VOLUME 65, NUMBER 10 (SUPPLEMENT) OCTOBER 2013

ABSTRACT SUPPLEMENT

2013 ANNUAL MEETING

October 25–30, 2013
San Diego, CA

AMERICAN COLLEGE OF RHEUMATOLOGY
EDUCATION • TREATMENT • RESEARCH

WILEY-BLACKWELL

Get **On-Demand** Annual Meeting Education with *SessionSelect!*

ATTENDEE BONUS!

Your annual meeting registration fee gives you FREE access to the online content of the 2013 annual meeting for one year!

SessionSelect is a comprehensive digital library of recorded presentations from the annual meeting. Within 24 hours of virtually every live session, you can view fully-synchronized presentations with speaker slides and audio—just as if you were actually in the room. Take advantage of the most convenient way to experience the education from the annual meeting at your own pace.

With ***SessionSelect*** you can:

- Stay up to date on the most relevant information and research pertaining to rheumatic diseases
- Apply session information to your practice to enhance your knowledge, competence and performance
- View content on your mobile device or download MP3 files for listening to audio on-the-go

SessionSelect Lounge

No Need to Miss a Session While You're Onsite!

Got some down time between sessions? Relax while you replay sessions—at your convenience—on dedicated computer terminals.

Location: Hall D Lobby

Hours:

Monday, October 28.....7:00 AM – 6:00 PM
Tuesday, October 29.....7:00 AM – 6:00 PM
Wednesday, October 30.....7:00 AM – 1:00 PM

ACR SessionSelect

Your source for educational sessions, online

To learn more about *SessionSelect* or to view a demo, come by the Discovery Center, located in the Exhibit Hall F-G (Booth #1421) or the Concierge Center, located in the Sails Pavilion.

Recordings of individual sessions are subject to change. Ticketed sessions and pre-meeting courses are not included in complimentary access.

The supplement was not financed by profit-making organizations or by organizations representing for-profit interests. The editorial and peer review processes were handled entirely by the American College of Rheumatology (ACR) according to its peer review process for abstracts submitted for presentation at the ACR Annual Meeting.

ACR/ARHP 2013 Annual Meeting Overall Needs Assessment/Practice Gaps

The American College of Rheumatology and the Association of Rheumatology Health Professionals are committed to providing comprehensive education to improve the knowledge and performance of physicians, health professionals and scientists. Through evidence-based educational programs, the organization strives to enhance practice performance and improve the quality of care in those with or at risk for arthritis, rheumatic and musculoskeletal diseases. The 2013 annual meeting program has been developed independent of commercial influence.

The program is the result of a planning process that identified educational needs to change or enhance the knowledge, competence or performance of rheumatology professionals. The program's content was derived from both needs assessment and practice gap analysis based on professional activities, practice setting, ABIM recertification requirements and physician attributes.

Program Highlights

- Educational tracks to help attendees identify content targeted to them. Tracks include: basic science, business/administration, clinical practice and clinical science.
- Latest science and best-practices presented through peer-reviewed and selected clinical and scientific abstracts, and invited speakers providing clinical, evidence-based and quality focused content.
- Diverse formats of education delivery, including: didactic lectures, debates, and interactive sessions, such as poster tours, Meet the Professors and Workshop sessions.
- A larger forum for discussion of practical management issues such as the Curbside Consults – Ask the Professors session.
- Extensive learning opportunities in the basic science of rheumatology, an area of the program developed by a subcommittee of US and internationally prominent basic scientists.
- Clinical management sessions, including the Thieves' Market, Curbside Consults – Ask the Professors, The Great Debate and the ACR Knowledge Bowl.
- Specific pediatric rheumatology content integrated throughout the program designed to provide a high-level educational program to pediatric rheumatologists; and relevant updates to adult rheumatologists.
- Formal presentations of new practice guidelines provided to alert the membership and explain, in an open forum, the data supporting the guidelines and propose approaches for implementation.
- Over 35 workshops designed to provide hands-on skills training.

For additional details, refer to the session level learning objectives at www.ACRannualmeeting.org.

About The Annual Meeting

Participation Statement

This annual meeting is sponsored by the American College of Rheumatology for educational purposes only. The material presented is not intended to represent the only or the best methods appropriate for the medical conditions being discussed, but rather is intended to present the opinions of the authors or presenters, which may be helpful to other healthcare professionals at arriving at their own conclusions and consequent application. Attendees participating in this medical education program do so with full knowledge that they waive any claim they may have against the College for reliance on any information presented during these educational activities. The College does not guarantee, warrant or endorse any commercial products or services.

Global Learning Objectives

At the conclusion of the 2013 ACR/ARHP Annual Meeting, participants should be able to:

- identify recent developments in the diagnosis and management of patients with rheumatic diseases
- outline new technologies for the treatment of rheumatologic problems
- describe potential challenges in the delivery of care to patients with rheumatic diseases and to specify possible solutions
- utilize new research data to improve the quality of care of patients with rheumatic diseases
- summarize recent rheumatology research findings

Certificates of CME Credit or Participation

Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education to provide continuing medical education for physicians.

Designation Statement: The ACR designates this live educational activity for a maximum of 51.75 *AMA PRA Category 1 credits™*. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

International Physicians: International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)™*, must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers, and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit™* to EACCME credit should contact the UEMS.

Health Professionals: Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)™*. For non-CME sessions, attendees may also request a certificate of participation.

Meeting Evaluations, CME Credit Certificates of Participation

Use ***My Annual Meeting*** to complete your session evaluations online. Access ***My Annual Meeting*** at www.ACRannualmeeting.org to e-mail or print your CME certificate. Computers are also available for you to complete your CME/Certificate of Participation and session evaluations online during the meeting at the Technology Center located in the Sails Pavilion.

International physicians, requiring a Certificate of Attendance, can obtain one at the ACR registration counter located in the Sails Pavilion or in the Discovery Center location in the center of Exhibit Hall F-G, booth 1421. If your country recognizes *AMA PRA Category 1 Credit(s)™* in accordance with AMA PRA requirements, please complete the session evaluations and CME application online using ***My Annual Meeting***. Your evaluation of the meeting is very important.

Conflict of Interest/Disclosure Statements

As an educational provider accredited by the Accreditation Council for Continuing Medical Education (ACCME), the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities.

Therefore, all speakers and moderators participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

None: Nothing to disclose

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part-time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Speakers, moderators and abstract authors submitted their disclosure online prior to publication. Disclosures for invited speakers are listed in the indices by presenters' last name.

Abstract author disclosures are published in an online supplement of the October 2013 issue of *Arthritis & Rheumatism*. Disclosures for the late-breaking abstracts are published online and in the December issue *of Arthritis & Rheumatism.* Any individual who refuses to disclose relevant financial relationships will be disqualified from being a planning committee member, a presenter, an author of a CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Disclosure Policy

It is the policy of the American College of Rheumatology to ensure that its CME activities are independent and free of commercial bias.

To ensure content objectivity and balance, and guarantee that the content presented is in the best interest of its learners and the public, the ACR requires that everyone in a position to control content disclose all relevant financial relationships with any commercial interest if the relationship is financial and occurred within the past 12 months. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's Procedures for Disclosure and Resolution of Personal Conflicts of Interest related to CME Activities prior to the participation of the individual in the development or presentation of CME content.

Copyright Materials Policy

The annual meeting is a private event. Programs presented at the meeting are for the education of attendees and purchasers of recorded presentations as authorized by the ACR. The information and materials displayed and presented during this meeting are the property of the ACR and the presenter and cannot be photographed, copied, photocopied, transformed to electronic format, reproduced, or distributed without written permission of the ACR and the presenter. Any use of the program content for commercial purposes, which includes, but is not limited to oral presentations, audiovisual materials used by speakers, and program handouts without the written consent of the ACR is prohibited. This policy applies before, during and after the meeting. The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

The names, insignias, logos and acronyms of the ACR, the ARHP and the RRF are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the ACR.

Embargo Policy

Accepted abstracts are made available to the public online in advance of the meeting and are published in a supplement of *Arthritis & Rheumatism*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR website.

However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) **is under embargo until 4:30 PM Pacific Time on Saturday, October 26, 2013**. Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate.

Authors are responsible for notifying financial and other sponsors about this policy.

ACR Poster Session A
Antiphospholipid Syndrome: Clinical Manifestations and New Biomarkers in Antiphospholipid Syndrome
Sunday, October 27, 2013, 8:30 AM–4:00 PM

1

Anti-β2GP1-Domain-1 Antibodies Are a Marker Of APS Severity. Nancy Agmon-Levin[1], Luciana Seguro[2], Cristina Rosário[3], Michael Mahler[4], Mariele Gatto[5], Nir Tomer[6], Elaine P. Leon[7], Andrea Doria[8], László Kovács[9], Nathalie Costedoat-Chalumeau[10], Boris Gilburd[11] and Yehuda Shoenfeld[12]. [1]The Zabludowicz Center for Autoimmune Diseases, Tel-Hashomer, Israel, [2]Division of Rheumatology, University of São Paulo School of Medicine, Sao Paulo, Brazil, [3]Internal Medicine Department, Hospital de Pedro Hispano, Rua Dr. Eduardo Torres Matosinhos, Porto, Portugal, [4]INOVA Diagnostics, San Diego, CA, [5]Department of Medicine, University of Padova, Padova, Italy, [6]The Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Ramat Gan, Israel, [7]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [8]University of Padova, Padova, Italy, [9]University of Szeged, Szeged, Hungary, [10]Hopital Cochin, Paris, France, [11]The Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel, [12]Sheba Medical Center, Ramat Gan, Israel.

Background/Purpose: Autoantibodies targeting Domain-1(D1) of beta-2-glycoprotein-1(β2GP1) are common among patients with the antiphospholipid syndrome (APS)[1]. However, few studies assessed their clinical relevance and correlation with other anti-phospholipid antibodies (aPLA). Thus, in the current study we evaluated the correlations between anti-β2GP1-D1 levels and APS clinical and serological parameters.

Methods: Serum samples of 178 APS patients, 50 healthy subjects and 47 patients diagnosed with sepsis were utilized to determine levels of IgG-antibodies to cardiolipin(aCL), β2GP1 and β2GP1-D1 (BIO-FLASH®, INOVA). Demographic, clinical and serological (i.e. Lupus anticoagulant (LAC)) data were analyzed.

Results: Among APS patients aCL, anti-β2GP1 and anti-β2GP1-D1 were present in 60%, 70% and 49%, respectively. The presence of anti-β2GP1-D1 antibodies correlated with the presence of LAC (91 vs. 67%; $p<0.001$), aCL (98 vs. 23%; $p<0.001$). Triple aPLA positivity was present in 89% of anti-β2GP1-D1 positive sample compared with 16% among anti-β2GP1-D1 negative samples ($p<0.001$). Anti-β2GP1-D1 antibodies correlated with higher titers of aCL antibodies ($p<0.001$) and anti -β2GP1 ($p=0.03$).

Anti β2GP1 antibodies correlated with the occurrence of venous thrombosis ($p< 0.009$). Anti-β2GP1-D1 positivity (>20CU) related to the occurrence of any thrombotic event (91% vs. 79% OR 2.54; 95% CI 1.05–6.15; $p=0.039$). Medium levels of anti-β2GP1-D1 (>30CU) correlated with arterial thrombosis (55% vs. 33% OR=2.5; 95%CI 1.37–4.67; $p = 0.006$). High levels of anti-β2GP1-D1 (>64CU) were associated with multiple thrombotic events (62% vs. 31% OR 3.58; 95%CI 1.49–8.61; $p=0.005$) arterial thrombosis (60% vs. 33% OR 3.04; 95%CI 1.61–5.73; $p=0.001$) and CNS manifestations (45% vs. 27% OR 1.99; 95%CI 1.03–3.81; $p=0.038$).

Conclusion: In our cohort of APS patients, anti-β2GP1-D1 antibodies were a marker of high risk aPLA profile. Moreover their presence, particularly in med-high levels correlated with repeated thromboses, arterial occlusion and CNS-related manifestations. Thus, anti-β2GP1-D1 may potentially serve as a biomarker of thrombosis in APS.

2

Charaterization Of Micrornas Involved In The Regulation Of Atherothrombosis In Antiphospholipid Syndrome and Systemic Lupus Erythematosus. Chary Lopez-Pedrera Sr.[1], Patricia Ruiz-Limon[1], Raul Teruel[2], Ángeles Aguirre Zamorano[1], Rosario M. Carretero-Prieto[1], Nuria Barbarroja[1], Antonio Rodriguez-Ariza[1], Eduardo Collantes-Estevez[1], Rocio gonzalez-Conejero[2], Constantino Martinez[2], M[a] Jose Cuadrado[3] and Carlos Perez-Sanchez[1]. [1]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [2]Regional Centre for Blood Donation, University of Murcia, Murcia, Spain, [3]The Rayne Institute, London, United Kingdom.

Background/Purpose: miRNAs are key players in pathophysiological processes, but no previous studies have investigated their asscociation with the cardiovascular and atherothrombotic risks observed in primary antiphospholipid syndrome (APS) and systemic lupus erythematosus (SLE).

The aim was to characterize the miRNAs involved in pro-inflammatory, prothrombotic and pro-oxidative status in SLE and APS patients.

Methods: In silico search was performed and six putative miRNAs regulating factors involved in the proinflammatory and pro-oxidative status of APS and SLE patients (miR-124a, -125a, -125b, -146a, -155, and -222) were selected and quantified by RT-PCR in neutrophils and monocytes from 11 APS and 17 SLE patients, and 26 healthy donors. Pro-inflammatory and prothrombotic proteins and oxidative stress markers were evaluated by flow cytometry. Proteins related to the biogenesis of miRNAs were quantified by RT-PCR and Western Blot.

Results: Expression of selected miRNAs was significantly decreased in neutrophils from SLE and APS patients compared to healthy donors. However, only miR-124a was found significantly reduced in monocytes from SLE and APS patients. The expression of those miRNAs negatively correlated with autoimmunity-related parameters (anti-dsDNA and aCL-IgG), disease activity (SLEDAI), inflammation (IL-2, -6, -8 and MCP-1) and oxidative stress (peroxides). Low levels of specific miRNAs in neutrophils and monocytes from both SLE and APS were found further associated with thrombotic events and pathological carotid intima media thickness. This selective decrease miRNA expression was related to a significant reduction in the expression of miRNAs biogenesis genes (Xportin-5, Drosha, Dicer, Ago-1 and Ago-2) in neutrophils from APS and SLE patients compared to healthy donors. I*n vitro* treatment of healthy monocytes with purified antiocardiolipin antibodies from APS patients caused a significant decrease in the levels of miR-124a. Notably, when this miRNA was transfected into monocytic THP-1 cells a significant decrease (~30%) in MCP-1, STAT3 and p38 expression was observed, pointing at these proteins as potential targets of miR-124a.

Conclusion: 1. Decreased expression of a number of miRNAs in monocytes and neutrophils from APS and SLE patients correlates with autoimmunity, inflammation, thrombosis and oxidative stress and atherothrombotic markers. 2. A down-regulation of miRNA processing might explain the low expression of evaluated miRNAs in APS and SLE neutrophils. 3. Antiocardiolipin antibodies directly regulate miR-124a expression, which is directly involved in the proatherosclerotic profile of APS and SLE patients.

3

The Global Antiphospholipid Syndrome Score (GAPSS) In Primary APS. Savino Sciascia[1], Giovanni Sanna[2], Veronica Murru[3], Dario Roccatello[1], Munther A. Khamashta[3] and Maria Laura Bertolaccini[3]. [1]Centro di Immunopatologia e Documentazione su Malattie rare, Torino, Italy, [2]Louise Coote Lupus Unit, St. Thomas' Hospital, London, United Kingdom, [3]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom.

Background/Purpose: Antiphospholipid Syndrome (APS) is a heterogeneous entity with a wide variation in clinical course and laboratory profile. We aimed to evaluate the clinical utility of GAPSS (Global APS Score) in a cohort of primary APS patients. GAPSS is derived from the combination of independent risk for thrombosis and pregnancy loss (PL), taking into account the antiphospholipid antibodies (aPL) profile, the conventional cardiovascular risk factors, and the autoimmune antibodies profile.

Methods: This study included 62 consecutive with primary APS. Data on clinical manifestations, conventional cardiovascular risk factors, and antiphospholipid antibodies profile were collected. GAPSS scoring system was calculated for each patient by adding together the points corresponding to the risk factors, based on a linear transformation of the corresponding β regression coefficient as follows: 3 for hyperlipidemia, 1 for arterial hypertension, 5 for aCL IgG/IgM, 4 for anti-β2GPI IgG/IgM, 3 for aPS/PT IgG/IgM and 4 for LA.

Results: Higher values of GAPSS were showed in patients who experienced thrombosis alone compared to those with pregnancy loss (PL) alone (11.5 ± 4.6 and 8.7 ± 3.2,$p=0.0378$). Patients with both thrombosis and pregnancy loss showed higher GAPSS compared to those pregnancy loss alone (12.5 ± 4.6 vs 8.7 ± 3.2,$p=0.0152$). Higher values were also shown sub-grouping for the site of thrombosis, compared to pregnancy loss alone

(12.2±5.2, for arterial thrombosis; 12.±4.0 for venous and 8.7±3.2, p=0.0214 and p=0.0472, respectively). Patients with thrombotic recurrences showed higher values of GAPSS compared to those without (13.7±3.1Vs 9.4±3.9,p=0.0205, respectively). Higher values were also seen when comparing recurrences Vs no recurrences according to the site of thrombotic event (13.9±3.6 and 11.0±4.3,p=0.0143 for arterial; 13.6±2.18 Vs 8.91±3.6,p=0.001, for venous events, respectively).

GAPSS values higher or equal to 11 were strongly associated with higher risk of recurrences (OR 18.27 [95%IC 3.74–114.5] for cut off 11, OR 20.64[3.92–185.92] for cut off 12, 21.64[3.89–189.56] for cut off 15, respectively. GAPSS values higher or equal to 11 seemed to have the best accuracy, in terms of sensitivity and specificity.

Conclusion: GAPSS is demonstrated to be a valid tool to a substantial improvement in risk stratification for thrombosis in primary APS, also in terms of recurrences.

Disclosure: S. Sciascia, None; **G. Sanna**, None; **V. Murru**, None; **D. Roccatello**, None; **M. A. Khamashta**, None; **M. L. Bertolaccini**, None.

4

Proteomic Analyses Of Monocyte Responses To IgG From Patients With Antiphospholipid Syndrome. Vera M. Ripoll, Anastasia Lambrianides, Wendy Heywood, Anisur Rahman, Yiannis Ioannou and Ian Giles. University College London, London, United Kingdom.

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune disorder characterised by recurrent vascular thrombosis (VT) and/or pregnancy morbidity (PM) caused by antiphospholipid antibodies (aPL). Whilst aPL are known to activate monocytes by inducing production of tissue factor and pro-inflammatory cytokines, upstream mechanisms leading to this pattern of cellular activation are not fully understood. There is evidence that aPL from VT and PM patients stimulate different monocyte intracellular pathways but these have not been characterised in detail. We therefore carried out proteomic analysis of human monocytes treated with IgG from VT, PM and healthy controls (HC) using two different techniques.

Methods: Human monocytic cell line U937 and healthy monocytes were treated with 200 μg/ml of IgG purified from patients with VT, PM or HC. Proteomic analysis was performed using two dimensional difference gel electrophoresis (2D DiGE) and Label Free Quantitative LC-MS/MS. Differentially upregulated proteins were identified by mass spectrometry and validated using quantitative PCR (qPCR) and western blotting.

Results: The table shows the numbers of proteins whose expression in 2D DiGE analysis was regulated by at least two-fold (up or down) in cells exposed to VT IgG or PM IgG compared to HC IgG.

	U 937	Healthy monocytes
VT IgG	41 upregulated, 11 downregulated	119 upregulated, 21 downregulated
PM IgG	22 upregulated, 1 downregulated	105 upregulated, 22 downregulated

Monocytes showed more regulated proteins than U937 cells. Far more proteins were upregulated than downregulated in both cell types. 11 proteins showing the most significant regulation were identified by mass spectrometry analysis. Of these, vimentin and zinc finger CCCH domain-containing protein 18 (ZCH18) were the most significantly upregulated in both U937 cells and monocytes. Additionally, Myeloperoxidase (MPO) and CAP Gly domain-containing linker protein 2 (CLIP2) were significantly induced in monocytes. Upregulation of vimentin, ZCH18, MPO and CLIP2 was confirmed by qPCR. Induction of vimentin and MPO was also validated by western blotting. Anti-cardiolipin/vimentin antibodies have been reported in APS. We found anti-vimentin in serum of 35% of patients with APS but no correlation between anti-vimentin level and ability of IgG to up-regulate monocyte vimentin.

LC-MS/MS of healthy monocytes exposed to VT IgG revealed over 100 proteins that were differentially regulated compared to monocytes exposed to HC IgG. Pathway analysis showed that these proteins were involved in cytoskeletal, coagulation and integrin-signaling functions; all relevant to APS. S100 A11 and POTE ankyrin domain family member E were significantly upregulated whereas Plasminogen activator inhibitor 2 and Coronin 1 were downregulated. Targets were validated using qPCR.

Conclusion: Two different proteomic techniques were used to identify novel proteins involved in the actions of aPL on monocytes. Several of these proteins are strongly associated with autoimmune disease and coagulation and could become potential new therapeutic targets for APS.

5

Plasma Levels Of PF-4var/CXCL4L1, A Non Allelic Variant Of Platelet Factor-4 (PF-4/CXCL4), Are Elevated In Patients With Antiphospholipid Syndrome (APS). Marina Sikara[1], Markos Patsouras[1], Elias Eliopoulos[2] and Panayiotis Vlachoyiannopoulos[1]. [1]School of Medicine, National University of Athens, Athens, Greece, [2]Agricultural University of Athens, Athens, Greece.

Background/Purpose: Platelet derived chemokines, such as PF-4 and a recently isolated protein product of its nonallelic variant gene PF-4var, are implicated in several aspects of vascular thrombosis and inflammation. The above chemokines present only 4.3% aminoacid divergence in the mature proteins; however they exhibit distinct platelet secretion mode and function. The precise role of PF-4var regarding the haemostatic balance is not yet studied.

Previous study from our group demonstrates a novel interaction between β2-glycoprotein I (β2GPI), the major autoantigen in APS, and PF-4 or PF-4var. This complex formation leads in the stabilization of β2GPI dimeric structure which facilitates the antibody recognition and platelet activation, as indicated by p38MAPK phosphorylation and thromboxane production.

To determine PF-4var plasma levels and platelet PF-4var expression (RNA level) in patients with APS and evaluate the correlation with clinical and laboratory parameters of the disease.

Methods: From 70 patients, who fulfill the revised diagnostic criteria for APS, blood samples were taken and separate samples of serum, plasma and platelets were isolated. Complete blood count, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), aPTT, anti-cardiolipin (anti-CL) and anti-β2GPI antibodies were measured. A healthy control (n=30) and a disease control group (SLE, n=26) were included in the study.

Plasma levels of PF-4var were determined using a commercially available ELISA, which absolutely discriminates PF-4var from PF-4 protein. Statistical analyses were evaluated by Mann-Whitney t-test and Kruskal-Wallis test.

Platelet PF-4var and PF4 RNA levels were determined in RNA isolated from donor's and patient's platelet preparations using quantitative Real-Time PCR.

Results: APS patients showed higher levels of plasma PF-4var compared to healthy individuals (median 137 pg/ml; intarquartile range 66.4–200.5 pg/ml versus 79.03 [40.3–99.2] pg/ml, p=0.0052). In addition, RT-PCR revealed significantly higher PF-4var expression in platelets derived from patients comparing to healthy donors ($2^{-\Delta\Delta CT}$: 1.540; [1.020–1.943] versus 0.89 [0.705–1.203], p<0.001). PF-4var levels were significantly elevated in patients suffering from primary APS (PAPS) than those with APS secondary to SLE (SAPS), (197.7 [113.3–304.8] pg/ml versus 126.6 [49.94–170] pg/ml, p=0.0086). Regarding the clinical presentation of the disease, patients who experienced thrombotic events versus pregnancy morbidity or arterial versus venous thrombotic events do not show statistically significant difference in PF-4var levels. A positive correlation was also revealed between the presence of thrombocytopenia and the elongation of aPTT with the higher PF-4var levels (p=0.0048 and p=0.0195, respectively).

Conclusion: Preliminary results suggest that higher PF-4var levels are present in plasma of APS patients and especially in those with PAPS and these are associated with laboratory characteristics indicative for higher risk of thrombotic complications.

Researchers' Own Experience In Managing Obstetric Complications In Pregnant Women With Antiphospholipid Syndrome. Lidia Ostanek[1], Danuta Bobrowska - Snarska[1], Barbara Nestorowicz[2] and Marek Brzosko[3]. [1]Pomeranian Medical University, Szczecin, Poland, Szczecin, Poland, [2]Pomeranian Medical University, Szczecin, Poland, Szczecin, Poland, [3]Department of Rheumatology and Internal Diseases Pomeranian Medical University in Szczecin, Szczecin, Poland.

Background/Purpose: 1. To analyse risk factors for obstetric pathology in patients with antiphospholipid syndrome (APS).

2. To assess the effectiveness of treatment depending on pharmacotherapy.

Methods: The courses of 275 pregnancies and deliveries in patients with diagnosed APS (PAPS-68, SAPS-41 patients) were analysed. 101

pregnancies were treated according to current recommendations. The treatment was consistently followed up with both a rheumatologist and an obstetrician. A retrospective analysis of previous pregnancies and deliveries, both treated and untreated was conducted. The immunological profile of the patients (ANA, SS-A, SS-B, Ro52, lupus anticoagulant (LA), anticardiolipin antibodies (aCL), anti β2GPI (aβ2GPI), antiprothrombin antibodies (aPTR), anti-phosphatidylserine (aPS), complement component 3 and complement component 4) was investigated. Assessment of metabolic and environmental factors influencing pregnancy (smoking, arterial hypertension, lipid profile, hyperglycaemia, uric acid concentration) was carried out. Yate's chi-sqared test, Pearson's ch-sqared test, Spearman's rank correlation and logistic regression analysis were used to conduct the statistical analysis.

Results: Risk factors for unsuccessful pregnancy included: young age at the diagnosis and during pregnancy (p<0,001), presence of LA (p=0,0046), aPTR (p=0,034), arterial hypertension (p=0,012), hyperuricemia (p=0,005). Miscarriages were more frequent in patients with PAPS than with SAPS (p=0,007), in patients with aCL IgM (p=0,042) and in patients treated with glucocorticosteroid (GS) (p=0,027). Premature births were more frequent in young patients (p=0,002), with SAPS (p=0,005), with presence of ANA (p=0,0026), LA (p=0,045), low concentration of C3 (p=0,006), patients with smoking history (p=0,018) and those treated with GS (p=0,000). The presence of LA involved the risk of fetal death (p=0,027). Chances of successful pregnancy were enhanced by: the application of low molecular weight heparin (LMWH)(p=0,000), aspirin (ASA) (p=0,001), combined treatment: LMWH+ASA (p=0,002), and immunoglobulins iv (p=0,002).

Conclusion: 1. The occurrence of aPL and diagnosis of APS increase the risk of obstetric pathology.

2. Apart from immunologic factors (aCL, LA, aPTR, ↓ C3), there are other factors which determine the risk of pregnancy failure, i.e. demographic factors (age), environmental factors (smoking, hyperuricemia) and associated treatment (GS).

3. PAPS increases the risk of miscarriage, SAPS increases the risk of premature birth.

4. Treating APS patients with ASA, LMWH, and in justified cases with immunoglobulins iv, increases the chances of successful pregnancy.

Prospective Validation Of The Global Antiphospholipid Syndrome Score (GAPSS). Savino Sciascia[1], M[a] Jose Cuadrado[2], Giovanni Sanna[3], Veronica Murru[4], Dario Roccatello[1], Oier Ateka[5], Munther A. Khamashta[4] and Maria Laura Bertolaccini[4]. [1]Centro di Immunopatologia e Documentazione su Malattie rare, Torino, Italy, [2]The Rayne Institute, London, United Kingdom, [3]Louise Coote Lupus Unit, St. Thomas' Hospital, London, United Kingdom, [4]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [5]Lupus Unit, London, United Kingdom.

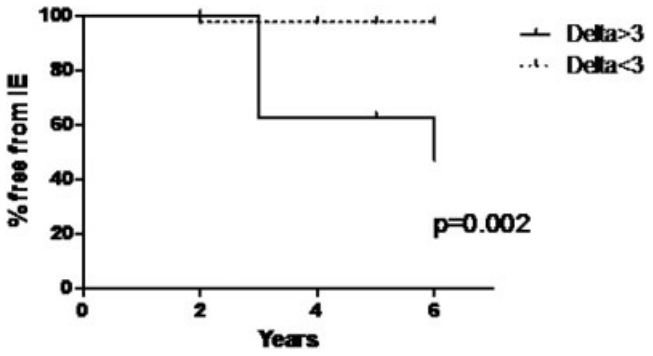
Prospective Validation of the Global Antiphospholipid Syndrome Score (GAPSS)

Background/Purpose: Backgrounds: This study was performed to prospectively and independently validate the GAPSS (1) (Global APS Score), a score system derived from the combination of independent risk factors for thrombosis, taking into account the antiphospholipid antibodies (aPL) profile and the conventional cardiovascular risk factors.

Methods: GAPSS were prospectively applied to 52 consecutive SLE patients with positive aPL (51 female, mean age 39.1±10.6, mean follow-up 47.53±19.15 months). GAPSS scoring system was calculated yearly for each patient by adding together the points corresponding to the risk factors.

Results: An increase in the GAPSS (entry Vs. last visit) was seen in patients who experienced thrombosis (n=5, 6±5.05 Vs 9.4±4.93, p=0.0388). No changes were observed in those without thrombotic event (n=47, 8.28±4.88 Vs 7.13±5.75, p= NS).

An increase of more than 3 points in GAPSS during the follow-up was strongly associated with higher risk of thrombosis (HR 25.00 [95%IC 3.74–189.1]). The risk of thrombosis was also evaluated by Kaplan-Meier analysis (fig.1; IE: ischemic event) and the cumulative proportion of thrombosis-free individuals was higher (p=0.002) in the patients whose GAPSS was not increased by 3 or more points.



Conclusion: We have prospectively demonstrated that GAPSS is a valid tool for accurate prediction of thrombosis in SLE patients with aPL.

Clinical Evaluation Of Two Anti-Beta$_2$glycoprotein I Domain 1 Autoantibody Assays To Aid In The Diagnosis and Risk Assessment Of The Antiphospholipid Syndrome. Rohan Willis[1], Michael Mahler[2], Francesca Pregnolato[3], Charis Pericleous[4], Anisur Rahman[4], John Ioannou[5], Ian Giles[4], Gabriella Lakos[2], Roger Albesa[2], Navid Zohoury[2], Pier-Luigi Meroni[6] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]INOVA Diagnostics, San Diego, CA, [3]Lab of Immunology, IRCCS Istituto Auxologico Italiano, Milan, Italy, [4]University College London, London, United Kingdom, [5]Rayne Institute, University College London, London, UK, London, United Kingdom, [6]University of Milan, Milano, Italy.

Background/Purpose: Antiphospholipid Syndrome (APS) is characterized by the presence of antibodies to phospholipids (aPL) and to $\beta_2$glycoprotein I (β_2GPI) in patients with thrombosis or pregnancy morbidity. Several studies provided evidence that antibodies to domain 1 of β_2GPI (β_2GPI-D1) represent a promising biomarker for the diagnosis and risk assessment of APS. Several immunoassays have been described to detect those antibodies, but harmonization of those tests as well as correlation of those assays has not been properly addressed. Here we aimed to compare two assays for the detection of anti-β_2GPI-D1 antibodies using clinically defined patients samples.

Methods: A total of 72 APS patients and 45 controls (including healthy individuals, patients with infectious or autoimmune diseases) were tested for anti-β_2-GPI antibodies by ELISA (in-house, London, UK and INOVA Diagnostics, San Diego, US) and for anti-β_2GPI-D1 by QUANTA Flash CIA (INOVA) and by ELISA (in-house, London, UK). History of thrombosis was known for 94 patients (39 with and 55 without history of thrombosis).

Results: Both anti-β_2GPI-D1 assays showed good qualitative (79.5%, 95% CI 71.0–86.4; *kappa*=0.60, 95% CI 0.46–0.74) and quantitative agreements (spearman's *rho*=0.76, 95% CI 0.67–0.83) as well as similar discrimination between APS patients and controls as shown by ROC analysis.

Comparison between assays

Qualitative (Total Agreement %/*kappa*) Quantitative (Spearman)	B2 ELISA (INOVA)	D1 ELISA (UK)	D1 CIA
B2 ELISA (UK)	88.9 (0.77) 0.82 (0.75–0.87)	86.3 (0.73) 0.83 (0.76–0.88)	89.7 (0.79) 0.84 (0.78–0.89)
B2 ELISA (INOVA)	/	82.1 (0.65) 0.68 (0.57–0.77)	85.5 (0.71) 0.76 (0.67–0.83)
D1 ELISA (UK)	/	/	79.5 (0.60) 0.76 (0.67–0.83)

Comparison between APS patients and controls

Assay	Area under the curve (95% Confidence interval)	LR+/LR− at cut-off	LR+/LR− at LR+ max	Sensitivity (95% Confidence interval)	Specificity (95% Confidence interval)
D1 CIA	0.89 (0.83–0.96)	9.69/0.15	13.8/0.71	86.1 (75.9–93.1)	91.1 (78.8–97.5)
D1 ELISA	0.83 (0.75–0.90)	4.02/0.44	11.25/0.77	62.5 (50.3–73.6)	84.4 (70.5–93.5)
B2 ELISA (UK)	0.90 (0.84–0.96)	6.25/0.19	9.69/0.60	83.3 (72.7–91.1)	86.7 (73.2–94.9)
B2 ELISA (INOVA)	0.93 (0.88–0.97)	7.5/0.19	24.4/0.47	83.3 (72.7–91.1)	88.9 (75.9–96.3)

Discrimination between patients with and without history of thrombosis

	D1 CIA	D1 ELISA	B2 ELISA (UK)	B2 ELISA (INOVA)
Sensitivity	89.7	64.1	87.2	79.5
Specificity	76.4	74.5	72.7	80.0
Likelihood ratio (+)	3.80	2.52	3.20	3.97
Likelihood ratio (−)	0.13	0.48	0.18	0.26

Conclusion: Anti-β_2GPI-D1 antibodies are a promising biomarker to aid in the diagnosis and risk assessment of APS patients. Confirmatory studies using multi-centric setups and large patient cohorts are necessary to confirm the data.

9

Domain 1 Is The Main Specificity Of Anti-$\beta_2$glycoprotein I Antibodies In Systemic Autoimmune Diseases. Laura Andreoli[1], Cecilia Nalli[1], Maria-Orietta Borghi[2], Francesca Pregnolato[3], Alessandra Zanola[1], Claudia Grossi[4], Maria Gerosa[5], Flavio Allegri[1], Michael Mahler[6], Gary L. Norman[6], Pier Luigi Meroni[7] and Angela Tincani[1]. [1]Rheumatology Unit, University of Brescia, Brescia, Italy, [2]Lab of immunology, IRCCS Istituto Auxologico Italiano, Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy, [3]Lab of Immunology, IRCCS Istituto Auxologico Italiano, Milan, Italy, [4]Laboratory of Immuno-rheumatology, IRCCS Istituto Auxologico Italiano, Milan, Italy, [5]Division of Rheumatology, Gaetano Pini Institute, Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, [6]INOVA Diagnostics, San Diego, CA, [7]Division of Rheumatology, Gaetano Pini Institute, Milano, Italy.

Background/Purpose: Anti-$\beta_2$glycoprotein I antibodies (a-β_2GPI) are involved in the pathogenesis of the Antiphospholipid Syndrome (APS). Antibodies to the domain 1 of β_2GP1 (a-β_2GPI-D1) have been suggested as a marker of thrombosis, while antibodies to domain 4/5 (a-β_2GPI-D4/5) have been described in non-thrombotic, non-autoimmune conditions. The clinical significance of these biomarkers is still evolving. We analyze different groups of patients affected by systemic autoimmune diseases and asymptomatic carriers of anti-phospholipid antibodies (aPL).

Methods: 154 patients with positive IgG a-β_2GPI at routine assay were enrolled in this multicenter study: A) 55 thrombotic (+/− obstetric) primary APS (PAPS); B) 31 women with pure obstetric PAPS; C) 42 Systemic Lupus Erythematosus (SLE)/Undifferentiated Connective Tissue Disease (UCTD) with positive aPL but without any APS event in their medical history; D) 14 asymptomatic aPL carriers; E) 12 Rheumatoid Arthritis (RA). As controls, 99 adult normal healthy donors (NHD) were included. IgG a-β_2GPI-D1 and IgG a-β_2GPI-D4/5 were tested on research ELISAs containing recombinant β2GPI domain antigens. The results were considered as optical density (OD) values.

Results: Table shows median OD values in each group. To define the preferential specificity of a-β_2GPI, the ratio between a-β_2GPI-D1 and a-β_2GPI-D4/5 was calculated. A p value less than 0.05 was considered as significant (ns=not significant).

	IgG a-β_2GPI (routine assay)	IgG a-β_2GPI-D1	IgG a-β_2GPI-D4/5	Mann-Whitney Test a-D1 vs a-D4/5	D1–D4/5 RATIO (median)
Thrombotic PAPS (n=55)	1.324	0.458	0.171	p<0.0001	2.3
Obstetric PAPS (n=31)	1.058	0.312	0.154	p=0.0003	2.4
SLE/UCTD with aPL (n=42)	0.953	0.497	0.204	p<0.0001	2.1
aPL carriers (n=14)	1.030	0.317	0.228	p=ns	1.2
RA (n=12)	0.917	0.202	0.519	p=ns	1.0
NHD (n=99)	0.041	0.109	0.080	p=ns	1.4

Conclusion: A-β_2GPI-D1 is the prevalent specificity of a-β_2GPI not only in PAPS with thrombosis, but also in PAPS with pure obstetric disease and in SLE/UCTD patients with no APS manifestations. In the latter group, the pathogenic potential of a-β_2GPI-D1 might be mitigated by the absence of additional risk factors and/or to the presence of adequate prophylaxis. aPL carriers appear not to have a polarized profile, suggesting that a-β_2GPI-D1 may be a fingerprint of systemic autoimmune diseases.

10

Autoantibodies Targeting Domain 1 Of Beta 2 Glycoprotein I As Promising Marker In The Diagnosis and Risk Stratification Of The Antiphospholipid Syndrome. Navid Zohoury[1], Munther A. Khamashta[2], Tatsuya Atsumi[3], Jacek Musial[4], Toshiyuki Watanabe[5], Maria Papp[6], Concepción González-Rodríguez[7], Roger Albesa[1], Gary L. Norman[1], Pier-Luigi Meroni[8] and Michael Mahler[1]. [1]INOVA Diagnostics, San Diego, CA, [2]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [3]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [4]Jagiellonian University Medical College, Krakow, Poland, [5]Hokkaido University Graduate School of Medicine, Hokkaido, Japan, [6]University of Debrecen, Debrecen, Hungary, [7]Virgen Macarena University Hospital, Seville, Spain, [8]University of Milan, Milano, Italy.

Background/Purpose: Antiphospholipid Syndrome (APS) is characterized by the presence of antibodies to phospholipids (aPL) and to $\beta_2$glycoprotein I (β_2GPI) in patients with thrombosis or pregnancy morbidity. Several studies provided evidence that antibodies to Domain 1 of β_2GPI (β_2GPI-D1) represent a promising biomarker for the diagnosis and risk assessment of APS patients. Here we aimed to analyze the diagnostic potential of β_2GPI-D1 antibodies and the value in risk stratification of APS patients using a large multi-centric cohort of patients.

Methods: A total of 273 APS patients and 1096 controls (including healthy individuals, patients with infectious or autoimmune diseases) were tested for anti-β_2GPI-D1 by QUANTA Flash CIA (INOVA). A reduced number of samples (n=622) were also tested on anti-β_2GPI by QUANTA Flash CIA (INOVA). Clinical data including the history of thrombosis was known in 89 APS patients (58 had a history of thrombosis).

Results: In the entire cohort, anti-β_2GPI-D1 antibodies differentiated APS and controls with a sensitivity and specificity of 49.8% and 99.6%, respectively. The likelihood ratios were LR+ 136.5 and LR- 0.5. The prevalence of anti-β_2GPI antibodies was higher in primary than in secondary APS and reach significance for anti-β_2GPI-D1 (p=0.0029), but not for anti-β_2GPI antibodies (p=0.06). When compared with the anti-β_2GPI assay, both assays showed good qualitative (79.8%, 95% CI 69.1–86.5; *kappa*=0.60, 95% CI 0.44–0.76) and quantitative agreements (spearman's *rho*=0.81, 95% CI 0.73–0.87) as well as similar discrimination between APS patients and controls as shown by ROC analysis. In the smaller sub-cohort (n=622), sensitivity/specificity were 50.2%/99.2% (β_2GPI-D1) and 72.8%/87.3% (β_2GPI), respectively.

Assay	Cut-off	Sensitivity (95% Confidence interval)	Specificity (95% Confidence interval)	LR+/LR− at cut-off
β_2GPI	20 CU	72.8 (66.6–78.4)	83.7 (79.7–87.3)	4.5/0.33
β_2GPI-D1	20 CU	50.2 (43.6–56.8)	99.2 (97.8–99.8)	64.8/0.50
β_2GPI	50.9 CU	62.1 (55.6–68.4)	96.9 (94.6–98.4)	20.0/0.39
β_2GPI-D1	7.3 CU	60.0 (53.4–66.3)	96.9 (94.6–98.4)	19.4/0.41
β_2GPI	91.1 CU	57.4 (50.9–63.9)	99.0 (97.4–99.7)	55.6/0.43
β_2GPI-D1	11.1 CU	56.2 (49.6–62.6)	99.0 (97.4–99.7)	54.3/0.44

When APS patients were stratified according to the history of thrombosis, anti-β_2GPI-D1 and anti-β_2GPI antibodies showed sensitivities/specificities of 37.9%/93.5% and 60.3%/67.7% respectively. At high specificity (96.8%), the sensitivity for thrombosis was significantly higher for β_2GPI-D1 than for β_2GPI (22.4% vs. 12.1%; p<0.05).

Assay	Cut-off	Sensitivity (95% Confidence interval)	Specificity (95% Confidence interval)	LR+/LR− at cut-off
β_2GPI	20 CU	60.3 (46.6–73.0)	67.7 (48.6–83.3)	1.87/0.59
β_2GPI-D1	20 CU	37.9 (25.5–51.6)	93.5 (78.6–99.2)	5.88/0.66
β_2GPI	4868 CU	12.1 (5.0–23.3)	96.8 (83.3–99.9)	3.74/0.91
β_2GPI-D1	286.9 CU	22.4 (12.5–35.3)	96.8 (83.3–99.9)	6.95/0.80

Conclusion: Anti-β_2GPI-D1 and anti-β_2GPI antibodies show similar performance characteristics in differentiation of APS patients and controls. The correlation with history of thrombosis appears to be stronger for anti-β_2GPI-D1 compared to anti-β_2GPI-antibodies. Therefore, anti-β_2GPI-D1 antibodies are a promising biomarker to aid in the diagnosis and risk assessment of APS patients, but further studies are needed to verify those preliminary findings.

Catastrophic Antiphospholipid Syndrome (CAPS): Clinical, Immunologic Features, and Outcome Of 441 Patients From The "CAPS Registry". Ignasi Rodriguez[1], Gerard Espinosa[2] and Ricard Cervera[3]. [1]Fellow, Barcelona, Spain, [2]Department of Autoimmune Diseases, Hospital Clínic, Barcelona, Barcelona, Spain, [3]Hospital Clinic, Barcelona, Spain.

Background/Purpose: To analyze the clinical and laboratory features as well as the precipitating factors, treatment and outcome of patients with catastrophic antiphospholipid syndrome (CAPS).

Methods: We analyzed the clinical and serologic features of the patients included on May 31, 2013, in the "CAPS Registry", a web-site based international registry of patients with this condition. Categorical variables are presented as frequencies and continuous variables are presented as mean ± standard deviation. Comparative analysis was performed with chi-square test for categorical variables and t-test for quantitative variables using non-parametric tests when parametric tests were not applicable.

Results: The entire series includes 441 patients (456 episodes). Thirteen (2.9%) patients recurred twice and 2 recurred three times. Three hundred (68%) patients were female and 136 (30.8%) were male. They had a mean age of 38.4 ± 17.0 years (range, 0–85). Male patients were older than female (43.4 years vs. 36.2 years; $p<0.001$). The main underlying conditions were primary APS (59.4%), systemic lupus erythematosus (SLE) (30.4%), and lupus-like disease (3.4%). The catastrophic episode was the first manifestation of the APS in 223 (50.6 %) patients. A precipitating factor was reported in 286 (62.7%) episodes, including infections (30.3%), malignancy (10.7%), surgery (10.5), oral contraceptive pills (7.2%), drugs (4.4%), cesarean section (4.2%), lupus flare (2.0%) and trauma (1.1%).

A variety of thrombotic manifestations involving the majority of organs were recorded, including renal (73.6%), lung (58.4%), cerebral (56.3%), heart (49.3%), hepatic (36.3%), gastrointestinal (24%), splenic (16.3%), adrenal (10.4%), and pancreatic (7.1%) manifestations.

Patients with APS associated with SLE had more episodes of *livedo reticularis* (29.1% vs. 15% $p=0.001$), heart valve lesions (22.1% vs. 10.4%; $p=0.01$), seizures (12.8% vs. 6.9%; $p=0.042$), pancreatitis (13.4% vs. 4.4%; $p=0.001$) and more frequently exhibited thrombocytopenia (72.4% vs. 62.5%; $p=0.05$). No differences in clinical manifestations were found between male and female patients.

Regarding immunologic features, IgG anticardiolipin antibodies (aCL) were positive in 81.6% of the patients, lupus anticoagulant in 81.3%, IgM aCL in 48.6%, IgM anti-β2GPI in 3.2% and IgG anti-β2GPI in 11.1%. Female patients had a higher frequency of hemolysis and schistocytes. One hundred and seventy-five (38.6%) patients died at the time of the CAPS event.

Conclusion: The CAPS is an uncommon but potentially life-threatening condition that needs a high clinical awareness. CAPS may affect any organ of the body and display a broad spectrum of manifestations.

Phosphatidiyserine-Prothrombin Complex (aPS/PT) IgG Antibodies Correlate With Lupus Anticoagulant and Specific Pregnancy Complications In Patients With Antiphospholipid Syndrome. Rohan Willis[1], Anne E. Tebo[2], Gabriella Lakos[3], Michael Mahler[3], Gary L. Norman[3], Ware D. Branch[4], Jane Salmon[5], Marta M. Guerra[5] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]University of Utah, Salt Lake City, UT, [3]INOVA Diagnostics, San Diego, CA, [4]Univ of Utah, Salt Lake City, UT, [5]Hospital for Special Surgery, New York, NY.

Background/Purpose: Criteria laboratory tests for antiphospholipid syndrome (APS) include lupus anticoagulant (LAC) as well as IgG and IgM antibodies for cardiolipin and beta2 glycoprotein. Of these tests, only the LAC strongly predicts thrombosis. A recent study (PROMISSE) also showed that LAC was the primary predictor of adverse pregnancy outcome after 12 weeks gestation in aPL(antiphospholipid antibody)-associated pregnancies. Antibodies to phosphatidylserine-prothrombin complex (aPS/PT) have been suggested to strongly correlate with the presence of LAC. Anti-PS/PT antibodies are detected with immunoassay, which is more likely to be amenable to standardization than LAC testing, and can be performed on patients during anticoagulation therapy. Using the PROMISSE cohort we investigated if aPS/PT, similarly to LAC, can predict pregnancy outcomes.

Methods: A total of 97 samples from the PROMISSE study were analyzed at the APLS Laboratory using QUANTA Lite® PS/PT IgG and IgM ELISA kits (INOVA Diagnostics). LAC test results were obtained from PROMISSE investigators. Qualitative agreements, kappa scores, and univariate and multivariable logistic regression analyses were done with SPSS software.

Results: The prevalence of LAC positivity was 53/97 (54.6%), aPS/PT IgG was 35/97 (36.1%), aPS/PT IgM was 51/97 (52.6%) and any aPS/PT was 64/97 (66.0%). The inter-assay agreement between the aPS/PT and LAC is shown in Table 1. Both aPS/PT IgG and IgM showed significant correlation to LAC ($p<0.001$ and $p=0.015$). Anti-PS/PT IgG was significantly associated with any pregnancy morbidity ($p=0.002$; OR=6.2, 95% CI 1.7–22.8) and any pregnancy losses ($p=0.006$; OR=4.3, 95% CI 1.5–12.7). The correlation with preeclampsia did not reach significance ($p=0.061$; OR=3.4, 95% CI 1.0–11.3). Anti-PS/PT IgM was not correlated with adverse pregnancy outcomes. In a multivariable model, anti-PS/PT IgG remained a significant predictor of pregnancy morbidity and pregnancy losses.

Table 1. Inter-assay agreement and association of aPS/PT with LAC

	Total/Positive/Negative agreement (Kappa)	Chi squareP value OR (95% CI)
PS/PT IgG	67.0/63.6/69.8 (0.357)	P=0.000 5.920 (2.241–15.637)
PS/PT IgM	62.9/65.4/60.0 (0.254)	P=0.015 2.842 (1.243–6.496)
ANY PS/PT	68.0/73.5/56.7 (0.341)	P=0.001 4.710 (1.901–11.670)

Conclusion: Anti-PS/PT IgG antibodies show good correlation to LAC and association with pregnancy complications in APS patients. This suggests that aPS/PT may be a promising biomarker for obstetric risk assessment in APS given its advantages with respect to clinical applicability and standardization.

A MORE Specific Immunoassay For The Diagnosis Of APS. Claudia Grossi[1], Maria Borghi[1], Elizabeth Papalardo[2], Silvia S. Pierangeli[3] and Pier Luigi Meroni[4]. [1]Lab of immunology, IRCCS Istituto Auxologico Italiano, Milano, Italy, [2]Louisville APL Diagnostics, Inc, Seabrook, TX, [3]University of Texas Medical Branch, Galveston, TX, [4]Division of Rheumatology, Gaetano Pini Institute, Milan, Italy, Milan, Italy.

Background/Purpose: Anticardiolipin (aCL) antibody assays are sensitive for the detection of antiphospholipid antibodies (aPL) in patients with the Antiphospholipid syndrome (APS) but are known to have suboptimal clinical specificity due to cross-reaction with infectious diseases and other non-APS sera. The APhL ELISA® is an immunoassay that detects antibodies to negatively charged phospholipids in the presence of β_2GPI and has been shown to be more specific than the aCL in the diagnosis of APS. The objective of this study was to evaluate and compare the clinical sensitivity and specificity of the APhL ELISA® with two aCL

Methods: Serum samples from confirmed primary and secondary APS patients (n=54), syphilis (n=20), infectious diseases (n=30), hyperglobulinemias (n=15), paraproteinemias (n=15) and healthy controls (n=54) were evaluated for IgG and IgM aPL antibodies in the APhL ELISA® (Louisville APL Diagnostics) and in two aCL assays (Louisville APL Diagnostics, Inc; LAPL) and in a laboratory developed test (LDT). Samples were obtained from Prof Meroni's laboratory and kits were provided at no cost by the

manufacturer. Assays were considered positive when above the stated cut-off for each test. Clinical sensitivities, specificities, positive predictive (PPV) and negative predictive values (NPV) were calculated individually by isotype or combined (IgG and IgM) for each assay.

Results:

	APhL ELISA® IgG	APhL ELISA® IgM	APhL ELISA® IgG and IgM	aCL LAPL IgG	aCL LAPL IgM	aCL LAPL (IgG and IgM)	aCL LDT IgG	aCL LDT IgM	aCL LDT IgG and IgM
Clin Sens %	83.0	92.5	94	83.3	90.7	96	73.5	39.6	81.0
Clin Spec %	95.5	95.5	91	77.6	59.7	52.0	73.1	77.6	61.0
PPV %	88.0	89.0	81.0	56.9	52.6	44.0	52.0	42.0	45.2
NPV %	92.0	96.9	97.6	91.7	94.1	97.2	87.5	76.4	91.1

Conclusion: The APhL ELISA® showed better PPV, NPV, combined sensitivities and specificities whether analyzed for IgG or IgM independently or combined, when compared to the two aCL assays. The APhL ELISA® may be used as a first line of testing and certainly could be recommended as a confirmatory assay for the diagnosis of APS.

Isotype Dependent Performance Of Beta$_2$glycoprotein I Immunoassays In Two Diverse Patient Cohorts: Implications For Assay Harmonization and Standardization. Anne E. Tebo[1], Rohan Willis[2], Troy Jaskowski[3], Jane E. Salmon[4], Michelle Petri[5], Ware D. Branch[6] and Silvia S. Pierangeli[2]. [1]University of Utah, Salt Lake City, UT, [2]University of Texas Medical Branch, Galveston, TX, [3]ARUP Laboratories, Salt Lake City, UT, [4]Hospital for Special Surgery, New York, NY, [5]Johns Hopkins University School of Medicine, Baltimore, MD, [6]Univ of Utah, Salt Lake City, UT.

Background/Purpose: The presence IgG and/or IgM beta$_2$ glycoprotein I (β_2GPI) antibodies are associated with thrombosis and/or pregnancy-related morbidity in antiphospholipid syndrome (APS) and/or systemic lupus erythematosus (SLE). Some reports show that IgA β_2GPI antibodies may be of clinical relevance in certain patient groups. There are, however, concerns regarding the diagnostic performance of these assays probably due to lack of international calibration materials amongst other factors. This study was designed to determine isotype-specific prevalence and correlation between four different aβ_2GPI immunoassays in two cohorts of patients.

Methods: IgG, IgM, and IgA β_2GPI antibodies were determined in 97 pregnant women with positive antiphospholipid (aPL) antibodies (PROMISSE cohort) and 204 SLE patients ('HOPKINS' cohort) with 4 commercial kits (Bio-Rad, Corgenix, INOVA, Phadia). Results were expressed in kit-specific arbitrary units (AU) for IgG, IgM, and IgA as well as in the recently established international consensus units (IU) for IgG and IgM isotypes. Isotype-specific prevalence, Kappa and Spearman's Rho correlation coefficients were calculated using Analyse-it™.

Results: The positivity rates of the aβ_2GPI tests ranged from 1.0–10.2% and 40.6–63.2% (IgG); 3.9–6.3% and 32.3–47.4% (IgM); and 10.7–20.0% and 18.8–85.3% (IgA) in the HOPKINS and PROMISSE cohorts, respectively. The overall agreement between any two assays ranged from 92.2–99.6% (IgG), 95.4–98.8% (IgM) and 77.6–92.2% (IgA) in both cohorts. While the Kappa coefficients (k) showed moderate-to-almost-perfect agreement for IgG and IgM (0.54–0.98), the analysis revealed fair-to-substantial correlations for IgA β_2GPI tests (0.24–0.75). Despite differences in the positivity rates and varying agreements, good quantitative Rho Spearman's correlation was observed for the IgG and IgM in all 4 kits. Rho correlations were significantly improved when results of the IgG and IgM β_2GPI determinations were expressed in IU. However, suboptimal correlations were obtained for the IgA β_2GPI assays, with better agreement observed between the Phadia and INOVA kits and between the Bio-Rad and Corgenix assays, respectively.

Conclusion: Overall, our study demonstrates good qualitative agreements between these immunoassays for the determination of IgG and IgM antibody isotypes. The use of consensus IU clearly indicates an improvement in the harmonization of the IgG and IgM β_2GPI. Further standardization of the IgA β_2GPI assays is warranted.

Establishment Of Standardized International Units For IgM ANTI-$\beta_2$glycoprotein Antibody Measurement. Rohan Willis[1], Claudia Grossi[2], Maria Borghi[2], Pier Luigi Meroni[3], Gabriella Lakos[4], Tammy Buckner[5], Fernando S. Cavalcanti[6], Maria Crisostomo[7], Corina Dima[8], Kerrie Jaskal[9], Matthias Kast[10], Luis R. Lopez[11], Nina Olschowka[10], Sarah Paul[12], Tony Prestigiacomo[7], Josep Puig[6], Wendy Vandam[7], Alfredo Villarreal[12], Roger Walker[7], Mike Watkins[12] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Lab of immunology, IRCCS Istituto Auxologico Italiano, Milano, Italy, [3]Division of Rheumatology, Gaetano Pini Institute, Milan, Italy, Milan, Italy, [4]INOVA Diagnostics, San Diego, CA, [5]Corgenix, Broomfield, CO, [6]Biokit, Barcelona, Spain, [7]Bio-Rad Laboratories, Hercules, CA, [8]Theratest Laboratories Inc, Lombard, IL, [9]Instrumentation Laboratories, Bedford, MA, [10]Phadia Thermofisher, Freiburg, Germany, [11]Corgenix Inc, Broomfield, CO, [12]Bio-Rad Laboratories, Benicia, CA.

Background/Purpose: Recurrent IgG or IgM anti-$\beta_2$glycoprotein (ab$_2$GPI) antibody positivity is a key laboratory indicator for classification of antiphospholipid syndrome (APS). Considerable inter-laboratory variation still exists for both isotyopes hindering efforts at standardization. At the 13th International Congress on Antiphospholipid Antibodies in 2010, the "Criteria aPL Testing" task force recommended both the development of international units (IU) and of suitable polyclonal and monoclonal reference material (RM) for aβ_2GPI measurement. As such, we sought to prepare polyclonal RM and establish IU for the measurement for IgM aβ_2GPI antibodies.

Methods: IgM aβ_2GPI fractions were affinity-purified (AP) from the sera of 3 APS patients using a combination of ion exchange and affinity chromatography. Purity was confirmed using SDS-PAGE; high-activity fractions were pooled, concentrated and sterile-filtered. The Bradford assay was used to assign IU values (1 IU/ml = 1μg/ml AP- aβ_2GPI). The RM serum was assigned an IU value using the AP- ab$_2$GPI material and sent with 30 samples to six commercial companies (INOVA, Bio-Rad, Corgenix, Phadia, Human and Instrumentation Laboratory) for testing in their kits (eight total) according to an approved protocol to evaluate linearity, unit equivalency and commutability (CLSI guidelines EP14-A2 and C53-A).

Results: The pooled AP material had a protein concentration of 15.125 μg/ml and was assigned a value of 15 IgM aβ_2GPI IU/ml. The RM had a value of 220.3 IgM aβ_2GPI IU/ml. The linearity (R^2) of the RP curve for the various assays ranged from 0.9649 to 0.9996. The value of the RM in the various arbitrary kit units ranged from 71.6 to 568 units. Commutability among the different assays was confirmed as demonstrated in figure 1 (representative of all assays) in which dilutions of the IgM RM fell within the 95% prediction interval limits of the regression curve created by the 30 native serum samples. Commutability was also demonstrated using principal components analysis.

Table. Performance of IgM RM in various IgM aβ_2GPI assays

Kit	Method	Cut-off	Linearity	RM in kit units
Bio-Rad Bio-plex	ELISA	<20 M units	R^2: 0.99	93.8 M Units
Bio-Rad ELISA	Multiplex	<20 M units	R^2: 0.96	96.4 M Units
Corgenix ELISA	ELISA	<20 M units	R^2: 0. 98	77.4 M Units
IL ACUSTAR	Chemiluminescence	<10 U/ml	R^2: 0.99	69.1 U/ml
INOVA ELISA	ELISA	<20 SMU	R^2: 0.99	98.4 SMU
INOVA Bio-Flash	Chemiluminescence	<10 U/ml	R^2: 0.99	72.5 CU
Phadia	Immunofluoroescence	<10 U/ml	R^2: 0.99	568 U/ml
Human GmbH	ELISA	<7 U/ml	R^2: 0.99	71.6 U/ml

Conclusion: The results of linearity and commutability studies suggest that this material can be used as a calibrant/reference in a wide array of assays of different formats and new international consensus are now available for IgM-aβ_2GPI measurement. These studies contribute significantly to the much-needed standardization of aβ_2GPI immunoassays and further characterization by international bodies (IRMM/IFCC) will be done Performance of IgM RM in various IgM ab$_2$GPI assays

Only IgG and IgA $\beta_2$glycoprotein I Antibody Isotypes Are Associated With Venous Thrombosis In Systemic Lupus Erythematosus. Anne Tebo[1], Rohan Willis[2], Troy Jaskowski[3], Laurence S. Magder[4], Silvia S. Pierangeli[2], Ware Branch[5] and Michelle Petri[6]. [1]University of Utah, Salt Lake City, UT, [2]University of Texas Medical Branch, Galveston, TX, [3]ARUP Laboratories, Salt Lake City, UT, [4]University of Maryland, Baltimore, MD, [5]Univ of Utah, Salt Lake City, UT, [6]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: The current APS Classification Criteria recommend testing for IgG and IgM antibodies for $\beta_2$glycoprotein I (β_2GPI), and do not differentiate between primary and secondary APS. This study was designed to investigate the clinical performance of different β_2GPI IgG, IgM and IgA antibody tests in a SLE with arterial and/or venous thrombosis.

Methods: IgG, IgM, and IgA anti-β_2GPI antibodies were determined in 200 patients from a lupus cohort with 3 ELISA (Bio-Rad, Corgenix and INOVA) and 1 fluoro-enzyme immunoassay commercial kits (Phadia), following the manufacturers' instructions. Kits were provided at no cost by the manufacturers, and assays were performed at ARUP laboratories. The degree of agreement between the different kits was quantified using a Kappa statistic. Univariate and multivariate analyses were performed to assess the association between kit results and lifetime history of venous or arterial thrombosis.

Results: The pairwise agreement between the different kits was high for IgG and IgM with Kappa coefficients ranging from 0.64 to 0.98 and 0.74 to 0.93 respectively. This measure was somewhat lower for IgA with Kappa coefficients ranging from 0.24 to 0.78. Twenty-seven (14%) had a history of venous thrombosis. For all assays and all kits, those with a positive assay result were more likely to have a history of venous thrombosis than those with a negative assay result. These differences reached statistical significance in univariate and multivariate analyses of IgG and IgA, adjusted for age, race, and anti-htn medications. The observed differences were not statistically significant for IgM, in part due to the relatively small number of patients positive for IgM. Thirty-four patients (17 %) had a history of arterial thrombosis. There was not strong evidence of an association between the assay results and arterial thrombosis.

Table 1. Proportion(%) with a history of Venous Thrombosis by antibody status.

		Proportion(%) with history of Venous Thrombosis (n=27)			
Assay	Company	Antibody-positive	Antibody-negative	P-value[1]	Adjusted P-value[2]
IgG	Phadia	6/20 (30%)	21/180 (12%)	0.04	0.015
	Bio-Rad	4/9 (44%)	23/191 (12%)	0.02	0.016

	Bio-Rad	4/29 (14%)	30/171 (18%)	0.80	0.40
	Corgenix	6/41 (15%)	28/159 (18%)	0.80	0.50
	INOVA	6/21 (29%)	28/179 (16%)	0.20	0.20
	Any	10/56 (18%)	24/144 (17%)	0.84	0.80
Any Assay		12/65 (18%)	22/135 (16%)	0.70	0.80

[1] Fisher's Exact Test.
[2] Based on Logistic Regression, controlling for age, race, and anti-htn medications.

Conclusion: Only IgG and IgA isotypes were associated with venous thrombosis in SLE, using the p-value adjusted for age and ethnicity. Although the IgA kits showed variable agreements, our data indicate that testing for β_2 GPI IgA isotype may be of clinical relevance in the evaluation of venous thrombosis in APS associated with SLE.

Autoantibodies Against Component Of Complement One Contribute To The Complement Activation and Clinical Manifestation Of Antiphospholipid Syndrome (APS) Especially In Refractory Cases. Kenji Oku[1], Olga Amengual[1], Ikuma Nakagawa[1], Toshiyuki Watanabe[2], Yusaku Kanetsuka[1], Toshiyuki Bohgaki[1], Tetsuya Horita[1], Shinsuke Yasuda[1] and Tatsuya Atsumi[1]. [1]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Hokkaido University Graduate School of Medicine, Hokkaido, Japan.

Background/Purpose: In the pathogenic mechanisms of antiphospholipid syndrome (APS), it is recognized that pathogenicity of antiphospholipid antibodies (aPL) has dominant effects. Complement is the part of the innate immune system and is one of the main effector mechanisms of antibody-mediated immunity. We have previously reported that complement activation prevalently coexists in sera of antiphospholipid syndrome (APS) patients and functions as source of procoagulant cells activation. Recently, autoantibodies against C1q, the component of complement 1, were reported to correlate with complement activation in patients with systemic lupus erythematosus (SLE). They are not neutralizing antibodies but target the neoepitopes of deformed C1q bound to various molecules such as anionic phospholipids. The binding of anti-C1q antibodies to C1q induces accelerated activation of complement pathway. There are no previous studies discussing the involvement of anti-C1q antibodies in APS patients. The purpose of this study is to investigate the existence and significance of anti-C1q antibodies in APS patients.

Methods: This study was comprised of 40 consecutive primary APS patients that visited Hokkaido University Hospital rheumatology clinic from 2002 to 2013 that had more than 2 years history of APS. Informed consent was obtained from every patients and the study was approved by ethics committee of the Hokkaido University Hospital. All the patients were retrospectively analyzed of their clinical manifestations and laboratory data. Ten patients had refractory APS defined as a clinical status of relapsing thrombosis or pregnancy morbidity during adequate secondary prophylaxis. Twenty non-SLE connective tissue disease patients without APS and 20 healthy control subjects were also included. An enzyme-linked immunosorbent assays (ELISA) were used to measure serum levels of anti-C1q antibody titers and anaphylatoxins (C3a,C4a).

Results: Anti-C1q antibodies were more frequently detected in primary APS patients (14/40) than in non-SLE connective tissue disease patients (2/20) ($p<0.01$). In APS patients, anti-C1q antibodies titers were significantly correlated with serum C4a levels ($p=0.013$) and showed tendency of inverse correlation with serum C3a levels ($p=0.07$). The prevalence or the titers of anti-C1q antibodies were not associated with any of the specific clinical manifestations of APS or titers of aPLs. However, refractory APS patients, compared with APS patients without flare, had higher positivity (9/10 vs 3/20, $p=0.01$) and higher titers of anti-C1q antibodies ($32.9+/-6.95$ vs $10.9+/-1.89$, $p=0.01$). Using a cut-off level of 20, the hazard ratio of the anti-C1q positivity for the reoccurrences of the APS manifestation during adequate secondary prophylaxis were 80.0 (95%CI 7.45–880, $p=0.000007$).

Conclusion: These findings indicate that anti-C1q antibodies are associated with complement activation in APS and may contribute to the manifestation especially in the refractory cases.

Clinical Correlates Of Positive Anti-Cardiolipin and β-2 Glycoprotein 1 Antibodies In a Cohort Of 110 Patients At Mayo Clinic. Uma Thanarajasingam, Cynthia S. Crowson, Melissa R. Snyder, Rajeev Pruthi, Harvinder S. Luthra and Kevin G. Moder. Mayo Clinic, Rochester, MN.

Background/Purpose: Testing for antiphospholipid antibodies is typically indicated for diagnosis and prognosis of antiphospholipid syndromes, however, selected patients undergo testing for other reasons. The clinical significance of positive antibodies in this subgroup of patients is unclear. In this study, we sought to identify patient characteristics and events associated with positive anti-cardiolipin (aCL) and anti-beta-2 glycoprotein 1 (anti-B2GP1) antibodies in a large cohort of patients. The patients with positive results were compared to age and gender -matched controls who had tested negative for the same antiphospholipid antibodies.

Methods: We included 110 adults and 110 age and gender-matched controls tested for aCL and anti-B2GP1 antibodies within the same calendar year (2009) at a large academic medical institution. Clinical and laboratory data was abstracted from 1998 through 2013.

Results: Of the 110 cases, the mean age was 54.1 years and 76 (69.1%) were female. The majority of patients (84) were positive for aCL-IgG (41), IgM (25) or both (18); 29 were additionally tested for anti-B2GP1-IgG (14 positive)and IgM (15 positive). ANA was positive in 52 patients (61%). Thrombotic events were seen in 64 patients (59%); these included 31 (29%) with DVT/PE, 29 (27%) with stroke/TIA, 18 (22%) with any fetal loss, and 6 (6%) with any peripheral arterial events. Thirty-six patients (33%) met criteria for APS and 23 (21%) had SLE. Compared to controls, those with positive antiphospholipid antibodies were significantly more likely to be ANA positive ($p<0.003$), experience a thrombotic event ($p<0.018$), suffer fetal loss ($p<0.022$) and have SLE ($p<0.001$). There were non-statistically significant trends towards increased prevalence for DVT/PE ($p=0.067$) and peripheral arterial events ($p=0.055$). No statistically significant differences were seen between the cases and controls with respect to total number of pregnancies, oral contraceptive and stroke/TIA.

Conclusion: Over one-half of patients who tested positive for antiphospholipid antibodies experienced thrombotic events. When compared to controls, those with positive antiphospholipid antibodies had a statistically significant increase in ANA positivity, any thrombotic event, fetal loss and a diagnosis of SLE. To our knowledge, this is the first study examining the frequency of clinically significant conditions and associated events in a large cohort of patients with positive anti-cardiolipin and anti-beta-2 glycoprotein antibodies as compared to age and sex matched controls with negative antibodies.

19

Association Of Antiphospholipid Antibodied Detected In The Aphl ELISA With Clinical Manifestations Of The Antiphospholipid Syndrome In Two Lupus Cohorts. Silvia S. Pierangeli[1], Rohan Willis[1], Michelle Petri[2], Hong Fang[2], Monica Smikle[3], Karel de Ceulaer[4] and E. Nigel Harris[5]. [1]University of Texas Medical Branch, Galveston, TX, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]University of the West Indies, Kgn 7, Jamaica, [4]University of the West Indies, KIngston, Jamaica, [5]The University of the West Ind, Kingston, Jamaica.

Background/Purpose: Antiphospholipid Syndrome (APS) is characterized by the presence of antibodies to phospholipid (aPL) and to $\beta_2$glycoprotein I (β_2GPI) in patients with thrombosis or pregnancy morbidity. Anticardiolipin (aCL) assays are used to confirm the diagnosis of APS. Although a sensitive assay, aCL is often found positive in a number of infectious, drug-induced and non APS related autoimmune diseases. The APhL ELISA is an immunoassay that detects antibodies to negatively charged phospholipids in the presence of β_2GPI and has been shown to be more specific and as sensitive as the aCL in the diagnosis of APS. Here we examined the association aPL antibodies detected in the APhL ELISA with clinical manifestations of APS in two lupus cohorts.

Methods: A total of 590 serum samples from patients with lupus (diagnosed according to ACR criteria) from the HOPKINS cohort (n=543) and from the University of the West Indies Rheumatology Department Jamaica cohort (n=47) were analyzed for IgG and IgM aPL antibodies using the APhL ELISA (Louisville APL Diagnostics), following the manufacturer's instructions. Samples were considered positive when above 15 GPL or MPL units for IgG and IgM, respectively. Association of venous thrombois, arterial thrombosis, any thrombosis, diagnosis of APS (Sapporo revised criteria), any miscarriage, any pregnancy morbidity or toxemia with a positive APhL test (either IgG or IgM) was assessed by univariate analysis, using the SPSS® v20.0 software.

Results:

IgG APhL	P	OR	95% CI
Venous thrombosis	0.000	3.5	1.9–6.3
Arterial thrombosis	0.070	1.8	1.0–3.5
Any thrombosis	0.000	3.1	1.7–5.8
Diagnosis of APS	0.000	5.8	2.7–12.1
Any miscarriage	0.022	2.2	1.1–4.1
Any pregnancy morbidity	0.007	2.5	1.3–4.7
Toxemia	0.007	3.1	1.4–6.8

Any APhL positive test was significantly associated with venous, arterial, any thrombosis and with diagnosis of APS, but no association of IgM APhL positivity with clinical manifestations was observed. There was no difference in the results when data were calculated combined or individually in each cohort.

Conclusion: The APhL ELISA is an excellent test to detect aPL associated with thrombosis and pregnancy morbidity in patients with lupus.

Complement Deposition On Platelets Is Associated To Venous Thrombosis In Systemic Lupus Erythematosus. Christian Lood, Helena Tydén, Birgitta Gullstrand, Gunnar Sturfelt, Andreas Jönsen, Lennart Truedsson and Anders A. Bengtsson. Lund University, Lund, Sweden.

Background/Purpose: Anti-phospholipid (aPL) antibodies are associated with development of venous thrombosis and stroke in the autoimmune disease systemic lupus erythematosus (SLE). The underlying mechanism for aPL-mediated thrombosis is not known but may include activation of platelets and the complement system. The aim of this study was to investigate if aPL antibodies could interact with platelets and support complement activation. Furthermore, we investigated if this mechanism was operating in SLE patients and whether complement deposition on platelets was associated to venous thrombosis and specific for SLE.

Methods: Complement deposition was measured by flow cytometry in patients with SLE, rheumatoid arthritis, systemic sclerosis, myocardial infarction and healthy individuals. Associations to cardiovascular disease were analyzed with logistic regression analysis and adjusted for traditional risk factors. Anti-cardiolipin antibodies were used to investigate if aPL antibodies supported platelet activation and complement deposition

Results: Platelet deposition of C1q and C4d was increased in SLE as compared to healthy individuals ($p<0.0001$), but high levels were also seen in some patients with rheumatoid arthritis and systemic sclerosis. Complement deposition was clearly associated to venous thrombosis and aPL antibodies in SLE. In vitro, anti-cardiolipin antibodies increased platelet activation and supported C4d deposition on platelets.

Conclusion: Platelet C1q and C4d deposition are identified as markers of venous thrombosis in SLE patients. Several mechanisms are operating in SLE to amplify platelet complement deposition, of which anti-cardiolipin antibodies was identified as one important contributor. Further studies are needed to elucidate the role of platelet complement deposition in development of venous thrombosis.

Factor Xa Reactive Antibodies In Patients With Systemic LUPUS Erythematosus and Antiphospholipid Syndrome Have Differential Effects Upon Coagulation Assays and Endothelial CELLS. Bahar Artim-Esen, Natalia Smoktunowicz, Charis Pericleous, Vera M. Ripoll, Ian Mackie, Rachel Chambers, David A. Isenberg, Anisur Rahman, Yiannis Ioannou and Ian Giles. University College London, London, United Kingdom.

Background/Purpose: Antiphospholipid antibodies have been shown to bind serine proteases (SP) involved in the coagulation cascade. Previously, we found that IgG anti-Factor(F)Xa antibody levels were higher in patients with the antiphospholipid syndrome (APS) and patients with systemic lupus erythematosus (SLE) but no APS compared with disease and healthy control (HC) groups. Given that FXa has important haemostatic and cellular effects we hypothesized that anti-FXa antibodies may be important in the pathogenesis of APS and SLE. Therefore, we investigated whether differences exist in the avidity and functional effects of APS and SLE anti-FXa IgG upon the coagulant and cellular functions of FXa.

Methods: IgG was purified from patients with APS (n=15) and SLE (n=15) who had medium or high serum levels of anti-FXa binding and HC (n=10) negative for anti-FXa IgG. The avidity of IgG-FXa binding was measured under chaotropic conditions using a NaCl gradient. We measured effects of anti-FXa IgG on FXa-activated clotting time (ACT) and on FXa enzymatic activity in a chromogenic assay in the absence and presence of antithrombin (AT)III. Cellular effects of IgG on FXa-protease-activated receptor (PAR) mediated intracellular calcium release in human umbilical vein endothelial cells (HUVEC) were measured using the fluorescent image plate reader (FLIPR).

Results: All SLE-IgG displayed significantly lower (less than 25 % binding) avidity compared to APS-IgG (25–70% binding) to FXa at 0.13 to 1M concentrations of NaCl ($p<0.05$). The mean residual binding of APS-IgG to FXa was significantly higher than that of SLE-IgG below 2M NaCl (26 vs 13 %; $p<0.05$ at 1 M). FXa enzymatic activity was significantly reduced by APS-IgG (90%) and SLE-IgG (92 %) compared to HC-IgG (98 %) (APS vs HC $p<0.05$, SLE vs HC $p<0.05$, APS vs SLE $p=0.04$). ATIII mediated inhibition of FXa however, was significantly reduced by APS-IgG (62%) compared with HC (79%) and SLE (81 %) ($p<0.05$). The greatest prolongation of FXa-ACT was observed with APS-IgG followed by SLE-IgG and HC-IgG (74, 63 and 26 sec respectively). In cultured HUVEC, APS IgG caused significantly greater enhancement of FXa-mediated Ca^{2+} flux compared to SLE and HC-IgG at the same concentration (400 μg/ml) (APS vs HC $p<0.05$, APS vs SLE $p=0.03$) and this effect was reduced at lower IgG concentration (200 μg/ml).

Conclusion: FXa reactive IgG isolated from patients with APS displayed higher avidity binding to FXa and had greater functional effects upon FXa activity, ATIII mediated inhibition of FXa and FXa-PAR mediated signalling in cultured endothelial cells than SLE-IgG. Further work is now underway to further characterise the cellular effects of these anti-FXa IgG.

What Is The Prevalence Of Non-Criteria Antiphospholipid Antibodies in Patients With Antiphospholipid Syndrome? Veronica Rodriguez-Garcia[1], Yiannis Ioannou[2], D.A. Isenberg[2] and Ian Giles[2]. [1]Hospital Regional Universitario Carlos Haya, Malaga, Spain, [2]University College London, London, United Kingdom.

Background/Purpose: Increasing interest has focused upon assays which are not currently included in the Antiphospholipid syndrome (APS) classification criteria to detect antibodies directed against other phospholipids (PL), PL binding proteins, coagulation factors and a mechanistic test for resistance of Annexin A5 (AA5) anticoagulant activity. Therefore, we carried out a systematic review to try and establish the prevalence of each non-criteria assay in APS and control populations.

Methods: We searched PubMed and EMBASE using the keywords APS, antiphospholipid antibodies (aPL), non criteria, new assays, aCL, LA, anti-domain (aD)I, Ig A antiB2 GPI, antiphosphatidylserine (aPS), antiphosphatidylethanolamine (aPE), antiphosphatidic acid (aPA), antiprothrombin (aPT), antiphosphatidylserine-prothtombin (aPS-PT), anticardiolipin/vimentin (CL/Vm) and AA5 resistance. Each publication was systematically examined.

Results: We selected 15 (6 retrospective, 1 case-control and 8 cross-sectional studies from which we were able to extract original data on prevalence of non-criteria aPL in 1535 patients with APS and 1184 healthy and disease controls. We found the largest APS sample size from 3 studies of aDI, which found a prevalence of 34.26% of aDI in 645 patients with APS patients versus 3.3% in 30 healthy controls (HC). In reducing order of samples size. Three studies found an overall prevalence of 7.8% of IgM and 4.3% IgG aPE in 337 patients with APS compared with 3.9% IgM and 0.9% IgG aPE in 340 HC. IgA aCL were found in 37.46% of APS patients (n=262), 37.8% autoimmune disease (n=37) controls and 3.4% in healthy and atherosclerosis (n=527) controls. In contrast, 55% of 196 patients with APS were positive for IgA anti-B2GPI, versus 32.9% in 382 atherosclerosis and 13% in 145 healthy controls. The prevalence of AA5 resistance from 3 studies was 66.83% in 163 patients with APS compared with 0% in 80 HC. In 132 APS patients, 27.56% were positive for IgM aPT and 36% positive for IgG aPT versus 5% IgG and 0% IgM in HC.

All of the remaining studies contained less than 100 patients with APS. Studies of other non-criteria aPL identified: 24% IgM and 65.5% IgG aPA in 67 APS patients versus 0% IgM/G aPA in 104 HC; 36.6% IgM and 50.8% IgG aPS in 89 APS patients versus 1% IgM and 0% IgG aPS in 104 HC; 33.8% IgM and 38.8% IgG aPI in 89 APS patients versus 0% in HC; 25% IgM and 27.5% IgG aPS/PT in 44 APS patients versus 3% IgM and 0% IgG in 138 disease controls; and 80% IgM and 92.4% IgG anti-CL/Vm in 40 APS patients versus 0% IgM/G in 32 HC.

Conclusion: We found the highest prevalence of non-criteria aPL in the largest number of patients with APS in studies of AA5 resistance and aDI. Further prospective studies however are urgently required to confirm these findings.

Seizures In Systemic Lupus Erythematosus Are Not An Inflammatory Manifestation Of Lupus Anticoagulant. Michelle Petri and Hong Fang. Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: About 50% of SLE patients make an antiphospholipid antibody and 10% develop classic antiphospholipid syndrome. Seizures are one of the components of the SLICC classification criteria, and can occur due to SLE itself or secondary to stroke. Because seizures have been proposed as an inflammatory (non-thrombotic) manifestation of antiphospholipid antibodies, we determined whether seizures in SLE were associated with the lupus anticoagulant.

Methods: 2206 SLE patients were enrolled in a prospective cohort. Their mean age was 43 years; 93% were female, 55% Caucasian, 38% African-American and 7% other ethnicity. 27% had a history of lupus anticoagulant, 9% stroke and 10% seizures. The association of seizure with lupus anticoagulant and then excluding those with stroke was determined using chi-squared analyses. The lupus anticoagulant was determined by dRVVT with confirmatory testing.

Results: Table One shows the association of seizure with the lupus anticoagulant ($p = 0.0017$).

Table 1. Association between Lupus Anticoagulant and Seizure (All Patient Analysis)

	LA Pos (N=591)	LA Neg (N=1615)	P-value
Seizure	13.03%	8.54%	0.0017

Table 2 shows the association of seizure with the lupus anticoagulant, but excluding those with stroke. The p-value was 0.22.

Table 2. Association between Lupus Anticoagulant and Seizure (Excluding Those with Stroke)

	LA Pos (N=493)	LA Neg (N=1515)	P-value
Seizure	9.33%	7.59%	0.22

Conclusion: The apparent association of the lupus anticoagulant is explained by the association with stroke. Thus, seizures in the absence of stroke should not be attributed to the lupus anticoagulant. Seizures should not be added to the classification criteria for antiphospholipid syndrome.

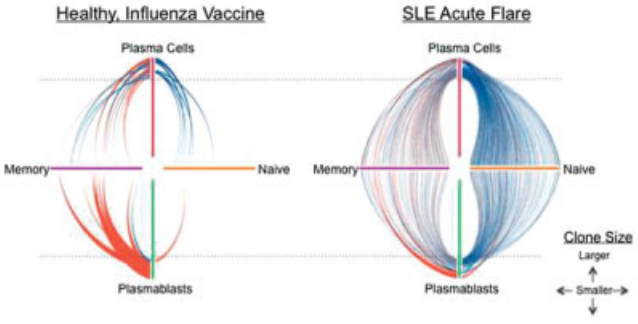
Plasma Cells In Acute Systemic Lupus Erythematosus Flares Are Characterized By a Highly Diversified Repertoire Accentuated By Clonal Expansions Of VH4-34 Antibodies. Christopher Tipton[1], Christopher Fucile[2], Alex Rosenberg[2], Scott Jenks[3], Jennifer Hom[1], F. Eun-Hyung Lee[1] and Inaki Sanz[1]. [1]Emory University, Atlanta, GA, [2]University of Rochester, Rochester, NY, [3]Emory University School of Medicine, Atlanta, GA.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease in which faulty B cell tolerance promotes the generation of multiple autoantibodies of which anti-ds DNA, anti-Sm and VH4–34-encoded 9G4 antibodies, are highly specific for this disease. Acute SLE flares are typically accompanied by a substantial expansion of circulating antibody-secreting plasmablasts (PB) and plasma cells (PC). Similar expansions of PB/PC populations in healthy subjects post-immunization are comprised of large clonal expansions of antigen-specific cells derived from pre-existing memory cells. To determine if SLE PB/PC expansions follow the same model, and to understand the diversity, origin and antigenic specificity of SLE PB/PC expansions, we used immunoglobulin heavy chain (IGH) deep sequencing to analyze sorted cells obtained from patients experiencing acute flares.

Methods: Peripheral blood lymphocytes were sorted into various B cell populations. Multiple VH family-specific primer sets were used to amplify the IGH gene from extracted RNA and then sequenced using the Illumina MiSeq platform. Sequences were analyzed using internally designed analysis software. Our software conducts quality filtering, detailed mutational analysis and identifies inter-population relationships between samples.

Results: PB/PC expansions in SLE acute flares are a highly diversified repertoire with lower VH mutation rates than memory cells. However, within this diverse pool significant clonal expansions accounting for 0.5% or more of the entire repertoire were regularly detected. Strikingly, VH4–34 sequences comprised the largest clones in all SLE samples. Also of interest, a substantial fraction of PB/PC in SLE were highly evolutionarily related to a pool of activated naïve precursors. This was in stark contrast to results obtained in PB/PC samples from healthy, vaccinated subjects, which contained large, clonal expansions, high VH mutation rates, were largely related to memory cells, and had an absence of autoreactive VH4–34 clonal expansions. Figure 1 shows clonal relationships between the top 20% of PB and PC sequences and Naive and Memory clones. Clones are arranged in increasing size from center to outer edge, and lines link matching clones.

Fig. 1



Conclusion: Combined, our data support a model of generalized naïve and memory activation underlying the activation phase of human SLE. This polyclonal activation is accentuated, and possibly promotes, antigen-selected clonal expansions dominated by VH4–34-encoded autoreactive 9G4 antibodies. Ongoing monoclonal antibody studies will clarify the nature of the selecting antigens.

SLE Flares Are Characterized By Generalized Polyclonal Expansions Of Antibody Secreting Cells Without Preference For Autoimmune Responses. H. Travis Ichikawa Emory University, Atlanta, GA.

Background/Purpose: Increased circulating antibody secreting cells (ASC), including both CD138- plasmablasts and CD138+ plasma cells (PB/PC), correlate with SLE activity and are prominent during Lupus flares. We tested whether this expansion is predominantly driven by typical SLE autoreactivities including anti-dsDNA, -Sm and -Ro and 9G4+ antibodies.

Methods: Peripheral blood lymphocytes (PBL) were collected from SLE patients (n=12; 4 mild-severe flare patients defined by SELENA-SLEDAI) with high serum levels of ≥1 autoantibody (anti-dsDNA, anti-Sm or anti-Ro). PB/PC frequency was calculated as % of total B-cells by flow cytometry. Anti-dsDNA, anti-Sm and anti-Ro60, 9G4+ and anti-microbial (anti-tetanus toxoid and anti-influenza) IgG ASC were detected by ELISPOT and expressed as % of total IgG ASC. Memory cells were activated by stimulation with R848 and IL-2 for 7 days. Frequencies of antigen specific IgG memory cells were determined by ELISPOT as before.

Results: PB/PC frequencies were increased for up to 25-fold in SLE compared to HC and comprised up to 38 % of total B-cells. Of total IgG ASC, frequencies of each SLE specific IgG ASC responses (anti-dsDNA, anti-Sm and anti-Ro60) never exceeded 3.4% (mean ± SD, 0.25 ± 0.65%) in patients with high serum antibody levels. 9G4+ ASC, which include several SLE-specific autoreactivities including anti-dsDNA and anti-apoptotic cells, were the most abundant autoreactivity but did not exceed 6% (mean ± SD, 2.2 ± 1.7%). Combined, all the lupus–related autoreactivities accounted for <10% of all IgG ASC. No correlation was found between PB/PC frequencies and SLE specific or 9G4+ IgG ASC frequencies. Furthermore, anti-Tetanus and/or anti-influenza ASC, usually not found in healthy PBL, were found in SLE PBL in frequency similar to autoreactive responses (0.06 ± 0.09% and 0.37 ± 0.12%, respectively). Anti-Sm, anti-Ro and 9G4 as well as anti-tetanus and anti-influenza reactive IgG memory cells were present in frequencies typically higher than that found for ASC of the same antigenic reactivity. Notably, in 5 out of 6 patients with high anti-Ro serum titers, anti-Ro IgG memory cells represented > 2% of all IgG memory cells. In contrast, anti-dsDNA IgG memory cell frequencies (0.01 ± 0.02%) were as low as anti-tetanus memory cell frequencies (0.12 ± 0.31%).

Conclusion: Combined, conventional lupus autoreactivities only account for <10% of the greatly expanded numbers of circulating ASC characteristic of lupus flares. In addition, these frequencies are lower than the frequency of memory cells for the corresponding autoantigens. Moreover, antimicrobial responses are present in circulating ASC with frequencies similar to autoimmune responses. While our studies did not test for other potential SLE autoreactivities, our results are consistent with a polyclonal expansion of ASC during lupus flares that is not predominantly driven by conventional autoantigens even in patients with high titers of serum antibodies. These studies have important implications for our understanding of the mechanisms underlying lupus flares and the contribution of different cellular compartments to the generation of serum autoantibodies at different times in the course of the disease.

Autoantibodies Directed Against Cell Surface Components In Autoimmune Disease Patients: Proposal Of a Novel ELISA For The Detection Of Anti-Endothelial Cell Antibodies. Keiji Miura[1], Ayako Kondo[2], Kazuo Takahashi[2], Daisuke Hirano[2], Yoshiyuki Hiki[1], Shunji Yoshida[2], Yukio Yuzawa[2] and Yoshikazu Kurosawa[1]. [1]Fujita Health Universtiy, Toyoake, Japan, [2]Fujita Health Universtiy School of Medicine, Toyoake, Japan.

Background/Purpose: Sera from patients with systemic vasculitis or inflammatory conditions have been reported to contain antibodies that bind to endothelial cells (EC), i.e., AECA (anti-endothelial cell antibodies). AECA are known to play immunogenic effects by triggering EC activation and vascular damage, but the immunopathological role of AECA is not clear. SDS-PAGE and Western blotting have previously been used for detecting target antigens of AECA. However, we assumed that these methods are not appropriate for searching genuine target antigens on cell surface, and developed a novel solubilized cell surface protein-capture ELISA (CSP-ELISA).

Methods: Antigens were obtained as cell surface proteins from the plasma membrane of human umbilical vein endothelial cells (HUVEC); these

cell surface proteins were biotinylated, solubilized with detergent, and captured on ELISA wells coated with NeutrAvidin biotin binding protein. AECA titers in serum from 126 autoimmune disease patients and 122 healthy controls (HC) were tested. Additionally, sera from 52 patients with biopsy-proven lupus nephritis (LN), 25 with systemic lupus erythematosus (SLE) without renal involvement (non-LN SLE), 10 disease controls (DC) and 81 healthy controls were tested for IgG- and IgA-AECA to human glomerular EC (HGEC) by CSP-ELISA.

Results: IgG-AECA were detected in 28 of 36 (78%) of SLE patients; in 13 of 16 (81%) of mixed connective tissue disease (MCTD) patients; in 5 of 9 (56%) of systemic sclerosis (SSc); and in 4 of 122 (3%) of healthy controls. Relatively weak denaturation of antigens on ELISA wells caused loss of binding of these autoantibodies. Titers of IgG- and IgA- AECA to HGEC were significantly higher in LN and non-LN SLE patients than in the combined DC and HC ($P < 0.001$) groups. The level of IgG-AECA did not correlate with active lesions, but the level of IgA-AECA to HGEC did correlate with histological evidence of active lesions in LN patients ($P < 0.001$). Immunocytochemical analysis showed AECA recognized membrane proteins on HGEC. The significant correlation of titer of AECA to both HGEC and HUVEC ($R = 0.95$ for IgG-, 0.93 for IgA-AECA, respectively) indicated AECA in LN patients recognize membrane proteins expressed on HGEC and HUVEC. To identify specific antigens against AECA, biotinylated CSPs were incubated with sera from LN patients with high titers of IgG-AECA, immunoprecipitated with immobilized protein G followed by immobilized avidin, and blotted with NeutrAvidin. A 150-kDa protein band that shifted to a 55-kDa protein band under reducing conditions was detected in patients with LN, but not in HC.

Conclusion: This newly developed CSP-ELISA method enables the detection of antibodies to the labile epitopes of autoantigens such as membrane proteins, and this method is generally applicable to various kinds of membrane proteins and the antibodies against them. IgA-AECA was observed to be associated with pathological activity in LN. These EC membrane components recognized by AECA may be linked with the pathogenesis of LN. We propose CSP-ELISA for measuring AECA in serum samples for routine laboratory testing.

Specificity Of Autoantibodies In Patients With Rheumatologic Inflammatory Syndrome Following Mineral Oil Injections Is Similar To Those In Mice With Adjuvant Mineral Oil-Induced Autoimmunity. Minoru Satoh[1], Olga Vera-Lastra[2], Claudia Martínez[3], Jesús Sepulveda- Delgado[3], Luis J. Jara[4], Raúl Vargas-Ramírez[5], Beatriz Teresita Martin-Marquez[6], S. John Calise[1], Edward K.L. Chan[1] and Monica Vázquez-Del Mercado[7]. [1]University of Florida, Gainesville, FL, [2]MD, Mexico City, Mexico, [3]Hospital de Especialidades Centro Médico Nacional La Raza, IMSS, Mexico City, Mexico, [4]Hospital de Especialidades Centro Medico La Raza, México City, Mexico, [5]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Universidad de Guadalajara, Guadalajara, Jalisco, México, Mexico, [6]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Guadalajara, Mexico, [7]Universidad de Guadalajara, Guadalajara, Jalisco, México, Mexico.

Background/Purpose: Intraperitoneal injection of pristane or adjuvant mineral oil (incomplete Freund's adjuvant) in non-autoimmune strains of mice mainly induces autoantibodies to U1RNP and Su/argonaute2 (Ago2). Injection of mineral oil as a cosmetic procedure has been commonly performed in certain countries including Mexico, however, inflammatory syndrome among these subjects have been reported. In the present study, autoantibody specificity in patients who had mineral oil injection and inflammatory syndrome were examined and compared with data from animal models

Methods: Twenty-one cases of patients, who had mineral oil injections (17 buttocks, 9 breast, 5 thigh, 2 legs, 1 face) and developed rheumatologic symptoms after mineral oil injections were studied. Autoantibodies were tested by immunofluorescence antinuclear antibodies (ANA) using HEp-2 slide, immunoprecipitation (IP) of ^{35}S-methionine-labeled cell extract and anti-Ro52 and U1RNP-70kD ELISA. Autoantibody specificities were compared with those in BALB/cByJ mice that received a single 0.5 ml intraperitoneal injection of adjuvant mineral oils (incomplete Freund's adjuvant or pristane). Clinical information was from medical record

Results: By immunofluorescence ANA, 62% (13/21) were positive in nuclear (5 cases), nucleolar (3 cases), mitochondria-like (3 cases), or GW bodies (2 cases) pattern. By IP, one had anti-U1RNP, 2 had anti-Su/Ago2 (both had GW body staining in ANA) and 3 had anti-Ro60. Two were positive by anti-Ro52 ELISA and one was positive in anti-U1RNP-70kD ELISA (positive for U1RNP by IP). Among 6 cases with these autoantibodies (2 had more than one), a case with anti-Su+Ro52 had a diagnosis of SLE, however, other 5 cases had non-specific rheumatological symptoms only. It is of interest that anti-U1RNP and –Su/Ago2 that are the main autoantibody specificity induced by adjuvant mineral oils in animal models, was also seen in mineral oil injected human subjects. Prevalences of these antibodies was not as high as pristane-treated mice but similar to those in adjuvant mineral oil-injected mice.

Conclusion: Patients with rheumatologic inflammatory syndrome after mineral oil injections have autoantibody specificity similar to those in mice with adjuvant mineral oil-induced autoimmunity (anti-U1RNP and Su/Ago2). In addition, they also developed anti-Ro60 and Ro52.

Table. Prevalence of autoantibodies by immunoprecipitation

	Human	BALB/cByJ mice	BALB/cByJ mice
Chemical injected	Mineral oil	Adjuvant mineral oil (incomplete Freund's adjuvant)	pristane
Site of injection	buttocks, breast, thigh, leg, face	intraperitoneal	intraperitoneal
Features	rheumatologic symptoms		immune complex glomerulonephritis
N =	21	20	20
Anti-U1RNP	4%	10%	55%
Anti-Su/Ago2	10%	10%	45%
Anti-U1RNP or Su	14%	20%	85%
Anti-Ro60	14%	0%	0%

Differentiation, Activation, and Autoreactivity Of CD11c+ B Cells (ABCs). Alice E. Wiedeman, Natalia V. Giltiay, Lena Tanaka and Keith B. Elkon. University of Washington, Seattle, WA.

Background/Purpose: Recently, a population of CD11c+ age-associated B cells (ABCs) was identified in normal aged female mice. These cells could be expanded following activation by TLR7 agonists and their presence was associated with autoantibody production. The goals of the current study were to determine: a) when ABCs develop during B cell maturation in the spleen; b) how B cell intrinsic and extrinsic factors influence ABC generation; and c) how TLR7 expression influences ABC generation in a B cell receptor (BCR) transgenic (Tg) mouse with specificity for RNA (the TLR7 ligand).

Methods: Knock-in mice that overexpressed TLR7 on a B6 background (TLR7 Tg) were crossed with either IFNaR knockout (KO), RNAse Tg, HEL-specific BCR Tg, or RNA specific BCR Tg (H564) mice. Mixed chimeras were generated with combinations of wildtype B6 and TLR7 Tg bone marrow. Flow cytometry was used to identify splenic B cell subsets and analyze CD11c expression. CD11c+ (ABCs) and CD11c- (non-ABCs) B cells were sorted using a BD FACS Aria, and cultured for 6d with or without TLRs 4, 7, or 9 agonists. Ig production was quantified by ELISA.

Results: While in wildtype mice, CD11c+ ABCs were increased only in females greater than 6 months of age, TLR7 Tg mice had significantly expanded ABCs as young as 3 months in both males and females (1.1 ± 0.2 % in B6 versus 3.4 ± 1.1 % in TLR7 Tg, $p < 0.003$). ABC accumulation was greatest in the transitional B cell stages but the relative proportion of ABCs was also higher in marginal zone than follicular B cells. To address whether generation of ABCs was intrinsic or extrinsic we used WT:TLR7 Tg mixed bone marrow chimeras, and observed that ABC expansion of TLR7 Tg B cells had a definite cell-intrinsic component. However, when TLR7 Tg mice were crossed with RNAse Tg or IFNaR KO mice to remove the RNA ligand or response to IFN-I respectively, ABCs were modestly but statistically significantly reduced. In TLR7 Tg mice, serum levels of anti-RNA autoantibody correlated with % ABCs in spleen and we also observed that ABCs produced more antibody (including anti-RNA autoantibodies) in response to innate stimulation in vitro. Consistent with these findings, crossing TLR7 Tg and autoreactive H564 BCR mice further increased ABC accumulation, while

crossing to an HEL mouse resulted in expansion of ABCs in the polyclonal but not in the HEL-specific subset.

Conclusion: CD11c+ ABCs are B cells that appear early during B cell maturation, and are increased under conditions of TLR7 hyperreactivity. ABC generation is, in part, cell intrinsic but is also influenced by exposure to self antigen and to IFN-I. ABCs can be directly implicated in autoantibody production by comparing antibody concentrations following stimulation of ABCs and non-ABCs in vitro as well as by enhanced ABC expansion in a TLR7 Tg mice that has specificity to self antigen (RNA) but not to non-self (HEL). Since these results suggested that ABCs, at least in part, contribute to autoantibody production, CD11c+ B cells may be a good target for amelioration of autoimmunity without broadly impairing host defense.

A Novel CD27$^{(-)}$ B-Cell Subset Identified Based On Intracellular Characteristics Is Expanded In SLE. S.J. Fleischer[1], Capucine Daridon[2] and Thomas Dörner[3]. [1]Charité University Medicine Berlin, Berlin, Germany, [2]Charité University Medicine / German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany, [3]Charité university medecine/ German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany.

Background/Purpose: Several studies linked the emergence of autoimmunity to abnormalities of the B-cell receptor (BCR) due to disturbances of signaling molecules or its co-receptors. Therefore this study focused on spleen tyrosine kinase (Syk), a key molecule of early BCR signaling in autoimmunity. Our model is systemic lupus erythematosus (SLE) which is an autoimmune disease known to be associated with a breakdown of self-tolerance resulting in auto-antibody production, B-cell hyper-reactivity and disturbed B-cell homeostasis of peripheral B-cell subsets.

Methods: Peripheral blood was taken from 31 healthy, 61 SLE patients, 15 patients with rheumatoid arthritis (RA) and 16 primary Sjögren's syndrome (pSS) patients. The expression of Syk and basal / BCR-induced phosphorylation of Syk by B-cells were studied by phosphoflow analysis. To assess the localization of Syk within B-cells, immunofluorescence was performed and analyzed by confocal microscopy. In addition, characterization of B-cells was evaluated by flow cytometry using the following markers CD19, CD20, CD27, CD38, IgD, CD95 and Ki67. Finally, the capacity of B-cells to differentiate into antibody producing cells was evaluated by flow cytometry and Elispot after 5 days of *in vitro* culture.

Results: In this study, two different subsets according their expression of Syk (Syk^{bright} and Syk^{dim}) within the CD20^{+}CD27$^{(-)}$ population have been identified. The frequency of CD27$^{(-)}$Syk^{bright} B-cells were significantly increased in SLE compare to HD, however the disease activity (SLEDAI) do not correlate with the frequency of this subset. No significant increase in the frequency of this population was observed in others autoimmune diseases (*i.e.* RA and pSS). This subset showed an accumulation of Syk within the cytoplasm, a superior response to the BCR and plasma cell differentiation compared to CD27$^{(-)}$ Syk^{dim} B-cells. Finally, this subset exhibited a memory-like phenotype.

Conclusion: A novel subset of B-cells defined as CD27$^{(-)}$Syk^{bright} B-cells and carrying memory features has been identified in SLE patients. This population represents a prime candidate how peripheral check point control of conventional B cells can be possibly bypassed in SLE.

Gene Expression Profiling Analysis Of Human B-Cell Subsets In Health and Systemic Lupus Erythematosus. Chungwen Wei[1], Edward Ramos[1], Norm Allaire[2], Suzanne Szak[2], Susan Kalled[2], Ann Ranger[2] and Ignacio Sanz[1]. [1]Emory University, Atlanta, GA, [2]Biogen Idec Inc, Cambridge, MA.

Background/Purpose: SLE is an autoimmune disease, which exhibits multiple B cell abnormalities including expanded populations of plasmablasts and DN memory cells as well as a contracted unswitched memory subset. The transcriptional profiles that underlie these homeostatic changes are poorly understood. To remedy this knowledge gap and generate insight into the disease pathogenesis, we carried out transcriptome analysis of sorted B cell subsets.

Methods: B cell subsets were flow sorted from 12 healthy controls (HC) and 13 SLE patients with low disease activity (SLEDAI<6): naïve (IgD^{+}CD27^{-}), unswitched memory (IgD^{+}CD27^{+}), switched memory (IgD^{-}CD27^{+}), DN memory (IgD^{-}CD27^{-}) and plasmablasts (IgD^{-}CD27^{++}CD38^{++}). Total RNA was hybridized to Human Genome U133 Plus 2.0 GeneChip (Affymetrix). The scans were subjected to quality control measures and the resulting CEL files normalized with Robust Multi-array Average (RMA). All calculations and analyses were carried out using R/Bioconductor computational tools. To identify differentially expressed genes (DEGs) between groups of samples, a two-way ANOVA model using Method of Moments was applied. Gene that exhibited a FDR <0.05 and fold change >2 or <-2 were considered significantly different.

Results: Overall, there are fewer DEGs among the three memory B cell subsets than between naïve and each of the three memory subsets in both healthy subjects and SLE patients, suggesting that the gene expression program is quite similar among all the memory B cells in HC and SLE. IL4R and IL21R are upregulated in naïve cells whereas IL6R is over-expressed in memory cells. Also upregulated in naïve cells is TCL1A, which promotes Akt-mediated survival. TACI is upregulated in the switched and unswitched memory subsets compared to naïve cells in HC and SLE, and is higher in SLE DN B cells compared to the same population in HC. SLE DN cells had also higher levels of AICDA and FcRL4. Overall, most DEGs differentials between the two cohorts were identified in the DN subset. Within either cohort, thousands of DEGs were observed between plasmablasts and the other four B cell subsets.

Conclusion: The transcriptome of multiple B cell subsets was remarkably similar between HC and SLE patients with low disease activity suggesting that most differences in active disease may be due to extrinsic differences. Our results are consistent with the important role of IL-4 and IL-21 as growth factors for naïve cells and the known activity of IL-6 in memory differentiation into plasma cells. Of great interest is the upregulation of TACI, AICDA and FcRL4 in DN B cells, a population expanded in SLE. The implications for the potential germinal center origin and activation status of these cells, reported to represent exhausted cells in HIV infection, will be discussed.

IgD- CD27- B Cells From Systemic Lupus Erythematous Patients Have Increased Expression Of Genes Involved In RNA Sensing and Toll-Like Receptor 3 Signaling Pathways. Scott Jenks[1], Edward Ramos[2] and Ignacio Sanz[1]. [1]Emory University School of Medicine, Atlanta, GA, [2]Emory University, Atlanta, GA.

Background/Purpose: SLE patients have perturbations in B cell subsets including a large expansion of IgD-CD27- B cells (DN) in patients with active disease. Patients also have changes in PBMC gene expression, particularly increased expression of interferon regulated genes (IRG). However, data on gene expression in SLE B cells is limited. The purpose of this study was to understand the function and potential dysregulation of DN in SLE by comparing differences in gene transcription between B cell subsets from SLE patients and healthy control donors (HCD).

Methods: RNA was isolated from B cells from 3 HCD and 3 SLE patients with elevated DN sorted into naive (IgD+CD27-CXCR5+), switched memory (IgD-CD27+CXCR5+), and DN (IgD-CD27-CXCR5-) subsets. After amplification, high throughput sequencing of cDNA was used for transcriptional expression profiling. Sequencing data was processed and analyzed using the Tuxedo suite and EdgeR software package. Genes were tested for differential expression using a three way ANOVA model.

Results: 115 of the 249 genes differentially expressed in B cells between SLE patients and HCD were IRG. In addition to previously defined IRG, pathway analysis found several genes involved in TLR-3 and RNA sensing signaling pathways. These included RNA sensing molecules RIG1 and MDA5, downstream kinases IKBKE and TBK1, kinase substrate and transcription factor IRF-7, and HERC5 and TRIM21, molecules that regulate IRF stability. Of these only IRF-7 has been previously described as differentially expressed in SLE B cells. While, expression for most genes was increased in all B cell subsets, the DN subset showed the largest increase in expression for all genes except IKBKE and TRIM21. The DN subset also had increased expression and differential splicing of TOLLIP, an inhibitor of MyD88 mediated TLR signaling.

Conclusion: IKBKE and TBK1 are key signaling kinases for detecting RNA through the TLR3 and MDA5/RIG1 pathways. These pathways detect viral RNA but are also activated by endogenous RNA from apoptotic cells. Increased expression of IKBKE and TBK1 in SLE B cells is accompanied by the expression of both the upstream receptors and downstream kinase substrate. Furthermore, while TRIM21 mediates degradation of IRF-7, expression of TRIM21 was lowest in the DN and these cells expressed high levels of HERC5, which prevents IRF degradation. Coordinated expression of these genes strongly suggests these pathways are more active in SLE B cells and particularly in the DN population. In SLE, RNA from apoptotic cells can be internalized in RNP and Ro60 immune complexes through Fc receptors(FCR) and are thus available to MDA5/RIG1 and TLR-3. DN express high levels of FCR. This combined with increased expression of these signaling molecules likely results in RNA antigens having a powerful pro-inflammatory influence on DN.

Understanding The Stimulatory Pathways Responsible For Naïve B Cell Activation In Systemic Lupus Erythematosus. Emily Blalock, Chris Scharer, Scott Jenks, Jeremy Boss and Ignacio Sanz. Emory University School of Medicine, Atlanta, GA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a recurrent autoimmune disease characterized by multiple B cell abnormalities, including the activation of naïve B cells. However, gaps in terms of our knowledge regarding the extent and mechanisms of activation remain. We therefore investigated the expression of activation markers on activated naïve (aN) and resting naïve (rN) B cells of SLE patients as well as the stimulatory pathways responsible for their expression.

Methods: Multidimensional flow analysis was utilized to determine levels of B cell activation markers including CD21, CD23, CD24, CD25, CD69, CD80, CD83, CD86, and IgM on aN and rN B cells of SLE patients with active disease versus healthy controls (HC). In addition, total PBMCs from SLE and HC patients were stimulated *ex vivo* with B cell receptor (anti-kappa or anti-lambda), T cell (CD40L), or cytokine stimulation for 16 h, 48 h, and 4 days and compared via flow analysis. Lastly, we compared the epigenome of SLE aN and rN by analyzing their genome-wide DNA methylation status using MeDIP-Seq.

Results: Compared to HC, aN B cells, globally defined by Mitotracker green retention, from SLE patients exhibited low levels of CD21, CD24, CD69, and CD83, while CD86 levels were up-regulated. Following stimulation, aN B cells of SLE patients exhibited increased levels of CD21, CD25, CD69, CD80, CD83, and CD86 and decreased levels of CD24 at 16 h post-stimulation. Levels of CD21 and CD25 decreased at 48 h, followed by CD83 levels on day 4 post-stimulation. Expression of CD69, CD80, and CD86 remained high at all time points. However, aN B cells of SLE patients exhibited differential expression of CD23 and IgM based on stimulation type. Global DNA methylation analysis of aN B cells from an SLE patient revealed several genes, including interferon-regulated genes, were hypomethylated when compared to the HC. Interestingly, the CD83 gene was hypermethylated in aN B cells of the SLE patient; a result consistent with low CD83 levels observed via flow staining and RNASeq transcriptional analysis performed on several SLE patients.

Conclusion: Activated naïve B cells of SLE patients differentially express activation markers including CD21, CD24, CD83, and CD86. The stimulation of total PBMCs through distinct pathways reveals that activation markers are temporally expressed on aN B cells of SLE patients only to decrease with prolonged stimulation, as would be expected *in vivo*. Epigenetic analysis indicated hypermethylation of CD83, a result consistent with flow and transcriptional studies. Decreased expression of CD83 could help explain several phenotypic characteristics of lupus B cells including: decreased marginal zone maturation, decreased IL-10 production, and increased Ig secretion [1, 2]. Our results provide important clues regarding abnormal B cell function, highlighting the power of integrated experimental approaches to address this problem.

B Cell Receptor Signaling As A Potential Clinical Parameter In Lupus. Michael Faludi, Christian A. Pineau, Evelyne Vinet, Ann E. Clarke, Sasha Bernatsky, Joyce Rauch and Emil P. Nashi. McGill University Health Center, Montreal, QC.

Background/Purpose: B cells are central to SLE. Signaling through the B cell receptor (BCR) controls critical processes at various stages of B cell development. Murine BCR manipulation and human genomic studies have implicated the BCR pathway in SLE, but few studies have assessed this pathway in patients.

Methods: Ethics committee approval was obtained. Blood lymphocytes were isolated from patients with SLE and other autoimmunities, and normal controls; cells were frozen in liquid nitrogen. Detailed clinical parameters were obtained. 100 000 B cells were stimulated with 20 ug/mL anti-IgM and anti-IgG for 0 or 5 minutes, and a 10-color flow cytometry panel was used to identify the following B cell subsets: naïve mature, transitional, IgM memory, IgG memory, IgG B1 and IgM B1. We assayed surface BCR levels, pSyk (early signaling), pPLC-γ2 (mid-point), pERK1/2 (late) and carboxy-pLyn (regulation). Triplicates of each assay, daily bead-based voltage adjustment, and replication of all experiments on separate days ensured signal stability.

Results:

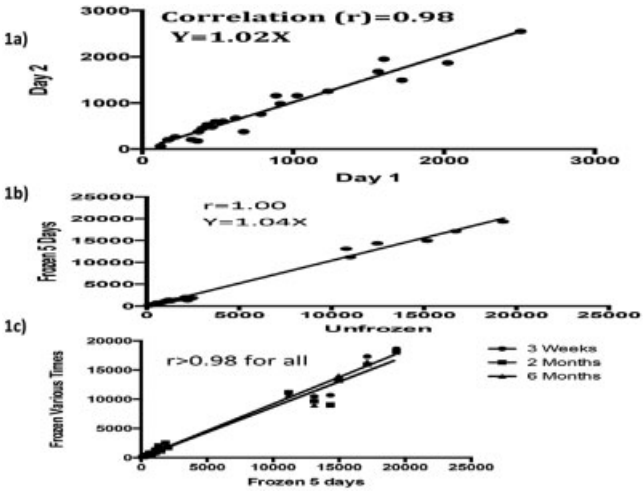

Fig 1. Stability of BCR signal. We found consistently high correlation between assays run on separate days (1a), between frozen and unfrozen cells (1b) and cells obtained at various times from the same person (1c). Each dot represents the fluorescence of one signaling parameter in a specific B cell subset.

2a)

pERK1/2	Transitional	IgM Memory	IgG Memory
Patient 1	1390 ↑	1200 ↓	1625 ←→
Patient 2	1244 ↑	1038 ↓	1613 ←→
Patient 3	1124 ↑	993 ↓	1718 ←→
Average for all patients	938	1859	1782

2b)

Transitional B cells	IgM	pSyk	pPLC-g2	pERK1/2
Patient 1	27334	381	1047	1390
Patient 2	16643	427	767	1895
Patient 3	16014	196	558	760
Average for all patients	17056	229	602	938

Fig 2. The importance of studying different B cell subsets and BCR stages. Some patients had increased signal in one subset but decreased or normal in other subsets (2a). Signaling deviation can occur at different stages (2b, yellow highlights).

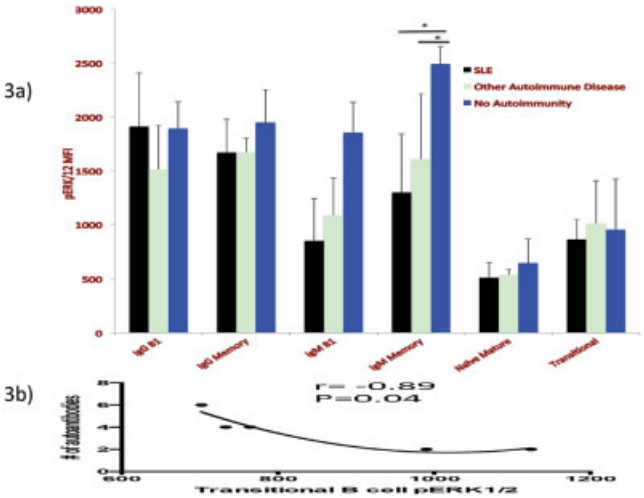

Fig 3. Signaling in 15 patients. Diminished IgM Memory BCR signal was found in SLE and other autoimmunities versus controls (3a). Among SLE patients, diminished signal in transitional B cells correlated with increased number of autoantibody specificities (3b).

Conclusion: We have optimized a flow cytometry-based technique that allows simultaneous study of BCR signaling in B cell subsets, at various stages of signaling, in a manner that yields stable results over time. We found that diminished BCR signaling in transitional B cells correlates with increased diversity of autoantibodies in SLE patients. We will study 150 patients. Clinical BCR measurement may inform SLE pathogenesis and guide emerging BCR-targeted therapies.

Dichotomous Responses Of Human Systemic Lupus Erythematosus B Cell Subsets To B Cell Receptor Stimulation. Franziska Matzkies, Anthony DeFranco, Andrew J. Gross, Maria Dall'Era and Michelle Hermiston. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Autoantibody production is a hallmark of Systemic Lupus Erythematosus (SLE), supporting a central role for B cells in disease pathogenesis. Prior studies have demonstrated augmented B cell receptor (BCR) signaling in a subset of SLE patients relative to healthy controls (HC). Both B cell intrinsic factors such as aberrant signal network wiring and B cell extrinsic factors such as excessive cytokines have been implicated in loss of B cell tolerance and B cell hyperactivity. However, previous studies have generally examined these parameters in total peripheral blood B cells rather than in well defined subpopulations. This is an important distinction because BCR signaling in mature naive B-cells leads to proliferation and survival, while these same signals lead to receptor editing, depletion or anergy in immature cells. We hypothesize that dysregulation of these signaling networks could contribute to SLE pathogenesis.

Methods: Peripheral blood was obtained from 12 patients satisfying ACR SLE criteria and 12 HC that lacked a family history of autoimmune disease. To minimize confounding influences of cytokines, patients had low disease activity (SLEADI$<$5). B cells were enriched with RosettespTM and ficoll, rested at 37°C for 1 hr, stimulated with 10 μg/ml (low dose) or 50 μg/ml (high dose) of F(ab')2 goat anti-human IgM or phorbal 12-myristate 13-acetae (PMA), immediately fixed, and processed for flow cytometry. Phosphorylation of intracellular signaling proteins (pSyk, pPLCg, pERK, pAKT, pS6) in transitional ($CD20^{+}CD27^{-}CD24^{Hi}CD38^{Hi}$) and naïve ($CD20^{+}CD27^{-}CD24^{Int}CD38^{Int}$) B cells was measured using FlowJo 8.8.7 and Cytobank software.

Results: The basal phosphorylation states of Syk, ERK, PLCg, and S6 were increased in both transitional and naïve B cells of SLE patients relative to HCs. Upon BCR ligation, both transitional and naïve SLE B cells demonstrated augmented phosphorylation of SYK, ERK, and PLCg relative to HC. Surprisingly, these same patients displayed hypo-phosphorylation of S6 in response to the same stimuli. Interestingly, hypo-activation of S6 was observed in mature naïve but not transitional B cells. The response to stimulation with PMA, which bypasses proximal signaling machinery, was equivalent in SLE and HC B cell subsets, indicating that the difference in signaling was upstream of S6.

Conclusion: We find that both transitional and naïve B cells obtained from SLE patients with well-controlled disease have increased activation of the MAPK pathway in the basal state and in response to BCR stimulation. Phosphorylation of S6, which is downstream of the PI3K/AKT/mTOR pathway, is also elevated in the basal state in SLE B cell subsets, but surprisingly *hypo*phosphorylated in naïve mature but not transitional B cells in response to BCR ligation in these same patients. While S6 is a target of the PI3K pathways after BCR ligation, it also receives inputs through growth hormone and cytokine receptors as well as the mTOR complex, which plays a key role in sensing energy and nutritional levels. Current investigations are under way to identify the mechanisms mediating these observations and their relation to SLE pathogenesis.

Defective Regulatory Function Of Granzyme B-Producing B Cells In Patients With Systemic Lupus Erythematosus. Naoko Ueki, Hiroaki Niiro, Shun-ichiro Ota, Hirofumi Tsuzuki, Siamak Jabbarzadeh-Tabrizi, Yuri Hirosaki, Kumiko Noda, Naoyasu Ueda, Atsushi Tanaka, Masahiro Ayano, Sho Ueda, Satomi Hisamoto, Daisuke Oryoji, Mitsuteru Akahoshi, Yojiro Arinobu, Hiroshi Tsukamoto, Takahiko Horiuchi and Koichi Akashi. Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan.

Background/Purpose: The efficacy of B-cell depletion therapy highlights a pathogenic role of B cells in autoimmune diseases. In certain conditions, elimination of B cells can lead to exacerbation of these diseases, suggesting the existence of regulatory B cells (Bregs). Bregs are often referred to as IL-10-producing B cells, however it is possible that Bregs can exert a regulatory function by an IL-10-independent mechanism. Granzyme B (GzmB) is known to exert both cytotoxic and non-cytotoxic effects on various cell types. In this study, we have determined whether granzyme B (GzmB)-producing B cells could function as another type of Bregs in humans, and also have tested their functions in patients with systemic lupus erythematosus.

Methods: Levels of GzmB mRNA and protein in B cells were assessed using quantitative real-time PCR and intracellular staining, respectively. To evaluate the function of GzmB-producting B cells, they were co-cultured with activated T cells, and growth, survival and cytokine production of T cells were then assessed using flow cytometry.

Results: Among the stimulators tested, IL-21 was the potent inducer of GzmB in normal B cells and it acted synergistically with antigen receptor stimulation. Naive B cells produced higher levels of GzmB as compared with memory B cells. In addition, GzmB-producing B cells inhibited the growth, survival and cytokine production of T cells, which is in line with the idea that these cells function as Bregs in normal subjects. In SLE patients, naive B cells similarly produced more GzmB than memory B cells, however levels of its production in both subsets were apparently higher than those in normal subjects. Intriguingly, however, GzmB-producing B cells in SLE patients were without regulatory effects on T cell functions. A molecular explanation for these findings is now in progress.

Conclusion: Our current findings could help to better understand a role of Bregs in the pathogenesis of autoimmune diseases as well as to provide a novel clue to manipulate the generation of Bregs for therapeutic application in the future.

IFN-α Induces Altered Transitional B Cell Signaling and Function In Systemic Lupus Erythematosus. Joan E. Wither[1], Nan-Hua Chang[2], Timothy Li[2], Julie Kim[2], Carolina Landolt-Marticorena[3], Paul R. Fortin[4], Dafna D. Gladman[5] and Murray B. Urowitz[5]. [1]Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON, [4]Centre de Recherche du Chu de Québec et Université Laval, Quebec City, QC, [5]University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Previous experiments suggest that the B cells of lupus patients are hyper-responsive to B cell receptor engagement resulting in increased tyrosine phosphorylation and Ca^{2+}mobilization. However the precise B cell populations that are affected and the mechanisms leading to this hyper-responsiveness have yet to be determined. In this study we have used Phosflow to address these questions.

Methods: PBMC were isolated from 27 healthy controls and 39 SLE patients with $\geq$ 4 ACR criteria. Phosflow was used to assess the levels of p-SYK, p-PLCγ2, or p-ERK following Ig receptor engagement with goat anti-human IgM $F(ab')_2$in distinct B cell subsets defined by anti-CD19,-CD27, -IgD, -IgM and -CD38. B cell proliferation and apoptosis following anti-IgM stimulation were assessed by flow cytometry, using CFSE and annexin V staining, respectively. For some experiments, healthy control B cells were incubated with IFN-α, or 50% plasma $\pm$ anti-IFN or irrelevant Ab. Lupus associated SNPs were determined by TaqMan genotyping.

Results: There were increased basal levels of p-SYK and p-ERK in naïve B cells ($CD19^+CD27^-IgD^+$) from lupus patients as compared to controls. The levels of basal p-SYK correlated with CD86 expression suggesting that these cells had already been activated in-vivo. Following crosslinking with anti-IgM, there was a significant increase in the proportion of p-SYK^+ cells above basal levels in the naïve B cell population of lupus patients as compared to controls. Similar trends were seen for the proportion of p-PLC$\gamma2^+$ and p-ERK^+ cells. The increases seen in p-SYK^+ cells were most marked for the transitional B cell subset ($CD19^+CD27^-IgD^+CD38^{hi}IgM^{hi}$), where the levels of p-SYK correlated with enhanced proliferation and survival. There was no correlation between lupus associated SNPs in BLK, LYN, PTPN22, and CSK, and the proportion of p-SYK^+ cells following IgM crosslinking. The proportion of p-SYK^+cells in the transitional B cell subset fluctuated between visits, suggesting a possible role for pro-inflammatory factors. Consistent with this, incubation of lupus plasma with control B cells enhanced SYK phosphorylation following IgM crosslinking, which was blocked by pre-incubation of plasma with anti-IFN but not irrelevant Ab. Incubation of healthy control cells with recombinant IFN-α enhanced SYK phosphorylation, proliferation, and survival following IgM crosslinking, particularly of the transitional B cell subset.

Conclusion: IFN-α alters transitional B cell function leading to enhanced survival and proliferation. As purging of transitional B cells plays an important role in preventing autoreactive B cells from entering the mature B cell pool, it is likely that elevated levels of IFN-α exacerbate the breach of B cell tolerance in lupus.

Follicular Entry Of Lymphotoxin-Expressing B Cells Via Type I Interferon Disrupts Marginal Zone Barrier Integrity and Exacerbates Systemic Autoimmunity. Hao Li[1], Hui-Chen Hsu[2], Qi Wu[1], Jun Li[1], PingAr Yang[1], Yang-Xin Fu[3] and John D. Mountz[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Birmingham VA Medical Center, Birmingham, AL, [3]The University of Chicago, Chicago, IL.

Background/Purpose: Marginal zone macrophages (MZMs), a small subset of specialized splenic macrophages located in the MZ, act as final follicular entry barrier to clear apoptotic cells (ACs) to prevent AC antigens (Ags) entering to the spleen follicles. We recently reported reduced tolerogenic function, frequency and numbers of MZMs in the spleen of lupus prone BXD2 mice. Loss of MZMs were further confirmed in B6 Sle1.Sle2.Sle3 mice and lupus patients. Expression of lymphotoxin (LT) by B cells has been implicated as a critical factor to maintain MZMs. The present study investigated how type I interferons (IFNs) dissociated this interaction and induced MZM loss in lupus.

Methods: Confocal microscope and FACS analysis were carried out to determine the percentages and location of of MZMs, B cells and the distribution of LT and its receptor (LTβR) in the spleen. A mixed bone marrow (BXD2-GFP^+*Ifn$\alpha r^{+/+}$*:BXD2-GFP^-*Ifn$\alpha r^{-/-}$* =1:1) reconstitution in BXD2 *Rag2*$^{-/-}$ mice was carried out to determine if type I IFNs affect MZ integrity through direct action on MZMs or indirectly by affecting B cells. LT-LTβR interaction *in vivo* was disrupted by repeated injection of mice with a low dose of LTR fusion protein (LTR:Fc, 15 ug/mouse per week, 4 weeks) or by administrations of CpG (2.5 ug/mouse, every other day for 2 weeks).

Results: Repeated injections of CpG to B6, but not B6-*Ifn$\alpha r^{-/-}$* mice, induced loss of MZMs. Consistent with this, the spontaneous loss of MZMs and the elevated autoantibodies against MZM Ags, Marco and scavenger receptor A, in BXD2 mice were prevented in the absence of type I IFN signaling. Marginal zone B cells (MZs) are the major LT expressing cells in the marginal zone. Although there was comparable expression of LT, MZs were mainly localized in the follicles in BXD2 mice but in the marginal zone in both B6 and BXD2-*Ifn$\alpha r^{-/-}$* mice. BM reconstitution experiment further shows that the absence of type I IFNR did not directly affect MZM repopulation, but rather affected MZ B cell distribution. GFP^+*Ifn$\alpha r^{+/+}$* B cells mainly migrated to the follicles whereas GFP^-*Ifn$\alpha r^{-/-}$*B cells remained in the marginal zone and became the source of LT to support MZMs. Administration of a low dose of LTR:Fc to BXD2 mice selectively depleted MZMs and enhanced the spontaneous germinal center (GC) response without affecting follicular dendritic cell networks.

Conclusion: Our present study suggests a novel mechanism associated with type I IFN-promoted immune response against apoptotic self-Ags as a result of follicular migration of LT expressing and self-antigen carrier B cells. The shift of LT expressing B cells from the MZ to the follicles by type I IFNs

promoted apoptotic Ag delivery and LT stimulation to FDCs via breaking down the marginal zone barrier and finally exaggerated the production of pathogenic auto-antibodies.

Use Of An In Vitro Whole Blood Depletion ASSAY To Compare The Efficacy Of B CELL Depleting Agents In Patients With Systemic LUPUS Erythematosus. Venkat Reddy[1], Geraldine Cambridge[1], D.A. Isenberg[1], Mark Cragg[2] and Maria Leandro[1]. [1]University College London, London, United Kingdom, [2]Southampton University, Southampton, United Kingdom.

Background/Purpose: Variability in clinical response to B-cell depletion therapy (BCDT) with the anti-CD20mAb rituximab (RTX) has been well described in Systemic Lupus Erythematosus (SLE). Poor clinical response is associated with incomplete depletion which suggests that improving the efficiency of depletion might result in improved therapeutic outcome. GA101 is a recombinant, afucosylated fully human type II anti-CD20 mAb that has shown more effective depletion and clinical response in phase II trials in lymphoma. We have therefore compared the in vitro B-cell cytotoxicity (cytotoxicity index, CTI) of BHH2 (glycosylated GA101) with RTX, in lymphocytes from patients with SLE.

Methods: We included 23 patients with SLE, who met the American College of Rheumatology revised classification criteria. An *in vitro* autologous whole blood depletion assay (WBD) was used to assess the CTI. Briefly, 100μl of heparinised blood was incubated with either RTX, BHH2 or without antibody, at a concentration of 1μg/ml at 37°C, 5% $CO_2$for 24hours. Samples were then analysed by flow cytometry for CD45 (all lymphocytes), CD3 (T cells) and CD19 (B cells). The CTI was calculated using the formula:CTI of mAb=100-[(number of B:Tcells in sample without antibody-number of B:Tcells with mAb)/number of B:T cells in sample without antibody) $\times$ 100] and the mean from triplicate well calculated. The relationship between the relative expression (mean fluorescence intensity;MFI) of CD20 and CD32B (FcgRIIB) on B cells and CTI was determined using spearman rank correlation. Concurrent clinical and laboratory parameters including anti-dsDNA and C3 were collected and assessed.

Results: The mean CTI of BHH2 was higher than RTX in all but one patient. Median CTI in 23 SLE patients was 20% (range9–70) and 15% (range 1–42), for BHH2 and RTX, respectively ($p=0.0002$). CTI was $<25\%$ in 5 (21%) and 16 (73%) patients, for BHH2 and RTX, respectively. The mean$\pm$SD MFI of CD20 and CD32B on SLE-B cells was 9079$\pm$4025 and 4223$\pm$1587, respectively. The CTI of neither mAb correlated with the expression of CD20 ($r^2=-0.332,0.204$, for BHH2 and RTX, respectively). Also, there was no correlation between the CTI of mAbs and lymphocyte-count, serum creatinine, total IgG, C3, positivity for ENAs or anti-dsDNA.

Conclusion: These results indicate that BHH2 is superior to RTX at inducing cytotoxicity *in vitro* in B cells from patients with SLE. This study provides the preliminary data to consider type II mAbs (GA101-like) as an alternative BCD agent for SLE in a clinical trial setting.

Chaperone-Mediated Autophagy As a Target Of Therapeutic P140 Peptide Used In Lupus. Sylviane Muller. CNRS, Strasbourg, France.

Background/Purpose: In the pipeline of molecules with a potential for treating lupus patients, the P140 peptide/Lupuzor holds a lot of promise. P140 is a 21-mer linear peptide (sequence 131–151) that is derived from the small nuclear ribonucleoprotein U1–70K and that is phosphorylated at the Ser^{140}position. In a multicenter, randomized, placebo-controlled phase IIb study, Lupuzor was safe and met its primary efficacy end points in lupus patients (Zimmer et al., 2012). These results confirm data generated in MRL/lpr lupus-prone mice in which the preclinical studies were performed. The mechanism of action of P140 was further studied in this mouse model.

Methods: Immunocytochemical analyses were used to identify the way of P140 entry into B cells, and CMA activity was assessed in fibroblasts stably expressing a photoactivable CMA reporter. FACS analyses after LysoTracker and LysoSensor staining of isolated B cells were used to study the number and acidity of lysosomes in B cells from MRL/lpr mice.

Results: We found previously that P140 reduces autophagic flux in MRL/lpr B cells (Page et al., 2011) and that macroautophagy (the best characterized type of autophagy) is abnormally enhanced in T lymphocytes from lupus mice and patients (Gros et al., 2012). In this work, we show that a selective form of autophagy, chaperone-mediated autophagy (CMA), is a key target of P140 and demonstrate that the P140 inhibitory effect on CMA results from its ability to alter the integrity of the HSC70/hsp90 heterocomplex of lysosomal chaperones. Expression of HSC70 and LAMP-2A, the two main CMA components, which is increased in MRL/lpr B cells, is down-regulated after P140 treatment. P140 enters MRL/lpr B lymphocytes via a clathrin-dependent endo-lysosomal pathway and accumulates at the lysosomal lumen. There, it may act both by directly hampering HSC70 chaperoning functions and, as a result of loss of hsp90 function, by destabilizing LAMP-2A in lysosomes. This dual effect may interfere with the endogenous (auto)antigen processing and loading to MHCII molecules and as a consequence, lower activation of autoreactive T cells.

Conclusion: Our findings provide the first demonstration showing that P140 peptide acts directly on CMA. These results shed light on mechanisms by which P140 can modulate lupus disease and by which it may operate in humans affected by this disorder.

Preclinical Characterization Of a Humanized Antagonistic Anti-CD40 Mab. Kerry Ralph, Amy Nicoletti, Eunice Musvasva, Susan Cannan, Susan VanTongeren, Diann Blanset, Scott Brodeur, Jennifer Ahlberg, Hua Li, Steve Fogal, Sudha Desai, Kathy O'Shea, Rachel Kroe-Barrett, Gerald Nabozny, Helen Wu, Gale Hansen, Keith Canada, Sanjaya Singh, Meera Ramanujam and Christine Grimaldi. Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT.

Background/Purpose: CD40-CD40L interactions play a central role in T-B cell costimulation. Targeting this pathway has generated great interest; however early attempts to target CD40L failed mainly due to thrombotic complications observed in the clinic. In addition, developing antagonistic CD40 antibodies with suitable potency, favorable PK and no agonistic activity has proven to be challenging. BI 655064 is an anti-human CD40 mAb being developed for the treatment of autoimmune disorders. BI 655064 is engineered as a human IgG1 molecule with a mutated Fc region to abrogate effector function. Here we describe the preclinical characterization of BI 655064.

Methods: Binding of BI 655064 to CD40 expressed on primary B cells was measured by flow cytometry. The ability of BI 655064 to block CD40L-induced B cell proliferation *in vitro* was measured by tritium uptake. A subcutaneous PK/PD study in the cynomolgus monkey was performed to establish correlations between BI 655064 exposure, target coverage using a receptor occupancy assay and pharmacodynamic effects using an *ex vivo* CD54-induction assay. *In vivo* blockade of B cell function was also tested in a human-peripheral blood lymphocyte (huPBL) induced SCID mouse model of graft-versus-host disease (GvHD) and in cynomolgus monkeys immunized with keyhole limpet hemocyanin (KLH).

Results: BI 655064 binds human CD40 on B cells present in whole blood with an EC90 value of 6.85 nM $\pm$ 0.74. Blockade of CD40L-induced B cell proliferation was observed at an average IC50 of 0.4 nM. In the PK/PD study, cynomolgus monkeys dosed with greater than 1 mg/kg of BI 655064 exhibited complete blockade of *ex vivo* CD54 upregulation corresponding to full CD40 target coverage on B cells. *In vivo*, BI 655064 demonstrated clear effects on B cell function in the GvHD model where both human IgM and IgG responses were abrogated. As part of a repeat dose tolerability study, BI 655064 given to cynomolgus monkeys prior to immunization with KLH resulted in inhibition of KLH-specific IgM and IgG antibody responses. At doses of 5 mg/kg and above, germinal center size was decreased microscopically in Peyer's patches, lymph nodes, spleens and tonsils in treated monkeys.

Conclusion: BI 655064 is a humanized antagonistic anti-CD40 mAb which is to be tested in human clinical trials for autoimmune disorders to establish safety and efficacy. BI 655064 demonstrated relevant pharmacologic *in vitro* and *in vivo* activity, blocking CD40-related functions at clinical dosing levels of $>$ 1 mg/kg in animal models.

Targeting Cereblon With The High Affinity Immunomodulatory Compound CC-220: A Novel Therapeutic Agent For Autoimmunity. Peter Schafer[1], Emily Rychak[2], Derek Mendy[2], Stacey Parton[1], Lori Capone[1], Antonia Lopez-Girona[2], Dorota Cedzik[1], Jolanta Kosek[1], Ling-Hua Zhang[1] and Rajesh Chopra[1]. [1]Celgene Corporation, Summit, NJ, [2]Celgene Signal Research, San Diego, CA.

Background/Purpose: Cereblon (CRBN) is a component of the E3 ubiquitin ligase complex including CUL4A, DDB1, and ROC-1. CC-220 is a novel immunomodulatory compound currently in development for the treatment of immune conditions. The effects of CC-220 on CRBN binding and ubiquitination, and on immune cell responses were profiled.

Methods: Binding studies to CRBN were conducted using endogenous CRBN from human U266 plasmacytoma cells and affinity beads in a competition assay by quantitative immunoblot determination. CRBN ubiquitination was measured in HEK293T cells transfected with a His-biotin-tagged CRBN construct, treated with the MG132 proteasome inhibitor (to arrest degradation of ubiquitinated proteins). Cells were lysed and processed to measure CRBN ubiquitination by SDS-PAGE and immunoblot analysis. T-cell costimulation was measured in purified primary human T cells stimulated using immobilized anti-CD3 antibody. Cytokine secretion was measured by ELISA. Immunoglobulin M and G (IgG and IgM) production was measured from normal donor peripheral blood mononuclear cells by culturing in the presence of the B cell differentiation factors IL-2, IL-6, IL-10, IL-15, CD40L, and TLR9 ligand. IgM and IgG were measured by ELISA. Cell proliferation studies were conducted in H929 plasmacytoma cells assessed by 7-aminoactinomycin D (7-AAD) staining. Toll-like Receptor 4 (TLR4) stimulation was performed in human PBMC from subjects with SLE and SSc using lipopolysaccharide (LPS).

Results: In the competitive CRBN binding studies, CC-220 had a 50% inhibitory concentration (IC_{50}) of approximately 0.1 μM, compared with 3 μM for pomalidomide. CRBN ubiquitination studies in the transfected HEK293T cells resulted in an IC_{50} of 0.19 μM. CC-220 costimulated IL-2 production by T cells with an EC_{50} of approximately 0.29 nM, compared with 10 nM for pomalidomide. CC-220 inhibited IgM and IgG production with an IC_{50} of 0.35 and 2.1 nM, respectively, compared to 17 nM and 63 nM for pomalidomide. The IC_{50} value for inhibition of proliferation by CC-220 was 0.01 μM in the H929 plasmacytoma cell line. A 50% decrease in cell cycle (S-phase) was evident after 24 hours of treatment of H929 cells with CC-220. At 48 hours, CC-220 decreased expression of survivin and retinoblastoma protein (pRB) and increased expression of the cyclin-dependent kinase inhibitor p27. In LPS-stimulated PBMC from systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) patients, CC-220 significantly reduced production of pro-inflammatory cytokines including TNF-α, IL-1α, IL-1β, and IL-6, and increased production of IL-10.

Conclusion: The results indicate that CC-220 binds to CRBN and inhibits CRBN ubiquitination CC-220 enhances T cell IL-2 production, but inhibits B cell production of immunoglobulin and reduces plasma cell line proliferation. This compound also reduces the production of several key inflammatory mediators by SLE and SSc patients cells stimulated via the TLR4 pathway. In summary, CC-220 is a novel high affinity CRBN ligand with immunomodulatory effects and is currently in development for the treatment of immune and inflammatory diseases.

42

Inhibition Of B Cell Differentiation To The Plasmablast and Plasma Cell Lineage By CC-220, a Potent Modulator Of The Cereblon E3 Ubiquitin Ligase Complex. Peter Schafer, Lori Capone, Lei Wu and Rajesh Chopra. Celgene Corporation, Summit, NJ.

Background/Purpose: CC-220 is an immunomodulatory compound which binds to the CUL4 family E3 ubiquitin ligase complex protein cereblon (CRBN) with high affinity and modulates the ubiquitination of substrate proteins. To explore the effects of CRBN targeting on the differentiation of B cells to the plasmablast and plasma cell lineages, CC-220 was tested in an in vitro model of primary human B cell differentiation.

Methods: CD19+ peripheral blood human B cells from normal donors, or total PBMC for patients with systemic lupus erythematosus (SLE), were cultured in the presence of cytokines and stimulatory ligands for one week. Cells were counted, viability assessed, and expression of CD20, CD38, CD44, and CD83 were measured by flow cytometry. Plasmablast lineage factors IRF-4, BLIMP-1, XBP-1, and IgJ, and germinal center markers PAX-5 and BCL-6 were measured by qRT-PCR. Intracellular protein expression was measured by laser scanning cytometry. Secreted immunoglobulins IgG and IgM were measured by ELISA.

Results: In B cell cultures, CC-220 decreased the percentage of viable CD20-CD38+ plasmablasts on day 7 from 30.4% in control cultures in a dose-dependent manner to 27.3%, 2.1%, and 0.4% at 2 nM, 20 nM, and 200 nM CC-220, respectively. On Day 7, qRT-PCR analysis showed that CC-220 (20 nM) reduced expression of the plasmablast lineage factors IRF-4, BLIMP-1, XBP-1, and IgJ gene expression to 20.5%, 14.3%, 15.1%, and 31.5% of control, respectively ($P \leq 0.001$). By intracellular flow cytometry, CC-220 (20 nM) significantly decreased IRF-4 ($P<0.5$), BLIMP-1 ($P<0.05$), and XBP-1 ($P<0.05$) protein expression at Day 4, but significantly increased BCL-6 ($P<0.05$) protein expression on Day 7. By laser scanning cytometry on Day 7, CC-220 (20 nM) reduced CD38+ cell intracellular protein expression of IRF-4 ($P \leq 0.001$), and BLIMP-1 ($P \leq 0.001$), and increased BCL-6 expression ($P \leq 0.05$) (n=3). CC-220 inhibited secreted IgG production with an IC_{50}=1.8 nM (n=3).

In PBMC from SLE patients, CC-220 (20 nM) had similar effects as in normal B cells, reducing BLIMP-1, XBP-1, and IgJ gene expression to 52.8%, 49.2%, and 13.6% of control, respectively ($P \leq 0.001$, n=3). CC-220 (20 nM) significantly reduced CD38+ plasmablast intracellular protein expression of BLIMP-1 ($P \leq 0.01$) and IRF-4 ($P \leq 0.001$), and increased BCL-6 ($P \leq 0.05$) (n=3). CC-220 inhibited secreted IgM and IgG production by SLE patient PBMC with IC_{50}s of 0.9 nM and 3.2 nM, respectively (n=3).

Conclusion: These results demonstrate that targeting of the E3 ubiquitin ligase complex substrate co-receptor CRBN with the small molecule immunomodulator compound CC-220 results in potent inhibition of B cell differentiation to the plasmablast lineage, as shown by a reduction in the percentage of viable CD38+ cells, a decrease in BLIMP-1, XBP-1, IRF4, and IgJ gene and protein expression, and inhibition of secreted immunoglobulin production. These data implicate the CUL4-CRBN complex in the differentiation of B cells to the plasma cell lineage furthermore define a novel pathway for treatment of immune inflammatory conditions. CC-220 is currently entering clinical development for the treatment of immune diseases associated with autoantibody production.

Overexpression Of Lamin A In Mesenchymal Stem Cells Compromises Chondrogenesis and Enhances Adipogenesis. Jesús Mateos[1], Arancha Landeira[1], Alexandre De la Fuente[1], Iván Lesende-Rodríguez[2], Pablo Fernández-Pernas[2], Maria Carmen Arufe[1] and Francisco J. Blanco[3]. [1]CIBER-BBN, Zaragoza, Spain, [2]Department of Medicine, Area of Anatomy and Human Embryology, University of A Coruña-INIBIC, A Coruña, Spain, [3]Department of Medicine. University of Santiago de Compostela, Santiago de Compostela, Spain.

Background/Purpose: Previous work by our group and others indicated that an accumulation of lamin A (LMNA) is associated with the osteoarthritis (OA) chondrocyte phenotype. Mutations of this protein are linked to laminopathies and specifically to Hutchinson-Guilford Progeria Syndrome (HGPS), an accelerated aging disease. Some authors have proposed that a deregulation of LMNA affects the differentiation potential of stem cells. In the present study, we examined the effect of the over-expression of LMNA, on the mesoderm and, specifically, chondrocyte differentiation potential of Mesenchymal Stem Cells (MSCs).

Methods: MSCs from human umbilical cord (UC) stroma have previously been isolated, expanded and differentiated towards mesoderm cell lineages. For efficient gene delivery of wt LMNA and GFP (Green Fluorescence Protein) as control, we used a lentiviral expression system. Osteogenic potential was studied by with alizarin red staining and Real-Time PCR of ALP, OC and Runx2 to assess early and late osteogenic differentiation.

Adipogenic potential was studied with Oil Red staining and Real-Time PCR of LPL, FABP and ADIPOQ, for early and late adipogenic differentiation. Chondrogenesis and hypertrophy were studied using immunohistochemistry and Real-Time PCR of Aggrecan, MMP-13, Type II Collagen, Type I Collagen and Type I Collagen. Reactive oxygen species (ROS) generation was measured by flow cytometry and oriented migration capacity was tested in a Modified Boyden′s chamber assay.

