial defects in subregions without adjacent pathology showed the highest risk of subsequent cartilage loss (adjusted odds ratio [aOR] 9.4, 95% confidence interval [95% C] 7.0–12.1). Results were comparable for subregions with adjacent subregional pathology.

Figure 1. Risk of cartilage loss at 30 months for subregions with normal cartilage and with different grades of prevalent baseline damage severity

* significant at p <0.05
[1] adjacent pathology: meniscal damage and/or meniscal extrusion and/or bone marrow lesion
[2] adjacent pathology: bone marrow lesion
[3] adjusted for age, gender, BMI, malalignment, radiographic OA severity, synovitis, effusion
TF-tibio-femoral, PF - patello-femoral, FU - follow-up, aOR - adjusted odds ratio, 95% CI - 95% confidence interval

Conclusion: In comparison to subregions without cartilage damage, risk of subsequent cartilage loss is markedly increased for subregions with prevalent damage regardless of adjacent pathology. Small superficial defects have the highest risk of further deterioration in the tibio-femoral and patello-femoral joints.

1077

Prevalence of Cam and Pincer-Type Deformities on Hip MRI in a Swiss Female Population: A Cross-Sectional Study. Stephan Reichenbach[1], Peter Jüni[1], Stefan Werlen[2], Andreas Limacher[1], Christian W. Pfirrmann[3], Reinhold Ganz[1] and Michael Leunig[4]. [1]University of Bern, Bern, Switzerland, [2]Hospital Sonnenhof, Bern, Switzerland, [3]Balgrist University Hospital, Zurich, Switzerland, [4]Schulthess Clinic, Zurich, Switzerland

Background/Purpose: Femoroacetabular impingement (FAI) has been proposed to cause early osteoarthritis (OA) in the non-dysplastic hip. FAI usually occurs as one of two different types, either "cam" or "pincer". Cam impingement is caused by the presence of a cam-type deformity with a non-spherical femoral head and/or a decreased anterior head-neck offset. Pincer impingement results from increased acetabular depth with over-coverage of the femoral head, while the head-neck configuration may be normal.

We previously reported the prevalence of cam-type deformities in a young asymptomatic male population to be 24%. The prevalence of increased acetabular depth was 6%. The aim of this study was to determine the prevalences of both types of impingement as potential risk factors for hip OA in a quasi population-based cross-sectional cohort study of young females.

Methods: Study subjects were young females aged 18 to 19 attending grammar school or selected vocational schools for manual or non-manual occupations. Participants completed a set of questionnaires pertaining to pain, stiffness, and physical function, and internal rotation was measured reliably using a validated examination chair. A random sample of the examined participants was subsequently invited to obtain magnetic resonance images

(MRI) of the hip. Cam-type deformities were assessed semiquantitatively using scores from grades 0 to 3: 0=normal, 1=mild, 2=moderate, 3=severe. The depth of the acetabulum was defined as the distance (in mm) between the center of the femoral neck and the line connecting the anterior acetabular rim to the posterior acetabular rim. The value was positive if the center of the femoral neck was lateral to the line connecting the acetabular rim. Values ≤3 mm were considered to represent increased acetabular depth. Overall prevalence estimates with 95% confidence intervals (95% CI) accounted for the oversampling of participants with decreased (<40°) and increased (≥50°) internal rotation using post-stratification weights. Prevalences were calculated separately for participants with decreased, normal, and increased internal rotation.

Results: Subjects who underwent imaging included 80 asymptomatic participants with a mean age of 19.3 years and a mean body mass index of 21.2 kg/m^2. Grade 1 cam-type deformities were found in 22% (95% CI 13 to 34). No MRI showed evidence of a definite cam-type deformity (grade ≥2). The prevalence of increased acetabular depth was 10% (95% CI 5 to 19). This prevalence did not differ between participants with decreased internal rotation and those with normal or increased internal rotation (Table 1, p-value for trend 0.71).

Table 1. Prevalence of increased acetabular depth in the general female population

Internal rotation (IR)	Number of MRIs examined	Number with increased acetabular depth	Prevalence [%] of increased acetabular depth (95% CI)
IR < 40°	26	4	15 (6 to 35)
40° ≤ IR < 50°	30	2	7 (2 to 23)
50° ≤ IR	24	3	13 (4 to 32)
Overall	**80**	**9**	**10 (5 to 19)**

Conclusion: Definite cam-type deformities on MRI in young women are rare compared to men, whereas the prevalence of increased acetabular depth is higher, suggesting that FAI has different gender-related biomechanical mechanisms.

1078

Systemic Bone Mineral Density Change and Body Mass Index, but Not Bone Mineral Density Are Related to Knee Cartilage Loss in Knee Osteoarthritis. Ji Yeon Lee[1], Timothy E. McAlindon[1], Lori Lyn Price[1] and Eric Miller[2]. [1]Tufts Medical Center, Boston, MA, [2]Tufts University, Medford, MA

Background/Purpose: Longitudinal studies that examined BMI and BMD in relation to cartilage loss in KOA have generated rather inconsistent results. These could be due to the methods that these studies used to detect progression. Therefore, we conducted a longitudinal study to examine relationship of systemic BMD, BMD change, and BMI with progression of KOA using continuous outcome measurements that are sensitive to small changes and are not constrained by ceiling effects.

Methods: We studied participants in a double-blinded randomized controlled trial of vitamin D for KOA (Kellgren Lawrence grade 2–4). The treatment effect of vitamin D was null. BMD of the femoral neck was measured in g/cm^2 at baseline and 2 year visits. BMI was measured in kg/m^2 at baseline. 1.5 Tesla knee MRIs were obtained at baseline, 1 and 2 year follow-up visits. A single reader used ANALYZE© software to register baseline and follow-up knee MRIs for each participant, and segmented the femoral and tibial cartilage volumes (Intra-tester reliability ICCs were 0.96 & 0.90 for cross-sectional volume and volume loss). Using a MatLab (The MathWork, Natick, MA) custom program, cartilage thickness was derived from cartilage segmentation. We expressed cartilage volume % loss per year, femoral and tibial cartilage thickness loss per year as continuous outcomes. We used linear regression to evaluate the effect of BMI, femoral neck BMD and BMD change over 2 years as predictors of change, adjusting for possible confounders (age, sex, alignment status, and vitamin D treatment).

Results: Among 146 study participants, analyzable data were available from 124 for total cartilage volume %loss, 123 for femoral cartilage thickness change and 126 for tibial cartilage thickness change. Their mean age was 62.7yrs (sd 8.58), 61% were female, mean femoral neck BMD was 0.95g/cm^2 (sd 0.14), mean change of BMD over 2 years was −0.01 g/cm^2 (sd 0.04), mean baseline BMI was 30.3 kg/m^2 (sd 5.71), 48.8% had varus alignment,18.6% valgus; 52% received vitamin D. The mean cartilage volume loss per year was 2.25%, mean femoral cartilage thickness loss per year was 0.035 mm, and mean tibial cartilage thickness loss per year was 0.030 mm. No correlation was found between BMI and BMD (r=0.14, p=0.12). BMD was not associated with any cartilage parameters. However, BMD change and baseline BMI were both significantly related to cartilage volume loss in the univariate linear models (beta= −8.00, p=0.02 for BMD change; beta= 0.06, p=0. 007 for BMI), and this trend persisted when adjusted for potential confounders (see Table).

Table. Ajusted associations of BMI, BMD, BMD change with cartilage loss

	Cartilage volume loss per year(%)		Femoral cartilage thickness loss per year(mm)		Tibial cartilage thickness loss per year(mm)	
	Estimate	**Pr(>|t|)**	**Estimate**	**Pr(>|t|)**	**Estimate**	**Pr(>|t|)**
Model 1*						
BMI	0.06	0.005	0.0005	0.19	0.0009	0.08
Femoral BMD	−0.40	0.66	−0.003	0.84	−0.018	0.38
Model 2*						
BMI	0.07	0.005	0.0006	0.14	0.0009	0.09
BMD change	−6.64	0.06	−0.086	0.17	−0.143	0.06

* Adjusted for age, sex, alignment status and treatment group.

Conclusion: We have confirmed that greater BMI predicts cartilage volume loss in knee OA. We also found a modest association of cartilage volume loss with longitudinal loss of femoral neck BMD but not baseline BMD. These findings highlight the need to intervene on body weight to reduce progression of knee OA, and also suggest a role for interventions on bone loss.

1079

Adiposity and Serum Inflammatory Markers Are Associated with Increases in Knee Pain Over 5 Years in Old Adults. Chang-Hai Ding[1], Oliver Stannus[2], Flavia Cicuttini[3] and Graeme Jones[2]. [1]University of Tasmania & Monash University, Hobart, Australia, [2]University of Tasmania, Hobart, Australia, [3]Monash University, Central and Eastern Clinical School, Melbourne, Australia

Background/Purpose: The associations between adiposity, inflammation and increase in knee pain over time are uncertain. This study aimed to determine if body fat and serum levels of inflammatory markers were associated with change in knee pain over 5 years in older adults.

Methods: A total of 755 randomly selected subjects (mean 62 years, range 51–81, 50% female) were studied at baseline, 2.6 and 5 years later. Knee pain (on flat surface, going up/down stairs, at night, sitting/lying and standing upright) at baseline and 5 years was assessed using WOMAC. Fat-suppressed MRI of the right knee was performed to determine knee cartilage volume and defects at baseline and 2.6 years. Fat mass and lean mass (both in kg) were measured by a Hologic Delphi dual X-ray absorptiometry (DXA) scanner. In first 149 subjects, serum levels of tumor necrosis factor (TNF)-α, interleukin (IL)-6 and high-sensitivity C-reactive protein (hs-CRP) were measured by radioimmunoassay at baseline and 2.6 years.

Results: In multivariable analysis, increase in total knee pain score over 5 years was significantly and positively associated with female sex, knee radiographic osteoarthritis, medial tibiofemoral cartilage defects, lateral tibiofemoral cartilage defects, change in medial cartilage defects over 2.6 years and loss of medial tibial cartilage volume over 2.6 years. Increase in knee pain was positively associated with the adiposity measures including weight (OR = 1.03 per kg, P<0.001), body mass index (OR=1.07 per kg/m^2, P=0.004), percentage body fat (OR = 1.05 per %, P=0.019), percentage trunk fat (OR = 1.05 per %, P=0.007), waist-hip ratio (OR=32.72, P=0.012) and waist circumference (OR=1.03 per cm, P<0.001), but negatively associated with percentage total lean mass (OR=0.96 per %, P=0.009). Increase in knee pain was also associated with baseline TNF- α (OR=1.15, P=0.046) and change in TNF- α over 2.6 years (OR=1.52, P=0.046). When change in knee pain was used as the outcome measure, both baseline (β=0.27per mL/pg, P=0.029) and change per annum (β=0.91 per mL/pg, P=0.010) in TNF-α were positively associated with change in total knee pain. In addition, baseline IL-6 levels were positively associated with change in the standing sub-scale of pain (β=0.18per mL/pg, P=0.046), and baseline hs-CRP was positively associated with change in total knee pain (β=0.38 per ml/pg, P=0.048), as well as change in the sub-scales for pain while lying in bed (β=0.14 per mL/pg, P=0.019) and sitting (β=0.13 per mL/pg, P=0.004).

Conclusion: Multiple factors contribute to an increase in knee pain over 5 years. This is the first study to report that adiposity and inflammatory markers predict increased knee pain, while total body lean mass is protective against an increase in knee pain in older adults.

1080

Serum Adipokines in End-Stage Osteoarthritis; Comparison with Healthy Controls and Relations with Intra-Articular Joint Characteristics. T.N. de Boer[1], Simon C. Mastbergen[1], A.M. Huisman[2], J.W.J. Bijlsma[1] and F.P.J.G. Lafeber[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Sint Franciscus Gasthuis, Rotterdam, Netherlands

Background/Purpose: Obesity is an important risk factor for osteoarthritis (OA). Body mass index (BMI) is strongly associated with the prevalence and incidence of knee OA. It is established that metabolic factors exert an extra systemic effect on top of the mechanical effect of overweight in OA. Adipose tissue is considered an endocrine tissue releasing cytokines (IL-1β and TNFα) and adipokines (adiponectin, leptin, and resistin). Adipokines have been reported to be involved in the disease process. The exact mechanisms by which adipokines exert their effects in OA are still unclear. The aim of this study is to compare serum adipokines in end-stage OA with healthy controls and to evaluate the relationship of serum adipokines with actual cartilage damage and synovial inflammation in the affected joint.

Methods: 172 severe knee OA patients selected for total knee replacement (TKR) surgery were included. Serum was collected shortly before TKR surgery. Serum was also collected from a healthy control (HC) group of 132 individuals without any sign of radiographic knee OA. Characteristics were collected and serum adipokine (adiponectin, leptin and resistin) levels measured by ELISA. Of the OA patients cartilage and synovial tissue were collected at TKR surgery. Histological damage, proteoglycan turnover, histological inflammation, IL-1β and TNFα production were measured in cartilage and synovium. The study was conducted according to the declaration of Helsinki and received ethics approval of the hospital.

Results: Adipokine levels were higher in OA compared to HC, even after correction for age and BMI. In both OA and HC differences between men and women were seen: Adiponectin and leptin levels were higher in women than in men (Adiponectin: 24$\pm$13 vs. 14$\pm$7 μg/ml, p=0.000 and leptin: 90$\pm$64 vs. 33$\pm$28 ng/ml, p=0.000 in OA and 22$\pm$11 vs. 5.3$\pm$3 ng/ml, p=0.000 in HC). Resistin levels did not differ between women and men. In OA adiponectin levels were inversely related with BMI (R=-0.218, p=0.004) and positively correlated with age (R=0.283, p=0.000). Leptin levels showed a positive correlation with BMI (R=0.604, p=0.004 and R=0.495, p=0.000, for OA and HC, resp.). Resistin levels were inversely related with age (R=-0.206, p=0.012). In OA all adipokines correlated positively with synovial inflammation. Adiponectin, leptin and resistin with synovial tissue IL-1β production (p=0.02 all (p=0.04 for women), p=0.09 all, and p=0.02 men, resp.). Leptin and resistin with synovial tissue histological inflammation (p=0.06 all (p=0.02 in men) and p=0.09 all, resp.). And resistin with TNFα (p=0.09 all, p=0.02 for men). None of the adipokines were associated with histological or biochemical cartilage characteristics.

Conclusion: In this study we demonstrate that adipokine levels are significantly increased in end-stage knee OA patients considered for TKR surgery compared to a healthy control group. Also a clear relation of these adipokines with age and with BMI is demonstrated and a clear difference between men and women. Most interestingly, the serum (peripheral) adipokines correlated with local parameters of inflammation of OA joints. This implies that systemically measured adipokines play a role locally at the joint level in the OA disease process.

Synovial Fluid Leptin Levels and Joint Pain in End-Stage Osteoarthritis: A Potential Explanation for Increased Pain in Women and in Obese Patients. Anne Lübbeke[1], Axel Finckh[2], Gabor J. Puskas[1], Domizio Suva[1], Alexandre Lädermann[1], Sylvette Bas[2], Daniel Fritschy[1], Cem Gabay[1] and Pierre Hoffmeyer[1]. [1]Geneva University Hospitals, Geneva, Switzerland, [2]University Hospital of Geneva, Geneva, Switzerland

Background/Purpose: Synovial leptin levels are increased in osteoarthritis (OA), particularly in women and in obese patients. Furthermore, in these two patients groups higher pain levels before joint replacement have been described. A possible link between obesity, adipocytokines and pain severity has been suggested in studies on weight loss. Weight reduction has consistently resulted in decreased joint pain in patients with OA, and in addition, weight loss decreased blood leptin levels.

We hypothesized that synovial fluid (SF) leptin concentrations correlate with pain severity, and thus mediate the association between increased joint pain and (1) female gender and (2) obesity

Methods: Cross-sectional study including all patients with primary hip and knee OA undergoing total joint arthroplasty in a large orthopedic center, between January and December 2010. On the day of intervention, SF and serum were sampled and leptin concentrations were assessed using an ELISA kit. The main outcome was severity of joint pain measured preoperatively with the Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) and the VAS pain scale.

Results: 250 patients were included, 134 total hip and 116 total knee arthroplasties. Mean ($\pm$SD) age was 72 ($\pm$9) years, 62% were women (n=155). Mean BMI was 27.3 kg/m^2 in the hip and 29.1 kg/m^2 in the knee group. Mean SF leptin levels were 22.5 ($\pm$ 25.3) ng/ml in women and 5.3 ($\pm$5.5) ng/ml in men (p<0.001). SF leptin levels strongly correlated with BMI (r=0.518) and serum leptin levels (r=0.910). SF leptin concentrations > 19.6 ng/ml (highest quartile) were significantly associated with increased pain levels on both WOMAC and VAS pain scale (see Table). The association remained unchanged after adjusting for presence of contra-lateral arthritic joints and diabetes (WOMAC adjusted mean difference $-$10.8 (95% CI: $-$16.5; $-$5.1) and VAS pain adjusted mean difference 0.7 (95% CI: 0.1; 1.3)). Significant associations between increased joint pain and (1) female gender and (2) BMI observed in univariate analysis disappeared after adjusting for FS leptin concentrations, suggesting that these associations are mediated by leptin levels.

Patient characteristics and preoperative pain levels according to leptin concentration (in quartiles*) in synovial fluid of patients undergoing hip or knee arthroplasty (n=250)

	Leptin 1st quartile ≤3.2 ng/ml (n=61)	Leptin 2nd quartile 3.21–9.1 ng/ml (n=62)	Leptin 3rd quartile 9.11–19.6 ng/ml (n=65)	Leptin 4th quartile >19.6 ng/ml (n=62)	p –value*	4th vs. other quartiles:** RR (95% CI) Mean difference (95% CI)
Men (%)	43 (45.3)	35 (36.8)	14 (14.7)	**3 (3.2)**		
Women (%)	18 (11.6)	27 (17.4)	51 (32.9)	**59 (38.1)**	<0.001	12.1 (3.9; 37.4)
Age, mean, SD	72.7 (±8.9)	71.3 (±10.0)	73.1 (±9.2)	**70.9 (±8.8)**	0.535	−1.4 (−4.1; 1.2)
BMI, mean, SD	24.8 (±3.5)	27.6 (±4.1)	27.8 (±3.5)	**32.2 (±5.4)**	<0.001	5.5 (4.0; 6.9)
BMI ≥ 30kg/m^2 (%)	5 (7.1)	12 (17.1)	16 (22.9)	**37 (52.9)**	<0.001	3.8 (2.5; 5.8)
<>Hip arthroplasty (%)	34 (25.4)	40 (29.9)	36 (26.9)	**24 (17.9)**		
Knee arthroplasty (%)	27 (23.3)	22 (19.0)	29 (25.0)	**38 (32.8)**	0.034	1.8 (1.2; 2.9)
Arthritic contralateral joint (%)	30 (21.1)	35 (24.6)	36 (25.4)	**41 (28.9)**	0.079	1.5 (0.9; 2.4)
Diabetes (%)	10 (29.4)	12 (35.3)	8 (23.5)	**4 (6.5)**	0.059	0.4 (0.2; 1.1)
Leptin blood level, mean, SD	4.1 (±2.7)	12.3 (±7.4)	27.2 (±14.2)	**68.9 (±45.6)**	<0.001	53.6 (45.7; 61.5)
Pain assessment						
WOMAC pain, mean, SD	43.8 (±17.9)	38.4 (±18.7)	41.9 (±18.9)	**31.0 (±15.0)**	0.004	−10.5 (−16.1; −4.9)
VAS pain, mean, SD	5.8 (±1.7)	6.0 (±1.9)	5.8 (±2.0)	**6.5 (±1.8)**	0.079	0.6 (0.1; 1.2)

* p-value obtained with use of linear regression (leptin, continuous as dependent variable) for continuous variables and with use of chi-squared test for trend for categorical variables
** The 4th quartile was compared to the other three quartiles taken together. Relative risks (RR) and their 95% CIs were presented for categorical variables and mean differences and their 95% CIs for continuous variables.

Conclusion: Joint pain is strongly associated with SF leptin concentrations. Increased pain observed in women and in obese patients may be related to high leptin levels.

1082

Comparison of Cytokine Levels in the Synovial Joint Fluid Between Rapidly Destructive Coxopathy, Hip Osteoarthritis, Rheumatoid Arthritis, and Hip Oseteonecrosis. Hirohito Abe[1], Takashi Sakai[1], Wataru Ando[2], Masaki Takao[1], Takashi Nishii[1], Nobuo Nakamura[3], Hideki Yoshikawa[1] and Nobuhiko Sugano[1]. [1]Osaka University Graduate School of Medicine, Suita, Osaka, Japan, [2]Kansai Rousai Hospital, Amagasaki, Japan, [3]Kyowakai Hospital, Suita, Japan

Background/Purpose: Rapidly destructive coxopathy (RDC) represents destruction of the femoral head and/or acetabulum within 6 to 12 months mostly in elderly females. RDC causes severe hip pain and disabilities and results in total hip arthroplasty (THA). Several conditions have been suggested as the primary causes of RDC, including increasing pelvic posterior inclination as a mechanical factor, and high serum concentration of MMP-3, MMP-9 as biological factors. However, the cytokine levels of the synovial joint fluid with RDC and other hip diseases have not been well documented. The purpose of this study is to determine the characteristics of the cytokine levels compared between RDC, hip osteoarthritis (OA), rheumatoid arthritis (RA), and hip oseteonecrosis (ON) using synovial joint fluid collected during THA.

Methods: 56 hips in 55 patients were investigated in this study. The mean age was 67.3 years (range; 25 to 85 years). They consisted of 9 males and 46 females. There were 22 hips with RDC, 13 hips with OA, 6 hips with RA, and 15 hips with ON which were divided into 6 hips with collapsed ON and 9 hips with terminal ON. The diagnosis of RDC was done on plain radiographs or MRI of the hip, which showed diffuse low signal intensity area in the femoral head and neck on T1WI, and high signal intensity area on T2WI with or without rapidly destructive findings. All hips with RDC and terminal ON showed widespread obliteration of the joint space. The synovial joint fluid was collected during THA and was stored at −80°C. The cytokine levels including IL-1β, IL-6, IL-8, and TNF-α were measured by using Homogenous Time Resolved Fluorescense (HTRF). We compared the cytokine levels between hip diseases. In ON group, we also compared the cytokine level between the collapsed ON and the terminal ON to investigate the influence of the severity of joint destruction on the cytokine level. The statistical analysis was performed by Kruskal-Wallis test and Mann-Whitney U test. The level of significance was set at $p<0.05$.

Results: The mean IL-8 level (pg/ml) was 3536±2678 in RDC, 1521±1319 in OA, 2171±1176 in RA, and 2885±3232 in ON, respectively. IL-8 level in RDC were significantly higher than that in OA ($p=0.02$). There were no differences in IL-1β and TNF-α between all the hip disease categories. IL-6 level (pg/ml) in the collapsed ON was significantly higher than that in the terminal ON (collapsed ON: 2478±2026 vs terminal ON: 707±708, $p=0.03$).

Conclusion: There were few reports concerning the cytokine levels of the synovial joint fluid in hip diseases. In the present study, IL-8 levels were significantly higher in RDC hips. Although some studies had reported that knee with RA had significantly higher level of IL-8 than that with OA, there was no difference between RA and OA in the present study. Some studies have also reported that the severity of joint destruction had influenced on the Il-1β level of the joint fluid of the knee. In the ON group, IL-6 level in the collapsed ON was significantly higher than that in the terminal ON. The staging of the hip joint destruction have influenced on the cytokine level of the joint fluid of the hip. IL-8 in synovial joint fluid may be useful to diagnose the RDC.

Presence of Gout Is Associated with Increased Osteoarthritis Prevalence and Severity. Rennie N. G. Howard[1], Jonathan Samuels[1], Soterios Gyftopoulos[1], Svetlana Krasnokutsky[2], Joseph Leung[3], Christopher Swearingen[4] and Michael H. Pillinger[1]. [1]NYU Langone Medical Center/NYU Hospital for Joint Diseases, New York, NY, [2]NYU Hospital for Joint Disease, New York, NY, [3]New York, NY, [4]University of Arkansas for Medical Sciences, Little Rock, AR

Background/Purpose: There is a pressing need to identify biomarkers of osteoarthritis (OA) presence/progression, and remediable risk factors that may promote OA therapeutic approaches. Uric acid (UA) in both soluble and crystalline forms is biologically active, and gout often occurs in a similar age group as OA. We tested whether subjects with gout or asymptomatic hyperuricemia (AH) have increased prevalence/severity of knee OA.

Methods: Male subjects age 55–85 were consecutively recruited during primary care visits to an urban VA hospital. Subjects were interviewed and assessed for gout (ACR Clinical Criteria). Background medical histories and serum UA levels were obtained. Exclusion criteria included non-gout inflammatory arthritis, psoriasis, inflammatory bowel disease, hemodialysis, severe knee trauma or knee replacement. Enrolled subjects were categorized into 3 groups: gout, AH (no gout, UA ≥ 6.9 mg/dL), and controls (no gout, UA ≤ 6.8 mg/dL). On a 2nd visit subjects underwent OA assessment: knee pain history, WOMAC and RAPID3 surveys, musculoskeletal exam, weight-bearing bilateral knee X-ray, and knee/MTP ultrasound (US) to assess MSU crystal deposition. OA was diagnosed using ACR Clinical and Clinical/Radiographic criteria, and differences in summary statistics between groups were estimated using the Kruskal-Wallis and Chi-square tests. Images were read on a blinded basis (US by 2 independent reviewers, X-rays by a musculoskeletal radiologist).

Results: Of 129 subjects screened, 119 were enrolled and 75 completed both visits: 25 gout, 25 AH, and 25 controls. Mean age/race were similar among all groups, but BMI was highest in the gout group. 68% of gout, 52% of AH and 28% of control subjects had knee OA by Clinical/Radiographic criteria (gout vs control, $p=0.017$). The unadjusted odds ratio for knee OA in gout vs control was 5.46 (95% CI [1.63, 18.36], $p=0.040$), and remained significant after BMI adjustment (OR 3.80, 95% CI: [1.06, 13.57, $p=0.040$]). Mean Kellgren-Lawrence grades were significantly higher in gout vs control for right ($p=0.013$) and left ($p=0.049$) knees. Bilateral knee OA was also more common in the gout group. WOMAC (knee pain, stiffness and functional limitation) and RAPID3 scores among gout subjects were higher compared to the other groups, but not statistically different. Crystal deposition detected by US was more common in subjects with vs without knee OA (40.5% vs 16.2%, $p=0.020$), but was not associated with OA in specific joints. Subjects with AH had knee OA prevalence/severity intermediate between control and gout patients.

Conclusion: Our data suggest that presence of gout puts subjects at significantly higher risk for increased knee OA prevalence and severity. AH may independently convey knee OA risk but our sample size was inadequate for statistical confirmation. MSU crystal deposition as detected by US was also significantly higher in subjects with knee OA. Presence of gout or AH, as well as MSU crystal deposition on US, could potentially serve as useful biomarkers for knee OA risk, severity and progression. The possibility that gout and/or AH might contribute to OA risk suggests that UA management should be assessed as a potential intervention in OA patients.

Expression of Human Endogenous Retrovirus Herv-K18 In Osteoarthritis Patients. Benjamin Fernandez-Gutierrez[1], Marta Garcia-Montojo[2], Jose Hoyas[1], Inmaculada Dominguez-Mozo[2], Esther Villafuertes[1], Pilar Tornero-Esteban[1], Ana Arias-Leal[2], Lydia Abasolo[1], Roberto Alvarez-Lafuente[2] and Jose Ramon Lamas[2]. [1]Department of Rheumatology, Hospital Clinico San Carlos, Madrid, Spain, [2]Hospital clinico San Carlos, Madrid, Spain

Background/Purpose: The etiology of OA remains to be completely understood; however, epidemiological studies have revealed that there are both endogenous and exogenous risk factors for OA. Human endogenous retroviruses (HERV) are assumed to be remnants of ancient exogenous retroviral infections of our ancestors germ-line cells, DNA, resulting in vertical transmission in a Mendelian fashion. HERV sequences constitute approximately 3–8% of the human genome. These include endogenous retrovirus 3 (ERV-3) [4], HERV-W [5], and a number of members of the HERV-K family, suggesting the potential for involvement in autoimmunity [6]. Thus, it has been suggested that ERV-3 may provide a biomarker for osteoarthritis [7]; also, the HERV-K family, that contains some of the most active retroviral elements in the human genome, it has been related with active rheumatoid arthritis [8]. Recently, it has been described a superantigen activity for HERV-K18 [9], and a significantly elevated expression in patients with juvenile rheumatoid arthritis has been found [10].

The purpose of this study was to evaluate the involvement of HERV-K18 in Osteoarthritis (OA), through the analysis of the expression levels in OA patients in comparison with healthy controls, and through the analysis of different qualitative and quantitative clinical variables.

Methods: One hundred and thirteen OA patients and 62 controls were included. To analyze HERV-K18 mRNA expression, quantitative RT-PCR was performed; the transcriptional expression was expressed in a relative manner as a normalization ratio (NR), and for controls were assigned a NR=1. The Western Ontario and McMasters Universities Osteoarthritis Index (WOMAC), Lequesne Index, and the Stanford Health Assessment Questionnaire (HAQ) were analyzed in relation to the expression levels of HERV-K18.

Results: We found that 54/113 (47.8%) of OA patients and 22/62 (35.5%) of controls had detectable expression levels of HERV-K18. We found statistical significant differences when we compared the results of the Womac Index, Lequesne Index for knee and hip, and HAQ between OA patients with higher expression (NR>10) vs. OA patients without HERV-K18 expression ($p=0.0003$, $p=0.0005$, $p=0.002$, and $p=0.05$, respectively), and also when the comparison was made between OA patients with higher expression (NR>10) vs. OA patients with low expression of HERV-K18 (NR=1) for the Womac Index, and Lequesne Index for knee and hip ($p=0.002$, $p=0.013$, and $p=0.006$, respectively).

Conclusion: It seems to be a relation between the health status measurement systems and severity index for OA with the levels of expression of HERV-K18. These results suggest the possible involvement of HERV-K18 in the etiopathogenesis of the disease.

1085

Varus Thrust and Knee Frontal Plane Dynamic Motion in Persons with Knee Osteoarthritis. Alison Chang, Joan Chmiel, Kirsten Moisio, Orit Almagor, Yunhui Zhang, September Cahue, Clifton Saurel and Leena Sharma. Northwestern University, Chicago, IL

Background/Purpose: Varus thrust visualized during walking is associated with a greater peak external knee adduction moment and an increased likelihood of medial knee osteoarthritis (OA) disease progression. Gait observation for a thrust is a simple and inexpensive clinical screening tool that enables identification of some individuals at higher risk for disease progression. How observed varus thrust relates to quantitative gait kinematic data is

not known. We hypothesized that varus thrust presence is associated with greater knee frontal plane dynamic movement during the stance phase of gait.

Methods: Participants all had knee OA (by osteophyte presence) in at least one knee. Knee motion in the frontal plane during ambulation on a 35 × 4 foot walkway was captured at a rate of 120 Hz, using external passive reflective markers and an 8-camera Digital Real-Time Eagle motion analysis system. Frontal plane motion was measured using the peak knee varus angle during stance (and each subdivision of stance), peak knee varus angular velocity, and total knee varus-valgus motion during stance. Following a protocol and blinded to the knee frontal plane motion data, trained examiners assessed participants for varus thrust presence during ambulation in a 10-meter walkway. To examine the relationship between varus thrust and frontal plane knee dynamic motion, we used multivariable regression analysis with generalized estimating equations (GEE) to account for correlations between knees within persons; presence of thrust was coded using an indicator variable. Models were adjusted for age, gender, BMI, and gait speed. Findings are reported as mean differences between knees with vs. without thrust and 95% confidence intervals (CIs).

Results: The study sample consisted of 236 persons [mean age 64.9 (SD 10.4), BMI 28.5 (5.5), 179 (76%) women] contributing 440 knees for analysis. 82 knees (19%) had a definite varus thrust. Table 1 shows the mean (SD) for each frontal knee motion measure. As shown in Table 2, knees with varus thrust had a greater peak knee varus angle during the entire stance and each sub-phase as well as greater peak knee varus angular velocity.

Table 1. Means (SDs) Knee Frontal Plane Quantitative Motion Measures during Gait by Varus Thrust Status

Measures of frontal plane motion during gait	All knees n = 440 Mean (SD)	Knees *with* varus thrust n = 82 Mean (SD)	Knees *without* varus thrust n = 358 Mean (SD)
Peak knee varus angle during stance (°)	1.77 (1.28)	2.51 (1.55)	1.60 (1.15)
Peak knee varus angle during early stance (°)	0.72 (0.98)	1.55 (1.29)	0.53 (0.79)
Peak knee varus angle during mid-stance (°)	1.32 (1.50)	2.27 (1.64)	1.10 (1.38)
Peak knee varus angle during terminal stance (°)	1.42 (1.22)	2.03 (1.47)	1.28 (1.11)
Peak knee varus angle during pre-swing (°)	−0.16 (1.51)	0.66 (1.67)	−0.35 (1.40)
Peak knee varus angular velocity (°/sec)	0.29 (0.16)	0.36 (0.15)	0.28 (0.16)
Total knee varus-valgus range of motion (°)	8.69 (3.37)	8.53 (3.07)	8.72 (3.44)

Table 2. Estimated Differences in Means for Knee Frontal Plane Motion Measures Based on Presence vs. Absence of Varus Thrust, from the GEE Regression Models

Measures of frontal plane motion during gait	Difference* (95% confidence interval)		
	Unadjusted	Adjusted for age, gender, and BMI	Adjusted for age, gender, BMI, and gait speed
Peak knee varus angle during stance (°)	**0.91 (0.52, 1.30)**	**0.97 (0.56, 1.37)**	**0.98 (0.57, 1.38)**
Peak knee varus angle during early stance (°)	**1.02 (0.68, 1.35)**	**1.03 (0.69, 1.38)**	**1.04 (0.70, 1.38)**
Peak knee varus angle during mid-stance (°)	**1.16 (0.73, 1.60)**	**1.31 (0.85, 1.77)**	**1.30 (0.84, 1.77)**
Peak knee varus angle during terminal stance (°)	**0.75 (0.36, 1.14)**	**0.82 (0.42, 1.23)**	**0.83 (0.43, 1.23)**
Peak knee varus angle during pre-swing (°)	**1.01 (0.56, 1.45)**	**0.94 (0.48, 1.41)**	**0.94 (0.48, 1.41)**
Peak knee varus angular velocity (°/sec)	**0.08 (0.04, 0.12)**	**0.08 (0.04, 0.12)**	**0.08 (0.04, 0.12)**
Total knee varus-valgus range of motion (°)	−0.19 (−0.96, 0.58)	0.40 (−0.39, 1.20)	0.45 (−0.34, 1.23)

* Positive difference indicates greater mean value for knees with varus thrust vs. those without varus thrust. 95% CI that excludes 0 indicates a statistically significant difference between the groups.