Results: We found that over-expression of LMNA by lentiviral gene delivery leads to alterations in differentiation potential. Adipogenic capacity is increased in LMNA-MSCs, accompanied by an accumulation of Fatty Acid Synthase, as revealed by Western-blotting. The chondrogenic potential is defective in LMNA-MSCs, showing a decreased COL2/COL1 ratio and an increase in hypertrophy markers. These cells present lower levels of manganese superoxide dismutase (MnSODM) and an increase of mitochondrial MnSODM-dependent reactive oxygen species (ROS). This stable extra ROS generation is accompanied by alterations in the oriented migratory capacity of these cells under the effect of pro-inflammatory cytokines. ROS synthesis was partially and totally reverted by incubation with the ROS scavenger N-Acetyl Cystein (NAC) for 1 hour in culture. In addition, defects in chondrogenesis detected by immunohistochemistry and Real Time-PCR are partially reversed by periodic incubations with NAC for 1 hour.

Conclusion: Overall, our results show that chondrogenic differentiation of UC-MSCs is compromised by Lamin A deregulation whereas adipogenic differenciation is enhanced. We also demonstrated that this deregulation alters the oxidative stress balance in MSCs, modifies their migratory properties and induces defects in their capacity to differentiate into chondrocytes in our in vitro model. Further experiments are necessary to determine the in vivo significance of those alterations and to explore putative key targets for stem cell therapies in OA and other aging syndromes.

Suppressor Of Cytokine Signaling 3 Negatively Modulates Leptin-Mediated Catabolic and Proinflammatory Effects In Cartilage - New Potential Mechanism To Target Obesity-Induced Osteoarthritis. Anna Koskinen, Katriina Vuolteenaho, Riku Korhonen, Teemu Moilanen and Eeva Moilanen. The Immunopharmacology Research Group, University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland.

Background/Purpose: Adipocytokine leptin has been suggested to link obesity and osteoarthritis (OA). Initially leptin was found to regulate energy metabolism through central nervous system. More recent studies have shown that leptin is also a proinflammatory factor in arthritis and has detrimental effects on cartilage including upregulation of proinflammatory and catabolic factors. However, we and others have found a significant variation in the leptin responses in cartilage samples between different donor patients. One of the factors that regulate the metabolic effects of leptin in hypothalamus is suppressor of cytokine signaling 3 (SOCS-3). SOCS-3 is also known as an important negative feedback mechanism of inflammatory signals in leukocytes. The aim of the present study was to investigate SOCS-3 as a possible modulator of leptin's detrimental effects in cartilage.

Methods: Cartilage samples from 97 OA patients undergoing knee replacement surgery were collected. Cartilage explants were cultured with leptin (10 μg/ml) for 42 hours. The expression of SOCS-3, inducible nitric oxide synthase (iNOS) and cyclooxygenase (COX)-2 were measured by Western blotting. Matrix metalloproteinase (MMP)-1, MMP-3 and IL-6 were measured in the culture media by ELISA, and nitric oxide (NO) by the Griess reaction. The results were analyzed in an ANOVA model allowing for intergel variation of SOCS-3, and adjusting for BMI and age. The role of SOCS-3 in leptin signaling was further studied in H4 chondrocytes by downregulating SOCS-3 with siRNA.

Results: Leptin significantly enhanced the expression of NO, IL-6, MMP-1, MMP-3, iNOS and COX-2 in the cultured cartilage samples (fold of increase: 2.7 (6.2); 8.3 (30.5); 2.8 (3.4); 1.8 (1.2); 11.7 (160); 6.9 (18); median (IQR), respectively). There was a considerable variation in these responses between the cartilage samples from different donor patients, which was not explained by any clinical factor measured (BMI, age, sex, diabetic status, radiographic scaling of OA or macroscopic scaling of cartilage defects). Leptin responses were significantly higher in the cartilage samples with low SOCS-3 expression than in the samples with high SOCS-3 expression. In the ANOVA model, SOCS-3 was confirmed to negatively explain leptin-induced expression of NO, IL-6, MMP-1, MMP-3, iNOS and COX-2 independently of BMI and age ($p = 0.008$; 0.009; 0.064; 0.008; 0.001; 0.006, respectively). Accordingly, downregulation of SOCS-3 by siRNA in H4 chondrocytes enhanced leptin-induced expression of NO, iNOS, IL-6, MMP-3 and MMP-13.

Conclusion: Previous studies have shown that leptin levels are increased in obesity and leptin has detrimental effects in cartilage. The present results show that SOCS-3 negatively regulates catabolic and proinflammatory effects of leptin in cartilage, suggesting that SOCS-3 could be a future drug target in the treatment or prevention of obesity-induced OA.

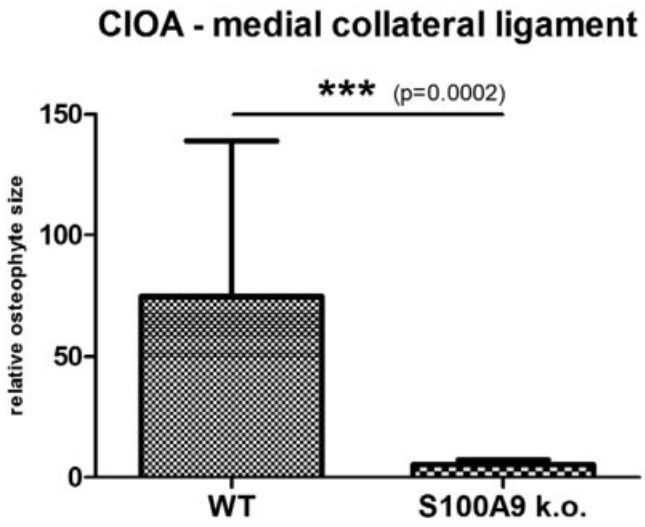
Alarmins S100A8/A9 Regulate Osteophyte Formation In Experimental Osteoarthritis With High Synovial Activation. Rik Schelbergen[1], Arjen B. Blom[1], Wouter de Munter[1], Annet W. Sloetjes[1], Thomas Vogl[2], Johannes Roth[2], Wim B. van den Berg[3] and Peter L.E.M. van Lent[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]University of Muenster, Muenster, Germany, [3]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Osteophytes are cartilage capped, bony outgrowths that limit joint movement and originate from the periosteum or from ligaments during osteoarthritis (OA). There is increasing belief that the synovium contributes to OA joint pathology since a large subset of OA patients shows synovial activation. As shown recently in our lab, alarmins S100A8 and S100A9 (major products of activated synovial macrophages) are involved in cartilage degradation and synovial activation during human and murine OA. In the current study, we explored the involvement of S100A8/A9 in osteophyte formation in experimental OA

Methods: Experimental OA was elicited in C57Bl/6 (WT) mice and S100A9−/− mice (in which peripheral myeloid cells lack functional S100A8), either by intra-articular collagenase injection (CIOA), or by transsection of the medial anterior meniscotibial ligament (DMM). Osteophyte size was assessed by a blinded observer using image analysis software. Chondrogenesis was induced by bringing human fetal mesenchymal stem cells (hMSCs) in pellet or murine C3H10T1/2 in micromass culture and stimulating for 5 (hMSCs) or 21 days (C3H10T1/2) with BMP-2 and TGFβ1, with 1 or 5 μg/ml human or mouse recombinant S100A8. Proteoglycan content was quantified on SafO stained sections, expression of mRNA with RT-qPCR

Results: Synovial activation, which is high in CIOA, was significantly reduced in S100A9−/− mice. Osteophyte size at day 42 of CIOA was dramatically reduced in the S100A9−/− compared to WT in the medial collateral ligament (92,5% reduction, Figure 1), but also significantly at the medial side of both tibia and femur (68,2% and 64,6% reduction) (n=10). One explanation for the reduced osteophyte size in S100A9−/− mice may be a direct effect of S100-proteins on chondrogenesis. To investigate this, we first stimulated murine C3H10T1/2 MSCs in micromass culture with 5 μg/ml S100A8 (in the presence of BMP-2 and TGFβ1) and found a marked increase in MMP3 and aggrecan mRNA as well as a strongly altered morphology, indicating increased remodeling. In line with that, stimulation of human MSCs in pellet culture with 1 or 5 μg/ml S100A8 (again together with BMP-2 and TGFβ1) strongly increased proteoglycan deposition as measured by redness in SafO staining (27% and 71% increase respectively). Finally, we determined osteophyte size in the DMM model, in which synovial involvement is very low. At day 56, we observed no significant differences in osteophyte size between the S100A9−/− and WT at the medial femur and tibia (105% and 136% of WT, n=8).



Conclusion: S100A8/S100A9 play a crucial role in osteophyte formation in an OA model that shows high synovial involvement, probably by stimulating chondrogenesis. Considering also the deleterious effect of S100A8/A9 on joint destruction in OA, targeting these alarmins during OA may be very promising.

Exogenous Hydrogen Sulfide Donors Show Anti-Catabolic and Anti-Inflammatory Properties But Limited Anti-Oxidant Capability On Human Articular Osteoarthritic Chondrocytes. Elena F. Burguera[1], Angela Vela-Anero[1], Rosa Meijide-Failde[2] and Francisco J. Blanco[1]. [1]Tissue Engineering and Cellular Therapy Group (CBTTC-CHUAC), CIBER BBN/ISCIII, A Coruña, Spain, [2]Department of Medicine, University of A Coruña, A Coruña, Spain.

Background/Purpose: Osteoarthritis (OA) is characterized by an imbalance between catabolism and anabolism, higher than normal levels of matrix metalloproteinases (MMPs), an increase in inflammatory markers (i.e. interleukins (ILs) or eicosanoids), and an increase in reactive oxygen species (ROS). Hydrogen sulfide (H_2S) is a novel endogenous gas and signaling molecule. Here we looked into the effects of H_2S donors as anti-catabolic, anti-oxidant and anti-inflammatory agents in human articular chondrocytes (hCs) from OA tissue.

Methods: We used an *in vitro* model in which hCs were stimulated with one of two H_2S donors: NaHS or GYY4137; 50mM to 1000mM; 48h; H_2S-only-treated (S)-group. In some tests, IL1β (5ng/mL) or Lipopolysaccharide (LPS, 1μg/mL) were also added. We chose MMP1, 3 and 13, collagen-II (COLII) and aggrecan (ACAN) as matrix degradation and synthesis markers. The prostaglandin E2 (PGE2) synthesis pathway and IL6, for inflammation. Superoxide dismutase(SOD)-2 and catalase (CAT) as scavenger enzymes. ROS synthesis (mitochondrial(M)-ROS and cytoplasmatic(C)-ROS) was measured with cell cytometry. Effects on gene expression were quantified with qRT-PCR and those on proteins with immunocytochemistry (ICC) or enzymatic immunoassays (EIA).

Results: 1. Catabolism: The two H_2S donors reduced MMP3 and MMP13 expression in the S-group, although $p>0.05$. On IL1β-group, MMP3 and 13 (Fig.1A) expressions in the IL1β condition (182 and 52 fold vs. the basal (B)), were reduced to 124 and 10 (1000mM GYY4137, respect.) and 91 and 13 (1000mM NaHS, respect.). There was a marked reduction in MMP3 protein levels (ICC). **2. Anabolism:** 200mM NaHS and GYY4137 counteracted COLII and ACAN repressed expression on the IL1β-group. **3. Inflammation:** H_2S donors reduced IL-6 (Fig.1B), cyclooxygenase (COX)-2 mRNA expression in the IL1β-group without significantly affecting COX-1. **4.ROS:** Only 200mM NaHS reduced C-ROS in the S-Group (from 27.7$\pm$5.7 to 21.5$\pm$1.9UA). On the IL1β-group, H_2S donors did not reduce ROS. SOD2 (Fig.1C) and CAT expression levels were unaffected ($p>0.05$) in either group. Only 200mM GYY4137 reduced M-ROS in the LPS-Group to B level.

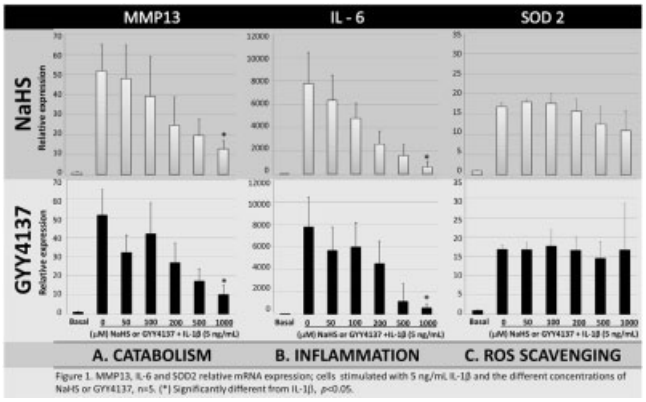

Figure 1. MMP13, IL-6 and SOD2 relative mRNA expression; cells stimulated with 5 ng/mL IL-1β and the different concentrations of NaHS or GYY4137, n=5. (*) Significantly different from IL-1β), $p<0.05$.

Conclusion: Exogenous H_2S donors NaHS and GYY4137 show anti-inflammatory, anti-catabolic and pro-anabolic properties in an *in vitro* model with human OA chondrocytes. However, in the conditions of the present study, they do not reduce pathological ROS levels found in OA chondrocytes and do not increase the anti-oxidant capacity of the cells.

The In Vivo Role Of Bone Specific EphB4 Receptor Overexpression In Osteoarthritic Synovial Membrane. Gladys Valverde-Franco[1], David Hum[1], Bertrand Lussier[2], Koichi Matsuo[3], Jean-Pierre Pelletier[1], Mohit Kapoor[1] and Johanne Martel-Pelletier[1]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]Department of Clinical Sciences, Faculty of Veterinary Medicine, University of Montreal, Saint-Hyacinthe, QC, [3]Laboratory of Cell and Tissue Biology, School of Medicine, Keio University, Tokyo, Japan.

Background/Purpose: Osteoarthritis (OA) is characterized by progressive destruction of all joint tissues including inflammation of the synovial membrane. The histological changes that occur in OA present a range of abnormalities in the synovial membrane including fibrosis. Members of the ephrin family, the EphB4 receptor and its specific ligand ephrin-B2, were found to positively impact the abnormal structure and metabolism of OA subchondral bone and cartilage. In the context of evaluating the in vivo effect of the EphB4 receptor, we further investigated in vivo in mice the effect of bone-specific EphB4 overexpression (TgEphB4) on synovial membrane during OA.

Methods: Knee OA was surgically induced by the destabilization of the medial meniscus (DMM) in 10-week-old male EphB4 homozygous (TgEphB4) and wild-type (WT) mice. Synovial membrane evaluations were performed at 12 weeks post-surgery using histology, immunohistochemistry, and real-time PCR.

Results: Data demonstrated a significant decrease in the synovial membrane thickness ($p\leq0.02$), pro-collagen type I ($p\leq0.01$), and fibrin ($p\leq0.04$) in DMM-TgEphB4 compared to DMM-WT. The expression of the fibrotic markers connective tissue growth factor (CTGF, $p\leq0.02$), smooth muscle actine α (SMAα, $p\leq0.03$) and serum cartilage oligomeric matrix protein (COMP, $p\leq0.03$) were all significantly reduced in DMM-TgEphB4 compared to DMM-WT. Although the TGF-β was decreased in the DMM-TgEphB4 mice, the difference did not reach statistical significance. However, the synthesis of a member of the heat shock protein family (HSP), HSP90β, known to have a crucial role in enhancing TGF-β signaling, was significantly decreased ($p\leq0.03$) in DMM-TgEphB4.

Conclusion: This is the first in vivo evidence showing that protecting the subchondral bone prophylactically reduces the severity of pathological changes in the synovial membrane during the OA process. This study thus stresses the in vivo importance of subchondral bone biology in OA tissues. It also provides evidence that changes in the synovial membrane are an integral part of the OA disease process. In addition, these data define the EphB4 receptor as a potential novel therapeutic avenue for the treatment of the disease.

Chondrocyte-Specific Bone Morphogenetic Protein-2 Overexpression Results In Severe Aggravation Of Osteophyte Formation In Experimental Osteoarthritis Without Altering Cartilage Damage In Young Mice.

Esmeralda N. Blaney Davidson[1], Elly L. Vitters[1], Miranda B. Bennink[2], Fons AJ Loo[1], Wim B. van den Berg[2] and Peter M. van der Kraan[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: In murine osteoarthritis (OA) models chondrocytes surrounding lesions express elevated levels of Bone Morphogenetic Protein-2 (BMP2). This growth factor is well known for its ECM inducing qualities and capability to induce new cartilage and bone. The functional consequence of these elevated BMP2 levels near OA lesions is unclear. We made a collagen type II dependent, doxycycline-inducible BMP2 transgenic mouse to investigate the consequence of elevated chondrocyte-specific BMP2 on experimental OA (DMM-model).

Methods: We cloned a lentivirus with BMP2 controlled by minCMV promoter coupled to a tet responsive element (Lv-TRE-BMP2).We crossed a Col2-cre with a floxed rtTA mouse and transfected homozygote embryo's with Lv-TRE-BMP2 to gain a mouse expressing collagen type 2 dependent BMP2 solely in chondrocytes only upon doxycycline (dox) exposure (Col2-rtTA-TRE-BMP2). Experimental OA was induced (DMM model) in Col2-rtTA-TRE-BMP2 mice with or without dox exposure in food starting one week before DMM, lasting until the end of the experiment (8 weeks after DMM). We isolated knee joints for histology. Left knee joints served as non-OA controls.

Results: Mice with DMM alone showed osteophyte formation predominantly on the medial side of the joint originating from the periost near the femoral-tibial joint and extruding from the medial meniscus. Upon chondrocyte-specific BMP2 exposure, DMM-induced osteophyte formation aggravated severely resulting in outsized osteophytes, enthesophytes on the enthesis of the medial collateral ligament, new bone formation within the collateral ligament near the extruded meniscus and osteophyte formation originating from the femoral growth plate, predominantly but not exclusively on the medial side of the joint. There were no significant differences in non-OA knee joints comparing dox versus non-dox treated transgenics. In contrast, dox treatment resulted in large osteophytes in thoracic or cervical area of the spine. Strikingly, despite apparent changes in knee joint morphology due to large osteophytes there was no detectible difference, with regard to structural damage and Safranin O staining intensity, in cartilage damage when comparing DMM with or without dox exposure.

Conclusion: Elevated BMP2 levels in chondrocytes did not induce structural changes in articular cartilage of young mice. Moreover, unchallenged dox treated joints had no structural alterations in cartilage. In DMM, BMP2 overexpression greatly enhanced de novo cartilage formation, eventually turning into bone (osteophytes), which was not seen in non-OA knee joints with BMP2. We postulate that newly-induced chondrocytes produce high BMP2 levels in dox-treated transgenics, that boost outgrowth of these structures. In spine however, osteophytes developed in dox-treated transgenics without additional triggers. This could rely on chondrocyte precursor subpopulation that is stimulated to undergo chondrogenesis under control of BMP2 alone.

Our data show that chondrocyte-specific elevation of BMP2 levels does not alter the course of cartilage damage in an OA model in young mice but results in severe aggravation of osteophyte formation.

Cartilage Matrix Remodeling and Activation Of Canonical Wnt- Signaling Precedes Calcification and OA-Like Changes In Mice.

Jessica Bertrand[1], Tabea Kräft[2], Yvonne Nitschke[2], Thelonius Hawellek[3], Jan Hubert[3], Lars Godmann[1] and Thomas Pap[1]. [1]University Hospital Münster, Münster, Germany, [2]University Hospital Münster, Muenster, Germany, [3]University Hospital Hamburg, Hamburg, Germany.

Background/Purpose: Calcification of cartilage is a common finding during osteoarthritis (OA) and is directly linked to the severity of cartilage degradation. We have found in a previous study that NPP1 is an important player in OA associated cartilage calcification in mouse and humans. The observed cartilage changes resemble aspects of endochondral ossification. In this study we aim to investigate the matrix changes and calcification of cartilage during the development of OA- like changes in mice.

Methods: The tip-toe walking (ttw/ttw) mouse that carries a mutation in the *enpp1* gene encoding for NPP1 was used as a natural model of OA. Using von Kossa staining in combination with Safranin-orange staining of knee sections we assessed the calcification of articular cartilage and the severity of OA using the Mankin-Score over a time course from 4 to 22 weeks. We analysed the compostion of cartilage matrix using toluidine blue, alcian blue/PAS staining. To investigate cartilage matrix remodelling we performed immunohistological stainings for collagen II, collagen X and the aggrecan cleavage marker BC-3. We performed the same stainings in knee joint sections of wild type mice with induced OA (DMM model). The influence of basic calcium phospahe (BCP) crystals on neonatal chondrocytes was investigated in micro mass cultures with alcian blue and alizarin red staining. Using Western Blot for β- catenin and pCamKII we investigated the activation of WNT signalling.

Results: We found a loss of proteoglycans in the joint cartilage of ttw/ttw mice already at an age of 8 weeks, whereas no changes of cartilage matrix were detectable in wild type mice. An increased Mankin Score in ttw/ttw compared to wild type mice also reflected these changes. Early matrix remodelling in ttw/ttw cartilage was followed by an increased calcification starting at the border to the subchondral bone. The straight border of the tide mark gets broken down by multiple calcified chondrocytes that give the border a wave-like appearance. Looking at the matrix changes in more detail we found an increase in sulphated proteoglycans in the ttw/ttw cartilage as well as in the induced OA cartilage. The same pattern was observed in the growth plate in the area of hypertrophic chondrocytes. We found an increased expression of collagen X in the cartilage and collagen II was down-regulated with increasing age and OA severity. Using neonatal chondrocytes of wild type and ttw/ttw mice we found that BCP crystals induce production of highly sulphated matrix and reduce proliferation of chondrocytes. Chondrocytes of ttw/ttw mice show an increase in β- catenin, which was also observed in wild type chondrocytes stimulated with BCP crystals.

Conclusion: We conclude from our data that matrix remodelling precedes cartilage calcification. The calcification seems to be associated with activation of canonical WNT signalling. Taken together, the data support the notion that OA is characterized by the re-initiation of developmental programms associated with endochondral ossification.

Collagen-Based Microspheres Delivering TGF-β3 For Mesenchymal Stem Cell Differentiation: An Innovative Strategy For Cartilage Engineering.

Marc Mathieu[1], E Belamie[2], M-N Labour[2], Sylvain Vigier[2], Christian Jorgensen[3] and Daniele Noel[4]. [1]INSERM U844, Montpellier, France, [2]ICGM UMR 5253, MONTPELLIER, France, [3]Inserm U844, CHU Saint-Eloi, Université Montpellier 1, CHU Lapeyronie, Montpellier, France, [4]UM1, Montpellier, France.

Background/Purpose: Because of a poor self-healing ability, joint cartilage undergoes progressive degradation in the course of aging or following traumatic injuries. One promising therapeutic approach is the use of mesenchymal stem cells (MSC), which have the potential to differentiate into chondrocytes. However, anchorage of MSC to the sites of injury and their differentiation *in situ* require combining cells with a biomaterial releasing a differentiation factor such as TGFβ3. Our objective was to design and test a new scaffold to support chondrogenic differentiation.

Methods: Microspheres were formed using an acidic type I collagen solution and perfluorated oil, stabilized by a surfactant. Spherical microparticles of fibrillar collagen were obtained through a sol-gel transition induced in aqueous droplets in contact with ammonia vapors. Microspheres were impregnated with TGFβ3 and release of this factor was measured using a reporter gene assay. Impregnated microspheres were combined with human MSC and cultivated *in vitro* or subcutaneously injected into immunodeficient mice. Expression of chondrocyte markers was monitored by RT-qPCR and immunohistochemistry.

Results: Microspheres are constituted by a gel of striated collagen fibrils and are 300 ± 67 μm in diameter. Fibrils occupy ca. 5% of the total volume, forming an entangled network with pores of 1–10 μm. After MSC adhesion onto the microspheres and *in vitro* culture for 21 days, they differentiate into chondrocytes expressing the specific markers, such as collagen type II variant

B and aggrecan. The type I collagen matrix is progressively degraded and replaced by the cartilaginous matrix. *In vivo*, MSC form a tissue histologically resembling cartilage which stain positive for collagen II and aggrecan.

Conclusion: The biomaterial described here is promising for cartilage engineering. Future improvements aim at obtaining microspheres of smaller and more homogenous sizes, which will facilitate their injection; covalently linking the TGFβ3 to the microspheres to prevent its dispersal in the organism.

Altered Lipid Metabolism In Osteoarthritis With Subsequent Proinflammatory Properties Of Apolipoprotein A-I. Dominique de Seny[1], Gaël Cobraiville[1], Edith Charlier[1], Sophie Neuville[1], Laurence Lutteri[2], Denis Malaise[3], Olivier Malaise[1], Jean-Paul Chapelle[2], Biserka Relic[1] and Michel G. Malaise[1]. [1]GIGA Research - University of Liège - CHU Liège, Liège, Belgium, [2]Medical Chemistry - CHU Liège, Liège, Belgium, [3]University of Liège, Liège, Belgium.

Background/Purpose: Osteoarthritis (OA) is associated with a local inflammatory process. It is now considered as a metabolic syndrome rather than due to aging or mechanical stress. Several evidences point to the direction of an altered lipid metabolism as an underlying cause for the development of OA. Recently, we have studied the role played by an apolipoprotein, the acute phase serum amyloid A (A-SAA), as a pro-inflammatory marker in OA joints (de Seny et al., Plos One, 2013). Apolipoprotein A-I (ApoA1) is another major protein component of high-density lipoprotein (HDL) cargo molecules in plasma, and both are playing a major role in back cholesterol transport from peripheral tissues to the liver.

Methods: Lipoproteins, anti-oxidized LDL antibodies, cholesterol, ApoA1 levels and inflammatory parameters (IL-6, MMP-1 and MMP-3) in blood and synovial fluids of OA (n=29) and rheumatoid arthritis (RA) (n=27) patients were quantified and compared to those in matched healthy volunteers (HV) (n=35). Primary chondrocytes and fibroblast-like synoviocytes (FLS) were isolated respectively from cartilage and synovial membrane obtained from OA patients during joint replacement. Cells were stimulated with purified human ApoA1 in the presence or not of recombinant human A-SAA (rhSAA) protein, and with lipoproteins at physiological concentration encountered in OA. IL-6, MMP-1 and MMP-3 expression levels were quantified by ELISA after stimulation.

Results: 1) In the serum of OA patients, LDL/HDL ratio was significantly higher compared to HV and RA but remained similar in both OA and RA synovial fluid.

2) Although LDL and cholesterol serum levels were higher in OA than in RA, both were lower in the OA synovial fluid than in the RA.

3) In the OA and RA synovial fluid, cholesterol levels were positively correlated to LDL, HDL and ApoA1 levels, and HDL levels were positively correlated to ApoA1 levels. But of interest, OA synovial fluid had the unique characteristic of LDL levels being positively correlated to HDL and ApoA1 levels, which was not observed neither in the synovial fluid of RA patients nor in the serum of OA, RA and HV.

4) LDL and ApoA1 levels were also significantly correlated to IL-6 levels, another uncommon characteristic of OA synovial fluid suggesting local dysregulated processes within lipidic and inflammatory parameters. We also observed using *in vitro* experiments that the purified human ApoA1 likewise rhSAA induced IL-6, MMP-1 and MMP-3 expression in primary chondrocytes and FLS obtained from OA patients. ApoA1-induced IL-6, MMP-1 and MMP-3 expression was downregulated by TAK242, a specific TLR4 inhibitor. Presence of HDL at OA physiological concentration did not abolished ApoA1-induced IL-6, MMP-1 and MMP-3 expression.

Conclusion: Lipid diffusion into the joint cavity is dependent on the degree of inflammation. If inflammation is largely superior in RA compared to OA, we can nonetheless hypothesize that local inflammatory process and lipid diffusion inside OA joint cavity can also occur. In this study, several arguments have been raised in favour of an abnormal lipid profile in OA synovial fluid. This abnormal lipid profile was linked to the local pro-inflammatory process.

Adenosine A_{2A} Receptor As a Potential New Therapeutic Target For The Prevention/Treatment Of Osteoarthritis. Aranzazu Mediero[1], Tuere Wilder[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Osteoarthritis, the most common type of arthritis in the United States, results from trauma and other mechanical factors as well as metabolic changes in bone and cartilage. We have previously demonstrated that adenosine, acting via the A_{2A} receptor, inhibits inflammation and plays a critical role in regulating bone metabolism. Thus, adenosine A_{2A} receptor knockout mice are osteopenic as a result of increased osteoclast number and activity. We have observed that aging adenosine A_{2A} receptor knockout mice experience difficulty in movement, taking food and walking and so we determined whether changes in their bone or joint structure or function could explain these changes.

Methods: 4 month old C57Bl/6 wild type (WT) and A_{2A}KO mice (n=4) were sacrificed and knee joints were prepared for microCT analysis and histology. PAS (Periodic Acid Staining) and Trichrome staining of decalcified sections of leg were carried out. MicroCT analysis of knees of WT and KO mice were carried out and analysis of bone was performed on the distal femur below the growth plate.

Results: microCT analysis of the knees of A_{2A}KO mice showed osteophyte formation together with mild remodeling and subchondral sclerosis when compared to WT mice. As we have previously reported A_{2A} KO mice suffered from osteopenia; bone volume/total volume (BV/TV) was significantly decreased in A_{2A}KO mice when compared to control (33.324 ± 0.56 vs 35.782 ± 0.78, respectively, $p<0.01$). The same decrease was observed for trabecular thickness (0.0685 ± 0.0035 vs 0.081 ± 0.002, $p<0.05$) and bone mineral density (BMD) (0.3795 ± 0.003 vs 0.4265 ± 0.01, respectively, $p<0.5$), with no change in trabecular number (4.8795 ± 0.17 vs 4.646 ± 0.23, p=ns). H&E and trichrome staining showed a loss in collagen in the cartilage together with diminished subchondral bone and chondrocyte hypertrophy and proliferation. PAS staining correlated with these results showing a loss in proteoglycans both in the articular cartilage and in the growth plate in A_{2A}KO mice together with an increase in chondrocyte proliferation.

Conclusion: Deficiency in adenosine A_{2A} receptors leads to spontaneous osteoarthritis and suggests that adenosine receptors may be novel targets for development of therapies to ameliorate or prevent osteoarthitis.

Anti-Fibrotic and ANTI-Hypertrophic Effect Of Adipose Mesenchymal Stromal Cells On Osteoarthritic Chondrocytes. Marie Maumus[1], C. Manferdini[2], Karine Toupet[1], A. Piacentini[2], A. Gabusi[2], A. Facchini[2], G. Lisignoli[2], Christian Jorgensen[3] and Daniele Noel[4]. [1]INSERM U844, Montpellier, France, [2]IOR BOLOGNA, BOLOGNA, Italy, [3]Inserm U844, CHU Saint-Eloi, Université Montpellier 1, CHU Lapeyronie, Montpellier, France, [4]UM1, Montpellier, France.

Background/Purpose: Mesenchymal stem cells (MSC) isolated from bone marrow (MSC) or adipose (ASC) tissues secrete a large amount of trophic factors. The possibility that these cells, through their paracrine potential, may influence the course of chronic degenerative disorders and prevent cartilage degradation is promising for the treatment of osteoarthritis (OA). Indeed, the aim of our work was to evaluate the effects of these cells on OA chondrocyte phenotype.

Methods: OA ASC were isolated from intra-articular (Hoffa-ASC) or hip (hip ASC) subcutaneous adipose tissue and healthy ASC from subcutaneous abdominal depot (abdo-ASC). BM-MSC and chondrocytes were obtained from OA donors. ASC or MSC were co-incubated with chondrocytes cultured in monolayer during 7 days using cell culture inserts. Expression of markers specific for mature and hypertrophic chondrocytes or fibroblasts was quantified by RT-qPCR or ELISA. Isotypic or anti-HGF antibodies (100ng/ml) were added during the coculture.

Results: After 7 days of ASC or MSC co-cultures with chondrocytes, a stable expression of the markers specific for mature chondrocytes (Col IIB, Agg, link, Sox9) was observed, while expression of hypertrophic (MMP13,

AP) and fibrotic (Col I and III) markers was significantly decreased. Compared to abdo-ASCs, Hoffa- and Hip-ASC reduced less efficiently the expression of hypertrophic/fibrotic markers and some markers of mature chondrocytes were decreased with Hip-ASC. Finally, factors known to be involved in fibrosis and matrix remodeling (TIMP-1 and -2, MMP-1 and -9, IL1-RA) were not changed. On the contrary, HGF secretion was induced and addition of neutralizing anti-HGF antibody reversed the anti-fibrotic effect of ASC whereas the hypertrophic markers were not modulated.

Conclusion: ASC from abdominal subcutaneous fat and MSC were the most efficient to reduce hypertrophy and dedifferentiation of articular chondrocytes. This effect was at least partly due to the induction of HGF secretion confirming the interest of using ASC in therapies of osteo-articular diseases.

Glucocorticoid Receptor Modulator Compound A Does Not Induce Leptin In Human Osteoarthritic Synovial Fibroblasts and In Dedifferentiated Chondrocytes. Olivier Malaise, Biserka Relic, Edith Charlier, Mustapha Zeddou, Florence Quesada-Calvo, Sophie Neuville, Dominique de Seny and Michel G. Malaise. GIGA Research - University of Liège - CHU Liège, Liège, Belgium.

Background/Purpose: Leptin is generally considered detrimental in osteoarthritis (OA) as it can induce IL-8 in synovial fibroblasts (SF) and matrix metalloproteinases in chondrocytes. We recently showed that SF themselves were able to produce leptin and express leptin receptor (Ob-R) *in vitro*, strongly induced by glucocorticoid (GC) prednisolone, through TGF-β pathway and Smad1/5 phosphorylation (Stem Cell Dev 2012; 21: 1948–55). It is generally believed that transrepression of transcription factors by monomeric GC receptor (GR) is associated with GC anti-inflammatory properties, whereas side-effects (mellitus diabetes, lipid abnormalities, osteoporosis) would be mostly resulting in GR dimer-dependent transactivation. Compound A (CpdA), a plant-derived phenyl aziridine selective GR agonist, is efficient to reduce inflammation in a murine arthritis model and does not induce mellitus diabetes nor osteoporosis, offering a better benefit/risk ratio than GC. The aim of this study is to determine, in human OA SF and dedifferentiated chondrocytes (DDC), whether CpdA, as prednisolone, is leptin and Ob-R inducer.

Methods: Human SF and chondrocytes were isolated from OA patients during knee or hip surgery. Cells were treated with prednisolone (1 μM), TNF-α (10 ng/ml) and/or CpdA (1, 5 or 10 μM). ELISA measured leptin and IL-6 production in culture supernatant. Ob-R, GR, TGF-βRII, phospho-Smad1/5, phospho-Smad2, Smad1, Smad2, GILZ and α-tubulin were analyzed in total cell extracts by Western Blot.

Results: 1. Like prednisolone, CpdA down-regulated endogenous and TNF-α-induced IL-6 secretion by SF and DDC in a dose-dependent manner, supporting its anti-inflammatory action. **2.** By contrast to prednisolone, CpdA did not induce leptin and further decreased endogenous Ob-R expression in a dose-dependent manner in the same cells. Moreover, unlike prednisolone, CpdA did not induce TGF-βRII expression nor Smad1/5 phosphorylation and did not reduce Smad2 phosphorylation. Lastly, also opposite to prednisolone, CpdA poorly induced GR degradation and did not induce GILZ expression.

Conclusion: Unlike prednisolone, CpdA, a dissociative glucocorticoid receptor agonist, did not induce leptin nor Ob-R in human OA SF and in DDC and could even decrease Ob-R expression. As leptin favors osteoblastic differentiation of mesenchymal stem cells, our findings might explain why CpdA also fails to induce such a differentiation. Leptin is a new target where dissociative properties of CpdA can apply.

Age-Related Loss Of The Transforming Growth Factor Beta Receptor ALK5 Precedes Osteoarthritis Development In Cartilage. Arjan van Caam, Esmeralda N. Blaney Davidson, Eva Thijssen, Wim B. van den Berg and Peter M. van der Kraan. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Osteoarthritis (OA) is the most common joint disease and (old) age is its main risk factor. One of OA's main hallmarks is degradation of articular cartilage. TGFβ-superfamily signaling plays an important role in cartilage homeostasis via induction of Smad phosphorylation (pSmad). pSmad2/3 is a potent inhibitor of chondrocyte terminal differentiation and cell death, whereas pSmad1/5/8 induces these processes. In cartilage, TGFβ receptors that induce Smad phosphorylation are ALK1 for Smad1/5/8 and ALK5 for Smad2/3. We showed an age-related shift in receptor balance towards dominant Alk1 expression compared to Alk5 expression, and linked elevated Alk1 levels to increased *Mmp13* and *ColX*expression and cartilage damage in mice. However, OA development and ageing are concurrent in mice, and possibly both processes interfere. To uncouple ageing and OA-related processes, we investigated if age-related changes in TGFβ-superfamily signaling occur without interference of the OA process, and if these changes result in an altered cellular response to growth factors. We chose healthy bovine cartilage explants as a model system because bovine samples can be obtained in a wide age range without concurrent OA development.

Methods: From the metacarpophalangeal joint of cows (*Bos Taurus*) ($<$ 3 h *post mortem*), full thickness cartilage explants were collected. Macroscopically none of the animals showed any signs of OA. Samples were either immediately frozen in liquid nitrogen or, after 24 h equilibration in serum free medium, stimulated with growth factors for 24 h. Subsequently, mRNA was isolated and gene expression was measured by qPCR, using cDNA specific primers and SYBR-green.

Results: Gene expression analysis of bovine explants ranging from 0.5 up to 12 years old showed a very significant 100-fold ($R^2 = 0.7$, $p < 0.0001$) decrease in *Col2a1* expression and a 3-fold decrease in *Tgfb1* ($R^2 = 0.3$, $p = 0.002$) expression with increasing age compared to 4 reference genes; *Gapdh*, *Rpl22*, *Rps14* and *Gusb*. Furthermore, *Alk5* expression decreased 4-fold ($R^2 = 0.3$, $p = 0.0004$) whereas *Alk1* expression remained unchanged. In 8 year old explants, expression of the Smad2/3p response gene *Serpine1* (*Pai1*) was 11-fold less ($p = 0.01$) responsive to 1 ng/ml of the ALK5 ligand TGFβ_1 compared to 1 year old explants. In contrast, the response of 8 year old cartilage to the ALK1 ligand BMP9 (5 ng/ml) was not significantly different compared to 1 year old cartilage as measured by expression of the Smad1/5/8 response gene *Id1*.

Conclusion: The loss of *Col2a1* and *Tgfb1* expression are two characteristics of ageing cartilage, and confirm our system as valid to study age-related changes in cartilage. Because no signs of OA could be detected on macroscopic level, changes in TGFβ-superfamily receptor expression appear to occur independently of the OA process. The observed decrease in *Alk5* expression results in loss of Smad2/3p signaling in response to TGFβ_1, indicating that TGFβ_1's cartilage protective function is lost with increasing age. We propose that this loss of response predisposes chondrocytes for the OA process.

Role Of Procatabolic Cytokines In Dysregulation Of O-Linked N-Acetylglucosamine Modified Proteins In Human Osteoarthritic Chondrocytes. Raquel Largo[1], Ane Larranaga-Vera[2], Sandra Pérez-Baos[2], Gabriel Herrero-Beaumont[2] and Jessica Andrés-Bergós[3]. [1]Jiménez Díaz Foundation University Hospital, Madrid, Spain, [2]Joint and Bone Research Unit. IIS-Fundación Jiménez Díaz. UAM, Madrid, Spain, [3]Tissue Engineering Repair and Regeneration Program, Hospital for Special Surgery and Weill Cornell Medical College, New York, NY.

Background/Purpose: Nuclear and cytoplasmic protein glycosylation by the addition of O-linked N-Acetylglucosamine (O-GlcNAc) to serine and threonine residues is a widespread post-translational modification that has been described in degenerative and age-related diseases, such as Alzheimer's and diabetes. This modification is catalyzed by the O-GlcNAc transferase (OGT) which uses UDP-GlcNAc as a donor, and O-GlcNAc can be removed by the O-GlcNAc-glucosaminidase (OGA). We have seen that O-GlcNAc glycosylation levels in the articular cartilage of patients with OA were increased as well as the expression of the different isoforms of OGT and OGA was dysregulated. The goal of this study was to assess whether a procatabolic cytokine, IL-1α, can be responsible of the changes in O-GlcNAc system found in OA human cartilage.

Methods: OA knee articular cartilage was obtained during replacement surgery. Twelve OA patients were included in this study (6 woman/6 men; mean age 71$\pm$3 years), with a Mankin score for knee specimens between 11

and 14. Human osteoarthritic chondrocytes (HOC) were isolated by protease digestion for primary culture. At confluence, cells were stimulated with different concentrations of IL-1α for different doses and periods of time after they were deprived of serum for 48 h. The level of O-GlcNAcylation, OGT and O-GlcNAcase expression was assessed by western-blot employing specific antibodies.

Results: The amount of O-GlcNAcylated proteins was increased in HOC 24 h after stimulation with different doses of IL-1α (1, 10 and 100 ng/ml), showing the highest accumulation with 10 ng/ml. This concentration was chosen for stimulation of HOC during different periods of time (3, 6, and 24 h). The increase in O-GlcNAc proteins amount showed a peak of induction at 6 h. This accumulation occurs especially in proteins between 50 to 150 KDa therefore showing a similar O-GlcNAcylated proteins pattern to that observed in OA cartilage. We also observed an increased expression of the three OGT isoforms, nucleo-cytoplasmic (ncOGT), mitochondrial (mOGT) and small (sOGT) in HOC as early as 3 h, although the peak of induction was at 6 h. Three isoforms were increased in a similar grade, without prevalence of sOGT as found in OA cartilage. IL-1α also increased the presence of both OGA isoforms, long (OGA-L) and short (OGA-S) after 3 and 6 h of stimuli. A clear prevalence of long isoform was found along IL-1α stimulation whereas OGA-S had the highest prevalence in OA cartilage.

Conclusion: To our knowledge, this is first evidence of procatabolic cytokines involvement in O-GlcNAc modifications. IL-1α can induce accumulation of O-GlcNAc proteins in human OA chondrocytes. Although both regulatory enzymes of this modification, OGT and OGA, are also increased with IL-1α stimulation, characteristic distribution of the different isoforms in OA cartilage was not reached. IL-1α is in part responsible of a dysregulation in the O-GlcNAc proteins modification during OA although other processes must be involved.

Saturated Fatty Acids Act Synergistically With Interleukin 1 Beta To Increase Inflammation, Endoplasmic Reticulum Stress and Cell Death In Human Articular Chondrocytes. Oscar Alvarez-Garcia[1], Nicole H Rogers[2], Roy G Smith[3] and Martin K. Lotz[4]. [1]Department of Molecular and Experimental Medicine, The Scripps Research Institute, La Jolla, CA, [2]California Institute for Biomedical Research (Calibr), La Jolla, CA, [3]Department of Metabolism and Aging, The Scripps Research Institute, Jupiter, FL, [4]The Scripps Research Institute, La Jolla, CA.

Background/Purpose: Obesity is a major risk factor for the development of osteoarthritis (OA). Altered biomechanics have been postulated as the main causative mechanism, but recent data showing a higher incidence of hand OA in obese patients suggest the existence of a systemic component. Obesity is commonly associated with a state of low-grade inflammation, increased circulating adipokines and free fatty acids (FFA) released by adipose tissue. Whereas low-grade inflammation has received some attention in the recent years, little is known about the role of FFAs in OA pathogenesis. The aim of this study was to analyze effects of saturated (palmitate) and monounsaturated (oleate) FFAs on articular cartilage and chondrocytes.

Methods: Human Articular Chondrocytes (hAC) obtained from young healthy donors (21.3$\pm$2.9 years) were grown in monolayer cultures until confluence. For cell viability and caspase 3/7 activation assays, hAC were treated with 0.5 mM palmitate, 0.5 mM oleate or vehicle, in the presence or absence of 1 ng/ml IL-1β for 72 hours. For gene expression studies, shorter treatment time (24-hours) and lower IL-1β concentration (10 pg/ml) were used. Levels of proinflammatory factors, extracellular matrix proteins, extracellular proteases and endoplasmic reticulum (ER) stress markers were measured. In addition, bovine articular cartilage explants were cultured with FFA for 72 with or without IL-1β and cartilage integrity was studied.

Results: Palmitate induced caspase 3/7 activation and cell death in IL-1β -stimulated hAC, and significantly upregulated IL-1β -induced IL-6 and Cox-2 gene expression as well as IL-6 protein secretion, whereas oleate had no additive effect. Exposure to FFAs did not modify type II collagen, aggrecan, ADAMTS-4, -5, and MMP13 gene expression after 24 hours. ER stress markers were potently increased by palmitate alone, but not oleate, and this effect was further enhanced by IL-1β. Preliminary experiments showed that palmitate accelerated cartilage destruction driven by IL-1β in bovine explants, as evidenced by a significant increase in cell death and glycosaminoglycan release.

Conclusion: Saturated fatty acids, specifically palmitate, have catabolic effects on articular cartilage and can accelerate its breakdown in the context of low-grade inflammation by synergizing with IL-1β to increase proinflammatory mediators, ER stress and caspase-associated cell death. Collectively, our data suggest that elevated levels of saturated FFA may contribute to OA pathogenesis in obese patients.

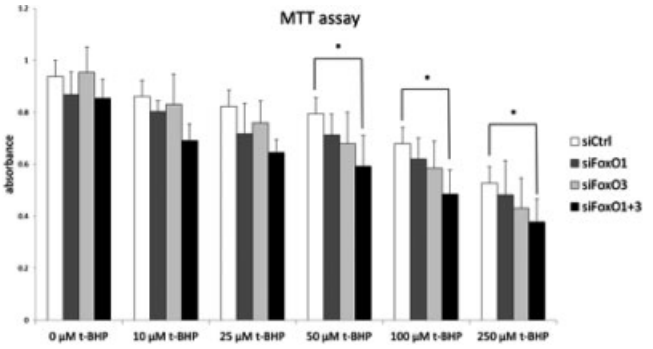
Downregulated Forkhead-Box Class O Transcription Factors Attenuate Oxidative Stress Resistance In Human Chondrocytes. Yukio Akasaki and Martin K. Lotz. The Scripps Research Institute, La Jolla, CA.

Background/Purpose: Aging-associated changes in articular chondrocytes represent a major risk factor for osteoarthritis (OA). The major signaling pathway that regulates cellular aging is the Insulin/IGF-1/Pl3k/Akt/forkhead-box class O (FoxO) transcription factor axis. The FoxO factors play a central role in oxidative stress resistance regulating antioxidants, autophagy and protein quality control. Previously, we observed that FoxO factors are dysregulated in aged and OA cartilage. FoxO expression is reduced during the aging process and phosphorylation of FoxOs (inactivation form) is increased in OA cartilage. However, the impact of downregulated FoxOs on chondrocytes is still unknown. The objective of this study was to investigate the role of FoxOs in anti-oxidative stress resistance in human chondrocytes

Methods: Normal human cartilage was obtained at autopsy from 4 adult donors. OA human cartilage was obtained from 5 patients undergoing knee replacement surgery. Small interference RNA for FoxO1 and FoxO3 were transfected into chondrocytes. The effects of down-regulated FoxO proteins on cell viability against the oxidant tert-Butyl hydroperoxide (t-BHP) were analyzed by MTT assay. Antioxidants and autophagy related proteins in FoxO-siRNA transfected cells were analyzed by Western blot. The changes in inflammatory mediators and extracellular matrix components following treatment with IL-1β or TGF-β were also examined

Results: FoxO1 and FoxO3 but not FoxO4 mRNA expression was significantly lower in OA cartilage compared to normal cartilage. MTT assay showed that the combination of siFoxO1 and siFoxO3 significantly reduced cell viability compared to control siRNA under treatment with t-BHP ($\geq$ 50 μM) (Figure 1). Knock-down of FoxO1 and FoxO1+3 resulted in significant reductions of GPX-1, catalase, LC3, Beclin1, p62, and Sirt1 proteins following treatment with t-BHP. Expression of iNOS was significantly increased in FoxO-siRNA transfected chondrocytes.



Conclusion: Down-regulated FoxO transcription factors in chondrocytes increased susceptibility to cell death induced by oxidative stress, and this was associated with reduced antioxidants and autophagy related proteins. Our data provide evidence for a key role of FoxO transcription factors as regulators of oxidative stress resistance in human chondrocytes.

O-Linked N-Acetylglucosamine Modified Proteome Of Human Osteoarthritic Cartilage: Biological Significance. Jessica Andrés-Bergós[1], María Luisa Hernáez[2], Miguel Otero[1], Ane Larranaga-Vera[3], Sandra Pérez-Baos[3], Mary B. Goldring[1], Gabriel Herrero-Beaumont[3] and Raquel Largo[4]. [1]Tissue Engineering Repair and Regeneration Program, Hospital for Special Surgery and Weill Cornell Medical College, New York, NY, [2]Proteomics Unit, Universidad Complutense de Madrid-Parque Científico de Madrid, ProteoRed ISCIII, Madrid, Spain, [3]Joint and Bone Research Unit. IIS-Fundación Jiménez Díaz. UAM, Madrid, Spain, [4]IIS-Fundación Jiménez Díaz, Madrid, Spain.

Background/Purpose: O-linked N-acetylglucosamine (O-GlcNAc) post-translational modifications have been implicated in the control of different signaling cascades and in the development and progression of degenerative and age-related diseases. We previously showed that accumulation of O-GlcNAc-modified proteins alters chondrocyte gene expression, leading to increased expression of chondrogenic markers in vitro and increased chondrogenic differentiation in vivo (Andrés-Bergós J, JBC 2012). We also showed that the total amount of O-GlcNAcylated proteins was significantly increased in human osteoarthritic (OA) cartilage compared to that of healthy cartilage (Tardío L, Arthritis Rheum, submitted). Here, we aimed to better profile and identify the O-GlcNAc-modified proteins in human OA cartilage.

Methods: Human OA cartilage was isolated from patients undergoing total knee replacement surgery (n=6), while healthy cartilage was obtained from age- and gender-matched donors (n=6). Wheat germ agglutinin (WGA) chromatography was used to selectively pull-down O-GlcNAc-modified proteins. To this end, equal amounts of proteins isolated from OA and healthy cartilage were loaded on WGA-affinity columns. The eluted fractions containing O-GlcNAc-modified proteins were processed by nano-LC-M/MS, using a 5500QTRAP mass spectrometer (AB Sciex), and subsequently analyzed using GeneCodis software, which grouped proteins based on predefined biological processes.

Results: Healthy and OA human cartilage shared a number of O-GlcNAc-modified proteins; however, our WGA-based analysis identified subsets of proteins O-GlcNAc-modified differentially in health and disease. Around a 26% of healthy cartilage specific proteins were involved in cytoskeleton organization, and more than 16% play an important role in cell adhesion. None of these biological processes were found in the analysis of OA differential proteins suggesting that these protein modifications may have an important role in preserving cell structural integrity in a healthy state. Interestingly, O-GlcNAc modifications in proteins involved in growth plate cartilage development, cartilage condensation, or inhibition of angiogenesis were absent in OA samples and prominent in healthy cartilage. More importantly, O-GlcNAc modifications of proteins implicated in extracellular matrix degradation, cell growth, or complement activation were higher in OA cartilage than in non-OA/healthy cartilage, clearly separating healthy and damaged tissue based upon biological processes and subsets of O-GlcNAc-modified proteins.

Conclusion: We report here for the first time subsets of differentially O-GlcNAc-modified proteins in healthy and OA human articular cartilage. Biological processes involving O-GlcNAc proteins are different in OA cartilage in comparison with the healthy one. Our results further highlight the contribution of this means of protein control to the development and progression of OA and, more importantly, may contribute to the identification of potential biomarkers and/or therapeutic targets in OA.

Epigenome-Wide DNA Methylation Study Reveals Hypermethylated Collagen Genes and Suggests a Role for TGFβ in Osteoarthritis. Matlock A. Jeffries[1], Amr H. Sawalha[2] and Judith A. James[3]. [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]University of Michigan, Ann Arbor, MI, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Osteoarthritis (OA) is the leading cause of chronic disability in the U.S., affecting 40% of individuals over the age of 70 and costing $128 billion annually in the US alone. Late-stage OA chondrocytes exhibit a host of gene transcription changes leading to upregulation of enzymes that contribute to cartilage breakdown. Herein, we characterize epigenome-wide DNA methylation changes in osteoarthritic compared to healthy cartilage from the same joints.

Methods: Twelve femoral heads were obtained at the time of hip arthroplasty for primary OA. Articular cartilage tissue was dissected from grossly affected and grossly normal areas, flash frozen in liquid nitrogen, and DNA was extracted. Following sodium bisulfite-treatment, DNA methylation was quantified at >485,000 CpG sites across the genome using Illumina HumanMethylation450 arrays. CpG sites with an absolute methylation difference between OA and normal cartilage (Db) $\geq$ 15%, and $P < 0.01$ after correction for multiple testing using a false discovery rate (FDR) of 5%, were considered statistically significant and used for subsequent analysis.

Results: We found 442 differentially methylated CpG sites in OA compared to normal cartilage from the same joints: 260 hypo- and 182 hypermethylated. Overrepresented gene sets included "Connective tissue disorder" (n=53, p=4.73E-6 to 7.36E-3), "Developmental disorder" (n=44, p=4.73E-6 to 7.36E-3), and "Skeletal & muscular disorder" (n=59, p=4.73E-6 to 7.36E-3). Particularly interesting methylation changes in OA include hypermethylation of *COL11A2*, which functions to maintain spacing and diameter of type II collagen and is mutated in patients with Stickler syndrome and OSMED. Additional DNA methylation changes detected include hypermethylation of *COL6A2*, hypomethylation of the fibrillar collagen gene *COL1A1*, and hypermethylation of *COL18A1*. Hypermethylation was also noted in multiple CpG sites within the WNT pathway co-receptor *LRP5*, which is associated with OA in mice and is a genetic susceptibility gene for OA in humans. Hypomethylation was found at multiple CpG sites in the transcription factor *RUNX1*. Upstream regulator analysis identified significant association of TGFβ1 with 44 differentially methylated genes. Finally, canonical pathway analysis identified enrichment of several pathways, most prominently the ERK signaling pathway among differentially methylated genes (p=1.51E-4).

Conclusion: We detected significant methylation changes in multiple collagen genes in OA. Our data suggest an epigenetic basis for defective collagen production in OA. Furthermore, we found evidence for epigenetic dysregulation of WNT signaling, and enrichment of genes associated with TGFβ- and ERK-pathway signaling, both of which are enticing targets for OA therapeutics. This work reinforces a role for genetic/epigenetic interaction in the pathogenesis of OA.

Tenogenic Effect Of Homeobox Mohawk gene for Bone Marrow Mesenchymal Stem Cells. Koji Otabe, Hiroyuki Nakahara, Akihiko Hasegawa, Martin K. Lotz and Hiroshi Asahara. The Scripps Research Institute, La Jolla, CA.

Background/Purpose: Mohawk homeobox (MKX) has been demonstrated as a tendon and ligament specific transcriptional factor. MKX knock-out mice showed hypoplastic tendons throughout the body, due to reduced type I collagenproduction in tendon cells. Our group also demonstrated expression of MKX decreased in mature human knee ligament tissues, during joint aging and further decreased in osteoarthritis (OA). The aims of this study were to characterize factors that may promote tenogenic differentiation of bone marrow derived mesenchymal stem cells (BMMSCs) and to investigate the role of MKX in ligament/tenogenic differentiation of BMMSCs.

Methods: Human BMMSCs (n=9 from 3 donors) were purchased from Lonza, and treated with putative tenogenic factors (50ng/ml BMP12, 5ng/ml TGFbeta or 50ng/ml PDGF). Tendon/ligament related gene expression was analyzed by qRT-PCR at 1–5 days after treatment. BMMSCs were infected with adenoviruses expressing MKX or Scleraxis (Scx), also a tendon specific transcription factor and tendon related gene expression was analyzed levels at days 1, 2 and 7.

Results: Basal MKX and SCX expression levels were low in BMMSCs. BMP12 increased expression of MKX and SCX genes in BMMSCs at day 5 ($p<0.01$, n=6). COL1a1 levels were higher in BMP12 and TGFbeta treated groups ($p<0.01$, n=6). Decorin (DCN) and tenascin B (TNXB), important extracellular matrix (ECM) components of ACL, were also higher in BMP12 treated group ($p<0.05$, n=6). The expression of COL1a1 and TNXB were increased by overexpression of MKX in BMMSCs ($p<0.05$, n=9). Tenomodulin (TNMD), a marker of late stage tenogenic differentiation, was expressed at higher levels in Ad-Mkx and Ad-Scx groups than in Ad-Mock group ($p<0.05$, n=9).

Conclusion: This is the first report to compare several potential tenogenic factors in BMMSCs and to investigate the MKX expression and function in human BMMSCs. The present findings demonstrate that BMP12 most effectively enhanced tenogenesis related genes including Mkx, and overexpression of MKX was associated with increased tendon ECM production. Thus, MKX is represents a key factor for tenogenic differentiation of BMMSCs.

Investigations On The Role Of Delta/Notch Like EGF-Related Receptor In The Pathogenesis Of Osteoarthritis. Lucija Berninger[1], Anna Balkenhol[1], Clemens Baier[2], Stefan Rehart[3], Markus Rickert[4], Ulf Müller-Ladner[1], Elena Neumann[1] and Matthias Geyer[1]. [1]Justus-Liebig-University of Gieβen, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]University of Regensburg, Bad Abbach, Germany, [3]Markus-Hospital, Frankfurt, Germany, [4]University Hospital Giessen and Marburg, Giessen, Germany.

Background/Purpose: Delta/Notch like EGF-related receptor (DNER) is a single-pass transmembrane protein with characteristic EGF-like repeats in the extracellular domain, similar to those of the Notch receptor and its ligand Delta. In our previous study, an overexpression of DNER mRNA was observed in lesional areas of human osteoarthritis (OA) articular cartilage compared to unaffected zones of the same tissue sample. Based on these findings and on the fact that Notch signaling pathway plays a major role in cell fate regulation and differentiation of human articular chondrocytes, we analyzed the role of DNER in the pathogenesis of OA.

Methods: Human articular cartilage was obtained from knee joint explants of OA patients undergoing total joint replacement surgery. The expression of DNER in human cartilage was analyzed by immunohistochemistry. Isolated primary chondrocytes were nucleofected with siRNA targeting human DNER or with a plasmid for DNER overexpression (pDNER), respectively. Knockdown and overexpression were confirmed by immunocytochemical staining for DNER in the nucleofected chondrocytes at different time points of cultivation. RNA was isolated and the effects of the artificially modified DNER expression on specific cartilage metabolic parameters (collagen type 2 and 1, Sox9, MMP9, ADAMTS4 and 5) analyzed using quantitative real-time PCR.

Results: Histologically, DNER was significantly increased in the affected cartilage of all patients (n=3) on the protein level compared to the intact zones of the same tissue. An overexpression of DNER in primary human OA chondrocytes peaked 24 h after nucleofection (increase: 50000 fold). 72 h after nucleofection, a down-regulation of collagen type 2 (−7,89 fold) and an up-regulation of collagen type 1 (2,07 fold) as well as Sox 9 (7.39 fold) mRNA was measured.The overexpression of DNER was detectable at different time points on the protein level. In contrast, following knockdown of DNER, its expression was significantly decreased ($p \leq 0.001$) but there was no significant change in the expression profile of collagen type 2 (0.94 fold; $p \leq 0.621$), collagen type 1 (0.74 fold; $p \leq 0.097$), Sox9 (0.83 fold), MMP9 (0.97 fold), ADAMTS4 (0.64 fold) and 5 (1.2 fold). The confirmation of the DNER knockdown on the protein level at different time points identified that DNER is still to be constitutively found in the membrane.

Conclusion: Since DNER overexpression led to a down-regulation of collagen type 2 in human articular chondrocytes whilst the expression of collagen type 1 and Sox9 were up-regulated, our preliminary results could lead to the assumption that DNER might contribute to the dedifferentiation of human OA chondrocytes within a "regenerative" attempt in order to de-organize and re-assemble adapted cartilage extracellular matrix to reconstitute physiological homeostasis and the ability to re-sustain to physical load during the course of human OA.

Fibulin-3 In Joint Aging and Osteoarthritis Pathogenesis. Akihiko Hasegawa[1], Tomo Yonezawa[2], Noboru Taniguchi[2], Koji Otabe[2], Yukio Akasaki[2], Tetsuya Matsukawa[2], Masahiko Saito[3], Masashi Neo[4], Lihua Y. Marmorstein[5] and Martin K. Lotz[2]. [1]Osaka Medical College, Takatsuki, Osaka, Japan, [2]The Scripps Research Institute, La Jolla, CA, [3]Toho University Sakura Medical Center, Sakura, China, [4]Osaka Medical College, Osaka, Japan, [5]University of Arizona, Tucson, AZ.

Background/Purpose: Osteoarthritis (OA) is the most common joint disease. Among the earliest lesions during OA development is disruption of the superficial zone (SZ) of articular cartilage. The SZ of articular cartilage contains adult mesenchymal progenitor cells and is unique in extracellular matrix composition. Recently, we found that the EFEMP1 gene encoding fibulin-3 is specifically expressed in SZ. However, the expression pattern of fibulin-3 in articular cartilage and its role is unknown. The objectives of this study were to examine fibulin-3 expression patterns in joint aging and OA and to investigate the role of fibulin-3 in OA pathogenesis.

Methods: Immunohistochemical analysis was performed on human and mouse knee cartilage to determine changes in fibulin-3 expression during joint aging and in OA. To examine the role of fibulin-3 in cartilage homeostasis, experimental OA was induced in wild type and fibulin-$3^{-/-}$mice. The mice were euthanized 10 weeks after the knee surgery for histological analysis. To address whether fibulin-3 is involved in regulating chondrocyte differentiation, human articular chondrocytes were transfected with fibulin-3-specific siRNA. Cells were harvested at 48 hours and 72 hours for quantitative PCR and Western blot analyses. To further address the role of fibulin-3 during chondrogenesis, bone marrow mesenchymal stem cells (MSC) were transduced with lentivirus (LV) encoding EFEMP1 or control LV expressing LacZ, then MSC pellets were prepared and analyzed for chondrogenesis.

Results: Fibulin-3 was specifically expressed in the SZ of normal cartilage in human and mouse knee joints. Fibulin-3 expression was intracellular and in the extracellular matrix (ECM) and declined with aging. Both aging-related OA and experimental OA were significantly more severe in fibulin-$3^{-/-}$mice compared with wild type mice. Fibulin-3 expression was high in MSC and decreased during chondrogenesis. Suppression of fibulin-3 by siRNA in MSC significantly increased SOX9, collagen II and aggrecan in articular chondrocytes, while the overexpression of fibulin-3 inhibited chondrogenesis in MSC.

Conclusion: We found that fibulin-3 is specifically expressed in the SZ of articular cartilage and its expression is reduced in aging and OA. Fibulin-3 regulates survival and differentiation of adult progenitor cells and its aging-related decline is an early event in OA pathogenesis. Preventing or restoring aging-associated loss of fibulin-3 in SZ chondrocytes has potential to delay or prevent onset of OA.

The Frequency Of Bone Marrow Oedema Adjacent To The Cruciate Ligament Peri-Entheseal Vascular Channels In Inflammatory and Degenerative Arthritis. Daniel Binks[1], Melissa Matzelle[2], Diane Bergin[3], Richard J. Hodgson[1], Ai Lyn Tan[1], Ellen M. Gravallese[4], Dennis McGonagle[5] and Aleksandra Radjenovic[1]. [1]University of Leeds, Leeds, United Kingdom, [2]University of Massachusetts Medical School, Worcester, MA, [3]Galway University Hospitals, Galway, Ireland, [4]UMass Memorial Medical Center, Worcester, MA, [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

Background/Purpose: We noted in mouse models of inflammatory arthritis (IA) that an early point of entry of inflammation into the marrow space occurred at sites where penetrating vessels entered the bone. The role of penetrating vessels in erosion formation in man has not been explored in IA, nor has the role of vascular channels in bone marrow oedema (BME) in osteoarthritis (OA) been explored. The purpose of this work was to investigate the frequency of BME in inflammatory and degenerative arthropathies in close proximity to the peri-entheseal ACL and PCL vascular channels

Methods: Normal microanatomy was defined in 21 cadaveric knees using 3T MRI and histology. MRI of 89 patients from the Osteoarthritis Initiative study and 27 patients with inflammatory arthritis were evaluated for BME at the same locations. An animal model of inflammatory arthritis was evaluated to ascertain whether the putative peri-entheseal vascular regions influenced the propensity of osteitis and bone erosion

Results: Data from the animal model of IA showed inflammation entering the marrow space along the adventitia of blood vessels that penetrate the cortical bone in close proximity to the cruciate ligament insertions. On 3T MRI, a vascular channel adjacent to the ACL tibial insertion was observed in 64% of cadaveric specimens examined. Similarly, a vascular channel adjacent to the PCL was seen in 71% of cases. BME was observed in the regions corresponding to the location of the vascular channel in 51% of knees for both

the anterior and posterior channel. Histological evaluation of 10 cadaveric specimens confirmed the location of the vascular channels along with the presence of associated subclinical microdamage including subchondral bone damage (80% of cases) and micro-cyst formation (50%). Evaluation of patient MRIs showed the prevalence of oedematous features in the same topographic locations in patients with early OA (41% ACL, 59% PCL) and IA (44% ACL, 33% PCL), (Figure 1).

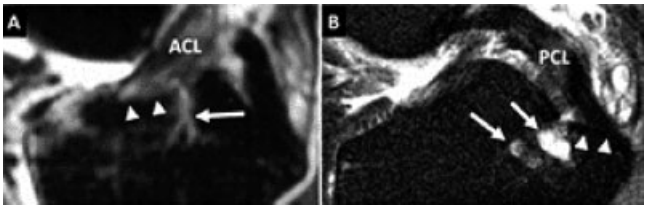

Figure 1. Sagittal fluid-sensitive MRI showing examples of **A,** tibial vascular channel (**arrow**) posterior to the anterior cruciate ligament insertion (**arrowheads**) in a patient with inflammatory arthritis and **B,** bone marrow lesions (**arrows**) seen in the region anterior to the PCL insertion (**arrowheads**) in a patient with osteoarthritis. Bone marrow lesions/oedema were seen adjacent to both cruciate ligament insertions in both inflammatory and degenerative types of arthritis.

Conclusion: Our findings show that the vascular channels adjacent to the anterior and posterior cruciate ligament entheses are common locations for erosion formation and damage in both inflammatory and degenerative arthritis. Furthermore, we have found a significant clustering of subclinical microdamage in these regions in normal cadaveric samples. Therefore, we conclude that peri-entheseal vascular channels are likely to present a common pathogenesis focus for both OA and IA.

Follistatin-Like Protein 1 Is An Important Regulator Of Chondrogenesis. Yury Chaly[1], Sonja Smith[1], Daniel Bushnell[2], Brian Campfield[2], Harry Blair[3] and Raphael Hirsch[1]. [1]University of Iowa Carver College of Medicine, Iowa City, IA, [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background/Purpose: Chondrocytes play a pivotal role in osteoarthritis (OA) because they are the only cells in the articular cartilage that are responsible for maintenance of the extracellular matrix (ECM). Articular cartilage intrinsic regenerative capacity is strongly downregulated in humans with age. The use of mesenchymal stromal cells (MSC) is an attractive approach for cartilage repair because MSC are capable of proliferating and differentiating into chondrocytes in vitro. However, without detailed knowledge of how chondrogenic pathways are induced it has not been possible to produce true hyaline cartilage in vitro or in vivo, or to maintain cartilage growth. The present study was undertaken to determine whether follistatin-like protein 1 (FSTL1) regulates chondrogenic differentiation of MSC. We hypothesized that FSTL1 may enhance cell proliferation and anabolic activity in articular chondrocytes and, therefore, play an important role in maintaining cartilage homeostasis.

Methods: To study the role of FSTL1 in chondrogenesis, we made use of FSTL1 knockout (KO) mice generated in our laboratory. MSC were obtained from skulls of E18.5 embryos. Proliferative capacity of MSC was analyzed by flow cytometry using CFSE labeling. Differentiation of MSC into chondrocytes was carried out in a pellet culture system. Gene expression microarray analysis was performed on MSC isolated from FSTL1 KO and wild-type embryos. For signaling study, protein extracts from TGFb-stimulated MSC were analyzed for phospho (p)-SMAD3, p-p38 MAPK, p-AKT by Western blotting.

Results: Homozygous FSTL1 KO mice showed extensive skeletal defects, supporting a role for FSTL1 in chondrogenesis. FSTL1 KO embryos had decreased cellularity in the embryonic vertebral cartilage and FSTL1 KO MSC had reduced proliferative capacity. Microarray analysis of gene expression in FSTL1 KO MSC revealed dysregulation of multiple genes known to be involved in chondrogenesis, including COL1A2, COL2A1, COL10A1, SOX5, SOX9, TGFBR2, CTSK, GREM1, IGFBP4, WISP1. We also demonstrated that FSTL1-deficient MSC displayed defects in TGFb-induced differentiation into chondrocytes, including decreased production of ECM proteoglycans and reduced expression of type II collagen. TGFb-induced phosphorylation of SMAD3, p38 MAPK, and AKT were significantly decreased in FSTL1 KO cells.

Conclusion: These results demonstrate that FSTL1 is a crucial component of the regulatory mechanism controlling chondrocyte proliferation, differentiation, and expression of ECM molecules. Our findings may lead to the development of novel strategies for cartilage repair and provide new disease modifying treatments for OA.

Heparin-Binding Epidermal Growth Factor-Like Growth Factor (HB-EGF) As a Potential Mediator In Osteoarthritis. Richard F. Loeser[1] and David A. Long[2]. [1]Wake Forest School of Medicine, Winston-Salem, NC, [2]Wake Forest University, Winston-Salem, NC.

Background/Purpose: We recently reported changes in gene expression in knee joint tissue from 12 week-old and 12 month-old mice after OA was induced by surgical destabilization of the medial meniscus (DMM). Heparin-binding EGF-like growth factor (HB-EGF) was found by gene array to be significantly up-regulated at 8 weeks after surgery in both age groups. HB-EGF is a known ligand for the EGF receptor (EGFR) which signals through MAP kinases and the small GTPase Rac. EGFR signaling has been implicated in OA pathogenesis but a potential role for HB-EGF has not been examined. The purpose of this study was to determine if HB-EGF was present in human OA cartilage and to test the ability of HB-EGF to stimulate production of chondrocyte MMP-13 which can contribute to matrix destruction in OA.

Methods: Real-time PCR was used to confirm the HB-EGF gene array results using RNA isolated from knee joint tissues (n=9 mice per surgical group) from 12 week-old and 12 month-old male C57/BL6 mice that had undergone DMM or sham control surgery. Immunohistochemistry for HB-EGF was performed using knee joint tissue collected from normal tissue donors or age-matched patients who had undergone knee replacement for OA (n=4 each). *In vitro* stimulation studies used cultured human articular chondrocytes isolated from normal donor tissue (n'3 independent donors for each experiment). Fibronectin fragments (FN-f) were used as a catabolic stimulus relevant to OA. Effects of recombinant HB-EGF, ± FN-F, on MMP-13 production were measured by immunoblotting and real time (RT)-PCR and on Rac activity using an activity assay.

Results: HB-EGF expression was about two-thirds lower ($p<0.05$) in the sham control joints of the older mice compared to young controls but increased by >6-fold ($p<0.001$) in the older DMM joints vs 1.4-fold in the young DMM when compared to the age-matched sham. Immunohistochemical staining revealed increased HB-EGF in human OA cartilage relative to age-matched normal where little to no staining was observed. Treatment of cultured human chondrocytes with FN-f increased HB-EGF expression which peaked at almost 60-fold (by RT-PCR) at 3 hours. Overnight FN-f stimulation increased HB-EGF secretion into conditioned media. We found that HB-EGF at 10ng/ml stimulated chondrocyte Rac activity and phosphorylation of the EGFR, ERK and p38 but not JNK. High dose (100ng/ml) but not low dose (10ng/ml) HB-EGF stimulated MMP-13 production in conditioned media, detected by immunoblotting. However, low dose HB-EGF enhanced the MMP-13 production induced by FN-F by 1.4-fold over FN-f alone and this was completely inhibited by blocking Rac1 with 100μM NSC23766 or EGFR with 250 nM AG1478.

Conclusion: HB-EGF was detected in human OA cartilage but not normal cartilage. FN-fs, known to be present in OA cartilage and to stimulate catabolic pathways, were found to stimulate HB-EGF production by normal chondrocytes. Given the finding that HB-EGF signals through the chondrocyte EGFR and promotes MAP kinase and MMP-13 production and that it is present in human OA cartilage, further evaluation of its role in OA is warranted.

Autophagy Activation Protects From Mitochondrial Dysfunction In Human Chondrocytes. Beatriz Caramés[1], Paloma López de Figueroa[1], Martin Lotz[2] and Francisco J. Blanco[3]. [1]Osteoarticular and Aging Research Lab, INIBIC–Complejo Hospitalario Universitario A Coruña, SPAIN, A Coruña, Spain, [2]The Scripps Research Institute, La Jolla, USA, La Jolla, CA, [3]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC- University of A Coruña, A Coruña, Spain.

Background/Purpose: A common feature of aging-related diseases, such as osteoarthritis (OA), is the progressive accumulation of damaged macromolecules leading to cell dysfunction and death. Autophagy, a key pathway for cellular homeostasis by removing such damaged molecules and organelles, including mitochondria, has a protective and survival-promoting function. Recent studies indicated that autophagy decreases with aging and OA contributing to the accumulation of damaged macromolecules. In addition, there is increasing evidence that mitochondrial dysfunction plays a critical role in accelerating the aging process and several lines of evidence demonstrated mitochondrial dysfunction in OA cartilage. *The objective of this study is to determine whether activation of autophagy protects from mitochondrial dysfunction in human chondrocytes.*

Methods: Human chondrocytes were treated with Rotenone (10 μg/ml), Antimycin (40 μg/ml) and Oligomycin (10 μg/ml), a mitochondrial respiratory chain (MRC) inhibitors of complex I, III and IV, respectively. Mitochondrial function and cell death were evaluated by Flow Cytometry (FC) and Fluorescence Microscopy (FM). Autophagy activation was analyzed by determination of LC3, a main marker of autophagy activation by Immunofluorescence (IF). To investigate whether autophagy protects from mitochondrial dysfunction, autophagy was induced by mTOR inhibition, using mTORC1 selective inhibitor Rapamycin (Rapa, 10 μM) and mTORC1 and mTORC2 inhibitor Torin 1 (50 nM). The effects on autophagy, mitochondrial function and chondrocyte viability were analyzed by IF, FC and FM.

Results: Mitochondrial dysfunction was induced by 6 h treatment with MRC inhibitors, which significantly decreased mitochondrial membrane potential ($\Delta\Psi$m) (ROT: 26.17 $\pm$ 5.9; AA: 18.21 $\pm$ 3.28; Oligo: 41.74 $\pm$ 7.59, expressed as % vs control; *$p < 0.01$). These results are consistent with increased ROS production (26.8 %, 44.6 % and 25.7 % for ROT, AA and Oligo, respectively; *$p < 0.001$) and cell death by apoptosis at 12 h (Control: 13.56 $\pm$ 1.83; ROT: 33.66 $\pm$ 5.55; AA: 29.05 $\pm$ 4.262; *$p<0.05$). Autophagy activity determined by LC3 expression significantly reduced in response to MRC inhibitors at 12 h. To evaluate whether autophagy regulates mitochondrial dysfunction, chondrocytes were pretreated with Rapa and Torin 1 for 4 h and then treated with the MRC inhibitors for 12 h. The results show an increase in LC3 expression compared to MRC inhibitors alone. Furthermore, autophagy inducers Rapa and Torin1 increased $\Delta\Psi$m (Rapa: 125.8 $\pm$ 20.74; Rapa+ROT: 44.67 $\pm$ 10.37; Rapa+AA: 30.71 $\pm$ 5.949; Rapa $\pm$ Oligo: 108.5 $\pm$ 55.03 and Torin 1: 90.34 $\pm$ 9.17; Torin 1+ROT: 35.24 $\pm$ 2.7; Torin 1+AA: 41.98 $\pm$ 6.49; Torin 1+Oligo: 98.19 $\pm$ 16.81; *$p<0.05$), decreased ROS production (*$p<0.05$) and reduced cell death, suggesting a protective effect of autophagy activation on pharmacologically induced mitochondrial dysfunction.

Conclusion: These data identify autophagy activation as a protective mechanism from mitochondrial dysfunction in human chondrocytes. Pharmacological interventions that enhance autophagy may have chondroprotective activity in articular cartilage with defects on mitochondrial function.

Interconnected Cellular Projections and Gap Junctions Mediate Metabolic Coupling Between Chondrocytes Located In Different Layers Of The Tissue: Cell-To-Cell Communication In Normal and Osteoarthritic Cartilage. Maria Dolores Mayan[1], Paula Carpintero-Fernández[2], Raquel Gago-Fuentes[2], Patricia Fernández-Puente[3], Purificacion Filgueira-Fernandez[3], Noa Goyanes[3], Virgin Valiunas[4], Peter Brink[4], Gary Goldberg[5] and Francisco J. Blanco[6]. Background/Purpose: We have recently found that articular chondrocytes from human adults contain long cytoplasmic arms that cross the extracellular matrix and physically connect two chondrocytes located in distant lacuna. Besides, we have also demonstrated that primary chondrocytes from adults are able to communicate with each other via gap junctions (GJ) as evidenced by the intercellular transfer of tracer dyes.

Methods: For immunohistochemistry (IHC) assays, in situ cartilage was frozen immediately using Tissue-Tek O.C.T. and isopentanol in liquid nitrogen. For Scanning Electron Microscope (SEM), samples were embedded in cacodylate buffer before dehydratation. Dual Voltage-clamp methods along with the study of glucose and oligonucleotides transference and in situ electroporation were used for the study of gap junctional communication (InSitu Porator™ Cell Projects Ltd). Transwell co-culture system and mass spectrometry were used for the identification and quantification of transjuctional amino acids. Primary chondrocytes were previously cultured in SILAC® Dulbecco's Modiffied Eagle's Medium containing L-lisina [$^{13}C_6$] and L-arginina [$^{13}C_6$, $^{15}N_4$]. Prior to LC analysis amino acids were derivatized using the tEZ: faastTM kit. Detection of analytes was performed with a Thermo Scientific LTQ-Orbitrap.

Results: IHC, electrophysiology experiments and "metabolic capture" assays revealed that GJs play a metabolic function by exchanging nutrients including glucose and essential amino acids between cells. Microinjection of the fluorescent glucose derivative 2-NBDG showed a progressive fluorescence intensity increase in the contacted recipient cells during 22 and 35 minutes after dye injection. In situ electroporation of donor cells confirmed that adult chondrocytes efficiently exchange glucose between adjacent cells (18–20 cells deep). When cells were pre-incubated for 1 hour with 250μg/ml of the GJ inhibitor GAP27, the transference of glucose was severely reduced (1–2 cells deep). For Transwell co-culture system, donors previously cultured in "heavy medium" were allowed to settle for 4 hours, time enough to form cell projections on the membrane right side up containing receivers. Mass spectrometry analysis revealed the transference of 3,5 pmol/ml of [$^{13}C_6$]-L-lysina and 3 pmol/ml of [$^{13}C_6$, $^{15}N_4$]-L-arginina. The results were confirmed using in situ electroporation and fluorescent labelled amino acids. IHC experiments in cartilage from patients with osteoarthritis (OA) revealed significantly elevated levels of the GJ protein Cx43 in the superficial zone and down through the next 1000 μm of tissue. Besides OA condrocytes contain longer cytoplasmic projections.

Conclusion: The results here presented demonstrated that chondrocytes from human adult cartilage are physically connected to each other forming a three-dimensional cellular network, and are able to transfer nutrients such as glucose and essential amino acids through GJ channels. The levels of Cx43 protein and the length of cells projections suggest alterations in the normal homeostasis control and cell-cell communication between chondrocytes in cartilage of patients with OA.

Chondrocyte Hypertrophy, Measured By The Secretion Of Collagen Type X, Is Associated With Cartilage Degradation and Systemic Inflammation In Osteoarthritis. Yi He[1], Natasja Stæhr Gudman[2], Niels Ulrik Hansen[1], Jianxia Wang[3], Di Su[3], Qinlong Zheng[3], Ole Simonsen[4], Kristian Kjaer Petersen[5], Moustapha Kassem[6], Morten Asser Karsdal[2] and Anne C. Bay-Jensen[2]. [1]Nordic Bioscience, Herlev, Denmark, [2]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [3]Nordic Bioscience China, Beijing, China, [4]Frederikshavn Hospital, Frederikshavn, Denmark, [5]Center for Sensory-Motor Interaction, Aalborg, Denmark, [6]Odense University Hospital and University of Southern, Odense, Denmark.

Background/Purpose: Osteoarthritis (OA) is the most common degenerative joint disease, of which the pathogenesis is inadequately understood. The hypertrophy-like changes, such as expression of hypertrophy markers and matrix calcification have been observed in the initiation and progression of OA. The aim of this study was to investigate the relationships of chondrocyte hypertrophy, cartilage degradation and systemic inflammation by measuring 3 biomarkers in serum of 283 OA patients.

Methods: i) A competitive ELISA, C-Col10, was developed as a marker of chondrocyte hypertrophy, through measurement of type X collagen (ColX). ii) C-Col10, C2M (matrix metalloproteinase-derived fragments of type II collagen) and hsCRP were quantified by ELISA in serum of the patients, stratified by Kellgren-Lawrence (KL) score 0–4. iii) Association between serum levels of the 3 biomarkers were analyzed (Pearson correla-

tions were done on log transformed data). The data is shown as mean [95%-CI]. iv) Full-depth cartilage biopsies from OA patients with different disease stages were immunostained with the C-Col10 and C2M antibodies.

Results: The C-Col10 assay was specific for the C-terminal of type X collagen. The measurement range of the C-Col10 assay was 22–500pg/ml, with intra- and inter-assay CVs of 4.2% and 13%. There was a trend towards increasing C-Col10 levels with increasing KL score: KL0 52[24–80] pg/ml, (n=10); KL1 67 [56–78] pg/ml, (n=59); KL2 87[74–99] pg/ml, (n=144); KL3 80pg/ml [60–101], (n=36), and KL87 [47–127] pg/ml, (n=22). There was significant correlation of levels between C-Col10 and hsCRP (r=0.23, P<0.0001), and C2M (r=0.55, P <0.0001). There was no correlation between C2M and hsCRP. Age and BMI adjustment didn't change the significant correlations. OA patients with above normal hsCRP (>5) levels showed increased C-Col10, however this was independent from cartilage degradation. These data was supported by immunoloclization of C-Col10 and C2M in the OA cartilage biopsies, which showed distinct staining patterns: C-Col10 was observed in the deep zone around the pre-hypertrophic chondrocytes in mild OA, and around chondrocyte clusters in severe OA. Whereas C2M was consistently observed in all layers of the OA cartilage.

Conclusion: Elevated C-Col10 levels were measured in OA patients and significantly higher in patients with above normal hsCRP levels, suggesting that inflammation is associated with chondrocyte hypertrophy. Correlation between C-Col10 and cartilage degradation indicated that chondrocyte hypertrophy may be involved in the cartilage degradation. All data show that chondrocyte hypertrophy is an essential step in the pathogenesis of OA and C-Col10 measurement can provide the critical information of OA disease status.

Subchondral Bone Turnover and Osteophyte Formation Are Key Aspects In The Progression Of Osteoarthritis and May Be Assessed and Predicted By a-CTX. Morten Asser Karsdal[1], Janet L. Huebner[2], Virginia Byers Kraus[2], Diana J. Leeming[1], Edward Coleman[2], Gary E. McDaniel[2], Kim M. Huffman[2], Kim Henriksen[1] and Anne C. Bay-jensen[1]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Duke University Medical Center, Durham, NC.

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritic disease. It is characterized by pathological changes in both bone and cartilage turnover as well as structure in which subchondral bone remodeling is speculated to be both an initiator and driver of OA. The aim of the current study was to evaluate a biomarker of high localized bone resorption, a-CTX, previously used for bone metastasis. OA patients were characterized by; radiographic knee OA, severity, progression and localized knee bone turnover as assessed by bone scintigraphy, a dynamic and sensitive indicator of symptomatic knee OA.

Methods: A total of 149 participants (111 women, 38 men) were included who met ACR criteria for symptomatic OA and had the presence of Kellgren Lawrence (K/L) grade 1–4 radiographic OA in at least one knee. Late-phase bone scan images of both knees were obtained 2 hours after administration of ^{99m}Tc-MDP. The intensity of uptake was scored semi-quantitatively and summed for each joint site. Radiographic knee OA severity, based on the summed scoring of osteophytes (OST) and joint space narrowing (JSN) was assessed using the standardized OARSI radiographic atlas. Progression status was determined by calculating the sum of the change score in either JSN or OST between baseline and the 3-year follow-up assessment. The concentrations of urinary a-CTX and CTX-II were determined by ELISA and normalized to creatinine concentration.

Results: a-CTX was related to OST formation independent of the effects of age, gender, BMI, and HRT (p=0.009). a-CTX did not correlate with severity of knee OA based on OST and JSN, but did correlate with bone turnover assessed by intensity of ^{99m}Tc-MDP uptake in the medial knee compartment. Concentrations of urinary CTX-II were strongly associated with knee OA severity based on osteophyte, intensity of total knee ^{99m}Tc-MDP uptake, and joint space narrowing.

Conclusion: a-CTX was associated with subchondral bone turnover, and osteophyte formation, both central features of the pathogenesis of OA. CTX-II was correlated to JSN, and burden of disease as previously reported. The significant and strong association of a-CTX to bone turnover in the subchondral region suggests that this marker may be a non-invasive surrogate for active bone turnover in knee OA. Such markers may assist in the identification patients whom may benefit from strong anti-resorptives which inhibit bone and subchondral bone turnover.

Autophagy Changes During Aging: A Study In GFP-LC3 Mice. Beatriz Carames[1], William B. Kiosses[2], Merissa Olmer[3] and Martin Lotz[4]. [1]Osteoarticular and Aging Research Lab, INIBIC–Complejo Hospitalario Universitario A Coruña, SPAIN, A Coruña, Spain, [2]The Scripps Research Institute, La Jolla, CA, [3]The Sripps Research Institute, La Jolla, CA, [4]The Scripps Research Institute, La Jolla, USA, La Jolla, CA.

Background/Purpose: Aging is a main risk factor for osteoarthritis (OA), the most prevalent musculoskeletal disorder. Aging-associated changes in autophagy, an essential cellular homeostasis mechanism, have recently been observed in several tissues, including articular cartilage. The objective of this study is to establish the patterns of autophagy in young and aging cartilage using GFP-LC3 mice.

Methods: In GFP-LC3 transgenic mice, GFP-LC3 is ubiquitously expressed under the control of CAG promoter, and the accumulation of GFP punctate, which represents autophagosome, is observed in almost all tissues after 24–48 h fasting period. Homozygous GFP-LC3 mice (tg/tg) were employed to monitore autophagy in liver and joint tissues in response to aging (6 months old and 28 months old mice) by confocal microscopy analysis of vibratome sections. Two sets of control mice were included: Wild-type C57BL/6J mice were used to determine the background level of green fluorescence and young homozygous GFP-LC3 mice (6 months old) to provide a baseline for autophagy activity in liver and joints. Morphological changes in the articular cartilage were examined by histology using a semiquantitative scoring system. Furthermore, cellularity was determined by Hematoxylin-Eosine staining (H&E) and expression of the autophagy proteins Atg5 and LC3 was analyzed by immunohistochemistry (IHC) in 6, 18, 24 and 28 months old mice.

Results: GFP-LC3 mice from 6 and 28 months old were employed to analyze the effect of aging on autophagy activation in liver and cartilage in the knee joints. In response to aging (28 months old mice), we observed a reduction in the GFP-LC3 signal in liver and cartilage. This reduction was statistically significant based on the total number of vesicles per cell ($P < 0.01$) and on the total area of vesicles per cell (um^2) ($P < 0.01$) compared to the control group (6 months old mice). In addition, the histological evaluation showed a significant decrease in cartilage score ($P < 0.01$) in the old mice compared to the young control group. These results were accompanied with a reduction on cartilage cellularity and with a decrease in the expression of Atg5 and LC3 in an age-dependent manner, indicating a correlation between autophagy defects and aging-related OA in mice.

Conclusion: These results support the hypothesis that autophagy is decreased with aging and that compromised autophagy represents a novel mechanism in the development of OA.

Fibrillin-1 Expression and Function Is Needed For Normal Joint Function and Mutations Leads To Osteoarthritis. Wasabha Ramanayake[1], Helen Jones[1], Isabel Orriss[2], Tim Arnett[2], Andrew Pitsillides[3], Christopher P. Denton[1], David J. Abraham[1] and Blandine Poulet[1]. [1]UCL Medical School, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Royal Veterniary College, London, United Kingdom.

Background/Purpose: Osteoarthritis (OA) is a common degenerative disease leading to pain and disability in >6 million british people. The TGFb signalling pathway has been shown to play a major role in joint homeostasis and in OA development. Fibrillin-1 is an extracellular matrix protein that may play a structural role in the matrix of articular cartilage, but also regulates the bioavailability of TGFb to the cell. Thus Fibrillin-1 mutations, such as those seen in the Tight Skin mouse (or TSK), have been shown to increase TGFb signalling. The aim of this study is therefore to determine changes in

fibrillin-1 expression during osteoarthritis in mice and to characterise the effect of Fibrillin-1 mutations in ageing-induced OA development in TSK mice.

Methods: Immunohistochemistry for Fibrillin-1 expression was performed in Str/ort mice, a known model of spontaneous OA, and in control aged-matched non-OA CBA mice, in knee joints with different degrees of OA severity. The knees of TSK and littermate control male mice of 60–80wks of age were fixed and microCT scanned. Abnormal ectopic calcified regions were analysed. After scanning, joints were decalcified and processed for paraffin embedding; serial coronal sections were cut at 6um and sections at regular intervals stained with Toluidine Blue.

Results: Fibrillin-1 was localised in the pericellular matrix of articular chondrocytes in normal joints. During the development of OA in Str/ort mice, however, Fibrillin-1 immunolabelling was decreased, in particular around articular cartilage lesions. TSK mice microCT images showed important ectopic calcification in various ligaments, as well as osteophyte formation on the margins of the joints. Preliminary data suggest that articulate cartilage degradation was increased in TSK mice compared to aged-matched control mice.

Conclusion: Our preliminary study shows that Fibrillin-1 protein expression is decreased during OA development in a well known model of spontaneous OA, suggesting TGFb bioavailability may be modified during this period. In addition, mutations in Fibrillin-1 in the TSK mouse lead to abnormal ossification in the knee joint as well as severe OA development. These data suggest that Fibrillin-1 plays an important role in joint homeostasis and that abnormal expression or mutations in its gene can lead to OA development.

Terminal Uridyltransferase Enzyme ZCCHC11 Regulates Interleukin-6 Expression In Primary Human Osteoarthritis Chondrocytes. Abdul Haseeb[1], Mohammad Shahidul Makki[1], Ahmad Arida[2] and Tariq M. Haqqi[2]. [1]Northeast Ohio Medical University (NEOMED), Rootstown, OH, [2]North East Ohio Medical University, Rootstown, OH.

Background/Purpose: Non-template addition of nucleotides on the 3' termini of mRNAs acts as a mechanism that controls mRNA stability. ZCCHC11 is a member of the non-canonical poly A polymerase (ncPAP) family. It has been implicated in post-transcriptional regulation of various genes, including some cytokines, by modification of their poly A tails or by modification of microRNAs that target these mRNAs. Role of ZCCHC11 in chondrocyte physiology and in the pathogenesis of osteoarthritis (OA) has not been studied. In the present study we determined the expression of ZCCHC11 in damaged and undamaged cartilage obtained from OA patients. We also studied the effect of IL-1b on the expression of ZCCHC11 in primary human chondrocytes. We further investigated the effect of gene silencing of ZCCHC11 on the secreted levels of several cytokines.

Methods: Primary human chondrocytes were isolated from the deep zone of the cartilage obtained from OA patients who underwent total knee joint replacement surgery. Silencing of ZCCHC11 gene was carried out by using ON-TARGETplus siRNA pool (Thermo Fisher Scientific, Waltham, MA). Protein levels of 40 cytokines in culture supernatants after siRNA transfections were analyzed simultaneously using a glass-based human cytokine microarray (RayBio Human Cytokine Array). Poly A tail length analysis was performed by reverse transcription followed by PCR using an adaptor reverse primer and a forward primer specific for IL-6 mRNA. The PCR products were run on 2% agarose gel and visualized by EtBr staining. mRNA levels of ZCCHC11 and IL-6 genes were quantitated by using the TaqMan assays (Applied Biosystems, Carlsbad, CA). Data were derived using Origin 6.1 software and $P<0.05$ was considered significant

Results: There was higher expression of ZCCHC11 mRNA in damaged cartilage as compared to unaffected smooth cartilage obtained from OA patients. mRNA expression of ZCCHC11 was significantly up-regulated by treatment of human primary chondrocytes with IL-1b. Cytokine protein array analysis revealed a significant decrease in secreted levels of IL-6 and a subset of cytokines upon siRNA mediated silencing of ZCCHC11 gene. Quantitative PCR analysis showed that mRNA expression of IL-6 gene was also suppressed in human chondrocytes with depleted ZCCHC11 mRNA. Poly A tail length analysis showed a significant shortening of IL-6 mRNA poly A tail upon silencing of ZCCHC11 gene indicating that ZCCHC11 is required for IL-6 mRNA stability.

Conclusion: The data presented here for the first time show the expression of ZCCHC11 in human cartilage. Differential expression of ZCCHC11 in damaged and undamaged cartilage and its stimulation by IL-1b, a cytokine up-regulated during OA, point to a role of this enzyme in osteoarthritis. Furthermore, our gene silencing studies show the effect of ZCCHC11 on secretion of IL-6, an important cytokine involved in the pathogenesis of OA, via modifying its mRNA at the 3' end. Taken together, the present study reveals a novel RNA modifying enzyme ZCCHC11 as an important player in OA pathophysiology.

Decorin-Deficiency Alters Cartilage Stiffness and Attenuates The Development Of Osteoarthritis In Mice. Tobias Gronau[1], Uwe Hansen[1], Daniela Seidler[1], Renato Iozzo[2], Attila Aszodi[3], Carina Prein[4], Hauke Clausen-Schaumann[4], Karsten Krüger[5], Frank Mooren[5], Jessica Bertrand[1], Thomas Pap[1], Peter Bruckner[1] and Rita Dreier[1]. [1]University Hospital Münster, Münster, Germany, [2]Thomas Jefferson University, Philadelphia, PA, [3]Ludwig-Maximilians-University Munich, Munich, Germany, [4]Munich University of Applied Sciences, Munich, Germany, [5]Justus-Liebig University Giessen, Giessen, Germany.

Background/Purpose: In articular (AC) and growth plate (GP) cartilage, the small leucine-rich proteoglycan decorin is mainly present within the interterritorial regions (ITs) of the extracellular matrix. Within the extracellular matrix it is associated with thick, well-banded collagen fibrils. Here we analyzed the impact of decorin-deficiency ($Dcn^{-/-}$) on the biomechanical properties of cartilage and the development of osteoarthritis via forced exercise.

Methods: Diverse cartilaginous tissues of $Dcn^{-/-}$ mice and wild-type (WT) mice were examined at different developmental time points by histology/immunohistochemistry and by atomic force microscopy (AFM). The levels of active TGF-β were analyzed by ELISA. Expression of glycosaminoglycan (GAG) modifing enzymes was assesed via semi-quantitave RT-PCR. Osteoarthritic changes (OA) were induced in 3 month-old $Dcn^{-/-}$ and WT mice via forced running on a treadmill. The severity of the disease was evaluated via a modified Mankin score.

Results: In P14.5 and adult $Dcn^{-/-}$ mice, Alcian blue (pH 1.0) stained highly sulfated GAGs intensely throughout the entire GP and AC. In WT mice, staining was weaker and mainly restricted to the pericellular/territorial zones. Likewise, antibodies to stubs of chondrotin-4-sulfate (ΔC4S) chains intensely labeled all zones of GP and AC in $Dcn^{-/-}$ but not in WT mice. Futhermore, mutant mice showed an increased expression of enzymes involved in GAG modification (PAPSS1, C4ST2). By contrast, the distribution and staining intensities of core proteins like aggrecan or biglycan were similar in both genotypes. AFM analysis of AC sections at 3 months of age revealed slightly altered fibril architecture and increased compressive stiffness of the ITs from $Dcn^{-/-}$ mice. Those abnormalities were accompanied by enhanced levels of TGF-β in mutant mice. Both genotypes exhibited osteoarthritic changes in knee joint cartilage after six weeks of forced running. However, the changes were less severe in $Dcn^{-/-}$ than in WT mice (Mankin score 4.5 versus 6.5).

Conclusion: We propose the following mechanism attenuating OA in $Dcn^{-/-}$ mice: Reportedly, decorin sequesters the cytokine TGF-β in the extracellular matrix. Higher levels of active TGF-β in cartilage of $Dcn^{-/-}$ mice are likely to prevent inappropriate chondrocyte hypertrophy and, hence, induction of osteoarthritis. TGF-β is also known to affect sulfation of GAGs. Probably an increased sulfation leads to an augmented immobilization of water, increased osmotic swelling pressure and accordingly a stiffer cartilage matrix. Therefore, $Dcn^{-/-}$ mice are less prone to develop osteoarthritis due to a combination of elevated active TGF-β levels and enhanced compressive stiffness of the articular cartilage.

Protective Effect Of Intra-Articular Injection Of Alginate-Chitosan Beads In An Hydrogel Against The Development Of Experimental Osteoarthritis Lesions In Rabbit. Frédéric Oprenyeszk[1], Mickael Chausson[2], Véronique Maquet[2], Jean-Emile Dubuc[3] and Yves Henrotin[1]. [1]Bone and Cartilage Research Unit, Liège, Belgium, [2]KitoZyme SA, Herstal, Belgium, [3]Orthopaedic Department, Bruxelles, Belgium.

Background/Purpose: Today, there is no treatment to cure osteoarthritis (OA) or to delay effectively its progression. Current treatments are mainly based on the alleviation of painful symptoms but are unable to restore the cartilage. The development of biomaterial is a promising approach. Herein, we report the evaluation of a new biomaterial composed of alginate-chitosan (AC) beads dispersed in an (H) hydrogel derived from chitosan on OA rabbit model.

Methods: OA was surgically induced by the transection of the anterior cruciate ligament (ACLT) in HYLA albino rabbits. One week after surgery, animals were randomly divided into 3 groups: group I (n=7): mix of AC beads and H hydrogel; group II (n=7): H hydrogel alone; group III (n=7): saline solution (control). The treatments (900 μl) were injected intra-articularly. X-rays from the right knee were performed before surgery, at the time of injection and at sacrifice. The standard radiographs were acquired in extension and scored by the Kellgren and Lawrence (K&L) scale. After 6 weeks, animals were euthanized and the right joint was dissected. The macroscopic evaluation of cartilage from femoral condyles and tibial plateaus stained with India ink was done. Histological sections from bearing areas of each compartment and synovial membrane were stained with Safranine-O/fast green or hematoxylin/eosin. Histological evaluation was done according to the OARSI histological score where 0 represented a normal situation and 24 points the maximum severity score. Blood samples were collected the day of injection and prior the sacrifice. Prostaglandin E_2 (PGE_2) and C-reactive protein (CRP) were measured in serum using immunoassays.

Results: The X-rays analysis showed a significant decrease ($p < 0.05$) of the K&L score in group I (AC beads and H hydrogel; 1.5 ± 0.2) compared with group II (H hydrogel; 2.2 ± 0.5) and group III (saline solution; 3.0 ± 0.4). The size and the severity of the macroscopic OA cartilage lesion tended to decrease in group I compared to the other groups. The histological global score that refers to all compartments of the knee joint was significantly decreased in group I (11.0 ± 0.7) compared to group II (14.4 ± 0.6, $p < 0.01$) and group III (14.8 ± 0.6, $p < 0.001$). The injection of AC beads and H hydrogel also tended to reduce the synovial membrane inflammation. No significant variation of PGE_2 and CRP serum levels were observed in each after 6 weeks follow-up whatever the treatment injected.

Conclusion: Alginate-chitosan beads dispersed in H hydrogel prevented OA in rabbit after ACL transection. This effect was not observed with the hydrogel alone, suggesting that AC beads play a role in joint protection. The preventive effect was observed in all joint compartments indicating a global protective effect of this new injectable biomaterial.

Human Mesenchymal Stem Cells Cultured On Collagen Scaffolds For Cartilage Tissue Engineering. Clara Sanjurjo-Rodríguez[1], Adela Helvia Martínez-Sánchez[1], Tamara Hermida-Gómez[1], Isaac M. Fuentes-Boquete[2], Francisco J. De Toro[2], Julia Buján[3], Silvia Díaz-Prado[2] and Francisco J. Blanco[1]. [1]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC- University of A Coruña, A Coruña, Spain, [2]INIBIC-Universidade da Coruña, A Coruña, Spain, [3]Department of Medical Specialties, Madrid, Spain.

Background/Purpose: Osteoarthritis is a degenerative disease without a treatment. Tissue Engineering could provide an alternative tool for cartilage repair. The aim of this study was to evaluate the neotissue formed using human bone marrow mesenchymal stem cells (hBM-MSCs) and collagen scaffolds.

Methods: hBM-MSCs were cultured on collagen (Col), Col+heparan sulfate (HS), Col+chondroitin sulfate (CHS) and Col+heparin (OLH3) scaffolds, in chondrogenic medium supplemented by TGFβ-3. Chondrogenic differentiation and the constructs were evaluated by histochemistry, immunohistochemistry, and molecular biology. Cellular morphology and ultrastructure were studied by electron microscopy. Culture supernatants were collected and the amount of secreted collagen was measured by ELISA.

Results: Haematoxilin-Eosin staining showed that hBM-MSCs have grown through the scaffolds. The cellular percentage respect the whole scaffold area was higher than 50% in all the biomaterials and it was observed a big amount of extracellular matrix (ECM) in all of them, except in Col+OLH3. The ECM showed proteoglycans, by means of safranin O (SO) staining, and immunopositivity for Col II in all the constructs, except in Col+OLH3 (Figure). By measurement of relative expression levels (REL) we observed that COLII were expressed by cells in Col I (0.63), Col I+Col II (1.00), Col I+3%HS (0.47), Col I+Col II+HS (0.93), Col I+Col II+CHS (3.57) and Col I+OLH3 (5.20). Moreover, REL of AGG were higher in Col I+Col II+HS (6.47) constructs than in Col I (0.00), Col I+Col II (0.95),Col I+3%HS (0.17), Col I+Col II+CHS (0.00) and Col I+OLH3 (0.00). Electron microscopy showed cells with a big amount of mitochondria and with spherical and oval shapes (Figure). Col released was detected in all supernatant cultures, obtaining the highest concentration (μg/total volume) at all times, in Col I+3%HS cultures except at day 21: Col I (137.33), Col I+Col II+HS (3.33), Col I+Col II (0.00),Col I+3%HS (0.00), Col I+Col II+CHS (13.90) and Col I+OLH3 (0.00).

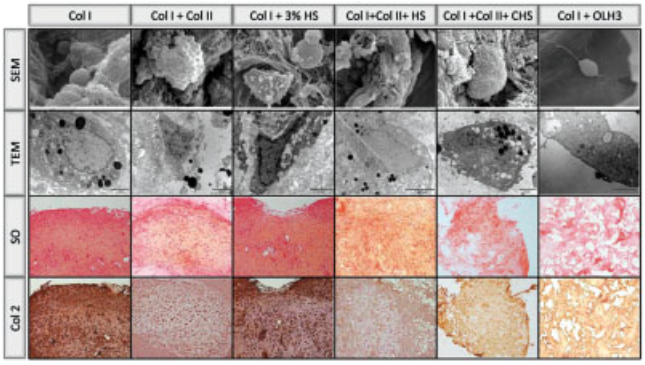

Figure. Images collected from the different constructs by electron microscopy analysis, histochemistry and immunohistochemistry. Vertically in columns are shown the constructs from the different types of collagen scaffolds. Ordered in rows are shown the different analysis: Scanning Electron Microscopy (SEM), Transmission Electron Microscopy (TEM), Safranin O staining (SO) and Collagen type II immunostaining (Col 2).

Conclusion: Data showed that hBM-MSCs are capable of growing on collagen scaffolds. On HS enriched collagen scaffolds was kept the differentiated phenotype. The ECM characteristics and the gene expression showed the synthesis of a cartilage-like neotissue which could be useful for cartilage tissue engineering. *Acknowledgements*: Opocrin S.P.A.; CAM (S2009/MAT-1472); CIBER-BBN CB06-01-0040; SAI-UDC; REDICENT; Diputación de A Coruña; Jiménez Díaz Fundation.

Norepinephrine (NE) Inhibits Mesenchymal Stem Cell (MSCs) Chondrogenesis By Accelerating Hypertophy – Relevance For Cartilage Regeneration. Zsuzsa Jenei-Lanzl[1], Peter Angele[2], Frieder Kees[3], Georg Pongratz[4] and Rainer H. Straub[5]. [1]Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Regensburg, Germany, [2]Department of Trauma Surgery, University Hospital Regensburg, Germany, Regensburg, Germany, [3]University of Regensburg, Regensburg, Germany, [4]University Hospital Regensburg, Regensburg, Germany, [5]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany.

Background/Purpose: The high potential of mesenchymal stem cells (MSCs) in cartilage regeneration is undoubtful. The presence of MSCs in healthy or arthritic cartilage has also been confirmed. In addition, MSCs migrating from synovium into the cartilage and differentiating into chondrocytes has been described, which might be the reason for increased MSC number in OA. Furthermore, it is known that sympathetic nerve fibers are present in healthy and osteoarthritic (OA) synovium and that the sympathetic nervous system mediates numerous effects on adult skeletal system. Therefore, the aim of this study was to investigate the effects of the most important sympathetic neurotransmitter norepinephrine (NE) on MSC chondrogenesis.

Methods: To find possible natural sources of local catecholamines in human joint material, we studied sympathetic nerve fibers (tyrosine hydroxylase (TH) expression), catecholamine biosynthesis and synovial fluid levels. Human bone marrow derived MSCs were expanded and chondrogenesis was initiated in a 3D aggregate culture. Endogenous catecholamine production of hMSCs was analyzed during proliferation and chondrogenesis via HPLC. Parallel to control conditions, aggregates were incubated with different NE concentrations and specific β-adrenoceptor agonist (isoproterenol) or antagonist (nadolol). After 21 days, chondrogenesis quality was evaluated macroscopically, histologically and biochemically. Furthermore, specific adrenoceptors (AR) were detected.

Results: In the human joint, TH-positive fibers and/or single cells were present in synovial tissue, meniscus, and subchondral bone marrow. In addition, knee-traumatized patients demonstrated high NE concentrations in synovial fluid. At various stages of human MSC chondrogenesis, βAR were expressed. No endogenous catecholamine synthesis was detected during chondrogenesis. Chondrogenic MSC aggregates treated with NE or isoproterenol synthesized lower amounts of type II collagen and glycosaminoglycans. NE and isoproterenol dose-dependently increased markers of cartilage hypertrophy (collagen type X and MMP-13). Nadolol reversed inhibition of chondrogenesis and up-regulation of cartilage hypertrophy.

Conclusion: The suppression of MSC-dependent chondrogenesis by high NE or isoproterenol suggests that the β-adrenoceptors mediate this effect. By inhibition of cartilage repair, these sympathetic influences can be important after multiple minor and major joint traumata. These findings can be a basis for novel neuro-chondrogenic therapeutic options.

Synovial Activation In Experimental OA Drives Immuno suppressive Effects Of Adipose-derived Stem Cells After Local Administration and Protects Against Chondrogenesis In Ligaments. Peter L.E.M. van Lent[1], Rik Schelbergen[1], Menno C. ter Huurne[1], Arjen B. Blom[1], Johannes Roth[2], Thomas Vogl[2], Christian Jorgensen[3] and Wim B. van den Berg[4]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]University of Muenster, Muenster, Germany, [3]Inserm U844, CHU saint-Eloi, Université Montpellier 1, CHU Lapeyronie, Montpellier, France, [4]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: A substantial subpopulation of patients with early osteoarthritis (OA) show a thickened synovial lining layer comprising macrophages expressing an activated phenotype (reflected by production of IL-1β and S100A8/A9). Recently we have shown that adipose derived stem cells (ADSC) inhibit joint destruction after local application to knee joints with experimental OA. The goal of our study was to explore the effect of synovial activation on the immunosuppressive capacity of ADSCs to modulate joint destruction after local administration to experimental OA knee joints.

Methods: ADSCs were isolated from fat surrounding the popliteal lymph nodes and cultured for two weeks. Collagenase induced OA (CIOA) was induced by injection of collagenase into murine knee joints. ADSCs were injected into the same joints at day 7 after induction of OA. Joint destruction was measured within 6 weeks after induction. Total knee joints were isolated and processed for histology. Synovial thickening was measured using an arbitrary scale of 0–3. Synovium was isolated at various time-points after injection of ASC and washouts were measured for S100A8/A9 and IL-1 using Luminex. Chondrogenesis/bone formation inside ligaments was measured using image analysis.

Results: A single dose of ADSCs (20×10^3) was injected into the knee joint of mice, 7 days after induction of CIOA. Thickening of the synovial lining layer, which is characteristic for this model, was high (2,6+/−1) and was significantly inhibited by ADSC treatment at day 14 (9%) and day 42 (35%) when compared to control (serum) treated OA joints. Washouts of synovium taken at 6 hrs, 48 hrs, day 14 and day 42 after injection of ADSCs showed that protein levels of IL-1β and S100A8/A9 were significantly decreased already 48 hrs after injection of ADSC (IL-1β 57% and S100A8/A9 by 22%) and rapidly declined thereafter. Serum levels of S100A8/A9 were inhibited with 85% (from 794+/− 294 to 117+/− 29 ng/ml) at day 14 after ADSC treatment suggesting that the effect on synovial activation is very rapid. Strikingly, ADSCs had a protective effect on chondrogenesis in medial and cruciate ligaments at day 42 after treatment (inhibition 92% and 43% respectively). Next, we explored the effect in a condition with less synovial inflammation. Synovial thickness at day 42 was 62% lower when compared to the former study (from 2.6 +/−1 to 1 +/−0.2) which was reflected by lower S100A8/A9 serum levels (at day 14 around 50 ng/ml compared to 800 ng/ml). Injection of the same dose of ADSCs at day 7 after induction of OA, did not inhibit synovial thickening nor chondrogenesis in the collateral (1.3+/−0.2 versus WT controls 1.1+/−0.3) and cruciate ligaments (1.8+/−0.3 versus WT controls 1.9+/−0.2) when measured at day 42.

Conclusion: Our study indicates that synovial activation rapidly drives anti-inflammatory effects of ADSCs after local administration in murine knee joints with experimental OA and protects against development of ligament damage.

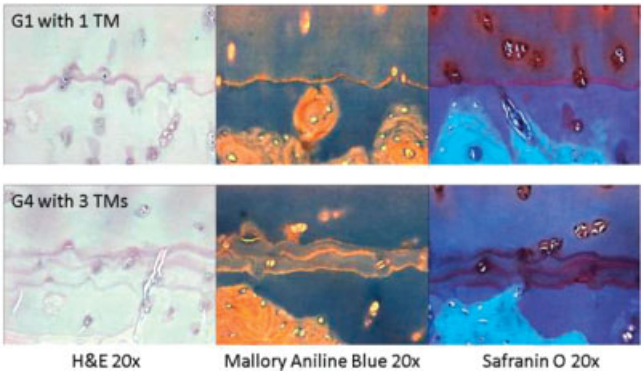
Tidemark Duplication In Osteoarthritis: Evidence Of Incremental Progression? Martine P. Roudier, Paul A. Manner and Peter A. Simkin. University of Washington, Seattle, WA.

Background/Purpose: Osteoarthritis (OA) is commonly envisioned as a gradual, relentlessly progressive process of "wear and tear" leading to eventual joint failure. As we see the tidemark (TM) between hyaline and calcified cartilage, we read a different message.

Methods: We studied the femoral condyles and tibial plateaux of 18 elderly body donors for evidence of tidemark duplication. We used 62 specimens representing at least 2 specimens per donor. Specimens were photographed, sampled, radiographed, decalcified using 10% formic acid, processed and embedded in paraffin, sectioned then stained with H&E, Safranine O and Mallory Aniline Blue. They were graded using the OARSI 2005 6 point-grading system (G0-G6). When two lesions existed in the same specimen, each lesion was individually graded. A TM number was recorded for each graded lesion. A Spearman correlation between the lesion grade and the number of tidemarks was determined using Graphpad Prizm software.

Results: TM number correlated significantly with OA histological grade ($r=0.81$, $p<0.0001$). Thirty three of the 62 specimens had 2 lesions generating 95 grades. Twelve grades were without visible TM (1 G5, 7 G6 and 4 technical issues) and were excluded from the study. Of the 83 remaining grades, 17 were G0 and had 1 TM, 27 were G1 and had 1 or 2 TMs, 22 were G2 and had 2 or 3 TMs, 9 were G3 and had 1, 2 or 3 TMs, and 8 were G4 and had 3 or 5 TMs.



Conclusion: The number of TMs correlated highly with the OARSI histological grade, suggesting that the TM number is a reflection of the OA disease stage. Since the TMs were distinct, we believe that duplication represents the legacy of abrupt, sequential changes leading to regional calcification of deep hyaline cartilage. The calcification buries the previous tidemark and causes the tidemark formation process to begin anew at a higher level. The most probable precipitating event would be a change in joint loading such as that resulting from a focal microfracture of subchondral bone.

Synovial Expression Of CCL19, MCP-1, and Their Receptors In Patients With Meniscal Injury: Variability and Relationship With Knee Symptoms. Justin B. Gan, Anjali Nair, Kanta Saha, Nikhil Verma, Charles Bush-Joseph, Matthew Tetreault, Anne-Marie Malfait, Kumar B. Rajan and Carla R. Scanzello. Rush University Medical Center, Chicago, IL.

Background/Purpose: Patients with meniscal injury are at increased risk for symptomatic knee osteoarthritis (OA), and often already have intraoperative signs of early-stage cartilage degradation. We previously reported that patients with meniscal tears often exhibit synovial inflammation, which is associated with more severe knee symptoms. We further demonstrated that synovitis was associated with expression of mRNA for CCL19, a lymphocyte chemoattractant, and its receptor CCR7. Others have reported a relationship between MCP-1, a macrophage chemoattractant, and knee pain in patients with knee injuries including meniscal tears. We sought to determine whether CCL19 and MCP-1 are measurable in synovial fluid (SF) of patients undergoing meniscal arthroscopies, and if protein levels are associated with knee symptoms or dysfunction. We also investigated expression patterns of CCR7 (CCL19 receptor) and CCR2 (MCP-1 receptor) within synovium to gain insight into the cell types that might be responsive to these factors.

Methods: We recruited subjects undergoing arthroscopy for meniscal tears. SF CCL19 and MCP-1 were measured by ELISA (R&D systems). Knee symptoms and dysfunction were preoperatively assessed using the Knee Injury and Osteoarthritis Outcome Score (KOOS), consisting of 5 subscales measuring pain, other knee symptoms, function in daily living (ADL), recreational activities, and quality of life. Associations with KOOS scores were tested using Pearson correlations. Multivariate linear regression models adjusted for age, gender, BMI, and degree of radiographic OA (Kellgren-Lawrence scores). Synovial CCR7 and CCR2 expression was characterized using immunohistochemical (IHC) staining, and compared to staining patterns in synovium from asymptomatic organ donors.

Results: 32 patients with meniscal tears were included. Median age (IQR) was 55 (47–61), and gender ratio M:F was 17:15. CCL19 was detectable in 25/32 (78%) while MCP-1 was detectable in all patients. Mean concentration+/−SD of CCL19 was 374.28+/−367.58 pg/mL, and MCP-1 was 450.13+/−273.85 pg/mL. CCL19 concentration correlated with worse KOOS-ADL subscores (Pearson r= −0.362, p=0.049), but was not independent of other factors in adjusted regression analyses. In the model, BMI was an independent predictor of KOOS-ADL subscores (p=0.01), and there was a correlation between BMI and CCL19 levels (Pearson r=0.430, p=0.02). MCP-1 levels did not correlate with KOOS subscores. IHC staining identified CCR7 expression in the synovial lining layer, endothelium, and perivascular inflammatory infiltrates, while CCR2 expression was identified primarily in the lining layer. CCR7 and CCR2 staining was more pronounced in patients with meniscal tears than in asymptomatic organ donors.

Conclusion: In patients with meniscal tears, CCL19 and MCP-1 are detectable in SF. Although SF CCL19 was not an independent predictor of knee symptoms, CCL19 may be related to increased BMI. CCR7 did appear increased in meniscal tear patients, and its expression by multiple cell types in synovium suggests that CCL19/CCR7 activity may be involved in development of synovial changes seen in these patients.

Anatomical Variation In The Morphology Of The Posterior Cruciate Ligament Synovio-Entheseal Complex and Correlation With Degenerative Change. Daniel Binks[1], Diane Bergin[2], Tony Freemont[3], Aleksandra Radjenovic[1] and Dennis McGonagle[4]. [1]University of Leeds, Leeds, United Kingdom, [2]Galway University Hospitals, Galway, Ireland, [3]University of Manchester, Manchester, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

Background/Purpose: Ligament attachments are often found to form complex anatomical functional units involving the ligaments themselves as well as associated synovium and bony tuberosities. Furthermore, stress minimising accessory fibrocartilages are frequently observed in the immediately adjacent joint cavities. Collectively, these structures are termed synovio-entheseal complexes (SECs) and are subject to the full gamut of degenerative changes associated with the osteoarthritis (OA) disease process.[1] Here we have investigated the SEC formed at the posterior cruciate ligament (PCL) tibial insertion using high resolution magnetic resonance imaging (MRI) and matched histology to show the involvement of the PCL-SEC in the phenotypic expression of knee OA.

Methods: High-resolution 3T MRI and comparative histological evaluation were performed on 14 normal cadaveric knee joints. SEC microanatomy and OA features of the PCL tibial attachment were evaluated on serial histological sections stained with H&E and Masson's Trichrome. Bilateral 3T MRI images were evaluated in 49 patients with early OA from the Osteoarthritis Initiative cohort for SEC morphology and for lesions associated with the early OA disease process at the PCL tibial enthesis. Differences among groups were determined by calculation of chi-square values.

Results: Histological evaluation confirmed the SEC microanatomical structure comprising the PCL, adjacent tibial bone plateau and intervening synovium along with sesamoid, periosteal and enthesis accessory cartilages and the posterior horn of the medial meniscus. Evidence of microanatomical damage was observed throughout the PCL-SEC, including; neovascularisation, chondrocyte cell clustering, tide mark duplication and mild inflammatory changes. In the early OA cohort, 3T MRI showed a high prevalence of SEC related lesions including bone marrow oedema (BME) immediately anterior to the PCL insertion (seen in 61% of knees) and osteophytosis lateral to the PCL insertion (85%). Signal hyperintensity on fluid sensitive sequences compatible with posterior recess synovitis immediately adjacent to the PCL was seen in 48% of knees and correlated with SEC cartilage abnormality (χ^2 =7.25, p<0.01). Furthermore, the frequency of BME at the PCL insertion was associated with a medial meniscus posterior horn deficient SEC anatomical variant (χ^2 =10.02, p<0.05).

Conclusion: The PCL has a prominent SEC configuration that is associated with microscopic evidence of OA in normal tissue. In early knee OA, pathological features were commonly observed at the PCL-SEC and immediately adjacent locations on 3T MRI. Although the PCL rarely fails in OA, the PCL-SEC could play a hitherto unappreciated but important role in the phenotypic expression of early knee OA.

Oleuropein Or Rutin Consumption Decreases The Spontaneous Development Of OA In Hartley Guinea Pig. Christelle Sanchez[1], Marie-Noëlle Horcajada[2], Fanny Membrez Scalfo[2], Pierre Drion[3], Fanny Comblain[3], Elizabeth Offord[2] and Yves Henrotin[3]. [1]University of Liège, Liege, Belgium, [2]Nestle Research Center, Lausanne, Switzerland, [3]University of Liège, Liège, Belgium.

Background/Purpose: To assess the potential protective effect of oleuropein and rutin, two polyphenols found in olive oil, fruits or vegetables, on osteoarthritis development

Methods: Sixty 4 weeks old Hartley guinea pig were randomized in four groups and received daily during 31 weeks either standard guinea pig food (control group) or a standard guinea pig food enriched with oleuropein, rutin or rutin/curcumin association. Animals were weighted each week and blood sampled every 6 weeks and at the time of euthanasia (week 35). Biomarkers COLL2-1, COLL2-1NO2, Fib3-1, Fib3-2, as well as PGE_2, were quantified in the serum. Histological assessments of knee cartilage and synovial membrane were performed at week 35.

Results: At week 35, guinea pigs in the control group spontaneously developed important cartilage lesions with mild synovial inflammation. The histological scores of cartilage lesion and synovitis were well correlated with the increase of serum biomarkers level.. Histologically, all treated groups significantly reduced the cartilage degradation (p<0.01), and oleuropein group showed a significant decrease of the synovial modification (p<0.05) compared to the control group. Oleuropein decreased the PGE_2 levels found in serum at week 35 (p<0.01). Serum COLL2-1 and Fib3-1 were decreased by rutin and rutin/curcumin mixture, Fib3-2 was only decreased by rutin/curcumin mixture, while COLL2-1NO2 was significantly decreased by all treatments (p<0.05).

Conclusion: Oleuropein and rutin significantly slow down the progression of OA lesions in guinea pig developing spontaneously OA. Furthermore, oleuropein significantly decreased PGE_2 and COLL2-1NO2 serum levels, and reduced synovitis, indicating the potent anti-inflammatory properties of these compounds.

New Formulation With Potential To Prevent and Treat Osteoporosis and Osteoarthritis. A. Torrent[1], E. Montell[1], J. Vergés[1], P. Dalmau[2], R. Ruhí[2], M.C. Carceller[3], A. Blanco[3], M.C. Terencio[3], M.L. Ferrándiz[3] and M.J. Alcaraz[3]. [1]Pre-Clinical R&D Area, Pharmascience Division, BIOIBERICA S.A., Barcelona, Spain, [2]Technological Extraction Dept, BIOIBERICA S.A., Palafolls, Spain, [3]Department of Pharmacology and IDM, University of Valencia, Burjassot, Spain.

Background/Purpose: Osteoarthritis (OA) is a multidimensional disease that affects all anatomical joint structures, particularly cartilage, synovium and subchondral bone. In turn, osteoporosis (OP) is a skeletal disorder characterized by a compromised bone strength which substantially increases the risk of fracture. In the past, attention was focused on a supposed inverse relationship between OA and OP, since both disorders usually affect the elderly, but were regarded to rarely coexist in a single person. However, recent studies have revealed several factors which contribute to the pathogenesis of both disorders (Bultink et al, 2013). Despite this, there is not any drug at the moment approved for the simultaneous prevention and treatment of osteoporosis and osteoarthritis.

The aim of this study was to investigate the effect of a new formulation in a combined rat model of OP and OA. The formulation (BIS076) contains Vitamin D3, Hydroxyapatite as a source of calcium and a natural extract from porcine cartilage. The latter is rich in bioactive substances due to the mild conditions used in the manufacturing process.

Methods: OP was induced by ovariectomy (OVX) in female Wistar rats and, two weeks after, OA was induced by Anterior Cruciate Ligament Transection (ACLT). Sixty female rats were assigned into the following groups: Sham Group, OVX + ACLT Group (Vehicle) and BIS076 Groups. BIS076 was administered daily during 12 weeks at two doses, 163.5 mg/kg/day and 245 mg/kg/day which correspond approximately to 1400 mg/day and 2100 mg/day in humans. For the assessment of OA, histology was performed and cartilage degeneration was evaluated by means of the OARSI score (Pritzker et al, 2006). Synovitis degree was estimated according to the score proposed by Krenn et al (2006). Bone microarchitecture and density were assessed by Micro-Computed Tomography (microCT).

Results: The preparation BIS076 has been shown to induce, at the 2 doses tested, a significant reduction (approximately 50%) of the cartilage degradation according to the OARSI score. Synovial inflammation was strongly reduced as well. In addition, microCT revealed that BIS076 treatment exerted a positive effect in bone structure, especially at the high dose: Significant increase in bone volume ($p<0.05$), bone surface density ($p<0.01$), trabecular number ($p<0.01$) and significant reduction in the trabecular bone pattern factor ($p<0.01$) compared to the Vehicle Group.

Conclusion: Our data demonstrate that treatment with BIS076 could be an effective strategy to control the progression of experimental Osteoarthritis and Osteoporosis. This approach holds promise for the development of improved therapies targeting these chronic and disabling diseases.

Cartilaginous Uric Acid Deposition In Advanced Osteoarthritis: Innocent Bystander Or Promotor Of Cartilage Destruction? Tim Bongartz, Andre M Oliveira, Rafael J Sierra, Arlen D Hanssen and Michael J Taunton. Mayo Clinic, Rochester, MN.

Background/Purpose: Recent studies have suggested that synovial fluid uric acid could contribute to tissue inflammation, disease severity and progression of osteoarthritis (OA). Intraarticular uric acid has been associated with OA disease severity and may promote cartilage destruction through inflammasome activation.We aimed to explore if intraarticular uric acid deposition does indeed occur in patients with osteoarthritis of the knee who have never experienced an episode of gout.

Methods: We recruited patients with advanced osteoarthritis of the knee and no history of gout who were scheduled to undergo knee replacement surgery. All subjects underwent dual-energy scanning of the target joint. CT images were screened for areas of uric acid deposition.During knee replacement surgery, samples of tibial and femoral condyle cartilage, menisci and synovium were obtained. Areas of possible uric acid deposition as identified through DECT were particularly targeted for sample collection.A musculoskeletal pathologist performed light (DeGalantha and H&E stains) and polarizing microscopy and recorded the presence of uric acid crystals in a descriptive manner.

Results: 5 patients with advanced osteoarthritis of the knee did undergo DECT. In all subjects, DECT indicated areas of uric acid deposition within the joint cartilage and the menisci. In 4 of these 5 patients, histopathology exam confirmed presence of uric acid crystal clusters in the cartilage and/or menisci. In 2 patients, uric acid deposition did also involve the synovium. Of note, synovial fluid in all patients was negative for MSU crystals as determined through polarizing microscopy. The mean serum uric acid level was 5.7mg/dl, range 5.0–6.4 mg/dl.

Conclusion: This pilot study did reveal evidence of cartilaginous uric acid deposition in the majority of patients with advanced osteoarthritis.Future studies will have to confirm this finding in a larger patient cohort and clarify if intracartilaginous urate crystals accelerate cartilage damage or are simply a result of matrix exposure and subsequent MSU crystallization without significant effects on disease progression.

The Role Of Meniscal Cells In Osteoarthritis Calcification. Andrea Roberts[1], David Mauerhan[2] and Yubo Sun[2]. [1]Carolinas Healthcare System, Charlotte, NC, [2]Carolinas Medical Center, Charlotte, NC.

Background/Purpose: Osteoarthritis (OA) is a disease that is characterized by the breakdown or loss of articular cartilage due to biomechanical and biochemical changes in the joints of the knees, hips and hands. Chondrocytes, the cells present in articular cartilage, have traditionally been thought to be exclusively responsible for inducing the calcification observed in OA, and therefore are believed to play an essential role in the development of OA pathogenesis. However, recent reports suggest that meniscal degeneration and calcification are correlated with articular cartilage degeneration in the knee of OA patients. Joint calcification correlates greatly with OA, as 70% of OA patients show an increase in calcium crystal deposition compared to non-OA patients. There are two main types of crystals present in advanced OA patients: calcium pyrophosphate dehydrate (CPPD) and basic calcium phosphate (BCP). However, it is still unclear which tissue (cartilage or meniscus) produce these calcium crystals. The role of meniscal cells in calcification is poorly understood at present, thus the purpose of this study is to determine the role of meniscal cells in the pathogenesis of osteoarthritis (OA) in the knee. Our central hypothesis states that meniscal cells play an unrecognized role in the development of OA in part by inducing calcification in the meniscus.

Methods: *Tissue was collected* from menisci and articular cartilage obtained from OA patients undergoing joint replacement surgery. *Calcium Crystals* were detected using alizarin red and Eosin Y staining. *Cell were isolated* from OA menisci and articular cartilage tissue. The cells were treated with and without extracellular ATP (a calcification inducer) and calcification medium for seven days in a monolayer culture. *Alizarin Red* staining was used to detect calcification present in a monolayer. Images were obtained using Sony Imaging software with an inverted scope and alizarin red was quantified measuring HCL absorbance at 405 wavelength using a microplate reader. *^{45}Calcium Assay* was used to quantify calcification induced by chondrocytes and meniscal cells in the presence and absence of extracellular ATP. The cells were cultured in a monolayer environment for 5 days. ^{45}Calcium was measured as counts per minute using a liquid scintillation counter.

Results: Our data, using a ^{45}Calcium assay and alizarin red staining, suggest that meniscal cells, similar to chondrocytes, induce the formation of calcium crystals in the presence of extracellular ATP and calcification medium, with meniscal cells inducing calcification at a slightly higher rate than chondrocytes. Additionally, OA patients have been shown to contain many types of calcium crystals in the knee cartilage, with BCP and CPPD crystals being the most abundant. Both of which have been implicated in the development and progression of knee OA. Our preliminary data shows the

meniscus of OA patients contains both BCP and CPPD crystals of which about 44% are CPPD crystals.

Conclusion: Our results suggest meniscal cells like chondrocytes induce calcium crystal formation and both BCP and CPPD crystals are present in the meniscus of OA patients.

Global and Country Specific Burden Of Musculoskeletal Disorders:a Report From The Global Burden Of Diseases Musculoskeletal Expert Group. Lyn March[1], Damian Hoy[2], Emma Smith[3], Rachelle Buchbinder[4], Marita Cross[3], Peter Brooks[5], Theo Vos[2] and Anthony D. Woolf[6]. [1]University of Sydney Institute of Bone and Joint Research, Royal North Shore Hospital, St Leonards, Australia, [2]School of Population Health, University of Queensland, Brisbane, Australia, [3]University of Sydney, Insitute of Bone and Joint Research, Royal North Shore Hospital, St Leonards NSW, Australia, [4]Monash Department of Clinical Epidemiology at Cabrini Hospital, Department of Epidemiology and Preventive Medicine, Monash University, Malvern, Victoria, Australia, [5]Australian Health Workforce Institute, University of Melbourne, Melbourne, Australia, [6]Royal Cornwall Hospital, Truro Cornwall, United Kingdom.

Background/Purpose: The first Global Burden of Diseases (GBD) Study was conducted by the World Bank and WHO during the 1990's and ranked diseases by their contribution to burden as measured by disability adjusted life years (DALYs). All MSK disorders, with 2.1% of DALYs, ranked 12th. These were considered to be underestimates. The GBD 2010 Study aimed to repeat these DALYs to look for trends in diseases from 1990 to 2010 with updated disease definitions and literature review. The MSK Expert Group (EG) aimed to identify data for OA, RA, Back Pain, Neck Pain, Gout and Other MSK.

Methods: Systematic reviews of Medline, EMBASE, CINAHL, SIGLE and WHOLIS were screened from 1980 to 2010. Data were extracted from population-based studies using a Quality Assessment tool developed by the MSK EG. These prevalence and incidence data, together with estimates of possible covariates and relative risk of mortality, were entered into the DISMOD3 software developed by the IHME. Disability weights for health states related to MSK conditions were adjusted for distribution of severity and duration and frequency of each condition to calculate years lived with disability (YLDs) for each of the MSK conditions – OA of hip or knee, RA, Low Back Pain (LBP), Neck Pain (NP), Gout and Other MSK.

Results: Globally non-communicable chronic disorders were identified as the growing concern and of these MSK was highlighted.

In the overall global burden (DALYs) MSK disorders had increased from 4.7% in 1990 to 6.8% in 2010, and ranked 5th behind Cardiovascular (11.8%), Injuries (11.2%), All neoplasms (7.6%) and Mental and behavioural disorders (7.4%). For burden (DALYs) of specific disorders, LBP ranked 6th; NP 21st; and Other MSK 24th. In the global disability (YLD) estimates, mental and behavioural disorders combined at 22.7% ranked 1st, while combined MSK disorders at 21.3% was a close 2nd. Collectively MSK conditions affect 2,933,367,000 people, account for 166 million YLDs and represent a relative increase of 44.7% since 1990. For disease specific causes of disability (YLDs), LBP ranked 1st globally with 83.1 million; NP ranked 4th with 33.6 million; Other MSK 6th with 28.2 million; OA was 11th with 17.1 million; and RA was 6.7 million. OA was felt to be underestimated in this analysis. OA was identified as one of the most rapidly rising (64% increase) conditions with a rank of 15th in 1990 to 11thin 2010. When developed country level data are examined MSK conditions play an even greater role, for example in Australia where combined MSK conditions (15% of DALYs) were a close second only to combined Cancer (16% of DALYs) as the leading causes of disease burden, and LBP was estimated as the leading disease specific cause of total burden (DALYs). For disability in Australia MSK conditions were the leading cause with 27% of YLDs. Country level data are derived from ihme.org.

Conclusion: Data are lacking from the African nations, South America, Eastern Europe and Australasia. OA Knee is the most common MSK condition and is showing the greatest increase. Low back and neck pain account for the greatest proportion of MSK burden globally. In many countries MSK disorders are the leading cause of disability.

Musculoskeletal Diseases Have The Worst Impact On Physical Health Compared With Other Diseases - Results Of The Dutch cross-Sectional Study. Antje van der Zee-Neuen[1], Polina Putrik[1], Sofia Ramiro[2], Andras P. Keszei[3], Rob de Bie[1], Astrid M. Chorus[4] and Annelies Boonen[5]. [1]Maastricht University, Maastricht, Netherlands, [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]School for Oncology and Developmental Biology, Maastricht, Netherlands, [4]Netherlands Organization for Applied Scientific Research, Leiden, Netherlands, [5]Maastricht University Medical Center, Maastricht, Netherlands.

Background/Purpose: Musculoskeletal conditions (MSKC) are among the most common chronic conditions. Increasingly, patients suffer from more than one disease. Moreover, the presence of a co-morbid disease adds to the burden of single diseases worldwide. The aim of this study was to understand 1) what is the impact of the number of morbidities on health and 2) whether MSKC has a higher impact on health compared with other diseases or has an important impact when being a co-morbidity.

Methods: In a Dutch cross-sectional study, 8904 subjects (>18 years old, random sample) completed a questionnaire on socio-demographic factors (age, gender, education, work status, origin and place of residence (postal code code)), BMI, self-reported physician-diagnosed diseases and the 12-Item Short-Form Health Survey (SF-12). Complete cases (n=7600) were analyzed. Multivariable linear regression was computed to identify 1) whether multimorbidity in terms of number of diseases was significantly associated with the SF-12 physical (PCS) and mental (MCS) subscales and 2)which diseases contributed the most to changes in health related quality of life (HrQol). Interactions of all diseases with MSKC were checked. Models were adjusted for age, gender, education (5 groups, from no education to university) origin (western vs. non-western) and BMI.

Results: Multimorbidity was present in 1432 subjects (19%). MSKC confirmed by a physician was reported by 1438 (19%) participants. 408 (5%) reported diabetes, 1460 (19%) CVD, 199 (3%) cancer, 547 (7%) a respiratory condition, 526 (7%) a skin condition, 462 (6%) a mental disorder, 334 (4%) migraine and 262 (3%) bowel disease. A linear relation between the number of diseases and health (both univariably and in fully adjusted model) was observed (Table 1). MSKC had the highest negative impact on PCS compared to other diseases (Table 2).

Table 1. Association of number of morbidities and health *(physical and mental component SF-12)*

	SF-12

Meta-Analysis of Randomized Controlled Trials Assessing the Effects of Vitamin D Supplementation On Skeletal Muscle Strength. Charlotte Beaudart[1], Fanny Buckinx[2], Véronique Rabenda[1], Sophie Gillain[3], Etienne Cavalier[3], Jean Petermans[3], Jean-Yves Reginster[1] and Olivier Bruyere[1]. [1]University of Liege, Liege, Belgium, [2]University of Liège, Liège, Belgium, [3]CHU de Liege, Liege, Belgium.

Background/Purpose: Currently, there is growing evidence that vitamin D plays a role on several tissues including skeletal muscle. Previous studies suggested that vitamin D deficiency is associated with low muscular strength. The objective of this meta-analysis is to summarize the effects of vitamin D supplementation on muscle strength

Methods: A systematic research of randomized controlled trials (RCTs), performed between 1966 and February 2013, assessing the effect of vitamin D supplementation on muscle strength has been conducted by two independent reviewers (data sources: Medline, Cochrane Database of Systematics Reviews, Cochrane Central Register of Controlled Trials, manual review of the literature and congressional abstracts). All forms and doses of vitamin D supplementation, with or without calcium supplementation, compared with placebo or control were included. Muscle strength was assessed either by grip strength and/or lower limb muscle strength. The quality of the RCTs was evaluated using the Jadad criteria.

Results: Out of the 214 potentially relevant articles, 19 RCTs involving 4824 individuals (mean age: 66.0 years) met the inclusion criteria. Studies show a mean quality score of 3.8/5 points. Results reveal a significant positive effect of vitamin D supplementation on global muscle strength *(Figure)* with a standardized mean difference (SMD) of 0.096 (95% CI=0.007–0.184; p=0.034). No significant between-study heterogeneity is found (Q-value= 23.6; p= 0.21; I^2= 19.6%). No publication bias was observed as shown with the Egger's regression analysis (p=0.13). Regarding the individual type of strength, 13 studies assessed the effect of vitamin D supplementation on grip strength and 15 on lower limb muscle strength. Results show no significant effect of vitamin D supplementation on grip strength (SMD=0.062, p=0.264), but a significant positive effect on lower limb muscle strength (SMD=0.169, p=0.03).

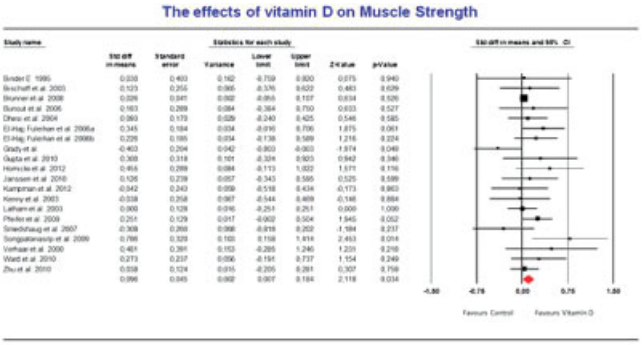

Figure: Forest plot for summary standardized mean difference for global muscle strength

Conclusion: Based on the studies included in this meta-analysis, vitamin D supplementation has a positive impact on global muscle strength, and more especially, on lower limb muscle strength.

Insufficient Evidence For An Increase In Prevalence and Incidence Of Gout: A Systematic Review and Meta-Regression Analysis. José M.A. Wijnands[1], Wolfgang Viechtbauer[1], Kristof Thevissen[2], Ilja C.W. Arts[1], Pieter C. Dagnelie[1], Coen D.A. Stehouwer[2], Sjef van der Linden[2] and Annelies Boonen[2]. [1]Maastricht University, Maastricht, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands.

Background/Purpose: Estimates on the prevalence and incidence of gout in the general population vary widely and an increase is commonly reported. However, studies on the occurrence of gout have not been reviewed and appraised systematically. The aims of this study were: 1) to estimate the pooled prevalence and the incidence of gout in the general population; 2) to explore which factors contribute to the variation in estimated prevalence and incidence.

Methods: Pubmed, Embase and Web of Science were systematically searched for primary studies on the prevalence and incidence of gout in the general population. Two reviewers independently extracted data on prevalence and incidence as well as sources of clinical heterogeneity, methodological heterogeneity, and variation in outcome reporting. Prevalence rates were pooled using a random-effects model and were adjusted for a series of clinical and methodological study characteristics in a meta-regression analysis using the mixed-effects model.

Results: Of 1466 articles screened, 77 articles were included, of which 71 reported the prevalence and 12 the incidence of gout. The pooled prevalence based on a random effects model was 0.8% (95% CI 0.6; 1.0) with a high level of heterogeneity (I^2 =99.9%). Results from a mixed-effects meta-regression model indicated that gender (p<0.001), continent (p<0.001), consistency in data collection (p=0.003), and case definition (p=0.001) were significantly associated with gout prevalence and jointly accounted for 77.2% of the heterogeneity. Start of data collection was not associated with the prevalence. The incidence in the total population ranged from 0.06 to 2.68 per 1000 person-years and an increase in incidence was only seen in two studies.

Conclusion: The large variation in the prevalence data on gout in the general population is explained not only by well-known factors such as gender and continent on which the study was performed, but also by the case definition of gout. There was insufficient evidence for an increase in prevalence or incidence of gout in recent years.

Risk Factors For Incident Hyperuricemia During Mid-Adulthood In African American and White Men and Women Enrolled In The Atherosclerosis Risk In Communities Study. Mara McAdams DeMarco[1], Andrew Law[2], Janet W. Maynard[3], Josef Coresh[1] and Alan N. Baer[4]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Johns Hopkins, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD.

Background/Purpose: Increased serum urate levels are associated with poor outcomes including but not limited to gout. Better understanding of which patients are at risk of developing hyperuricemia may aid in clinical decision-making about treatment of asymptomatic hyperuricemia. However, hyperuricemia risk prediction has been limited because previously published studies were not prospective in nature. The objective of this study is to identify risk factors for the development of hyperuricemia over 9 years in a population-based study, ARIC

Methods: This cohort recruited 15,792 individuals in 1987–1989 from 4 US communities and contained 9-years of follow-up; 8,212 participants who had serum urate levels <7.0 mg/dL were included in this analysis. Risk factors for 9-year incident hyperuricemia (plasma urate level of ≥ 7.0 g/dL at visit 4) were identified using an AIC-based selection approach in a modified Poisson regression model. We considered baseline, 3-year, and change in serum urate level over 3 years.

Results: The 9-year cumulative incidence of hyperuricemia was 4% and subgroup cumulative incidences were: 5% for men; 3% for women; 6% for African Americans and; 3% for whites. The final adjusted model included 8 predictors for incident hyperuricemia over 9 years: male sex (RR=1.78, 95% CI: 1.39–2.27), African-American race (RR=1.54, 95% CI: 1.19–2.00), current smoking (RR=1.36, 95% CI: 1.04–1.79), as well as basic education (RR=1.28, 95% CI: 0.99–1.64), hypertension (RR=1.73, 95% CI: 1.37–2.19), coronary heart disease (RR=1.57, 95% CI: 0.97–2.54), obesity (class I obesity: RR=2.82, 95% CI: 1.97–4.04 and ≥class II, RR= 3.93, 95% CI: 2.62–5.91) and eGFR<60 (RR=3.04, 95% CI: 1.73–5.34). In separate models, serum urate levels at baseline, 3 years after baseline, and change in serum urate level over 3 years in addition to demographic and clinical risk factors were all associated with the development of hyperuricemia (Table).

Table. Predictors of incident hyperuricemia over 9 years.

Risk Factor	Model 1: Baseline Serum Urate Adjusted	Model 2: 3 Year Serum Urate Adjusted	Model 3: Change in Serum Urate Adjusted
Male sex	1.09 (0.84, 1.42)	1.02 (0.80, 1.31)	1.57 (1.24, 2.01)
Black race	1.54 (1.20, 1.99)	1.38 (1.08, 1.77)	1.43 (1.11, 1.84)

Kidney Function and Alcohol Intake and The Risk Of Incident Gout In a Population-Based Cohort Of Adults: Atherosclerosis Risk In Communities Study. Mara McAdams DeMarco[1], Anna Kottgen[2], Andrew Law[3], Janet W. Maynard[4], Morgan Grams[3], Josef Coresh[1] and Alan N. Baer[5]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]University Hospital Freiburg, Freiburg, Germany, [3]Johns Hopkins, Baltimore, MD, [4]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD, [5]Johns Hopkins University, Baltimore, MD.

Background/Purpose: Reduced kidney function is associated with higher urate levels as well as an increased risk of gout. Additionally, alcohol intake is known to increase serum urate levels and is associated with both kidney function and the development of gout. The interaction of modifiable risk factors for gout and kidney function on the development of gout is understudied. We estimated the risk of developing gout over a range of estimated glomerular filtration rate (eGFR) values and stratified by alcohol intake in participants enrolled in the Atherosclerosis Risk in Communities (ARIC) cohort study

Methods: ARIC is a prospective population-based cohort recruited in 1987–1989 from 4 US communities, consisting of 4 visits over 9 years. Participants were included in this analysis if they answered the gout query and were free of gout at baseline. Incident gout was defined as self-reported onset between baseline and visit 4 (9 years after baseline). Serum creatinine was estimated using a modified kinetic JaffŽ reaction. Glomerular filtration rate (eGFR) was estimated using the CKD-Epi equation and alcohol intake was ascertained using a food frequency questionnaire. Using a Cox Proportional Hazards model (age as time scale), we estimated the hazard ratio (HR) and 95% confidence intervals (CI) of incident gout by baseline eGFR (modeled as a linear function and a spline), adjusted for confounders (sex, race, and center) and clinical factors (diuretic use, diabetes, hypertension, and obesity) and stratified by alcohol intake.

Results: A total of 10,858 ARIC participants were included in the analysis. The study population was 43% male, 21% African American and the mean age at cohort entry was 54 years (SD=5.7). The mean eGFR was 92 (SD=14.9) ml/min/1.73 m^2. At baseline, 2% participants were classified as having eGFR<60 ml/min/1.73 m^2; 41% with an eGFR between 60 and 90 ml/min/1.73 m^2; and 57% with an eGFR >90 ml/min/1.73 m^2. The mean alcohol intake was 40.2 grams/week. There were 274 incident gout cases. There was slight evidence that the risk of gout by kidney function was higher in those who drank ≥50 g/week of alcohol (Table; P for interaction=0.08). For those with alcohol intake≥50 g/week and an eGFR<60, there was 1.65-times (95% CI: 1.10–2.48, P=0.02) the risk of gout for every 10 ml/min/1.73 m^2 decrease in eGFR. The risk of gout by eGFR was similar for those with alcohol intake <50 g/week.

Conclusion: There is slight evidence, potentially due to limited power, that the impact of reduced kidney function is greater for adults with alcohol intake ≥50 g/week than for those with lower alcohol intake.

Risk of Gout by eGFR stratified by alcohol intake

	Binary alcohol intake (>=50 g per week) HR (95% CI) N=2,542	p-value	Binary alcohol intake (<50 g per week) HR (95% CI) N=8,316	p-value
eGFR*	1.18 (1.03, 1.34)	0.01	1.12 (1.02, 1.23)	0.02
eGFR≥90*	0.92 (0.68, 1.25)	0.61	1.05 (0.85, 1.29)	0.64
60^{2}eGFR<90*	1.25 (0.96, 1.61)	0.09	1.17 (0.97, 1.41)	0.11
eGFR <60*	1.65 (1.10, 2.48)	0.02	1.16 (0.66, 2.07)	0.6

Adjusted for sex, race, center, diuretic use, hypertension, diabetes, and obesity.
* for each 10 unit decrease in eGFR.

Higher Consumption Of Sugar-Sweetened Soft Drinks Increases The Risk Of Hyperuricemia In Korean Population: The Korean Multi-Rural Communities Cohort Study. Seong-Kyu Kim[1], Jisuk Bae[1], Jung-Yoon Choe[1], Byung-Yeol Chun[2], Pil Sook Park[3] and Dong Hoon Shin[4]. [1]Catholic University of Daegu School of Medicine, Daegu, South Korea, [2]Kyungpook National University School of Medicine, Daegu, South Korea, [3]Kyungpook National University, Daegu, South Korea, [4]School of Medicine Keimyung University, Daegu, South Korea.

Background/Purpose: The aim of this study is to clarify the association between sugar-sweetened soft drinks and fruit drinks made from oranges and apples and the risk of hyperuricemia in the Korean Multi-Rural Communities Cohort.

Methods: A total of 9400 subjects were enrolled in the Korean Multi-Rural Communities Cohort Study. Five quintiles (Q1 to Q5) according to consumption of soft drinks and other fruit/fruit juices were classified and then categorized into three groups (Q1-Q3, Q4, Q5) to assess the risk of hyperuricemia. Information on dietary intake was collected by well-trained interviewers using validated food frequency questionnaires.

Results: Higher consumption of sugar-sweetened soft drinks (Q5) increased the risk of hyperuricemia in males (adjusted OR 1.35, 95% CI 1.07–1.71) with a linear trend (p for trend = 0.01) and in females (adjusted OR 1.40, 95% CI 1.03–1.90) with no linear trend (p for trend = 0.09), compared to lower consumption (Q1-Q3). However, there were no significant differences of serum uric acid level according to the three categories of soft drink consumption, Q1-Q3, Q3, Q5, in males ($p = 0.21$) or in females ($p = 0.16$), whereas all subjects showed statistical significance of serum uric acid level within the categories ($p < 0.001$). Estimated amount of soft drink intake was associated with serum uric acid level in males (b = 0.001, $p = 0.01$) but not in females (b = 0.0005, $p = 0.10$).

Conclusion: Higher consumption of sugar-sweetened soft drinks increased the risk of hyperuricemia in the Korean population, showing a differential linear trend for hyperuricemia according to gender.

Smoking and The Risk For Incident Gouty Arthritis. Weiqi Wang[1], Vidula Bhole[2] and Eswar Krishnan[3]. [1]stanford university, palo alto, CA, [2]EpiSolutions Consultancy Services, Thane, India, [3]Stanford University, Palo Alto, CA.

Background/Purpose: Historically, the published literature have suggested that smoking tobacco is associated with lower serum urate concentrations. However, whether smoking impacts the risk for incident gout or not has not been addressed in detail. Our aim was to test this hypothesis and assess if any such link is merely a reflection of the inverse relationship between smoking and obesity.

Methods: The analysis was based on Framingham heart study (FHS) visits 1 to 26, covering 52 years from 1948 to 2000. Gout was defined by presence of any of the following: self-report, physician diagnosis, gout medication use, and radiographic changes. Smoking was defined as any usage of tobacco. Hypertension was defined by presence of any of the following: systolic blood pressure >= 140 mm Hg or diastolic blood pressure >= 90 mm Hg or usage of anti-hypertensive medications. Diabetes were defined according to FHS official review. BMI was obtained from FHS raw data. Statistical analyses were performed using Cox proportional hazard regression models in STATA, where the dependent variable was the time from a patient first enrolled to his incident gout. All covariates that entered the multivariable models (smoking, sex, age, BMI, hypertension, diabetes, kidney disease and alcohol use) were treated as time varying in the regression models. Missing values were addressed by multiple imputations.

Results: There were 5079 participants that were included, among whom 3703 used tobacco. At the baseline the proportion of men was 45.17%. Overall there were 414 incident cases of gout during the follow up. The incidence rate per thousand person-years of gout in the smoking group was 2.55 and in the non-smoking group was 4.57. The unadjusted and age adjusted hazard ratio of smoking were 0.75 (95% confidence interval 0.58–0.99) and 0.73 (0.55–0.96) respectively. In multivariable Cox models, smoking was associated with a hazard ratio of 0.65 (0.44–0.96). The results were not different when men and women were analyzed differently.

Conclusion: Smoking was associated with lower risk for gout and this association was not confounded by obesity or other risk factors.

Hip Osteoarthritis and Risk Of All Cause and Disease-Specific Mortality Among Older Women: A Population-Based Cohort Study. Kamil E. Barbour[1], Li-Yung Lui[2], Charles G. Helmick[1], Kristina A. Theis[1], Michael C. Nevitt[3], Nancy E. Lane[4], Louise Murphy[1], Jennifer M. Hootman[5], Marc C. Hochberg[6] and Jane A. Cauley[7]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]California Pacific Medical Center, San Francisco, CA, San Francisco, CA, [3]University of California, San Francisco, San Francisco, CA, [4]UC Davis School of Medicine, Sacramento, CA, [5]Centers for Disease Control and Prevention, Kennesaw, GA, [6]University of Maryland, Baltimore, MD, [7]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: The morbidity of osteoarthritis (OA) is well documented; however few comprehensive studies have examined the effect of OA on mortality.

Methods: We used data from the Study of Osteoporotic Fractures, a US population-based cohort study of 9704 white women, ages 65 years or older. Hip radiographs were obtained at baseline (1986–1988) and visit 5 (1995–1996). A summary Croft grade of 0–4 for each hip was based on 5 individual radiographic features: joint space narrowing (JSN), osteophytes, subchondral sclerosis, cysts formation, and deformity of the femoral head. Radiographic hip OA (RHOA) was defined as having Croft grade of <2 in at least one hip (definite JSN or osteophytes plus one other radiographic feature). Clinical hip OA (CHOA) was defined as having both RHOA and self-report of hip pain "on most days for at least one month in the year" in the same hip. Mortality was confirmed through July, 2012 by death certificates and hospital discharge summaries, if available. All-cause mortality (cumulative incidence=64%) was analyzed along with three disease-specific causes of death (ICD-9-CM, cumulative incidence): cardiovascular disease (CVD) (390–459.9, 24.8%), total cancer (140–239.9, 11.5%), gastrointestinal disease (520–579.9, 1.8%), and all other causes (25.9%). Cox proportional hazards regression with time-dependent covariates (at baseline and visit 5) were used to estimate the hazard ratios (HRs) and 95% confidence intervals (CIs). All disease-specific mortality models accounted for competing risks of mortality.

Results: Mean follow-up time was 16.0 ± 6.1 years. The baseline prevalence of RHOA and CHOA was 7.4% and 3.2%, respectively, whereas the visit 5 prevalence was higher (9.7% and 3.9%, respectively). Having RHOA was associated with increased risk of all-cause [HR: 1.20; 95% CI: (1.10, 1.31)] and CVD [HR: 1.29; 95% CI: (1.13, 1.48)] mortality after adjusting for age, body mass index, health status, walking for exercise, diabetes, and stroke. Adjusting for potential mediating factors (i.e., physical function, falls, and disability) did not markedly attenuate these associations. CHOA was not associated with all-cause or any disease-specific mortality outcomes.

Conclusion: RHOA was associated with an increased risk of all-cause and CVD mortality in a cohort of older white women followed for a mean of 16 years.

96

Epidemiology and Health Services Use For Osteoarthritis By First Nations People In Alberta, Canada. Cheryl Barnabe[1], Allyson Jones[2], Ed Enns[3], Don Voaklander[2], Christine Peschken[4], Joanne Homik[2], John Esdaile[5], Sasha Bernatsky[6], Brenda Hemmelgarn[1] and Deborah Marshall[1]. [1]University of Calgary, Calgary, AB, [2]University of Alberta, Edmonton, AB, [3]Alberta Bone and Joint Health Institute, Calgary, AB, [4]University of Manitoba, Winnipeg, MB, [5]University of British Columbia, Vancouver, BC, [6]Research Institute of the McGill University Health Ctre, Montreal, QC.

Background/Purpose: Self-reported survey data and a single provincial administrative data source have previously indicated that the First Nations (FN) population in Canada has a 1.5 fold higher prevalence of osteoarthritis (OA), but the health services use by this population is unknown. Our objective was to determine whether OA prevalence and healthcare use in Alberta, Canada varies by FN status.

Methods: Using population-based healthcare administrative data (years 1993 to 2010), we defined a cohort of patients with OA (2 physician claims within 2 years or 1 hospitalization with diagnosis code ICD9 715x, or ICD10 M15–19). FN patients were identified based on premium payer status and represent 3.8% of the Alberta population. OA prevalence (fiscal year 2007/2008) and outpatient visits for OA to primary care physicians, specialists (orthopedic surgeons and rheumatologists), and arthroplasty (hip or knee) are reported for FN and non-FN populations.

Results: The age and sex standardized OA prevalence in FN Albertans is twice that of the non-FN population (161.0 vs 78.2 cases/1,000 population, standardized rate ratio 2.06; 95%CI 2.00–2.12). Prevalence is highest in people residing in rural locations and in females (Table 1).

Table 1. Prevalence of Osteoarthritis in Alberta (/1,000 population)

		First Nations	non-First Nations
Overall Prevalence	Age and sex standardized	161.0	78.2
Location of Residence	Rural	186.7	88.5
	Urban	135.9	76.2
Sex	Females	184.9	93.1
	Males	148.8	72.3

Per year, FN persons had a mean of 3.4 primary care outpatient visits specifically for OA (20.3% of FN total primary care contacts) compared to 1.6 visits per year for non-FN persons (14.4% of non-FN total primary care contacts) ($p<0.001$). Contact with specialists was significantly lower for FN persons, with one-third fewer outpatient visits to orthopedics and rheumatology compared to non-FN persons (Table 2).

Table 2. Healthcare Use for Osteoarthritis in Alberta (/1,000 person-years)

	First Nations	non-First Nations
Primary Care Visits	3380.1	1557.4
Orthopedic Surgeons	218.3	405.0
Rheumatologists	39.0	51.4

FN with OA were two-thirds less likely to have arthroplasty of the hip or knee. This did not appear to be driven by the presence of other medical comorbidities (Table 3).

Table 3. Arthroplasty Rates for Osteoarthritis in Alberta (/1,000 person-years)

	First Nations	non-First Nations
Overall	8.1	26.4
Diabetes	8.6	23.5
Any Comorbidity	8.8	25.7

Conclusion: We demonstrate disparities in OA care in FN persons given an estimated 2-fold higher disease prevalence from administrative data sources. While this finding may be driven in part by an increased probability of diagnosis through frequent primary care contact, it is unlikely to account for the large gap in use of specialty services and arthroplasty in FN compared to non-FN persons. This care gap may be due to access barriers for FN patients.

Incidence and Trend Of Osteoarthritis In An Administrative Database From British Columbia, Canada. M Mushfiqur Rahman[1], Jolanda Cibere[2], Charles H Goldsmith[3], Aslam H. Anis[4] and Jacek A. Kopec[2]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]University of British Columbia, VANCOUVER, BC, [3]Simon Fraser University, Burnaby, BC, [4]Centre for Health Evaluation and Outcome Sciences, Vancouver, BC.

Background/Purpose: Data on the incidence of osteoarthritis (OA) are limited and there is little information on the trend in incidence of OA over time. The objective of this study was to calculate the incidence rates and to describe the changes in OA incidence rates using two case definitions in 18 years of administrative health records.

Methods: We analyzed all visits to health professionals and all hospital admission records of a random sample (n = 540,000) from British Columbia, Canada for the fiscal years 1991/92 through 2008/09. Administrative OA was defined in two ways: 1) at least one physician diagnosis or one hospital admission (Def1) and 2) at least two physician diagnoses in two years or one hospital admission (Def2). Incidence rate was defined as the number of new OA cases during a fiscal year divided by the person-years at risk. New adult (age 20 years and older) OA cases were identified for the fiscal year 2008/2009 after deleting the prevalent cases from April 1991 to March 2008. To see the pattern of incidence, we have rates from 2000/01 through 2008/09, using nine years of run-in, that is, nine years was used to delete the prevalent cases. Both crude and age-standardized incidence rates for each sex were obtained after deleting prevalent cases for nine years. Finally, the annual relative change (ARC = (exp (β) – 1) × 100) was estimated from the weighted Poisson regression model for each sex.

Results: In 2008/09 fiscal year the overall incidence of OA using Def1 was 14.6 (12.7 in men and 16.5 in women) per 1000 person years, and 8.2 (7.2 in men and 9.3 in women) per 1000 person years in Def2. Between 2000/01 and 2008/09, crude incidence rates of OA based on Def1 varied from 11.8 to 14.2 per 1000 person years in men and from 15.7 to 18.5 per 1000 person years in women and the rates were lower to about 53–55% using Def2 (Table). For the crude rates, the ARCs were 3% ($p < 0.01$) and 2% ($p < 0.01$) for men and women respectively, in Def1, and the changes were similar in Def2. The age-standardized ARCs were not significantly different from 0% in both case definitions.

Table. Crude and age-standardized incidence of osteoarthritis per 1000 person years using nine years of run-in to delete the prevalent cases.

	Men Def1[1]		Men Def2[2]		Women Def1[1]		Women Def2[2]	
Year	**Crude**	**Standardized**	**Crude**	**Standardized**	**Crude**	**Standardized**	**Crude**	**Standardized**
00/01	11.8	12.7	6.3	6.8	15.7	17.0	8.5	9.2
01/02	11.6	12.3	6.1	6.5	15.7	16.7	8.8	9.4
02/03	11.7	12.1	6.2	6.4	15.4	16.0	8.5	8.9
03/04	12.5	12.7	6.6	6.8	16.9	17.2	9.3	9.5
04/05	12.6	12.6	6.7	6.7	17.3	17.3	9.7	9.7
05/06	13.6	13.2	7.1	6.9	17.8	17.4	9.7	9.5
06/07	13.5	12.8	7.5	7.1	18.1	17.3	9.8	9.3
07/08	13.9	12.9	7.4	6.8	18.1	16.9	10.2	9.4
08/09	14.2	12.9	7.9	7.1	18.5	16.8	10.2	9.2
ARC*	3%	1%	3%	1%	2%	0%	3%	0%
p-value	<0.01	0.43	<0.01	0.31	<0.01	0.71	<0.01	0.91

[1]Def1: one visit to a health professional or one hospital diagnosis. [2]Def2: two visits to a health professional in two years or one hospital diagnosis. *ARC stands for annual relative change = (exp (β) – 1) × 100 and was estimated from Poisson regression.

Conclusion: Our study suggests that physician diagnosed incidence of OA is higher in both men and women. Crude incidence rates of OA are increasing slightly over the years but the age-standardized rates do not show an increasing or decreasing pattern over the years. These data have implications in public health services for forecasting prevalence and costs of OA and in epidemiologic research.

Prevalence Of Femoroacetabular Impingement Among Chinese Living In Vancouver, Canada: A Population-Based Study. Linda C. Li[1], Jacek A. Kopec[2], Hubert Wong[3], Jolanda Cibere[2], Charlie Zhang[4], Eric C. Sayre[2], Joanna Ye[2], Morgan Barber[2], Helen Prlic[5] and John Esdaile[6]. [1]Arthritis Centre of Canada, Richmond, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]St Paul's Hospital, University of British Columbia, Vancouver, V6Z 1Y6, Canada, Vancouver, BC, [4]University of British Columbia, Vancouver, BC, [5]Arthritis Research Centre of Canada, Vancouver, BC, [6]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: Femoroacetabular Impingement (FAI) is one source of hip pain in young adults and has been suggested as a major cause of hip osteoarthritis (OA). Studies have shown that the prevalence of FAI was over 50% in populations with established OA[1–3] and 45% in a primarily Caucasian population in Denmark[4]. Radiographic hip OA is extremely rare in Chinese; however, the prevalence of radiographic FAI in the Chinese population is unknown. The current study aims to estimate the prevalence of hip pain and FAI among Chinese living in Metro Vancouver, Canada (population=2.3 million, 2011 Census), where 19% of the population are ethnic Chinese. Over 25% of new immigrants to Vancouver in the past 5 years were from mainland China.

Methods: This study was conducted within IMPAKT-HiP*, a large multi-faceted study on the role of FAI and physical activity in cartilage damage and hip pain. Chinese participants were recruited in a cross-sectional telephone survey of a random sample of residents in Metro Vancouver. Individuals were eligible if they were between the age of 20 and 49, reported both parents were Chinese descent, and were available for an onsite assessment and x-ray session. Pregnant women were excluded. All calls were initiated in English. Non-English-speaking Chinese respondents received a second call by an interviewer fluent in Mandarin and Cantonese to assess eligibility. Participants were asked if they had any pain, stiffness or discomfort in the groin or the front of the upper thigh (i.e., hip pain) in the past 12 months. All hip x-rays were read by a trained reader using a standardized protocol. Pincer-type FAI was defined by: 1) presence of focal acetabular retroversion or 2) a lateral center edge angle >40°. Cam-type FAI was defined by an alpha angle >55°. Prevalence of hip pain and FAI were defined by participant, with a case represented by involvement of one or both hips.

Results: 201 eligible individuals (89 English-speaking, 112 Mandarin/Cantonese-speaking) were recruited between April 2012 and January 2013. The majority were women (n=134, 66.7%) with a mean age of 38.7 years (SD=9.0). 8 participants (4.0%) had been told they had hip OA by a health professional. Hip pain in the past 12 months was reported by 59 participants (29.4%; women=41, men=18). FAI was found in 76 individuals (37.8%; bilateral=55, 27.4%; unilateral=21, 10.4%). FAI was present in 44/134 women and 32/67 men. 58 participants (28.9%) had pincer FAI, 13 (6.5%) had cam FAI and 5 (2.5%) had mixed FAI.

Conclusion: Our findings contribute new information on the prevalence of FAI among Chinese living in North America. Further research to examine prevalence of FAI, using standardized methodologies, in populations with high (e.g., Aboriginal populations) vs. low hip OA prevalence may provide further insight into the cause of hip OA.

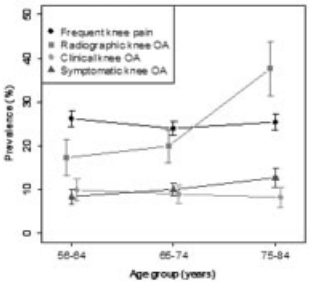
Twenty-First Century Prevalence Of Frequent Knee Pain, Radiographic, Symptomatic and Clinical Knee Osteoarthritis According to American College Of Rheumatology Criteria In Southern Sweden.
Aleksandra Turkiewicz[1], Maria Gerhardsson de Verdier[2], Gunnar Engström[3], Stefan Lohmander[1] and Martin Englund[1]. [1]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [2]Astra Zeneca R&D Molndal, Molndal, Sweden, Molndal, Sweden, [3]Dept of Cardiovascular epidemiology, Clinical Sciences, Lund University, Lund, Sweden.

Background/Purpose: To provide current estimates of the prevalence of knee pain, radiographic, symptomatic, and clinical knee osteoarthritis (OA) in middle-aged and elderly in Sweden.

Methods: In 2007 a random sample of 10 000 56 to 84 year old Region Skåne residents from the Malmö Diet and Cancer Study (Manjer et al 2001) were sent a mailed questionnaire about knee pain in the last 12 months; this being the first part of the Malmö Osteoarthritis Study (MOA). We classified subjects reporting knee pain with duration of at least 4 weeks as having *frequent knee pain*. A random sample of 1300 subjects with frequent knee pain and a random sample of 650 subjects without (out of the 7737 questionnaire responders) were invited for a clinical and radiographic examination including assessment of *clinical knee OA* according to the American College of Rheumatology (ACR) clinical criteria. Participants underwent radiography of both knees in weight-bearing and semi-flexion. An independent radiologist who was blinded to clinical data assessed all frontal and patellofemoral radiographs. We considered subjects who fulfilled criteria approximating Kellgren and Lawrence (KL) grade 2 or worse to have *radiographic knee OA*. Those with frequent knee pain and having radiographic knee OA were classified as having *symptomatic knee OA*. We used weighting to adjust for different sampling probabilities depending on the knee pain status as well as for the nonresponse and volunteer bias in MOA study using data on age, sex, body mass index and highest education level collected within the Malmö Diet and Cancer Study and the knee pain status from the MOA survey.

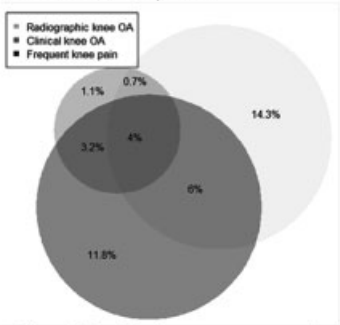
Results: The 10 000 random sample had mean (SD) age of 70.3 (7.6) years, mean (SD) body mass index was 27.1 (5.0) and 62% were women. The response rate in mailed questionnaire was 77.4% and 1527 invited subjects (78.3%) attended the clinical visit. The prevalence of *frequent knee pain* in one or both knees during the last 12 months was 25.1% (95%CI: 24.1 to 26.1), 20.8% in men and 27.7% in women and was similar in all age groups (Figure 1). The prevalence of *radiographic knee OA* (KL grade ≥2) was 25.4% (95%CI: 22.6 to 28.5), the prevalence of *symptomatic knee OA* was 10.5% and both increased with increasing age. The prevalence of *clinical knee OA according to the ACR criteria* was 9.0%. The prevalence of frequent knee pain in the subjects with radiographic knee osteoarthritis was 42.1%. Among those with symptomatic knee OA 40% fulfilled the ACR clinical knee OA criteria. In the study sample 11.8% of subjects reported frequent knee pain but did not fulfill OA criteria, neither for clinical ACR nor radiographic knee OA (Figure 2).

Figure 1. The prevalence of frequent knee pain, radiographic, symptomatic, and clinical ACR knee osteoarthritis (OA) in Swedish adults 56 to 84 years old.



Frequent knee pain – knee pain in one or both knees in last 12 months with duration of at least 4 weeks; Radiographic knee OA –changes on x-ray approximating Kellgren-Lawrence grade 2 or worse; Clinical knee OA – clinical knee OA according to the American College of Rheumatology clinical criteria, recursive positioning method; Symptomatic knee OA – frequent knee pain as defined above in combination with radiographic knee OA as defined above.

Figure 2. The prevalence and overlap of frequent knee pain, radiographic and clinical knee OA in Swedish adults 56 to 84 years old.



Radiographic knee OA –changes on x-ray approximating Kellgren-Lawrence grade 2 or worse, Clinical knee OA – clinical knee OA according to the American College of Rheumatology clinical criteria, Frequent knee pain – knee pain in one or both knees in last 12 months with duration of at least 4 weeks.

Conclusion: The prevalence of knee OA in southern Sweden in the age group 56 to 84 years varied from 9.5% to 25.4% depending on the definition used. The estimates from Sweden are lower than those from the United States. A lower body mass index in the Swedish population may be one explanation.

Myocardial Infarction and Mortality after Joint Surgery in Patients with Rheumatoid Arthritis Compared with the General Population.
Joanne Tropea[1], Mark Tacey[2], Megan Bohensky[2], Caroline Brand[2], Ian Wicks[1] and Sharon Van Doornum[2]. [1]Royal Melbourne Hospital, Melbourne, Australia, [2]The University of Melbourne, Melbourne, Australia.

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of myocardial infarction (MI) and post-MI fatality compared with the general population. In a previous study examining post-MI treatment in RA compared with controls we noted that a higher proportion of the RA patients had experienced MI following a surgical procedure. The aim of this study was to compare the incidence of MI and mortality (all-cause and cardiovascular (CV)) at 6 weeks and 12 months following joint surgery in patients with RA compared with the general population.

Methods: Individuals who had undergone joint surgery in Victoria, Australia between 1 July 2000 and 30 June 2007 were retrospectively identified from routinely collected hospital administrative data. Individuals were classified as having RA using International Classification of Diseases codes recorded at the time of surgery or during any hospitalisation in the 2 years prior. Incidence of MI and mortality at 6 weeks and 12 months post-operatively was determined from hospital data and linked death registry data. Logistic regression analyses were performed with adjustment for age, sex, comorbidities, socioeconomic status and admission type (elective vs emergency).

Results: A total of 308,589 episodes of joint surgery occurred among 240,571 individuals, with 3654 (1.2%) occurring among patients with RA. The RA cohort was older (mean (SD) age in years 62.4(13.4) vs 52.5(18.6)), with a female preponderance (74.6% vs 45.6%) and had a higher burden of comorbidities, lower socioeconomic status and fewer elective admissions compared to the non-RA cohort. The number (prevalence) of events in the RA and non-RA cohorts respectively was as follows; MI at 6 weeks: 25 (0.68%) vs 838 (0.27%); death at 6 weeks: 22 (0.60%) vs 569 (0.19%); MI at 12 months: 59 (1.61%) vs 1968 (0.65%); death at 12 months: 93 (2.55%) vs 2411 (0.79%).

Figure 1 shows the adjusted odds ratios (OR) for each of these outcomes in the RA patients compared with the non-RA patients. At 6 weeks post joint surgery the adjusted OR of MI was 1.50 (95% CI 0.96–2.33), all-cause death was 1.87 (95% CI 1.12–3.11) and CV death was 1.93 (95% CI 1.10–3.39). At 12 months post joint surgery the

adjusted OR of MI was 1.71 (95% CI 1.28–2.29), all-cause death was 2.17 (95% CI 1.65–2.85) and CV death was 2.30 (95% CI 1.65–3.21).

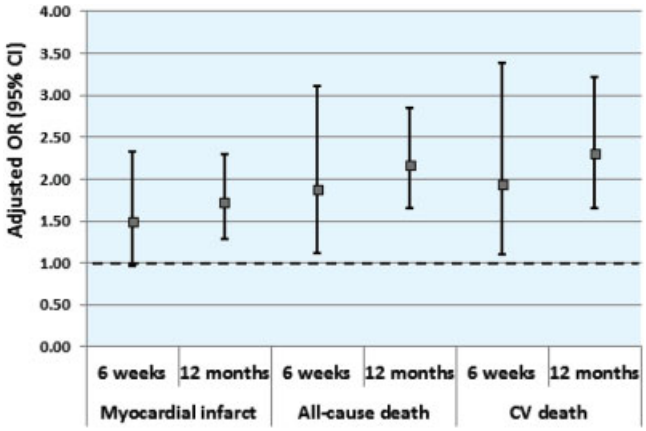

Figure 1. Risk of 6 week and 12 month myocardial infarction, all-cause death and cardiovascular death in patients with rheumatoid arthritis following joint surgery.

Conclusion: Following an episode of joint surgery RA patients have a significantly increased risk of death at 6 weeks, and MI and death at 12 months, compared to the general population. The reasons for this remain to be elucidated but in the meantime RA patients should be considered at higher risk in the peri-operative period.

Trends In Prescription Of Opioids From 2003–2009 In Persons With Knee Osteoarthritis. Elizabeth Wright[1], Jeffrey N. Katz[1], Stanley Abrams[1], Daniel H. Solomon[2] and Elena Losina[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: Osteoarthritis (OA) of the knee is a painful condition affecting ~13% of persons >65 years of age. OA is often accompanied by comorbidities. Effective pain control is important for managing this chronic disease. In the last decade, physicians have become increasingly aware of contraindications to NSAIDs due to comorbid conditions. We sought to examine whether physicians have begun to use opioids more frequently.

Methods: We assembled national cohorts of individuals with knee OA using data from waves of the Medicare Beneficiary Survey (MCBS) administered in the years 2003, 2006, and 2009. We examined temporal trends in opioid prescriptions in these cohorts over time. The MCBS survey consists of a nationally representative sample of Medicare beneficiaries. The MCBS survey data can be linked to Medicare claims. Survey respondents provided data on demographics, health status and prescribed medications. We selected knee OA cohorts from each of the three years from community-dwelling MCBS respondents aged 65 and older who had at least one outpatient visit in Medicare Parts A or B with an ICD-9-CM diagnostic code of a) 715.x6 (OA of knee) or b) ICD-9 code of 719.46 (knee pain) plus 715.x8, 715.x9 or 715.x0 (OA at other specified sites, at multiple sites and at unspecified sites, respectively). Functional status was categorized as poor if the survey respondent indicated "a lot of difficulty" or "inability" to walk ¼ mile or 2–3 blocks. The following six comorbidity categories were assigned from Medicare Parts A or B claims: cancer, cardiovascular disease, musculoskeletal disease other than OA, diabetes, depression and chronic obstructive pulmonary disease (COPD). We included all prescribed medication records classified as opioids under the MCBS antiarthritic or analgesic categories. The outcome was defined as receiving at least one prescription for an opioid in the year of study. We used multivariate logistic regression to establish whether opioid use changed over time and identify factors leading to greater utilization of opioids in elderly persons with OA.

Results: 488 (5%) subjects from the 2003 MCBS survey, 477 (5%) from the 2006 MCBS and 422 (5%) from the 2009 MCBS were identified with knee OA. Mean age and sex were similar across years (77 years, 70% females). We found a significant increase in opioid prescribing between 2003 and 2009, with 31% of the patients receiving opioids in 2003, 39% in 2006 and 40% in 2009 (OR 1.5, 95% CI 1.1, 2.0 for both years 2006 and 2009 compared to 2003). Across all time periods, independent correlates of opioids use included: female sex (OR 1.5, 95% CI 1.2, 2.0), functional limitations (OR 2.1, 95% CI 1.7, 2.7), poor self-reported health status (OR 1.6, 95% CI 1.2, 2.0), COPD (OR 1.4, 95% CI 1.0, 1.8) and musculoskeletal disease in addition to OA (OR 1.9, 95% CI 1.2, 2.8).

Conclusion: Opioid use in elderly persons with knee OA increased substantially between 2003 and 2009. The more frequent use of opioids is likely due to low efficacy and to toxicity of other classes of analgesics drugs currently used for pain relief in knee OA patients. As prevalence and incidence of knee OA continues to grow the public health impact of greater use of opioids should be monitored carefully.

Association Of Area-Level Socioeconomic Status With Pain and Function At Presentation For Total Knee Arthroplasty. Candace H. Feldman[1], Yan Dong[2], Jeffrey N. Katz[2], Laurel Donnell-Fink[2] and Elena Losina[2]. [1]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Prior studies suggest that individuals with lower socioeconomic status (SES) both under-utilize joint replacement procedures and present with increased pain and poorer function. Area-level SES is often used as a proxy when individual-level SES is unavailable and may also capture neighborhood-level effects. We examined the relationship between area-level SES and pain and function at presentation for total knee arthroplasty (TKA).

Methods: We examined a cohort of individuals undergoing TKA from 2010–2013 at an academic medical center. We obtained demographic information and measures of pain and functional status (WOMAC) and depression (MHI-5) from baseline surveys. We used the Geographic Information System (GIS) to geocode individual home addresses and linked these to U.S. Census data at the block group level. For P.O. Boxes, we used post office addresses. We constructed a previously validated composite area-level SES index that included occupation, income, wealth, education, and housing-related Census variables. We assessed bivariate associations between age (<65 or ≥65), sex, race (White or non-White), area SES (divided into quartiles, with highest two combined), BMI (<25, 25–30, 30–35, >35) and depression (MHI5>68 or less) and two outcomes –pain and functional status (WOMAC ≤30, 30–55, >55) –using Chi-squared tests. Linear regression models allowed us to identify independent correlates of high pain and low function (WOMAC >55). Covariates included age, sex, BMI, depression and area SES.

Results: Among 320 individuals, 181 (58%) were female. The mean age was 66 years (SD 10), and 282 (89%) were White. Addresses were geocoded for 297 street addresses and 20 P.O. Boxes. Our mean SES index score was 59 (SD 6, median 59, range 42–78); the U.S. population median SES is 51. In bivariate analyses, younger age, higher BMI, female sex, and higher depression scores were associated with higher pain and lower function ($p<0.05$). Higher BMI was also associated with lower area SES ($p<0.01$). Adjusted analyses showed striking associations between SES and baseline pain and functional status: 35% (95% CI 26–44) with the lowest area SES and 18% (95% CI 11–25) with the highest presented with high pain, while 31% (95% CI 22–40) with the lowest area SES and 18% (95% CI 11–25) with the highest presented with low function (**Figure**).

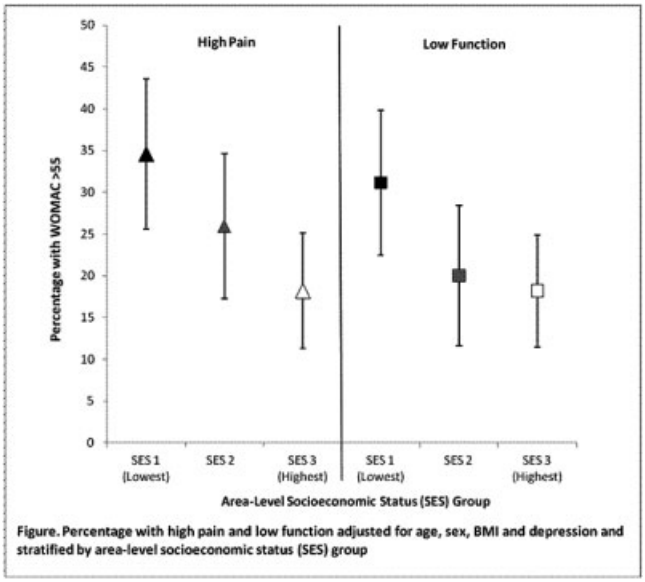

Figure. Percentage with high pain and low function adjusted for age, sex, BMI and depression and stratified by area-level socioeconomic status (SES) group

Conclusion: In this cohort of individuals with, on average, higher area-level SES than the general U.S. population, those from the highest SES areas presented for TKA with lower perceived pain and higher functional status than those from lower SES areas. Further research is needed to confirm these trends and understand why TKA appears to be utilized in higher socioeconomic status patients with relatively mild pain and high function.

103

Proportion Of U.S. Older Adults Meeting Inclusion Criteria For 2010 ACR Recommendations On Glucocorticoid-Induced Osteoporosis. Robert A. Overman[1], Joshua C. Toliver[2], Jun-Yen Yeh[3], Margaret L. Gourlay[2] and Chad L. Deal[1]. [1]Cleveland Clinic, Cleveland, OH, [2]University of North Carolina, Chapel Hill, NC, [3]Long Island University, Brooklyn, NY.

Background/Purpose: Glucocorticoid-induced osteoporosis (GIO) is the most common cause of secondary osteoporosis. Fracture related to GIO increases a patient's mortality risk and reduces quality of life. The American College of Rheumatology (ACR) released updated guidelines on the prevention and treatment of GIO in 2010. For postmenopausal women (PMW) and men ≥50 years of age with past or anticipated oral glucocorticoid (GC) use of ≥90 days, treatment recommendations are stratified according to low (<10%), medium (10–20%) and high (>20%) 10-year risk of a major osteoporotic fracture calculated using the World Health Organization's FRAX® fracture risk assessment tool, with recommendations taking into account dose and duration of therapy. We estimated the proportion of the US population currently taking oral GC from the National Health and Nutrition Examination Survey (NHANES) and calculated the proportion of the US population that should be treated for GIO according to the ACR guidelines.

Methods: This study used 3 cycles between 2005 and 2010 of NHANES, a bi-annual US cross-sectional study designed to be representative of the entire non-institutionalized population. PMW aged ≥40 and men aged ≥50 with height and weight measurements who self-reported current use of an oral GC were included. FRAX® risk scores were calculated using NHANES risk factor data, and with femoral neck bone mineral density (BMD) when available. Anti-osteoporosis pharmaceutical treatment (AOP) was defined as reported use of a bisphosphonate, estrogen, raloxifene, or teriparatide. Results are presented as weighted percents (95% confidence interval) using interview weights and NHANES specific methodology for combining multiple cycles; population estimates are made from mid-year current population survey totals for 2005–2010.

Results: An estimated 825,284 PMW in the US population used GC and met inclusion criteria, with mean age 64.8 (62.5, 67.1) years. GC were used by 1.66% (1.19, 2.14) of PMW; based on ACR GIO risk categories, 0.5% were low-risk (0.2, 0.7); 0.3% medium-risk (0.1, 0.5); and 0.9% high-risk (0.5, 1.2).

An estimated 683,784 men aged ≥50 in the US population used GC and met inclusion criteria, with mean age 66.0 (63.1–68.8) years. GC were used by 1.65% of the men; based on ACR GIO risk categories 0.6% were low-risk (0.3, 0.9); 0.6% medium-risk (0.3, 1.0); and 0.4% high-risk (0.2, 0.7).

Chronic GC use (≥90 days) was reported by 81.2% (69.2, 93.3) of PMW GC users, of whom 55.5% (40.7, 70.3) would be recommended AOP treatment by ACR guidelines. Chronic GC use was reported by 75.8% (63.2, 88.5) of men aged ≥50, of whom 51.8% (38.3, 65.3) would be recommended AOP treatment by ACR guidelines. Of those who met ACR criteria for treatment, only 13.8% (2.2, 25.4) of PMW and 5.0% (0.0, 11.5) of men aged ≥50 reported AOP use.

Conclusion: Based on NHANES data, we estimate that greater than 1.5 million US PMW and men aged ≥50 were using an oral GC between 2005 and 2010. Using ACR guidelines, treatment would be recommended in greater than 50% of this population. However, less than 15% of PMW and 5% of men aged ≥50 reported use of an AOP medication. These results indicate a treatment gap in the management of GIO in the US.

Incidence Of Osteoporotic Hip Fractures In Estonia Between 2005 and 2012. Mikk Jürisson[1], Anneli Uusküla[1], Riina Kallikorm[1], Sigrid Vorobjov[2] and Margus Lember[1]. [1]Faculty of Medicine, Tartu University, Tartu, Estonia, [2]National Institute for Health Development, Tallinn, Estonia.

Background/Purpose: Monitoring the incidence of hip fractures is essential to measuring population health and the value of improvements in health care. Data on recent trends in hip fractures from Eastern European countries is limited

Methods: Ecologic trend study uses data from the public health insurance fund covering the whole country to estimate the incidence of hip fracture. For the incident hip fracture case definition was based on the ICD 10 diagnosis code S72.0 on the health care bill for a person who had not been treated for the same cause in a preceding 12 months.

Age-specific fracture rates were calculated for males and females in 10 year age brackets and for population aged over 40 years. Age-standardized incidence rates were estimated using direct standardization method with the European population set as standard; trend in the rates over time was assessed using linear regression.

Results: In 2012, 833 patients were admitted for inpatient care for the incidence case of the hip fracture: 68% of the patients were women; the mean age was 76.7 years (SD 11.9; mean age for women 79.0 years, men 71.7 years; p-value<0.001). The age-specific incidence rates among women ranged from 9/100 000 (age group of 40–49) to 654/100 000 (age group 80+ years). The age-specific incidence rates among men ranged from 16/100 000 (age group of 40–49) to 577/100 000 (age group 80+). 57% and 34% of hip fracture cases were attributed to the oldest age group (80+ years) among women and men accordingly.

Unlikely for women and other age groups among men, age-specific incidence rates for men over 80 years were increasing between 2005 and 2012.

Over the period of 2005–2012 the estimated age-standardized incidence rates ranged from 102/100 000 (95%CI 89−114; in 2005) to 81/100 000 (95%CI 70−91; in 2012) among women, and from 91/100 000 (95%CI 83−100; in 2005) to 74/ 100 000 (95%CI 67−81; in 2012) among men. For both genders, the age-standardized incidence rates decreased over the period of 2005–2012 (men: p= 0.022; women; p- 0.02).

Conclusion: To our knowledge this is the first population-based analysis of hip fracture incidence in Estonia. There was no statistical difference between age-standardized incidence rates among women and men. The incidence among men was comparable to that reported from men from other European countries. However, the incidence observed among Estonian women is lower than that reported from their European counterparts. There was a decline in age-standardized incidence over the study period among both genders.

Medication Use With Denosumab (Prolia®) In a Large Claims Database In The United States. Emily Durden[1], Lung-I Cheng[2], Elnara Eynullayeva[1], Christopher Gregory[1] and Bradley Stolshek[2]. [1]Truven Health Analytics, Washington, DC, [2]Amgen, Inc., Thousand Oaks, CA.

Background/Purpose: Persistence and compliance with osteoporosis therapies is associated with significantly fewer vertebral, nonvertebral and hip fractures. A number of studies have examined medication-taking behavior with oral bisphosphonates and teriparatide, and the 1-year persistence rates have ranged from 39.9% to 56.7%. Limited real-world data are available regarding persistence and compliance with newer osteoporosis therapies, such as denosumab, a RANK ligand inhibitor administered every 6 months as a subcutaneous injection. The purpose of this study is to assess persistence and compliance among patients treated with denosumab in a large claims database in the U.S.

Methods: In this retrospective, observational cohort study, patients 18 years of age and older newly initiating denosumab between January 1, 2012 and March 31, 2012 were identified for inclusion from the *MarketScan Research* Databases. The date of the denosumab claim was defined as the index date. Patients were required to have at least 24 months of pre-index continuous enrollment with medical and pharmacy benefits. Patients were also required to have at least 8 months of post-index continuous enrollment for the interim analysis and at least 12 months of post-index continuous enrollment for the final analysis. Patients with Paget's disease of the bone, osteogenesis imperfecta, hypercalcemia, malignant cancer and metastasis, HIV, and patients receiving preventive treatment for risk of breast cancer or denosumab in the pre-index period were excluded from the study. In the post-index period, patients with a cancer or metastasis diagnosis appearing prior to a medical claim for denosumab were also excluded. The current report contains results from the interim analysis. Persistence as indicated by continuous use of denosumab without a gap of 60 days or more between injections, medication coverage ratio (MCR) as the proportion of days covered by denosumab, switching to another osteoporosis therapy, and patients not returning for denosumab therapy were assessed during the 8-month follow-up period.

Results: 1,570 patients newly treated with denosumab (mean [SD] age: 69.6 [12.0] years; 98.2% female) were identified. In the pre-index period, an osteoporosis diagnosis as indicated by ICD-9-CM codes was identified in 76.1% of the patients, while 4.0% had a diagnosis code of osteopenia, 7.1% had a diagnosis code of renal insufficiency, and the mean (SD) Charlson Comorbidity Index score was 1.1 (1.5). Pre-index osteoporosis treatment was identified in 57.5% of the patients, and 17.6% had an osteoporosis-related fracture in the pre-index period. During the 8-month post-index period, 70.0% of patients were persistent with denosumab, 1.5% switched to another osteoporosis therapy, and 28.5% did not return for denosumab therapy. The mean (SD) MCR over 8 months was 89% (10%), with 67.4% of patients having an MCR greater than 80%.

Conclusion: Rates of persistence and compliance with denosumab observed in this study appear to be higher than those with other osteoporosis medications reported in previous studies. This study provides real-world evidence on denosumab utilization, and its high rates of persistence and compliance.

Antinuclear Antibodies Positive But No Autoimmune Disease. M Herold[1] and Werner Klotz[2]. [1]Medical University of Innsbruck, Innsbruck, Austria, [2]Innsbruck Medical University, Innsbruck, Austria.

Background/Purpose: Antinuclear antibodies (ANAs) are tested in sera of patients suspicious of an autoimmune disorder. ANAs are part in many classification criteria of autoimmune (AI) diseases. In healthy individuals ANAs may also be found and are most often anti-DFS70 antibodies (Mahler M et al. Autoimmun Rev 2012;11:642–5). The frequency of anti-DFS70 antibodies was tested in sera of patients who were hospitalized or attended our outpatient clinic.

Methods: 336 consecutive and ANA positive samples were screened on Hep-2 cells for the presence of a typical DFS70 pattern defined as dense fine speckled staining of nucleoli of interphase cells and intensive staining of the condensed chromosomal material in mitotic cells or similar immunofluorescence patterns (e.g. homogenous, fine speckled, combination of homogenous and fine speckled patterns, centromere and others). Presence of anti-DFS70 autoantibodies was confirmed using a new chemiluminescence immunoassay (CLI; BIO-FLASH - DFS70 Assay; kindly provided by Inova Diagnostics, USA, within an unrestricted research grant).

Results: A pattern indicative of DFS70 autoantibodies could be found in 103 samples; in 82 of them (80 %) presence of anti-DFS70 autoantibodies could be confirmed by the CLIA vs. 9 in 233 samples (4 %) with other patterns. Numbers of other patterns were 70 with fine speckled, 66 homogenous and fine speckled, 43 homogenous, 4 centromere and 50 with mixed or other patterns.

In 298 of 336 patients a clinical diagnoses was found in the medical records. An autoimmune disease was given in 12 out of 78 patients (15 %) with DFS70 pattern (6 with juvenile arthritis, 5 with rheumatoid arthritis, 1 SLE) vs. 86 out of 220 patients (39 %) with other patterns (31 with SLE, 28 with RA, 2 with ANCA-associated vasculitis, 6 juvenile arthritis, 4 Sjogren's syndrome, 4 UCDT, 11 other AI diseases) and 8 out of 71 patients (11 %) with DFS70 autoantibodies in specific immunoassay (3 with juvenile RA, 2 with RA, 2 SLE, 1 patient suspect of MCDT) vs. 88 out of 227 DFS70 negative patients (39 %) (31 with RA, 30 with SLE, 9 juvenile RA, 4 Sjogren's syndrome, 2 UCDT, 12 with other AI diseases).

Conclusion: Anti-DFS70 was most often found (85 %) in people without other signs of an autoimmune disorder.

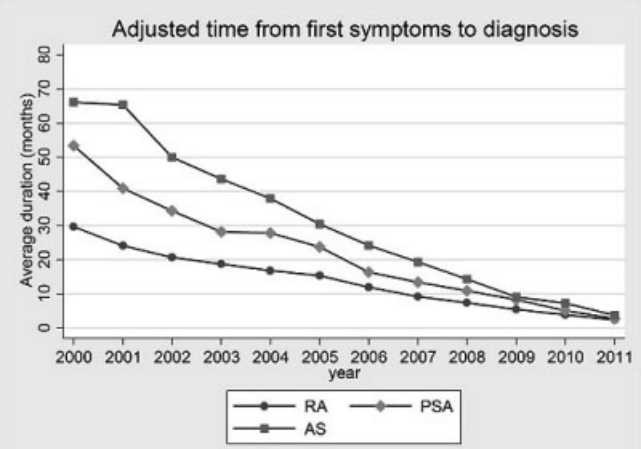
Duration Of Symptoms Before Diagnosis In Patients With Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis. Merete Lund Hetland[1] and Jan Sørensen[2]. [1]The Danish Rheumatologic Database (DANBIO), Glostrup Hospital., Copenhagen, Denmark, [2]Center for Applied Health Services Research, University of South Denmark, Odensen, Denmark.

Background/Purpose: Early diagnosis is important for the treatment of many rheumatic diseases. Little is known about the duration of symptoms before establishment of diagnosis, and if the delay in diagnosis has changed during recent years. We aimed to study the duration from onset of symptoms to diagnosis in patients with RA, PSA and AS using data from DANBIO from the last 12 years.

Methods: Month and year of initial symptoms and diagnosis, gender, year of birth, hospital and date of first entry into DANBIO were obtained for patients with RA, PSA or AS. Duration from symptom onset to diagnosis was modeled using generalized linear regression. Predicted values represent adjusted mean durations dependent of year of symptom onset. Sensitivity analyses including only patients who had symptom onset less than two (n=4,656) and five years (n=6,663) prior to first entry into DANBIO were performed and showed largely similar results (not shown).

Results: The figure shows the mean duration (in months) from initial symptoms to diagnosis adjusted for gender, age (10 year age groups), year of DANBIO entry, geographical region and social status. The duration from symptom to diagnosis for both RA, PSA and AS declined steadily during the period from 30, 52 and 68 months in year 2000, respectively, to 3–4 months by year 2011. The patients with valid data (RA: 10,737 (73%), PSA: 1,970 (68%), AS: 1,334 (65%)) did not differ significantly from the whole population, except for more missing data in the early years.



Conclusion: Since 2000, a dramatic reduction in the duration from symptoms to diagnosis was observed, probably reflecting a stronger awareness of the importance of early diagnosis.

Cost-Effectiveness Analysis Of Diagnostic Tests In The Work-Up Of Patients With Intermediate Risk Of Developing Rheumatoid Arthritis. Jolanda J. Luime[1], Maureen Rutten[2], Leander Buisman[2], Mark Oppe[2] and Johanna M.W. Hazes[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus University, Rotterdam, Netherlands.

Background/Purpose: With technological improvements in genomics, cytomics and metabolomics many promising biomarkers for stratifying individuals at risk of developing Rheumatoid Arthritis will enter the market. However, research into the potential cost-effectiveness of applying these biomarkers in actual clinical settings has been lacking. This study shows an initial assessment of cost-effectiveness for 4 different technologies (MRI, il6-serum test, RNA B cell signature, genetic assay) applied to intermediate risk patients (3–5 points on the ACR/EULAR criteria for RA) using a one-year time horizon.

Methods: The cost-effectiveness of the 4 technologies was simulated with a decision model using data from the Rotterdam Early Arthritis Cohort (REACH; prevalence of RA 55%). The comparator was the 2010 ACR/EULAR classification criteria. Test properties (sensitivity, specificity and costs) were based on literature and expert opinion (see table 1). Patients were classified true positive (TP) if they score >=6 points on the criteria or were tested positive and used MTX at 12 months follow-up. True negative (TN) patients were those that scored <6 points, were test negative and did not use MTX at 12 months. Costs included test costs, rheumatology visits and treatment costs. Changes in utilities within 1 year were assigned to TP (+0.1), TN (+0.1), false positive (FP; +0.05) and false negative (FN; −0.05). Outcome assessment included changes in the TP and the FP rate, the diagnostic net reclassification benefit (NB) for intermediate patients, QALYs, costs and ICER.

Results: Table 1 shows the results of the new technologies as add-on test to the ACR/EULAR classification strategy. Given the current test properties, the largest net benefit would be achieved by adding RNA B cell signature with an incremental cost effectiveness ratio of €13,939. To stay below a willingness to pay (WTP) threshold of €20,000/QALY gained (given the current assumptions in utilities) the add-on test strategy for intermediate risk patients can cost €230 at maximum.

Table 1. Test properties and modeling results for the 4 technologies tested in intermediate patients only

	Se	Sp	Price	Δ TP*	Δ FP*	uNB#	QALY	COSTS	ICER
RA2010	0.65	0.76	-	-	-	-	0.66	€1,084	-
MRI	0.90	0.60	€488	13%	13%	0%	0.67	€1,334	€38,541
B cell	0.60	0.90	€150	9%	3%	45%	0.67	€1,163	€13,939
Il6	0.70	0.53	€100	10%	15%	−37%	0.66	€1,148	€17,343
SNP	0.75	0.85	€1000	11%	5%	37%	0.67	€1,571	€70,347

*Difference in TP or FP rate between ACR/EULAR RA2010 and the new test as a % of the total sample; #uNB is the unweighted net benefit ((Δ TP- Δ FP/ diseased intermediate patients)*100%)

Conclusion: When applying new biomarker technologies in patients with intermediate risk of developing RA the largest net benefit would be achieved for RNA B cell signature, a test assigned moderate sensitivity and high specificity. Under the current utility assumptions and a WTP of €20,000/QALY a test strategy would be cost-effective for intermediate risk patients if it costs no more than €230.

Comparison Of Characteristics In Rheumatoid Arthritis Between International and National Databases In Europe: A Systematic Literature Review. E. Gvozdenovic[1], R. Koevoets[1], J. Langenhoff[1], C.F. Allaart[1] and R. Landewe[2]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: RA (Rheumatoid Arthritis) cohorts and registers are established for daily practice in clinical care. There are still differences between registries in disease activity and outcome, despite existing guidelines and international consensus about preferred drug therapies, which might be due to varying definitions for disease, inclusion criteria and variety in usage of biological agents. To improve collaboration between European rheumatologists, EULAR (European League Against Rheumatism) has recently started a repository of databases, which can be used as a platform for researchers to start collaborative projects. Our aim is to evaluate current European inter (national) databases and observational cohorts, and to compare inclusion criteria, aims, collected data and participation in the EULAR repository of databases.

Methods: An extensive search strategy was performed in Pubmed, Web of Science (WOS), Embase, Academic Search Premier, Wiley-Blackwell and LWW. Articles reporting on European inter (national) databases and prospective cohorts in RA with at least half a year of follow-up and >200 patients included were selected. We extracted data on national and international databases with details on aim, size, selection criteria, year of inception, frequency of data collection, physician/clinical evaluation, patient reported outcomes, laboratory information, funding and rheumatologic diseases captured.

Results: In total, 418 articles were included, which described 4 international and 39 national databases and cohorts. International databases were roughly similar and are mostly initiated to monitor and compare clinical patient care among countries. Also no restriction was present in frequency of data collection and selection criteria. The national databases differ in clinical features, such as aims (most registers aimed at efficacy and safety of treatment or monitoring disease activity in clinical practice), distribution among countries (not evenly distributed) and inclusion criteria (e.g. early RA registers versus routine care registers). Half of the national registers were connected to the EULAR repository of databases.

Conclusion: International databases have similar characteristics and the patients represent a large range of clinical activity (from inactive to active) and severity (from mild to severe). Regarding the national databases and cohorts heterogeneity is far greater, relevant differences exist in inclusion criteria, aims, frequency of data collection and distribution among Europe. Also only half of the databases are connected to the EULAR repository of databases. These differences may indicate that among researchers there is little awareness in guidelines to set up registers or cohorts and in the existence of the collaboration network of the EULAR.

Differing Disease Expression In Latin American Mestizo and Spanish Caucasian Patients With Rheumatoid Arthritis With The Same Access To Healthcare and Antirheumatic Treatment. Virginia Ruiz-Esquide[1], Sonia Cabrera[2], Julio Ramirez[3], M. Victoria Hernández[4], José Inciarte[3], J. D. Cañete[3] and Raimon Sanmarti[4]. [1]Hospital Clinic of Barcelona, Barcelona, Spain, [2]Hospital Clínic, Barcelona, Spain, [3]Hospital Clinic, Barcelona, Spain, [4]Hospital Clínic of Barcelona, Barcelona, Spain.

Background/Purpose: Rheumatoid arthritis (RA) prevalence and clinical phenotype varies between ethnic groups. Few studies have analyzed differences in disease expression between Latin-Americans mestizos (LA) and Caucasians in a population with the same access to healthcare. The purpose of this study is to compare the activity, severity and prognostic factors, of RA in Spanish Caucasians and LA followed at the same Spanish health centre and with the same access to healthcare and antirheumatic therapy.

Methods: Cross-sectional case-control study of RA patients (ACR 1987 criteria) aged 18–65 years attending a specialized RA clinic of a tertiary Spanish hospital between September 2011 and December 2012. For each LA patient, 2 Spanish Caucasians matched by disease duration (± 12 months) were selected. Sociodemographic variables, disease activity, prognostic markers, serology and treatment were collected and compared between the two groups.

Results: Of a total of 314 patients with RA, a sample of 153 RA patients (51 LA and 102 Spanish Caucasians) were finally included. The mean age was 47.3 ± 10 years and 88% were female. Disease duration and age at disease onset was similar between groups. LA had more active disease than Spanish Caucasians as measured by DAS28, number of tender and swollen joints, patient global health assessment or ESR (see table). Remission or low disease activity defined by DAS28 was achieved less frequently by LA

patients (15.7% vs. 40.2%, p=0.002, OR 3.61, 95% CI: 1.54 – 8.47 and 31.3% vs. 56.8%, p=0.003, OR 2.88, 95% CI: 1.42– 5.86, respectively). Disability measured by mHAQ and erosive disease were similar in the two groups. There were no significant differences in the treatment received between groups, although LA patients more frequently received glucocorticoids, synthetic DMARDs and biologic therapy. LA patients more frequently had seropositive RA (rheumatoid factor and/or anti-CCP positive) and were less frequently current and past smokers. Other factors that may be related to disease activity, such as obesity and vitamin D deficiency, were significantly more frequent in LA patients.

Table. Disease activity and disability in Caucasian and Latin American patients with RA.

	Total n=153	Caucasian n=102	Latin American n=51	p
Age at diagnosis	40.11 ± 11.84	40.54 ± 12.04	39.24 ± 11.51	0.523
Disease duration (months)	91.25 ± 93.03	91.13 ± 92.94	91.5 ± 94.14	0.982
Disease duration < 2 years %	33.98%	22.55%	23.53%	0.892
Age at inclusion	47.30 ± 10.59	47.76 ± 10.73	46.37 ± 10.34	0.554

Identifying Groups At Increased Risk Of Developing Rheumatoid Arthritis Using Family History and Genetic Risk Scores. Jeffrey A. Sparks[1], Chia-Yen Chen[2], Xia Jiang[3], Johan Askling[4], Linda T. Hiraki[5], Lars Klareskog[6], Lars Alfredsson[3], Karen H. Costenbader[1] and Elizabeth W. Karlson[1]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Karolinska Institutet, Stockholm, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden, [5]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [6]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: The identification of high risk groups is crucial for RA prevention strategies. Individuals with family history (FH) of autoimmunity are at increased risk for RA. Genetic markers have been associated with RA and genetic risk scores (GRS) have incorporated these markers for RA risk. We aimed to identify groups at increased risk of RA using FH and GRS.

Methods: We investigated the association between FH and GRS and risk of RA in a nested case-control study in the Nurses' Health Study (NHS) and replicated in the Epidemiological Investigation of RA (EIRA). RA cases in NHS were validated by chart review and matched to controls. In EIRA, RA cases at diagnosis were matched to controls. All cases satisfied the 1987 ACR criteria for RA classification and were Caucasian. FH data were obtained from questionnaires (FH of RA or lupus for NHS) and registries (FH of RA for EIRA). Serologic status was defined as +RF/ACPA for NHS and by +ACPA for EIRA. Weighted genetic risk scores (GRS-HLA using 8 HLA shared epitope alleles, and GRS-39 using 8 HLA shared epitope alleles and 31 SNPs associated with RA) were calculated based on prior studies. GRS were dichotomized as high or low based on the 75th percentile of the GRS in controls. The joint effect of low/high GRS and no/any FH was examined using logistic regression models adjusted for matching factors and confounders (age, sex, smoking pack-years, body mass index, alcohol intake, education, parity, and occupational exposures) to estimate odds ratios (OR) and 95% confidence intervals (CI) for all, seropositive/ACPA+, and seronegative/ACPA- RA, with the reference of low GRS and no FH.

Results: We analyzed 492 cases and 501 controls among women in NHS and 1,752 cases and 1,361 controls among men and women in EIRA with available FH data. Compared to low GRS-HLA/no FH, the OR for high GRS-HLA and +FH was 8.56 (95% CI 3.87–18.93) in NHS and 6.17 (95% CI 3.86–9.85) in EIRA for all RA (**Table 1**). The OR for high GRS-39 and +FH was 6.63 (95% CI 3.30–13.31) in NHS and 8.24 (95% CI 4.64–14.64) in EIRA for all RA compared to low GRS-39/no FH (**Table 2**). There were no significant multiplicative interactions between GRS-HLA or GRS-39 and FH.

Table 1. Joint effect of family history (FH) and GRS-HLA for RA phenotypes in the Nurses' Health Study (NHS) and the Epidemiological Investigation of RA (EIRA) study.

		Low GRS-HLA		High GRS-HLA

	Any	35/36	2.43 (1.47–4.01)	80/14	**14.20 (7.82–25.75)**
ACPA-RA	**None**	456/984	1.0 (Ref)	224/327	1.32 (1.07–1.62)
	Any	21/36	1.17 (0.672.07)	23/14	**3.65 (1.83–7.26)**

All models are adjusted for age, smoking pack-years, body mass index, alcohol intake, education, and parity. EIRA models are also adjusted for sex and occupational exposures.

Conclusion: Using genetic risk scores and family history, we have identified groups at increased risk of developing RA. Genetic risk scores utilizing only HLA shared epitope alleles performed similarly to genetic risk scores incorporating a larger set of genetic markers for RA. Genetic testing, particularly HLA shared epitope alleles, among those with family history may identify groups at increased risk for RA.

Sugar-Sweetened Soft Drink Consumption and Risk Of Developing Rheumatoid Arthritis In Women. Yang Hu[1], Karen H. Costenbader[2], Frank Hu[3], Daniel H. Solomon[4], Elizabeth W. Karlson[2] and Bing LU[5]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Harvard School of Public Health, Boston, MA, [4]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA, [5]Brigham & Women's Hospital and Harvard Medical School, Boston, MA.

Background/Purpose: Sugar-sweetened soft drink (SSSD) consumption is associated with weight gain, obesity, and increased risk of t*ype 2 diabetes (T2DM)* and cardiovascular disease (CVD). Previous studies have found that obesity may increase risk of rheumatoid arthritis (RA), while T2DM and CVD may share common pathways with RA development. We aimed to examine the relationship between SSSD intake and incident seropositive RA or incident seronegative RA in the Nurses' Health Study (NHS) and Nurses' Health Study II (NHS II), two large prospective cohort studies.

Methods: The NHS was established in 1976 and enrolled 121,701 US female registered nurses, ages 30–55 years. The NHS II was initiated in 1989 and comprised 116,430 female registered nurses, aged 25–42 years. RA cases were initially self-reported then confirmed by medical record review for 1987 ACR criteria. Seropositive RA was defined as positive RF or ACPA. SSSD consumption (colas and carbonated non-cola, but not low-calorie soft drinks) was assessed with a validated food frequency questionnaire (FFQ) completed every 4 years from 1980–2006 in NHS and 1991 – 2009 in NHS II. To reduce the measurement error and the potential reverse causality bias, we calculated average values from the preceding SSSD measures excluding the most recent dietary record. Time-varying Cox models were used to study the association between SSSD consumption and risk of seropositive and seronegative RA after adjusting for potential confounders. Pooled hazard ratio estimates from the two cohorts were calculated using a fixed effects model

Results: During the 1,906,661 person-years of follow-up from 1980 to 2008 in NHS, 366 seropositive and 215 seronegative RA cases were confirmed, and during 1,524,433 person-years from 1991 to 2009 in NHS II, 197 seropositive and 105 seronegative RA cases were confirmed. In the pooled analysis after adjusting for age, smoking, alcohol, BMI, reproductive factors, physical activity, multivitamin use,, diet quality, and diabetes history, we found a significant positive association between SSSD and increased risk of seropositive RA (P for trend 0.005); women consuming ≥1 serving of SSSD per day had 1.71 (95% confidence interval 1.23–2.38) fold increased risk of developing seropositive RA compared to those consuming none or less than 1 serving per month (Table). However, we did not find any significant association between SSSD and seronegative RA in both cohorts.

Table. Hazard ratios for incident seropositive RA according to sugar-sweetened soft drink consumption in Nurses' Health Study (NHS, 1980–2008) and Nurses' Health Study II (NHS II, 1991–2009)

	<1 serving/ month	1–4 servings/ month	2–6 servings/ week	≥1 serving/ day	*p* for trend
		NHS			
Cases/person-years	144/757,671	75/376,048	116/539,330	31/97,461	
Age-adjusted model	1.00	1.06 (0.80,1.40)	1.17 (0.91,1.50)	1.82 (1.23,2.71)	0.015
Multivariable-adjusted model [a]	1.00	1.09 (0.82,1.45)	1.25 (0.96,1.62)	1.96 (1.29,2.98)	0.006
		NHS II			
Case/person-years	104/806,188	26/220,867	48/365,248	19/103,555	
Age-adjusted model	1.00	0.88 (0.57,1.35)	1.04 (0.74,1.46)	1.55 (0.95,2.53)	0.258
Multivariable-adjusted model [a]	1.00	0.96 (0.62,1.50)	1.10 (0.76,1.60)	1.34 (0.78,2.32)	0.351
		NHS and NHS II pooled [b]			
Age-adjusted model	1.00	1.00 (0.79,1.27)	1.12 (0.92,1.37)	1.71 (1.26,2.33)	0.009
Multivariable-adjusted model [a]	1.00	1.05 (0.82,1.33)	1.20 (0.97,1.49)	1.71 (1.23,2.38)	0.005

a. Adjusted for age, median income (quartiles), cigarette smoking pack-years (never, <20 pack years, ≥20 pack years), alcohol consumption (<5.0, 5.0–15.0, ≥15 grams/day), age at menarche (<12, 12, >12 years), parity and breast feeding (nulliparous, parous/no breastfeeding, parous/1–12 months breastfeeding, parous/ >12 months breastfeeding), hormone use (pre-menopausal, post-menopausal with never use, current use and past use), physical activity (0–3, 3–9, 9–18, 18–27, ≥27 METs/week), multi-vitamin use, healthy eating index (quartiles), body mass index (<20, 20–22.9, 23–24.9, 25–29.9, ≥30kg/m^2), diabetes history and total energy (Kcal, quintiles).
b. P-values for heterogeneity were non-significant (p>0.05) in all pooled estimates

Conclusion: Data from two large prospective cohort studies suggest that regular consumption of SSSD is associated with increased risk of developing seropositive RA in women.

Posttraumatic Stress Disorder and Risk For Incident Rheumatoid Arthritis. Yvonne C. Lee[1], Susan Malspeis[1], Jessica Agnew-Blais[2], Katherine Keyes[3], Laura Kubzansky[2], Andrea Roberts[2], Karestan Koenen[3] and Elizabeth Karlson[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Columbia University Mailman School of Public Health, New York, NY, [4]Brigham and Woman's Hospital, Boston, MA.

Background/Purpose: Posttraumatic stress disorder (PTSD) is associated with autoimmune dysfunction, but the relationship between PTSD and the incidence of autoimmune disorders has not been studied prospectively. We examined the prospective association between PTSD and rheumatoid arthritis (RA) risk and tested markers of adverse health behaviors, cigarette smoking and body mass index (BMI), as possible mediators

Methods: The Nurses' Health Study II (NHSII) is a longitudinal cohort of 116,430 female nurses enrolled in 1989 at ages 25–42 years. A subset (N = 50,347) completed the Brief Trauma Questionnaire and the Lifetime PTSD screen, validated questionnaires that include date of worst trauma (proxy for date of PTSD onset). Participants were categorized into 5 groups based on trauma exposure and PTSD symptoms: 1) no trauma (referent), 2) trauma but no PTSD symptoms, 3) trauma and 1–3 PTSD symptoms, 4) trauma and 4–5 PTSD symptoms and 5) trauma and 6–7 PTSD symptoms. Incident RA (N = 185) after 1989 was confirmed by medical record review. Cox proportional hazards models were used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) for the association between PTSD and RA risk, adjusted for age, questionnaire year, race and parental education. We also examined the association between PTSD and seropositive and seronegative RA risk. To assess whether BMI and smoking mediated these associations, BMI and smoking measured after PTSD onset were added to the models. To assess whether BMI and smoking were confounders, we performed a subgroup analysis, including variables assessed before PTSD onset (BMI at age 18 and smoking before age 19) among women who experienced PTSD onset after age 20

Results: Compared to women unexposed to trauma, women exposed to trauma and reporting more than 4 PTSD symptoms were at higher risk for incident RA. RA risk increased with increasing number of PTSD symptoms (4–5 PTSD symptoms: HR 1.78, 95% CI 1.03–3.09; 6–7 PTSD symptoms: HR 1.91, 95% CI 1.03–3.56) (**Table**). Results were similar for the association between PTSD and seropositive RA risk (4–7 PTSD symptoms: HR 1.90, 95% CI 1.09–3.33). This trend was also noted in a subanalysis predicting seronegative RA, but the HR was lower and did not reach statistical significance (1.68, 95% CI 0.69–4.08). Both BMI and smoking status attenuated the association between PTSD and incident RA. In secondary analyses among patients who developed PTSD at age > 20, the HR for association with PTSD was lower (HR 1.57, 95% CI 0.56–4.43), but neither BMI at age 18 nor smoking before age 19 changed the HR (HR 1.58, 95% CI 0.56–4.45).

Table. Reported PTSD in the NHSII cohort analysis through 2009 (N = 49,276, including 185 women who developed RA)

Variable	RA cases	Person Years	Age-adjusted PTSD* HR (95% CI)	Multivariate* HR (95% CI)
No trauma, no PTSD symptoms	36	239023	1.00 (REF)	1.00 (REF)
Trauma, no PTSD symptoms	92	462310	1.26 (0.85, 1.85)	1.26 (0.86, 1.86)
Trauma, 1–3 PTSD symptoms	23	107007	1.28 (0.75, 2.16)	1.27 (0.75, 2.15)
Trauma, 4–5 PTSD symptoms	20	65928	1.78 (1.03, 3.08)	1.78 (1.03, 3.09)
Trauma, 6–7 PTSD symptoms	14	42360	1.89 (1.02, 3.53)	1.91 (1.03, 3.56)

*P-value for trend: age-adjusted model: 0.0142, multivariate model: 0.0134
** Cox proportional hazards models, adjusted for age, questionnaire-year, race (Caucasian, non-Caucasian) and parental education (^{2} high school, > high school)

Conclusion: These results suggest that PTSD may increase RA risk. Additional studies are needed to elucidate the pathways by which PTSD is associated with RA risk, specifically to assess whether this association is due to adverse health behaviors, increased reporting and healthcare utilization or alterations in immune pathways due to dysregulated stress response.

Patients With Regular Physical Activity Before Onset Of Rheumatoid Arthritis Present With Milder Disease. Maria E.C. Sandberg[1], Sara Wedren[2], Christina H. Opava[3], Lars Klareskog[4], Lars Alfredsson[1] and Saedis Saevarsdottir[4]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [3]Karolinska Institutet, Huddinge, Sweden, [4]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Physical activity is a crucial factor in human health; lack thereof is the third most important cause of preventable deaths today. Several biological mechanisms are affected by physical activity and decreasing markers of chronic inflammation have been shown in numerous studies. The aim of this study was to investigate whether the clinical presentation of rheumatoid arthritis (RA) might be affected by physical activity before disease onset.

Methods: Among the cases from the large, population-based, case-control study EIRA, with clinical data from the Swedish Rheumatology Quality Register, we compared patients with regular physical activity 5 years before diagnosis (N=288), to less active patients (N=329), we also investigated a possible dose-response relationship with physical activity in four levels. Logistic regression was used to calculate the odds of having above median level of 28-joint disease activity score (DAS28), physician assessment (5 categories), pain (visual-analog scale, VAS-pain) and activity limitation (health assessment questionnaire, HAQ). The analyses were adjusted for potential confounders (sex, age at diagnosis, period of diagnosis, smoking, body mass index, alcohol consumption, socioeconomic status, vegetable intake and physically demanding work (5 years before diagnosis).

Results: RA patients with *regular* physical activity before diagnosis had statistically significant decreased odds of having DAS28, physician assessment, and/or VAS-pain above median, while HAQ was not affected (see Table). We further found indications of a dose-response relationship for physical activity and DAS28, physician assessment and VAS-pain, for HAQ, however, only in the highest category of physical activity gave an effect (OR= 0.49 [95% CI: 0.24 – 0.99]). Further; statistically significant effects were found both for the combined objective components (swollen joint count, erythrocyte sedimentation rate, C-reactive protein) and combined subjective components (tender joint count, patient global assessment) of DAS28. Neither anti-CCP positivity, body-mass index, sex, physically demanding work nor socioeconomic status modified the observed associations.

	Physical activity at leisure time	Events (N)	OR	95% CI
DAS28 ≥5.3	No regular physical activity	189	1.00	Ref.
	Regular physical activity	122	**0.56**	**0.39–0–82**
Physician assessment >2	No regular physical activity	130	1.00	Ref.
	Regular physical activity	82	**0.62**	**0.42–0.92**
VAS-pain >50	No regular physical activity	181	1.00	Ref.
	Regular physical activity	127	**0.67**	**0.47–0.98**
HAQ ≥1	No regular physical activity	194	1.00	Ref.
	Regular physical activity	142	0.84	0.58–1.23

Conclusion: The findings of this study implicate that RA patients who were physically active before disease onset present with a milder disease according to both patient-reported, physician-reported and laboratory measures. No previous studies have evaluated the influence of physical activity on the clinical presentation of RA. However, DAS28 has been reported to improve after physical activity interventions among established RA-patients, and some trials also reported improvements in VAS-pain and/or HAQ. The results of the present study adds to the growing evidence of the general health benefits of physical activity, and might be an important, helpful message for individuals at increased risk of RA.

Association Between History Of Periodontitis and Risk Of Rheumatoid Arthritis In Individuals With and Without Diabetes Mellitus: A Population-Based Cohort Study. Hsin-Hua Chen[1], D.Y. Chen[2] and Nicole Huang[1]. [1]National Yang-Ming University, Taipei, Taiwan, [2]Taichung Veterans General Hospital, Taichung, Taiwan.

Background/Purpose: To examine whether the association between periodontitis (PD) history and the rheumatoid arthritis (RA) risk differs between individuals with and without diabetes mellitus (DM)

Methods: We conducted a population-based retrospective cohort study using the 1997–2009 National Health Insurance (NHI) claims data of one million representative individuals from all NHI enrollees. Adults with DM (aged ≥20 years) newly treated during 2001–2009 were classified as DM subjects and those without a DM diagnosis during 1997–2009 were classified as non-DM subjects. We identified 7097 DM subjects with PD history within one year before initiating anti-diabetes treatment (index date). By matching these 7097 subjects for age on the index date, sex, and year of the index date, we randomly extracted 14,194 DM subjects without PD history, 14,194 non-DM subjects with PD history, and 28,388 non-DM subjects without PD history. Adjusted hazard ratios (aHRs) with a 95% confidence interval (CI) were calculated by applying Cox proportional hazards models to quantify the association between PD history and RA risk.

Results: Compared with subjects without PD history, the adjusted HR of RA among those with PD history was 2.26 (95%CI, 1.26–4.04). In subgroup analysis, this association was evident among DM subjects (aHR, 3.77; 95%CI, 1.48–9.60) but not among non-DM subjects (aHR, 1.56; 95%CI, 0.73–3.37; *P* for interaction 0.212).

Conclusion: The effect of PD exposure on RA risk was evident in newly treated DM subjects but not in non-DM subjects; no significant modifying effect of DM was observed.

Lack Of Association Between Preclinical Markers For Cardiovascular Disease and Rheumatoid Arthritis-Related Autoimmunity In First-Degree Relatives Without Rheumatoid Arthritis. Jill M. Norris[1], Ryan W. Gan[1], Jan M. Hughes-Austin[2], Kevin D. Deane[3], M. Kristen Demoruelle[3], Elaine M. Urbina[4], Kerrie Moreau[3], Peter K. Gregersen[5], Michael H. Weisman[6] and V. Michael Holers[3]. [1]Colorado School of Public Health, Aurora, CO, [2]University of California, San Diego, La Jolla, CA, [3]University of Colorado School of Medicine, Aurora, CO, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Feinstein Institute for Medical Research, Manhasset, NY, [6]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Rheumatoid arthritis (RA) is characterized by systemic inflammation and immune dysregulation, including the presence of autoantibodies and elevated inflammatory biomarkers in subjects with classifiable RA as well as prior to the development of clinically-apparent RA. In addition, the risk for cardiovascular disease (CVD) is greatly increased in patients with RA, with autoantibodies and systemic inflammation believed to be major contributors to the pathogenesis of CVD. Furthermore, the increased risk for CVD may precede the development of classifiable RA, leading to the hypothesis that autoantibodies and systemic inflammation are influencing the development of CVD in subjects even prior to the onset of joint symptoms in RA. The Studies of the Etiology of RA (SERA) demonstrated previously an association between autoantibody positivity and increased levels of circulating cytokines in subjects without RA but at elevated risk for future RA, as they are first-degree relatives (FDRs) of probands with RA. We utilized SERA FDRs to test the hypothesis that CVD may be apparent in subjects at-risk for future RA, and related to the presence of RA-related autoantibodies.

Methods: Eighty-six autoantibody positive and negative FDRs from the larger SERA cohort were evaluated after a 10-hour fast for the following measures related to CVD: carotid intima media thickness (cIMT), carotid stiffness, flow-mediated dilation (FMD) of the brachial artery, abdominal adipose tissue using computed tomography (CT), blood pressure, lipids, lipoproteins and adipokines. Levels of these pre-clinical CVD phenotypes were log-transformed and compared by current autoantibody positivity status using mixed linear models to account for varying group sizes, adjusting for age, sex and ever smoked status.

Results: Nineteen FDRs were positive for anti-cyclic citrullinated peptide (either CCP2 or CCP3.1), 22 FDRs were positive for rheumatoid factor (RF) (either RF by nephelometry, or RF isotype-IgM, IgA, IgG), and 45 were negative for CCP and RF. The ApoB/ApoA ratio differed across autoantibody groups, with the Ab negative FDRs having the highest ratio, indicating increased CVD risk. Otherwise, there were no significant differences in CVD-related measures and current autoantibody status in FDRs (see Table).

Table. CVD-related measures between CCP positive, RF positive and Ab Negative FDRs. Adjusted for age, gender, race, and smoking status; values are back-transformed.

	CCP Positive n=19† Mean (SE)	RF Positive n=22 Mean (SE)	Ab Negative n=45 Mean (SE)	P

Elastic Modulus, Incremental (mmHg)	1873.8 (286.3)	1688.2 (292.1)	1909.5 (270.5)	0.69
Young's Elastic Pressure Modulus (mmHg/mm)	355.2 (49.3)	327.0 (51.9)	361.4 (48.2)	0.75
Arterial Compliance (mm^2/mmHg)	0.1 (0.01)	0.1 (0.01)	0.1 (0.01)	0.34
Flow Mediated Dilatation (FMD) (Δ%)**	6.6 (1.7)	6.7 (1.4)	5.7 (0.9)	0.58

*Sample size reduced as not everyone participated in CT scan (CCP n=5, RF n=16, Ab- n=28).
**Sample size reduced as not everyone was measured for FMD (CCP n=11, RF n=13, Ab- n=20).
† 11 CCP positive cases were also positive for RF.

Conclusion: This analysis suggests that CCP and RF positive FDRs did not have worse biochemical, structural or functional indicators of vascular health compared to autoantibody negative FDRs, which is contrary to our *a priori* hypothesis. These results tentatively indicate that the increased risk for CVD that is seen in RA is not detectable in the early preclinical autoantibody phase of the disease, using the biochemical, structural or functional vascular changes measured herein. It is possible that the increased CVD risk seen in RA is manifested outside of these pathways and other mechanisms/measures should be explored.

Postmenopausal Hormone Therapy and The Risk Of Rheumatoid Arthritis: Results From The Swedish EIRA Study. Cecilia Orellana[1], Saedis Saevarsdottir[1], Lars Klareskog[2], Lars Alfredsson[1] and Camilla Bengtsson[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden.

Background/Purpose: The importance of hormonal/reproductive factors has been hypothesized to contribute to the risk of Rheumatoid arthritis (RA), but the literature is somewhat contradictory. The use of postmenopausal hormone (PMH) has previously been observed to provide increased [1], decreased [2], as well as no association [3] with the risk of RA. The aim of the present work was to study the association between the use of PMH and the risk of developing RA in postmenopausal women (aged 50–70), by stratifying the cases according to presence/absence of antibodies to citrullinated peptides (ACPA).

Methods: Data from the Swedish population-based EIRA (Epidemiological Investigation of RA) case-control study was analyzed. In total, 380 incident postmenopausal female cases, aged 50–70 years, and 780 randomly selected controls (matched by age and residential area) were included between 2006–2009. Of the cases, 239 (62.9%) were ACPA-positive. The use of PMH was assessed by means of an identical questionnaire answered by the participating cases and controls. Current and past users of PMH were compared with never users to obtain odds ratios (ORs) with 95% confidence intervals (CI) by means of unconditional logistic regression models.

Results: A decreased risk of developing ACPA-positive RA was observed among current users compared with never users of PMH (OR 0.5, 95% CI 0.3–0.9). Among past users of PMH no association was found when comparing with never users (OR 1.2, 95% CI 0.8–1.7). For ACPA-negative RA no association was found among current (OR 1.0, 95% CI 0.6–1.8) or past (OR 1.2, 95% CI 0.8–2.0) users of PMH.

Conclusion: Our results indicate that current use of PMH is associated with a decreased risk of ACPA-positive RA in postmenopausal women aged 50–70, but has no association with the risk of ACPA-negative RA. The striking difference in the results for ACPA-positive and ACPA-negative RA adds further evidence to the notion that RA consists of two different entities with partly different etiology. Further research is needed in order to explore the biological mechanisms behind our findings.

The Controversies and Points Of Debate That Remain a Challenge For Fibromyalgia Care. Mary-Ann Fitzcharles[1], Peter A. Ste-Marie[1], Don L. Goldenberg[2], John X. Pereira[3], Susan Abbey[4], Manon Choinière[5], Gordon Ko[6], Dwight E. Moulin[7], Pantelis Panopalis[1], Johanne Proulx[8] and Yoram Shir[1]. [1]McGill University Health Centre, Montreal, QC, [2]Newton-Wellesley Hosp, Newton, MA, [3]University of Calgary, Calgary, AB, [4]University of Toronto, Toronto, ON, Canada, Toronto, ON, [5]University of Montreal, Montreal, QC, [6]University of Toronto, Toronto, ON, [7]University of Western Ontario, London, ON, [8]Patient Representative, Montreal, QC.

Background/Purpose: Fibromyalgia (FM) continues to present challenges for the health care community, with perceptions of disease and attitudes of physicians being highly polarized. Neurophysiologic studies provide reassurance of validity of FM, but clinical care remains dependant on the traditional "art of medicine". In the process of formulating Canadian guidelines for care of FM patients, debate was generated on a number of highlighted clinical issues (1). This report examines these contentious issues in order to provide insight regarding challenges surrounding FM.

Methods: In developing evidence based guidelines for the clinical care of FM, 11 of 60 recommendations did not achieve 80% approval at the first round of voting by a nationwide multidisciplinary health care panel. Modifications according to panel input were made and resubmitted for a second voting, at which time all passed, and form the basis of this report.

Results: Contention was seen in the following areas. *1. Criteria for diagnosis*: The healthcare community remains fixated on application of diagnostic criteria, the absence of which causes uncertainty. The tender point count (TPC) remains entrenched in clinical practice. Agreement was obtained by recommending that the 2010 ACR criteria *may be used* to validate a clinical diagnosis, and TPC may be done by choice, but neither is required for diagnosis. *2. Treatments*: Initial recommendation to *discourage use* of complementary and alternative medicine (CAM) treatments in absence of evidence for efficacy was modified to emphasize *lack of evidence to support* CAM use, thereby allowing for individual choice. Although antidepressants in all classes have shown some efficacy, individual bias favoured the newer serotonin norepinephrine reuptake inhibitors. Resolution was achieved by recommending that the specific choice be tailored to the patient according to physicians' knowledge and evidence for efficacy. *3. Terminology:* Recommendation to change the terminology of antidepressants and anticonvulsants to pain modulators was rejected in favour of promoting their pain modulating effects rather than a nomenclature change. *4. Past/triggering events:* Causation in FM is contentious with experts recommending acknowledgement of previous negative lifetime events, but without excessive emphasis on its importance. *5. Work and disability:* Recommendation to remain in the workforce was softened to state that continued work is ideal, with application of a rehabilitation program to improve function and *possible* return to work.

Conclusion: The healthcare community must adopt a rational and unified approach to the management of FM to dispel false notions that hinder management. The abundance of anecdotal literature, strong advocacy from various groups and the subjective nature of FM symptoms may all have played a part in diagnosis and treatment uncertainty. These guidelines reflect the available evidence with clinically applicable input from health care workers from various disciplines and adhere to strict standards of development. Continued dialogue will help dispel misperceptions and facilitate optimal patient care.

Routine Assessment Of Patient Index Data 3 In Fibromyalgia: A Rapid and Reliable Instrument For Evaluating Disease Severity? Ece Kaptanoglu, Ozlem Sahin, Yunus Durmaz, Ahmet Kivanc Cengiz and Sami Hizmetli. Cumhuriyet University, Sivas, Turkey.

Background/Purpose: Routine Assessment of Patient Index Data 3 (RAPID 3) is a patient based questionnaire which was designed for evaluation of disease activity without formal joint counts for rheumatoid arthritis (RA) for busy clinical settings. Besides RA, it's usage is being serached for some other diseases, too. We aimed to search the effectiveness of RAPID 3 in evaluating severity of fibromyalgia (FM) which is a generalized pain syndrome sharing many symptoms of RA like stiffness and fatigue besides many somatic symptom.

Methods: 38 female volunteered patients with FM were involved in the study. All patients were requested to complete the RAPID 3, Fibromyalgia Impact Questionnaire (FIQ), Revised Fibromyalgia Impact Questionnaire (FIQR) and FM symptom severity scale.

Results: Mean age of the patients were 46±10,9 years and the mean disease duration was 4,8±3.8 years. There were significant correlations between RAPID 3 and FIQR (r=0.598 p=0.000), symptom severity (r=0.573 p=0.000), FIQ total (r=0.742 p=0.000) and subgroups of FIQ (FIQ physical impairment r=0.434 p=0.007, feel good r=0.524 p=0.001, work missed r=0.577 p=0.000, do work r=0.634 p=0.000, pain r=0.733 p=0.000, fatigue r=0.045 p=0.005, stiffness r=0.492 p=0.002, anxiety r=0.378 p=0.019, depression r=0.398 p=0.013 except rested r=0.197 p=0.236. The correlation of FIQR and FIQ total was also good (r=0.763 p=0.000). The correlations of FIQ total and FIQR with symptom severity were r=0.626 p=0.000 and r=0.481 p=0.005 respectively.

Conclusion: RAPID 3 has a good correlation with FIQ, FIQR and symptom severity scale which are gold standarts in follow up of FM. Though it is not a spesific questionnaire for FM, it successfully puts forward the severity of the disease in a quicker and easier way. These preliminary results justify further investigation of the usage of this questionnaire in FM.

The Symptom Severity In Korean Patients With Fibromyalgia Is Associated With Socioeconomic Status, But Not With Obesity. Dong-Jin Park[1], Shin-Seok Lee[2], Seong-Ho Kim[3], Seong-Su Nah[4], Ji Hyun Lee[5], Seong-Kyu Kim[6], Yeon-Ah Lee[7], Seung-Jae Hong[7], Hyun-Sook Kim[8], Hye-Soon Lee[9], Hyoun Ah Kim[10], Chung-Il Joung[11] and Sang-Hyon Kim[12]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [3]Division of Rheumatology, Inje University College of Medicine, Haeundae Paik Hospital, Busan, South Korea, [4]Soonchunhyang University Cheonan Hospital, Cheonan, South Korea, [5]Maryknoll Medical Center, Busan, South Korea, [6]Catholic University of Daegu School of Medicine, Daegu, South Korea, [7]Kyung Hee University, Seoul, South Korea, [8]Division of Rheumatology, Department of Internal Medicine, Soonchunhyang University of Korea, Seoul, Korea, Seoul, South Korea, [9]Hanyang University Guri Hospital, Guri, South Korea, [10]Ajou University Hospital, Suwon, South Korea, [11]Konyang university hospital, Daejeon, South Korea, [12]Division of Rheumatology, Department of Internal Medicine, Keimyung University School of Medicine, Daegu, South Korea.

Background/Purpose: Fibromyalgia (FM) is a chronic pain disorder characterized by widespread pain, tenderness, and various associated symptoms including sleep disturbances, chronic fatigue, depression, and other somatic symptoms. Several longitudinal and cross-sectional studies in western countries have shown that a high body mass index (BMI) is a strong and independent risk factor for future development of FM and is associated with higher levels of FM symptoms. In addition, obese patients have more physical and emotional impairments compared with nonobese patients. The purpose of this study was to determine whether obesity and socioeconomic factors influence symptom severity in Korean patients with FM.

Methods: A total of 343 patients with FM were recruited from outpatient clinics at 11 medical centers across the Republic of Korea. All patients met the ACR 1990 classification criteria for FM. We interviewed these patients using a structured questionnaire that included sociodemographic data, current or past FM symptoms, and current use of relevant medications at the time of enrollment. Tender point counts and scores were assessed by thumb palpation. Patients were asked to complete a Korean version of the Fibromyalgia Impact Questionnaire (FIQ), the Brief Fatigue Inventory (BFI), the SF-36, the Beck Depression Inventory (BDI), the State-Trait Anxiety Inventory (STAI), the Self-Efficacy Scale, and the Social Support Scale.

Results: Based on an obesity definition of a BMI of ≥25, 76 (22.1%) of the 343 patients were obese. Obese patients were not different from nonobese patients in terms of tender points and scores, FIQ, BFI, SF-36, BDI, STAI, Self-Efficacy, and Social Support scores. After age-, gender-, and symptom duration adjustment by propensity score matching, no significant differences were also found between obese and nonobese patients. However, socioeconomic status such as employment, insurance, and education were significantly associated with symptom severity of FM. The unemployed patients had higher FIQ scores ($p = 0.011$), higher BFI scores ($p = 0.013$), lower physical and mental component SF-36 scores ($p = 0.012$, $p = 0.005$), higher BDI scores ($p = 0.005$), and higher STAI II scores ($p = 0.041$). Lower-income patients had higher FIQ score ($p=0.040$), lower physical and mental SF-36 scores ($p = 0.047$, $p = 0.006$), higher BDI scores ($p < 0.000$), and lower Self-Efficacy scores ($p = 0.016$). Finally, patients with an education of <12 years had higher tender points ($p = 0.034$), higher BDI scores ($p = 0.007$), and higher STAI II scores ($p = 0.045$).

Conclusion: Our findings show that, contrary to Western patients, symptom severity in Korean patients with FM is associated with socioeconomic status, but not with obesity.

Comparative Burden Of Chronic Widespread Pain and Fibromyalgia In The US Population. Caroline Schaefer[1], Rachael Mann[2], Elizabeth T. Masters[3], Joseph C. Cappelleri[4], Shoshana Daniel[5], Gergana Zlateva[3], Heather McElroy[6], Arthi B. Chandran[3], Edgar H. Adams[1], Annlouise R. Assaf[4], Michael McNett[7], Philip Mease[8], Stuart L. Silverman[9] and Roland Staud[10]. [1]Covance Market Access Services Inc., Gaithersburg, MD, [2]Covance Market Access Services Inc., San Diego, CA, [3]Pfizer Inc., New York, NY, [4]Pfizer Inc., Groton, CT, [5]Covance Market Access Services Inc., Conshohocken, PA, [6]Covance Market Access Services, Sydney, Australia, [7]Aurora Pain Program, Milwaukee, WI, [8]Swedish Medical Center, Seattle, WA, [9]Cedars-Sinai Medical Center, UCLA Center of Excellence, Beverly Hills, CA, [10]University of Florida, Gainesville, FL.

Background/Purpose: Few data exist on the comparative burden of chronic widespread pain (CWP) and fibromyalgia (FM) in the general population.

Methods: 8,382 nationally representative participants (≥18 years old) completed an online screener including sociodemographic questions and the London Fibromyalgia Epidemiology Study Screening Questionnaire (LFESSQ). Subjects who screened positive (bilateral pain, above/below waist, lasting ≥1 week in the past 3 months; CWP+), and a control group without CWP (CWP-) were invited for a site visit for physician evaluation of FM including a tender point exam. Of 1,331 CWP+ and 502 CWP- subjects who consented to be scheduled for a visit, mutually exclusive groups of CWP- (n=125), CWP+ (n=176) and confirmed FM subjects based on physician evaluation (n=171) completed a visit and an online questionnaire to assess clinical characteristics and patient-reported outcomes (including Brief Pain Inventory-short form [BPI-SF], Medical Outcomes Study Sleep Scale [MOS-SS], 12-Item Short Form Health Survey v2 [SF-12], EQ-5D-3L). Statistical significance was tested at the 0.05 level across the 3 groups using ANOVA for continuous variables and chi-square or Fisher's exact test for categorical variables.

Results: Age and race were similar among the 3 groups, but mean body mass index (kg/m^2) increased from CWP- (28.8) to CWP+ (30.7) to FM (32.1) (P=.0044). Among those reporting comorbidities, the mean (SD) number increased from 2.4 (1.6) to 3.2 (2.0) and 4.9 (3.0) for CWP-, CWP+, and FM, respectively (P<.0001), with a corresponding greater prevalence of specific physical conditions (e.g. arthritis, headache/migraine, irritable bowel syndrome; all P<.003) and affective disorders (anxiety, depression; both P<.0001). Pain severity and interference with function progressively increased from CWP- to CWP+ to FM (P<.0001) (Table), including all BPI-SF interference subscales. Sleep quantity and quality significantly differed across the groups as indicated by the MOS-SS total score (Table) and subscales. The EQ-5D-3L and SF-12 showed progressive reduction in health status, and physical and mental health, respectively (Table); all SF-12 domains scores were lowest with FM followed by CWP+ and CWP- (P<.0001). Relative to CWP-, higher proportions of CWP+ and FM groups were taking pain-related prescription medications, 32.8%, 52.8% and 62.6%, respectively (P<.0001); opioids were the single most frequently reported pain medication class.

Table. Comparative Burden in Subjects by Chronic Widespread Pain (CWP) and Fibromyalgia (FM) Status

	Mean (standard deviation)			
Measure	**CWP−**	**CWP+**	**FM**	***P*-value**
	(n=125)	**(n=176)**	**(n=171)**	
BPI-SF[a]				
Pain Severity Index	3.0 (2.1)	4.4 (2.1)	5.5 (2.0)	<.0001
Pain Interference Index	2.5 (2.5)	4.3 (2.6)	5.8 (2.4)	<.0001
MOS-SS total score[a]	32.8 (18.7)	48.2 (18.5)	59.6 (17.5)	<.0001
SF-12[b]				
Physical Component Summary score	48.1 (10.8)	38.9 (11.0)	33.7 (10.5)	<.0001
Mental Component Summary score	49.1 (10.4)	44.9 (10.8)	40.4 (10.8)	<.0001
EQ-5D-3L[b]				
Health state valuation	0.85 (0.13)	0.73 (0.18)	0.61 (0.21)	<.0001
Overall health status rating	79.8 (16.0)	68.7 (18.8)	58.7 (20.0)	<.0001

[a]Higher score=worse outcomes; [b]lower score=worse outcomes

Conclusion: In a nationally representative sample, CWP+ and FM were characterized by a high disease burden relative to CWP- including more comorbidities and pain-related medications, poorer sleep, and reduced function and health status; the burden was highest with FM. Health status observed in FM was lower than has been reported for chronic conditions, such as cancer and diabetes (Luo et al. *Health Outcomes Res Med.*2011;e203–14).

Rheumatologists Lack Confidence in Their Knowledge of Cannabinoid Molecules and Use in the Management of Rheumatic Disease Patients: Analysis of a Needs Assessment. Mary-Ann Fitzcharles[1], Peter A. Ste-Marie[1], Daniel J. Clauw[2], Shahin Jamal[3], Jacob Karsh[4], Sharon Leclercq[5], Jason J. McDougall[6], Yoram Shir[1], Kamran Shojania[3] and Zach Walsh[7]. [1]McGill University Health Centre, Montreal, QC, [2]University of Michigan, Ann Arbor, MI, [3]University of British Columbia, Vancouver, BC, [4]Ottawa Hosp Riverside, Ottawa, ON, [5]University of Calgary, Calgary, AB, [6]Dalhousie University, Halifax, NS, [7]University of British Columbia, Kelowna, BC.

Background/Purpose: The pharmacologic treatment of chronic rheumatic pain is often sub-optimal, leading patients to seek alternate treatments. Although herbal cannabis (marihuana) has had medicinal use for pain management for centuries, scientific study of cannabinoid effects is recent. With patient advocacy for access to cannabinoids, regulatory bodies worldwide are considering the merits of legalizing medical cannabis. As arthritis is cited as a common reason for medical cannabis use, rheumatologists should be better informed to advise patients. We have assessed rheumatologists' self-reported confidence in their knowledge of cannabinoids and their perceived competence in providing prescriptions.

Methods: Using a 19-question needs assessment survey, sent via email to the entire Canadian Rheumatology Association membership, we have examined rheumatologists' confidence in 1) knowledge of cannabinoids in general, including phyto-, syntheto- and endocannabinoids, and 2) perceived competence and ability to advise patients regarding indications, use and precautions for cannabinoids in general, and herbal cannabis specifically.

Results: 128 (25%) of all 510 members responded. Over three quarters were not confident in their knowledge of cannabinoid molecules, with two thirds reporting poor knowledge of the physiology of the endocannabinoid system. While 45 % of respondents stated no current role for any cannabinoid preparations for rheumatology patients, 70% believe this applies specifically to medical cannabis. Only 16 (13%) had ever previously recommended a trial of medical marihuana. Over 90% were not confident in writing a prescription for medical cannabis when required to indicate dosing, frequency and method of administration. When respondents were grouped as "Confident" in knowledge of cannabinoid molecules (n=33) vs. "Not-Confident" (n=95), the following were reported respectively: Current role for medical cannabis 48% vs. 23%; Previous prescription of pharmacological cannabinoid 33% v.12%; Previous recommendation for medical cannabis 27% vs.7%; No previous recommendation for either 39% vs. 81%; Would not recommend any cannabinoid in future 33% vs. 67%. Only 33% of knowledge confident respondents reported competence in prescribing medical cannabis. Concerns about risks of marihuana use were in line with current literature.

Conclusion: The overwhelming majority of rheumatologists reported lack of confidence in their knowledge of cannabinoids, and uncertainty about their competence to prescribe cannabinoid treatments and herbal cannabis in particular. This survey highlights a major disconnect between patients' advocacy, policy makers and physician need to provide competent patient care within the bounds of medical ethics and deontology. Guidance is required to inform rheumatologists on the prevailing evidence for the safe and effective use of cannabinoids in rheumatic conditions.

Association Of Rheumatic Diseases With Symptom Severity, Quality Of Life, and Treatment Outcome In Patients With Fibromyalgia. Juan Jiao, John M. Davis III, Ann Vincent, Connie A. Luedtke, Stephen Cha and Terry H. Oh. Mayo Clinic, Rochester, MN.

Background/Purpose: Fibromyalgia is often associated with various comorbid conditions. A high prevalence of fibromyalgia in patients with rheumatic diseases has been reported. Previous studies showed that patients with rheumatoid arthritis (RA) and fibromyalgia had worse RA symptoms, greater disease activity, and worse physical and mental quality of life (QOL) compared with patients who have RA without fibromyalgia. How a comorbidity of rheumatic disease affects symptom severity, QOL, and treatment outcome in patients with fibromyalgia is unknown. This study aims to evaluate the association of rheumatic diseases with symptom severity, QOL, and treatment outcome in patients with fibromyalgia.

Methods: The initial study population consisted of 978 patients who were confirmed to have fibromyalgia and completed the brief multidisciplinary fibromyalgia treatment program (FTP), with emphasis on cognitive behavioral therapy (CBT). We based the present analysis on the 536 patients who returned survey questionnaires during the 6- to 12-month follow-up period (mean follow-up duration was 11.7 months; overall survey response rate, 54.8%). The Fibromyalgia Impact Questionnaire (FIQ) and the Short Form-36 Health Status Questionnaire (SF-36) were completed at initial evaluation and at 6- to 12-months follow-up period. Information about the presence or absence of inflammatory rheumatic disease (IRD) of each participant at initial evaluation in the FTP was collected retrospectively from the electronic medical record by an investigator. Presence of IRD was determined by physician diagnosis. Two-sample *t* test and multivariate regression analyses were performed to compare the rheumatic and nonrheumatic groups.

Results: Thirty-six patients (6.7%) had documented IRDs, with undifferentiated inflammatory arthritis and rheumatoid arthritis being the common IRDs. At baseline, the rheumatic group had poorer scores in SF-36 physical functioning ($P=.02$), pain index ($P=.01$), and physical component summary ($P=.009$) than the nonrheumatic group. After the FTP, both groups tended to improve; however, the rheumatic group had significantly less improvement in the FIQ subscales in pain ($P=.02$) and work missed days ($P=.02$), and in the SF-36 physical functioning ($P=.02$) compared to the nonrheumatic group.

Conclusion: Our findings suggest that IRD is a relatively common comorbidity among patients with fibromyalgia, with a prevalence of about 7% in the study population. Fibromyalgia patients with IRDs have worse SF-36–assessed physical health and pain but not for mental health at baseline compared to fibromyalgia patients without rheumatic diseases. In addition, the rheumatic group demonstrated lower treatment response to the FTP compared to the nonrheumatic group. Our study suggests that our brief FTP based on CBT is less efficacious in patients with fibromyalgia who have IRDs than in those who do not have IRDs. Further studies that seek to identify the relations and the pathophysiologic mechanisms linking fibromyalgia and IRDs will likely advance the understanding of these overlapping chronic conditions.

Disability In Fibromyalgia Is Associated With Greater Self-Reported Symptoms and Functional Impairment. Emmanouil Rampakakis[1], Mary-Ann Fitzcharles[2], Peter A. Ste-Marie[2], John S. Sampalis[1] and Yoram Shir[2]. [1]JSS Medical Research, St-Laurent, QC, [2]McGill University Health Centre, Montreal, QC.

Background/Purpose: It is intuitive that disablement due to illness should be reflected in illness severity. When illness measurement is based on subjective report only, without objective validation, the reliability of symptom report is crucial and requires critical evaluation. Societal costs for fibromyalgia (FM) are high with disability rates up to 30% reported in the developed world. We have examined clinical characteristics of FM patients currently employed or receiving disability payments.

Methods: Of 246 participants in a tertiary care cohort study of FM patients, 90 were employed, 77 receiving disability payments. Demographic and disease severity measures included: pain visual analog scale (VAS), patient global assessment (PGA), Fibromyalgia Impact Questionnaire (FIQ), Health Assessment Questionnaire (HAQ), McGill Pain Questionnaire (MPQ), Pain Disability Index (PDI), Pain Catastrophizing Scale (PCS), anxiety and depression by Arthritis Impact Measurement Scale (AIMS). Between-group differences in discrete and continuous variables were assessed for statistical significance with the Chi-Square test and the independent-samples t-test, respectively. Linear regression was used to assess between-group differences in disease activity while adjusting for potential confounders.

Results: The prevalence of disablement was 30.8%. Disabled patients were significantly older (49.1 vs. 45.9; $P=0.020$), more likely to smoke cigarettes (33.8% vs. 15.6%; $P=0.006$) or use marijuana (13.0% vs. 3.3%; $P=0.020$). No significant differences were observed in pain duration (10.7 years) and gender (female: 91.0%). Prior/current occupation type differed significantly between groups: disabled patients were more likely previously employed in manual professions or service industry, with employed patients occupied in education/clerical/health fields ($P=0.001$). Significant between-group differences were observed for management strategies: disabled patients used a greater count of medications ($P=0.001$), more opioids ($P=0.001$), antidepressants ($P=0.032$), tranquilizers ($P<0.001$), and cannabinoids ($P=0.053$), and participated less in exercise activity ($P=0.009$). Those disabled demonstrated more allodynia ($P=0.027$) and pain related behaviour ($P=0.002$). Except for depression and anxiety, all other parameters were significantly higher in the disabled group: pain VAS ($P<0.001$), PGA ($P<0.001$), FIQ ($P<0.001$), HAQ ($P<0.001$), MPQ ($P<.0001$), PCS ($P=0.005$) and PDI ($P<0.001$). All associations remained significant except for HAQ, MPQ, and PCS when adjusted for age and education.

Conclusion: The results of this analysis suggest that a significant proportion of FM patients are unemployed due to disability. The subjective report of symptom severity for those disabled may be explained by true disease severity, negative impact of medications, or patient perception of illness and suffering. Alternately, justification for ongoing disablement may be the driver for augmentation of subjective illness report. As all measurements in FM are subjective, disabled patients may be an important confounder for understanding outcome in FM.

Correlation Of Findings In Clinical and High Resolution Ultrasonography Examinations Of The Painful Shoulder. Raphael Micheroli[1], Diego Kyburz[2], Adrian Ciurea[2], Beat Dubs[3], Martin Toniolo[2], Samuel Bisig[4] and Giorgio Tamborrini[5]. [1]University of Zurich, Zurich, Switzerland, [2]University Hospital of Zurich, Zurich, Switzerland, [3]Sonography Institute Bethanien Zurich, Zurich, Switzerland, [4]Swiss Federal Institute of Technology Zurich, Zurich, Switzerland, [5]Bethesda Hospital Basel, Basel, Switzerland.

Background/Purpose: High resolution ultrasonography (HRUS) is a non-painful and non-invasive imaging technique which is increasingly used for evaluating patients with musculoskeletal disorders. In particular, HRUS is useful for an assessment of shoulder pain causes, as clinical examination often does not allow an exact diagnosis. The aim of this study was to establish the role of HRUS in the diagnosis of shoulder problems as well as to form an evidence base for clinical interpretation of most common clinical tests of the painful shoulder.

Methods: Non-interventional observational study of 100 adult patients suffering from unilateral shoulder pain. Exclusion criteria were shoulder fractures, prior shoulder joint surgery and prior shoulder injections (local anesthetics or steroids) in the past month. The HRUS examination was performed according to the guidelines of the Swiss Society of Ultrasound in Medicine (SGUM, musculoskeletal section). The clinical tests were: bursitis sign, Jobe's test, painful arc, drop arm sign, Hawkins and Kennedy impingement tests, lift off test, belly press test, m. infraspinatus test, acromioclavicular (AC) joint tenderness, Abbott-Saunders test, palm up test, Yergason test and Hueter sign. The physicians performing clinical and HRUS examination were blinded to each other. In the statistical analysis HRUS findings were used as the gold standard.

Results: In the HRUS examination pathologies of the bursa subacromialis were found in 87 %, of the m. supraspinatus tendon in 67 %, of the AC joint in 24 %, of the long biceps tendon in 20 %, of the m. subscapularis tendon in 11 %, of the m. infraspinatus tendon in 10 % and of the m. pectoralis major tendon in 1 % of all cases.

In order to detect pathology of the m. supraspinatus tendon, the Hawkins Kennedy impingement tests showed the highest sensitivity (0.86) whereas the Jobe's test showed the highest specificity (0.55). To identify m. subscapularis tendon pathology the lift off test showed a

sensitivity of 1, whereas the belly press test showed the higher specificity (0.72) as the lift off test (0.55). The m. infraspinatus test showed a high sensitivity (0.90) and specificity (0.74). All three AC tests (painful arc II[a], AC joint tenderness[b], cross body action[c]) showed low sensitivities ([a]0.25, [b]0.38, [c]0.38) but high specificities ([a]0.96, [b]0.99, [c]0.96). To evaluate the long biceps tendon the palm up test showed the highest sensitivity (0.47), the Yergason test showed the highest specificity (0.88).

Conclusion: Knowledge of sensitivity and specificity of various clinical tests is important for the interpretation of clinical examination test results and the identification of cases in which further imaging procedures are necessary to make a distinct diagnosis. Thus, clinical test results should be confirmed by HRUS examination, which allows a reliable differentiation of the various pathologies leading to a painful shoulder.

126

Subgrouping Of Rheumatoid Arthritis Patients Based On Pain, Fatigue, Inflammation and Psychosocial Factors. Yvonne C. Lee[1], Michelle A. Frits[1], Christine K. Iannaccone[1], Michael E. Weinblatt[1], Nancy A. Shadick[1], David A. Williams[2] and Jing Cui[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Univ of MI Hlth System-Lobby M, Ann Arbor, MI.

Background/Purpose: Among rheumatoid arthritis (RA) patients, pain may be due to peripheral inflammation or other causes, such as central pain mechanisms. The objective was to use self-report measures and physical examination to identify clusters of RA patients who may have diverse causes of pain and different prognoses and treatment options.

Methods: Data were analyzed from 169 RA patients in a prospective observational study who had any pain > 0/10 and completed questionnaires about pain, fatigue, depression, anxiety, catastrophizing and sleep problems. Systemic inflammation was assessed using serum C-reactive protein (CRP) levels. A hierarchical agglomerative clustering procedure with Ward's method was used to obtain subgroups. Multivariate analysis of variance was used to determine the contribution of each variable in a cluster. General linear regression models were used to examine differences in clinical characteristics across subgroups. Discriminant analyses were performed to determine coefficients for linear combinations of variables that assigned cluster membership to individual cases.

Results: Cluster analyses identified three groups of RA patients (**Figure**). Cluster 1 consisted of the largest number of patients (N = 89, 52.7%) and was characterized by the lowest swollen joint counts and the lowest levels of fatigue and depression (**Table**). Cluster 2 consisted of 57 participants (33.7%), characterized by low swollen joint counts and high levels of fatigue, catastrophizing and sleep problems, indicative of a chronic widespread pain syndrome. Cluster 3 consisted of 23 participants (13.6%), characterized by high swollen joint counts and moderate levels of fatigue, catastrophizing and sleep problems, consistent with active inflammatory disease.

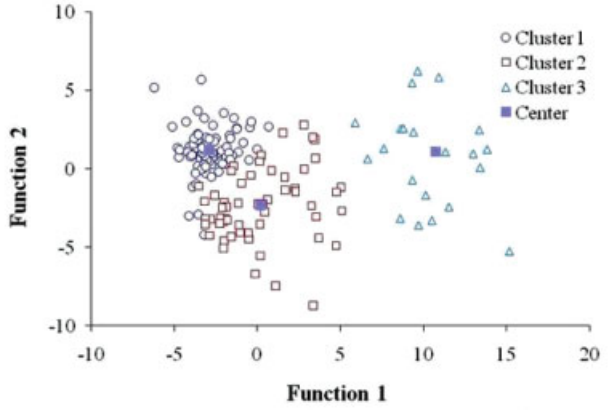

Figure 1. Cluster analyses identified three groups, which were distinguished by two discriminant functions, accounting for 88.3% and 11.7% of the variance (P <0.0001).

Table. Clinical characteristics used to define the clusters. Values are expressed as medians and interquartile ranges.[a]

Characteristic	Cluster 1 (N = 89)	Cluster 2 (N = 57)	Cluster 3 (N = 23)	*P*-value[b]
	0.0 (0.0–1.0)	2.0 (0.0–4.0)[c]	12.0 (10.0–14.0)[d,e]	<0.0001
BPI pain intensity	3.0 (2.0–4.0)	3.0 (2.0–5.0)[c]	3.0 (2.0–5.0)	0.03
Fatigue	20.0 (10.0–30.0)	70.0 (50.0–80.0)[c]	60.0 (25.0–80.0)[d]	<0.0001
Sleep problems	27.2 (16.1–41.1)	38.3 (27.2–46.7)[c]	35.6 (17.5–47.8)	0.009
HADS Depression	3.0 (1.0–5.0)	4.0 (1.0–7.0)[c]	5.0 (2.0–8.0)[d]	0.004
Illness burden[f]	1.0 (0.0–3.0)	2.0 (1.0–3.0)[c]	1.0 (0.0–2.0)[e]	0.06
Catastrophizing	6.0 (1.0–12.0)	12.0 (5.0–21.0)[c]	9.0 (3.0–18.0)	<0.0001

[a]BPI = Brief Pain Inventory, HADS = Hospital Anxiety and Depression Scale.
[b]*P*-value that any one cluster is different from the others.
[c]Cluster 2 is significantly different from cluster 1 at $P \leq 0.05$.
[d]Cluster 3 is significantly different from cluster 1 at $P \leq 0.05$.
[e]Clusters 3 is significantly different from cluster 2 at $P \leq 0.05$.
[f]Illness burden was quantified using a count of patient-reported symptoms of headaches, migraines, poor concentration, poor memory and poor word-finding.

Conclusion: Although most patients had low levels of inflammation, pain and fatigue, 47.3% continued to report moderate to high pain and fatigue. These results indicate that: 1) chronic widespread pain syndromes are common among patients with established RA; 2) active inflammatory disease does not explain all problems with pain, fatigue and psychosocial problems; and 3) chronic widespread pain syndromes are associated with significantly diminished quality of life (assessed by depression, fatigue and sleep problems), even compared to patients with active inflammatory disease.

127

Clinical Application Of Pain Diagrams In Fibromyalgia. Amanda Steele[1], Dana Dailey[2] and Kathleen Sluka[2]. [1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]University of Iowa, Iowa City, IA.

Background/Purpose: Fibromyalgia is a condition characterized by chronic widespread pain. Accurately assessing the subjective experience of pain using objective measures remains a challenging clinical problem, particularly among patients with Fibromyalgia. Commonly utilized self-report pain measures are often time consuming (completing and scoring), potentially decreasing their clinical utility. The current study sought to establish a reliable scoring method of pain diagrams completed by patients with primary fibromyalgia.

Methods: Prior to data collection, IRB approval was received and written consent was obtained. 43 people with fibromyalgia (42 female, 1 male), aged 25–76 years, completed this study (duration of fibromyalgia 7.55 years; range 0.25 to 20 years). Subjects filled out the Fibromyalgia Impact Questionnaire (FIQ), McGill Pain Questionnaire (MPQ) and a visual analog scale (0–10) for pain at rest and movement (walking). Patients were instructed to mark a body diagram showing areas of pain. To assess inter-rater reliability, a scoring protocol, which included applying a transparent overlay to each patient's diagram, was designed and tested. A score of 0–46 was assigned to each diagram, based on the number of areas marked. Ten randomly selected diagrams were scored independently by two raters three times and inter-rater reliability assessed (intraclass correlation, ICC). The number of body areas was correlated with pain, FIQ, and MPQ scores (Pearson's, *p=0.05, **p=0.01).

Results: Means ± SEM: Average pain at rest was 4.39 ± 0.39, pain with movement was 5.23 ± 0.39, FIQ was 58.17 ± 2.24 and MPQ was 44.93 ± 2.5. Scores on the body diagram (n=43) averaged 16.55 ± 1.3 (95% CI 13.92 to 19.18) with the most common areas as neck (91%), shoulders (81%), and low back (63%). Inter-rater reliability for the body diagram scoring was excellent (ICC=0.952; 95% CI 0.912 to 0.974). Higher scores on the body diagram significantly correlated with higher scores on MPQ (R^2= 0.44**), pain at rest (R^2=0.324*), pain with movement (R^2=0.380*) but not FIQ (R^2=0.298).

Conclusion: Preliminary results indicate this protocol may be a reliable method of scoring pain diagrams among patients with Fibromyalgia and that higher scores significantly correlated with worse pain but not the impact of pain on function and quality of life (movement-pain,

FIQ). These diagrams provide a quick, simple and clinically applicable self-report measure that can be completed and scored in a very brief period of time. Thus, quantitative analysis of the body diagram may be useful to gain an understanding of the severity of pain but not the global impact of pain as measured by the FIQ.

128

Frequency Of Axial Spondyloarthropathy Among Patients Suffering From Fibromyalgia A Magnetic Resonance Immaging Study With Application Of The Assessment Of Spondylo-Arthritis International Society Classification Criteria. Jacob N. Ablin[1], Iris Eshed[2], Valerie Aloush[1], Irena Wigler[3], Dan Caspi[1], Maria Likhter[1], Mark Berman[1], Yonatan Wolman[1], Daphna Paran[4], Marina Anouk[5] and Ori Elkayam[3]. [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Sheba Medical Center, Tel Hashomer, Israel, [3]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [4]Tel Aviv Sourasky Medical Ctr, Tel-Aviv university, Tel Aviv, Israel, [5]Tel Aviv Sourasky Medical Ctr, Tel-Aviv University, Tel Aviv, Israel.

Background/Purpose: Fibromyalgia Syndrome (FMS), considered the result of increased processing of pain by the central nervous system, is a non-inflammatory condition characterized by chronic, widespread musculoskeletal pain and tenderness.

Axial spondyloarthritis (SpA) is the hallmark of Ankylosing Spondylitis (AS), an inflammatory joint disease primarily involving the sacroiliac joints and axial spine. Although FMS and axial SpA differ vastly in their pathogenesis, a considerable clinical overlap may exist between these conditions. Chronic nocturnal back pain and disturbed sleep may accompany either condition. We have previously described an increased prevalence of (secondary) FMS among female AS patients. The Assessment of Spondylo-Arthritis international Society (ASAS) has published updated classification criteria for axial SpA. These criteria are based on the evaluation of patients suffering from chronic back pain with an age of onset of less than 45.

Objective: To evaluate the prevalence of axial SpA among FMS patients, utilizing the 2010 ASAS criteria (1).

Methods: Patients suffering from FMS (ACR 1990 classification criteria) were recruited consecutively from a specialized FMS clinic. Patients were interviewed regarding the presence of SpA features, as defined by the ASAS group (Inflammatory back pain, arthritis, enthesitis, uveitis, dactylitis, psoriasis, Crohn's / colitis, good response to NSAIDSs, family history of SpA) and underwent HLA-B27 testing and CRP measurement. MRI examinations of the sacro-iliac joints were performed on a 1.5 T MRI unit using semicoronal T1-weighted, STIR and FSPGR pre- and post-contrast injection sequences. FMS severity was assessed by the FIQ and SF-36 questionnaires and physical examination of the tender points using a dolorimeter. SpA symptom severity was assessed by the BASDAI questionnaire

Results: 61unselected patients were recruited and MRI results were available for 56.

Table 1. Summarizes MRI findings, HLA-B27 results and ASAS criteria positivity among FMS patients (N=56):

Sacroiliitis (2)	Erosions	Sub-chondral sclerosis	Fatty replacement	HLA-B27	ASAS criteria positive
4 (7.1%)	11 (19.6%)	12 (21.4%)	4 (7.1%)	3 (5.4%)	4 (7.1%)

Sacroiliitis, based on ASAS definition (2), was found among 4 patients, 3 of which fulfilled ASAS SpA criteria. One additional patient fulfilled SpA criteria based on HLA-B27 positivity and additional SpA features.

Conclusion: Imaging changes suggestive of inflammatory SpA were common among patients presenting with a clinical diagnosis of FMS. Definite sacroiliitis and ASAS criteria SpA positivity were diagnosed among 7.1% of patients and additional changes typical of SpA were frequent. These findings suggest that FMS may mask an underlying SpA, a diagnosis with important therapeutic implications. Thus, physicians involved in the management of FMS should remain vigilant to the possibility of underlying inflammatory disorders and actively search for such co-morbidities.

Identifying Predictors Of A Fibromyalgia Diagnosis: A Retrospective Electronic Medical Record Analysis. Elizabeth T. Masters[1], Jack Mardekian[1], Andrew Clair[1] and Stuart L. Silverman[2]. [1]Pfizer Inc, New York, NY, [2]Cedars-Sinai Medical Center, UCLA Center of Excellence, Beverly Hills, CA.

Background/Purpose: Fibromyalgia (FM) is a chronic pain condition characterized by a constellation of symptoms and comorbidities. Consequently, FM diagnosis can be challenging and it often goes undetected. This study used electronic medical record (EMR) data to identify factors associated with FM that may facilitate earlier identification and diagnosis.

Methods: Subjects ≥18 years old who had ≥1 diagnosis code for common pain conditions were extracted from the Humedica de-identified EMR database, which has broad geographic representation and includes information on demographics, diagnoses, inpatient/outpatient encounters, medications, procedures, lab results, and select data from physicians' notes. Records are linked using a unique patient identifier. Subjects with continuous enrollment in an integrated healthcare delivery system in 2010 and a first FM diagnosis in 2011 (cases) were compared with subjects without an FM diagnosis during 2011 (controls). Patients with an FM diagnosis prior to 2011 were excluded. FM diagnosis was based on ICD-9 code 729.1 (myalgia and myositis, unspecified). Sequential stepwise logistic regression was performed with FM diagnosis as the response variable, and demographic, clinical, and healthcare resource use as predictor variables. Variables with significant associations ($P \leq .05$) were retained in the model and expressed as odds ratios (OR) with their 95% confidence intervals (95% CI).

Results: Subjects were 2,823 individuals with an FM diagnosis and 210,495 without an FM diagnosis in 2011. Although mean (SD) age was similar between groups, 51.4 (15.3) years for cases and 51.4 (16.4) years for controls, the FM population had more females (72.3% vs 60.4%; $P < .0001$), and significant differences between groups were observed for other baseline characteristics including race and healthcare resource use (higher in cases; $P < .001$), and the presence of specific comorbidities (higher in cases; $P \leq .05$). The model identified 17 variables significantly associated with an FM diagnosis. The first variable (i.e., the variable with the smallest p-value when included as a predictor by itself) that made it into the model was the number of pain medication prescriptions (OR 1.03 (95% CI 1.02, 1.04), followed by the number of musculoskeletal pain conditions (OR 1.19 (95% CI 1.16, 1.23). Several clinical variables, including the presence of gastrointestinal and sleep disorders were also predictive: OR 1.38 (95% CI 1.26, 1.51) and 1.33 (95% CI 1.15, 1.55), respectively. Other healthcare resource utilization variables that entered into the model included number of outpatient visits and hospitalizations.

Conclusion: The model identified several demographic and clinical variables as significant predictors of an FM diagnosis. These results suggest analysis of EMR data can help identify variables associated with FM in a real world setting, and may inform earlier identification of FM patients.

Mindfulness Is Associated With Psychological Symptoms, Self-Efficacy and Quality Of Life Among Patients With Fibromyalgia. Nani Morgan[1], Lucas Morgan[2], Lori Lyn Price[3] and Chenchen Wang[4]. [1]University of Hawaii, Honolulu, HI, [2]University of Massachusetts, Honolulu, HI, [3]Tufts University, Boston, MA, [4]Tufts Medical Center, Boston, MA.

Background/Purpose: Mindfulness is the ability to observe, describe, or be aware of present moment experiences without judgment or reactivity. Preliminary evidence suggests that interventions aimed at increasing mindfulness may be effective in reducing chronic pain as well as symptoms of anxiety and depression commonly experienced among patients with fibromyalgia. Our objective was to evaluate whether mindfulness is associated with the overall impact of fibromyalgia on physical and psychological impairment, sleep quality, self-efficacy, and quality of life.

Methods: We conducted a secondary analysis of baseline data from our randomized trial comparing Tai Chi and aerobic exercise among patients with fibromyalgia as defined by the American College of Rheumatology criteria. Patients enrolled in the trial completed the Five Facet Mindfulness Questionnaire (FFMQ), a 39-item, self-report questionnaire, in which higher total

scores indicating higher levels of mindfulness in daily life. Patients also completed well-validated measures commonly used to assess patients with fibromyalgia (Revised Fibromyalgia Impact Questionnaire [FIQR], Perceived Stress Scale [PSS], Beck Depression Inventory Second Edition [BDI-II], Pittsburgh Sleep Quality Index [PSQI], Arthritis Self-Efficacy Scale Short Version [ASES-8] and Medical Outcomes Short Form-36 [SF-36]). We calculated Pearson's correlation coefficients to evaluate hypothesized associations between mindfulness and measures of fibromyalgia impact on physical and psychological impairment, sleep quality, self-efficacy, and quality of life.

Results: Our analysis included data from 81 patients with an average age of 52.04 (SD=11.92); 92% were female. All correlations were in the hypothesized direction. Patients reporting higher levels of mindfulness tended to report fewer symptoms of anxiety and depression as measured by the PSS ($r=-0.55$, $p<0.0001$) and BDI-II ($r=-0.49$, $p<0.0001$), respectively. They also tended to report higher self-efficacy as well as higher quality of life as measured by the ASES-8 ($r=0.26$, $p=0.02$) and SF-36 Mental Component Summary ($r=0.51$, $p<0.001$), respectively. There were no significant correlations between mindfulness and the FIQR, PSQI, or SF-36 Physical Component Summary.

Conclusion: Our results suggest that mindfulness is associated with psychological symptoms, self-efficacy, and quality of life among patients with fibromyalgia. Mindfulness may help to change patients' relationship to their symptoms and functional limitations through promotion of awareness and acceptance. Longitudinal studies are underway to evaluate whether changes in mindfulness are associated with changes in psychological symptoms, self-efficacy, and quality of life in patients with fibromyalgia and other chronic pain conditions.

Prevalence and Antecedents Of Fibromyalgia In Elderly Women. Brian T. Walitt[1] and Frederick Wolfe[2]. [1]Washington Hospital Center, Washington, DC, [2]National Data Bank for Rheumatic Diseases, Wichita, KS.

Background/Purpose: Although epidemiological studies demonstrate that fibromyalgia (FM) prevalence increases with age, there have been no large-scale studies of FM in the elderly. In the clinic, elderly subjects usually receive treatment for common problems like diabetes, hypertension, back pain syndromes and other chronic illnesses; and the presence of FM is rarely recognized. In 2013 we performed a pilot study to estimate FM prevalence in the elderly by studying 882 women participants of the Women's Health Initiative (WHI). Because the WHI study is longitudinal, we used prior data to investigate factors that predicted subsequent FM development.

Methods: In 2013, we administered the 2010 modified American College of Rheumatology (ACR) survey criteria questionnaire to 882 randomly selected WHI participants. We utilized a wide range of questionnaire data that had been collected at WHI enrollment 16 years previously, including a range of questions from the SF-36, CESD depression scale, symptoms scales, and other questionnaires. We used logistic regression and baseline variables to predict current FM.

Results: In 2013, the age of participants was 78.4 (SD 6.0) and they had been followed by the WHI for 16.4 years. The (2013) prevalence of fibromyalgia was 6.6% (95% CI 4.9–8.2). The average questionnaire scores in the population were: widespread pain index (WPI, 2.8 (2.8)), the symptom severity scale (SS, 2.9 (2.3), and the polysymptomatic distress score (PSD - sum of WPI and SS) 5.7 (4.3). To identify predictors of FM at initiation, we first excluded possible FM cases (15%) at study onset from further analysis if they reported moderate or severe body pain during the past 4 weeks. Of the remaining 746 subjects, the 2013 FM prevalence was 4.7% (3.1–6.2). In univariate analyses the following variables predicted FM 16 years later: social function, physical function, body pain, pain interference, general health, energy/fatigue, sadness in last two weeks, upset stomach, depression, headaches, low back pain, neck pain, diarrhea, aches and pain, constipation, and tiredness. In multivariate analyses, the following variables were included after backward stepwise regression filtering: constipation, pain severity, general health, energy/fatigue, neck pain, pain interference, and aches and pains. The area under the ROC for the final logistic model was 0.85.

Conclusion: Fibromyalgia (by criteria) was common in WHI participants as they approached 80 years of age. FM appeared to develop primarily in those baseline pain, aching, fatigue, impaired general health, and GI symptoms. Psychological factors did not seem to be important predictors.

Table 1. Multivariable baseline predictors of fibromyalgia

Variable	Odds Ratio	P-Value	95% CI
Constipation (Y/N)	2.92	0.005	1.37, 6.25
Neck pain (Y/N)	3.57	0.002	1.59, 8.04
Pain interference (Y/N)	3.09	0.088	0.85, 11.30
SF-36 General Health	0.97	0.052	0.95, 1.00
SF-36 Energy/fatigue	0.98	0.019	0.96 1.00
SF-36 pain	1.05	0.042	1.00, 1.00
Aches and pains			
Aches and Pains-Mild	3.44	0.120	0.72, 16.39
Aches and Pains-Moderate or >	13.22	0.004	2.24, 77.99

Relation Of Age With Symptom Severity and Quality Of Life In Patients With Fibromyalgia. Juan Jiao, Ann Vincent, Connie A. Luedtke, Stephen Cha and Terry H. Oh. Mayo Clinic, Rochester, MN.

Background/Purpose: The relationship of age and fibromyalgia symptom severity and quality of life (QOL) is still debated. Reports range from no differences between patients younger and older than 60 years, to less symptom burden in older patients, and worse symptoms as well as QOL in older patients with fibromyalgia. The goals of this present study were to examine the relationship of age with symptom severity and QOL in patients with fibromyalgia and to compare QOL in physical and mental health of our female patients with the female general population.

Methods: Nine hundred seventy eight patients with fibromyalgia who presented to a tertiary care fibromyalgia clinic were divided into 3 age groups: young (≤ 39 years), middle-aged (40–59 years) and older (≥60 years). They completed the Fibromyalgia Impact Questionnaire (FIQ) and the Short Form-36 Health Status Questionnaire (SF-36) at the time of their evaluation. A standardization of the SF-36 physical and mental component summaries of our female patients was made in accordance with the normative data from the US female general population. One-way ANOVA and Post Hoc pairwise *t*-tests analyses were performed to detect differences across age-groups.

Results: The mean age of 978 patients was 48.6 years (range, 19 to 87 years). Our patients age distribution in young, middle-aged and older were 233 (23.8%), 560 (57.3%), and 185 (18.9%), respectively. The young and middle-aged patients were more likely to be unmarried, employed, and current smokers, and to have a higher education level and more abuse history, a lower BMI, and a shorter duration of symptoms compared with the older patients. Pairwise comparison within 3 age-groups showed the young and middle-aged patients having worse fibromyalgia symptoms in the FIQ total score and all subscales except for the anxiety subscale when compared to the older patients ($Ps \leq 0.014$). Similarly, those young and middle-aged patients had worse QOL in the SF-36 mental component summary, as well as SF-36 general health perceptions, vitality, social functioning, and mental health index compared to the older patients ($Ps < 0.001$). When QOL of our female patients was compared to the U.S. female general population of similar age, all age groups had lower QOL in physical as well as mental health with more prominent reduction on physical health, particularly in the young patients.

Conclusion: Our study illustrates that symptom severity and QOL differs across age-groups in patients with fibromyalgia. Young and middle-aged patients had poorer QOL and worse fibromyalgia symptoms compared to older patients. When the QOL of our female patients was compared with the US female general population of similar age, all age-groups had lower QOL in physical as well as mental health, particularly on physical health in the young patients. Further studies are needed to demonstrate the physiologic and pathological mechanisms underneath this phenomenon in patients with fibromyalgia according to age.

Cross-Sectional Neurocognitive Data Do Not Support a Transition From Fibrofog To Alzheimer's Disease In Fibromyalgia Patients. Robert S. Katz[1] and Frank Leavitt[2]. [1]Rush Medical College, Chicago, IL, [2]Rush University Medical Center, Chicago, IL.

Background/Purpose: The issue of progressive decline in cognitive abilities is a source of concern to many patients with fibromyalgia. The fear

of progressing from fibrofog in middle age to Alzheimer's or other forms of dementia is central to the worries shared by many. To determine if cognitive impairment progresses over time in fibromyalgia, a cross sectional study of cognitive functioning was conducted with a battery of neuro-cognitive tests known to be sensitive to cognitive change.

Methods: In a cross-sectional study, cognitive disparities on 14 neuro-cognitive measures were evaluated in two cohorts of fibromyalgia subjects who met the new criteria for fibromyalgia. The first cohort contained 69 subjects with a short duration of cognitive problems (12 months or less). The second cohort contained 39 subjects with a long duration of cognitive problems (≥ 84 months or greater).

Results: The two groups were similar in terms of mean (±SE) education (15.0±2.2 vs. 14.9±2.5), Vocabulary Scale score (11.2 ± 2.3 vs. 11.9 ± 2.8), and depression (17.5±9.4 vs. 17.8±9.3). The Long Duration Cohort was significantly older (45.6 ± 10.8 vs. 52.3± 9.1 years; $p<0.001$). Cognitive data of the two cohorts are displayed in Table 1. No significant differences were found between the two duration derived cohorts on 13 of the 14 cognitive measures. Performance declined with the duration of cognitive problems on Trails A, a measure of spatial scanning and cognitive sequencing. However, the skills of Trails A are incorporated inTrails B, where performance of the two groups was essentially equivalent. Measures of episodic memory and processing speed, markers of preclinical Alzheimer's disease, are in the normal range for both cohorts

Conclusion: Fibromyalgia patients' fear of developing Alzheimer's or other forms of dementia was not borne out by the data. Duration of cognitive problems was not a determiner of cognitive severity. People with a duration of 84 months or greater were not significantly more cognitively disabled than those with a duration of 12 months or less. The data do not support later transitions to dementia. The fact that individuals suffering cognitive dysfunction from 7 to 26 years did not exhibit a broad based deficit relative to those suffering cognitive dysfunction for a duration of a year of less should allay the worries of many with fibromyalgia who fear that fibrofog in the middle years is the start of a dementing process.

Lower Socioeconomic Status Associates With Increased Symptom Severity and Functional Impairment In Fibromyalgia. Mary-Ann Fitzcharles[1], Emmanouil Rampakakis[2], Peter A. Ste-Marie[1], John S. Sampalis[2] and Yoram Shir[1]. [1]McGill University Health Centre, Montreal, QC, [2]JSS Medical Research, St-Laurent, QC.

Background/Purpose: Persons with lower socioeconomic status (SES) have poorer health status for many medical conditions. Reasons for this finding are multiple, but access to care, health related behaviours and adherence likely play a role. As fibromyalgia (FM) is a clinical construct with psychosocial implications, it is possible that SES may influence symptom expression and severity. We have examined the effects of SES (measured as proxy by level of education) for disease severity in a cohort of FM patients.

Methods: In a prospective cohort study of patients with FM followed at a tertiary care multidisciplinary clinic, patients were stratified according to education level: high school or less (Group 1; N=99), college (Group 2; N=84), and university (Group 3; N=63). Demographic and disease severity measures included pain visual analog scale (VAS), patient global assessment disease activity (PGA), Fibromyalgia Impact Questionnaire (FIQ), Health Assessment Questionnaire (HAQ), McGill Pain Questionnaire (MPQ), Pain Disability Index (PDI), Pain Catastrophizing Scale (PCS), and anxiety and depression by Arthritis Impact Measurement Scale (AIMS). Between-group differences in discrete and continuous variables were assessed for statistical significance with the Chi-Square test and one-way analysis of variance, respectively. Linear regression was used to assess between-group differences in disease activity while adjusting for potential confounders.

Results: The cohort comprised 246 patients with a mean ± SD age of 47.8 ± 10.4 years, disease duration of 10.8 ± 9.8 years, and 91.1% female. Baseline values were: pain VAS 6.5 ± 2.3, PGA 6.7 ± 2.1, FIQ 67 ± 17, HAQ 1.19 ± .59, MPQ 41 ± 15, PDI 38 ± 14, PCS 29 ± 12, AIMS anxiety 6.3 ± 1.8, AIMS depression 4.9 ± 1.8, with a mean medication count of 2.6 ± 1.3 per patient. There were no significant differences between groups for the following parameters: disease duration, marital status, cigarette smoking, previous eating disorder or alcohol abuse, current medication categories, and total number of medications used per patient. Higher education was associated with greater use of alternative medicines ($P<0.001$) and chiropractic, massage or osteopathic treatments ($P=0.021$). Lower education level was significantly associated with older age ($P=0.039$), previous drug abuse ($P=0.016$), current unemployment ($P<0.001$) and higher score in the following measures of symptom severity: PGA ($P=0.019$), FIQ ($P=0.002$), HAQ ($P=0.001$), MPQ ($P=0.026$), PDI ($P=0.031$), and PCS ($P=0.015$). These associations remained significant even upon adjusting for age and gender differences. No significant differences in pain severity, anxiety, and depression were observed between groups.

Conclusion: Similar to other health conditions, FM patients with lower SES reported greater symptom severity, functional impairment and unemployment, but not mood disorder. Although FM spans all socioeconomic groups, societal factors, rather than specific disease characteristics or mental status, appear to play an important role in patients' perception of illness.

Evaluation Of The Quality Of Life and Sleep In Patients With Benign Joint Hypermobility Syndrome. Ilknur Albayrak[1], Halim Yilmaz[1], Ekrem Akkurt[1], Ali Salli[2] and Gulten Karaca[3]. [1]MD, Konya, Turkey, [2]MD, KONYA, Turkey, [3]Associate Professor, Konya, Turkey.

Background/Purpose: Traction injuries at tendon or ligament attachment sites, joint instability, low back, back and neck pain can be seen in patients with benign joint hypermobility syndrome (BJHS). The most important complaint of such patients is pain. Due to pain, impairment in the quality of sleep and life and fatigue resulting in effects on psychological condition. In this study, we aimed to evaluate pain, fatigue, quality of sleep, depression level and quality of life in patients with BJHS and compare these parameters with those of healthy controls.

Methods: 26 patients who had diagnosed with BJHS according to Brighton diagnostic criteria and 40 healthy controls were included in the study. In all patients and healthy controls, pain severity evaluation was performed using visual analog scale (VAS), fatigue severity was performed using Checklist Individual Strength Scale (CIS), quality of sleep was performed using Pittsburg Sleep Quality Index (PSQI), depression level was evaluated using Beck Depression Scale (BDS), and quality of life was evaluated using Short Form-36 (SF-36).

Results: Mean age was 31.4±7.6 years in the patient group, and 31.3±6.9 years in the control group. There were no statistically significant differences between the two groups with respect to age, gender, body mass index and marital status ($p>0.05$). In the patient group, VAS score during movement was 6.6±0.9. Total CIS scores were 4.3±1.09 in the patient group and 3.2±1.2 in the control group ($p=0.001$), global PSQI scores were 7.8±3.1 in the patient group and 4.9±2.9 in the control group ($p<0.001$), BDS scores were 17.6±8.8 in the patient group and 6.8±5.8 in the control group ($p<0.001$), SF-36 physical component scale scores were 52.7±14.6 in the patient group and 56.09±9.07 in the control group ($p>0.05$), and SF-36 mental component scale scores were 42.01±15.04 in the patient group and 54.3±10 in the control group ($p<0.001$).

Conclusion: This study shows that the levels of pain, fatigue and depression are increased and the quality of sleep and quality of life are adversely affected in patients with BJHS. Therefore, patients with BJHS should be evaluated in terms of pain, fatigue, depression, quality of sleep and quality of life during their diagnostic procedures and follow-up, and multi-faceted treatment programs should be planned.

136

The Detection Of Primary Hyperparathyroidism In Patients Diagnosed With Fibromyalgia. Michael Tsoukas, Peter A. Ste-Marie, Yoram Shir, Mary-Ann Fitzcharles and Elliot Mitmaker. McGill University Health Centre, Montreal, QC.

Background/Purpose: Some illnesses, such as hypothyroidism or small fiber neuropathy, may present similarly to fibromyalgia (FM), or may in turn lead to an augmented polysymptomatic distress, mimicking FM, by concomitant illness. Primary hyperparathyroidism (HPT), diagnosed biochemically by the measurement of parathyroid hormone in the context of serum calcium and phosphate levels, has a reported general population prevalence in the order of 0.1%. Its symptoms of musculoskeletal pain, fatigue, mood disorders, and sleep disturbances closely mimic those of FM. Given the commonality of

symptoms and possible underdiagnosis of HPT, we have examined the prevalence of HPT in a pilot study of FM patients.

Methods: A retrospective chart review of a convenience sample of FM patients attending a tertiary care multidisciplinary pain center was undertaken to assess parathyroid and calcium status. Consecutive patients attending the clinic between December 2012 and March 2013, had a primary diagnosis of FM as defined by clinical criteria, and had routine biochemistry screening during the preceding year. Routine blood tests included measurements for bone health, vitamin D, parathyroid hormone, calcium and phosphate levels. Hyperparathyroidism was diagnosed by the following biochemical parameters: parathyroid hormone (PTH) level > 9.3 pmol/L (93 pg/mL) with inappropriately non-suppressed calcium (true HPT or normocalcemic HPT), and/or an elevated serum ionized calcium > 1.32 mmol/L (5.3 mg/dL) with inappropriately high PTH levels (normohormonal HPT).

Results: Thirty-eight patients, 35 female, with a mean ± standard deviation of age 51.6 ±10.6 years, and similar disease duration comprised the cohort. Based on their constellation of biochemical indices, 4 patients of the cohort, representing 10.5% of subjects studied, were diagnosed with hyperparathyroidism.

Conclusion: In this small exploratory study, we have identified that unsuspected hyperparathyroidism in diagnosed FM patients has a prevalence of greater than 10%, as compared to 0.1% in the general population, representing a 100-fold difference. As no previous study has examined HPT in FM patients, these preliminary findings call for a more thorough study of parathyroid hormonal status in FM.

A Population-Based Survey and Physician Assessment Of The Characteristics and Prevalence Of Fibromyalgia. Edgar H. Adams[1], Shoshana Daniel[2], Arthi B. Chandran[3], Heather McElroy[4], Caroline Schaefer[1], Rachael Mann[5], Gergana Zlateva[3], Joseph C. Cappelleri[6], Elizabeth T. Masters[7], Annlouise R. Assaf[6], Michael McNett[8], Stuart L. Silverman[9], Roland Staud[10] and Philip Mease[11]. [1]Covance Market Access Services Inc., Gaithersburg, MD, [2]Covance Market Access Services Inc., Conshohocken, PA, [3]Pfizer Inc., New York, NY, [4]Covance Market Access Services, Sydney, Australia, [5]Covance Market Access Services Inc., San Diego, CA, [6]Pfizer Inc., Groton, CT, [7]Pfizer Inc, New York, NY, [8]Aurora Pain Program, Milwaukee, WI, [9]Cedars-Sinai Medical Center, UCLA Center of Excellence, Beverly Hills, CA, [10]University of Florida, Gainesville, FL, [11]Swedish Medical Center, Seattle, WA.

Background/Purpose: No large-scale, national study estimating fibromyalgia (FM) prevalence in the United States (US) has been conducted involving physician evaluation. The study objective was to provide contemporary data on characteristics and prevalence of FM among a subset of a nationally representative sample of US adults who completed an online subject screener and physician evaluation.

Methods: This multi-stage study included an online subject screener, a site visit for physician evaluation of FM, and an online subject questionnaire. Subjects were required to be at least 18 years old. Nationally representative participants were invited to complete the online screener, which included the London Fibromyalgia Epidemiology Study Screening Questionnaire (LFESSQ) to identify those with chronic widespread pain (bilateral, above/below waist for ≥1 week in the past 3 months) (CWP) and sociodemographic questions. Subjects who screened positive (CWP+) and a control group who screened negative (CWP-) were invited to schedule a site visit at one of 20 sites for physician evaluation of FM including a manual tender point exam until the established cap was met. CWP+ subjects who were diagnosed with FM based on the physician's evaluation were designated as having FM and included in prevalence estimates. Point prevalence estimates of FM were calculated using an adjusted approach for a two-phase study design, and sampling weights reflecting the underlying screened population were used to refine estimates. Following the site visit subjects completed the subject questionnaire including validated patient-reported outcome instruments to measure FM impact, symptoms, and pain.