Conclusion: Knees with a varus thrust during gait had greater peak knee varus angle and knee varus angular velocity during stance than knees without a thrust. These findings provide evidence that visualized varus thrust is associated with objective and quantitative measures of dynamic frontal plane instability.

1086

Shoe Flexibility Reduces Dynamic Joint Loads in Knee Osteoarthritis: Results of a Pilot Study. Najia Shakoor[1], Roy H. Lidtke[1], Louis F. Fogg[2], Markus A. Wimmer[1], Kharma C. Foucher[1], Rachel A. Mikolaitis[1] and Joel A. Block[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center

Background/Purpose: Recent evidence suggests that footwear can significantly affect dynamic knee loading and that flat, flexible shoes may result in lower knee loads compared to more supportive, stiff-soled shoes. Here, we further evaluate the longitudinal effects of flexible footwear ("mobility" shoe) compared to an identical stiff-soled "control" shoe on knee loading.

Methods: Subjects with radiographic (KL grades ≥ 2) and symptomatic (at least 30mm pain of 100mm scale while walking) medial compartment knee OA were recruited and randomized to receive a flexible soled shoe (mobility shoe) or identical appearing "control" shoe with stiffer sole. The stiffness of the soles was evaluated using a biomaterial testing system and was substantially different between the shoes. Investigators and participants were blinded to shoe assignment. Baseline gait analyses were performed using an optoelectronic camera system and multi-component force plate in subjects' "own shoes", study shoes, and barefoot. Subjects were instructed to wear the study shoes at least 6 hours/day for 6 days/week. Gait analysis was repeated at 6 and 12 weeks. The peak knee adduction moment (PAddM), a validated marker of medial compartment loading, was evaluated. Since this was a pilot trial and group sizes were not expected to demonstrate statistically significant differences, relative load reduction and effect sizes (ES) were evaluated between groups.

Results: 13 participants (10 women, mean age 54±8 years) were assigned to the control shoe and 8 (6 women, mean age 58±8 years) to the mobility shoe. Compared to their own shoes at baseline, the mobility group experienced an 11% reduction in the PAddM by 6 weeks (3.75±1.29 to 3.35±1.02 %BW*ht) while the control group experienced no change (3.28±0.69 to 3.29±0.65 %BW*ht), yielding an ES of 0.5 for the active intervention compared to control. By 12 weeks, the overall reduction in the PAddM was 20% for the mobility group (3.01±1.19 %BW*ht) while the control group also experienced a 13% reduction (2.85±0.66 %BW*ht) compared to their own shoes at baseline (ES=0.36). The Figure shows the changes in the PAddM over 12 weeks with participants own shoes, study shoes, and barefoot for both groups. The mobility shoe loads very closely approximated those during barefoot walking while the control shoe loads were similar to those of the participants own shoes.

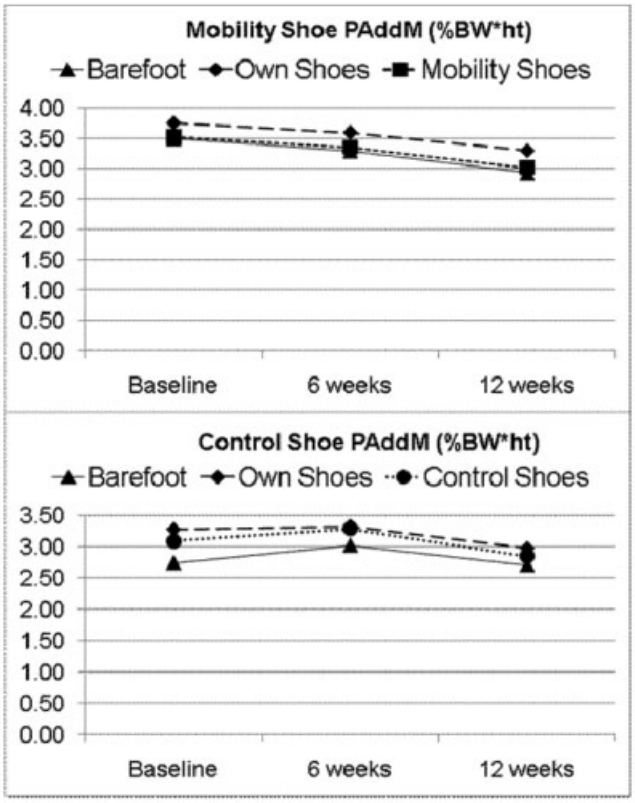

Figure. PAddM over 12 weeks in Mobility and Control groups

Conclusion: This pilot study suggests that shoe sole flexibility has a moderate effect in reducing knee loads in participants with knee OA. The "control" shoe in this study also yielded an expected load reduction compared to the participants own shoes, but this occurred entirely after 6 weeks and could be related to "wearing in" of the shoe sole stiffness with use. These results suggest that shoe sole flexibility may be one feature of footwear to consider when targeting biomechanical interventions for knee OA.

1087

Sagittal Plane Hip Motion During Gait and Function and Disability in Knee Osteoarthritis. Kirsten Moisio, Carmelita J. Colbert, Orit Almagor, Joan S. Chmiel, Alison Chang, Yunhui Zhang, September Cahue, Karen W. Hayes, Clifton Saurel and Leena Sharma. Northwestern University, Chicago, IL

Background/Purpose: Studies have established that sagittal plane range of knee motion during gait is associated with physical function in knee osteoarthritis (OA) (Maly 2006). The impact of knee OA on range of knee motion during gait may lead to a greater reliance on the hip. Even when knees are healthy, hips play a critical role in daily activities. With knee OA, the compensatory role of the hip may be considerable. In persons with knee OA, reduced range of hip motion during gait may be a result of shortness of two joint hip flexor muscles such as the rectus femoris or the tensor fascia lata-iliotibial band complex. We hypothesized that reduced sagittal plane range of hip motion during gait is associated with worse function and greater disability in persons with knee OA.

Methods: We studied 250 persons with knee OA (defined by osteophyte presence in at least one knee). Quantitative gait analysis was performed at the participant's self-selected normal walking speed to calculate kinematic and kinetic data for the hip and knee. Function was evaluated using: WOMAC function scale (higher score worse); Late Life Function Instrument (LL-FI), basic and advanced lower extremity function scales (lower score worse); and 20 m walk time. Disability was measured using: Late Life Disability Instrument (LL-DI), activity frequency and activity limitation scales (lower score worse). To evaluate the relationship between sagittal range of motion during gait (independent variable) and function or disability (dependent variables), linear regression models were used (analyzing the data from the limb with less sagittal motion). The results are reported as regression coefficients (slopes) and associated 95% confidence intervals (95% CIs), separately for each dynamic range of motion variable, adjusted for age, gender, and BMI.

Results: 250 persons had a mean age of 64.8 years (SD 10.2), BMI 28.6 kg/m^2 (5.6), and 76% were women. Mean (SD) sagittal range of hip motion during gait was 43.1° (5.6), and mean (SD) sagittal range of knee motion was 60.9° (5.5). The table shows adjusted coefficients per 5° (95% CI); significant values are bolded. Range of hip motion during gait was significantly associated with function by self-report, performance function, and both measures of disability; range of knee motion during gait was associated with function measures but not these measures of disability.

Table. Dynamic Sagittal Plane Hip and Knee Motion and Measures of Function and Disability

	WOMAC function scale	20 meter walk time	LL-FI, basic LE function	LL-FI, advanced LE function	LL-DI, activity frequency	LL-DI, activity limitation
Sagittal *hip* motion (°)	**−2.37 (−3.60, −1.15)**	**−1.53 (−1.77, −1.29)**	**3.04 (1.61, 4.47)**	**2.86 (1.54, 4.17)**	**1.37 (0.64, 2.11)**	**2.35 (0.95, 3.74)**
Sagittal *knee* motion (°)	**−1.75 (−3.06, −0.44)**	**−0.89 (−1.20, −0.58)**	1.49 (−0.06, 3.05)	**1.47 (0.02, 2.93)**	−0.50 (−1.30, 0.31)	1.12 (−0.40, 2.63)

Conclusion: Sagittal range of hip motion during gait was consistently associated with measures of function and disability, supporting a compensatory role played by the hip in the setting of knee OA. Longitudinal studies will help to elucidate whether range of hip motion during gait should be a rehabilitative target (e.g., stretching the hip flexors with concomitant strengthening of hip extensors, gait training) to potentially enhance outcome for persons with knee OA.

Vibratory Sense in Patients At High Risk of Knee Osteoarthritis. Jonas B. Thorlund[1], Najia Shakoor[2], Eva Ageberg[3], Louise F. Sandal[1], Joel A. Block[2] and Ewa M. Roos[1]. [1]Research Unit for Musculoskeletal Function and Physiotherapy, Institute of Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark, [2]Rush University Medical Center, Chicago, IL, [3]Department of Health Sciences, Lund University, Lund, Sweden

Background/Purpose: Patients with knee osteoarthritis (OA) have impaired proprioception and vibratory sense. Vibratory sense is a separate yet closely related sensory pathway to proprioception, but is able to be more reliably tested than proprioception. It remains unclear if sensory deficits, which may alter neuromuscular activity and affect mechanical knee joint load, precede or follow as a consequence of OA. Young patients with previous anterior cruciate ligament injury are at high risk of knee OA. Furthermore, middle-aged patients with degenerative meniscus tears are suggested to be at high risk of knee OA or have early changes of knee OA. As such, they represent two distinctly different groups of patients to study early factors involved in OA pathogenesis. The aim of this study was to investigate the hypothesis that patients at high risk or with very early changes of knee OA would already display characteristic OA sensory deficits compared with age-matched controls.

Methods: *Patients:* 39 ACL injured patients (ACL) (24.0±5.2 yrs, BMI 24.0±2.9 kg/m^2, time since injury 21.9±21.6 month) were compared with 28 controls (ACL-C) (25.6±4.4 yrs, BMI 23.6±2.2 kg/m^2). Furthermore, 22 patients meniscectomized for a degenerative tear (APM) (49.6±4.8 yrs, BMI 24.7±2.7 kg/m^2, time since surgery 49.6±5.0 month) were compared with 25 controls (APM-C) (49.4±5.2 yrs, BMI 25.2±4.9 kg/m^2).

Self-reported outcomes: The Knee Injury and Osteoarthritis Score (KOOS) was used to assess knee-related pain, symptoms, function in daily life (ADL), sports and recreation function (Sport/Rec) and quality of life (QOL). Separate subscale scores from 0 to 100, worst to best, were calculated.

Vibratory perception threshold (VPT): VPT was assessed using a biothesiometer at two different sites (i.e. the most prominent point of the medial malleolus (MM) and the medial femoral condyle MFC)). The mean of two measurements was noted as the VPT (i.e. higher value indicates worse vibration sense).

Results: ACL self-reported substantially worse than ACL-C on all KOOS subscales ($p<0.001$). APM self-reported worse QOL ($p=0.007$) than APM-C and a tendency for more pain ($p=0.079$) and symptoms ($p=0.084$) than controls. No difference was observed between APM and APM-C in ADL and Sport/Rec. In contrast, no evidence of somatosensory deficit was observed in either the ACL or the APM group. Linear regression (adjusting for age and sex) showed no sign of sensory deficits (i.e. increased VPT score) in ACL compared with ACL-C at either of the two sites (MM: 9.4 (8.6 – 10.3) vs. 11.0 (9.7 – 12.3) volts, $p=0.034$ MFC: 15.7 (14.0 – 17.5) vs. 18.1 (15.8 – 20.4), $p=0.122$ in the patients and controls, respectively) or in APM compared with APM-C (MM: 14.4 (12.2 – 16.6) vs. 16.6 (13.6 – 19.6), $p=0.182$ MFC: 18.9 (15.9 – 21.9 vs. 23.0 (19.3 – 26.8), $p=0.092$ in the patients and controls, respectively).

Conclusion: These data do not support the hypothesis that sensory deficits precede overt OA in post-traumatic OA, at least in young ACL-injured patients and middle-aged meniscectomized patients at high risk or in the very early phase of knee OA. Further study is necessary to distinguish the time course of somatosensory loss in OA.

1089

Generalized Sensory Deficits in Radiographic Knee Osteoarthritis: The MOST Study. Najia Shakoor[1], Tuhina Neogi[2], David T. Felson[3], Jingbo Niu[3], Laura Frey-Law[4], Cora E. Lewis[5] and Michael C. Nevitt[6]. [1]Rush University Medical Center, Chicago, IL, [2]Boston University, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]University of Iowa, Iowa City, IA, [5]University of Alabama, Birmingham City, Birmingham, AL, [6]University of California-San Francisco, San Francisco, CA

Background/Purpose: Somatosensory abnormalities have been observed in knee osteoarthritis (OA). Whether sensory deficits are localized abnormalities at an affected OA joint versus part of a generalized neurologic process is still not clear. We evaluated vibratory sense in participants in a large cohort study of knee OA.

Methods: MOST is a NIH-funded longitudinal study of persons with symptomatic knee OA or at increased risk of OA. At the 60-month visit, participants underwent bilateral evaluation of vibratory perception threshold (VPT), using a biothesiometer. The applicator tip of the instrument was placed on the dorsum of the first MTP joint, the tibial tuberosity and, the radial styloid. The voltage was initially set at "0" and then increased by 1 volt/second until the participant acknowledged sensation and this was defined as the VPT. Participants had bilateral weight bearing x-rays which defined radiographic knee OA (RKOA) if Kellgren Lawrence grade was ≥2. Those with baseline total knee replacement or diabetes (participants taking medication for diabetes) were excluded in this analysis. In light of the large differences in VPT with age, participants were divided into age subgroups, < and ≥65 years. Because unaffected knees of persons with unilateral RKOA may be intermediate in VPT between knees with OA and knees without RKOA, for the lower extremity sites, a knee-based analysis was performed with three knee groups: 1) RKOA 2) contralateral "normal" knee of unilateral RKOA and 3) control knee (no RKOA in either knee). For the upper extremity (radial styloid), a person based analyses was performed (bilateral or unilateral RKOA and control). Linear regression was used to compare VPT between groups adjusted for age, BMI, gender, race and clinical site. In limb based analyses, GEE was used to account for between limb correlations.

Results: 977 women and 630 men with a mean age (SD) of 67±8 years were included. In men and women age ≥65, VPT was worse at the MTP and tibial tuberosity both in knees with RKOA as well as the contralateral "unaffected" knee of those with unilateral RKOA (Table). At the radial styloid, VPT was worse in those with unilateral but not bilateral RKOA, compared to controls (Table). There were no significant associations of VPT with RKOA status in men and women < 65 years of age.

Table

		Mean VPT (95% CI) adjusted for age, gender, race, BMI, and clinical site	P value (compared to control)
Men and Women Age ≥65 years			
MTP (n=knees)	RKOA (n=734)	23.7 (22.5, 25.9)	0.026
	Contralateral (n=207)	23.9 (22.1, 25.7)	0.048
	Controls (n=827)	22.0 (20.7, 23.3)	
Tibial tuberosity (n=knees)	RKOA (n=750)	25.8 (24.7, 26.8)	0.015
	Contralateral (n=209)	26.3 (24.6, 28.0)	0.019
	Controls (n=835)	24.0 (22.9, 25.2)	
Radial styloid (n=persons)	Bilateral RKOA (n=257)	9.0 (8.5, 9.5)	0.284
	Unilateral RKOA (n=210)	10.3 (9.7, 10.8)	0.004
	Controls (n=422)	9.4 (8.9, 9.8)	

Conclusion: In this cohort study, among persons age ≥65 vibratory sense was decreased at the affected as well as the unaffected contralateral limb of those with RKOA. Upper extremity vibration sense was also reduced in those with unilateral RKOA. These results suggest that alterations in vibratory sense may be part of a more generalized neurologic process in OA. The association of VPT with OA was only observed in those greater than 65 years of age in this cohort, suggesting that there may be an age-related component to sensory alterations in OA.

The Impact of a Community-Based Aerobic Walking Program for Older Individuals with Mild to Moderate Knee Osteoarthritis: A Knowledge Translation Randomized Controlled Trial. Lucie Brosseau[1], George A. Wells[2], Glen Kenny[3], Robert Reid[4], Andreas Maetzel[5], Peter Tugwell[6], Maria Huijbregts[7], Carolyn McCullough[7], Lily Chen[8] and Gino De Angelis[9]. [1]University of Ottawa, Ottawa, ON, [2]Univ of Ottawa Faculty of Med, Ottawa, ON, [3]School of Human Kinetics, Faculty of Health Sciences, University of Ottawa, Ottawa, ON K1N 6N5, Canada, Ottawa, ON, [4]University of Ottawa Heart Institute, Ottawa (Ontario), Canada, [5]Univ Health Network, Toronto, ON, [6]Institute of Population Health, Ottawa, ON, [7]Baycrest Centre, (Toronto), Canada, Toronto, ON, [8]University of Ottawa Heart Institute, Ottawa (Ontario), Canada, Ottawa, ON, [9]Univeristy of Ottawa, Ottawa, ON, Ottawa, ON

Background/Purpose: The objective of this study was to determine whether, after 3, 6, 9, 12, 15 and 18 months, the integration of a 12-month structured/supervised community-based aerobic walking program (SCAWP) with a behavioural strategy (WB) is more effective in improving compliance in older individuals with OA than a SCAWP only (W)? How does each of these treatment arms compare to a low cost, unsupervised/self-directed control group in which subjects receive an educational pamphlet on walking and OA (C) at 3, 6, 9, 12, 15 and 18 months?

Methods: A single-blind, randomized control trial was conducted which included 223 individuals with a confirmed diagnosis of OA of the knee. Subjects were randomized to one of three groups: 1) Group WB received an integrated behavioural strategy in combination with a structured community-based aerobic walking program (SCAWP) based on Ottawa Panel guidelines (implementation strategy); 2) Group W was provided with a SCAWP only(implementation strategy); 3) Group C was a self-directed and non structured walking program using an educational pamphlet only (dissemination strategy). All three comparative groups received an educational pamphlet on the benefits of regular walking, a logbook and a pedometer. The supervised walking sessions for groups W and WB were scheduled 3 times a week for 12 consecutive months.

Results: Individuals is the WB group demonstrated better short-term adherence when compared to the C group ($p<0.012$) after 3 months. For long term adherence (up to 6 to 12 month), WB had better adherence than the other two groups (W and C), but did not demonstrate statistical significance. As expected, all participants from each group showed improvements for all the clinical and quality of life (QoL) outcomes measured as the walking component has already proven to be effective. With the exception of a few situations, there was no statistical significance among the groups regarding clinical outcomes and QOL.

Conclusion: All participants from each group showed improvements. There is marginal significance when both types of SCAWP are combined (W +WB) to enhance long-term adherence, thereby producing greater improvements in QoL and functional status. The three KT strategies appear to be equivalent in implementing a walking program for older individuals with OA. This study was financially supported by the Canadian Institute of Health Research (CIHR) (CIHR # RCT-161122).

Self-Efficacy Status Is Associated with Pain, Partially Mediating the Effect of Communication Style in Acupuncture Treatment for Knee Osteoarthritis. Grace H. Lo[1], Vanessa Cox[2], Richard L. Street Jr.[3] and Maria E. Suarez-Almazor[4]. [1]Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX, [2]UT MD Anderson Cancer Center, Houston, TX, [3]Texas A&M University, College Station, TX, [4]University of Texas. M.D Anderson Cancer Center, Houston, TX

Background/Purpose: In a recent study of acupuncture, high expectation style of communication of the interventionist showed greater improvement of pain in the treatment and sham acupuncture arms. Because the mind-body relationship is potentially important in acupuncture, self-efficacy status could be an important determinant of response to treatment. For this ancillary study, we had two aims: (1) to evaluate the relationship between self-efficacy and pain in knee OA and (2) to evaluate whether self-efficacy status is a mediator for the relationship between communication style and treatment effect.

Methods: This is an ancillary study of a 3 arm (traditional acupuncture, sham acupuncture, and wait list) randomized controlled trial for symptomatic knee OA. Those with a baseline and 3 month follow-up visit were included. Participants receiving either traditional or sham acupuncture were equally randomized to a high expectation and neutral communication style.

Self-Efficacy status was assessed using an abbreviated version of the Arthritis Self-Efficacy Questionnaire at the baseline and 3 month follow-up visit. Seven questions were averaged together to provide an overall self-efficacy score. Knee pain was assessed using the WOMAC pain subscale. The WOMAC pain scale was re-scaled to have a maximum score of 100. We performed correlations between baseline self-efficacy and pain; subsequently between change over 3 months of these two variables. For those in the traditional acupuncture and sham acupuncture arms, we then performed a linear regression with change in WOMAC pain score as the outcome, allocation of communication style as the predictor, and change in self-efficacy as a covariate. We repeated the model, including an interaction term between change in self-efficacy and communication style.

Results: Participants (N=485), 62% female, had a mean age of 64.7 (SD 9.2), BMI 32.4 (SD 7.5), baseline self-efficacy score 3.5 (SD 0.8) and baseline WOMAC pain 45.1 (SD 17.9). At baseline, the self-efficacy score was correlated with the WOMAC pain score, $R = -0.23$ ($p < 0.0001$). The mean change in self-efficacy over 3 months was 0.08 (SD 0.80), mean change in WOMAC pain was −12.9 (SD 18.3). Change in self-efficacy was correlated with change in WOMAC pain with an $R = -0.25$, $p < 0.0001$. In the linear regression model, allocation of communication style had a $p = 0.74$ while self-efficacy had a $p < 0.0001$. In the subsequent model, the interaction term had a $p = 0.20$.

Conclusion: In a randomized controlled trial of acupuncture for symptomatic knee OA, arthritis self-efficacy was highly correlated with knee pain scores cross-sectionally and longitudinally with higher self-efficacy being associated with lower pain severity level. As previously reported, communication style has an important effect on pain reduction. This effect may be partially mediated by change in arthritis self-efficacy. Identification ofadditional interventions effective in modifying self-efficacy may have the potential of improving pain in knee OA.

1092

Double Blind Cross-Over Study of the Efficacy of a Tart Cherry Juice Blend In Treatment of Osteoarthritis (OA) of the Knee. H. Ralph Schumacher[1], Sally W. Pullman-Mooar[2], Smita R. Gupta[3], Janet E. Dinnella[4], Rosa Kim[5] and Malachy McHugh[6]. [1]VA Medical Center and University of Pennsylvania, Philadelphia, PA, [2]Philadelphia Veterans Hospital, Philadelphia, PA, [3]University of Pennsylvania, Santa Monica, CA, [4]University of Pennsylvania, Philadelphia, PA, [5]The Children's Hospital of Philadelphia, Philadelphia, PA, [6]Nicholas Institute of Sports Medicine and Athletic Trauma, New York, NY

Background/Purpose: Consumption of cherries or cherry juice has been claimed to alleviate pain in arthritis, have anti-inflammatory and anti-oxidant

effects, alleviate muscle pain after exertion, and decrease pain (and uric acid levels) in gout. We tested effects of cherry juice (CJ) in patients with OA.

Methods: This double-blind cross-over study tested 6 weeks use of a tart cherry juice preparation (blended with apple juice to decrease tartness) given daily as 2 8-ounce bottles each containing the equivalent of 45 tart cherries. The comparator was Kool-aid (Kraft, Ryebrook, NY) with an added clouding agent to produce similar appearances. Both CJ and control servings contained 31 grams of sugar. Non-diabetic patients with Kellgren grade 2–3 OA and VAS pain of 4–9 were withdrawn from NSAIDS for at least 1 week. After 1 week washout treatments were crossed over for an additional 6 weeks. The primary outcome measures were WOMAC scores at 6 weeks; walking times, hsCRP levels, any acetaminophen use, and serum urate (because of past reports in gout) were also recorded.

Results: 59 patients were enrolled with 27 randomized to begin with CJ and 32 with the control. There were 53 completers for each group. WOMAC and pain scores decreased significantly after CJ but not after the control (Table 1), but differences between the treatments were not significant. Acetaminophen use and walking times did not change. hsCRP levels declined on CJ and rose on the control possibly related to initial withdrawal from NSAIDs and later withdrawal from CJ (Fig. 1) ($p<0.01$). WOMAC improvement correlated with hsCRP falls ($p<0.01$). Serum urate levels were mostly normal and did not change. 7 AEs lead to early discontinuations (4 with CJ and 3 control). AEs possibly related to CJ included one rash, and one "GI symptoms". 1 subject during the control treatment and 1 after the CJ had elevated blood sugar. Blinding was considered adequate. At the end of the CJ arm only 57% of subjects believed they were on CJ.

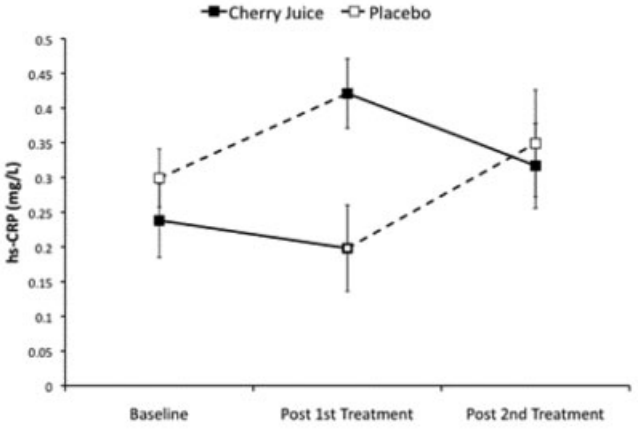

Figure 1. hsCRP values for cherry juice and placebo treatments displayed according to treatment order. Time by treatment order $P<0.01$. Mean±SE displayed.

Table 1. WOMAC Results

		Cherry Juice n=53	Placebo n=53	Difference n=49	P Value
WOMAC Score	Pre Treatment	46.1 ± 23.2	45.8 ± 23.5	1.7 ± 17.1	P=0.98
	Post Treatment	39.2 ± 25.1	43.0 ± 27.0	−2.7 ± 17.6	P=0.58
	Difference	6.9 ± 13.7	2.8 ± 16.9	4.4 ± 23.6	P=0.2*
	P Value	P=0.002	P=0.23	P=0.2*	
Pain Score	Pre Treatment	42.1 ± 22.9	41.5 ± 24.4	0.9 ± 18.0	P=0.99
	Post Treatment	36.3 ± 27	40.0 ± 26.6	−3.6 ± 20.5	P=0.46
	Difference	5.8 ± 17.7	1.5 ± 17.4	4.5 ± 27.3	P=0.20*
	P Value	P<0.05	P=0.99	P=0.20*	

mean±SD; *Significance of time by treatment interaction; other P values adjusted for planned pairwise comparisons (P values times 2).

Conclusion: Patients taking cherry juice had improved WOMAC scores and had significantly decreased hsCRP levels compared to controls. Both CJ and control were generally well tolerated.

1093

Fish Oil in Knee Osteoarthritis: A Two Year Randomized, Double-Blind Clinical Trial Comparing High Dose with Low Dose. Catherine L. Hill[1], Graeme Jones[2], Lynette March[3], Ruth Battersby[1], Kristen Hynes[2], Tanya Fedorova[4], Sue Lester[5], Susanna Proudman[6] and Leslie G. Cleland[6]. [1]The Queen Elizabeth Hospital, Woodville, Australia, [2]University of Tasmania, Hobart, Australia, [3]University of Sydney, Insitute of Bone and Joint Research, Royal North Shore Hospital, St Leonards NSW, Australia, [4]University of Sydney, St Leonards NSW, Australia, [5]Queen Elizabeth Hospital, Woodville South, Australia, [6]Royal Adelaide Hospital, Adelaide, Australia

Background/Purpose: Fish oil is widely used for the symptomatic treatment of osteoarthritis. However, its effect has not previously been investigated in an RCT. The objective of this study was to determine whether high dose fish oil is superior to low dose fish oil in the treatment of symptomatic knee osteoarthritis.

Methods: Investigator initiated, government funded, randomized, double-blind, multicenter 24 month trial. Patients older than 40 years, with knee OA as defined by the ACR clinical criteria, suffering from regular knee pain were randomized 1:1 to (1) high dose fish oil liquid (EPA 18% and DHA 12%) 15mL/day or (2) low dose fish oil (blend of fish oil and sunola oil in a ratio of 1:9) 15mL/day. Each oil was also flavored with citrus to provide a comparable taste and ensure masking. Prior to randomization, a 4- week run in period with a similar oil was performed to exclude patients who were intolerant to liquid fish oil. Baseline knee radiographs were scored according to OARSI atlas. The primary end point was change in pain scale (WOMAC index) from baseline to 3,6, 12 and 24 months. Secondary endpoints included changes in disability scale (WOMAC index) and OMERACT-OARSI Responder Index. Intention-to-treat analysis (LOCF) was undertaken.

Results: Participants (N=202) were 49% female, mean age 60.9 yrs (SE 0.7), mean BMI 29.0 (SE 4.7), with comparable baseline characteristics. There was significantly greater and earlier dropout in the high dose group (34.6%, median 3 months), compared to the low dose group (19.8%, median 7.5 months). In intention to treat analysis, both groups demonstrated a clinically important improvement in WOMAC pain and disability scores compared to baseline (Table 1, $p<0.003$). There was no difference between the 2 groups for change in WOMAC pain or function in the first year, however, the low dose group were superior to the high dose group for both pain and function at month 24. There was a trend towards better OARSI response at 24 months in the low dose group over the high dose group (Table 2, $p=0.06$).

Table 1.

	Change in WOMAC pain		Change in WOMAC disability	
	Low dose	High dose	Low dose	High dose
Month 3	−2.0	−2.5	−5.7	−8.3
Month 6	−3.2	−2.8	−8.6	−9.2
Month 9	−2.7	−2.7	−8.3	−10.7
Month 12	−4.5	−2.9	−13.8	−10.2
Month 18	−4.1	−2.5	−11.9	−8.9
Month 24	−5.2	−2.8	−12.7	−8.0

Table 2.

	PROPORTION OF RESPONDERS		
	low dose	high dose	p-value
Month 3	17%	22%	0.37
Month 6	21	23	0.66
Month 9	21	27	0.99
Month 12	32	28	0.27
Month 18	33	26	0.16
Month 24	39	27	0.06

Conclusion: Fish oil in either low dose or high dose improves the symptoms of knee OA. In contrast to RA, however, high dose fish oil was not superior to low dose particularly in the second year of treatment. This may reflect the effect of non-differential drop out rates or may suggest that low dose is sufficient for OA due to lower levels of inflammation.

1094

The Efficacy and Safety of Duloxetine Treatment in Older Patients with Osteoarthritis Knee Pain: A Post Hoc, Subgroup Analysis of Data From 2 Placebo-Controlled Trials. Joseph L. Micca[1], Richard C. Risser[2], Jonna Ahl[2] and Madelaine M. Wohlreich[2]. [1]Patient Centered Healthcare, Altanta, GA, [2]Lilly USA, Indianapolis, IN

Background/Purpose: Osteoarthritis (OA) of the knee is common in the elderly and a leading cause of disability. Alleviation of pain symptoms should be the focus of knee OA treatment. The purpose of this study was to examine the efficacy and safety of duloxetine (DLX) treatment in older aged patients with OA knee pain.

Methods: This was a post-hoc analysis of data from two 3-month randomized double-blind placebo-controlled trials in patients with symptomatic knee OA. In both studies, patients were randomized to DLX 60mg QD vs. placebo for 7 weeks. For the remaining 6 weeks, in Study I, DLX patients were re-randomized to receive either DLX 60 mg QD or 120 mg QD. In Study II, only DLX non-responders (defined as <30% improvement from baseline on Brief Pain Inventory 24-h average pain item score) had their dose increased to 120 mg. For each study, patients were stratified according to age:

<65 (younger) and ≥ 65 years (older). Dosing arms for each age group were: DLX 60 mg for patients who remained on this dose, and DLX 120 for patients who had their dose increased, and placebo. Pain severity (0–10) was assessed daily and recorded in patient diaries. Change in weekly average pain was analyzed with a mixed-models repeated measures model including terms up to and including the 3-way interaction between treatment, age group, and week, which assesses differential treatment effects between age groups over time. Treatment-emergent adverse events (TEAEs) were compared between treatments and subgroups using a logistic regression model including the terms up to and including the interaction between treatment and age group, which assesses the differential treatment effects between age groups.

Results: Across both studies, average age in years was 56 for younger subgroup and 72 for older subgroup. Average pain duration in younger and older groups was 7 and 10 years, respectively, and average baseline pain score was 6 in both age groups. The older subgroup included: DLX 60, n=68; DLX 120, n=35; PLA, n=136; and the younger subgroup included: DLX 60, n=95; DLX 120, n=41; PLA, n=154. After 13 weeks treatment, in Study I, there was significantly greater pain reduction in older patients with DLX 60 mg and 120 mg vs. PLA (−3.3 (60 mg) and −4.1 (120 mg) vs. −2.0; both p<.01). Among younger patients, those receiving DLX 120 had significantly greater pain reduction vs. PLA (−3.1 vs. −2.2; p=.03); improvement in pain did not differ from PLA in patients receiving DLX 60 mg. In Study II, all patients receiving DLX 60 mg had significantly greater improvement in pain vs. PLA (older: −3.2 vs. −1.8, p<.01; younger: −3.0 vs. −2.0, p<.01); improvement in pain did not differ from PLA in patients receiving DLX 120 mg. Among TEAEs with frequency ≥ 2% for DLX, only dizziness showed significant treatment by subgroup interaction (p =.022), with greater incidence over placebo in younger patients (6.6% vs 0.6%, p =.024) but not in the older patients (1.0% vs 3.2%, p =.292).

Conclusion: In older patients, duloxetine 60 mg/day for the treatment of OA knee pain was efficacious and well tolerated.

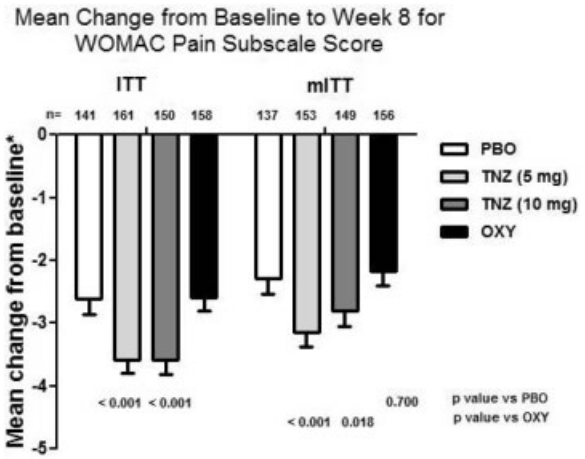
1095

A Phase 3 Placebo- and Oxycodone-Controlled Study of Tanezumab in Adults with Osteoarthritis. James Fidelholtz[1], Marvin Tark[2], Egilius Spierings[3], Gernot Wolfram[4], Karen Annis[4], Michael D. Smith[4], Mark T. Brown[4] and Christine R. West[5]. [1]Hilltop Physicians, Inc., Cincinnati, OH, [2]Pain Solutions Treatment Centers, Marietta, GA, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]Pfizer, Groton, CT, [5]Pfizer, Williamston, MI

Background/Purpose: A randomized, double-blind, placebo (PBO)- & active-controlled study, investigated efficacy & safety of tanezumab (TNZ), a humanized monoclonal antibody that specifically inhibits nerve growth factor, vs. oxycodone (OXY) continuous release as analgesic treatment for knee or hip osteoarthritis (OA).