Results: 8,382 (1,939 CWP+, 6,443 CWP-) subjects completed the screener. A total of 475 subjects attended a site visit: 350 of 1,331 CWP+ and 125 of 502 CWP- who consented to be scheduled for a site visit. The mean age (years) of the screened sample was 44.1, and there was representation across racial groups with 75.1% white and 12.3% black/African American. Females were intentionally over-sampled (79.3%) in order to generate precise estimates. Estimated prevalence (95% CI) of FM was 9.5% (7.2, 11.7) after adjusting for CWP status, gender, age, and race in the screened sample and weighted by 2010 census results for gender to the US population. Gender-specific prevalence estimates were 12.4% (11.0, 13.8) and 6.8% (4.1, 9.5) among adult women and men, respectively. The majority (55.0%) of subjects with physician-confirmed FM were obese per WHO criteria (BMI ≥30 kg/m^2). Subjects with physician-confirmed FM had a mean (SD) of 14.4 (3.3) tender points, and 90.1% had ≥11 tender points.

Conclusion: Based on the results of this nationally representative sample, the FM prevalence among US adults was higher than previously estimated by regional prevalence studies. The higher prevalence estimate may be a function of changing demographic and clinical characteristics of the US population, increased awareness of FM among patients and providers, study design and factors that influenced study participation. Clinical characteristics of subjects with FM in this study are consistent with the FM clinical profile in the literature.

Long Term Outcomes In Fibromyalgia. Lesley M. Arnold and Thomas Blom. University of Cincinnati College of Medicine, Cincinnati, OH.

Background/Purpose: There are few studies on the long-term prognosis of fibromyalgia. This study assessed the natural history of fibromyalgia in patients receiving usual medical care and identified predictors of outcome.

Methods: Over about 3 years, patients from the Fibromyalgia Treatment Program completed questionnaires for demographics, pain, mood, fatigue, sleep, health-related quality of life, coping mechanisms, stressful life events, and global assessments. Clinicians evaluated pain thresholds, psychiatric comorbidity, medical history, and global assessments. Patient Global Impression of Improvement (PGI) at endpoint was used to define two groups: 1) definitely improved (much or very much better); and 2) not markedly improved (minimally improved, no change, or worse). Spearman correlation coefficients were calculated for baseline variables versus PGI endpoint scores. A general linear model was used to examine the relationship between baseline variables and PGI score at endpoint.

Results: Sixty-nine patients completed the baseline assessment and had at least 1 follow-up visit. About half (n=34) of the patients definitely improved. There were no significant differences in any demographic variable between the two groups. Among those who reported global improvement, there was significant improvement in fatigue. Having baseline maladaptive coping (catastrophizing), lower pain thresholds, more negative fibromyalgia impact, and impairment in quality of life were correlated with poorer global assessment at endpoint. In the regression analysis, only baseline catastrophizing remained a significant predictor of endpoint PGI.

Conclusion: Fibromyalgia patients who improved were less likely to use catastrophizing at baseline. Interventions directed at improving pain coping skills should be a major component of fibromyalgia management.

Pain and Other Symptoms During The Childhood Of Fibromyalgia Patients. Robert S. Katz[1], Alexandra Small[2], Ben J. Small[3] and Susan Shott[4]. [1]Rush Medical College, Chicago, IL, [2]University of Illinois Medical School, Chicago, IL, [3]Rush University Medical School, Chicago, IL, [4]Rush University Medical Center, Chicago, IL.

Background/Purpose: We investigated the severity of pain and other symptoms during childhood, before age 12 and before age 18, that might be related to fibromyalgia (FMS).

Methods: 115 FMS patients and 63 control patients with other rheumatic diseases answered a rheumatology office questionnaire that included questions about symptoms experienced before the ages of 12 and 18. Patients were asked to rate each symptom as 1 = no problem, 2 = seldom, 3 = occasional,

4 = moderate, and 5 = severe problem. The chi-square test of association and Fisher's exact test were used to compare percentages, and the Mann-Whitney test was done to compare FMS and control patients with respect to age and symptom severity ratings. A 0.05 significance level was used and all tests were two-sided.

Results: The mean age was 48.1 ±12.3 years for FMS patients and 50.7 ±13.6 for rheumatic disease control patients ($p = 0.092$). 81.7% of the FMS patients and 61.9% of the control patients were women ($p = 0.004$). FMS patients had significantly worse severity ratings than did control patients for the following symptoms before age 18 (all with $p < 0.001$): "growing pains" (FMS 2.1± 1.5 vs. controls 1.4± 0.9), sleep problems (FMS 2.3± 1.4 vs. controls 1.3± 0.9), fatigue (FMS 2.2 ± 1.4 vs. controls 1.4 ±0.9), concentration problems (FMS 2.3 ±1.4 vs. controls 1.5± 0.8), memory problems (FMS 2.2±1.5 vs. controls 1.4 0.8), anxiety (FMS 2.1 ±1.4 vs. controls 1.4± 1.0), headaches (FMS 2.7 ±1.4 vs. controls 1.6 1.0), stomach aches (FMS 2.3 ±1.4 vs. controls 1.3 ±0.8), and depressed mood (FMS 2.1± 1.3 vs. controls 1.3± 0.7). Similar results were obtained for the same symptoms before age 12 (all with $p< 0.022$).

Conclusion: Pain, sleep problems, fatigue, concentration, and memory complaints were reported to be more common before the ages of 18 and before 12 in FMS subjects. Though recall bias could be a limitation of this study, the data suggest that fibromyalgia patients frequently have symptoms in childhood. Other studies have suggested that fibromyalgia may be related to a trait (fibromyalgianess). This study points out that the vulnerability to this illess might be manifested early in life.

Fibromyalgia and Pregnancy: Challenges Of The Savella® (Milnacipran) Pregnancy Registry. Damien Hirsch[1], Denise Leclair[1], Robert H. Palmer[1], Vikki Brown[2], Susan Sinclair Roberts[2] and Janice McLean[2]. [1]Forest Research Institute, Inc., Jersey City, NJ, [2]INC Research, LLC, Wilmington, NC.

Background/Purpose: During pregnancy, women with fibromyalgia (FM) often experience worsening of symptoms, which include widespread pain, fatigue, sleep disturbances, cognitive difficulties, and reduced daily functioning. Although the safety and efficacy of milnacipran in FM patients has been demonstrated in large clinical trials, these studies excluded pregnant women and milnacipran safety in this population is largely unknown. Milnacipran is a serotonin and norepinephrine reuptake inhibitor approved in the US for the management of FM. As with other drugs in this class, milnacipran is currently designated by the FDA as a Pregnancy Category C drug. As FM disproportionally affects women and, as a result, there is potential for exposure to milnacipran in women of child-bearing age, a pregnancy registry was established in October 2009.

Methods: This ongoing, voluntary, prospective, observational, US-based registry employs an exposure-registration cohort design that allows for the evaluation of birth defects and other pregnancy outcomes in women ≥18 years exposed to milnacipran at any time during pregnancy. Women are followed throughout pregnancy, with their infants followed until 1 year of age. Enrollment in the Registry is initiated by the woman or by her healthcare provider. Pregnancies with evidence of birth defects prior to enrollment are considered retrospective and excluded from the primary analysis to minimize selection bias. All data are reviewed at least yearly by the Registry's Scientific Advisory Committee.

Results: To date, 2 prospective subjects have enrolled in the Registry. Both gave birth to premature infants (at 32 and 35 weeks of gestation, respectively). No birth defects have been reported at this time. Enrollment is considerably lower than projected, and is far from the goal of 350 exposed pregnancies and 196 live births. Postmarketing surveillance data from 01Nov11 to 31Oct12 indicate that milnacipran was primarily prescribed to women (88.7%); however, only 21.5% of these women were 18–40 years of age (ie, women with the highest childbearing potential). Healthcare utilization data suggest that the pregnancy rate in women prescribed milnacipran may be <0.5% per year, well below the estimated general population rate of 7%. Other reasons for low enrollment may include pregnancy avoidance due to FM symptoms, the Category C classification, or lack of interest in participating in a voluntary registry.

Conclusion: Possibly due to the demographics of the target population, enrollment in the Registry has been challenging. The sample size is insufficient to reach conclusions about milnacipran safety in pregnancy. However, the Registry will continue to monitor milnacipran-exposed pregnancies for teratogenicity signals or other negative pregnancy outcomes. Increasing awareness of the Registry among pregnant women who have taken milnacipran and healthcare providers remains a major focus.

Skin Disease and Fibromyalgia: Dermatologic Diagnoses Encountered In a Series Of 845 Patients With Fibromyalgia At Mayo Clinic In 2008. Valerie Laniosz, David Wetter and Desiree Godar. Mayo Clinic, Rochester, MN.

Background/Purpose: To determine the common dermatological diagnoses and skin-related complaints in a cohort of patients with fibromyalgia seen in a tertiary referral center.

Methods: A retrospective chart review was performed of all patients with a diagnosis of fibromyalgia from January 1st, 2008-December 31st2008, whose diagnosis of fibromyalgia was confirmed in the Fibromyalgia Clinic at Mayo Clinic in Rochester, Minnesota. Charts were reviewed for dermatologic conditions and cutaneous symptoms. Demographic and clinical data were collected to assess for the frequency of skin-related issues in patients with fibromyalgia.

Results: Of 2233 patients screened, 845 patients met the inclusion criteria of having a confirmed diagnosis of fibromyalgia. Amongst these 845 patients with fibromyalgia, various dermatologic conditions and cutaneous complaints were identified including hyperhidrosis in 270 (31.8%); burning of the skin or mucous membranes in 29 (3.4%); and various unusual cutaneous sensations in an additional 14 (1.7%). Pruritus without identified cause was noted by 28 patients (3.3%); with another 16 (1.9%) with neurotic excoriations, prurigo nodules, or lichen simplex chronicus. 77 patients (9.1%) were found to have some form of dermatitis other than neurodermatitis.

Conclusion: Patients with fibromyalgia may have skin-related symptoms associated with their fibromyalgia. There does not appear to be any single dermatologic diagnosis overrepresented in this population with the exception of a subjective increase in sweating.

Disclosure: V. Laniosz, None; **D. Wetter**, None; **D. Godar**, None.

Home Tender Point Measurement In Fibromyalgia Patients. Robert S. Katz[1], Hannah Bond[2] and Jessica L. Polyak[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: To determine whether: 1) patients with the fibromyalgia syndrome (FMS) can accurately evaluate their own tender points, similar to self-administered testing for other purposes (blood pressure and glucose), and 2) whether this might be helpful for monitoring the illness.

Methods: We enrolled 24 patients with a known diagnosis of FMS (meeting the 2010 ACR criteria) and 27 healthy controls. Dolorimetry was performed on each patient by a rheumatology nurse, who also instructed the patient in self-dolorimetry using a pressure gauge smaller than a standard dolorimeter, (Wagner Force Dial FDK/FDN Series Push Pull Force Gage).

Tender points were assessed using self-administered dolorimetry. Tender points were checked at 8 paired fibromyalgia tender point areas: occiput, lower cervical spine, chest wall, lateral epicondyles, knees, trapezius muscles, gluteus muscles, and greater femoral trochanters.

Results: FM patients' ages were 45 y.o. +/−20, 18F and 10M. Normal controls ages were 48 y.o. +/−15, 15F and 10M. Self-measured dolorimetry readings for fibromyalgia patients ranged from 3–20 pounds of pressure and for normal controls from 10–30. When we compared readings performed by a nurse with those done by patients, there were no significant differences. Dolorimetry exams of the trapezius muscle yielded the following results: 32 FMS patients recorded a mean reading of 5.86 pounds per pressure, while 32 controls had a mean reading of 12.05 pounds per pressure.

Conclusion: Using self-administered dolorimetry, our results show that tender points can be measured by patients easily and with reasonable accuracy. The sites providing the best discrimination between patients and controls were the occiput, trapezius muscles, and gluteal muscles. Currently, clinician rated VAS scales are used to monitor the efficacy of

treatment in FMS. Self-administered dolorimetry may also allow patients to assess treatment efficacy. This method of home monitoring would be a convient and inexpensive option for patients to monitor flares of disease.

Rapid Infrared Microscopy (IRMS) For Differential Diagnosis Of Fibromyalgia and Other Central Sensitivity Syndromes. Kevin V. Hackshaw, Luis Rodriguez-Saona, Irving L. Rosenberg, Marcal Plans and C.A. Tony Buffington. The Ohio State University, Columbus, OH.

Background/Purpose: The aim of this study was to investigate the ability of a rapid blood-spot-based method for diagnosis of Fibromyalgia (FM) using mid-infrared microspectroscopy (IRMS) to differentiate patients with FM from those with osteoarthritis (OA) and rheumatoid arthritis (RA) as well as another central sensitization disorder – Interstitial Cystitis (IC) - and to identify molecular species associated with the spectral patterns.

Methods: Under IRB approval, blood samples were collected from patients diagnosed with FM (n = 14), RA (n = 15), or OA (n = 12) and IC (n = 20). Samples were prepared, placed onto a highly reflective slide, and spectra were collected using IRMS and compared using multivariate statistical modeling to differentiate groups. Aliquots of samples also were subjected to metabolomic analysis.

Results: IRMS separated subjects into classes based on spectral information with no misclassifications among FM, RA, OA and IC patients. Discriminating power was greatest based on spectral bands centered at 1560cm^{-1}, which are associated with indole ring vibrations of tryptophan or its derivatives. Metabolomic analysis revealed that RA and OA groups were metabolically similar, whereas biochemical differences were identified in the FM that were quite distinctive from those found in the other groups.

Conclusion: These results support the use of IRMS to differentiate patients with FM from those with other chronic pain or central sensitivity syndromes. The accuracy and simplicity of the test may make it useful for earlier diagnosis of these syndromes.

Cytokines, Oxidative Stress Markers and Brain-Derived Neurotrophic Factor In Fibromyalgia Syndrome. Aline Ranzolin[1], Claudio Antônio da C. Neto[2], Bruna Maria Ascoli[3], Bianca Wollenhaupt-Aguiar[4], Angela Luzia B. Pinto Duarte[2], Markus Bredemeier[5], Flávio Kapczinski[3] and Ricardo M. Xavier[6]. [1]Programa de Pós-Graduação em Ciências Médicas da Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Faculdade de Medicina, Universidade Federal de Pernambuco - Hospital das Clínicas de Pernambuco, Recife, Brazil, [3]Programa de Pós-Graduação em Ciências Médicas da Universidade Federal do Rio Grande do Sul: Psiquiatria, Porto Alegre, Brazil, [4]Programa de Pós-Graduação em Ciências Biológicas: Bioquímica, da Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [5]Hospital Nossa Senhora da Conceição - Grupo Hospitalar Conceição, Porto Alegre, Brazil, [6]Faculdade de Medicina, Universidade Federal do Rio Grande do Sul - Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

Background/Purpose: The pathophysiology of Fibromyalgia Syndrome (FMS) is incompletely understood. An imbalance of pro- and anti-inflammatory cytokines is assumed to play a role in the induction and maintenance of pain, but the many studies that have investigated cytokine levels in patients with FMS presented diverse results. The objective of our study was to analyze different cytokines, oxidative stress markers and brain-derived neurotrophic factor (BDNF) in patients with FMS. Considering that depression is also a possible cause of alteration in some of these markers, its presence was analyzed.

Methods: A total of 130 female subjects (69 FMS and 61 healthy controls) were included in the present study. The cytokines (IL-6, IL-10 and TNFα), oxidative stress markers (Thiobarbituric Acid Reactive Substances – TBARS – and carbonyl) and BDNF expression patterns were evaluated in all subjects. The Hamilton and Beck's depression scales, as well as the Fibromyalgia Impact Questionnaire (FIQ), were applied in FMS patients. BDNF serum levels were measured by sandwich-ELISA; the concentration of serum cytokines was determined by flow cytometry; levels of lipid peroxidation were measured by the method of TBARS and oxidative damage to proteins were analyzed by the determination of carbonyl groups content in proteins.

Results: Age was similar between groups (44.5 ± 6.4 years in FMS and 44.0 ± 6.7 in controls; p= 0.613). In the FMS group, the mean of FIQ was 70.3 ± 18.1 and almost all patients had depression (95.6 %) considering an abnormal score on specific scales. The majority of patients had mild/moderate depression (52.2% on Beck scale and 66.6% on Hamilton scale). IL-10 levels where significantly higher in FMS subjects, but other cytokines and biomarkers did not differ between the groups. (table). There was no correlation of any biomarker or cytokine with the FIQ and the Hamilton and Beck's depression scales.

Comparison of oxidative stress markers, BDNF and cytokines in FMS patients and healthy controls

	FMS patients (n=69) median (IQR)	Healthy controls (n=61) median (IQR)	p value*
Neuropsychiatric biomarkers			
TBARS (μM of MDA)	13.2 (9.8, 20.5)	14.4 (8.7, 29.2)	0.808
BDNF (ng/mL)	30.8 (21.8, 37.1)	30.7 (21.1, 35.4)	0.595
Carbonil (nmol/mg)	0.019 (0.015, 0.022)	0.021 (0.015, 0.027)	0.132
Cytokines (fg/mL)			
IL-6	1498.7 (743.5, 2595.6)	1077.1 (720.0, 2119.1)	0.128
IL-10	593.5 (348.4, 890.2)	441.4 (266.6, 569.8)	0.006
TNF-α	187.3 (145.7, 670.3)	187.3 (76.1, 352.9)	0.255

*Mann-Whitney test; the p value is not adjusted for multiple comparisons. IQR: interquartile range

Conclusion: The significant increase of serum IL-10 in patients with FMS found in this study may indicate a disregulation of antiinflammatory cytokines in this disease. This finding was also seen in patients with chronic fatigue syndrome, disease that is also characterized for chronic pain and tiredness.

Autonomic Nervous System "Decomplexification" In Fibromyalgia. A Proof Of Concept Study Looking At The Fractality Of Heart Rhythms. Manuel Martinez-Lavin, Claudia Lerma, Laura Aline Martinez-Martinez, Oscar Infante and Angelica Vargas. National Institute of Cardiology, Mexico City, Mexico.

Background/Purpose: Prevailing linear-reductionist medical model seems unable to explain complex diseases like fibromyalgia (FM) and similar maladies. As consequence of this divorce, some physicians disparage the fibromyalgia concept. Paradigms derived from the new complexity theory may provide a coherent framework for these elusive illnesses. Along these lines is the proposal that FM represents a degradation of our main complex adaptive system (the autonomic nervous system), in a failed effort to adjust to a hostile environment (Semin Arthritis Rheum 2008;37:260).

Resilient complex systems have fractal structures (fractal is defined as an object or quantity that displays self-similarity at different scales). Fractality loss would signal degradation of a given system. Heart rate variability (HRV) fractal scaling index (alpha) is a novel non-linear method to assess autonomic nervous system resilience: high vagal influence produces less auto-correlated behavior (alpha values below 1.0) while increased sympathetic activity produces more auto-correlated and stiffer behavior (alpha greater than 1.0). Alpha values close to 1.0 indicate resilient fractal-like behavior (Open Cardiovasc Med J 2009;3:110).

The objective of this study was to estimate the HRV fractal scaling index in FM patients, and to correlate this scaling index with clinical symptoms.

Methods: We studied 30 women with FM (1990 ACR criteria) that were free from any medication that may affect the autonomic nervous system. Thirty age - matched healthy women served as controls. HRV was measured during 24 hrs with a Meigaoyi DSM-3 Holter monitor, while subjects were doing their routine activities. The fractal scaling index was estimated with the detrended fluctuation analysis method using custom computer programs which were previously validated. The scaling index was estimated in short-term scales or alpha 1 (4 to 11 heartbeats) and long-term scales or alpha 2 (greater than 11 heartbeats). Mean values between groups were compared with Student t test. Correlations between alpha indexes and symptoms scales were calculated with Pearson′s or Spearman′s correlations.

Results: Demographic features and main results are shown in the table. The short-term fractal scaling index (alpha1) was higher in FM patients when compared to controls (1.22 +/−0.10 vs. 1.16 +/− 0.10 p = 0.035). There was a positive correlation of fractal scaling index alpha 1 with total FIQ score (Rho=0.322, p=0.012).

	Group				
	FM n =30		Controls n = 30		
	Mean	Standard Deviation	Mean	Standard Deviation	*P*
Age	31	8	31	8	0.856 NS
BMI	23.8	4.4	24.4	3.2	0.550 NS
FIQ score	63.24	16.38	10.30	10.05	<0.0001
Fractal scaling	1.22	0.10	1.16	0.10	
index alpha 1	0.93	0.04	0.95	0.05	**0.035**
Fractal scaling index alpha 2					0.143

Conclusion: The short-term HRV fractal scaling index is altered in FM patients with values indicating stiffer autonomic behavior. This fractal index correlated with total FIQ score. This tangible non-linear finding supports the notion that FM represents a degradation of our main complex adaptive system, namely the autonomic nervous system.

The Arthritis Severity Locus *Cia4* Is An Early Regulator of IL-6, IL-1β, and NFκB activators' Expression in Pristane-Induced Arthritis. Max Brenner, Teresina Laragione and Percio Gulko. Hosftra North Shore-LIJ School of Medicine, Manhasset, NY.

Background/Purpose: *Cia4* is a quantitative trait locus on rat chromosome 7 that regulates disease severity and joint damage in three models of rheumatoid arthritis including pristane-induced arthritis (PIA). To identify cellular and molecular processes regulated by *Cia4*, we studied the expression over 23,000 genes in synovial tissues from MHC identical DA (severe erosive disease) and DA.F344(Cia4) congenics (mild and non-erosive disease) rats.

Methods: Synovial tissues from DA and DA.F344(Cia4) congenics were collected at pre-clinical (day 10 and day 14 post-pristane administration; qPCR) and recent onset (day 18; microarray and qPCR) stages following the induction of PIA and analyzed for gene expression levels.

Results: *Il6* levels were 135-fold higher in DA compared with congenics at very early pre-clinical stages (day 10), and remained significantly increased. The *Il6* increase preceded the modest increase in *Il1b* (4.2-fold) suggesting that *Il6* could be driving cytokine expression and the early histologic inflammatory infiltration. 187 genes had significantly different expression and included inflammatory mediators expressed in increased levels in DA such *Slpi* (10.94-fold) and its receptor *Plscr1* (2.31-fold), *Cd163* (5.85-fold), *Ccl7* (5.17-fold) and *Litaf* (2.09-fold). *Syk* or NFκB pathway activating and interacting genes were increased in DA synovial tissues. Fifty-nine genes implicated in cancer-related phenotypes were increased in DA, while genes involved in cell metabolism, transport across membranes and tissue protection such as *Acat1, Dgat1, Dhcr7, Slc25a29*, and *Slc1a1* were increased in DA.F344(Cia4) congenics. 21 genes differentially expressed, or expressed in only one of the two strains were located within the *Cia4* interval, and could be the gene accounting for the arthritis effect.

Conclusion: The *Cia4* interval contains a new arthritis gene that regulates early *Il6*, *Il1b* expression, and other inflammatory mediators central to arthritis, and processes involved in cancer that could be mediating the development of synovial hyperplasia and invasion, and cartilage and bone destruction.

Modular Analysis Of In Peripheral Blood Gene Expression In Rheumatoid Arthritis Captures Reproducible Gene Expression Changes In TNF Responders. Mark Curran[1], Michaela Oswald[2], Sarah Lamberth[1], Carrie Brodmerkel[1], Zhenya Cherkas[1] and Peter K. Gregersen[3]. [1]Janssen Research & Development, LLC., Spring House, PA, [2]The Feinstein Institute for Medical Research, Manhasset, NY, [3]Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: The use of whole blood gene expression to predict and follow the response to TNF inhibition therapy in RA has been challenging due to the complex nature of the data.

Methods: Here we employ an approach to gene expression analysis that is based on gene expression "modules" previously reported by Chassubel (Immunity 2:150–64, 2008). Whole blood RNA (PAXgene) was obtained at baseline and 12 or 14 weeks on two cohorts of rheumatoid arthritis patients beginning anti-TNF therapy.

Results: The initial cohort was enrolled by the ABCoN and contains 50 subjects stratified by EULAR Good Responders (N=14), Moderate Responders (N=21) and Non Responders (N=15) at 12 weeks after starting therapy. Good and Moderate Responders exhibited highly significant changes in multiple modules using a hypergeometric analysis. These included dramatic decreases in modules related to the myeloid lineage and inflammation, along with increases in B cell and plasma cell modules as well as in a number of modules related to the MHC and ribosomal proteins and other "undefined" module groups. Strikingly, Non Responders exhibited very little change in any modules. We have replicated these data in patients enrolled in a clinical trial of Simponi®, with full expression data available on 29 Good Responders, and 37 Moderate Responders. We observed nearly identical modular changes to those identified in the ABCoN Responders after 14 weeks of treatment. Only 6 Non Responders were available for study in this dataset, making convincing replication difficult for this subgroup. Several other replication datasets are currently being analyzed.

Conclusion: These data suggest that using gene expression modules related to inflammatory disease may provide a valuable method of characterizing the responder status of RA patients treated with TNF inhibitors or other biologic therapies.

Microarray Analysis Of Synovial Specimen of Early Human (CHECK) and Experimental Osteoarthritis to Identify Pathways and Processes Associated with Pathology. Arjen B. Blom[1], Peter L. van Lent[1], Martijn H. van den Bosch[1], Hans Cats[2], Frank H.J. van den Hoogen[3], Peter M. van der Kraan[1] and Wim B. van den Berg[4]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Centre Sint Maartenskliniek, Nijmegen, Netherlands, [3]Rheumatology Centre Sint Maartenskliniek and University Medical Centre St Radboud, Ubbergen (Nijmegen), Netherlands, [4]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: The majority of osteoarthritis (OA) patients show synovial inflammation, even relatively early during the disease. We used microarray analysis of synovial tissue of early OA patients and of experimental OA, to identify common pathways that determine joint damage in this disease.

Methods: Expression analysis was performed on murine synovial tissue at day 7, day 21 and day 42 in collagenase induced OA (CIOA) and the surgically induced DMM model (destabilization of the medial meniscus). CIOA was induced by intra-articular injection of collagenase, which causes joint instability. From a subpopulation of patients (n= 25) that entered the CHECK Cohort study (Cohort Hip and Cohort Knee) and 7 controls, synovial biopsies were collected at year 0, 2 and 5. CHECK is a prospective 10-year follow-up study on participants with early osteoarthritis-related complaints (less than 6 months before inclusion) initiated by the Dutch Arthritis Association. Kellgren&Lawrence-score (KL) at inclusion was determined (n=18) and follow up measurements were performed at 2 and 5 years. Affymetrix was used for microarray, and pathway analysis was done using DAVID.

Results: Among the genes that were strongly upregulated on all 3 time points after induction of CIOA were MMP-3 (6-fold), MMP-13 (16-fold), MMP-14 (6-fold). Wound healing, phagocytosis, chemotaxis and metalloproteases were significantly enriched, as were the complement pathway, the TLR-, TGFβ, BMP and wnt-signaling pathways. Highly similar results were obtained in the DMM model for OA. However, at day 42 in this model very view genes were still regulated in the synovium compared

to other time points or CIOA, indicating that synovial activation differs late between the models. This was underlined by histological examination. All in all, the expression patterns in experimental OA showed compelling similarities with human OA synovium. Gene expression profiles of control synovia were compared to CHECK synovia. Analysis using DAVID indicated enrichment of several biological processes and signaling pathways, including macrophage presence, cell migration, TGFβ-, BMP- and wnt-signaling. This indicates activation of the synovium in the early OA versus controls. Next we compared synovial tissue of CHECK-patients with radiological damage (KL$\geq$1) with CHECK-patients without joint damage (KL=0). In the top 30 genes that were associated with cartilage damage were MMP-1 (18-fold), MMP-3 (10-fold) and S100A8 (6-fold), all of which have been associated with cartilage damage. FAC analysis further underlined response to wounding, chemotaxis, innate immune response and metalloproteases to be strongly enriched. In particular, complement-activation pathway, TGFβ- and BMP-signaling and TLR-activation were striking.

Conclusion: Activation pathways and processes in the two models for OA were highly similar. A major difference lies in the presence of late synovial activation. The data suggest an active role for the synovium in OA pathology, and identifies pathways that may be involved. Activation of the complement-pathway was strongly associated with damage. In addition, synovial MMP expression was associated with joint damage, underlining an active role of synovium in OA pathology.

Comparative Proteomic Analysis Of Neutrophils From Patients With Microscopic Polyangiitis and Granulomatosis With Polyangiitis. Teisuke Uchida[1], Kohei Nagai[2], Toshiyuki Sato[3], Nobuko Iizuka[3], Mitsumi Arito[3], Yukiko Takakuwa[4], Hiromasa Nakano[4], Seido Ooka[4], Manae Kurokawa[3], Naoya Suematsu[3], Kazuki Okamoto[3], Shoichi Ozaki[4] and Tomohiro Kato[3]. [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]Kinki University, Wakayama, Japan, [3]St. Marianna University Graduate School of Medicine, Kawasaki, Japan, [4]St. Marianna University School of Medicine, Kawasaki, Japan.

Background/Purpose: Both microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) belong to ANCA-associated vasculitis (AAV), in which neutrophils are thought to be involved in their pathology. Clinically, it is often difficult to distinguish MPA from GPA. To discriminate between MPA and GPA, protein profiles of peripheral blood polymorphonuclear cells (PMNs) of MPA and GPA patients and healthy controls (HC) were analyzed.

Methods: Proteins extracted from peripheral blood PMNs of 11 MPA patients, 9 GPA patients, and 10 HC were separated by two-dimensional difference gel electrophoresis (2D-DIGE). Differentially expressed protein spots were identified by mass spectrometry analysis. Then, to find biomarker candidates which discriminate between MPA and GPA, the obtained protein profiles were subjected to the multivariate data analysis using SIMCA-P+ containing principal component analysis (PCA) and orthogonal partial-least-squares-discriminate analysis (OPLS-DA), and subjected to the receiver operating characteristic (ROC) analysis.

Results: In all the 864 protein spots detected, intensity of 55 spots was found to be significantly different ($p < 0.05$) among the three groups by an analysis of variance (ANOVA). 31 out of the 55 spots were identified by mass spectrometry. The OPLS-DA analysis revealed that the expression profile of the protein spots discriminated the AAV group from the HC group completely and also discriminated the MPA group from the GPA group completely. 13 protein spots were considered as biomarker candidates to distinguish between MPA and GPA. In those, spots whose intensity was higher in MPA than in GPA included actin with various p*I* values, while a considerable part of spots whose intensity was higher in GPA than MPA were proteins related with the activity of neutrophils. Among the candidate proteins, ROC analysis showed that a combination of neutrophil gelatinase-associated lipocalin and a kinase anchor protein 7 isoforms beta had a high diagnostic potential.

Conclusion: In the study, we determined that the protein profile of the neutrophil was clearly different between AAV and HC, and between MPA and GPA. In Particular, GPA was characterized by high expression level of the proteins associated with the activity of the neutrophil.

A Subset Of Osteoarthritis Individuals Has Elevated IL-6 Pathway Activation Associated With Worse Symptoms. Michael Kuziora[1], Zheng Liu[1], Brandon W. Higgs[1], Philip Brohawn[1], Kim Lehmann[1], Fernanda Pilataxi[1], Katie Streicher[1], Lydia Greenlees[1], Meina Liang[2], Rozanne Lee[2], Amy Schneider[2], Raffaella Faggioni[2], Yihong Yao[1] and Koustubh Ranade[1]. [1]MedImmune, LLC, Gaithersburg, MD, [2]MedImmune, LLC, Hayward, CA.

Background/Purpose: Elevated levels of the pro-inflammatory cytokine IL-6 have been found in the affected joint of patients with osteoarthritis (OA), although the prevalence of OA patients demonstrating IL-6 pathway activation is not well-characterized. Our goal was to estimate the proportion of OA patients with increased IL-6 signaling in the diseased joint, and to correlate IL-6 pathway activation with Western Ontario and McMaster Universities Arthritis Index (WOMAC) scores.

Methods: Synovial membranes were obtained from OA patients (N=101) undergoing knee replacement surgery. The WOMAC pain questionnaire was used to assess levels of pain on a visual analog scale of 100mm. Scores within each WOMAC subfunction (pain, stiffness and physical function) were averaged to derive a single composite subfunction score, and the WOMAC total score was calculated as the average of all subfunction scores. Synovial fluid and serum collected at the time of surgery was assayed for IL-6 and CCL8 proteins. Gene expression levels were measured using Affymetrix HG-U133Plus2 microarrays. Transcripts with >2-fold over-expression following treatment with IL-6 and IL6R in synovial fibroblasts were identified. Hierarchical clustering using expression levels of these inducible transcripts in synovial tissue was used to identify OA patients showing high levels of IL-6 activity. A signature score was calculated as the median expression intensities of IL-6 –inducible genes for each subject.

Results: CCL8 and SOCS3 were identified as IL-6 inducible genes in synovial fibroblasts and clustering of synovial membrane specimens from OA subjects revealed a cluster (19/101 subjects, 19%) with a 3.5-fold increase in the median expression of these two genes compared to the remaining subjects (388.4 ± 270.1 vs 111.4 ± 38.7, $p=3.0\times10^{-4}$) suggesting significantly elevated IL-6 pathway activation in this subgroup. These "IL-6 signature high subjects" also had significantly higher mean levels of IL-6 (155.2 ± 4.6 pg/mL vs 58.6 ± 4.1 pg/mL $p=7.4\times1-^{-3}$) and CCL8 (30.5 ± 2.5 pg/mL vs 14.4 ± 2.1 pg/mL $p=7.2\times10^{-5}$) proteins in synovial fluid. The levels of CCL8 and IL-6 proteins in synovial fluid were significantly correlated (rho=0.52, $p=1.6\times10^{-7}$). Compared to subjects with low levels of IL-6 inducible genes in the synovium, with those in the IL-6 signature high cluster were more likely to be women (Odds ratio 4.2 95% C.I. [1.1, 15.4] p=0.03), and had higher mean WOMAC scores for pain (65.6 ± 16.4 vs 55.6 ± 18.3, $p= 4\times10^{-2}$), stiffness (76.9 ± 17.0 vs 60.5 ± 24.8, $p=3.4\times10^{-3}$), physical activity (67.2 ± 15.8 vs 56.3 ± 18.2, $p=4.4\times10^{-2}$) and total score (69.9 ± 14.6 vs 57.5 ± 18.1, $p=8.9\times10^{-3}$).

Conclusion: An IL-6 inducible gene signature consisting of CCL8 and SOCS3 was used to identify a subgroup of OA subjects with elevated IL-6 pathway activation in the synovial membrane. OA subjects in this IL-6-signature high group were more likely to be women and had higher mean WOMAC pain scores. CCL8 is a potential biomarker of IL-6 pathway activation in the affected joint.

The mtDNA Haplogroups Influence The Cartilage Integrity In Osteoarthritis. Data From The Osteoarthritis Initiative (OAI). Ignacio Rego-Pérez[1], Angel Soto-Hermida[1], Mercedes Fernández-Moreno[1], Sonia Pértega-Díaz[2], Juan Fernández-Tajes[1], María Eugenia Vázquez-Mosquera[1], Estefanía Cortés-Pereira[1], Sara Relaño-Fernández[1], Natividad Oreiro-Villar[1], Carlos Fernández-López[1] and Francisco J. Blanco[3]. [1]INIBIC-Hospital Universitario A Coruña. Rheumatology Division. Genomic Group, A Coruña, Spain, [2]INIBIC-Hospital Universitario A Coruña. Epidemiology and Public Health Unit, A Coruña, Spain, [3]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC- University of A Coruña, A Coruña, Spain.

Background/Purpose: Magnetic resonance imaging (MRI) is ideally suited for detect structural changes and degradation in cartilage against the limitations of radiographic common methods. Changes in volume and thickness are the most widely used variables to measure progression in OA with MRI. The aim of this study is to elucidate the influence of the mtDNA haplogroups on cartilage integrity based on MRI data obtained from different OAI projects.

Methods: We analysed the influence of the mtDNA haplogroups on quantitative measurements of cartilage morphology from MRI scans, mean cartilage thickness and volume of cartilage, in the whole knee joint by means of both cross-sectional and longitudinal studies during a follow-up period of 24 months. We selected for analysis 326 patients from project 18 (cross-sectional) and 358 from project 9 (longitudinal), all of them belonging to the progression subcohort of the OAI. Appropriate statistical analyses adjusting by gender, age and body mass index (BMI) at baseline were carried out using SPSS software (v.19) and R 2.10.0 (The R Foundation for Statistical Computing).

Results: The cross-sectional analyses showed that OA patients that carry the mtDNA haplogroup T had increased median values of cartilage volume in medial tibia (2.35×10^3 mm^3 vs 1.95×10^3 mm^3; $p=0.009$) and medial tibia femoral (3.56×10^3 mm^3 vs 3.02×10^3 mm^3; $p=0.015$) compartments, when compared with the most common mtDNA haplogroup H. In relation to mean cartilage thickness, OA patients that carry the mtDNA haplogroup T also showed higher mean cartilage thickness in medial tibia, however this difference borderline the statistical significance (1.85 mm vs 1.73 mm; $p=0.07$).

During the follow-up period of 24 months, OA patients that carry the haplogroup T suffered a significant smaller decline of volume in medial tibia femoral ($p=0.015$) and central medial femur ($p=0.016$) compartments when compared with the most common mtDNA haplogroup H. Even when the normalized cartilage volume of these two subregions was analysed, the results obtained were similar ($p=0.023$ and $p=0.031$ respectively). In relation to mean cartilage thickness, patients with the mtDNA haplogroup T suffered a significant smaller decline in central medial tibia femoral (weight bearing) ($p=0.011$), medial tibia femoral ($p=0.019$), medial tibia (anterior) ($p=0.007$) and central medial femur (center) ($p=0.013$) compartments when compared with the mtDNA haplogroup H.

The statistical models applied in the longitudinal approach showed both age and gender (female) as risk factors for volume loss ($p<0.02$ and $p<0.0001$ respectively) and thickness loss ($p<0.05$ and $p<0.0001$ respectively) in articular cartilage over time.

Conclusion: The mtDNA haplogroups manifest an intrinsic relation with OA progression in terms of cartilage integrity; carriers of this mitochondrial variant show a slower disease progression than haplogroup H carriers (most common in Caucasian population). The early haplogroup assignment could be crucial for an effective follow-up of the disease and a fit treatment.

The Uncoupling mtDNA Haplogroup T Associates With Better Radiographic Progression Of Osteoarthritis. Data From The Osteoarthritis Initiative (OAI). Angel Soto-Hermida[1], Ignacio Rego-Pérez[1], Mercedes Fernández-Moreno[1], Sonia Pértega-Díaz[2], Juan Fernández-Tajes[1], María Eugenia Vázquez-Mosquera[1], Estefanía Cortés-Pereira[1], Sara Relaño-Fernández[1], Natividad Oreiro-Villar[1], Carlos Fernández-López[1] and Francisco J. Blanco[3]. [1]INIBIC-Hospital Universitario A Coruña. Rheumatology Division. Genomic Group, A Coruña, Spain, [2]INIBIC-Hospital Universitario A Coruña. Epidemiology and Public Health Unit, A Coruña, Spain, [3]CIBER-BBN-ISCIII, Madrid, Spain.

Background/Purpose: The Osteoarthritis Initiative (OAI) is a multicentre study focused on identifying and evaluating risk factors of knee osteoarthritis (OA). Previous studies carried out by our group showed the role of the mitochondrial DNA (mtDNA) haplogroups on the prevalence and severity of OA. The aim of this study is to replicate our previous findings about the influence of the mtDNA haplogroups on OA progression in the well characterized cohort of the OAI.

Methods: We assigned the mtDNA haplogroups in 891 Caucasian samples of the progression subcohort of the OAI to analyse their influence on radiographic OA progression attending to: KL grade, joint space narrow (JSN), presence of osteophytes and subchondral sclerosis in media tibial compartment between baseline and visit 6 (48 months). The progression criteria for KL grade consisted in an increase of at least one (KL or OARSI) grade at any visit and any knee; for JSN if an increase in score by a grade[3] 0.5 of the OARSI scale at any visit and any knee occurred. Additionally, we also analysed the four-year change in radiographic medial joint space width (mJSW) at $x=0.225$ in ($N=265$) patients with baseline unilateral JSN in both JSN knees (OARSI atlas grade ≥ 1) and non-JSN knees (OARSI atlas grade < 1).

Appropriate statistical analyses adjusting by gender, age and body mass index (BMI) at baseline were carried out using SPSS software (v.19) and R software v2.10.0 (The R Foundation for Statistical Computing).

Results: OA patients in the progression subcohort that carry the mtDNA haplogroup T showed the lowest significant cumulative probability of progression in terms of KL grade (Relative Risk (RR) = 0.490; 95% Confidence Interval (CI): 0.208–0.762; $p < 0.05$), osteophytes (RR = 0.490; 95% CI: 0.208–0.762; $p < 0.05$), subchondral esclerosis (RR = 0.490; 95% CI: 0.208–0.762; $p < 0.05$) and JSN (RR = 0.490; 95% CI: 0.208–0.762; $p < 0.05$) when compared with OA patients that carry the most common mtDNA haplogroup H.

Regarding to mJSW at $x=0.225$ in both knees of patients with unilateral JSN during the follow-up period of 48 months, the results obtained showed that carriers of the haplogroup T had a significant smaller decline in the mJSW at $x=0.225$ in non-JSN knees ($p = 0.033$). For JSN knees, though carriers of the haplogroup T showed the smallest decline too, the differences did not reach the statistical significance.

Conclusion: This work strength the hypothesis that mitochondrial genome is a key factor in the progression of the OA disease. The early identification and classification of patients with haplogroup T and the most common haplogroup H would permit to carry out a more personalized follow-up of the disease.

Identification Of Autoimmune Disease Risk Alleles That Are Under Recent Selection In The Sea Island Gullah African Americans. Carl D. Langefeld[1], Satria Sajuthi[1], Jasmin Divers[1], Yiqi Huang[2], Uma Nayak[2], Wei-Min Chen[2], Kelly J. Hunt[3], Diane L. Kamen[3], Gary S. Gilkeson[3], Jyotika K. Fernandes[3], Ida J. Spruill[3], W. Timothy Garvey[4], Michèle M. Sale[2] and Paula S. Ramos[3]. [1]Wake Forest School of Medicine, Winston-Salem, NC, [2]University of Virginia, Charlottesville, VA, [3]Medical University of South Carolina, Charleston, SC, [4]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: The reasons for the ethnic disparities in rheumatic and autoimmune diseases (AIDs) are largely unknown. Given the increasing evidence of selection at loci associated with human diseases, identification of alleles under selection may provide further insight into disease susceptibility. The Gullahs form a unique population of African ancestry in the U.S. In addition to their relative genetic and environmental homogeneity and low European admixture, a shorter genetic distance between the Gullahs and Sierra Leoneans has also been reported, suggesting that population genetic signals, such as regions under recent selection, may be more easily detected in the Gullahs than in other African American (AA) populations. We sought to capitalize upon the relative closeness between the Gullah and Sierra Leoneans to identify regions that differentiate both populations and may hence be under recent population-specific selective pressures. The goal of this study was to identify regions that might be under recent positive selection in the Gullah and that harbor risk loci for AIDs, which may help explain the higher prevalence of autoimmunity in AA.

Methods: We computed a linear regression model using the principal component of the HapMap Yoruba (YRI) population from Nigeria (PC2) as a quantitative outcome, using 277 Gullah and 400 Sierra Leonean samples genotyped on the Affymetrix Genome-Wide Human SNP Array 6.0. We adjusted for European admixture via inclusion of the HapMap Caucasian (CEU) population component (PC1) as a covariate. In total, 679,513 SNPs with MAF>5% were used in this analysis. In order to exclude spurious loci, only regions where at least one SNP met genome-wide significance (P<5E-10) and a second significant SNP (P<E-07) in LD with it were considered. We then checked for the presence of immune/autoimmune-related genes in these regions.

Results: Nine regions met our criteria as those that best differentiate the Gullah from the Sierra Leonean. The most significant was a ~2 Mb region at Xq22.2-q22.3 around the IL1RAPL2 gene, where 4 SNPs had P<5E-10. Of the other 8 regions, half encompass immune-function genes: TLR3 at 4q35.1, CD83 at 6p23, the extended HLA at 6p22.1-21.32, and RAPGEF5-IL6 at 7p15.3. The CD83 region is associated with rheumatoid arthritis, the HLA region with all AIDs, and the RAPGEF5-IL6 region with dialysis-related mortality in AA and CRP levels.

Conclusion: We have identified several regions that harbor immune function genes and differentiate the Gullah from the Sierra Leoneans, suggesting that recent selection may be operating at these loci. Given the relative homogeneity of the Gullah and their genetic proximity to Africans from Sierra Leone, identification of regions that might be under selection and harbor immune-related genes in the Gullah has the potential to elucidate AID risks in AA.

154

Identification Of Autoimmune Disease Genes In Regions Under Selection In The Gullah African American Population Of South Carolina. Paula S. Ramos[1], Nathan Titus[2], Satria Sajuthi[2], Jasmin Divers[2], Yiqi Huang[3], Uma Nayak[3], Wei-Min Chen[3], Kelly J. Hunt[1], Diane L. Kamen[1], Gary S. Gilkeson[1], Jyotika K. Fernandes[1], Ida J. Spruill[1], W. Timothy Garvey[4], Michèle M. Sale[3] and Carl D. Langefeld[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]University of Virginia, Charlottesville, VA, [4]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Most autoimmune diseases (ADs) are more prevalent in specific ethnic groups. We hypothesize that one reason for the ethnic disparity may be an effect of population-specific selection influencing the allele frequencies at some loci. Selection for specific alleles that improves fitness and survival in a specific environment can lead to increased disease risk in a different environment. Given the growing number of disease-associated loci in regions that show evidence of selection, identification of alleles under selection may provide insight into disease susceptibility. Relative to other African-Americans (AA), the AA Gullah population has lower European admixture and higher ancestral homogeneity from the Sierra Leone area in Far-West Africa. The shorter genetic distance between the Gullahs and Sierra Leoneans suggests that population genetic signals, such as regions under recent selection, may be more easily detected in the Gullahs than in other African American (AA) populations. The goal of this study was to identify regions under recent positive selection in the Gullahs that may harbor risk loci for ADs.

Methods: We computed the cross population extended haplotype homozygosity test (XP-EHH) to identify alleles with higher than expected frequency relative to their haplotype length in one population relative to another. We compared 277 control Gullahs to 400 Sierra Leonean controls and to 203 HapMap Yorubans (YRI) from Nigeria. A total of 679,513 SNPs with MAF>5% met all statistical quality control criteria. Regions that met genome-wide significance ((|XP-EHH|>4, P<E-07) were followed to assess for overlap with regions known to be associated with ADs.

Results: We identified multiple regions with evidence of recent selection. Over 20 regions showed evidence of selection between the Gullah and the Sierra Leoneans (|XP-EHH|>4, P<E-07). They revealed an enrichment of genes involved in resistance to HIV infection (P-Bonferroni=0.017). Half of these regions showed evidence of selection in the Gullahs, including regions associated with ADs: *DAB1* (Kawasaki disease), *KCNH8* (Crohn's disease, psoriasis), and *LPP* genes (vitiligo, celiac disease). Twenty four regions showed evidence of selection between the Gullah and the YRI, revealing an enrichment of genes involved in cytokine/chemokine mediated immunity (P-Bonferroni= 0.0015), but only two regions were being selected for in the Gullahs, none of which has previously shown evidence of association with an AD. Regions associated with ADs showing evidence of selection in the YRI population include those of the the HLA region (all ADs), the *CCR2* (celiac disease), and *SMOC2* genes (vitiligo), with *CCR2* also showing evidence of selection in the Sierra Leone population. This scan also identified the region around the APOL1 gene, which has been shown to be under selection and associated with multiple kidney diseases in AAs.

Conclusion: We have identified several risk alleles for ADs that are targets of recent positive selection in an AA population. Given the increased prevalence of several ADs in AAs and the homogeneity of the Gullahs, identification of these regions in the Gullahs has the potential to elucidate AD risks in AAs and help explain the ethnic disparity.

Exome Sequencing For Identification Of Potential Causal Variants For Diffuse Cutaneous Systemic Sclerosis. Angel CY Mak[1], M Kari Connolly[2], Tamiko Katsumoto[3], Paul Wolters[4], Clare Cleveland[3], Blanca M Herrera[1], Paul LF Tang[1], Simi Mathauda[1], Richard Lao[1], Pui-Yan Kwok[1] and Lindsey A. Criswell[3]. [1]University of California, San Francisco, Institute for Human Genetics, San Francisco, CA, [2]University of California, San Francisco, Department of Dermatology, San Francisco, CA, [3]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA, [4]University of California, San Francisco, Department of Medicine, Pulmonary Division, San Francisco, CA.

Background/Purpose: Scleroderma is a genetically complex autoimmune disease with substantial phenotypic heterogeneity. Previous genome-wide association studies (GWAS) have identified a large number of gene regions associated with disease risk. However, GWAS directly capture only common genetic variation that are presumably in linkage disequilibrium with causal variants, which may be rare in the general disease population. Our goal was to identify rare and potentially causal variants through performance of whole exome sequencing. We focused on patients with severe disease, and specifically those with diffuse cutaneous systemic sclerosis (dcSSc), to limit disease heterogeneity.

Methods: Our initial exome-sequencing studies were performed on 24 dcSSc patients using the Illumina HiSeq2500 platform and the Nimblegen SeqCap EZ v3.0 exome enrichment protocol. We also studied 60 healthy control subjects who underwent exome sequencing in the same laboratory using comparable methods. Exome sequencing reads were processed using the automated pipeline for next-generation sequencing data (bcbio-nextgen, https://github.com/chapmanb/bcbio-nextgen) and variants were annotated with ANNOVAR. We applied a gene burden test to identify genes that were enriched or depleted with rare (MAF≤0.01) and functionally deleterious (SIFT≤0.05) variants in dcSSc patients compared to control individuals.

Results: Paired 100bp end reads were generated with a mean coverage of 56X on the targeted exome regions (64Mb). We identified 31 genes that were enriched or depleted with rare and functionally deleterious variants in dcSSc patients. Among the 31 genes, 6 genes (*ADAMTS8, ALMS1, CHST15, DACH1, FMNL2, RELN*) were in previously identified scleroderma susceptibility loci or pathways implicated in scleroderma pathogenesis.

Conclusion: Using exome sequencing and gene burden analysis, we identified 31 genes that contain rare and potentially functionally deleterious variants that may contribute to the development of dcSSc. This pilot study demonstrates the potential value of whole exome sequencing for the identification of causal variants that contribute to scleroderma risk and/or severity.

Cartilage Peptide Profiling: Identifying Novel OA Biomarkers For Early Disease Detection. Valentina Calamia, Lucía Lourido, Diego López, Jesus Mateos, Patricia Fernández-Puente, Carolina Fernández-Costa, Beatriz Rocha, Cristina Ruiz-Romero and Francisco J. Blanco. Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-ISCIII, INIBIC-CHUAC, A Coruña, Spain.

Background/Purpose: Cartilage secretome contains a complex matrix of proteolytically derived peptides that may provide useful information of the biological events occurring in the articular joint in normal and pathological condition. Moreover, the low-molecular-weight subset of the cartilage proteome may have a diagnostic potential in osteoarthritis (OA) research, not fully exploited yet. The aim of this study is to investigate cartilage secretome by means of peptidome analysis and to provide a novel source for OA biomarker discovery.

Methods: Tissue explants were obtained from the dissection of human OA cartilages, both from the wounded zone (WZ) and the unwounded zone (UZ). The study was approved by the local ethical committee. Cartilage shavings from each zone were cut into 6 mm discs and five discs/zone were placed into 96 wells plates and incubated (37 °C/5% CO2) in serum-free DMEM up to 6 days. Conditioned media from each condition were collected at day 1, 3 and 6. Selective extraction of endogenous peptides was realized by combining ultrafiltration and solid phase extraction. Then, the peptides were directly analyzed by nano reversed-phase liquid chromatography (RP-LC) in an Easy nLC II system coupled to an ion trap LTQ Orbitrap Velos Pro mass spectrometer (Thermo Scientific) without trypsin digestion. Protein/peptide identifications were searched against human database using the SEQUEST algorithm (Proteome Discoverer 1.3, Thermo Scientific).

Results: Firstly we compared the profiles of peptides released to the media at different times (0, 3, and 6 days in culture). At day 3 we detected the highest number of unique peptides and proteins, and the lowest serum contamination. Thus, we selected day 3 as the best point for the next proteomic analysis in which we compared peptide profiles from WZ and UZ. This study led to the detection of a panel of 262 peptides corresponding to 36 proteins that were differentially released from the WZ and UZ in OA cartilage. Most of them were cartilage ECM proteins or proteins with well-established matrix functions, such as collagens and proteoglycans, thus indicating the high cartilage-specific biomarker concentration present in our samples. 18 peptides were detected only in the WZ (corresponding to 5 proteins: K1C9, K1C10, PRPC, FIBA, and DCD) while 60 peptides only in the UZ (corresponding to 20 proteins: ACAN, CILP1, CILP2, COL11A2, COL1A2, COL25A1, LTBP2, MGP, and PRELP among others) (Table 1). 11 proteins (BGN, CLU, COL1A1, COL2A1, COL3A1, COL5A2, COMP, and FN1 among others) were detected in both zones but in all the cases the number of peptides was higher in the UZ than in the WZ.

Table 1. Examples of peptides detected at high levels (High) in UZ samples and not detected (ND) in WZ samples, potentially useful as early OA biomarkers.

Conclusion: To our knowledge this is the first proteomic study specifically focused on cartilage peptidome analysis. In this work we analysed the cartilage endogenous peptides profile and highlighted its potential application as novel OA biomarker source for early disease detection.

Application Of a Multiplex Gene Polymorphism Assay For Variants Associated With Rheumatoid Arthritis Susceptibility: Results Of 168 Single Nucleotide Polymorphisms In The Optima Study. Jeffrey F. Waring[1], Viswanath Devanarayan[2], Kenneth Idler[1], Feng Hong[2], Josef S. Smolen[3], Arthur Kavanaugh[4], Hartmut Kupper[5], Hendrik Schulze-Koops[6] and Alla Skapenko[6]. [1]AbbVie Inc., North Chicago, IL, [2]AbbVie Bioresearch Center, Worchester, MA, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [4]University of California San Diego, La Jolla, CA, [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [6]University of Munich, Munich, Germany.

Background/Purpose: Genetic factors have been identified that may be associated with the development and severity of rheumatoid arthritis (RA), disease progression, or response to treatment. In-depth knowledge about RA susceptibility genes may thus prove useful for the development of future diagnostic tests or personalized therapeutics. Frequencies from previously investigated RA susceptibility gene polymorphisms from patients enrolled in the OPTIMA trial were compared to a control database to identify genetic risk factors for RA.

Methods: OPTIMA was a 78-week, multicenter, randomized study designed to assess adalimumab plus methotrexate therapy in early RA patients.(1) Of 1032 patients, genetic analysis was conducted on 921 patients who signed an additional informed consent for genetic analyses. Frequency rates for 168 identified RA susceptibility alleles from 88 genes were compared to the European cohort of the 1000 Genomes Project as a reference control.(2) Genotypic variants were assayed using the Illumina BeadXpress GoldenGate Assay. The largest deviations in the OPTIMA minor allele frequencies (MAFs), those > 0.05 compared to the control, were further investigated. Logistic regression was used to calculate odds ratios (OR) for RA susceptibility. Association of alleles with 28-joint count disease activity score (DAS28) and age were conducted using ANOVA comparing the OPTIMA cohort with the control cohort.

Results: The majority of single nucleotide polymorphism (SNP) MAFs from the OPTIMA study did not deviate > 0.05 from MAFs reported in the European cohort from the 1000 Genomes Project. Within known RA susceptibility genes or those with treatment response, 7 of 63 SNPs previously investigated as being associated with increased RA risk deviated > 0.05 from reference controls in OPTIMA patients and were investigated further; 11 SNPs that had not been previously associated with RA susceptibility had MAF differences > 0.05 comparing OPTIMA with the reference control. The BTLA SNP rs9288952 G allele displayed the highest OR for RA risk, 3.60 (95% CI, 2.49 – 5.20), was weakly associated with higher baseline DAS28, and also associated with patient age (mean ages were 50.9, 49.0, and 44.3 for genotypes A/A, A/G, and G/G, respectively), suggesting a potential association with onset at earlier or later age. STAT4 rs7574865 minor allele homozygosity was associated with higher baseline DAS28 scores. Of the previously unidentified RA susceptibility gene SNPs, only PDZD2 rs1532269 was significantly associated with higher baseline DAS28 scores.

MAF, minor allele frequency; SNP, single nucleotide polymorphism.
** and
*** denote statistical significance at the $p < 0.01$ and 0.001 levels, respectively.
# significant when homozygous for the minor allele.

Conclusion: Genes identified with increased RA risk have known roles in immune responses including mediation of lymphocyte signaling,

proliferation, and differentiation. The MAFs of 18 gene SNPs in the OPTIMA study differed from a healthy control population; further investigation into these SNPs will clarify their role in RA susceptibility and disease progression.

The Use Of "Autoantigenomics" To Rapidly Identify Targets Of Human Autoantibodies. Wei-Hong Yang, Emily G. Bloch, Daniel F. Berenson, Rita L. Galdos, Pankaj Arora, Connie Wu and Donald B. Bloch. Massachusetts General Hospital and Harvard Medical School, Boston, MA.

Background/Purpose: The messenger RNA (mRNA) processing body (P-body) is a cellular structure that regulates the stability of cytoplasmic mRNA. Approximately 5% of patients with the autoimmune disease primary biliary cirrhosis (PBC) have antibodies directed against this structure and some patients have antibodies that react with several different known P-body components. In this study, we used a proteomic array and serum from a PBC patient to rapidly and efficiently identify a new P-body component.

Methods: Serum from patient 0081 was used to probe a high density protein macroarray which contains approximately 17,000 proteins. The proteins were produced *in situ* on a polyvinylidene difluoride (PVDF) membrane by *Escherichia coli* transformed with a prokaryotic expression cDNA library. This library was derived from mRNA prepared from phyto-hemagglutinin treated human T-lymphocytes. Human auto-antibodies that bound to the protein macroarray were detected using horse-radish peroxidase-conjugated rabbit anti-human IgG antiserum and chemiluminescence. Immunoreactive protein targets of these autoantibodies were determined by their locations on the PVDF membrane. Immunoblot was then used to confirm that serum 0081 contained antibodies that reacted with newly indentified auto-antigens. Human epidermoid cancer cells (HEp-2 cells) were transfected with plasmids encoding green fluorescent protein (GFP) fused to the new P-body component candidates, to confirm that the proteins localized to P-bodies.

Results: Serum 0081 reacted with fifty-six proteins on the protein macroarray membrane. One of these new proteins, Limkain B (LMKB), was chosen for further study because it was previously reported to localize to a "subset of peroxisomes", a staining pattern that might appear similar to the P-body pattern. Antibodies in serum 0081 reacted with glutathione *S*-transferase (GST)-LMKB, but not GST alone, by immunoblot. A plasmid encoding full-length LMKB fused to GFP was used to express the protein in HEp-2 cells. LMKB localized to cytoplasmic dots and co-localized with Ge-1, a known P-body component.

Conclusion: Our findings demonstrate that the combination of proteomic array technology and human autoantibodies provides a useful tool for identifying new autoantigens. "Autoantigenomics" can be used to rapidly and efficiently discover new proteins in cellular structures. Using this method, we identified LMKB as a novel component of mRNA processing bodies.

Transcriptomic Blood Markers and Molecular Stratification In Sarcoidosis. Robert Su, Michael Li, Nirav Bhakta, Misha Agarwal, Prescott Woodruff and Laura Koth. University of California San Francisco, San Francisco, CA.

Background/Purpose: Sarcoidosis is a heterogeneous disease with diverse manifestations and varied clinical courses. Currently there are no reliable non-invasive biomarkers of disease activity or severity. The aim of this study was to identify "pathway-specific" blood gene expression signatures in subjects with sarcoidosis and to ascertain whether these signatures identify distinct subsets of patients and correlate with measures of disease severity.

Methods: We analyzed whole blood RNA (PAXgene RNA tubes) from 38 patients with sarcoidosis and 20 healthy controls using Affymetrix U133 Plus 2.0 microarrays (Affymetrix Inc., Santa Clara, CA). Correcting with the Benjamini-Hochberg method, we found differentially expressed (DE) genes that were upregulated in sarcoidosis compared to controls. We performed Ingenuity Pathway Analysis (IPA) and then hierarchical clustering (MultiExperiment Viewer) using selected genes representative of canonical pathways highly up-regulated in sarcoid. Standardized expression levels of DE genes were correlated with measures of pulmonary function testing (PFT). Whole blood DE genes expression levels were compared to levels found in publically available sarcoidosis tissue gene expression datasets (Gene Expression Omnibus GSE32887, GSE19976).

Results: 193 DE genes associated with a B-statistic > 0 (adjusted p value <0.006) were upregulated in sarcoidosis. These genes were associated with interferon (IFN), TNFα, and TGF-β1 signaling pathways. Hierarchial clustering of subjects using genes representative of IFN and TNFα pathways revealed different patient subsets, including subjects with IFN-high/TNFα-low or IFN-low/TNFα-high signatures, and subjects with dual IFN/TNFα-high or dual IFN/TNFα low signatures. Expression levels of TGF-β1-associated genes (*SKIL*, *USP15*, *LPCAT2*) correlated with PFT measures of restrictive lung volumes and decreased oxygenation, including FVC% predicted ($R^2 = 0.39$, $p<0.0001$), TLC% predicted ($R^2 = 0.26$, $p = 0.001$), and DLCO% predicted ($R^2 = 0.2$, $p = 0.004$). Expression levels of TNFα-inducible genes (*TNFAIP2, PLAUR, ICAM1*) correlated with degree of pulmonary obstruction as measured by FEV1/FVC ($R^2= 0.26$, $p = 0.001$). Expression of these pathway-specific genes was elevated in lesional sarcoid skin and progressive fibrotic sarcoid lung biopsy gene expression datasets.

Conclusion: Based on these data we hypothesize that IFN-, TNFα-, and TGF-β1-specific gene expression biomarkers reflect distinct subgroups of patients with sarcoidosis and signaling pathways that may play a pathogenic role in sarcoidosis. TGF-β1-associated DE gene expression levels may reflect severity of pulmonary fibrosis. We plan to test this hypothesis in a larger longitudinal cohort to 1) validate our groupings, 2) determine whether these signatures are stable over time or vary with disease activity, 3) determine whether these groupings have prognostic value.

Association Analysis Of The Organic Anion Transporter 4 and Urate Transporter 1 Locus With Gout In New Zealand Case-Control Sample Sets Reveals Multiple Ancestral-Specific Effects. Tony R. Merriman[1], Amanda Phipps-Green[1], Jade E. Hollis-Moffatt[1], Marilyn E. Merriman[1], Ruth Topless[1], Grant Montgomery[2], Brett Chapman[2], Lisa K. Stamp[3], Nicola Dalbeth[4] and Tanya Flynn[1]. [1]University of Otago, Dunedin, New Zealand, [2]Queensland Institute of Medical Research, Brisbane, Australia, [3]University of Otago, Christchurch, Christchurch, New Zealand, [4]University of Auckland, Auckland, New Zealand.

Background/Purpose: There are genetic variants in urate transporters SLC22A11 (OAT4) and SLC22A12 (URAT1) that influence serum urate levels in European Caucasian. However, there is no consistent evidence for association with risk of gout. The aim of this study was to test genetic variation across the SLC22A11 and SLC22A12 locus for association with gout risk in New Zealand sample sets. The sample sets include Mβori and Pacific Island (Polynesian) participants, who exhibit higher prevalence and more severe gout than European Caucasian.

Methods: Twelve single nucleotide polymorphism (SNP) variants in four haplotype blocks were genotyped using TaqMan¨ and Sequenom MassArray in 1003 gout cases and 1156 controls. Gout was classified according to the 1977 American Rheumatism Association criteria. Association analysis of single markers and haplotypes was done using PLINK and STATA.

Results: SNP *rs17299124* (upstream of *SLC22A11*) in haplotype block 1 was associated with gout in the Polynesian sample sets with higher Polynesian ancestry, but not in Maori and Pacific with lower Polynesian ancestry and European Caucasian (OR=3.38, P=0.001; OR=0.94, P=0.54, respectively) (Table). A protective block 1 haplotype, rarer in Polynesian, was driving the association (OR=0.28, P=0.001). Within haplotype block 2 (*SLC22A11*) we could not replicate previous reports of association of *rs2078267* with gout in European Caucasian and people

with lower Polynesian ancestry (OR=1.00, P=1.00), however this SNP was associated with gout in people with higher Polynesian ancestry (OR=1.84, P=0.012). Within haplotype block 3 (including *SLC22A12*) there was evidence for association for SNP *rs3825018* in all ancestral groups (OR=1.27, P=0.002). Analysis of haplotypes revealed a haplotype with trans-ancestral protective effects (OR=0.80, P=0.004), and a second haplotype conferring protection in the less admixed Polynesian sample sets (OR=0.63, P=0.028) but risk in European Caucasian samples (OR=1.33, P=0.039).

Table. Allelic associations

SNP (haplotype block)	European Caucasian and low ancestry Polynesian			High ancestry Polynesian			All ancestries

rs12289836 (4)	0.87 [0.72–1.05]	0.16	0.44	0.89 [0.70–1.13]	0.33	0.72	0.88 [0.76–1.02]	0.085	0.86
rs642803 (4)	0.97 [0.81–1.16]	0.73	0.27	0.95 [0.76–1.19]	0.66	0.86	0.96 [0.84–1.11]	0.59	0.82

[1]Heterogeneity P-value, $P < 0.05$ indicates significant heterogeneity.

Conclusion: Our analysis demonstrates several ancestral-specific effects across the SLC22A11/SLC22A12 locus indicating that multiple common variants influence the activity of both OAT4 and URAT1 in relation to risk of gout. These results clarify some of the previous inconsistent gout associations seen, and indicate that further fine mapping of the association signal is needed.

H3K9 Demethylation By LSD1 Contributes To IL-1-Induced mPGES-1 Expression In OA Chondrocytes. Fatima Ezzahra El Mansouri and Hassan Fahmi. Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC.

Background/Purpose: Microsomal prostaglandin E synthase-1 catalyzes the terminal step in the biosynthesis of PGE_2, which plays a critical role in the pathophysiology of osteoarthritis. To investigate the role of histone H3 (H3K9) methylation in interleukin-1b (IL-1)-induced microsomal prostaglandin E synthase-1 (mPGES-1) expression in human osteoarthritic (OA) chondrocytes.

Methods: Chondrocytes were stimulated with IL-1 and the expression of mPGES-1mRNA was analyzed using real-time reverse transcriptase-polymerase chain reaction. H3K9 methylation and the recruitment of the histone demethylase LSD1 to the mPGES-1 promoter were evaluated using chromatin immunoprecipitation assays. The role of LSD1 was further evaluated using the the amino oxidase inhibitor tranylcypromine (a potent inhibitor of LSD1 activity).

Results: Treatment with IL-1 induced mPGES-1 expression in a time dependent manner. The induction of mPGES-1 expression by IL-1 was associated with H3K9 demethylation at the mPGES-1 promoter. These changes were concomitant with the recruitment of the histone demethylase LSD1. Treatment with tranylcypromine inhibited IL-1-induced H3K9 demethylation as well as IL-1-induced mPGES-1 expression.

Conclusion: These results indicate that H3K9 demethylation by LSD1 contributes to IL-1-induced mPGES-1 expression and suggest that this pathway could be a potential target for pharmacological intervention in the treatment of OA and possibly other arthritic diseases.

Disclosure: F. E. El Mansouri, None; **H. Fahmi**, None.

Genotypic and Haplotypic Effects Of 7 Single-Nucleotide Polymorphisms In the *CRP* Gene On Levels Of C-Reactive Protein and DAS28 In a Cohort Of 180 Untreated Newly Diagnosed Rheumatoid Arthritis Patients (OPERA Study). Christian G. Ammitzbøll[1], Rudi Steffensen[2], Peter Junker[3], Mikkel Østergaard[4], Julia Johansen[5], Jan Pødenphant[6], Merete Lund Hetland[7], Hanne M. Lindegaard[8], Torkell Ellingsen[9] and Kristian Stengaard-Pedersen[1]. [1]Arhus University Hospital, Aarhus, Denmark, [2]Aalborg University Hospital, Aalborg, Denmark, [3]University of Southern Denmark, Odense, Denmark, [4]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [5]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark, [6]Copenhagen University at Gentofte, Hellerup, Denmark, [7]The Danish Rheumatologic Database (DANBIO), Glostrup Hospital, Copenhagen, Denmark, [8]Odense University Hospital, Odense, Denmark, [9]Diagnostic Centre Region Hospital Silkeborg Denmark, 8600 Silkeborg, Denmark.

Background/Purpose: Single nucleotide polymorphisms (SNPs) in the *CRP* gene are implicated in the regulation of the basal C-reactive protein (CRP) expression and its response to pro-inflammatory stimuli. Previous reports suggest these effects may have an impact on clinical decision-making based on CRP, e.g. DAS28 (1). We aimed to investigate for the first time the possible association between 7 SNPs in the *CRP* and the serum level of CRP/ DAS28 in a cohort of 180 untreated inflammatory active early RA patients

Methods: 180 DMARD naïve RA patients with disease duration <6 months were included in a randomized double blind placebo-controlled trial (OPERA-study,NCT00660647) of methotrexate, intraarticular glucucorticoids + either adalimumab or placebo. SNPs were analyzed by the TaqMan OpenArray system. The 7 SNPs (Table 2) were selected based on previously reported effects on CRP levels(1). CRP was measured using CRP QUICK-READ (range 8–160 mg/l). The associations between SNPs (and haplotypes of SNPs) and CRP and DAS28 levels were evaluated using linear regression analysis adjusted for age, sex and treatment. For the analysis of genotypic and haplotypic effects, the common allele homozygous genotype/haplotype was selected as reference, and the effects are presented as percentage. 'Haplo.stats' package for R was used

Results: Baseline characteristics were similar in the two groups, Table 1. There were no significant genotypic or haplotypic effects of the 7 SNPs on CRP levels at baseline or one year (P≥0.080). Homozygosity for the minor allele of rs2808632 reduced borderline significant the baseline DAS28 levels to 54% P=0.055, and heterozygosity for rs1800947 increased DAS28 levels at one year to 158% P=0.03. Six haplotypes were constructed encompassing 94% of the cohort, Table 3. The H4 haplotype reduced baseline DAS28 score to 51% P=0.009, and the H6 haplotype increased the DAS28 score at one year to 168% P=0.02. No further haplotypic effect on DAS28 were observed at baseline or one year.

Table 1. Patient characteristics

	OPERA Placebo treated group (n=91)	OPERA Adalimumab treated group (p=89)	P value
Patient characteristics			
Female sex	69%	63%	0.46
Age, years	54 (28–77)	56 (26–78)	0.71
Disease duration, days	83 (42–150)	88 (42–162)	0.74
Anti-CCP positive	70%	60%	0.17
IgM-RF positive	74%	70%	0.67
DAS28	5.6 (3.8–7.3)	5.5 (3.8–7.8)	0.53
C-reactive protein, mg/l	15 (7–109)	15 (7–133)	0.54
Tender joint count(28)	11 (3–24)	10 (3–27)	0.78
Swollen joint count(28)	8 (2–22)	8 (2–26)	0.66
VAS-patient global, mm	65 (17–96)	70 (12–100)	0.27
Baseline x-ray erosions (ES≥1)	52%	54%	0.94
Disease activity, 1 year			
DAS28	2.6 (1.7–4.7)	2.0 (1.7–5.2)	0.009
C-reactive protein, mg/l	7 (7–44)	7 (7–21)	0.21

Values are medians with 5–95% percentile values in parentheses, unless otherwise stated. Anti-CCP = anti-cyclic citrullinated peptide, RF = rheumatoid factor, DAS28 = disease activity score 28 joints, VAS = visual analogue scale, ES = Sharp/van der Heijde Erosion Score.

(#) The 7 SNPs defining the 6 haplotypes are listed as follows (rs11265257, rs1130864, rs1205, rs1800947, rs2808632, rs3093077, rs876538). ref.=reference

Conclusion: Seven selected *CRP* gene SNPs had no impact on pre- and one year post-treatment levels of CRP. Minor genotypic and haplotypic effects on DAS28 scores were observed, but these were not consistent between baseline and one year. This study shows that DAS28 can be used for clinical decision-making without adjustment for *CRP* gene variants.

The Frequency Of Single Nucleotide Polymorphisms In Urate Transporter Genes and Their Association With Uric Acid Concentration Based On Data From Genome-Wide Association Studies In The Korean Population. Chan-Nam Son[1], So-Young Bang[2], Sang-Cheol Bae[1] and Jae-Bum Jun[1]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Hanyang University Guri Hospital, Guri, South Korea.

Background/Purpose: Gouty arthritis is characterized by hyperuricemia, which results from overproduction of, or impaired renal excretion of, uric acid. Recently, interest has increased in renal urate transporters, which control the excretion of uric acid. Genome-wide association studies (GWASs) are now identifying risk alleles among renal urate transporter genes. At present, few studies of factors affecting uric acid regulation have been conducted on Koreans. We therefore aimed, first, to investigate the minor allele frequencies (MAFs) of single nucleotide polymorphisms (SNPs) associated with serum uric acid (SUA) level in the Korean population, and compare these with data from other ethnic groups (Study 1). Second, to investigate whether the SNPs are associated with altered SUA levels (Study 2).

Methods: Study 1: We used datasets derived from two available GWASs. The first study was the Korean RA GWAS, including 800 rheumatoid arthritis (RA) cases and 757 controls, and the second was Korean systemic lupus erythematosus (SLE) GWAS, comprising 400 SLE cases (a total of 1957 subjects). We explored the GWAS results already obtained from subjects without gout to examine the frequencies of risk alleles, and investigated the MAFs of 40 previously described SNPs associated with SUA level in the Korean population, and compared results with data for other ethnic groups. Study 2: A total of 402 RA subjects satisfying the inclusion and exclusion criteria were selected from Study 1. The representative value of SUA level in this study was determined by the highest value among SUA levels, obtained by searching the medical records of subjects in the GWAS from December 2000 to October 2012. Subjects with renal insufficiency as well as SLE patients were excluded. Also, we used the highest SUA values obtained before use of drugs that could increase SUA concentrations, such as antituberculosis medication. We analyzed associations with serum uric acid concentrations based on data from GWASs in the Korean population, and also tested whether polymorphism of any of the 40 SNPs associated with SUA identified previously were associated with SUA levels.

Results: Study 1: We compared the MAFs of 13 SNPs in Koreans with those in other ethnic groups. Overall, the MAFs of SNPs associated with SUA level in the Korean population were quite similar to those among Japanese, but not in populations of European descent. Study 2: SNP rs12734001 (PPP1R12B) proved to have the most probable association with SUA concentrations (P_trend $= 2.29 \times 10^{-9}$). We also analyzed 13 SNPs shown previously by meta-analysis to be associated with SUA, and SNP rs3741414 (INHBC) was found to have ther strongest association with SUA level observed in the present study (P_trend $=$ 0.01).

Conclusion: The pattern of variants controlling SUA levels in the Korean population is quite similar to that in the Japanese population, but not in populations of European descent. SNP rs12734001 (PPP1R12B) is significantly associated with SUA level, and SNP rs3741414 (INHBC), previously identified SNP, is strongly associated with SUA levels among Koreans.

Haptoglobin Chains As Potential Biomarkers In Serum Of Osteoarthritis Disease. Carolina Fernandez-Costa[1], Valentina Calamia[1], Patricia Fernandez-Puente[1], Jesus Mateos[1], Beatriz Rocha[1], Lucia Lourido[1], Jose Luis Capelo[2], Cristina Ruiz-Romero[3] and Francisco J. Blanco[1]. [1]Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-ISCIII, INIBIC-CHUAC, A Coruña, Spain, [2]BIOSCOPE Group, REQUIMTE, Departamento de Química, Faculdade de Ciências e Tecnologia, FCT, Universidade Nova de Lisboa,, Caparica, Portugal, [3]CIBER-BBN, INIBIC-CHUAC, A Coruña, Spain.

Background/Purpose: The aim of this study is to search for osteoarthritis (OA) biomarkers in human serum using an easy and fast approach and the validation of the potential biomarkers found with two independent methods.

Methods: The serum samples for the biomarker discovery experiment were obtained from 20 OA patients and 20 non-symptomatic controls. Samples were grouped into four pools of 10 samples each. The pools were subjected to a chemical sequential depletion protocol to reduce the high dynamic range of the proteins. Then, the proteomics comparison between OA and control sera was performed across two dimensional difference in-gel electrophoresis (2D-DIGE) experiment. The quantitative image analysis was performed using Same Spots software. For protein identification, gel spots were digested and analyzed by mass spectrometry (MALDI-TOF/TOF) and identified using Mascot with SwissProt knowledgebase.

Haptoglobin chains validation was performed with two different methods, immunoblotting and multiple reaction monitoring (MRM) technology with the QTRAP mass spectrometer.

Results: We studied the combination of a chemical sequential depletion method combined with 2D-DIGE for the search of OA biomarkers in 40 serum samples. The analysis resulted in 46 spots significantly and reproducibly altered between OA and control samples (29 increased and 17 decreased). These 46 spots correspond to 14 different proteins, Table 1. The most interesting result was the modulation of the protein haptoglobin (HPT), three different spots were opposite modulated and were identify as the three chains of haptoglobin. In human, HPT exists in two allelic forms that produce three known phenotypes. The presence of the different alpha chains in patients depends on which phenotype their express. Interestingly, HPT beta and HPT alpha-1 chains were increased in OA sera whereas HPT alpha-2 chain was decreased in OA sera versus control. Using western blot analysis and MRM mass spectrometry technique on 30 new individual samples from OA and control donors (15

from each condition), we confirmed the different modulations of the alpha and beta HPT chains.

Table 1. Proteins identified in this work as altered in Osteoarthritis (OA) vs Control (N) sera.

Protein ID	Proteins increased in OA	Ratio OA:N
A1AT	Alpha-1-antitrypsin	1,4
FETUA	Alpha-2-HS-glycoprotein	2
ANGT	Angiotensinogen	1,1
APOA1	Apolipoprotein A-I	2,2
HPT	Haptoglobin beta chain	2
HBB	Hemoglobin subunit beta	1,6
A2GL	Leucine-rich alpha-2-glycoprotein	1,5
TTHY	Transthyretin	2,2
HPT	Haptoglobin alpha-1 chain	1,4
	Proteins decreased in OA	
APOA2	Apolipoprotein A-II	0,7
APOA4	Apolipoprotein A-IV	0,6
APOC3	Apolipoprotein C-III	0,8
HPT	Haptoglobin alpha-2 chain	0,5
IGKC	Ig kappa chain C region	0,6
LAC2	Ig lambda-2 chain C regions	0,6
SAA	Serum amyloid A protein	0,8

Conclusion: We were able to identified 16 protein forms altered in the disease (9 increased and 7 decreased), and we verified for the first time the OA- dependent alteration of the haptoglobin chains. The haptoglobin protein provides two different OA biomarkers easily to measure in serum samples at the same time.

New Insights Into The Metabolic Origin Of Osteoarthritis. Ignacio Rego-Pérez[1], María Eugenia Vázquez-Mosquera[1], Angel Soto-Hermida[1], Mercedes Fernández-Moreno[1], Juan Fernández-Tajes[1], Estefanía Cortés-Pereira[1], Sara Relaño-Fernández[1], Natividad Oreiro-Villar[1], Carlos Fernández-López[1] and Francisco J. Blanco[2]. [1]INIBIC-Hospital Universitario A Coruña. Rheumatology Division. Genomic Group, A Coruña, Spain, [2]INIBIC-Hospital Universitario A Coruña, A Coruña, Spain.

Background/Purpose: Metabolic alterations take place in osteoarthritis (OA) and the mtDNA haplogorups influence the prevalence and severity of the disease. The aim of this work is to analyze the metabolic behavior in OA from different points of view, including the analysis of gene polymorphisms, mitochondrial variants and gene expression.

Methods: The first approach consisted in the analysis of the influence of the mtDNA haplogroups in the body mass index (BMI) in a cohort of 638 OA patients and 474 healthy controls from Spain. This approach was followed by a second one that included the analysis of the expression levels of genes related to both lipid and glucose metabolism in RNA isolated from 24 OA and 22 healthy normal (N) cartilage samples; for this purpose we also used the chondrocyte cell line TC28a2 in order to analyse the glucose overload (at 1, 4.5 and 18 g/l) during 48 hours in the expression levels of these genes as well as of both MMP-3 and IL-6; finally, we search for possible interactions between the mtDNA haplogroups and the SNP -866C/T (rs659366) in the promoter region of UCP2 to assess their incidence in the prevalence of OA in a cohort of 137 OA patients and 133 healthy controls from Spain. Nucleic acid isolation was carried out using commercial kits following the manufacturer recommendations with some modifications. Appropriate data analysis was performed with SPSS software (v19) and qBase plus software (Biogazelle).

Results: The mtDNA haplogroup J and OA are independently associated with BMI, so that carriers of this mitochondrial variant show significant lower BMI values ($p=0.006$) meanwhile OA patients show significant higher values ($p<0.001$), being the BMI a risk factor for OA. The obtained OA/N expression ratio of GLUT1 (0.8 ± 0.26), GLUT3 (0.73 ± 0.01), GLUT5 (0.68 ± 0.19), HK1 (1.09 ± 0.02), HK2 (1.59 ± 0.21), INSR (0.99 ± 0.08), CPT1B (1.30 ± 0.1), ACADM (2.65 ± 0.36), HADHB (1.68 ± 0.09), PPARg (0.61 ± 0.11), PPARa (1.41 ± 0.33) did not show significant differences ($p > 0.05$). However, a significant increased expression of UCP2 (3.86 ± 0.12) as well as a decreased expression of PDK4 (0.20 ± 0.01) was detected in OA cartilage samples ($p<0.05$). Gene expression of OLR-1 was only observed in OA cartilage samples. The experiments of glucose overload carried out in the cell line TC28a2 showed a direct correlation between glucose concentration and the expression levels of UCP2 (correlation coefficient (c.c)$=0.965$; $p=0.102$), MMP-3 (c.c$=0.992$; $p=0.08$) and IL-6 (c.c$=0.996$; $p=0.05$) as well as an inverse correlation with PDK4 (c.c$=-0.914$; $p=0.265$). The analysis of the interaction between the mtDNA haplogroups and the SNP rs659366 showed that carriers of both haplogroups J or T (mtDNA cluster TJ) that also carry the T allele of rs659366 have a significant decreased risk of OA (OR$=0.581$; CI: 0.357 – 0.948; $p=0.029$).

Conclusion: This work provides strong evidence on metabolic alterations that occur in OA. These alterations involve the lipid and glucose metabolism, through the mitochondrial pathway, as well as the switch that modulates the balance between both metabolisms which, in turn, would lead to the increased inflammatory process that takes place in OA.

The Potential Role Of Protein Tyrosine Phosphatase Receptor D (PTPRD) Gene Copy Number Variation In Susceptibility To Rheumatoid Arthritis. Su Jin Yoo[1], Mi Kyoung Lim[2], Donghyuk Sheen[2], In Seol Yoo[1], Jinhyun Kim[1], Seong Wook Kang[1] and Seung-Cheol Shim[3]. [1]Chungnam National University School of Medicine, Daejeon, South Korea, [2]Eulji University Hospital, Daejeon, South Korea, [3]Chungnam National University Hospital, Daejeon, South Korea.

Background/Purpose: Since it is important to explore genetic variations associated with rheumatoid arthritis (RA), genome-wide association studies (GWAS) have led to the identification of RA genetic variants putatively associated with susceptibility. Recently, copy number variation (CNV) may also affect susceptibility to diseases, which have been already observed in diverse autoimmune diseases. Protein tyrosine phosphatase receptor D (PTPRD) is a member of the receptor-like PTP which expresses in the B cell lines and thymus and could be involved in the pathogenesis of autoimmune diseases. In this study, we investigated whether the variation of the *PTPRD* gene copy number related with susceptibility to RA.

Methods: To investigate whether the variation of the *PTPRD* gene copy number influence the pathogenesis to RA, blood samples and clinical records were obtained from 217 RA patients (184 females, 33 males) and 205 healthy controls. The genomic DNA of RA patients and healthy controls was extracted from leukocytes in peripheral blood using the Genomic DNA Extraction kit (iNtRON Biotechnology, Korea). To measuring the copy number of *PTPRD* gene, the quantitative real-time PCR (QPCR) was carried out using Mx3000P QPCR system (Stratagene, La Jolla, CA) and each sample for each gene was assayed in triplicate. Western blot was conducted to detect expression levels of *PTPRD*.

Results: The copy number of *PTPRD* gene in RA patients was compared with that in healthy controls. The proportion of the individuals with <2 copy of *VPREB1* was significantly higher in patients than in controls, while that of the individuals with >2 copy was lower in patients than in controls. The average relative copy number of the *PTPRD* gene in RA patients (1.14, 95 % CI (1.12–1.16)) was significantly lower than that in healthy controls (1.65, 95 % CI (1.12–1.16), $p < 0.0001$). Furthermore, we also investigated association between copy number of *PTPRD* and RA phenotype such as RF factor and anti-CCP levels, which showed no association between copy number of *PTPRD* and both RA phenotypes. Western blot showed the lower expression of *PTPRD* in patients with RA compared to control subjects.

Conclusion: This is the first evidence showing the association between low copy number of the PTPRD gene and susceptibility to RA, which may help understanding the pathogenesis of RA and other autoimmune disorders like affecting maturation and differentiation of T cell and B cells.

Association Of Functional Polymorphisms In *IRF2* With Systemic Lupus Erythematosus In a Japanese Population. Aya Kawasaki[1], Hiroshi Furukawa[2], Nao Nishida[3], Eiji Warabi[1], Yuya Kondo[1], Satoshi Ito[4], Isao Matsumoto[1], Makio Kusaoi[5], Akiko Suda[6], Shouhei Nagaoka[7], Keigo Setoguchi[8], Tatsuo Nagai[9], Shunsei Hirohata[9], Katsushi Tokunaga[10], Yoshinari Takasaki[5], Hiroshi Hashimoto[11], Takayuki Sumida[1], Shigeto Tohma[2] and Naoyuki Tsuchiya[1]. [1]University of Tsukuba, Tsukuba, Japan, [2]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan, [3]National Center for Global Health and Medicine, Ichikawa, Japan, [4]Niigata Rheumatic Center, Shibata, Japan, [5]Juntendo University, Tokyo, Japan, [6]Yokohama City University, Mecical Center, Yokohama, Japan, [7]Yokohama Minami Kyousai Hospital, Yokohama, Japan, [8]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan, [9]Kitasato University School of Medicine, Sagamihara, Japan, [10]The University of Tokyo, Tokyo, Japan, [11]Juntendo University School of Medicine, Tokyo, Japan.

Background/Purpose: Interferon regulatory factor (IRF) families are transcription factors involved in type I interferon (IFN) pathway. Recent genetic studies identified association of IRF family genes, *IRF5*, *IRF7*, and *IRF8*, with systemic lupus erythematosus (SLE). IRF2 is thought to negatively regulate the type I IFN signals. In addition, IRF2 has a role in induction of Th1 differentiation and NK cell development. So far, association of *IRF2* with SLE has not been published. In this study, we conducted an association study to examine whether *IRF2* contributes to susceptibility to SLE in a Japanese population.

Methods: A case-control association study was performed in 501 Japanese patients with SLE and 551 healthy controls on 46 tag SNPs in the *IRF2* gene, selected based on linkage disequilibrium (LD) and minor allele frequencies ($r^2 \geq 0.8$, minor allele frequency≥ 0.05), using the DigiTag2 and the TaqMan allele discrimination assays. To identify functional SNPs, resequencing of the *IRF2* region was performed using the next-generation sequencing. Effect of *IRF2* SNPs on transcriptional activity was analyzed using a luciferase assay.

Results: Among the *IRF2* tag SNPs, rs13146124T in intron 1 was most significantly associated with SLE (dominant model, $P=7.4\times10^{-4}$, odds ratio [OR] 1.60, 95% confidence interval [CI] 1.22–2.11). Resequencing identified SNPs in LD with rs13146124. Eight SNPs including rs62339994 were in almost absolute LD with rs13146124 (r^2: 0.98–1), whereas rs66801661 showed moderate LD (r^2: 0.52).

We next examined association of rs66801661 with SLE. rs66801661A allele was significantly increased in SLE (allelic model, $P=3.7\times10^{-4}$, OR 1.75, 95%CI 1.29–2.39). Haplotype analysis identified three haplotypes constituted by rs66801661 and rs13146124, and the haplotype carrying both of the risk alleles, rs66801661A - rs13146124T, was significantly increased in SLE (SLE: 10.8%, control: 6.4%, permutation $P=2.0\times10^{-4}$). On the other hand, the haplotype formed by the non-risk alleles, rs66801661G - rs13146124C, was decreased in SLE (SLE: 83.1%, control: 87.9%, permutation $P=0.0014$).

To examine the functional significance of the risk haplotype, *IRF2* region containing the promoter region, exon 1 and the 5' part of intron 1 encompassing rs66801661 and rs62339994, which was in tight LD with rs13146124, were inserted upstream of the luciferase gene. Three constructs corresponding to the naturally-occurring haplotypes were transfected, and the luciferase activities were compared. The construct carrying both of the risk alleles, rs66801661A and rs62339994A (in LD with rs13146124T), was associated with the highest transcriptional activity in Jurkat cells under IFNγ stimulation (ANOVA, $P=1.3\times10^{-4}$).

Conclusion: *IRF2* polymorphisms are associated with susceptibility to SLE in a Japanese population. The SLE risk haplotype appeared to be associated with transcriptional activation of *IRF2*.

Predicting The Severity Of Joint Damage In Rheumatoid Arthritis; The Contribution Of Genetic Factors. Hanna W. van Steenbergen, Roula Tsonaka, Tom W.J. Huizinga, Saskia le Cessie and Annette H.M. van der Helm-van Mil. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: The severity of radiologic progression is variable between rheumatoid arthritis (RA) patients. Recently several genetic severity variants have been identified and replicated. This study determined the contribution of the established genetic severity factors to the explained variance in radiologic progression and evaluated whether genetic factors, in addition to traditional clinical and serological risk factors, improved the accuracy of predicting the severity of radiologic progression.

Methods: 417 early RA patients with yearly radiologic follow up were studied. The main outcome measure was the progression in Sharp-van der Heijde scores (SHSs) over six years. Genetic variants in the following genes were studied: HLA-DRB1, CD40, IL-15, DKK-1, IL2RA, GRZB, IL-4R, SPAG16, C5orf30, MMP-9 and OPG. Linear regression analyses were used to determine the explained variance and the net improvement in reclassifications of prediction models without and with genetic risk factors. For studying reclassification, the continuous outcome was categorized based on the severity of radiologic progression in progression in SHSs over six years $\leq$6, 7–30 and $>$30 units, indicating mild, moderate and severe radiologic progression.

Results: Treatment effects and a combination of traditional risk factors explained 7.1% and 31.2% of the variance in progression in SHSs over six years. The genetic factors together explained 18.1%. When added to treatment effects and traditional factors, the genetic risk factors additionally explained 7.4% of the variance. Compared to a prediction model without genetic factors, a prediction model also including genetic factors yielded a net correct reclassification of 5.9% of the patients; now 62% of those patients were correctly classified. Thus with a model including known traditional and genetic factors 38.1% of the patients were still not correctly classified. Evaluating the reclassifications per severity group, the net percentages of patients that were additionally correctly classified were 0%, 5.1% and 13.2% for the groups with mild, moderate and severe progression respectively. Hence, including genetic factors led to improved identification of patients with severe radiological progression in particular. Sensitivity analyses using imputation of missing radiographs yielded comparable results.

Conclusion: When added to a model consisting of traditional factors, genetic risk factors improved the predictive accuracy. Nonetheless, the predictive performance was still insufficient for use in clinical practice.

Effects Of Chondroitin Sulfate On The Gene Expression Profile In Interleukin-1β Stimulated Synovial Fibroblast Cells Cultures. Cécile Lambert[1], Jean-Emile Dubuc[2], Eulalia Montell[3], Josep Verges[3] and Yves Henrotin[1]. [1]Bone and Cartilage Research Unit, Liège, Belgium, [2]Orthopaedic Department, Bruxelles, Belgium, [3]Pre-Clinical R&D Area, Pharmascience Division, BIOIBERICA S.A., Barcelona, Spain.

Background/Purpose: Chondroitin sulfate (CS) is one the most used molecules in the management of OA. Its mechanism of action remains to be detailed. In this study, we perform a microarray analysis to identify a differential expression profile between control and IL-1β stimulated synovial fibroblast cells cultures and to investigate the effects of CS on this gene expression profile

Methods: OA synovial specimens were obtained from 12 patients undergoing knee replacement. Synovial fibroblast cells (SFC) were enzymatically isolated and used after four passages (P4). SFC were pre-treated 1 hour with highly purified bovine CS (200 μg/ml, Bioibérica S.A., Barcelona, Spain) before treatment with IL-1β (1 ng/ml) for 24 hours. Gene expression profiling was performed using Illumina's multi-sample format Human HT-12 BeadChip (Illumina Inc.). Differential analysis was performed with the BRB array tools software. Class comparison test between control (Ctl) and interleukin (IL)-1β conditions, Ctl and Ctl/CS and IL-1β and IL-1β/CS conditions was based on paired t-test where Ctl and IL-1β, Ctl and Ctl/CS and IL-1β and IL-1β/CS were paired for each patient. The biological relevance of regulated genes was analyzed with Ingenuity Pathways Analysis (Ingenuity® Systems). Probes with a p-value below 0.001 were chosen and classified as up- or down-regulated.

Results: 3308 genes were identified as differentially expressed genes between Ctl and IL-1β conditions. A differential profile of expression of major pathways involved in OA pathogenesis was observed. In the inflammatory network, the most upregulated cytokines were IL-8 and IL-6 (fold change: 156.25 and 58.8 respectively). We identified several chemokines, enzymes and metallothioneins (MTs). Complement factor B (CFB) and complement component 3 (C3) are two factors upregulated in the inflamma-

tory complement cascade. We identified some genes implicated in the angiogenesis pathway. The most upregulated was Stanniocalcin 1 (STC1) (fold change: 9.09). The differential expression of intermediates in cartilage anabolism and catabolism revealed an imbalance in favour of catabolism. MMP-3 was largely upregulated (fold change: 62.5). Wnt 5A and low density lipoprotein receptor-related protein (LRP8) were significantly upregulated while frizzled homolog 2 (FZD2) and dickkopf homolog 3 (DKK3) were downregulated in the Wnt signaling. The class comparison test highlighted 660 differentially expressed genes between Ctl and Ctl/CS conditions and 241 genes between IL-1β and IL-1β/CS. Among them, our attention was focused on two genes upregulated in the presence of CS: lysyl oxidase-like 4 (LOXL4) and claudin 11 (CDLN11), two genes that negatively regulate cell invasion.

Conclusion: We here evidenced in synovial fibroblast cells the modulation of gene expression following IL-1β stimulation. We also demonstrated the modulatory effects of CS on gene expression and isolated several CS-modulated genes of interest such as LOXL4 and CDLN11, which could constitute new mechanisms of action of the molecule and contribute to explain the symptomatic efficacy of CS in the treatment of OA.

Association Of BMI, 8 SNPs Reported To Be Related To Gout Phenotype and Their Interaction In Gout Incidence In Framingham Heart Study. Jasvinder A. Singh[1], Ana Vazquez[2], Richard Reynolds[2], Vinodh Srinivasasainagendra[3], S. Louis Bridges Jr.[2] and David Allison[2]. [1]University of Alabama, Tuscaloosa, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of alabama at birmingham, birmingham, AL.

Background/Purpose: We aim to assess the association of 8 serum urate SNPs and BMI and their interactions with incident gout in a population-based cohort study.

Methods: We used the Framingham Study including subject from the Original and the Offspring cohort (N=4,967). We assessed the effect of 8 SNPs in the recently described genetic urate score on incident gout. Subjects were genotyped with Affy500K platform, and two of the SNPs associated to gout rs1165196 and rs1106766 were present in that platform. The SNPs rs1967017, rs780093, rs13129697, rs2199936, rs675209 and rs2078267 were not present in the Affy SNP array, thus we imputed them with IMPUTE2. BMI was taken at the time of gout or, at the time of censoring if the subject is healthy or died without gout. We fitted logistic regression models to assess the associations. Estimated effects in the liability scale, odd ratios, and p-values are reported for all SNPs, covariates, and interactions. 408 patients had incident gout (74% males), with 169 from the FHS original cohort and 293 from the Offspring cohort.

Results: In a model with main effects of BMI and SNPs, three of eight SNPs and BMI were significantly associated with incident gout ($p<=0.008$ for all). Zero SNPs showed significant main effects on gout in the model that adjusted for all BMI*SNP interaction terms. However, BMI remained significant ($p=0.003$) and the rs2199936*BMI interaction was nearly significant ($p=0.06$). Gender and duration of follow-up were also significant predictors ($p<=0.009$) in all models.

Conclusion: SNPs known to predict urate levels moderated the association of BMI with gout, suggesting the possibility that the extent to which BMI increases the risk for got may depend on a person's a priori genetic risk for high urate levels.

Effects Of Chondroitin Sulfate On The Gene Expression Profile In The Inflamed Synovial Membrane. Cécile Lambert[1], Jean-Emile Dubuc[2], Eulalia Montell[3], Josep Verges[3] and Yves Henrotin[1]. [1]Bone and Cartilage Research Unit, Liège, Belgium, [2]Orthopaedic Department, Bruxelles, Belgium, [3]Pre-Clinical R&D Area, Pharmascience Division, BIOIBERICA S.A., Barcelona, Spain.

Background/Purpose: Chondroitin sulfate (CS) is one the most used molecules in the management of OA. Its mechanism of action remains to be detailed. The aim of the present work is to identify the differentially expressed genes between the inflammatory (I) and normal/reactive (N/R) synovial areas using a unique ex vivo culture model and to investigate the genetic modulatory effects of CS in this model.

Methods: Synovial cells (SC) were isolated from OA synovial specimens from 12 patients undergoing knee replacement. The synovial membrane was dissected and SC from N/R and I areas cultured separately for a period of 7 days with or without highly purified bovine CS (200 μg/ml, Bioibérica S.A., Barcelona, Spain). Gene expression profiling was performed using Illumina's multi-sample format Human HT-12 BeadChip (Illumina Inc.). Differential analysis was performed with the BRB array tools software. Class Comparison test between N/R and I conditions, N/R and N/R-CS conditions and I and I-CS conditions was based on paired t-test where N/R and I, N/R and N/R-CS and I and I-CS were paired for each patient. The biological relevance of up- and down-regulated genes was analyses with Ingenuity Pathways Analysis (Ingenuity® Systems).

Results: From among 47000 probes, 18253 were filtered out. Probes with a p-value below than 0.005 were chosen and classified as up- or down-regulated ones. By this way, 465 differentially expressed genes between N/R and I areas were identified. Many inflammatory mediators appear differentially expressed. The interferon alpha-inductible protein 6 (IFI6) was the most up-regulated. We also identified the hydroxysteroid (11-beta) dehydrogenase 1 (HSD11B1), the cathepsin K (CTSK), the chemokine (C-X-C motif) ligand 1 (CXCL1) and the EBV-induced G-protein coupled receptor 2 (EBI2). The differential expression of intermediates involved in angiogenesis pathway was also revealed between N/R and I areas. Among them, R-spondin-3 (RSPO3), the secreted phopshoprotein 1 (SPP1) and aquaporin 9 (AQP9) were up-regulated whereas ADAMTS1 was down-regulated. Finally, in the Wnt signaling, RSPO3 was up-regulated unlike dickkopf homolog 3 (DKK3) which was in turn down-regulated. We next performed a class comparison test between N/R and N/R-CS in one hand and between I and I-CS the other hand. 489 genes were identified as differentially expressed genes between N/R and N/R-CS conditions while 219 genes were identified between I and I-CS conditions. In this latter, our attention was focused on the down-regulated genes. Among them, we identified a number implicated in angiogenesis and cell migration pathways. Thus, the endothelial cell-specific molecule-1 (ESM1), the Transmembrane-4-L-six-family-1 (TM4SF1), the 5'-Ectonucleotidase (NT5E) and the growth arrest-specific gene 6 (GAS6) were down-regulated by CS.

Conclusion: Our work demonstrates the differential gene expression profile between paired inflammatory and normal/reactive areas of synovial membrane as well as the modulatory effects of CS on gene expression in the inflammatory areas, especially regarding genes involved in both angiogenesis and cell migration.

Transcript Profiling Of Kidney Biopsies From Chinese Patients With Lupus Nephritis Suggests a Prevalence Of Infiltrating CD8+ T Cells, Monocytes/Macrophages, and B Cells In ISN/RPS Class IV Disease. Zheng Liu[1], Chris Morehouse[1], Xinfang Huang[2], Philip Brohawn[1], Nan Shen[3], Gabor G. Illei[1], Yihong Yao[1] and Brandon W. Higgs[1]. [1]MedImmune, LLC, Gaithersburg, MD, [2]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, [3]Cincinnati Children's Hospital Medical Center, cincinnati, OH.

Background/Purpose: Lupus nephritis (LN) affects ~60% of patients with systemic lupus erythematosus (SLE). The International Society of Nephrology and the Renal Pathology Services (ISN/RPS) classification system categorizes LN into 6 main classes based on the underlying renal pathology. Among these, Classes I and II rarely require immunosuppressive treatment and Class-VI is associated with irreversible glomerulosclerosis. Class-IV (diffuse proliferative nephritis) is the most severe form with the largest proportion of all diagnosed cases (~40%) followed by Class-III (focal proliferative nephritis), representing ~25% of all diagnosed cases. These classes have similar histopathological and clinical characteristics while Class-V (membranous nephritis) representing ~10% of LN cases is different both in its clinical course and histological appearance. We examined kidney biopsies from a group of ISN/RPS Class III, IV, and V LN subjects to evaluate molecular differences between these classes.

Methods: Kidney biopsies were procured from 6 healthy donor (HD) and 25 LN (8 Class-III, 6 Class-IV, and 11 Class-V) Chinese subjects. The

Affymetrix U133+ array was used to transcript profile specimens. Fold changes were calculated for each LN subject relative to the average HD expression. Previously defined cell type-specific gene signatures were identified to be differential between ISN/RPS classes.

Results: Several gene signatures were significantly over-expressed ($p<0.05$) in Class-IV subjects relative to both Class-III and -V subjects. These included: a chemokine, MHC class I, monocyte, macrophage, and CD8+ T cell gene signatures. An immunoglobulin (Ig) signature was also significantly over-expressed in Class-IV subjects compared to Class-V subjects, but not Class-III subjects. The following gene signatures did not significantly differ between the three classes: neutrophil, CD4+ T cell, and type I IFN.

Conclusion: Transcript profiling was used to correlate the molecular differences between LN disease classifications and cell infiltrate prevalence. In addition to pathways upregulated in all three forms of LN, we identified cell type-specific signatures which were over-expressed in Class-IV. The increased CD-8+ signature suggests that CD8+ effector T cell infiltration may correlate with more active disease status. Monocytes/macrophages are also more prevalent in this more active disease class, suggesting an increase in infiltration from damage caused by these CD8+ T effector cells, which may also lead to an increase in Ig products.

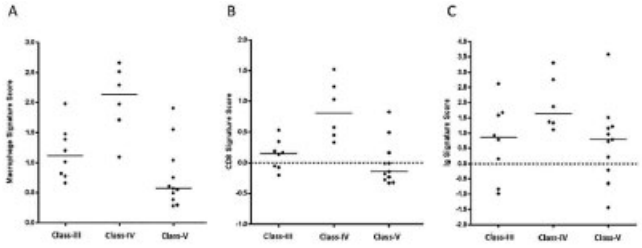

Figure 1. Distribution of A) macrophage, B) CD8+ T cell, and C) Ig gene signatures for LN patients with Class-III, -IV, or -V disease.

***HLA-DRB1*08:02* Is Associated With Bucillamine-Induced Proteinuria In Japanese Rheumatoid Arthritis Patients: A Case-Control Study.** Hiroshi Furukawa[1], Shomi Oka[1], Kota Shimada[2], Shoji Sugii[2], Atsushi Hashimoto[1], Akiko Komiya[1], Naoshi Fukui[1], Taiichiro Miyashita[3], Kiyoshi Migita[3], Akiko Suda[4], Shouhei Nagaoka[5], Naoyuki Tsuchiya[6] and Shigeto Tohma[1]. [1]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan, [2]Tokyo Metropolitan Tama Medical Center, Tokyo, Japan, [3]Nagasaki Medical Center, National Hospital Organization, Omura, Japan, [4]Yokohama City University, Mecical Center, Yokohama, Japan, [5]Yokohama Minami Kyousai Hospital, Yokohama, Japan, [6]University of Tsukuba, Tsukuba, Japan.

Background/Purpose: Bucillamine (Buc) is one of the commonly used disease-modifying anti-rheumatic drugs (DMARDs) in Japan. Drug-induced proteinuria can occur in rheumatoid arthritis (RA) patients treated with Buc, and represents a drug hypersensitivity reaction. Striking associations of human leukocyte antigen (HLA) alleles with adverse reactions have recently been reported for many drugs.

Methods: We investigated the association of HLA class II with Buc-induced proteinuria (BI-Pro) in 485 Japanese RA patients treated with Buc, of which 25 had developed BI-Pro.

Results: This study showed a highly significant association of *DRB1*08:02* with BI-Pro ($P=1.09\times10^{-6}$, corrected P [Pc]$=1.96\times10^{-5}$, odds ratio [OR] 25.17, 95% confidence interval [CI] 7.98–79.38). *DQB1*04:02* was also significantly associated with increased risk of BI-Pro ($P=2.44\times10^{-5}$, $Pc=2.69\times10^{-4}$, OR 10.35, 95%CI 3.99–26.83).

Conclusion: We detected striking HLA class II associations with proteinuria induced by Buc in Japanese RA patients. This association merits confirmation in future large-scale studies for its potential clinical usefulness as a biomarker to prevent adverse reactions.

Genetic Association On Disease Severity In Rheumatoid Arthritis: A Validation Study In Japanese Patients. Shinji Yoshida[1], Katsunori Ikari[1], Koichiro Yano[1], Yoshiaki Toyama[2], Atsuo Taniguchi[1], Hisashi Yamanaka[3] and Shigeki Momohara[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Keio University School of Medicine, Shinjuku, Japan, [3]Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: The disease severity of rheumatoid arthritis (RA) is objectively measured by radiographic joint destruction, which is reflective of the cumulative burden of inflammation. Recently, the heritability has been proven to be partly involved in progression of joint destruction in RA, and several genetic variants and gene-gene interactions have been reported to be associated with progression of joint destruction in European multi-cohort studies. However, the presence of genetic heterogeneity in RA susceptibility genes has been demonstrated in many population-based studies, and the genetic predisposition factors for progression of joint destruction remain to be poorly understood in Asian patients with RA. The purpose of this study was to identify genetic variants associated with progression of joint destruction in Japanese patients with RA.

Methods: This study included 865 Japanese patients with RA for whom Sharp/van der Heijde scores (SHS) of hands were available at a disease duration of 5 years. DNA samples of the subjects were obtained from the Institute of Rheumatology Rheumatoid Arthritis cohort study (IORRA) DNA collection. All of the patients who donated DNA samples consented to participate in this study in accordance with the process approved by the Tokyo Women's Medical University Genome Ethics Committee, and satisfied the American College of Rheumatology 1987 revised criteria for the classification of RA. Nine of the single nucleotide polymorphisms (SNPs) reported in European multi-cohort studies were selected and genotyped in the DNA samples: rs6821171, and rs1521761 which is in absolute linkage disequilibrium ($r^2=1$) with rs7667746, in *interleukin15 (IL15)*; rs8192916, in *granzyme B (GZMB)*; rs1896368, rs1896367, rs1528873, and rs10762715, in *Dickkopf-1 (Dkk-1)*; rs4792909, and rs6503475, in *sclerostin (Sost)*. SNP genotyping was performed by using the TaqMan fluorogenic 5' nuclease assay (Applied Biosystems, Tokyo, Japan). Univariate linear regression analyses were performed to examine the association of each SNP and several combinations of SNPs with progression of joint destruction in the first 5 years after onset of RA, calculated as SHS of hands at the 5-year disease duration. All SHS were log-transformed to obtain a normal distribution.

Results: Univariate linear regression analyses revealed that all of the SNPs and combinations of SNPs tested in this study were not associated with progression of joint destruction (Table 1).

Table 1

Gene	SNP	Allele (minor/major)	MAF	Tested model	β	P value
L15	rs6821171	C/A	0.30	additive	−0.05	0.48
				recessive	−0.13	0.36
	rs1521761	T/A	0.15	additive	−0.10	0.21
				recessive	−0.13	0.36
GZMB	rs8192916	A/G	0.45	additive	−0.01	0.91
				recessive	0.05	0.65
Dkk-1	rs1896368	A/G	0.42	additive	0.07	0.21
				recessive	0.12	0.16
	rs1896367	A/G	0.30	additive	−0.11	0.09
				recessive	−0.13	0.31
	rs1528873	C/A	0.22	additive	−0.07	0.28
				recessive	−0.02	0.90
Dkk-1	rs1528873	C/A	0.22	additive	−0.02	0.59
Sost	rs6503475	G/A	0.45			
	rs10762715	T/C	0.22	additive	0.01	0.78
	rs4792909	T/G	0.40			
	rs10762715	T/C	0.22	additive	0.02	0.59
	rs6503475	G/A	0.45			

Conclusion: Genetic variants in *IL15*, *GZMB*, *Dkk-1*, and *Sost* were not associated with progression of joint destruction in Japanese patients with RA.

These results indicate the presence of genetic heterogeneity in risk loci of progression of joint destruction in RA between Caucasian and Asian patients. The heritability of the rate of joint destruction might be different among ethnic populations.

Dynamics Of The Inflammatory Response In Rheumatoid Arthritis Patients Following Traumatic Injury: Insights From *In Vivo*, *In Silico*, and Single Nucleotide Polymorphism Studies. Rajaie Namas[1], Rami Namas[2], Harpreet Sagar[3], Felix Fernandez-Madrid[3], Timothy Billiar[2] and Yoram Vodovotz[2]. [1]Wayne State University/ Henry Ford Health System, Detroit, MI, [2]University of Pittsburgh, Pittsburgh, PA, [3]Wayne State University, Detroit, MI.

Background/Purpose: Both traumatic injury/hemorrhagic shock (T/HS) and rheumatoid arthritis (RA) are inflammatory diseases that are major sources of morbidity worldwide. We hypothesize that RA modifies T/HS-induced dynamic inflammatory networks, and that anti-inflammatory therapy for RA may modify T/HS-induced inflammation and outcomes. Accordingly, we sought to compare a prolonged time course of post-injury inflammatory mediators and outcomes in T/HS patients with or without RA.

Methods: From a cohort of 472 blunt trauma survivors studied following IRB approval, 12 patients diagnosed with seropositive RA according to 2010 ACR criteria (8 males and 4 females; age: 65±4; ISS: 17±1, receiving Methotrexate and tumor necrosis factor-a [TNF-a]-inhibitors) were matched with 12 non-RA control patients (8 males and 4 females; age: 68±4, ISS: 17±2). Serial blood samples were obtained from all patients (3 samples within the first 24 h and then daily from days 1 to 7 post-injury). Twenty-three plasma inflammatory mediators were assayed using Luminex™, along with NO_2^-/NO_3^- assayed using nitrate reductase, respectively. Statistically significant differences ($P < 0.05$) between both groups were determined using the two-way analysis of variance (ANOVA) followed by the Holm-Sidak *post hoc* test. *In silico* Dynamic Bayesian Network (DBN) inference was utilized to infer causal relationships among inflammatory mediators based on probabilistic measures. Human genomic DNA was isolated and amplified for known TNF-α, IL-6, IL-10, and IFN-γ single nucleotide polymorphisms (SNPs) using PCR, along with TLR4 (Asp299Gly and Thr300I1e) SNPs using gel-DNA sequencing.

Results: There was no statistical difference in the ICU length of stay, total length of stay, days on mechanical ventilation, and Marshall score (a measure of organ dysfunction) in RA vs. non-RA patients. Plasma levels of TNF-α, IL-6, IL-10, IL-17, MIG, MIP-1β, and NO_2^-/NO_3^-were significantly elevated within the 24 h in the RA group and up to day 7 when compared to the non-RA group. In contrast, plasma IP-10 and MCP-1 levels were significantly lower in the RA group within the first 24 h when compared to controls. DBN suggested that the inflammatory response in RA trauma patients is mainly driven by MIG, whereas MCP-1 drives the inflammatory response via forward-positive loops with IP-10 and MIG in non-RA patients. The incidence of all of the measured SNPs was not significantly different between trauma patients with or without RA.

Conclusion: To our knowledge, this is the first pilot study that characterizes the inflammatory response in RA patients following blunt trauma. Our analysis suggested that different cytokine patterns emerge, particularly in the early events post-injury, in RA patients independent of the injury severity score on admission. Network analysis points to MIG as a key driver of this process. Larger cohorts are needed to clarify the role that T/HS plays in RA disease activity and therapy.

Identification Of Major Histocompatibility Complex Class II Alleles Associated With Systemic Sclerosis Through Imputation Strategy. Jose Ezequiel Martin[1], Carmen P. Simeón[2], Norberto Ortego-Centeno[3], Patricia Carreira[4], Miguel A. Gonzalez-Gay[5], Nicolas Hunzelmann[6], Shervin Assassi[7], Filemon K. Tan[7], Frank C. Arnett[7], Xiaodong Zhou[7], T.R.D.J. Radstake[8], Maureen D. Mayes[7], Paul de Bakker[9], Javier Martin[10] and B. P. C. Koeleman[8]. [1]Instituto de Parasitología y Biomedicina López-Neyra, IPBLN-CSIC, Granada, Spain, [2]Hospital Valle de Hebron, Barcelona, Spain, [3]Hospital Clínico San Cecilio, Granada, Spain, [4]Hospital Universitario 12 de Octubre, Madrid, Spain, [5]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IFIMAV, Santander, Spain, [6]University of Cologne, Cologne, Germany, [7]University of Texas Health Science Center at Houston, Houston, TX, [8]University Medical Center Utrecht, Utrecht, Netherlands, [9]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [10]Instituto de Parasitologia y Biomedicina López-Neyra, IPBLN-CSIC, Granada, Spain.

Background/Purpose: Different alleles of MHC class II molecules have been associated either with risk to systemic sclerosis (SSc) or its subphenotypes. Due to the high cost of HLA typing, studies have been limited to small sample sizes, preventing definitive statements as to which HLA alleles are likely causal

Methods: We have imputed the MHC class I and II alleles of 2,296 cases and 5,356 controls from four countries with a method previously developed. Besides classical HLA alleles, we also imputed amino acid changes encoded by genetic variants within the different MHC molecules. We compared the frequencies of the different alleles between cases and controls for SNPs, amino acids and classical HLA alleles

Results: The accuracy of the imputations ranged from 84% to 94% depending on the alleles being imputed with an average of 92% for all alleles in both populations. We confirmed previous associations of HLA alleles with SSc or its auto-antibody positive subgroups (*e.g.* HLA-DRB1*0701, HLA-DPB1*1301, HLA-DRB1*1104, HLA-DQB1*0501). We define in deeper detail some of these associations down to the level of aminoacidic positions which affect epitope binding and relocate some previous SSc associations within auto-antibody positive subgroups. Furthermore, we describe new association of the HLA allele HLA-DRB1*0801 with the presence of anti-centromere auto-antibodies.

Conclusion: Our data indicate that most HLA associations are specific to the presence of auto-antibodies. Also, only MHC class II alleles are associated and not MHC class I.

Differences and Overlap Of Immunological Pathways Implicated In The Aetiology Of Anti-Citrullinated Peptide Antibody Positive and Negative Rheumatoid Arthritis. Sebastien Viatte[1], Paul Martin[2], Andrew Brass[3], Mark Lunt[4], Anne Barton[4] and Stephen Eyre[4]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [3]School of Computer Science, University of Manchester, Manchester, United Kingdom, Manchester, United Kingdom, [4]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom.

Background/Purpose: Genome-wide association studies have been successful in identifying single nucleotide polymorphisms (SNPs) associated with disease. However, previous studies have been under-powered to detect differences between anti-citrullinated peptide antibody (ACPA) positive and negative patients. Using a custom Illumina® Infinium® array, the RA Consortium for Immunochip (RACI) allows comprehensive analysis of disease associations in both ACPA positive and negative patients. Pathway analyses can identify whether a molecular pathway is associated with disease by testing for enrichment of genes associated with disease. This involves mapping SNP associations to genes, which can often be subjective.

Objectives: The objectives of this study, therefore, were to develop a robust workflow-based method to assign SNPs to genes and to compare the pathways significantly enriched in ACPA positive and negative patients.

Methods: Excluding HLA, the top 100 most associated SNPs from the Immunochip analysis were selected for ACPA positive patients along with the top 100 most associated SNPs from the ACPA negative analysis. Genes were assigned to these SNPs using a Taverna workflow which defines an associated region using SNPs in linkage disequilibrium (LD) with the associated SNP. This prevents the bias introduced by researchers assigning SNPs to 'biologically plausible' genes and provides a robust, reproducible method for assigning genetic associations to genes. These genes were subsequently tested for enrichment in PANTHER pathways and Gene Ontologies (GO) using the Expression Analysis tool to calculate an enrichment binomial probability. To correct for the enrichment of genes with immunological functions present on the Immunochip, the statistical significance of enrichment binomial probabilities was calculated by permutation.

Results: Overall we show that the proportion of pathways shared between the two RA serological subtypes is significantly larger than expected by chance, indicating a high degree of overlap. On the other hand, we identified some pathways specifically and significantly enriched in the ACPA positive gene list (Interleukin Signalling Pathway: permutation p-value for enrichment = 7.0E-03, while in ACPA negative p = 0.46) and in the ACPA negative gene list (Interferon-Gamma Signalling Pathway: p = 1.2E-03, while in ACPA positive p = 0.33).

Conclusion: This study provides the first comparative pathway analysis of RA serological subtypes based on large numbers of RA cases. The methods developed here present a quantitative framework to compare different diseases at the pathway level. The findings not only suggest shared processes between the two disease sub-groups, but also identify serotype-specific pathways.

Fc-Gamma Receptor Genetic Variation In Kawasaki Disease. Carline E. Tacke[1], Willemijn B. Breunis[2], Long T. Hoang[3], Eileen Png[3], Judy Geissler[2], Sietse Nagelkerke[2], Justine Ellis[4], Sonia Davila[3], Chiea Chuen Khor[3], Michael Levin[5], David Burgner[4], Chisato Shimizu[6], Jane C. Burns[6], Martin L. Hibberd[3] and Taco W. Kuijpers[2]. [1]Emma Children's Hospital/Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Sanquin Resarch and Landsteiner Laboratory (AMC), Amsterdam, Netherlands, [3]Genome Institute of Singapore, Singapore, Singapore, [4]Murdoch Childrens Research Institute, Parkville, Australia, [5]Imperial College London, London, United Kingdom, [6]UC San Diego, School of Medicine, La Jolla, CA. Abstract on behalf of the International Kawasaki Disease Genetics Consortium.

Background/Purpose: Kawasaki disease (KD) is a pediatric vasculitis of unknown etiology with a substantial genetic contribution to susceptibility. KD is complicated by coronary artery aneurysms in 25% of untreated patients. Intravenous immunoglobulin (IVIG), a polyclonal IgG preparation, decreases the aneurysm rate to <10%. In our recent GWAS, a functional variant in *FCGR2A* (131H>R; rs1801274) was associated with KD at genome-wide significance. *FCGR2A* encodes the Fc-gamma receptor (FcγR) IIa, one member of a family of glycoproteins on leukocytes that bind the Fc-domain of IgG. The balance between the various activating and a single inhibiting FcγR (FcγRIIb) determines the level of cell activation. Hence, altered FcγR expression may result in unbalanced immunity or autoinflammation. *FCGR2A* is located within the *FCGR2/3* gene cluster. This cluster contains extensive gene copy number variations (CNVs) and several important single nucleotide polymorphisms (SNPs). We hypothesized that CNV and additional SNPs within the *FCGR* locus, regulating gene transcription and expression of the FcγRs, may be important in KD susceptibility.

Methods: The *FCGR*-specific Multiplex-Ligation Probe-dependent Amplification (MLPA) assay was performed in 426 patients and 710 controls of Caucasian origin, and in 510 patient-parent trios of mixed ethnic origin. First, the association between *FCGR* genotype status (including CNV, *FCGR2A-131H>R, FCGR2A-27Q>W, FCGR2C-ORF* and *FCGR2B -386G>C)* and KD susceptibility was analyzed. Second, the genetic variation at the *FCGR2/3* locus was correlated to the expression of these genes. Transcriptional expression data (pre-IVIG acute and post-IVIG convalescent samples) were available in a subset of 169 patients.

Results: An increased allele frequency of the open-reading frame (ORF) of *FCGR2C* encoding an additional activating FcγRIIc was found in patients as compared to controls (OR 1.4 [95%CI 1.1–1.7], p=0.016). We also observed a significant overrepresentation of *FCGR2A-27Q>W* (OR 1.5 [95%CI 1.1–1.9, p=0.006) and the -386G>C promoter polymorphism of *FCGR2B* and *FCGR2C* (OR 1.5 [95%CI 1.1–1.9], p=0.004) in KD. No significant difference was found in the allele frequency of *FCGR2A-131H>R* in KD patients and controls (43.8% versus 45.4%, p=0.467). The frequency of CNV in the *FCGR2C, FCGR3A* and *FCGR3B* genes was not significantly different between the groups. A positive correlation was observed between gene expression and dosage of *FCGR2C, FCGR3A* and *FCGR3B*, which may affect the activating FcγRs expression level on leucocytes. Results of the patient-parent trios data using transmission disequilibrium tests (TDT) will be used for further validation of our fine-mapping studies on the *FCGR2/3* genes in KD.

Conclusion: A significant overrepresentation of *FCGR2C-ORF*, as well as *FCGR2A-27Q>W* and the *FCGR2B/C*-386G>C promoter polymorphisms, was observed in Caucasian KD patients compared to the controls. Genetic variation at the *FCGR2/3* gene cluster may lead to a shift in the balance towards the activating FcγRs and may therefore contribute to the development of the inflammatory response in KD.

The Association Between Single Nucleotide Polymorphism ABCG2 rs2231142 and Hyperuricemia: A Case-Control Study. Bingqing Zhang[1], Weigang Fang[2], Yun Zhang[2], Shufen Liu[2], Yuanjie Li[2] and Xuejun Zeng[2]. [1]Peking Union Medical College, Beijing, China, [2]Peking Union Medical College Hospital, Beijing, China.

Background/Purpose: The prevalence of hyperuricemia and gout in China increased markedly in the past decades. Genome-wide association studies in Caucasian population have identified multiple gene loci associated with hyperuricemia and gout, including single nucleotide polymorphism (SNP) of rs2231142 in the ABCG2 gene, which leads to an amino acid change from glutamine to lysine at position 141 of the membrane transporter. However, this association was not consistently observed in Asian population.

Methods: A case-control study was carried out to investigate the association between locus ABCG2 rs2231142 polymorphism and hyperuricemia in a Chinese cohort of faculty and staff members at an academic health center in Beijing. Blood samples were drawn and stored during their annual health examination in 2008. Physical examination and biochemical assay were performed for all participants at that time. Hyperuricemia was defined as serum urate ≥7 mg/dl in men or ≥6 mg/dl in women. Each case of hyperuricemia with glomerular filtration rate '30ml/min/1.73m^2 was matched with one or two controls that were randomly sampled from individuals with the same sex, age group, chronic kidney disease stage and body mass index classification as the case in the cohort. SNP rs2231142 was assayed for both cases and controls by amplification refractory mutation system polymerase chain reaction (ARMS-PCR) in 2013. Conditional logistic regression analysis was performed to study the association between SNP rs2231142 and hyperuricemia.

Results: A total of 198 subjects and 370 controls were identified in the cohort. The overall A allele frequency of the ABCG2 gene was 30.81% in the cohort, but it was significantly higher in the cases than the controls (38.38% vs. 26.76%, p<0.01). Compared to individuals with genotype CC, the Odds Ratios (ORs) of hyperuricemia in individuals with A allele (genotype AA + CA), genotype CA and AA were 2.89 (95% CI 1.91–4.37, p<0.01), 2.84 (95% CI 1.86–4.32, p<0.01) and 3.30 (95% CI 1.60–6.81, p<0.01), respectively. After adjustment of hypertension, hyperglycemia and dyslipidemia, the ORs of A allele, genotype CA and AA were 2.99 (95% CI 1.94–4.62, p<0.01), 2.99 (95% CI 1.93–4.66, p<0.01) and 2.99 (95% CI 1.39–6.48, p<0.01), respectively. Subgroup analysis showed the ORs of A allele, genotype CA and AA were higher in males (3.83, 3.62, and 6.34, respectively) than those in females (2.30, 2.34, and 2.04, respectively), but the interaction of allele and gender was not significant with OR 1.66 (95% CI 0.71–3.87, p=0.23).

Conclusion: ABCG2 SNP rs2231142 A allele is an independent risk factor of hyperuricemia in Chinese. The risk of hyperuricemia in individuals with A allele appears to be higher in males than that in females, but the interaction of allele and gender is not significant.

Familial Aggregation Of Female Premenopausal Gout –Monogenic, Polygenic Or Clinical Coincidence? Bingqing Zhang[1], Shufen Liu[2], Nuo Si[3], Yun Zhang[2] and Xuejun Zeng[2]. [1]Peking Union Medical College, Beijing, China, [2]Peking Union Medical College Hospital, Beijing, China, [3]Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China.

Background/Purpose: Primary gout is a multifactorial disease, in which genetic background and environmental factors interact with each other. Genetic predisposition is particularly prominent in those seemingly low risk patients, such as the young and females. Women usually do not have gout until menopause, with menses as one of the most well-known protective factors of gout and hyperuricemia. We have found a rare family with three female gout patients, all of whom developed gout before menopause. The concentration of female patient with gout before menopause in this family highly suggests the involvement of genetic factors. The aim of this study is to explore the genetic factors related to gout in this female premenopausal gout family.

Methods: Medical history, physical examination and laboratory work-up of this family were collected. Allele sharing examination and exon sequencing were carried out to study the causative genes of familial juvenile hyperuricemia nephropathy, including UMOD, RENIN, HNF1B and FJHN3, as well as HPRT1 of Lesch-Nyhan syndrome. Serum uric acid concentration quantitative trait locus ABCG2, SLC2A9, and SLC22A12 were screened by exon sequencing

Results: The family was composed of 4 generations and 21 members (figure 1). All three patients were females; none of the male members had gout or hyperuricemia. The proband (III-5) was a female patient who had gout at the age 28; she started allopurinol since the second attack, but her renal function deteriorated. Her mother (II-5) had recurrent acute monoarthritis since the age of 16; she was diagnosed with gout at the age of 38, with obvious decreased renal function. The aunt of the proband (II-1) had gout at the age of 46, when she still had menses. None of the three patients had other known disease prior to gout attack.

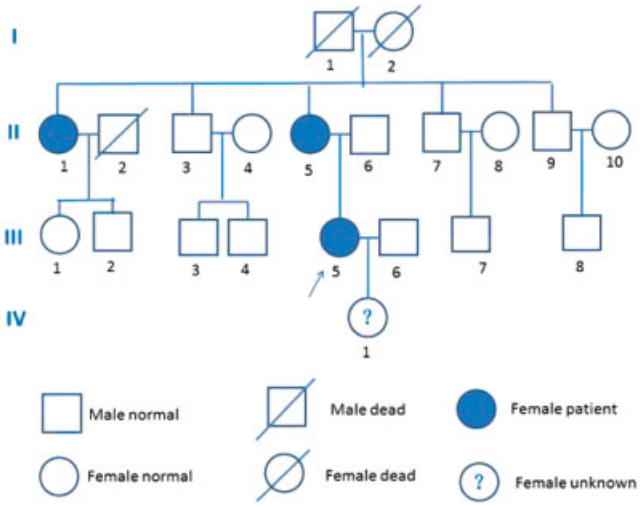

Figure 1. Pedigree of the family.

RENIN, the causative gene of Hyperuricemic Nephropathy, Familial Juvenile, type2 (HNFJ, MIM: #613092) was found to be shared in this family but not UMOD, HNF1B or FJHN3. Exon sequencing of RENIN and UMOD of patient II-5 was proved to be normal. HPRT1 of the rare Lesch-Nyhan syndrome was excluded by exon sequencing.

Multiple single nucleotide polymorphisms of gene ABCG2, SLC2A9 and SLC22A12 were found in patient II-5, including one locus known to be highly associated with gout, SNP rs2231142 (C>A) of gene ABCG2. Nearly all of the family members carry the risk A allele.

Conclusion: In this premenopausal gout family, all known causative genes of gout were found to be negative. ABCG2 rs2231142 (C>A) polymorphism was found in both female patients and male healthy members of this family.

Rheumatoid Arthritis Quality Measure Results In a Large Managed Care Population. Roxanne Meyer[1], Lorie A. Ellis[2], Susan C. Bolge[2], Andrew Howe[3] and Yunping Zhou[3]. [1]Janssen Scientific Affairs, LLC, Horsham, NY, [2]Janssen Scientific Affairs, LLC, Horsham, PA, [3]Comprehensive Health Insights, Louisville, KY.

Background/Purpose: Improvement in quality of care is of growing interest to both physicians and payers. Both the American College of Rheumatology and National Quality Forum (NQF) recommend monitoring of quality measures in rheumatoid arthritis (RA) patients. The purpose of this study is to describe the proportion of RA patients in a large managed care population that achieved NQF quality measures specific to RA.

Methods: This is a retrospective analysis of Humana's Commercial and Medicare database. Claims were reviewed to evaluate compliance with four NQF quality measures in calendar year 2011. NQF definitions were used for the numerator (N) and the denominator (D) for each measure. Descriptive statistics were calculated on the specific measures.

NQF Measure	Definition
0054 Arthritis: disease modifying antirheumatic drug (DMARD) therapy in rheumatoid arthritis	Percentage of patients 18 years and older, diagnosed with rheumatoid arthritis who have had at least one ambulatory prescription dispensed for a DMARD
0590 Rheumatoid Arthritis New DMARD Baseline Liver Function Test	This measure identifies adult patients with a diagnosis of rheumatoid arthritis who received appropriate baseline liver function testing (AST or ALT) within 90 days before to 14 days after the new start of sulfasalazine, methotrexate, leflunomide, azathioprine, cyclosporine or cyclophosphamide during the measurement year.
0592 Rheumatoid Arthritis Annual ESR or CRP	This measure identifies adult patients with a history of rheumatoid arthritis who have received erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) lab tests during the measurement year
0601 New Rheumatoid Arthritis Baseline ESR or CRP within Three Months	This measure identifies adult patients newly diagnosed with rheumatoid arthritis during the first 8 months of the measurement year who received erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) lab tests either 4 months (3 months + 1-month grace period) before or after the initial diagnosis.

Results: The proportion of adult RA patients who received at least one prescription for a DMARD (measure 0054) was 72.8% (N=17,066, D=23,440). Liver function testing in patients with a new DMARD as defined by measure 0590 was achieved by 84.7% (N=3,130, D=3,694) of adult RA patients. The proportion of newly diagnosed adult patients receiving a baseline ESR or CRP (measure 0601) was 54.7% (N=2,595, D=4,742). For measure 0592 the proportion of adult patients receiving an annual ESR or CRP was 58.2% (N=13,125, D=22,538).

Conclusion: This analysis of an RA population in a large managed care population suggests that 15% to 45% of patients do not attain NQF quality measure standards. These findings suggest that improvements in patient care could be made with the goal of improving the proportion of patients achieving RA specific NQF measures. Further studies are warranted to understand whether attainment of these measures translates into better overall health or RA-related outcomes and may enhance physician and patient awareness about the benefits of quality of care.

National Quality Forum Measures Among Rheumatoid Arthritis Patients In a Large Managed Care Population. Roxanne Meyer[1], Lorie A. Ellis[2], Susan C. Bolge[2], Joseph Tkacz[3], Peter Kardel[3] and Charles Ruetsch[3]. [1]Janssen Scientific Affairs, LLC, Horsham, NY, [2]Janssen Scientific Affairs, LLC, Horsham, PA, [3]Health Analytics, LLC, Columbia, MD.

Background/Purpose: The American College of Rheumatology and National Quality Forum (NQF) recommend monitoring quality measures among rheumatoid arthritis (RA) patients. This study describes the proportion of RA patients within a large managed care population meeting the criteria of RA specific NQF quality measures.

Methods: Definitions of NQF RA quality measures 0054, 0589, 0590, 0592, 0597–0599, and 0601 were applied to claims data of a commercially-insured population from Optum Insight's Clinformatics database for calendar years 2007–2011. NQF definitions may be found at www.qualityforum.org/Home.aspx.

Results: Measure 0054 defines the proportion of RA patients treated with a DMARD in a defined measurement year. At each year studied, approximately 70% achieved this measure.

Measures 0589, 0590 pertain to laboratory monitoring of adult RA patients with a new DMARD in the measurement year. Measures 0589 (baseline serum creatine) and 0590 (baseline liver function test; LFT) were achieved by only one-third of patients. The proportion of patients achieving these measures appeared to increase annually between years 2007 and 2010 but declined during 2011.

Measures 0597, 0598 and 0599 were designed to monitor adult RA patients within 12 weeks of a new methotrexate (MTX) prescription. Approximately one-third of patients met the criteria for Measure 0597 (LFT within 12 weeks), and 40% met the criteria for 0599 (serum creatinine within 12 weeks). In contrast, approximately 70% of new MTX-treated patients met the criteria for 0598 (complete blood count within 12 weeks). Slight variations in the proportions of patients achieving these measures were observed from year to year.

Measures 0592 and 0601 pertain to monitoring of ESR or CRP in adult RA patients. Measure 0601 (proportion of newly diagnosed RA patients who received an ESR or CRP measure within 3 months of diagnosis) was achieved by approximately 70% of patients. Proportions of patients achieving this measure were improved slightly over time. However, annual ESR or CRP (0592) was achieved in slightly more than half the patients.

NQF Measure Results 2007–2011	2007	2008	2009	2010	2011
0054 Arthritis: disease modifying antirheumatic drug (DMARD) therapy in rheumatoid arthritis					
Denominator (f)	21,156	26,514	27,034	24,852	26,420
Percent (%)	70.0%	71.2%	71.1%	72.1%	70.5%
0589 Rheumatoid Arthritis New DMARD Baseline Serum Creatinine					
Denominator (f)	2,438	3,868	3,388	3,181	3,160
Percent (%)	32.3%	31.3%	35.8%	38.3%	27.7%
0590 Rheumatoid Arthritis New DMARD Baseline Liver Function Test					
Denominator (f)	2,681	4,183	3,716	3,524	3,488
Percent (%)	29.7%	30.3%	36.5%	39.0%	26.7%
0592 Rheumatoid Arthritis Annual ESR or CRP					
Denominator (f)	14,792	21,702	25,474	25,416	26,776
Percent (%)	58.4%	57.7%	55.8%	54.9%	55.5%
0597 Methotrexate: LFT within 12 weeks					
Denominator (f)	7,126	8,743	8,589	7,977	8,285
Percent (%)	30.9%	33.2%	37.4%	37.3%	33.8%
0598 Methotrexate: CBC within 12 weeks					
Denominator (f)	7,126	8,743	8,589	7,977	8,285
Percent (%)	72.4%	72.7%	72.4%	72.8%	71.8%
0599 Methotrexate: Creatinine within 12 weeks					
Denominator (f)	7,126	8,743	8,589	7,977	8,285
Percent (%)	38.6%	41.0%	44.7%	45.0%	41.6%
0601 New Rheumatoid Arthritis Baseline ESR or CRP within Three Months					
Denominator (f)	3,249	4,144	4,283	4,540	4,709
Percent (%)	66.2%	67.8%	69.2%	71.6%	71.5%

Conclusion: This analysis of a large national health plan suggests that between 30% and 70% of RA patients do not meet NQF quality measure criteria. Further studies are needed to understand: 1) the relationship between NQF measures and health outcomes and cost; 2) drivers of meeting NQF quality standards; and 3) interventions that improve NQF scores within health plans.

The Performance Of a Point Of Care Test For Detection Of Anti-Mutated Citrullinated Vimentin and Rheumatoid Factor In Early Rheumatoid Arthritis. Preeda Rojanasantikul[1], Prapa Pattrapornpisut[2], Kulvara Anuruckparadorn[3] and Wanruchada Katchamart[1]. [1]Division of Rheumatology, Department of Internal Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]Department of Internal Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [3]Department of Transfusion Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Background/Purpose: Besides rheumatoid factor (RF), anti-cyclic citrullinated peptide antibody (ACPA), a newer serologic marker, was added to the new American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria 2010. Most commercially available assay used for detection of ACPA and RF is the ELISA-based method. This assay is a multi-step and time-consuming procedure requiring special equipments and experienced technicians. ACPA therefore may not be available worldwide. Moreover, the results of these tests may take too long to be of value in daily practice, leading to delayed diagnosis. Recently, a serological point-of-care test (POCT) for detection of anti-MCV and RF using a lateral flow immunochromatographic assay (LFIA) has been developed for a rapid result, and it also has wider availability. The diagnostic performance of this POCT was documented in established RA; however, its performance in patients with 'early' RA is still unknown. Our objective was to determine the diagnostic performance of a point of care test (POCT) for detection of anti-mutated citrullinated vimentin (MCV) and rheumatoid factor (RF) in early rheumatoid arthritis (RA) with 2 years of disease duration or less. Additionally, we evaluated the agreement of these tests when using EDTA whole blood and capillary blood.

Methods: Patients with RA and other rheumatic disorders were consecutively recruited from the Rheumatology outpatient clinic. The POCT for detection of anti-MCV and RF using capillary blood and EDTA whole blood was performed in 78 patients with early RA, 55 patients with other rheumatic disorders, and 55 healthy blood donors.

Results: The sensitivity and specificity of anti-MCV POCT in patients with early RA were 64% and 97%, respectively, while the sensitivity and specificity of RF POCT were 51% and 95% respectively. The positive likelihood ratio of the POCT for anti-MCV was higher than those for RF (23.5 vs.9.4). The negative likelihood was 0.37 for anti-MCV and 0.52 for RF. There were 3 cases with false positive for anti-MCV including a patient with psoriatic arthritis and the other two with systemic sclerosis. The agreement between capillary blood and EDTA whole blood testing for anti-MCV and RF was low to moderate with Cohen's kappa of 0.58 and 0.49, respectively.

Conclusion: This POCT for detection of anti-MCV and RF yielded high specificity and may be a valuable tool for the diagnosis of early RA. Using this POCT with EDTA whole blood instead of capillary blood is not recommended.

Are Physician Gender, Age and Clinical Experience Associated With Discrepancy In Global Disease Score In Rheumatoid Arthritis, Ankylosing Spondylitis and Psoriatic Arthritis? Data From The Nationwide Danbio Registry. Cecilie Lindstrom Egholm[1], Niels Steen Krogh[2], Lene Dreyer[3], Torkell Ellingsen[4], Bente Glintborg[5], Marcin Kowalski[6], Tove Lorenzen[7], Ole Rintek Madsen[8], Henrik Nordin[9], Claus Rasmussen[10] and Merete L. Hetland[11]. [1]Regional Research Unit, Region Zealand, Roskilde, Denmark, [2]ZiteLab ApS, Copenhagen, Denmark, [3]Copenhagen University Hospital at Gentofte, Copenhagen, Denmark, [4]Diagnostic Centre Region Hospital Silkeborg Denmark, 8600 Silkeborg, Denmark, [5]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup Hospital, Glostrup, Denmark, [6]Aalborg University Hospital, Aalborg, Denmark, [7]Department of Rheumatology, Region Hospital Silkeborg, Silkeborg, Denmark, [8]Copenhagen University Hospital in Gentofte, Copenhagen, Denmark, [9]Department of Infectious Diseases and Rheumatology, Rigshospitalet, Copenhagen, Denmark, [10]Vendsyssel Teaching Hospital/ Aalborg University, Hjoerring, Denmark, [11]Copenhagen University Hospital Glostrup, Copenhagen, Denmark.

Background/Purpose: A global estimate on a 100 mm Visual Analogue Scale (VAS) assessed by patients (PATGL) and physicians (DOCGL) is commonly used to measure disease activity and to monitor treatment response in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA). Several studies in RA have shown that PATGL and DOCGL are discordant (>20 mm difference) in about 1/3 of the encounters and have mainly focused on whether clinical measures and patient characteristics explain this. The influence of physician characteristics has not yet been examined across different arthritis diagnoses. Studies in other clinical areas suggest that treatment decisions are affected by physician gender and clinical experience. The aim of the study was therefore to assess whether physician characteristics are associated with discordance between DOCGL and PATGL in patients with RA, AS and PSA.

Methods: Physician characteristics were collected by a questionnaire sent to DANBIO physicians (n = 265). Patient characteristics and clinical measures as well as PATGL and DOCGL scores were obtained from DANBIO first encounters. A difference between DOCGL and PATGL of up to 20 mm was considered concordant, yielding three groups: PATGL>DOCGL, PATGL=DOCGL and DOCGL>PATGL. The two latter groups were merged due to few patients in DOCGL>PATGL. We used mixed effects logistic regression analyses with discordance (yes/no) as the dependent variable, performing independent analyses for each diagnosis. The model was adjusted for patient and clinical variables (e.g. age, gender, disease activity, treatment, disease duration), which were entered as covariates.

Results: 90 physicians (44% females, 61% rheumatologists, median age 52 years) returned the questionnaire (34%) and were pairwise matched with 7,619 RA, 1,291 PsA and 469 AS first encounters.

Discordance was independent of physician's gender and age, both for patients with RA, and for patients with AS or PSA, see table. Less experienced physicians (i.e. not yet specialized) had lower odds of discordance 0.69–0.92, although it only reached statistical significance in patients with RA, see table.

Table. Mixed effects logistic regression of predictors of discordance between patient and physician assessments of global disease activity.

	RA (N: 7,619 encounters)		AS (N: 469 encounters)		PsA (N: 1,291 encounters)	
	Adjusted OR (95% CI)	P	Adjusted OR (95% CI)	p	Adjusted OR (95% CI)	p
Physician gender, male (female=1.0)	0.83 (0.69–1.01)	NS	1.25 (0.70–2.26)	NS	1.04 (0.73–1.49)	NS
Physician age >52 years (≤52 =1.0)	1.10 (0.89–1.37)	NS	1.16 (0.59–2.30)	NS	1.17 (0.79–1.74)	NS
Rheumatologist (specialized), no (yes=1.0)	0.72 (0.55–0.93)	*	0.69 (0.31–1.52)	NS	0.92 (0.56–1.51)	NS

Concordant group is reference group.
The model was adjusted for swollen and tender joint counts (0–28), C-reactive Protein, disease duration (years), biological treatment (yes/no), country of medical exam, and doctor's subjective rating of factors important for DOCGL (inflammation, fibromyalgia, structural joint damage, comorbidity and social factors). To account for clustering by physician and patient, these variables were included in the model as random effects.
***=p<0.001,
**=p<0.01,
*=p<0.05, NS=not significant

Conclusion: Data from clinical practice covering >9,000 DANBIO first encounters between 90 physicians and their patients with rheumatoid arthritis, ankylosing spondylitis and psoriatic arthritis showed that, regardless of diagnosis, discordance (i.e. difference between patient's and doctor's global scores >20 mm) was independent of physician's age and gender. This is reassuring for the monitoring of patients in routine care. Having specialized in rheumatology seemed to be associated with increased odds of discrepancy compared to less experienced colleagues.

No Secular Trends In Real Live Radiographic Progression Of Rheumatoid Arthritis In Recent Year. Miriam Gärtner[1], Farideh Alasti[1], Gabriela Supp[1], Josef S. Smolen[2] and Daniel Aletaha[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: Progression of joint damage as measured radiographically is a hallmark of rheumatoid arthritis (RA), and its reduction a key claim for traditional and novel antirheumatic drugs. Data from clinical trials may be interpreted to indicate that the observed progression of RA has decreased over the past two decades.[1] Although these observations mainly stem from clinical trials, it has been hypothesized that RA in general may have become a less destructive disease.

It was the aim of this study, to evaluate the frequency and degree of radiographic progression in real life routine RA patients over the past decade

Methods: RA patients of our outpatient clinic, who had two x-rays performed over a three to five year interval between the years 2000 and 2012 were included. X-rays of the hands and feet were scored according to the Sharp van der Heijde (SvdH; range 0–448) method.[2] Clinical and demographic data were collected from the patients' charts. Patients were separated into three periods of time (2000–2004, 2005–2008, 2009–2012) and the annual radiographic progression was calculated based on the observed progression in these periods. Disease activity was assessed using the time averaged clinical disease activity index (CDAI). The mean number of joints with radiographic progression per patient, as well as the mean grade of progression per joint (erosion/joint space narrowing, JSN) were evaluated. Lack of progression was defined as no progression in total SvdH

Results: Of the 444 patients included (mean duration of RA 7.4±9.4 years, 64.8% rheumatoid factor positive, 63.7% ACPA positive), 406 (91.4%) showed radiographic progression over a mean of 3.8±0.6 years. We found no significant difference neither in clinical nor in radiographic results comparing patients between the three time periods. In all progressors we found no difference in rates of annual radiographic progression, erosion score, or JSN, within the three different time periods (Figure 1). Although the annual rate of progression was stable, baseline SvdH scores decreased across the three periods (43.2±57.4 2000–2004 vs 43.0±49.7 2005–2008 vs 33.2±48.9 2009–2012).

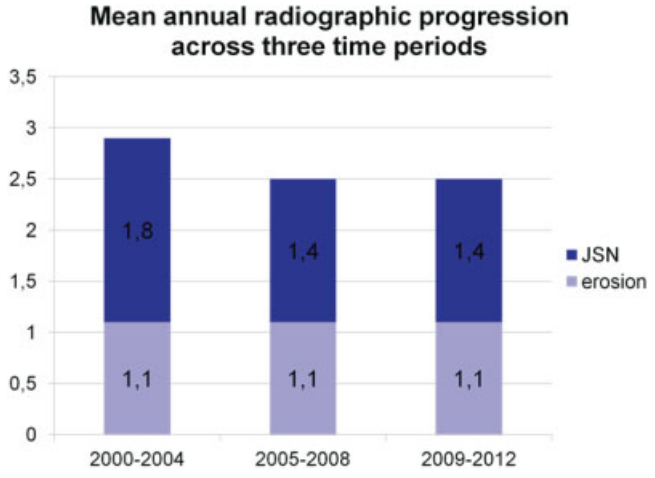

Figure 1. Patients with radiographic progression (n=406) during three time periods. The figure shows the mean annual radiographic progression rates for total SvdH-Score, erosions as well as JSN. There was no significant difference between the different time periods.

Conclusion: Only a minority of patients did not progress structurally over three to five years. The temporal trend analysis indicates that on the background of similar average disease activity and similar mix of treatment, the overall annual progression was constant during the last decade. However, in general progression of joint damage was low.

Delay In Consultation and Starting Disease Modifying Anti-Rheumatic Drugs In Patients With Rheumatoid Arthritis In Argentina. How Early Arthritis Clinics Impact On Health Barriers? Natalia Zamora[1], Christian A. Waimann[1], Maria Florencia Marengo[1], Gustavo Citera[1], Amelia Granel[2], Ana Inés Marcos[2], Emilio Buschiazzo[3], Ricardo V. Juarez[3], Dora Pereira[4], Gisela Pendón[4], Andrea D'Orazio[5], Mariana Salcedo[6], Judith Sarano[7], María Victoria Collado[7], Graciela Gómez[7], Alejandra Medina[8], María Eugenia Lara[9], Juan C. Barreira[9], María Alicia Lázaro[10], Alejandra Cusa[10], Luciana González Lucero[11], María Silvia Yacuzzi[11], Raúl Nicolas Martínez[11] and Pablo Arturi[12]. [1]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Hospital San Roque de Gonnet, La Plata, La Plata, Argentina, [3]Hospital Señor del Milagro, Salta, Argentina, [4]Hospital Ricardo Gutierrez, La Plata, La Plata, Argentina, [5]Hospital de la Asociacion Medica de Bahía Blanca, Bahía Blanca, Argentina, [6]Consultorio Privado, San Nicolás, Argentina, [7]Instituto de Investigaciones Medicas Alfredo Lanari, Buenos Aires, Argentina, [8]Hospital General de Agudos "Dr. E. Tornu", Ciudad Autónoma de Buenos Aires, Argentina, [9]Buenos Aires British Hospital, Buenos Aires, Argentina, [10]Hospital central de San isidro Dr A. Posse, San Isidro, Argentina, [11]Hospital Angel C. Padilla de San Miguel de Tucumán, San Miguel de Tucumán, Argentina, [12]Hospital Italiano de La Plata, La Plata, Argentina.

Background/Purpose: An early and intensive treatment has become the cornerstone in the treatment of Rheumatoid Arthritis (RA). For this reason, an early consult with a rheumatologist is crucial. The aim of our study was to evaluate the delay in consultation and starting disease modifying anti-rheumatic drugs (DMARDs) in patients with RA, and to assess the impact of early arthritis clinics and health barriers on such delay.

Methods: We carried out a retrospective multicenter study including patients with a diagnosis of RA of less than 5 years of disease evolution. Data collected included clinical, economic, sociodemographic characteristics, health insurance status and health care center (private vs. public hospital; early arthritis clinics vs. routine care hospitals). In addition, we evaluated the presence of health barriers in those patients with <2 years of disease duration, including geographical location, social support, family and work responsibilities, economics issues, accessibility to health care, self-treatment and patient-physician relationship. Three time-points were evaluated: time to first medical contact, time to rheumatologist and time to initiation of first DMARD. The association between variables and time-points were assessed using univariate and multivariate models.

Results: A total of 316 patients were included; 86% were female, mean age was 47 $\pm$ 14 years, disease duration 7 $\pm$ 5 years, 73% had a low income (less than 1000 dollars/month), and 11 $\pm$ 4 years of formal education. Two third were from public hospitals and one third from private sector, 8% lived alone and 23% were unemployed. The median time to first medical contact was 30 (IQR 10–60) days, being the clinician the initial physician (52%) followed by traumatologist and rheumatologist (24% for both). The total time to arrive to the rheumatologist was 90 (IQR 35–210) days, but 32% of the patients delayed more than six months to contact a rheumatologist. Twenty five percent of patients were never referred by their clinicians duplicating the access time to rheumatologists to 165 (IQR 30–365) days. The median time to start DMARDs treatment by the rheumatologist was 24 (IQR 6–365) days, which result on a total median time from onset of symptoms of five months. One quarter of patients took longer than 12 months to start a DMARD. Three health barriers were significantly associated with delay in consultation and treatment: geographical location, family and work responsibilities, and lack of economic issues. After adjusting for multiples confounders (health insurance, health care center, marital status, household members, comorbidities and age), the presence of health barriers was independently associated with increased delay to rheumatologist and initiation of the first DMARD. In addition, being attended in early arthritis clinics was significantly associated to shorter delay in receiving DMARD treatment.

Conclusion: The delay in starting treatment with DMARDs was about 5 months. However, one-quarter of patients took longer than one year to start the treatment. The implementation of early arthritis clinics, a fast referral system and limitation of health barriers could be a good strategy to optimize the prompt treatment of the patients with RA.

The Health and Economic Consequences Of Delay In Starting Disease-Modifying Anti-Rheumatic Drugs In Australian Patients With Early Rheumatoid Arthritis. Danny Liew, Mark Tacey and Sharon Van Doornum. The University of Melbourne, Melbourne, Australia.

Background/Purpose: Several international studies suggest that the time between symptom onset and DMARD initiation in RA patients is longer than is considered optimal. We sought to assess the health economic impact of this delay in an Australian context.

Methods: The delay in DMARD initiation was estimated from a study of 135 Australian RA patients referred to hospital-based and community-based rheumatologists. RA-associated utilities and costs were sourced from published data. Patients not taking and taking DMARD therapy were assumed to have utilities of 0.59 and 0.64, respectively. The annual direct cost of DMARD therapy was assumed to be AUD$1200, consistent with the most expensive first-line agents in Australia. It was also conservatively assumed that DMARD therapy did not reduce non-DMARD RA costs. (NB: The Australian dollar is near parity with the US dollar.)

Results: The median time from time of symptom onset to initiation of DMARD therapy was 0.46 years. Over this time a mean of 0.27 quality-adjusted life years (QALYs). Had DMARDs been commenced at symptom onset, 0.30 QALYs would have been lived per patient, and AUD$555 of additional healthcare costs incurred. Hence early initiation of DMARDs would have saved 0.023 QALYs, equating to an incremental cost-effectiveness ratio (ICER) of AUD$24,000 per QALY saved. An additional AUD$600 could be spent per patient to reduce the time to DMARD initiation before the ICER breached the arbitrary cut-off of AUD$50,000 per QALY saved. Our analysis was conservative in it did not consider the long-term health and cost savings associated with avoidance of permanent joint damage.

Conclusion: The considerable delay in the initiation of DMARD therapy among patients with RA leads to significant health loss. Reducing the time to initiation of DMARDs represents a cost-effective means of reducing the burden of RA

Can MDHAQ/RAPID3 Be Used In Usual Care Of Patients With Systemic Lupus Erythematosus? Narender Annapureddy[1], Theodore Pincus[2], Joel A. Block[1] and Meenakshi Jolly[1]. [1]Rush University Medical Center, Chicago, IL, [2]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY.

Background/Purpose: Disease-specific patient reported outcome (PRO) tools are uniquely informative for the management of systemic lupus erythematosus (SLE) patients. However, it is difficult to incorporate distribution of appropriate disease specific PRO measures in busy clinical settings. A single, simple PRO measure for all patients, irrespective of their underlying disease diagnosis, can easily be integrated into the clinic check-in processes without requiring additional processes/ personnel. Multi-Dimensional Health Assessment Questionnaire (MDHAQ) is a PRO tool developed for patients with musculoskeletal diseases; RAPID 3 (Routine Assessment of Patient Index Data) scores are easily and rapidly calculated from the MDHAQ. We compared RAPID3 and LupusPRO (a disease specific PRO tool for SLE) and disease activity indices in patients with SLE seen during usual care.

Methods: 78 consenting patients meeting 4 ACR criteria for SLE completed both MDHAQ and LupusPRO during a routine clinic visit. Disease activity was assessed using SELENA-SLEDAI (Physician Global Assessment-PGA 0–3), and demographic data were obtained. We compared

LupusPRO domain scores for 8 Health Related Quality of Life-HRQOL and 4 Non-Health Related Quality of Life-Non-HRQOL scales (all scored 0–100,higher scores=Better Quality of Life) and physician global assessment (DOCGL), SELENA-SLEDAI stratified by disease severity to RAPID3 scores in 4 categories,≤ 3 Remission; 3.1–6.0 Low severity; 6.1–12 Medium Severity and >12 High severity. Statistical significance was analyzed using Kruskall-Wallis non-parametric tests; a p value of ≤ 0.05 was considered significant on two tailed tests.

Results: Mean (SD) age, Physician global assessment (or DOCGL) and total SELENA-SLEDAI scores were 42.4 (13.8) yrs, 0.7 (0.7) and 3.9 (4.7) respectively. Mean (SD) RAPID3 score was 9.8 (7.6). Table 1 shows the median (IQR) disease activity and LupusPRO domain scores for the RAPID3 disease severity categories. Disease activity scores did not vary between RAPID3 disease severity categories. This phenomenon has been previously reported with all PRO tools (Generic or Disease Specific) used in SLE. Seven of the 12 LupusPRO domains differed significantly in patients in the 4 RAPID3 disease severity categories - lupus symptoms, cognition, physical health, pain-vitality, emotional health, body image, and desires- goals, while 5/12 domains - Procreation, Lupus Medications, Social Support, Coping and Satisfaction with Treatment, did not differ in the 4 groups. The composite HRQOL LupusPRO scores differed significantly in the RAPID3 disease severity categories, while the composite non-HRQOL did not differ.

Table 1. Disease Activity and LupusPRO scores stratified by RAPID3 Disease Severity.

	RAPID 3 Based Disease Severity				
Median (IQR)	**0–3**	**3.1–6**	**6.1–12**	**>12**	**P value**
Physician Global Assessment	0.0 (1.0)	0.25 (0.50)	1.0 (1.0)	0.5 (1.1)	0.101
Total SELENA-SLEDAI	2.0 (4.0)	2.0 (6.0)	4.0 (5.8)	4.0 (4.0)	0.130
LupusPRO-HRQOL					
Lupus Symptoms	91.7 (8.3)	90.6 (14.6)	66.7 (33.3)	50.0 (41.7)	<0.001
Cognition	100 (37.5)	81.3 (43.8)	56.3 (46.9)	50.0 (50.0)	<0.001
Procreation	100.0 (0.0)	100.0 (0.0)	100.0 (0.0)	100.0 (0.0)	0.120
Lupus Medications	100.0 (0.0)	75.0 (46.9)	81.3 (50.0)	87.5 (37.5)	0.030
Physical Health	100.0 (0.0)	100 (12.5)	80.0 (43.8)	55.0 (32.5)	<0.001
Pain-Vitality	95.0 (20.0)	75.0 (20.0)	50.0 (30.0)	30.0 (17.5)	<0.001
Emotional Health	83.3 (33.3)	75.0 (11.5)	79.2 (45.8)	45.8 (30.2)	<0.001
Body Image	100 (15.0)	97.5 (38.8)	77.5 (38.8)	50 (57.6)	<0.001
Composite HRQOL	91.7 (14.1)	86.7 (4.3)	76.3 (19.4)	57.9 (18.6)	<0.001
LupusPRO-Non-HRQOL					
Desires-Goals	93.8 (25.0)	78.1 (29.7)	68.8 (25.0)	46.9 (42.2)	<0.001
Social Support	100 (37.5)	100.0 (0.0)	87.5 (50.0)	93.8 (40.6)	0.227
Coping	83.3 (41.7)	91.7 (25.0)	66.7 (41.7)	75.0 (27.1)	0.314
Satisfaction Treatment	87.5 (62.5)	100 (0.0)	100 (34.4)	90.6 (31.3)	0.146
Composite Non-HRQOL	75.0 (26.0)	87.5 (9.9)	75.0 (30.7)	72.7 (12.9)	0.300

Conclusion: RAPID3 may be used as a PRO for HRQOL in busy clinical settings to add to management of SLE patients.

Implementation Of a Methotrexate Self-Injection Education Video – Reducing Teaching Time While Maintaining Patient Confidence and Knowledge. Steven J. Katz and Sylvia Leung. University of Alberta, Edmonton, AB.

Background/Purpose: To compare the effect of standard nurse led methotrexate self-injection patient education to a methotrexate self-injection web based education video added to standard teaching on 1) Patient satisfaction with teaching 2) Patient self-confidence in performing the injection 3) Patient knowledge around injection technique & precautions & 4) nursing time required

Methods: Consecutive rheumatology patients at the University of Alberta Medicine Clinic seen by the Clinic Nurse for methotrexate self-injection education were asked to participate in the study. Each patient's pre-education confidence for self-injection (Visual Analog Scale 1–10), age, gender, & education level was ascertained. Patients were randomized 1:1 to either standard teaching or the intervention: a 12 minute video reviewing the steps before, during and after methotrexate self-injection, followed by further in-person nurse education with a focus on reviewing patient concerns and questions arising from the video, and practicing self-injection similar to the non-intervention group. At the end of the teaching session, patients recorded their post-education confidence for self-injection, their satisfaction with the teaching process (VAS 1–10), and answers to 4 specific knowledge based questions on methotrexate self-injection (graded as a score out of 6). The nurse recorded the number of minutes spent providing direct education to the patient

Results: 29 patients participated in this study: 15 had standard (S) teaching and 14 were in the intervention group (VS). Average age (49), gender (VS=6 males, S=5), & education level was similar in both groups. Both groups were very satisfied with the quality of teaching (9.9/10). There was no difference in pre-confidence (S=5.5/10 vs. VS=4.7/10, p=0.44) or post-confidence (S=8.8, VS=8.8, p=0.93) between the groups, although there was a trend to greater improvement in confidence in the video group (p=0.15). Further, there was a trend towards improved patient knowledge in the video group vs. the standard group, with an average of more correct answers in the video group (S=4.7/6, VS=5.5/6, p=0.15). Nurse teaching time was significantly less in the video group compared to the standard group (S=60 minutes, VS=44 minutes, p=0.012).

Conclusion: A web based education video may be a good supplement to standard in person nurse teaching for methotrexate self-injection. It has equally as good benefit on patient confidence and knowledge base while decreasing teaching time by 25%.

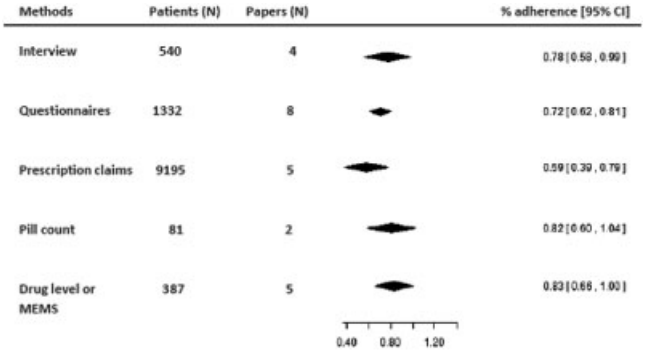
A Meta-Analysis and Systematic Literature Review: Effect Of The Method Used To Measure Adherence In Rheumatoid Arthritis On Its Rate, and Evaluation Of Associated Factors. Anat Scheiman-Elazary[1], Cortney Shourt[1], M. Cameron Hay[2] and Daniel Furst[3]. [1]Rheumatology UCLA, Los Angeles, CA, [2]Anthropology Miami University, Oxford, OH, [3]David Geffen School of Medicine, UCLA, Los Angeles, CA.

Background/Purpose: Adherence reported in the literature for RA varies widely (49.5–98%)[1]. This variability may result in part from different methods used to measure adherence. Our aim was to examine whether adherence is influenced by the method used to measure it through a meta-analysis. We also conducted a systematic literature review (SLR) on factors that are associated with adherence.

Methods: Systematic literature review was conducted using PubMed and Cochrane central database as well as associated reference lists from reviews from 1970 to Nov. 2012. Papers were included if they reported DMARD adherence data or factors associated with adherence in adult RA patients and if adherence was defined. Aspirin/NSAID or non pharmaceutical therapy were excluded. Papers were divided according to the method used to measure adherence. A Random effects model estimated adherence and a Binomial significance test was used to identify significant factors associated with adherence.

Results: Out of an initial 273 articles, 26 papers were included, including 34,700 RA patients. Figure 1 details the results of the meta-analysis for adherence, showing 2–8 articles for each method. Adherence rates were statistically similar when measured by interview, questionnaires, pill count, drug level or medication effect monitoring system (MEMS), although there was an 11% mean numerical range. There was a numerically but not statistically lower adherence when measured by prescription claims (0.59 for prescription claims versus 0.72–0.83 for the other methods).



Associated factors- Three factors were associated with increased adherence. 1. Patients belief about the necessity of medications and the ability to control pain, disease activity or negative mood related to arthritis. 2. Use of Infliximab compared to either Etanercept, Methotrexate or Anakinra. 3. Use of DMARDs prior to anti TNF therapy. Two factors were associated with decreased adherence, use of Sulfasalazine compared to Methotrexate and use

of Anakinra compared to Etanercept. Limitations- there were few articles using any one method and quality was variable, resulting in increased variability and decreased ability to separate the methods.

Conclusion: There was a numerical tendency for decreased rate of adherence when measured by prescription claims versus the other methods. Patient beliefs and specific DMARDs are associated with adherence.

Does Specific Joint Involvement In Rheumatoid Arthritis Patients Predict Patient Reported Outcomes? Implications For Clinical Practice.

Regan Arendse[1], William G. Bensen[2], Andrew Chow[3], Jude F. Rodrigues[4], Sanjay Dixit[5], Dalton E. Sholter[6], Philip Baer[7], Milton F. Baker[8], Denis Choquette[9], Isabelle Fortin[10], Algis Jovaisas[11], Emmanouil Rampakakis[12], John S. Sampalis[12], Francois Nantel[13], Susan M. Otawa[13], May Shawi[13] and Allen J. Lehman[13]. [1]University of Saskatchewan, Saskatoon, SK, [2]St. Joseph's Hospital and McMaster University, Hamilton, ON, [3]Credit Valley Rheumatology, Mississauga, ON, [4]Rheumatology, Windsor, ON, [5]McMaster University, Burlington, ON, [6]Rheumatology Associates, Edmonton, AB, [7]Rheumatology, Scarborough, ON, [8]University of Victoria, Victoria, BC, [9]Institut de Rhumatologie de Montréal, Montreal, QC, [10]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [11]University of Ottawa, Ottawa, ON, [12]JSS Medical Research, St-Laurent, QC, [13]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Assessment of functional (dis)ability in rheumatoid arthritis (RA) is subject to patient judgment when appraising their ability to do daily activities. The aim of this analysis was to describe the impact of specific joint involvement on patient reported outcomes (PROs) - functional activity, pain and patient global assessment of disease activity (PtGA) - and to identify joints most resistant to treatment over time.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective, registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. In this analysis, RA patients treated with infliximab between 2002 and 2012 or with golimumab between 2010 and 2012 were included. Based on joint involvement seven groups were created: shoulder(s), elbow(s), metacarpophalangeal (MCP), wrist(s), proximal interphalangeal (PIP), knee(s), and thumb(s). The impact of specific joints on patient outcomes was assessed with the independent-samples t-test. Linear regression was used in order to produce adjusted estimates.

Results: A total of 935 RA patients with 4854 assessments were included. Swelling, tenderness, and swelling and/or tenderness in all joint groups were associated with significantly ($P<0.001$) higher HAQ-DI, PtGA, and pain. Upon adjusting for age, gender and the total number of swollen (SJC28) and tender (TJC28) joints, swelling in all joint groups but the thumb(s) had a significant impact on PtGA, pain and HAQ. Similarly, tenderness in all joints but PIP had a significant impact on these parameters. Overall, swelling and/or tenderness at specific joints, shoulders, wrists and knees, had the greatest impact on HAQ-DI, PtGA, and pain ($P<0.001$). Swollen and/or tender PIP(s) did not have a significant effect on any PRO. At baseline, the MCP joint(s) and the wrist(s) were the most commonly swollen (86.4% and 67.9% of patients, respectively) or tender (82.9% and 73.1%, respectively) joints. Upon 12 months of treatment, the MCP joints were the joints most resistant to treatment, still remaining affected.

Table 1. Impact of Specific Joint Involvement on PROs

	Joint Group	HAQ-DI	PtGA	Pain
Swelling	Shoulder(s)	0.055*	0.049*	0.061*
	Elbow(s)	0.090*	0.059*	0.053*
	MCP	0.085*	0.103*	0.100*
	Wrist(s)	0.106*	0.113*	0.108*
	PIP	0.048*	0.032	0.044*
	Knee(s)	0.085*	0.098*	0.102*
	Thumb(s)	0.032	0.015	0.014
Tenderness	Shoulder(s)	0.114*	0.075*	0.090*
	Elbow(s)	0.075*	0.060*	0.065*
	MCP	0.042*	0.042*	0.049*
	Wrist(s)	0.100*	0.112*	0.109*
	PIP	0.014	0.002	0.007
	Knee(s)	0.102*	0.103*	0.106*
	Thumb(s)	−0.045*	−0.029	−0.034*
Swelling and/or Tenderness	Shoulder(s)	0.130*	0.082*	0.103*
	Elbow(s)	0.096*	0.069*	0.072*
	MCP	0.015	0.041*	0.043*
	Wrist(s)	0.105*	0.088*	0.086*
	PIP	0.008	−0.016	−0.015
	Knee(s)	0.095*	0.097*	0.101*
	Thumb(s)	−0.031	−0.034*	−0.040*

*$P<0.05$. Standardized coefficients upon adjusting for age, gender, and number of affected joints

Conclusion: Significant variability in PROs exists based on the presence of swelling and/or tenderness in specific joint groups. Swelling/tenderness of shoulders, wrists and knees were the main drivers of HAQ-DI, PtGA and pain. The results have important implications for the achievement of disease remission and would suggest that the joint type in addition to the number of affected joints has unique impact on PROs.

Can Routine Assessment Of Patient Index Data (RAPID)3 Be Used As a Patient Reported Assessment Tool For Patients With Ankylosing Spondylitis?

Muhammet Cinar[1], Sedat Yilmaz[1], Fatma Ilknur Cinar[2], Suleyman Serdar Koca[3], Hakan Erdem[1], Salih Pay[1], Yusuf Yazici[4], Ayhan Dinc[5] and Ismail Simsek[1]. [1]Gulhane School of Medicine, Ankara, Turkey, [2]Gulhane Military Medical Academy, School of Nursing, Ankara, Turkey, [3]Department of Rheumatology, Faculty of Medicine, Firat University, Elazig, Turkey, [4]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY, [5]Patio Clinic, Ankara, Turkey.

Background/Purpose: The assessment of disease activity in rheumatology is essential in both clinical trials and practice. The patient reported questionnaires have shown to reflect disease activity appropriately and is especially feasible in busy clinical settings. On the other hand, distribution of multiple questionnaires to patients with different diseases in a reception area might be difficult. A single questionnaire regarding to disease activity for all rheumatic diseases may present advantages to introduce quantitative measurement into routine care. Recently, a questionnaire that has been widely used and validated for rheumatoid arthritis, routine assessment of patient index data 3 (RAPID3), consists of patient function, pain, and patient global assessment, and has been suggested as suitable index for all rheumatic diseases. The aim of this study was to evaluate correlation of RAPID3 with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), AS Disease Activity Score (ASDAS), Bath AS Functional Index (BASFI), patient global assessment (PGA), and physician's global assessment (PhGA) in AS patients.

Methods: This single-centre, cross-sectional study was performed in a rheumatology department at a tertiary-care hospital. We included 341 consecutive AS patients who met the modified New York classification criteria. All patients completed BASDAI, BASFI, and MDHAQ at each visit, and their physicians completed physician global assessment. ASDAS scores were calculated using defined formulas. Spearman's rho correlation test was used to determine the linear association between RAPID3 and other disease activity measures.

Results: The median age of AS patients was 34.0 (21.0–69.0) years and the median disease duration 10.0 (2.0–35.0) years; 273 patients (80.1%) were male. Median scores for RAPID3, BASDAI, BASFI, ASDAS-CRP, ASDAS-ESR, PGA and PhGA were 13.0 (0.0–27.3), 4.7 (0.0–9.7), 3.0 (0.0–9.4), 3.0 (0.4–5.8), 2.5 (0.5–6.3), 5.0 (0.0–10.0) and

3.5 (0.0–9.5), respectively. RAPID3 was strongly correlated with PGA, BASDAI, and ASDAS-ESR (r=0.843, r=0.842, r=0.815; p<0.001, respectively) (Table 1).

Table 1. Correlation analysis between all disease activity measures.

	PhGA	PGA	ASDAS-ESR	ASDAS-CRP	BASFI	BASDAI
RAPID3	0.637	0.843	0.815	0.790	0.793	0.842
BASDAI	0.581	0.796	0.828	0.829	0.764	
BASFI	0.545	0.737	0.717	0.673		
ASDAS-CRP	0.672	0.824	0.888			
ASDAS-ESR	0.718	0.821				
PGA	0.606					

Conclusion: RAPID3 was found to have good levels of positive correlation with BASDAI, BASFI, ASDAS-CRP, ASDAS-ESR, PGA and PhGA and seems to be as informative as those established disease activity indices. One might conclude that this index can be replaced for them in the follow-up patients with AS and it may offer an additional advantage of being easier to implement in a routine care setting.

193

Physician Variability In Rheumatoid Patients Not Receiving Biologics Or Non-Biologic Dmards: Implications For Quality Reporting. Dimitrios A. Pappas[1], Lang Chen[2], Leslie R. Harrold[3], George W. Reed[4], Joel M. Kremer[5], Jeffrey D. Greenberg[6] and Jeffrey R. Curtis[7]. [1]Columbia University, College of Physicians and Surgeons, New York, NY, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Massachusetts Medical School, Worcester, MA, [4]CORRONA, Inc., Worcester, MA, [5]Center for Rheumatology, Albany Medical College, Albany, NY, [6]NYU Hospital for Joint Diseases, New York, NY, [7]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background/Purpose: Current quality of care guidelines recommend that all patients with Rheumatoid Arthritis (RA) be treated with biologic and/or non-biologic (nb) DMARDs. However, some RA patients are not treated with these agents for a variety of reasons, which may impact perceptions of the quality of care their physicians are providing.

To estimate physician-level variability on the proportion of RA patients who receive no biologic or nbDMARDs over a sustained period of time in a large U.S. Registry

Methods: Data from the Consortium of Rheumatology Researchers of North America (CORRONA) was used to identify rheumatologist-diagnosed RA patients. Patients were characterized as being on RA treatment (biologics and/or nbDMARDs, irrespective of glucocorticoids/NSAID/narcotics) based upon their most 3 consecutive visits in the registry. They were categorized as consistently on no treatment (0 of 3 visits), consistently on treatment (3 of 3 visits), and inconsistently on treatment (1–2 of 3 visits). Alternating logistic regression was used to evaluate physician-level clustering, controlling for patient-level factors including patient age, sex, RA disease duration, disease activity measured by CDAI, disability (by mHAQ), and comorbidities.

Results: A total of 361 CORRONA physicians and 22,889 of their RA patients contributed to the analysis (median [IQR] number of RA patients per physician 19 [4, 78]). Using data from the 3 most recent CORRONA visits, 3.5 % of patients were consistently on no treatment, 84.7% consistently on treatment, and 11.8% inconsistently on treatment. The proportion of physicians' patients on no RA treatment is shown (Figure) and ranged from 0 – 20%. For patients consistently on no RA treatment (n = 805), 31.4% were in remission, 37.1% were in low disease activity, and 31.4% were in moderate or high disease activity at the most recent CORRONA visit. After controlling for patient factors, physician clustering was independently associated with RA patients being on no RA treatment (adjusted OR = 1.81, 95% CI 1.17 – 2.80). Ongoing work is evaluating other potential reasons why patients may be untreated.

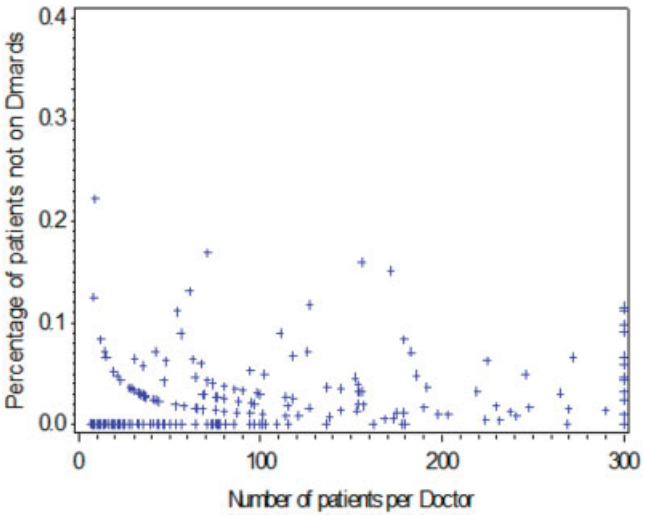

Figure. Proportion of Rheumatologists' RA patients consistently on no treatment

Conclusion: A modest proportion of RA patients are treated with no biologics or DMARDs over a sustained period of time. Even after controlling for RA-related and other patient characteristics, meaningful variability in the proportion of patients on no RA treatment was observed between physicians, suggesting the possibility of inappropriate variation in quality of care. Further efforts to explain and/or ameliorate quality gaps in RA appear warranted and have implications on reporting systems that judge rheumatologists' quality of care. Except in the circumstance where patients are in clinical remission, codifying other evidence-based reasons why offering no RA treatment is appropriate is likely to be useful.

194

Team Managed Care From a Patient's Perspective: A Study Of Biological Patients At a Canadian Centre. Dawn Heap[1], Margaret Saldanha[1], Melissa Deamude[1], Cynthia Mech[1], Helena Ross[1], Kathy Kislinsky[1], Lauri Vanstone[2], Arthur N. Lau[3] and William G. Bensen[4]. [1]Rheumatology Health Team, St. Joseph's Hospital Hamilton, Hamilton, ON, [2]Rheumatology Health Team, Hamilton, ON, [3]McMaster University, Hamilton, ON, [4]St. Joseph's Hospital and McMaster University, Hamilton, ON.

Background/Purpose: In Canada, there is a widening care gap in Inflammatory Arthritis due to the increased aging population, higher disease prevalence, dwindling numbers of practicing rheumatologists and decreased access to care. As a result, there is delay in diagnosis, delay in initiating treatment, and delay in starting biological therapy. In 2008, our practice developed a team based program where trained Registered Nurses were assigned as the primary care nurse to patients receiving biological therapy in order expedite and more efficiently manage patient care. Currently more than 1300 biological patients are followed in this clinic.

In this unique to Canada practice, patients are first seen and assessed by a registered nurse who do a complete history, review medications, assess joints, and provide health teaching. The nurse then discusses the patient and their needs with the Rheumatologist, and together they devise a plan which the nurse then implements and follows through.

Methods: 175 consecutive patients with a confirmed diagnosis of inflammatory arthritis (Rheumatoid Arthritis, Ankylosing Spondylitis or Psoriatic Arthritis) receiving biological therapy between May and June of 2013 were sampled and given a confidential survey with 15 questions to determine their level of satisfaction with a multidisciplinary, team approach to care. They were asked questions regarding their general demographics, current treatment, and their confidence in the nurse that primarily follows them, whether or not the team addresses their questions or concerns, and treatment goals. 22 questionnaires had more than 2 questions left blank and therefore withdrawn from analysis.

Results: More than 150 patients surveyed were included in this analysis studying patient satisfaction using a team approach model of patient care. The majority of patients surveyed were middle aged (40–75) and predominantly female. 85 percent of patients strongly agreed that they felt comfortable discussing their health and issues centring on their arthritis treatment with the nurse and confirmed that these goals were discussed at each visit. 97 percent of patients were confident in the nurse's assessment skills and ability to manage their arthritis care and 99 percent of patients valued this team based model of care in comparison to seeing the physician alone.

Conclusion: Our results from this study demonstrate a high degree of confidence in team- based rheumatology care. Currently this practice manages the biological volume of about 10 clinical rheumatologists who practice independently. Nurses are able to establish a rapport with patients in a unique and different way than a physician, and are not only able to address the patient's physical needs but their psychosocial issues as well. Patients have the confidence that these highly trained specialty nurses are providing them with optimal care, allowing them to work toward achieving targeted treatment goals and better arthritis disease control. This study further affirms that team managed care is the only way we will be able to meet treat to target guidelines in our exponentially growing disease prevalence.

Major Cost Savings Associated With Reduced Biologic Dosing Frequency In Inflammatory Arthritis. Claire-Louise Murphy[1], Miriam O'Sullivan[2], Sohail Awan[2], Shawn Chavrimootoo[2], Clara Bannon[2], Linzi Martin[2], Trevor Duffy[2], Eithne Murphy[2] and Maurice Barry[2]. [1]Connolly hospital, Dublin 15, Dublin, Ireland, [2]Connolly hospital, Dublin, Ireland.

Background/Purpose: Biologic agents are highly effective in Inflammatory Arthritis (IA) but are extremely expensive. A sustained reduction in biologic dosing frequency would lead to major cost savings. The purpose of this study was to explore whether patients with Inflammatory Arthritis would remain in remission following a reduction in biologic dosing frequency and therefore lead to cost savings.

Methods: This prospective non-blinded non-randomised study commenced in 2010. Patients with Inflammatory Arthritis (Rheumatoid Arthritis, Psoriatic Arthritis or Ankylosing Spondylitis) being treated with a biologic agent were screened for disease activity. A cohort of those in remission according to standardized disease activity indices (DAS28<2.6, BASDAI<4) was offered a reduction in the dosing frequency of two commonly used biologic therapies (etanercept 50mg once per fortnight instead of weekly, adalimumab 40mg once per month instead of fortnightly). Patients were assessed for disease activity at 3, 6 and 12 months following reduction in dosing frequency. Cost saving was calculated as the difference between the cost of the actual amount of biologic agent used over one year compared with the cost if the dosing interval had not changed.

Results: Seventy nine patients with inflammatory arthritis in remission were recruited. Fifty seven per cent had rheumatoid arthritis (n=45), 13% psoriatic arthritis (n=10) and 30% ankylosing spondylitis (n=24). Fifty seven per cent (n=45) were taking etanercept and 43% (n=34) adalimumab. The percentage of patients in remission at 12 months was 61% (n=48). Using paired sample t-tests in SPSSv20, no significant difference in measures of disease activity or functional status (DAS28, HAQ or BASDAI scores) was identified from baseline to 12 months in those who remained in remission. This resulted in an actual saving to the state of approximately 300,000 euro over the year.

Conclusion: This small study suggests reduction in biologic dosing frequency is feasible in inflammatory arthritis. The study resulted in considerable cost savings at 1 year. The potential for major cost savings in biologic usage should be pursued further.

Uptake Of The American College Of Rheumatology's Rheumatology Clinical Registry: Quality Measure Summary Data. Jinoos Yazdany[1], Salahuddin Kazi[2], Rachel Myslinski[3] and Melissa Francisco[3]. [1]University of California, San Francisco, San Francisco, CA, [2]UT Southwestern Medical Center, Dallas, TX, [3]American College of Rheumatology, Atlanta, GA.

Background/Purpose: The RCR provides ACR members with an infrastructure for quality reporting related to rheumatoid arthritis, gout, osteoarthritis, osteoporosis, and drug safety. Currently in its fourth year of operation, the RCR contains data on over 32,000 patients.

Here we report the uptake of the RCR by U.S. rheumatologists and performance on quality measures regarding functional status, disease modifying drug (DMARD) use, tuberculosis screening, prognosis, and disease activity assessment for RA patients in 2011 and 2012.

Methods: Data derive from retrospective medical records abstractions performed by providers and/or designated practice staff for a sample of patients seen by rheumatologists. Reporters submit data on quality measures via a secure, web-based registry system. Patients included in the denominator of all quality measures are >18 years of age with a diagnosis of RA who are receiving treatment by the reporting rheumatology provider. Additional details of each measure are listed in Table 1. We report the mean performance on each quality measure, defined as percentage of eligible patients receiving recommended care.

Results: Table 1 summarizes performance on RA measures reported through the RCR. From January 1, 2012 to December 31, 2012, 301 rheumatology providers in 138 practices submitted data on 9154 encounters with RA patients. Comparative data are provided for the previous reporting period. These data summarize 8096 encounters with RA patients submitted by 257 rheumatology providers in 143 practices from January 1, 2011–December 31, 2011. Reporting providers practice in sites ranging from solo offices to large academic medical centers.

Table 1. Performance on RA Measures Assessed through the RCR

	CY2011		CY2012	
	Patients (N)	QM Performance Rate	Patients (N)	QM Performance Rate
Disease activity assessed at least once within 12 months, using a standardized descriptive or numeric scale or composite index, and classified as low, moderate or high	8075	43.3%	6485	54.4%
Functional status assessment performed at least once within 12 months, and documented	8077	70.5%	6485	86.6%
using a standardized descriptive or numeric scale, standardized questionnaire, or notation of assessment of the impact of RA on patient activities of daily living				
Patient prescribed, dispensed, or administered at least one ambulatory prescription for a DMARD within 12 months	7808	97.9%	6485	86.6%
Documentation of TB screening performed and results interpreted within 6 months prior to receiving first course DMARD	1650	73.6%	1048	92.9%
Assessment and classification of disease prognosis at least once within 12 months	7771	49.5%	6441	73.4%

Conclusion: Performance rates increased on four out of five measures from CY2011 to CY2012. Based on preliminary results, the ACR plans to complete in-depth analyses of both measure and population performance.

Discordance Of Patient-Physician Assessments Of General Health In a US Hispanic Population With Rheumatoid Arthritis. Leyda Díaz-Correa[1], Mariely Nieves-Plaza[2], Yesenia C. Santiago-Casas[1], Tania González-Rivera[3], Grissel Ríos[1] and Luis M. Vilá[1]. [1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Michigan School of Medicine, Ann Arbor, MI.

Background/Purpose: Instruments to measure rheumatoid arthritis (RA) activity such as the 28-Joint Disease Activity Score (DAS28) are used to assess response to treatment. One component of the DAS28 is the patient

global assessment of general health. This is a subjective measurement that has been shown to be influenced by multiple factors such as depression. Moreover, some studies have reported discordance between patient and physician ratings of general health; however, the factors associated with these discrepancies have not been well established. The aims of this study were to determine the level of discordance of patient-physician assessments of general health in a group of US Hispanics with RA, and to evaluate the factors associated with such discordance.

Methods: A cross-sectional study was conducted in 213 US Hispanics with RA (per 1987 ACR criteria) participating in an observational study. Demographic parameters, clinical manifestations, disease activity (per DAS28), comorbid conditions, functional status (per Health Assessment Questionnaire [HAQ]), pharmacologic profile, and patient and physician global assessments (measured on a visual analogue scale [VAS]) were determined. Positive discordance of general health was defined as a patient rating minus physician rating >25 mm on a 100-mm VAS. Differences between study groups were evaluated using multivariable logistic regression analysis. All variables with a $p \leq 0.10$ in the bivariable analysis plus age, gender and disease duration were entered into the regression model.

Results: The mean (standard deviation [SD]) age of RA patients was 56.6 (13.6) years; 88.0% were females. The mean (SD) disease duration was 11.2 (10.0) years. Positive patient-physician discordance was found in 78 (36.6%) patients. Only 2 patients exhibited negative discordance. In the multivariable analysis, patients with positive discordance were more likely to have a higher global assessment of pain (OR=1.05, 95% CI 1.03–1.07, $p<0.001$) and HAQ scores (OR=3.19, 95% CI 1.70–6.00, $p<0.001$), and were more likely to receive therapy with biologic agents (OR=3.06, 95% CI 1.40–6.71, $p=0.005$) than those without discordance. Conversely, patients with positive discordance had lower physician's assessment of function (OR=0.96, 95% CI 0.93–0.98, $p=0.002$). No association was found for comorbidities including depression and fibromyalgia syndrome.

Conclusion: In this group of patients with RA, a large number differed from their physicians in the assessment of general health. Positive discordance was associated with patients' self-report of pain and disability, and the use of biologics. The awareness of these factors may help to better assess disease activity and treatment response in this population.

198

Accuracy Of International Classification Of Diseases (Ninth Revision) Coding For Rheumatoid Arthritis In The Primary Care Setting. Sheena Ogando, Karolina M. Weiss and Harry D. Fischer. Albert Einstein College of Medicine at Beth Israel Medical Center, New York, NY.

Background/Purpose: Current quality measures are diagnosis driven and focus on management. For rheumatoid arthritis (RA), the Physician Quality Reporting System requires that a disease modifying anti-rheumatic drug (DMARD) therapy be prescribed. Quality measures do not account for incorrect diagnoses. Diagnostic error can stem from a physician or from a patient report of a medical history. Prior studies have shown a discrepancy between patient report and physician diagnosis. One study reported diabetes - a well defined disease - had no variance, while arthritis - a less clearly defined disease - had a 15% variance, with patients over reporting the disease. Our objective is to determine the accuracy of RA diagnosis in our institution's primary care offices and to evaluate if quality measures are met

Methods: Adult patients with the International Classification of Diseases, Ninth Revision (ICD-9) code for Rheumatoid Arthritis (714.0) were searched from April 2011 to April 2013 using our institution's primary care electronic medical record. The medication list was reviewed for the presence of a DMARD. The paper chart of patients seen in our institution's rheumatology clinic was reviewed for a more accurate diagnostic code.

Results: 246 patients were identified by ICD-9 code using the primary care electronic medical record; 172 were used for evaluation. The average age of the patient population was 60.4 with a standard deviation of 12.7. 88.4% (152) were female. The rate of incorrect ICD-9 coding by primary care physicians was 24–38% [CI of 95%]. The top 5 rheumatologist established diagnoses in these patients were osteoarthritis (20), other inflammatory arthritis (10), undifferentiated connective tissue disease (8), osteoporosis/osteopenia (5), and systemic lupus erythematosus (5). In patients with rheumatologist confirmed RA, 12–26% [CI of 95%] did not have a DMARD in the primary care medication list.

Conclusion: The high incidence of primary care physicians erroneously utilizing the 714.0 ICD-9 code in our institution can be attributed to inaccurate reporting of the disease by the patient and its usage to rule out the disease. In 48 cases, a patient reported to their primary care physician that they suffered from rheumatoid arthritis when in fact they had another diagnosis. These patients with inaccurate ICD-9 codes will be inappropriately categorized as receiving poor levels of care by not meeting RA quality measures. In patients with true disease, a lower percentage is noted to not meet the quality measure of DMARD treatment. Interestingly, it was observed that injectible medications were not documented in the primary care medication list. This could be due to the fact that patients often bring physical bottles for medication reconciliation and not the injectables. Taking this into consideration, the percentage of RA patients not meeting quality measures is likely considerably lower. In conclusion, since quality measures do not address the issue of inaccurate diagnosis, its emphasis on management and its potentially associated penalties should be reevaluated. Further studies are needed to determine if patients with inaccurate coding are subjected to unnecessary treatment or testing.

199

Overcoming The Barriers To Adequate Hydroxychloroquine Retinal Toxicity Screening. Cristina Arriens[1] and Elizabeth Blair Solow[2]. [1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX.

Background/Purpose: Hydroxychloroquine (HCQ) is considered a minimal risk drug in the treatment arsenal for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and other rheumatic diseases; however it has a well-documented risk of retinal toxicity in approximately 1% of patients following 5 years of use. Adequate ophthalmologic examination monitoring can limit the impact of toxicity on vision by early detection. The American College of Rheumatology's position statement regarding screening for HCQ retinopathy recommends baseline ophthalmologic examination within the first year of treatment and annual examinations after 5 years of therapy as the minimum for healthy patients. It was recognized that multiple patients in a busy county hospital system receiving treatment with HCQ lacked retinopathy screening exams. A quality improvement project to ascertain the factors that lead to failure within this system was devised with the goal of improving compliance with the accepted guidelines.

Methods: In this busy county hospital outpatient rheumatology clinic we performed a chart review to evaluate provider, patient, and system factors to determine where the level of breakdown in achieving baseline eye examinations occurred. A referral to ophthalmology clinic was required for the provider to adequately fulfill their role. A scheduled appointment with ophthalmology was required for the system to meet its responsibility. The patients' role was assessed by their appointment attendance. A physician-initiated, patient driven intervention was instituted in which rheumatology physicians provided the ophthalmology clinic phone number and asked the patient to call to schedule their appointment. Compliance with screening guidelines was re-assessed 1 year later.

Results: The average age of the 60 patients was 48 years and included 30 RA, 20 SLE, and 10 other connective tissue diseases. Prior to the intervention, 32 patients (53%) had completed a baseline retinal toxicity exam, 2 (3%) were not referred, 6 (10%) had no-showed an appointment, and 20 (33%) had a referral without an appointment scheduled. Failure occurred at the system level. Following the intervention, of the 53 patients still taking HCQ, now 36 (68%) had completed their screening visit, 0 (0%) were not referred, 1 (0.2%) had no-showed, and 16 (30%) were referred with no appointment. Pre- intervention 25 of the remaining 53 were compliant with screening examination and eleven more patients became compliant post-intervention, a statistically significant improvement determined by McNemar's test ($p=0.0026$).

Conclusion: In this quality improvement project the major barrier to patients receiving baseline eye exams for HCQ toxicity was found to be a system issue. The physician-initiated, patient driven intervention was successful in improving compliance in the 1 year time frame of study. In addition to this intervention, future efforts will be aimed at inter-departmental communication and education between ophthalmology and rheumatology regarding the necessity of timely retinal evaluations.

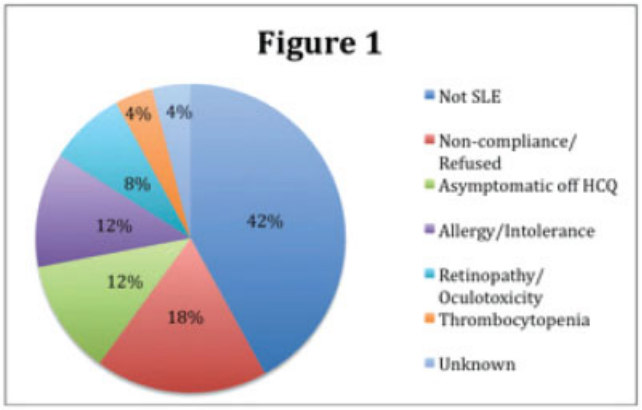
Hydroxychloroquine Use Among Systemic Lupus Erythematosus Patients In An Academic Rheumatology Practice. James G. Miceli[1] and Harry D. Fischer[2]. [1]Beth Israel Medical Center, New York, NY, [2]Albert Einstein College of Medicine at Beth Israel Medical Center, New York, NY.

Background/Purpose: Hydroxychloroquine (HCQ) is a mainstay in the current treatment of systemic lupus erythematosus (SLE). HCQ has been shown to reduce the incidence of SLE flares, reduce the risk of irreversible end-organ damage, and improve survival in SLE patients. Yet, few studies have been devoted to examining its prevalence of use. Prior papers have either examined HCQ use as a secondary endpoint (56–64%) or as a primary endpoint in a community practice (55%). Our study aims to identify the prevalence of HCQ use in an urban academic rheumatology practice and to identify the reasons for nonuse

Methods: A search of medical records with a diagnostic code for systemic lupus erythematosus (710.0) was performed for patients seen within a three-month period (September 1–December 1, 2011) at Beth Israel Medical Center's rheumatology clinic. Charts for 211 patients were reviewed for active use of HCQ; if the patient was not on HCQ, the chart was further reviewed and an explanation for nonuse was documented if present.

Results: A total of 161 out of 211 SLE subjects (76.3%) were found to be actively using hydroxychloroquine. Among nonusers, 21 (42%) did not have a definitive diagnosis of SLE; 9 (18%) were either non-compliant or refused treatment; 6 (12%) had an allergy or intolerance to HCQ; 6 (12%) were not taking HCQ for unclear reasons but were asymptomatic; 4 (8%) reported a history of HCQ-induced oculotoxicity; and 2 (4%) developed thrombocytopenia presumed secondary to HCQ (Figure 1).



Conclusion: The use of HCQ in SLE patients at our institution exceeded rates of use reported elsewhere. Nonetheless, almost ¼ of potential candidates for treatment were not prescribed HCQ. Almost half of the non-prescribed patients lacked a definitive diagnosis of SLE. The majority of the other non-takers had a documented explanation. Our results help to better define reasons for nonuse of HCQ in patients with SLE. It is hoped that recognition of these factors could help to further increase the use of HCQ in SLE patients.

Comparison To Organisational Models For EARLY Rheumatoid Arthritis Management: Routine Care Versus EARLY Arthritis Clinic. Giovanni Ciancio[1], Ilaria Farina[1], Federica Pignatti[2] and Marcello Govoni[1]. [1]Rheumatology Unit-Azienda Ospedaliera-Universitaria Sant'Anna, Ferrara, Italy, [2]Rheumatology Unit-Azienda Ospedaliera-Universitaria Sant'Anna, Ferrara, Italy, ferrara, Italy

Background/Purpose: although the Early Arthritis Clinic (EAC) institution is considered the best approach for the management of rheumatoid arthritis (RA) at an early stage, to the best of our knowledge there is no formal demostration that this organisational model is better than a conventional model in terms of public health care and of improved clinical, therapeutic and radiographic outcomes. Our purpose was to evaluate whether significant differences in clinical and therapeutic outcomes exist between two groups of patients with Rheumatoid Arthritis followed in a EAC and in a routin care (RC) model, respectively.

Methods: Two groups of RA patients fulfilling 1987/ACR criteria were retrospectively analised. In the first group, RA diagnosis was made in our centre between 2002 and 2008 and patients were followed with a RC model. In the second one, RA diagnosis was made in our centre between 2009 and 2013 and patients were followed in our EAC. Patients with a follow-up of at least 2 years were included. For each patient of the two groups, lag time from symptom onset to diagnosis and from symptom onset to the beginning of DMARDs therapy were calculated. Disease activity were compared between the two groups using DAS28 and EULAR response criteria at baseline (T0) and after 6 (T6), 12 (T12) and 24 (T24) months. The ratios (%) of patients who started a biological therapy within 24 years after diagnosis were compared between the two groups

Results: A total of 273 RA patients, divided into two groups, were evaluated: 209 (mean age 59 ± 24.04 years,165 F, 44 M) followed in RC and 64 (mean age 59 ± 13.44 years, 50 F,14 M) in EAC. Lag time from symptom onset to diagnosis resulted significally lower ($p<0,0001$) in patients assessed in EAC (5.73 ± 8.09 mesi) compared to that of the other group (20.90 ± 30.3 mesi) and treatment beginning occured before in EAC population (7.17± 8.26 mesi) respect to that followed in RC (21.98±32.39 mesi) with a significant difference ($p<0.0004$). At baseline DAS28 evaluation was similar between groups (4.76±1.24 in RC vs 4.94 ± 1.41 in EAC) and was significally reduced to 2.82 ± 1.24 (RC) and 2.46 ±1.12 (EAC) after 24 months ($p<0.036$). A significant statistical difference emerged from the comparison to the mean VES value (19.9 ±15.9 RC vs 13.6 ± 11.3 EAC, $p<0.003$) and SJ (swollwn joints) value (1 ± 1.8 RC vs 0.43 ± 1.2 EAC, $p<0.02$) at T-24. Within 24 months, biologic therapy was initiated in 29% of patients followed in RC and in 9.3% of patients followed in EAC population ($p<0,0013$).

Conclusion: In comparison with the RC model, the EAC institution has allowed in our experience a significant reduction of the time for diagnosis and for the therapeutic intervention, with an improvement in clinical outcomes, less use of biological drugs and a significant long-term savings on pharmaceutical spending

Analysis Of Non-Steroidal Anti-Inflammatory Drug Burden Among Rheumatoid Arthritis Patients Using The Dougados Algorithm. E Alemao[1], L Xie[2], R Wong[1], G Lltalien[1] and O Baser[3]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]SATinMED Research, Ann Arbor, MI, [3]STATinMED Research and University of Michigan, Ann Arbor, MI

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are used to alleviate RA pain symptoms, but they may be associated with adverse events. Previous studies examining clinical and economic outcomes associated with NSAID use in RA have not implemented a systematic algorithm for NSAID use, which would more precisely define the NSAID burden. This study evaluated the correlation between the NSAID intake score developed by Dougados *et al.*[1] and other traditional measures of NSAID burden. In addition, clinical and economic outcomes in patients with high versus low NSAID scores were compared.

Methods: A retrospective analysis was performed on RA incidence populations using National Medicare claims data (01/01/2006–12/31/2010) with a 12-month baseline and 24-month follow-up period. Patients had to have at least two RA diagnoses at least 60 days apart between January 1, 2007 and December 31, 2009. The date of the first RA diagnosis was designated as the index date. High, middle and low cohorts were created based on the distribution of the NSAID intake score.[1] The correlation between NSAID score and traditional measures was determined by univariate analysis. Clinical and economic outcomes during follow-up were compared with a generalized linear model (GLM).

Results: Approximately 19% (n=10,313) of 52,973 incident patients with RA used NSAIDs during the baseline period. Dougados NSAID score correlated with percentage of days with at least one NSAID intake (0.69 [$p<0.05$]) and number of NSAID tablets (0.59 [$p<0.05$]). At baseline, 36.34% of patients had a low NSAID score (≤10% follow-up time on diclofenac 150 mg or equivalent), 58.33% had a medium NSAID score (11–90% time on diclofenac 150 mg or equivalent) and 5.32% had a high NSAID score (>90% time on diclofenac 150 mg or equivalent). Compared with the high NSAID cohort, the low NSAID cohort were older (mean age 75.9 vs 74.4 years, $p<0.05$), had higher Charlson Comorbidity Index scores (3.2 vs 2.8, $p=0.05$), and higher rates of chronic kidney disease (CKD) (11.39 vs 6.38%, $p<0.05$), chronic obstructive pulmonary disease (22.9 vs 18.94%, $p<0.05$), and respiratory disorders (57.54 vs 52.28%, $p<0.05$). Prior to

baseline adjustments, patients in the low NSAID cohort had fewer gastrointestinal perforation cases (0.53 vs 1.28%, $p<0.05$), and lower per patient per year (PPPY) total costs ($26,235 vs $30,078, $p<0.05$) and outpatient pharmacy costs ($4,347 vs $6,547, $p<0.05$) than patients in the high NSAID cohort. After adjusting for baseline differences in demographic and clinical characteristics with the GLM, patients in the high NSAID cohort had a higher risk for CKD (20.23 vs 17.31%, $p<0.05$), higher PPPY inpatient costs ($13,187 vs $10,652, $p<0.05$) and higher PPPY outpatient pharmacy costs ($4,605 vs $3,515, $p<0.05$) during the follow-up period.

Conclusion: The Dougados NSAID algorithm, developed to evaluate NSAID burden in spondyloarthritis, is also applicable to the RA patient population. Medicare patients with RA with high NSAID scores had a higher probability of CKD and higher average in/outpatient costs. Therapies that reduce NSAID burden in elderly patients may protect those with RA from CKD and help reduce cost.

Belief In Self-Adjustability Of Medication Dosing Is Negatively Correlated With Medication Adherence In Patients With Rheumatoid Arthritis. Wenxin Sun[1], Dianne Carrol Tan Bautista[1], Xiaohui Xin[2], Yu Ting Saw[2], Wee Boon Tan[2], Kanchanadevi Balasubramaniam[2], Wan Pin Lee[2], Steve Thein Htay Oo[2], Yin Bun Cheung[1] and Julian Thumboo[2]. [1]Duke-NUS Graduate Medical School, Singapore, Singapore, [2]Singapore General Hospital, Singapore, Singapore.

Background/Purpose: Medication adherence in Rheumatoid Arthritis (RA) is reported to be generally low. This major problem needs to be addressed because it leads to reduced treatment benefits and greater healthcare costs. We hypothesized that specific medication beliefs would influence adherence to disease-modifying anti-rheumatic drugs (DMARDs) in RA patients, and assessed this in a cross-sectional study.

Methods: Based on focus groups and a quantitative survey, we identified 5 belief factors in patients with RA: that DMARDs harm health; that DMARDs benefit health; that DMARD dosing/regimens can be changed by patients; that DMARD side effects can be effectively managed; that DMARD side effects cannot be effectively managed. In this IRB approved study, we administered a Medication Behavior Survey (n=21, developed from focus group data) assessing these 5 belief factors and the 8-item Morisky Medication Adherence Scale (MMAS-8, score range 0–8.0) to measure non-adherence in a consecutive sample of English-speaking RA patients during routine outpatient visits from November 2012 to April 2013 at our tertiary referral center. Multiple linear regression (MLR) was used to examine the relationship between the 5 belief factors and MMAS-8, as well as MMAS-8 intentional and unintentional non-adherence subsets, adjusting for demographic factors (gender, race, age and education).

Results: Among 279 English-speaking RA patients (82% females; 56% Chinese, 15% Malays, 22% Indians; mean age (SD) 53.8 (12.7) years). MLR with MMAS-8 scores showed that a stronger belief that DMARD dosing/regimens can be changed by patients was significantly negatively correlated with MMAS-8 scores (beta=−0.53, 95% CI −0.75 to −0.37, $p<0.001$) in a model that also included the other 4 factors (none of which was significantly associated with MMAS-8 scores). Similarly, MLR with MMAS-8 subsets showed that a stronger belief that DMARD dosing/regimens can be changed by patients was negatively correlated with both intentional and unintentional non-adherence MMAS-8 subsets (beta=−0.25, 95% CI −0.39 to −0.11, $p<0.001$; beta=−0.28, 95% CI −0.42 to −0.14, $p<0.001$, respectively). Additionally, belief that DMARDs side effects cannot be effectively managed was negatively associated with intentional non-adherence MMAS-8 subset (beta = −0.18, 95% CI −0.32 to −0.03, $p=0.019$).

Conclusion: We found that stronger belief that DMARD dosing/regimens can be changed by patients was an important factor associated with non-adherence in an urban Asian population. Other beliefs do not apparently provide additional value in accounting for non-adherence. If confirmed in prospective studies, this observation may provide a simple and rapid way to identify patients who are more likely to be non-adherent with DMARD therapy.

Evaluation Of Hospitalizations and Costs In Patients With Rheumatoid Arthritis In United States Medicare Population. E Alemao[1], L Wang[2], G Lltalien[1], O Baser[3], H Yuce[4] and M Hochberg[5]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]STATinMED Research, Dallas, TX, [3]STATinMED Research and University of Michigan, Ann Arbor, MI, [4]New York City College of Technology (CUNY), Brooklyn, NJ, [5]University of Maryland, Baltimore, MD

Background/Purpose: RA-related hospitalization and surgery (e.g. total joint arthroplasty [TJA]) are important long-term outcomes in RA. While advances in treatment for RA have resulted in decreased admissions for active disease, the national rates of RA-related procedures, hospitalizations and their costs in elderly patients with RA have not been reported. We evaluated the rates of first and subsequent RA-related surgery, hospitalization and mortality in a US Medicare population, analyzed predictors of RA-related surgery and compared total costs between RA patients with and without surgery.

Methods: Data from patients enrolled in the US Medicare Claims Database from January 1999 to December 2009, who had ≥2 RA diagnoses (ICD 714.0) ≥2 months apart during the identification period were analyzed. The date of the first RA diagnosis was designated as the index date. Those with a baseline period <12 months (i.e. those diagnosed during 1999 and 2000) were considered prevalent cases. Kaplan–Meier analysis was used to estimate the cumulative incidence of orthopedic surgery following RA diagnosis. Cox proportional hazards (CPH) modeling identified factors associated with surgery (TJA, TJA-associated procedures, non-TJA) and overall mortality. Estimated healthcare costs (mean and standard deviation) for all RA patients with surgery were compared with those for RA patients without surgery.

Results: The study population comprised 360,912 patients with RA enrolled in Medicare who met the study inclusion criteria. Cumulative 4- and 10-year TJA incidence rates were 7.5 and 13.2%, respectively; mortality rates were 13.2 and 27.9%. Of all RA patients with surgical experience, 86.5% had a TJA procedure. Patient characteristics are shown (Table). Based on CPH models, predictors of surgery varied by type of procedure; positive factors often included regional demographic and co-morbid osteoarthritis (OA) at baseline, and negative predictors often included follow-up therapy and minority race. For example, for TJA, patients with OA and patients living in the Midwest had a higher hazard (hazard ratio [HR]=2.11, $p<0.01$; HR=1.38, $p<0.01$, respectively). Patients receiving combination (MTX + biologic DMARD) RA therapies during follow-up had a lower hazard (HR=0.41, $p<0.01$). RA patients with surgery had almost double the average inpatient cost at $19,382 vs $10,282 for patients without surgery ($p<0.01$). RA patients with surgery also had significantly higher outpatient, outpatient emergency room, and office costs ($p<0.01$).

	Patients with surgery	Patients without surgery	Standard deviation
Mean age, years	74	76	22.45
White	88%	82%	17.76
Mean Charlson's Comorbidity Index scores	2.27	2.60	17.04
OA	63%	46%	33.85
High RA severity score	35%	27%	17.91

Conclusion: Medicare patients with RA continue to experience high rates of RA-related surgery, hospitalization and overall mortality. However, biologic DMARD therapies appear to have a protective effect on all outcomes. Greater availability of efficacious RA therapies has the potential to reduce RA-related surgery, hospitalization and costs.

Temporal Trends In The Prescribing Of Disease Modifying Anti-Rheumatic Drugs For Rheumatoid Arthritis and The Impact Of Guidelines. Gemma L Wallace[1], C. J. Edwards[2], Nigel K. Arden[3], Daniel Prieto-Alhambra[4] and Andrew Judge[5]. [1]University of Oxford, Oxford, United Kingdom, [2]University Hospital Southampton, Southampton, United Kingdom, [3]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, United Kingdom, [4]URFOA-IMIM, Parc de Salut Mar; Idiap Jordi Gol; University of Oxford; University of Southampton, Barcelona, Spain, [5]Oxford University, Oxford, United Kingdom

Background/Purpose: Disease modifying anti-rheumatic drugs (DMARDs) are standard initial treatments for rheumatoid arthritis (RA). Many RA treatment guidelines have been published including from the American College of Rheumatology (ACR), European League Against Rheumatism (EULAR) and British Society for Rheumatology (BSR). However, there is little evidence to demonstrate that guidelines alter prescribing practice. BSR guidelines for treatment of RA were published in 2006 and recommended initiation of DMARDs in the first 90 days after RA diagnosis. We aimed to test whether publication of these guidelines changed clinical practice.

Methods: We used the Clinical Practice Research Datalink, consisting of primary care records & prescriptions, secondary care referral details, procedures and diagnoses, for >10 million patients from a representative sample of primary care practices in the UK. DMARDs are usually initiated in the UK by a rheumatologist, with ongoing DMARD prescribing usually performed by primary care physicians with supervision by a rheumatologist. Incident diagnoses of RA in persons aged ≥18 years between 1995–2010 were identified. For each calendar year and quarter, the proportion of patients receiving any DMARD prescription within 90 days and 1 year of diagnosis was ascertained. An interrupted time-series regression model was used to assess whether trends in the proportion of patients receiving DMARDs within 90 days and 1 year changed following publication of the 2006 BSR Guidelines.

Results: Between 1995 and 2010, 25,963 incident cases of RA were identified, 69% female, average age of diagnosis 59 years. There was a progressive increase in the proportion of patients prescribed a DMARD by a primary care physician within 90 days from 16.6% in 1995 to 23.5% in 2005. The proportion receiving DMARD/s within 90 days increased more rapidly following publication of the BSR guidelines (Figure 1) to 27.9% by end 2006 and 36.0% in 2010 (p=0.01). A similar pattern was observed for the proportion of patients receiving DMARD/s within 365 days of diagnosis (p=0.002).

FIGURE: Time series of proportions of patients receiving DMARD within 90 or 365 days of rheumatoid arthritis diagnosis in UK by quarter from January 1995 to December 2010

Conclusion: The proportion of patients prescribed a DMARD in primary care in this study is lower than generally accepted estimates. This may reflect reality for patients with RA outside of specialist centres although secondary care prescribing is not captured within this database. Nevertheless, prescriptions that are captured should be representative of overall trends in prescriptions within the UK and suggests that guidelines published by a national body can improve the proportion of patients receiving DMARD treatment in the first year after diagnosis of RA.

American College Of Rheumatology's Rheumatology Informatics System For Effectiveness Registry Pilot. Peter J. Embi[1], William Stephens[2] and Rachel Myslinski[3]. [1]The Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH, [3]American College of Rheumatology, Atlanta, GA

Background/Purpose: There is a significant need in the rheumatology community to access and integrate data across diverse patient populations in order to aid quality improvement efforts, help rheumatologists meet quality reporting requirements, as well engage in clinical research. We report on the pilot results of the American College of Rheumatology's registry expansion initiative that links disparate clinical data resources across multiple clinical sites and systems in support of rheumatology practice and research. This effort is aimed at providing a reliable, cost-effective means of connecting data from multiple EHR systems, using these data for quality improvement, quality reporting, and research querying.

Methods: The design and execution of effective quality improvement projects and clinical studies requires access to high quality, longitudinal data. In most instances, such data are collected, formalized, stored and retrieved using project- or organization-specific disease registries or data warehouses. It is increasingly desirable to access data across multiple clinical sites for quality improvement and clinical research purposes, but disparate EHR systems remain difficult to connect for data interchange. Furthermore, in these types of settings, organizational and policy barriers often preclude the use of centralized repositories. To address this need, the ACR is piloting this system – called the Rheumatology Informatics System for Effectiveness (RISE) – to enhance registry efforts to benefit rheumatic disease research and quality reporting efforts. RISE is a federated system of interconnected clinical data repositories. The RISE architecture allows data to remain at the sites thereby allowing sites full control of their data. Data is accessed by a Federated Query Processor service that maintains no source practice data internally, but instead acts as a secure router and aggregator for information as it passes through the grid. The RISE system enables access to clinical data across multiple sites while maintaining high levels of data security.

Results: The model employed by RISE uses an approach to enable the federated query of geographically distributed data sources. This platform is being implemented at 6 sites, with several more planned. The initial sites include a variety of academic and community centers, which demonstrate feasibility for implementation in a variety of practice settings. The following table shows aggregate data from two of the initial sites:

Query	Aggregate Result
Number of patients with an RA diagnosis	6,131
Number of patients with a RAPID score ≥ 3	260*
Number of patients taking methotrexate	6,724
All patients in the registry	44,390

Conclusion: The design, deployment and initial use of the ACR RISE network addresses the need for data access across disparate sites using otherwise non-interoperable information systems and creates the opportunity for a robust source of rheumatology clinical data that can be used for multiple purposes. We believe that such an approach to distributed data sharing in rheumatology will help advance science and improve clinical practice.

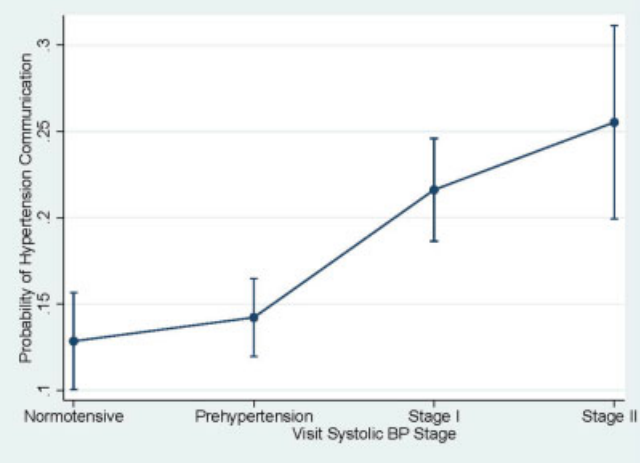
Frequency and Predictors Of Hypertension Communication In Rheumatoid Arthritis Visits. Christie M. Bartels, Heather Johnson, Elizabeth A. Jacobs, Patrick McBride and Maureen Smith. University of Wisconsin School of Medicine and Public Health, Madison, WI

Background/Purpose: Patients with rheumatoid arthritis (RA) have a 60% higher cardiovascular disease (CVD) event risk, yet previously we demonstrated they were ~30% less likely to have hypertension diagnosed. We sought to examine the frequency and predictors of documented hypertension/blood pressure (BP) communication during rheumatology visits for RA patients with undiagnosed and/or uncontrolled hypertension.

Methods: Electronic health record searches from 2004–11 identified RA patients (defined by ICD-9 algorithm) who had uncontrolled or undiagnosed

hypertension and who had encounters at 1 of 3 rheumatology clinics. Using Joint National Committee-7 criteria, undiagnosed was defined as ≥3 BPs ≥140/90 mmHg or 2 readings ≥160/100 mmHg without prior diagnosis or antihypertensive medication; BP control was ≥3 consecutive BP's <140/90 mmHg. We abstracted rheumatology clinic notes from first eligible date for hypertension diagnosis/control through date of hypertension control or end of data. We examined the frequency and predictors of any hypertension communication beyond vital sign documentation. We used multivariate logistic regression to examine the impact of systolic BP stage at a rheumatology visit on the predicted probability (PP) of hypertension communication. Covariates included patient sociodemographics, comorbidity, utilization, visit date, and rheumatologist.

Results: Among 1267 RA patients, 501 were studied who had uncontrolled hypertension, and 232 of the 501 patients met criteria and lacked a hypertension diagnosis. Mean age was 62 years, 76% were female, 11% were current and 35% former smokers, and prior CVD was noted in >20%. In 2677 abstracted visits, BP's varied with 20% Normotensive (<120 mmHg) at a given visit, 45% Prehypertensive (≥120 - <140 mmHg), 32% with Stage I (≥140 - <160 mmHg) and 11% with Stage II (≥160 mmHg) elevations. Overall 23% of RA visits contained any hypertension communication. After adjustment, even in visits with systolic BPs ≥160 mmHg, only 25% contained hypertension communication (PP 25%, CI 20,31). Compared to Stage I systolic elevations, Stage II elevations did not significantly increase the probability of communication (Figure 1), although both were higher than normotension and prehypertension. When examining other predictors, active tobacco users were least likely to have hypertension communication (PP 12%, CI 8,16).



Conclusion: Despite higher CVD risk, many RA patients had undiagnosed or uncontrolled hypertension. Even with systolic BPs≥160 mmHg only 1 in 4 rheumatology encounters documented communication about hypertension, demonstrating lost opportunities for identifying and managing modifiable CVD risks. Future research should investigate patient and provider role perceptions and other barriers and facilitators of hypertension management to systematically improve CVD prevention in RA patients.

Three Approaches To Evaluating Step Therapy Policies For Immune Disorder Specialty Pharmaceuticals. Michael P. Ingham[1], Andrew Paris[2], Lorie A. Ellis[1] and Chris Kozma[3]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Vigilytics, Victor, NY, [3]CK Consulting, Saint Helena Island, SC

Background/Purpose: Rheumatology practices are increasingly exposed to patient health care benefit plans that include "step therapy" (ST) policies which affect medication choice. Managed care companies implement ST policies for specialty pharmaceuticals to reduce utilization of infused biologics (IV) in new patients, based on an assumption that there will be cost savings. To assess whether managed care policies that limit access to infusion biologics in order to shift new patients to injection biologics (SQ) have had the desired effect.

Methods: The share of utilization of biologic products for plans identified with ST policies, were evaluated versus a comparison cohort using three separate methodologies. ST plans were first identified using data from Symphony Health Solutions Corp.'s ProMetis database. This database provides a unique opportunity for this type of analysis, as it spans multiple identifiable plans which can be cross-referenced to known ST policies. Data included payer, prescription and procedure claims with unique anonymised patient identifiers. Analyses #1 & #2 included data from plans with ST policies throughout 2010. Analysis #1 compared the percentage of patients with biologic claims for plans with ST policies to all other plans in the database during the same time period (ALL OTHER). Analysis #2 compared the percentage of patients with biologic claims for plans with ST policies to a set of plans matched roughly to the ST plans based on region and relative size (MATCHED). Analysis #3 included data from 1/1/2006 through 4/30/2011 for plans with a known ST implementation date (index date) and with available biologic claims within 365 days before and after this index date. Analysis #3 evaluated the period after ST policy implementation to the period before implementation (PRE/POST). Data for each analysis were descriptive of the number of patients with access and using any biologic in the ST and comparison cohorts. The net change in percentage of patients with infusion claims is reported.

Results: Sixteen different plans were identified with a ST policy. The only analysis to demonstrate a shift in patient utilization away from IV biologics was the ALL OTHER comparison (−5.1%). When comparison plans were MATCHED to ST plans, or when evaluating existing plans using PRE/POST methods, patient access and use of infusion biologics increased (+7.0% and +2.8% respectively).

Conclusion: These data suggest that policies designed to reduce overall patient proportions using infusion biologics may not have the intended effect, or may at most affect 5.1% of biologic users in any given year. The limited potential benefit needs to be weighed against the cost of implementing and monitoring this type of policy, as well as the provider resource implications.

Focus on cardiovascular Risk Factor Recording In a Rheumatology Outpatient Clinic. Eirik Ikdahl[1], Silvia Rollefstad[1], Inge C. Olsen[1], Tore K. Kvien[2], Inger Johanne Widding Hansen[3], Dag Magnar Soldal[4], Glenn Haugeberg[4] and Anne Grete Semb[1] [1]Diakonhjemmet Hospital, Oslo, Norway, [2]University of Oslo, Oslo, Norway, [3]Hospital of Southern Norway Trust, Kristiansand, Norway, Kristiansand, Norway, [4]Hospital of Southern Norway Trust, Kristiansand, Norway

Background/Purpose: There is an unmet need of implementing the knowledge of cardiovascular (CV) risk in patients with rheumatoid arthritis (RA) into clinical practice. Our aim was to evaluate CV risk factor (CVRF) recording in a rheumatology outpatient clinic (ROC), where the standard was annual CVRF recording for all patients. Moreover, we evaluated how various clinical models influenced the extent of CVRF recording, comparing a regular ROC (RegROC) to an arthritis clinic (AC), a structured, team-based model.

Methods: Of the 1142 RA patients visiting ROC at the Hospital of Southern Norway during 2012, 612 attended RegROC and 530 attended the AC. Allocation to either RegROC or the AC was based on clinical judgement by the rheumatologist and did not include any inclusion criteria. For all patients, CVRFs were to be recorded in the medical journal as well as in a computerized journal program, GoTreatIT-rheuma (GTI-r). We searched both journal systems to ascertain how many patients had CVRFs recorded.

Results: Overall, 38.2% of patients had CVRFs recorded and only 26.9% had recorded all the CVRFs included in the CV risk calculator, SCORE. When comparing the AC to the RegROC, odds ratios (OR) for CVRFs being recorded in the medical journal was for: lipids: 5.0–6.0, blood pressure (BP): 12.4, glucose: 9.1, and HbA1c: 6.1 (p for all < 0.001) (Table). In the GTI-r

journal the discrepancies between the AC and RegROC were even more pronounced. OR for CVRFs being recorded was for lipids: 15.9, BP: 27.5 and for having recorded all the CVRFs included in SCORE: 21.0 (p for all < 0.001).

Table. Cardiovascular risk factors recorded in patients attending rheumatology consultations in a rheumatology outpatient clinic

Cardiovascular Risk factors	ROC (n=1142)	AC (n=530)	RegROC (n=612)	OR* (95% CI)	AC vs. RegROC P-value*
Medical journal: *n (%)*					
Brachial BP	576 (50.4)	421 (79.4)	155 (25.3)	12.36 (9.27, 16.48)	< 0.001
Total cholesterol	537 (47.0)	354 (66.8)	183 (29.9)	5.02 (3.89, 6.48)	< 0.001
LDL-cholesterol	503 (44.1)	347 (65.5)	156 (25.5)	5.87 (4.53, 7.62)	< 0.001
HDL-cholesterol	515 (45.1)	350 (66.0)	165 (27.0)	5.59 (4.31, 7.23)	< 0.001
Triglycerides	472 (41.3)	333 (62.8)	139 (22.7)	6.02 (4.63, 7.82)	< 0.001

Medication Adherence In Patients With Gout: A Systematic Review. Mary De Vera[1], Sharan Rai[1] and Vidula Bhole[2]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]EpiSolutions Consultancy Services, Thane, India

Background/Purpose: Recent data suggesting the growing problem of medication non-adherence in gout has called for the need to understand the magnitude of the problem as well as its determinants. To date, only one systematic review has summarized medication adherence across a variety rheumatic diseases, including three studies in gout. To update this data as well as better understand patterns and determinants of adherence in this population, our objective was to a conduct a systematic review of the literature examining medication adherence among patients with gout.

Methods: We conducted a systematic search of MEDLINE (1946-), EMBASE (1974-), and INTERNATIONAL PHARMACEUTICAL ABSTRACTS (1970-) databases and selected original studies that included patients with gout and measured and/or reported medication adherence in real-world settings. We extracted information on: 1) study design, 2) sample size, 3) length of follow-up, 4) data source (e.g. prescription records vs. electronic monitoring vs. self-report), and 5) adherence measures and reported estimates. We assessed quality of studies by adapting and applying published recommendations for the reporting, assessment, and evaluation of medication adherence studies.

Results: After screening 963 potential articles, 14 met inclusion criteria. We divided studies according to methods used to measure adherence including prescription records (9), electronic monitoring devices (1), and self-report (4). Studies using prescription records have the largest sample sizes and lowest reported adherence, ranging from 17% to 44%. Higher adherence rates (or scores) were reported in studies based on self-report, which may be due to social desirability bias. With respect to determinants, younger age has been shown as a predictor of poor adherence while other factors including gender and gout-related factors (e.g., flares) are less consistent across studies.

Conclusion: This is the first systematic review of medication adherence, with particular focus on gout patients. Adherence rates may vary according to methods used to measure adherence. Overall, synthesis of current evidence suggest that medication non-adherence is substantial in gout. Findings highlight the importance of discussing adherence with gout medications during health care professional encounters with gout patients.

Study	N	Follow-up	Adherence Measure	Main Result
Prescription Records				
Riedel 2004	5,597	2 yr	weighted average compliance rate	18% adherent

The Economic Burden Of Gout: A Systematic Review Of Direct and Indirect Costs. Sharan Rai[1], Aliya Haji[1], Lindsay C Burns[2] and Hyon K. Choi[3]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]University of British Columbia, Vancouver, BC, [3]Boston University School of Medicine, Boston, MA

Background/Purpose: The prevalence of gout, an excruciating and disabling joint disease, has been increasing in recent decades such that it now constitutes the most common inflammatory arthritis in the US. A high rate of uncontrolled disease and high comorbidity burden suggest that the economic impact of gout could potentially be substantial. To clarify this impact, we systematically reviewed the literature on the productivity loss and healthcare costs associated with gout.

Methods: We conducted a mapped search of MEDLINE, EMBASE, IPA, and CINAHL databases for articles published between Jan 1993 to Jun 2013 that reported either direct or indirect costs of gout, encompassing healthcare utilization and productivity loss, respectively. Our search strategy employed mapped subject headings terms together with keywords for unindexed terms relating to the themes of gout and cost. Titles and abstracts were reviewed for preliminary inclusion criteria of: 1) full-text, original, published article; 2) gout patient population; 3) direct or indirect costs reported; 4) English language. Non-human studies and case-reports/series were excluded. Where possible, data were abstracted and tabulated on annual all-cause and gout-related direct and indirect costs per patient.

Results: Our search strategy yielded a total of 2,954 unique articles. Of these, 11 studies reporting direct and indirect costs for gout met our inclusion criteria and were included for review. Seven studies reported gout-specific data on direct costs (medical services + prescriptions), 5 on medical services, and 4 on indirect costs (work productivity loss). US estimates of the annual direct costs per patient ranged from $3,985–$22,562 for all-cause costs and $192–$5,924 for gout-specific costs. Annual per-patient medical services costs ranged from $3,122–$14,866 and corresponding indirect costs ranged from $915–$3,900 US. Patient characteristics associated with increased costs included: 1) ≥ 3 flares per year; 2) serum uric acid levels ≥ 6 mg/dL; 3) presence of tophi (**Table**).

DIRECT (MEDICAL SERVICES + PRESCRIPTION) COSTS

Gout Population	All-Cause Healthcare Cost	Gout-Related Healthcare Cost	Country	Cost Year	References

<3 attacks/year	$915[a]	USA	2011	Lynch *et al.* 2013
≥3 attacks/year	$2,021[a]	USA	2011	Lynch *et al.* 2013
Employee with gout	$2,885[c]	USA	2001–2004	Brook *et al.* 2006
SUA ≥ 6.0 mg/dL	$3,900[b]	USA	2006	Edwards *et al.* 2011
≥3 attacks/year	€ 88[f]	Spain	2007	Sicras-Mainar *et al.* 2013
1–2 attacks/year	€ 29[f]	Spain	2007	Sicras-Mainar *et al.* 2013

[a]Adjusted for age, sex, marital status, race, exempt status, full-time status, salary, tenure, region, and history of flares
[b]Unadjusted cost
[c]Adjusted for age, sex, annual salary, tenure, exempt status, race, marital status, location, and Charlson comorbidity index
[d]Adjusted for age, sex, insurance, Charlson comorbidity index, presence of hypertension, and number of all-cause prescriptions
[e]Adjusted for age, sex, index year, Charlson comorbidity index, and medication use
[f]Adjust for age, sex, resource utilization, and Charlson comorbidity index

Conclusion: Overall, the economic burden of gout was found to be substantial, with direct healthcare costs comparable to chronic rheumatic conditions such as rheumatoid arthritis. There was a paucity of data on indirect costs associated with gout, the population costs of gout (rather than patient subgroups), a lack of standardized cost reporting, and a lack of validated instruments for cost assessment in gout. Characteristics associated with increased costs generally reflected poorly controlled disease and were largely modifiable. As gout represents a metabolically-driven arthropathy that can be fully controlled with proper therapeutic approaches, substantial resources could be spared through by closing the gap between guideline recommendations and practice.

Dual-Energy Computed Tomography for Monitoring of Urate Deposition in Tophaceous Gout: A Prospective Longitudinal Study Examining Sensitivity to Change. Ashwin Rajan[1], Opetaia Aati[1], Ramanamma Kalluru[2], Gregory Gamble[1], Anne Horne[1], Anthony Doyle[1], Fiona M. McQueen[1] and Nicola Dalbeth[1] [1]University of Auckland, Auckland, New Zealand, [2]Department of Rheumatology, Auckland District Health Board, Auckland, New Zealand

Background/Purpose: Dual-energy computed tomography (DECT) is an advanced imaging method with potential for monitoring urate deposition in patients with gout. The aim of this prospective longitudinal study was to analyse the sensitivity to change of DECT urate volume measurement.

Methods: Seventy-three patients with tophaceous gout attended study visits at baseline and 12 months. All patients had a comprehensive clinical assessment including serum urate (SU) testing and DECT scanning of both feet at both visits. Two readers analysed the DECT scans for the total urate volume in both feet. Paired scans were read in chronological order. The readers were blinded to each other's measurements and all clinical measures including serum urate concentrations. Analysis included inter-reader intra-class correlation coefficients (ICCs) and limits of agreement, and calculation of the smallest detectable change (SDC).

Results: Allopurinol was prescribed in 85% patients during the study period. Mean (SD) SU concentration for both timepoints was 6.3 (1.5) mg/dL. The median (IQR) baseline DECT urate volume was 0.49 (0.16, 2.18) cm^3, and change in DECT urate volume was −0.01 (−0.40, 0.28) cm^3. Inter-reader ICCs were 1.00 for baseline DECT volumes and 0.93 for change values. Inter-reader bias (SD) for baseline volumes was −0.18 (0.63) cm^3 and for change was −0.10 (0.93) cm^3. The SDC was 0.91cm^3. There were 47 (64%) patients with baseline DECT urate volumes <0.91cm^3. Higher mean SU concentrations were observed in patients with increased DECT urate volumes above the SDC (one way ANOVA p=0.006). However, a relationship between changes in DECT urate volumes and mean SU concentrations was not observed in the entire group (Figure).

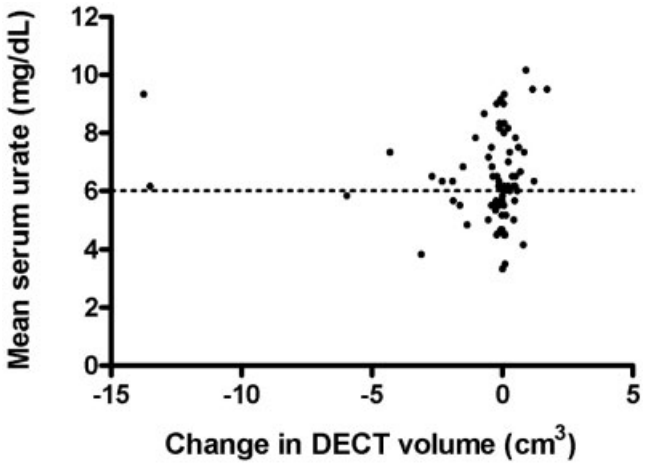

Figure. Scatter plot showing the relationship between change in DECT urate volumes and mean serum urate concentrations (baseline and Year 1).

Conclusion: DECT urate volume measurement has high inter-reader agreement but low sensitivity to change over one year in patients with tophaceous gout receiving conventional urate-lowering therapy. These data raise questions about the role of DECT as an outcome measure for clinical studies of gout.

Digital Tomosynthesis for Measurement of Bone Erosion in Gout: Comparison With Computed Tomography. Nicola Dalbeth[1], Anthony Doyle[1], Mark Roger[2], Angela Gao[2] and Fiona M. McQueen[1]. [1]University of Auckland, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand

Background/Purpose: Digital tomosynthesis is a recently developed imaging method in which multiple projected images obtained at different angles are collected with a digital detector. These projected images are used to reconstruct multiple thin planar images of the scanned object in a plane parallel to the detector. Recent reports indicate that this technology allows low-cost, low-radiation detection of bone erosion in patients with inflammatory arthritis. The aim of this study was to determine the sensitivity and reproducibility of tomosynthesis, compared with conventional computed tomography (CT), for measurement of bone erosion in gout.

Methods: Tomosynthesis and CT scans of the dominant wrist were prospectively obtained in 37 patients with gout (mean disease duration 18 years, 86% with subcutaneous tophi) (Figure). Each scan was scored separately by two radiologists for bone erosion using semi-quantitative volume assessment (sites and 0–10 scoring as for RAMRIS erosion method).

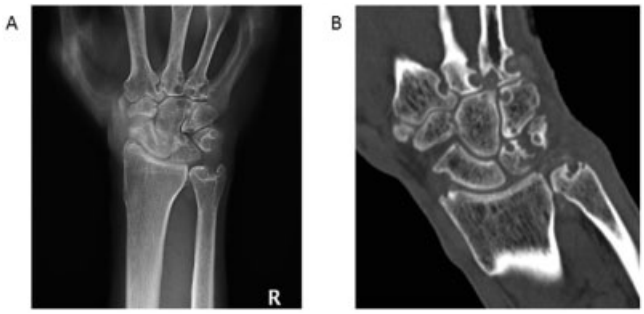

Figure. A. Tomosynthesis and B. corresponding coronal CT images of the right wrist in a participant with tophaceous gout.

Results: The mean total erosion score in the tomosynthesis scans was lower than CT scans (10.8 vs 13.2, $p=0.004$). For many individual sites (radius, scaphoid, triquetrum, trapezium, capitate, MC1 base), tomosynthesis erosion scores were significantly lower than CT scores. There were no sites where tomosynthesis scores were higher than CT. The inter-reader intraclass correlation coefficients (ICC) for the total erosion score was 0.64 (0.59–0.89) for tomosynthesis and 0.80 (0.64–0.94) for CT. At all individual sites except MC2 base, ICCs were lower for tomosynthesis than CT. We were unable to identify a combination of sites for which mean scores or ICCs for tomosynthesis approximated those of CT. There was a high correlation between tomosynthesis and CT total scores ($r=0.95$, $p<0.0001$) and at most individual sites. Total erosion scores for both tomosynthesis and CT correlated highly with hand tophus count, grip strength, and Health Assessment Questionnaire scores ($p<0.001$ for all).

Conclusion: Tomosynthesis erosion scores correlate highly with CT erosion scores and clinical measures of disease severity in patients with gout. However, tomosynthesis has lower reproducibility and detection of erosion compared with CT. These findings indicate that CT remains the gold standard for measurement of bone erosion in gout.

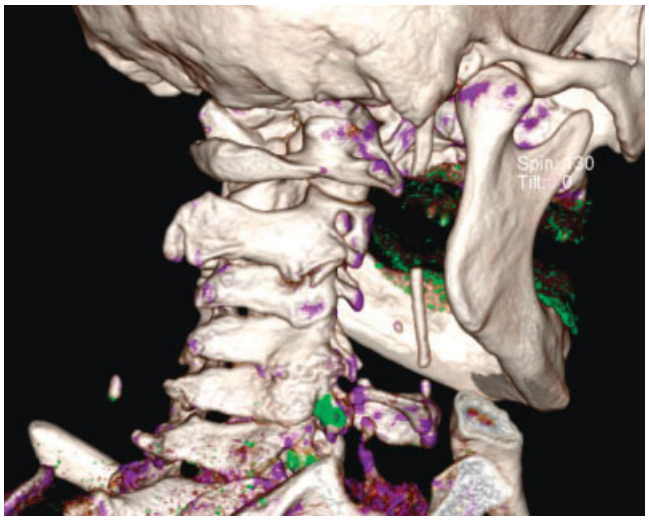
Use Of Dual-Energy Computed Tomography In Evaluation Of Axial Gout. Kristin Logee[1], Ranadeep Mandhadi[1], William Traverse[2] and Santhanam Lakshminarayanan[3]. [1]University of Connecticut, Farmington, CT, [2]Saint Francis Hospital and Medical Center, Hartford, CT, [3]University of Connecticut School of Medicine, Farmington, CT

Background/Purpose: Axial (spinal) involvement has become increasingly recognized as a potential manifestation of gouty arthritis. The presentation can vary widely from mild, asymptomatic disease to severe back pain, radiculopathy or frank spinal cord compression. Axial gout is frequently a missed diagnosis for a variety of reasons: it can mimic other spine diseases, is under-recognized as a possible manifestation of gout, and current imaging techniques (X-ray, MRI and CT) often produce non-specific findings which do not distinguish gouty erosions and tophi from other pathologies.

Dual-energy CT has recently been recognized as very sensitive and specific for identifying monosodium urate (MSU) crystal deposition. By using a specific display algorithm that assigns different colors to materials of different chemical composition, MSU can be color-coded and thereby distinguished from surrounding structures. Up until now, it has been used mainly to image peripheral sites but has not been evaluated as a diagnostic tool for axial gout.

Methods: We present two cases that demonstrate the efficacy of dual-energy CT in detecting MSU deposition within the axial skeleton. Patient X was a 91 year-old male with severe neck pain, fevers and leukocytosis. MRI showed abnormal T2 signal around the C4-C5 facet joint with fluid consistent with synovitis. However, septic arthritis could not be ruled out. The patient also complained of right knee pain and swelling. Aspirate of the knee revealed intracellular MSU crystals with negative cultures, consistent with acute gout flare. This raised suspicion that the patient's presentation could be secondary to spinal involvement of gout. Patient Y was a 29 year-old male with a long-standing history of chronic tophaceous gout who presented with incapacitating mid-low back pain. Traditional CT showed extensive subchondral erosions throughout the lumbar spine and right sacroiliac joint.

Results: Dual-energy CT of the cervical spine of Patient X (Image 1) showed MSU deposition on the cervical facet joints (color-coded in green) which correlated with the MRI findings. The patient's symptoms quickly resolved with colchicine and IV methylprednisolone. Similarly, lumbar spine dual-energy CT of Patient Y (Image 2) showed extensive MSU deposition along the transverse processes and pelvic bony structures. Symptoms remitted with colchicine and oral prednisone.



Conclusion: Dual-energy CT can be used to visualize the presence of axial MSU deposition. This may lead to appropriate diagnosis and management of axial gout while avoiding invasive procedures and erroneous treatment.

Relationship Between Structural Joint Damage and Urate Deposition In Gout: A Site-By-Site Analysis Using Plain Radiography and Dual Energy Computed Tomography. Nicola Dalbeth[1], Opetaia Aati[1], Ramanamma Kalluru[2], Anne Horne[1], Anthony Doyle[1] and Fiona M. McQueen[1]. [1]University of Auckland, Auckland, New Zealand, [2]Department of Rheumatology, Auckland District Health Board, Auckland, New Zealand

Background/Purpose: Structural joint damage, including erosion, joint space narrowing (JSN) and new bone formation (NBF), is frequently observed in patients with tophaceous gout. Although imaging studies have implicated tophi in the development of these changes, the relationship between monosodium urate (MSU) crystals and structural joint damage has not been examined. The aim of this work was to examine the relationship between joint damage and MSU crystal deposition in patients with tophaceous gout.

Methods: Plain radiographs and dual energy computed tomography (DECT) scans of the feet were prospectively obtained from 92 patients with tophaceous gout. Two readers analysed the 10 metatarsophalangeal joints (MTPJs) for the presence of MSU crystals using DECT (920 total joints analysed, inter-reader agreement 94.2% and kappa 0.82). For the purposes of analysis, DECT MSU crystal deposition was considered present if recorded by both readers. A further reader, who was blinded to the DECT results, scored the same joints on plain radiography for Sharp-van der Heijde erosion score (0–10), JSN score (0–4) and presence of NBF features (spur, sclerosis and osteophyte).

Results: DECT MSU crystal deposition was more frequently observed in joints with erosion (odds ratio (OR) 11.2), JSN (OR 5.1), spur (OR 13.4), osteophyte (OR 5.3) and sclerosis (OR 9.1), $p < 0.0001$ for all. For those joints with any erosion, erosion scores were higher in joints with DECT urate deposition compared with those without MSU crystals (mean (SD) erosion scores 5.2 (2.7) and 3.3 (2.11) respectively, $p<0.0001$). A strong linear relationship was observed in the frequency of joints affected by MSU crystals with increasing radiographic erosion score ($p<0.0001$). In contrast, for those joints with any narrowing, JSN scores were no different in those with and without DECT urate deposition ($p=0.75$). DECT MSU crystal deposition and all features of joint damage were most frequently observed at the 1st MTPJ (Figure). There was a very high correlation between the number of joints at each site affected by MSU crystal deposition and all features of radiographic joint damage ($r>0.88$ for all, $p<0.05$ for all).

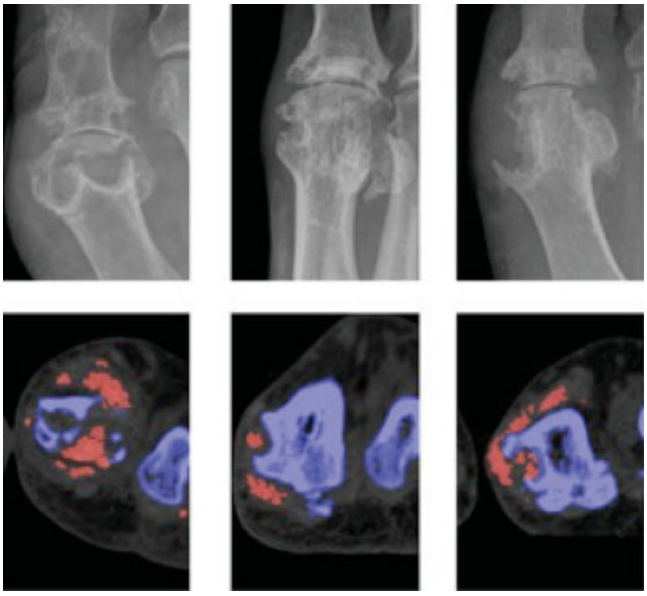

Figure. Examples of plain radiographs (upper panel) and corresponding axial DECT images (lower panel) of eroded 1st MTPJs from three separate participants. MSU crystals are shown as red on DECT images.

Conclusion: MSU crystals are frequently present in joints affected by radiographic damage in patients with gout. These findings support the concept that MSU crystals directly interact with articular tissues to influence the development of structural joint damage in this disease.

Systematic Staging For Uric Acid Deposits With Dual-Energy Computed Tomography and Ultrasound In Suspected Gout. Wolfgang A. Schmidt[1] and Alexander Huppertz[2]. [1]Med Ctr Rheumatology Berlin Buch, Immanuel Krankenhaus Berlin, Berlin, Germany, [2]Imaging Science Institute Charité, Berlin, Germany

Background/Purpose: To evaluate the diagnostic accuracy of Dual-Energy Computed Tomography (DECT) and ultrasound for detecting monosodium urate crystal deposits in patients with clinically suspected gout.

Methods: In this case control study DECT and comprehensive ultrasound of feet, knees, hands, wrists, and elbows were performed bilaterally in 60 consecutive patients (49 males; 11 females; mean age, 62 years; age range, 36–82 years) of a tertiary rheumatology referral center with suspected gout and compared with pooled clinical information including polarization microscopy, maximum documented uric acid levels, presence of podagra and the final rheumatological diagnosis as standard-of-reference.

Results: Finally, 39 patients were classified as gout positive, 31 of which had been newly diagnosed. Sixteen of these patients had gout and a concomitant rheumatic disease. Although an experienced rheumatologist aimed at receiving material from tissue or joint aspirates of every patient, if necessary with ultrasound guidance, the diagnosis could be confirmed by polarization microscopy only in 46% of the gout patients.

DECT had a sensitivity of 84.6%. Ultrasound had a sensitivity of 100%. The specificity for the diagnosis of gout was 85.7% for DECT and 76.2% for ultrasound. The positive predictive value was 0.92 for DECT and 0.89 for ultrasound. The negative predictive value was 0.75 for DECT and 1 for ultrasound.

Uric acid deposits occurred most commonly in the medial and lateral aspects of the knee joint, in the quadriceps tendon and in the first MTP 1 joints. The evaluation on a joint-basis compared to ultrasound as reference revealed a sensitivity of 46.2% and a specificity of 97.6% for DECT. Ultrasound detected smaller crystal deposits than DECT. DECT failed to show crystal deposits on the cartilage, representing the "ultrasound double contour sign", but delineated larger intra-articular and extra-articular tophi.

Ultrasound was false positive in one patient with calcium pyrophosphate dihydrate disease (CPPD), hydroxyapatite deposition disease and rheumatoid arthritis, respectively, and in two patients with severe peripheral arterial occlusive disease.

DECT was false positive in 3 patients showing minimal deposits suggestive of gout tophi in the lateral menisci. One patient was finally diagnosed with CPPD, one with psoriatic arthritis and one with undifferentiated oligoarthritis. Small signals that are not representing urate deposits also appear in nails.

The DECT volumetry computed a mean uric acid deposit load of 2.0 cm^3 (SD 9.6 cm^3). A mean effective dose between 0.4 and 0.5 mSv was estimated.

Conclusion: DECT is specific for the diagnosis of gout particularly when excluding small signals in the lateral menisci and in the nails. However, it fails to detect small uric acid deposits. It is particularly useful for patients with ambivalent findings, concomitant rheumatic diseases, and for those whose joint aspiration and microscopy did not successfully detect gout crystals.

Clinical Value Of ^{18}f-Fluoro-Dexoxyglucose Positron Emission Tomography In Patients With Adult-Onset Still's Disease. Hiroyuki Yamashita, Kazuo Kubota, Yuko Takahashi, Hiroshi Kaneko, Toshikazu Kano and Akio Mimori. National Center for Global Health and Medicine, Tokyo, Japan

Background/Purpose: The aim of this study was to assess the usefulness of 18F-fluoro-dexoxyglucose positron emission tomography/Computed tomo-

graphy (18F-FDG PET/CT) for the diagnosis or the evaluation of Adult-onset Still's disease (AOSD) visually.

Methods: 7 consecutive AOSD patients who had undergone PET at our department between 2007 and 2012 were included in the study. In addition, the literature review was performed about 6 previously reported AOSD patients who had undergone PET. We evaluate FDG uptake for characteristic findings in patients with AOSD.

Results: FDG accumulation was positive mainly in the bone marrow (70%), spleen (80%), lymph nodes (77.8%), and joints (50%). In addition, FDG uptake was positive in the pericardium, pleura, salivary glands, eyelids, muscle, and major blood vessels. 8 patients underwent FDG PET/CT for evaluating the efficacy of treatment. The follow-up PET showed diminished FDG accumulation in the bone marrow, spleen, lymph nodes, with SUVmax being significantly reduced from 4.03±0.95 to 2.20±0.75 (P=0.04), from 4.15±1.10 to 2.55±1.13(P=0.04), and from 5.47±5.19 to 2.10±1.91 (P=0.11), respectively. No significant correlation was found between max SUVs in each site and the laboratory data; the only significant correlation was between LDH and the spleen SUV.

Conclusion: Our study suggests that 18F-FDG PET may play a potential role in diagnosing or monitoring of disease activity marker in patients with AOSD. Additionally, we suspect that future PET/CT imaging will reveal that AOSD is a disease involving lesions with a little clinical description.

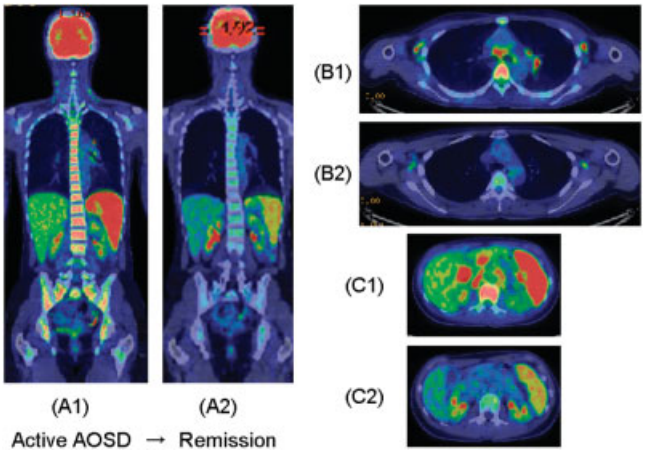

Fig. 1. FDG-PET/CT images at diagnosis (A1,B1,C1) and after steroid and Tocilizmab treatment (A2,B2,C2) in a 32-year-old woman (Patient 4) with AOSD.

Marked FDG accumulation was observed in the bone marrow, spleen and multiple lymph nodes at the time of diagnosis before treatment. After treatment, bone marrow FDG uptake improved from SUVmax 004.02 (A1) to 2.50 (A2) and spleen FDG uptake decreased from SUVmax 006.05 (A1,C1) to 4.38 (A2,C2). In addition, multiple lymph node FDG uptake observed in the axilla, mediastinum, hilar region of the lung, hilar region of the liver and para-aortic region declined or disappeared (B1/C1→B2/C2).

The Role Of Salivary GLAND Ultrasound In Sjogren Syndrome: A Single Center Experience. Giuseppe Germanò[1], Niccolò Possemato[1], Olga Addimanda[1], Pierluigi Macchioni[1] and Carlo Salvarani[2]. [1]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [2]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy

Background/Purpose: There is increasingly scientific evidence of salivary gland ultrasonography accuracy and usefulness in diagnosing Sjogren Syndrome. [1–2]

Methods: 82 patients with suspected Sjogren Syndrome from a single center were evaluated. Demographic (age and sex), clinical (sicca syndrome, artralgia), ultrasonographic (salivary gland ultrasound following the score proposed by Ariji et al [3], serologic (anti nuclear antibodies – ANA, anti ENA, anti HCV) and histological (salivary glands biopsy with Chisholm-Mason score evaluation) features were analyzed. Patients were classified according to ACR/EULAR criteria for SS (AEC).[4]

Results: all patients with HCV infection were counted out as well as all the patients with one of the exclusion criteria present in the Primary Sjogren Syndrome classification. Male/female ratio was 1/9; 91.2 % of patients presented xerostomia, 75% xerophthalmia. Schirmer test was positive in 72% of the patients; break up time positive in 65%. The biopsy was positive (Chisholm and Mason score >1) in 61% and ultrasound was positive (score ≥2 out of 4) in 40.2%. ENA test (SSA and\or SSB) was positive in 37.4%. The diagnosis of Sjogren Syndrome has been assessed, according to AECG classification criteria, in 36 patients out of 82 (43.9%). 80.6% of patients with positive ultrasound were classified as affected by Sjogren Syndrome, 89.1% of patients with negative ultrasound didn't fill the classification criteria. The ultrasound score presented a positive likelihood ratio of 4.58 (95% *confidence interval 2.34<x>8.98) and a negative one of 0.135 (0.058<x<0.313). The test showed a sensibility of 80.6% and a specificity of 89.1%. Concordance (Cohen K) between classification criteria and US score was 0.701 (medium level), higher than that between classification criteria and biopsy Chisholm-Mason score (0.572). Surprisingly ENA screening didn't add diagnostic power to the ultrasound scan due to a wide overlapping of the two tests.*

Conclusion: in our experience salivary gland ultrasound seems to be an useful tool in the diagnostic process of Sjogren Syndrome due to its good sensibility and specificity. Moreover the exam is simple to perform, fast, incruent and well accepted by patients.

Contrast-Enhanced Ultrasound Of The Sovraortic Arteries: The Potential Role In Monitoring Disease Activity and Response To Treatment In Large Vessel Vasculitis. Giuseppe Germanò[1], Pierluigi Macchioni[1], Niccolò Possemato[1] and Carlo Salvarani[2]. [1]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [2]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy

Background/Purpose: promising data has been recently published about the role of contrast-enhanced ultrasound (CEU) in the diagnosis and follow up of Takayasu arteritis (TA) −1,2-

Objective: To assess the role of CEU examination of the carotid artery in patients with large vessel vasculitis (LVV) compared to Positron Emission Tomography (PET).

Methods: 10 patients (8 TA,2 LVV, mean age 46±19y, mean disease duration 3.9±3.1y) were contemporary evaluated with total body PET and carotid arteries US gray scale and CEU (Esaote MyLab70, 13-5MH linear probe, contrast agent Sonovue). All the patients underwent complete clinical examination and laboratory determination of acute phase reactants. Imaging results were reported using a semiquantitave score ranging from 0 (no activity) to 3 (high activity). Comparison between the two tests were made using Cohen K test.

Results: At US gray scale examination 8/10 patients have high intima/media thickness (mean 1,5 mm ±0.46). In patients with positive contrast enhanced ultrasound the mean carotid intima-media thickness was 2,1mm ±0.48, while patients with negative contrast enhanced ultrasound presented a mean wall thickness of 0,9mm ±0.47; P = 0.009. There was no significant differences in clinical, demographic and laboratory data between patients with active and inactive disease. All the 4 patients with high/medium carotid activity at PET examination presented positive (activity score >1) CEU. Five of the 6 patients with low/absent PET signal have negative (activity score <2) CEU (K test = 0.800, good concordance).

Conclusion: CEU have a good concordance with PET. These results outline the potential role of CEU to be used in monitoring disease activity and response to treatment in LVV

Asymptomatic Myocardial Ischemic Disease In Takayasu's Arteritis: Detection By Magnetic Resonance Imaging. Cloé Comarmond[1], Philippe Cluzel[2], Dan Toledano[3], Nathalie Costedoat-Chalumeau[4], Richard Isnard[5], Fabien Koskas[6], Patrice Cacoub Sr.[7] and David Saadoun[8]. [1]Hôpital Pitié Salpétrière, Paris, France, [2]Pitié-Salpétrière, Paris, France, [3]Hôpital Pitié-Salpêtrière, Paris, France, [4]Hopital Cochin, Paris, France, [5]CHU Pitié-Salpêtrière, 47-83 Boulevard de l'hôpital, 75651 Paris Cedex 13, Paris, France, Paris, France, [6]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [7]CHU Pitié-Salpêtrière, Paris, France, [8]Pitié-Salpêtrière Hospital, APHP, Paris, France

Background/Purpose: Takayasu's arteritis (TA) may affected myocardium and caused coronary stenosis. The aim of this study was to assess the prevalence and pattern of myocardial disease in patients with TA, using late gadolinium enhancement (LGE) of cardiac magnetic resonance imaging (CMRI).

Methods: Twenty-seven consecutive patients with TA and 80 age and sex matched controls without known cardiovascular disease underwent CMRI. The prevalence of myocardial ischemic disease, as revealed by LGE, was compared between patients with TA and controls, and factors associated with myocardial disease were identified in patients with TA.

Results: Myocardial ischemic disease, as characterized by LGE on CMRI, was present in 7 (25.9%) of 27 patients with TA, and imaging with LGE showed a typical pattern of myocardial infarction (MI) in 6 patients (22.2%). Although both patients with TA and control subjects shared a similar risk of cardiovascular events, the prevalence of myocardial ischemia was more than 5 times higher in patients with TA ($P = 0.002$ versus controls). No association was found between myocardial disease in patients with TA and cardiovascular atherosclerotic risk factors. The presence of myocardial scarring tended to be more closely associated with specific features of TA, such as renovascular hypertension, older age at the onset of TA symptoms, male gender, aneurysmal dilatation, and numano type V.

Conclusion: The finding of a significant and unexpectedly high prevalence of occult myocardial scarring in patients with TA indicates the usefulness of CMRI with LGE for the identification of occult myocardial disease in such patients.

Detection Of Cerebral Microvascular Lesions In Patients With Acute Phase Neuropsychiatric Systemic Lupus Erythematosus By 7Tesla MRI. Nobuhito Sasaki, Okinori Murata, Yukari Ninomiya, Yuka Oikawa, Hitoshi Kobayashi, Kohei Yamauchi, Makoto Sasaki, Takashi Sawai and Yutaka Nakamura. Iwate Medical University School of Medicine, Morioka, Japan

Background/Purpose: The cerebral microvascular lesions of patients with neuropsychiatric systemic lupus erythematosus (NPSLE) have not been fully elucidated. The 7Tesla MR scanner has high image resolution and can be expected to detect cerebral microvascular lesions that have never before been visible. We examined the cerebral microvascular lesions of NPSLE using a 7Tesla MR scanner.

Methods: We studied 7 acute phase-NPSLE patient and 11 non-NPSLE. MRI was performed using a 1.5Tesla MR scanner and 7Tesla MR scanner (T1-weighted imaging, T2-weighted imaging, diffusion-weighted imaging, magnetic resonance angiography). Two radiologists performed the interpretation without clinical information. Diagnosis of was determined by a neurologist, psychiatrist and rheumatologist.

Results: Examination by the 7Tesla MRI revealed cerebral microvascular lesions(under 100 micrometer) in 6 of 7 NPSLE patient. These findings were not detected in any of the patients with non-NP SLE. These findings were not detected by 1.5 Tesla MRI. There were not findings at all in 1.5Tesla MRI, and the case that included findings was found in only 7TeslaMRI. The cerebral microvascular lesions were found around the central sulcus especially in T2-weighted image. These MRI findings disappeared after central nervous symptom improvement in two of the three NPSLE patient that reexamined three months later. However, we did not find a direct association between the MRI findings and the neuropsychology dysfunction.

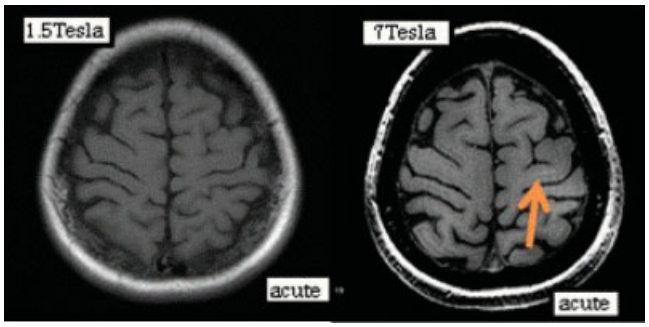

Image: 41 years old female She had both legs motor nerve disorder.

The cerebral microvascular lesions were found around the central sulcus in T2-weighted image. It could be find only by using 7TeslaMRI.

Conclusion: Cerebral microvascular lesions could be detected in patients with NPSLE by 7 Tesla MRI, suggesting that 7 Tesla MRI is a useful tool for diagnosing the cerebral lesions of NPSLE. It will be necessary to elucidate the association between cerebral microvascular lesions and neuropsychological dysfunction.

Comparison Of Whole Body Versus Targeted Magnetic Resonance Imaging For Assessing Disease Activity and Damage In Idiopathic Inflammatory Myopathies. Adam Schiffenbauer[1], Evrim Turkbey[2], Lisa G. Rider[1], Suvimol Hill[2], Irene Z. Whitt[3], Songtao Liu[2], David A. Bluemke[2] and Frederick W. Miller[1]. [1]NIEHS, NIH, Bethesda, MD, [2]NIH, Bethesda, MD, [3]Duke, Durham, NC

Background/Purpose: In the idiopathic inflammatory myopathies (IIM) MRI imaging is traditionally focused on the proximal upper or lower extremities. Whole body MRI (WBMRI) is a technique where the entire body is scanned into one complete study. The purpose of this study was to assess what additional information is gained from WBMRI and to determine its relationship to clinical parameters.

Methods: 24 patients with a variety of IIM, including juvenile dermatomyositis (JDM, n=7), dermatomyositis (DM, n=6), polymyositis (PM, n=4), sporadic inclusion body myositis(s-IBM, n=3), and familial inclusion body myositis (f-IBM, n=4) underwent WBMRI. Using a Siemens 3 Tesla MRI scanner the patients were scanned in a head to toe manner and had T1, T2, and STIR images obtained. These images were then scored in a blinded manner across 34 muscle groups and each group was scored on a scale of 0 to 3 for T2/STIR intensity, T2/STIR area of involvement, and fatty infiltration on T1. WBMRI and thigh MRI (THMRI) scores were evaluated for correlation with a variety of measures of disease activity and damage.

Results: 3 out of 24 patients (12.5%) who were scored to have activity (at least a 1 for STIR intensity) on WBMRI had no activity present on THMRI. Similarly, 4 of 24 patients (16.67%) had fatty replacement on WBMRI, but no fatty replacement on THMRI. Patients had MRI STIR abnormalities by WBMRI in many areas that would not be scanned in a MRI of the thigh or proximal arms, including the paraspinal muscles (20% of patients) and the chest (16% of patients) as well asforearms and distal extremities (Table).

Region	Percentage positive on Right	Percentage positive on Left
Anterior forearm	7.69	7.14
Posterior forearm	30.77	21.43
Distal lower extremity anterior	20.83	45.83
Distal lower extremity posterior	37.5	37.5

Among all IIM patients, physician global disease damage on a visual analogue scale (VAS) and a Likert scale correlated with imaged fatty infiltration ($p<0.0001$). R squared for comparison of WBMRI and THMRI fatty replacement with physician global disease damage were 0.796 and 0.695 respectively. Also amongst all patients serum levels of creatine kinase (CK), aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactate dehydrogenase (LDH) were found to correlate significantly with WBMRI STIR intensity and involvement scores, as well as with THMRI STIR intensity scores ($r^2=0.23–0.49$, $p<0.05$ for all).

In adult and juvenile DM and PM patients, the physician global activity by VAS correlated with WBMRI and THMRI intensity and involvement scores ($r^2=0.28–0.33$, $p<0.05$). WBMRI and THMRI intensity and involvement scores also correlated significantly with CK, AST, ALT, and LDH ($r^2=0.42–0.81$, $p<0.05$) in this population.

Conclusion: WBMRI was able to detect areas of muscle edema and fatty infiltration in IIM patients that would not be detected on traditional focal MRI of the thighs or arms. WBMRI also correlated well with physician assessment of disease activity and damage as well as with multiple laboratory markers of disease activity. These findings suggest utility of WBMRI in assessing patients across the IIM spectrum.

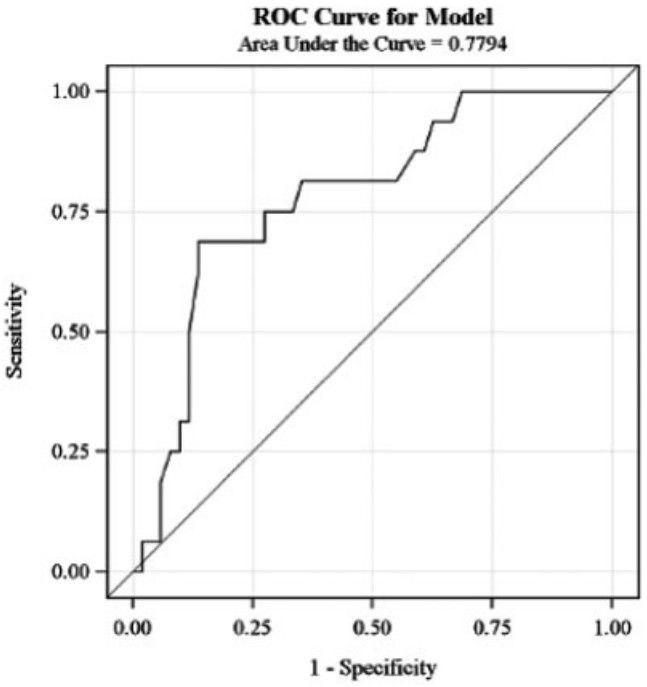
Clinical Predictors For Subcutaneous Power Doppler Signals Detected By Ultrasound in Hands Of Scleroderma Patients. Anat Scheiman-Elazary[1], Ami Ben-Artzi[2], V.K. Ranganath[2], Nabeel Borazan[1], Philip J. Clements[2], Suzanne Kafaja[2] and Daniel Furst[2]. [1]Rheumatology UCLA, Los Angeles, CA, [2]David Geffen School of Medicine, UCLA, Los Angeles, CA

Background/Purpose: Skin thickening in scleroderma was demonstrated previously in US studies, although subcutaneous tissue was not yet evaluated. We evaluated scleroderma patients for subcutaneous Power Doppler signal (SCPD) on the dorsal aspect of the MCPs of the dominant hand. Out of 74 patients, 17 (22.9%) had a positive signal. Our aim was to compare SCPD positive (N= 17, 22.9%) versus SCPD negative (N=57, 77.1%) patients and to look for clinical and laboratory predictors for SCPD.

Methods: Seventeen SCPD positive patients were compared with 57 SCPD negative patients. US exam was performed using GE logic E9 scanner with a linear array (5–16 MHz) for PD in subcutaneous tissue. SCPD was defined as a positive PD signal in the subcutaneous tissue on the dorsal aspect of either MCPs 2–5 in both longitudinal and short views that was not involving the tendon. At least one MCP had to be involved. A binary grading was used to score SCPD (0–1). Patients were divided into 2 groups, with or without SCPD. GS and PD examinations of 13 joints (wrist, MCP 2–5, PIPs 2–5) and tendons were done. A step wise linear regression model was used to identify predictors for SCPD. The following parameters were included: age, gender, disease duration, disease type (limited or diffuse), modified Rodnan skin score (MRSS), lung involvement (symptoms, pulmonary function test and high resolution CT), pulmonary hypertension (echo), ESR, CRP, ulcers, calcinosis, sclerodactaly and contractures.

Results: After univariate analysis with $P<0.2$ cut-off, MRSS, disease duration and lung involvement were included. MRSS ($OR=0.93$, $p=0.14$) and lung disease($OR=0.28$, $p=0.047$) decreased the likelihood for SCPD while longer disease duration increased its likelihood ($OR=1.117$, $p=0.036$). The final model included only lung and disease duration with a ROC curve, AUC of 0.77 (figure 1). There was no statistical difference in mean joint GS and PD between both groups (mean joint GS 0.34 and 0.31 in the negative and positive SCPD patients respectively, mean joint PD 0.08 and 0.04 in the negative and positive SCPD patients respectively). Mean ESR was 21 and 18 mm/h in the positive and negative SCPD patients respectively (P value 0.94).



Conclusion: Twenty two percent of patients with scleroderma had positive subcutaneous power doppler signal above the dorsal aspect of the MCPs. Patients with this phenomenon had longer disease duration and less lung involvement with moderately good predictive value (ROC AUC- 77). There was not increased synovitis or elevated ESR in this group. We therefore assume that this is not an inflammatory phenomenon. We speculate that SCPD may be related to increased blood flow to the skin during the resolution phase of the skin. Further studies are needed to understand the underling mechanism.

224

Ultrasound Evaluation Of Joints, Tendons and Subcutaneous Tissue Of Hands In 74 Scleroderma Patients. Anat Scheiman-Elazary[1], Ami Ben-Artzi[2], Suzanne Kafaja[2], V Ranganath[2], Nabeel Borazan[1], Philip J. Clements[2] and Daniel Furst[2]. [1]Rheumatology UCLA, Los Angeles, CA, [2]David Geffen School of Medicine, UCLA, Los Angeles, CA

Background/Purpose: A previous ultrasound study of the hands in scleroderma (SSC) and rheumatoid arthritis (RA), found mild inflammatory changes in the tendons and joints of the SSC patients. Our aim was to evaluate joints, tendons and subcutaneous tissue in SSC patients compared to RA patients and healthy controls (HC).

Methods: A total of 74 SSC patients and 14 HC were examined in this cross sectional study and compared to a database of 32 RA patients. The patients underwent clinical and laboratory assessment. Blinded US exam of 13 joints (Wrist, MCPs 2–5, PIPs 2–5,DIPs 2–5) was performed, using GE logic E9 scanner with a linear array (5–16 MHz). Gray scale (GS) (0–1) and Power Doppler (PD) (0–3) scoring were used for tendons. GS and PD (0–3) scoring were used to evaluate joints. In 13 patients, we were unable to examine all 13 joints due to contractures. We therefore calculated separate GS and PD scores for joints and tendons by summing up scores for individual joints and dividing it by the number of joints examined. Subcutaneous tissue over the dorsal aspect of the MCPs was evaluated by PD (SCPD). Tuft resorption was examined by evaluating shortening of the distal second to fifth phalanges on the palmar and dorsal aspects. RA patients only had data on 5 joints (wrist, MCPs 2–3 and PIPs 2–3) and this subset was compared across the groups.

Results: Mean age was similar between all 3 groups. Percentage of females was 82, 90, and 71 for SSC, RA and HC respectively. Mean disease duration was 6.9 and 5.7 in the SSC and RA patients (Table 1). Mean DAS28

and CDAI in the RA patients was 5.07 and 22 respectively. For SSC patients 13.5% had tuft resorptions compared to none of the RA patients and HC. Mean GS and PD score for joints and tendons of the 13 joints exam were significantly higher in the SSC patients then HC (mean joint GS 0.33 and 0.08, mean join PD 0.07 and 0.01, mean tendon GS 0.08 and 0, mean tendon PD 0.09 and 0 for the SSC and HC respectively, $p<0.05$ for all). For the 5 joint exam, mean GS and PD for tendons and joints was significantly higher in the SSC versus HC as well as RA patients except PD for tendons which was not significant in the SSC compared to HC. RA patients had a higher frequency of +2 or +3 PD in joints and tendons while HC had none (Table 1). Twenty one percent of SSC patients with swollen joint count of zero, had +2 or +3 PD signals in joints or tendons. Subcutaneous PD signals were found nearly exclusively in SSC patients.

	Age	% F	Disease duration (y)	Mean ESR	5 Joint GS	5 Joint PD	5 Tendon GS	5 Tendon PD	% patients with +2 or +3 join PD	% Patients with +2 or +3 Tendon PD	% SCPD (N)
SSC (N=74)	53.46	82	6.9	18.6	0.42	0.09	0.11	0.1	16	24	22 (17)
RA (N=32)	53.75	90	5.7	39.6	1	0.52	0.33	0.41	93	62	0.03 (1)
HC (N=14)	52.2	71	NA	NA	0.08	0.004	0.01	0	0	0	0
Total	0.97	0.26	0.012	0.0013	<0.01	<0.01	<0.01	<0.01	<0.01	<0.01	<0.01
P value											
SSC-RA P value	NA	NA	NA	NA	<0.01	<0.01	<0.01	<0.01	<0.01	0.0003	0.0113
SSC-HV P value	NA	NA	NA	NA	<0.01	0.0328	0.0133	0.0662	0.208	0.0642	0.0459

HC-Healthy controls, SSC-scleroderma, SCPD- subcutaneous power Doppler, PD-Power Doppler, GS-gray scale, F-females, NA-not applicable

Conclusion: Joint and tendon inflammation in scleroderma is increased compared to HC but milder then in RA. US detected synovitis more frequently than physical examination in the SSC patients. Since it is sometimes difficult to estimate synovitis on physical examination in SSC patients due to tight skin and contractures, US would be useful in the assessment of synovitis in these patients.

Cardiovascular Involvement In Erdheim-Chester Disease: A Magnetic Resonance Imaging Study On Seven Patients. Enrica Rossi, Lorenzo Buttarelli, Augusto Vaglio, Davide Gianfreda, Chiara Martini and Massimo De Filippo. University of Parma, Parma, Italy

Background/Purpose: Erdheim-Chester Disease (ECD) is a rare non-Langherans form of histiocytosis, characterized by xanthomatous or xanthogranulomatous infiltration of tissues by foamy histiocytes, surrounded by fibrosis. ECD is a multisystemic disease and its clinical course depends mostly on cardiovascular manifestations, that are responsible for poor prognosis and death. In order to assess the cardiovascular extent of the disease, we studied 7 consecutive cases with biopsy-proven ECD by magnetic resonance imaging (MRI).

Methods: The patients underwent cardiac and thoracic aorta MRI. Images were acquired with a 1,5T RM, using T2W with and without fat suppression, long and short axis cine B-TFE and late gadolinium enhancement sequences evaluated by dedicated software.

Results: Four patients (57%) showed abnormal heart imaging. Four patients had myocardium involvement with typical pseudo-mass aspects in the anterior and lateral walls of right atrium. In three cases it extended to the right atrioventricular sulcus, sheathing the right coronary artery; only in one case both coronary arteries were surrounded by periarterial infiltration. None of the cases showed signs of coronary stenosis. One case also presented atrial septal thickening. In three cases imaging studies recognized pericardial effusion; just in one case it was massive (50mm), even if without signs of cardiac tamponade. The pericardium facing the right ventriculum was thickened in two cases.

Imaging showed a mild cardiomegaly in one patient, but no atrial enlargement was detected. In no case we recognized cardiac insufficiency or cardiac signs of systemic hypertension. No patients had valvular defects.

The angiography assessment suggested the presence of periaortic fibrosis with "coated aspect" in two cases. In these, epiaortic vessels were surrounded by irregular, non stenosing fibrosis.

Conclusion: Our study confirms the frequent cardiovascular involvement in ECD. A systematic cardiac and aortic evaluation by MRI would be indicated in patients with ECD.

Omeract Definitions For The Sonographic Appearance Of The Normal Pediatric Joint. Johannes Roth[1], Sandrine Jousse-Joulin[2], Silvia Magni-Manzoni[3], Ana Narrodi[4], Nikolay Tzaribachev[5], Annamaria Iagnocco[6], Esperanza Naredo[7], Maria-Antonietta D'Agostino[8] and Paz Collado[9]. [1]University of Ottawa, Ottawa, ON, [2]C.H.U. La Cavale Blanche, Brest, France, [3]Ospedale Pediatrico Bambino Gesù, Rome, Italy, [4]Rheumatology, Madrid, Spain, [5]Center for Rheumatic Diseases, Bad Bramstedt, Germany, [6]University La Sapienza, Rome, Italy, [7]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [8]Ambroise Paré Hospital, and Versailles Saint Quentin en Yvelines University, Boulogne-Billancourt, France, [9]Severo Ochoa University Hospital, Madrid, Spain

Background/Purpose: Musculoskeletal ultrasound (MSUS) has significant potential in the assessment of disease activity and early structural damage in childhood arthritides. In order to assess pathology, the ultrasonographic characteristics of the normal pediatric joint need to be defined first. The aims of this study were to develop definitions for the various components of the pediatric joint that can be evaluated by MSUS through a consensus process and to validate these definitions in their practical application.

Methods: In a first step, members of the pediatric group of the OMERACT Ultrasound Task Force developed definitions of the ultrasonographic appearance for various components of the pediatric joint through a Delphi process. In a second step, standardized scans of the knee and ankle joint were acquired on 4 healthy volunteers aged 12, 10 and 4 years old (2 volunteers) by seven members of the group on the same day. Subsequently, for each of the stored images, the applicability (validity) of each of the definitions was scored by all 7 participants on a 1–5 Likert scale. A minimum of 80 % grade 4 or 5 agreement across all images was required in order to validate the definition.

Results: Five definitions were developed through the Delphi process addressing articular bone, cartilage, joint capsule, the epiphyseal ossification centre and the synovial membrane. A total of 224 images were acquired by the seven participants. 172 of these images were selected for analysis and on each of them the five definitions were rated by all 7 participants. In the first practical application on stored images the minimum of 80 % agreement was not met for either definition. After further modification of the definitions 95%, 81%, 86%, 97% and 91% agreement were reached respectively.

Conclusion: In this study, definitions of the ultrasonographic appearance for the various components of the normal pediatric joint were successfully developed through a Delphi process and validated in a practical exercise. These results represent the essential first step in order to develop definitions for pathology and support the standardization of the ultrasonographic assessment of the pediatric joint. This carries relevant implications in defining the role of MSUS both in routine clinical assessment and as an outcome measure in research.

Quantitative Image Analysis Of Articular Involvement In Blau Syndrome By Radiographic Calpal Length and Ultrasound Assessment. Tsuyoshi Yamatou[1], Tomohiro Kubota[1], Harumi Akaike[1], Yuichi Yamasaki[1], Yukiko Nonaka[1], Yasuhito Nerome[1], Tomoko Takezaki[1], Hiroyuki Imanaka[1], Kei Ikeda[2], Naotomo Kambe[3], Syuji Takei[1] and Tomokazu Nagakura[4]. [1]Kagoshima University, Kagoshima, Japan, [2]Chiba University Hospital, Chiba, Japan, [3]Chiba University Graduate School of Medicine, Chiba, Japan, [4]House of Meguminoseibo, Usuki, Japan

Background/Purpose: Blau syndrome (Blau) is a rare auto-inflammatory disease, and it has now been shown to be caused by *NOD2/CARD15* gene

mutations. Clinical features of Blau consist of granulomatous inflammation in the joints, eyes, and skin. However, most of the patients were initially miss-diagnosed as JIA because the symmetrical polyarthritis occurred in early phase of the disease, and "boutonniere" deformities-like fingers appeared during the disease course. However, the articular involvement in Blau has been considered as non-erosive. Therefore, we evaluate the joint damage in Blau patients by measuring calpal length (CL), an objective tool for evaluating cartilage damage in polyariticular JIA (poJIA)[1–2].

Methods: A total of 6 Blau patients were followed up their CL for mean 9.2 years. Their disease duration at the first CL measurement was 5.2 years. Since biologic agents were used in 5 of 6 of the Blau patients, changes in CL of 46 poJIA patients treated with biologics were also followed up. CL was analyzed by standard deviation (SD) calculated by Poznanski's formula established from healthy children[3)].

In addition, ultrasound examination was carried out in 4 Blau patients at the last observation. A total of 3 joints and 4 tenosynovial sites in the wrist were scanned and the ultrasound images of gray-scale (GS) or Power Doppler (PD) findings were graded from 0 (normal) to 3 (severe).

Results: Though all Blau patients had comptodactyly with "boutonniere" deformities like fingers, CL(SD) maintained normal range (within −2SD to +2SD) during the observation period regardless of biologic therapy (Figure 1). On the contrary, CL(SD) in poJIA decreased with disease course especially before initiating biologic therapy, and there were negative correlation between the CL(SD) and the disease duration in both RF positive (p=0.0018) and RF negative (p=0.008) poJIA patients.

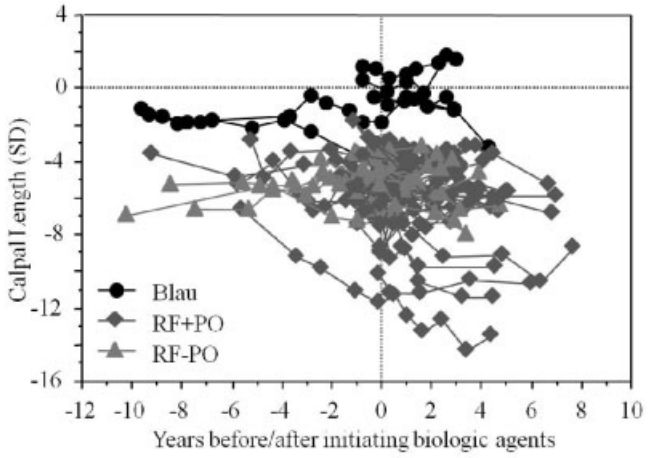

Figure 1: Changes in calpal length (SD) during treatment period
Blau: Blau syndrome, RF−PoJIA:RF positive polyarticular JIA

Ultrasound examination revealed that tenosynovitis was more frequent and severe than intra-articular synovitis in the 8 wrists of 4 Blau patients; Grade 1–3 findings were found in 62.5% by PD and 31.2% by GS in scanned tenosynovium sites, while it was 29.2% by PD and 4.2% by GS in intra-articular synovium sites (tendon vs intra-articular sites: p=0.0169 by PD, p=0.0161 by GS).

Conclusion: Comptodactyly with "boutonniere" deformities-like findings, a characteristic feature of Blau, may be caused by tenosynovitis but not by cartilage destruction in finger joints. The finding indicates the usefulness of CL and ultrasound examination in differentiating Blau from JIA, and is also suggestive that tenosynovitis may be more predominant than intra-articular synovitis in Blau syndrome.

The Composition and Structure Of Calcifications In Juvenile Dermatomyositis Differs From Calcified Aortic Valves Removed From Adults Without JDM. Lauren M. Pachman[1], Gabrielle A. Morgan[1], Patrick M. McCarthy[2], Anna Huskin[2], S. Chris Malaisrie[2], Lyudmila Spevak[3], Stephen Doty[3] and Adele Boskey[3]. [1]Ann & Robert H. Lurie Children's Hospital of Chicago Research Center, Chicago, IL, [2]Northwestern University Feinberg School of Medicine Bluhm Cardiovascular Institute, Chicago, IL, [3]Hospital for Special Surgery, New York, NY

Background/Purpose: Juvenile Dermatomyositis (JDM) is a systemic vasculopathy, primarily involving the micro vasculature. Soft tissue calcification occurs in 15–30% of cases, and is associated with increased morbidity and mortality. The calcifications develop in conjunction with chronic inflammation, and are often located at pressure points of daily trauma (elbows, buttocks, hands). In contrast, calcifications of aortic heart valves in non-JDM patients are more common and are associated with interrelated factors such as hypertension, hyperlipidemia, obesity, smoking and diabetes. The purpose of this investigation was to compare the composition and structure of the calcific deposits obtained from children with JDM with those in removed aortic valves.

Methods: Five children (2 boys, 3 girls) previously reported (Arthritis Rheum 54:10 2006, 3345–3350) with definite JDM, had a mean age of JDM onset, 3.3 years ± 1.9 years. They had sustained persistent cutaneous inflammation for 81.3 ± 58.7 months, and donated calcium deposits, after obtaining informed consent. The calcifications, removed by surgery, were a focus of constant pain and contributed to decreased range of motion. Fresh, calcified aortic heart valves were obtained at cardiovascular surgery, after obtaining informed consent, from 5 White adult donors without JDM (age range 43–85, mean age= 69.2 years), two were women, with severe aortic stenosis. Four of the donors were hypertensive, one had diabetes and one smoked. Fourier transform infrared radiography images (FTIRI) were obtained of the calcifications, which had been fixed in 90% ethanol, embedded in polymethyl methacrylate (PMMA) and sectioned. Transmission Electron Microscopy was performed.

Results: In JDM, electron microscopy documented extensive macrophage and giant cell infiltration; the mineral definitely formed crystals, even within the cytoplasm of the affected cells, whereas in plaque the calcium appeared to be associated with large lipid deposits were not crystalline (verified by EDAX microanalysis).

Average FTIRI Parameters for the 5 Calcified Aortic Valves

	Min/Mat	CO3/min	XLR	XST
Mean	12	0.0104	4.20	1.10
SD	1.7	0.0013	0.90	0.05
Average FTIRI Parameters for the 5 JDM Deposits				
Mean	25	0.014	5.0	1.12
SD	14	0.013	1.8	0.06
Average FTIRI Parameters for 2 Pediatric Iliac Crest Biopsies Cortical Bone				
Mean	4.57	0.0065	3.17	1.25
SD	0.64	0.0004	0.02	0.02
Average FTIRI Parameters for 2 Pediatric Iliac Crest Biopsies Cancellous Bone				
Mean	4.53	0.0065	3.18	1.20
SD	0.20	0.0003	0.08	0.001

On FTIRI, the mineral/matrix ratio of the calcified aortic valves was greater than in human cortical or cancellous bone, but less than those in JDM deposits; JDM calcifications were much more punctate. The ratios of carbonate to phosphate and the carbonate/matrix ratios were not different from those of bone, nor were the values for collagen maturity and crystallinity. In JDM calcifications, but not calcified aortic valves, intracellular crystals were present.

Conclusion: The composition and structure of calcifications occurring in aortic valves differ from those that develop in the soft tissue of children with JDM, suggesting that the deposition mechanism differs as well.

Positron Emission Tomography Assessment Of Children With Systemic-Onset Juvenile Idiopathic Arthritis. Taichi Kanetaka, Tomo Nozawa, Kenichi Nishimura, Masako Kikuchi, Tomomi Sato, Nodoka Sakurai, Ryoki Hara, Kazuko Yamazaki and Shumpei Yokota. Yokohama City University School of Medicine, Yokohama, Japan

Background/Purpose: Systemic-onset juvenile idiopathic arthritis (s-JIA) is a systemic inflammatory disorder manifesting spiking fever, rheumatoid rash, and arthritis. The onset is nonspecific, and may be triggered by infectious agents. A body of evidence indicates involvement of cells and inflammatory cytokines produced in innate immune response in the induction phase of the disease, and then augmented in an auto-inflammatory fashion, suggesting that s-JIA may be one of the auto-inflammatory diseases. However, the causative agents and the responsible organs for exaggerated innate immune responses are still to be elucidated. The ^{18}F-FDG-Positron Emission Tomography (PET) is a hybrid imaging technique displaying the sites of high metabolic turnover of both physiologic and pathologic origin and visualizes infection focus and inflammatory lesions as well as malignancy. Application of ^{18}F-FDG-PET to patients with s-JIA will possibly localize inflammatory lesions of this disease.

To examine and delineate inflammatory focus in patients with s-JIA, ^{18}F-FDG-PET was applied to patients with s-JIA and polyarticular (p)-JIA, and the images of these patients were compared.

Methods: Sixty eight children (57 with s-JIA and 11 with p-JIA) were included in this study who needed the diagnosis work-up of fever-of-unknown origin. The diagnosis of s-JIA and p-JIA was done to meet the ILAR criteria (2004). After fasting for at least 6 hours, whole body PET-scans were acquired 60 minutes after intravenous injection of 3–5 MBq/kg ^{18}F-FDG. The interpretation of ^{18}F-FDG uptake was based on visual characteristics.

Results: ^{18}F-FDG uptake in shoulder joint areas was found in 42 out of 57 patients with s-JIA (74%) and in 5 out of 11 patients with p-JIA (45%). ^{18}F-FDG uptake in knee joint areas was demonstrated in 19 patients with s-JIA (33%) and 7 patients with p-JIA (64%). Although in patients with s-JIA ^{18}F-FDG uptake was found in shoulder areas, physical examination failed to reveal inflammatory symptoms/signs around shoulders. Additionally, two types of PET images were outstanding in s-JIA; one was ^{18}F-FDG uptake in red bone marrow such as the spine, femur heads, and pelvis as well as spleen (11 cases), and other type was the uptake in the major joints such as hips, elbows, wrists, knees, and ankles (7 cases). The former findings were correlated with elevated levels of inflammatory markers (WBC, ESR, and ferritin) while the latter were with significantly increased levels of MMP-3 ($P<0.05$).

Conclusion: There was a noticeable accumulation of ^{18}F-FDG uptake in bone marrow of s-JIA patients which may indicate the inflammatory focus of this disease and play an important role in the pathogenic basis of arthritides and systemic inflammation of s-JIA.

An Examination Of Shoulder Pain Using Magnetic Resonance Imaging In Older People. Tiffany K. Gill[1], E. Michael Shanahan[2], Dale Allison[3], Daniel Alcorn[3] and Catherine L. Hill[4]. [1]University of Adelaide, Adelaide, South Australia, Australia, [2]Flinders University, Bedford Park, South Australia, Australia, [3]Bensons Radiology, Adelaide, Australia, [4]The Queen Elizabeth Hospital, Woodville, Australia

Background/Purpose: Shoulder pain is a common problem in the general population and can cause significant difficulties with activities of daily living. Magnetic resonance imaging (MRI) is often used in the assessment of shoulder pain. This pilot study aimed to determine if the pathology demonstrated on shoulder MRI correlates with the pain reported by study participants.

Methods: Participants for this pilot study were obtained from the North West Adelaide Study (NWAHS), a longitudinal cohort study of 4056 randomly selected adults aged 18 years and over at the time of recruitment from the northern and western regions of Adelaide, Australia. Thirty participants aged 55 to 74 years were recruited from the cohort and allocated to one of three groups, those with no shoulder pain in Stage 2 and 3 of the NWAHS, those with pain in Stage 2 but not Stage 3 and those with pain in Stage 2 and Stage 3. Range of movement was assessed and the Shoulder Pain and Disability Index (SPADI) completed. An MRI and X-ray were undertaken of the affected or previously affected shoulder, or matched side (in those with no current or previous shoulder pain). The X-rays and MRIs were read independently by two radiologists blinded to the participant group and each other. All participants provided written informed consent.

Results: Overall, 30 participants took part in the study. The mean range of flexion, abduction and external rotation were all lower for the pain group compared to the other two groups. The mean SPADI percentage score for the pain group was 41.80 (SD 20.10, range 18–74) and the mean percentage function score was 31.88 (SD 20.41, range 8.75–60). On X-ray there were few differences between each group. The MRI findings are presented in Table 1. Subacromial bursitis was common (90%) in each group, 90% of participants also demonstrated a degree of acromioclavicular degeneration. There was a slightly higher number of supraspinatus tendinosis/tears and involvement of the LHB in the current pain group.

Table 1. MRI findings

	No shoulder pain		Previous shoulder pain		Current shoulder pain	
	n	%	n	%	n	%
Supraspinatus						
Normal/Equivocal	3	30.0	3	30.0	-	-
Tendinosis	1	10.0	2	20.0	2	20.0
Partial thickness tear with/without tendinosis	4	40.0	3	30.0	6	60.0
Full thickness tear with/without tendinosis	2	20.0	2	20.0	2	20.0
Infraspinatus						
Normal/Equivocal	7	70.0	4	40.0	7	70.0
Tendinosis	3	30.0	5	50.0	1	10.0
Partial thickness tear with/without tendinosis	-	-	1	10.0	2	20.0
Subscapularis						
Normal/Equivocal	4	40.0	3	30.0	5	50.0
Tendinosis	2	20.0	5	50.0	1	10.0
Partial thickness tear with/without tendinosis	4	40.0	2	20.0	4	40.0
Teres Minor						
Normal/Equivocal	10	100.0	10	100.0	10	100.0
Long head of biceps						
Normal/Equivocal	8	80.0	6	60.0	2	20.0
Tendinosis	1	10.0	3	30.0	3	30.0
Partial thickness tear with/without tendinosis	1	10.0	1	10.0	4	40.0
Full thickness tear	-	-	-	-	1	10.0
GHJ cartilage degeneration						
Normal/Equivocal	2	20.0	3	30.0	4	40.0
Mild	8	80.0	7	70.0	5	50.0
Moderate	-	-	-	-	1	10.0

Conclusion: Shoulder pathology is present on imaging in people with shoulder pain, those who have a history of shoulder pain, and those who have never had shoulder pain. Clinical symptoms do not necessarily match the radiological findings. The value of MRI as a clinically useful diagnostic investigation for shoulder pain is questionable.