Methods: Eligible patients had moderate to severe pain from knee or hip OA, Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) Pain subscale score ≥5, WOMAC Physical Function subscale score ≥4, Patient Global Assessment of OA of 'Fair', 'Poor' or 'Very Poor', & Kellgren-Lawrence Grade of ≥2 at Baseline. Patients received up to two doses of TNZ (10 or 5 mg IV in 8-week intervals), OXY (10–40 mg every 12 hours; up-titrated & modified according to tolerability & pain relief) or PBO after appropriate prior analgesic pain medication washout. The primary endpoint was WOMAC Pain subscale score. The study was partially completed due to a FDA-imposed clinical hold so primary endpoint timing was amended from Week 16 to Week 8 to maximize planned analyses. Primary efficacy comparisons of TNZ vs. PBO were made in the intent-to-treat population (ITT; patients who received ≥1 IV injection) whereas comparisons of TNZ vs. OXY & OXY vs. PBO were conducted on the modified intent-to-treat population (mITT; all ITT patients with Week 8 visit or discontinued on or before clinical hold). Incidence of adverse events (AEs) was assessed.

Results: Both TNZ doses (p<0.001), but not OXY (p=0.700) resulted in significant improvements in WOMAC Pain subscale vs. PBO at Week 8 (Figure). WOMAC Pain subscale improvements with TNZ 10 mg & TNZ 5 mg were also superior to OXY (p≤0.018). Overall AE rate was higher with OXY (63.3%) than TNZ (40.7 – 44.7%) or PBO (35.5%). AEs reported in >5% of patients were nausea, constipation, vomiting, dizziness, pruritus, & headache with OXY & arthralgia with TNZ 10 mg. Incidence of patients who discontinued due to an AE was highest with OXY (10.1%), followed by TNZ 10 mg (2.7%), PBO (1.4%), & TNZ 5 mg (1.2%). Incidence of serious AEs was similar among treatments & <3%. The AE profile for TNZ was similar to that of previous TNZ studies. Two patients in TNZ 10 mg group were reported to have osteonecrosis (ON; 2/150; 1.3%; one was reported as worsening of pre-existing ON) & underwent total joint replacement (TJR). An external adjudication committee did not confirm ON, but indicated one patient had rapidly progressing OA & the other had normally progressing OA. One additional patient in the TNZ 10 mg group, one in TNZ 5 mg and one in PBO underwent TJR not associated with an AE. One patient in the OXY group underwent TJR for an AE of OA.



Conclusion: Treatment with TNZ (10 mg or 5 mg) resulted in superior analgesic efficacy as measured by WOMAC Pain subscale compared to PBO & OXY. Results from this study indicate that TNZ is efficacious in the treatment of OA pain. No new safety signals were identified.

1096

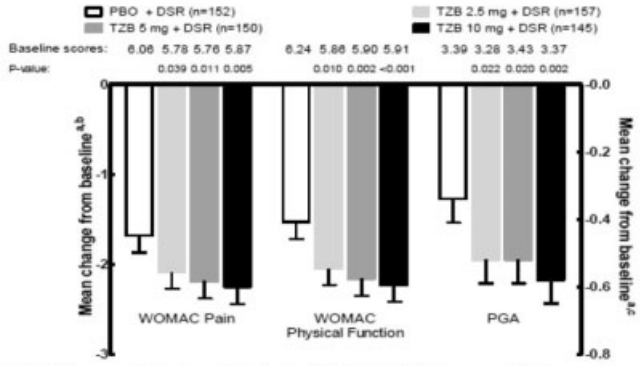
Efficacy and Safety of Tanezumab Added on to Diclofenac in Patients with Knee or Hip Osteoarthritis (NCT00864097). Eugen Feist[1], Andra Balanescu[2], Gernot Wolfram[3], Isabelle Davignon[3], Michael D. Smith[3], Mark T. Brown[3] and Christine R. West[4]. [1]Charité Medical School, Berlin, Germany, [2]Sf. Maria Hospital, Bucharest, Romania, [3]Pfizer, Groton, CT, [4]Pfizer, Williamston, MI

Background/Purpose: Tanezumab (TZB), a monoclonal antibody that inhibits nerve growth factor, reduces hip or knee osteoarthritis (OA) pain. A European randomized, double-blind, controlled multicenter study was conducted to evaluate efficacy and safety of intravenous (IV) TZB added to oral diclofenac sustained release (DSR) in patients with hip or knee OA.

Methods: Patients (N=604) with moderate to severe knee or hip OA tolerating stable oral diclofenac 150 mg/day were randomized and treated in a 1:1:1:1 ratio to IV TZB 2.5, 5, or 10 mg, or placebo (PBO) at weeks 0, 8, and 16, combined with oral DSR 75 mg BID. Co-primary efficacy endpoints (Western Ontario and McMaster Universities OA Index [WOMAC] Pain subscale, WOMAC Physical Function subscale, and Patient Global Assessment [PGA] of OA) were assessed at Week 16. Statistical analysis was made using Analysis of Covariance (ANCOVA), with model terms for baseline value, OA type (knee or hip) and treatment group, with Last Observation Carried Forward as primary imputation for missing data. Comparisons were made by prespecified step-down testing for TZB dose + DSR versus PBO + DSR, in the order of tanezumab doses of 10 mg, 5 mg then 2.5 mg. Each treatment comparison across co-primary endpoints had to be significant to conclude superiority.

Results: For all TZB doses, mean changes from baseline to Week 16 with TZB + DSR were statistically significant versus PBO + DSR for all co-primary endpoints (p≤0.039; 9 of 9 comparisons; Figure). Safety was similar to previous TZB trials although incidence of adverse events (AEs) of abnormal peripheral sensation was lower. No new safety signals emerged. Overall incidence of AEs was higher with TZB + DSR (45.2–49.7%) than with PBO + DSR (34.9%). Serious AE rates were similar across treatments (5.3–7.6%) with OA and osteonecrosis (ON) the most frequently reported (in 6 patients each across treatments). ON was reported as a serious AE in 6 of 452 patients with TZB + DSR (1.3%), but an external adjudication committee was unable to confirm ON in any patient. Three patients had insufficient x-ray information to allow

adjudication, 1 had rapidly progressing OA, 1 had subchondral fracture and 1 had an old femoral neck fracture at baseline. Overall combined incidence of total joint replacement due to reported ON, OA or arthralgia was 2.8% with TZB 10 mg + DSR, 2.0% with TZB 5 mg + DSR, 1.3% with TZB 2.5 mg + DSR and 0.7% with PBO + DSR. Incidence of AEs causing withdrawals was 3.9% for PBO + DSR and 5.1–7.3% in TZB + DSR groups. Treatment-emergent serious AEs involving fractures were reported more frequently in TZB + DSR (6 of 452 patients; 1.3%) versus PBO + DSR (0 of 152 patients) other serious AEs were not observed in ≥1 patient in any group.



DSR, diclofenac sustained release; PBO, placebo; PGA, Patient Global Assessment; TZB, tanezumab; WOMAC, Western Ontario & McMaster Universities Osteoarthritis Index; [a]Least square mean change from baseline; [b]WOMAC subscales were assessed on a 0-10 numerical rating scale; [c]PGA was assessed on a 5-point Likert scale; Last Observation Carried Forward used as the primary imputation for missing data

Conclusion: Addition of TZB to stable oral diclofenac in OA patients resulted in greater improvement in pain, function, and global assessments than diclofenac alone across co-primary endpoints with no new safety signals.

ACR/ARHP Poster Session B
Osteoporosis and Metabolic Bone Disease: Clinical Aspects and Pathogenesis
Monday, November 7, 2011, 9:00 AM–6:00 PM

1097

Is Femoral Neck Fracture Associated with Hip Structural Analysis Measurements? Alexander G. S. Oldroyd[1], John P. Halsey[2], Bronwen Evans[2], Cathi Greenbank[2], Nicola Goodson[3] and Marwan Bukhari[2]. [1]Lancaster University, Lancaster, United Kingdom, [2]Royal Lancaster Infirmary, Lancaster, United Kingdom, [3]University Hospital Aintree, Liverpool, United Kingdom

Background/Purpose: The association between a lower femoral neck bone mineral density (BMD) and a higher fragility fracture risk is well known. Studies have also identified the dependency of bone fracture resilience upon morphometric shape of bone. Densitometry scans have the ability to measure the shape of the proximal femur, called hip structural analysis (HSA).

This study aimed to investigate if the shape and density of the proximal femur are associated with previous femoral neck fracture.

Methods: Dual X-ray Absorptiometry (DXA) scan results between 1996 and 2010 from a single scanner in the North west of England were collated. The following basic information of each individual was recorded: age, sex, body mass index (BMI) and social deprivation score of place of residence. The BMD of the femoral neck was collated. All HSA measurements were collated, including the hip axis length (HAL), cross-sectional moment of inertia (CSMI) and proximal femur strength index (SI). The previous femoral neck fragility fracture status of each patient was ascertained. Densitometry data of those who had previously sustained a unilateral femoral neck fracture was collated from their contralateral un-fractured femoral neck.

Logistic regression analysis, adjusted for age, sex, BMI, social deprivation score and femoral neck BMD, was used to investigate for significant differences of HSA measurements between those who had and had not sustained a femoral neck fracture. Differences of femoral neck BMD was also investigated for, adjusted for age, sex, BMI and social deprivation score.

Results: 580 (75.69% female) subjects had previously sustained a unilateral fracture of the femoral neck. 8389 (84.45% female) subjects had not previously sustained a fragility fracture of any body site.

Analysis revealed a significant difference of HAL, CSA, length and diameter of the femoral neck (represented by d1, d2, d3, y) and SI between the two fracture groups, independent of age, sex, BMI and social deprivation score.

Following further adjustment for femoral neck BMD, the only HSA measurements that varied between the two fracture groups were those of the diameter and length of the femoral neck: d1, d2, d3 and y; femoral neck fracture was significantly associated with a shorter and wider femoral neck. Femoral neck BMD of the fracture group was significantly lower compared to the non-fracture group.

	Adjusted for age, sex, BMI and social deprivation score Odds ratio (95% CI)	Adjusted for age, sex, BMI, social deprivation score and femoral neck BMD Odds ratio (95% CI)
HAL/mm	1.05 (1.03, 1.07)	0.96 (0.91, 1.02)
CSMI/m^4	0.99 (0.95, 1.03)	1.03 (0.90, 1.17)
CSA/mm^2	0.98 (0.97, 0.98)	1.01 (0.98, 1.04)
d1/cm - distance from centre of femoral head to centre of femoral neck	1.04 (1.01, 1.07)	0.87 (0.78, 0.97)
d2/cm - distance from centre of femoral head to axis intersection of femoral neck and shaft	0.98 (0.97, 0.99)	0.96 (0.91, 0.99)
d3/cm - mean diameter of femoral neck	1.11 (1.07, 1.15)	1.13 (1.03, 1.24)
y/cm - distance from centre of mass of femoral neck to superior neck margin	1.26 (1.19, 1.35)	1.22 (1.04, 1.44)
Neck/shaft angle^o	0.98 (0.96, 1.00)	0.99 (0.94, 1.05)
SI	0.58 (0.41, 0.79)	1.38 (0.91, 2.10)
Mean femoral neck BMD g/cm^2	0.05 (0.01, 0.90)	–

Conclusion: Femoral neck fracture is significantly associated with a shorter and wider femoral neck. Measurement of a patient's shape of their proximal femur may allow for more accurate assessment of their femoral neck fracture risk. Further work on the fragility-fracture predictive ability of HSA measurements is warranted.

1098

The Analysis of Denosumab Discontinuation and Associated Fracture Incidence in the FREEDOM Trial. Jacques P. Brown[1], Jens-Erik Beck Jensen[2], Chris Recknor[3], Christian Roux[4], Ove Tørring[5], Matt Austin[6], Andrea Wang[6], Andreas Grauer[6] and Rachel B. Wagman[6]. [1]CHUQ-CHUL Research Centre, Laval University, Quebec City, QC, [2]Hvidovre Hospital, Hvidovre, Denmark, [3]United Osteoporosis Centers, Gainesville, GA, [4]Paris Descartes University, Paris, France, [5]Institution for Clinical Science and Education Södersjukhuset Karolinska Institutet, Stockholm, Sweden, [6]Amgen Inc., Thousand Oaks, CA

Background/Purpose: Denosumab, a reversible RANKL inhibitor, decreases osteoclast formation, function, and survival. In the pivotal phase 3 fracture trial, FREEDOM, denosumab 60 mg administered every 6 months decreased the risk for new vertebral, nonvertebral, and hip fractures over 3 years compared with placebo (Cummings *NEJM* 2009). Osteoporosis is a chronic disease, and continued treatment is required to provide anti-fracture efficacy. While cessation of denosumab treatment has been associated with transient increases in bone remodeling and declines in bone mineral density (BMD) (Miller *Bone* 2008; Bone *JCEM* 2011), the effect on fracture risk is not as well characterized.

Methods: To understand fracture incidence in an osteoporotic population after treatment cessation, we evaluated subjects in FREEDOM who discontinued treatment after receiving 2 to 5 doses of investigational product (IP), either denosumab or placebo, and continued study participation for ≥ 6 months since the last dose + 1-month study visit window (≥ 7 months). The off-treatment observation period, which varies from subject to subject, began 7 months after the last dose of IP and lasted for approximately 6 to 24 months (for subjects who received 5 and 2 doses, respectively).

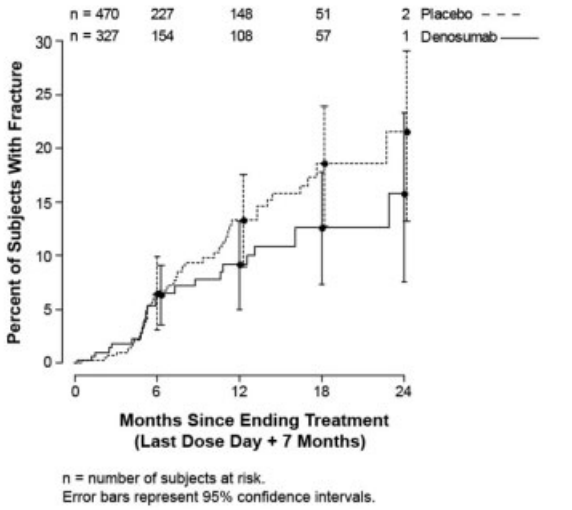
Table. Subject Characteristics at Treatment Discontinuation

	Placebo (N = 470)	Denosumab (N = 327)
Number of doses received		
2	114 (24)	86 (26)
3	138 (29)	99 (30)
4	90 (19)	68 (21)
5	128 (27)	74 (23)
Fracture during treatment*	90 (19)	36 (11)
Significant BMD reduction† during treatment*	80 (17)	4 (1)
Treatment discontinuation due to requiring alternative therapy or disease progression	116 (25)	29 (9)
Started alternative therapy after last dose	197 (42)	90 (28)

Values are number (%) of subjects. N = number of subjects who discontinued treatment after receiving 2 to 5 doses of investigational product, either denosumab or placebo, and continued study participation for ≥ 7 months after the last dose. *Treatment period = first dose through last dose + 7 months. †Significant BMD reduction is defined as > 7% BMD reduction at the total hip within any 12-month period, ≥ 10% BMD reduction at total hip from baseline at any time point, or total hip BMD T-score < −4 at any time point.

Results: This subgroup of 797 subjects (470 placebo, 327 denosumab) showed similar baseline characteristics for age, prevalent fracture, and lumbar spine and total hip BMD T-scores. During the treatment period, more subjects treated with placebo as compared with denosumab sustained a fracture and had significant decreases in BMD (Table). In addition, 42% of placebo-treated subjects vs 28% of denosumab-treated subjects initiated an alternative therapy after the last dose. After treatment discontinuation, similar percentages of subjects in both groups sustained a new fracture (9% placebo, 7% denosumab), resulting in a fracture rate per 100 subject-years of 13.5 for placebo and 9.7 for denosumab (HR 0.82; 95% CI: 0.49, 1.38), adjusted for age and total hip BMD T-score at baseline. There was no apparent difference in fracture occurrence pattern between the treatment groups during the off-treatment period (Figure).

Figure: Time to First Osteoporotic Fracture During the Off-treatment Period



Conclusion: We conclude from this analysis that there was not an excess in fracture risk after treatment cessation with denosumab compared with placebo during the off-treatment period for up to 24 months.

Vertebral and Femoral Strength Increased In Postmenopausal Women with Osteoporosis Treated with Teriparatide for 18 Months. Tony M. Keaveny[1], Michael Maricic[2], David Kopperdahl[3], Valerie Ruff[4], Xiaohai Wan[5] and Kelly Krohn[6]. [1]University of California, Berkeley, CA and O.N. Diagnostics, LLC, Berkeley, CA, [2]Catalina Pointe Rheumatology, Tucson, AZ, [3]O.N. Diagnostics, LLC, Berkeley, CA, [4]Lilly USA, LLC, [5]Eli Lilly and Company, [6]Lilly USA, LLC, Indianapolis, IN

Background/Purpose: Finite element analysis of quantitative CT scans is a widely accepted method for non-invasive assessment of vertebral and femoral strength in clinical studies. Since very few finite element data have been reported on changes in vertebral and femoral strength for patients treated with teriparatide [rhPTH (1–34)], the biomechanical effects of teriparatide treatment in postmenopausal women with osteoporosis are not well known. To address this issue, we used finite element analysis to assess the effects of 18 months of treatment with teriparatide on vertebral and femoral strength in postmenopausal women with osteoporosis. We also assessed changes in volumetric bone mineral density (BMD), areal BMD, and early changes in bone turnover markers (P1NP and CTX).

Methods: 30 postmenopausal women (T-score of −2.0 or lower with ≥1 minimal trauma vertebral/nonvertebral fracture or T-score of −3.0 or lower with no prior fracture) received teriparatide 20 μg administered subcutaneously once daily for 18 months in this open-label study. Quantitative CT of the lumbar spine and hip was performed at baseline and 18 months (or early termination visit). All patients with 2 evaluable CT scans at both time points were included in the analysis. Volumetric density was measured for the trabecular, peripheral (outer 2–3 mm of bone that contained both cortical and some adjacent trabecular bone), and both ("integral") compartments. Nonlinear finite element analysis was performed for uniform compression for the spine and a sideways fall for the hip to provide estimates of vertebral and femoral strength. DXA of the spine and hip was performed at baseline and 18 months (or early termination) to determine areal BMD. Serum P1NP and CTX were assessed at baseline, 3 and 6 months.

Results: Vertebral and femoral strength increased compared to baseline. Significant increases were observed at 18 months in both trabecular and peripheral volumetric densities for the spine, and a significant increase was seen in the trabecular density for the hip, with no change in the peripheral density (Table). Areal BMD also increased significantly at the lumbar spine. Both P1NP and CTX showed significant increases at Months 3 and 6 (Figure).

Table. % Change from Baseline to Month 18 Median (interquartile range)

Outcome	Vertebra (n=30)	Femur (n=26)
Strength	16.6 (7.4, 24.7)*	2.3 (−1.6, 6.8)*
Strength-to-Density Ratio[a]	5.5 (2.8, 10.0)*	0.0 (−1.4, 1.5)
Volumetric Bone Density		
Integral	9.9 (4.4, 14.4)*	2.2 (0.0, 4.7)*
Trabecular	12.8 (4.9, 18.2)*	3.9 (1.5, 7.0)*
Peripheral	5.8 (3.8, 9.2)*	0.0 (−1.6, 1.9)
Mean (standard deviation)		
Areal BMD	(n = 25)	(n = 28)
Lumbar spine	6.3 (5.0)**	
Femoral neck		1.8 (4.8)
Total hip		0.2 (3.4)

[a] Ratio of strength to integral density
* $P < 0.05$ vs baseline; ** $P < 0.0001$ vs baseline

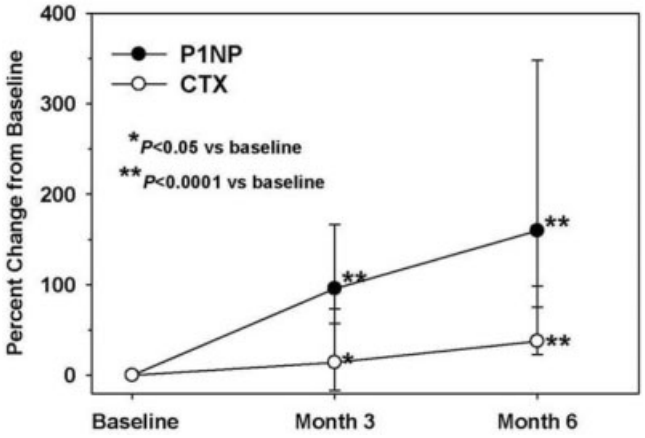

Figure. % Change from Baseline, Median (interquartile range), in Bone Turnover Markers

Conclusion: In women with postmenopausal osteoporosis, both vertebral and femoral strength increased after 18 months of treatment with teriparatide.

Risk Factors for Osteoporosis in Patients with Rheumatoid Arthritis (TOMORROW STUDY). Tadashi Okano[1], Masahiro Tada[1], Yuko Sugioka[1], Kenji Mamoto[2], Shigeyuki Wakitani[1], Hiroaki Nakamura[1] and Tatsuya Koike[1]. [1]Osaka City University Medical School, Osaka, Japan, [2]Higashisumiyoshi Morimoto Hospital, Osaka, Japan

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease characterized by inflammation of the synovial joint, cartilage degradation, and subsequent bone destruction. Bone damage is often manifested as localized juxta-articular bone loss, or generalized bone loss. The later is likely attributed to a number of factors including disease activities itself, reduced daily physical activity, glucocorticoid use or common postmenopausal osteoporosis. We have started prospective cohort study (TOMORROW research) to investigate comorbidities of the RA patients. In this study, we examined the risk factors that affected osteoporosis in RA patient.

Methods: Subjects included 208 RA patients (112 patients receiving biological agents and 96 patients receiving conventional therapy) and 205 age- and sex-matched healthy volunteers (N=413). Measurements of body composition, bone mineral density (BMD, QDR-4500, Hologic), urine pentosidine, urine NTX, ucOC and homocysteine levels were performed. In the analysis of BMD, the patients who had the prosthesis in their joints were excluded.

Results: In the baseline data, lean body mass was lower and fat mass was higher in RA patients than volunteers (table 1). The arms, lower limbs, the thoracic vertebra and the lumbar vertebra significantly indicated a low value

in the bone density in the RA group compared to the volunteer group ($p<0.05$) (Table 2). Moreover, urine pentosidine, urine NTX and homocysteine levels were significantly higher in RA patients (Table 2). Bone density correlated with lean body mass positively, and showed negative correlations with the fat mass. Stepwise multiple regression analysis using whole body BMD as a dependent variable resulted in age, weight, whole body lean mass, whole body % fat and NTX as independent variables. Age and whole body lean mass were also selected as independent variables for upper arm, thoracic spine, lumber spine and leg BMD.

Table 1. Clinical data at baseline

Parameter	Whole population (n=413)	Control (n=205)	RA (n=208)	P*
Age	57.9 ± 12.9	57.4 ± 13.1	58.4 ± 12.8	NS
Women (n [%])	349 (85)	172 (84)	177 (85)	NS
Height (cm)	156.4 ± 8.4	157.6 ± 7.8	155.3 ± 8.8	NS
Body weight (kg)	55.6 ± 10.2	56.3 ± 10.4	54.9 ± 10.1	NS
BMI (kg/m^2)	22.7 ± 3.4	22.6 ± 3.2	22.7 ± 3.6	NS
Girth of the abdomen (cm)	81.1 ± 10.0	81.6 ± 9.3	80.6 ± 10.6	NS
Whole body lean mass	38377.5 ± 7538.0	39566.2 ± 7662.2	37206.0 ± 7242.8	<0.01
Whole body % Fat	28.3 ± 6.6	27.2 ± 6.2	29.4 ± 6.8	<0.01

(* comparison between control and RA subject)

Table 2. BMD and biomarker

Parameter	Whole population (n=413)	Control (n=205)	RA (n=208)	P*
Left arm BMD	0.607 ± 0.098	0.632 ± 0.085	0.582 ± 0.104	<0.01
Right arm BMD	0.613 ± 0.105	0.639 ± 0.091	0.587 ± 0.111	<0.01
Thoracic spine BMD	0.725 ± 0.128	0.750 ± 0.126	0.701 ± 0.125	<0.01
Lumbar spine BMD	0.913 ± 0.164	0.930 ± 0.163	0.896 ± 0.164	<0.05
Left leg BMD	0.993 ± 0.144	1.022 ± 0.126	0.961 ± 0.155	<0.01
Right leg BMD	1.005 ± 0.144	1.034 ± 0.123	0.973 ± 0.158	<0.01
Whole body BMD	0.989 ± 0.129	1.005 ± 0.123	0.968 ± 0.134	<0.01
Urine pentosidine (pmol/mg Cr)	63.8 ± 33.7	54.2 ± 23.1	73.6 ± 39.5	<0.01
Urine NTX (nmolBCE/mmolCr)	51.7 ± 32.5	44.3 ± 22.4	59.0 ± 38.7	<0.01
ucOC (ng/ml)	4.06 ± 2.73	3.97 ± 2.34	4.16 ± 3.07	NS
Homocysteine (μmol/l)	10.0 ± 4.0	9.1 ± 2.6	10.9 ± 4.8	<0.01

(* comparison between control and RA subject)

Conclusion: RA patients showed lower BMD at any part of body compared to age- and sex- matched volunteers. Lower BMD in RA patients might be explained by lower lean mass and higher % fat. The effects of other factors such as medication, duration of inflammation might be explored by our continuous cohort study.

Adherence with Intravenous Zoledronic Acid and Ibandronate for Osteoporosis Among U.S. Medicare Beneficiaries. Jeffrey R. Curtis[1], Huifeng Yun[2], Robert Matthews[2], Kenneth G. Saag[1] and Elizabeth S. Delzell[2]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: To evaluate adherence beyond one year among new users of zoledronic acid and IV ibandronate among U.S. Medicare enrollees.

Methods: We used Medicare data for the random 5% sample from January 2005 through December 2009 to evaluate new users of IV zoledronic acid and ibandronate. Eligible individuals must have had continuous Medicare part A + B + D coverage and not be enrolled in a Medicare Advantage plan. Results were multiplied by 20 to extrapolate to the national U.S. Medicare Fee for Service population. A one year base period was used to characterize covariates of interest. All patients must have had 18 months of follow-up time after their first infusion to assess adherence.

The outcome of interest during the 18 month follow-up period was high adherence. For zoledronic acid, adherence was defined as receiving at least 2 infusions of zoledronic acid or switching to IV ibandronate; for ibandronate, adherence was defined as receiving at least 5 ibandronate infusions or switching to zoledronic acid. Factors hypothesized to be associated with adherence with zoledronic acid beyond 1 year were evaluated with multivariable logistic regression.

Results: Among 22,220 eligible Medicare beneficiaries, 15,100 were new users of zoledronic acid (Z) and 7,120 were new, users of IV ibandronate (I). The median (IQR) age of the zoledronic acid and ibandronate users was 78 (8) and 78 (9) years. Of these, approximately 95% were women and 95% were white. A majority of patients received at least one prescription for oral glucocorticoids (62 and 73%, respectively). For both drugs, 43% of first infusions were given in the outpatient hospital setting; for those given in physician offices, 26 (Z) and 31% (I) were administered by rheumatologist/endocrinologists, 15 (Z) and 6% (I) by oncologists, and 10 (Z) and 13% (I) by internal medicine doctors.

The proportion of zoledronic acid users persistent beyond one year was 65.7% and was greater than the proportion persistent with IV Ibandronate (34.6%, $p < 0.0001$). After adjustment, factors associated with zoledronic acid adherence (referent to those non-persistent with zoledronic acid) included male gender (odds ratio [OR] = 0.35, 95% CI 0.11 – 1.11), age 85+ (referent to age 65–69) (OR = 0.41, 95% CI 0.21 – 0.80), glucocorticoid use (OR = 0.74, 0.53 – 1.03), prior non-adherence with osteoporosis medications (OR = 0.66, 95% CI 0.42 – 1.04) and prior factures (OR=0.89, 95% CI 0.51–1.56). Compared to infusions administered by an oncologist, adherence was greater among patients receiving infusions administered by an internal medicine physician (OR = 1.84, 0.92 – 3.70) and rheumatologists/endocrinologists (OR = 1.45, 0.86 – 2.45).

Conclusion: Adherence beyond 1 year with IV zoledronic acid and IV ibandronate was comparable or somewhat greater than prior reports of adherence with oral bisphosphonates. However, more than 1/3 of IV bisphosphonate users did not continue beyond 12 months. Less frequently dosed medications may improve adherence but ongoing efforts are still needed to maximize long term adherence with osteoporosis therapies.

1102

Glucocorticosteroids but Not Hand Bone Density Is Associated with Distal Radius Fracture Severity in Elderly Women. Alvilde Dhainaut[1], Adalstein Odinson[2], Kamil Daibes[3], Mari Hoff[2], Unni Syversen[1] and Glenn Haugeberg[1]. [1]The Norwegian University of Science and Technology, Trondheim, Norway, [2]St Olavs Hospital, Trondheim, Norway, [3]Sørlandet Hospital, Kristiansand, Norway

Background/Purpose: Distal radius is one of the most common sites for fractures (fx) in elderly people. Both reduced bone mineral density (BMD) and the use of glucocorticosteroids (GC) have been identified as independent risk factors for fragility distal radius fx [1]. GC do not only reduce BMD, but do also impair bone quality. Reduced BMD measured in the hand with Digital X-ray Radiogrammetry (DXR) has been shown to predict distal radius fx [2]. The aim of this study was to explore if there is an association between severity of distal radius fx and hand DXR-BMD or other potential associates including GC.

Methods: The study population consisted of 110 women > 50 years with a recent low-energy distal radius fx assessed 10 days after fx. Demographic, clinical and treatment data were collected. BMD at the spine (L2–4) and femoral neck was assessed by dual energy X-ray absorptiometry (DXA) and hand BMD was assessed by the Sectra DXR software calculating cortical BMD from hand radiographs. Fx were scored according to the AO Classification of Fractures of Long Bones on the primary X-rays where fx were divided into A, B and C types, each with 3 subgroups. A is extra-articular, B partial articular and C intra-articular. Intraarticular fx were defined as more severe than extra-articular fx. The association between extraarticular or intraarticular fx as dependent variable and BMD, clinical and treatment variables were tested separately in unadjusted logistic regression analyses. Variables with a p value ≤ 0.20 were included in adjusted analyses. Statistical tests were applied using SPSS and significance level was $p < 0.05$.

Results: Mean age was 68 years. 75% had an extraarticular fx (34 A2; 49 A3) and 25% had an intraarticular fx (4 B1, 1 B2, 17 C1, 3 C2 and 2 C3). In the intraarticular group a significant higher proportions of patients were ever user of GC compared to the extraarticular group (5/81 vs 5/24 $p=0.016$). No significant differences between the two groups were found for age, height, weight, smoking, alcohol use, current exercise, presence of chronic inflammatory or endocrine disease, use of calcium, vitamin D, bisphosfonate orestrogen, DXA BMD at spine or femoral neck or DXR hand BMD. In logistic regression analyses none of the BMD measurements were significantly associated to fx severity in univariate analyses. Ever use of GC had a significant result with an increased risk of having an intraarticular fx both in univariate and adjusted analyses (Table 1). In the adjusted analyses DXA BMD showed a reverse effect with higher BMD increasing the risk for intraarticular fx.

Table 1.

	Univariate		Adjusted		Adjusted	
	OR	P	OR	P	OR	P
GC, ever use	5.07	0.01	5.87	0.04		
GC, current use	3.71	0.12			1.15	0.89
Spine BMD mg/cm^2	1.00	0.14	1.00	0.01	1.00	0.01
Exercise†	0.44	0.09	0.53	0.28	0.22	0.50
Chronic disease‡	2.28	0.09	2.01	0.24	2.78	0.09
Calcium, current use	0.99	0.14	0.99	0.12	0.99	0.04

Conclusion: We found no association between cortical hand DXR BMD and the severity of distal radius fx expressed with the AO classification. However, our data indicate a potential association between the use of GC and the risk for intraarticular fx.

Extended Safety Observations From Denosumab Administration in Postmenopausal Women From the FREEDOM and FREEDOM Extension Trials. J. P. Brown[1], H. G. Bone[2], R. Chapurlat[3], C. Libanati[4], M. L. Brandi[5], E. Czerwinski[6], M.-A. Krieg[7], Z. Man[8], D. Mellström[9], S. C. Radominski[10], J.-Y. Reginster[11], H. Resch[12], J. A. Román Ivorra[13], Christian Roux[14], N. S. Daizadeh[4], A. Grauer[4], S. R. Cummings[15] and S. Papapoulos[16]. [1]CHUQ-CHUL Research Centre, Laval University, Quebec City, QC, [2]Michigan Bone & Mineral Clinic, Detroit, MI, [3]Hôpital Edouard Herriot, Lyon, France, [4]Amgen Inc., Thousand Oaks, CA, [5]University of Florence, Florence, Italy, [6]Krakow Medical Center, Krakow, Poland, [7]University Hospital of Lausanne, Lausanne, Switzerland, [8]Centro TIEMPO, Buenos Aires, Argentina, [9]Sahlgrenska University Hospital, Göteborg, Sweden, [10]Universidade Federal do Paraná, Curitiba, Brazil, [11]University of Liège, Liège, Belgium, [12]St. Vincent Hospital, Vienna, Austria, [13]Hospital Universitario La Fe, Valencia, Spain, [14]Paris Descartes University, Paris, France, [15]San Francisco Coordinating Center, CPMC Research Institute, San Francisco, CA, [16]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Denosumab (DMAb) is an approved therapy for the treatment of postmenopausal women with osteoporosis at increased risk for fracture. A favorable DMAb risk/benefit profile was demonstrated in the pivotal, 3-year FREEDOM trial. All women who completed FREEDOM, did not discontinue investigational product, and did not miss > 1 dose were eligible to participate in an extension study to investigate the safety and efficacy of DMAb treatment for up to 10 years. We previously reported that 5 years of DMAb treatment maintained bone turnover reduction, increased BMD, and was associated with low fracture rates. Here, we provide details on the yearly incidence of serious adverse events (SAEs) of infection and adverse events (AEs) of malignancy in FREEDOM and the extension.

Methods: Of the 5928 women eligible for the extension, 4550 (77%) enrolled. During the extension, all women receive 60 mg DMAb every 6 months and supplemental calcium and vitamin D daily. For the analyses reported here, women from the FREEDOM DMAb group received 2 more years of DMAb for a total of 5 years of exposure (long-term group; N=2343) and women from the FREEDOM placebo group received 2 years of DMAb exposure (cross-over group; N=2207). The analyses of AEs were descriptive and are reported as exposure-adjusted subject incidence rates.