Variable Imaging Characteristics Identified By Point-Of-Care Ultrasound For Greater Trochanteric Pain Syndrome. Minna J. Kohler[1], Naina Rastalsky[1] and Liana Fraenkel[2]. [1]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT

Background/Purpose: Greater trochanteric pain syndrome (GTPS) is a common cause of musculoskeletal pain that has been typically attributed to trochanteric bursitis. It encompasses a spectrum of disorders [gluteal tendinopathy, tears, bursitis, and iliotibial band (ITB) syndrome] that are difficult to distinguish by clinical exam alone. Few modalities for the treatment of GTPS exist and are recommended without consideration of the structural etiology of pain. Better understanding of ultrasound (US) imaging characteristics in relation to clinical symptoms may be helpful in identifying those patients who would most benefit from the various treatment options available.

Methods: A prospective, observational, descriptive study was performed to describe the soft tissue and bony structural US findings identified in the lateral hip in patients presenting with GTPS to a dedicated outpatient rheumatology musculoskeletal US clinic. US imaging was obtained using a standardized protocol by 2 US-trained rheumatologists (NR, MK). Eligible subjects included ages 18 and above with lateral hip pain thought to be due to GTPS with pain for at least 1 week and a pain score of at least 2 out of 10 on an 11-point numeric rating scale at rest or with activity. For subjects with bilateral GTPS, the most symptomatic hip was considered the study hip. Most important ineligibility criteria included Body Mass Index (BMI) >40, groin pain, and symptomatic osteoarthritis of the hip. All US images were reviewed by both doctors for consensus of image interpretation.

Results: 74 eligible subjects were identified ranging in age from 25–85, with a mean BMI of 28 (±4.77); 62 (84.0%) were female. Forty-five (60.8%) had concomitant low back pain and 11 (14.9%) had chronic widespread pain. The mean duration of symptoms was 18 (±23.0) weeks. The mean level of pain at rest and activity were 4.8 (±2.87) and 6.7 (±2.36) respectively. Twenty-five (35.0%) had a prior episode of lateral hip pain. The most common location of bursal fluid was the subgluteus maximus bursa. Frequency and percentage of various imaging characteristics are summarized in the Table.

US Imaging Characteristics	N (%)
Bony changes (Grade 0)	42 (56.8)
Bony changes (Grade 1)	18 (24.3)
Bony changes (Grade 2)	13 (17.6)
Bony changes (Grade 3)	1 (1.4)
Bursal fluid collections	34 (46.0)
Calcifications of gluteus medius	29 (39.2)
Calcifications of gluteus minimus	7 (9.5)
Calcifications in other locations	4 (5.4)
Enthesophytes in gluteus medius	7 (9.5)
Enthesophytes in gluteus minimus	1 (1.4)
Gluteus medius tendinopathy	57 (77.0)
Gluteus medius partial thickness tear	11 (14.9)
Gluteus medius full thickness tear	1 (1.4)
Gluteus minimus tendinopathy	10 (13.5)
Gluteus minimus partial thickness tear	3 (4.1)
Gluteus minimus full thickness tear	0 (0.0)
Tensor fascia latae abnormality (tendinopathy, tear, fluid)	14 (18.9)
Distal ITB tendinopathy	6 (8.1)
Distal ITB peritendinous fluid	3 (4.1)

Conclusion: GTPS is commonly attributed to trochanteric bursitis, but only 46% of the subjects had US evidence of true bursitis. The addition of US evaluation to the clinical assessment of GTPS increase may diagnostic accuracy and improve medical decision making.

Can Musculoskeletal Ultrasonography Examination (MSUS) Predict Outcome In Shoulder Impingement Syndrome (SIS)? A Prospective Blinded Study. Mumtaz Khan[1], Karen McCreesh[2], Aamir Saeed[1], Tomas Ahern[3] and Alexander D. Fraser[4]. [1]Limerick University Hospital, Limerick, Ireland, [2]University of Limerick, Limerick, Ireland, [3]St. Vincent's University Hospital, Dublin, Ireland, [4]Limerick Univeristy Hospital, Limerick, Ireland

Background/Purpose: Steroid injection and active physiotherapy are the two standard conservative therapies used to treat SIS and the outcome from these two treatments varies depending on numerous prognostic factors. Outcome predictors may identify patients suitable for specific therapies.The role of MSUS in the diagnosis of rotator cuff disease is well documented, however its utility in determining prognosis and selecting treatment pathways has not been yet assessed. This prospective investigation was designed to assess the utility of MSUS in determining which patients may respond to guided steroid injection or active physiotherapy in SIS.

Methods: Twenty consecutive patients with a new diagnosis of isolated SIS (symptoms duration less than 6 months) underwent MSUS. Participants chose to receive either ultrasound guided steroid injection or active physiotherapy. Participants were assessed at baseline, 6 weeks and 12 weeks. Assessments included shoulder pain and disability index (SPADI) and clinical assessment by an independent (blinded) rheumatologist. This clinical assessment included determination of the physician global assessment (PGA), the presence of Hawkins sign and the presence of supraspinatus tendon (SST) tenderness. Data are expressed as median (interquartile range) or as number (percentage).

Results: At baseline and at 12 weeks there were no significant differences in assessed parameters. 12 (60%) of the cohort had an abnormal initial MSUS: of these 5 (42%) received a steroid injection and 7 (58%) received active physiotherapy. After six weeks those who received a steroid injection had significantly different clinical parameter measurements than those receiving active physiotherapy:

- decrease in PGA was 80% (61–88%) vs 38% (30–43%, p=0.003);
- decrease in SPADI was 85% (37–90%) vs 14% (10–23%, p=0.01);
- resolution of SST tenderness occurred in 5 (100%) vs 0 (0%, p=0.003); and
- resolution of Hawkins sign occurred in 4 (100%) vs 1 (14%, p=0.006).

10 (50%) of the cohort received a steroid injection: of these 5 (50%) received had an abnormal MSUS. After six weeks those with an abnormal MSUS had significantly different clinical parameters measurements than those with a normal MSUS:

- decrease in PGA was 80% (61–88%) vs 20% (20–35%, p=0.008);
- decrease in SPADI was 85% (37–90%) vs 19% (10–63%, p=0.05);
- resolution of SST tenderness occurred in 5 (100%) vs 0 (0%, p=0.002); and
- resolution of Hawkins sign occurred in 4 (100%) vs 0 (0%, p=0.002).

Resolution of SST tenderness and Hawkins sign remained significantly different at 12 weeks.

Conclusion: The presence of a significant structural abnormality at baseline MSUS suggests that outcome, in the short term at least, may be superior when patients receive a guided injection rather than physiotherapy. And conversely a normal baseline scan may indicate that physiotherapy is the preferred option. Adequately powered randomized clinical trials are required to determine whether treatment decision-making based on MSUS findings is superior to standard management without use of MSUS.

Ultrasonographic Evaluation Of Patellar Cartilage and Triangular Fibrocartilage In Patients With Familial Benign Hypercalcemia. Alberto Batticciotto[1], Diana Certan[2], Valentina Varisco[1], Marco Antivalle[1], Fabiola Atzeni[1], Maurizio Bevilacqua[2] and Piercarlo Sarzi-Puttini[1]. [1]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy, [2]Endocrinology Unit, L. Sacco University Hospital, Milan, Italy

Background/Purpose: Familial benign hypercalcemia (FBH) is a rare autosomal dominant disease that is caused by a mutation in calcium sensing receptor (CaSR) genes and characterised by hypercalcemia and hypocalciuria with normal serum parathormone levels. The typical clinical symptoms are fatigue, weakness and polydipsia, but rare cases may be associated with chondrocalcinosis, pancreatitis and gallstones. One sensitive and specific means of diagnosis is an oral calcium and peptone load test.

The aim of this study was to evaluate the presence of calcium deposits in patellar cartilage and triangular fibrocartilage levels in FBH patients using the same ultrasonographic guidelines as those proposed for patients with gout and chondrocalcinosis.

Methods: Twenty-three patients with FBH (2 M, 21F; mean age 69 yrs, range 51–85; mean serum ionised calcium level 1.33 mmol/L, range 1.2–1.5) and 22 controls (1 M, 20 F; mean age 68 yrs, range 45–89; mean serum ionised calcium level 1.1 mmol/L, range 1.1–1.3), with normal serum ionised calcium levels who had negative oral calcium and peptone load test results, were evaluated be means of patellar cartilage and triangular fibrocartilage ultrasonography (ESAOTE My Lab 70, linear probe 13–18 MHz).

Results: The two groups were statistically similar in terms of age (p=0.709), serum parathormone levels (p=0.548), serum vitamin D levels (p=0.508) and calciuria levels (p=0.194), but different in terms of serum ionised calcium levels (p<0.001). Ultrasonography revealed microcrystalline deposits in at least one cartilage in 16/23 (69.6%) FBH patients and in 8/22 (36,4%) controls with a statistically significant difference (p=0.026).

Conclusion: Patients with hypercalcemia due to FBH have a higher prevalence of ultrasonographically detectable microcrystalline deposits in patellar cartilage and triangular fibrocartilage than normocalcemic controls.

	FBH	Control Group	P
Age (yrs)	69 (range 51–85)	68 (range 45–89)	0.709
Parathormone (pg/ml)	49,1 ± 11,4	46,67 ± 13,67	0.548
Ionised Calcium (mmol/L)	1.33 ± 0.6	1.18 ± 0.5	0.001
Vitamine D (ng/ml)	37.3 ± 13.6	40±13.9	0.508
Calciuria /24h (mg/dl)	216 ± 120.8	170 ± 88.3	0.194

The Power Doppler Modalities Of 5 Ultrasound Machines Perform Very Differently, Ascertained By a Microvessel Flow Phantom. David F. Ten Cate, Jolanda J. Luime, Myrthe van der Ven, Johanna M.W. Hazes, Klazina Kooiman, Nico De Jong and Johannes G. Bosch. Erasmus University Medical Center, Rotterdam, Netherlands

Background/Purpose: In many patients with rheumatoid arthritis (RA) subclinical disease activity can be detected with ultrasound (US), especially using power Doppler US (PDUS).[1–3] However, in our experience, PDUS is highly dependent on type of machine. This is a problem when conducting multicentre trials or in clinical practice. US machines should be able to detect the blood flow velocities in capillaries as low as 0.5 mm/s. [4–5] The objective of the study was to determine the lowest detectable flow by PDUS of 5 different US machines using microvessel flow phantom.

Methods: The flow phantom, consisted of an acrylic (PMMA) container filled with tissue mimicking material(TMM)[6], with 3 microvessels (150, 1000, 2000 micron). The blood mimicking fluid was based on the recipe by Ramnarine.[7] A syringe pump generated the flows. We tested the Aloka α7, Esaote MyLab60, Philips iU22, Ultrasonix SonixTouch, and VisualSonics Vevo2100. Settings were optimised to detect the lowest flows by adjusting pulse repetition frequency, velocity range, wall filters, frequency and gain. Lowest possible flow was defined as a continuous PDUS signal. Flow velocities were calculated from pump flow setting and microvessel diameter.

Results:

Table 1. Lowest detected flow velocity (mm/s), still resulting in a continuous positive PDUS signal; N.D. = none detected.

	Flow velocity		
Vessel size (micron)	**2000**	**1000**	**150**
Machine (probe)			
Aloka α7(UST-5411)	4	2.2	11.1
Esaote MyLab 60 (LA 435)	<0.05	0.06	0.11
Philips iU22 (L9-3)	1	0.56	1.68
Ultrasonix SonixTouch (L14-5/38)	1	0.56	N.D.
Visual Sonics Vevo2100 (MS200)	0.5	0.33	N.D.

Conclusion: The performance of the PDUS modality of 5 US machines for detecting very low flows in small vessels was very different, when tested on a microvessel flow phantom. The large differences found between the machines are partly explained by different lower limits of PRF and wall filter, but also by fundamental differences in processing of the PD signal or internal settings inaccessible to users. In the 150 micron vessel, minimal detectable velocity is higher because of sensitivity issues. The actual flow velocity in the 1000 micron vessel was probably slightly higher than calculated and similar to that in the 2000 micron vessel. A reason for this could be compression by the TMM and a more parabolic flow velocity profile in the 1000 micron vessel, with a relatively high peak flow, as compared to the 2000 micron vessel. Caution should be exercised when conducting a multi-machine trial or when making treatment decisions based on PDUS. Based on the results of our study it would be advisable to standardise and validate US machines both for rheumatological clinical practice and for clinical trials. Our flow phantom could be used for this purpose.

Meniscal Extrusion Is a Better Predictor Of Radiographic Osteoarthritis Change Over Ten Years Compared To Cartilage Volume Loss. Louisa Chou[1], Hussain Ijaz Khan[1], Andrew McBride[1], Dawn Aitken[1], Changhai Ding[1], Leigh Blizzard[1], Jean-Pierre Pelletier[2], Johanne Martel-Pelletier[2], Flavia Cicuttini[3] and Graeme Jones[1]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [3]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: Change in joint space narrowing (JSN) on radiographs is currently the gold standard for monitoring disease progression of knee osteoarthritis in clinical trials and is considered a surrogate marker for cartilage volume. However, this method can be unreliable due to high measurement error and it is insensitive to early change. Furthermore, cross-sectional studies have shown that JSN not only reflects hyaline articular cartilage but also meniscal pathology. Therefore, the aim of this study was to quantitate the correlation between changes in meniscal extrusion and cartilage volume loss over two years and radiographic osteoarthritis (ROA) change over ten years.

Methods: A sample of 220 subjects (mean age 45 years at baseline; age range 26–61 years) was evaluated at baseline, two, and ten years. Approximately half were adult offspring of subjects who had a knee replacement performed for knee osteoarthritis and the remaining were randomly selected controls that were initially matched by age and sex. Knee cartilage volume and meniscal extrusion were determined using T1-weighted fat-suppression MRI techniques at baseline and two years. ROA, JSN, and osteophytes were scored using fixed flexion radiographs at baseline and ten year using standard protocols. Spearman-ranked correlation analysis was used to analyse the correlation between changes in medial meniscal extrusion (MME) and medial tibial cartilage (MTC) loss with changes in ROA, JSN, and osteophytes. All were adjusted for age, sex and BMI.

Results: The mean MTC volume was 2234mm^3 at baseline with a 2.5% loss per annum over two years. At baseline, 8% of participants had any medial meniscal extrusion and 3% had an incident meniscal extrusion over two years. An increase in MME over two years predicted a change in ROA over ten years in adjusted analysis (r=0.22, p=0.003), an increase in medial JSN (r=0.30, p=<0.001) and an increase in medial osteophytes (r=0.15, p=0.046) [Fig 1]. However, a change in MTC over two years did not correlate with a change in ROA over ten years (r=−0.12, p=0.096) or a change in medial JSN (r=−0.10, p=0.182) and weakly with change in medial osteophytes (r=−0.14, p=0.045) [Fig 1].

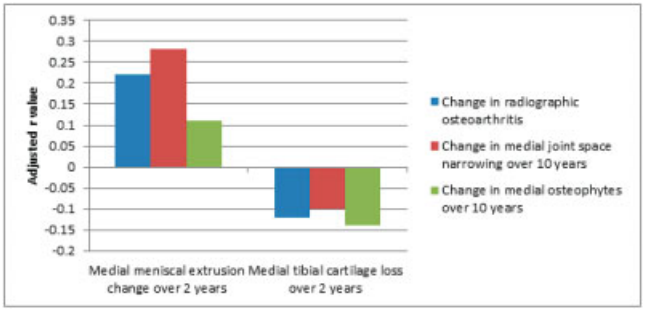

Figure 1. Correlation between changes in medial meniscal extrusion and medial tibial cartilage loss over two years with radiographic changes over ten years

Conclusion: In a midlife cohort at higher risk of osteoarthritis, a change in MME, despite being quite rare, is more strongly correlated with subsequent change in ROA than cartilage volume loss. These findings suggest ROA is a composite measure of joint pathology and does not primarily or sufficiently reflect cartilage loss.

Hip Bone Marrow Lesions In Asymptomatic and Osteoarthritic Adults: Prevalence, Risk Factors and Significance. L Dawson[1], Yuanyuan Wang[1], Anita Wluka[1], Kim Bennell[2], Andrew Teichtahl[1] and Flavia Cicuttini[3]. [1]Monash University, Melbourne, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: Bone marrow lesions (BMLs) at the knee have an important role in the pathogenesis of osteoarthritis (OA), being associated with increased pain, accelerated cartilage loss, and increased risk of total knee replacement. However, data is limited for the role of BMLs at the hip. The aim of this study was to determine the prevalence and associations of BMLs at the hip in an asymptomatic and an osteoarthritic population.

Methods: 142 asymptomatic and 19 participants with hip OA were recruited from existing cohorts. Hip magnetic resonance imaging was performed and used to assess femoral head BMLs, cartilage volume and bone area.

Results: The demographic characteristics of the asymptomatic versus the OA population were as follows: age 66.8 +/− 7.4 vs. 59.5 +/− 7.6 years ($p<0.001$), female 55.6% vs. 57.9% ($p=0.85$), body mass index 27.6 +/− 4.8 vs. 27.2.+/−.4.8 kg/m2. ($p=0.73$). The prevalence of BMLs was 17.6% in the asymptomatic population and 63.2% in the OA population ($p<0.001$). BMLs were strongly associated with OA after adjusting for age, gender and body mass index (odds ratio 5.32, 95% CI 1.78, 15.9, $p=0.003$). BMLs were associated with lower femoral head cartilage volume in the whole population (regression coefficient −245.7 mm3, 95% CI −455.5, −36.0, $p=0.02$). In the OA population, BMLs were also associated with lower femoral head cartilage volume (regression coefficient −426.6 mm3, 95% CI −855.2, 2.14, $p=0.05$) after adjusting for age, gender, body mass index, femoral head bone area and hip OA (for analysis of the total population).

Conclusion: Femoral head BMLs are common in those with OA, but are also present in asymptomatic individuals with no clinical hip OA. They are associated with reduced hip cartilage volume. These findings suggest that BMLs at the hip may provide a novel target for the treatment and prevention of hip OA.

The Association Of Radiographic Disease With Lesions On MRI In Lateral Compartment Knee Osteoarthritis: The Osteoathritis Initiative. Barton L. Wise[1], Jingbo Niu[2], Felix Liu[3], John A. Lynch[4], Yuqing Zhang[2], Ali Guermazi[5], David T. Felson[2], C. Kent Kwoh[6] and Nancy E. Lane[1]. [1]UC Davis School of Medicine, Sacramento, CA, [2]Boston University School of Medicine, Boston, MA, [3]University of California at San Francisco, San Francisco, CA, [4]University of California-San Francisco, San Francisco, CA, [5]Boston University, Boston, MA, [6]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Lateral compartment knee tibio-femoral radiographic osteoarthritis (ROA) is associated with pain and disability, and the epidemiology of this form of knee OA is not well known. We examined MRI abnormalities and their association with lateral compartment ROA.

Methods: We analyzed knees from participants in the Osteoarthritis Initiative (OAI), an NIH-funded study of persons aged 45–79 at baseline with, or at high risk of knee ROA. Baseline radiographs with central readings and MRIs were used to assess knee structure lesions. We defined cases as knees with Kellgren/Lawrence (K/L) grade >=2 and with joint space narrowing (JSN) >0 in the lateral compartment but JSN = 0 in the medial compartment; controls were defined as having K/L=0 and JSN=0 in all compartments. Cases and controls were matched by sex and age in 10-year bands. MRI readings for cases and controls were obtained from two ancillary studies in the OAI and further MRI readings were generated for this analysis. MRIs were scored at each subregion for cartilage lesions, bone marrow lesions, and meniscal tear or extrusion using the MOAKS scoring system. The score for each lesion was dichotomized into "any" or "none". Lesions in medial and lateral compartments were defined separately for whether any of the subregions in each compartment exhibited that lesion. We compared cases and controls for each structural lesion separately in both lateral and medial compartments using conditional logistic regression, adjusting for age, race, body mass index (BMI), and clinic site.

Results: Included in this analyses were 200 cases (mean age: 63.8, 34.5% men, mean BMI 29.5, and 76.5% white) and 200 controls (mean age: 63.1, 34.5% men, mean BMI 27.1, and 87.5% white). Isolated lateral compartment ROA was strongly associated with lateral compartment cartilage lesions (odds ratio (OR)=89.9, 95%CI 29.7–271.9), BMLs (OR=40.0, 95% CI: 21.1–75.7) and meniscal tear or extrusion (OR= 93.8, 95% CI 43.5–202.3). Medial compartment cartilage lesions, BMLs and meniscal abnormalities were also associated with isolated lateral compartment ROA; the magnitude of association, however, was much smaller. (See table)

		Medial TF Compartment MRI damage n/N (%)		Adjusted Model for Medial Compartment		Lateral TF Compartment MRI damage n/N (%)		Adjusted Model for Lateral Compartment	
Exposure	Level	among control knees	among case knees	OR (95% CI)	p-value	among control knees	among case knees	OR (95% CI)	p-value
BML>0 in any subregion	Lesion	24/200 (12%)	63/200 (31.5%)	3.44 (1.99, 5.94)	<.0001	21/200 (10.5%)	158/200 (79%)	39.96 (21.11, 75.65)	<.0001
	No Lesion	176/200 (88%)	137/200 (68.5%)	1		179/200 (89.5%)	42/200 (21%)	1	
Cartilage lesion area>0 in any subregion	Lesion	72/200 (36%)	122/200 (61%)	2.48 (1.63, 3.79)	<.0001	89/200 (44.5%)	196/200 (98%)	89.85 (29.69, 271.90)	<.0001
	No Lesion	128/200 (64%)	78/200 (39%)	1		111/200 (55.5%)	4/200 (2%)	1	
Meniscal tear or extrusion	Lesion	55/200 (27.5%)	82/200 (41%)	1.85 (1.19, 2.89)	0.0066	28/200 (14%)	183/200 (91.5%)	93.77 (43.46, 202.32)	<.0001
	No Lesion	145/200 (72.5%)	118/200 (59%)	1		172/200 (86%)	17/200 (8.5%)	1	

Conclusion: Knees with isolated radiographic OA in the lateral compartment have more MRI abnormalities of cartilage, meniscus and BMLs in the lateral compartment than knees without radiographic OA. Isolated lateral compartment ROA is also associated with medial compartment MRI lesions, but less strongly.

Structural Predictors Of Ten Year Knee Cartilage Volume Loss. Dawn Aitken[1], Hussain Ijaz Khan[1], Changhai Ding[1], Leigh Blizzard[1], Jean-Pierre Pelletier[2], Johanne Martel-Pelletier[2], Flavia Cicuttini[3] and Graeme Jones[1]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [3]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: Cartilage volume loss is considered a key feature of knee osteoarthritis (OA) and increased loss over two years is associated with future knee replacement surgery. Previous studies have identified structural predictors of cartilage loss over 2–3 years including baseline cartilage volume, cartilage defects, bone marrow lesions (BMLs), meniscal pathology and bone area. These are now considered important risk factors for osteoarthritis progression. However no study has examined whether these features predict loss over longer timeframes. The aim of this study was to examine structural predictors of cartilage volume loss over ten years.

Methods: 220 participants [mean age 45 (26–61); 57% female] were studied at baseline, two, and ten years. Approximately half were adult offspring of subjects who had a knee replacement performed for knee OA and the remaining were randomly selected controls that were initially matched by age and sex. Cartilage volume (tibial, patella), cartilage defects (tibial, femoral), BMLs (tibial, femoral, patella), meniscal extrusion (medial, lateral) and bone area (tibial) were measured using MRI. Predictors of ten year cartilage loss were examined using linear regression and all models were adjusted for age, sex, BMI, and offspring-control status. Interactions between offspring-control status and knee structures on cartilage loss were explored.

Results: Cartilage change over ten years was −2.5% per annum (pa), −1.1% pa, and −2.1% pa for the medial and lateral tibial and patella sites respectively.

BMLs predicted tibial ($\beta = -433$ mm^3 per 1 unit increase in BML size, $P < 0.01$) but not patella cartilage loss. Meniscal extrusion predicted lateral tibial cartilage loss ($\beta = -872$ mm^3 in those with a baseline extrusion versus those without, $P < 0.01$) but not medial tibial or patella cartilage loss. Cartilage volume at baseline predicted tibial and patella ten year cartilage loss ($\beta = -0.26$ to -0.41 mm^3 per unit increase in baseline volume, $P< 0.01$).

There was interaction between offspring-control status for cartilage defects. Baseline defect score predicted lateral tibial cartilage loss in offspring (B= −242 mm^3 per unit increase in defect score, $P < 0.01$); but, surprisingly defects appeared to be protective against medial and lateral tibial cartilage loss in controls ($\beta = 276$ to 327 mm^3 per unit increase in defect score, $P<0.01$).

Both change in cartilage volume (r = −0.58 to −0.62, all $P < 0.01$) and progression of cartilage defects (r = −0.18 to −0.58, all $P < 0.01$) over two years predicted ten year tibial cartilage loss.

Bone area did not predict ten year change in cartilage.

Conclusion: Structural features which have been identified as risk factors for cartilage loss over 2–3 years appear to predict long-term cartilage changes with the most consistent data for BMLs. This was seen in a largely pre-radiographic cohort and indicates that bone marrow lesions, presence of meniscal extrusion; and to a lesser extent, cartilage volume and cartilage defects, may be used to identify individuals who will lose the most cartilage long-term. Additionally this study demonstrates that cartilage loss and cartilage defect progression over two years are reasonable predictors of long-term cartilage changes.

A Family History Of Knee Joint Replacement Increases The Progression Of Knee Joint Radiographic Osteoarthritis and Cartilage Volume Loss Over Ten Years. Hussain Ijaz Khan[1], Dawn Aitken[1], Louisa Chou[1], Andrew McBride[1], Changhai Ding[1], Jean Pierre Pelletier[2], Johanne M. Pelletier[3], Leigh Blizzard[1], Flavia Cicuttini[4] and Graeme Jones[1]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [4]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: Osteoarthritis (OA) is a disease of multifactorial origin with a modest but significant heritable effect for disease severity in the knee joint. The aim of this study was to describe radiographic osteoarthritis (ROA) progression and cartilage loss over 10 years in a midlife cohort at higher risk of osteoarthritis and community based controls.

Methods: 220 participants [mean age 45 (26–61); 57% female] were studied at baseline and ten years. Approximately half were the adult offspring of subjects who had a knee replacement performed for knee OA and the remaining were randomly selected controls that were initially matched for age and sex. Joint space narrowing (JSN) and osteophytes on radiographs and cartilage volume (tibial, patella) on MRI were assessed using standard protocols. Negative binomial and linear regression were used to describe radiographic changes (expressed as difference in ratios (dr)) and cartilage loss (expressed as difference in means (dm)) respectively. Multivariable analyses were first adjusted for age, sex and the corresponding baseline measures (i.e. baseline cartilage volume for cartilage loss).Then the four baseline measures which were significantly different between offspring and controls (BMI, knee pain, cartilage defects and tibial bone area) were added to the model.

Results: In unadjusted analysis for radiographic changes, there was a significant difference between offspring and controls for changes in total ROA, medial JSN, total tibial, total femoral and total osteophyte scores (Table 1). The associations persisted after adjusting for age, sex, and corresponding baseline measures. However, with the exception of medial JSN, most of the other associations were markedly attenuated after adjustment for baseline pain, weight, cartilage defects and tibial bone area.

Table 1. Differences between offspring and controls

Outcome factor	Unadjusted	Adjusted*
Radiographic changes	**Difference in ratios and 95% confidence interval**	
Increase in medial JSN	**+2.0 (+1.1, +3.5)**	**+1.9 (+1.0, +3.5)**
Increase in lateral JSN	+0.8 (+0.3, +2.8)	+0.5 (+0.2, +1.9)
Increase in total JSN	+1.5 (+0.9, +2.6)	+1.4 (+0.82, +2.3)
Increase in total tibial osteophytes	**+2.1 (+1.2, +3.9)**	+1.7 (+0.9, +3.1)
Increase in total femoral osteophytes	**+2.4 (+1.1, +5.0)**	+1.6 (+0.72, +3.4)
Increase in total osteophytes	**+2.3 (+1.3, +4.0)**	+1.6 (+0.9, +2.9)
Increase in total ROA score	**+1.9 (+1.3, +3.0)**	+1.5 (+0.9, +2.3)
Cartilage loss	**Difference in means and 95% confidence interval**	
Medial tibial	**−91.5 (−181.6, +1.33)**	**−83.4 (−166.2,−0.53)**
Lateral tibial	−3.0 (−107.9, +101.8)	+32.1 (−72.9, +137.1)
Total Tibial	−89.6 (−263.0, +83.8)	−56.2 (−221.4, +109.0)
Patellar	−0.9 (−171.6, +169.8)	+77.2 (−70.1, +224.1)

Bold denotes statistical significance
*Adjusted for age, sex, corresponding baseline measure and baseline differences(BMI, knee pain, cartilage defects and tibial bone area)
JSN(Joint Space Narrowing)
ROA(Radiographic Osteoarthritis)

In unadjusted analysis for cartilage loss, offspring lost more cartilage at the medial tibial site only. This persisted after adjustment for age, sex, baseline cartilage volume and baseline differences.

Conclusion: The offspring of subjects having a total knee replacement have greater incidence of radiographic osteoarthritis (both joint space narrowing and osteophytes) and higher medial tibial cartilage loss over ten years. This is mediated, in part, by baseline differences in pain, weight, cartilage defects and tibial bone area and suggests this group could be a target for early prevention strategies.

Longitudinal Femorotibial Cartilage Thickness Increase In Young Athletes At The End Of Adolescence. Felix Eckstein[1], Heide Boeth[2], Gerd Diederichs[3], Wolfgang Wirth[1], Martin Hudelmaier[1], Sebastian Cotofana[1] and Georg Duda[2]. [1]Paracelsus Medical University, Salzburg, Austria, [2]Julius Wolff Institute, Charité – Universitätsmedizin Berlin, Berlin, Germany, [3]Department of Radiology, Charité - Universitätsmedizin Berlin, Berlin, Germany

Background/Purpose: Anterior or posterior cruciate ligament (ACL/PCL) ruptures are thought to lead to early knee osteoarthritis (KOA) and thus considered scientifically valuable "models" of pre-radiographic change. Further, longitudinal studies can be initiated at a precise set-point, which is the time of the trauma. Quantitative measurement of cartilage thickness change with MRI provides a powerful and sensitive tool for longitudinal analysis of structural cartilage change before, during, and after the onset of radiographic KOA. Because ACL/PCL rupture frequently occurs in young athletes, the purpose of this study was to obtain reference data of normal longitudinal subregional femorotibial cartilage thickness change in such subjects, specifically at the end of adolescence.

Methods: The knees of the dominant leg (the one used for take off) of 18 young top volleyball athletes (Olympic center Berlin) were examined. One participant was retrospectively excluded because of a history of ACL rupture, and one because of an imaging artifact. The age range (n=16; 8 female, 8 male) was 15–17 y at baseline. MR images were acquired using a 3D VIBE with water excitation, at baseline and two years later. Femorotibial cartilage thickness was measured by manual segmentation, using the images and commercially available software (Chondrometrics GmbH, Ainring, Germany). Cartilage thickness data were computed in the medial (MFTC) and lateral femorotibial compartment (LFTC), in tibial and femoral cartilages, and in 16 femorotibial subregions.

Results: Of the 16 subjects, 11 displayed open epiphyses at baseline, and all showed closed epiphyses at follow-up. In the MFTC, a cartilage thickness increase of +114±126μm (mean±standard deviation) or +3.3±3.7% was observed, with a standardized response mean (SRM= mean/standard deviation of change) of +0.90. This increase was less in the LFTC (+2.3±2.5%; SRM +0.93); and was greater in the weight-bearing medial femur (+4.4±3.7%; SRM +1.19) than in the medial tibia (+2.0±4.3%; SRM +0.46). The greatest increase was observed in the internal aspect of the medial femur (+5.5±5.8%; SRM +0.94) whereas no increase was seen in the internal aspect of the medial tibia (−0.5±6.6%; SRM −0.07). Over the two years, the subchondral bone area (tAB) increased by 0.8±1.5% in the MFTC and by 1.2±1.2% in the LFTC.

Conclusion: A substantial increase in femorotibial cartilage thickness (and subchondral bone area) was observed in young athletes towards the end of adolescence, i.e. a period during which the epiphyseal line is closing. This increase should be considered when measuring longitudinal cartilage change in young athletes after ACL/PCL rupture. Further studies need to clarify whether the increase is due mainly to normal growth, or to high exercise levels. Longitudinal studies in young adults with cruciate ligament rupture should hence include healthy reference cohorts of similar age (and activity level), to adequately differentiate pathological (post traumatic) change from that occurring physiologically.

Exploratory Factor Analysis Of a Parsimonious Medial Cartilage Damage Index Reveals One Factor Associated With Radiographic Severity and Symptoms: Data From The Osteoarthritis Initiative. Grace H. Lo[1], Lori Lyn Price[2], Ming Zhang[3], Jeffrey B. Driban[3], Daniel Harper[3] and Timothy E. McAlindon[3]. [1]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [2]Tufts University, Boston, MA, [3]Tufts Medical Center, Boston, MA

Background/Purpose: The cartilage damage index (CDI) is a parsimonious method of measuring articular cartilage approximating regional cartilage volume based on 18 locations within the knee, 9 in the medial tibia and femur (figure). Understanding locations that are simultaneously pathologic may better clarify the pathophysiology of knee osteoarthritis (OA). Therefore, we conducted an exploratory factor analysis of the CDI.

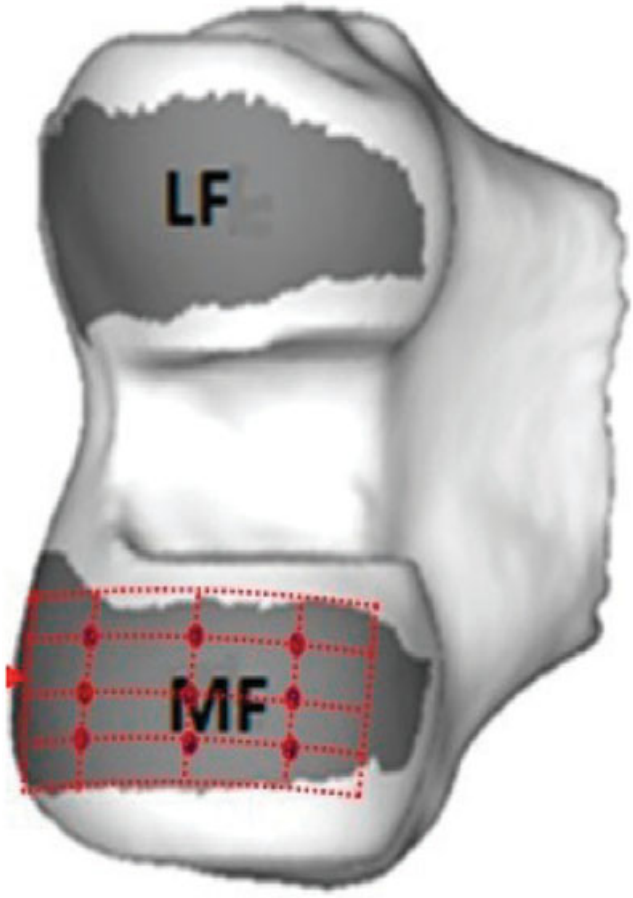

Figure. Spatial diagram of 9 of the femoral CDI points. Each red dot in the grid represents a separate location where CDI of articular cartilage is measured.

Methods: We included a convenience sample of 200 participants of the progression cohort of the Osteoarthritis Initiative (OAI) with 3T knee MRIs, PA radiographs, and WOMAC pain scores (0 – 20) at the OAI 24- month visit. Long limb films obtained at the OAI 12-, 24-, or 36- month visits were used to measure Hip-Knee-Ankle (HKA) angle using a semi-automated program (negative = varus). One assessor performed CDI measurements on MRI sagittal DESS sequences. Medial joint space narrowing (JSN) (0–3) and Kellgren-Lawrence (KL) score (0–4) were centrally assessed. An exploratory factor analysis was conducted on the 18 CDI points. To assess the characteristics of factors resulting from that analysis, we performed Spearman's correlations with the full CDI measure, the separate factors, medial JSN (construct we are trying to capture), KL score (OA severity), HKA (risk factor for medial OA), and WOMAC score (OA symptoms).

Results: Mean age was 62.5 (9.5) years, mean BMI was 30.0 (4.5) kg/m^2, 47% were female. 3 factors resulting from the factor analysis were: (1) anterior and weight bearing portions of the femur and tibia (AntWB) (2) posterior tibia (PostTib) and (3) posterior femur (PostFem), explaining 75%, 11%, and 9% of the data variation.

Table. Spearman's correlations of CDI, anterior weight-bearing (Ant WB) CDI, posterior tibia (PostTib) CDI, posterior femur (PostFem) CDI, Medial JSN, KL Score, HKA, and WOMAC scores

Conclusion: These findings suggest 3 patterns of cartilage damage occur in the medial tibia and femur. While PostTib and PostFem CDI are correlated with the full CDI, they are at best weakly correlated with medial JSN and not correlated with KL score, static alignment or pain. The AntWB CDI pattern contributes most of the variation in the 18 points and shows construct validity, correlating with medial JSN, KL score, static alignment, and pain, better than the full CDI measurement. Future studies confirming these findings are warranted.

Elevated Systemic Blood Pressure Is Associated With Increased Prevalent Knee Osteoarthritis and Knee Pain: Data From The Osteoarthritis Initiative. Grace H. Lo[1], Timothy E. McAlindon[2], Jeffrey N. Katz[3], Jeffrey B. Driban[2], Lori Lyn Price[4], Charles Eaton[5], Nancy Petersen[6], Christie Ballantyne[7] and Maria E. Suarez-Almazor[8]. [1]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [2]Tufts Medical Center, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Tufts University, Boston, MA, [5]Brown University, Providence, RI, [6]Michael E. DeBakey VA Medical Center Health Services Research and Development Center of Excellence, Houston, TX, [7]Baylor College of Medicine, Houston, TX, [8]University of Texas MD Anderson Cancer Center, Houston, TX

Background/Purpose: Epidemiologic studies have linked osteoarthritis (OA) to atheromatous vascular disease, both age-related diseases. Systemic hypertension (HTN) is an important risk factor for cardiovascular disease and may also be for OA. The objective of this study was to evaluate whether there is an association between HTN and prevalent knee OA and pain in the Osteoarthritis Initiative (OAI).

Methods: This is a longitudinal study of the OAI, a multi-center observational study of knee OA. Systolic (SBP) and extensive medication data were accumulated on participants at their OAI baseline, 12-, 24-, and 36-month visits. Bilateral PA knee radiographs were taken at the OAI 48-month visit. Central readers assessed radiographic OA severity, Kellgren and Lawrence (KL) grade (0–4). WOMAC pain scores were assessed for both knees at the 48-month visit. The greatest WOMAC score within one participant represented the maximal WOMAC score. There may be a lag between exposure to HTN and development of OA; therefore, we evaluated a 4 year interval between exposure and outcome. We performed logistic regression of quartiles of baseline SBP and 48-month status of prevalent radiographic OA (KL > 2) in either knee. We evaluated prevalent instead of incident knee OA to minimize the likelihood of right sided censorship. We performed a least square means of the maximum WOMAC score by quartile of SBP. The adjusted model included age, sex, and body mass index (BMI) as covariates. To eliminate the influence of HTN treatments, we performed subgroup analyses of those not taking anti-HTN medications at the baseline visit. To address the possibility that participants' SBPs fluctuated over time, we performed a sensitivity analysis using mean SBP over the baseline, 12-, 24-, and 36-month OAI visits as the exposure.

Results: 3644 people were included with a mean age of 61.1 (9.1), mean BMI of 28.5 (2.7), 42% were male. 61% of participants were not on anti-HTN medications. 20%, 13%, 5%, and 1% were on 1, 2, 3, and > 4 anti-HTN medications.

Table. Systolic blood pressure is associated with prevalent radiographic knee osteoarthritis and knee pain. Logistic regression of SBP quartile and prevalent knee OA. Least Squared Means of maximal WOMAC score by SBP quartiles, adjusted for age, sex, BMI, and radiographic OA status

	Outcome = Prevalent Knee OA	Outcome = Knee Pain		
N = 3644	Prevalence of Knee OA by SBP Quartile	Unadjusted Odds Ratio (95% CI)	Odds Ratio (95% CI) Adjusted for Age, Sex, BMI	LS Means of Maximal WOMAC Score, Adjusted for Age, Sex, BMI, Rad OA status
SBP Quartile 1 (76 – 112)	531/1031 (52%)	Referent	Referent	2.6 (2.4–2.8)
SBP Quartile 2 (114 – 122)	519/846 (61%)	1.5 (1.2–1.8)	1.2 (1.0–1.5)	2.8 (2.6–3.0)
SBP Quartile 3 (123 – 134)	586/865 (68%)	2.0 (1.6–2.4)	1.4 (1.2–1.7)	2.9 (2.7–3.1)
SBP Quartile 4 (135 – 210)	619/902 (69%)	2.1 (1.7–2.5)	1.3 (1.0–1.6)	3.2 (3.0–3.4)
		p-for trend < 0.0001	p-for trend = 0.006	p trend = 0.0016

Sensitivity analyses of participants who did not report anti-HTN medications showed similar results, as did using mean SBP over baseline – OAI 36 month as the exposure.

Conclusion: To our knowledge, this is the first epidemiologic study to show elevated systemic blood pressure is associated with increased prevalence of knee OA and greater levels of knee pain. The associations were weakened when adjusting for age, sex, and BMI, but were still significant. These findings suggest a new and promising avenue for research on disease modification as well as symptom control in knee OA. Future epidemiologic studies are needed to confirm these findings.

The Association Between Metabolic Syndrome and Hand Osteoarthritis - Data From The Framingham Study. Ida K. Haugen[1], Vasan Ramachandran[2], Devyani Misra[2], Tuhina Neogi[2], Jingbo Niu[2], Yuqing Zhang[2] and David T. Felson[2]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Boston University School of Medicine, Boston, MA

Background/Purpose: Metabolic factors may have a negative effect on cartilage, and may be especially relevant in the pathogenesis of hand OA. Our aim was to investigate whether metabolic syndrome and its components were associated with prevalent and incident hand OA in a large community-based sample.

Methods: We included participants from the Framingham Offspring cohort, who were examined for OA at exam 5 (1991–95) and 7 (1998–2001). Inclusion criteria were: available data on symptomatic hand OA, clinical data, no anti-hypertensive, anti-diabetic and lipid-lowering treatment, no rheumatoid arthritis, and age 50–75 years at exam 5. Symptomatic hand OA was defined as Kellgren-Lawrence grade ≥2 and pain in the same joint(s). Metabolic syndrome was defined as central obesity (men: ≥37.0 inches, women: ≥31.5 inches waist circumference) plus two of the following: hypertension (systolic ≥130 mmHg and/or diastolic ≥85 mmHg), elevated fasting blood glucose (>100 mg/dL), elevated triglycerides (>150 mg/dL) and low HDL (men: <40 mg/dL, women: <50 mg/dL). In cross-sectional analyses, we examined whether metabolic syndrome and its components were associated with presence of symptomatic hand OA using logistic regression. In longitudinal analyses, we examined the associations between metabolic syndrome and incident symptomatic hand OA at exam 7. We adjusted for age and sex.

Results: Of the 748 participants who fulfilled the inclusion criteria, 74 (9.9%) had symptomatic hand OA. Participants with symptomatic hand OA were older than those without (mean (SD) 62.2 (5.9) vs. 57.7 (6.0) years) and more likely to be women (75.7% vs. 51.0%). There was no significant association between metabolic syndrome and symptomatic hand OA (Table). The strength of association between metabolic syndrome and symptomatic hand OA was attenuated when we adjusted for body mass index (BMI) (cross-sectional association: OR 1.19, 95% CI 0.68–2.10). When evaluating the individual components of metabolic syndrome separately, we found a significant association between central obesity and symptomatic hand OA in the adjusted cross-sectional analyses (Table). In the longitudinal analyses, we found a statistically significantly *lower* risk of incident symptomatic hand OA associated with elevated triglycerides (Table). The association remained after adjustment for lipid-lowering treatment (data not shown). Similar results were found when we included BMI in the adjusted models (data not shown).

Table. Associations between metabolic syndrome and hand OA.

	Frequency of metabolic syndrome (%)		Logistic regression OR (95% CI)	
	No hand OA	Hand OA	Crude analyses	Adjusted for age and sex
Cross-sectional analyses[1]				
Metabolic syndrome	39.0	48.6	1.48 (0.91–2.40)	1.44 (0.87–2.38)
Central obesity	64.2	79.7	2.19 (1.22–3.94)	2.24 (1.22–4.12)
Hypertension	40.2	50.0	1.49 (0.92–2.41)	1.27 (0.77–2.11)
High blood-glucose	27.5	24.3	0.85 (0.49–1.48)	0.89 (0.49–1.61)
High triglycerides	33.4	33.8	1.02 (0.61–1.69)	1.01 (0.60–1.73)
Low HDL	64.1	70.3	1.32 (0.78–2.23)	1.30 (0.75–2.23)
Longitudinal analyses (only those without hand OA at baseline were included)[2]				
Metabolic syndrome	38.6	31.5	0.73 (0.45–1.18)	0.77 (0.47–1.25)
Central obesity	63.5	59.8	0.85 (0.56–1.43)	0.90 (0.56–1.43)
Hypertension	37.4	41.3	1.18 (0.74–1.86)	1.24 (0.77–1.20)
High blood-glucose	28.0	18.7	0.59 (0.33–1.04)	0.64 (0.35–1.14)
High triglycerides	34.0	21.7	0.54 (0.32–0.92)	0.56 (0.33–0.96)
Low HDL	64.9	55.4	0.67 (0.43–1.06)	0.67 (0.42–1.05)

[1] n=674 and n=74 without and with symptomatic hand OA at exam 5, respectively,
[2] n=430 and n=92 without and with incident symptomatic hand OA at exam 7, respectively (n=152 lost to follow-up),

Conclusion: Metabolic syndrome was not associated with higher probability of presence or development of hand OA. If anything, we observed a *lower* probability of incident symptomatic hand OA in participants with high triglycerides.

Association Between Serum Adipokine Levels and Extent Of Symptomatic Joint Involvement In Hip and Knee Osteoarthritis. Anthony V. Perruccio[1], Vinod Chandran[2], Nizar N. Mahomed[3] and Rajiv Gandhi[4]. [1]Toronto Western Hospital, Toronto Western Research Institute, and University of Toronto, Toronto, ON, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]University Health Network and University of Toronto, Toronto, ON, [4]University Health Network, Arthritis Program, Toronto, ON

Background/Purpose: Osteoarthritis (OA) has not traditionally been considered a systemic joint disease. However, a growing body of evidence suggests that OA cannot solely be accounted for by a single phenotype, and that systemic factors may play a contributing role in its pathogenesis. Obesity is an important risk factor for OA, but the underlying mechanisms are not fully understood (e.g. strong association between obesity and hand OA cannot be explained by mechanical stresses). Finally, the presence of multiple symptomatic joints among many with OA further suggests potentially underlying systemic mechanisms. In this pilot study, we investigated the association between serum levels of adipokines and the extent of symptomatic joint involvement among patients scheduled for hip and knee replacement surgery for OA.

Methods: Serum levels of adipokines (leptin, adiponectin, adipsin, resistin) were determined by ELISA in 78 patients (45 females, 33 males) scheduled for total hip or knee replacement surgery for OA. Individuals reporting inflammatory arthritis, cardiovascular disease or diabetes were excluded. Patients indicated on a homunculus all joints that were symptomatic on most days for at least a month in the past 12 months. A count score of symptomatic regions (neck; spine; shoulders; elbows; wrists; hands; hips; knees; ankles; feet) (not including surgical joint) was developed (range: 0 to

9). Analysis was stratified by sex, and Poisson analyses used to investigate associations.

Results: Bivariate associations suggested opposite effects of leptin, adiponectin, and adipsin between women and men. Adjusted for age, BMI, and hip/knee group membership, higher levels of leptin and adiponectin, and lower levels of adipsin (all $p<0.01$) were associated with a greater regional joint count among women (Table 1). However, among men only resistin was significantly ($p=0.03$) associated in adjusted analyses, with higher levels of resistin associated with lower regional joint counts.

Table 1. Multivariate adjusted associations between regional joint count (outcome) and adipokines.

	IRR*	Lower 95% CL	Upper 95% CL	Pr > ChiSq
Predictors		**Females**		
Age	**1.03**	1.005	1.058	**0.0204**
BMI	1.01	0.973	1.054	0.5407
Knee vs. hip	1.25	0.765	2.048	0.3725
Leptin (ng/ml)	**1.03**	1.010	1.047	**0.0021**
Adiponectin (μg/ml)	**1.03**	1.011	1.056	**0.0031**
Adipsin (mg/ml)	**0.85**	0.751	0.961	**0.0094**
Resistin (ng/ml)	1.01	0.987	1.038	0.3613
		Males		
Age	1.02	0.979	1.054	0.4017
BMI	1.03	0.933	1.143	0.5330
Knee vs. hip	0.92	0.430	1.949	0.8181
Leptin (ng/ml)	0.97	0.923	1.020	0.2485
Adiponectin (ug/ml)	0.97	0.937	1.010	0.1563
Adipsin (mg/ml)	0.96	0.790	1.176	0.7190
Resistin (ng/ml)	**0.97**	0.942	0.997	**0.0307**

*IRR: Incident rate ratio, per unit of measurement - Poisson analysis; 95% CL: 95% confidence limits.

Conclusion: This work suggests to some degree that there may be a dose-response association between OA (using extent of regional symptomatic joint involvement as an indicator) and serum levels of adipokines. However, these associations differ between women and men. This suggests the possibility of distinct OA phenotypes, and supports potential systemic effects in OA. OA as a systemic disorder entails a need to reevaluate OA treatment and management strategies, with consideration for multimodal approaches. Systemic factors in OA may also help explain high levels of comorbidity in these populations and may be a target for comorbidity prevention.

C-Reactive Protein But Not Erythrocyte Sedimentation Rate Is Associated With Decrease In Muscle Strength In Patients With Knee Osteoarthritis: A 2 Year Follow Up Study. Diana C Sanchez-Ramirez[1], Marike van der Leeden[2], Martin van der Esch[2], Leo D. Roorda[3], Sabine Verschueren[4], Jaap van Dieen[5], Joost Dekker[6] and Willem F. Lems[6]. [1]VU university Amsterdam, Amsterdam, Netherlands, [2]Reade, Amsterdam, Netherlands, [3]Reade, centre for rehabilitation and rheumatology, Amsterdam, Netherlands, [4]KU University of Leuven, Leuven, Belgium, [5]VU University, Amsterdam, Netherlands, [6]VU University Medical Center, Amsterdam, Netherlands

Background/Purpose: In patients with knee osteoarthritis activity limitations and disease progression have been associated with muscle weakness (OA). Muscle weakness might be determined by factors such as increased pain, immobilization, disuse, avoidance of activities and aging. Additionally, recent cross-sectional studies have found an association between elevated inflammatory markers and a decrease in knee muscle strength in this group of patients (1;2). However, longitudinal studies which assess the association between inflammatory markers and muscle strength in patients with OA are still needed. Therefore, the aim of the study was to examine the associations of serum c-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) with changes in muscle strength in patients with knee osteoarthritis (OA) after two years.

Methods: Data from 186 patients with knee OA part of the Amsterdam Osteoarthritis cohort (AMS-OA) were gathered at baseline and at two years follow up. CRP (mg/l) and ESR (mm/l) were measured in serum from patients' blood. Strength of quadriceps and hamstrings muscles was assessed using an isokinetic dynamometer. Univariable and multivariable linear regression analyses were used to assess the association of CRP and ESR with changes in muscle strength, adjusting for relevant confounders.

Results: Persistently elevated or increased serum CRP values ($\beta=-0.23$; $p=0.002$), but not ESR values ($\beta=-0.05$; $p=0.55$), were associated with a decrease in knee muscle strength after two years, even after adjustment for age, sex, comorbidities, NSAIDs use, BMI, pain, physical activity and baseline muscle strength.

Conclusion: Our results indicate that persistently elevated or an increase in inflammatory markers are independently related to decreased muscle strength in patients with knee OA. Although the mechanism to explain this relationship is not clear yet, targeting inflammation might have the potential to control the loss of muscle strength in this group of patients.

246

Bone Mineral Density and the Risk of Knee Osteoarthritis: The Johnston County Osteoarthritis Project. Kamil E. Barbour[1], Jennifer M. Hootman[2], Charles G. Helmick[1], Louise Murphy[3], Jordan B. Renner[4] and Joanne M. Jordan[5]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]Centers for Disease Control and Prevention, Kennesaw, GA, [3]CDC, Atlanta, GA, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC

Background/Purpose: There is credible evidence that high bone mineral density (BMD) is associated with an increased risk of incident radiographic osteoarthritis (ROA) of the knee. However, less is known about the relationship of BMD and the outcome with greater clinical and public health relevance, incident symptomatic ROA (sROA).

Methods: Using data (N=951) from the Johnston County Osteoarthritis Project's first (1999–2004) and second follow-up (2005–2010), we examined the association between BMD and both incident knee ROA and sROA among participants aged ≥45 years. Total hip BMD at baseline was measured using dual-energy X-ray absorptiometry. Participants were grouped into sex-specific BMD quartiles because of large sex-specific differences in BMD. Incident knee ROA was defined as development of a Kellgren-Lawrence grade of ≥2 in a knee at second follow-up. Incident knee sROA was defined as onset of both ROA and symptoms in at least one knee at second follow-up. Weibull regression modeling, which accounted for interval censored data, was used to estimate hazard ratios (HR) and 95% confidence intervals (95% CIs). Multivariate models adjusted for age, BMI, sex, race, education, smoking, physical activity, and history of knee injury.

Results: Median follow-up time was 6.8 (range=4.0–10.2) years. Compared with participants in the lowest BMD quartile, the multivariable adjusted HRs (95% CIs) of sROA for participants in the second, third, and highest quartiles of total hip BMD were 1.4 (0.9 to 2.4), 1.7 (1.1 to 2.7), and 1.6 (1.02 to 2.5), respectively, p trend=0.03. Risk of sROA risk did not vary by total hip BMD quartiles, nor was the test of trend significant across BMD quartiles (p trend=0.23).

Conclusion: Although high levels of BMD may significantly increase one's risk of knee ROA, we found no evidence of an association between BMD and the more clinically relevant outcome of knee sROA. These findings suggest that adults can achieve and maintain a healthy BMD without the tradeoff of increasing their risk of the painful and potentially debilitating outcome of sROA.

Associations Between Levels Of Urinary C-Telopeptide Fragments Of Type II Collagen and Knee Structure In Asymptomatic Middle-Aged Women. Binghui Wang[1], Hans Kurniawan Pramono[1], Flavia Cicuttini[2], Anita Wluka[1], Fahad Hanna[1], Susan Davis[1], Robin Bell[1], Andrew Teichtahl[1] and Yuanyuan Wang[1]. [1]Monash University, Melbourne, Australia, [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: There is evidence for an association between levels of urinary C-telopeptide fragments of type II collagen (uCTX-II) and the risk of knee osteoarthritis. The aim of this study was to examine the association between uCTX-II levels and knee cartilage and bone changes in a cohort of asymptomatic women.

Methods: 140 women, aged 40–67 years with no history of knee pain, injury or clinical knee disease, underwent knee MRI at baseline and two years later. Cartilage volume, cartilage defects, tibial plateau bone area and bone marrow lesions (BMLs) were measured using validated methods. Baseline uCTX-II concentrations were determined using enzyme-linked immunosorbent assay (ELISA).

Results: Increased uCTX-II level was associated with increased prevalence of medial tibiofemoral cartilage defects (OR 4.5, 95% CI 1.6–12.5, p = 0.004) and lateral tibiofemoral BMLs (OR 10.6, 95% CI 1.8–61.8, p = 0.01), greater medial (regression coefficient 80.2 mm^2, 95% CI 9.3–151.1, p = 0.03) and lateral (regression coefficient 86.0 mm^2, 95% CI 33.3– 138.7, p = 0.02) tibial plateau bone area. No significant association was found for tibial cartilage volume. Baseline uCTX-II levels were not associated with the changes in cartilage and bone over two years.

Conclusion: In asymptomatic women, increased uCTX-II levels were associated with adverse knee structural changes, as evidenced by increased prevalence of cartilage defects and BMLs, and bigger tibial plateau bone area. These data suggest that uCTX-II may be a sensitive biomarker for early knee cartilage changes. Longitudinal studies with larger sample size and longer follow-up are needed.

Hand Osteoarthritis Is Associated With Increased Type II Collagen Degradation In Women: The Ofely Study. Jean-Charles Rousseau[1], Elisabeth Sornay-Rendu[1], Cindy Bertholon[1], Patrick Garnero[2] and Roland Chapurlat[3]. [1]INSERM UMR 1033, Lyon, France, [2]INSERM, UMR 1033, Lyon and Cisbio Bioassays, Bagnols/Cèze, France, [3]INSERM UMR 1033 and Université de Lyon, Hôpital Edouard Herriot, Lyon, France

Background/Purpose: Hand osteoarthritis (OA) is one of the most common sites of OA and predominantly affects women. Patients with knee, hip or spine OA exhibit increased cartilage type II collagen degradation as detected by the urinary excretion of C-terminal crosslinking telopeptide of type II collagen (CTX-II), but data on hand OA is lacking. The aim of this study was to investigate the relationship between urinary CTX-II and hand OA in women.

Methods: We investigated 590 women from the OFELY population-based study (mean age: 61.8 years ± 10.2), including 475 postmenopausal women. Clinical hand OA was defined according to the ACR criteria (Altman *et al*, 1990), slightly modified (without functional complains). At the same time of hand OA evaluation, knee and spine OA were assessed by radiographs and self-reported hip OA was recorded. Levels of urinary CTX-II measured by ELISA (Urine CartiLaps®, IDS) in the 186 women with hand OA (mean age: 67.2 years ± 8.4) were compared to those of the 404 other women without hand OA (mean age: 59.4 years ± 10.1). All analyses were adjusted for age and concomitant knee, hip or spine OA.

Results: Urinary CTX-II levels were significantly increased in women with hand OA (237 ±134 ng/mmolCr) compared to controls (165 ± 97 ng/mmolCr, p = 0.001) after adjustment for age and for prevalent knee, spine and hip OA. When urinary CTX-II concentrations were considered in quartiles, subjects with levels in the highest quartile had an increased risk of prevalent hand OA, with an odds-ratio of 2.06 (95% CI: 1.3–3.2; p = 0.002), after adjustment for OA at the other anatomical sites.

Conclusion: Hand OA is characterized by increased type II collagen degradation. Urinary CTX-II could be a useful biomarker for the clinical investigation of hand OA.

Biomarkers Reflect Differences In Osteoarthritis Phenotypes Of The Lumbar Spine: The Johnston County Osteoarthritis Project. Adam P. Goode[1], Amanda E. Nelson[2], Virginia B. Kraus[3], Jordan B. Renner[4] and Joanne M. Jordan[2]. [1]Duke University, Durham, NC, [2]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC, [3]Duke University Medical Center, Durham, NC, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: We have previously identified differences in associations between joint metabolism biomarkers and radiographic features of the lumbar spine (disc space narrowing (DSN) and osteophytes (OST)). Due to anatomical differences, there may be distinct associations between biomarkers and different phenotypes of osteoarthritis (OA) in the spine. Therefore, our aim was to determine if differences exist in the associations between biomarkers and OA in the spine, defined as 1) facet osteoarthritis (FOA) and 2) the combination of DSN and OST at the same level; we further explored variations by gender, race and low back symptoms.

Methods: Of the 1,015 participants enrolled in the Johnston County OA Project from 2003–04, 547 participants had complete data for serum hyaluronan (sHA), serum Cartilage Oligomeric Matrix Protein (sCOMP), serum collagen neoepitope (sC2C), serum C-propeptide (sCPII), and urinary N-terminal telopeptide (uNTX-I); 529 participants had complete data for urinary cross-linked C-telopeptide of type II collagen (uCTX-II). The mean age and body mass index (BMI) were 62 (SD 10) years and 30 (SD 6) kg/m^2, respectively; 62% were female, 38% were African American (AA), 29% had knee OA, 24% hip OA, 28% hand OA and 49% low back symptoms. Each lumbar spine level was graded for OST and DSN in a semi-quantitative fashion (0–3) and FOA was graded as present or absent according to the Burnett Atlas. Spine OA was defined as the presence of DSN and OST grade 1 or more at the same lumbar level. Biomarkers were natural log (ln) transformed. Linear regression was used to determine adjusted geometric mean values of biomarkers and binary logistic regression models were used to estimate adjusted odds ratios (aOR) and 95% confidence intervals (CI) between biomarkers and spine radiographic variables. All analyses were adjusted for demographic (age, race, gender), clinical (BMI) and radiographic (knee, hip, hand and spine OA or FOA) variables. Interactions were tested with likelihood ratio tests at a p-value$<$0.05.

Results: FOA was present at least at one level of the lumbar spine in 57% of participants, while spine OA was present in 49%. Geometric mean biomarker levels of lnHA were significantly (p=0.04) greater in the presence of FOA while lnCTX-II levels were significantly (p$<$0.01) greater with in presence of spine OA. Significant associations were found between lnHA and FOA (aOR=1.26 ((95% CI 1.02, 1.55)) whereas lnCTX-II was significantly associated with spine OA (aOR=1.64 ((95% CI 1.22, 2.21)). The association between lnHA and FOA was significantly (interaction p$<$0.01) greater among Caucasians (aOR=1.56 ((95% CI 1.18, 2.05)) than with AA (aOR=0.92 ((95% CI 0.68, 1.25)). The association between lnCOMP and spine OA was significantly greater (interaction p=0.03) among those with low back symptoms (aOR=2.14 ((95% CI 1.08, 4.28)), than those without (aOR=0.76 ((95% CI 0.51, 1.68)).

Conclusion: Joint metabolism biomarkers reflect the anatomical (HA with FOA and CTX-II with spine OA), demographic (HA with race and FOA) and clinical (COMP with spine OA and symptoms) differences between FOA and a composite definition of spine OA. This may indicate a different pathophysiologic process exists for these two phenotypes of OA in the lumbar spine.

Synovial Inflammation In Meniscal Tear Patients: CCL19 mRNA Expression Is Independently Associated With Knee Related Disability. Anjali Nair, Charles Bush-Joseph, Nikhil Verma, Matthew Tetreault, Kanta Saha, Arkady Margulis, Louis F. Fogg and Carla R. Scanzello. Rush University Medical Center, Chicago, IL

Background/Purpose: In patients with knee osteoarthritis (OA), synovitis is associated with severity of knee symptoms. Previously, we demonstrated that in patients undergoing partial meniscectomy without radiographic OA, synovitis is associated with worse preoperative knee pain and function using the Lysholm score, which measures knee-specific pain and disability on a single scale. mRNA expression levels of the chemokine CCL19 and its receptor CCR7 were associated with presence of synovitis, and strongly correlated with worse Lysholm scores. However, unlike the patients in our previous study, most patients with meniscal tears indicated for arthroscopy already have pre-existing cartilage degeneration indicative of early-stage OA. In this study we sought to validate these markers in more typical patients presenting for arthroscopy to determine their utility as markers of more symptomatic early knee disease. To measure knee specific pain and functional deficits we used the Knee Injury and Osteoarthritis Outcome score (KOOS).

Methods: Synovial biopsies were collected during surgery from 19 patients undergoing arthroscopic meniscal procedures. Relative mRNA expression levels (RE) of CCL19 and CCR7 were measured using Real Time polymerase chain reaction. The KOOS was administered preoperatively and measures knee function and disability on 5 separate domains: Pain, symptoms, activities of daily living (ADL), sport and recreation function, knee-related quality of life (QOL). Pearsons correlations were used to determine relationships between mRNA levels and KOOS scores. Multivariable linear regression models were run to test if associations were independent of age, gender, BMI, cartilage degeneration (measured using Outerbridge Classification) and radiographic OA (Kellgren-Lawrence (K/L)) scores. Post-hoc power analysis showed our study was powered at 73% to detect a moderate correlation ($\rho = 0.5$) between chemokine levels and KOOS scores.

Results: The majority of patients had grade 2–4 Outerbridge scores and median K/L scores of 2, indicative of pre-existing OA. CCL19 and CCR7 transcripts were detected in all patients. Unadjusted analysis revealed CCL19 RE was associated with KOOS ADL ($r = -0.620$, $p = 0.005$), Pain ($r=-0.547$, $p=0.015$), and QOL scores ($r=-0.479$, 0.038). Adjusted analyses showed CCL19 RE was independently associated with KOOS ADL scores ($\beta = -4.201$, 95% CI [−8.071, −0.331], $p = 0.036$). Trends were observed for associations with KOOS Pain (CCL19 $\beta = -3.252$, 95% CI [−6.748, 0.243], $p = 0.065$) and KOOS QOL CCL19 $\beta = -3.719$, 95% CI [−7.786, 0.349], $p = 0.070$).

Conclusion: CCL19 is important in lymphocyte recruitment and was identified in our previous work as a marker of synovitis. Our current work extends these findings by demonstrating a relationship between CCL19 expression and knee-related difficulty with activities of daily living in typical patients presenting for arthroscopic meniscal surgeries. These findings increase the potential for this marker to be useful in identifying patients with synovitis after a meniscal tear and with early-stage OA. Future work is needed to determine the role of this marker in development and pathogenesis of symptomatic OA after meniscal injury.

Physical Activity Is Associated With Reduced Incident Disability: Evidence From The Osteoarthritis Initiative. Dorothy D. Dunlop[1], Jing Song[1], Pamela A. Semanik[1], Leena Sharma[1], Joan M. Bathon[2], Charles Eaton[3], Marc C. Hochberg[4], Rebecca D. Jackson[5], C. Kent Kwoh[6], W, Jerry Mysiw[5], Michael C. Nevitt[7] and Rowland W. Chang[8]. [1]Northwestern University, Chicago, IL, [2]Columbia University, New York, NY, [3]Brown University, Providence, RI, [4]University of Maryland, Baltimore, MD, [5]Ohio State University, Columbus, OH, [6]University of Pittsburgh, Pittsburgh, PA, [7]University of California, San Francisco, San Francisco, CA, [8]Northwestern University Medical School, Chicago, IL

Background/Purpose: Over 56 million people in the U.S. are classified as disabled. Physical activity is a low cost, broadly applicable approach to improve cardiovascular fitness, but it is not established if improved fitness translates to reduced disability, a key to containing healthcare costs. This study evaluated whether accelerometer measured physical activity is related to incident disability.

Methods: We prospectively examined the relationship of accelerometer measured physical activity with two-year development of disability measured by instrumental and basic activity of daily living limitations (IADL/ADL). We studied 1666 participants aged 49 years or older from the Osteoarthritis Initiative observational study of adults at high risk for or having knee OA and were free of baseline IADL/ADL limitations. This sample represents a large segment of community-dwelling adults at elevated risk for disability. Hazard ratios were estimated from discrete survival methods to investigate a graded relationship between baseline physical activity quartile groups and the development of disability within two years.

Results: Higher physical activity levels had a significant inverse association with the development of disability. For higher active physical activity quartiles, hazard ratios for incident disability were 1.00, 0.67, 0.51, and 0.36, respectively (P for trend, <0.001) controlling for socioeconomic (age, gender, race/ethnicity, education, income) and health factors (comorbidity, depressive symptoms, obesity, smoking, lower extremity pain, function, and knee factors: osteoarthritis severity, pain, symptoms, prior injury). Consistent trends between greater physical activity and less incident disability were demonstrated from analyses stratified by age, gender, and presence/absence of knee osteoarthritis and analyses based on time spent in moderate-intensity or light-intensity physical activities. Sensitivity analyses applying a more stringent definition of disability based on reported IADL/ADL dependency/assistance also demonstrated a statistically significant inverse graded relationships.

Conclusion: These prospective data demonstrated an inverse relationship between higher physical activity levels and the development of disability in community-dwelling adults at elevated risk for disability. Importantly, this study demonstrated greater physical activity, regardless of intensity, was related to less incident disability. Reduced incident disability was associated with greater time spent in light intensity as well as moderate-to-vigorous intensity activities. These findings support policies that encourage adults, including persons with arthritis, to increase their physical activity of any intensity to prevent and slow disability.

The Association Of Knee Buckling With Vibratory Perception and Muscle Strength: The Multicenter Osteoarthritis Study. Najia Shakoor[1], David T. Felson[2], Jingbo Niu[2], Neil A. Segal[3], Uyen Sa D.T. Nguyen[2], Jasvinder A. Singh[4] and Michael C. Nevitt[5]. [1]Rush University Medical Center, Chicago, IL, [2]Boston University School of Medicine, Boston, MA, [3]University of Iowa, Iowa City, IA, [4]University of Alabama, Tuscaloosa, AL, [5]University of California, San Francisco, San Francisco, CA

Background/Purpose: Knee buckling ("giving way") is a common symptom in knee osteoarthritis (OA). Yet, little is known regarding risk

factors for buckling. Knee buckling has been found to be associated with muscle weakness, a treatable cause, in one study and this finding needs to be confirmed. In addition, vibratory deficits have been shown to be present in knee OA, and may create alterations in knee position, increasing vulnerability to buckling but this has not been examined. Here, we evaluate the association of muscle strength and vibratory perception with buckling in older adults with, or at high risk for, knee OA.

Methods: MOST is a NIH-funded longitudinal study of persons with symptomatic knee OA or at increased risk of OA. At the 60-month visit, participants underwent evaluation of isokinetic muscle strength at the right leg, bilateral evaluation of vibratory perception threshold (VPT) at predetermined anatomic sites, and were asked about buckling and its frequency in the past 3 months. Knee buckling was defined in each subject as (a) any buckling and (b) repeated buckling (≥ 2 episodes). VPT was evaluated using a biothesiometer. The applicator tip of the instrument was placed on preselected anatomic bony prominences and the voltage increased by 1 volt/sec until the participant acknowledged sensation. Mean VPT between the limbs was used for analyses. Quadriceps strength was measured as the maximum torque during active isokinetic extension using a dynamometer and scaled to body size by dividing the maximum torque by BMI. VPT and strength were categorized into groups based on ±1 SD of the gender-specific mean of the sample. A person-based analyses using logistic regression to estimate adjusted odds ratios for the association of VPT and strength with buckling in the past 3 months was performed. We adjusted in analyses for age, sex, BMI, race, clinic site, and WOMAC knee pain.

Results: We evaluated 2,291 subjects (60% women, age±SD=68±8 yrs, BMI±SD=31±6 kg/m^2). 16.7% of participants reported buckling and 13.4% reported repeated buckling in the past 3 months. Results are summarized in the Table. A borderline association was found between muscle strength and any buckling episode, however, a significant association was observed with repeated buckling. High quadriceps strength was associated with a significantly decreased odd of repeated buckling (Adj OR: 0.59[0.36,0.99]. There was no significant association found between VPT and buckling.

Table

		Adjusted OR (95% CI)*	p value	Adjusted OR (95% CI)**	p value
Any buckling					
VPT at tibial tuberosity	Low	1.20 (0.88, 1.62)	0.244	1.13 (0.83, 1.54)	0.441
	Normal	1 (referent)		1 (referent)	
	High	1.15 (0.88, 1.49)	0.301	1.15 (0.88, 1.49)	0.312
Quadriceps muscle strength	Low	1.47 (1.16, 1.87)	0.002	0.97 (0.75, 1.25)	0.787
	Normal	1 (referent)		1 (referent)	
	High	0.51 (0.34, 0.75)	0.001	0.70 (0.46, 1.05)	0.087
Repeated buckling					
VPT at tibial tuberosity	Low	1.36 (0.98, 1.90)	0.067	1.24 (0.88, 1.76)	0.225
	Normal	1 (referent)		1 (referent)	
	High	1.22 (0.91, 1.64)	0.180	1.21 (0.90, 1.62)	0.204
Quadriceps muscle strength	Low	1.71 (1.31, 2.21)	<0.001	1.09 (0.82, 1.44)	0.568
	Normal	1 (referent)		1 (referent)	
	High	0.42 (0.26, 0.69)	<0.001	0.59 (0.35, 0.98)	0.041

*VPT adjusted for muscle strength and muscle strength adjusted for VPT
**adjusted for all covariates

Conclusion: In this large cohort of participants with knee OA or at high risk for knee OA, greater quadriceps strength was found to be associated with decreased odds of repeated knee buckling. There was no significant association found between vibratory perception and knee buckling. Future studies should continue to evaluate for other potential risk factors for buckling in knee OA.

Higher Leg Extensor Muscle Power Output Is Associated With Reduced Pain and Better Quality Of Life In Patients With Symptomatic Knee Osteoarthritis. Kieran F. Reid[1], Lori Lyn Price[2], William F. Harvey[2], Jeffrey B. Driban[2], Roger A. Fielding[1] and Chenchen Wang[2]. [1]Tufts University, Boston, MA, [2]Tufts Medical Center, Boston, MA

Background/Purpose: Muscle strength, the maximal force generating capacity of skeletal muscle, has been widely characterized in patients with knee osteoarthritis. However, skeletal muscle power, defined as the product of dynamic muscular force and the velocity of muscle contraction, declines earlier and more precipitously than muscle strength across the adult life span. In older populations, peak muscle power is also a more robust predictor of functional outcomes compared to muscle strength, particularly when assessed during closed chain testing. Despite its clinical relevance as a potential determinant of disease burden in knee osteoarthritis (OA), no study to date has comprehensively evaluated lower extremity muscle power output in patients with knee OA. The purpose of this investigation was to examine the relationships between lower extremity muscle power and perceived disease severity in a large population of patients with symptomatic knee OA. We hypothesized that, compared to muscle strength, peak muscle power assessed during bilateral leg press exercise would be a more influential determinant of self-reported pain and health-related quality of life within this patient population.

Methods: We used baseline data collected as part of a 4-year randomized controlled clinical trial in 181 patients (mean age: 60.2 ± 10yrs, BMI: 32.7 ± 10 kg/m^2, 69% female, 52% Caucasian) who met the American College of Rheumatology criteria for knee OA. Pain was measured using the pain subscale of the Western Ontario and McMaster Osteoarthritis Index (WOMAC) and health-related quality of life was measured using the Medical Outcomes Study Short Form 36 physical component summary and mental component summary. One-repetition maximum (1RM) strength was measured using the bilateral leg press exercise and peak leg press muscle power was measured during 5 repetitions performed as fast as possible with resistance set to 40% of the 1RM (Keiser Pneumatic Leg Press A420, Keiser Corporation, Fresno, CA).

Results: In univariate regression analysis, greater peak muscle power output was significantly and inversely associated with lower WOMAC pain score ($r = -0.17$, $P = 0.02$). Peak muscle power was also significantly and positively associated with SF36 physical component summary score ($r = 0.15$, $P = 0.05$) but not mental component summary score ($r = -0.02$, $P = 0.8$). After adjusting for age, BMI, sex, race and depressive symptoms, peak muscle power was a significant and independent predictor of SF 36 physical component summary score ($P = 0.02$). Muscle strength was not associated with any measure of disease severity or quality of life ($P \geq 0.07$).

Conclusion: Leg press muscle power output is a significant determinant of perceived disease burden in patients with symptomatic knee OA. While the overall magnitude of these relationships are modest, peak muscle power exerts a greater influence on self reported pain and quality of life compared to muscle strength within this patient population. These data suggest that the efficacy of resistance training interventions specifically designed to improve leg extensor muscle power output should be examined in patients with knee OA.

The Relationship Of Foot Pronation During Walking To Risk Of Incident Medial Tibiofemoral and Lateral Patellofemoral Cartilage Damage: The Multicenter Osteoarthritis Study. K. Douglas Gross[1], Howard J. Hillstrom[2], Yuqing Zhang[3], Emily K. Quinn[1], Michael C. Nevitt[4], Neil A. Segal[5], Cora E. Lewis[6] and David T. Felson[3]. [1]Boston University, Boston, MA, [2]Hospital Special Surgery (HSS), New York, NY, [3]Boston University School of Medicine, Boston, MA, [4]University of California, San Francisco, San Francisco, CA, [5]University of Iowa, Iowa City, IA, [6]University of Alabama, Birmingham, Birmingham, AL

Background/Purpose: Studies of older adults suggest an association between plantar pressure measures of foot pronation and medial tibiofemoral (med TF) cartilage damage, while studies of younger adults suggest an association with lateral patellofemoral (lat PF) pain. These were cross-sectional studies, however. We assessed the longitudinal relationship of foot pronation in walking with 2-year risk of incident med TF and lat PF cartilage damage in at-risk older adults.

Methods: The Multicenter Osteoarthritis Study (MOST) includes adults aged 50–79 years that have or are at risk of knee OA. At the 60 month exam, plantar pressure was assessed using an EmedX to quantify Center of Pressure Excursion Index (CPEI) during 5 trials of self-paced walking (14-day retest ICC > 0.82). Smaller CPEI values indicate increased pronation. From 1.0 T MRIs obtained at 60 and 84 months readers scored one knee per subject for cartilage damage in each sub-region comprising the med TF and lat PF compartments using WORMS grades (weighted kappa > 0.63). Among

sub-regions with WORMS < 2 at 60 months, incident cases had WORMS ≥ 2 at 84 months. With the highest quintile (least pronated feet) as a reference, separate logistic regression models estimated relative odds of incident med TF and lat PF damage in each case-based CPEI quintile while adjusting for age, BMI, sex, and using GEE to account for non-independent sub-regions of a compartment.

Results: 1123 participants (mean age 66.8 ± 7.5 yrs, BMI 29.7 ± 4.8 kg/m^2, 62.4% female) contributed one knee each (mean CPEI 19.8 ± 6.6) to the analysis of med TF damage, while 904 participants with similar characteristics contributed to the analysis of lat PF damage. Only 3.6% and 2.6% of sub-regions had incident med TF and lat PF damage, respectively. Although relative odds of lat PF damage were increased (OR = 2.04; 95% CI: 0.72, 5.82) among the most pronated feet (CPEI 13.7 to −7.7), pronation was not strongly associated with odds of med TF damage (see table). With few incident cases contributing, no findings achieved statistical significance ($p > 0.05$).

Table. Relative odds (OR) of incident medial tibiofemoral and lateral patellofemoral cartilage damage in quintiles of increasing foot pronation during walking.

	CPEI (high)	Center of Pressure Excursion Index (CPEI) Increasing Pronation →			CPEI (low)
	44.2, 24.9	24.8, 20.9	20.8, 17.6	17.5, 13.8	13.7, −7.7
Incident Medial Tibiofemoral Cartilage Damage					
# Knees	243	220	214	190	189
# Sub-regions	864	756	784	654	682
% Damage	3.8%	4.1%	3.8%	3.2%	3.7%
Adj OR* (95% CI)	1.00 (ref)	0.96 (0.54, 1.70)	0.93 (0.50, 1.73)	0.78 (0.42, 1.44)	0.81 (0.41, 1.58)
	CPEI (high)	Increasing Pronation →			CPEI (low)
	44.2, 25.6	25.5, 21.4	21.3, 17.9	17.8, 13.8	13.7, −7.7
Incident Lateral Patellofemoral Cartilage Damage					
# Knees	160	174	190	161	165
# Sub-regions	259	266	290	237	243
% Damage	2.3%	1.9%	1.7%	2.1%	4.1%
Adj OR* (95% CI)	1.00 (ref)	0.82 (0.25, 2.70)	0.78 (0.24, 2.58)	0.97 (0.29, 3.24)	2.04 (0.72, 5.82)

* Adjusted for age, BMI, sex, and non-independent sub-regions of a knee compartment.

Conclusion: In the first longitudinal data on foot pronation and risk of knee cartilage damage, we cannot confirm cross-sectional findings of an association between excessive pronation and med TF disease. Yet, this data does suggest a possible association between extreme foot pronation and elevated risk of lat PF damage. Studies with higher incidence rates are needed to confirm this.

History Of Knee Injury Is Weakly Associated With Knee Structural Change In Middle Or Older Aged Adults. Hussain Ijaz Khan[1], Dawn Aitken[1], Changhai Ding[1], Leigh Blizzard[1], Jean Pierre Pelletier[2], Johanne M. Pelletier[3], Flavia Cicuttini[4] and Graeme Jones[1]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [4]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: History of knee joint injury is a strong risk factor for the development of knee osteoarthritis (OA) but it's not clear how different structures comprising the knee joint are affected by injury. The aim of this study was to describe the association between history of knee injury and knee structural changes on MRI in middle aged and older adults.

Methods: This study included two population based samples. (I)the Offspring Study comprised of middle aged adults (n=372; mean age 45.0 years, range 26–61 years; 57.5% female). Approximately half were adult offspring of subjects who had a knee replacement performed for knee OA and the remaining were randomly selected controls that were initially matched by age and sex.(II) the Tasmanian Older Adult Cohort (TASOAC) Study comprised of older adults(n=430; mean age 63.0 years, range 51 – 79 years; 51% female) which were selected from the electoral roll using sex-stratified simple random sampling without replacement. 1.5 T MRI scans of the right knee at baseline was performed in both studies to measure bone marrow lesions (BMLs), cartilage volume, tibial bone area, cartilage defects, and meniscal pathology. History of knee injury was assessed using a self-administered questionnaire. The association between knee injury and knee structures was determined using multiple linear and log binomial regression models.

Results: In middle aged adults, only BML prevalence (Prevalence Ratio (PR)=1.6 (1.2, 2.0)) was significantly higher in those with knee injury in adjusted analysis (Table 1). In older adults, cartilage defects (PR=1.3 (1.0,1.7), total tibial cartilage volume (Difference of Means (df)= −323 (−616,−32)) and BMLs (PR=1.4 (1.0,1.9)) showed significant associations with knee injury in adjusted analysis. Meniscal tears and extrusions showed no significant associations in either of the two cohorts and tears were very common.

Table 1. Association between injury and bone marrow lesions in the knee

BMLs Absent/ Present(site)	Injury	No Injury	Unadjusted PR (95% CI)	Adjusted* PR (95% CI)

Classification Of Alignment By Self-Report Versus Radiograph Results In Unexpected and Discrepant Pain and Functional Outcomes. E Megan Erickson, Jeffrey B. Driban, Lori Lyn Price, Chenchen Wang, Timothy E. McAlindon and William F. Harvey. Tufts Medical Center, Boston, MA

Background/Purpose: Malalignment is a potential risk factor for structural progression of knee osteoarthritis (OA), but data conflict as to its association with knee pain. We hypothesize that subjective alignment measures are less burdensome and yield results similar to radiographic measures. As obesity is also associated with pain in knee OA, there could be interactions between obesity and alignment when assessing pain and function. Thus, we investigated if pain and function differ between obese and non-obese individuals with and without knee malalignment using both radiographic and self-reported classification of alignment.

Methods: We used baseline data derived from two clinical trials for symptomatic knee OA. Both trials used similar definitions of knee OA (ACR radiographic criteria). We assessed pain and function at baseline with the WOMAC and Short Form 36 Health Survey (SF-36) subscales and chair stand time. Participants were asked if they perceived themselves as bow-legged, straight-legged, or knock-kneed. One reader measured anatomic axis from posteroanterior fixed-flexion weight-bearing knee radiographs using a validated standard method [ICC (3, 1) = .94]. We adjusted anatomic axis measures (female, −3.5°; male, −6.4°) to better reflect mechanical axis and categorized them using typical definitions (see table). To analyze the influence of malalignment, obesity, and their interaction, we performed a 2 (obesity) × 2 (alignment) analysis of variance for each outcome. We conducted analyses using the self-report and radiographic classifications with varus (< 178°) and valgus (> 182°) groups collapsed.

Results: Characteristics of our 201 participants, stratified by obesity and radiographic alignment, are shown in the table. Using radiographic classification, malaligned groups had better WOMAC pain and function, SF-36 body pain, and chair stand time, independent of obesity. Using self-report classi-

fication, malaligned groups had worse WOMAC pain and function, SF-36 body pain and physical function, and chair stand time, again independent of obesity, but no outcome reached statistical significance. We found no significant interactions between obesity and either alignment method. Multiple sensitivity analyses using 3 categories of alignment, restricting analyses to women, and examining the trials separately, did not change the results.

Table. Study Sample Characteristics

Outcome	Radiographic Alignment: Non-obese (≤ 30 kg/m^2) Neutrally aligned (178°–182°) (n = 21)	Non-obese (≤ 30 kg/m^2) Malaligned (<178° or >182°) (n = 65)	Obese (> 30 kg/m^2) Neutrally aligned (178°–182°) (n = 32)	Obese (> 30 kg/m^2) Malaligned (<178° or >182°) (n = 83)	*p*-value: Obesity Main Effect	*p*-value: Alignment Main Effect	*p*-value: Obesity* Alignment Interaction

*Smaller is better.
** Larger is better.

Conclusion: Conventional wisdom suggests that both obesity and malalignment should cause more pain in people with knee OA. However, our results suggest that assessing the exposure of malalignment using radiographs vs. self-report may yield different, counterintuitive, results. Because more people classified themselves as neutrally aligned, the discrepancy could not have been due to a perceived connection between malalignment and pain. Studying these classifications of exposure with longitudinal outcomes will provide further insights into their relative utilities.

The Association Of Proximal Tibia Shape With Sex: The Osteoarthritis Initiative. Barton L. Wise[1], Felix Liu[2], Neeta Parimi[3], John A. Lynch[4], Yuqing Zhang[5], Lisa Kritikos[1] and Nancy E. Lane[1]. [1]UC Davis School of Medicine, Sacramento, CA, [2]University of California at San Francisco, San Francisco, CA, [3]California Pacific Medical Center Research Institute, San Francisco, CA, [4]University of California-San Francisco, San Francisco, CA, [5]Boston University School of Medicine, Boston, MA

Background/Purpose: Knee osteoarthritis (OA) manifests disproportionately in women and the etiology remains unclear. Bone shape has been found to be associated the development of knee OA in prior studies. To further explore this relationship, we examined the association of proximal tibia shape with sex to begin to understand these relationships.

Methods: We used information from the NIH-funded Osteoarthritis Initiative (OAI), a cohort of persons aged 45–79 at baseline who either had symptomatic knee OA or were at high risk of it. We randomly sampled knees from women and men from the OAI cohort who had Kellgren/Lawrence grade of 0 in central readings on baseline radiograph who were aged between 45 and 60 years. Using baseline radiographs we characterized proximal tibia shape using Active Shape Modeling to generate the modes of shape difference across our selected population. Given that all modes were normally distributed, we performed linear regression to examine the association of proximal tibia shape with sex, adjusting for age, race, body mass index (BMI) and clinic site. Beta estimates and 95% confidence intervals report the amount of standard deviation increase or decrease in mode shape among women compared to men.

Results: The mean age of subjects in the analysis was 52.7 years (±4.3 SD) for both men and women. There were 191 female knees and 149 male knees. 10 modes were derived for tibial shape. The 10 modes described 95.5% of the total variance in proximal tibia shape in the population sampled. Mode 2 had the highest significance for association with sex (p=0.009). (See table for beta estimates and description of first 5 modes.)

Mode	Adjusted Beta (95%CI)	P-value	Mode Description – primary alteration of shape with increased SD weighting
1	−0.2 (−0.42 to 0.02)	0.0797	Decreased concavity, elevation of lateral compartment plateau, and decreased shaft width
2	−0.29 (−0.51 to −0.07)	0.0091	Tibial head shifted laterally in relation to the shaft, and head width increased. The lateral tibial plateau is more concave
3	−0.22 (−0.43 to −0.01)	0.0376	Slightly increased tibial width, depression of medial plateau and elevation of lateral plateau
4	−0.23 (−0.45 to −0.02)	0.0324	Increased concavity of medial compartment and elevation of medial lip, with broadening of lateral plateau
5	−0.01 (−0.23 to 0.2)	0.9097	Narrowed medial plateau width and slight elevation of lateral plateau

Conclusion: Tibial knee shape may be associated with sex. Further work to understand how these shape modes are associated with knee OA, and whether they can explain differences in prevalence of OA by sex, is warranted.

Underdiagnosis and Undertreatment Of Knee Osteoarthritis In The Obese Population: The Need For Physician Education and Advocacy. Janice Lin, Ryan Flanagan, Jay Bhatia, Manish Parikh, Christine Ren-Fielding, Renata La Rocca Vieira, Steven B. Abramson and Jonathan Samuels. NYU Langone Medical Center, New York, NY

Background/Purpose: Obesity is a modifiable risk factor of knee osteoarthritis (KOA). While medical treatments for KOA can have a limited effect, an alternative strategy would target weight loss to reduce the arthritis burden. Supportive of other literature, we recently showed in a retrospective analysis that 51% of patients who underwent LapBand surgery reported complete improvement in KOA pain after 18 months. Therefore we began a prospective study to evaluate the prevalence of knee pain and KOA in the obese population, observe how knee pain is treated, and track how bariatric weight loss affects KOA-related pain and physical function.

Methods: We screened consecutive patients prior to bariatric surgery with the LapBand, sleeve gastrectomy, or gastric bypass. We enrolled patients (age'21) with knee pain for ≥1 month and a visual analog scale (VAS) pain score ≥30mm, excluding lupus, inflammatory arthritis, or psoriasis. Treatment history for knee pain was recorded. Baseline assessments included validated questionnaires: Western Ontario McMasters Universities Osteoarthritis Index (WOMAC), Assessment of Obesity-Related Comorbidities, and Knee Injury and Osteoarthritis Outcome Score. Those with radiographic KOA by the Kellgren-Lawrence (KL) grading scale >1 will repeat questionnaires post-surgery.

Results: We evaluated 262 patients, with 136 reporting knee pain and 62 consenting for the study (88.7% female, mean BMI 44.5 kg/m^2±8.3, range: 32.0–60.4, and mean age 44 years±10.3, range:22–70). 52% were scheduled for sleeve gastrectomy (mean BMI=43.0 kg/m^2), 26% for Lapband (BMI=43.7), and 22% for gastric bypass (BMI=48.8). The mean VAS score was 65.4 (±19.1;range:30–100), WOMAC pain 265.1 (±101.8;range:13–466), WOMAC stiffness 99.1 (±59.2;range:0–187) and WOMAC physical function 917.1 (±427.9;range:0–1589). Baseline radiographs revealed that 96% had evidence of OA (70.6 % KL 2–4 and 25.4% KL1). Despite significant knee pain in this cohort, only 4.8% (3/62) had seen rheumatologists and 17.7% orthopedists – while 55% were treated by primary care and 22.5% had never discussed their knee pain treatment with a physician. Only 37% had taken x-rays previously to evaluate knee pain. Not surprisingly, the ACR OA treatment guidelines were not met in a majority of our cohort: Only 40.3% had been referred for physical therapy, 80.6% tried acetaminophen, 70.9% NSAIDs, 6.4% narcotics, 1.9% SSRI, 12.9% tramadol, 11.2% topical NSAIDs, 16.1% intra-articular steroids, and 3.2% viscosupplementation.

Conclusion: In this early phase of our prospective study of bariatric patients, we found that moderate radiographic KOA is common in obese patients with knee pain. In many cases, pain had been attributed to mechanical load from obesity without proper evaluation or treatment. Few patients were referred to rheumatologists, though would benefit from such evaluation and management. These data indicate that knee OA in obese patients is underdiagnosed and undertreated. There is a need to educate primary care and bariatric providers that knee pain from OA and other pathology in obese patients should be diagnosed and treated appropriately to maximize their function and quality of life.

Examining Patient Reported Outcome Measurement Information System Measures In Community Dwelling Adults With Arthritis. Ana-Maria Orbai[1], Leigh F. Callahan[2], Rebecca J. Cleveland[3], Sharon R. Ghazarian[1], Susan J. Bartlett[1] and Clifton O. Bingham III[1]. [1]Johns Hopkins University, Baltimore, MD, [2]University of North Carolina, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: Arthritis is the leading cause of disability in the US and impacts on multiple aspects of health-related quality of life (HRQoL). Many multidimensional HRQoL measures used in arthritis have complex scoring algorithms and are sometimes proprietary limiting their utility in clinical care and research. The Patient Reported Outcome Measurement Information System (PROMIS) was developed by NIH using modern psychometrics to provide publicly available, population normalized measures to assess domains of physical, emotional, and social health. Assessments of PROMIS measures in arthritis have been limited to pain, function and fatigue in small numbers of patients. It was our goal to evaluate PROMIS measures in a large group of adults with self-reported arthritis.

Methods: Six PROMIS short forms for pain interference (6 items), physical function (10), fatigue (7), sleep quality (8), depression (8), and satisfaction with social roles (7) were administered to community dwelling adults with self-reported arthritis enrolled in the Walk with Ease (WWE) study. Raw scores were transformed to T scores for analysis, with the population mean 50 and standard deviation 10. Other measures included general health; pain, fatigue and stiffness VAS; and the improved HAQ (score range 0 to 100). Analyses were conducted to examine the effect of age and BMI using Stata 12.

Results: Instruments were administered to 439 adults with arthritis: 88% female, 70% White, 26% Black or African-American; general health 34% very good and excellent, 48 % good and 18 % fair; mean (SD) age 64 (12) BMI 30 (7); pain VAS 38.1 (25.3) fatigue VAS 37.3 (28.3), stiffness VAS 42.4 (26.7), IHAQ 14 (14). Mean (SD) PROMIS T scores were: pain interference 54.5 (6.9), fatigue 52.3 (8.3), physical function 42.8 (6.5), depression 49 (7.8), sleep quality 50.1 (9.66), satisfaction with social roles 48.6 (9). After adjustment for age, T scores were significantly worse for obese vs. non-obese for pain interference, fatigue, physical function, satisfaction social roles (Table).

Table. PROMIS T scores in obese versus non-obese people with self-reported arthritis

	T scores Mean (SD)		
	BMI<30 (n=254)	BMI ≥30 (n=185)	Age adjusted p-value
PROMIS Pain Interference	53.4 (7.4)	55.9 (6.3)	<0.001
PROMIS Fatigue	50.7 (8.3)	54.5 (7.8)	<0.001
PROMIS Physical Function*	43.8 (6.7)	41.4 (5.9)	<0.001
PROMIS Depression	48.4 (7.3)	49.8 (8.4)	0.1
PROMIS Sleep Quality	49.9 (9.7)	50.6 (9.4)	0.7
PROMIS Satisfaction with Social Roles	50.1 (8.8)	46.4 (9.0)	<0.001

*Lower scores represent worse physical function

Conclusion: PROMIS measures identify worse pain interference, fatigue, and physical function in people with self-reported arthritis compared to population-based norms. PROMIS social role satisfaction measures indicate arthritis impacts participation in valued life activities. Significantly worse fatigue (0.4 SD) and decreased satisfaction with social roles (0.4 SD) were seen in obese vs. non-obese, after adjustment for age. Studies are ongoing to evaluate responsiveness of PROMIS measures compared with legacy measures with an exercise intervention in the WWE study. Further studies are needed to evaluate the impact of obesity on other measures of HRQL in individuals with arthritis.

Pain, Functional Impairment and Ultrasound Detected Changes In Patients With Erosive and Non-Erosive Hand Osteoarthritis. Olga Sleglova[1], Olga Ruzickova[2], Karel Pavelka[2] and Ladislav Senolt[3]. [1]Institute of Rheumatology, Prague, Prague, Czech Republic, [2]Institute of Rheumatology and Department of Rheumatology, 1st Medical Faculty, Charles University Prague, Prague, Czech Republic, [3]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

Background/Purpose: Hand osteoarthritis (HOA) is a common and frequent cause of pain. HOA is a heterogeneous group of disorders with two main subsets including non-erosive disease and erosive, sometimes referred to as inflammatory, HOA. Few studies demonstrated inflammatory ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconclusive. The aim of the study was to compare pain, stiffness, physical impairment and ultrasound features between patients with erosive and non-erosive HOA in a cross-sectional study.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint tenderness and swelling were assessed. Patients reported joint pain on 100 mm visual analogue scale (VAS) was completed. Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined and erosive disease was defined by at least one erosive interphalangeal joint. Effusion, synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes.

Results: Altogether, 81 patients (five male) with symptomatic nodal HOA were included in this study between April 2012 and April 2013. Out of these patients, 46 had erosive disease. Patient's characteristics are given in table 1. The intensity of pain assessment on VAS ($p<0.05$), duration of morning stiffness ($p<0.05$) and number of clinically swollen joints ($p<0.05$) were significantly higher in patients with erosive compared with non-erosive disease. Accordingly, functional impairments assessed by AUSCAN showed more disability in patients with erosive compared with non-erosive disease ($p<0.05$). US-detected pathologies (gray-scale synovitis, power Doppler signal and osteophytes) were common in both groups of patients. Although, synovial hypertrophy was higher in patients with erosive compared with non-erosive disease (total score: 7.7 vs. 3.8; $p<0.05$), the differences in intensity of power Doppler signal and number of osteophytes did not differ between both groups.

Table 1.

	All patients	Non-erosive HOA	Erosive HOA
Age, years (mean ± SD)	66.74 ± 8.87	64.49 ± 8.21	68.46 ± 8.97
Female, no. (%)	76 (96.30%)	33 (94.29%)	43 (93.48%)
Disease duration, years (mean ± SD)	8.78 ± 8.18	7.91 ± 8.57	9.43 ± 7.81
BMI, kg/m2 (mean ± SD)	28.36 ± 5.42	28.98 ± 6.06	27.88 ± 4.82
AUSCAN, total (mean ± SD)	22.94 ± 11.43	20.51 ± 10.51	24.78 ± 11.53
AUSCAN A, pain (mean ± SD)	8.47 ± 4.41	8.03 ± 4.45	8.80 ± 4.36
AUSCAN B, function (mean ± SD)	2.00 ± 0.89	1.83 ± 1.06	2.13 ± 0.71
AUSCAN C, stiffness (mean ± SD)	12.04 ± 6.52	10.37 ± 6.21	13.30 ± 6.46
VAS, pain (mm)	43.19 ± 24.20	39.71 ± 24.80	45.84 ± 23.40
Tender joints, no.	9.49 ± 6.58	9.26 ± 7.23	9.67 ± 6.04
Swollen joints, no.	3.49 ± 4.28	2.83 ± 3.52	4.00 ± 4.71
NSAIDs, no. (%)	37 (45.68%)	16 (45.71%)	21 (46.65%)
SYSADOA, no. (%)	55 (67.90%)	23 (65.71%)	32 (69.57%)

Conclusion: This study shows that patients with erosive HOA have more hand pain, joint stiffness and functional limitation associated with US-

detected synovial hypertrophy, but not with inflammatory signs or osteophyte formation.

Concordance Of Hip Pain With Radiographic Hip Osteoarthritis In An Urban US Community: The Framingham Osteoarthritis Study. Kyu Chan Kim[1], David T. Felson[2], Katherine D. Linsenmeyer[1], Ali Guermazi[3], Steven C. Vlad[3], Mary M. Clancy[3] and Jingbo Niu[2]. [1]Boston Medical Center, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Boston, MA

Background/Purpose: While it is well known that knee pain and radiographic knee osteoarthritis (OA) are often discordant, little is known of the concordance of hip pain with the presence of radiographic hip OA. From a prevalence study of hip osteoarthritis done in Framingham, Massachusetts, we examined the relationship between hip pain and radiographic hip OA.

Methods: We performed a community based study of OA among persons age 50–79 living in Framingham in 2002–2005 with recruitment by random digit dialing and subjects studied without respect to joint pain or arthritis. Anteroposterior standing long-limb radiographs of the lower extremities including the pelvis were obtained and were read for radiographic hip OA(ROA) by two trained physicians. Cases of ROA were confirmed by an experienced musculoskeletal radiologist. ROA was defined as Kellgren-Lawrence score ≥ 2. Using a homunculus in which the hip joint was depicted as a large circle in the groin, participants were asked whether they had hip pain on most days. Those who said 'yes' were defined as having hip pain. If they had hip pain, subjects then answered another question asking location of pain: groin, front of the leg (anterior), outside the leg (lateral), lower back, or buttocks. Also, many participants had a standardized hip exam during which they were asked about pain during passive internal rotation. We examined sensitivity (Sn), specificity (Sp) and positive and negative predictive values (PPV, NPV) of different constellations of hip pain and location specific pain with ROA.

Results: Radiographs from 948 participants were evaluated including 419 men and 529 women. The average age was 63.5 years (s.d. 9 yrs). One hundred sixty participants (87 men and 73 women) had ROA (16.9%). One hundred eighty-two participants (19.2%) had hip pain. Only 22% of participants with hip pain had ROA in the same hip whereas 15.7% of participants without hip pain had ROA in that hip. The Sn of hip pain for ROA was 25%, the Sp of hip pain for ROA was 82%, and the PPV for hip pain was 22% (See table). However, when we restricted analyses to those with hip pain who localized this pain to the groin, the PPV rose to 38.1%. But of those with ROA, only 6.3% had hip and groin pain. For hip pain with anterior pain, the PPV was 27.8%, and the Sn was 7%. The diagnostic test performance for other sites of pain was poorer. If a participant had hip pain and pain with passive internal rotation, 18% had ROA.

	Sensitivity	Specificity	PPV	NPV
Hip Pain	25% (40/160)	82% (646/788)	22.0% (40/182)	84.3% (646/766)
Hip Pain with Groin Pain	6.3% (8/128)	98% (646/659)	38.1% (8/21)	84.3% (646/766)
Hip Pain with Anterior Pain	7.0% (9/129)	96.4% (646/670)	27.8% (9/33)	84.3% (646/766)
Hip Pain with Lateral Pain	13% (18/138)	89.7% (646/720)	19.6% (18/92)	84.3% (646/766)
Hip Pain with Low Back Pain	10% (12/132)	90% (646/719)	14.1% (12/85)	84.3% (646/766)
Hip Pain with Buttocks Pain	5.5% (7/127)	95% (646/680)	17.1% (7/41)	84.3% (646/766)
Hip Pain with Pain on Internal Rotation	6.3% (8/128)	94.7% (646/682)	18.9% (8/44)	84.3% (646/766)

Conclusion: We found poor agreement between hip pain on most days and radiographic OA in the ipsilateral hip. Many older persons with frequent hip pain including pain in the groin or front of the thigh did not have positive x-rays in that hip, and many persons with radiographic OA did not have hip pain. Of the constellation of questions for hip pain, those with the highest PPV were hip pain with groin or anterior pain.

Is There a Role For Non-Mendelian Inheritance In Severe Osteoarthritis Of The Knee. Allen D. Sawitzke[1], Richard Pimentel[2], Jathine Wong[2], Helena Martinez[3], Marta Herrero[4], Josep Verges[5] and Daniel O. Clegg[6]. [1]University of Utah, Salt Lake City, UT, [2]University of Utah, Salt Lake, UT, [3]BIOIBERICA, S.A:, Barcelona, Spain, [4]Bioiberica, Barcelona, Spain, [5]Pharmacological Research Unit, Scientific Medical Department, Bioibérica, S.A., Barcelona, Spain, [6]George Wahlen VA Medical Center/University of Utah, Salt Lake City, UT

Background/Purpose: Although the etiopathogenesis of osteoarthritis of the knee remains largely unknown, it is clear that genetic risks are contributory. Traditional family, twin, case control and GWAS designs have all contributed to the extensive knowledge in this area. Recently, groups have reported that mitochondrial genes are involved (1) and not-involved (2) in OA risk. The Utah Population Database (UPDB), a unique genealogic resource housed at the University of Utah has previously been used to study large founder pedigrees for evidence of many heritable diseases and we have used it to examine traditional Mendelian inheritance in OA of the knee. We hypothesized that these pedigrees could also be used to assess the potential role of non-Mendelian inheritance, specifically mitochondrial inheritance on the development of OA of the knee by comparing the statistical measures of mitochondrial models (MP) to autosomal models (AP) in these same founder families.

Methods: All OA cases who underwent TKA in Utah were selected based on billing codes in the International Classification of Diseases and data pulled from statewide hospital discharge data for a ten year period (1996–2007). Cases and controls matched for gender and age and their families were linked to the UPDB for analysis. The software kinship analysis tool (KAT) was used to analyze mitochondrial (MP) with autosomal (AP) by comparing familial standardized incidence ratio (FSIR) under each inheritance models.

Results: Over 18,000 OA patients who underwent TKA in Utah hospitals were linked to the UPDB and analysis performed for mitochondrial inheritance. The linkage resulted in 683 founder families with at least 5 affected members for analysis in comparison to randomly selected control families.

Pattern	FSIR	Extended Bayes FSIR	PAR
Autosomal Pattern	1	1.75 (1.61–1.91)	0.21 (0.18–0.24)
Mitochondrial Pattern	1.015	1.77 (1.61–1.96)	0.14 (0.12–0.15)

MP had a very low population-attributable risk, PAR value, 14, where AP has a higher value of 0.21. It suggested approximately *% of the population who have OA of the knee could be from mitochondrial inheritance, whereas 21 percent of OA of the knee resulting in TKA are familial.

Conclusion: The UPDB is a resource that has confirmed a Mendelian heritable risk for OA of the knee with a PAR of 21%. Now, it has also been used to shown non-Mendelian, in particular mitochondrial inheritance is not likely responsible for a large fraction of the heritability of OA of the knee severe enough to result in TKA as its associated PAR is 14.

"Generalized Osteoarthritis": A Systematic Review. Amanda E. Nelson[1], Michael W. Smith[2] and Yvonne M. Golightly[3]. [1]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC, [2]Saint Luke's Hospitals, Kansas City, MO, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: To perform a systematic review of definitions, risk factors, and outcomes in "generalized osteoarthritis" (GOA).

Methods: We performed a systematic review of Medline literature using the terms osteoarthritis, generalized, polyarticular, multiple joint, multi-joint, and others to obtain articles related to GOA, following PRISMA guidelines.

The search was completed on 9/25/12 by a professional librarian. The initial searches produced 948 articles for title and abstract review (performed by MWS and AEN), after which 108 underwent full text review (AEN and YMG). Of these, 74, along with 24 identified through bibliographic review of included articles (total=98), were included for data extraction (AEN) based on pre-specified criteria including the requirement for a clearly stated definition of OA (clinical, radiographic, or symptomatic) assessed at more than one body site.

Results: In the 98 included articles, 24 large cohorts (n~30,000) were represented along with numerous clinical series (n~9000), across 22 countries and 60 years (1952–2012). The sites assessed, and OA definitions at each site, varied widely but most often included the hands and knees. In 30 studies where a definition of GOA was stated, no less than 15 definitions of GOA were given; at least 6 groups used a summed score of joints or radiographic grades at multiple sites (Table). While interphalangeal joints were almost always included, there was debate about the appropriateness of including other joints such as spine and hip. Estimates of the prevalence of such variably defined GOA ranged from 1–80%, although a majority were in the 5–25% range.

A variety of risk factors and outcomes were considered in the included papers. Increased risk of GOA or its progression was associated with age, female sex, and genetic/familial factors. GOA constructs were generally identified more frequently among individuals of European descent. Associations with increased BMI or other measures of body mass were not consistent across studies. A higher BMD was seen in GOA patients in some series but not others. One study estimated the heritability of GOA at 42%. Biomarker (cartilage oligomeric protein [COMP] and urinary type II collagen C-telopeptide [uCTX-II]) levels increased with greater numbers of involved joints. Increased OA burden was associated with higher mortality, poorer health and function, and increased disability.

Conclusion: While there remains no clear or widely agreed upon definition of GOA, this term is commonly used in the literature. There remains substantial debate regarding the existence of GOA as a distinct disease entity, and in what populations, although there appears to be a greater impact on health in the presence of OA in more than one joint. It may be more appropriate for individual studies to clearly define joints evaluated and involved with OA, and use alternate, more descriptive terms, such as multi-joint or polyarticular OA.

The Proportion Of Knee Osteoarthritis Patients In Southern Sweden That Seek Medical Care. Aleksandra Turkiewicz[1], Maria Gerhardsson de Verdier[2], Gunnar Engström[3], Stefan Lohmander[1] and Martin Englund[1]. [1]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [2]Astra Zeneca R&D Molndal, Molndal, Sweden, Molndal, Sweden, [3]Dept of Cardiovascular epidemiology, Clinical Sciences, Lund University, Lund, Sweden

Background/Purpose: To provide estimates of the proportion of subjects with knee osteoarthritis (OA) that seek healthcare for knee OA or joint pain within an 8-year period.

Methods: In 2007 a random sample of 10 000 56 to 84 year old Region Skåne residents from the Malmö Diet and Cancer Study (Manjer et al 2001) were sent a mailed questionnaire about knee pain in the last 12 months; this being the first part of the Malmö Osteoarthritis Study (MOA). We classified subjects with knee pain with duration of at least 4 weeks as having *frequent knee pain*. A random sample of 1300 subjects with frequent knee pain and a random sample of 650 subjects without (out of the 7737 questionnaire responders) were invited for a clinical and radiographic examination including assessment of *clinical knee OA* according to the American College of Rheumatology (ACR) clinical criteria. Participants underwent radiography of both knees in weight-bearing and semi-flexion. An independent radiologist who was blinded to clinical data assessed all frontal and patellofemoral radiographs. Subjects who fulfilled criteria approximating Kellgren and Lawrence (KL) grade 2 or worse were considered as having *radiographic knee OA*. We considered those having radiographic knee OA and frequent knee pain to have *symptomatic knee OA*. Using the subject's personal identification number and individual linkage with the Skåne Health Care Register, covering the entire population in the county, we retrieved information on all doctor visits with a diagnosis of knee OA (ICD-10 code M17) or pain in joint (joint unspecified, ICD-10 code M25.5) for the years 2004 to 2011, i.e. the 8-year period preceding and following the MOA examination. We used weighting to adjust for different sampling probabilities depending on the knee pain status as well as for the nonresponse and volunteer bias in the MOA study. We used multiple imputation to account for missing diagnostic codes in the register.

Results: The 10 000 MOA subjects had mean (SD) age of 70 (7.6) years, mean (SD) body mass index was 27.1 (5.0) and 62% were women. The response rate in mailed questionnaire was 77.4% and 1527 invited subjects (78.3%) attended the clinical visit. Out of subjects classified as having *symptomatic knee OA*, 74.6% (95%CI: 70.0% to 79.3%) had consulted a physician during the 8-year time frame and received a diagnosis of knee OA or pain in joint (Table). Among subjects having *clinical knee OA* the corresponding percentage was 66.8% (95%CI: 59.1% to 74.6%). The ICD-10 diagnosis of knee OA was set in 62.9% (95%CI: 57.7% to 68.1%) of subjects with *symptomatic knee OA* and 49.9% (95%CI: 41.8% to 58.1%) of patients with *clinical knee OA*.

Table. The percentage of subjects with knee osteoarthritis (OA) who received a diagnosis of knee OA or pain in joint, respectively, set by a physician during the examined 8-year time frame (2004–2011).

OA definition	Diagnosis of knee OA or pain in joint % (95% CI)*	Diagnosis of knee OA % (95% CI)*	Diagnosis of pain in joint % (95% CI)*
Radiographic knee OA†	56.8(49.1–64.5)	43.4(36.5–50.4)	31.3(23.7–39.0)
Clinical knee OA†	66.8(59.1–74.6)	49.9(41.8–58.1)	39.7(31.0–48.4)
Symptomatic knee OA†	74.6(70.0–79.3)	62.9(57.7–68.1)	40.8(35.2–46.4)
Symptomatic or clinical knee OA†	68.9(63.8–74.0)	53.2(47.6–58.9)	40.1(34.3–45.9)

*- 95%CI: 95% confidence intervals.
†- Radiographic knee OA - changes on x-ray approximating Kellgren-Lawrence grade 2 or worse; Clinical knee OA - clinical OA according to the American College of Rheumatology clinical criteria, recursive positioning method; Symptomatic knee OA - knee pain of duration at least 4 weeks in the last. 12 months in combination with radiographic OA as defined above.

Conclusion: Only 2 of 3 subjects with clinical or symptomatic knee OA consult a physician for his/her knee(s) symptoms in an 8-year time frame. Self-management or coping strategies as well as over-the-counter pain treatments are plausible explanations.

All-Cause Mortality and Incident Cardiovascular Disease In Knee Osteoarthritis: The Framingham Study. Devyani Misra[1], David T. Felson[1], Ida K. Haugen[2], Martin Englund[3] and Tuhina Neogi[1]. [1]Boston University School of Medicine, Boston, MA, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden

Background/Purpose: Studies examining the relation of osteoarthritis (OA) to mortality or cardiovascular disease (CVD) have reported conflicting results, raising the question of whether OA itself increases such risks, or rather OA may simply be a marker of these outcomes due to its relation to other factors that heighten such risks, such as obesity. We assessed the relation of knee OA to mortality and incident CVD in a population-based cohort of older adults in which knee OA status, death and CVD were comprehensively assessed in a standardized, validated manner.

Methods: We included participants aged 50–75 from the Framingham OA Study comprising the Original and Offspring cohorts with knee x-rays obtained at exam 18 (1983–85) for the Original cohort, and exam 7 (2002–2005) for the Offspring cohort. Radiographic knee OA (ROA) was defined as Kellgren and Lawrence grade ≥2, and symptomatic knee OA (SxOA) as ROA plus pain in the same knee. All-cause mortality was defined as death due to any cause. *Incident* CVD was defined as a new diagnosis of coronary heart disease, intermittent claudication, CHF, stroke or TIA in the absence of any of these diseases prior to knee OA assessment. All deaths and CVD events were adjudicated by a panel of cardiologists and neurologists using published criteria to review clinical data and hospitalization records. Follow-up started from the date of knee OA ascertainment and continued until the outcome (death/incident CVD) or last assessment in 2009. We truncated follow-up at 10 years to avoid universal occurrence of events in these older subjects. In sensitivity analyses, we evaluated outcomes beyond 10 years. For the incident CVD analysis, only those free of CVD at the time of knee OA ascertainment were eligible for inclusion. The relation of knee OA to overall mortality and incident CVD were examined in both cohorts combined as well as separately, using Cox proportional hazards models, adjusting for age and sex in the first model, and then additionally adjusted in a second model for body mass index (BMI), diabetes mellitus, hypertension, renal disease, aspirin use, lipid-lowering medications and smoking status.

Results: Among 2037 participants (mean age 66 yrs, 58% women, mean BMI 27 kg/m^2, 499 ROA, 163 SxOA), there were 873 deaths and 624 incident CVD cases. No association was found between knee OA (ROA or SxOA) and overall mortality or incident CVD (Table), with effect estimates in the adjusted models ranging from 0.93–1.27. Results were similar when the cohorts were analysed separately and in the sensitivity analyses. While OA was associated with obesity and other risk factors for CVD, additionally adjusting for these factors did not affect the risk of the outcomes.

Table. Relation of Knee Osteoarthritis to All-cause mortality and incident cardiovascular disease in Framingham Original and Offspring cohorts combined

Knee OA status	N (%)	Mean follow-up (years)	Crude HR	Adjusted HR* (95% CI)	Adjusted HR** (95% CI)
		All-cause mortality			
ROA					
Yes (N=499)	258 (52)	6.06	0.99	0.93 (0.78, 1.10)	1.04 (0.85–1.28)
No (N=1538) (referent grp)	615 (40)	5.23			
SOA					
Yes (N=163)	58 (36)	4.53	0.99	0.98 (0.71, 1.35)	1.00 (0.67, 1.50)
No (N=1852) (referent grp)	802 (43)	5.48			
		Incident Cardiovascular Events			
ROA					
Yes (N=499)	183 (42)	4.22	1.13	1.06 (0.84, 1.34)	0.97 (0.75, 1.27)
No (N=1538) (referent grp)	441 (31)	3.56			
SOA					
Yes (N=163)	50 (34)	2.28	1.23	1.23 (0.81, 1.91)	1.27 (0.77, 2.07)
No (N=1852) (referent grp)	566 (34)	3.80			

*Adjust for age and sex only.
**Additionally adjusted for BMI, diabetes mellitus, hypertension, renal disease, aspirin use, lipid-lowering medication use, smoking.

Conclusion: In this large cohort of community-dwelling older adults, there was no significant relation of knee OA to mortality or incident CVD, suggesting knee OA itself likely does not have systemic effects.

Cardiovascular Disease In Osteoarthritis: Hip Versus Knee and The Influence Of Multiple Symptomatic Joint Involvement. Anthony V. Perruccio[1], Rita A. Kandel[2] and Aileen M. Davis[3]. [1]Toronto Western Hospital, Toronto Western Research Institute, and University of Toronto, Toronto, ON, [2]Mount Sinai Hospital and University of Toronto, Toronto, ON, [3]Health Care and Outcomes Research, Toronto Western Research Institute; Departments of Rehabilitation Science and Health Policy, Management and Evaluation, University of Toronto, Toronto, ON

Background/Purpose: The strength of association between obesity and osteoarthritis (OA) is reported to vary by joint (e.g. stronger association with knee than hip). As well, the association between obesity and non weight-bearing joints, such as the hands, suggests that systemic/metabolic factors are involved. The presence of multiple symptomatic joints among individuals with severe OA in at least one joint further suggests likely systemic factors in OA. Given known associations between systemic/metabolic factors and cardiovascular disease (CVD) risk, this study investigated the likelihood of reporting CVD between those with hip vs. knee OA, and further considered if the number of symptomatic joints influenced this likelihood.

Methods: Patients with severe OA (443 hip; 540 knee) reported CVD, diabetes, high blood pressure (HBP), symptomatic joints, height, weight, age and sex. The cross-sectional association between study measures and prevalent CVD was investigated using logistic regression, with the inclusion of an interaction term between symptomatic joint count and knee/hip group membership. Subsequently, the analysis was stratified by knee/hip.

Results: Knee: ages 41–88 years, 64% female, 4% CVD, 14% diabetes, 50% HBP. Hip: ages 40–91 years, 55% female, 5% CVD, 9% diabetes, 43% HBP. Mean joint count was 5 (±4), ranging from 1–20. Adjusted for age, sex, body mass index, and presence of diabetes or HBP, the knee cohort had odds 4 times greater than hips for reporting CVD ($p<0.01$). There was a significant interaction between joint count and knee/hip group status, such that the effect of increasing joint count was greater for the hip cohort. From stratified analyses, joint count was associated with CVD in the hip cohort only, with a 25% increased odds with each numerical increase in symptomatic joint count (odds ratio (OR): 1.25, $p<0.001$). In the knee cohort, the presence of diabetes or HBP was significantly associated with reporting CVD (OR: 3.74, $p=0.02$), whereas a similar association was not found in the hip cohort (OR: 1.23, $p=0.68$).

Conclusion: The variable association observed with CVD between hip and knee OA, alongside the differential influence of the extent of symptomatic joint involvement between joint groups suggests different OA phenotypes, with potentially varying roles for systemic factors. This has potential implications for our understanding of OA, and suggests a potential need for multimodal approaches to treatment and management.

Risk Of Falls Increases With Additional Symptomatic Osteoarthritic Joints: The Johnston County Osteoarthritis Project. Adam Dore[1], Yvonne M. Golightly[1], Vicki Mercer[1], Jordan B. Renner[1], Xiaoyan A. Shi[2], Joanne M. Jordan[3] and Amanda E. Nelson[3]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]SAS Institute, Inc, Cary, NC, [3]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC

Background/Purpose: Falls, a growing problem among older adults, often lead to hospitalizations, surgeries, and death. Knee and hip osteoarthritis (OA) are known risk factors for falls, but whether they together additionally contribute to falls risk is unknown. This study utilizes a cohort of African American and Caucasian men and women with and without OA to examine the influence of body OA burden on risk for future falls.

Methods: A longitudinal analysis was performed using data from 2 time points of the Johnston County OA Project. The outcome of interest was falls at follow up (~5 years after initial visit), based on the response to the question "In the last 12 months, have you had any falls of any type?" Baseline risk factors included age, sex, race, body mass index, and prior falls, with a focus on symptomatic OA of the hip and knee (Model 1). Symptomatic OA was defined as patient reported symptoms (pain, aching, or stiffness on most days) and radiographic evidence of OA (Kellgren Lawrence grade ≥ 2 or joint replacement secondary to OA in the tibiofemoral or hip joint) in the same

joint. Additional potential contributing factors were 6 comorbid conditions, alcohol and medication use (sleep aids, narcotics, vitamin D, and bisphosphonates), and low back symptoms (Model 2). Logistic regression analyses were used to determine associations (adjusted odds ratios [aOR]) between baseline covariates and falls at follow-up in both Models 1 and 2.

Results: Participants (n=1,619) had a mean age of 62 years (SD 9.03); 72% were Caucasian, 35% male, 22% had ≥ 1 fall within 12 months of the baseline time point and 26% had ≥1 fall within 12 months of the follow up visit. Caucasians (aOR 1.37), females, older adults, those who reported a history of lung problems (aOR 1.56) and particularly those who had a fall at baseline (aOR 2.42) had greater odds of a fall at follow-up (Model 1; Table 1). When controlling for baseline characteristics (Model 1), patients who had symptomatic knee or hip OA had increased odds for falling (aOR 1.41 and 1.70, respectively). In Model 2, Caucasians (aOR 1.41), older adults, those who had a previous fall (aOR 2.38), reported a history of depression (aOR 1.02), and symptomatic hip OA (aOR 1.56) had increased odds of falls. However, the association between falls and symptomatic knee OA as well as female sex were no longer significant. The odds of falls increased with an increasing number of knee and/or hip joints with symptomatic OA: the aOR for patients with 1 involved joint was 1.56 (95% CI 1.12, 2.17), for 2 joints was 1.85 (CI 1.28, 2.68), and for 3–4 joints was 1.91 (95% CI 1.01, 3.65).

Table 1. Characteristics of the Sample (n=1619)

	Frequency	**Model 1**	**Model 2**
Characteristic	*Baseline n(%) or mean (range)*	*OR (95% CI)*	*OR (95% CI)*
Caucasian	1245 (71.6)	**1.37 (1.04 ,1.81)**	**1.41 (1.05 ,1.88)**
Male	484 (34.7)	**0.72 (0.55 ,0.93)**	0.80 (0.61 ,1.05)
Mean Age (years)	62 (45–89)	**1.03 (1.01 ,1.04)**	**1.03 (1.01 ,1.04)**
Mean BMI (kg/m^2)	30.8 (17.1–65.8)	1.01 (0.99 ,1.03)	1.01 (0.99 ,1.03)
Falls at baseline	352 (21.8)	**2.42 (1.85 ,3.17)**	**2.38 (1.80 ,3.14)**
Symptomatic Knee OA	321 (20.2)	**1.41 (1.05 ,1.91)**	1.28 (0.92 ,1.78)
Symptomatic Hip OA	196 (12.9)	**1.70 (1.22 ,2.36)**	**1.56 (1.08 ,2.25)**
Lung problems[1]	311 (19.2)	–	**1.56 (1.15 ,2.10)**
Narcotic use[2]	50 (3.1)	–	1.70 (0.88 ,3.29)
CES-D[3]	6.1 (0–53)	–	**1.02 (1.00 ,1.03)**
Low Back Symptoms[4]	776 (48.0)	–	1.00 (0.77 ,1.29)

1. Includes patient report of chronic bronchitis, emphysema or other chronic lung trouble (dichotomous).
2. Defined as self-reported narcotic use for > 2 weeks (dichotomous).
3. Center for Epidemiologic Studies Depression scale (continuous, 0–60).
4. Answer to: "On most days, do you have pain, aching, or stiffness in your low back?"

Conclusion: This study confirms that symptomatic knee and particularly hip OA are important risk factors for falls and reveals that the risk increases with additional symptomatic knee and hip joints. Future interventions aimed at enhancing fall prevention should not ignore the impact of multiple symptomatic OA joints.

Inflammatory Bowel Disease In Juvenile Idiopathic Arthritis Patients Upon Biologics. Deborah Barthel[1] and Gerd Horneff[2]. [1]Asklepios Clinic Sankt Augustin, Sankt Augustin, Germany, [2]Centre of Pediatric Rheumatology, Sankt Augustin, Germany

Background/Purpose: Inflammatory bowel disease (IBD) is a matter of interest in patients with juvenile idiopathic arthritis (JIA) treated with biologics.

Methods: Baseline demografics, clinical characteristics and medication have been documented in the German BIKER JIA registry between 2001 and 2013. Exposure time of treatment was used to calculate IBD incidence. Published data of IBD incidence in the general pediatric population were used as reference.

Results: 3070 patients were followed in the BIKER registry with a total observation time of 8389 patient years (py). 13 events of IBD-flares in 12 patients (33% male), 8 with Crohn's disease (CD, 67%) and 4 with ulcerative colitis (UC, 33%). were documented.

4 patients had extended oligoarthritis (eoJIA, 33%), 3 seronegative polyarthritis (RF-JIA, 25%), 3 enthesitis-related arthritis (ERA, 25%) and 2 psoriatic JIA (PsA, 17%). HLA-B27 was positive in 3 (25%) and anti-nuclear antibodies were positive in 7 IBD patients (58%).

Thus patient with IBD as adverse event more commonly had ERA, eoJIA and PsA than expected in the total BIKER cohort, but not statistitically significant. No IBD occurred in systemic JIA, RF positive or pers-oligo JIA. IBD incidence in patients with pers-oligo JIA was significantly decreased.

IBD incidence in JIA patients was 143/100,000 py and significantly higher than IBD incidence in the general pediatric population (5.2/100,000 py, p<0.001; OR 27.50 [15.54–48.67]). Mean disease duration until IBD was 7.8 ± 4.0 years (1.8–16.8).

The total exposure time was 4575PY for NSAIDs, 1981PY for corticosteroids, 195PY for sulfasalazine (SUL), 5455PY for methotrexate (MTX), 212PY for leflunomide (LEF), 3557PY for ETA and 369PY for adalimumab (ADA). Incidence of IBD was significantly higher in patients treated with etanercept (p<0.05; OR 4.53 [1.25–16.47]), leflunomide (p<0.05; OR 7.03 [1.55–31.91]) and also sulfasalazine (p<0.001; OR [12.63 (3.45–46.24]). In patients treated with methotrexate the IBD incidence decreased significantly (p<0.05; OR 0.16 [0.04–0.59]).

At admission to the registry, JIA patients later developing IBD had been treated with MTX (100%), steroids (67%), SUL (33%), azathioprine (25%), LEF (17%) and hydroxychloroquine (8%). At time of IBD diagnosis 83% were on ETA, 33% on steroids, 25% on MTX, 25% on SUL, 17% on LEF and 1 on ADA. Thus, therapy with non-biologic agents has markedly been reduced.

* Reference population children aged <16 years (see Sawczenko et al.)

Conclusion: Incidence of IBD in JIA patients is higher than expected. Especially patients with ERA, PsA and eoJIA are at risk. IBD seems to be associated with treatment of ETA, LEF and SUL, while MTX turned out to be protective. The impact of discontinuation of MTX, AZA and corticosteroids in patients later on developing IBD has to be discussed. Unfortunately case numbers so far are too small for further statistical analyses including linear regression models.

Marked Improvement In Patient Reported Outcomes Of Children With Active Systemic Juvenile Idiopathic Arthritis With Canakinumab Treatment – Results Of The Phase III Program. Rayfel Schneider[1], Hermine I. Brunner[1], Nicolino Ruperto[2], Nico Wulffraat[2], Pierre Quartier[3], Riva Brik[2], Liza McCann[2], Helen E. Foster[2], Michael Frosch[2], Valeria Gerloni[2], Liora Harel[2], Claudio Len[2], Kristin Houghton[1], Rik Joos[2], Ken Abrams[4], Karine Lheritier[5], Sophia Kessabi[5], Alberto Martini[2] and Daniel J. Lovell[1]. [1]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati, OH, [2]Pediatric Rheumatology International Trials Organization (PRINTO)-Istituto Gaslini, Genova, Italy, [3]Necker-Enfants Malades Hospital, Paris, France, [4]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [5]Novartis Pharma AG, Basel, Switzerland

Background/Purpose: Efficacy and safety of canakinumab (CAN), a selective, fully human, anti-interleukin-1β monoclonal antibody, in systemic

juvenile idiopathic arthritis (SJIA) patients has been demonstrated in two phase 3 trials (1 and 2). [1]SJIA is associated with severe functional impairment and chronic pain that markedly affect the health-related quality of life (HRQoL). Here, we present the effects of CAN therapy on patient-reported outcomes (PROs) from the phase 3 studies.

Methods: In Trial 1, 84 pts were randomized to CAN (43) and PBO (41) and followed for 1 month. In Trial 2, 177 pts (including 71 from Trial 1) received open label CAN in Part 1, of which 100 CAN-responders entered part 2 and were randomized 1:1 to placebo or continued CAN. PROs considered were functional ability by the Childhood Health Assessment Questionnaire [CHAQ©], pain as measured on a visual analog scale [VAS] of 0–100 mm, and HRQoL by the Child Health Questionnaire–Parent Form (CHQ-PF50 for pts age 5–18 yrs) with rating on physical (PhS) and psychosocial (PsS) health status. Between-treatment differences were evaluated using analysis covariance models with repeated measures adjusting for treatment group, time, stratification factors and the treatment group-by-time interaction as explanatory variables.

Results: At the end of Trial 1, there was significant improvement ($p=0.0002$) in functional ability with CAN, resulting in an estimated difference (ED) in CHAQ score of -0.69 between the CAN and PBO group at Day 29 from baseline [BL]; this ED constitutes about 3.6x the minimal clinically important difference $(-0.19)^2$ in the CHAQ score. Pain intensity significantly declined (both $p<0.0001$) in the CAN group vs. PBO both at Day 15 (ED, -46.42) and Day 29 (ED, -41.86). Similarly, HRQoL significantly improved from BL for CAN vs. PBO, with an ED in CHQ-PF50 PhS scores of 12.07 and 7.28 for the CHQ-PsS (both, $p<0.005$) over 1 month with CAN, respectively. Even more pronounced improvements in functional ability, pain and HRQoL were observed in Trial 2 (Table).

Patient Reported Outcomes in Trial 2

Outcome measure, mean (SD)	Baseline CAN, N=177	End of Part 1 CAN, N=177	End of Part 2 CAN, N=50	End of Part 2 PBO*, N=50
CHAQ disability score	1.7 (0.8)	0.74 (0.9)	0.5 (0.9)	0.6 (0.8)
Pain intensity by 0–100 mm VAS	66.6 (23.3)	20.2 (25.8)	13.6 (26.9)	17.0 (24.2)
CHQ-PF50 PhS score	16.1 (14.3)	37.7 (17.2)	43.6 (17.4)	39.0 (18.1)
CHQ-PF50 PsS score	41.6 (11.1)	50.7 (11.1)	53.6 (11.3)	52.7 (9.8)

Note: Results are based on patients with both baseline and post-baseline values. n<N (177/50) for CHQ-PF50 as assessment not done in pts <5 and >18 years old. *PBO pts received CAN during Part 1 of Trial 2.

Conclusion: Treatment with CAN demonstrated rapid, marked and continued improvement in patient-reported outcome of SJIA patients, including a significant increase in functional ability, reduction of pain and HRQoL.

Canakinumab In The Treatment Of Systemic Juvenile Idiopathic Arthritis: Results From a 12-Week Pooled Post-Hoc Analysis For Efficacy. Hermine Brunner[1], Pierre Quartier[2], Tamas Constantin[3], Shai Padeh[3], Inmaculada Calvo[3], Muferet Erguven[3], Laurence Goffin[3], Michael Hofer[3], Tilmann Kallinich[3], Sheila Oliveira[3], Yosef Uziel[3], Stefania Viola[4], Kiran Nistala[3], Carine Wouters[3], Karine Lheritier[5], Josef Hruska[5], Ken Abrams[6], Alberto Martini[3], Nicolino Ruperto[3] and Daniel J. Lovell[1]. [1]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati, OH, [2]Necker-Enfants Malades Hospital, Paris, France, [3]Paediatric Rheumatology International Trials Organization (PRINTO), Genova, Italy, [4]Pediatria 2, Genova, Italy, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ

Background/Purpose: Interleukin-1β (IL-1β) plays a key role in the pathogenesis of systemic juvenile idiopathic arthritis (SJIA), a severe disabling subtype of JIA characterized by arthritis plus systemic symptoms. Canakinumab (CAN), a selective, fully human, anti-IL-1β monoclonal antibody has demonstrated efficacy and safety in 2 phase III trials in SJIA patients (pts). Here we present results of a post-hoc pooled analysis evaluating the 12-week efficacy of CAN 4 mg/kg every 4 weeks.

Methods: Pooled data from the 3 phase III trials were used. Pts aged 2–19 yrs with active SJIA were enrolled and received subcutaneous CAN 4 mg/kg or placebo every 4 weeks. The post-hoc analysis presented here focuses on response to CAN therapy in the initial treatment period for a total of 178 CAN-naïve pts. Methodological factors precluded a comparator group, so this analysis is of a descriptive nature.

Results: At baseline (BL), 94% of pts had intermittent spiking fever due to SJIA and 73% were on steroids (mean dose 0.38 mg/kg/d). By Week 2, evidence of profound SJIA improvement was observed (Table), with 20% of pts achieving inactive disease status.

Table. Percentage of patients with adapted JIA ACR (aACR) response* and inactive disease

	CAN, N=178; n (%)	
	Week 2	Week 12
aACR30	142 (80%)	125 (70%)
aACR50	125 (70%)	122 (69%)
aACR70	102 (57%)	108 (61%)
aACR90	65 (37%)	87 (49%)
aACR100	38 (21%)	54 (30%)
Inactive disease	36 (20%)	50 (28%)

*Data from missing patients not shown; aACR response = ACR response level plus absence of fever

The median CRP level of 158 mg/L at BL decreased by a median of 82% and 94% by Weeks 2 and 12, respectively. There was a rapid improvement in the median number of active joints from 10 at BL to 2.5 at Week 2 and 0 at Week 12. Similarly, for joints with limitation of motion, median values decreased from 9 at BL to 2.5 at Weeks 2 and 1 at Week 12, respectively. While 94% pts had fever due to SJIA at BL, only 13% at Week 2 and 2% at Week 12 had fever. Notably, CAN therapy resulted in marked improvements in patient-reported outcomes: parent/patient assessment of pain (0–100 mm, VAS) decreased from a mean of 67 mm at BL to 22 mm at Week 2 and 11 mm at Week 12. The median CHAQ disability score decreased from 1.8 at BL to 0.6 at Week 2 and 0.3 at Week 12. Between BL and Week 12, the median parent's/patient's assessment of overall well-being improved from 63 mm to 4.5 mm and the physician's global assessment of SJIA activity (0–100 mm, VAS) decreased from 70 mm to 3 mm.

Conclusion: Based on this post-hoc analysis, response of the SJIA patients studied in the CAN program showed rapid and clinically important improvements in patient reported outcomes and disease activity by Week 12

of therapy, with aACR 50 or higher responses reached by the majority of SJIA pts within 2 weeks of the initial CAN dose.

Baseline Characteristics Of Patients With Active Systemic JIA On Canakinumab Therapy Successfully Discontinuing Corticosteroids: Secondary Analyses From A Pivotal PHASE 3 Study. Hermine Brunner[1], Nicolino Ruperto[2], Tamás Constantin[2], Nico Wulffraat[2], Gerd Horneff[2], Jordi Anton[2], Reinhard Berner[2], Fabrizia Corona[2], Rubén J. Cuttica[2], Marine Desjonqueres[2], Michel Fischbach[2], Maria Alessio[2], Alice Chieng[2], Wolfgang Emminger[2], Elie Haddad[1], Karine Lheritier[3], Ken Abrams[4], Josef Hruska[3], Daniel J. Lovell[1] and Alberto Martini[2]. [1]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati, OH, [2]Pediatric Rheumatology International Trials Organization (PRINTO)-Istituto Gaslini, Genova, Italy, [3]Novartis Pharma AG, Basel, Switzerland, [4]Novartis Pharmaceuticals Corporation, East Hanover, NJ

Background/Purpose: Interleukin-1β (IL-1β) is a key cytokine in the pathogenesis of systemic juvenile idiopathic arthritis (SJIA). Canakinumab (CAN), a selective fully human anti-IL-1β monoclonal antibody, is efficacious in the treatment of SJIA.[1] Limitation of use of corticosteroids (CS), a current mainstay of therapy for SJIA, is desirable given their well-known long-term side effects. The present study was aimed to determine patient characteristics that are associated with CS discontinuation with CAN therapy and provide details for the CS-reducing potential of CAN in SJIA.

Methods: As part of the phase 3 program of CAN, patients aged 2–19 years with active SJIA plus fever received CAN (4 mg/kg; max:300 mg) every 4 weeks subcutaneously.[1] During a CS-tapering phase of up to 20 weeks, CS were reduced as per pre-specified rules, provided patients achieved an adapted JIA ACR50.[1] Here, we present patient baseline features pertinent to CS tapering successes, defined as at least a 25% reduction of the baseline CS dose (primary endpoint), reaching a low-dose CS requirement, i.e. $\leq$0.2 mg/kg/day and CS-free status (secondary endpoints).

Results: At baseline, 128/177 patients used daily CS [median (range) mg/kg dose: 0.27 (0.02–1.00)] of whom 72% (92/128) entered the CS-tapering phase. Upon completion of the CS-tapering phase 57/128 patients (44.5%; $p<0.0001$; 90%CI: 37.1–52.2) qualified as CS-tapering successes (primary endpoint). Of note, the majority of the patients either discontinued CS entirely (n=42) or required only low-dose CS (n=24) (secondary endpoints). Compared to patients still on CS (n=86), the 42 patients achieving CS-free status [values are all medians (1st, 3rd quartile)] had fewer joints with active arthritis [15 (8, 29) vs. 7 (3, 13)], fewer joints with limitation on motion [14 (7, 33) vs. 5.5 (2, 12)] at baseline. The groups were no different in terms of gender, race, SJIA duration, CRP, number of flares in 6-months period preceding baseline, or specific types of systemic features (hepatosplenomegaly, lymphadenopathy or serositis). Additional associations of CS-free status, initial CAN response, and select laboratory baseline features will be provided.

Conclusion: Findings of the Phase III program of CAN in SJIA suggest that CS requirements are substantially reduced after as few as 4 injections. The CS-sparing potential of CAN appears to be great as CS were discontinued entirely in a sizeable proportion of patients with active SJIA in this study.

Predictive Markers Of Joint Damages Of Children With Systemic-Onset Juvenile Idiopathic Arthritis In Long-Term Course Of Treatment With Tocilizumab. Tomo Nozawa, Taichi Kanetaka, Kenichi Nishimura, Masako Kikuchi, Tomomi Sato, Nodoka Sakurai, Ryoki Hara, Kazuko Yamazaki and Shumpei Yokota. Yokohama City University School of Medicine, Yokohama, Japan

Background/Purpose: Systemic-onset juvenile idiopathic arthritis (s-JIA) is a subtype of chronic childhood arthritis characterized by spiking fever, rash, and arthritis. Tocilizumab (TCZ), an anti-IL-6 receptor monoclonal antibody, has dramatically improved patients' inflammatory symptoms/signs as well as their prognosis. In the long-term treatment of s-JIA patients with TCZ, however, there found joint damages in some patients on X-ray examination although their clinical inflammatory symptoms/signs and laboratory findings were well-controlled. The objective of this study was to determine predictive markers of joint damages of s-JIA patients under the TCZ treatment.

Methods: Although 62 patients have been treated with TCZ, 33 patients were excluded from the study because 17 patients were effectively treated with TCZ to be drug-off, and the duration of TCZ treatment in 16 patients was shorter than 48 months and/or progression of radiographic joint damages were not detectable. Twenty-nine patients (16 boys and 13 girls) with s-JIA were eligible in this study who have been treated with TCZ over 48 months. The following blood tests were determined before and 6, 12, 24, 36, 48 months after the TCZ administration: CBC, CRP/ESR, D-dimer, liver function tests, creatinine, and MMP-3. The radiographs were serially examined before and after TCZ treatment.

Results: The mean age of disease onset was 5.2$\pm$2.9 years old. Of the 29 patients, 12 patients (41.3%) had radiographic progression of joint damages during the long-term TCZ treatment (JD (+)), and 17 patients (58.7%) had no joint damages on X-ray examinations (JD (−)) although there were no systemic inflammatory symptoms/signs demonstrable in both groups. Before TCZ treatment there were no significant differences of laboratory data between JD (+) and JD (−). By 12 months after TCZ treatment WBC counts were apparently more increased to normal range in JD (+) group than JD (−) group ($p<0.05$). By 24 months after TCZ treatment MMP-3 levels were still higher in JD (+) group than in JD (−) group ($p<0.05$). Taken together, although TCZ completely blocked clinically the inflammatory symptoms/signs as well as laboratory changes of inflammation such as CRP and ESR, there found a part of patients who had progressive joint damages even under the TCZ treatment, suggesting some biological mechanisms which were IL-6-independent will play an important role in damaging joints. For the patients who complained of something different on their joints, the tapering of prednisolone tended to be delayed. As the results, the mean doses of prednisolone at 12 months were significantly higher in JD (+) group than JD (−) group.

Conclusion: The long-lasting elevation of MMP-3 levels and higher WBC counts in patients with s-JIA treated with TCZ will be predictive of radiographic progression of joint damages.

Neutropenia With Tocilizumab Treatment Is Not Associated With Increased Infection Risk In Patients With Systemic Juvenile Idiopathic Arthritis. Fabrizio De Benedetti[1], Hermine I. Brunner[2], Eileen M. Baildam[3], Ruben Burgos-Vargas[3], Gerd Horneff[4], Hans-Iko Huppertz[3], Kirsten Minden[5], Barry L. Myones[2], Karen Onel[2], Jianmei Wang[6], Kamal N. Bharucha[7], Daniel J. Lovell[2], Alberto Martini[8] and Nicolino Ruperto[3]. [1]IRCCS Ospedale Pediatrico Bambino Gesú, Rome, Italy, [2]PRCSG, Cincinnati, OH, [3]PRINTO, Genoa, Italy, [4]Pediatric Rheumatology International Trials Organization (PRINTO)-Istituto Gaslini, Genova, Italy, [5]pediatric rheumatology, Berlin, Germany, [6]Roche, Welwyn Garden City, United Kingdom, [7]Genentech, South San Francisco, CA, [8]Istituto Giannina Gaslini, Genova, Italy.

Background/Purpose: In the phase 3 TENDER trial of tocilizumab (TCZ) in patients with systemic juvenile idiopathic arthritis (sJIA), decreases in neutrophil count were commonly observed. The purpose of this analysis was to determine if neutropenia was associated with increased risk of infection and to investigate variables associated with development of neutropenia in patients treated with TCZ for up to 2 years in TENDER.

Methods: One hundred twelve children with active, persistent sJIA were randomized 2:1 to receive TCZ by body weight (12 mg/kg $<$30 kg or 8 mg/kg $\geq$30 kg) or placebo IV every 2 weeks for 12 weeks and continued in an ongoing TCZ open-label extension.[1] Worst Common Toxicity Criteria (CTC) neutropenia grade (grade 1, $\geq$1.5 and $<2.0\times10^9$/L; grade 2, $\geq$1.0 and $<1.5\times10^9$/L; grade 3, $\geq$0.5 and $<1.0\times10^9$/L; grade 4, $<0.5\times10^9$/L) and lowest observed neutrophil count (10^9/L) were identified for each patient. Univariate linear regression analysis was performed to investigate association of patient characteristics with lowest observed neutrophil count. Rates of infections and serious infections (per 100 patient years [PY]) in periods $\pm$15 days around grade1–2 neutropenia (22.9 PY) and around grade 3–4 neutropenia (5.5 PY) were compared to corresponding rates in periods with normal neutrophil count (173.6 PY).

Results: Up to week 104, 64/112 patients (57.1%) had at least 1 episode of grade 1–4 neutropenia; worst grade: 1 (n=2), 2 (n=34), 3 (n=26), and 4 (n=2). Rates of infections and serious infections during period of normal neutrophil counts (276.5/100 PY [95% CI: 252.3, 302.3] and 11.5/100 PY [95% CI: 7.0, 17.8], respectively) were comparable to those observed $\pm$15 days around grade 1–2 neutropenia (226.7/100 PY [95% CI: 169.3, 297.3]; 8.7/100 PY [95% CI: 1.1, 31.5]) and grade 3–4 neutropenia (292.5/100 PY [95% CI: 167.2, 475.0]; 0/100 PY), with no trend toward increased risk with higher grade neutropenia. Methotrexate (MTX) use (Yes/No) was significantly associated with lowest observed neutrophil count (difference: –0.575 [95% CI: –1.02, –0.13], p=0.012), with 62% of 77 patients receiving MTX vs 46% of 35 patients not receiving MTX having grade 1–4 neutropenia. Younger age was borderline associated with lowest observed neutrophil count (β=0.04661, p=0.047). Concurrent use of glucocorticoids (GC) and TCZ exposure were not associated with lowest observed neutrophil count ($p>0.3$).