Results: The year-to-year observed subject incidence rates of SAEs of infection (Table 1) and AEs of malignancy (Table 2) in the placebo group exhibited some variation during the 3 years of the FREEDOM trial. The yearly subject incidence rates in the first 2 years of the extension for the long-term and cross-over groups were similar to or lower than the observed yearly rates in the FREEDOM placebo group. This was also the case for individual SAEs of infection (by preferred term) including cellulitis or erysipelas (Table 1) and individual malignancies (by preferred term; Table 2). One case of oral osteomyelitis and one case of bone necrosis in the cross-over group were adjudicated as consistent with ONJ.

Table 1. Yearly Incidence of Serious Adverse Events of Infection

		FREEDOM			Extension	
		Year 1	Year 2	Year 3	Year 1	Year 2
		r (n)	r (n)	r (n)	r (n)	r (n)

Plasma cell	Cross-over (Pbo/DMAb)	0	< 0.1 (2)	< 0.1 (2)	< 0.1 (2)	< 0.1 (1)
	Long-term (DMAb/DMAb)	< 0.1 (1)	0	0.1 (5)	< 0.1 (1)	< 0.1 (2)
Endocrine	Cross-over (Pbo/DMAb)	0	0	< 0.1 (2)	< 0.1 (1)	< 0.1 (1)
	Long-term (DMAb/DMAb)	0.1 (5)	< 0.1 (1)	< 0.1 (1)	0.1 (3)	0
Nervous system	Cross-over (Pbo/DMAb)	< 0.1 (1)	0	0.2 (6)	< 0.1 (1)	0
	Long-term (DMAb/DMAb)	< 0.1 (2)	< 0.1 (1)	< 0.1 (2)	0	0

Treatment groups are the original randomized assignments in the FREEDOM study. All subjects in the extension study receive denosumab. Denosumab treatment is shown in gray. Events are listed if ≥ 4 subjects reported an adverse event in any group in any year.
r = exposure-adjusted subject incidence per 100 subject-years. n = total number of subjects with ≥ 1 adverse event.

Conclusion: The year-to-year observed AE rates in placebo subjects provide a valuable indicator of the expected variation in untreated subjects and assist in the interpretation of safety results associated with therapy. Yearly incidences of SAEs of infection and AEs of malignancy did not increase over 5

years of continuous DMAb treatment of postmenopausal women with osteoporosis. The imbalances in SAEs of skin infections reported in the original FREEDOM study were not observed with DMAb treatment in the extension study.

Strontium Ranelate in the Treatment of Male Osteoporosis. One Year Results of a Placebo Controlled Study. Jean-Marc Kaufman[1], Maurice Audran[2], Gerolamo Bianchi[3], Steven Boonen[4], Robert Josse[5], Roger M. Francis[6], Stefan Goemaere[1], S. Palacios[7], M. Diaz-Curiel[8], Johann-Diederich Ringe[9] and Dieter Felsenberg[10]. [1]Ghent University Hospital, Ghent, Belgium, [2]CHU Angers, Angers, France, [3]Ospedale La Colletta, Arenzano-GE, Italy, [4]Leuven University Hospital, Leuven, Belgium, [5]St Michael's Hospital, Toronto, [6]Institute for Ageing and Health, Newcastle, United Kingdom, [7]Instituto Palacios, Madrid, Spain, [8]Fundacion Jimenez Diaz, Madrid, Spain, [9]Klinikum Leverkusen, University of Cologne, Cologne, Germany, [10]Charité Campus Benjamin Franklin, Berlin, Germany

Background/Purpose: Male osteoporosis is increasingly recognised as a major public health issue. The efficacy and safety of strontium Ranelate (Sr Ran) have been established for treatment of post menopausal osteoporotic women. The male Osteoporosis study assessed the efficacy and safety of SrRan in men with primary osteoporosis.

Methods: The study was a 2-year double-blind placebo-controlled randomised trial (SrRan 2g/day/placebo 2:1). Bone mineral density (BMD) at the lumbar and femoral sites was measured every 6 months. Primary endpoint was relative changes from baseline of lumbar BMD L2-L4 (LS BMD) at 1 year. An ITT analysis was applied.

Results: Baseline characteristics were similar in both groups (mean ±SD): age: 73.1±6.1 vs 72.6±5.7 yrs; LS T-Score: − 2.7±0.9 vs – 2.4±1.2, femoral neck T-score: − 2.3±0.6 vs – 2.3±0.7, prevalent vertebral fractures and prevalent peripheral osteoporosis fracture = 28.2% vs 25.3% and 11.5% vs 10.3% respectively.

Over 1 year, LS BMD increased significantly in the SrRan group compared to placebo from baseline to endpoint, by 5.3%±0.75 ($p<0.001$); femoral neck BMD increased by 2.9%±0.62, ($p<0.001$). There was a decrease in bone resorption (estimate of adjusted means difference (SrRan-placebo) for s-CTX: –25.9%(7.86), p=0.0011) and a maintenance of bone formation (estimate of adjusted means difference for bALP:4.5%(3.0),NS). An improvement (i.e. score decrease) in both groups of the Quality of life was observed, more marked in the SrRan group (−0.16±0.6 vs. −0.07±0.5 in the placebo group,NS), particularly regarding 'pain interfering with patient sleep' (16.2% vs 5.1%, p=0.016).

Furthermore, the serum strontium levels and the magnitude of the increases in lumbar (6.38%±0.81) and femoral neck (3.19%±0.70) BMD at M12 in this male population, were similar to those previously observed in PMO women studies as shown in the table below:

Relative changes (M0–M12) versus placebo (%)		Maleo N=243	PMO studies N=6551	Effects in Men versus Women
Lumbar spine BMD %	E(SE)	6.38% (0.81)	7.04% (0.35)	p-value[1] = 0.442
	95% CI	[4.1,8.0]	[6.7,7.4]	
	p-value	p<0.001	p<0.001	
Femoral neck BMD %	E(SE)	3.19% (0.7)	3.52% (0.14)	p-value[1] = 0.655
	95% CI	[1.8,4.6]	[3.3,3.8]	
	p-value	p<0.001	p<0.001	

E(SE): Estimate and Standard Error of the adjusted mean difference (S 12911 2g minus Placebo)
(1) p-value of the Student test
No new safety concern has been detected in this male population.

Conclusion: In a male population at high risk of fractures, a marked increase in the mean lumbar L2-L4 and femoral neck BMD were observed, similar to that previously observed in women. Considering the present results in men and the previously established relationship between change in BMD and reduction in new vertebral and hip fractures risk with SrRan treatment in women, a similar anti-fracture efficacy is expected in men. Safety results did not reveal any unexpected adverse events in men exposed to SrRan.

1105

The Lancaster Osteoporosis Predictor—a Novel Tool to Identify Individuals with Osteoporosis. Alexander G. S. Oldroyd[1], John P. Halsey[2], Nicola Goodson[3], Bronwen Evans[2], Cathi Greenbank[2], David Gore[2] and Marwan Bukhari[2]. [1]Lancaster University, Lancaster, United Kingdom, [2]Royal Lancaster Infirmary, Lancaster, United Kingdom, [3]University Hospital Aintree, Liverpool, United Kingdom

Background/Purpose: A number of tools have been developed to predict an individual's OP risk and guide referral for a densitometry scan, including SCORE, FRAX, pBW and OST. Apart from FRAX, currently available tools were developed with only small cohorts. No currently available tool considers the presence of less common osteoporosis risk factors alongside the traditional.

Methods: Data was collated from 25912 individuals that attended for a DXA scan at the Royal Lancaster Infirmary (UK) between 1992 and 2010. The following data was collated: age, body mass index (BMI kg/m^2), diagnosis of rheumatoid arthritis, post-menopausal status (females only), diagnosis of osteoporosis (t-score of the lumbar spine or femoral neck less than −2.5). The presence of less common osteoporosis risk factors was collated, which included: more than 1 year of amenorrhoea, untreated early menopause before 45 years of age, previous breast cancer, inflammatory bowel disease, coeliac disease, hyperthyroidism. The total number of osteoporosis risk factors of each individual was ascertained.

The cohort was randomly divided into development and validation cohorts. Logistic regression models for males and females were formed separately, using a diagnosis of osteoporosis (binary) as the outcome variable and the following as predictor variables: age, BMI, diagnosis of rheumatoid arthritis (binary), number of osteoporosis risk factors and post-menopausal status (only included in the female model). Only variables with a p-value less than 0.05 were included in the final model. The logistic regression models were translated into receiver operator characteristic (ROC) curves. Tools were validated using the validation cohorts. Individual tools for males and females were developed.

Results:

	Female n = 22003		Male n = 3909	
Variable	Development n = 14661	Validation n = 7342	Development n = 2554	Validation n = 1355
Mean Age/years (SD)	62.30 (12.47)	62.26 (12.31)	64.79 (12.17)	64.54 (13.76)
Mean BMI/kg/m^2 (SD)	26.60 (5.27)	26.58 (5.37)	26.74 (4.57)	26.67 (4.47)
No. rheumatoid arthritis (%)	423 (2.89)	214 (2.91)	120 (4.70)	53 (3.91)
No. post-menopausal (%)	5661 (38.61)	2804 (38.19)	—	—
No. osteoporotic (%)	4500 (30.69)	2196 (31.27)	895 (35.04)	462 (34.10)
Mean no. osteoprosis risk factors (SD)	1.65 (1.40)	1.65 (1.40)	1.73 (1.37)	1.66 (1.33)

The coefficients of the female logistic regression model were: intercept −4.44, age/years 0.06, BMI kg/m^2 −0.06, number of osteoporosis risk factors 0.51, post-menopausal status 1.67. The area under the ROC curve was 0.85. A threshold of −1.3 gave 86% sensitivity and 68% specificity. Therefore, individuals with a score higher than −1.3 were deemed to be osteoporotic. Validation of this tool gave 86% sensitivity and 68% specificity.

The coefficients of the male logistic regression model were: intercept −2.40, age/years 0.03, BMI kg/m^2 −0.05, number of osteoporosis risk factors 0.61. The area under the ROC curve was 0.74. The threshold that gave a sensitivity of 85% was −1.2, of which the specificity was 44%. Therefore, males with a score higher than −1.2 were deemed to be osteoporotic. Validation of the tool gave a sensitivity of 85% and a specificity of 43%.

Conclusion: Use of this tool, which was developed with a large cohort, can reduce the number of DEXA scans by 51% in females and 32% in males; 8.6% of females and 16% of males not scanned will be osteoporotic. Further validation and optimal threshold identification is required before clinical implementation.

Allowing Patient Self-Referral of Dual Energy X-Ray Absorptiometry Significantly Improves Osteoporosis Screening in Two Regional Healthcare Systems. Amy H. Warriner[1], Ryan C. Outman[1], Jeffery R. Curtis[1], Adrianne C. Feldstein[2], Roslin Nelson[3], David T. Redden[1], Junling Ren[3], Mary M. Rix[2], Brandi E. Robinson[3], Douglas W. Roblin[3], A. Gabriela Rosales[2], Monika M. Safford[1] and Kenneth G. Saag[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Kaiser Permanente Center for Health Research, Portland, OR, [3]Kaiser Permanente Center for Health Research, Atlanta, GA

Background/Purpose: Current U.S. guidelines recommend bone density screening with central dual energy x-ray absorptiometry (DXA) in all women 65 years or older. However, less than one-third of eligible U.S. women undergo this testing. We evaluated whether a simple, low-cost intervention for patients to more easily schedule DXAs might improve osteoporosis screening rates compared to the current requirement of physician referral.

Methods: We conducted a group randomized controlled trial involving 14 primary care clinics within the Kaiser Permanente Northwest Region (KPNW) and 15 primary care clinics within the Kaiser Permanente Georgia Region (KPG). Women 65 years or older with no identifiable DXA scan in the past 5 years and no identifiable anti-osteoporosis treatment in the past 12 months were eligible for the study. Clinics were randomized into 1 of 3 groups: A self-referral intervention (SELF) (eligible patients invited by mail to get a DXA and provided opportunity to self-schedule a DXA); self referral + DVD (SELF+DVD) (consisting of

SELF, plus an educational brochure and DVD promoting patient-provider communication about osteoporosis screening, enhanced through patient story-telling); and, Usual Care (UC) (No DVD or self referral). Providers in all groups were directed to web-based CME training on osteoporosis screening and treatment.

Results: Of 8800 eligible women from KPNW, 3191 women were randomized to SELF, 3720 to SELF+DVD, and 1889 to UC. A total of 24.3% of women in SELF and 24% in SELF+DVD completed a DXA scan, compared to 6% of women in UC; the risk difference for DXA receipt in SELF and DVD+SELF vs. UC was 18.1 (95% CI 16.6–19.6). Of 3239 eligible women from KPG, 1064 women were randomized to SELF, 1005 to SELF+DVD, and 1170 to UC. A total of 16.4% of women in SELF and 14.5% in SELF+DVD completed a DXA scan, compared to 5.2% of women in UC; the risk difference for DXA receipt in SELF and DVD+SELF vs. UC was 10.3 (95% CI 8.2–12.3).

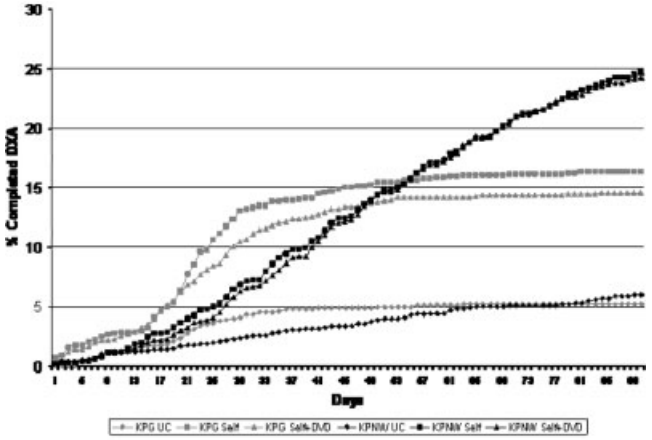

Figure. Receipt of DXA scans by Day

Conclusion: In both regions, DXA scan scheduling and receipt was improved significantly by allowing patients to self-schedule their own scans. The addition of an educational DVD using patient story-telling to promote patient-provider communication did not significantly improve DXA screening over DXA self-scheduling alone. Allowing eligible women to self-schedule screening DXA scans (similar to mammography self-scheduling) may be an effective low cost strategy to increase rates of osteoporosis screening.

1107

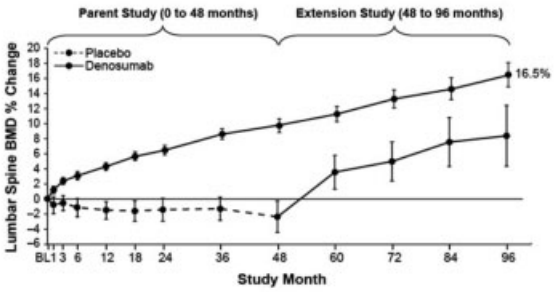
Effects of Denosumab on Bone Mineral Density and Biochemical Markers of Bone Turnover Over 8 Years. Michael R. McClung[1], E. Michael Lewiecki[2], Michael A. Bolognese[3], Munro Peacock[4], Richard L. Weinstein[5], Beiying Ding[6], Michelle L. Geller[6], Andreas Grauer[6], Rachel B. Wagman[6] and Paul D. Miller[7]. [1]Oregon Osteoporosis Center, Portland, OR, [2]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, [3]Bethesda Health Research Center, Bethesda, MD, [4]Indiana University, Indianapolis, IN, [5]Diablo Clinical Research, Inc., Walnut Creek, CA, [6]Amgen Inc., Thousand Oaks, CA, [7]Colorado Center for Bone Research, Lakewood, CO

Background/Purpose: Denosumab is a fully human monoclonal antibody that inhibits RANKL, reduces bone resorption, increases BMD, and reduces the risk of new vertebral, hip, and nonvertebral fractures at 3 years compared with placebo (Cummings *NEJM* 2009). With its unique mechanism of action, long-term experience with denosumab therapy is of clinical interest. Here we present the effects of 8 years of continuous denosumab treatment on bone mineral density (BMD) and bone turnover markers (BTM) from a phase 2 study.

Methods: In the 4-year, phase 2 parent study, postmenopausal women with a BMD T-score between –1.8 and –4.0 (lumbar spine) and/or –1.8 and –3.5 (total hip or femoral neck) were randomized to receive placebo, alendronate, or 1 of 7 different doses of denosumab. After 2 years on study, subjects were reallocated to maintain, discontinue, or discontinue and reinitiate denosumab; discontinue alendronate; or maintain placebo for an additional 2 years (Miller *Bone* 2008). The parent study was then extended for 4 years. All subjects in the extension study received open-label denosumab 60 mg every 6 months (Q6M). Here our results focus on subjects who received denosumab treatment for 8 years total in the parent and extension studies, and those who received placebo for 4 years in the parent study followed by denosumab for 4 years in the extension study.

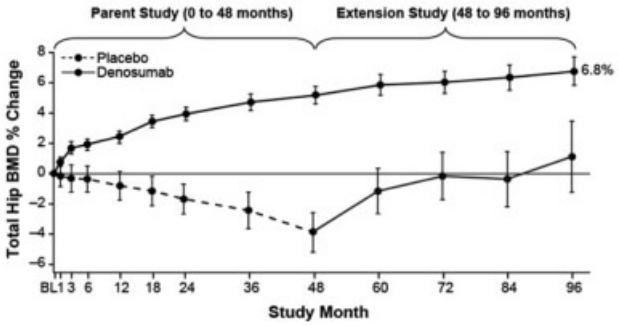
Results: Of the 262 subjects who completed the parent study, 200 enrolled in the extension study and of these, 138 (69%) completed the 4-year extension study. For the 88 subjects who received 8 years of continuous denosumab treatment, BMD at the lumbar spine and total hip increased on average by 16.5% and 6.8%, respectively, compared with their parent study baseline, and by 5.7% and 1.8%, respectively, compared with their extension study baseline (Figures 1 and 2). For the 12 subjects in the previous placebo group, 4 years of denosumab treatment resulted in gains in BMD comparable with those observed during the first 4 years of 60 mg Q6M in the parent study. Reductions in CTX and BSAP were sustained over the course of continuous denosumab treatment. Reductions in these BTMs were also observed when the placebo group transitioned to denosumab treatment. The adverse event profile was overall similar to what has been reported previously. There were no atypical fractures or ONJ events.

Figure 1: Percent Change in Lumbar Spine BMD From Parent Study Baseline



Data are least squares mean (95% CI). Subjects with parent study baseline and ≥ 1 post-baseline measurement were included.

Figure 2: Percent Change in Total Hip BMD From Parent Study Baseline



Data are least squares mean (95% CI). Subjects with parent study baseline and ≥ 1 post-baseline measurement were included.

Conclusion: These data demonstrated that continuous denosumab treatment for up to 8 years was associated with continued gains in BMD and persistent reduction in markers of bone turnover, and was well tolerated.

1108

Transitioning to Denosumab Leads to Further Increases in BMD throughout the Skeleton in Postmenopausal Women Who Received 5 or More Years of Continuous Alendronate Therapy. Michael A. Bolognese[1], Henry G. Bone[2], David L. Kendler[3], Maria Luisa Brandi[4], Anthony Hodsman[5], Philippe Orcel[6], Hoi-Shen Radcliffe[7], Andreas Grauer[8] and Cesar Libanati[8]. [1]Bethesda Health Research Center, Bethesda, MD, [2]Michigan Bone and Mineral Clinic, Detroit, MI, [3]University of British Columbia, Vancouver, BC, [4]University of Florence, Florence, Italy, [5]University of Western Ontario St. Joseph's Health Center, London, ON, [6]Lariboisière University Hospital, Paris, France, [7]Amgen Inc., Cambridge, United Kingdom, [8]Amgen Inc., Thousand Oaks, CA

Background/Purpose: Denosumab treatment led to significantly greater BMD gains throughout the skeleton in women who transitioned from alendronate to denosumab compared with those who remained on alendro-

nate, as reported in STAND (Study of Transitioning from Alendronate to Denosumab; Kendler DL, et al. *JBMR*. 2010;25:72). To participate in STAND, women had to have received alendronate for ≥ 6 months. The median alendronate exposure in STAND was 36 months (range 6 to 192 months); the primary endpoints have been previously reported. Because an increasing number of women are presently discontinuing their treatment after 5 or more years of bisphosphonate administration, we now report on the efficacy and safety from a subset of women from STAND who transitioned to denosumab after 5 or more years of continuous alendronate therapy.

Methods: STAND was a randomized, double-blind, double-dummy study in 504 postmenopausal women aged 67.6 ± 7.8 years with low BMD. Women were transitioned to denosumab (60 mg every 6 months subcutaneously) or were continued on branded alendronate therapy (70 mg weekly) for 12 months. All analyses were post-hoc and exploratory.

Results: In STAND, 149 women aged 70.0 ± 7.6 years had received alendronate for ≥ 5 years. These women were slightly older and had worse total hip but not lumbar spine BMD than those treated with alendronate for < 5 years. A total of 70 women transitioned to denosumab and 79 women remained on alendronate. Transitioning to denosumab for 12 months led to further significant increases in BMD of 2.95% (lumbar spine), 1.66% (total hip), and 1.02% (femoral neck). In contrast, those who remained on alendronate had smaller changes in BMD of 1.55% (lumbar spine), 0.97% (total hip), and 0.25% (femoral neck). A treatment-by-prior alendronate exposure interaction analysis did not indicate any differences in greater gains in BMD observed with the transition to denosumab in the subgroup exposed to alendronate for ≥ 5 years compared with the overall STAND population results at all measured sites.

Of the women who received alendronate for ≥ 5 years, a similar number of adverse events were reported by those who transitioned to denosumab and those who continued to receive alendronate (81.4% and 84.8%, respectively). The most frequently reported adverse events were nasopharyngitis (16.1%), back pain (11.4%), nausea (7.4%), bronchitis (7.4%), pain in extremity (7.4%), and arthralgia (7.4%). There were no cases of osteonecrosis of the jaw, delayed fracture healing, or atypical femoral fractures.

Conclusion: Consistent with the results from the overall STAND study, transitioning to denosumab after ≥ 5 years of continuous alendronate treatment led to further significant gains in BMD at the lumbar spine, total hip, and femoral neck, and demonstrated a similar safety profile compared with those who continued on alendronate.

1109

Current Vs. Past Exposure to Corticosteroids: Which Is Most Associated with Osteoporotic Fractures in Systemic Lupus Erythematosus Patients?
Laurence S. Magder[1] and Michelle Petri[2]. [1]University of Maryland, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: SLE patients are at excess risk for osteoporotic fractures. It is widely thought that this excess risk is explained, in part, by exposure to corticosteroids, but there is uncertainty whether cumulative past exposure or current levels of exposure are most important to fracture risk. In addition, other possible risk factors in SLE such as avoidance of sunlight for those with cutaneous SLE, renal failure, or chronic arthritis have been postulated but not confirmed. We explored risk factors for incident osteoporotic fracture in a large cohort of SLE patients.

Methods: The cohort consists of patients with SLE who are followed quarterly. This analysis was based on the cohort experience of 2044 patients who did not have an osteoporotic fracture prior to cohort entry. The patients were 90% women, 56% Caucasian, and 37% African-American. Osteoporotic fracture was defined as fracture by x-ray, CT or MRI in a patient with known osteopenia/osteoporosis. We calculated fracture rates in subgroups, and assessed the effect of predictors controlling for confounders using pooled logistic regression.

Results: 184 incident fractures were experienced over 12,039 person-years of observation (Rate=15.3 per 1000 person years). Adjusting for age, rates were significantly higher among Caucasians and those with hyperlipidemia (Table). A slight increased rate was seen among those with cutaneous SLE, but no increase was seen with renal or musculoskeletal involvement. The effect of corticosteroids was mainly seen for those with both current use and cumulative exposure. Rates were not significantly higher among those with current use if they had low levels of cumulative exposure, or for those with moderate levels of cumulative exposure but no current use. These relationships persisted after adjustment for all the above variables in a multivariable model.

Table. Rates of fracture, by patient exposures and characteristics

	Subgroup	Observed Number of Fractures	Rate of events per 1000 person-years	Rate Ratios based on a model that adjusts for age (95% CI)	P-value
Age	18–39	56	9.5	1.0 (Ref. Gp)	0.056
	40–49	45	14.0	1.5 (1.0, 2.2)	<0.0001
	50–59	52	26.8	2.8 (1.9, 4.1)	0.0016
	60–69	18	22.4	2.4 (1.4, 4.0)	<0.0001
	70+	13	62.0	6.5 (3.6, 11.9)	
Sex	Female	174	15.7	1.0 (Ref. Gp)	0.12
	Male	10	10.4	0.6 (0.3, 1.1)	
Race	Caucasians	126	20.1	1.0 (Ref. Gp)	<0.0001
	African-Americans	52	10.0	0.5 (0.4, 0.7)	0.31
	Other	6	10.1	0.7 (0.3, 1.5)	
Most recent Cholesterol	<150	15	7.2	1.0 (Ref. Gp)	0.022
	150–199	73	15.0	1.9 (1.1, 3.3)	0.0001
	200+	70	26.0	3.0 (1.7, 5.3)	
History of Arthritis	No	92	14.5	1.0 (Ref. Gp)	0.99
	Yes	91	16.4	1.0 (0.7, 1.3)	
History of Cutaneous lupus	No	56	12.5	1.0 (Ref. Gp)	0.084
	Yes	127	17.5	1.3 (1.0, 1.8)	
Renal Involvement	None	99	15.3	1.0 (Ref. Gp)	0.87
	Protein in urine	34	13.0	1.0 (0.7, 1.4)	0.32
	Nephrotic syndrome	10	9.1	0.7 (0.4, 1.4)	0.54
	Renal Insufficiency	41	21.9	1.4 (1.0, 2.1)	
Mean Serum Creatinine during cohort	<1.0	105	15.4	1.0 (Ref. Gp)	0.71
	1.0–1.2	23	20.3	1.1 (0.7, 1.7)	0.85
	1.2+	14	17.7	0.9 (0.5, 1.7)	
BMI	<20	13	15.2	1.0 (Ref. Gp)	0.91
	20–25	51	16.1	1.0 (0.5, 1.8)	0.38
	25–30	41	14.3	0.8 (0.4, 1.4)	0.76
	30+	61	17.6	0.9 (0.5, 1.7)	
Corticosteroids					
Current dose of corticosteroids	none	71	13.0	1.0 (Ref. Gp)	0.14
	1–9 mg/day	50	17.2	1.3 (0.9, 1.9)	0.0001
	10–19 mg/day	41	24.4	2.2 (1.5, 3.2)	0.0144
	20+ mg/day	15	19.9	2.0 (1.2, 3.5)	
Cumulative past dose of corticosteroids	None	21	14.0	1.0 (Ref. Gp)	0.94
	<3650 mg	17	12.8	1.0 (0.5, 1.9)	0.40
	3650–10,950	25	15.4	1.3 (0.7, 2.3)	0.071
	10,950–36,499	55	20.0	1.6 (1.0, 2.6)	0.0090
	36,500+	26	26.5	2.2 (1.2, 3.8)	
Current vs. Cumulative Dose	Low current[1], low cumulative[2] dose	55	14.0	1.0 (Ref Gp)	0.35
	Low current, high cumulative dose	41	17.0	1.3 (0.8, 1.8)	0.53
	High current, low cumulative dose	8	13.7	1.2 (0.6, 2.7)	<0.0001
	High current, high cumulative dose	40	31.5	2.8 (1.8, 4.2)	

[1] Low current means < 10mg/d
[2] Low cumulative means <3650 mg

Conclusion: Our data suggest that both cumulative and current exposure to corticosterioids are needed to incur an increased risk of fracture. This suggests that rates return to close to baseline after stopping corticosteroids, and are not increased with short-term use. However, additional studies are needed to confirm these findings.

1110

Severe Vitamin-D Deficiency in HIV-Infected Patients: Relationships with Inflammation, Bone Metabolism and Functional Status.
Thiphaine Ansemant[1], Paul Ornetti[1], Christine Piroth[1], Sophie Mahy[2], Jean C. Guilland[3], Laurence Duvillard[3], Delphine Croisier[2], Stephanie Ewing[3], Christian Tavernier[1], Pascal Chavanet[2], Jean Francis Maillefert[1] and Lionel Piroth[2]. [1]Rheumatology, Dijon, France, [2]Infectious diseases department, Dijon, France, [3]INSERM U866 and laboratory of biochemistry, Dijon, France

Background/Purpose: to assess the relationships between severe hypovitaminosis D (SHD) with lifestyle habits, comorbidities, HIV infection and antiretroviral history, and inflammation in HIV infected patients.

Methods: 263 unselected HIV infected outpatients consulting during spring 2010 were included in a cross sectional study. Apart from clinical examination, data on their medical history, food habits, sun exposure and addictions were collected. Fasting blood samples were taken for immunological, virological, inflammation, endocrine and bone evaluations.

Results: SHD (<10ng/ml) was found in 95 (36%) patients, and mild deficiency (10–30 ng/ml) in 135 (51%). In multivariate analysis, SHD was associated i) with mean daily sun exposure (OR +1 hour: 0.84, 95% CI: 0.74–0.94, p=0.03), current (OR: 2.63; CI95%: 1.27–5.45, p=0.009) or past (OR: 2.74; 95% CI: 1.17–6.43, p=0.02) smoking, Hepatitis C (OR: 1.87; 95% CI: 0.92–3.85, p=0.09) and B (OR: 2.76; CI95%:1.17–6.54, p=0.005) coinfections, functional status (OR for past history of fall: 1.80 95% CI: 1.00–3.27, p=0.02), and ii) with increased IL-6 levels (OR +1 pg/ml, 1.13, 95% CI: 1.02–1.25, p=0.02), and elevated C-Telopeptides × (CTX) (OR:2.44 95% CI: 1.23–4.81, p=0.01).

Conclusion: SHD appears to be more closely associated with comorbidities and functional status than with the history of HIV infection and the therapies used. Certain antiretroviral drugs may have a negative impact, which could be counterbalanced by a positive impact on inflammation. Increased CTX reflects higher oscteoclastic activity and the risk of bone fracture, and underlines the need to improve functional status and the management of comorbidities, in addition to vitamin D supplementation.

1111

Inhibitory Effects of 1′,2′-Dihydrorotenone On Osteoclast Differentiation and Bone Resorption. Chang-Hoon Lee[1], Myung-Soon Sung[2], Eun-Gyeong Lee[2], Myong Joo Hong[2] and Wan-Hee Yoo[2]. [1]Department of Internal Medicine, School of medicine, Wonkwang university, Iksan, Chonbuk, South Korea, [2]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea

Background/Purpose: Osteoclasts, which are bone-resorbing multinucleated cells, are derived from hematopoietic cells of the monocyte-macrophage lineage and play a key role in bone resortion. Regulation of osteoclast fusion is important to treat of bone resorbing disease such as osteoporosis and rheumatoid arthritis. The aim of this study was to identify a new compound that inhibits osteoclast differentiation and bone resorption.

Methods: Osteoclast formation was evaluated in bone marrow cells (BMC) in the presence or absence of 1′,2′-dihydrorotenone. The expression of c-fos and NFATc1 mRNA in osteoclast precursor were assessed by RT-PCR. The levels of c-fos and NFATc1 protein were assessed by western blot. Also the MAPKs and NF-κB pathways were measured using Western blot analysis. Osteoclast function was evaluated with resorption pit assay. With LPS treated mouse model, We evaluated the effects of 1′,2′-dihydrorotenone on LPS induced bone loss when co-treated with it by using micro CT and histomorphometric analysis.

Results: 1′,2′-dihydrorotenone inhibited receptor activator of NF-kB ligand (RANKL)-induced osteoclast differentiation of cultured bone marrow macrophages (BMMs) in a dose-dependent manner. However, 1′,2′-dihydrorotenone did not exert cytotoxic effect on BMMs. 1′,2′-dihydrorotenone suppressed the expression of c-fos and NFATc1 as well as osteoclast specific genes in BMMs treated with RANKL. Treatment with RANKL inhibited the expression of inhibitors of differentiation/DNA binding (Id)1, 2, and 3; however, in the presence of 1′,2′-dihydrorotenone, RANKL did not suppress the expression of Id1, 2, and 3. Furthermore, 1′,2′-dihydrorotenone inhibited bone resorption and considerably attenuated the erosion of trabecular bone induced by lipopolysaccharide treatment.

Conclusion: Taken together, these results suggest that 1′,2′-dihydrorotenone has the potential to be applied in therapies for bone-related diseases.

1112

Interesting Roles of IL-1 in Osteoclast Differentiation. Chang-Hoon Lee[1], Myung-Soon Sung[2], Eun-Gyeong Lee[2], Myong Joo Hong[2] and Wan-Hee Yoo[2]. [1]Department of Internal Medicine, School of medicine, Wonkwang university, Iksan, Chonbuk, South Korea, [2]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea

Background/Purpose: Osteoclast differentiation plays key role in bone resorption in many erosive bone disease and inflammatory situation. Osteoclasts are multinucleated cells that are formed by the fusion of mononuclear osteoclasts, which is an essential process in bone resorption leading to bone remodeling. The aim of this study was to evaluate the exact effects of IL-1, known as proinflammatory cytokine, on osteoclasogenesis, especially on fusion of mononuclear osteoclasts.

Methods: Prefusion osteoclasts (pOCs) were generated from bone marrow macrophages treated with M-CSF and RANKL. pOC cultures have been used to investigate the effect of IL-1 on multinuclear cell formation. Expression of c-Fos, NFATc1, and DC-STAMP were determined by RT-PCR and Western blot analysis. We used constitutively active (CA)- MKK6 adenovirus to evaluation of the signaling of p38 induced by IL-1

Results: we showed that IL-1 promoted the fusion of prefusion osteoclasts (pOCs). IL-1 induced the expression of DC-STAMP and Atp6v0d2 that were mediated by inducing NFATc1 via induction of c-Fos. The expression of c-Fos and NFATc1 was regulated by the p38 signaling pathway. Inhibition of p38 and NFATc1 suppressed the expression of DC-STAMP Atp6v0d2 and led to the inhibition of pOC fusion. However, retrovirus-mediated expression of NFATc1 in pOCs rescued the defect in pOC fusion, despite the presence of SB. The ectopic expression of CA-MKK6 induced DC-STAMP and Atp6v0d2 expression and fusion of pOCs under stimulation of IL-1. DC-STAMP and Atp6v0d2 expression increased with constitutively active (CA)-NFATc1. Expression of DC-STAMP and Atp6v0d2 with NFATc1 inhibitor, cyclosporine was reduced.

Conclusion: IL-1 induced fusion of pOCs to form multinucleated osteoclast by inducing expression of c-fos, NFATc1 through p38 pathway.

1113

Application of Combined Algorithms with Peripheral Bone Mineral Density (BMD) and Risk Indeces to Reduce the Requirement for Central Dual X-Ray Absorptometry (DXA). María América López-Lasanta[1], Francisco G. Jiménez-Núñez[1], Carmen M. Romero-Barco[1], Sara Manrique-Arija[1], Verónica Rodriguez-García[1], Miguel A. Descalzo[2], Blanca Panero[1], Jose Mancera Romero[3], Silvia Mesa González[3], Maria Carmen Ordóñez[1], Inmaculada Ureña[1], Manuel Rodríguez-Pérez[1] and Antonio Fernandez-Nebro[4]. [1]Hospital Regional Universitario Carlos Haya., Málaga, Spain, [2]Spanish Society of Rheumatology, Madrid, Spain, [3]Health Center "Ciudad Jardín", Malaga, Spain, [4]Hospital Regional Universitario Carlos Haya, Málaga, Spain

Background/Purpose: Currently the diagnosis of osteoporosis (OP) by BMD as defined by the WHO is applied to central DEXA. PIXI devices are smaller, portable, and faster, and cheaper than central DEXA, so that a PIXI scan may cost 70–85% less than a DEXA scan. However, PIXI results cannot be interpreted using the WHO definition and do not correlate perfectly with BMD at central DEXA. Objective: To analyse if using risk indices and PIXI scans jointly would reduce requirement for central DEXA to diagnose postmenopausal OP.

Methods: A stratified sample of postmenopausal women was selected: a random sample of 305 postmenopausal women from Primary care, and 200 consecutive postmenopausal women referred for central DXA measurement from tertiary care. Inclusion criteria: Caucasian female, age ≥50 yrs, and full menopause (amenorrhea ≥12 mo.). Exclusion criteria: previous diagnose of OP, previous treatment with OP drugs (calcium and/or vitamin D and/or estrogens for menopausal symptoms treatment were allowed) or steroids and other drugs related with low BMD, and institutionalized persons OR Steinbrocker's functional grade 4. Informed consent was obtained. Four risk indices were calculated: SCORE, ORAI, OSIRIS, and OST. All participants underwent two different BMD measurements: a non-dominant heel BMD-(PIXI Lunar, Software #50699, GE Corp.), and a central DXA of the hip and lumbar spine (Lunar Prodigy Advance, Software ENCORE 2006, PA+300274, GE Corporation). OP definition according to the WHO was used. Statistical analyses: The diagnostic utility was measured by ROC curves. We calculated the sensitivity and specificity for risk indices, PIXI, and all possible combinations. Logistic regression was performed to build a risk model with the presence or absence of osteoporosis at the central DEXA as dependent variable. The thresholds was established in 2 ways: 1) a cutoff point where the sensitivity and specificity are maximized, and 2) with two cutoff points, where both it sensitivity and specificity reached 90%.

Results: 505 Caucasian women with a mean (SD) 61 (8) yrs, were recruited. Median (p25-p75) scores for each risk index were: OST 1 (0–3), ORAI10(7–14), and SCORE 8(6–11). The mean (SD) PIXI T-score of the calcaneus was −0.33 (1.14). The mean (SD) femoral neck T-score was −1.01 (1.05), total femur was −0.59 (1.19) and lumbar T-score was −1.18 (1.36). The prevalence of osteoporosis by central DXA was 20%(n = 102), 19% (57) in primary care and 23% (45) in tertiary care. The combined algorithm PIXI + OST + SCORE was the greatest area under the curve obtained: 75%(95%CI, 71 to 79). Most favorable threshold for this algorithm stratified subjects into high, medium, and low risk according to 2 cutoff (−20 and −5, respectively), and the most favorable subsequent decision was referral for central DXA if the medium or high risk categories were reached. According to this algorithm (table) 11 (2.2%) false positives were obtained, but 257 (52%) central DEXA were avoided and a 20 – 35% in costs could have been saved.

Conclusion: A triage based on a combined algorithm composed of PIXI + OST + SCORE reduces reduce the requirements of central DEXA a 52%, and may savings cost.

1114

Fractures and Mortality in Relation to Different Osteoporosis Treatments. Huifeng Yun[1], Elizabeth S. Delzell[1], Robert Matthews[1], Meredith Kilgore[1], Kenneth G. Saag[1], Cathleen Colon-Emeric[2], Christopher M. O'Connor[3], Kenneth W. Lyles[3], Michael Morrisey and Jeffrey R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Duke University Medical Center and the Durham VA GRECC, Durham, NC, [3]Duke University School of Medicine, Durham, NC

Background/Purpose: Few studies have assessed the effectiveness of different drugs for postmenopausal osteoporosis (OP). We compared fracture incidence and mortality among Medicare beneficiaries initiating various OP medications.

Methods: Using the Medicare national random 5% sample, we identified new users of oral bisphosphonates (BPs), intravenous (IV) ibandronate (IBN), IV zoledronic acid (ZOL), calcitonin (CAL), raloxifene (RAL) and parathyroid hormone (PTH). Eligible subjects were >=65 years; continuously enrolled in fee for service and part D Medicare; and newly treated during 2006–2008. New treatment was defined as therapy initiated after 12 month baseline during which no prescription was filled for the drug. Subjects remained in their initial drug category regardless of any switching of medication during follow-up. Cox proportional hazards models evaluated associations between different OP drugs and mortality and also first hip, distal radius/ulna, clinical vertebral, or humerus fracture. Analyses used IV ZOL as the referent and adjusted for multiple confounders. Further confounder control was examined using propensity score (PS) quintile adjusted and PS matched analyses.

Results: We identified 24537 new users for oral BPs, 750 for IV IBN, 1962 for IV ZOL, 7231 for CAL, 986 for PTH and 2222 for RAL. These cohorts experienced, respectively, 8.4%,, 12.9%, 8.8%, 17.0%, 13.6%, 7.8% fractures and 8.8%, 7.6%,6.1%, 21.2%,12.9% and 6.4% deaths during follow-up. After multivariable adjustment (ZOL referent), hazard ratios for fracture were 1.41 (95% CI: 1.03–1.93) for IV IBN, 1.33 (1.06–1.66) for oral BPs; 1.47 (1.16–1.86) for CAL, 1.27 (0.97–1.67) for RAL and 1.05 (0.78–1.42) for PTH; and for mortality were 0.84 (0.60–1.22) for IBN, 0.94 (0.76–1.18) for oral BPs, 1.47 (1.17–1.85) for CAL, 0.99 (0.75–1.31) for RAL and 1.31 (0.98–1.75) for PTH.

Table. Compare the crude and adjusted hazard ratios between different osteoporosis drugs

	Fractures		Death	
Treatment	**Crude**	**Adjusted**	**Crude**	**Adjusted**
IV Zoledronic acid	Ref	Ref	Ref	Ref
IV Ibandronate	2.30 (0.95–1.76)	1.41 (1.03–1.93)	0.86 (0.60–1.22)	0.84 (0.59–1.20)
Oral BP	0.82 (0.67–1.00)	1.33 (1.06–1.66)	1.04 (0.84–1.28)	0.94 (0.76–1.18)
Calcitonin	1.63 (1.30–2.04)	1.47 (1.16–1.86)	2.48 (1.99–3.09)	1.47 (1.17–1.85)
Raloxifene	0.73 (0.56–0.95)	1.27 (0.97–1.67)	0.75 (0.57–0.98)	0.99 (0.75–1.31)
Parathyroid Hormone	1.21 (0.90–1.62)	1.05 (0.78–1.42)	1.46 (1.10–1.93)	1.31 (0.98–1.75)

Note: We adjusted age, gender, race, geographic region, income, osteoporosis related conditions, other comorbidities and medications at baseline.

Conclusion: Compared to IV ZOL, fracture rates among users of other BPs or CAL were 33–47% higher; mortality was 47% greater among users of CAL. While fracture benefit may be in part mediated through improved adherence to IV ZOL, the mechanism for a possible mortality benefit remains unclear.

1115

Bach1 Regulates Osteoclastogenesis Via Heme Oxgenase-1 Dependent and Independent Pathways. Maasa Hama[1], Yohei Kirino[1], Mitsuhiro Takeno[1], Kaoru Takase[1], Ryusuke Yoshimi[1], Atsuhisa Ueda[1], Akihiko Muto[2], Kazuhiko Igarashi[2] and Yoshiaki Ishigatsubo[1]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Tohoku University Graduate School of Medicine, Sendai, Japan

Background/Purpose: Bone destruction of rheumatoid arthritis (RA) is caused by abnormally activated osteoclasts (OCs). It is suggested that induction of heme oxygenase (HO)-1 is beneficial for the treatment of RA by reducing inflammation. However the function of HO-1 in bone metabolism remains unclear. The objective of this study is to clarify the influence of HO-1 and its repressor BTB and CNC homolog 1 (Bach1) on osteoclastogenesis.

Methods: *In vitro* osteoclastogenesis was compared between Bach1 deficient and wild type mice. OCs were generated from bone marrow derived macrophages (BMM) by stimulation with M-CSF and RANKL. Osteoclastogenesis and OC function were assessed by tartrate-resistant acid phosphatase staining, expression of OC-related genes, and the pit resorption assay. Intracellular signal pathways in OC precursors were also assessed. HO-1 shRNA was transduced into *Bach1*$^{-/-}$ BMM to examine the role of HO-1 in osteoclastogenesis.

Results: Transcription of HO-1 was down-regulated by RANKL stimulation in the early stage of OC differentiation. *Bach1*$^{-/-}$ BMM were partially resistant to the RANKL dependent HO-1 reduction and showed impaired osteoclastogenesis, which was associated with reduced expression of RANK and components of the downstream TRAF6-c-Fos-NFATc1 pathway as well as the expression of Blimp-1. Treatment with HO-1 shRNA increased the number of OCs and expression of the OC-related genes except Blimp-1 during the *in vitro* osteoclastogenesis from *Bach1*$^{-/-}$ BMM. Furthermore, osteoclastogenesis in *Bach2*$^{-/-}$ BMM was similar to WT whereas *Bach1*$^{-/-}$*Bach2*$^{-/-}$ similar to *Bach1*$^{-/-}$.

Conclusion: Bach1 regulates osteoclastogenesis via both HO-1 dependent and independent mechanisms. Inhibition of Bach1 function thus may be a promising therapy for inflammatory bone loss in diseases including RA.

1116

Maintenance of Antifracture Efficacy Over 10 Years with Strontium Ranelate in Postmenopausal osteoporosis. J.-Y. Reginster[1], Jean-Marc Kaufman[2], Jean-Pierre Devogelaer[3], Claude-Laurent Benhamou[4] and Christian Roux[5]. [1]University of Liège, Liège, Belgium, [2]Ghent University Hospital, Ghent, Belgium, [3]St-Luc University Hospital, Brussels, Belgium, [4]Hopital de la Source, Orleans, [5]Paris Descartes University, Paris, France

Background/Purpose: Postmenopausal osteoporosis is a chronic disease requiring long-term treatment. Strontium ranelate (SrRan) 2g/day has proven efficacy against vertebral and non vertebral fractures including hip over 5 years in postmenopausal women. Results showing the continuous benefit on osteoporotic fractures and bone mineral density (BMD) over 8 years have already been reported (1). This abstract presents efficacy results over 10 years.

Methods: The two double blind placebo-controlled phase III studies included a total of 6740 Caucasian women with postmenopausal osteoporosis. In SOTI, patients were randomly assigned to receive SrRan 2g/day or placebo for 4 years and during the 5th year, half of the SrRan group continued with SrRan. In TROPOS, patients were randomly assigned to receive SrRan 2g/day or placebo for 5 years. Patients having participated in both studies up to 5 years were invited to enter a 3-year open-label extension study, subsequently extended by 2 years, and then received strontium ranelate up to 10 years. Here are presented the efficacy results in patients treated with SrRan for 10 years.

Results: At SOTI and TROPOS baseline, patients treated for 10 years (n= 233) had a profile similar to the whole population with a mean (SD) age of 72.0(5.5) years, a mean (SD) lumbar spine and femoral neck BMD T-score of –3.30(1.38) and –2.95(0.57) respectively. Over the 10-year period, lumbar BMD increased continuously and significantly ($p<0.05$ up to year 10) with, at 10 years, a relative change from baseline of 34.5%±20.2. At the femoral neck and total hip sites, the BMD increased significantly until year 7, with a relative change from baseline of 10.7%±12.1 and 11.7%±13.6 respectively, and then remained stable.

The cumulative incidences of new vertebral and non vertebral fractures (20.6% and 13.7% respectively) over the 5-year extension were not statistically different ($p=1.00$ and 0.672 respectively) to the cumulative incidences over the 5 years in the original studies (18.5% and 12.9% respectively). To assess the anti-fracture efficacy of SrRan in the absence of placebo group, we searched for a matching population in the placebo group of TROPOS using the 10-year probability of major osteoporotic fracture calculated with FRAX® as matching variable. The mean 10-year probability of major osteoporotic fracture, calculated with FRAX®, in the 233 patients treated for 10 years with SrRan was 25.8% at the time of their inclusion in the extension study. The incidences of vertebral and non-vertebral fracture observed over the 5 years of TROPOS were significantly higher ($p<0.05$) in the matching placebo group than those observed in the "10-year" population over the 5- year extension, with a relative risk reduction with SrRan of 35% and 38% for vertebral fractures and non-vertebral fractures respectively.

Strontium ranelate remained safe and well tolerated over 10 years with no unexpected adverse event.

Conclusion: These results are in favour of the maintenance of the efficacy of strontium ranelate over 10 years, with a good safety profile.

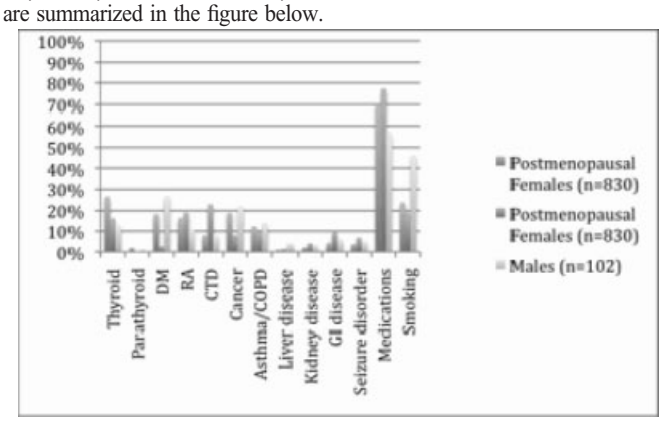
Analysis of Prevalence of Low Bone Mineral Density and Secondary Causes In Patients Undergoing Bone Density Measurement. Andrew Wilson, Anuj Patel, Toni Peters and Vikas Majithia. University of Mississippi Medical Center, Jackson, MS

Background/Purpose: There are a number of known secondary causes (SC) of low bone mineral density (BMD) i.e. osteopenia and osteoporosis. These have not been well quantified and may be prevalent at different rates in younger populations and males. This study aims to describe the prevalence of number and kind of SC in men and women with low BMD.

Methods: Retrospective chart review of patients who had a DEXA scan performed at center between Jan 2009 - Dec 2009. Prevalence of Low BMD, defined as presence of a T-score less than −1.0, co-morbid illness, medications and SC was calculated.

Results: A total of 1,339 patient charts were reviewed (112 premenopausal, 1,088 postmenopausal, 139 men). We found low BMD was common and seen in 75% (1,007/1,339) of patients. Low BMD was seen in 67% (75/112) of pre-menopausal patients, 76% (830/1088) of post-menopausal patients, and 73% (102/139) of men. The SC were also very prevalent among these patients with about 80% having at least one and 40 % of these patients had a normal Z-score. The most prevalent SC and co-morbid conditions were medication use including steroids, smoking, thyroid disease, diabetes mellitus, cancer, rheumatoid arthritis, and connective tissue disease. These results are summarized in the figure below.



The prevalence of these variables was different among the patients with low BMD among 3 subgroups—postmenopausal females, premenopausal females and males. Postmenopausal women had a significantly higher prevalence ($p<0.05$) of thyroid disorders, hyperparathyroidism, diabetes, cancer, asthma/COPD and GI diseases than premenopausal females, who had a higher prevalence of other CTD. Male had significantly higher prevalence ($p<0.05$) of liver disorders, smoking and a lower prevalence of thyroid disorders, diabetes and medication use. There was no significant difference among the white and African-Americans.

Conclusion: The results show a high prevalence of low BMD in this cohort of patients across all 3 subgroups including young females and males, who traditionally are felt to have normal bone mass. In addition there was a high prevalence of the secondary causes in this cohort and presence of multiple SC. There were significant differences in their prevalence across the subgroups as highlighted above. Although population prevalence cannot be calculated from this cohort study, these findings suggest that low bone density is fairly prevalent and is usually associated with a contributing co-morbidity or SC in both females and males even with normal Z-score. Low BMD on DEXA scan even with a normal Z-score should prompt work-up for secondary causes. Conversely, presence of known secondary causes should alarm the clinician to obtain the measurement of BMD to prevent serious consequence of fractures.

Long-Term Warfarin Use Is Not Associated with Fracture Risk. Devyani Misra[1], Yuqing Zhang[2], Christine Peloquin[2], Hyon K. Choi[2] and Tuhina Neogi[2]. [1]Boston University Medical Centre, Boston, MA, [2]Boston University School of Medicine, Boston, MA

Background/Purpose: Vitamin K deficiency has been associated with osteoporotic fractures but the mechanism for this association is unclear. Skeletal effects of vitamin K are mediated through Gla-proteins, which require vitamin K for conversion into their functional forms. Osteocalcin, a skeletal Gla-protein, promotes binding of calcium to hydroxyapetite in bones in its functional form. Warfarin, a vitamin K antagonist, has been shown to reduce functional osteocalcin levels, thus potentially increasing the risk for osteoporosis and related fractures. While some studies have reported increased risk of fracture, mainly at vertebral site, others have not found an association. We examined the association of long-term warfarin use with hip and wrist fractures, which are two common osteoporotic fracture sites, in a large population based cohort of elders with atrial fibrillation and long follow-up time.

Methods: Participants were men and women 65 years or older with incident atrial fibrillation followed between 1990–2010 from The Health Improvement Network (THIN), an electronic medical records database of more than 7.3 million patients in the UK containing clinical diagnoses and prescription data. Long-term warfarin use was defined in two ways: 1) warfarin use ≥1year; 2) warfarin use ≥3 years. Non-use was defined as never use of warfarin over the follow-up period. For each subject we calculated a propensity score using logistic regression with long-term use of warfarin as the dependent variable and age, sex, body mass index (BMI), high fall risk, heart failure, neuropsychiatric impairment, beta blockers, corticosteroids, bisphosphonates, smoking and alcoholism as independent variables. Each long-term warfarin user was matched to a non-user based on propensity score using the "greedy matching" method. We examined the association between long-term warfarin use and risk of hip and wrist fractures separately, using Cox-proportional hazards model adjusting for the covariates.

Results: We included 23,616 participants (48% women, mean age 77± 6.3y, mean BMI 27± 5.1 kg/m^2) in the hip fracture analysis and 23,302 participants with similar demographics in the wrist fracture analysis. Average follow up time was 1260±1020 days and 1258± 1024 days for hip and wrist fractures, respectively. There were 419 incident hip fractures and 197 incident wrist fractures. Long-term warfarin use, either ≥1 years or >3 years, was not associated with the risk of either incident hip fracture or incident wrist fracture (Table).

Table. Warfarin use and Risk of Hip and Wrist Fracture

	Hip Fracture			Wrist Fracture		
	Cases	Rates per 1000 person-years	Hazards Ratio* (95% CI)	Cases	Rates per 1000 person-years	Hazards Ratio* (95% CI)
Warfarin use ≥ 1 year	219	0.015	1.18 (0.91, 1.51)	101	0.007	1.0 (0.71, 1.41)
Non-use	200	0.014	1.0 (reference)	96	0.007	1.0 (reference)
Warfarin use ≥ 3 years	128	0.016	0.98 (0.71, 1.34)	52	0.007	1.17 (0.70, 1.97)
Non-use	136	0.017	1.0 (reference)	48	0.006	1.0 (reference)

* Adjusted for age, sex, body mass index (BMI), high fall risk, heart failure, neuropsychiatric impairment, beta blockers, corticosteroids, bisphosphonates, smoking and alcoholism.

Conclusion: In this large cohort of elderly men and women, we did not find an association between warfarin use and risk of hip or wrist fracture, despite a plausible biologic mechanism. Thus, warfarin use may not necessitate increased surveillance or prophylactic therapy for osteoporosis in elders.

1119

Possible Hypophosphatasia in Personalized Medicine Research Project. Less K. Shrestha, Fergus E. McKiernan, Richard L. Berg and Jay T. Fuehrer. Marshfield Clinic, Marshfield, WI

Background/Purpose: Personalized Medicine Research Project (PMRP) at Marshfield Clinic is a population-based cohort of ~20,000 adult subjects receiving care almost exclusively at Marshfield Clinic for whom we have comprehensive, searchable electronic medical record lab data since 1960, ICD-9 diagnosis codes since 1980 as well as stored DNA, plasma and serum. Hypophosphatasia (HPP) is a genetic metabolic disorder of skeletal mineralization with an estimated prevalence for severe disease of 1/100,000. We postulated that mild forms of HPP are more prevalent in an adult population than currently appreciated. The purpose of our study is to identify subjects with possible hypophosphatasia (HPP) in Personalized Medicine Research Project (PMRP).

Methods: The Marshfield Clinic electronic medical record of all PMRP enrollees with recorded serum alkaline phosphatase (ALP) values mostly ≤ 30 IU/L (normal 40–120 IU/L) were manually searched for diagnostic terms, ICD-9 codes and laboratory values suggesting the presence of HPP. Individual radiographic reports and all available radiographs were reviewed for chondrocalcinosis and metatarsal stress fractures. Previously unrecognized HPP was considered possible when, in the judgment of the PIs, the available clinical, biochemical and radiographic evidence suggested its presence.

Results: 21 subjects (14 Females/7 Males) were identified whose serum ALP was mostly ≤ 30 IU/L. Chondrocalcinosis was present in 7/21(33%) and often characterized as extensive. 6/21(29%) had suspected or proven acute crystalline arthritis or calcific tendonitis. 5/21(24%) had calcaneal spurs or symptomatic foot exostoses. 4/21(19%) had ≥ 1 metatarsal or femur shaft fracture. 2/21(10%) had hip dysplasia. 2/3 subjects with available DXA scans had axial Z-scores ≥ +2.5. One subject each had kyphoscoliosis, mild hypermobility, clavicular osteolysis or fibromyalgia. Onset of acute crystalline arthritis and metatarsal fractures was typically 20–40 years of age. No subject had alternate explanations for these conditions (e.g., hyperparathyroidism) or previously diagnosed HPP. At least 7 of 21 (33%) subjects in PMRP with serum ALP mostly ≤30 IU/L were considered likely to have previously unrecognized mild HPP. 5 of these 7 subjects have since been

personally evaluated (FM) and the clinical impression of mild adult HPP has been confirmed.

Conclusion: Subjects with persistently low serum ALP appear to have significant musculoskeletal disease burden and some may have previously unrecognized HPP. Further clinical and biochemical investigations are warranted.

Acute-Phase Response After Zoledronic Acid: Role of Vitamin D and of Previous Treatment with Oral Amino-Bisphosphonates. Marco Massarotti, Chiara Crotti, Nicola Ughi, Gianluigi Fabbriciani, Laura Belloli and Bianca Marasini. IRCCS Humanitas Clinical Institute, Rozzano (Milan), Italy

Background/Purpose: Amino-bisphosphonates (N-BPs) are currently considered the most important class of drugs used for the inhibition of osteoclast activity in common metabolic bone diseases, such as osteoporosis (OP), Paget disease, bone metastases, multiple myeloma and hypercalcemia. Recently, intravenous zoledronate has been licensed for the treatment of postmenopausal and male osteoporosis. The major adverse event of i.v. zoledronate is the development of an acute-phase response (APR), characterized by a transient mild flu-like syndrome with fever, fatigue, myalgia and malaise. The APR usually develops within 24 to 36 hours from the first infusion and resolves spontaneously within 2 to 3 days. The symptoms are due to an increased circulating level of interleukin 6 (IL-6), tumor necrosis factor β (TNF- β), and interferon-γ (IFN- γ). Recently an association between post-N-BPs APR and 25(OH)D has been disclosed, suggesting an interesting interplay among N-BPs, 25(OH)D and the immune system. The purpose of this study was to: a) Evaluate whether previous treatment with oral N-BP may influence APR after first zoledronate infusion; b) Confirm the association between 25(OH)D levels and APR.

Methods: We retrospectively evaluated 130 OP patients treated for the first time with i.v. zoledronate between October 2008 and April 2010 and selected a sample of 80 patient for which serum 25(OH)D levels had been dosed in the month preceding the infusion. We also recorded for these patients (81 F e 9 M; 72 $\pm$ 8 years of age): 1) previous treatment with oral N-BPs, 2) previous treatment with strontium ranelate and teriparatide, 3) serum calcium and PTH levels before the infusion, 4) concomitant treatments [corticosteroids; immunosuppressive drugs (eg MTX, AZA, CTX); aromatase inhibitors; statins].

Results: We verified the development of APR in 34 of the 80 patients in analysis (37.8% APR+ versus 62.2% APR-). 25(OH) D levels were significantly lower in the APR+ group than in the APR- subjects (29.9 $\pm$ 24.5 versus 39.4 $\pm$ 21.0; $p<0.05$) and the PTH levels resulted significantly higher in the APR+ group than in APR- subjects (60.7 $\pm$ 23.3 versus 50.4 $\pm$ 20.5; $p<0.0396$). Calcium levels were not significantly lower in the APR- group than in APR+ subjects (9.59 $\pm$ 0.4 versus 9.79 $\pm$ 0.5; $p=0.058$). Forty eight of the eighty patients were previously treated with orally N-BP (N-BPs+ 60% versus N-BPs- 40%). The APR frequency were significantly lower among the N-BPs+ subjects than the naive ones (31.3% vs 59.4%; $p=0.013$). We didn't find any relationship between the APR onset and age, previous treatment with teriparatide or strontium ranelate and the concomitant treatments evaluated (corticosteroids; immunosuppressive drugs; aromatase inhibitors; statins).

Conclusion: Our study confirms the association between low serum 25 (OH) levels and the development of APR and shows that a previous N-BPs treatment could reduce the APR incidence after the first i.v. zoledronate infusion; it also underlines, for the first time, the role of serum 25 OH levels in preventing APR induced by zoledronate, even in patients with previous treatment with N-BPs.

Use of Pharmacologic Agents for the Prevention of Osteoporosis Among Older Women with Low Bone Mass Is Discordant with National Osteoporosis Foundation Guidance. Jie Zhang, Jeffery R. Curtis, Elizabeth S. Delzell and Kenneth G. Saag. University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: To determine if treatment with pharmacologic agents among postmenopausal women with low bone mass (T score between -1.0 and -2.5) was in concordance with the current and recent National Osteoporosis Foundation (NOF) clinical guidelines.

Methods: Cross-sectional analysis from 2007 to 2009 among participants of the Global Longitudinal Study of Osteoporosis in Women (GLOW) recruited from one study site. Eligible subjects had a bone density test within 2 years prior to a GLOW survey and had their lowest T score (of either total hip, femoral neck, lumbar spine, or 1/3 radius) between -1.0 and -2.5. Those who reported a history of hip or spine fracture were excluded. Fracture risk factors and the use of anti-osteoporosis medications were self-reported. We examined the proportions of women managed in concordance with the NOF 2003 and 2008 guidelines, with concordance defined as ever (current or past) received treatment among those recommended for treatment and never received treatment among those not recommended for treatment. Univariate odds ratios (ORs) and 95% confidence intervals (CIs) were calculated.

Results: Mean age among 770 eligible women was 70$\pm$7 years. When NOF 2003 guidelines were applied, 463 (61%) women were managed in concordance with the guidelines. Those who met NOF 2003 criteria were more likely to have ever received treatment (OR, 2.5; 95% CI, 1.9–3.4). Women with lower T scores were more likely to be treated (Table 1). Among those not recommended for treatment, women with T scores between -2.0 and -1.5 and absent of major risk factors were more likely to be treated than women with T scores between -1.5 and -1.0. Three hundred and nine (52%) women were managed in concordance with NOF 2008 guidelines. Those who met NOF 2008 criteria were not more likely to have ever received treatment (OR, 1.1; 95% CI, 0.8–1.6). Compared to women not recommended for treatment, those satisfying both NOF FRAX criteria were more likely to be treated (OR, 1.7; 95% CI, 1.1–2.6), while those satisfying only one of the criteria were not more likely to be treated (OR, 0.8; 95% CI, 0.5–1.4).

Table 1. Univariate associations between meeting and not meeting National Osteoporosis Foundation criteria and having ever received anti-osteoporosis treatment

	N (%) Treated	Odds Ratio (95% Confidence Interval)
NOF 2003 Guidelines$^{\mu}$		
Overall		
Treatment recommended	262 (60.4)	2.5 (1.9–3.4)
Treatment not recommended	122 (37.8)	Reference
*By BMD category and presence of major risk factors**		
Treatment recommended		
T score ≤ -2.0	168 (63.9)	3.8 (2.6–5.7)
$-2.0 <$ T score ≤ -1.5 and presence of at least one of the following risk factors*	94 (55.0)	2.7 (1.7–4.1)
Treatment not recommended		
$-2.0 <$ T score ≤ -1.5 and absent of the following risk factors*	64 (46.0)	1.9 (1.2–2.9)
$-1.5 <$ T score < -1.0	58 (31.5)	Reference
NOF 2008 Guidelines$^{\mu}$		
Overall		
Treatment recommended	168 (54.2)	1.1 (0.8–1.6)
Treatment not recommended	147 (51.0)	Reference
By FRAX risk score		
Treatment recommended		
10 year probability of hip fracture $\geq$ 3% and 10 year probability of major osteoporotic fracture $\geq$ 20%	98 (64.1)	1.7 (1.1–2.6)
Either 10 year probability of hip fracture $\geq$ 3% or 10 year probability of major osteoporotic fracture $\geq$ 20%, but not both	70 (44.6)	0.8 (0.5–1.4)
Treatment not recommended		
10 year probability of hip fracture $<$ 3% and 10 year probability of major osteoporotic fracture $<$ 20%	147 (51.0)	Reference

$^{\mu}$ The NOF 2003 and 2008 criteria could not be evaluated in 13 and 172 women respectively due to missing values on key fracture risk factors.
* Risk factors include fracture since turning 45, parental hip fracture, body weight $<$ 127 lbs, current smoking, and current glucocorticoid use

Conclusion: Up to 50% of the women with osteopenia were not treated in concordance with NOF guidelines. Those having one but not both of the NOF FRAX criteria for intervention were not more likely to be treated than those having neither. These results may reflect a lack of awareness of and insufficient dissemination of the guidelines among physicians.

1122

The Relationship Between the Level of Serum Lipids and Bone Metabolism Among Pre and Postmenopausal Women. Yun Sung Kim[1], Hae-Rim Kim[2], Sang-Hyon Kim[3] and Hyun-Sook Kim[1]. [1]Internal Medicine, Chosun University Hospital, Gwangju, South Korea, [2]Konkuk University Medical Center, Seoul, South Korea, [3]Dongsan Medical Center, Keimyung University, Daegu, South Korea

Background/Purpose: Previous in vitro and animal studies showed that high serum cholesterol reduced bone mass densitometry (BMD) by

affecting the cell differentiation of osteoblasts, and hyperlipidemic drugs (HMG-CoA reductase inhibitors) were shown to help preserve bone mass and prevent osteoporosis induced fracture. However there were only few studies which investigated the correlation between human serum lipid levels with biochemical bone markers reflecting bone metabolism. Therefore, this study was done to investigate the correlation between the two.

Methods: The subjects included 133 female adults who visited a health promotion center from November 2005 to May 2006. Urine deoxypyridinoline osteocalcin, and alkaline phosphatase (ALP) were used as bone markers and BMD was measured.

Results: There was a positive correlation between urine deoxypyridinoline and triglyceride ($r = 0.20$, $P = 0.02$), and a negative correlation with HLD-cholesterol ($r = -0.24$, $P < 0.01$). No correlation was found between osteocalcin and serum lipids but a positive correlation was noted between ALP and HLD-cholesterol ($r = 0.21$, $P = 0.01$). In an effort to study the relationship between bone marker and serum lipids, multiple regression analysis was conducted after adjusting for age, menopause status, the period of menopause, BMI (Body mass index), muscle mass, fat mass, and exercise amounts. According to the analysis, deoxypyridinoline had a statistically significant correlation with total cholesterol ($P < 0.01$), triglyceride ($P < 0.01$), HDL-cholesterol ($P = 0.013$), and LDL-cholestrol ($P < 0.01$), but osteocalcin showed no correlation. ALP was found to have a significant correlation with triglyceride ($P = 0.014$) and LDL-cholesterol ($P = 0.045$).

Conclusion: Significant correlation was noted between serum lipid level and deoxypyridinoline as bone absorption index and ALP as bone formation index. Therefore, lipid metabolism can affect the bone metabolism, and dyslipidemia patients should be managed in order to prevent osteoporosis.

1123

Vitamin D in Obesity (VIDeO): Assessing Vitamin D Deficiency in the Bariatric Population. Arthur N. Lau[1], Maria Tiboni[1], Zara Khalid[1], Roman Jaeschke[1], Mehran Anvari[1] and Jonathan D. Adachi[2]. [1]McMaster University, Hamilton, ON, [2]Hamilton, ON

Background/Purpose: Gastric bypass surgery (GBS) is becoming an increasingly common intervention for the morbidly obese. Little is known about the effects of GBS on bone metabolism. Adiposity has been inversely associated with vitamin D levels across a range of BMI and cultural groups. Our goal was to assess the prevalence of vitamin D deficiency pre-operatively, and post-operatively. As a quality assurance initiative, we also wanted to assess if our center was doing a satisfactory role in promoting vitamin D and calcium supplementation in this population, and if aggressive screening and treatment of deficiency had any effect on 25-hydroxyvitamin D levels.

Methods: In a retrospective chart review of 173 bariatric patients, baseline 25-hydroxyvitamin D, PTH and calcium levels were obtained pre-operatively and post-operatively at 3 and 6 months. We also assessed the percentage of patients on oral vitamin D and calcium supplementation at baseline and at each follow-up visit, and the number of patients receiving aggressive treatment with 50,000 IU of Vitamin D2 weekly. All patients with vitamin D deficiency during the follow-up period (below 50 mmol/L) were treated with 50,000 IU of vitamin D2 weekly for eight week duration.

Results: Of the 173 patients, 170 had undergone laparoscopic roux-en-y bypass, 3 received a gastric sleeve. Their mean baseline BMI was 46.0 and weight of 126.8 kg. Baseline 25-hydroxyvitamin D levels were 55.4, PTH levels of 5.68, and Calcium of 2.46. From the 164 patients with baseline blood work, 76 had baseline vitamin D deficiency (<50mmol/l) and 130 had vitamin D insufficiency (77.8%). A total of 32/93 (34.4%) patients were vitamin D insufficient at 3 months, and 19/67 (28.4%) were at 6 months follow-up. Regarding vitamin D deficiency, 5/93 (5.4%) patients were found to have a 25-hydroxyvitamin D level in the deficient range at 3 months, and 2/67 (3.0%) at the 6 month follow-up. All 100% of patients at the 3 month follow-up assessment were on oral supplementation with calcium and vitamin D, and 75% were on supplementation at the 6 month follow-up.