Conclusion: No trend for association between neutropenia and increased risk of infections was observed in the TENDER trial. Background MTX, and somewhat younger age, was associated with increased risk of neutropenia, while TCZ exposure and concurrent GC use were not. Reference: 1. Reported Macrophage Activation Syndrome In Patients With Systemic-Onset Juvenile Idiopathic Arthritis Treated With Tocilizumab. Shumpei Yokota, Yasuhiko Itoh, Tomohiro Morio, Naokata Sumitomo and Seiji Minota. The Safety Evaluation Committee of Actemra® for JIA, Tokyo, Japan.

Background/Purpose: Systemic-onset juvenile idiopathic arthritis (s-JIA) is a subtype of chronic childhood arthritis that is characterized by a spiking fever, rash, and arthritis. About 7% of s-JIA patients develop macrophage activation syndrome (MAS), a potentially fatal complication. Although several biologic therapies have dramatically improved the prognosis of s-JIA, the risk of developing MAS under biologic therapy seems not vanished because there are several reports of MAS associated with etanercept and canakinumab in patients with s-JIA.

To evaluate the prevalence of MAS in patients with s-JIA under the treatment of tocilizumab.

Methods: During the post-marketing surveillance of tocilizumab conducted by Chugai Pharmaceutical Co. Ltd. in Japan from 2008 to 2012, a total of 394 patients was registered. Tocilizumab, 8 mg/kg, was administered to the patients every 2 weeks, and routine investigations including CBC, CRP/ESR, D-dimer, liver function tests, creatinine, urinary beta 2-microglobulin, total cholesterol/triglyceride, and serum ferritin were determined before each infusion. Among them, 23 patients (5.8%) were diagnosed by the pediatrician in attendance with MAS, suspected MAS, or hemophagocytic syndrome; and then clinical course and laboratory data of the patients were reported as severe adverse events. Data were analyzed by the members of the Safety Evaluation Committee. Data were provided by Chugai Pharmaceutical Co. Ltd.

Results: The Committee investigated the clinical manifestations and the changes of laboratory data along with the time course of each patient reported. Three patients were defined as definitive MAS (0.76%), 2 patients as EB virus-associated hemophagocytic syndrome (0.51%). Among other 18 patients, 11 patients (2.8%) were defined as probable MAS because the patients' information including laboratory data was incomplete. Seven patients (1.8%) were judged as possible MAS or non-MAS because the treatment intervention for MAS was too early to define as MAS, or other diseases such as infectious disease, and hemolytic-uremic syndrome were suspected. Among 8 out of 14 patients defined as definitive or probable MAS, clinical manifestations were quite different from those seen in MAS on conventional therapy were. One patient died due to multi-organ failure, and none experienced sequelae.

Conclusion: The frequency of definitive MAS under the tocilizumab therapy is estimated as 0.76%, and possible MAS as 2.8% (total 3.6%). Since the development of MAS in s-JIA patients under the conventional therapy was reported to be 6.8% $\sim$ 13%, tocilizumab may have reduced the frequency of MAS developing in s-JIA. However, the clinical symptoms/signs such as fever, rash and an anguish look were not apparent in about half of the patients, and the inflammatory markers such as CRP and ESR were suppressed owing to the inhibition of IL-6 by tocilizumab. Taken together, physical examination and laboratory tests should be carefully taken at each visit in patients on tocilizumab in order to detect deadly MAS incipiently.

Changes In Serum IL-18 Level In Systemic Juvenile Idiopathic Arthritis Patients Who Attained Drug-Free Remission By Tocilizumab. Tomohiro Kubota[1], Syuji Takei[1], Yuichi Yamasaki[1], Junko Yasumura[2], Naomi Kuwada[3], Yukiko Nonaka[1], Tomoko Takezaki[1], Tsuyoshi Yamatou[1], Tomokazu Nagakura[4], Yasuhito Nerome[1], Hiroyuki Imanaka[1] and Harumi Akaike[1]. [1]Kagoshima University, Kagoshima, Japan, [2]Hiroshima University, Hiroshima City, Japan, [3]Kumamoto University, Kumamoto City, Japan, [4]House of Meguminoseibo, Usuki, Japan

Background/Purpose: Tocilizumab (TCZ), anti-human interleukin-6 receptor monoclonal antibody, was the first biologic agent used in the treatment of systemic juvenile idiopathic arthritis (sJIA) in Japan. We have previously reported that long-term TCZ therapy could induce drug-free remission in sJIA patients resistant to conventional prednisolone (PSL) therapy[1)]. On the other hand, extremely high levels of serum IL-18 ($>$10,000

pg/ml) was reported in active phase of sJIA[2]. Therefore, serum IL-18 levels were monitored in order to find the way how to taper and discontinue TCZ in sJIA patients.

Methods: sJIA patients treated with 8 mg/kg of TCZ for more than 1 year who were initially resistant to 3 times of consecutive weekly methyl-PSL pulse therapy in active phase and/or had been refractory to long-term oral steroid therapy were recruited. Our tapering protocol for patients who maintained clinical remission by TCZ was as following; decrease PSL dose gradually to less than 0.2mg/kg/day, prolongation of TCZ interval from every 2w to 3w, discontinuation of PSL, and discontinuation of TCZ, in tern. Serum levels of IL-6/IL-18 were measured by ELISA.

Results: A total of 28 sJIA patients were recruited in this study; their mean disease duration was 4.1 years, and mean PSL dose was 0.5mg/kg/day at initiating TCZ.

Twenty-seven patients (96%) attained clinical remission with combination therapy of PSL<0.2mg/kg/day and TCZ every 3w. Thereafter, 10 patients (36%) completed PSL-free remission, and 7 (25%) attained drug-free remission by discontinued TCZ (Figure 1). No significant difference was found in TCZ treatment period between the two patient groups who achieved the drug-free remission (mean 7.0 yrs) and who maintained clinical remission (mean 5.5 yrs).

Serum IL-6 decreased quickly in correlating with improvement of clinical symptoms after starting TCZ. On the contrary, serum IL-18 did not decrease in a patient who was resistant to TCZ therapy, or in patients who flared or developed to macrophage activation syndrome during the TCZ therapy. In patients who attained clinical remission by TCZ, however, IL-18 steadily decreased with treatment course (figure 2). In all patients maintained the drug-free remission for more than 2 years, serum IL-18 was < 1,000 pg/ml when the TCZ was discontinued.

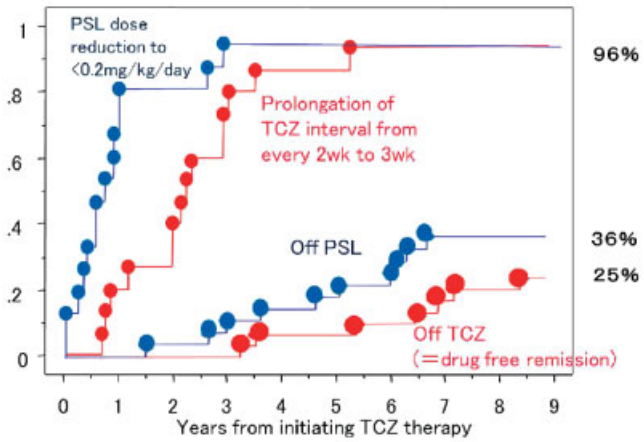

Figure1:Cumulative incidence of sJIA attained each endpoints

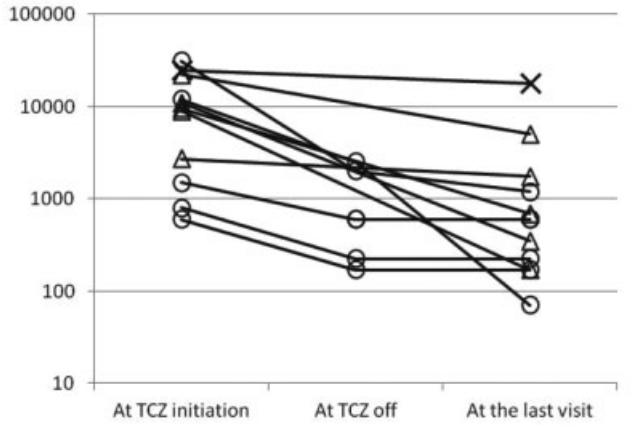

○ : Pts attained drug-free remission △ : Pts maintained clinical remission
× : Pts refractory to TCZ

Figure 2:Changes in serum IL-18 in sJIA treated with TCZ

Conclusion: TCZ had the potential to induce drug-free remission in 1/4 of sJIA patients who had been refractory to the conventional therapy. Serum IL-18 level could be a useful bio-marker in tapering the TCZ therapy in sJIA.

Assessment Of Radiographic Progression In Patients With Systemic Juvenile Idiopathic Arthritis Treated With Tocilizumab: 2-Year Results From The Tender Trial.

Clara Malattia[1], Nicolino Ruperto[2], Elena Palmisani[2], Silvia Pederzoli[2], Angela Pistorio[2], Hermine I. Brunner[3], Rubén J. Cuttica[4], Inmaculada Calvo[2], Stella Maris Garay[2], Despina Eleftheriou[2], Carine Wouters[2], Jianmei Wang[5], Clare Devlin[5], Daniel J. Lovell[3], Alberto Martini[6], Fabrizio De Benedetti[7] and Angelo Ravelli[6]. [1]Pediatria 2, Genoa, Italy, [2]PRINTO, Genoa, Italy, [3]PRCSG, Cincinnati, OH, [4]Pediatric Rheumatology International Trials Organization (PRINTO)-Istituto Gaslini, Genova, Italy, [5]Roche, Welwyn Garden City, United Kingdom, [6]Istituto Giannina Gaslini, Genova, Italy, [7]IRCCS Ospedale Pediatrico Bambino Gesú, Rome, Italy

Background/Purpose: A phase 3 trial (TENDER) demonstrated the efficacy of the interleukin-6 receptor inhibitor tocilizumab (TCZ) in patients with systemic juvenile idiopathic arthritis (sJIA).[1,2] The purpose of this analysis was to investigate progression of radiographic joint damage in patients with sJIA treated with TCZ for up to 2 years in TENDER.

Methods: One hundred twelve patients 2–17 years old with active, refractory sJIA of ≥6 months' duration and an inadequate response to previous non-steroidal anti-inflammatory drugs and oral corticosteroids were enrolled in TENDER. Patients were randomized 2:1 to receive TCZ according to body weight (12 mg/kg <30 kg or 8 mg/kg ≥30 kg) or placebo IV every 2 weeks for 12 weeks. Patients then received open-label TCZ in the ongoing long-term extension. Radiographic progression was calculated as change in adapted Sharp/van der Heijde score (aSH) score and/or Poznanski score, assessed on hand and wrist radiographs, from baseline to weeks 52 and 104. Radiographic progression was indicated by a positive aSH score change or negative Poznanski score change. Clinical efficacy endpoints included American College of Rheumatology (ACR) Pediatric (Pedi) 70/90 responses.

Results: Baseline and ≥1 postbaseline aSH and Poznanski scores were available for 47 and 33 patients, respectively (reasons for missing x-rays: early withdrawal, no consent, unreadable x-rays). Baseline characteristics for patients with radiographic data were similar to the whole TCZ population.[1] Patients with assessable aSH/Poznanski scores had 5.2/4.8-year disease duration, 21.3/19.2 active joints, 20.0/18.2 joints with limitation of movement, and erythrocyte sedimentation rates of 53.9/59.2 mm/h. At weeks 52 and 104, 20 and 19 patients, respectively, had aSH progression, and 8 and 6 patients, respectively, had Poznanski score progression. Median change in aSH score from baseline to weeks 52 and 104 were 0 and 0.5, respectively (Table). Median change in Poznanski score from baseline to weeks 52 and 104 were 0.3 and 0.17, respectively (Table).

	Week 52	Week 104
aSH score (n = 47), median (IQR)	0.00 (–8.70: 4.00)	0.50 (–7.50: 12.00)
Poznanski score (n = 33), median (IQR)	0.30 (–0.02: 1.03)	0.17 (0.01: 1.04)
ACR Pedi 70 (n = 112), n/N (%)	92/106 (86.8)	57/65 (87.7)
ACR Pedi 90 (n = 112), n/N (%)	67/106 (63.2)	46/65 (70.8)

IQR, interquartile range.

Conclusion: Though changes in radiographic scores over time were seen in many patients, on average, patients with sJIA did not experience

noticeable progression of radiographic damage over 2 years of treatment with TCZ.

Childhood Arthritis and Rheumatology Research Alliance (CARRA) Standardized Consensus Treatment Plans for New Onset Polyarticular Juvenile Idiopathic Arthritis. Sarah Ringold[1], Pamela F. Weiss[2], Robert A. Colbert[3], Esi Morgan DeWitt[4], Tzielan C. Lee[5], Karen Onel[6], Sampath Prahalad[7], Rayfel Schneider[8], Susan Shenoi[9], Richard K. Vehe[10] and Yukiko Kimura[11]. [1]Seattle Children's Hospital, Seattle, WA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, [3]NIAMS NIH, Bethesda, MD, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Stanford University School of Medicine, Stanford, CA, [6]PRCSG, Cincinnati, OH, [7]Emory Children's Center, Atlanta, GA, [8]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati, OH, [9]Seattle Children's Hospital, University of Washington, Seattle, WA, [10]University of Minnesota, Minneapolis, MN, [11]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ

Background/Purpose: There is no standardized approach to the initial treatment of polyarticular juvenile idiopathic arthritis (pJIA) among North American pediatric rheumatologists. Understanding the comparative effectiveness of the diverse therapeutic options available will result in better health outcomes for children with pJIA. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed consensus treatment plans (CTP) for use in clinical practice to facilitate such studies.

Methods: A case-based survey was administered to CARRA members to identify the most common treatment approaches for new-onset pJIA. Two face-to-face consensus meetings employed modified nominal group technique to agree on the treatment plans, operational case definitions, endpoints and data elements to be collected. A core workgroup reviewed the literature, refined the plans and developed medication dosing and monitoring recommendations. The final CTPs were presented for approval at a face-to-face meeting in April 2013.

Results: Sixty percent of 230 members answered the survey, which identified significant variability in treatment for new onset pJIA. 72 (2011) and 58 (2012) CARRA members attended consensus meetings to develop the 3 CTPs based on treatment strategies that focus on timing of introduction of medication categories (biologic and non-biologic DMARDs) for the first 12 months of therapy. Case definitions and clinical and laboratory monitoring schedules were established. The 3 CTPs include a Step-Up CTP (non-biologic with the addition of a biologic DMARD after 3–6 mos), Early Combination CTP (non-biologic plus biologic DMARD as initial treatment), and a Biologic Only CTP. This approach was approved by 96% of the 72 CARRA JIA Committee members attending the 2013 CARRA meeting.

Conclusion: Standardized CTPs based on 3 treatment timing strategies were developed for new-onset pJIA. Coupled with data collection at defined intervals, use of these CTPs will enable studying their comparative effectiveness in an observational setting like the CARRA Registry to optimize initial management of pJIA. Based on a high level of agreement among pediatric rheumatologists during the development process, sufficient participation and enrollment in all CTPs is anticipated.

Results Of a 24 Month Extension Study In Patients Who Participated In The Trial Of Early Aggressive Therapy In Polyarticular Juvenile Idiopathic Arthritis. Carol A. Wallace[1], John Bonsack[2], Steven J. Spalding[3], Hermine Brunner[4], Kathleen M. O'Neil[5], Diana Milojevic[6], Sarah Ringold[7], Laura E. Schanberg[8], Gloria C. Higgins[9], Beth S. Gottlieb[10], Joyce J. Hsu[11], Marilynn G. Punaro[12], Yukiko Kimura[13] and Audrey F. Hendrickson[14]. [1]Seattle Childrens Hosp & Research Institute, Seattle, WA, [2]University of Utah Health Sciences Center, Salt Lake City, UT, [3]The Cleveland Clinic, Cleveland, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Riley Hospital for Children, Indianapolis, IN, [6]University of California, San Francisco, San Francisco, CA, [7]Seattle Children's Hospital, Seattle, WA, [8]Duke University Medical Center, Durham, NC, [9]Nationwide Childrens Hosp, Columbus, OH, [10]Cohen Children's Medical Center of New York, New Hyde Park, NY, [11]Stanford University, Palo Alto, CA, [12]Texas Scottish Rite Hospital, Dallas, TX, [13]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [14]Seattle Children's Research Institute, Seattle, WA

Background/Purpose: The Trial of Early Aggressive Therapy in Polyarticular Juvenile Idiopathic Arthritis (TREAT-JIA) was a double-blind, randomized, placebo-controlled trial in 85 patients with onset of polyarticular JIA < 12 mos to determine if clinical inactive disease (CID) could be achieved by 6 months. Two aggressive treatment arms were used; (i) (MTX arm) SQ methotrexate (MTX; 0.5 mg/kg/wk) or (ii) (M-E-P arm) etanercept (ETN 0.8 mg/kg/wk), prednisolone (0.5 mg/kg/d tapered to zero by 17 wks) and MTX at the dose above. The purpose of this investigation was to follow these children beyond the original study for 2 additional years to understand the longer-term outcomes.

Methods: Patients who completed a minimum of 6 mos in the TREAT study were eligible to enroll in this extension study, regardless of response during the original trial and whether or not they continued to receive the same medications. Patients were treated as per standard of care. Physician, patient/parent and laboratory reported measures of disease status and safety information were collected at clinic visits every 3 mos for up to 2 years. Information regarding disease status and safety during the time period between studies was collected from chart review. Adverse events grade 3 and higher as well as infections requiring systemic therapy were reported.

Results: Twelve of the 15 original TREAT study sites participated and enrolled 52 of 77 (67.5%) eligible patients, 48 of whom returned for follow-up visits. TREAT baseline demographic and disease characteristics as well as disease state at the end of the TREAT trial did not differ between those who participated in the extension and those who did not. At enrollment into the extension study, 21 (44%) were receiving ETN and MTX, 13 (27%) MTX alone, 6 (12%) ETN alone, 7 (15%) no meds or NSAIDs alone, 1 patient each on prednisone, adalimumab and abatacept. Twenty-five (52%) entered the extension study in CID, while 23 (48%) had active disease. Patients were followed for a mean of 21.4 mos (range 9 to 24) and 27 (56%) patients spent more than 50% of their follow up time in CID. Eight patients were in CID >12 months and 2 were in CID off meds for the entire study. Disease activity during periods of AD tended to be low with means of MD global of 2.4; active joint count of 3.5; parent global evaluation of 2.4; CHAQ of 0.32; ESR 19; and morning stiffness of 23 minutes. Patients who were RF(−) tended to spend more study time in CID than RF(+) patients (52% vs 43%), as did patients who were ANA (−) 58% vs 47% ANA (+). Patients who achieved CID at 6 months in the TREAT study tended to spend more time in CID (58% vs 45%) than did those who ended the TREAT study in AD (55% vs 43%). There were no serious adverse events or adverse events grade 3 or higher reported. Four patients had 6 infections requiring systemic antibiotics.

Conclusion: Early aggressive therapy in this group of polyarticular JIA patients, with high initial disease activity and proportion with RF positivity, was associated with prolonged periods of CID in the majority of patients during this 24 month extension study. Those not in CID had low levels of disease activity.

Safety and Effectiveness Of Adalimumab In Children With Polyarticular Juvenile Idiopathic Arthritis Aged 2 To <4 Years Or ≥4 Years Weighing <15 Kg. Daniel J. Kingsbury[1], Pierre Quartier[2], Vipin Arora[3], Jasmina Kalabic[4], Hartmut Kupper[4] and Neelufar Mozaffarian[3]. [1]Legacy Emanuel Children's Hospital, Portland, OR, [2]PRINTO, Genoa, Italy, [3]AbbVie, North Chicago, IL, [4]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany

Background/Purpose: Adalimumab (ADA) is approved for use in moderate to severe juvenile idiopathic arthritis (JIA) in patients (pts) ≥4 years (yrs) old in the US, EU, and Japan. Limited data are available in pts <4 yrs old. The objective of this study was to assess the safety and effectiveness of >1 year of ADA therapy in pts aged 2 to <4 yrs old or ≥4 yrs old weighing <15 kg with moderately to severely active polyarticular JIA.

Methods: JIA pts were treated with ADA 24 mg/m^2 (maximum=20 mg/dose) every other week (wk) +/− methotrexate for 96 wks in an ongoing international, multicenter, open-label, phase 3b study until achieving the limit for age (≥4 yrs) and weight (≥15 kg). Adverse events (AEs) were summarized for all visits up to 96 wks. Clinical effectiveness endpoints included American College of Rheumatology pediatric (PedACR) 30/50/70/90 responses through wk 60, and JIA outcome parameters (PhGA, PaGA, DICHAQ, AJC73, LOM69, CRP, TJC, SJC, and POM75).

Results: 32 pts were randomized; through wk 60, two pts withdrew due to AEs (JIA worsening or flare) and 2 withdrew for other reasons. AE incidence rates included: any AEs (91%), serious AEs (16%), infectious AEs (78%), and serious infections (9%). No deaths, malignancies, or opportunistic infections were reported. 90% of pts had achieved PedACR30 at wk 60 (Table 1). High PedACR 50/70/90 response rates were achieved at wk 24 and maintained through wk 60. Statistically significant improvements in other JIA outcomes were also observed (Table 2). Growth was not adversely impacted by ADA treatment; based on CDC growth standards, at baseline, 50%/53% of pts were in the ≥33rd percentile for height and body mass index, respectively; at wk 60, this had increased to 76%/67%.

Table 1. PedACR Response Over Time (Observed Case Analysis)

	Week 24 Response Rate N=30 n (%)	Week 60 Response Rate N=20 n (%)
PedACR30	27 (90.0)	18 (90.0)
PedACR50	25 (83.3)	16 (80.0)
PedACR70	22 (73.3)	14 (70.0)
PedACR90	11 (36.7)	10 (50.0)

Table 2. JIA Outcomes at Week 60[a]

	Mean Change (SD) from Baseline N=20
PhGA of Disease Activity[b] (VAS 0–100 mm)	–42.7 (28.2)*
PaGA of Disease Activity[b] (VAS 0–100 mm)	–34.5 (33.3)*
Child Health Assessment Questionnaire[b] (DICHAQ)	–0.6 (0.7)**
Active Joint Count (AJC73)	–9.5 (7.5)*
Limitation on Passive Motion (LOM69)	–5.5 (8.3)**
CRP (mg/dL)	–0.3 (1.8)
Tender Joint count (TJC75)	–4.5 (5.9)**
Swollen Joint Count (SJC66)	–8.4 (7.2)*
Pain on Passive Motion (POM75)	–5.9 (5.3)*
PaGA of Pain[b] (VAS 0–100 mm)	–35.2 (34.4)*

[a]Observed case analysis. [b]N=21. *P<.001. **P<.05. SD, standard deviation.

Conclusion: In this very young population with polyarticular JIA, primary clinical trial data revealed that the safety profile and effectiveness of ADA were comparable to that observed in older children with JIA. No adverse effects on growth were observed; however, data did reflect improvement in growth through wk 60 of the study.

Background/Purpose: Etanercept (ETN) is approved for the treatment of pediatric patients with the polyarticular subtype of juvenile idiopathic arthritis (JIA). In addition, based on the interim 12-week data from the first part of the CLIPPER study,[1] ETN was recently approved in the EU for the treatment of pediatric patients with the extended oligoarticular (eo), enthesitis-related (ERA), and psoriatic (PsA) JIA subtypes. The majority of studies performed with ETN to date have enrolled subjects with polyarticular-onset JIA and limited information is available on the eoJIA, ERA, and PsA JIA subtypes. The objective of the second part of the CLIPPER study was to assess the long-term safety and clinical benefit of ETN in pediatric subjects with these JIA subtypes.

Methods: CLIPPER was a 96-week, Phase 3b, open-label, multicenter study. Subjects with eoJIA (2–17 years old), ERA (12–17 years old), or PsA (12–17 years old) received ETN 0.8 mg/kg once weekly (maximum dose 50 mg) for 96 weeks. Safety was assessed by reporting treatment-emergent adverse events (TEAEs) and serious TEAEs throughout the study. Efficacy endpoints included the proportions of subjects achieving JIA American College of Rheumatology (ACR) 30/50/90 responses and inactive disease criteria at Week 96.

Results: 127 subjects (eoJIA n=60, ERA n=38, PsA n=29) received ≥1 dose of ETN. Mean age was 11.7 (SD, 4.5) years and disease duration was 26.8 (SD, 26.4) months. Safety results are summarized in the table. Most frequently reported TEAEs were (number of events, events per patient year [EPPY]): headache (23, 0.107), pyrexia (12, 0.056), diarrhea (10, 0.046), leukopenia (8, 0.037), increased alanine aminotransferase (8, 0.037), and arthralgia (8, 0.037). The most commonly reported treatment emergent (TE) infections were (number of events, EPPY): upper respiratory tract infection (83, 0.386), pharyngitis (50, 0.232), gastroenteritis (22, 0.102), bronchitis (19, 0.088), and rhinitis (17, 0.079). No cases of malignancy, active tuberculosis, demyelinating disorders, or deaths were reported. At Week 96, the overall proportions (95% CI) of subjects achieving JIA ACR 30/50/90/inactive disease criteria were 99.1% (94.9, 100), 98.1% (93.5, 99.8), 65.4% (55.6, 74.4), and 34.0% (25.0, 43.8), respectively. Approximately a 2-fold and 3-fold increase in the percentage of JIA ACR 90 and inactive disease responders from Week 12 to Week 96, respectively, was noted.

Table. Safety Summary at Week 96

	eoJIA n = 60 EXP = 103.603 N (EPPY)*	ERA n = 38 EXP = 61.298 N (EPPY)*	PsA n = 29 EXP = 50.185 N (EPPY)*	Total n = 127 EXP = 215.086 N (EPPY)*
TEAEs†	136 (1.313)	112 (1.827)	52 (1.036)	300 (1.395)
TE infections	219 (2.114)	60 (0.979)	76 (1.514)	355 (1.651)
TE ISRs	22 (0.212)	29 (0.473)	12 (0.239)	63 (0.293)
TEAEs causing withdrawal,† n (%)	0	3 (7.9)	0	3 (2.4)
TE infections causing withdrawal, n (%)	1 (1.7)	0	1 (3.4)	2 (1.6)
Serious TEAEs†	2 (0.019)	11 (0.179)	3 (0.060)	16 (0.074)
Serious TE infections	4 (0.039)	3 (0.049)	3 (0.060)	10 (0.046)
Opportunistic infections‡	0	1 (0.016)	0	1 (0.005)
Infections considered preventable by vaccination in subjects not previously vaccinated	5 (0.048)	1 (0.016)	1 (0.020)	7 (0.033)
Infections considered preventable by vaccination in subjects previously vaccinated	1 (0.010)§	0	0	1 (0.005)
TE autoimmune disorders#	1 (0.010)	2 (0.033)	1 (0.020)	4 (0.019)

*All values are reported as number of events (N) per patient-year (EPPY) of exposure (EXP) to ETN, unless otherwise stated. †Excluding infections and injection site reactions (ISRs); ‡one case of herpes zoster affecting two dermatomes was considered to be an opportunistic infection and one case of latent tuberculosis (purified protein derivative conversion) was not considered to be an opportunistic infection; §one case of rubella; #two cases of uveitis, one case of iridocyclitis, and one case of Crohn's disease were TE and one case of Crohn's disease was not considered TE based on missing last dose data.

Conclusion: ETN treatment for 96 weeks was well-tolerated and effective in treating subjects with the JIA subtypes, eoJIA, ERA, or PsA, as expected from the previous data from polyarticular JIA.

GO-Kids Imaging Substudy: MRI Treatment Response To 30 Mg/m^2 4-Weekly Subcutaneous injections Of Golimumab In Children With Polyarticular JIA–Preliminary Results Of The Open Label Portion.

Nikolay Tzaribachev[1], Catrin Tzaribachev[1] and Bernd Koos[2]. [1]PRI - Pediatric Rheumatology Research Institute, Bad Bramstedt, Germany, [2]University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background/Purpose: The **GO-KIDS** trial is a double blind placebo controlled Phase III trial, where patients 2–17 yrs of age with pJIA receive open label SC GLM 30 mg/m^2 every 4 weeks until week 16, followed by 1:1 randomization to placebo or GLM from Weeks 1648 for children achieving ACR Pedi 30 response at Week 16. Primary endpoint is % of children who experience flares of JIA between Weeks 16 and 48.

173 patients were enrolled.

The aim of the MRI based **GO-KIDS Imaging** substudy is to evaluate the efficacy of GLM on MRI measurements within 16 weeks of drug initiation.

Methods: Patients participating in the **GO-KIDS** trial at a single center could voluntarily participate in the **GO-KIDS Imaging** substudy after obtaining separate informed consent. Gadolinium enhanced MRI of a reference peripheral joint region and the temporomandibular joints (TMJ) were obtained at week 0 (baseline) and week 16 (before randomization). MRI was scored (grade 0 – 3) for peripheral joints/TMJ for synovitis (S), synovial hypertrophy (SH) and for peripheral joints for tenosynovitis (TS). Statistical analysis: Shapiro- Wilk-W-test (for normality of distribution); non-parametric Wilcoxon rank-sum test (changes of the MRI scoring).

The clinical response data (ACR Pedi Score) were extracted from the **GO-KIDS** trial and compared to the MRI response.

Results: 19 children (10 female) with a median age of 9 (7–17) years at study inclusion participated in the **GO-KIDS Imaging** substudy. At week 16 the number of ACR Pedi 100 responders was 11/19, ACRPedi 90–15/19, ACR Pedi 70–17/19 and 2 children were non-responders.

At week 16 the MRI was significantly improved compared to week 0 in all components of the MRI scoring: peripheral joints ($p<0.001$ for S, $p=0.001$ for SH and $p=0.002$ for TS) and TMJ ($p<0.001$ for S and SH each). Eight patients showed no inflammatory activity on MRI at week 16 and 9 patients significantly ($p<0.002$) improved. Two patients did not demonstrate significant change on MRI (same as ACR Pedi non-responders).

MRI results did not completely correlate with improvements in ACR Pedi Score: 5 children showed inactivity on MRI but did not achieve an ACR Pedi Score of 100.

Conclusion: During the open label treatment with GLM of the **GO-KIDS** trial, children with pJIA demonstrated significant improvement on MRI measurements between Weeks 0 and 16 with a large proportion of patients achieving MRI inactivity. MRI appeared to be more sensitive in detecting inflammatory inactivity than ACR Pedi scoring systems.

Rates Of Flare-Free Survival In Juvenile Idiopathic Arthritis When Tapering Individual Components Of Tumor Necrosis Factor Inhibitor and Methotrexate Combination Therapy.

Caroline Y Chang, Rika Meyer and Andreas Reiff. Children's Hospital Los Angeles, Los Angeles, CA

Background/Purpose: Combination therapy of tumor necrosis factor inhibitors (TNFi) and methotrexate (MTX) is a well-established treatment that has dramatically changed outcomes in Juvenile Idiopathic Arthritis (JIA). Given the high relapse rate of patients with JIA, it is crucial to determine the appropriate timing and method of tapering medications once disease control is achieved.

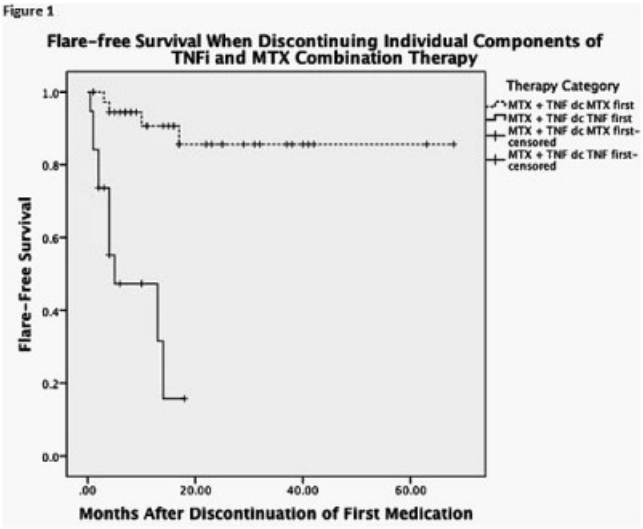
Methods: This is a retrospective single-center observational cohort study of patients with polyarticular JIA (pJIA) seen in our institution's pediatric rheumatology clinic between January 2000 and December 2011. Demographic information (Table 1), diagnosis, antibody status, medication history, and dates of achieving inactive disease and flare were extracted from patient charts. Inactive disease was defined per Wallace criteria and flare was defined as no longer fulfilling these criteria for more than 1 visit. We performed a flare-free survival analysis, looking at 4 treatment arms of patients who had achieved inactive disease and tapered medications: TNFi plus MTX, tapered off MTX first (group 1,n=45), TNFi plus MTX, tapered off TNFi first (group 2,n=19), MTX monotherapy (group 3,n=32), and TNFi monotherapy(group 4,n=6). We also evaluated outcomes based on rheumatoid factor (RF) status.

Results: We included 194 pJIA patients with a mean follow-up of 4.74 ± 2.8 years. After a mean of 23.6 months (range 5–120), 129/194 patients (66%) achieved inactive disease. Group 2 had a significantly worse outcome with only 47% of patients remaining flare-free for 12 months off TNFi despite continued MTX therapy compared to 90% of those who had weaned MTX first and continued TNFi ($p<.0005$) (Figure 1). After a mean of 21months (range 0–81) with inactive disease, 30% of patients were able to discontinue all medications. Of these, 33% flared within 3 months, 46% within 6 months, and 67% within 12 months. When comparing the 4 treatment arms, group 3 had a significantly better outcome in terms of flare-free survival off medications compared to group 1($p=0.007$). Time to flare was independent of time in remission and RF status.

Table 1

Demographic Information	N = 194 (%)
Female Sex	161 (83)
Ethnicity	
Hispanic	127 (65)
Non-Hispanic	67 (35)
Age at disease onset, mean years (range)	9.8 (1–18)
Mean follow-up, years (SD)	4.74 (2.8)
RF positive	90/187 (48)
CCP positive	56/106 (53)

Figure 1



Conclusion: This study confirms that flare rates in JIA patients are high. However, when tapering TNFi/MTX combination therapy to monotherapy, weaning TNFi first carries a significantly higher risk of flare than weaning MTX first. After discontinuation of all medications, patients on MTX

monotherapy had better flare-free survival compared to those on combination therapy, possibly due to inherently milder disease.

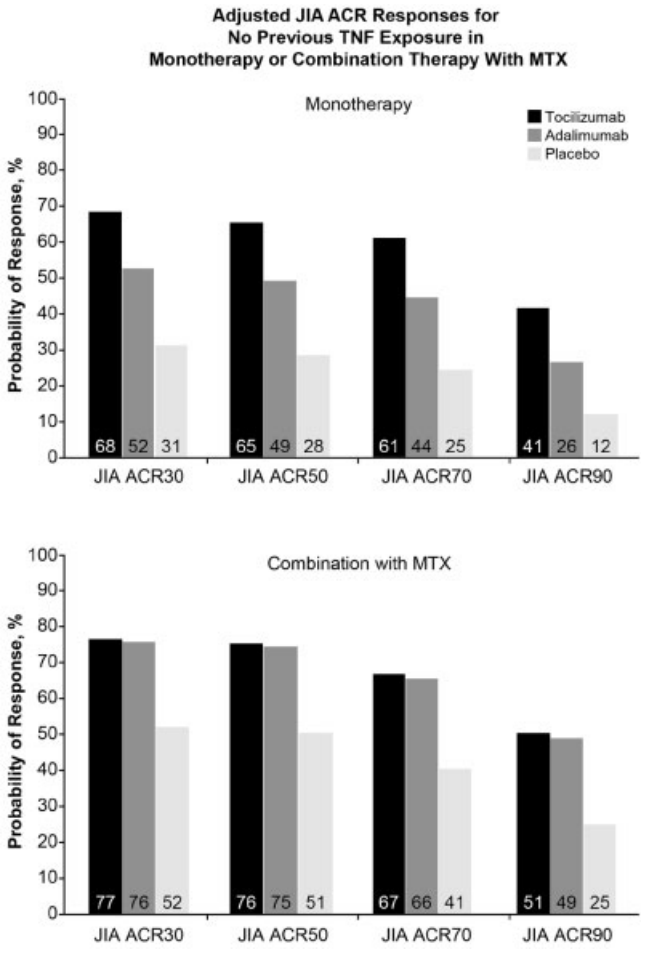
283

Efficacy Of Biologic Treatments In Juvenile Idiopathic Arthritis With a Polyarticular Course: An Indirect Comparison. Laura Sawyer[1], Alex Diamantopoulos[1], Hermine I. Brunner[2], Fabrizio De Benedetti[3], Nicolino Ruperto[4], Fred Dejonckheere[5] and Caroline Keane[6]. [1]Symmetron Limited, London, United Kingdom, [2]PRCSG, Cincinnati, OH, [3]IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, [4]PRINTO, Genoa, Italy, [5]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [6]Roche, Welwyn Garden City, United Kingdom

Background/Purpose: To date there are no head-to-head trials comparing the efficacy of biologic treatments for polyarticular-course JIA (pcJIA). The purpose of this study was to use statistical methods to estimate the relative efficacy of biologic treatments, alone and in combination with methotrexate (MTX), in the management of pcJIA by means of indirect comparison of randomised controlled trials (RCTs).

Methods: Based on a literature review, we identified RCTs of abatacept,[1] adalimumab[2] (ADA), etanercept,[3] infliximab,[4] and tocilizumab[5] (TCZ; CHERISH) in pcJIA. Comparative effectiveness was estimated on the reported American College of Rheumatology response rates (JIA ACR30/50/70/90) measured at the end of the randomized, double-blind phase by means of a Bayesian indirect comparison using a fixed-effects ordered probit model. Probabilities of achieving different levels of JIA ACR response were calculated for biologic treatments and placebo using all observed comparisons.

Results: The 5 RCTs identified showed differences in reporting JIA ACR responses with regard to methods of nonresponder imputation during the blinded, controlled phase, allowing only for the comparison of ADA and TCZ. After correction for previous biologic use (Figure), for a JIA ACR30 placebo response of 31%, TCZ monotherapy had a higher predicted probability of achieving JIA ACR30 (68%), JIA ACR50 (65%), JIA ACR70 (61%), and JIA ACR90 (41%) vs ADA monotherapy, with 52%, 49%, 44%, and 26%, respectively. On MTX background therapy and a JIA ACR30 placebo response of 52%, TCZ had a higher expected probability of response at JIA ACR30 (77%), JIA ACR50 (76%), JIA ACR70 (67%), and JIA ACR90 (51%) vs ADA, with 76%, 75%, 66%, and 49%, respectively. In neither monotherapy nor combination therapy did differences between TCZ and ADA reach statistical significance.



Conclusion: Based on JIA ACR response rates from this analysis, the expected efficacy of ADA vs TCZ appears comparable in pcJIA. As monotherapy, however, TCZ may be better than ADA. These data should be interpreted in the context of differences in the duration of the withdrawal phase, which was shorter in the TCZ study (CHERISH) than in the ADA trial and might have resulted in a smaller difference in the number of flares observed between placebo and TCZ.

What Is the Relative Priority of the ACR Pediatric Core Set Measures for Youth With Juvenile Idiopathic Arthritis and Their Parents? Jaime Guzman[1], Oralia Gomez-Ramirez[2], Susanne M. Benseler[3], Roberta A. Berard[4], Rollin Brant[2], Ciaran M. Duffy[5], Roman Jurencak[6], Kiem Oen[7], Ross E. Petty[8], Natalie J. Shiff[9] and Lori B. Tucker[2]. [1]BC Children's Hospital and University of British Columbia, Vancouver, BC, [2]University of British Columbia, Vancouver, BC, [3]Hospital for Sick Children, Toronto, ON, [4]Children's Hospital of Western Ontario, London, ON, [5]Children's Hospital of Eastern Ontario and University of Ottawa, Ottawa, ON, [6]University of Ottawa, Ottawa, ON, [7]University of Manitoba, Winnipeg, MB, [8]BCs Children Hosptial, Vancouver, BC, [9]University of Saskatchewan, Saskatoon, SK

Background/Purpose: The ACR has endorsed a core set of six measures to assess the course of JIA and the impact of treatment: active joint count, limited joint count, physician's global assessment of disease activity, functional ability, patient/parent's global assessment of well being and a laboratory measure of inflammation. We sought to determine the relative priority given by patients and their parents to the ACR pediatric core measures, in relation to other disease features.

Methods: Three separate study sessions consisting of focus group discussions and reciprocal interviews (participants interview each other), were conducted with youth with JIA, experienced parents and novice parents. Participant youth (7 female, 2 male, aged 16 to 23 years old) had JIA for 2 to 12 years (1 oligo, 2 poly, 2 systemic, 2 ERA, 1 psoriatic, 1 unclassified). Experienced parents (5 female, 5 male, 2 couples) participated 9 months to 14 years after JIA diagnosis in their child (4 oligo, 1 poly, 1 ERA, 1 psoriatic, 1 unclassified). Novice parents (5 female, 3 male, one couple) participated 2 to 6 months after JIA diagnosis in their child (2 oligo, 1 systemic, 1 ERA, 1 psoriatic, 2 unclassified). A list of 34 clinical features often used for the monitoring of JIA in cohort studies and therapeutic trials was provided to participants. The list included the core set ACR pediatric measures and lay language definitions for all the features. Participants were asked to add any other relevant features, and discuss the features' relative priority in describing the course of JIA. Focus group discussions were professionally facilitated, recorded, and transcribed. Reciprocal interview answers were reported in standard forms. Focus group transcripts and interview answers underwent content analysis by two investigators; themes and priority rankings were discussed with all co-authors.

Results: Among core set measures, the active joint count was considered to be of high priority by parents and of medium priority by youth. The parent's global assessment was considered to have medium priority by

parents and low priority by youth. The limited joint count and functional ability were considered to have low priority by the three groups. The physician global assessment was not discussed to any extent or given any priority, although the concept of disease activity was considered to be important. Laboratory measures were not discussed. By contrast, youth and parents gave high priority to pain, quality of life, medications required to control the disease and medication side-effects. Youth felt that visual analogue scales and standardized questionnaires were poor reflections of their experiences with JIA. Experienced parents were particularly interested in disease flares and flare triggers. Novice parents were still coming to terms with the emotional impact of their child's JIA diagnosis and found the prioritizing task difficult.

Conclusion: Among the six core measures, only the number of active joints has enough relevance in the eyes of youth and parents to be considered a central feature of JIA course. If more patient-relevant measures are desired, consideration should be given to include pain and quality of life indicators as core set measures.

285

Juvenile Idiopathic Arthritis Patients Demonstrate Alterations In HDL Functionality Without Accelerated Subclinical Atherosclerosis. Preethi Mani[1], Kiyoko Uno[2], Katherine Wolski[2], Steven J. Spalding[3], Stephen J. Nicholls[2] and M. Elaine Husni[2]. [1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]The Cleveland Clinic, Cleveland, OH

Background/Purpose: Previous literature supports an increase in cardiovascular (CV) morbidity and mortality in adults with inflammatory joint disease, however it is not known whether children with JIA also carry this risk. While the precise mechanism for accelerated atherosclerosis is unknown, impaired high density lipoprotein (HDL) functionality may contribute to increased CV risk in these patients. It has not been established if younger patients with JIA also have accelerated subclinical disease or alterations in HDL function.

Methods: HDL functionality, as measured by cholesterol efflux capacity and receptor expression, NMR spectroscopy, antioxidant activity, and promotion of endothelial function, were compared in JIA patients and controls. Carotid intima-media thickness (cIMT) was measured as a validated, non-invasive surrogate of subclinical atherosclerosis were also compared. Apolipoprotein B depleted serum capacity to promote cholesterol efflux via ABCA-I (J774 macrophages), ABCG-I (baby hamster kidney cells) and SR-BI (Fu5AH hepatoma cells) were measured. Change in mRNA expression of ABCA-I, ABCG-I, and SR-BI on murine bone marrow-derived macrophages upon exposure to serum was assessed. HDL particle distributions were characterized using NMR spectroscopy. Antioxidant activity by arylesterase and ability of serum to promote endothelial cell migration were compared.

Results: 29 patients with JIA and 14 healthy controls between the ages of 10–32 were studied. Patients were younger than controls (17.3±6 vs. 21.7±6 years, p= 0.05) and had lower HDL-C (47.0 (40, 56) vs. 56.0 (53, 63) mg/dL, p = 0.04). There was no difference in mean cIMT (0.5 ± 0.05 vs 0.5 ± 0.06, p = 0.27), however, alterations in HDL functionality were noted. JIA patient serum demonstrated greater cholesterol efflux via ABCA-I (17.3 (12.8, 19.7) vs. 10.0 (5.8, 16.0), p=0.05), but less efflux via ABCG-I (3.2 (2.0, 3.9) vs. 4.8 (3.5, 5.8), p=0.01) and SR-BI (6.9 (6.0, 8.4) vs. 9.2 (8.6, 10.2), p=0.002). Exposure of macrophages to patient serum resulted in less expression of ABCA-I (2±0.9 vs. 7±5.7 fold increase, p=0.01), but greater expression of ABCG-I (1.37 (0.88, 1.52) vs. 0.76 (0.71, 1.07) fold increase, p=0.04) and SR-BI (1.3± 0.47 vs. 0.65±0.25 fold increase, p=0.001). JIA patients had less large HDL (5.1 (3.7, 7.3) vs. 8.0 (6.7, 9.7) mg/dL, p=0.04) and less HDL particles (29.5 (27.9, 32.3) vs. 32.9 (31.6, 36.3) particles, p=0.05). Arylesterase activity was lower in JIA patients (128.9±27.6 vs. 152.0±45.2 umoles/min/mL, p = 0.04). Endothelial cell migration was lower upon exposure to patient serum (491.2±68.9 vs. 634.2±227.4 cells/field, p = 0.01).

Conclusion: Although JIA patients did not demonstrate increase in subclincal disease by cIMT compared to controls, they demonstrate changes in HDL functionality despite being on active treatment. These changes may lead to increased CV risk as these patients age further. While larger studies are critical to further characterize HDL functionality and subclinical disease in subsets of JIA patients, these patients warrant close monitoring of CV risk beginning at a younger age than the general population and aggressive, early implementation of CV risk management strategies.

286

Cardiovascular Risk In Adults With Juvenile Idiopathic Arthritis. Elizabeth Coulson[1], Wan-Fai Ng[2], Philip N. Platt[3] and H. E. Foster[4]. [1]Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [2]Newcastle University, Newcastle upon Tyne, United Kingdom, [3]Freeman Hospital, Newcastle upon Tyne, United Kingdom, [4]Musculoskeletal Research Group, Institute of Cellular Medicine, Newcastle University and Great North Children's Hospital, Newcastle Upon Tyne, United Kingdom

Background/Purpose: Increased cardiovascular mortality and morbidity have been observed in adults with Rheumatoid Arthritis. The long-term risk of cardiovascular disease for individuals with Juvenile Idiopathic Arthritis (JIA) remains uncertain. This study aims to determine whether adults with JIA have an increased risk of cardiovascular disease compared to the general population.

Methods: 51 patients with JIA (mean age 35.6 years, SD 13.23) were compared to 26 controls (mean age 37.3 years, SD 13.14). Data regarding traditional cardiovascular risk factors were collected including fasting blood glucose and lipid profile, blood pressure, BMI and history of hypertension, hypercholesterolaemia, diabetes mellitus, smoking history and family history of cardiovascular disease. Disease sub-type (ILAR criteria) and duration were recorded. In the patient group the sub-types were as follows: systemic 3/51 (5.9%), enthesitis-related arthritis (ERA) 5/51 (9.8%), extended oligoarticular 12/51 (23.5%), polyarticular 27/51 (52.9%), juvenile psoriatic (JPSA) 4/51 (7.8%). Median disease duration was 24 years (3–57). Many (23/51 (45%)) patients were taking biological therapy, 13 as monotherapy and 10 in combination with a DMARD; a further 17/51 (33%) patients were taking one or more DMARDs. Common carotid artery intima-media thickness (CCA IMT) was examined by B-mode ultrasound (Toshiba AplioXU and 12 MHz transducer) as a surrogate marker of cardiovascular disease. Images were analysed blinded using the M'athñ software package (Intelligence in Medical Technologies). Continuous, parametric variables were analysed using the independent samples T-test, non-parametric using the Mann Whitney U test and categorical data using the chi-squared test.

Results: The Table shows that a significantly higher proportion of patients had a pre-existing diagnosis of hypertension compared to controls (p=0.029) but no significant differences in other pre-existing traditional cardiovascular risk factors. The patient group had a significantly higher CRP (p=0.006). No significant differences were found in ESR, fasting glucose or lipid levels, BMI or systolic or diastolic blood pressures recorded in clinic. CCA IMT showed good correlation with age (Pearson's coefficient 0.76, p=0.000). The patient group had a significantly higher mean CCA IMT (0.54 vs. 0.49, p=0.037) compared to controls. Subgroup analysis revealed a significantly higher mean CCA IMT in those with polyarticular disease (0.56 vs. 0.48, p=0.01), but not for other subtypes. CCA IMT was not significantly higher in patients taking biologics (0.51 vs. 0.49 p=0.396) but was for those taking DMARDs (0.58 vs. 0.48, p=0.029) compared to controls.

	Patient n=51	**Control n=26**	***P value***

Long-Term Evaluation Of Cardiac Function In Juvenile Idiopathic Arthritis Under Anti-Tumor Necrosis Factor Therapy. Alessandro C. Lianza[1], Nadia E. Aikawa[1], Julio C. B. Moraes[2], Gabriela N. Leal[1], Samira S. Morhy[1], Eloisa Bonfa[1] and Clovis A. Silva[3]. [1]University of São Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil

Background/Purpose: Subclinical cardiac involvement was previously described in juvenile idiopathic arthritis (JIA) patients, however there is no data regarding echocardiography and cardiac biomarkers evaluations in JIA under biologic therapy. Therefore, the objectives of this study were to perform a global assessment of the long-term cardiac function in JIA patients under TNF blockage therapy.

Methods: Twenty-five polyarticular-course JIA patients pre-anti-TNF (etanercept or adalimumab) and 22 healthy controls underwent conventional/tissue Doppler imaging echocardiography and cardiac biomarkers measurements [N-terminal pro-brain natriuretic peptide (NT-pro-BNP, cut-off≥125pg/mL for elevated values) and troponin T (cut-off>0.01μg/l for myocardial damage) by electrochemiluminescence immunoassay] at baseline (BL). Additionally, 21 JIA patients completed six evaluations during two consecutive years: BL, and 3, 6, 12, 18 and 24 months after anti-TNF treatment. Number of active joints, patient and physician visual analogue scales (VAS), Childhood Health Assessment Questionnaire (CHAQ), acute phase reactants [erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)] were evaluated before and after anti-TNF therapy.

Results: JIA patients and controls were comparable regarding current age (11.6 vs. 9.2 years, p=0.15) and female gender (47 vs. 40%, p=1.0). The median of disease duration was 2.7 (0.4–9.9) years and 24 (96%) were under non-steroidal antiinflammatory drugs, 8 (32%) prednisone, 23 (92%) methotrexate, 5 (20%) leflunomide and 7 (28%) cyclosporine. At BL, on the conventional Doppler evaluation, there was a lower isovolumetric relaxation time of left ventricle in JIA patients compared to healthy controls [76 (56–89) vs. 81.5 (71–96)m/s, p=0.03]. On the tissue Doppler, all parameters were within normal values at BL, although ventricular septum velocity (VS) E' wave (p=0.014) and VS S wave (p=0.03) were lower in JIA patients compared to healthy controls. Frequencies of elevated NT-pro-BNP levels were similar in JIA patients and controls (28 vs. 13.6%, p=0.3). Further comparison of JIA patients according to NT-pro-BNP levels at BL revealed that JIA patients with elevated levels of this cardiac biomarker had significantly more active joints (8 vs. 3, p=0.03) and higher ESR (55 vs. 29 mm/1sthour, p=0.03) compared to those with normal levels. Positive correlations were observed between NT-pro-BNP levels and number of active joints (r=0.59, p=0.002) and between NT-pro-BNP levels and ESR (r=0.51, p=0.009). Prospective evaluation of 21 JIA patients revealed that none of the participants had symptoms of heart failure and all of them remained with normal ejection fraction, and no alteration was observed in other parameters of conventional and tissue Doppler imaging echocardiography. Only one patient had mild elevated levels of troponin T at 18 and 24 months evaluations.

Conclusion: Long-term TNF blockage safety was demonstrated in JIA patients in spite of the observed mild subclinical diastolic involvement. Elevated cardiac biomarker in these patients was associated with inflammatory parameters reinforcing the need for a careful interpretation of this finding in patients with active disease.

MRI Findings In Juvenile Spondyloarthopathy and Effects Of Treatment On Subsequent MRI. Clara Lin[1] and Diana Milojevic[2]. [1]University of California-San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA

Background/Purpose: The aim of our study was to

- describe pelvic MRI findings of juvenile spondyloarthopathy
- describe the treatment effects on subsequent MRIs in juvenile spondyloarthropathy
- determine predictors of active sacroiliitis in children

Methods: This was a retrospective chart and imaging review of children ages 5 to 21 year old seen in the pediatric rheumatology clinic from 2009 to 2012 with a MRI of the sacroiliac joints (MRI-SI). Data collected included demographics, patient's history, physical exam, and laboratory results at each visit. The pelvic joints (sacroiliac, hip, and facet)and entheses were reviewed on MRI-SI, and the sacroiliac joints were graded on a semi-quantitative scale (0–3) for bone marrow edema (BME), synovial enhancement, erosions to create a composite score ratio.

Results: 50 subjects with 76 MRI-SI were studied, and 32 subjects had sacroiliitis on 48 MRIs. Of the subjects with sacroiliitis, mean age± standard deviation was 13.68±2.59 years, 71% were male and 41% were HLA-B27 positive. In 22.9% of subjects with sacroiliitis, history and physical exam did not reveal signs of sacroiliitis. Inflammatory markers (ESR, CRP, WBC, Platelet count) were normal in 50% of cases of (+) sacroiliitis. In 16.7% of cases of sacroiliitis (n=8) in 7 subjects, physical exam of SI joints, Modified Schober's exam, and inflammatory markers were normal. In subjects with sacroiliitis, MRI also revealed hip arthritis and pelvic enthesitis in 71.4% and 40.6% of exams, respectively. Longitudinal data was available for 13 subjects. MRI-SI composite score ratio improved in 8 subjects with the greatest improvement occurring with initiation of etanercept therapy. Improvements in composite score ratio were due to improvement of BME and SE components, but erosion scores remained stable or worsened in all but 1 subject.

Conclusion: In our group of children with sacroiliitis, male:female ratio was 2.56 and HLA-B27 was present in 41% of subjects. Predicting active sacroiliitis from history, physical exam, and laboratory findings remains a challenge. Hip arthritis and pelvic enthesitis were common findings in cases of sacroiliitis in children. Greatest improvement of sacroiliitis on MRI was seen after initiating etanercept by decreasing bone marrow edema and synovial enhancement; however, erosions did not seem to improve on therapy.

Development and Validation Of The Cutoff Values For Disease Activity States Of The Three-Item Version Of The Juvenile Arthritis Disease Activity Score. Alessandro Consolaro[1], Sara Verazza[1], Maria C. Gallo[1], Giulia Bracciolini[1], Giorgia Negro[1], Alessia Frisina[1], Nicolino Ruperto[1], Alberto Martini[2] and Angelo Ravelli[2]. [1]Istituto Giannina Gaslini, Genova, Italy, [2]University of Genova, Genova, Italy

Background/Purpose: A new approach to the measurement of disease activity in juvenile idiopathic arthritis (JIA) is based on the Juvenile Arthritis Disease Activity Score (JADAS). The feasibility of the JADAS for use in standard clinical practice may be enhanced by implementing a 3-item version, which does not include the acute phase reactant. Inflammatory markers frequently are not obtained or available at a visit. The lack of this information would hinder the potential to make immediate therapeutic decisions based on the JADAS and, thus, the potential benefit of intensifying therapy. As for the original tool, the use of the cJADAS as a guide to pursuing tight disease control requires cutoff values to identify the target disease activity states. Aim of the study was to determine cutoff values in the cJADAS that correspond to the states of inactive disease (ID), minimal disease activity (MDA) and high disease activity (HDA), and to the parent/child acceptable symptom state (PASS/CASS).

Methods: For the selection of cutoff values, data from a clinical database including 609 patients were used. Optimal cutoffs were determined against external criteria by calculating the 75th percentile of cumulative score distribution for ID, MDA, PASS and CASS and the 25th percentile cumulative score distribution for HDA, and through receiver operating characteristic curve analysis. External criteria were based on formal definitions for ID and MDA, on the subjective rating of satisfaction with illness outcome by parents and patients for PASS and CASS, and on the therapeutic decision made by the attending physician at the time of the visit for HDA. MDA and HDA cutoffs were developed separately for oligoarthritis and polyarthritis. The choice of optimal cutoffs was made on clinical and statistical grounds. Cross-validation

was performed using 5 JIA patient samples that included a total of 1,421 patients, and was based on assessment of construct, discriminant, and predictive validity.

Results: The table shows the selected cutoff values for the cJADAS10 and the sensitivity (se) and specificity (sp) of each cutoff. In cross-validation analyses, the cutoffs revealed strong ability to discriminate between different levels of ACR Pedi response in 2 clinical trials (one on methotrexate and one on abatacept) and revealed good concordance with the subjective assessment of the disease state (remission, continued activity or flare) by the physicians and the parents. Furthermore, they proved able to predict functional and radiographic outcomes.

	cJADAS10 cutoff (se/sp)
Inactive disease	**1 (84.1/87.0)**
MDA oligoarthritis	**1.5 (75.4/91.7)**
MDA polyarthritis	**3.5 (96.8/94.7)**
PASS	**4 (75.6/91.4)**
CASS	**3.5 (77.5/86.5)**
HDA oligoarthritis	**7 (74.9/93.5)**
HDA polyarthritis	**11 (76.9/93.2)**

Conclusion: The cutoff values in the cJADAS that correspond to the states of ID, MDA, PASS, CASS, and HDA in JIA were developed. In cross-validation analyses, they proved to have strong construct and discriminant validity and ability to predict disease outcome.

Children With JIA Show Distinct Patterns Of Improvement In Their Health-Related Quality Of Life During The First Year On Treatment: Growth Mixture Modeling Of a Prospective Cohort Of Newly Diagnosed Patients. Bin Huang[1], Chen Chen[2], Stacey Niehaus[2], Hermine Brunner[1], Rina Mina[1] and Michael Seid[1]. [1]Cincinnati Children's Hospital Medical Center/University of Cincinnati School of Medicine, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: Health-related quality of life (HRQOL) is a key outcome in clinical care and research for children with JIA. Despite excellent clinical control and the availability of biologic treatment, HRQOL remains suboptimal in half of patients with JIA. The aims of the study were, for children with JIA during the first year post diagnosis with JIA, to: 1) identify distinct patterns of improvement in HRQOL; and 2) identify baseline disease, patient/parental characteristics that predict improvement in HRQOL.

Methods: Patients were enrolled within 6 months of diagnosis (N=230; 2–16 years of age), and followed up semi-annually. Patient HRQOL (Generic and Rheumatologic Core via self-report if ≥5 years and parental proxy-report) and non-medical patient/parental characteristics were obtained via survey during clinic visits; disease medical characteristics were obtained from clinical database. Primary outcome Generic PedsQL total score has mean 83 in healthy children, with <78.6 considered suboptimal. Longitudinal growth mixture model (GMM) was used to identify patterns (latent class) of improvement in HRQOL. Multivariable multinomial logistic regression with stepwise selection was used to predict GMM latent class membership using baseline measures; the model predictive ability was evaluated by the receiver operation characteristics (ROC, 1.0 being perfect).

Results: Table 1 presents study results for primary study outcome. Three distinct patterns of improvement were identified for patient self-report: 72% of patients maintained HRQOL at healthy norm (class I: 84.46+0.23×month), 21% improved (class III: 54.46+2.03×month), but 13% of patients with initial suboptimal HRQOL deteriorated over time (class II: 66.63-1.40×month). Modeling parent proxy-report, four latent classes were identified. The final logistic regression model for patient self-report found that less pain, adherence barriers, better self-efficacy managing emotion, and social support from parents are most predictive to more favorite pattern of HRQOL improvement (ROC 0.90). The final model for parental proxy-report found that parent- reports of less child pain and adherence barriers, better functional status and lower parental distress at baseline predicts more favorite pattern of improvement in child HRQOL (ROC 0.83).

Table 1. Latent Class of Pattern of Improvement (GMM Results) and their predictors (multinomial logistic regression results)

	HRQOL Self-Report (N = 180)			HRQOL Proxy-Report (N = 230)

JIA Subtype: Oligo vs. Poly		1.61 (0.21, 12.17)	0.21 (0.03, 1.45)		0.47 (0.19, 1.12)	1.21 (0.24, 6.15)	0.05 (0.00, 3.23)
JIA Subtype: Other vs. Poly		1.27 (0.21, 7.76)	1.19 (0.33, 4.27)		1.49 (0.65, 3.41)	0.45 (0.10, 2.15)	0.48 (0.05, 4.21)
Less Pain (PedsQL Rheu. Core)		0.96 (0.93, 1.00)	0.95*** (0.92, 0.98)		0.98** (0.96, 0.99)	0.94*** (0.91, 0.97)	0.87*** (0.81, 0.94)
Less Adherence Barriers (PedsQL Rheu. Core)		0.93** (0.89, 0.97)	0.93*** (0.90, 0.97)				
Childhood Health Assessment Questionnaire (CHAQ)					1.52 (0.81, 2.84)	7.62*** (3.06, 19.01)	0.50 (0.10, 2.59)
Better Self-Efficacy Emotion (CASE)		0.44* (0.22, 0.90)	0.54* (0.33, 0.88)				
Better Parental Social Support (SSC)		0.29 (0.05, 1.81)	0.13** (0.03, 0.50)				
More Parental Distress (SCL)					3.96** (1.56, 10.04)	5.67** (1.57, 20.46)	12.68*** (2.93, 54.93)

* indicates P<.05; ** indicates P<.01; *** indicates P<.001

Conclusion: During the first year on treatment, children newly diagnosed with JIA showed distinct patterns of improvement in HRQOL. Although a majority of JIA patients maintained or reached healthy norm, 28–43% of patients remained or deteriorated below healthy norm, despite therapy, suggesting at risk factors of poor HRQOL outcomes need to be better considered in the care of children with JIA.

Growth In Children and Adolescents With Juvenile Idiopathic Arthritis (JIA) After 2 Years Of Treatment With Etanercept: Results From The British Society For Paediatric and Adolescent Rheumatology (BSPAR) Etanercept Cohort Study. Lianne Kearsley-Fleet[1], Rebecca Davies[1], Mark Lunt[1], Kimme L. Hyrich[2], Taunton R. Southwood[3] and on Behalf Of The BSPAR Etanercept Cohort Study[1]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [3]Institute of Child Health, University of Birmingham and Birmingham Children's Hospital, Birmingham, United Kingdom

Background/Purpose: Etanercept (ETN) is licensed in Europe for use in children with Juvenile Idiopathic Arthritis (JIA) and is routinely prescribed after failure of other disease-modifying antirheumatic drugs. Children with JIA are reported to have restricted growth, with the estimated prevalence of short stature in JIA ranging from 1 to 17%. Chronic inflammation with or without corticosteroid use are thought to contribute. The objective of this study was to investigate the influence of ETN on vertical growth in patients with severe JIA over the initial 2 years of treatment.

Methods: The British Society for Paediatric and Adolescent Rheumatology (BSPAR) initiated a national ETN register in 2004. This analysis was restricted to children in the ETN cohort who had complete height data at baseline, 1 and 2 years. Patient height at each follow-up was age and sex matched with The WHO Child Growth Standards to calculate a z-score. The change in z-score from baseline to 2 years was calculated. Multiple imputation was used to account for missing data. Multivariate linear regression was used to identify factors associated with change in height z-score from baseline. Growth over 2 years was also compared in those who had and had not achieved Minimal Disease Activity (MDA; defined as polyarticular

JIA = PGA ≤ 3.4cm, PGE ≤ 2.1cm, ≤ 1 swollen joint; oligoarticular JIA = PGA≤ 2.5cm, no swollen joints) at 3 months.

Results: 191 ETN treated patients were included; median baseline age 11.0 (7.3–12.9), 65% female, and median disease duration at start of treatment 3.5 years (1.7–7.1) (Table). At baseline the mean height z-score was 0.74 (1.4) standards deviations below the reference mean. After 2 years of ETN treatment the mean height z-score increased by 0.29 (0.5) to a mean of 0.45 (1.4) standard deviations below the reference mean (p=0.041). There was a trend towards better improvement in growth over 2 years in children who achieved MDA at 3 months (42%) although this did not reach statistical significance (p=0.281) (Figure). In multivariable analysis, factors associated with an improvement in height z-score included lower baseline z-score (−0.112 per unit z-score [95% CI −0.163, −0.061] p<0.001) and no steroid use at baseline (−0.194 [95% CI −0.345, −0.043] p=0.012).

Table. Baseline Characteristics of the Cohort [N=191]:

	N (%)/median (IQR)
Female	124 (65%)
Age [years]	11.0 (7.3, 12.9)
Steroid Use	71 (38%)
Concomitant MTX	108 (58%)
Disease Duration [years]	3.5 (1.7, 7.1)
ILAR Category	
Systemic arthritis	25 (13%)
Enthesitis-related arthritis	14 (7%)
Oligoarthritis [Extended]	41 (22%)
Oligoarthritis [Peristent]	7 (4%)
Polyarthritis RF-	68 (36%)
Polyarthritis RF+	12 (6%)
Psoriatic arthritis	8 (4%)
Undifferentiated arthritis	15 (8%)
Disease Activity	
Active Joint Count	5.5 (3, 10)
Limited Joint Count	5 (2, 10)
Physician Disease Global (PGA)	4 (2, 6)
Parent Global Well-Being (PGE)	4.5 (2, 6.9)
CHAQ	1.1 (0.6, 1.9)
VAS	4.3 (2.4, 6.7)
ESR	18.5 (6, 41)
CRP	9 (5, 39)
JADAS	16.1 (10.3, 22.4)
Height z-score; mean (SD)	–0.74 (1.4)
1 year	–0.57 (1.4)
2 years	–0.45 (1.4)
BMI z-score; mean (SD)	0.67 (1.7)

Conclusion: ETN therapy was associated with a higher rate of improvement in height z-score over the first 2 years of therapy. Children who were not receiving concurrent steroids had a greater improvement, which may be a marker for less severe disease.

Body Surface Area-Based Dosing Approach Produced Comparable Golimumab Exposure Across Different Age Ranges After Subcutaneous Administration Of Golimumab In Pediatric Patients With Juvenile Idiopathic Arthritis. Jocelyn H. Leu[1], Alan M. Mendelsohn[1], Joyce Ford[2], Hugh M. Davis[1] and Zhenhua Xu[1]. [1]Janssen Research & Development, LLC., Spring House, PA, [2]Janssen Research and Development, LLC., Spring House, PA

Background/Purpose: To evaluate the pharmacokinetics (PK) of body surface area (BSA)-adjusted dosing of SC golimumab 30 mg/m^2 every 4 weeks (q4w) + methotrexate (MTX) in pediatric patients with juvenile idiopathic arthritis (JIA) and to determine the similarity in golimumab exposure between these patients and adult rheumatoid arthritis (RA) patients following SC administration of 30 mg/m^2 or 50 mg fixed dose q4w, respectively.

Methods: A dosing regimen of SC golimumab 30 mg/m^2 (maximum 50 mg) q4w + MTX in pediatric patients with JIA was predicted to be equivalent to SC golimumab 50 mg q4w + MTX in adult RA patients. GO-KIDS is a randomized-withdrawal, double-blind, placebo-controlled, parallel-group, multicenter Phase 3 trial of SC golimumab 30 mg/m^2 (maximum 50 mg) q4w + MTX in pediatric patients aged 2 to < 18 years old with active JIA despite current MTX therapy. PK, safety, and efficacy evaluations were performed every 4 weeks. Serum golimumab trough concentrations for 119 patients were determined via a validated, specific and sensitive immunoassay at weeks 0, 4, 8, 12 and 16 and were summarized by age.

Results: Treatment with SC golimumab 30 mg/m^2 q4w resulted in median trough serum golimumab concentrations of 1.05 to 1.28 μg/mL at steady state in three different age groups of JIA patients (Table). The steady-state trough concentrations in patients with JIA were similar to that seen in adult RA patients (median: 0.93 μg/mL; mean [SD]: 1.17 [0.99] μg/mL) who received golimumab 50 mg + MTX.

	<6 Years Old	≥6 to <12 Years Old	≥12 Years Old	Combined
N	17	29	63	109
Mean (SD) (μg/mL)	1.28 (0.620)	1.05 (0.670)	1.10 (0.801)	1.12 (0.740)
Median (μg/mL)	1.34	1.12	1.09	1.15

Conclusion: The study results confirmed that serum golimumab exposure in pediatric patients with JIA following administration of 30 mg/m^2 q4w was similar to that observed with 50 mg q4w in the adult RA population and was consistent across the various age groups studied.

The Efficacy Of Etanercept In Patients With Juvenile Idiopathic Arthritis With Inadequate Response To Infliximab As a First TNF Inhibitor. Ekaterina Alekseeva[1], Tatyana Bzarova[2], Anna Fetisova[2], Tatyana Sleptsova[2], Saniya Valieva[2], Kseniya Isayeva[2], Rina Denisova[2], Elena Mitenko[2], Evgeniya Chistyakova[2] and Nikolay Taybulatov[2]. [1]PRINTO, Genoa, Italy, [2]Scientific Center of Children's Health of RAMS, Moscow, Russia

Background/Purpose: Lack of efficacy of Methotrexate, primary and secondary resistance to biologics and their intolerance lead to juvenile idiopathic arthritis (JIA) of progression. Therefore, the problem of switching to another biologic agent is very urgent.

The objective of this work was to evaluate the efficacy and safety of Etanercept plus Methotrexate in patients with JIA in case of infliximab primary/secondary inefficacy or intolerance.

Methods: 32 children were examined, 12 of them had oligoarthritis, 20 - polyarthritis. The average age of the children was 9.6 (3.0; 17.0) years. Duration of disease was 5,0 (3,0;8).

All patients received Infliximab as a first biologic agent. It was withdrawn in 8 cases due to primary inefficacy within first 3 months of therapy, in 21 - due to secondary inefficacy, and in 3 - to intolerance. The secondary Infliximab inefficacy developed at different periods of drug administration: within 3 m in 2 children, 6 m - 3 children, 9 m - 4 children, 14 m - 2 children, 18 m - 3 children, 24 m - 5 children, 36 m - 1 child, and 48 m 1 child. All patients were switched to Etanercept. Etanercept was given in the form of ubcutaneous injections twice a week at a dose 0.4 mg/kg on the background of Methotrexate at a dose 15 mg/m^2/week. The observation period was 52 weeks. The efficacy of the therapy was assessed according to American College of Rheumatology (ACR-Pedi) criteria 50, 70, 90% improvement and remission criteria (Wallace, 2011).

Results: The perfect effect of switching to the second inhibitor was obtained both in patients with the Infliximab secondary inefficacy and intolerance and in patients with the primary inefficacy of the first TNFα inhibitor. The pain was arrested in the patients within 1 m (the number of painful joints decreased from 6 (3;10.5); to 0; g <0,001); the number of joints with active arthritis significantly decreased (6 (3,5;12); 1 (0;3,5) before and after Week 4, respectively; g <0,001); and the number of joints with limited motion also decreased (6 (13,5;3,5); 2 (1;6,2) before and after Week 4, respectively; g <0,01). Remission of arthritis was observed within 3 m. Joints function recovered completely in 30 patients within 6 m of follow up. The permanent normalization of the serum CRP level and ESR was observed in all patients within 9 and 2 m, respectively. Within 1 month improvement according to ACR pedi criteria 50, 70, 90% was achieved in 84, 66, and 55% of patients, respectively. Within 3 months improvement 50/70 was achieved in 92 and 85% of patients, respectively.

Inactive disease was registered in all patients within 6 months of follow up, the remission was observed in 85% of patients within 9 months and in 100% of patients within 12 months of observation. No withdrawals of the product due to primary, secondary inefficacy or intolerance were observed 1 year after switching. Adverse events were mild or moderate: acute bronchitis (1), local allergic reaction (2).

Conclusion: Switching of patients with JIA with inadequate response to Infliximab to Etanercept ensured the development of remission and contributed to almost complete recovery of joint function in all patients. In addition to high therapeutic efficacy, Etanercept demonstrated good tolerability.

Physical Activity In Children With Juvenile Idiopathic Arthritis (JIA): The LEAP (Linking Exercise, Activity and Pathophysiology in Childhood Arthritis) Study. Lori B. Tucker[1], Heather A. McKay[1], Leanne M. Ward[2], Jaime Guzman[3], Adam Baxter-Jones[4], Kiem Oen[5], Alan M. Rosenberg[6], Johannes Roth[2], Elizabeth Stringer[7], Rae SM Yeung[8], Kristin M. Houghton[1], Heather Macdonald[9], Debbie Ehrmann Feldman[10], Ciaran M. Duffy[11] and LEAP Study Investigators[12]. [1]University of British Columbia, Vancouver, BC, [2]University of Ottawa, Ottawa, ON, [3]BC Children's Hospital and University of British Columbia, Vancouver, BC, [4]College of Kinesiology, University of Saskatchewan, Saskatoon, SK, [5]University of Manitoba, Winnipeg, MB, [6]Royal University Hospital, Saskatoon, SK, [7]IWK Health Centre and Dalhousie University, Halifax, NS, [8]The Hospital for Sick Children and University of Toronto, Toronto, ON, [9]The University of British Columbia, Vancouver, BC, [10]Université de Montréal, Montreal, QC, [11]Children's Hospital of Eastern Ontario and University of Ottawa, Ottawa, ON, [12]BC Children's Hospital, Vancouver, BC

Background/Purpose: Although children with JIA have lower fitness levels than healthy peers, little is known about their level of habitual physical activity. The LEAP study is a prospective longitudinal multicentre study of children and teens with JIA, aimed at describing the trajectory of physical activity (PA) in JIA, and its relationship to disease factors, inflammation, quality of life, bone health and muscle function. Here we report PA levels of children and teens with JIA in early and late disease at study entry.

Methods: We enrolled patients with JIA (aged 8–16 y) at 12 pediatric rheumatology centres in Canada as either an inception cohort (early disease; within 6 months of diagnosis) or an established disease cohort (late disease; > 2yr after diagnosis). We assessed PA with a validated Physical Activity Questionnaire for children (PAQ-C, age 8–13 y) or teens (PAQ-A, age 14–16 y). This 7-day recall self-report tool has scores from 0 (no PA) to 5, high level ofPA. Participants record weekly PA across a wide range of activities and sports; normative data has been published. Patients completed a pain scale (VAS 0–100), the Childhood Health Assessment Questionnaire (CHAQ), and Juvenile Arthritis Quality of life Questionnaire (JAQQ). Examining physicians recorded physician global assessment of disease activity (VAS 0–100) and presence of active joints. We used descriptive statistics and two-way ANOVA to assess differences between groups. We used PAQ standard population normative values to compare to JIA patients (female 2.69, SD 0.62; male 3.0 SD 0.72).

Results: We collected complete PA data from 127 patients (85 F, 42 M, med age 9.5 y) from March 2012-April 2013. The early cohort included 49 patients (enrolled median 1.2 mo after diagnosis) and the late cohort included 78 patients (enrolled median 3.3 yr after diagnosis). Active arthritis was found in 48 patients, with a mean of 5.4 active joints (range 1–56); PGA was a mean of 12.7 (range 0–74). Overall mean PAQ score for the JIA patients was 2.6 (SD 0.73, range 1–4).Table 1 describes PAQ scores by sex, disease cohort, and presence of active arthritis. When controlled for sex, PAQ scores were significantly different between new onset and late disease. Factors significantly associated with PAQ score included patient-reported pain ($p=0.001$), CHAQ score ($p<0.0001$), JAQQ score ($p=0.0001$), number of active joints ($p=0.002$) and PGA ($p=0.001$); ESR and presence of joints with limited range of motion were not associated with PAQ score.

Table 1. PAQ scores in patients with JIA

	Total	Female (mean, SD)	Female z-score (mean, SD)	Male (mean, SD)	Male z-score (mean, SD)
Total	2.5 (O.73)	2.4 (0.66)	–0.46 (1.08)	2.71 (0.822)	–0.39(1.14)
Early disease	2.34 (0.73)	**2.31 (0.67)**	–0.60 (1.08)	**2.38 (0.85)**	–0.85 (1.18)
Late disease	2.60 (0.71)	2.45 (0.66)	–0.38 (1.07)	2.96 (0.72)	–0.05 (1.0)
Active joints present	2.27 (0.68)	**2.12 (0.6)**	–0.92 (0.97)	**2.56 (0.76)**	–0.61 (1.06)
No active joints	2.68 (0.71)	2.62 (0.63)	–0.10 (1.01)	2.81 (0.86)	–0.44 (1.14)

Conclusion: Children with JIA reported significantly lower levels of PA than healthy peers; this was especially evident in girls, patients with active arthritis, and early in disease. Disease activity, self reported quality of life and functional status may play a role in moderating PA in JIA. The longitudinal data collection of the LEAP study will provide important insight into factors associated with poor PA in JIA.

Uveitis In The Nordic Juvenile Idiopathic Arthritis Cohort; High Incidence, Frequent Complications, and Gender Associated Risk Factors. Ellen Nordal[1], Lillemor Berntson[2], Kristiina Aalto[3], Suvi Peltoniemi[3], Susan Nielsen[4], Troels Herlin[5], Anders Fasth[6] and Marite Rygg[7]. [1]University of Tromsø, Tromsø, Norway, [2]Uppsala University Hospital, Uppsala, Sweden, [3]Helsinki University Children's Hospital, Helsinki, Finland, [4]Juliane Marie Centret, Rigshospitalet, Copenhagen, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark, [6]University of Gothenburg, Gothenburg, Sweden, [7]St Olav University Hospital, Trondheim, Norway

Background/Purpose: Uveitis is the most common extra-articular manifestation of juvenile idiopathic arthritis (JIA). Both incidence and reported outcome varies, and population-based data are scarce. Early identification of asymptomatic cases is important in order to avoid complications and reduced vision. The pupose of the study was to identify incidence, risk factors and outcome of uveitis in a cohort of Nordic children with JIA followed for eight years in a population-based setting.

Methods: Consecutive cases of JIA from defined geographical areas of Denmark, Finland, Sweden and Norway with disease onset in 1997–2000 were included. The incidence of JIA in the study area in 1997–98 was 15 per 100 000. The study aimed to be as close to population-based as possible, as centers participated only if they were able to include all children diagnosed with JIA in their catchment area. Clinical and ophthalmologic data were registered at regular follow-up visits.

Results: Of 500 children included at baseline, 440 were followed for at least 7 years, and 389 (78%) had available ophtalmologic data. Uveitis developed in 89 (23%) of the 389 children; acute uveitis in 12 and chronic uveitis in 77 children. Fifty percent (6/12) of patients with acute uveitis were HLA-B27 positive. Young age at onset of JIA was a significant predictor of chronic uveitis in girls ($p=0.0001$), but not in boys ($p=0.47$). Also the presence of anti-nuclear antibodies (ANA Hep-2) ($p=0.003$) was a significant predictor in girls ($p=0.003$), but not in boys ($p=0.05$). Neither female gender nor oligoarticular onset JIA category was significantly associated with uveitis. Chronic uveitis was diagnosed at a median of 0.8 years after onset of disease, and in 88 % within the first four years after onset of disease. The longest interval between JIA onset and uveitis development was 8.6 years. Complications occurred in 39 eyes in 22 of the 89 patients with uveitis (25%), glaucoma occurred in 19 eyes and cataract in 14 eyes. At the last visit visus <0.5 in 10 eyes in 9 patients.

Conclusion: We found high incidence of uveitis among Nordic children with JIA, and the majority develop early after onset of disease. Age at onset of JIA and presence of ANA Hep-2 were associated with development of uveitis in girls, but not in boys. Complications were present seven years after onset of arthritis in 25%, showing that uveitis contributes significantly to morbidity and disability in children with JIA.

Declines In Levels Of Disease Activity and Physical Disability In Children With Juvenile Idiopathic Arthritis Seen In Standard Clinical Care Over The Last 25 Years. Alessandro Consolaro[1], Stefano Lanni[1], Francesca Minoia[1], Sergio Davì[1], Sara Dalprà[1], Benedetta Schiappapietra[1], Rossana Pignataro[1], Cristina Ferrari[1], Alberto Martini[2] and Angelo Ravelli[1]. [1]Istituto Giannina Gaslini, Genova, Italy, [2]University of Genova, Genova, Italy

Background/Purpose: Over the last 3 decades there have been important advances in the management of juvenile idiopathic arthritis (JIA), which include the introduction of methotrexate and, later on, the tendency toward its earlier initiation, the widespread use of intra-articular corticosteroid injections, and, more recently, the availability of the biologic response modifiers. Although this therapeutic progress is likely to have led to a marked improvement in the outlook of children with JIA, the prognostic impact of the newer therapeutic modalities is still poorly documented.

Methods: The clinical information recorded during visits made in children with JIA from January 1987 to March 2012 was retrieved from the study center database. Visits were divided in the following time intervals: 1987–1995 (n=826), 1996–2000 (n=1,337), 2001–2005 (n=2,022), 2006–2012 (n=2,317). Measures of disease activity included the physician's and parent's global ratings (both made on a 0–10 cm visual analog scale, VAS), the parent's pain rating (made on a 0–10 cm VAS) and the count of joints with swelling, pain on motion/tenderness and active disease. Measures of disability included the count of joints with restricted motion and a physical function tool (the Childhood Health Assessment Questionnaire, CHAQ before March 2007 and the Juvenile Arthritis Functionality Scale, JAFS after that date). To enable comparability of functional ability evaluations, both CHAQ and JAFS scores were converted to a 0–10 scale (0=best; 10=worst). Parent's global and pain ratings as well as functional ability assessment were not available for visits made prior to 1995 because before this year these assessments were made on scales not comparable with those used afterwards.

Results: A total of 6,502 visits made in 1,079 patients were identified. The mean (SD) values of disease activity and physical disability measures recorded in visits made at the various time intervals are presented in the table.

	Physician global (0–10)	Active joints	Restricted joints	Parent global (0–10)	Parent pain (0–10)	Physical function (0–10)
1988–1996	5.4 (2.8)	8.2 (9.4)	8.0 (10.4)	–	–	–
1996–2000	5.0 (3.4)	5.7 (8.4)	5.5 (9.5)	2.8 (2.5)	2.5 (2.5)	1.7 (2.0)
2001–2005	4.0 (3.5)	3.8 (5.7)	3.1 (6.2)	2.4 (2.5)	2.4 (2.7)	1.3 (1.8)
2006–2012	2 (2.7)	2.2 (4.5)	1.9 (4.2)	2.1 (2.5)	1.9 (2.6)	0.4 (0.9)

Conclusion: We observed a progressive decline in the levels of disease activity and physical disability over time among children with JIA seen from the mid of the 1980s to the 2010s. This finding confirms the notion that the recent advances in the management of JIA have led to a substantial improvement in disease outcome.

Plasma Nicotinamide Phosphoribosyltransferase Correlates With Markers Of Inflammation and May Predict Early Therapeutic Response To Low-Dose Methotrexate In Juvenile Idiopathic Arthritis. Ryan S. Funk, Leon van Haandel, Marcia Chan, Lanny J. Rosenwasser, Andrew Lasky, Maria F. Ibarra, Mark F. Hoeltzel, S.Q. Ye, J.S. Leeder and Mara L. Becker. Children's Mercy Hospital, Kansas City, MO

Background/Purpose: Despite a poor understanding of its biochemical role in the inflammatory process, nicotinamide phosphoribosyltransferase (NAMPT) has been implicated in a number of autoimmune conditions, and its inhibition has resulted in the reduction of pro-inflammatory cytokines. This study evaluates pre- and post-treatment plasma levels of NAMPT and other inflammatory biomarkers in response to initiation of low-dose methotrexate (MTX) in JIA.

Methods: Plasma samples from thirty-two JIA patients between 3 and 17 years of age were evaluated. Samples were collected prior to and 3 months after the initiation of MTX therapy, with twenty-six patients providing samples for both sampling periods. Plasma levels of IL-1α, IL-1β, IL-1RA, IL-6 and TNFα were determined by multiplex analysis (Milliplex MAP, Millipore). Plasma NAMPT levels were determined by competitive EIA. Therapeutic response was determined by Peds ACR and JADAS-71 scoring at 3 months on therapy. Statistical analyses were conducted by Spearman's rank correlation, simple linear regression, Wilcoxon signed rank, and Wilcoxon rank-sum tests, as appropriate.

Results: Plasma levels of Nampt were found to correlate with IL-1α (ρ=0.45, p<0.001), IL-1β (ρ=0.31, p<0.05), IL-1ra (ρ=0.49, p<0.001), IL-6 (ρ=0.34, p<0.01) and CRP (ρ=0.28, p<0.05). At 3 months on MTX, significant reductions in IL-1α (p<0.05), IL-1β (p<0.05), IL-1RA (p<0.001) and TNFα (p<0.05) were observed, however IL-6 and NAMPT did not decrease significantly. Patients achieving Peds ACR 30 had lower plasma IL-1α levels at 3 months than non-responders (4.2±7.7 vs. 17.5±14.3 pg/mL, p < 0.05), and JADAS-71 scores were associated with 3 month IL-6 (p<0.01) and TNFα (p<0.05) concentrations.

Pre-treatment NAMPT concentrations were lower in patients achieving a Peds ACR 50 response at 3 months (11.9±2.1 vs. 16.7±4.1 ng/mL, p< 0.01). In addition, an inverse relationship was observed between pre-treatment NAMPT concentrations and the change in active joint count (p<0.01) and change in JADAS-71 (p=0.06) from baseline to 3 months on MTX therapy.

Conclusion: Plasma NAMPT correlates with several cytokines observed in inflammatory arthritis, and although NAMPT concentrations did not significantly change over the treatment period, pre-treatment NAMPT concentrations were lower in JIA responders at 3 months. Therefore, NAMPT may provide a novel predictive biomarker of early therapeutic response in JIA patients treated with low-dose MTX.

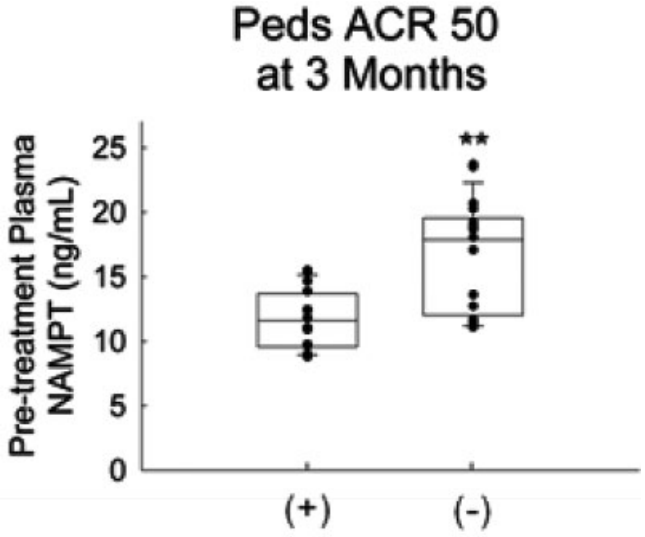

Figure. Pre-treatment plasma NAMPT levels are lower in JIA patients with a Peds ACR 50 response (+) as compared to those failing to meet the response criteria (−) after 3 months of low-dose MTX therapy (**, p-value < 0.01).

Preliminary Prospective Study Of Ultrasonography In Patients With Juvenile Idiopathic Arthritis In Clinical Remission: Subclinical Synovitis May Predict Flare? Vanessa B Miotto e Silva[1], Sônia A.V. Mitraud[1], Rita NV Furtado[2], Jamil Natour[1] and Maria Teresa Terreri[2]. [1]Escola Paulista de Medicina/Universidade Federal de São Paulo (EPM/UNIFESP), São Paulo, Brazil, [2]Escola Paulista de Medicina/Universidade Federal de São Paulo (EPM/UNIFESP), Sao Paulo, Brazil

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood and has variable prognosis, characterized by periods of activity and remission. Studies in patients with JIA in remission evaluated by ultrasonography (US) demonstrated presence of subclinical synovitis. It is unclear whether subclinical synovitis detected by

imaging techniques can predict progressive joint damage and functional deterioration in clinically asymptomatic joints. The aim of our study were: 1) to assess if the presence of subclinical synovitis detected by US in patients with JIA in remission may predict flare over a two years follow up and 2) to detect associations between disease activity and clinical, laboratory, functional and ultrasonographic features.

Methods: Inclusion criteria: oligoarticular and polyarticular JIA, clinical and laboratory remission, aged between 5 and 18 years. Clinical assessment: active/limited joint count, functional capacity by the Childhood Health Assessment Questionnaire, physician global visual analogue scale (VAS), patient global VAS, medications on use. The clinical, laboratory and ophthalmological evaluations were performed at baseline and every 6 months for up to 30 months. US assessed 17 joints bilaterally at baseline and every 12 months for up to 24 months. The US parameters evaluated were synovial hypertrophy and synovial blood flow on Power Doppler (PD). Subclinical synovitis was considered in the presence of moderate to severe degree of synovial hypertrophy and/or any positive synovial flow on PD. Flare was considered in the presence of at least one joint active until six months after each US evaluation.

Results: Thirty-five patients, 28 girls, mean age at assessment was 11.5 ± 3.7 years and mean age at disease onset was 4.4 ± 3.2 years, with a total of 1190 joints assessed. Fifiteen patients had persistent oligoarticular JIA, 11 extended oligoarticular and 9 polyarticular with negative rheumatoid factor. Regarding the type of remission, 8 were off medication and 27 were on medication, with an average time of remission of 1.9 ± 2.2 years. So far, a total of 74 evaluations were performed by US and 28 (37.8%) showed subclinical synovitis in at least one joint (28 with synovial hypertrophy and 9 with positive synovial flow on PD). There were 15 flares and in 8 of these episodes the US showed previously subclinical synovitis (p=0,166). There was also no association between positive synovial flow on PD and flares (p=0,676).

Conclusion: Subclinical synovitis was present in patients with JIA in clinical remission and may predict flare. These data are still preliminary.

Phenotypic Cluster Analysis Of Juvenile Idiopathic Arthritis: Relationship To International Leagues Of Associations For Rheumatology Classification Criteria. Jay Mehta[1], Juan Lin[2], Norman T. Ilowite[3] and for The CARRA Registry Investigators[4]. [1]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]The Children's Hospital at Montefiore, Bronx, NY, [4]Multiple Affiliations, Palo Alto, CA

Background/Purpose: The ILAR classification of Juvenile Idiopathic Arthritis (JIA) delineated categories of childhood chronic arthritis based on predominant clinical and laboratory features. As consensus criteria, they may not reflect clinically significant disease patterns that exist among patients. Phenotypic analysis of patient characteristics may provide a more optimal way to group patients. The aim of this study was to identify distinct clusters of JIA patients based on demographic, clinical, laboratory, and imaging features.

Methods: The source population was subjects with JIA enrolled in the CARRA Registry from May 2010 to April 2012, representing 60 centers throughout the US. Demographic, clinical, laboratory, and imaging data were gathered through patient reporting, physician assessment, and chart review. K-means clustering analysis was performed to identify distinct clusters of patients based on major features. Weighted gap statistics were used to estimate the number of clusters present in the dataset. Association between cluster assignment and physician-assigned ILAR JIA category was determined using Fisher's exact test.

Results: A total of 4810 subjects with JIA were enrolled in the CARRA registry during the enrollment period. 3872 patients had data for all items used in the cluster analysis and were therefore included. 10 distinct clusters were identified and are shown in Table 1. For each variable used in the analysis, at least one cluster was significantly different (p<0.001) from all other clusters. Fisher's exact test revealed that cluster assignment was highly correlated (p<0.001) to physician-assigned ILAR JIA category (see Table 2).

Table 1. Distribution of demographic, clinical, laboratory and imaging variables among clusters in JIA patients

Cluster #	Whole cohort	1	2	3	4	5	6	7	8	9	10

Table 2. Comparison of cluster assignment to physician-assigned ILAR JIA category

Cluster #	Whole cohort	1	2	3	4	5	6	7	8	9	10
N (%)	3872	159	284	219	829	294	285	1006	328	348	120
Physician-assigned JIA category											
Systemic	7.8	0.6	95.8	2.3	0.8	0.0	1.1	1.2	0.0	0.6	0.8
RF-negative polyarticular	29.7	1.9	2.5	33.8	3.3	26.9	24.2	69.1	9.1	46.0	6.7
RF-positive polyarticular	6.9	88.6	0.7	4.1	0.6	0.3	0.7	7.7	1.2	8.3	0.0
Oligoarticular - persistent	29.4	3.8	0.0	30.1	79.0	52.7	51.9	1.1	4.6	21.3	8.3
Oligoarticular - extended	7.6	0.6	0.4	8.2	2.4	13.9	13.0	12.0	2.7	12.4	2.5
Psoriatic	5.6	0.6	0.4	8.7	4.0	3.1	1.4	4.0	6.7	2.6	65.8
Enthesitis-related	10.1	0.0	0.4	6.8	6.8	2.0	4.9	3.2	70.1	6.3	12.5
Undifferentiated	1.9	1.9	0.0	3.7	2.5	0.7	2.1	1.7	1.5	1.7	3.3

Conclusion: Children with JIA have distinct phenotypical patterns of demographics, and clinical, laboratory, and imaging findings. However, patient groupings based on these patterns may not be of more utility than the currently available, consensus-driven, categorizations. Further registry data that provides patient outcome data, which is actively being collected, will be of use to determine whether phenotypic clustering has prognostic value.

Higher Disease Activity In Psoriatic Arthritis Is Associated With Elevated Total Cholesterol and Triglycerides. Monalyn Labitigan[1], Asha Shrestha[1], George W. Reed[2], Robert P. Magner[3], Nicole Jordan[1], Joel M. Kremer[4], Jeffrey D. Greenberg[5], Asena Bahce-Altuntas[1] and Anna R. Broder[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]CORRONA, Inc., Southborough, MA, [3]University of Massachusetts Medical School, Worcester, MA, [4]Center for Rheumatology, Albany Medical College, Albany, NY, [5]New York Hospital for Joint Diseases, New York, NY

Background/Purpose: Psoriatic Arthritis (PsA) is linked to both obesity and an increased cardiovascular risk. However, the relationship between PsA disease activity and lipids, a major cardiovascular risk factor, has not been well studied. We assessed the relationship between PsA disease activity and lipid profiles in the Consortium of Rheumatology Researchers of North America (CORRONA) Registry.

Methods: We performed a cross-sectional analysis of all CORRONA participants followed from 6/2008 to 10/2012 with complete data for lipids and disease activity. Longitudinal subanalysis of PsA patients with paired lipid measurements on stable statin doses was also performed. Moderate to high disease activity was defined as CDAI>10 and/or presence of enthesitis/dactylitis. Abnormal lipids were defined as: total cholesterol (TC)>200 mg/dl (5.17 mmol/L), High Density Lipoprotein (HDL)<40 mg/dl (1.0 mmol/L, men), HDL<50 mg/dl (1.3 mmol/L, women), Low Density Lipoprotein (LDL)>100 mg/dl (2.59 mmol/L), Triglycerides (TG)>150 mg/dl (1.7 mmol/L), and atherogenic ratio (TC/HDL) >5. Models were adjusted for gender, duration of PsA, mHAQ, disease-related medication use, smoking, body mass index (BMI), diabetes (DM), use of cholesterol lowering medications and fish oil.

Results: Of 5713 PsA patients, 725 had complete data for lipids and disease activity. 284/725 (39%) had moderate to high disease activity. Compared to the low disease activity group, the moderate to high disease activity group had more women (57% vs 46%, p=0.006) and smokers (12.7% vs 7.7%, p=0.029), and had shorter disease duration (mean 8.7 vs 11.2 years, p=0.001). Moderate to high disease activity patients were more likely to be prescribed prednisone (13% vs 4.5%, p<0.001) and non-biologic DMARDs (63% vs 51%, p=0.002), but were less likely to be prescribed anti-TNFs (57% vs 66%, p=0.015). Mean BMI in the moderate to high and low groups were 31.7kg/m2 and 30.6kg/m2, respectively, p=0.02. There were no differences between age, rate of DM, frequency of cholesterol lowering medications, and fish oil use.

Moderate to high disease activity was associated with higher odds of TC>200 mg/dl, OR 1.6 (1.1, 2.2 95%CI), p=0.01, and higher odds of TG>150 mg/dl, OR 1.6 (1.2, 2.3 95% CI), p=<0.01. Enthesitis/dactylitis was positively associated with TC>200 mg/dl, OR 1.6 (1.1, 2.5), p=0.02. There was no significant association found between disease activity and other lipid measures in the moderate to high disease vs low disease groups.

In the longitudinal analysis of 54 PsA patients with paired lipid measurements, higher PsA activity was associated with higher TG levels (β 3.85, p=0.02) and lower HDL levels (β −0.62, p<0.01) adjusted for duration between visits.

Conclusion: Moderate to high disease activity in PsA is associated with increased levels of TC and TG. Increasing disease activity is associated with increasing TG and decreasing HDL. This pattern of dyslipidemia in PsA is similar to the pattern observed in obesity. Our findings suggest a commonality between PsA disease mechanisms and lipid metabolism providing a possible link between obesity, PsA and cardiovascular disease.

Arthritis and Nail Involvement In Patients With Plaque-Type Psoriasis. Odirlei Andre Monticielo[1], Karen Regina Rosso Schons[2], Cristiane Faccin Knob[2], Walter Neumaier[2], Maristela de Oliveira Beck[2] and André Avelino Costa Beber[2]. [1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Universidade Federal de Santa Maria, Santa Maria, Brazil.

Background/Purpose: Psoriasis is a chronic disease that presents in individuals of all ages, affecting skin, nails and joints. Nail changes are estimated to be present in 10–80% of psoriatic patients at some point in their lives, with consequent aesthetic and functional repercussions and quality of life impairment. In Brazil, there are no epidemiological studies on nail psoriasis (NP) so far. The aim of this study is to evaluate the nails of a sample of psoriatic patients from the south of Brazil, determining the prevalence of nail involvement and its association with arthritis and other clinical features.

Methods: This is a cross-sectional study that evaluated 65 outpatients with plaque-type psoriasis treated at the Hospital Universitário de Santa Maria - RS, from January 2012 to March 2013. Skin severity was evaluated using the PASI method and the nail changes were assessed using the NAPSI score. Psoriatic arthritis was determined by CASPAR criteria. Demographic variables were assessed by specific questionnaire.

Results: The prevalence of NP was 46.1%. Patients with NP had an average of 8.1±5 nails affected and the main morfological sign found was onycholysis (80%). Most patients (63.3%) reported functional or aesthetic discomfort related to nails involvement. When compared to patients without nail changes, patients with NP showed lower mean age of onset of psoriasis (27,6±14,9 vs. 42,7±15,9 years, p=0.001) and longer duration of the disease (17,5±10,7 vs. 9,1±9,7 years, p=0.003). Patients with NP also had higher PASI score (11,1±8,3 vs. 6,5±6,1, p=0.024), higher frequency of family history of psoriasis (40% vs. 7,4%, p=0.011) and higher frequency of psoriatic arthritis (43,3 vs. 3,7, p=0,002).

Conclusion: The NP is still poorly studied, despite its clinical consequences such as pain, functional limitation and aesthetic disorders. Its importance as a predictor of joint involvement and more severe cutaneous disease was demonstrated by this study. Family history and early onset of disease were also associated with NP.

Maintenance Of Efficacy and Safety Of Ustekinumab In Patients With Active Psoriatic Arthritis Despite Prior Conventional Nonbiologic and Anti-TNF Biologic Therapy: 1-year Results Of a Phase 3, Multicenter, Double-Blind, Placebo-Controlled Trial. Christopher T. Ritchlin[1], Iain B. McInnes[2], Arthur Kavanaugh[3], Lluis Puig[4], Proton Rahman[5], Carrie Brodmerkel[6], Shu Li[6], Yaung-Kaung Shen[6], Mittie K. Doyle[6], Alan M. Mendelsohn[6] and Alice B. Gottlieb[7]. [1]University of Rochester, Rochester, NY, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of California, San Diego, La Jolla, CA, [4]Universitat Autònoma de Barcelona, Barcelona, Spain, [5]Memorial University, St. Johns, NF, [6]Janssen Research & Development, LLC., Spring House, PA, [7]Tufts Medical Center, Boston, MA.

Background/Purpose: Ustekinumab (UST) has demonstrated substantial efficacy and an acceptable safety profile, and is approved for use, in treating moderate-to-severe psoriasis. UST has also demonstrated efficacy in pts with active psoriatic arthritis (PsA) at wk24 in the Phase 3, multicenter, PBO-controlled PSUMMIT2 trial. Results through wk52 PSUMMIT 2 are presented herein.

Methods: 312 adults with active PsA were randomized to UST 45mg or 90mg at wk0, wk4, and q12w or PBO at wks0, 4, and 16 followed by crossover to UST 45mg at wk24, wk28, and wk40. Randomization was stratified by site, weight (≤100kg, >100kg) and baseline MTX use, and pts previously treated with biologic anti-TNF agents were eligible. At wk16, pts with <5% improvement in both tender/swollen joint counts entered blinded early escape (PBO→UST 45mg, 45mg→90mg, 90mg→90mg). The primary endpoint was ACR20 at wk24. Secondary endpoints were HAQ-DI, ACR50, ACR70, and ≥75% improvement in the Psoriasis Area and Severity Index (PASI75).

Results: Anti-TNF-experienced pts had more active disease at baseline than anti-TNF-naïve pts. More UST (43.8%-combined, 43.7%-45mg, 43.8%-90mg) than PBO (20.2%) treated pts had ACR20 at wk24 (all P<0.001). Significant treatment differences were also observed for ACR50 and PASI75 response at wk24 (table). Efficacy was sustained through wk52. At wk52, 51% and 44% of pts who were and were not, respectively, receiving MTX at baseline had ACR20. UST efficacy at wk52 was more robust in anti-TNF-naïve (ACR20 59–73%) than anti-TNF-experienced (37–41%) pts and pts who had previously received 1 (50–55%) vs. 2 (13–39%) or ≥3 (13–30%) anti-TNF agents. UST was generally well tolerated, with no deaths or tuberculosis and similar rates of AEs (78.6%-45mg, 77.9%-90mg), serious AEs (5.8%-45mg, 5.8%-90mg), and AEs leading to discontinuation (5.8%-45mg, 3.8%-90mg) reported across doses through wk60. Two pts, both anti-TNF-experienced, had malignancies (breast cancer-45mg, squamous cell carcinoma-90mg); 2/287 (0.7%) of UST-treated pts (both 90mg) had serious infections. Three pts (2–45mg, 1–90mg) had major adverse cardiovascular events (myocardial infarctions) through wk60, all had multiple cardiovascular risk factors and prior anti-TNF experience.

Table. Summary of efficacy among randomized PsA pts

(N)	Placebo (104)	UST 45 mg (103)	UST 90 mg (105)	Combined UST (208)
BASELINE				
Anti-TNF experienced pts				
Tender(0–68)/swollen (0–66) joints	24/11	24/15	26/13	25/14

WEEK 52 EFFICACY (N)	**Placebo→UST 45 mg, (**77)	**UST 45 mg** (94)	**UST 90 mg** (95)	**Combined UST** (189)
ACR20/ACR50/ACR70	55.8/28.6/15.6%	46.8/27.7/12.8%	48.4/26.3/17.9%	47.6/27.0/15.3%
ACR20 by baseline MTX use (Yes/No)	51.2/61.1%	46.0/47.7%	56.5/40.8%	51.0/44.1%
ACR20 – anti-TNF-naïve/ exper	73.0/40.0%	60.0/37.0%	58.5/40.7%	59.3/38.9%
ACR20 by no. of prior anti-TNF agents (1/2/ ≥3)	54.5/12.5/30.0%	52.4/25.0/29.4%	50.0/38.9/12.5%	51.0/32.4/24.0%
% improve dactylitis/ enthesitis[1]	33.3/100.0%	36.7/95.0%	60.0/90.9%	50.0/95.0%
PASI75[2]	56.1%	56.5%	64.4%	60.6%

*, **, *** indicate p < 0.05, 0.01, 0.001, respectively, versus placebo. Data are reported as % of pts or median. [1]Among patients with dactylitis or enthesitis at baseline. [2]Among pts with ≥ 3% body surface area psoriasis involvement at baseline (mean PASI scores at baseline were 11.3 for placebo, 13.4 for UST 45 mg, and 12.1 for UST 90 mg).
ACR=American College of Rheumatology, HAQ-DI=Health Assessment Questionnaire-Disability Index, PASI=Psoriasis Area and Severity Index, TNF=tumor necrosis factor, UST=ustekinumab, VAS=visual analogue scale.

Conclusion: Both UST doses (45/90 mg q12w) yielded significant and sustained improvements in PsA signs/symptoms with favorable and comparable safety profiles. UST was effective in both anti-TNF-naïve and anti-TNF-experienced pts, with greater efficacy in anti-TNF naïve pts and anti-TNF-experienced pts previously treated with 1 or 2 anti-TNF agents.

Risk Of Cardiovascular Events In Patients With Psoriatic Arthritis, Psoriasis, and Rheumatoid Arthritis: A General Population-Based Cohort Study.

Alexis Ogdie[1], Yiding Yu[2], Kevin Haynes[3], Samantha Maliha[1], Thorvardur Love[4], Andrea Troxel[3], Sean Hennessy[1], David Margolis[1], Stephen Kimmel[1], Nehal N. Mehta[5], Hyon K. Choi[6] and Joel Gelfand[3]. [1]University of Pennsylvania, Philadelphia, PA, [2]Brigham and Women's Hospital, Boston, MA, [3]University of Pennsylvania., Philadelphia, PA, [4]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [5]NHLBI, National Institutes of Health, Bethesda, MD, [6]Boston University School of Medicine, Boston, MA.

Background/Purpose: Psoriatic arthritis (PsA), psoriasis, and rheumatoid arthritis (RA) are associated with an increased risk for major adverse cardiovascular events (MACE; myocardial infarction (MI), cerebrovascular accidents (CVA), and cardiovascular death) but are also associated with traditional cardiovascular risk factors (TCVRFs). Little is known about the risk for MACE in patients with PsA after adjusting for TCVRFs or relative rates of MACE among these 3 diseases. We aimed to determine the risk of MACE among patients with PsA compared to psoriasis without known PsA, RA, and the general population after adjusting for TCVRFs.

Methods: Longitudinal cohort studies were conducted for the following outcomes: cardiovascular death, MI, CVA, and MACE (composite outcome). Data from 1994–2010 from The Health Improvement Network (THIN), a primary care medical record database in the United Kingdom, were included. Patients aged 18–89 were selected if they had a diagnosis of PsA, RA, or psoriasis (PsA, RA, psoriasis, MI, and CVA have been validated in THIN). Up to 10 unexposed controls matched on practice and start date within the practice were selected for each patient with PsA. Cox proportional hazards models were used to calculate the relative hazards for each of the outcomes adjusted for TCVRFs (age, sex, diabetes, smoking, hypertension, hyperlipidemia) and additional confounders which changed the main effects by >10%. *A priori* we hypothesized an interaction between disease status and disease modifying anti-rheumatic drug (DMARD) use and this was significant ($p<0.02$) for all endpoints.

Results: Patients with PsA (8,706), RA (41,752), psoriasis (138,424) and unexposed controls (81,573) were identified. After adjusting for TCVRFs, the risk of MI was increased in all disease groups although not statistically significant in patients with psoriasis without a DMARD prescription. The risk for MACE was increased in all disease groups but not significant in patients with PsA not prescribed a DMARD. These results were not affected by sensitivity analyses varying definitions of the outcomes, restricting to patients followed regularly, utilizing multiple imputation for smoking and body mass index, and imputing additional DMARD users.

Conclusion: Patients with PsA, psoriasis, and RA are at increased risk for MACE, particularly MI, compared to the general population but patients with RA and severe psoriasis have a substantially higher risk than unexposed controls.

Table. Incidence Rate and Hazard Ratios (95% CIs) for Major Adverse Cardiovascular Events

COMPOSITE OUTCOME		**Incidence per 1000 PYs**	**Age-Sex Adjusted HR**	**Fully Adjusted* HR**
Unexposed		5.03	Ref	Ref
PsA	No DMARD	6.76	1.34 (1.13–1.58)	1.24 (1.03–1.49)
	DMARD	4.61	1.15 (0.94–1.40)	1.16 (0.93–1.43)
RA	No DMARD	13.54	1.43 (1.33–1.53)	1.38 (1.28–1.50)
	DMARD	11.09	1.62 (1.51–1.74)	1.57 (1.50–1.70)
Psoriasis	No DMARD	5.41	1.17 (1.11–1.23)	1.08 (1.02–1.14)
	DMARD	6.50	1.31 (1.13–1.52)	1.31 (1.12–1.53)
MYOCARDIAL INFARCTION		**Incidence per 1000 PYs**	**Age-Sex Adjusted**	**Fully Adjusted***
Unexposed		1.96	Ref	Ref
PsA	No DMARD	3.02	1.46 (1.15–1.87)	1.36 (1.04–1.77)
	DMARD	2.28	1.33 (1.01–1.76)	1.34 (1.00–1.81)
RA	No DMARD	4.23	1.36 (1.21–1.54)	1.33 (1.17–1.51)
	DMARD	4.87	2.02 (1.82–2.24)	1.96 (1.75–2.19)
Psoriasis	No DMARD	2.20	1.18 (1.09–1.29)	1.07 (0.98–1.17)
	DMARD	2.67	1.36 (1.09–1.71)	1.31 (1.03–1.65)

*The fully adjusted model includes Age, Sex, Diabetes, Hypertension, Hyperlipidemia, Start Year in the Cohort, Smoking Status.
†DMARDs included azathioprine, leflunomide, hydroxychloroquine, chloroquine, methotrexate, sulfasalazine, mycophenolate, adalimumab, etanercept, and infliximab. Patients with psoriasis were considered to be on a "DMARD" if they had been prescribed etretinate, acitretin, hydroxyurea, PUVA or phototherapy.

Anti-Citrullinated Protein Antibodies In Patients With Psoriatic Arthritis: Clinical Relevance. Doquyen H. Huynh[1], Carol Etzel[2], Vanessa Cox[3], J. M. Kremer[4], Jeffrey D. Greenberg[5] and Arthur Kavanaugh[6]. [1]UC San Diego School of Medicine, San Diego, CA, [2]CORRONA, Inc, Southborough, MA, [3]UT MD Anderson Cancer Center, Houston, TX, [4]Albany Medical College and The Center for Rheumatology, Albany, NY, [5]NYU Hospital for Joint Diseases, New York, NY, [6]University of California San Diego, San Diego, CA.

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) have been considered a relatively specific marker for rheumatoid arthritis (RA), and may play a role in its pathogenesis. In recent years, it has been shown that ACPA can be found at a greater prevalence among psoriatic arthritis (PsA) patients (approximately 8% or more) than in the general population. Also, ACPA have been isolated from the synovial fluid of PsA patients. Several small anecdotal reports have suggested that PsA patients with positive ACPA may have greater swollen/tender joint counts with more deformities and radiologic changes than ACPA negative PsA patients; however, other studies have suggested no difference. The present study evaluated whether clinical features differ between PsA patients who are ACPA (+) from those who are ACPA (−).

Methods: A cross sectional study of patients with physician diagnosed PsA in the CORRONA database, a large national registry of patients with RA and PsA. ACPA was performed in local labs. ACPA (+) and ACPA (−) PsA patients were evaluated for differences in disease activity, disease severity and immunomodulatory medication use. Evaluations included: tender joint count, swollen joint count, HAQ, patient global assessment, physician global assessment, DAS 28, CDAI, presence of enthesitis, presence of dactylitis, skin psoriasis activity, presence of Sjogrens symptoms, and radiographic changes (defined by presence or absence of erosions, joint space narrowing and joint deformity). ACPA (+) and ACPA (−) groups were also assessed for smoking status and the presence of rheumatoid factor (RF) and repeat analysis was done to determine if RF presence contributed to any differences.

Results: Through 2012, there were 5,363 PsA patients in the CORRONA database, 17.7% of whom had test results for ACPA: 842 were ACPA (−) and 116 ACPA (+). There was no significant differences in any measures of disease activity or disease severity (including radiographic changes) or the use of immunomodulatory medications between ACPA (+) and ACPA(−) patients. Interestingly, ACPA (+) patients had a lower average tender joint count (a mean difference of −0.89; 95% CI −1.78, −0.02). Further stratification into subgroups based upon the presence of RF did not reveal any clinically important differences with the exception of ACPA (+)/RF (−) group who had a higher swollen joint count (a mean SJC of 4.57, p 0.003). There was also no difference in smoking status amongst ACPA (+) and ACPA (−) PsA patients.

Conclusion: In a large cohort of PsA patients in clinical practice, there were no differences in disease activity, disease severity (including radiographic changes) or the use of immunomodulatory medications between ACPA (+) and ACPA (−) PsA patients. The data suggest that different than for RA, the presence of ACPA(+) may represent only an epiphenomenon in PsA. The fine specifities of ACPA in PsA patients have not yet been defined.

Incidence of Herpes Zoster in Patients with Psoriatic Arthritis. Devy Zisman[1], Haim Bitterman[2], Ilan Feldhamer[3], Doron Comanesther[3], Erez Battat[3], Sari Greenberg-Dotan[3], Sarit Cohen[4] and Arnon-Dov Cohen[3]. [1]The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel, [2]Chief Physician's Office, Clalit Health Services, Haifa, Israel, [3]Chief Physician's Office, Clalit Health Services, Tel Aviv, Israel, [4]Carmel Medical Center, Haifa, Israel.

Background/Purpose: To assess the incidence of Herpes Zoster (HZ) in patients with psoriatic arthritis (PsA) and its relation to treatment regimen: Traditional disease-modifying anti-rheumatic drugs (c-DMARDs) versus anti-TNF α agents.

Methods: A retrospective cohort study of patients with PsA insured by Clalit Health Services between 2006 and 2012 was conducted. The incidence of HZ events was calculated among four groups of patients with PsA: no DMARDS treatment (Group A); treatment with c-DMARDS (Group B); treatment only with anti-TNF α agents, including infliximab, adalimumab or enbrel (Group C); treatment with an anti-TNF α agent (infliximab, adalimumab or enbrel) in combination with c-DMARDS (Group D). For each group, incidence rates of HZ events were calculated as well as hazard ratios (HR) adjusted for age, sex, steroid use, comorbidities index, current and previous treatment regimens. Crude incidence rates were calculated as the number of HZ infections per 1000 follow-up patient-years (under specific treatment). Survival analysis methods (Cox regression Andersen-Gill models) were applied to identify risk factors for HZ and to estimate the contribution of anti-TNF α treatment and time-independent and time-dependent covariates at the first development of HZ reactivation.

Results: The study population consisted of 3158 patients, with a mean age of 52.31±14.74 years; 1479 (46.8%) were male. During the accumulated study period of 15763 years, 156 HZ events occurred. The incidence rate (95% Confidence Interval (95%CI)) of HZ events per 1000 treatment years among Groups A-D were 8.59 (6.72–10.97), 10.28 (8.05–13.14), 9.45 (5.53–16.11), 18.42 (11.53–29.30), respectively. In a multivariate analysis, only age (HR=1.016, 95% CI 1.003–1.03, P=0.015), treatment with steroids (HR=1.079, 95% CI 1.027–1.133, p=0.003) and a combination of anti-TNF α agents and c-DMARDS (HR =2.29, 95%CI=1.204–4.358, p=0.012) were statistically significantly associated with the time until the first HZ event. Treatment with c-DMARDS, anti-TNF α agents alone, previous treatment with biological agents, sex and the Charlson Comorbidity Index Score did not statistically significantly influence the time to the first HZ event.

Conclusion: In the study population the incidence rate of an HZ event is 9.9 per 1000 treatment years. The risk of a first HZ event increased statistically significantly with patient age, treatment with steroids, and a combination of an anti-TNF α agent and c-DMARDS, but not with c-DMARDS or anti-TNF α therapy administrated separately.

Responsiveness To Change Of a Global Ultrasound Assessment Score In Psoriatic Arthritis Patients. Maria Laura Acosta Felquer[1], Santiago Ruta[1], Javier Rosa[1], David A. Navarta[1], Carla Saucedo[1], Ricardo Garcia-Monaco[2], Mirtha Sabelli[1] and Enrique R. Soriano[3]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, Argentina, [3]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina.

Background/Purpose: Psoriatic arthritis (PsA) manifests clinically in several ways, including arthritis, enthesitis, and dactylitis,. Assessment of disease activity in PsA should ideally record each feature. An Ultrasound (US) composite score could help in this evaluation. The objective was to analyze the responsiveness to disease activity change of a US global assessment score, including entheses tendons and joints in patients with PsA.

Methods: Consecutive PsA patients (CASPAR criteria), initiating or changing traditional DMARDs or TNF inhibitors as decided by their treating rheumatologists were included. US examination was performed by an experienced rheumatologist using both grey scale (GS) and power Doppler (PD). The following areas were assessed: 2–3 MCP joints, 2–3 proximal PIP joints, wrists, knees and second and fifth MTP joints. Knee and heel enthesis were examined. Both second and third flexor and fourth and sixth extensor tendons of the hands were examined for tenosynovitis. Synovitis, tenosynovitis and enthesitis were defined according to OMERACT definitions. Both GS and PD synovitis were graded on a semiquantitative scale from 0 to 3, and enthesis and tendons with a 0 to 1 scale. For each one of the structures examined (enthesis, tendons and synovial) an initial US score was obtained by multiplying the semiquantitative scale by the number of sites involved. Finally adding the US structure specific scores a global US score was constructed. Physical examination was performed before US examination and included swollen and tender joint counts, patient's pain and disease activity VAS, HAQ, DAS28, CDAI, SDAI, PASE, PASI, CPDAI, Leeds Enthesitis Index (LEI) and BASDAI. CRP level and ESR were obtained within 48 hours. All patients underwent both clinical and ultrasound assessment at the day entering the study and at three months follow-up.

Results: 26 patients (69% males, mean (SD) age: 51 (13), mean disease duration 3 years (95% CI: 1.45–4.66) were included. Eleven patients initiated

therapy with DMARDs, 6 changed DMARDs, 3 added second DMARDs, and finally, 6 patients started therapy with TNF inhibitors. Basal and three months follow up data are shown in the table. All features except LEI improved. Global Ultrasound assessment score and their different components also showed significant improvement after therapy change. After three months of treatment 14 (54%) patients achieved Minimal Disease Activity (MDA). The US score showed an area under the ROC curve of 0.64 (95% CI:0.43–0.87), for discrimination of non MDA and a score equal or greater than 10 showed 75% sensitivity and 64% specificity for the diagnosis of non MDA.

	Basal assessment, mean (95% CI)	Three months follow-up assessment, mean (95% CI)	P value (Wilcoxon signed Rank test)
DAS28	4.05 (3.4–4.7)	3.1 (2.3–3.8)	<0.0001
BASDAI	5.6 (4.1–7.1)	3.4 (1.9–5)	<0.0001
HAQ	0.84 (0.43–1.25)	0.55 (0.18–0.92)	0.0005
LEI	0.56 (0.01–1.1)	0.125 (0–0.3)	0.1178
Dactylitis	1.15 (0.41–1.9)	0.5 (0.01–1.01)	0.0017
ESR	21 (8.1–33.9)	15.3 (7.5–23.1)	0.0058
CRP	6.8 (2.3–11.2)	2.2 (0.87–3.5)	0.0091
PASI	2.8 (0.86–4.8)	1.8 (0.1–3.6)	0.0001
PASE	40.6 (32.9–48.2)	34.1 (25.8–42.3)	0.0003
CPDAI	4.5 (2.9–6.1)	1.9 (0.06–3.6)	<0.0001
CDAI	17.7 (11.9–23.5)	9.7 (4.5–14.9)	<0.0001
SDAI	18.8 (13–24.5)	10.2 (4.8–15.6)	0.0008
% MDA (95% CI)	3.8 (0.9–19.6)	54 (33–73)	0.0004 (chi2)
Ultrasound joint score	14.1 (6.7–21.5)	7.2 (2.6–11.9)	<0.0001
Ultrasound tendon score	1.3 (0.3–2.3)	0.3 (0.008–0.63)	0.0010
Ultrasound enthesitis score	9.75 (7.2–12.3)	5.1 (3.6–6.7)	<0.0001
Ultrasound total score	25.2 (17.1–33.2)	13.3 (8.1–18.5)	<0.0001

Conclusion: This new global ultrasound score showed responsiveness to treatment change over the short term in patients with PsA. Further validation in a larger population is needed.

Abnormal Imaging and Increased Osteoclast Precursors In a Psoriasis Cohort Are Associated with New Onset of Psoriatic Arthritis. Ralf G. Thiele, Yahui Grace Chiu, Francisco A. Tausk, Bethany A. Marston, Gregory Dieudonne, Vaseem Chengazi, Michelle Smith, Sharon Moorehead, Rick Barrett and Christopher T. Ritchlin. University of Rochester, Rochester, NY.

Background/Purpose: Psoriasis (Ps) precedes joint inflammation by about 10 years in patients who develop psoriatic arthritis (PsA). Several studies have documented abnormal musculoskeletal imaging findings and we found elevated osteoclast precursor (OCP) frequency in Ps patients without musculoskeletal signs or symptoms. The association of imaging abnormalities and OCP frequency with arthritis onset in a prospective psoriasis cohort, however, has not been examined.

Methods: Ps patients with >5 years of psoriasis or >10% body surface area (any disease duration) were enrolled if they scored less than 36 on the Psoriatic Arthritis Screening and Evaluation (PASE) questionnaire and showed no active arthritis or enthesitis on rheumatologic exam. All patients were imaged with a 3-phase bone scan and Power Doppler Ultrasound (PDUS) of joints and entheses. If the bone scan revealed evidence of inflammation, a gadolinium enhanced 3T MRI was performed on the joint with the highest scintigraphy signal. All imaging studies were analyzed by 2 radiologists. A diagnosis of PsA was confirmed by the CASPAR criteria on follow-up annual exams. Blood samples were drawn for OCP quantification after 8-day cell culture.

Results: 39 Ps patients (44% female) were enrolled with a mean age 45±6 years, disease duration 15±2 years, BMI 30±3 kg/m^2 and PASI score 9±2. Eleven subjects had normal studies, 8 had active joint inflammation on imaging but remained asymptomatic but 5 additional subjects with baseline imaging abnormalities subsequently developed PsA. Thirteen patients showed evidence of active or prior enthesitis (calcification at insertions) on imaging. Two patients had active tenosynovitis and 1 patient had plantar fasciitis. The patients were categorized into 4 subsets based on the imaging analysis and/or clinical features: (1) no imaging abnormality, n=11; (2) joint inflammation (imaging) without clinical symptoms, n=8; (3) development of PsA, n=5; (4) enthesitis or entheseal calcification, n=13. The OCP frequency was examined in cultured PBMC or purified monocytes isolated from these 4 patient subsets (Table 1).

Table 1. OCP frequency in 4 cohorts of Ps patients categorized by imaging results (mean+SEM).

	(1) Normal	(2) Imaging Arthritis	(3) PsA	(4) Enthesitis
PBMC	9 ± 9.3	140 ± 141	316 ± 267	64 ± 49
Monocytes	168 ± 96	1,209 ± 492	1,273 ± 549	467 ± 231

Conclusion: Among 39 Ps patients monitored for 3 months to 3 years, 8 patients showed baseline imaging abnormalities but remained asymptomatic; 5 patients with imaging abnormalities subsequently developed PsA, and 13 patients had acute or chronic entheseal signals. The OCP frequency was highest in patients with new onset PsA and inflammation on imaging studies. These results demonstrate the high prevalence of subclinical joint inflammation and entheseal changes in Ps and provide evidence that elevated OCP frequency may serve as a surrogate marker for joint inflammation and risk for arthritis in Ps patients.

Cross-Cultural Adaptation, Validation and Reliability Of The Brazilian Version Of The Psoriatic Arthritis Screening Evaluation Tool. Roberto Ranza[1], Claudia G Schainberg[2], Sueli Carneiro[3], Gladys Martins[4], Jose Joaquim Rodrigues[5], Jamille Carneiro[6], Ricardo Romiti[7], Thiago B. M. Barros[8], Ana Luiza Sampaio[9], Amanda Pedreira[9], Carolina Z Costa[10], Rogerio MC Pinto[11], M. Elaine Husni[12] and Abrar A. Qureshi[13]. [1]Universidade Federal de Uberlandia, Uberlandia MG, Brazil, [2]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [3]Brazilian Registry of Spondyloarthritis, São Paulo, Brazil, [4]Dermatologia Hospital Universitario Universidade de Brasilia, Brasilia, Brazil, [5]Dermatologia, Universidade Federal de Uberlandia, Uberlandia, Brazil, [6]Reumatologia, Universidade de Brasilia, Brasilia, Brazil, [7]Dermatologia Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [8]Reumatologia Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [9]Dermatologia Hospital Universitário e Faculdade de Medicina, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [10]Reumatologia, Universidade Federal de Uberlandia, Uberlandia, Brazil, [11]Matematica, Universidade Federal de Uberlandia, Uberlandia, Brazil, [12]Cleveland Clinic Foundation, Cleveland, OH, [13]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Psoriatic Arthritis (PsA) remains an underdiagnosed disease among patients with psoriasis (PsO). Dermatologists are not routinely trained to detect musculoskeletal manifestations hence arthritis, enthesitis and spondylitis may be frequently missed at dermatology settings. The Psoriatic Arthritis Screening and Evaluation (PASE) questionnaire is a patient reported outcome that may help dermatologists identify patients who may need a rheumatology referral. PASE is composed of 15 questions (2 subscales on symptoms and function), is reliable, generates a continuous score (15–75) higher in patients with PsA and is sensitive-to-change with disease severity and treatment. Purpose - to validate a Brazilian Portuguese version of the PASE (PASE-P).

Methods: PASE was translated into Portuguese with a wording adaptation of subscales titles and rating scale (disagree-agree substituted with false–true) to fit the cultural response style of Brazilian patients. A multicenter study was conducted in four university dermatology clinics, from January to March 2011. In each center, consecutive patients with a confirmed diagnosis of PsO responded to the PASE-P and were subsequently evaluated by a rheumatologist blind to the questionnaire. Based on clinical history and physical examination, patients were classified as: PsO only, PsO + osteoarthritis (OA) and/or chronic myofascial pain (CMP) syndrome, PsA (CASPAR criteria) ± OA and/or CMP. Laboratory tests and x-Ray imaging were performed as clinically indicated by the rheumatologist. PASE-P was retested in a sub-sample after a mean time of 20 days (12–30).

Results: 465 PsO patients completed the study. Mean age was 48.8±15.7 yrs, 50% were females and PsO mean duration was 15.5±11.8yrs. The PASE-P distinguished participants with PsA (158) from non-PsA (307), with mean scores of 37.8 ±17.2 vs 22.7±11.5 ($p<0.001$), ROC AUC of 0.777 (95%CI: 0.732–0.823); the best cut point was 25, giving 0.728 sensitivity (SE) and 0.735 specificity (SP). Patients with PsA not on any systemic treatment (42) had higher scores (mean 47.5±14.1) and the best cutoff from non-PsA was 38, SE 0.786, SP 0.876 (AUC 0.908, 95%CI 0.868–0.948). A subanalysis of PsA vs OA (66), showed scores of 37.8 vs 24.4±14.3 ($p<0.001$) and a cutoff of 22, 0.785 SE, 0.697 SP. (AUC 0.881, 95%CI 0.818–0.945). The internal consistency for PASE-P was high (Cronbach′s alfa 0.928) and the test-retest ICC was 0.974.

Conclusion: PASE-P is a newly translated tool that is reliable, sensitive and specific to screen for PsA in a population of Brazilian portuguese-speaking PsO patients seen in dermatology clinics.

Diagnostic Delay Of Even More Than 6 Months Contributes To Poor Radiographic and Functional Outcome In Psoriatic Arthritis. Muhammad Haroon, Phil Gallagher and Oliver FitzGerald. Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland.

Background/Purpose: Diagnostic delay in Psoriatic Arthritis (PsA) is not uncommon with a recent study of psoriasis patients attending a dermatology clinic showing that 29% of patients had undiagnosed PsA. Delay in diagnosis in turn delays introduction of appropriate disease-modifying treatment and may contribute to poor patient outcome. The objectives of this study were: 1) to investigate the demographic and clinical characteristics contributing to the delay from symptom onset to the first visit with a rheumatologist; 2) to compare clinical and radiographic features and patient-reported outcome measures in those who saw a rheumatologist early in their disease course compared to those who were diagnosed later, in a long-term follow-up cohort of PsA patients.

Methods: All PsA patients, fulfilling CASPAR criteria, with an average disease duration of >10 years were invited for detailed clinical evaluation. The total lag time from symptom onset to their first rheumatologic encounter was studied. All patients were interviewed in order to determine the date of symptom onset, defined as onset of stiffness, pain, or joint swelling, and the subsequent first visit to a rheumatologist, dates which were further confirmed by data extracted from referral letters and medical records. Patients were classified as early consulters or late consulters depending on whether they were seen by a rheumatologist within or beyond 6 months of symptom onset. Following informed consent, patients underwent a detailed skin and rheumatologic assessment including disease activity measures.

Results: A total of 283 PsA patients [mean age 54.6±12 years; 52% female; mean PsA duration of 19±9 years] were studied. Median lag time from the disease onset to the first rheumatologic assessment of the cohort was 1.00 years (IQR 0.5–2). Thirty percent (n=86) of the cohort was seen by a rheumatologist within 6 months of the disease onset. Similarly, 53% (n=149) and 71% (n=202) of the cohort was reviewed within one and 2 years of the symptoms onset, respectively. On univariate analysis, late consulters (>6 months delay at first encounter), had significantly more erosions (OR 4.58, p=<0.001), osteolysis (OR 3.6, p=0.01), sacroiliitis (OR 2.28, p=0.01), arthritis mutilans (OR 10.6, p=0.02), deformed joints (OR 2.28, p=0.002), number of deformed joints (OR 1.06, p=0.006), more DMARDs/TNFi failures (OR 1.47, p=0.007), less patients achieving drug free remission (OR 0.42, p=0.01), and worse functional disability as reflected by the HAQ scores (OR 2.17, p=0.003). On multiple step-wise regression analysis, the model predicted significant association of late consulters with the development of peripheral joint erosions (OR 4.25, p=0.001), radiographic sacroiliitis (OR 1.47, p=0.09) and worse HAQ scores (OR 2.2, p=0.004).

Conclusion: Even a 6 month delay from symptom onset to the first visit with a rheumatologist contributes to the development of peripheral joint erosions, sacroiliitis and worse long-term physical function.

Long-Term Safety and Tolerability Of Apremilast, An Oral Phosphodiesterase 4 Inhibitor, In Patients With Psoriatic Arthritis: Pooled Safety Analysis Of Three Phase 3, Randomized, Controlled Trials. Philip J. Mease[1], Arthur Kavanaugh[2], Dafna D. Gladman[3], Adewale O. Adebajo[4], Juan J. Gomez-Reino[5], Jürgen Wollenhaupt[6], Maurizio Cutolo[7], Georg Schett[8], Eric Lespessailles[9], Kamal Shah[10], ChiaChi Hu[10], Randall M. Stevens[10], Christopher J. Edwards[11] and Charles A. Birbara[12]. [1]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [2]University of California San Diego, San Diego, CA, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]University of Sheffield, Sheffield, United Kingdom, [5]Hospital Clinico Universitario, Santiago, Spain, [6]Schön Klinik Hamburg Eilbek, Hamburg, Germany, [7]University of Genova, Genova, Italy, [8]University of Erlangen-Nuremberg, Erlangen, Germany, [9]University of Orléans, Orléans, France, [10]Celgene Corporation, Warren, NJ, [11]University of Southampton, Southampton, United Kingdom, [12]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, works intracellularly to modulate inflammatory mediators. PALACE 1, 2, and 3 compared the efficacy and safety of APR with placebo (PBO) in pts with active PsA despite prior DMARDs and/or biologics. The overall safety and tolerability of APR was assessed in a pooled analysis of PALACE 1, 2, and 3.

Methods: Pts were randomized 1:1:1 to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by BL DMARD use. At wk 16, pts with <20% reduction from BL in swollen/tender joint counts qualified for protocol-defined early escape; those on PBO were re-randomized to APR20 or APR30 and those on APR remained on the initial APR dose. At wk 24, all remaining PBO pts were re-randomized to APR20 or APR30 through wk 52. Pts taking concurrent DMARDs were allowed to continue stable doses (MTX, sulfasalazine, leflunomide, or a combination). The analysis comprises data from the APR-exposure periods (wks 0-≥52).

Results: 1,493 pts received study drug (PBO, 495; APR20, 501; APR30, 497) and were included in the safety population. The APR-exposure period included 720 pts treated with APR20 (766.4 pt-yrs) and 721 with APR30 (769.0 pt-yrs). No new safety findings were identified; previously identified AEs were reported at a lower rate for wks 24–52 vs 0–24 (Table). The most common AEs were diarrhea (14.3%), nausea (12.6%), headache (10.1%), URTI (10.3%), and nasopharyngitis (7.4%). Diarrhea, nausea, and headache appeared to increase in a dose-dependent manner. Most AEs were mild/moderate in severity. Discontinuations due to AEs (APR20, 7.5%; APR30, 8.3%) were low, occurring primarily in the first 24 wks of treatment. Nausea and diarrhea were predominantly mild and occurred at a reduced incidence after the first month of dosing, with the highest incidence reported in the first 2 wks of treatment. Most cases resolved within 30 days despite continued therapy. The proportion of pts with severe nausea (APR20, 0.3%; APR30, 0.4%) and diarrhea (APR20, 0.6%; APR30, 0.3%) was low. GI AEs leading to APR discontinuation with ≥52 wks of exposure were 4% over 52 wks, with nausea (1.7%) and diarrhea (1.5%) being the most common. In the 24-≥52 wk period, no new severe AEs were reported for diarrhea, nausea, URTI, and nasopharyngitis vs 0–24 wks. Serious AEs occurred in 6.8% (APR20) and 7.2% (APR30) of pts. One death occurred (APR20) due to multiorgan failure not suspected to be treatment-related. Exposure-adjusted incidence rates of major adverse cardiac events, serious infections including systemic opportunistic infection, or malignancies were comparable to PBO. There were no clinically meaningful effects on laboratory measurements.

Overall Safety Profile

	Weeks 0–24 as Initially Treated*			Long-term APR Exposure§	
Patients, n (%)	PBO (n = 495)	APR20 (n = 501)	APR30 (n = 497)	APR20 (n = 720)	APR30 (n = 721)
≥1 AE	235 (47.5)	308 (61.5)	302 (60.8)	524 (72.8)	534 (74.1)
≥1 serious AE	19 (3.8)	17 (3.4)	19 (3.8)	49 (6.8)	52 (7.2)
≥1 severe AE	19 (3.8)	16 (3.2)	32 (6.4)	48 (6.7)	60 (8.3)
AE leading to drug withdrawal	21 (4.2)	28 (5.6)	36 (7.2)	54 (7.5)	60 (8.3)
Death‡	0 (0.0)	1 (0.2)	0 (0.0)	1 (0.1)	0 (0.0)

*PBO-controlled period includes all data through week 16 for patients initially assigned PBO who escaped and data through week 24 for all other patients.
§Includes all patients who received ≥1 dose of APR regardless of when randomized.
‡Multiorgan failure considered by investigator to be unrelated to study drug.

Conclusion: APR demonstrated an acceptable safety profile and was generally well tolerated for up to 52 wks with no new safety concerns identified with long-term exposure. These data do not indicate a need for laboratory monitoring.

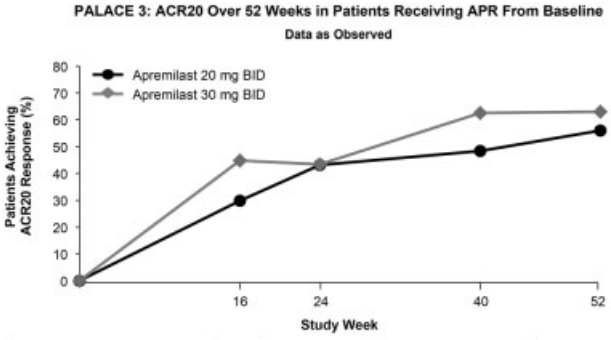
Long-Term (52-Week) Results Of a Phase 3, Randomized, Controlled Trial Of Apremilast, An Oral Phosphodiesterase 4 Inhibitor, In Patients With Psoriatic Arthritis and Current Skin Involvement (PALACE 3). Christopher J. Edwards[1], Francisco J. Blanco[2], Jeffrey Crowley[3], ChiaChi Hu[4], Randall M. Stevens[4] and Charles A. Birbara[5]. [1]University of Southampton, Southampton, United Kingdom, [2]INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [3]Bakersfield Dermatology, Bakersfield, CA, [4]Celgene Corporation, Warren, NJ, [5]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, works intracellularly to modulate inflammatory mediators. PALACE 3 compared the efficacy/safety of APR with placebo (PBO) in pts with active PsA and at least 1 psoriatic lesion ≥2 cm at baseline (BL) despite prior DMARDs and/or biologics.

Methods: Pts were randomized 1:1:1 to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by BL DMARD use and BSA ≥3%. At wk 16, pts with <20% reduction from BL in swollen/tender joint counts qualified for protocol-defined early escape; those on PBO were re-randomized to APR20 or APR30 and those on APR remained on the initial APR dose. At wk 24, all remaining PBO pts were re-randomized to APR20 or APR30 through wk 52. Pts taking concurrent DMARDs were allowed to continue stable doses (MTX, sulfasalazine, leflunomide, or combination).

Results: 505 pts were randomized and received ≥1 dose of study drug (PBO, 169; APR20 169; APR30, 167). At wk 16 (primary endpoint), significantly more APR20 (29.4%; $P=0.0235$) and APR30 pts (42.8%; $P<0.0001$) achieved ACR20 vs PBO (18.9%). For those pts originally randomized to APR and completing 52 wks of study, improvements were maintained or increased over 52 wks for multiple endpoints, including: (1) ACR20 of 56.0% (APR20) and 63.0% (APR30) (Figure); (2) HAQ-DI mean change from BL (SD) of −0.332 (0.505) for APR20 and −0.350 (0.505) for APR30 pts, meeting the MCIDs of 0.13 and 0.30; and (3) in pts with BL BSA ≥3%, PASI-75 was achieved by 28.6% (APR20) and 39.1% (APR30) of pts; PASI-50 was achieved by 49.2% (APR20) and 54.7% (APR30). The magnitude of responses was higher for APR30 than APR20. Pts randomized to APR at wks 16 or 24 demonstrated results consistent with those originally randomized to APR. APR was generally well tolerated. AEs occurring in ≥5% of all pts exposed to APR through wk 52 were diarrhea, nausea, headache, URTI, nasopharyngitis, and vomiting. The majority of AEs were mild/moderate and predominantly did not lead to discontinuation. Gastrointestinal AEs occurred at a reduced incidence rate after the first wk of dosing. SAEs occurred in 5.4% (APR20) and 4.1% (APR30) of pts. No new safety signals were identified and the incidence of pts experiencing any AE was comparable over the 0–24 and 0–52 wk periods. No imbalance in the exposure-adjusted incidence rates of severe AEs, SAEs, major adverse cardiac events, serious infections including systemic opportunistic infection, or malignancies between APR and PBO was observed. No cases of TB (novel or reactivation) were reported in the APR treatment groups; TB screening was not required per protocol.



Apremilast 20 mg BID, n=	161	146	124	116
Apremilast 30 mg BID, n=	154	145	131	127

Conclusion: Over 52 wks, APR continued to demonstrate efficacy in the treatment of PsA and associated psoriasis, including clinically meaningful improvements in signs and symptoms and physical function. APR demonstrated an acceptable safety profile with up to 52 wks of treatment and was generally well tolerated.

Effect Of Certolizumab Pegol Over 48 Weeks On Signs and Symptoms In Patients With Psoriatic Arthritis With and Without Prior Tumor Necrosis Factor Inhibitor Exposure. Philip J. Mease[1], Roy M. Fleischmann[2], Jürgen Wollenhaupt[3], Atul Deodhar[4], Dafna Gladman[5], Christian Stach[6], Bengt Hoepken[6], Luke Peterson[7] and Désirée van der Heijde[8]. [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]Schön Klinik, Hamburg, Germany, [4]Oregon Health & Science University, Portland, OR, [5]Toronto Western Hospital and University of Toronto, Toronto, ON, [6]UCB Pharma, Monheim, Germany, [7]UCB Pharma, Raleigh, NC, [8]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Previous reports of RAPID-PsA demonstrated efficacy and safety of certolizumab pegol (CZP), a PEGylated Fc-free anti-TNF, over 24 weeks (wks) in psoriatic arthritis (PsA) patients (pts), including pts with prior TNF inhibitor therapy.[1] We report the clinical efficacy and safety of CZP in PsA pts to Wk48.

Methods: The ongoing RAPID-PsA trial (NCT01087788) is double-blind and placebo (PBO)-controlled to Wk24 and dose-blind to Wk48.[1] Pts had active PsA and had failed ≥1 DMARD. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks 0, 2, 4) continued on their assigned dose in dose-blind phase; PBO pts entering dose-blind phase were re-randomized to CZP loading dose followed by CZP 200mg Q2W or CZP 400mg Q4W. We report efficacy for pts in randomized set (RS) originally randomized to CZP. Primary endpoints were ACR20 response at Wk12 and change from baseline (BL) in modified Total Sharp Score (mTSS) at Wk24.[1] Other pre-planned endpoints included PASI75/90 and ACR20/50/70 response, change from BL HAQ-DI, PsAQoL, pain (VAS) and fatigue (NRS) at Wk24 and 48, and mTSS at Wk48. Post-hoc analyses evaluated minimal disease activity (MDA) at Wk24 and 48, and compared ACR response rates to Wk48 in pts with and without prior TNF inhibitor exposure. NRI was used for categorical measures, LOCF for quantitative measures. Safety set consists of all pts treated with CZP at any stage of the 48-wk trial.

Results: 409 pts were randomized, of which 273 received CZP from Wk0. 54 (19.8%) combined CZP pts (200mg Q2W + 400mg Q4W) had prior TNF inhibitor exposure, with similar BL characteristics to pts without. Of CZP-randomized pts, 91% completed to Wk24 and 87% to Wk48. ACR20/50/70 and MDA response rates were maintained from Wk24 to Wk48 (Figure A), and similar ACR response rates to Wk48 were observed in pts with and without prior TNF inhibitor exposure (Figure B). Change from BL in HAQ-DI, PsAQoL, pain (VAS) and fatigue (NRS) were maintained to Wk48 (Figure A). In pts with ≥3% skin involvement at BL (60.8% CZP pts), PASI75 and PASI90 responses were maintained from Wk24 to Wk48 (Figure

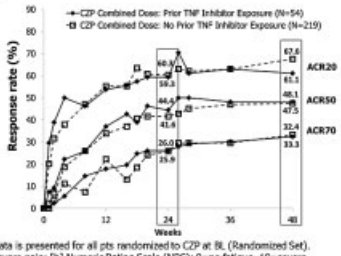
A). Radiographic progression in CZP-treated pts remained low (LS mean mTSS change from BL: Wk24, 0.00; Wk48, 0.13). In the safety set (N=393), adverse events (AEs) occurred in 304 pts (77.4%; event rate [ER] per 100 pt-yrs=394.6), serious AEs in 39 (9.9%; ER=15.3). Serious AEs included 8 infections (2.0%; ER=3.0), including 1 case of tuberculosis (0.3%; ER=0.3), and 3 deaths in the overall 48-week period (0.8%), including 1 death (0.3%) between Wk24 and 48 (breast cancer).

Figure: A) Clinical outcomes at Wk24 and Wk48 for all pts by treatment arm, B) ACR response rates for all CZP pts (200mg Q2W and 400mg Q4W) with and without prior TNF inhibitor exposure in the RAPID-PsA trial

A.