Conclusion: Our study shows a majority of bariatric patients have vitamin D deficiency at baseline. After GBS, much lower rates of vitamin D deficiency/insufficiency were seen compared to the current literature. We also found a high percentage of our patients were supplemented with calcium and vitamin D post-operatively. The aggressive screening for vitamin D deficiency, aggressive treatment when it was found, and emphasis on preventing vitamin D deficiency post-operatively with routine oral supplementation likely accounted for the low rates of vitamin D deficiency seen in our cohort.

1124

Osteogenesis and Osteoclast Inhibition Effects of Bisphosphonates Administered for Over 4 Years Alone or in Combination with Statin in Rheumatoid Arthritis Patients During a 12 Month Follow-up. Masakazu Nagashima. Tokyo Metropolitan Bokutoh Hospital, Tokyo, Japan

Background/Purpose: To investigate the effects of bisphosphonates (Bis) alone or in combination therapy with Bis (etidronate, alendronate, and risedronate) and statin on the BMD and bone metabolism of rheumatoid arthritis (RA) patients.

Methods: Seventy-five RA patients receiving prednisolone (PSL) and Bis for over 4 years were divided into 2 groups: Bis and Bis + statin (n=40 and35; average age, 66.1 and 65.3 years; average disease duration, 25.3 years and 20.8 years; average PSL dose, 2.5 and 2.9 mg, respectively). During a 12-month treatment and follow-up, we measured the serum levels of NTX, TRACP-5b, PICP, and RANKL. BMD levels of the 2 groups at the radius, lumbar spine, and femoral neck were compared by using QDR.

Results: A significant increase was observed in the BMD of the lumbar spine in the Bis + statin group and significant decreases were observed in the BMD of the radius and femoral neck in the Bis group. The serum level of NTX in the Bis group decreased during the follow-up period. The serum RANKL levels were significantly decreased at 12 months after the start of statin administration in the Bis + statin group, compared with the Bis group.

Conclusion: The combination of the Bis + statin had no significant influence on bone resorption and increased osteogenesis. However, the Bis group had inhibited bone resorption and decreased osteogenesis. These results suggest that the combination therapy regulated bone resorption and osteoclast induction via a decrease in RANKL levels, and up-regulated osteogenesis.

1125

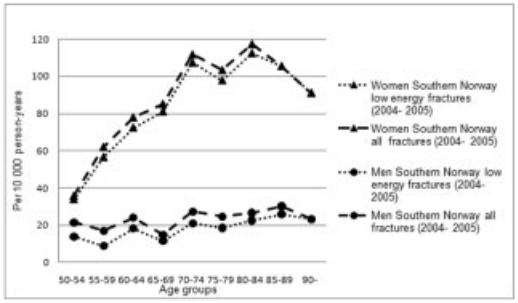
The Epidemiology of Low and High Energy Distal Radius Fracture in Middle-Aged and Elderly Men and Women in Southern Norway. Andreas P. Diamantopoulos[1], Gudrun Rohde[1], Inger M. Skoie[1], Irene Johnsrud[1], Marc Hochberg[2] and Glenn Haugeberg[1]. [1]Hospital of Southern Norway, Kristiansand, Norway, [2]University of Maryland School of Medicine, Baltimore, MD

Background/Purpose: Distal radius is among the most frequent sites for fractures in the elderly population. The overall incidence of distal radius fracture has been reported to be highest in the Scandinavian countries. There is a lack of epidemiology data on distal radius fractures in particular where low and high energy fractures have been studied separately. Thus our aim was to study the incidence of low and high energy distal radius fracture in middle-aged and elderly men and women in Southern Norway.

Methods: Patients with low and high energy distal radius fractures aged 50 years or older were identified from four hospitals in southern Norway in 2004 and 2005. Low energy fracture was defined as a result of minimal trauma, e.g. falling from standing height or less. Age adjusted and age specific incidence rates for men and women were calculated.

Results: A total of 799 (118 men and 681 women) individuals aged $\geq$ 50 yrs with low energy and 84 (48 men and 36 women) with high energy distal radius fracture were identified. Mean age for the low energy fracture patients was 70.1 yrs (66.8 men, 70.7 women) and for the high energy fracture patients 63.7 yrs (61.7 men, 66.3 women). A difference of approximately 5 years was found for age between low and high energy fracture patients both in men and women.Age specific incidence rates were significantly higher in women than in men for all age groups.The overall age adjusted incidence rate per 10.000 person years was 18.9 for men (low energy 12.8 vs. high energy 6.1) and 75.1 for women (low energy 71.1 vs. high energy 4.0). The prevalence of distal radius fractures in the two year period was significantly higher in winter compared with the other seasons ($p<0.001$). Between rural and urban areas a statistically significant difference in age adjusted incidence rates for all distal radius fractures was found for men (12.8 vs. 23.8, $p<0.005$) but not for women (69.0 vs. 82.6, $p< 0.06$). For low energy distal radius fracture the difference between rural and urban areas was statistically significant both for men ($p<0.008$) and women ($p<0.013$).

Fig.1. Age specific incidence rates of low energy and all distal radius fracture among women and men in Southern Norway (2004- 2005)



Conclusion: A fourfold higher age adjusted incidence rate for distal radius fracture was found for women compared with men. However the proportion of patients with high energy distal radius fracture is higher in men than in women (28.9% vs 5.9%). Our data indicate that individuals living in urban areas are at higher risk for low energy distal radius fracture than individuals living in rural areas. Increased awareness and better preventive strategies and treatment methods are still needed to reduce the risk of low energy distal radius fracture in the aging population of the western society.

The Efficacy and Mechanism of Bisphosphonate on Glucocorticosteroid-Induced Osteoporosis in Systemic Lupus Erythematosus Patients. Xiao Zhang and Yu-xing Qin. Guang Dong General Hospital, Guang Dong Academy of Medical Sciences, Guangzhou, China

Background/Purpose: Glucocorticoids (GCs) is a mainstay of treatment in many inflammatory and immune-mediated disorders. However, persistent use is associated with side-effects, such as bone loss and increased fracture risk. Bisphosphonate is an available medicine by FDA for the prevention and treatment glucocorticoid-induced osteoporosis(GIOP). And this trial was to investigate the clinical effect and mechanism of Alendronate in preventing Glucocorticosteroid-Induced Osteoporosis

Methods: 1.Clinical Study: 78 SLE patients, divided into 3 groups according to Bone Density (BMD). ① Standard Glucocorticoids (GCs) group(Blank Placebo), ② Standard GCs+ vitamin D3+calcium tablet group, ③ Standard GCs+ alendronate group (treatment group), All of the patients were examined bone mineral density(BMD) of lumbar and left femur in 0 week, 12 week and 24week.

2. Basic Sciences Study: ① 13 case in blank placebo group, 9 cases with GCs+ alendronate therapy group (treatment group), compared PPARγ and β-catenin expression with immunohistology and histomorphometry with HE staining after 24w. ② To inductd human bone mesenchymal stem cells (hBMSCs) to osteoblasts and adipocyte with addition different concentration Alendronate during the induction, PPRAγ-mRNA and β-catenin-mRNA were measured by Q-PCR after induction.

Results: 1. In alendronate group, there was significant difference before and after treatment(F value 15.622, *P* value 0.001; F value 11.294, *P* value 0.003) in BMD of lumbar and left femur; There were no significante in vitamin D3+calcium group (F 0.542, *P* 0.466; F 0.389, *P* 0.537).

2. The results of histomorphometry between treatment group and control group had statistically significant(trabeculae surface area percentatge, trabeculae thickness; *P* 0.033, 0.009),treatment group PPARγ average photodensity was lower than blank placebo group (*P*0.037); there were no statistical difference of β-catenin immunohistochemistry between two groups (*P*0.569). 3. Oil red O stain, PPARγ Q-PCR analysis indicated 10^{-5}mol/L, 10^{-7}mol/L Alendronate group and adipogenic induced group presents significant difference (*P* 0.000, 0.041), while β-catenin Q-PCR indicated no intergroup statistical difference (F 1.999, *P* 0.193).

Conclusion: Bisphosphonate presents determined efficacy in the treatment of GIOP, increasing patient bone mass to a certain degree; bisphosphonates increase trabeculae surface area density as well as thichness; and through the inhibition of PPARγ expression, reduces bone marrow matrix stem cell lipid differentiation, indirectly increasing bone formation, thus decreasing GIOP incidence.

1127

Changes in Serum Receptor Activator for Nuclear Factor κB Ligand and Osteoprotegerin After Glucocorticoid Therapy Reflect Regulation of Their Expression by Glucocorticoid in Osteoblasts *in Vitro*. Kaichi Kaneko, Natsuko Kusunoki, Nahoko Tanaka, Tatsuhiro Yamamoto, Yoshie Kusunoki, Kenji Takagi, Hirahito Endo and Shinichi Kawai. Toho University School of Medicine, Tokyo, Japan

Background/Purpose: Osteoporosis is serious complication of systemic glucocorticoid (GC) therapy. RANKL (receptor activator for nuclear factor κB ligand) is a major ligand that increases differentiation of osteoclast *in vitro*. Osteoprotegerin (OPG) is a decoy receptor for RANKL showing inhibitory effects of action of RANKL *in vitro*. However, the significance of serum RANKL and OPG in GC-induced osteoporosis have not clarified yet. To clarify the significance of serum RANKL and OPG in patients with systemic autoimmune diseases under GC therapy.

Methods: (1) This study was approved by the ethics committee of Toho University. Sixty patients (female 36, postmenopausal 20) with systemic autoimmune diseases (systemic lupus erythematosus 18, vasculitis syndrome 18, polymyositis/dermatomyositis 10/5, adult onset Still's disease 5, mixed connective tissue disease 4) who were started to receive prednisolone at 30 mg or higher (up to 60 mg) daily dose were prospectively included in this study. Regular doses of bisphosphonate (alendronate n=26 or risedronate n=34) were co-administered in all the patients. Serum samples were obtained just before and 1 to 4 weeks after the start of GC therapy. Serum levels of RANKL and OPG were determined by ELISA (enzyme-linked immunosorbent assay) (Biomedica, Vienna, Austria). (2) NHOst, normal human osteoblast cells (Lonza Inc, Williamsport, OH) were cultured in a humidified environment of 5% CO_2. The effects of dexamethasone (Dex) on mRNA and protein productions of RANKL and OPG were evaluated by reverse transcription-polymerase chain reaction and ELISA, respectively.

Results: (1) Serum mean RANKL level in all patients remained unchanged after GC therapy. However, RANKL levels in these patients were broadly distributed at baseline. Mean serum RANKL level in patients above the 75th percentile was significantly ($P<0.0001$) decreased [from 0.52 ± 0.12 (SE) to 0.29 ± 0.08 pmol/L] after GC therapy. In contrast, mean serum RANKL level in patients below the 75th percentile was significantly ($P<0.05$) increased (from 0.035 ± 0.009 to 0.072 ± 0.019 pmol/L) after GC therapy. The serum CRP levels in patients whose RANKL levels above the 75th percentile were significantly ($P<0.05$) increased when compared with those in patients below the 75th percentile. Mean serum OPG level in all patients was significantly ($P<0.0001$) decreased (from 2.2 ± 1.5 to 1.4 ± 1.4 pmol/L) after GC therapy. (2) mRNA and protein expressions of RANKL were increased, while those of OPG were decreased by addition of Dex in the culture medium of unstimulated NHOst. Expressions of mRNA and protein of RANKL and OPG were increased by IL-1β. IL-1β-stimulated expressions of mRNA and protein of RANKL and OPG were both suppressed by Dex treatment in NHOst.

Conclusion: We suggested that the effects of GC on RANKL and OPG in systemic autoimmune diseases showed dual regulations both *in vivo* and *in vitro*, possibly depending upon disease activity.

1128

Effects of Technetium-99 Conjugated with Methylene Diphosphonate on Rats with Glucocorticoid Induced Osteoporosis. Ying Ning, Xuewu Zhang, Jiaxin Zhu, Min Feng and Zhanguo Li. Peking University People's Hospital, Beijing, China

Background/Purpose: Yunke (technetium-99 conjugated with methylene diphosphonate, ^{99}Tc-MDP), a drug patented in China (patent No. ZL94113006.1), has been used in Chinese patients since 1997 and proven to be effective in the treatment of rheumatoid arthritis. In this study, we examined whether ^{99}Tc-MDP has therapeutic effect on glucocorticoid-induced osteoporosis, comparing with MDP (methylene diphosphonate)

Methods: Forty-eight Sprague-Dawley rats were randomly divided into six groups: blank group, negative control group, high dose group, medium dose group, low dose group and positive control group. During the induction period, dexamethasone is given to all five groups except the blank group. In the treatment period, blank and negative control groups were given 5mg/kg physiological saline, 10mg/kg,5mg/kg and 2.5mg/kg ^{99}Tc-MDP were given to high dose, medium dose and low dose groups respectively, and positive control group was given 5mg/kg MDP. Both tibiae from each rat were subjected to micro-computed tomography (micro-CT) and histomorphology analysis (hematoxylin-eosin staining) respectively.

Results: 1. Micro-CT quantitative analysis: (A) Analysis of cancellous bone: (1) compared to the blank group, rats in the negative control group had decreased Bone Volume/Total Volume(BV/TV) and Trabecular Number(Tb.N) as well as increased Bone Surface Area/Bone Volume (BSA/BV),Trabecular Spacing(Tb.Sp) and Trabecular Pattern Factor (TPF); (2) compared to the negative control group, rats in the low dose group had increased BV/TV and Tb.N, and decreased Tb.Sp and TPF; (3) For medium dose, high dose and positive control groups, the number of parameter improvement with statistical significance increases to five and six, respectively; (4) For positive control group, improvement of all six parameters has statistical significance. (B) Analysis of cortical bone: Cortical Thickness (Co.Th) decreased in the negative control group in contrast to the blank group; after treatment, Co.Th in all doses of ^{99}Tc-MDP groups increased comparing to the negative group; however, no improvement of Co.Th was noted in the positive control group comparing to the negative group. 2. Histomorphology: compared to the blank group, rats in the negative control group has sparse, disordered trabeculae; compared to the negative control group, all doses of ^{99}Tc-MDP groups and MDP group have denser and regular trabecular arrangement.

Conclusion: Our study suggests that: ^{99}Tc-MDP can reverse the microarchitecture changes of glucocorticoid-induced osteoporotic rats. Low dose of ^{99}Tc-MDP is effective and the efficacy improves as dose increases; ^{99}Tc-MDP and MDP show similar effect on cancellous bone while ^{99}Tc-MDP excels in improving cortical bone thickness.

1129

Prevention of Glucocorticoid-Induced Osteoporosis - We Are Not Doing Enough; What Else to Consider. Lucy E. Durham[1], Sima Patel[1], Leena Yalakki Jagadeesh[1] and Taher Mahmud[2]. [1]Kent and Sussex Hospital, Tunbridge Wells, United Kingdom, [2]Pembury Hospital, Tunbridge Wells, United Kingdom

Background/Purpose: Royal College of Physicians 2002 guidelines(1) recommend that people aged over 65 years on long term glucocorticoids are prescribed osteoporosis prophylaxis (bisphosphonates alone, or in combination with calcium and vitamin D supplementation) in order to reduce the risk of fragility fractures. In February 2011 we audited the extent to which these guidelines were met in a district general hospital.

Methods: All hospital inpatients were screened over a period of one week. Their drug charts and clinical notes were reviewed, patients were interviewed and their general practitioner contacted as needed. Patients aged over 65 years taking glucocorticoids for longer than 3 months or more than 3 short courses in 12 months were identified and the presence or absence of osteoporosis prophylaxis noted.

Results: 240 inpatients were screened. 27(19 female) met the criteria for the need for osteoporosis prophylaxis. Common indications for glucocorticoid use were chronic obstructive pulmonary disease (n=8) and polymyalgia rheumatica (n=8). Results showed that 12 (44%) of 27 patients in whom osteoporosis prophylaxis was indicated were actually receiving prophylaxis.

Conclusion: These results identify a failure of clinicians to prescribe prophylaxis and/or poor patient adherence. These results are infact worse than the results from a similar audit 2 years ago 44% now vs 68% then; we are using new appriaches to raise awareness about the need for steroid induced osteoporosis prevention. In addition to presenting the findings at the hospital clinical governance meeting we are using other strategies including training of new medical staff and nurses at induction, flagging the audit results, placement of osteoporosis guidelines on the hospital intranet and spot checks by inpatient pharmacy staff with use of fluorescent stickers on drug charts to identify patients eligible for prophylaxis.

We also plan to use social media to raise awareness about the need for secondary prevention of osteoporosis by using Tweeter and Facebook. We will re-audit after after 6 months to assess whether these measures have been effective.

Modeling Human Rheumatoid Arthritis In Non-Human Primate: Type II Collagen Induced Arthritis In Cynomolgus Macaques. Hong Zhang[1], June Liu[1], Jilin Deng[1], Liangtang Chang[1], Hellen Zheng[1], Cheng Yu[1], Jun Lu[1], Alison Bendele[2], Yunfeng Fu[1] and Jeff Duan[1]. [1]PharmaLegacy Laboratories, Shanghai, China, [2]Bolder BioPATH. Inc., Boulder, CO

Background/Purpose: Collagen induced arthritis (CIA) rodent models have been extensively used in rheumatoid arthritis (RA) research. An RA model in non-human primate (NHP) is particularly demanded because of the close phylogenesis that provides the cross-reactivity to human for different development compounds using most modern drug technologies. However, NHP RA model has been reported extremely difficult because of the low and inconsistent disease incidence.

Methods: We studied type II collagen induced arthritis in Cynomolgus monkeys. Following immunization with collagen, the disease progression was monitored for 8 weeks.

Results: Overall the arthritic incidence reached 87% and the average arthritic incidence of proximal interphalangeal (PIP) joint reached near 90%, significantly higher than what was previously reported. The average swelling of PIP joint increased approximately by 45%. Radiography, histopathology and histomorphometry analysis of the joint bones well supported the arthritic disease with the similar characteristics of human RA joints. The average arthritic score was significantly reduced with the single agent treatment of Methotrexate or Dexamethasone.

Conclusion: Our results demonstrated the successful establishment of an reliable CIA in Cynomolgus monkeys, providing a valuable tool for studies of RA disease in pathogenesis, biomarker, translational research, and most importantly, anti-arthritic therapeutics as well as other relevant diseases, such as anemia of chronic disease and arthritic pain.

Interferon Regulatory Factor 7 Deficiency Inhibits Collagen-Induced Arthritis: Regulation of Interleukin-6 and Matrix Metalloproteinase 3 Production. Susan E. Sweeney. UCSD School of Medicine, La Jolla, CA

Background/Purpose: Innate immune responses activate synoviocytes and recruit inflammatory cells into the rheumatoid joint. Transcription of many IFN response and pro-inflammatory cytokine genes is activated by IFN-regulatory factors (IRF) in response to innate sensor recognition. This study examined the effect of genetic deficiency of IRF7 in a murine collagen-induced model of arthritis (CIA).

Methods: CIA was induced in wild type DBA/1 (WT) and IRF7−/− DBA/1 mice by immunizing with type II collagen. Clinical arthritis scores and paw measurements were determined and histology was performed. Gene expression was evaluated by synovial tissue and splenic Q-PCR. Mouse serum was analyzed by ELISA. Draining lymph node cells from CIA were evaluated in vitro for cytokine production and proliferation.

Results: Arthritis severity and joint destruction was significantly decreased in IRF7−/− mice compared with WT CIA. Anti-type II collagen IgG levels were not significantly different in sera of IRF7−/− mice compared with WT. Synovial and splenic gene expression of IL-6 and synovial MMP-3 gene expression was significantly decreased in IRF7−/− mice compared with WT CIA mice. In addition, serum protein levels of IL-6 and MMP-3 were significantly decreased in IRF7−/− mice.

Conclusion: Genetic deficiency of IRF7 resulted in a significant decrease in both arthritis severity and joint destruction in CIA. Consistent with the clinical effect, IL-6 and MMP3 synovial gene expression and serum protein production were significantly decreased in IRF7−/− CIA. This study demonstrates an important role for IRF7-driven immunity in production of MMP as well as IL-6 in experimental arthritis and suggests the therapeutic potential for targeting IRF7 in RA patients.

1132

Improving Therapy Effect on Arthritic Rats by Co-Expression of CD40LIg and IκBα. Ping Fan, Lan He, Dan Pu, Wenxu Zhou, Xiaohong Lv, Yining Sun and Nan Hu. The First Affiliated Hospital Xi'an Jiaotong University School of Medicine, Xi'an, China

Background/Purpose: Rheumatoid arthritis (RA) is one of chronic autoimmune diseases that harm the human health for a long time. The pathogenesis of RA is still unknown, which refers to several aspects of the immune system. Especially, the aberrant activation of the lymphocytes and the NFκB dependent nonspecific inflammatory response are the two main points of joint inflammatory damage in RA. CD40/CD40L is the key co-stimulated molecular in the recognition and activation of the T cells. IκBα can suppress the inflammatory response and injury of joint synovium by cytokine at the key point by inhibiting the NFκB signaling. In this study, we used CD40LIg-IRES2- IκBα co-expressiong adenovirus vector to transfect the synovium tissue of arthritic rats to investigate the genes expression as well as the effect on the arthritic rats. In addition, we will compare the therapeutic effect of the co-expression gene adenovirus and the single gene adenovirus vector, to explore the potential gene therapy for RA.

Methods: Construction of pAdCD40LIg, pAdIκBα and pAdCD40LIg-IRES2-IκBα adenovirus vector had completed. Wistar rats were rendered arthritic by multi-subcutaneous injection of complete Freund's adjuvant. Arthritic rats were divided into four groups: group A with distal joint cavity injection of sterile water as control (n=5); group B with injection of pAdCD40LIg vector (n=5); group C with pAdIκBα vector injection (n=5); and group D with injection of pAdCD40LIg-IRES2-IκBα vector (n=5). Therapy effects were measured by the method of arthritis index score of rats. The levels of TNF-α/IL-2/IL-6 in synovial fluid collected by joint puncture were measured by ELISA methods 21 days after treatment.

Results: The mean arthritis index score of rats in group D was significantly lower than those in other three groups ($P<0.05$). The index in group B and C were significantly lower than that in group A ($P<0.05$). The rats in group D had the lowest TNF-α, IL-2 and IL-6 levels in synovial fluid followed by group C, B and A ($P<0.05$).

Conclusion: The expression CD40LIg and IκBα can effectively inhibit inflammatory reaction of arthritic rats. Simultaneous expression CD40LIg and IκBα can improve the therapeutic effect by synergistic effect.

1133

Mimicking Disruption of the Brain—Immune System—Joint Communication Results in Expression of Collagen Type II-Induced Arthritis in Non-Susceptible PVG Rats. Christine Wolff[1], Johannes Wildmann[2], Anke Randolf[2], Hugo O. Besedovsky[2], Adriana del Rey[2] and Rainer H. Straub[1]. [1]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, Department of Internal Medicine I, University Hospital, Regensburg, Germany, [2]Department of Immunophysiology, Institute of Physiology, Philipps University, Marburg, Germany

Background/Purpose: Disruption of brain-immune system-joint-communication has been demonstrated during collagen type II (CII) induced-arthritis in susceptible DA rats. In this study, we investigated whether immunization of non-susceptible PVG rats with CII results in changes in central and peripheral neuroendocrine mechanisms different from those observed in DA rats. We also investigated whether mimicking the disruption of the communication between the systems results in expression of arthritis in PVG rats.

Methods: PVG rats were immunized with CII in incomplete Freund adjuvant. Plasma corticosterone levels were evaluated by ELISA and joint innervation by immunofluorescence. Hypothalamic neurotransmitters were determined by HPLC and hypothalamic cytokine expression by real-time RT-PCR. Adrenalectomy was performed 14 days before immunization.

Results: Compared to DA rats, which developed a severe arthritis (score 16), only 12 out of 28 PVG rats showed minor arthritis symptoms (score 1–2). In PVG rats, plasma corticosterone levels and the sympathetic innervation in the joints did not change after immunization with CII. Also as opposed to arthritic DA rats, hypothalamic serotonin metabolism and tyrosine content were decreased on day 28 after immunization and there was an early increase in hypothalamic TNF gene expression in PVG rats. Following adrenalectomy, immunized PVG rats developed a severe arthritis in the hind paws (score 8), indicating that adrenal hormones contribute to control the expression of the disease.

Conclusion: In conclusion, immunization of non-susceptible PVG rats with CII results in changes in hypothalamic neurotransmitters and peripheral neuroendocrine mechanisms different from those observed in susceptible DA rats. Thus, disruption of immune-neuro-endocrine interactions seems to be relevant for the predisposition and course of arthritis, since mimicking such a disruption results in a marked change of arthritis severity.

1134

Regulation of Inflammatory Arthritis by the Upstream Kinase MKK7 in the c-Jun N-Terminal Kinase (JNK) Pathway. Sang-il Lee, David L. Boyle and Gary S. Firestein. UCSD School of Medicine, La Jolla, CA

Background/Purpose: The mitogen-activated protein (MAP) kinase JNK is a key regulator of matrix metalloproteinase (MMP) and cytokine production in rheumatoid arthritis (RA), and JNK deficiency markedly protects mice in animal models of inflammatory arthritis. JNK is regulated by two upstream kinases, namely MKK4 and MKK7. Previous studies demonstrated that cytokine-induced JNK activation and MMP production are solely dependent on MKK7 in fibroblast-like synoviocyte (FLS) and do not require MKK4. Therefore, we evaluated whether selective targeting of MKK7 in vivo using anti-sense oligonucleotides (ASO) would block arthritis-associated JNK activation and decreased severity of K/BxN serum transfer arthritis.

Methods: 2'-O-Methoxyethyl chimeric ASO for MKK7 and control ASO (25 and 50 mg/kg) were injected intravenously to assess their knockdown effect in normal C57BL6 mice. Arthritis was induced by injecting mice with K/BxN serum. Treatment included intravenous injections of PBS, control ASO, or MKK7 ASO (50 mg/kg twice a week, n = 7–8 for each group) from day −8 to 10. Arthritis severity was assessed using semiquantitative clinical scoring system. Ankle histology was scored for inflammation, bone erosion, and cartilage damage. Expression of MKK7 and JNK pathways were evaluated by quantitative PCR and western blot analysis of ankle joints.

Results: MKK7 ASO decreased MKK7 mRNA and protein levels in ankle joints of normal C57BL6 mice within 3 days in a dose-dependent manner, with greatest inhibition of nearly 40% at a dose of 50 mg/kg (n = 4 for each group). There was no effect of control ASO on MKK7 expression and MKK7 ASO did not decrease MKK4 levels. In the K/BxN serum transfer model, mice injected with MKK7 ASO had significantly less severe arthritis from day 4 to day 10 compared with control ASO. The peak clinical scores were: 11.1 ± 0.2 in control ASO, 4.9 ± 1.0 in MKK7 ASO; $p < 0.01$) and the changes in ankle diameter were: 0.59 ± 0.06 mm in control ASO and 0.22 ± 0.06 mm in MKK7 ASO; $p < 0.01$). The ankle joints from MKK7 ASO injected mice had significantly lower inflammation, bone erosion, cartilage damage, and overall histology scores than control ASO (overall scores: control ASO 2.7 ± 0.3 and MKK7 ASO 1.5 ± 0.3; $p < 0.05$). MKK7 deficiency decreased phospho-JNK by 67% and phospho-c-Jun by 62% in ankle extracts ($p < 0.05$). In addition, synovial MMP3 and MMP13 mRNA were decreased by 76.2%, and 70.8%, respectively ($p < 0.05$).

Conclusion: The upstream kinase MKK7 plays a critical regulatory in a murine model of inflammatory arthritis. MKK7 deficiency suppresses the entire JNK pathway, including key JNK-dependent genes like synovial MMPs. Targeting MKK7 rather than JNK could provide site and event specificity when treating synovitis, potentially decreasing side effects by blocking pathogenic JNK activation while permitting non-pathogenic MKK4-mediated events.

1135

Gingiva-Derived Mesenchymal Stem Cells-Mediated Therapeutic Intervention for Experimental Arthritis. Maogeng Chen[1], Xiao-Shun He[2] and Song G. Zheng[3]. [1]University of Southern California, Los Angeles, CA, [2]1st Affiliated Hospital of Sun Yat-sen University, [3]USC Keck School of Medicine, Los Angeles, CA

Background/Purpose: Current approaches are unable to cure rheumatoid arthritis. Accumulated evidence has revealed that manipulation of bone-marrow mesenchymal stem cells (BMSCs) has a potential promise to treat these diseases. Nonetheless, isolation and expansion of BMSCs for therapeutic usage is less feasible in the clinic. In the current study, we have observed that use of gengival-derived mesenchymal stem cells (GMSCs), mostly sharing similar phenotypic and functional characteristics with BMSCs, resulted in significantly therapeutic effects on the established collagen induced arthritis (CIA).

Methods: CIA, an experimental animal model of human rheumatoid arthritis (RA), has been induced with the immunization of type II collagen (CII) and CFA in DBA/1J mice. 2×10^6 GMSCs were injected i.v. into DBA/1J mice on day 0, 14 or 28 after immunization. Arthritic index was evaluated, the levels of CII-specific autoantibodies and pro- and antiinflammatory cytokines IL-10, IFN-γ, IL-17A, IL-4, and TNF-α in sera, spleens or draining lymph nodes were determined using ELISA and quantitative RT-PCR. The joint pathology was examined with H&E staining. In some experiments, injection of PC61 i.p. was used to delete Tregs in arthritis mice. Additionally, GMSCs were injected to the DBA/1J GFP knock-in mice immunized or not with CII and CFA, and numbers and function of Foxp3 (GFP+) regulatory T cells were examined with flow cytometry. Co-culture of GMSCs and naïve CD4 T cells were used to induce Foxp3+ Treg cells *in vitro* with or without transwell. To test the clinical relevance, the therapeutic effect of GMSCs was tested in humanized animal xeno-GVHD model. Injection of 20×10^6 human PBMC to SCID common γ chain KO mice can induce the typical syndromes of xeno-GVHD.

Results: Compared with CIA model, infusion of GMSCs to DBA/1J mice at day 14 or day 28 after CII/CFA immunization significantly decreased the severity of arthritis and pathology scores. Injection of GMSCs also significantly down-regulated inflammatory cytokine (IFN-γ, IL-17A) and CII-specific autoantidody levels. The role of GMSCs in controlling the diseases may partially depend upon the induction of CD4+Foxp3+ Tregs. Co-cultures of GMSCs and naïve CD4+Foxp3- cells induced the differentiation of CD4+Foxp3+ Tregs through soluble factors dependent mechanism and infusion of GMSCs resulted in the increase of CD4+Foxp3+ cells in naïve and CIA mice. Infusion of GMSCs to DBA/1J mice at day 14 after immunization partially interfered with the progress of the arthritis when Foxp3+ Tregs were depleted. Co-transfer of GMSC and human PBMCs significantly prolonged the survival of SCID mice.

Conclusion: Injection of GMSC to evident arthritis resulted in significantly therapeutic effects on CIA. The therapeutic effect of GMSCs was partially mediated by the increased frequency of CD4+Foxp3+ regulatory T cells. Transfer of GMSCs significantly suppressed the GVHD initiated from human donor cells in SCID mice, suggesting that GMSCs have clinical relevance. GMSCs can function as an immunomodulatory and anti-inflammatory component of the immune system *in vivo* and use of GMSC may provide a promising approach for the treatment of rheumatoid arthritis and other autoimmune diseases.

1136

VX-509, An Orally Available Janus Kinase 3 (JAK3) Specific Inhibitor, Showed Robust Activity in Pre-Clinical Models of Aberrant Immune/Inflammatory Function. Thomas Hoock[1], James Hogan[1], Sudipta Mahajan[1], Dina Shlyakhter[1], Luke Oh[2], Larry Park[2], George Ku[2], Ian Catlett[1], Meryll Corbin[1], Francesco Salituro[2] and Mark Namchuk[1]. [1]Vertex Pharmaceuticals Incorporated, Cambridge, MA, [2]Formerly of Vertex Pharmaceuticals Incorporated, Cambridge, MA

Background/Purpose: JAK3 is a promising target for the design of orally available, targeted immunosuppressive drugs. Cytokines, which signal through JAK3, are critical for lymphocyte development and T cell-mediated immune responses. JAK3 expression is largely restricted to the lympho-hematopoietic system while the other members of the JAK kinase family are more broadly expressed. Hence developing specific inhibitors of JAK3 may potentially provide future oral therapies for a number of autoimmune diseases.

Methods: The investigational compound, VX-509, is a potent inhibitor of JAK3 (enzyme K_i 2.5 nM + 0.7 nM) and has demonstrated potent inhibition of endogenous cellular JAK3 activity with IC_{50}s ranging from 50–170 nM. The compound showed excellent selectivity against non-JAK family kinases of nearly three orders of magnitude. Enzymatic selectivity over isolated protein kinase domains of the other JAK family members (JAK1, JAK2 and TYK2) was less than 10-fold, however a more physiologically relevant measure of JAK isotype selectivity using cellular assays dependent on different JAK family members demonstrated a selectivity window of approximately 25–150 fold, depending on the assay comparators.

Results: VX-509 was examined for activity following oral administration in animal models of aberrant immune/inflammatory function. In a rat model of rheumatoid arthritis (CIA), VX-509 showed a dose-dependent reduction in ankle swelling and paw weight and improved histological scores in affected paws, with the effects/potency exceeding the reference standard etanercept (Enbrel®). In the mouse oxazolone DTH model, VX-509 displayed dose-dependent effects in alleviating the T-cell mediated skin inflammatory response, which was comparable to the reference standard prednisolone.

Conclusion: Overall, VX-509 is a JAK3-specific inhibitor that was effective in several preclinical models of aberrant immune/inflammatory function with oral dosing that support BID and QD regimens. These results support the clinical testing of VX-509 in chronic, autoimmune/inflammatory disorders and VX-509 is currently undergoing clinical evaluation in rheumatoid arthritis.

1137

A New Derivative of Roxithromycin Modulates Immunological Responses and Ameliorates Collagen-Induced Arthritis. Noriko Otsuki[1], Satoshi Iwata[1], Emi Kumagai[1], Taketo Yamada[2], Tomoki Katayose[1], Yoshiko Kichikawa[1], Osamu Hosono[1], Hiroshi Kawasaki[1], Hirotoshi Tanaka[1], Nam H. Dang[3] and Chikao Morimoto[1]. [1]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, [2]School of Medicine, Keio University, Tokyo, Japan, [3]University of Florida Shands Cancer Center, Gainesville, FL

Background/Purpose: Macrolide antibiotics have many biological activities distinctly different from antibacterial functions. Previously we showed that Roxithromycin (RXM), a macrolide antibiotic with a 14-member macrocyclin ring, inhibited in vitro production of proinflammatory cytokines such as TNF-α and IL-6 by T cells and macrophages. More interestingly, oral administration of RXM in mice with collagen-induced arthritis (CIA) reduced the severity of arthritis and serum level of IL-6 as well as leukocyte migration into the affected joints and destruction of bones and cartilages. In the present study, we synthesized the new derivertive of RXM named 5-I with less antimicrobial activity and studied the immunomodulatory effects of 5-I both in vitro and in vivo.

Methods: Proliferative response and cytokine production by human PBMCs and T cells stimulated with anti-CD3 plus anti-CD28 mAbs, cytokine production by human monocytes stimulated with lipopolysaccharide, and transendothelial migration of human T cells were analyzed in the presence or absence of various concentration of 5-I and RXM. In addition, 5-I and RXM-mediated alteration of mRNA expressions were evaluated by cDNA microarray anaysis and RT-PCR using human $CD4^+$ T cells. The in vivo effect of the oral administration of 5-I or RXM was evaluated using collagen-induced arthritis model mice (DBA/1J strain) by scoring of arthritis and pathological examination.

Results: 5-I did not affect the proliferation of lymphocytes and the production of Th2-type cytokines, whereas it specifically inhibited production of Th1, Th17, and proinflammatory cytokines, such as IL-2, IFN-γ, TNF-α, IL-6, and IL-17A by human T cells and/or monocytes. Microarray analysis revealed that 5-I reduced the expression of RORγt which is the master regulator of Th17. 5-I also inhibited the activated T cells migration. We found that the administration of 5-I to collagens-induced arthritis mice reduced the severity of the desease in the comparable level to RXM. The effectiveness was also observed in the delayed administration after onset of the disease, suggesting 5-I may be useful in the treatment of CIA as well as its prevention.

Conclusion: Our findings strongly suggest that 5-I is a promising low molecular compounds for the possible clinical application in the treatment of rheumatoid arthritis in human. Furthermore, 5-I may be a useful lead compound to regulate the differentiation of Th17 population.

IL-6 Overproduction Is Predominantly Related to Arthritis in TNFα-Induced Adipose-Related Protein (TIARP) Deficient Mice. Asuka Inoue[1], Isao Matsumoto[1], Naoto Umeda[1], Yuki Tanaka[1], Satomi Tamaki[1], Masahiko Mihara[2], Satoru Takahashi[3] and Takayuki Sumida[1]. [1]University of Tsukuba, Tsukuba city, Ibaraki, Japan, [2]Chugai Pharmaceutical, Gotemba, Japan, [3]Department of Anatomy and Embryology, Doctoral Program in Biomedical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba city, Ibaraki, Japan

Background/Purpose: TNFα-induced adipose-related protein (TIARP) is a six-transmembrane protein induced by TNFα, IL-6 and IL-1β in adipose tissue. Recently, we found that TIARP is dominantly expressed in splenic macrophages and joints of two arthritic mouse models (collagen induced arthritis; CIA and glucose-6-phosphate isomerase (GPI) induced arthritis). In human, TIARP is also observed in human joints from patients with rheumatoid arthritis and clearly upregulated by TNFα stimulation, although the pathogenic mechanisms of arthritis remain unclear. In this study, to elucidate the role of TIARP in the development of arthritis, we have generated TIARP-deficient ($TIARP^{-/-}$) mice.

Methods:
(1) We generated TIARP$^{-/-}$ in C57BL/6 (B6) background. We investigated several organs in aged (12months old) TIARP$^{-/-}$ mice.
(2) Peritoneal macrophages were collected using thioglycolate and were cultured with TNFα for 96h. Then, the production of IL-6 in culture supernatant was measured by enzyme-linked immunosorbent assay (ELISA).
(3) We also examined the susceptibility of young (8–12weeks old) TIARP$^{-/-}$ mice to CIA. CIA was induced by immunization with 200ug of chicken type II collagen (CII) emulsified in complete freund's adjuvant (CFA) to B6 mice, followed by boost immunization after 21 days of primary immunization. The severity of arthritis was monitored by clinical score and evaluated histologically on day 60.
(4) Draining lymph nodes and splenocytes were isolated on day 10 and were cultured with CII for 72h in vitro. IFNγ, IL-17 and IL-4 in their culture supernatant were measured by ELISA.
(5) The level of IL-6 and TNFα in the serum on day 60 after CII immunization were measured.
(6) We examined the effects of anti-IL-6 receptor mAb (MR16-1) on the development of arthritis in TIARP$^{-/-}$ mice. We injected 2mg of MR16-1 intraperitoneally on day 21 after CII immunization.

Results:
(1) Aged TIARP$^{-/-}$ mice spontaneously developed weak synovitis with enthesitis.
(2) Peritoneal macrophages from TIARP$^{-/-}$ mice produced high amount of IL-6 with TNFα stimulation.
(3) The severity of arthritis score in TIARP$^{-/-}$ mice was higher than that in WT mice. Histological analyses showed that enhanced neutrophil infiltration, synovial proliferation, and cartilage destruction.
(4) The amount of IFNγ, IL-17 and IL-4 was comparable between TIARP$^{-/-}$ and WT mice.
(5) The serum IL-6 was significantly increased in TIARP$^{-/-}$ mice, whereas serum TNFα was not detected.
(6) Administration of MR16-1 on day 21 significantly suppressed the progression of arthritis in TIARP$^{-/-}$ mice.

Conclusion: These findings suggest that TIARP deficiency relates the development of arthritis via the overproduction of IL-6.

Inhibitory Effect of c-Fos/AP-1 Inhibitor T-5224 on the Levels of Cytokines and Chemokines in the Arthritic Lesion of Mice with Collagen-Induced Arthritis. Tomomi Date[1], Yukihiko Aikawa[1], Akira Hashiramoto[2], Tetsuya Yamamoto[1], Masaaki Mikami[1], Hirokazu Narita[1], Shuichi Hirono[3] and Shunichi Shiozawa[2]. [1]Research Laboratories, Toyama Chemical Co., Ltd, Toyama, Japan, [2]Department of Biophysics, Kobe University Graduate School of Health Sciences/Department of Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan, [3]Department of Pharmaceutical Sciences, School of Pharmacy, Kitasato University, Tokyo, Japan

Background/Purpose: Activator protein-1 (AP-1) directly regulates the expressions of inflammatory cytokines and matrix-degrading matrix metalloproteinases important in rheumatoid arthritis (RA). We have previously reported that a small molecule c-Fos/AP-1 inhibitor T-5224 prevented the development of arthritis and joint destruction in mice with collagen-induced arthritis (CIA). The purpose of this study was to investigate its effect on the expression profile of cytokines and chemokines in the arthritic hind paw of mice with CIA after a single administration of T-5224.

Methods: CIA was induced in DBA/1J mice by the immunization with bovine type II collagen twice on day 0 and 21. On day 35, hind paws and serum were collected at 0, 1, 3, and 6 hours after a single oral administration of 30 mg/kg of T-5224. The tissue extracts were prepared from each paw. The amounts of 23 cytokines/chemokines in the tissue extracts and sera were measured using Bio-Plex Mouse Cytokine 23-Plex Panel or ELISA.

Results: The arthritis developed from several days after the secondary immunization, and mice showed severe arthritis on day 35. When analyzing each of hind paws with full-blown arthritis, the levels of 9 cytokines/chemokines [IL-1β, IL-3, IL-6, IL-12 (p40), G-CSF, KC/groα, MCP-1, MIP-1β, and RANTES] significantly increased compared with those in the normal paws. Especially, the amounts of IL-1β, IL-6, and KC/groα in the arthritis hind paws were approximately 40 times higher than those in normal paws. A single administration of T-5224 at the dose of 30 mg/kg significantly decreased the levels of IL-1β, IL-6, and KC/groα within several hours. Eight cytokines/chemokines including TNFα could not be determined in the paws. The significant elevations of the levels of IL-1β, IL-3, IL-6, G-CSF, KC/groα, MCP-1, and MIP-1β were also observed in the sera from the same individuals. The serum levels of IL-1β and KC/groα were significantly decreased by the treatment of T-5224.

Conclusion: T-5224 immediately reduced the levels of inflammatory cytokines and chemokines in the arthritic lesion. The results suggest that the prompt inhibitory effect of T-5224 on the overexpression of cytokines and chemokines contributes to the anti-arthritic effects in the therapy of RA.

Colony Stimulating Factor 1 Receptor Inhibition Has Anti-Inflammatory and Potent Early Onset Bone and Cartilage Protective Effects. Myew-Ling Toh[1], Jean-Yves Bonnefoy[1], Nathalie Accart[1], Sandrine Cochin[1], Christophe Zemmour[1], Helene Haegel[1], Philippe Ancian[1], Bettina Sehnert[2], Sandy Pohle[2], Falk Nimmerjahn[3], Reinhard Voll[4] and Georg Schett[2]. [1]Transgene SA, Illkirch, France, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Erlangen, Germany, [4]Freiburg, Germany

Background/Purpose: The colony stimulating factor 1 (CSF-1)/CSF-1 receptor (CSF-1R) network plays a key role in macrophage and osteoclast differentiation which are current therapeutic targets in rheumatoid arthritis (RA). We determined CSF-1R expression in human RA synovium/bone, and the efficacy of CSF-1R antagonism using a humanized anti-CSF-1R monoclonal antibody (mAb) and an anti-murine CSF-1R MAb in arthritis models.

Methods: CSF-1R immunostaining was performed with a murine anti-human CSF-1R MAb (murine CXIIG6) in RA, osteoarthritis (OA) and healthy human synovium/bone. The efficacy of a humanized anti-CSF-1R MAb (H27K15) or anti-murine CSF-1R MAb (clone AFS98) was examined in a human osteoclast differentiation assay from CD34+ bone marrow precursors (TRAP5b activity, CTX levels) *in vitro* or collagen-induced and serum transfer induced arthritis *in vivo* respectively.

Results: CSF-1R expression was increased in RA synovium/bone compared to OA or healthy controls, in predominantly lining and sublining CD68+ macrophages, TRAP+ multinucleated mature osteoclasts and a small proportion of vimentin+ RA fibroblast-like synoviocytes and CD21+ follicular dendritic cells in germinal centre-like structures. CSF-1R expression was not detected in osteoblasts, T cells, B cells or immature or mature DC. *In vitro,* H27K15 significantly inhibited osteoclast differentiation and activity. *In vivo,* an anti-murine CSF-1R MAb reduced arthritis scores and synovial inflammation within 14 days of arthritis onset, associated with rapid inhibition in serum TRAP5b activity and complete abrogation of local bone and cartilage erosion in collagen-induced arthritis. Complete abrogation of serum TRAP5b activity and local bone erosion was confirmed in serum transfer-induced arthritis.

Conclusion: CSF-1R expression was abundant in macrophages and mature osteoclasts in human RA synovium/bone, and a humanized anti-CSF-1R MAb markedly inhibited human osteoclast differentiation and activity. We demonstrate an anti-inflammatory as well as early onset potent bone and cartilage protection by a specific anti-CSF-1R MAb in murine arthritis models. This supports evidence for CSF-1R as a therapeutic target in arthritis, inflammatory bone loss and other diseases associated with osteoclastic bone damage.

Overexpression of T-Bet Gene Regulates Collagen Induced Arthritis Via IFNγ Independent Suppression of IL-6 Signal Transduction. Yuya Kondo, Masahiro Tahara, Mana Iizuka, Hiroto Tsuboi, Satoru Takahashi, Isao Matsumoto and Takayuki Sumida. University of Tsukuba, Tsukuba city, Ibaraki, Japan

Background/Purpose: Recent studies reported that IL-17 producing Th-17 cells appear to play a critical role in the generation of several autoimmune arthritis models, and that IFNγ has anti-inflammatory effect in the development of autoimmune arthritis via the suppression of Th-17 cells. However, the function of Th-1 specific master transcriptional factor T-bet in the development of arthritis is not clarified. The aim of this study is to elucidate the role of T-bet on the pathogenesis of collagen induced arthritis (CIA).

Methods:
1) T-bet transgenic (T-bet Tg) mice under the promoter of CD2 gene were generated. CIA was induced in T-bet Tg mice and wild-type C57BL/6 (B6) mice.
2) Collagen type II (CII) reactive T-bet and RORγt mRNA expression level was analyzed by real-time PCR.

3) Criss-cross experiments using $CD4^+$ T cells of B6 or T-bet Tg mice, as well as $CD11c^+$ splenic dendritic cells (DCs) of B6 or T-bet Tg mice with CII were carried out, and then IL-17 and IFNγ in the supernatants were measured by ELISA. T-bet and RORγt expression on $CD4^+$ T cells was analyzed by FACS.
4) T-bet Tg × $IFN\gamma^{-/-}$ mice were generated by crossing T-bet Tg mice and $IFN\gamma^{-/-}$ mice. $CD4^+$ T cells from B6, T-bet Tg, or T-bet Tg × $IFN\gamma^{-/-}$ mice were cultured in the condition favoring Th-17 differentiation, then cytokine production and transcription factor expression (RORγt, SOCS3, and STAT3) were analyzed by real-time PCR and FACS.
5) IL-6 receptor expression and phosphorylation of STAT3 on $CD4^+$ T cells were analyzed by FACS.

Results:

1) T-bet Tg mice did not develop collagen-induced arthritis compared with B6 mice.
2) T-bet Tg mice showed overexpression of T-bet and downregulation of RORγt in CII reactive T cells.
3) Criss-cross experiments with $CD4^+$ T cells and splenic DCs showed significant reduction in IL-17 production from CII reactive $CD4^+$ T cells in T-bet Tg mice even upon co-culture with DCs of B6.
4) FACS analyses revealed that IL-17 production and RORγt expression were inhibited under Th-17 differentiation conditions in T-bet Tg mice and T-bet Tg × $IFN\gamma^{-/-}$ mice. SOCS3 and STAT3 mRNA expression was equivalent for among these mice.
5) IL-6 receptor expression was suppressed in T-bet Tg mice and T-bet Tg × $IFN\gamma^{-/-}$ mice. Phosphorylation of STAT3 on $CD4^+$ T cells were inhibited in T-bet Tg mice and T-bet Tg x $IFN\gamma^{-/-}$ mice.

Conclusion: Overexpression of T-bet in T cells suppressed the development of autoimmune arthritis. The regulatory mechanism of arthritis might involve inhibition of CII reactive Th17 differentiation by overexpression of T-bet via IFNγ-independent suppression of IL-6 signal transduction.

Lapatinib Ameliorates Experimental Arthritis in Rats. Metin Ozgen[1], Suleyman Serdar Koca[1], Ahmet Karatas[1], Adile Ferda Dagli[2], Fazilet Erman[3], Baris Gundogdu[1], Kazim Sahin[4] and Ahmet Isik[1]. [1]Department of Rheumatology, Faculty of Medicine, Firat University, Elazig, Turkey, [2]Department of Pathology, Faculty of Medicine, Firat University, Elazig, Turkey, [3]School of Health Sciences, Firat University, Elazig, Turkey, [4]Department of Animal Nutrition, Faculty of Veterinary Science, Elazig, Turkey

Background/Purpose: Angiogenesis and synovial hyperplasia have important roles in the pathogenesis of cartilage-bone destruction in rheumatoid arthritis (RA). Members of the epidermal growth factor receptor (EGFR) family and their associated ligands are commonly expressed by synovial cells, and may be involved in the synovial hyperplasia seen in RA and its disease progression. Lapatinib is an orally available, small-molecule, reversible inhibitor of both EGFR and human EGFR-2 (HER2) tyrosine kinases. Thus, we suggested that lapatinib may have potential joint-protective properties in RA. The purpose of this study was to investigate the therapeutic effect of lapatinib on collagen-induced arthritis (CIA) in rats**.**

Methods: Thirty Wistar albino female rats were randomized to three groups (n=10 in each group): Group-I as the control group, Group-II as the arthritis group, Group-III as the lapatinib group were assigned. Arthritis was induced by intradermal injection of chicken type II collagen combined with incomplete Freund's adjuvant in Group-II and III rats. One day after the onset of arthritis, Group-III rats were given lapatinib (30 mg/kg/day) via oral gavage until they were killed on day 29.

Animals were sacrificed at the 15th day after the onset of arthritis. The trunk bloods and paws of the rats were obtained for further analysis. Tumor necrosis factor (TNF)-α, interleukin (IL)-17, malondialdehyde (MDA) levels and superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) activities in serum, and articular tissue nuclear factor erythroid 2-related factor 2 (Nrf2) and heme oxgenase-1 (HO-1) expressions, perisynovial inflammation and cartilage-bone destruction were determined in the paws.

Results: When compared with Group-I, TNF-α, IL-17, and MDA levels were increased, and SOD, CAT, GPx activities and the expressions of Nrf2 and HO-1 were decreased in Group-II (Table). Histopathological analysis demonstrated the extensive perisynovial inflammation and marked cartilage-bone destruction in Group-II rats. Lapatinib treatment decreased the levels of TNF-α, IL-17, MDA, and increased the activities of SOD, CAT, GPx and the expressions of Nrf2 and HO-1, and decreased the perisynovial inflammation and cartilage-bone destruction in the paws.

Table: Clinical and laboratory data in the study groups

	Group-I (Control) (n=10)	Group-II (Arthritis) (n=10)	Group-III (Lapatinib) (n=10)
14th day arthritis score	—	1.4 ± 0.7	1.6 ± 0.5
29th day arthritis score	—	2.4 ± 0.5	0.3 ± 0.5[e]
Inflammation score	—	4.0 ± 0.0	2.1 ± 0.7[e]
Cartilage-bone destruction score	—	3.9 ± 0.3	1.2 ± 0.4[e]
TNF-α (pg/mL)	25.6 ± 5.0	62.7 ± 12.9[b]	26.4 ± 3.3[d]
IL-17 (pg/mL)	29.5 ± 8.3	65.7 ± 8.9[b]	47.0 ± 6.5[b,d]
MDA (μmol/L)	0.58 ± 0.23	1.6 ± 0.2[b]	0.92 ± 0.13[b,d]
SOD (U/mL)	12.0 ± 7.3	3.4 ± 1.6[b]	5.4 ± 1.1[b,c]
CAT (nmol/min/mL)	0.33 ± 0.07	0.12 ± 0.08[b]	0.24 ± 0.02[a,d]
GPx (nmol/min/mL)	335 ± 179	179 ± 45[b]	307 ± 62[d]

Data were presented as mean±standard deviation. TNF: Tumor necrosis factor, IL: Interleukin, MDA: Malondialdehyde, SOD: Superoxide dismutase, CAT: Catalase, GPx: Glutathione peroxidase. vs. Control group [a] $p<0.05$, [b] $p<0.01$; vs. Arthritis group [c] $p<0.05$, [d] $p<0.01$, [e] $p<0.001$

Conclusion: Our present study is the first report to identify that lapatinib suppresses inflammatory pathways and oxidative stress, and prevents synovial hyperplasia in CIA model. Lapatinib may be an effective option for the treatment of RA.

1143

IL-33 Mediates a Mast Cell-Fibroblast Amplification Loop That Primes Mast Cells for Activation Via Immune Complexes. Shinjiro Kaieda[1], Jun-Xia Wang[1], Ruslan Shnayder[1], Richard Lee[1], Richard Stevens[1] and Peter A. Nigrovic[2]. [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Children's Hospital Boston and Harvard Medical Scool, Boston, MA

Background/Purpose: Mast cells (MCs) have been recognized as potential participants in inflammatory arthritis. Recent studies have suggested that the IL-1 family cytokine IL-33 directly activates synovial MC in murine arthritis. However, knowing that MC participation in this condition requires expression of the immune complex receptor FcγRIII, we examined the possibility that the major role of IL-33 might instead be to promote the responsiveness in MC to immune complexes.

Methods: Arthritis was initiated in mice lacking the IL-33 receptor IL1RL1, as well as wild-type (WT) littermates, via intraperitoneal administration of K/BxN mouse serum. $FcgRII^{-/-}$ and WT mouse bone marrow-derived MCs (mBMMCs) were preincubated with or without recombinant mouse IL-33 for 4 h; they were activated by plate-bound anti-FcgRII/III antibody for 16h and assayed by multiple cytokine and chemokine array as well as by specific cytokine ELISA. Co-culture of WT or IL-1RL1-deficient mBMMCs with fibroblast-like synoviocytes (FLS), a known source of IL-33, was performed in a transwell system. Transcripts for IL-6, IL-1β and IL-33 in mBMMCs and FLS during co-culture were evaluated by RT-qPCR.

Results: $IL1RL1^{-/-}$ animals exhibited less severe arthritis than WT mice. Correspondingly, histological measures of arthritis were reduced, as was tissue expression of IL-1β and IL-6. Further, we found that MC-dependent acute vascular edema was reduced in the $IL\text{-}1RL1^{-/-}$ mice, in a timecourse inconsistent with direct activation via IL-33. A multiplex array revealed that preincubation of mBMMC with recombinant mouse IL-33 amplified the FcγRIII-mediated MC release of chemokine CXCL2 and the cytokines IL-1β, IL-6 and TNF-α. IL-1β is of particular significance, since MC represent a key source of this cytokine in early synovitis, whereas CXCL2 is implicated in IL-33-mediated neutrophil recruitment. In co-culture experiments, FLS induced mBMMCs to increase their levels of transcripts for IL-6 and IL-1β, and mBMMCs induced expression of IL-33 as well as IL-6 in co-cultured FLS. This reciprocal effect on FLS required MC expression of IL1RL1, indicating the presence of an IL-33-mediated MC-FLS pro-inflammatory loop in which IL-33 from FLS elicits MC mediators that further enhance IL-33 release from FLS.

Conclusion: These findings confirm a novel role for IL-33 as an amplifier of immune complex-mediated inflammation and identify a MC-FLS amplification loop dependent on IL-33 and its receptor. We conclude that "priming" of MCs via synovial fibroblast-derived IL-33 potentiates their activation via FcγRIII.

A High Fat Diet Causes Fat Uptake by Synovial Lining Macrophages and Enhances Joint Inflammation and Cartilage Destruction During Experimental Arthritis. Peter van Lent, Wouter de Munter, Arjen Blom, Annet Sloetjes and Wim van den Berg. Rheumatology, Nijmegen, Netherlands

Background/Purpose: Earlier studies have shown that synovial lining macrophages are crucial in mediating joint inflammation and cartilage destruction during experimental arthritis (1). Oxidised LDL (ox-LDL) has been shown to activate macrophages which may enhance joint inflammation and cartilage destruction. Uptake of Ox-LDL by macrophages is clearly seen in atherosclerotic lesions of mice made deficient for the LDL receptor which were given a high fat diet. In the present study, we investigated the effect of a high fat diet in $LDLr^{-/-}$ mice on uptake of fat by synovial lining macrophages and development of joint inflammation and cartilage destruction during experimental arthritis.

Methods: $LDLr^{-/-}$ mice were given a high fat or a normal fat diet for 50 days. Autoantibody-induced arthritis was elicited by giving 0,2 ml K/BxN serum systemically twice at alternate days. Arthritis was scored macroscopically using an arbitrary score and histologically using sections of forepaws. Sections were stained with Haematoxylin/eosin, Safranin-O or red oil. Cartilage destruction was measured as either proteoglycan depletion, cartilage matrix erosion and chondrocyte death. MMP mediated neoepitopes were determined using immunolocalisation and VDIPEN antibodies. Bone marrow derived macrophages were stimulated by oxidized LDL and expression of chemokines was determined using RT-PCR. Protein levels of cytokines was measured using Luminex.

Results: Induction of K/BxN arthritis in $LDLr^{-/-}$ mice given a high fat diet for 50 days showed a higher joint inflammation in the wrist of the fore-paws when compared to $LDLr^{-/-}$ which received a normal diet. At days 2, 5 and 12, the macroscopic score was 171%, 46% and 63% higher respectively. Cryostate sections of total knee joints stained with red oil showed strong accumulation of fat within the lining macrophages which was much lower in the $LDLr^{-/-}$ fed with a normal diet. Histology of forepaws taken at day 12 after arthritis induction showed significantly higher amounts of mainly PMN as seen after immunostaining with NIMPR14 antibody. When bone-marrow macrophages were stimulated with Ox-LDL for 24 hours, protein levels of PMN attracting chemokine KC was significantly higher whereas that of macrophage attracting chemokine MCP-1 was comparable to the production by control macrophages. Serum levels of triglyceride, cholesterol and IL-6 were significantly higher in high fat treated $LDLr^{-/-}$ mice when compared to $LDLr^{-/-}$ mice fed with a normal diet whereas levels of IL-1β and TNFα were undetectable. Cartilage destruction measured in four different distal carpals of the wrist was significantly higher in the fat-rich treated group when compared to the normal diet group. Proteoglycan depletion, erosion of the cartilage matrix and chondrocyte death were respectively 65%, 333% and 283% higher. In line with that a significantly higher VDIPEN expression was observed in the cartilage layers of the high fat diet group.

Conclusion: $LDLr^{-/-}$ mice given a high fat diet accumulate fat within synovial lining macrophages and exhibit enhanced joint inflammation and cartilage destruction during experimental arthritis.

Inhibition of Murine Collagen-Induced Arthritis by Overexpression of Glucocorticoid-Induced Leucine Zipper Locally in the Joints Using a Gene Therapy Approach. Devi Ngo[1], Elaine Beaulieu[1], Scott Loiler[2], Margriet Vervoordeldonk[3] and Eric Morand[1]. [1]Monash University, Melbourne, Australia, [2]Arthrogen B.V, Amsterdan, Netherlands, [3]Arthrogen B.V, AMC/University of Amsterdam, Amsterdan, Netherlands

Background/Purpose: Glucocorticoid-induced leucine zipper (GILZ) is an intracellular protein expressed in T cells, macrophages, synovial fibroblasts and endothelial cells, which inhibits NFkB- and ERK-dependent signaling. We previously have shown that silencing endogenous GILZ exacerbates murine collagen-induced arthritis (CIA) (Beaulieu et al, Arthritis Rheum 2010). Here, we investigated the therapeutic potential of exogenous GILZ in inflammatory arthritis, and the function of endogenous GILZ in adaptive and innate immune responses.

Methods: To study the therapeutic effect of GILZ in established arthritis, CIA was induced in DBA/1 mice. After onset of disease (day 27), recombinant adeno-associated virus-5 (rAAV5) expressing the gene for murine GILZ was injected in both knee and ankle joints ($3.85\times10\hat{}13$ vg/ml), and the therapeutic effect observed over 15 days. The activity of rAAV5-GILZ against NF-kB was studied in a human microvascular endothelial cell line. $GILZ^{-/-}$ mice were generated on a C57BL/6 background by targeting the canonical mouse GILZ isoform. Adaptive immune responses in $GILZ^{+/+}$ and $GILZ^{-/-}$ mice were studied in response to injection of chicken type II collagen (CCII)/CFA at the base of the tail on day 0 and 21. Innate immune responses mice were studied by measuring serum cytokines induced by intra-peritoneal injection of LPS (10mg/kg).

Results: In established CIA in DBA/1 mice, intra-articular rAAV5-GILZ injection resulted in significant decrease of clinical disease severity ($P<0.05$), associated with a significant increase in joint GILZ mRNA expression. TNF-induced NF-kB luciferase activity in vitro was significantly inhibited by rAAV5-GILZ. Adaptive immune responses, as evidenced by CII-induced proliferation of T cells from immunized mice, were significantly increased in $GILZ^{-/-}$ mice ($P<0.01$). No significant clinical arthritis or anti-CII antibodies were induced in $GILZ^{+/+}$ C57BL/6 mice, and GILZ deficiency did not result in increased arthritis susceptibility or anti-CII antibodies in this strain. GILZ expression was low in $GILZ^{+/+}$ mice in the setting of LPS administration, and LPS-induced serum IL-1, IL-6 and TNF concentrations were unaffected by GILZ deficiency.

Conclusion: These results suggest that intra-articular GILZ overexpression can inhibit established arthritis. Endogenous GILZ inhibits T cell responses to CII, but no effect of GILZ-deficiency on LPS-induced cytokines was observed. These findings provide proof of concept for the therapeutic potential of a GILZ-based therapy in arthritis, but suggest further investigation of the mechanism of action of GILZ is required.

Inhibiting IL-6 *Trans*-Signalling with Soluble gp130Fc Potently Reduces the Incidence and Severity of Collagen-Induced Experimental Arthritis. Shaun Smale[1], Sara Carty[1], Rhian Goodfellow[1], Ernest Choy[1], Stefan Rose-John[2], Simon Jones[3] and Anwen S. Williams[4]. [1]Cardiff University, Cardiff, ENGLAND, United Kingdom, [2]Christian Albrechts University, Kiel, Germany, [3]Cardiff University, Cardiff, Wales, [4]Cardiff University, Cardiff, United Kingdom

Background/Purpose: Cytohistomorphological analysis of the synovial joint provides researchers with an opportunity to unmask specific intra- and extra- cellular mechanisms that regulate the switch from acute to chronic pathology in arthritis. The signal transducer and activator of transcription (STAT) pathway orchestrates this transition and steers the effector functions of interleukin-6 (IL-6) within the inflamed joint. We used a pertinent inflammatory arthritis model, murine collagen-induced arthritis (mCIA), to define the timecourse of STAT3 expression within the inflamed joint and to test the potency of timely targeted therapy with an inhibitor of IL-6 *trans*-signalling (sgp130Fc).

Methods: Joint tissues were collected (pre and post arthritis) over the timecourse of mCIA. IL-6, soluble IL-6 receptor (sIL-6R) and STAT3 were measured in joint tissue homogenates by ELISA. To test sgp130Fc's efficacy, 2.5mg/Kg was injected daily. Control mice received either etanercept (2.5mg/Kg daily) or vehicle; they were administered using an identical dosing regimen. Arthritis severity was gauged macroscopically in each paw; the sum of scores provided a clinical arthritis index (CAI) for each mouse. Therapeutic outcome was determined microscopically in serial histological sections taken from joint tissue specimens at end point.

Results: In early mCIA, joint tissue homogenates recorded significant increases in IL-6 ($P<0.01$), sIL-6R ($P<0.05$) and STAT3 ($P<0.05$) levels; they coincided with arthritis onset. sgp130Fc treatment was therefore initiated at arthritis onset. sgp130Fc and etanercept delayed mCIA onset, after 5 doses arthritis incidence was 0% (sgp130Fc) versus 17% (etanercept) and 83% (vehicle). At endpoint (day 7 therapy) all mice had arthritis; CAI ($P<0.05$) and paw diameters ($P<0.05$) were significantly reduced in sgp130Fc and etanercept compared with vehicle controls. Histological damage was less severe in the etanercept group versus vehicle controls, but not statistically significantly different. All histological parameters were significantly lower in sgp130Fc vs vehicle controls (synovial hyperplasia ($P<0.01$), synovial tissue infiltrate ($P<0.01$)). Cytomorphometric analysis revealed that synovial $Ly\text{-}6G^{+}$-neutrophils ($P<0.05$), $F4/80^{+}$-macrophages ($P<0.01$) and $CD3^{+}$-T-cells ($P<0.01$) counts were also significantly lower in sgp130Fc vs. vehicle controls. Tissue protective functionality of sgp130Fc was highlighted further by the absence of lymphoid aggregates, diminutive tartrate resistant acid

phosphatase staining for osteoclasts and significantly less bone erosions ($P<0.05$) compared with vehicle controls. At the dosing regimen under investigation, electrophoretic mobility shift assays revealed that sgp130Fc lowered the level of nuclear factor-kappa B (NFkB) and STAT activation (predominantly STAT3) in joint tissues at endpoint whilst etanercept caused a partial reduction in NFkB.

Conclusion: Timely targeted inhibition of IL-6 *trans*-signalling with sgp130Fc potently reduces clinical disease severity in an experimental model of arthritis. Selective blockade of IL-6 *trans*-signalling could have therapeutic applicability in the management of rheumatoid arthritis.

Safety and Biodistribution of An Adeno-Associated Virus Vector, AAV5 hIFN beta (ART-I02), Delivered Via Intra-Articular Injection to Rhesus Monkeys with Collagen-Induced Arthritis. Caroline J. Aalbers[1], L. Bevaart[1], K. de Cortie[1], M.P.M. Vierboom[2], J.F. Wright[3], Paul P. Tak[4] and Margriet Vervoordeldonk[5]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Biomedical Primate Research Centre, Rijswijk, Netherlands, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam The Netherlands, Amsterdam, Netherlands, [5]Arthrogen B.V, Amsterdan, Netherlands

Background/Purpose: Recombinant AAV5.NFkB.hIFNβ (ART-I02) is an adeno-associated type 5 (rAAV5) vector expressing the human interferon β (hIFNβ) gene under control of an inflammation-inducible promoter, which is under development for the treatment of rheumatoid arthritis (RA). We investigated biodistribution and initial safety of the vector after intra-articular (ia) injection of the gene construct in rhesus monkeys with collagen-induced arthritis.

Methods: Mild arthritis was induced in 3 male and 3 female monkeys with chicken type II collagen (ChCII, 3 mg). All monkeys were naïve or showed limited (1:3.1–1:10) neutralizing antibody (Nab) titers to AAV5 at the start of the study. All animals were treated with a single dose of ART-I02 ia in the first involved PIP joint and in the ipsilateral knee and ankle joint (0.1, 0.5 and 1×10e13 vector genomes (vg), respectively). Clinical signs and symptoms were monitored for a maximum of 4 weeks until the human end-point in the study was reached. Serum, joints and organs were collected for histological analysis. Serum was analyzed for acute phase response (CRP, IL-6 levels) and Nab. Presence of ART-I02 vector genomes in 16 tissues was analyzed using qPCR. Expression of hIFNβ was analyzed in serum and knee synovial tissue (ST) samples by ELISA. Histological evaluation by an experienced pathologist was performed on all organs collected to evaluate potential toxicity induced by the vector.

Results: No adverse events were observed after ia injection of a high dose of ART-I02. All animals experienced a mild acute phase response (CRP > 50 mg/L-500 mg/L) with simultaneous rising of IL-6 levels and the production of anti-ChCII IgG antibodies, as expected in this model, associated with the development of mild arthritis. High titers of Nab to rAAV5 were observed (between 1:3.160 and 1:100.000) at the end of the study. Vector DNA was detected in ST of the injected knee joint and the popliteal (draining) lymph node (injected side) at the highest copy numbers. In 1 out of 3 animals one ovary tested positive for the vector DNA (100 copies/ug DNA). Importantly, no vector DNA was detected in testes (3/3) or brain (6/6). No abnormalities were observed after histological evaluation of all organs. In knee ST samples minimal expression of hIFNβ was observed due to low arthritis activity in the knee joints, preventing activation of the NFkB promoter in the vector. In serum no hIFNβ protein could be detected.

Conclusion: Intra-articular injection of a high dose of ART-I02 is well-tolerated and does not induce adverse events in the monkey collagen-induced arthritis model of RA. This study represents an important next step towards a phase I clinical trial in RA patients.

1148

Anti-IL17 and Etanercept Display An Overlapping Gene Profile for Inflammation and Osteoclastogenesis in Mice with Collagen-Induced Arthritis. Daigen Xu[1], Yong Kim[1], Kai-Yeung Lau[2], Mario Giron[2], Palanikumar Ravindran[2], Holly Hilton[2], Hans Bitter[2], Catherine Tribouley[2], Deborah Cockayne[1] and Jay S. Fine[1]. [1]Inflammation Discovery, Hoffmann-La Roche, Nutley, NJ, [2]Translational Research Sciences, Hoffman-La Roche, Nutley, NJ

Background/Purpose: Anti-TNFa and anti-IL-17 treatment are beneficial to patients with rheumatoid arthritis (RA). Both agents produce efficacy by suppressing chronic inflammation and joint destruction. To explore the mechanisms underlying these effects, we assessed the impact of an anti-IL17 (aIL17) and the TNFa blocker Etanercept on global gene expression in a mouse model of collagen-induced arthritis (CIA).

Methods: CIA was induced in adult male DBA1/J mice by 2 immunizations with bovine type II antigen. Upon the 2nd immunization (day 21), test agent (aIL17 or Etanercept), vehicle (PBS) or isotype control (rat IgG) was injected ip (10 mg/ml) every 48 hours. At the end of the study (day 35), both hind paws were collected for mRNA extraction and Affymetrix array (Mouse 430 2.0). Genes upregulated by ≥2 fold were assigned to different pathways based on their known functions. Effects of disease and drug treatment on gene expression were determined by comparing CIA (isotype) mice respectively with naive and test agent-treated CIA animals. % inhibition=100-($F_{treatment}$-1)/($F_{isotype}$ −1)*100, where F is fold/ naïve.

Results: Among 14340 genes, 458 were increased by ≥2 fold in isotype-treated CIA mice over naïve animals. Genes with the greatest degree of induction belong to pro-inflammatory cytokines/chemokines, neutrophil granule proteins, MMPs or acute phase proteins. Clusters of multiple genes critical for osteoclastogenesis, Wnt signaling, Adam/Adamts activities, monocyte/macrophage or eosinophil functions were also significantly upregulated, albeit to a lesser extent. Treatment with aIL7 or Etanercept inhibited the expression of highly induced pro-inflammatory genes (>5 fold, IL-6, IL-1b, CXCL1, 2, 3, 5, COX-2, Saa3), and that of genes implicated in joint destruction, including osteoclastogenesis (RANKL, cathepsin K, Atp6v0d2 and TRAP5, Oscar, Tm7sf4 and Ibsp), Wtn (Cthrc1, Rspo2, Sfrp2, Sai1, Wisp1 and Wisp2) and matrix metalloproteases (Adam8 and12, Adamts1, 3, 4, 9 and 12, MMP3, 8, 9 and 13) by ~80%.

By comparison, both agents displayed a smaller suppressive effect on the expression of markers for monocytes/macrophages (Chi3L3, Csf1r, Emr1 and Msr1; 50% for Etanercept vs. ~60% for aIL17) and neutrophils (Ngp, Camp, Elane, Lcn2, Prtn3, Mpo, Ltf, S100a8, S100a9, CD177; 19% for Etanercept vs. ~50% for aIL17). Moreover, neither agent inhibited the up-regulation of immunoproteasome subunits (Psmb8, 9 and 10) or eosinophil markers (Ear1, Epx, Prg2 and 3). Instead, Etanercept increased the expression of eosinophil markers by an average of ~30%.

Conclusion: Together, our data demonstrate that both Etanercept and aIL17 produced their anti-inflammatory and joint protective effects by suppressing the expression of pro-inflammatory genes (cytokines, chemokines and prostaglandins), as well as genes critical for osteoclastogenesis, Wnt signaling and extracellular matrix degradation. The data further show that these therapies are not as effective at eliminating effector inflammatory cells, which may cause sustained inflammation and prevent remission. Therefore, targeting these cells for removal may represent a useful strategy for treating RA.

1149

Importance of the Chymase-Family Member Mouse Mast Cell Protease-5 in Inflammatory Arthritis. Richard Stevens[1], H. Patrick McNeil[2], Kichul Shin[3] and David M. Lee[4]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]University of New South Wales, Sydney, Australia, [3]Seoul National University Hospital, Seoul, South Korea, [4]Brigham and Womens Hospital, Boston, MA

Background/Purpose: Human mast cells (MCs) contain large amounts of hTryptase-β and hChymase-1 bound to heparin proteoglycans. The ortholog of hTryptase-β is mouse MC protease (mMCP) −6. Mouse MCs express many chymase-like proteases but the amino acid sequence of mMCP-5 is most similar to that of hChymase-1. Although the MCs in the synovium of arthritic C57BL/6 mice store substantial amounts of mMCP-5- and mMCP-6-heparin complexes in their granules, the biologic significance of the coordinate expression of these two serine proteases and their preferred recognition of heparin has not been deduced. Targeted inactivation of the gene that encodes N-deacetylase N-sulfotransferase-2 results in the biosynthesis of undersulfated heparin which leads to diminished granule accumulation of mMCP-5, mMCP-6, and other neutral proteases. Experimental arthritis is markedly reduced in MC-deficient *W/W^v* mice, and the adoptive transfer of Kit^+/mMCP-5^+/mMCP-6^+ MCs into these Kit-defective animals restores arthritis when the mice are then given K/BxN mouse serum. Although arthritis is also reduced in mMCP-6-null C57BL/6 mice, inflammation and joint destruction are more pronounced in heparin-deficient mice than in the tryptase-deficient animals. These data raised the possibility that a second protease exocytosed from activated MCs bound to heparin contributes to experimental arthritis. The purpose of this study was to identify that neutral protease.

Methods: Using a homologous recombination approach, an mMCP-5-

null C57BL/6 mouse was created that was then backcrossed ten times with wild-type (WT) C57BL/6 mice. The resulting mMCP-5-null mice were characterized, and then subjected to the K/BxN mouse serum-transfer and methylated albumin/interleukin-1β arthritis models.

Results: mMCP-5-null C57BL/6 mice were healthy, and contained normal numbers of MCs in their tissues. However, these MCs were less granulated than the corresponding MCs in WT mice due to their mMCP-5 deficiency. mMCP-5 and mMCP-6 are functionally distinct in all disease models that have been evaluated so far. For example, mMCP-6 is more important in chemical-induced colitis and in bacterial and helminth infections, whereas mMCP-5 is more important in ischemia-reperfusion and burn injury. Because mMCP-6 participates in inflammatory arthritis, we anticipated that extensive arthritis would develop in mMCP-5-null mice as occurs in WT mice. Surprisingly, we discovered that arthritis was much less severe in mMCP-5-null mice than in WT mice, whether the mice had been given K/BxN mouse serum or methylated albumin and IL-1β. These data suggest that mMCP-5 and mMCP-6 work together to control the magnitude of MC-dependent inflammatory arthritis in mice.

Conclusion: The finding that arthritis is reduced in both mMCP-5- and mMCP-6-null mice suggests that these unrelated serine proteases are coordinately expressed in MCs so that they sometimes can act in synergy in normal and disease processes. In terms of the human relevance of our mouse data, it is likely that an anti-protease approach will be more effective in treating patients with rheumatoid arthritis if inhibitors are used that inactivate both hChymase-1 and hTryptase-β.

Deficiency of the Wnt-Inhibitor Sclerostin Promotes Inflammatory Joint Destruction in the Human Tumor Necrosis Factor Alpha Transgenic Mouse Model of Rheumatoid Arthritis. Corinna Wehmeyer[1], Christina Wunrau[1], Athanasios Stratis[1], Ina Kramer[2], Michaela Kneissel[2], George Kollias[3], Thomas Pap[1] and Berno Dankbar[1]. [1]University Hospital Muenster, Muenster, Germany, [2]Basel, Switzerland, [3]Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece

Background/Purpose: Progressive joint destruction is a hallmark of rheumatoid arthritis (RA) and results from increased bone resorption and the lack of repair mechanisms. TNFalpha contributes to both aspects of pathologic joint remodelling by increasing the number of bone-resorbing osteoclasts and decreasing the number of bone-forming osteoblasts. The Wnt-inhibitor sclerostin inhibits osteoblast differentiation by antagonizing the Wnt/beta-catenin signalling pathway. Since it has been shown that sclerostin is upregulated in response to TNFalpha, we studied its expression under inflammatory conditions in human RA and in hTNFtg mice, which develop an RA-like destructive arthritis. Moreover, we analyzed the effects of sclerostin deficiency on the development and severity of arthritis in these mice.

Methods: Sclerostin expression was assed by immunohistochemistry, western-blot-analysis, and RT-PCR. Sclerostin knockout ($SOST^{-/-}$) mice were crossed with hTNFtg mice to determine the functional role of sclerostin *in vivo*. The assessment of the clinical severity of disease in $SOST^{-/-}$/hTNFtg and hTNFtg mice, bone erosion, cartilage destruction and inflammation were evaluated by histomorphometric, x-ray and micro-CT analysis. TRAP staining was used to quantify the number of osteoclasts. DKK-1 expression was analyzed by immunohistochemistry and western-blot-analysis.

Results: Immunohistochemistry and western-blot-analysis revealed an increased sclerostin expression in synovial tissues of RA compared to OA patients. Ankle joints of hTNFtg mice showed high levels of sclerostin, especially in the infiltrating pannus, whereas only negligible staining was observed in wildtype animals. *In vitro*, expression of sclerostin was only found in osteoblasts, osteoclasts and hTNFtg synovial fibroblasts but could be induced in human RA synovial fibroblasts by TNFalpha. Surprisingly, knockout of sclerostin did not improve the clinical severity of arthritis in hTNFtg mice but most dramatically accelerated joint damage in this mouse model of RA. $SOST^{-/-}$/hTNFtg mice displayed significant higher bone erosion, synovial hyperplasia and osteoclast numbers compared to hTNFtg mice. Moreover, immunohistochemistry revealed higher levels of DKK-1 in joints of SOST-deficient hTNFtg mice.

Conclusion: We hypothesise that under inflammatory conditions, higher levels of DKK-1 in joints of sclerostin-deficient arthritic mice counteract the beneficial effect of sclerostin deficiency by increasing osteoclast development through enhanced blockade of the Wnt/beta-catenin signalling pathway by DKK-1. These results may have an impact on the use of blocking sclerostin antibodies in inflammatory joint diseases.

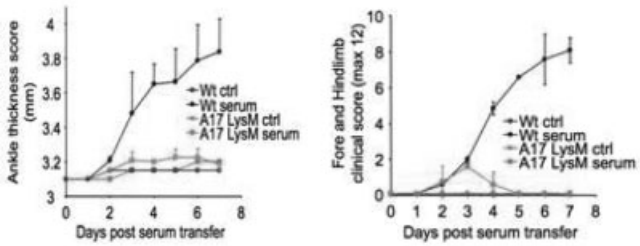
Deficiency of TACE in Myeloid Cells Prevents Arthritis in Mice. Priya Issuree[1], Thorsten Maretzky[2], Kei Horiuchi[3], Jane E. Salmon[4] and Carl Blobel[5]. [1]Weill Cornell Graduate School of Medical Sciences, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [4]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [5]Weill Cornell Medical College, Hospital for Special Surgery, New York, NY

Background/Purpose: The role of TNF-α in RA has been underscored by the success of anti-TNF-a therapies in the clinic. TNF-α is first synthesized as a homotrimeric 26-kDa membrane-bound protein and is proteolytic cleaved by the TNF-α-converting enzyme (TACE), also known as ADAM17, into an active 17-kDa soluble form. Small molecules that inhibit TACE and thus release of soluble TNF-α might provide an alternate approach to existing therapies. Since neutrophils and monocytes are the predominant cell types involved in the pathogenesis of the disease in patients as well as in various mice model of arthritis, such as the K/BxN passive serum transfer and the collagen antibody-induced arthritis, we investigated the benefit of inhibiting TACE in myeloid cells in the K/BxN passive serum transfer arthritis mouse model.

Methods: To generate mice lacking *Adam17* in myeloid cells, *Adam17flox/flox* mice were mated with *LysM-Cre* transgenic mice. *Adam17flox/flox/LysM-Cre* mice were maintained on a mixed genetic background (129Sv/C57BL6). K/BxN mouse serum was collected from 8-week-old K/BxN mice and pooled for each experiment. Arthritis was induced by intraperitoneal injection of 150 μl serum per mouse on day 0 and day 2. Ankle thickness was measured with a J15 micrometer (Blet) and inflammation was scored using a standard protocol.

Results: See Graph.



Conclusion: Inhibiting TACE in myeloid cells confers protection in K/BxN serum transfer arthritis and confirms the importance of myeloid cells in the effector phase of the disease. Furthermore, our data shows that myeloid cells are an importance source of TNF-α release and that inhibiting TACE on these cells may be an effective approach to limit TNF-α-driven joint damage.

Cell Penetrating Recombinant Foxp3 Protein Enhances Treg Function, Suppresses Th17 Cells and Ameliorate Arthritis. Kentaro Yomogida[1], Yong Zhu[2], Shili Wu[2] and Cong-Qiu Chu[3]. [1]Oregon Health & Science University, Portland, OR, [2]VivoScript, Inc, Costa Mesa, CA, [3]Oregon Health & Science Univ, Portland, OR

Background/Purpose: Foxp3 is the key transcription factor for T regulatory (Treg) cell differentiation and function. Deficiency in Foxp3 results in severe autoimmune inflammation. Foxp3 induces itself expression in Treg cells and negatively regulates Th17 cell differentiation by repressing RORγt. SKG mice have impaired Treg function and develop chronic arthritis closely resembling human rheumatoid arthritis. Arthritis in SKG mice is dependent on Th17 cells. This study aimed to test the therapeutic potential of cell penetrating recombinant Foxp3 protein in treating arthritis.

Methods: Recombinant Foxp3 protein was fused to a cell penetrating polyarginine (11R) tag to facilitate intracellular transduction. Arthritis was induced in SKG mice by intraperitoneal (i.p.) injection of 2 mg zymosan. Foxp3–11R was injected i.p. daily one week after arthritis induction and continued for seven days. Severity of arthritis was assessed by using a score system and followed up for 8 weeks. Treg function was assessed by inhibition of CD4+ T effector cell proliferation using CFSE dilution assay. Th1 and Th17 cells in lymph nodes and spleens from mice treated with Foxp3–11R were detected by intracellular cytokine staining.

Results: In vitro Foxp3–11R treated CD4+ cells showed a 50% increase in suppressive function compared with control protein treated cells. Severity of arthritis in Foxp3–11R treated SKG mice was reduced compared with those treated with a control protein (see Table 1). CD4+ T cells of lymph nodes and spleen from Foxp3–11R treated mice showed increased levels of Foxp3 expression compared with those of control protein treated with mean fluorescence intensity 38 ± 3 vs 30 ± 4 in draining lymph nodes and 40 ± 2 vs 30 ± 5 in the spleen ($p<0.05$). The number of IL-17 producing CD4+ T cells in the spleen was decreased in Foxp3–11R treated mice with 1.3% vs 2.5% in control protein treated. However, the number of IFN-γ producing cells was similar between Foxp3–11R and control protein treated groups.

Table 1. Arthritis score in SKG mice treated with Foxo3–11R or a control protein.

Week after arthritis induction	4	6	8
Foxp3 treated (n=5)	1.36 ± 0.93	1.08 ± 0.72	1.84 ± 1.90
Control (n=6)	1.47 ± 0.76	3.13 ± 2.95	4.18 ± 3.21
p	0.78	0.02	0.33

Conclusion: These results demonstrate that Foxp3–11R can enhance T cell suppressive function, suppress Th17 cells and ameliorate experimental arthritis. The data suggest that cell penetrating recombinant Foxp3 is a potentially useful agent in therapy of arthritis.

1153

Macrophage-Specific SHIP-1 Depletion Leads to Greatly Enhanced Arthritis. Shawn M. Rose and Harris R. Perlman. Northwestern University, Chicago, IL

Background/Purpose: Macrophages are critical effectors of innate immunity, as they are involved in the detection, response, and resolution phases of inflammation. The Src homology 2-domain-containing inositol-5'-phosphatase (SHIP-1) is an important negative regulator of the phosphatidylinositol 3-kinase (PI3K) pathway, and hence acts as a molecular rheostat to keep inflammation in check. Mice with a systemic deficiency of SHIP-1 demonstrate autoimmunity characterized by increased production of auto-antibodies, hematologic abnormalities, and lung and kidney disease. It has been reported that macrophages in SHIP-1-deficient mice are skewed toward the alternative M2 phenotype, which results from the exogenous effects of basophils in these animals *in vivo*. It is unknown whether macrophage-intrinsic properties contribute to this phenotype. We have exploited the Cre-LoxP system to generate animals with a macrophage-specific deletion of SHIP-1. To test whether M1 macrophage inflammatory activity occurs in these mice *in vivo*, we utilized the serum transfer induced arthritis model.

Materials & Methods: 8 week-old B6.SHIPflox x LyzCre and B6.SHIPflox control mice were injected intraperitoneally with K/BxN serum. Arthritis severity was assessed every other day for 2–3 weeks using measurements of joint width (mm) and a clinical inflammation index (0–3 scale, 4 paws). After euthanasia, ankle joints were harvested from the animals, fixed in paraformaldehyde, decalcified, processed for immunohistochemistry, and stained with Hematoxylin & Eosin.

Results: Both measures of arthritis were significantly greater in B6.SHIPflox x LyzCre compared to B6.SHIPflox control mice. Remarkably, joint inflammation did not resolve in B6.SHIPflox x LyzCre animals even out to 3 weeks. Pathologic analysis of ankle joint specimens confirmed more severe inflammatory infiltrates in B6.SHIPflox x LyzCre mice compared to B6.SHIPflox controls.

Conclusion: Our findings suggest that B6.SHIPflox x LyzCre mice develop very severe joint inflammation in the serum transfer induced model of arthritis. Hence, there may be an intrinsic M1 macrophage component in SHIP-1-deficient mice, although effects of the loss of SHIP-1 on neutrophils in this model cannot be excluded. Studies on the mechanism of arthritic inflammation in these animals are forthcoming.

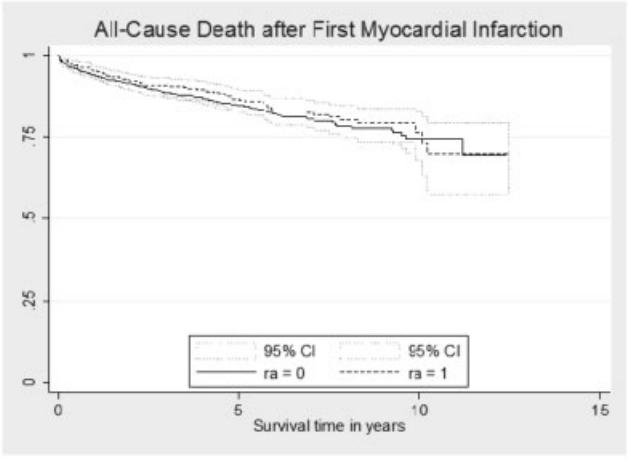
1154

Treatment and Mortality After Myocardial Infarction in Rheumatoid Arthritis—a Cohort Study of Incident Rhematoid Arthritis in Sweden. Marie Holmqvist[1], ängla Mantel[1], Tomas Jernberg[2], Lennart TH Jacobsson[3], Lars Alfredsson[4], Stefan James[5] and Johan Askling[1]. [1]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Solna, Sweden, [2]Department of medicine, Section of Cardiology, Karolinska University Hospital, Huddinge, Sweden, [3]Section of Rheumatology, Malmo, Sweden, [4]Institute of Environmental Medicine, Karolinska Institutet, Solna, Sweden, [5]Department of Cardiology, Uppsala University Hospital

Background/Purpose: To investigate whether RA-patients are at increased risk of dying after an MI and whether level of care and treatment intensity differs between RA-patients and general population comparators after an event.

Methods: RA-patients included in the Swedish Rheumatology Quality Register (SRQ) between 1 Jan 1995 and 1 Jan 2007 who had a symptom duration ≤12months when included and were free from ischemic heart disease prior to inclusion were matched on sex, calendar period, county, and age to an ischemic heart disease free general population comparator. 6,735 RA-patients and 33,692 general population comparators were identified. An index date was assigned to all individuals; date of inclusion in SRQ in RA and corresponding in comparators. Information on all first time hospitalizations for MI and on all who for the first time were treated in intensive coronary care units (ICCU) after index date was retrieved from Swedeheart, a nationwide register of all ICCU care given in Sweden, and the Swedish Inpatient register. Information on deaths was retrieved from the census register. To compare the risk of death after event, Cox models were constructed using time since event as time scale, adjusted for age and sex. Survival curves were fitted using the product limit estimator.

Results: 70% of the RA-patients and comparators were women. Mean age at index date was 57 in RA and comparators. 8% of RA-patients and 6.6% of the comparators were hospitalized with an MI after index date. 41% of RA-patients and 31% of the comparators hospitalized with an MI were treated in an ICCU. Of those hospitalized in an ICCU, there was no difference in the proportion of RA-patients and comparators undergoing coronary bypass surgery or percutaneous coronary interventions. The proportion of individuals prescribed with beta-blocking agents (85%), statins (66%), and nitrates (17 vs 21%) at discharge was similar in the two groups. Oral anticoagulants and antiplatelet medications were somewhat more common in RA-patients at discharge (56.5% vs 49.8%, p non-significant). 63.5% of RA-patients and 65.7% of comparators were assigned followup in a cardiology or internal medicine department. Overall survival after being hospitalized with an MI was similar in RA-patients and comparators (fig 1), RR 1.0 (95% CI 0.7, 1.3). 28-day survival and 1-year survival was also similar in the two groups.



Conclusion: In Sweden, patients with early RA who suffer an MI are as well treated and as likely to survive as the general population.

1155

Diastolic Heart Failure in Rheumatoid Arthritis Correlates with Reduction in Global Longitudinal Strain and Occurs Independent From Therapy with Tumor Necrosis Factor Inhibitors. A Study with Tissue Doppler, Strain Imaging, and NTproBNP Measurement. Demian A. Ridjab[1], Michael Gottwald[2], Andreas Krause[3], Thomas Schau[1], Christian Butter[1] and Michael Zaenker[2]. [1]Cardiology Dept., Immanuel Klinikum Bernau Heart Center Brandenburg, Bernau, Germany, [2]Immanuel Klinikum Bernau, Rheumatology Center North Brandenburg, Bernau, Germany, [3]Immanuel Krankenhaus Berlin-Buch, Berlin, Germany

Background/Purpose: Risk of heart failure is increased in patients with rheumatoid arthritis (RA) and is more likely to occur in RA patients with a preserved ejection fraction. It has been postulated that fibrosis plays an important role in the structural changes in the heart of patients with RA. Until now little is known about the prevalence of diastolic heart failure and its related structural changes. Therefore we examined RA patients with and without anti-TNFa therapy for diastolic heart failure using measurement of NT-pro-BNP level and echocardiography, including tissue doppler and strain imaging.

Methods: In a prospective consecutive study 74 patients from our outpatient clinic with RA according to ACR-Criteria treated with (n = 38) or without (n = 36) anti-TNFa-therapy were included. The cohort underwent blood sampling for NT-pro-BNP and echocardiography with assessment of left ventricular end-diastolic (LVEDV), end-systolic volume (LVESV), septal thickness, LV ejection fraction, LV diastolic function and global longitudinal strain with speckle-tracking. Diastolic heart failure was diagnosed when (1) E/E'-ratio > 15 or (2) NT-pro-BNP > 220 pg/ml with E/E'-ratio > 8 or in presence of atrial fibrillation.

Results: Sixty-six percent of the patients (n=49/74) were female. Mean age was 59.8 ± 13 years. RA activity score DAS28 showed a mean of 2.8 (± 0.9) with 32 % of patients in remission (DAS28 ≤ 2.6). Function score FFbH showed a mean of 66% (± 25). Mean BMI was 29.0 ± 4.7 kg/m^2. Twenty-three percent of the patients had hypertension (mean blood pressure 130.9 / 79.5 mmHg (± 19.9 /8.1). LV hypertrophy was found in 78 %, with mean septal thickness of 10.8 ± 1.4 mm. The following mean values were present: heart rate 81 ± 13 bpm, GLS –18.7 ± 2.8%, LVEDV and LVESV 70.7 ± 23.2 and 23.9 ± 9.7 ml, reps., LV ejection fraction 67.5 ± 6.4, E/A-ratio 1.03 ± 0.42, E/E'-ratio 8.37 ± 3.02. Only five percent of patients had relevant valvular disease (n=3 tricuspidal regurgitation II°, n=1 moderate aortic stenosis). According to the above mentioned criteria diastolic heart failure was diagnosed in 31 % of patients. Using a GLS value of −19% as a cut off, patients with diastolic heart failure showed a significant reduction in GLS in comparison to those with normal diastolic function (p = 0.02, OR 3.2 (95% CI:1.04–10.3)). There were no significant differences in LVEDV, LVESV, E/A-ratio, E/E′-ratio, NT-BNP, and mean GLS between groups, when anti-TNFa-therapy was considered.

Conclusion: In the studied RA cohort, there is a surprisingly high rate of diastolic heart failure (31 %) with preserved ejection fraction independent from concomitant anti-TNFa therapy. Imaging data revealed a significant reduction in the global longitudinal strain in patients with diastolic heart failure. This finding suggests the role of fibrotic changes in diastolic heart failure in RA. The endocardium is most susceptible to the deleterious effects of interstitial fibroris and GLS measurements detect abnormal longitudinal function of the subendocardial level at an earlier stage. We therefore suggest the use of global longitudinal strain measurement in addition to conventional echocardiography in diastolic heart failure.

1156

Progression of Subclinical Atherosclerosis Over Five Years in Patients with Early Rheumatoid Arthritis. Anna Södergren[1], Kjell Karp[2], Kurt Boman[3], Catharina Eriksson[4], Elisabeth Lundström[2], Torgny Smedby[5], Bozen Möller[6], Solbritt Rantapää Dahlqvist[1] and Solveig Wållberg Jonsson[1]. [1]Dept of Rheumatology, Umeå, Sweden, [2]Department of Surgical and Perioperative Sciences, Umeå, Sweden, [3]Department of Medicine, Skellefteå, Sweden, [4]Department of Clinical Immunology, Umeå, Sweden, [5]Östersunds Rehab Centrum, Östersund, Sweden, [6]Department of Rheumatology, Luleå, Sweden

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased mortality and morbidity due to cardiovascular disease (CVD). A premature atherosclerosis as measured by ultrasound of intima media thickness (IMT) has been demonstrated in patients with long-standing RA (1, 2). Endothelial dysfunction, shown to precede atherosclerosis in general population (3), can be measured by flow-mediated dilation (FMD). In patients with RA of recent onset we have found IMT and FMD to be similar as in controls (4). In this prospective 5-year follow up, we aimed to investigate for increased progression of atherosclerosis, as measured by FMD and IMT, in the patients with early RA compared to the controls. We also aimed to analyze the relationship between these measurements and biomarkers of endothelial dysfunction (5), taking inflammation and traditional CVD risk factors into account.

Methods: Patients from northern Sweden diagnosed with early RA are followed in an ongoing prospective study of co-morbidity. From these patients a subgroup of patients (n=71), aged ≤60 years, was consecutively included for measurements of IMT of the common carotid artery and FMD of the brachial artery. The ultrasound measurements were taken at inclusion (T0) and after 5 years (T5). Forty-two age/sex matched controls were included. The patients were clinically assessed (DAS28, TJC, SJC, DMARDs) and blood was drawn from all individuals for initial analysis of cholesterol, HDL-cholesterol, triglycerides, ESR, CRP, MCP-1, PAI-1, tPA-mass, VWF, sICAM, sVCAM, sE-selectin and sL-selectin.

Results: Patients with RA had a significant aggravation in both IMT (0.052 at T0 and 0.058 at T5, p<0.001) and FMD (0.090 at T0 and 0.070 at T5, p<0.001). Among the controls the increase was less evident and only significant for IMT (0.055 at T0 and 0.060 at T5, p<0.001). There was a trend towards a more pronounced worsening in the FMD among patients with RA (−0.022 in RA vs −0.010 on ctrls, p=0.097). In linear regression analyses among patients with RA, the IMT at T5 was significantly associated with several variables measured at T0: systolic and diastolic blood pressure (BP), cholesterol, triglycerides, tPA, VWF, and MCP-1 and it was inversely associated with sL-selectin. In the corresponding analyses of FMD at T5 it was significantly associated with sL-selectin and inversely associated with diastolic BP and VWF at T0. Amongst the controls, the IMT at T5 was significantly associated with cholesterol, HDL, triglycerides, body mass index, systolic and diastolic BP, and tPA at T0, whilst FMD related inversely with VWF at T0.

Conclusion: In five years, the increase in subclinical atherosclerosis was more evident among patients with early RA compared to the controls. The IMT at T5 was more highly predicted by baseline levels of biomarkers of endothelial activation in patients with RA compared to controls.

Treat to Target: Normal Cholesterol Values in Low Disease Activity Established RA. Inger L. Meek[1], H.S.J. Picavet[2], Harald E. Vonkeman[1] and Mart AF van de Laar[3]. [1]Rheumatology Center Twente, Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [2]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [3]Medisch Spectrum Twente & Twente University, Enschede, Netherlands

Background/Purpose: Over the past decades many reports have demonstrated the association between RA and dyslipidemia, the unfavourable lipid profiles having been observed >10 years before disease onset. Some have reported an association between disease activity and low HDL cholesterol levels, however in other studies no associations between disease duration or activity and lipid spectrum abnormalities could be found. Also, after treatment with biologicals improvement, as well as deterioration of lipid profiles has been observed. Dislipidemia might contribute to the observed raised cardiovascular mortality in RA, therefore more data concerning lipid profiles in currently treated RA patients are needed. The aim of this study was to compare the lipid profiles of RA outpatients with the general population, and to investigate risk factors for an artherogenic lipid profile in RA.

Methods: Comparison of lipid profiles, i.e. total cholesterol (TC), HDL cholesterol (HDL), and TC/HDL-ratio in a cohort of all consecutive patients between 36 and 75 years of age attending the Arthritis Center Twente (ACT), a large rheumatology outpatient department in The Netherlands (n=546), and a sample of the general population (GP) from the same geographic region

(n=4523). Multivariate analysis of the relationship between potential risk factors, i.e. disease activity (remission by DAS-28 or expert opinion), ESR, disease duration, biological use, and smoking and TC/HDL-ratio. Data were collected by direct measurements in 2009 (ACT), and from 2003 to 2007 (GP) respectively. Analyses were sex-specific and standardised by age.

Results: The RA cohort consisted of 341 women and 205 men, mean age 56 years, and mean disease duration 81 months, 19% being treated with biologicals, and 69% being in remission of RA. Preliminary analyses show that RA patients had similar frequencies of hypercholesterolemia (TC>6.5 mmol/L and/or use of lipid lowering medication; GP 18%, OR_{ACT} 1.1, 95% CI 0.9–1.4) and lowered HDL<1.0 mmol/L; GP 7.2%, OR_{ACT} 1.0, 95% CI 0.7–1.4) compared to the GP. TC/HDL ratios were lower in RA patients (GP 4.2, RA 3.9, p<0.05). In RA patients non-smoking and biological use were associated with lower TC/HDL ratios (p, 0.05), controlling for lipid lowering therapy.

Conclusion: Dislipidemia is not increased in RA patients treated according to the current standards aiming at remission. Non-smoking and biological use are associated with lower TC/HDL ratios.

Vitamin D Levels Are Independently Associated with the Metabolic Syndrome and Metabolic Dyslipidemia In Rheumatoid Arthritis. Joshua Baker[1], Nehal Mehta[2], Gary Toedter[3], Daniel G. Baker[4], Joan Marie Von Feldt[5] and Mary Beth Leonard[6]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, PA, [3]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Malvern, PA, [4]Centocor R & D, a division of Johnson & Johnson Pharmaceutical Research and Development, LLC, Malvern, PA, [5]Univ of Pennsylvania/Philadelphia VAMC, Philadelphia, PA, [6]The Children's Hospital of Philadelphia, Philadelphia, PA

Background/Purpose: Vitamin D deficiency has been associated with an increased risk of cardiovascular disease through unknown mechanisms. The association between vitamin D, dyslipidemia, and metabolic syndrome has not been evaluated in patients with rheumatoid arthritis (RA).

Methods: Baseline serum 25(OH)vitamin D levels were measured at baseline in a random sample of 499 participants, ages 18–85, enrolled in a randomized trial of golimumab (GO-Before Trial). Participants met ACR criteria for RA, had active disease, and were naïve to methotrexate and biologic therapy. Multivariable linear regressions were performed to assess associations between vitamin D and lipoprotein fractions at baseline. Multivariable logistic regression was performed to determine the risk of metabolic syndrome and hyperlpidemia in participants with low vitamin D.

Results: Low-density lipoprotein (LDL) and triglyceride (TG) levels were correlated with vitamin D (Spearman's Rho:-0.16 p=0.0006 and −0.16 p=0.0002, respectively). In linear regression analysis, the association was present controlling for age, sex, race, BMI, GFR, exercise, smoking, steroid use, diabetes, hypertension, CRP, geographic region, disease activity (DAS28), and season. Vitamin D deficiency (<20 ng/mL) was independently associated with an increased risk of hyperlipidemia (1.66 (1.10–2.45) p=0.014) as well as an increased risk of metabolic syndrome (OR 3.45 (1.75–6.80) p<0.001).

Conclusion: Vitamin D deficiency is independently associated with the metabolic syndrome and metabolic dyslipidemia in subjects with RA.

Table 1. Multivariable logistic regression analyses evaluating the odds of hyperlipidemia (defined as TG>150, LDL>160, HDL<40 for men or <50 for women of current use of lipid lowering therapy) by vitamin D status.

Variable	Odds Ratio	95% CI	P value
Model 1*			
< 20 ng/mL	1.64	1.14–2.35	0.008
Model 2†			
< 20 ng/mL	1.52	1.04–2.20	0.032
Model 3‡			
< 20 ng/mL	1.62	1.10–2.40	0.015
Model 4μ			
< 20 ng/mL	1.72	1.10–2.45	0.014

* Adjusted for age, sex, race
† Adjusted for age, sex, race, BMI, diabetes, hypertension, and smoking.
‡ Adjusted for age, sex, race, BMI, GFR, exercise, smoking, diabetes, hypertension, and CRP.
μ Adjusted for age, sex, race, BMI, GFR, exercise, smoking, steroid use, diabetes, hypertension, CRP, region, DAS28, and season.

Table 2. Multivariable logistic regression analysis for the odds of the presence of 1, 2, 3, or 4 components of the metabolic syndrome in vitamin D deficient subjects (<20 ng/mL). The adjusted mean vitamin D level for subjects with increasing components of the metabolic syndrome is also presented.

Components of Metabolic Synd.*	OR	95% CI	P value	Adjusted Mean Vitamin D*
0	1	—	—	21.68
1	1.29	0.78–2.14	0.32	20.77
2	1.65	0.93–2.93	0.085	19.86
3	2.93	1.40–6.16	0.004	19.01
4	4.84	1.44–16.30	0.011	18.15