Outcome	CZP 200mg Q2W N=138		CZP 400mg Q4W N=135	
	Wk24	Wk48	Wk24	Wk48
ACR20 (%)	63.8	66.7	56.3	65.9
ACR50 (%)	44.2	49.3	40.0	45.9
ACR70 (%)	28.3	34.8	23.7	30.4
MDA (%)	33.3	37.7	34.1	34.8
CFB HAQ-DI	-0.52	-0.56	-0.43	-0.49
CFB PsAQoL	-4.4	-4.8	-3.3	-3.5
CFB Pain [a]	-28.6	-31.6	-28.4	-29.5
CFB Fatigue [b]	-2.2	-2.4	-1.9	-2.0
PASI75 [c] (%)	62.2	66.7	60.5	61.8
PASI90 [c] (%)	46.7	48.9	35.5	42.1

B.



Presented data are mean values except where otherwise stated. Data is presented for all pts randomized to CZP at BL (Randomized Set). [a] Visual Analog Scale (VAS): 0–100mm: 0=no pain, 100=most severe pain; [b] Numeric Rating Scale (NRS): 0=no fatigue, 10=severe fatigue; [c] PASI response rates reported in patients with ≥3% body surface area skin involvement at BL (CZP 200mg, N=90; CZP 400mg N=76). ACR: American College of Rheumatology; CZP: Certolizumab Pegol; MDA: Minimal Disease Activity; CFB: Change From Baseline; HAQ-DI: Health Assessment Questionnaire – Disability Index; PsAQoL: Psoriatic Arthritis Quality of Life; PASI: Psoriasis Area and Severity Index.

Conclusion: Clinical efficacy of CZP was maintained over 48 wks in pts with PsA, including pts with and without prior TNF inhibitor exposure. Low radiographic progression and improvements in PASI were maintained to Wk48. Safety profile was in line with that observed for CZP in RA.

The DC-STAMP$^+$IL17A$^+$ Cell Subset Is Elevated In Psoriatic Arthritis (PsA) Patients and Declines Following Anti-TNFi Therapy. Yahui Grace Chiu, Edward M. Schwarz, Hua He, Francisco A. Tausk, Sharon Moorehead, Michelle Smith and Christopher T. Ritchlin. University of Rochester, Rochester, NY.

Background/Purpose: Approximately 25% of psoriasis (Ps) patients develop psoriatic arthritis (PsA), a potentially destructive joint disease, within 10 years of Ps onset. Although early diagnosis and therapy of PsA can prevent bone and joint damage, diagnostic and response biomarkers of psoriatic diseases are currently absent. To address this unmet need, we focused on Dendritic Cell-Specific Transmembrane protein (DC-STAMP), a valid marker of osteoclast precursors (OCP). We examined the frequency of the DC-STAMP$^+$IL-17$^+$ subset (monocytes and T cells) in the peripheral blood of healthy controls (HC), Ps and PsA patients and monitored this cell subset in PsA patients before and after the anti-Tumor Necrosis therapy (TNFi).

Methods: Ps was confirmed by a dermatologist and PsA by a rheumatologist based on the CASPAR criteria. Blood samples were collected from 61 subjects (Ps, n=19; PsA, n=17; HC, n=25). Blood samples from PsA patients were collected at baseline and 16 weeks following treatment with an anti-TNF reagent (adalimumab, infliximab or etanercept). Cell populations were analyzed by flow cytometry with an 11-color antibody cocktail and OC were enumerated by TRAP staining after 8-day cell culture in vitro.

Results: The DC-STAMP$^+$IL-17$^+$ subset was significantly increased in PsA but not in Ps or HC (Figure 1). The area under the Receiver Operating Characteristic (ROC) curve for DC-STAMP+IL17A+ cells (PsA vs. HC) was 0.769. The DC-STAMP$^+$IL17A$^+$ cell frequency decreased significantly following TNFi therapy in PsA patients considered as anti-TNFi responders (12 out of 17). Figure 2 summarizes the frequency of DC-STAMP$^+$IL17A$^+$ before and after anti-TNFi medication (8.2 ± 13.7 (prior) vs. 1.6 ± 1.5 (after), p=0.09). Intriguingly, the reduction in DC-STAMP$^+$IL17A$^+$ cell subset was associated with a decreased circulating OCP frequency (930 ± 857 (prior) vs. 142 ± 144 (after)/per 10^6 monocytes, p=0.004).

Conclusion: Our results demonstrate that the DC-STAMP$^+$IL17A$^+$ cell subset: (1) can distinguish PsA from HC and Ps subjects; (2) declines rapidly following TNFi therapy; (3) positively correlates with circulating OCPs. Collectively, these data reveal a novel susceptibility and response biomarker and underscore the importance of IL-17 expressing cells in PsA pathogenesis.

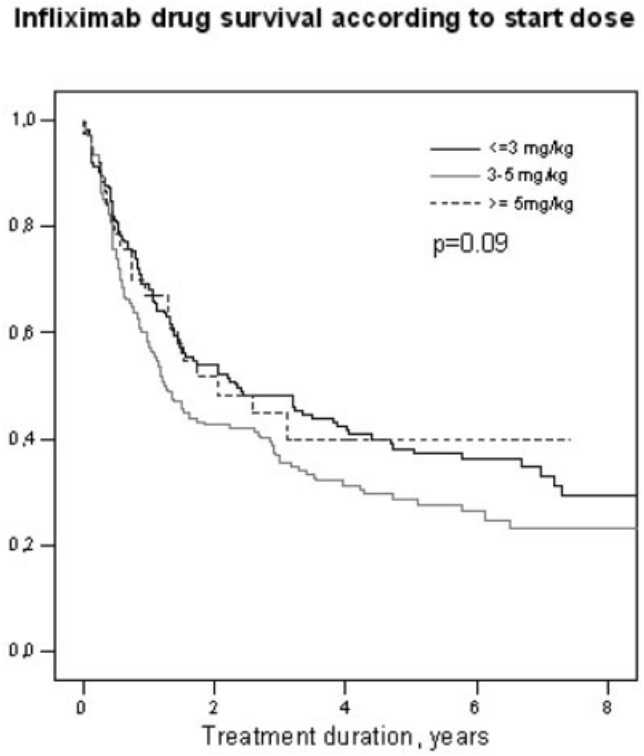
Background/Purpose: International guidelines recommend that in psoriatic arthritis infliximab should be dosed with 5 mg/kg bodyweight every 8th week. Data on the use of lower doses is however scarce. We aimed to describe dose regimens, the frequency of dose escalation and outcomes in patients with psoriatic arthritis treated with infliximab in routine care.

Methods: Observational cohort study based on the nationwide Danish DANBIO and Icelandic ICEBIO registries. Demographics and baseline characteristics among tumor-necrosis-factor-α inhibitor (TNFi) naïve patients treated with ≤3 mg infliximab/kg body weight, 3–5 mg/kg or ≥5 mg/kg with treatment scheduled at 0, 2, 6 and then every 8th week were described. Dose escalation was defined as an increase in either the dose and/or frequency. Treatment responses were evaluated by ACR20/50/70 and EULAR-good-response after 6 months' treatment and disease activity after one year's treatment. Kaplan-Meier plots and regression analyses were performed for drug survival analyses and to identify predictors of treatment response and drug survival.

Results: Among the 1589 psoriatic arthritis patients identified in the registries, 462 patients (29%, 376 Danish, 86 Icelandic) received treatment with infliximab. Start infliximab dose was ≤3 mg/kg in 174 patients (38%), 3–5 mg/kg in 174(38%), ≥5mg/kg in 38(8%) and unregistered in 76 patients (16%). After one years' treatment, corresponding percentages were 35, 53, 12 and 22%, respectively. Patients with higher body weight received lower infliximab doses per kg. The median time until first dose escalation (273 days (interquartile range, IQR 153–553) was independent of start dose (log rank 0.1, p=0.9). The ACR20/50/70 or EULAR-response rates, drug survival (Figure) and one-year disease activity were also independent of baseline dose. Icelandic patients received lower infliximab doses than Danish (2.3mg/kg (2.1–2.9) vs. 3.1mg/kg (3.0–3.8)) (median (IQR), p<0.05), they had also longer drug survival, but similar one-year response rates.



Figure

Conclusion: In clinical practice, >80% of infliximab treated patients with psoriatic arthritis received sustained treatment with doses less than the 5 mg/kg/8weeks recommended in international guidelines. Low infliximab start dose did not affect drug survival or treatment response. Low start dose with gradual dose escalation was a preferred and effective strategy.

Long Term Outcomes In Psoriatic Arthritis 2; A Prospective Multicentre Observational Study Of Work Disability In Psoriatic Arthritis: First Report Of The Clinical and Socioeconomic Associations Of Work Disability In Psoriatic Arthritis.

William Tillett[1], Gavin Shaddick[2], Ayman Askari[3], Annie Cooper[4], Paul Creamer[5], Gavin Clunie[6], Philip S. Helliwell[7], Lesley Kay[8], Eleanor Korendowych[1], Suzanne Lane[9], Jonathon Packham[10], Ragai Shaban[11], Lyn Williamson[12], Corinne deVries[2] and Neil McHugh[1]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]Robert Jones and Agnes Hunt Hospital, Shrophire, United Kingdom, [4]Royal Hampshire County Hospital, Winchester, United Kingdom, [5]North Bristol NHS foundation trust, Bristol, United Kingdom, [6]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [7]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [8]Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [9]Ipswich Hospital NHS Trust, Ipswich, United Kingdom, [10]Haywood Rheumatology Centre, Stoke-on-Trent, United Kingdom, [11]Queen Alexandra Hospital, Portsmouth, United Kingdom, [12]Great Western Hospitals NHS Foundation Trust, Swindon, United Kingdom.

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis that is associated with joint damage, impaired quality of life and high levels of work disability (WD). However, data on the associations of WD in PsA is limited. Long Term Outcomes in Psoriatic Arthritis II is a prospective UK multicentre observational study of the impact of PsA on WD and the effect of treatment intervention. In this first analysis we set out to determine to what extent structural damage, clinical disease activity, demographic and social factors are associated with WD.

Methods: Four hundred patients fulfilling CASPAR criteria for PsA were recruited from 23 hospitals across the UK at initiation of DMARD or anti-TNF therapy. Physician assessments (DAPSA score), radiographs (PsA Ratingen score) and patient reported outcomes (HAQ, EQ5D, FACIT, DLQI, global, joint and skin specific activity VAS scores, comorbidities, demographic details, education, location, employer awareness/helpfulness) and work type were collected. WD was assessed with the WPAI which reports work disability as percentage of absenteeism (work time missed), presenteeism (impairment at work/ reduced effectiveness) and work productivity loss (overall work impairment/absenteeism plus presenteeism). All variables were considered for inclusion. Logistic and linear regressions were conducted to investigate independent associations with WD. Age demonstrated a non-linear relationship with WD and was therefore included as a quadratic term.

Results: Of the 400 participants three hundred and fifty three were of UK working age (18–65 years), mean age 46.8 years (sd 11.02), mean disease duration 5.8 years (sd 8.00), 49.9% female. Two hundred and twenty six (64%) were in work with a further 10 over retirement age, but still working. Unemployed participants were older than those in employment, 55 years (sd 14.7) versus 47 years (sd 10.9), had longer disease duration, 8 years (sd 9.8) versus 6 years (sd 7.8), had worse physical function, HAQ 1.3 (sd 0.78) versus 1.0 (sd 0.68), had worse quality of life, EQ5D 0.4 (sd 0.36) versus 0.5 (sd 0.54) and had more radiographic damage, Ratingen score 19 (sd 31.9) versus 8 (sd 16.5). Of the 236 participants in work the mean absenteeism, presenteeism and productivity loss was 14% (sd 29.0), 39% (sd 27.2) and 46% (sd 30.4) respectively. Independent associations with WD are reported in table 1.

Table 1. Regression models for work disability associations

Variable	Model 1- logistic Employed Odds Ratio (CI)	Model 2- Logistic Absenteeism (0–1) Odds Ratio (CI)	Model 3- Linear Presenteeism (0–1) Estimate (CI)	Model 4- Linear Productivity loss (0–1) Estimate (CI)
Intercept	0.01 (0.000 to 1.622) p=0.07	0.04 (0.010 to 0.127) p<0.01	−0.02 (−0.114 to 0.074) p=0.67	−0.05 (−0.143 to 0.040) p=0.27
Age years	**1.31 (1.029 to 1.672) p=0.03**			
Age (quadratic) years	**0.99 (0.994 to 0.999) p=0.02**			
Disease duration 2–5 years	**0.41 (0.180 to 0.953) p=0.03**		0.02 (−0.066 to 0.112) p=0.61	
Disease duration >5 years	1.36 (0.557 to 3.319) p=0.49		**−0.09 (−0.167 to −0.021) p=0.01**	
Global activity VAS 0–10			**0.02 (0.001 to 0.053) p=0.01**	0.03 (0.001 to 0.06) p<0.01
Joint activity VAS 0–10		**1.04 (1.018 to 1.055) p<0.01**	0.03 (0.006 to 0.055) p=0.01	0.02 (0.000 to 0.049) p=0.05
HAQ 0–3	**0.56 (0.343 to 0.926) p=0.02**		**0.63 (0.005 to 1.200) p=0.03**	0.12 (0.066 to 0.182) p<0.01
Employer very helpful	**15.10 (4.658 to 48.753) p<0.01**			
Employer helpful	**17.46 (4.395 to 69.355) p<0.01**			
No help required	**3.22 (1.264 to 8.229) p<0.01**			
Employer unhelpful	1.29 (0.325 to 5.155) p=0.72			
Employer very unhelpful	0.39 (0.039 to 3.942) p=0.42			

Conclusion: Greater global, joint specific disease activity and worse physical function exerted a negative influence on presenteeism and productivity loss suggesting disease activity is important amongst those who are in work. Greater age, recent disease onset and worse physical function exert a negative influence on remaining in employment. Patient reported employer awareness and helpfulness exerts a strongly positive influence on remaining in employment, even if patients perceive no help is required.

Quantiferon-TB Test Can Be Usefull For Decision Of Anti-Tuberculosis Prophylaxis During Anti-TNF Treatment: Result Of Real Life. Umut Kalyoncu[1], Levent Kilic[1], Ahmet Cagkan Inkaya[2], Omer Karadag[3], Sule Apras Bilgen[2], Ali Akdogan[2], Sedat Kiraz[3] and Ihsan Ertenli[3]. [1]Hacettepe University School of Medicine, Ankara, Turkey, [2]Hacettepe University, Faculty of Medicine, Ankara, Turkey, [3]Hacettepe University Faculty of Medicine, Ankara, Turkey.

Background/Purpose: Anti-tumor necrosis factor (TNF) treatments may increase tuberculosis. Most of the national guidelines recommend tuberculin skin test (TST) for screening of latent tuberculosis. However, BCG vaccine is mandatory in some countries and TST may be positive in more than 80% of those country[1]. Thus, vast majority of those patients use isoniazid prophylaxis and this drug is not innocent. Objective of this study was to assess accuracy of QuantiFERON-TB Gold In-Tube (QFT-GIT) test for anti-tuberculosis prophylaxis during anti-TNF treatment.

Methods: TST have been used for detection of latent tuberculosis between 2003–2011 in our center. After March 2011, QFT-GIT test was replaced TST for these purpose in routine practice. All patients who started anti-TNF therapy were recorded in a database prospectively between March 2011 to June 2013 according to QFT-GIT test results. This database included name of anti-TNF drugs, switch of anti-TNF, duration of follow-up. Clinical signs of tuberculosis were examined every 3 months by physicians or experienced study nurses. Isoniazid prophylaxis started in patients with positive QFT-GIT test. In June 2013, all database screened regularly by a physician. If patients were not examined in last 3 months, patients were called by phone [112/516 (21,7%)] for drug survival and signs of tuberculosis. If patients were not reached by phone, data of tuberculosis extracted from "tuberculosis control dispensary of health ministry" [24/516 (6,2%) patients].

Results: A total of 516 (289 female, 56%) patients were started anti-TNF therapy. Mean age of patients were 40 ± 12 years. Initial diagnosis of patients were spondyloarthritis 309 (59,9%), rheumatoid arthritis 158 (30,6%), psoriatic arthritis 45 (8,7%) and juvenil idiopathic arthritis 4 (0,8%). Anti-TNF drugs were adalimumab 191 (37,0%), etanercept 177 (34,3%), infliximab 133 (25,8%) and golimumab 15 (2,9%). Anti-TNF drugs was switched in 64 (12,4%) patients. QFT-GIT test was found to be positive in 110 (21,6%) patients. Isoniazid prophylaxis started in those patients. Median follow-up duration of patients were 5 (0–24) months and 191 of 516 (37,0%) patients were followed more than 9 months. Patients were classified as follows; regularly follow-up 344 (66.7%), just started within last 3 months 60 (11,6%), never follow-up 47 (9.1%), and irregularly follow-up 65 (12,6%). None of the patients from this cohort had tuberculosis.

Conclusion: BCG vaccine is mandatory in our country. Unfortunately, BCG vaccine affects adversely on TST for detection of latent tuberculosis. Although median follow-up duration is limited in this study, QFT-GIT test may be effective and reliable alternative for detection of latent tuberculosis before commencement of anti-TNF treatment in real life.

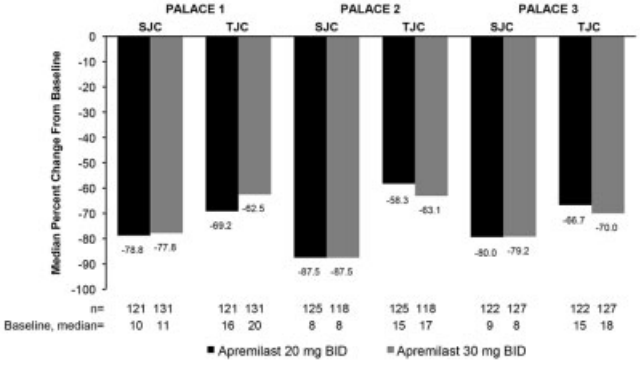
Apremilast, An Oral Phosphodiesterase 4 Inhibitor, Is Associated With Long-Term (52-Week) Improvement In Tender and Swollen Joint Counts In Patients With Psoriatic Arthritis: Results From Three Phase 3, Randomized, Controlled Trials. Maurizio Cutolo[1], Philip J. Mease[2], Dafna D. Gladman[3], Arthur Kavanaugh[4], Adewale O. Adebajo[5], Juan J. Gomez-Reino[6], Jürgen Wollenhaupt[7], Georg Schett[8], Eric Lespessailles[9], Kamal Shah[10], ChiaChi Hu[10], Randall M. Stevens[10], Christopher J. Edwards[11] and Charles A. Birbara[12]. [1]University of Genova, Genova, Italy, [2]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]University of California San Diego, San Diego, CA, [5]University of Sheffield, Sheffield, United Kingdom, [6]Hospital Clinico Universitario, Santiago, Spain, [7]Schön Klinik Hamburg Eilbek, Hamburg, Germany, [8]University of Erlangen-Nuremberg, Erlangen, Germany, [9]University of Orléans, Orléans, France, [10]Celgene Corporation, Warren, NJ, [11]University of Southampton, Southampton, United Kingdom, [12]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, works intracellularly to modulate pro- and anti-inflammatory mediators. The PALACE 1, 2, and 3 trials compared the efficacy and safety of APR with placebo (PBO) in pts with active PsA despite prior DMARDs and/or biologics.

Methods: Pts were randomized 1:1:1 to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by BL DMARD use. At wk 16, pts with <20% reduction from BL in swollen and tender joint counts (SJC/TJC) qualified for protocol-defined early escape; those on PBO were re-randomized to APR20 or APR30 and those on APR remained on the initial APR dose. At wk 24, all remaining PBO pts were re-randomized to APR20 or APR30 through wk 52. Pts taking concurrent DMARDs were allowed to continue stable doses (MTX, sulfasalazine, leflunomide, or a combination). Given the relative weighting of SJC/TJC in the ACR20 composite index and their clinical importance, we examined these measures across the 3 trials.

Results: APR resulted in statistically significant and clinically meaningful improvement in ACR20 response (primary endpoint) in all 3 PALACE trials. Median percent reductions (improvement) in SJC/TJC were statistically significant vs PBO at wk 16 in all 3 trials; SJC (PBO, APR20, APR30, respectively): −16.7%, −39.3% (P=0.0035), −50.0% (P<0.0001) (PALACE 1); −33.3%, −50.0% (P=0.0029), −53.9% (P=0.0009) (PALACE 2); 20.0%, −36.4% (P=0.0301), −50.0% (P=0.0014) (PALACE 3); TJC: −7.0%, −23.3% (P=0.0007), −42.9% (P<0.0001) (PALACE 1); −8.7%, −36.2% (P<0.0001), −33.3% (P=0.0015) (PALACE 2); −8.6%, −30.0% (P=0.0001), −43.7% (P<0.0001) (PALACE 3). Pts receiving APR20 and APR30 for 24 wks had median percent reductions in SJC in PALACE 1, 2, and 3, respectively, of −53.8% and −66.7%; −71.4% and −75.0%; and 61.3% and −69.2%. Median percent reductions in TJC for APR20 and APR30 were 46.2% and −59.4%; −51.0% and −47.1%; and −53.3% and −55.0%. In pts receiving APR for 52 wks, sustained improvements in SJC/TJC were observed at wk 52, with SJC improvements up to −87.5% and TJC improvements up to −70.0% (Figure). Pts randomized to APR at wks 16 and 24 demonstrated results consistent with those originally randomized to APR. No new safety findings were identified and the incidence of pts experiencing any AE was comparable over the 0–24 and 0–52 wk periods. No imbalance in the exposure-adjusted incidence rates of major adverse cardiac events, serious infections including systemic opportunistic infection, or malignancies between APR and PBO was observed. No cases of TB (novel or reactivation) were reported in the APR treatment groups; TB screening was not required per protocol.

PALACE 1, 2, and 3: SJC and TJC at Week 52 in Patients Receiving APR 20 and 30 mg BID From Baseline*



*A negative change from baseline indicates improvement.

Conclusion: Over 52 wks, APR continued to demonstrate efficacy in the treatment of PsA, including clinically meaningful improvements in SJC and TJC. APR demonstrated an acceptable safety profile and was generally well tolerated for up to 52 wks.

Effect Of Brodalumab (AMG 827) On Pain and Physical Functioning In Patients With Psoriatic Arthritis. Mark C. Genovese[1], Philip J. Mease[2], Hema Viswanathan[3], Dina Chau[3], JingYuan Feng[3], Ngozi Erondu[3] and Ajay Nirula[3]. [1]Stanford University, Palo Alto, CA, [2]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [3]Amgen Inc, Thousand Oaks, CA.

Background/Purpose: Psoriatic arthritis (PsA) has a significant impact on health related quality of life (HRQoL). This analysis evaluated the efficacy of brodalumab, a human anti-IL-17 receptor A monoclonal antibody, on HRQoL with an emphasis on pain and physical functioning in patients with PsA.

Methods: Analysis of data from a phase 2 study of subjects with PsA (Classification Criteria for PsA and ≥3 tender and ≥3 swollen joints) for ≥6 months randomized to brodalumab (140 or 280 mg Q2W) or placebo for 12 weeks followed by an open-label extension (OLE) in which all subjects received 280 mg brodalumab. Patient reported outcome (PRO) measures of pain and HRQOL included subject global assessment (SGA)-joint pain, SGA-disease activity, Health Assessment Questionnaire Disability Index (HAQ-DI), 36-item Short Form Health Survey (SF-36 v2), and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Analyses included available data up to week 24 of the ongoing OLE and were based on observed data.

Results: The majority of subjects enrolled (113 brodalumab and 55 placebo) were female (64%), white (94%), and rheumatoid factor negative (92%). Mean (SD) age, weight, and duration of PsA were 52 (12) years, 91 (21) kg, and 9 (8) years, respectively. 156 subjects enrolled in the OLE. Median (IQR) percent change in SGA-joint pain from baseline to week 12 was −23% (−54, 10) in the 140-mg group (P=.06) and −28% (−49, 10; P=.04) in the 280-mg group, compared with −5% (−32, 29) in placebo. Median (IQR) percent change in HAQ-DI from baseline to week 12 was −7% (−45, 6) in the 140-mg group (P = .30) and −14% (−36, 0) in the 280-mg group (P = .12), compared with −8% (−23, 13) in placebo. Compared with placebo, SGA-disease activity was significantly lower in the 140-mg group (least squares mean difference [95% CI] −17.2 [−32.7, −1.6]; P=.031) and the 280-mg group (least squares mean difference [95% CI] −24.6 [−40.3, −8.9]; P=.002). There was a significantly greater change in BASDAI score from baseline to week 12 in the 140-mg group (least squares mean difference [95% CI] −0.7 [−1.3, −0.1]; P=.03) and 280-mg group (least squares mean difference [95% CI] −0.8 [−1.4, −0.2]; P=.01) compared with placebo. Nonsignificant trends of improvement were observed for SF-36 physical component, mental component, and some other domain scores. During the OLE, all response measures continued to improve in both brodalumab groups and responses in the prior placebo group at week 24 were similar to those of the brodalumab group at week 12.

Conclusion: Brodalumab treatment was associated with significant improvements in joint pain and physical functioning in subjects with PsA.

Secukinumab Shows Substantial Improvement In Both Psoriasis Symptoms and Physical Functioning In Moderate-To-Severe Plaque Psoriasis Patients With Psoriatic Arthritis: A Subanalysis Of a Phase 3, Multicenter, Double-Blind, Placebo-Controlled Study. Alice B. Gottlieb[1], Bardur Sigurgeirsson[2], Andrew Blauvelt[3], Shephard Mpfofu[4], Ruvie Martin[5] and Charis Papavassilis[4]. [1]Tufts Medical Center, Boston, MA, [2]University of Iceland, Kópavogur, Iceland, [3]Oregon Health and Sciences University, Portland, OR, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharma AG, East Hanover, Switzerland.

Background/Purpose: Since interleukin (IL)-17A has a potential role in the pathogenesis and chronic inflammation of psoriatic disease, with similar pathways impacting skin and joints, strategies aimed at blocking IL-17A may be beneficial in the treatment of psoriasis and psoriatic arthritis (PsA). Secukinumab (AIN457) is a fully human anti-IL-17A monoclonal antibody.

Methods: A total of 738 subjects aged ≥18 years with moderate-to-severe plaque psoriasis (incl. Psoriasis Area and Severity Index (PASI) score ≥12) were randomized 1:1:1 to subcutaneous secukinumab 150 mg or 300 mg or placebo given at randomization, Weeks 1, 2, and 3, followed by dosing every four weeks starting at Week 4 through Week 48. At Week 12, subjects not achieving a PASI 75 response were re-randomized 1:1 to secukinumab 150 mg or 300 mg. A pre-specified subanalysis of PASI responses and changes from baseline in the Health Assessment Questionnaire–Disability Index (HAQ-DI) up to Week 52 in subjects with concomitant PsA at baseline is reported here.

Results: Baseline PASI and HAQ-DI scores were balanced across treatments. In 171 subjects with concomitant PsA, PASI 75 responses at Week 12 were 70% in the 150 mg group and 68% in the 300 mg group (4%, placebo); PASI 90 responses were 44% and 53% in the 150 mg and 300 mg groups, respectively (0%, placebo). PASI 75 responses (61%, 150 mg; 68%, 300 mg) and PASI 90 responses (37%, 150 mg; 56%, 300 mg) were maintained up to one year (Fig 1). Physical function as measured by HAQ-DI change from baseline was significantly greater at Weeks 4 and 12 with 300 mg vs placebo (P < 0.05). HAQ –DI responses were more pronounced in patients with more disability. In patients with baseline HAQ-DI ≥0.5, reduction in HAQ-DI score was statistically significantly greater for 150 mg at Week 12 and for 300 mg at Weeks 4 and 12 vs placebo (Fig 2) and responses continued up to Week 52. Secukinumab was well tolerated with no unexpected safety findings.

	PASI75 at Week 12	PASI75 at Week 52	PASI90 at Week 12	PASI90 at Week 52
Placebo (N=68)	4%		0%	
AIN 150 mg (N=46)	70%	61%	44%	37%
AIN 300 mg (N=57)	68%	68%	53%	56%

Figure 1. PASI 75/90 Response at Weeks 12 and 52
All PsA Patients (Non-Responder Imputation)

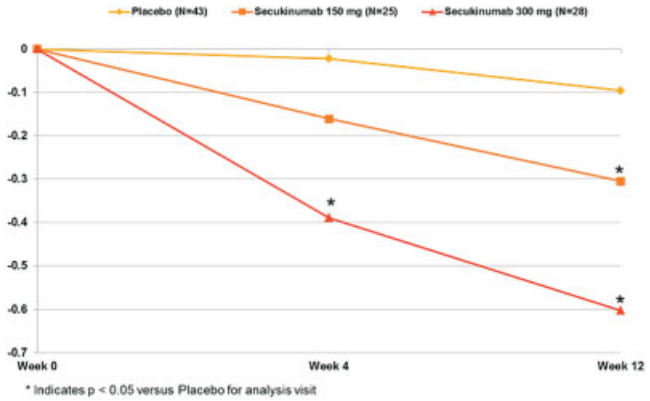

Figure 2. Change from Baseline in HAQ-DI Score to Week 12. *Placebo-comparison (LOCF) for patients with baseline HAQ-DI ≥0.5*

Conclusion: In subjects with psoriasis and concomitant PsA, secukinumab was associated with superior improvement in skin symptoms and physical functioning compared with placebo. These data strongly support continued evaluation of secukinumab in patients with PsA.

Sustained Improvement In Health-Related Quality Of Life, Work Productivity, Employability, and Reduced Healthcare Resource Utilization Of Patients With Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis Treated With Golimumab: 5-Year Results From 3 Phase III Studies. Chenglong Han[1], Arthur Kavanaugh[2], Mark C. Genovese[3], Benjamin Hsu[4], Atul A. Deodhar[5] and Elizabeth C. Hsia[6]. [1]Janssen Global Services, LLC., Malvern, PA, [2]University of California, San Diego, La Jolla, CA, [3]Stanford University, Palo Alto, CA, [4]Janssen Research & Development, LLC., Spring House, PA, [5]Oregon Health & Science University, Portland, OR, [6]Janssen Research & Development, LLC./U of Penn, Spring House/Philadelphia, PA.

Background/Purpose: To summarize changes from baseline in health-related quality of life (HRQOL), impact of disease on work productivity, employability, and healthcare resource utilization among patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) treated with golimumab (GLM) through 5 years.

Methods: Patients with active RA despite MTX (GO-FORWARD), active PsA (GO-REVEAL), and active AS (GO-RAISE) were randomized to placebo (PBO) or GLM (50mg or 100mg Q4w). In GO-FORWARD, treatment also included concomitant MTX (GLM monotherapy in GO-FORWARD was not included in this analysis). Patients randomized to PBO crossed over to GLM at wk 24, with follow-up through wk256. HRQOL was measured using 36-item short-form of health survey (SF-36); impact of disease on work productivity was measured using a VAS scale (0=no impact, 10=impact very much); Employable was defined as being actively employed or to be able to work if a job was available. Healthcare resource utilization included the number of physician visits in the past 4 wks, ER visit in the past 3 months, and hospitalizations in the past 12 months. Changes from baseline through wk 256 in SF-36 PCS and MCS, work productivity, employability, and healthcare resource utilization were summarized from observed patients.

Results: At baseline, *both* mean SF-36 PCS (30.19, 32.91, and 30.00) and MCS (43.65, 45.19, and 44.03) scores in the combined GLM group for RA, PsA, and AS, respectively were below the US norm, indicating impaired HRQOL. Baseline percent of RA, PsA, and AS patients unemployable before retirement were 13.7%, 12.1%, and 14.1%, respectively. At wk24, RA, PsA, and AS GLM-treated pts had statistically significant greater improvement in *both* mean SF-36 PCS (7.65, 7.83, and 9.36, $p<0.001$) and MCS (3.07, 3.84, and 4.01, $p<0.05$) and had a statistically significant greater mean change from baseline in reduction in impact of disease on work productivity in the combined GLM-treated patients vs PBO (−1.987, −2.242, −2.805, all $p<0.001$) in RA, PsA and AS, respectively. At wk256, sustained improvement in SF-36 PCS and MCS was observed in the RA, PsA, and AS GLM-treated patients (mean change from baseline: PCS 9.3, 9.8, and 13.0 and MCS 4.5, 4.7, and 5.1, respectively), while mean change in impact of disease on work productivity for RA, PsA, and AS was −2.71, −3.0, and, −3.9, respectively. In addition, RA, PsA, and AS patients employable at baseline remained employable (all >95%), while those unemployable at baseline became more likely to be employable (RA 33.3%, PsA 64.3%, and AS 76.5%) at Wk256. A reduction in physician visits (RA −84%, PsA −89%, and AS −88%) was observed, as well as a reduction in the number of hospitalizations, ER visits, and days hospitalized, although these events were rare. Patients randomized to PBO at baseline and crossed-over to active treatment achieved similar outcomes overtime as those patients who were randomized to active treatment at baseline.

Conclusion: Golimumab-treated patients showed sustained improvement in HR QoL, reduced impact of disease on work productivity, improved employability, and less healthcare resource utilization through 5yrs.

Evaluation and Comparison Of Performance Of Different Classification Criteria For Reactive Arthritis. Mariana Benegas[1], Rafael Chaparro[1], Oscar L. Rillo[1], Luciana Casalla[1], Emilce Schneeberger[2], Federico Ceccatto[3], Sergio Paira[3], Federico Zazzetti[4], Juan C. Barreira[5] and Emilio Busquiazzo[6]. [1]Hospital Gral. de Agudos Dr. E. Tornú, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [3]Hospital Jose María Cullen, Santa Fé, Argentina, [4]Hospital Británico, Buenos Aires, Argentina, [5]Buenos Aires British Hospital, Buenos Aires, Argentina, [6]Hospital del Milagro, Salta, Argentina.

Background/Purpose: Reactive Arthritis (Re.A) is an inflammatory joint disease that according to different records represents from 6% to 47% of the seronegative spondyloarthropathies (SS). These differences may be due to genetic and/or environmental variations as well as the absence of an agreement on the definition of case and validated classification criteria. Objective: to assess and compare the diagnostic value of the classification criteria for Re.A in a cohort patients.

Methods: consecutive adult patients (≥18 years old) were included from 5 Argentinian centers, with Re.A diagnosed by rheumatologists with broad experience in this entity, and as a control group, patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA). Clinical data, laboratory and radiological characteristics employed by the different criteria were retro-prospectively collected and recorded. We classified each patient according to different classification criteria: Calin, Third International Workshop of ReA, American College of Rheumatology (ACR), European Spondylarthropathy Study Group (ESSG), Amor and Assessment of Spondyloarthritis international Society (ASAS) for peripheral arthritis, having registered their fulfillment. *Statistical analysis:* we described the variables under study. Sensitivity, specificity, positive and negative predictive value (PPV/NPV) and likelihood ratios (LR) for each criteria were assessed by double entry table.

Results: thirty six patients with Re.A (78% male), were included, median age (SD): 36 (12) years, median (IQR) disease duration: 22 (2–444) months. Fifty-six percent presented urethritis, 28% gastroenteritis, 8% cervicitis and 8% other infections. Forty-four, 33 and 17% had mono, oligo y polyarthritis respectively, 86% asymmetrical and 61% predominant in lower limbs. Inflammatory spinal pain and sacroiliitis were detected in 56% and 36% respectively; enthesitis 50% and dactylitis 14%. Extra-articular manifestations: uveitis 17%, conjunctivitis and balanitis 8%, keratoderma blennorrhagica and genital ulcer 3%. Radiographic features: 30% had sacroiliitis. In the control group 36 patients (16 PsA, 15 RA, 5 AS) were evaluated; they had similar demographic characteristics and typical findings of each of these entities. The following table shows the sensitivity, specificity, PPV, NPV and LR obtained by the different classification criteria:

	Calin	ACR	Amor	ESSG	ASAS	3° Workshop
Sensitivity (%)	**81**	**64**	**53**	**97**	**97**	**64**
Specificity (%)	**100**	**100**	**47**	**57**	**50**	**100**
PV (%) +	100	54	50	69	66	100
PV (%) -	84	73	50	95	95	73
LR	∞	∞	1	2.19	1.94	∞

Conclusion: the highest sensitivity was observed by applying the ESSG, ASAS and Calin criteria. The highest specificity was obtained by applying the Calin, ACR and Third International Workshop criteria. We observe, in this study, that Calin's criteria showed excellent specificity, keeping a good sensitivity and high positive predictive values and likelihood ratios.

Ustekinumab Improves Physical Function, Quality Of Life, and Work Productivity Of Patients With Active Psoriatic Arthritis Who Were Methotrexate-naïve Or Previously Treated With Methotrexate Or Anti-Tumor Necrosis Factor Agent: Data From 2 Phase 3, Randomized, Placebo-Controlled Trials. Proton Rahman[1], Lluis Puig[2], Alice B. Gottlieb[3], Arthur Kavanaugh[4], Iain B. McInnes[5], Christopher T. Ritchlin[6], Shu Li[7], Yuhua Wang[7], Ning Zhao[8], Rita Ganguly[8], Michael Song[7], Alan M. Mendelsohn[7] and Chenglong Han[8]. [1]Memorial University, St. Johns, NF, [2]Universitat Autònoma de Barcelona, Barcelona, Spain, [3]Tufts Medical Center, Boston, MA, [4]University of California, San Diego, La Jolla, CA, [5]University of Glasgow, Glasgow, United Kingdom, [6]University of Rochester, Rochester, NY, [7]Janssen Research & Development, LLC., Spring House, PA, [8]Janssen Global Services, LLC., Malvern, PA.

Background/Purpose: To examine the impact of ustekinumab (UST) treatment on patient reported outcomes in patients with active psoriatic arthritis (PsA) using week 24 data from two Phase 3 clinical studies, PSUMMIT I and II.

Methods: Adult patients with active PsA despite DMARD and/or NSAID therapy (PSUMMIT I, n=617) or previously treated with anti-TNFα therapy (PSUMMIT II, n=312) were randomized to receive UST 45mg, 90mg, or placebo (PBO) at wks 0, 4, and q12wks, thereafter. Patient reported outcomes were measured using the Health Assessment Questionnaire (HAQ), Dermatology Quality Life Index (DLQI), SF-36 health survey questionnaire (SF-36), Visual Analogue Scales (VAS) for impact of PsA on work productivity (0–10), patient assessment of pain (0–10), and disease activity (0–10). Sub-analyses were conducted by combining both studies into 3 mutually exclusive groups based on treatment history: MTX naïve, previously treated with MTX therapy, and previously treated with anti-TNF therapy.

Results: At baseline, patients in both studies had moderate to severe physical disability and impaired health related quality of life with a mean HAQ score of ≥1.25, mean DLQI score of ≥10 and mean SF-36 PCS and MCS below 50 (normal population score). In PSUMMIT I, UST-treated patients achieved statistically significantly greater improvements in HAQ (−0.31 and −0.4 vs. −0.1), DLQI (−6.6 and −7.5 vs. −1.4), and SF-36 PCS (4.9 and 6.2 vs. 1.4), for the UST 45mg, 90mg, vs. PBO groups, respectively. When compared to PBO, greater proportions of UST-treated patients achieved clinical meaningful improvements in HAQ (≥0.3) (47.8% and 47.5% vs. 28.2%), DLQI (≥5) (58.6% and 63.1% vs. 32.9%), and SF-36 PCS (≥5) (45.5%, and 53.3% vs. 26.0%), for the UST 45mg, 90mg, vs. PBO groups, respectively. Similar results were observed in PSUMMIT II and in the sub-analyses by MTX naïve, prior MTX experienced, and prior anti-TNFα experienced patients. Similar results were also observed in SF-36 sub-scales, especially in bodily pain and physical health. In the anti-TNF naïve population, statistically significantly greater improvement in SF-36 MCS was observed in the combined UST 45mg and 90mg group vs PBO Additionally, UST-treated patients achieved statistically significantly greater improvements in patient assessment of pain, patient assessment of disease activity, and greater reduction in impact of disease on work productivity vs PBO-treated patients.

Conclusion: UST improves physical function, improves general, arthritis and skin-related quality of life, and reduces the impact of disease on work productivity in patients with active PsA regardless of current or prior MTX use or prior anti-TNF experience.

Safety Of Ustekinumab From The Placebo-Controlled Periods Of Psoriatic Arthritis and Psoriasis Clinical Developmental Programs. Iain B. McInnes[1], Kim Papp[2], Lluis Puig[3], Kristian Reich[4], Christopher T. Ritchlin[5], Bruce Strober[6], Proton Rahman[7], Arthur Kavanaugh[8], Alan M. Mendelsohn[9], Michael Song[9], Daphne Chan[9], Yaung-Kaung Shen[9], Shu Li[9] and Alice B. Gottlieb[10]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Probity Research, Waterloo, ON, [3]Universitat Autònoma de Barcelona, Barcelona, Spain, [4]Dermatologikum Hamburg, Hamburg, Germany, [5]University of Rochester, Rochester, NY, [6]University of Connecticut, Farmington, CT, [7]Memorial University, St. Johns, NF, [8]University of California, San Diego, La Jolla, CA, [9]Janssen Research & Development, LLC., Spring House, PA, [10]Tufts Medical Center, Boston, MA.

Background/Purpose: To describe the short-term safety experience of UST during the double-blind, PBO-controlled portion of the PsA & PsO clinical developmental programs.

Methods: Safety data for the PsA population were pooled from a Ph2 (n=146) & 2 Ph3 (PSUMMIT I [n=615], PSUMMIT II [n=312]) studies of UST in pts with active PsA. Safety data for the PsO population were pooled from 1 Ph2 (n=320) & 2 Ph3 (PHOENIX 1 [n=766] & PHOENIX 2 [n=1230]) studies of UST in pts with moderate-to-severe PsO, including a sub-grp of pts with documented PsA (history of or current) at baseline (BL) [n=628]. Pts were randomized to PBO, UST45mg, or UST90mg. The PBO-controlled period was 16wks for all PsA studies, 20wks for the Ph2 PsO study, & 12wks for Ph3 PsO studies. Concomitant therapy(i.e. stable doses of MTX/oral corticosteroids/NSAIDs) were permitted in PsA studies; no concurrent therapies for PsO/PsA were permitted in the PsO studies. Event rates for overall safety endpoints (overall AEs, infections, AEs leading to discontinuation, serious AEs [SAEs]) & AEs of interest (serious infections, nonmelanoma skin cancer

[NMSC], other malignancies, major adverse CV events [MACE]) were analyzed & compared between the PBO & UST grps within each population. Data for the UST dose grps were analyzed & presented as a combined grp. All pts who received ≥1 dose of tx were included in the analyses. Results were reported as number of events per 100 pt-yrs of follow-up (PY).

Results: 1071 treated pts (379 PBO, 692 UST) were included in the PsA population & 2314 treated pts (732 PBO, 1582 UST) were included in the PsO population (including 207 PBO, 421 UST in PsA sub-grp). BL demographics & medical history were generally comparable between the PsA & PsO populations with similar proportions of pts reporting relevant comorbidities, including diabetes, hyperlipidemia, hypertension & family history of coronary heart disease. In the PsA population, median duration of PsA at BL was ≥4 yrs & >75% had PsO with ≥3% BSA skin involvement. In the PsO population, median BSA involvement was 21%; median PASI score was 17 & 27% had PsA. Safety outcomes observed during the PBO-controlled period are detailed (Table). Within each population, rates of overall AEs, infections, & SAEs in pts receiving PBO or UST were generally comparable. Slightly higher rates of AEs leading to discontinuation were observed across all PBO grps & a slightly higher rate of SAEs was observed in the PBO grp in the PsA population. Event rates of AEs of interest were generally comparable, with overlapping confidence intervals, between the PBO & UST grps within the PsA & PsO populations.

Table. Overall safety during the PBO-controlled period of the PsA and PsO studies (Events per 100 PY)

	PSA studies		PSA sub-grp from PSO studies		All pts from PSO studies	
	PBO	UST	PBO	UST	PBO	UST
Treated pts (n)	379	692	207	421	732	1582
PY of follow-up	110	209	49	106	177	407
AEs	348.07	375.83	476.42	481.32	413.24	502.91
Overall infections	110.59	100.06	139.89	142.79	142.79	141.16
AEs leading to d/c	13.79	3.85	12.37	5.71	9.74	5.95
SAEs	12.69	5.75	4.05	6.62	6.78	7.62

AE of interests during the PBO-controlled period of the PsA and PsO studies (Events per 100 PY [95% CI])*

	PSA Studies		All Pts from PSO studies	
	PBO	UST	PBO	UST
Treated pts (n)	379	692	732	1582
PY of follow-up	110	209	177	407
Serious Infections	0.91 (0.02, 5.05)	0.00 (0.00, 1.43)	1.70 (0.35, 4.96)	1.23 (0.40, 2.87)
NMSC	0.00 (0.00, 2.72)	0.48 (0.01,2.67)	1.13 (0.14, 4.09)	0.74 (0.15, 2.16)
Other malignancies	0.00 (0.00, 2.72)	0.00 (0.00,1.43)	0.57 (0.01, 3.15)	0.25 (0.01, 1.37)
MACE	0.91 (0.02, 5.05)	0.00 (0.00, 1.43)	0.00 (0.00, 1.69)	1.23 (0.40, 2.87)

*Event rates for AEs of interest for the PsA sub-grp of the PsO studies are not presented separately due to low number of events observed.

Conclusion: During the PBO-controlled portion of the studies, UST was well-tolerated in pts with PsA & PsO. Overall safety observations were consistent between both populations, & safety event rates were generally comparable between pts receiving PBO & UST within each population.

Long-Term Safety Of Ustekinumab: 5 Years Of Follow-Up From The Psoriasis Clinical Development Program Including Patients With Psoriatic Arthritis. Kim Papp[1], Christopher E.M Griffiths[2], Kenneth B. Gordon[3], Mark Lebwohl[4], Philippe O. Szapary[5], Yasmine Wasfi[5], Daphne Chan[5], Yaung-Kaung Shen[5], Vincent Ho[6], Pierre-Dominique Ghislain[7], Bruce Strober[8] and Kristian Reich[9]. [1]Probity Research, Waterloo, ON, [2]Dermatology Centre, University of Manchester, Manchester Academic Health Science Centre, Salford Royal NHS Foundation Trust, Manchester, United Kingdom, [3]Northwestern University, Chicago, IL, [4]Mount Sinai Medical Center, New York, NY, [5]Janssen Research & Development, LLC., Spring House, PA, [6]University of British Columbia, Vancouver, BC, [7]7. Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium, [8]University of Connecticut, Farmington, CT, [9]Dermatologikum Hamburg, Hamburg, Germany.

Background/Purpose: Ustekinumab(UST) is approved for moderate-to-severe psoriasis (PsO), and is currently in Phase 3 development for psoriatic arthritis (PsA). We report the long-term safety experience of UST in the sub-group of PsO patients with a medical history of PsA (PsA Sub-group) compared with the overall PsO population (Overall Population) from the PsO development program with up to 5yrs of treatment and follow-up.

Methods: Pooled safety data across one Phase 2 and three Phase 3 [PHOENIX 1, PHOENIX 2, ACCEPT] clinical trials in pts with moderate-to-severe PsO were analyzed. Pts received UST 45mg or 90mg SC 12wkly through up to 5yrs. The presence or absence of PsA (history of or current) at baseline was reported. No concurrent treatment for PsO or PsA was permitted throughout the studies, except for low potency topical steroids for PsO during the open-label long-term extensions of PHOENIX 1 and 2. Event rates for overall safety endpoints (adverse events [AEs], infections, AEs leading to discontinuation, serious AEs [SAEs]) and AEs of interest (serious infections, nonmelanoma skin cancers [NMSC], other malignancies, major adverse CV events [MACE]) were analyzed. All patients who received ≥1 dose of UST were included in the analyses. Data from the two UST dose groups were analyzed as a combined group. Results are expressed in events per 100 pt-years of follow-up (PY) and compared between the PsA Sub-group and Overall Population.

Results: The Overall Population included 3117 pts (8998 PY) who received ≥1 dose of UST; with 1482 (47.5%) pts treated for ≥4yrs or more (including 838 [26.9%] for ≥5yrs). At baseline, the majority of pts were white (92.2%), male (68.5%), median age of 46yrs. Mean BSA involvement was 26.2%±16.7 and mean PASI score was 19.7±7.7; 27.5% of pts had concomitant PsA. Safety results for the PsA Sub-group and Overall Population are detailed in Table 1. Through Yr5, event rates for overall safety endpoints and AEs of interest were generally comparable between the groups.

Safety Through up to 5yrs Follow-up (Events per 100 pt-yrs of follow-up)

	PSA Sub-group	Overall Population
Treated pts(n)/Pt-yrs of follow-up	858/2490	3117/8998
Overall Safety:		
AEs	249.40 (243.23, 255.68)	232.59 (229.44, 235.76)
Infections	91.49 (87.77, 95.32)	86.52 (84.61, 88.47)
AEs leading to d/c	2.77 (2.16, 3.51)	2.40 (2.09, 2.74)
Serious AE	8.59 (7.48, 9.83)	7.10 (6.56, 7.67)
AEs of Interests:		
Serious infxns	1.53 (1.08, 2.09)	1.10 (0.89, 1.34)
NMSC/Other malignancies	0.48 (0.25, 0.84)/ 0.72(0.43, 1.15)	0.52 (0.39, 0.70)/ 0.60 (0.45, 0.78)
MACE	0.56 (0.31, 0.94)	0.44 (0.32, 0.61)

Conclusion: With continuous UST exposure for up to 5yrs and approximately 9000 patient-years of follow-up in the PsO development program, long-term safety in the Overall Population were consistent with previous reports at earlier follow-up and event rates were generally comparable to other currently approved biologic agents. Long-term safety in the sub-group of PsO patients with a history of PsA at baseline were generally comparable to those in the overall study population.

325

Certain Class I HLA Alleles and Haplotypes Have Important Positive and Negative Associations With Psoriatic Arthritis Phenotype. Muhammad Haroon[1], Robert Winchester[2], Jon T. Giles[3] and Oliver FitzGerald[1]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Columbia University, New York, NY, [3]Columbia University, College of Physicians & Surgeons, New York, NY.

Background/Purpose: Psoriatic arthritis (PsA) is strongly associated with the inheritance of several different class I alleles, suggesting separate patterns of MHC effect result in PsA. The present study was based on the hypothesis that the genetic heterogeneity also contributes to the clinical heterogeneity of PsA, and that severity of clinical features of disease may be associated to different HLA alleles or haplotypes.

Methods: A cohort of 282 PsA patients was studied. Following informed consent, HLA-B and HLA-C genotypes were determined. Patients underwent a detailed skin and rheumatologic assessments, and an extensive medical record review was performed to obtain information regarding their psoriatic disease features. We ranked PsA patients according to the number of PsA features present (enthesitis, dactylitis, sacroiliitis, joint deformity, joint fusion, erosion, and osteolysis) using a propensity score model, where the PsA patient with the smallest aggregate of these features was assigned the lowest score, and those with highest aggregate assigned the highest score.

Results: The studied cohort had following demographics and clinical characteristics: mean age 54.6±12 years; 52% female; mean PsA duration=19±9 years; 25% with sacroiliitis; 43.5% with peripheral joint erosions**.** Enthesitis was very strongly associated with the inheritance of HLA-B*270502 (OR 2.951, p=<0.0018), HLA-C*010201 (OR 3.53, p=<0.0018) and their shared haplotype B*270502.C*010201 (OR 3.71, p=<0.0018). Similarly, HLA-C*020202 was significantly associated with the presence of radiographic osteolysis (OR 3.07, p=<0.0018). Interestingly, we found relatively strong negative association of HLA-B*440301 with enthesitis, dactylitis, joint deformities and joint fusions (p=<0.05). Based on the composite severity propensity score the cohort was divided into tertiles (mild, moderate, severe). The more severe PsA phenotype was characterized by B*0801 (OR 2.42, p=0.001), C*020202 (OR 10.94, p=0.005), C*070101 (OR 2.27, p=0.002), B*0801-C*0701 (OR 2.35, p=0.002), and B*270502-C*020202 (OR 9.78, p=0.010). In contrast, B*44020101 (OR 0.35, p=0.008), any B*44 allele (OR 0.34, p=0.001) and B*44020101-C*05010101 (OR 0.36, p=0.01) were associated with milder disease.

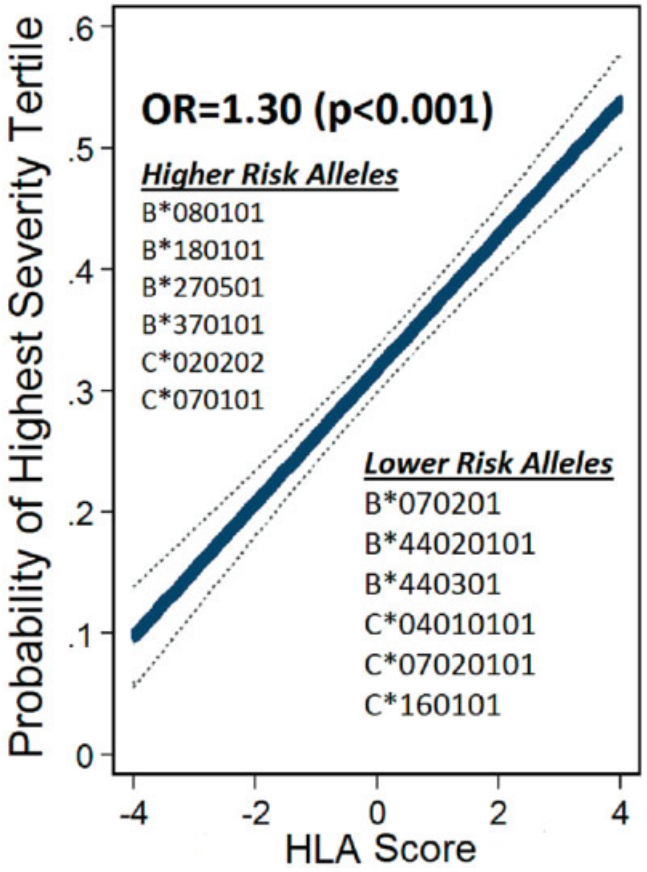

Figure. Each patient was assigned an HLA score based on their number of high and low risk alleles (from univariate modeling on the outcome of PsA Severity Propensity). A patient with 4 low risk alleles was assigned a score of -4, while one with 4 high risk alleles was assigned a score of +4. Each unit increase in the HLA score was associated with a 30% higher odds of being in the highest tertile of PsA Severity Propensity (p-value<0.001). The least squares estimator of the average probability (thick line) and 95% CI (dotted line) are depicted, with adjustment for age, current smoking, pack-years of smoking, duration of psoriasis and psoriatic arthritis, years between psoriasis and psoriatic arthritis, and TNF inhibitor use.

Conclusion: HLA genotype importantly influences the clinical phenotype, with certain alleles specifying a severe or milder disease phenotype, and that the phenotype is likely the result of cis and trans interactions of multiple individual alleles. Certain alleles, such as those of the HLA-B*0801-C*0701 haplotype, which were not strongly associated with PsA susceptibility, contributed much more importantly to disease severity.

326

Reduction Of Disease Burden On Workplace and Household Productivity In Psoriatic Arthritis Over 48 Weeks Of Treatment With Certolizumab Pegol. Arthur Kavanaugh[1], Dafna Gladman[2], Désirée M. van der Heijde[3], Oana Purcaru[4] and Philip J. Mease[5]. [1]University of California San Diego, San Diego, CA, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]Leiden University Medical Center, Leiden, Netherlands, [4]UCB Pharma, Brussels, Belgium, [5]Swedish Medical Center and University of Washington, Seattle, WA.

Background/Purpose: Compared to the general population, patients (pts) with psoriatic arthritis (PsA) suffer greater amounts of disability and substantially lower employment rates.[1] To date there is limited data on the burden of work and household productivity among pts with PsA.[2] The results from the RAPID-PsA study indicate significant improvements in work and household productivity with certolizumab pegol (CZP) vs placebo (PBO) up to Week

(Wk) 24.[3] The purpose of this report is to estimate the economic burden of moderate to severe PsA on productivity and to examine the long-term effect of CZP on workplace and household productivity in RAPID-PsA up to Wk48.

Methods: The ongoing RAPID-PsA trial (NCT01087788) is double-blind and PBO-controlled to Wk24 and dose-blind to Wk48.[4] Pts had active PsA and had failed ≥1 DMARD. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks 0, 2, 4) continued on their assigned dose in dose-blind phase; PBO pts entering dose-blind phase were re-randomized to CZP loading dose followed by CZP 200mg Q2W or CZP 400mg Q4W. The arthritis-specific Work Productivity Survey (WPS),[5] administered Q4W from baseline (BL), assessed the impact of PsA on workplace and household productivity in the randomized set (RS). Disease burden was evaluated at study BL. WPS responses (LOCF imputation) in both CZP groups are summarized descriptively over 48 wks.

Results: At BL, pts had a mean age of 48 years and 55% were female; 61.6% had psoriasis skin involvement ≥3% body surface area. 59.5% of pts were employed outside the home, 14.0% were work disabled due to PsA and 13.5% were retired at study BL. A high burden of PsA on workplace and household productivity was reported at study BL, with on average >1 wk of paid work affected (mean 6.7 days), ~2 wks of household duties (mean 13.3 days), and mean 3.7 days of social activities affected over previous month. In employed patients in both CZP groups, decreases in absenteeism and presenteeism reported to Wk24 were sustained up to Wk48 (Table). Additionally, the improvements in household productivity and increased participation in social activities reported in both CZP groups over 24 wks were maintained up to Wk48 (Table).

Table. Workplace and household productivity over 48 wks in the RAPID-PsA trial (RS population)

WPS responses, mean	CZP 200mg Q2W n = 138	CZP 400mg Q4W n = 135
Productivity at workplace (employed subjects)		
Work days missed due to arthritis per month [a]		
BL	2.0	1.6
Wk24	0.2	0.6
Wk48	0.1	0.6
Days with work productivity reduced by ≥50% due to arthritis per month [a,b]		
BL	5.2	5.1
Wk24	1.3	2.1
Wk48	0.8	1.9
Level of arthritis interference with work productivity (0–10 scale) [a,c]		
BL	4.4	3.8
Wk24	1.7	1.9
Wk48	1.2	1.8
Household productivity and social participation (all subjects)		
Household work days missed due to arthritis per month		
BL	5.9	5.5
Wk24	2.4	2.5
Wk48	2.0	2.7
Household work days with productivity reduced by ≥50% due to arthritis per month [b]		
BL	7.1	7.1
Wk24	2.9	3.5
Wk48	2.3	3.3
Level of arthritis interference with household productivity (0–10 scale) [c]		
BL	5.2	4.9
Wk24	2.2	2.6
Wk48	2.0	2.4
Days missed family/social/leisure activities due to arthritis per month		
BL	4.1	3.3
Wk24	1.1	1.0
Wk48	1.1	1.6

[a] Based only on employed pts at the specific visit; pts employed at BL (CZP 200 mg Q2W/ CZP 400mg Q4W): 83/83; [b] Does not include work days missed counted in the previous question; [c] 0–10 scale, 0 = no interference and 10 = complete interference.

Conclusion: PsA is associated with a high burden of disease on workplace and household productivity that could lead to large financial burden for pts and society. This analysis indicates that CZP improved workplace productivity in patients with PsA by reducing absenteeism and presenteeism and improved household productivity and increased participation in social and daily activities. The benefits of CZP were maintained up to Wk48.

Major Differences In The Pattern Of Joint Swelling and Tenderness In a Large Psoriatic Arthritis Cohort – Results From An Exploratory Hierarchical Cluster Analysis. Burkhard Möller[1], Daniel Stekhoven[2] and Peter M. Villiger[3]. [1]Inselspital, Bern, Switzerland, [2]Swiss Clinical Quality Management in Rheumatic Diseases-SCQM Foundation, Zurich, Switzerland, [3]Inselspital-University Hospital of Bern, Bern, Switzerland.

Background/Purpose: Psoriatic arthritis (PsA) shows the largest complexity in joint involvement among all inflammatory types of arthritis. In order to improve feasibility and to reduce the number of joints to be evaluated for a global PsA disease activity assessment, we aimed to identify clusters of joint involvement in the Swiss Clinical quality management (SCQM) PsA cohort.

Methods: From inclusion visits of all 1256 patients with PsA diagnosis, manifestations in the 66 swollen/68 tender joint score were clustered according to their dissimilarities in profiles by an iterative algorithm, at each stage joining the two most similar joint profiles into one cluster. The distances between clusters were recomputed by the Lance-Williams dissimilarity update formula. Dendrograms of hierarchical clustering were performed separately on the swollen and tender joint data. Distances between clusters were reported by the number of patients with differences in their state of joint involvement.

Results: Among 1256 individuals diagnosed of PsA by board certified rheumatologists, 749 patients (60%) fulfilled the CASPAR classification criteria. Numbers [in brackets] are from CASPAR+ patients. Patients had mean age 50 [48] years, mean disease duration 5.8 [5.9] years (IQR 2–12 for both) and 48% [45%] female gender. Current skin involvement was moderate to severe in 21 [24] %, absent in 21 [14] %, and nail involvement reported in 29 [29] %. Skin involvement was reported in the patient's history in 92 [98] %, arthritis in 84 [92] %, enthesitis in 62 [65] %, dactylitis in 57 [74] %, spine involvement in 45 [44] %, and a positive family history in 38 [41] % of the cases. Treatment at inclusion were: NSAIDs 54 [57] %, synthetic DMARDs 61 [65] % or biologics 50 [52] %. Mean SJC was 2;IQR 0–6 [3;IQR 0–7], and mean TJC 4; IQR 0–10 [5; IQR 1–11]. Favourable clustering and symmetry in 9 out of ten clusters was obtained only for tender joints. The level of agreement was likewise the highest for symmetric involvement of wrist and knee joints in all and in CASPAR+ patients. Other clusters, symmetric involvement of PIP 2–5, MCP 1, MCP 2–5 [−3], MTP 1–5, shoulder joints, ankle joints, IP 1 + DIP 2–3 [−5], and a very complex pattern in the 10th cluster were the same, but varied in sequence of agreement between analyses in all or only in CASPAR+ patients. In contrast, the cluster resolution for swollen joints was far from satisfying even when applying the Ward's method, which minimizes the increase of within-cluster variance in each merging step. With exception of the wrist, knee and ankle joint clusters, all other obtained SJ clusters differed substantially from TJ clusters. An oligoarticular pattern according to Moll & Wright was seen in 42% and polyarticular in 16%. In contrast to highly prevalent dactylitis, predominant DIP involvement was seen in only 3% of cases.

Conclusion: Swollen and tender joint patterns in PsA are hardly in agreement. The enormous complexity in type and pattern of joint involvement may limit the definition of joint involvement only on basis of clinical data. With regard to the many cases with oligoarticular disease, it appears that no joint from the 66/68 joint count should be omitted for a meaningful joint count based PsA disease activity assessment.

Clinical Characteristics Of Patients Who Switch Biologic Therapy Within The First Two Years: Results From a Large US Registry Population. Philip J. Mease[1], Emily Edson-Heredia[2], Katherine C. Saunders[3], Catherine L. Shuler[2], Baojin Zhu[2], Monica Chaudhari[4] and Jeffrey D. Greenberg[5]. [1]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [2]Eli Lilly and Company, Indianapolis, IN, [3]CORRONA, Inc., Southborough, MA, [4]Axio Research LLC, Seattle, WA, [5]New York Hospital for Joint Diseases, New York, NY.

Background/Purpose: The use of biologic therapy in psoriatic arthritis (PsA) has altered the disease course and has been shown to reduce disease activity. Data comparing the clinical characteristics of PsA patients and their biologic therapy switching patterns are sparse. We sought to compare baseline characteristics at biologic initiation between patients who go on to switch biologic therapy and those who do not switch in the setting of a real-world US registry population.

Methods: Patients with a current diagnosis of PsA in the CORRONA registry, a large observational registry population in the US, who initiated a biologic were followed for two years to identify whether or not they switched to second biologic. We did not restrict this analysis to patients who were biologic-naïve at initiation. We defined non-switchers as those who either continued to use initial biologic for the entire follow-up period, or discontinued their initial biologic but did not add a second biologic. Measures of disease activity including MD and patient global assessment of disease, tender and swollen joint counts, CDAI, presence of enthesitis or dactylitis, and MD and patient global assessment of skin were evaluated at initiation and at the end of the observation period. P-values comparing non-switchers to switchers were calculated using the Mann-Whitney-Wilcoxon test to account for skewed distribution of disease activity measures.

Results: In this population, mean age at PsA onset was 42.4 years: 42.6 for non-switchers and 41.2 for switchers. Median duration of PsA was 6 years: 7 for non-switchers, and 5 for switchers. 54.6% were bio-experienced (53.7% for non-switchers and 58.3% for switchers) and the majority of the population (79.7%) did not switch to another drug (Non-switchers were 451 vs 115 switchers). Switchers had significantly higher mean MD and patient assessment of disease activity, higher mean tender and swollen joint counts, higher mean CDAI and Physician assessment of skin. Patient assessment of skin (23.7 versus 24.9) was not found to be statistically different.

Table 1. Comparison of Non-Switchers and Switchers

	Non-Switchers N=451 Mean (SD)	Switchers N=115 Mean (SD)	P-value
Physician Global Assessment	17.6 (16.6)	26.1 (20.8)	<.001
Patient Global Assessment	29.2 (24.0)	41.0 (26.8)	<.001
Tender Joint Count	2.7 (4.8)	5.3 (6.9)	<.001
Swollen Joint Count	2.6 (4.3)	4.1 (5.6)	0.002
CDAI	10.0 (9.6)	16.3 (13.1)	<.001
Physician Assessment of Skin	28.0 (30.8)	37.3 (27.6)	0.006

Conclusion: At initiation, patients who go on to switch biologic therapy had worse disease activity compared to those who did not switch. Rheumatologists appear to switch biologics based on their assessment of both arthritis and skin related disease activity.

Health-Related Quality Of Life In Early Psoriatic Arthritis In Comparison With Early Rheumatoid Arthritis. A 5-Year Follow-Up Report From The Swedish Early Psoriatic Arthritis Registry and The Swedish Early Intervention In RA Registry. Lars Törnqvist[1], Tomas Husmark[2], Ulla R. C. Lindqvist[3], Gerd-Marie Alenius[4], Per Larsson[5], Annika Teleman[6], Mats Geijer[7], Lars Erik Kristensen[8], Ingrid Thyberg[9] and Elke Theander[10]. [1]Skåne University Hospital Malmö, Lund University, Sweden, Malmö, Sweden, [2]Department of Rheumatology, Falu Hospital, Falun, Sweden, [3]Department of Medical Sciences, Rheumatology, University Hospital, Uppsala university, Uppsala, Sweden, [4]Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden, [5]Karolinska University Hospital, Stockholm, Sweden, [6]Department of Rheumatology, Spenshult Hospital, Oskarstrom, Sweden, [7]Skåne University Hospital, Lund, Center for Medical Imaging and Physiology, Lund, Sweden, [8]Skåen University Hospital, Lund University, Lund, Sweden, [9]Linköping University Hospital, Linkoping, Sweden, [10]Lund University, Malmö, Sweden.

Background/Purpose: Studies on early psoriatic arthritis (ePsA) are still rare and data on health related quality of life (HRQoL) in ePsA are lacking completely. To assess the degree of HRQoL reduction compared to the background population in ePsA at diagnosis and during the first 5 years of follow-up in patients exposed to Swedish standard of care. To compare HRQoL in ePsA and early RA (eRA) and analyze associations and predictors at baseline.

Methods: Patients included in the Swedish early psoriatic arthritis (SwePsA) and the Swedish early Intervention in RA (TIRA 2) registries having available SF 36 assessments at baseline and 5-year follow-up, were included. Differences from expected levels were calculated for each individual patient and used for the analysis, thus making further age and gender adjustment unnecessary. Measures of physical function (HAQ), disease activity (DAS-28), delay before diagnosis, smoking (only in PsA), pain and general well-being (VAS) were used as explanatory variables. Adequate T-tests as well as uni-and multivariate linear regression analysis were performed.

Results: Both RA (n= 133, 73% women) and PsA (n=166, 52% women) patients displayed a profound statistically significant reduction of HRQoL when being diagnosed with their chronic joint disease. In general the degree of impairment at baseline was similar. However, after 5 years the eRA group had almost normalized their HRQoL, while the ePsA patients still suffered from significant decrease in several SF-36 domains. Figure. A comparison of baseline variables between RA and ePsA revealed longer symptom duration before diagnosis in PsA, a factor independently contributing to hampered improvement during follow-up. Disease activity measured as DAS-28 (and its components) and physical dysfunction measured as HAQ were more severe in TIRA 2-RA patients, possibly motivating early aggressive intervention. In ePsA high disease activity and impaired function at inclusion were associated with worse outcome. In ePsA also current smoking status contributed independently to persistent impairment of HRQoL.

Conclusion: Both newly diagnosed RA and PsA are characterized by profoundly reduced HRQoL. Normalization is seen in RA during the early phase of the disease, but not in ePsA, despite more severe disease in RA at inclusion. This paradox finding may be due to aggressive intervention provoked by the disease severity in RA and longer diagnostic delay in ePsA. Smoking contributed to HRQoL reduction in ePsA, no data were available for the RA group. Earlier detection, lifestyle intervention and more ambitious management strategies similar to those in RA may be needed for ePsA care.

Proteomic Profiling Of Synovial Fluid For The Identification Of Psoriatic Arthritis Soluble Biomarkers. Daniela Cretu[1], Fawnda Pellett[2], Rajiv Gandhi[3], Eleftherios Diamandis[4] and Vinod Chandran[2]. [1]University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, ON, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]University Health Network, Arthritis Program, Toronto, ON, [4]Mount Sinai Hospital, Department of Pathology and Lab Medicine, Toronto, ON.

Background/Purpose: There is a high prevalence of undiagnosed psoriatic arthritis (PsA) in patients seen in dermatology clinics. Identifying soluble biomarkers for PsA will help in screening psoriasis patients for appropriate

referral to a rheumatologist as well as provide further insight into disease pathogenesis. However, identification of novel protein biomarkers in peripheral blood is difficult and unreliable. Potential PsA biomarkers are likely to originate in sites of inflammation such as inflamed joints and subsequently enter systemic circulation. We hypothesize that quantitative proteomic analysis of synovial fluid (SF) obtained from PsA patients, will generate a comprehensive list of proteins specific to PsA, facilitating the identification of potential PsA screening biomarkers.

Methods: SF was obtained from swollen knee joints of PsA patients, and age/sex matched early osteoarthritis (OA) controls. Using strong cation exchange chromatography, followed by liquid chromatography and tandem mass spectroscopy, we extensively characterized the proteomes of pooled SF from ten PsA and ten controls. Extracted ion current (XIC) intensities were used to calculate protein abundance ratios, and were utilized to identify upregulated proteins (PsA/OA ratio>2). Selected reaction monitoring (SRM) assays were developed to relatively quantify potential markers in individual SF samples.

Results: We identified and quantified 443 proteins from both groups (False Discovery Rate <0.05). Only 45 proteins represented upregulated proteins in PsA SF ($p<0.05$). These were investigated using two publicly available databases (Ingenuity Pathway Analysis and DAVID Bioinformatics Resources 6.7) to identify disease relevant proteins. Gene ontology (GO) analysis classified these proteins into categories pertaining to five main biological processes: complement activation, defense response, immunoglobulin mediated response, response to wounding, and extracellular matrix remodeling, all of which are attributes of PsA. Application of subsequent filtering criteria yielded approximately 17 proteins, which served as putative PsA biomarkers. SRM validation confirmed that 13 proteins were indeed elevated in the 10 PsA SF samples, and these included positive controls, MMP3, S100A9, and CRP.

Conclusion: We have developed and utilized a high-throughput proteomics platform using LC-MS/MS to delineate the SF proteome from PsA patients and controls with early OA. Proteins that were differentially expressed were validated using targeted mass-spectrometric assays. Using these methods we have identified several candidate PsA biomarkers. In the future, these proteins must be verified using highly specific immunoassays in serum, in order to identify their clinical utility.

Apremilast, An Oral Phosphodiesterase 4 Inhibitor, Is Associated With Long-Term (52-Week) Improvement In Physical Function In Patients With Psoriatic Arthritis: Results From Three Phase 3, Randomized, Controlled Trials. Georg Schett[1], Philip J. Mease[2], Dafna D. Gladman[3], Arthur Kavanaugh[4], Adewale O. Adebajo[5], Juan J. Gomez-Reino[6], Jürgen Wollenhaupt[7], Maurizio Cutolo[8], Eric Lespessailles[9], Kamal Shah[10], ChiaChi Hu[10], Randall M. Stevens[10], Christopher J. Edwards[11] and Charles A. Birbara[12]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]University of California San Diego, San Diego, CA, [5]University of Sheffield, Sheffield, United Kingdom, [6]Hospital Clinico Universitario, Santiago, Spain, [7]Schön Klinik Hamburg Eilbek, Hamburg, Germany, [8]University of Genova, Genova, Italy, [9]University of Orléans, Orléans, France, [10]Celgene Corporation, Warren, NJ, [11]University of Southampton, Southampton, United Kingdom, [12]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, works intracellularly to modulate pro- and anti-inflammatory mediators. The PALACE 1, 2, and 3 trials compared the efficacy and safety of APR with placebo (PBO) in pts with active PsA despite prior DMARDs and/or biologics.

Methods: Pts were randomized 1:1:1 to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline (BL) DMARD use. At wk 16, pts with <20% reduction from BL in swollen and tender joint counts qualified for protocol-defined early escape; those on PBO were re-randomized to APR20 or APR30 and those on APR remained on the initial APR dose. At wk 24, all remaining PBO pts were re-randomized to APR20 or APR30 through wk 52. Patients taking concurrent DMARDs were allowed to continue stable doses (MTX, sulfasalazine, leflunomide, or a combination).

Results: APR administration resulted in statistically significant and clinically meaningful improvement in ACR20 response (primary endpoint) in all 3 PALACE trials. APR30 was associated with significant improvements in Health Assessment Questionnaire-Disability Index (HAQ-DI) ($P\leq0.03$) and SF-36 Physical Functioning (PF) domain ($P\leq0.05$) vs PBO at wk 24 across all 3 trials. For those pts originally randomized to APR and completing 52 wks of study, improvements were maintained or increased over 52 wks (Table). At wk 52, mean changes in HAQ-DI were −0.369 (APR20) and −0.318 (APR30) in PALACE 1; −0.192 (APR20) and −0.330 (APR30) in PALACE 2; and −0.332 (APR20) and −0.350 (APR30) in PALACE 3. Mean changes from BL exceeded minimal clinically important differences (MCID) thresholds‡ of ≥0.13 or ≥0.3 in pts treated with APR20 and APR30 for 52 wks, and the proportion of APR20 and APR30 pts achieving MCID was maintained between wks 24 and 52. Mean changes in SF-36 PF were 6.98 (APR20) and 5.69 (APR30) in PALACE 1; 4.05 (APR20) and 4.97 (APR30) in PALACE 2; and 5.68 (APR20) and 5.87 (APR30) in PALACE 3. Mean changes from BL exceeded MCID of ≥2.5 in pts treated with APR20 and APR30 for 52 wks, and the proportion of APR20 and APR30 pts achieving MCID was maintained between wks 24 and 52. Pts randomized to APR at wks 16 and 24 demonstrated results consistent with those originally randomized to APR. No new safety findings were identified and the incidence of pts experiencing any AE was comparable over the 0–24 and 0–52 wk periods.

PALACE 1, 2, and 3: Improvements in Physical Function at Week 52 in Patients Receiving APR From Baseline

	PALACE 1		PALACE 2		PALACE 3	
	APR20 (n = 168)	APR30 (n = 168)	APR20 (n = 163)	APR30 (n = 162)	APR 20 (n = 169)	APR30 (n = 167)
Baseline, Mean						
HAQ-DI (0–3)	1.156	1.249	1.133	1.220	1.118	1.184
SF-36 PF	35.13	33.02	34.54	33.67	34.88	34.17
SF-36 PCS	35.02	33.82	34.64	33.26	35.35	34.32
Mean Change From Baseline						
HAQ-DI (0–3)*	−0.369	−0.318	−0.192	−0.330	−0.332	−0.350
SF-36 PF§	6.98	5.69	4.05	4.97	5.68	5.87
SF-36 PCS§	7.81	6.45	5.05	6.35	6.29	5.91
Patients Achieving MCID, %						
HAQ-DI ≥0.13[1]	60.0	59.8	48.0	58.1	61.5	58.3
HAQ-DI ≥0.3[2]	45.8	44.7	36.8	47.0	45.1	52.0
SF-36 PF ≥2.5	64.2	60.0	51.6	53.9	61.2	58.3
SF-36 PCS ≥2.5	71.7	66.2	66.1	69.6	72.7	68.3

The n reflects randomized patients; actual number of patients available for each endpoint may vary.
*Decrease in score indicates improvement.
§Increase in score indicates improvement.

Risk Of Cardiovascular Disease Among Patients With Psoriatic Arthritis Compared To Ankylosing Spondylitis (retrospective cohort study). Zohair Abbas[1] and Marina N. Magrey[2]. [1]Case Western Reserve University at Metrohealth Medical Center, Cleveland, OH, [2]Case Western Reserve University School of Medicine at MetroHealth Medical Center, Cleveland, OH.

Background/Purpose: Both patients with psoriatic arthritis (PsA) and ankylosing spondylitis (AS) are at increased risk of cardiovascular disease (CVD). This increased risk is in part attributed to traditional cardiovascular risk factors. Patients with PsA have higher body mass index (BMI) compared to patients with AS. Based on this we hypothesized that patients with PsA are at higher risk of CVD compared to patients with AS. The purpose of the study is to compare the risk of CVD in patients with PsA to patients with AS.

Methods: Explorys is a clinical research informatics tool that uses unified medical language system ontologies to standardize, normalize and aggregate clinical data from multiple electronic heath records. The data are de-identified and presented through a secure web interface usable by researchers. At the time of this study several million patients from multiple distinct healthcare systems from year 1999 to 2012 were present in the Explorys database. Using the SNOMED hierarchy, we searched for all patients with a diagnosis of either PsA or AS using the terms "ankylosing spondylitis" and "psoriasis with arthropathy." This was further stratified by adding search term "anti tumor necrosis factor alpha drug", and only patients using anti TNF therapy were included in the analysis. Using the first Body mass index (BMI) recorded; we categorized patients into one of three categories: < 25 kg/m2 (normal weight); 25 kg/m2 to < 30 kg/m2 (overweight); and ≥ 30 kg/m2 (obese). Presence of CVD was defined by the occurrence of myocardial infarction (MI), cerebrovascular disease or peripheral vascular disease (PVD). The occurrence of CV events was searched in a temporal sequence. The comparison between the 2 cohorts was made using Fishers exact test.

Results: We identified 2360 cases of PsA and 1020 cases of AS from the database. Demographics are shown in the table 1. 52.5% patients with PsA had a BMI of more than 30 as compared to 37.8% patients with AS ($p=0.0001$). A total cholesterol > 200 was found in 41.9% patients with PsA compared to 36.6% with AS ($p=0.11$). HDL < 40 was found in 34.2% patients with PsA compared to 31% patients with AS ($p=0.34$).There was no significant difference between the PsA and AS cohorts in terms of prevalence of MI 2.1% vs 1.9% ($p= 0.79$), cerebrovascular disease 4.2% vs 2.9% (p-value 0.79) and PVD 5.9% vs 5.8% ($p=0.93$) respectively as shown in table 2.

Table 1.

		AS n=1020 (%)	PsA n=2360 (%)
Age			
	25–50	520 (50)	850 (36)
	50–65	350 (34)	1030 (43)
	>65	100 (10)	380 (16)
Gender			
	Male	673 (66)	1133 (48)
	Female	347 (34)	1227 (52)
Race			
	Caucasian	790 (77)	1900 (80)
	African American	80 (8)	80 (3)
	Asian		20 (1)

Table 2.

		AS (%)	PsA (%)	P value
BMI				
	<19.9	30/660* (4.5)	40/1580* (2.5)	0.016
	20–24.9	150/660 (22.7)	230/1580 (14.5)	0.0001
	25–29.9	230/660 (34.8)	480/1580 (30.3)	0.04
	>30	250/660 (37.8)	830/1580 (52.5)	0.0001
Metabolic Profile				
	Total Cholesterol (>200)	110/300 (36.6)	340/810 (41.9)	0.11
	HDL (<40)	90/290 (3)	260/760 (34.2)	0.34
	HbA1c (>7)	50/200	190/590	0.06
Cardiovascular Disease				
	MI	20/1020(1.9)	50/2360 (2.1)	0.79
	Cerebrovascular Disease	30/1020 (2.9)	100/2360 (4.2)	0.79
	PVD	60/1020 (5.8)	140/2360 (5.9)	0.93

Conclusion: Despite higher BMI in patients with PsA, the prevalence of acute MI, cerebrovascular disease and PVD was similar to patients with AS. The results did not support our hypothesis that increased BMI in PsA increases the risk of CVD. Hence, other risk factors need to be further investigated.

Changes In Weight Associated With Tumour Necrosis Factor Inhibition In Psoriatic Arthritis. Barry J. Sheane, Arane Thavaneswaran, Dafna D. Gladman and Vinod Chandran. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with progressive joint damage and disability. In the last 15 years, tumour necrosis factor inhibitors (TNFi) have emerged as an effective treatment in reducing the incidence of joint damage.

It has been reported that TNFi are associated with weight gain in both psoriasis and PsA. If true, such an adverse effect could contribute to the increased prevalence of cardiovascular disease in PsA and its associated risk factors. In the general population, however, weight increases with age. Studies that have reported weight gain with TNFi in PsA have not accounted for this natural tendency.

In this study, the aim was to investigate whether therapy with TNFi is associated with weight gain in patients attending a large PsA clinic.

Methods: Patients were selected for inclusion in this study if they had at least 2 weight measurements prior to, and after, commencing TNFi. The relevant data were obtained from the clinic database where clinical, radiologic and laboratory data are collected prospectively on all patients satisfying the CASPAR classification criteria for PsA. Change point modelling, to model weight using a random effects analysis, was used to assess differences in weight over time using the mean of the slope before and after starting TNFi. The 'pre' and 'post' slopes were compared using a t-test. All 4 TNFi licensed for use in PsA were analysed as a single entity.

Results: One hundred seventy two patients were eligible for inclusion, of which 60% were male. At the first clinic visit, mean age was 41.7 ± 12.8 years, while mean disease duration was 6.6 ± 8.0 years. At the visit prior to initiation of TNFi, mean number of tender and/or swollen joints was 10.2 ± 10.9, while 115 patients had clinical evidence of joint damage (mean number of damaged joints: 12.9 ± 12.9). Of those taking disease modifying therapy at the time of TNFi initiation, 51% (n=87) were prescribed methotrexate, 9% (n=16) sulphasalazine and 13% (n=22) leflunomide. Mean weight for visits prior to TNF use (adjusting for repeated visits) is 83.5 ± 17.0 kg, while the mean weight after TNFi use was 84.9 ± 17.7 kg ($p=0.006$).

The means of the pre- and post-TNFi slopes were 0.26 ± 0.17 and 0.13 ± 0.13, respectively, which were not significantly different ($p=0.55$). This implies that there was no weight gain after commencement of TNFi therapy in this patient population.

Conclusion: TNF inhibitors do not cause an increase in weight in PsA, contradicting previous reports pertaining to weight gain. The statistical methods employed along with consideration of adults' natural propensity for weight gain with age may account for our findings.

The Joint Effect Of Carotid Ultrasound and Preventive Cardiology Referral On Cardiovascular Risk Factor Modification in Psoriatic Arthritis Patients. Michael Lucke[1], Soo Hyun Kim[1] and M. Elaine Husni[2]. [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: Cardiovascular disease risk is elevated in psoriatic arthritis (PsA) compared to the general population. Prior studies have demonstrated suboptimal evaluation and control of modifiable cardiovascular risk factors in patients with inflammatory arthritis by both Rheumatologists and Primary Care providers. The presence of carotid plaque guides further risk stratification as it highly correlates with cardiovascular events. It is unclear if the addition of carotid plaque screening in PsA would alter medical management. This study investigates the value of screening asymptomatic PsA patients for carotid plaque on cardiovascular risk factor control.

Methods: 86 patients with PsA from the COMPASS database underwent carotid duplex ultrasound (CDU) and screened for the presence of plaque, which was defined using the Mannheim consensus criteria. Referral to preventive cardiology was automatically generated through the electronic health record upon study enrollment for all patients. Repeat US was performed at 12–24 months in 38 patients. Demographics, cardiovascular risk factors, PsA history and disease activity, and medication use were recorded. Fasting glucose, C-reactive protein, and lipid panels were assessed. Our institution has identified a primary prevention consensus algorithm regarding a minimal low density lipoprotein (LDL) goal of 100 mg/dL, initiation of antiplatlet therapy, and lifestyle counseling, as appropriate, in patients with PsA whom are deemed as high risk for cardiovascular disease.

Results: Carotid plaque was identified in 34 patients at baseline screening (39.5%). Of patients with baseline plaque, 18 had a repeat ultrasound within 12–24 months time and all had persistent plaque. Of patients without plaque at baseline, 15% (3/20) had new plaque formation on repeat ultrasound. Mean LDL was 120 and 102 mg/dL, mean HDL was 55 and 55, and mean triglycerides were 203 and 96 in the plaque and no plaque groups, respectively. Overall, 33% (12/36) of patients with repeat screening had an LDL under 100 and 27% (10/36) were on antiplatelet medication. Current statin use was 39% (7/18) by patients with plaque and none were on maximum doses. Despite automatic referral, only 12% (11/86) of patients were seen by Preventive Cardiology, and 14 other patients were seen by a cardiologist for other reasons.

Conclusion: Despite noninvasive screening and automatic referrals in a high risk population, few PsA patients completed consultations with the Preventive Cardiology service. Low utilization of preventive services was observed even in those patients with definitive evidence of atherosclerotic disease by identification of plaque. The percentage of patients with plaque is similar to other cohorts of PsA patients and is increased compared to the general population. A minority of patients met stated LDL goals and few were on antiplatelet therapy. Further characterization of lapses in the referral process is required to improve proactive modification of cardiovascular risk in PsA.

Comparing Adalimumab and Etanercept As First Line Agents In Patients With Psoriatic Arthritis. Data From The Rhumadata® Clinical Database and Registry. Sabrina Hoa[1], Denis Choquette[2], Louis Bessette[3], Diane Sauvageau[2], Boulos Haraoui[2], Jean Pierre Pelletier[2], Jean-Pierre Raynauld[2], Edith Villeneuve[2] and Louis Coupal[2]. [1]Centre hospitalier de l'université de Montréal (Hôpital Notre-Dame), Montréal, QC, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC.

Background/Purpose: No long term head-to-head comparative studies of anti-TNF agents in psoriatic arthritis have been published. Controversy exists over the selection of initial biologic therapy after DMARDs failure. We aim to assess if patients with psoriatic arthritis (PSO) treated with adalimumab or etanercept after failure to a first line agent (MTX-IR) have different drug survival rates. A secondary objective is to explore the role of MTX co-prescription.

Methods: PSO patients prescribed a first biologic agent after January 1st 2004 were included in the present analysis. The cohort use in the analysis includes patients prescribed either adalimumab (ADA) or etanercept (ETA) as a first biologic treatment. Baseline demographics for both cohorts included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluation (VAS), TJC, SJC, DAS 28 ESR, SDAI and patient-years of treatment. Statistical analysis was performed using SAS version 9.3. RHUMADATA® is a clinical database and registry used daily in clinical practice at the IRM and the CORQ.

Results: A total of 134 patients were analysed and no significant differences in baseline characteristics were noted between treatment groups except for morning stiffness and disease duration. The 5 year retention rate of ADA and ETA were respectively 64% and 47% without a significant statistical difference (Log-Rank p=0.084). When combining biologics, the use of DMARDs did not improve drug survival over biologic monotherapy (52% for combination therapy vs. 67% for monotherapy, Log-Rank p=0.74).

Conclusion: In this analysis, adalimumab and etanercept after DMARDs failure have statistically similar 5-years retention rates. Adalimumab, however, demonstrated numerical superiority over etanercept for the entire follow-up period. More data will be required to confirm this observation. Combination with methotrexate did not demonstrate improved 5-year retention.

Disclosure: S. Hoa, None; **D. Choquette**, None; **L. Bessette**, None; **D. Sauvageau**, None; **B. Haraoui**, None; **J. P. Pelletier**, None; **J. P. Raynauld**, None; **E. Villeneuve**, None; **L. Coupal**, None.

336

Cluster Analysis Of Psoriatic Arthritis Patients At Follow-Up. Arane Thavaneswaran, Vinod Chandran and Dafna Gladman. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Our previous research showed that baseline characteristics would enable the sub-categorization of psoriatic arthritis (PsA) into the distinct phenotypic groups of axial and peripheral disease using cluster analysis (CA). We aimed to determine if demographic and disease characteristics of PsA patients with at least five years of follow-up can be clustered into distinct groups.

Methods: 527 PsA patients from an observational cohort of patients seen from 1978 to 2013. Patients had at least 5 years of follow-up and genetic information in order to be included in the analysis. CA using Ward's method was conducted to identify groups of patients based on the following characteristics at follow-up: gender, type of psoriasis (type I or II), duration of PsA, race, family history of psoriasis, ESR, severe PASI, psoriasis vulgaris, nail disease, dactylitis, swollen joint count, damaged joint count, axial disease, presence of arthritis mutilans, presence of arthritis prior to psoriasis, HLA-B*27 and HLA-C*06. 7 clusters were formed and matched to non-overlapping arthritis patterns: distal arthritis, oligoarthritis, polyarthritis, axial only, distal arthritis and axial, oligoarthritis & axial, and polyarthritis & axial. Comparisons between the clusters and arthritis patterns were conducted using t-tests and Chi-squared analysis.

Results: The baseline characteristics of the 527 patients were as follows: 306 (58.1%) males, mean age at diagnosis of PsA 28.3 (14.2) yrs, mean age at first visit 42.5 (12.3) yrs, mean duration of PsA 6.8 (8.0) years, mean active joint count 10.6 (9.2), mean PASI 5.2 (8.1), mean Steinbrocker score 12.7 (25.9), HLA-B*27 94 (18%)]. At follow-up, mean age was 57.6 (12.6) yrs, mean PASI 4.6 (6.6), mean Steinbrocker score 28.0 (37.3) with an average follow-up of 15.0 (7.6) yrs. Two main clusters of patients were identified. One consisted of distal arthritis, oligoarthritis and polyarthritis and the other of axial only, distal and axial, oligoarthritis & axial, and polyarthritis & axial, thus clearly identifying patients into peripheral and axial disease. Comparison of the two clusters showed more patients with psoriasis vulgaris among patients with peripheral disease. Patients falling into the axial disease cluster had a higher prevalence of males and HLA-B*27, higher PASI, more dactylitis, higher clinically damaged joint and swollen joint count, more axial disease, more arthritis mutilans and more patients who developed arthritis first.

Table. Comparison of two clusters

Variable	Frequency (%) or Mean (sd)		p-value
	Cluster I	Cluster II	
Age at diagnosis of Ps (>40 vs. ≤40)	63 (20.9%)	44 (19.5%)	0.68
Duration of PsA	21.3 (11.1)	22.5 (9.8)	0.16
Gender (Males)	149 (49.5%)	157 (69.5%)	<0.0001
Race (Caucasian vs. others)	267 (88.7%)	210 (92.9%)	0.10
Family history of Psoriasis	142 (47.7%)	116 (51.6%)	0.38
Nail disease	124 (44.6%)	106 (51.0%)	0.16
Dactylitis	6 (2.0%)	18 (8.3%)	0.001
Psoriasis vulgaris	236 (81.9%)	142 (66.4%)	<0.0001
Severe PASI (≥10)	18 (7.2%)	30 (19.4%)	0.0002
ESR	15.9 (15.8)	15.3 (17.2)	0.69
Swollen joint count	0.74 (1.72)	1.40 (3.4)	0.008
Clinically damaged joints	8.4 (12.2)	14.7 (16.4)	<0.0001
Axial disease	104 (34.9%)	177 (79.0%)	<0.0001
Presence of arthritis mutilans	76 (25.3%)	99 (43.8%)	<0.0001
Presence of arthritis prior to psoriasis	30 (10.0%)	15 (6.6%)	0.18
HLA-B*27	44 (14.6%)	50 (22.1%)	0.03
HLA-C*6	83 (27.6%)	64 (28.3%)	0.85

Conclusion: Based on patients' characteristics at follow-up, CA analysis separated PsA patients into two predominant arthritis patterns coinciding with the results that looked at a the same cohort at baseline with the exclusion of B27 and C6 as clustering variables. The study provides further evidence to classify patients into just two groups based on the presence or absence of axial arthritis not only at baseline but also at follow-up.

Fatigue and Work Disability In Psoriatic Arthritis. Jessica Walsh[1], Molly McFadden[2], Gerald G. Krueger[1], Allen D. Sawitzke[1] and Daniel O. Clegg[3]. [1]University of Utah, Salt Lake City, UT, [2]University of Utah, SLC, UT, [3]George Wahlen VA Medical Center/University of Utah, Salt Lake City, UT

Background/Purpose: Fatigue and work disability (WD) are common in people with psoriatic arthritis (PsA). Pain and discomfort from PsA contribute to fatigue by impairing sleep quality. Inflammatory mediators implicated in the pathogenesis of PsA may also impact fatigue with direct effects on the central nervous system. It is unclear if fatigue contributes to WD, independently of musculoskeletal and cutaneous disease activity in people with PsA. The purpose of this study was to explore the relationships between fatigue, WD, and PsA activity.

Methods: Phenotype data were collected from participants in the Utah Psoriasis Initiative Arthritis registry between January 2010 and May 2013. WD was measured with the Work Limitations Questionnaire (WLQ). Two variables were used to assess fatigue, including question 1 from the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI #1), "How would you describe the overall level of fatigue/tiredness you have experienced?" and question 1 from the Psoriatic Arthritis Quality of Life Questionnaire (PsAQoL #1) "I feel tired whatever I do." PsA activity was assessed with tender joint count (TJC), swollen joint count (SJC), dactylitis count, enthesitis count, inflammatory back pain (IBP), and the product of a cutaneous physician global assessment (PGA) and body surface area (BSA) (PGAxBSA). Depressed mood was measured with PsAQoL question 4 (PsAQoL #4) "I feel there is no enjoyment in my life." Chi square, Fisher's exact test, t-test, and Wilcoxon rank sum statistics were used to compare demographics and disease characteristics. ANCOVA analyses were used to determine the adjusted mean WLQ scores for PsQOL #1 and BASDAI #1.

Results: Evaluations were completed with 107 participants. 54 (50.5%) were classified as having fatigue according to PsAQoL #1, and 64 (60.0%) were classified as high fatigue by BASDAI #1. TJC, SJC, enthesitis count, IBP, and depressed mood were highest or most frequent in fatigued participants (Table 1). After adjustments for PsA activity and depressed mood, WLQ work productivity loss was associated with fatigue, as measure by PsAQoL #1 (p=0.02) and BASDAI #1 (p= 0.002) (Table 1).

Table 1. Demographics and disease characteristics

	PsAQoL #1 Yes/No			BASDAI #1 0–10 Likert scale		
Characteristic	No fatigue n = 53	Fatigue n = 54	p	Low fatigue (BASDAI #1 <6) n = 43	High fatigue (BASDAI #1 ≥6) n = 64	p
Age	47.0 ± 11.9	48.4 ± 10.1	0.81	47.5 ± 12.4	48.0 ± 10.1	0.89
Male sex	32 (60.4)	28 (51.9)	0.37	27 (62.8)	33 (51.6)	0.25
White race	50 (94.3)	49 (90.7)	0.71	41 (95.3)	59 (92.2)	0.29
Body mass index	29.9 ± 7.8	32.7 ± 9.4	0.14	30.6 ± 10.7	31.8 ± 7.4	0.13
Duration of PsA (years)	10.4 ± 11.8	10.1 ± 10.6	0.57	10.2 ± 11.7	10.1 ± 10.8	0.48
Tender joint count (scale range 0–68)	4.1 ± 5.8	10.4 ± 10.9	0.001	4.0 ± 5.1	9.4 ± 12.4	0.003
Swollen joint count (scale range 0–66)	3.0 ± 5.3	4.7 ± 6.0	0.06	2.3 ± 3.7	4.7 ± 6.5	0.007
Dactylitis count (scale range 0–20)	0.6 ± 1.7	0.4 ± 1.0	0.76	0.4 ± 1.2	0.5 ± 1.4	0.49
Enthesitis count* (scale range 0–8)	0.4 ± 0.9	0.8 ± 1.0	0.01	0.3 ± 0.7	0.8 ± 1.1	0.004
Inflammatory back pain (yes/no)	12 (22.6)	29 (53.7)	<0.001	9 (20.9)	31 (48.4)	<0.001
PGAxBSA (scale range 0–500)	7.6 ± 16.4	3.0 ± 4.0	0.07	6.4 ± 16.1	4.5 ± 8.5	0.91
Depressed mood (yes/no)	3 (5.7)	11 (20.4)	0.03	3 (7)	11 (17.2)	<0.001

*Entheses included plantar fascia insertions, Achilles tendon insertions, lateral epicondyles, & medial femoral condyles

Table 2. Work Limitation Questionnaire scores in psoriatic arthritis participants with and without fatigue

	PsAQoL #1 Yes/No			BASDAI #1 0–10 Likert scale		
WLQ Scores	No fatigue* (Mean WLQ score)	Fatigue* (Mean WLQ score)	p	Increase in WLQ score for each 1 point increase in BASDAI #1*	SE	p
Composite WLQ Productivity Loss	7.6	10	0.02	0.87	0.18	0.002
Time management subscale	35.2	42.4	0.26	3.53	1.11	0.127
Mental-interpersonal subscale	24.2	31.6	0.09	3.29	0.71	<0.001
Output subscale	28.9	37.3	0.123	3.92	0.93	0.004
Physical subscale	33.6	49.2	0.005	2.49	0.99	0.05

*Adjusted for age, gender, tender joint count, swollen joint count, enthesitis count, inflammatory back pain, PGAxBSA, and depressed mood.

Conclusion: WD was associated with fatigue, and the associations were not entirely explained by the musculoskeletal, cutaneous, or psychiatric manifestations of PsA. Additional research is required to characterize the relationship between fatigue and WD in people with PsA.

Tailored Approach To Early Psoriatic Arthritis Patients: Ultrasonographic Predictors For Structural Joint Damage. Yasser El Miedany[1], Maha El Gaafary[2], Sally Youssef[2] and Annie Nasr[2]. [1]Medway Hospital, Gillingham, United Kingdom, [2]Ain Shams University, Cairo, Egypt.

Background/Purpose: To evaluate the use of musculoskeletal US as a predictor for inflammatory structural progression in psoriatic patients.

Methods: Measures of association (OR) were tested, in a prospective 1-year follow up study, between structural deterioration and the presence of baseline synovitis, or its persistence. 126 psoriatic patients were prospectively evaluated both clinically and by US (both US-GS and US-PD) at time 0, 6 and 12 months, in order to collect the following variables: 1. 42 joints (2 wrists, 10 MCP, 10 PIP, 10 DIP and 10 MTP) for the presence of synovial hypertrophy and vascularisation (0–3 scale), and the number and dimension of bone erosions; 2. Enthesitis: GUESS (Glasgow Ultrasound Enthesitis Scoring System) index scores was calculated; 3. Onychopathy. X-ray was carried out at time 0 and at 12 months and lesions were graded using the Sharp/van der Heijde. Potential prognostic determinants for structural joint damage obtained at the first examination and during follow-up were entered in a conditional logistic regression analysis.

Results: Structural deterioration was observed in 47% of the 5292 evaluated joints in 126 patients. Clinical variables associated with the risk of arthritis in psoriatic patients included: higher BMI (OR 1.7, 95% CI 1:02 to 1:10), percentage of body surface area affected (OR 1.13, 95% CI 1:01 to 1:09), family history of PsA (p <0.001/OR 5.72, 95% CI 2.79– 91.62). and nail involvement (OR 2.25, 95% 1:36 to 3:41). High BMI was significantly correlated (P < 0.01) with shorter interval of time for the onset of arthritis in psoriatic patients.

Baseline synovial score > 2/PD score ≥2 increased the risk of structural progression: OR=2.61 (1.26–2.94) p<0.001 versus 1.98 (1.05–2.65) p=0.01 versus 2.66 (1.08–2.76) (P< 0.001) for the clinical versus US-GS versus US-PD evaluation, respectively. In the joints with normal baseline examination (clinical or US), an increased probability for structural progression in the presence of enthesitis was also observed (OR=2.46 (1.15–4.12) (P< 0.01) and 3.50 (1.77–6.95) p<0.001 for US-GS and US-PD and 2.79 (1.05–5.41) P<0.001) for clinical examination. The baseline GUESS scores in psoriatic patients who developed PsA later was significantly higher than those of patients who did not develop joint disease (9.86 ± 2.4 vs. 5.62 ± 2.31, respectively, P< 0.01). Onychopathy was also associated with structural joint damage (OR 2.30, 95%CI 1.17– 3.69). In multiple conditional logistic regression analysis, persistent (vs disappearance) of synovitis/enthesitis at 6 months of therapy was also predictive of subsequent structural progression.

Conclusion: Identifying predictor risk factors for the development of inflammatory arthritis in psoriatic patients are essential to clinical practice. The presence of US determined synovial thickness, enthesitis and/or onycholopathy associated with positive PD signal at baseline and the persistent PD signal over time have relevant prognostic value for the development of articular damage in psoriatic patients. These results could be an appropriate reference to dermatologists and rheumatologists, and a step forward to tailor the medical management to the patient's condition.

The Association Between Obesity and Radiographic Progression Of Joint Damage Among Patients With Psoriatic Arthritis. Lihi Eder[1], Arane Thavaneswaran[1], Vinod Chandran[1], Richard J. Cook[2] and Dafna D. Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: The prevalence of obesity among patients with psoriatic arthritis (PsA) is increased compared to the general population. Obese patients with PsA tend to respond less favorably to TNF alpha blockers compared to patients with normal weight. We aimed to investigate whether obesity is associated with higher risk of development of radiographic damage among patients with PsA.

Methods: A retrospective cohort analysis was performed among patients who have been followed in a large PsA clinic from 1998 to 2013. Patients were followed according to a standard protocol at 6–12 month intervals. Body Mass Index (BMI) was calculated and patients were categorized accordingly into the following groups: Normal (<25), Overweight (25–30) and Obese (>30). Radiographs of the hands, feet and spine were performed at 2 years

intervals. Radiographic damage to 42 joints in the hands and feet was assessed according to a modification of the Steinbrocker method. Radiographic damage to the lumbar and cervical spine was scored using the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). For each patient all available radiographic data were included. Patients who initiated treatment with TNFα blockers were censored. The outcome of interest was the annual rate of radiographic progression that was calculated as the difference in modified Steinbrocker score and mSASSS compared to the previous radiographic assessment divided by the interval of time between the assessments. Multivariate regression analysis using Generalized Estimating Equations (GEE) for repeated measures was used to compare progression in radiographic damage across the three BMI categories incorporating available information from all time points.

Results: 339 PsA patients were included in the study (28.6% with normal weight, 38.9% were overweight and 32.4% were obese). At first visit, patients who were overweight and obese had higher mean erythrocyte sedimentation rate (p=0.007) and trended for higher CRP levels (p=0.06). There was no difference in the number of tender or swollen joints, dactylitic digits or active entheseal sites. At baseline, overweight and obesity were associated with the presence of radiographic damage (61.9% in normal weight, 65.2% in overweight and 75.5% in obese, p=0.03); however, no difference was observed in modified Steinbrocker score and mSASSS across the three groups. Regression analysis did not show an association between the rate of radiographic progression of modified Steinbrocker score and BMI category (p=0.85). In multivariate regression analysis only the use of disease modifying anti rheumatic drugs was associated with an increased rate of radiographic damage progression. Similarly, BMI category was not associated with rate of progression of mSASSS (p=0.9).

Conclusion: Among patients with PsA, increased BMI was associated with the presence of radiographic damage at first assessment. However, no association was found between BMI and the rate of radiographic progression of damage in the peripheral joints and the spine.

Baseline Characteristics and Treatment Outcomes In Psoriasis Patients With Polyarthritis Or Oligoarthritis. Philip S. Helliwell[1], Philip Mease[2], Eustratios Bananis[3], Heather Jones[3], Annette Szumski[3] and Lisa Marshall[3]. [1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [2]University of Washington School of Medicine, Seattle, WA, [3]Pfizer Inc., Collegeville, PA.

Background/Purpose: Most randomized control trials (RCTs) for psoriatic arthritis (PsA) include patients with asymmetric oligoarthritis (AO) and polyarthritis (PA). There are limited data from RCTs on the demographic and disease characteristics of PsA patients with either AO or PA and how these different patient groups respond to treatment. Our analyses compared baseline characteristics and treatment outcomes of AO and PA patients receiving ETN 50 mg QW for 24 wks in the PRESTA trial.

Methods: PRESTA was a large, randomized, 24-wk, multicenter study to evaluate the efficacy and safety of etanercept (ETN) in patients with moderate-to-severe psoriasis (≥10% of body surface) and active PsA ≥3 months. Patients received ETN 50 mg BIW or 50 mg QW for 12 wks in a double-blind phase, and open-label ETN 50 mg QW for 12 additional wks. Patients who received ETN 50 mg QW for 24 wks were included in this analysis if they received ≥1 dose of ETN and had ≥1 post-baseline efficacy value. AO (inflammation of 2–4 joints) and PA (inflammation of ≥5 joints) was based on clinical diagnosis by rheumatologists. Standard clinical outcomes were assessed among patients with AO or PA at baseline.

Results: A total of 363 subjects (46 with baseline AO, 317 with baseline PA) were included in these analyses. At baseline, patients with PA were significantly older (47.6 vs 43.0 years, P=0.01) and had significantly higher HAQ, PGA of arthritis, PGA of psoriasis, subject assessment of joint pain and numbers of painful and swollen joints than those with AO (Table). Significant improvement at wk 24 was observed for all endpoints in both groups; mean % change and adjusted mean change from baseline were similar for PA vs AO patients at wk 24. At 24 wks, a significantly greater proportion of AO than PA patients achieved HAQ ≤0.5 (Table). The proportion of patients achieving ACR/20/50/70, PASI75, and PGA of psoriasis ≤1 was not significantly different between AO and PA groups. Similar results between the 2 groups were observed after 12 wks of treatment.

Efficacy Assessment	Oligoarthritis (N=46)	Polyarthritis (N=317)	P-value
Baseline (Mean)			
HAQ	0.76 (0.7)	0.96 (0.7)	0.060
PASI	18.5 (9.8)	19.1 (9.9)	0.695
PGA Arthritis	41.7 (20.9)	51.5 (20.5)	0.004
PGA Psoriasis	3.37 (0.5)	3.65 (0.7)	0.006
Subject assessment of joint pain (VAS)	55.0 (28.5)	63.2 (24.5)	0.039
Total painful joints 68	2.89 (0.8)	19.71 (15.3)	<0.0001
Total swollen joints 66	2.37 (1.1)	12.70 (13.3)	<0.0001
Week 24 (LOCF) (% responders)			
ACR 20/50/70	70.5/54.5/36.4	71.6/53.0/36.4	0.879/0.851/0.994
HAQ ≤0.5	82.6	63.7	0.011
PASI 75	67.4	61.6	0.449
PGA ≤1	58.7	49.2	0.230

Conclusion: ETN 50 mg QW was effective in the treatment of PsA regardless of the subtype examined. As expected, AO patients had less baseline joint disease but achievement of low level joint disease activity at 24 wks was similar in PA and AO groups, whereas functional improvement was greater in the AO group. Similar significant improvement in skin disease was observed in both patients with PA and AO.

Impact Of Persistent Minimal Disease Activity On Long-Term Outcomes In Psoriatic Arthritis: Results From 5 Years Of The Long Term Extension Of a Randomized, Placebo-Controlled, Study. Arthur Kavanaugh[1], Iain B. McInnes[2], Philip J. Mease[3], Gerald G. Krueger[4], Dafna D. Gladman[5], Stephen Xu[6], Linda Tang[7] and Katrien van Beneden[8]. [1]University of California, San Diego, La Jolla, CA, [2]University of Glasgow, Glasgow, United Kingdom, [3]Swedish Medical Center and University of Washington, Seattle, WA, [4]University of Utah, Salt Lake City, UT, [5]University of Toronto, Toronto Western Hospital, Toronto, ON, [6]Janssen Research & Development, LLC., Spring House, PA, [7]Janssen Research & Development, LLC., Horsham, PA, [8]Janssen Biologics Europe, Leiden, Netherlands.

Background/Purpose: Although criteria for Minimal Disease Activity (MDA) in psoriatic arthritis (PsA) have been developed and validated, a paucity of data concerning the impact of reaching MDA on long-term outcomes remains. We assessed this concept using 5 yr long term extension (LTE) data from the GO-REVEAL study of PsA pts treated with golimumab (GLM).

Methods: Data were obtained from the open label LTE of GO-REVEAL, a double-blind, PBO controlled Ph3 study comparing the efficacy and safety of GLM 50 mg and 100mg q4wks to PBO in pts with active PsA (≥3 swollen, ≥3 tender joints, and psoriasis). Pts with <10% improvement in both tender and swollen joints could enter early escape at wk16; all pts received GLM from wk24 forward. Last GLM injection was at wk252. MDA was defined as the presence of ≥ 5 of the following: ≤ 1/66 swollen joints; ≤ 1/68 tender joints; PASI score ≤ 1; pt pain VAS ≤ 15 (0–100); pt global assessment of disease activity VAS ≤ 20 (0–100); HAQ-DI ≤ 0.5; ≤ 1 tender enthesis point.[1] These criteria were assessed at wks 14, 24, 52, 104, 148, 196, and 256. Pts were selected who never achieved MDA and who achieved persistent MDA (defined as MDA for at least 3 consecutive time points) through Wk 256. Comparisons between patients who achieved/did not achieve MDA and the relationship between HAQ-DI or radiographic progression measured using vdHS scores were performed. These analyses utilized observed data from randomized pts. Statistical tests used ANOVA with Van der Waerden normal score and chi-squared test.

Results: At the end of the PBO-controlled period until wk24, MDA was achieved in 7.7% and 28.1% of pts in the PBO and GLM groups, respectively. Through wk256, MDA was achieved in 44.2%-51.7% of pts (Table 1). Irrespective of treatment randomization, a better clinical meaningful HAQ improvement and less radiographic progression were observed in pts who achieved persistent MDA compared to pts who never achieved MDA (Table 2). While stratifying for treatment, pts achieving persistent MDA, who

crossed-over from PBO to GLM, experienced similar HAQ improvement and radiographic outcomes compared to pts randomized to the GLM groups (Table 2), suggesting that delayed initiation with GLM did not result in a worsening of physical function or radiographic progression. In contrast, for pts not achieving MDA, delayed start with GLM resulted in numerically less radiographic benefit.

Table 1. Proportion of pts who achieved MDA by randomized treatment and visit

	PBO	GLM combined	p-value
Week 14	1/104 (1.0%)	67/285 (23.5%)	<0.0001
Week 24	8/104 (7.7%)	80/285 (28.1%)	<0.0001
Week 52	29/96 (30.2%)	111/262 (42.4%)	0.0368
Week 104	32/87 (36.8%)	107/250 (42.8%)	0.3260
Week 148	41/84 (48.8%)	122/236 (51.7%)	0.6496
Week 196	37/82 (45.1%)	106/222 (47.7%)	0.6839
Week 256	34/77 (44.2%)	106/205 (51.7%)	0.2585

Table 2. MDA status and improvement in HAQ, SHS change after 5 yrs

Efficacy endpoints	Randomized treatment	Never achieved MDA	Achieved persistent MDA
HAQ improvement at wk 256			
No. of pts	PBO	30	27
Mean ± SD		0.25 ± 0.551	0.79 ± 0.553
p-value			<0.001
No. of pts	GLMcombined	70	94
Mean ± SD		0.28 ± 0.470	0.66 ± 0.516
p-value			<0.001
SHS change at wk 256			
No. of pts	PBO	29	25
Mean ± SD		1.29 ± 5.475	−0.78 ± 1.501
p-value			<0.05
No. of pts	GLMcombined	66	91
Mean ± SD		0.68 ± 3.993	−0.43 ± 2.392
p-value			<0.05

Combined GLM (50mg and 100mg groups).

Conclusion: The data of the current analysis show that MDA occurred in approximately 50% of pts receiving effective treatment through 5 years. Aiming for MDA may serve as an argument for a treat-to-target strategy since persistent MDA can improve long-term functional and radiographic outcomes in pts with active PsA.

TNF Blockage In Psoriatic Arthritis: Long-Term Effect On Lipid Profile.

Julio C. B. Moraes[1], Carla G.S. Saad[1], Ana Cristina Ribeiro[1], Claudia G Schainberg[2], Celio R. Gonçalves[2], Percival D Sampaio-Barros[1] and Eloisa Bonfá[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Psoriatic arthritis (PsA) patients have increased cardiovascular morbidity and mortality. Altered lipid profile is an important risk factor for the development of these complications. There are, however, no data regarding prospective long-term evaluation of lipid profile in PsA patients under TNF blockers. The purpose of this study is to evaluate prospectively the long-term effect of anti-TNF therapy on lipid profile in PsA patients.

Methods: Thirty-two consecutive PsA patients, who were eligible to receive anti-TNF therapy, were prospectively enrolled. All patients were treated with TNF blockers, and they were evaluated for lipid profile, atherogenic index (AI), body mass index (BMI), waist circumference and disease parameters at baseline and at 104 weeks after treatment. Lipoprotein risk level for coronary heart disease (CHD) were defined by National Cholesterol Education Program (total cholesterol > 240 mg/dL, LDL-cholesterol >160 mg/dL, HDL-cholesterol < 40mg) or patients requiring statin during study period. Patients using statin at study entry were excluded but initiation of this drug was allowed during follow-up.

Results: Prospective evaluation of lipid profile revealed a significant increase in levels of total cholesterol (177±39mg/dL vs. 195±45mg/dL, p=0.002) and LDL-cholesterol (105±34mg/dL vs. 117±40mg/dL, p=0.007), in spite of statin introduction in one fourth of these patients during the study. No changes were found in the concentration of HDL-cholesterol (48±12mg/dL vs. 50±12mg/dL, p=0.26), triglycerides [105 (69–160)mg/dL vs. 112 (92–183)mg/dL p=0.06], in AI (3.9±1.4 vs. 4.1±1.3, p=0.48), BMI (28.4±5.2kg/m2 vs. 29.1±5.7kg/m2, p=0.62) and waist circumference (92.2±15cm vs. 97.8±14.9cm, p=0.23. The frequency of patients with high risk levels for total cholesterol (6.3% vs. 28.1%, p=0.023) and high/very high LDL- (6.3% vs. 28.1%, p=0.023) significantly increased from entry to 104 weeks whereas no change in the frequency of HDL-cholesterol and triglycerides classification rate were observed. Anti-TNF treatment improved inflammation parameters: C-reactive protein (p<0.001), and erythrocyte sedimentation rate (p<0.001).

Conclusion: The novel demonstration that anti-TNF therapy has a specific pattern of long-term deleterious effect in lipid profile of PsA patients reinforces the importance of this cytokine as a potent lipid metabolism regulator and emphasizes the recommendation for a close monitoring and a more vigorous intervention in this modifiable cardiovascular risk factor.

Conventional Dmards For Psoriatic Arthritis: Data On 1351 Treatment Courses With Methotrexate, Sulfasalazine and Leflunomide.

Elisabeth Lie[1], Karen M. Fagerli[1], Erik Rødevand[2], Synnøve Kalstad[3], Knut Mikkelsen[4], Ada Wierød[5], Désirée van der Heijde[6] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]St. Olavs Hospital, Trondheim, Norway, [3]University Hospital of Northern Norway, Tromsø, Norway, [4]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [5]Vestre Viken Hospital Drammen, Drammen, Norway, [6]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Methotrexate (MTX), sulfasalazine (SSZ) and leflunomide (LEF) are recommended treatments for PsA patients with active peripheral arthritis. In the publication of a recent negative placebo-controlled randomised trial of MTX in PsA, it was suggested that the sequencing of conventional DMARDs before biologics should be re-evaluated[1]. Our objective was to assess the pattern of conventional DMARD use, and to compare the effectiveness of MTX, SSZ and LEF in a longitudinal observational study (LOS) of patients with PsA.

Methods: Data were extracted from NOR-DMARD, a LOS of arthritis patients starting a new DMARD treatment, with follow-up at 3, 6, 12 months and then yearly. Patients diagnosed with PsA and starting treatment with MTX, SSZ or LEF were identified. We studied baseline characteristics and 3- and 6-month treatment responses overall, and performed statistical comparisons between treatments. For the statistical comparisons we selected the first inclusion of those patients included sequentially with several DMARDs so that only individual patients were included. Unadjusted comparisons were done by ANOVA, Kruskall-Wallis or Chi^2 test, as appropriate, and analyses with adjustment for important baseline differences were performed by ANCOVA and logistic regression analysis. Swollen and tender joint counts included the standard 28 joints for RA and ankles and forefeet bilaterally (32-SJC and 32-TJC, respectively).

Results: A total of 1351 prescriptions of MTX (n=1000), SSZ (n=212) and LEF (n=139) in 1212 individual patients were identified – 128 patients were registered with >=2 of the drugs and 11 patients with all 3 drugs. Among MTX/SSZ/LEF patients 71% vs. 61% vs. 6.5% were

DMARD na·ve, respectively, and 47% of patients on LEF had failed both MTX and SSZ. Patients treated with LEF also had longer disease duration. Mean baseline DAS28 for MTX/SSZ/LEF was 4.2/4.0/4.3, respectively. The baseline characteristics across groups for the first inclusion per patient (MTX n=949, SSZ n=177, LEF n=86) were very similar (baseline DAS28 4.2/3.9/4.3 for MTX/SSZ/LEF, respectively). Selected 3- and 6-month outcomes are shown in the Table. Responses were numerically similar for the overall group of patients (n=1351). Two-year drug survival was superior for MTX (0.71) vs. SSZ (0.40; HR 1.96; p<0.001) and LEF (0.29; HR 2.47, p<0.001), with no significant difference between SSZ and LEF. Reasons for discontinuation were inefficacy and intolerance in roughly the same frequency (40–50%) for both SSZ and LEF. Mean dose of MTX was 15.1 mg at 6 months; for SSZ 88% used >=2000 mg daily and for LEF 86% used 20 mg daily at 6 months.

Table. 3- and 6-month responses (individual patients)

	3 months					6 months				
	MTX n=781	SSZ n=143	LEF n=73	*P**	*P***	MTX n=700	SSZ n=97	LEF n=52	*P**	*P***
ACR20¤	32.0%	29.4%	34.7%	0.72	0.39	40.5%	31.9%	29.2%	0.10	0.34
ACR50¤	17.4%	12.5%	8.3%	0.07	0.34	22.8%	17.6%	8.3%	0.04	0.25
ACR70¤	6.5%	2.2%	5.6%	0.15	0.17	11.6%	7.7%	4.4%	0.17	0.39
DAS28	−0.77	−0.77	−0.47	0.17	0.40	−1.04	−0.86	−1.03	0.52	0.62
32-SJC	−1.9	−1.4	−1.4	0.28	0.66	−2.5	−1.9	−1.4	0.08	0.80
32-TJC	−1.7	−1.3	−2.8	0.13	0.48	−2.2	−1.6	−2.3	0.55	0.46
CRP, mg/L	−5.9	−2.1	−3.7	0.07	0.02	−6.4	−1.4	−4.9	0.01	0.32
PGA	−12.6	−8.5	−6.1	0.03	0.09	−13.9	−11.9	−9.2	0.37	0.75

Values are percentages and means. *Unadjusted. **Adjusted for age, sex, number of previously used DMARDs, disease duration, and for continuous outcomes the respective baseline values. PGA=Patient Global Assessment. ¤Based on 32-joint counts.

Conclusion: MTX was the most commonly used first-line DMARD while LEF was rarely used as a first-line DMARD. Effectiveness was modest and generally similar, but MTX performed better for some measures, including drug survival.

Clinical Phenotype Of Patients With Arthritis Mutilans Has Important Differences Compared To Other Patients With Psoriatic Arthritis. Muhammad Haroon, Phil Gallagher and Oliver FitzGerald. Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland.

Background/Purpose: Arthritis mutilans (AM), a severe form of psoriatic arthritis (PsA), is characterised clinically by digital shortening resulting from osteolysis and/or erosions. It is still unclear whether AM is simply the end-stage of polyarticular PsA, or whether it is a unique entity with different pathogenic mechanisms. Given its rarity, there is little data regarding its clinical and laboratory associations. The objectives of our study were 1) to investigate the prevalence of AM in an ethnically homogenous consecutive cohort of established PsA, 2) to identify the clinical phenotype of AM and its effect on quality of life, functional impairment and fatigue scores compared to those PsA patients who do not have AM.

Methods: A cohort of 283 consecutive PsA patients, fulfilling CASPAR criteria, was included. Following informed consent, patients underwent detailed skin and rheumatologic assessments including disease activity measures [PASI, Body Surface Area (BSA) for psoriasis; tender and swollen joint counts, CRP, ESR] HAQ (health assessment questionnaire), Dermatology Life Quality Index (DLQI), Bristol Rheumatoid Arthritis Fatigue Numeric Rating Scale (BRAF-NRS) and SF-36. Radiographs were taken of involved joints along with hands, feet and sacroiliac joints. AM was considered present when there was one or more shortened digit accompanied on radiographs by osteolysis or erosions on both sides of the joint.

Results: A total of 283 PsA patients [mean age 55±12 years; 47% male; mean PsA duration=19±9 years; 25% with sacroiliitis; 44.5% with radiographic erosions; 34% with enthesitis; 53% with dactylitis; 79% with psoriatic nail disease, 60% of this PsA cohort requiring TNFi therapy] were studied. Among this cohort, 8% (n=23) of patients were found to have AM, with 65% female and a mean age of 56.5±11 years. On univariate analysis, longer PsA duration (OR 1.06, p=<0.001), longer diagnostic delay (OR 1.10, p=0.01), more tender joint counts (OR 1.07, p=0.009), more swollen joint counts (OR 1.09, p=0.009), PsA requiring TNFi (OR 3.37, p=0.03), oral corticosteroids usage (OR 9.2, p=<0.001), earlier PsA age of onset (OR 0.96, p=0.08), lower CRP maximum (OR 0.98, p=0.07), lower ESR maximum (OR 0.98, p=0.13) and higher HAQ score (OR 1.07, p=0.10), MCS-SF36 (OR 1.02, p=0.16) and PCS-SF36 (OR 1.00, p=0.80). Given the small number of AM patients, few models were tested on multivariate regression analysis, but it was noted that heavier alcohol intake (OR 1.08, p=0.002), lower CRP rise (0.96, p=0.007), greater oral corticosteroids usage (OR 7.6, p=0.003) and longer duration of PsA (OR 1.08, p=0.001) all remained significantly associated with the diagnosis of AM.

Conclusion: The clinical profile of patients with AM when compared to other PsA patients suggests that non-inflammatory pathogenic mechanisms, possibly related to bone turnover, may explain this unique clinical phenotype.

Prevalence Of Peri-Articular Manifestations (Enthesitis and Dactylitis) and Disease Activity In Psoriatic Arthritis Patients: Impact Of Treatment With TNF Inhibitors In a Real-World Canadian Population. Proton Rahman[1], Denis Choquette[2], William G. Bensen[3], Majed M. Khraishi[4], Isabelle Fortin[5], Andrew Chow[6], Maqbool K. Sheriff[7], Julie Vaillancourt[8], John S. Sampalis[9], Susan M. Otawa[10], Allen J. Lehman[10] and May Shawi[10]. [1]Memorial University, St. Johns, NF, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]St. Joseph's Hospital and McMaster University, Hamilton, ON, [4]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [5]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [6]Credit Valley Rheumatology, Mississauga, ON, [7]Nanaimo Regional General Hospital, Nanaimo, BC, [8]JSS Medical Research, Montreal, QC, [9]JSS Medical Research, St-Laurent, QC, [10]Janssen Canada Inc, Toronto, ON.

Background/Purpose: To determine the point prevalence of periarticular manifestations (PAMs) in psoriatic arthritis (PsA) patients treated with anti-TNF in a real-world, Canadian, routine clinical practice setting.

Methods: BioTRAC is an ongoing, prospective, registry of patients initiating treatment for PsA, AS or RA with infliximab or golimumab as first biologics or after having been treated with a biologic for < six months. In this analysis of data collected since 2010, 91 PsA patients with available baseline information on PAMs were included: enthesitis (n=62), dactylitis of hands (n=76) or feet (n=77), nail pitting of hands (n=76) or feet (n=75).

Results: Baseline characteristics included mean (SD) age, disease duration of 48.7 (10.3), 6.5 (6.9) years, respectively, and mean (SD) DAS28-CRP score of 4.1 (1.2).

Among all patients at baseline, 50 (54.9%) had a PAM. Dactylitis (feet − 39.0%; hands – 15.8%) was the most common PAM followed by enthesitis (27.4%), and nail pitting (hands–26.3%; feet–24.0%). Patients with enthesitis had greater mean (SD) DAS28-CRP (4.7 (1.0) vs. 3.9 (1.3); P=0.042) and HAQ-DI (1.33 (0.73) vs. 0.94 (0.77); P=0.076) compared to patients without enthesitis. However, mean (SD) age (47.0 (10.0) vs. 48.8 (9.5) years; P=0.544), disease duration (6.1 (7.3) vs. 6.0 (6.2) years; P=0.937), and morning stiffness (52.6 (43.4) vs. 56.7 (45.2) min; P=0.750) were comparable between-groups. Among patients with/without dactylitis, baseline mean (SD) parameters were: age (46.8 (12.5) vs. 50.5 (8.9) years; P=0.145), disease duration (6.2 (6.8) vs. 7.0 (7.7) years; P=0.666), DAS28-CRP (4.5 (0.9) vs. 4.0 (1.4); P=0.105), HAQ-DI (1.08 (0.69 vs. 1.09 (0.69); P=0.925), and morning stiffness (73.2 (44.8 vs. 51.6 (42.0) min; P=0.033).

Upon six months of treatment, significant improvement in all disease activity parameters studied was observed. Six-month PAM data were available for 50 (54.9%) patients. Overall, the prevalence of PAMs decreased from baseline to six months post-treatment (P=0.001). Among patients with available six-month information that had a PAM at baseline (n=33), (48.5%) did not present any manifestation after six months. The incidence of new PAMs by six months was minimal.

Conclusion: In this Canadian real-world cohort of PsA patients, a high prevalence of PAMs was observed at treatment initiation. Patients with enthesitis or dactylitis had increased disease activity compared to patients without PAMs. Infliximab or golimumab treatment for six months was associated with a significant improvement in patient parameters and reduction in the prevalence of PAMs.

Rheumatoid Arthritis, a More Severe Disease Than Psoriatic Arthritis? A Comparison Of Disease Activity In Patients With Psoriatic Arthritis and Rheumatoid Arthritis From The Swedish Early Psoriatic Arthritis Registry (SwePsA) and The Swedish Rheumatology Registry For Early Rheumatoid Arthritis (SRR). Gerd-Marie Alenius[1], Tomas Husmark[2], Elke Theander[3], Per Larsson[4], Mats Geijer[5], Annika Teleman[6] and Ulla R. C. Lindqvist[7]. [1]Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden, [2]Department of Rheumatology, Falu Hospital, Falun, Sweden, [3]Lund University, Malmö, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden, [5]Skåne University Hospital, Lund, Center for Medical Imaging and Physiology, Lund, Sweden, [6]Department of Rheumatology, Spenshult Hospital, Oskarstrom, Sweden, [7]Department of Medical Sciences, Rheumatology, University Hospital, Uppsala university, Uppsala, Sweden.

Background/Purpose: In clinical practise patients with psoriatic arthritis (PsA) seem to have milder disease expression compared with patients having rheumatoid arthritis (RA). Studies have, however, shown that PsA is a more severe disease than known before. The aim of this study was to compare the disease activity and treatment between psoriatic arthritis (PsA) and rheumatoid arthritis (RA) in patients with early disease, and after five years of disease duration.

Methods: 208 patients included in SwePsA were compared to 381 patients included in SRR. The patients were matched (1:1–2) for age, gender, year of inclusion in the registries and region of residence. Inflammatory parameters such as DAS28, its components, CRP, HAQ, pain VAS and treatment (DMARDs, steroids and biologics), were measured at inclusion and at 5 year-follow up. Single and multiple regression analyses were performed and the stratified proportional hazards model has been used to model the 1–2 or 1-1 matching designs depending on the number of controls available for a case.

Results: At inclusion, patients with RA had significantly higher DAS28, ESR, CRP, tender joint counts (TJC), swollen joint counts (SJC), HAQ, pain VAS and patient global VAS (PGVAS) compared to patients with PsA (Table 1). After 5 years all parameters had decreased and ESR was slightly higher in RA-patients compared with PsA-patients (15.22 vs 12.36, p=0.046), while tender joint count now was higher in patients with PsA (3.58 vs 1.95, p=0.000). No other differences between the groups were seen (See Table). DMARDs, steroids and biologics were less common among PsA-patients than RA-patients at inclusion (40.9 % vs 84.7%, 9.1 vs 39.6 and 0.5 vs 2.8% respectively), and at 5-year-follow up (46.2% vs 80%, 8.2% vs 18.7%, and 13% vs 37.7% respectively).

Table.

	Inclusion			5-year-follow up		
	PsA Mean (±SD)	RA Mean (±SD)	P (95% CI)	PsA Mean (±SD)	RA Mean (±SD)	P (95% CI)
DAS28	3.34 (±1.34)	5.04 (±1.34)	**0.000 (0.330–0.485)**	2.62 (±1.22)	2.81 (±1.38)	0.281 (0.812–1.062)
ESR	18.72 (±20.13)	32.98 (±25.03)	**0.000 (0.954–0.976)**	12.36 (±12.47)	15.22 (±14.58)	**0.046 (0.970–1.000)**
CRP	16.67 (±25.65)	30.51 (±33.36)	**0.000 (0.970–0.987)**	7.28 (±8.71)	8.09 (±13.54)	0.540 (0.980–1.010)
TCJ	5.59 (±7.82)	7.17 (±5.65)	**0.000 (0.934–0.990)**	3.58 (±6.39)	1.95 (±3.58)	**0.000 (1.035–1.123)**
SJC	4.31 (±4.87)	8.73 (±5.76)	**0.009 (0.787–0.868)**	1.53 (±2.87)	2.03 (±3.35)	0.089 (0.894–1.008)
PGVAS	43.48 (±25.59)	49.43 (±25.60)	**0.008 (0.983–0.997)**	31.86 (±23.83)	29.49 (±23.64)	0.193 (0.998–1.012)
PainVAS	44.15 (±25.72)	50.75 (±25.07)	**0.003 (0.982–0.996)**	31.50 (±25.38)	29.20 (±23.16)	0.216 (0.997–1.012)
HAQ	0.62 (±0.53)	0.99 (±0.60)	**0.000 (0.179–0.391)**	0.48 (±0.6)	0.54 (±0.59)	0.521 (0.668–1.227)

Conclusion: In this study, the disease activity at inclusion was higher in patients with RA compared to PsA. At 5-year-follow up the disease activity had decreased in both patient groups and there were only significant differences in two of the parameters, ESR that was slightly higher in the RA-patients and TJC that was higher in the PsA-patients showing that PsA-patients suffer from joint pain. The patients in the RA-group were more often aggressively treated with steroids, DMARDs and biologics indicating that RA may be a more severe disease. However, after 5 years the PsA-patients had more tender joints which could have an effect on quality of life.

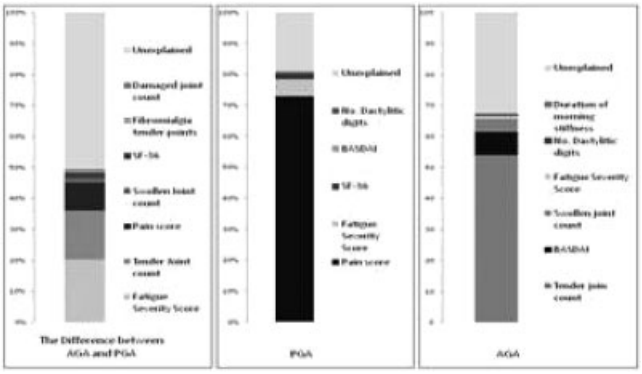
Factors Explaining The Discrepancy Between Patient and Physician Global Assessment Of Disease Activity In Psoriatic Arthritis. Lihi Eder[1], Arane Thavaneswaran[1], Vinod Chandran[1], Richard J. Cook[2] and Dafna Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: Patients and physicians often perceive the extent of disease activity differently. We aimed to assess the factors contributing to the variability in scoring of patient global assessment (PGA), physician (assessor) global assessment (AGA) of disease activity and the discrepancy in scoring between PGA and AGA among patients with psoriatic arthritis (PsA).

Methods: A cross sectional study was conducted of patients attending a large PsA clinic from 2008 to 2013. Three different outcomes were studied: AGA, PGA and the difference between AGA and PGA. The scores of PGA and AGA ranged from 0 (no disease activity) to 10 (high disease activity). The difference between AGA and PGA reflected the discrepancy between the physician and patient global assessment of joint activity and could take values from −10 (worse estimation of disease activity by the patient) to 10 (worse estimation of disease activity by the physician). Predictors of these outcomes included demographics, skin and joint assessment by the physician, patient reported information about function, quality of life and fatigue. Multivariate linear regression identified variables that contributed significantly to each of the outcomes. The proportion of variability of each outcome explained by each predictor was expressed using a partial R^2.

Results: A total of 565 patients were included in the analysis. Their mean age was 51.7±13.2 years and 58.6% were males. The mean duration of psoriasis and PsA were 24±13.8 and 14.3±19.4 years, respectively. 81% of the variability in PGA and 68% of the variability in AGA were explainable. The main factors associated with PGA were pain ($R^2_{partial}$ =72.9%, Figure 1), fatigue (by Fatigue Severity Scale (FSS) $R^2_{partial}$ =5.5%) and disability scores (by Short Form (SF) −36 $R^2_{partial}$ =2.1%). The main factors associated with AGA were tender joint count ($R^2_{partial}$ =53.9%), swollen joint count ($R^2_{partial}$ =4.2%) and patient perception of joint activity (by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) $R^2_{partial}$ =7.5%). Increased fatigue by FSS accounted for 20.4% of the variation in the difference between AGA and PGA and pain ($R^2_{partial}$ =9.2%) and disability scores by SF-36 ($R^2_{partial}$ =1.6%) were also important; these led to worse patient assessments while increased tender joint count ($R^2_{partial}$ =15.9%) and swollen joint counts ($R^2_{partial}$ =1.7%) resulted in a worse physician assessment of arthritis.



Conclusion: Fatigue, pain, disability, tender and swollen joint counts were the most important factors contributing to discrepancy between patient and physician assessment of joint activity.

Laboratory Abnormalities In Patients With Psoriatic Arthritis Receiving Apremilast, An Oral Phosphodiesterase 4 Inhibitor: Pooled Safety Analysis Of Three Phase 3, Randomized, Controlled Trials. Philip J. Mease[1], Arthur Kavanaugh[2], Adewale O. Adebajo[3], Juan J. Gomez-Reino[4], Jürgen Wollenhaupt[5], Dafna D. Gladman[6], Maurizio Cutolo[7], Georg Schett[8], Eric Lespessailles[9], Kamal Shah[10], ChiaChi Hu[10], Randall M. Stevens[10], Christopher J. Edwards[11] and Charles A. Birbara[12]. [1]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [2]University of California San Diego, San Diego, CA, [3]University of Sheffield, Sheffield, United Kingdom, [4]Hospital Clinico Universitario, Santiago, Spain, [5]Schön Klinik Hamburg Eilbek, Hamburg, Germany, [6]University of Toronto, Toronto Western Hospital, Toronto, ON, [7]University of Genova, Genova, Italy, [8]University of Erlangen-Nuremberg, Erlangen, Germany, [9]University of Orléans, Orléans, France, [10]Celgene Corporation, Warren, NJ, [11]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [12]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, works intracellularly to modulate inflammatory mediators. The PALACE 1, 2, and 3 trials compared the efficacy and safety of APR with placebo (PBO) in pts with active PsA despite prior DMARDs and/or biologics. The impact of APR on laboratory measurements was assessed in a pooled analysis of PALACE 1, 2, and 3.

Methods: Pts were randomized 1:1:1 to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline (BL) DMARD use. At wk 16, pts with <20% reduction from BL in swollen/tender joint counts qualified for protocol-defined early escape; those on PBO were re-randomized to APR20 or APR30 and those on APR remained on the initial APR dose. At wk 24, all remaining PBO pts were re-randomized to APR20 or APR30 through wk 52. Pts taking concurrent DMARDs were allowed to continue stable doses (MTX, sulfasalazine, leflunomide, or a combination). The analysis comprises all data from the APR-exposure periods (wks 0-≥52).

Results: 1,493 patients received study drug (PBO, 495; APR20, 501; APR30, 497) and were included in the safety population. The APR-exposure period included 720 pts treated with APR20 (766.4 pt-yrs) and 721 pts treated with APR30 (769.0 pt-yrs). Over the APR-exposure period, there were no clinically meaningful effects on laboratory measurements. Marked abnormalities in hematology and chemistry laboratory variables at any time during the exposure period were infrequent, with no treatment or dose effect evident. All marked hematological abnormalities occurred in a similar percentage of PBO pts vs APR pts during the PBO-controlled phase and continued without any significant changes during the APR-exposure period (wks 24-≥52). Overall, mean changes from BL clinical chemistry parameters were small and not clinically significant; no dose relationships were noted. Median values for both hematological and chemistry labs did not change meaningfully from BL during the trials. Most of the marked abnormal laboratory changes were transient, did not recur in spite of continuation of study drug, did not lead to study discontinuation, and were not clinically significant requiring specific treatment. Most pts had ALT and AST values ≤1 × ULN; ALT and AST values ≥3 × ULN were asymptomatic and transient with increased values returning to normal or BL in most pts despite continued treatment with APR, and similar to hematology parameters, without recurrence. There were no cases of liver function test elevations meeting Hy's Law (ALT/AST ≥3 ULN along with bilirubin ≥2 ULN without relevant clinical finding may indicate potential for drug-induced liver injury) during the APR-exposure period.

Select Markedly Abnormal Laboratory Parameters Over 0–≥52 Weeks of Apremilast Exposure

Serum CTX-I Predicts Systemic Bone Loss At The Hip Over 1 Year In Patients With Early Psoriatic Arthritis. Agnes Szentpetery, Mark Kilbane, Myra P. O'Keane, Muhammad Haroon, Phil Gallagher, Susan van der Kamp, Malachi McMenna and Oliver FitzGerald. Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland.

Background/Purpose: There is a growing interest in bone and cartilage biomarkers that could be used predicting and assessing changes in structural damage in inflammatory arthritis. Disease-related bone loss assessed by dual-energy X-ray absorptiometry (DXA) is a well known feature in RA and PsA, however data on bone loss during the first year of treatment in early disease are limited.

The aim of this study was (1) to study changes in serum levels of bone biomarkers and bone mineral density (BMD) measurements in early PsA and RA prior to and 12 months after introducing an anti-rheumatic drug; (2) to explore associations between disease-related variables, serum bone biomarkers and BMD measurements; (3) to investigate if serum bone biomarkers prior to treatment predict systemic bone loss over 1 year in patients with PsA and RA.

Methods: Recent-onset (<12 months), active, treatment naive PsA and RA patients were recruited. We measured serum bone-specific alkaline phosphatase (bone ALP), a marker of bone formation, and C-terminal cross-linking telopeptide (CTX-I), a degradation marker of type-I collagen reflecting systemic bone resorption at baseline, 3 and 12 months by immunoassay. We assessed bone remodelling balance by calculating bone ALP/CTX-1 ratios. BMD measurements were obtained at left total hip and lumbar spine at baseline and 12 month by DXA. Clinical parameters were correlated with bone biomarkers and BMD measurements.

Results: 64 patients (32 PsA, 32 RA) were included with median age 43 years. 95% of the patients were commenced on a DMARD therapy at baseline and 11.7 % (12.5% RA; 10.7% PsA) were also started on a TNF inhibitor. At 12 months 94.8% of the patients were on a DMARD and 34.5% on TNF inhibitor (33.3 % RA; 35.7% PsA).

Bone ALP levels did not change significantly in either cohort during the study. CTX-I levels decreased after 3 months of treatment in RA ($p=0.013$) and in the entire group ($p=0.043$) remaining lower at 12 months ($p=0.042$; $p=0.012$ respectively) compared to baseline. Bone ALP/CTX-I ratio was higher ($p=0.05$) at 1 year compared to baseline in the entire group reflecting improvement in bone remodelling balance.

Hip BMD decreased in both diseases, significantly in RA ($p=0.021$), whilst spine BMD decreased in RA ($p=0.056$) but increased in PsA ($p=0.017$).

CTX-I levels were correlated inversely with hip BMD in PsA at both baseline and 12 months ($r = -0.38$, $p=0.04$; $r = -0.51$, $p=0.007$) and similarly in the entire group ($r = -0.29$, $p=0.03$; $r = -0.3$, $p=0.02$). Baseline CTX-I levels correlated with the change in hip BMD over 12 month in the whole group ($r = 0.31$, $p=0.03$).

Stepwise multiple logistic regression analysis revealed significant associations of baseline CTX-I levels with change in BMD of the hip over 12 months in PsA (OR 2.8, $p=0.009$) and in the entire cohort (OR 2.5, $p=0.014$) with the model also including bone ALP, ESR, CRP, DAS28 CRP and HAQ.

Conclusion: The improvement in bone remodelling balance seen in early PsA and RA patients is most likely due to decrease in bone resorption after 1 year of appropriate anti-rheumatic therapy. High baseline levels of serum CTX-I may predict systemic bone loss at the hip over 1 year in patients with PsA.

Cortical Bone Density As Measured By Digital X-Ray Radiogrammetry Correlates with Radiographic Joint Damage In The Hands Within 1 Year In Psoriatic Arthritis. Agnes Szentpetery, Muhammad Haroon, Phil Gallagher, Eric J. Heffernan and Oliver FitzGerald. Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland.

Background/Purpose: Structural destruction in peripheral joints may occur over time in both PsA and RA. We previously reported that 47% of early PsA patients treated with DMARD developed erosions within 24 months of disease onset. Digital X-ray radiogrammetry (DXR) is a sensitive method for quantifying changes in cortical bone mineral density (DXR-BMD) in the early phase of the disease. Radiological assessment using conventional X-rays is essential as an outcome measure to evaluate treatment efficacy.

The aim of this study was (1) to investigate radiographic changes in early PsA and RA prior to and 3, 12 months after introducing an anti-rheumatic drug; (2) to explore associations between radiographic assessment and DXR-BMD; and (3) to study if DXR-BMD measurements are predictive for radiographic progression over 12 months in patients treated with a DMARD or in combination with a TNFi.

Methods: Recent-onset (<12 months), active, treatment naïve PsA and RA patients were selected. Hand X-rays were obtained at 0, 3 and 12 months and read by a radiologist blinded for the study. Sharp-van der Heijde modified scoring method for PsA was used. Erosion (ES) and joint space narrowing scores (JSNS) were calculated. X-rays from PsA patients were also scored for proliferation (PS) according to the Ratigen Score. DXR-BMD was measured on the same X-rays scored for joint damage. Mean DXR-BMD (mg/cm^2) values of both hands and changes in DXR-BMD (mg/cm^2/month) were calculated. Regression analysis was used to assess predictors for radiographic progression from baseline to 12 months.

Results: 64 patients (32 PsA, 32 RA) were included. 95% were commenced on DMARD at baseline and 11.7 % (12.5% RA; 10.7% PsA) were also started on a TNFi. At 12 months 94.8% of the patients were on DMARD and 34.5% on TNFi (33.3 % RA; 35.7% PsA).

53% of RA and 66% of PsA patients had normal X-rays at baseline; 53% and 61% at 12 months respectively. Erosions were present in 41% of RA and 22% of PsA patients at baseline; 40% and 25% at 12 months.

There was no significant difference in mTSS between RA and PsA, but mTSS was higher in PsA at 12 months compared to baseline and 3 months ($p=0.05$). There was little radiographic progression over 1 year in both groups (2 RA and 4 PsA patients). ES and mTSS were higher, JSNS was lower in RA compared to PsA at all time points.

Inverse correlations were observed approaching significance between mTSS and DXR-BMD at all time points in PsA and in the entire cohort at 3 and 12 months. Changes in DXR-BMD from 3 to 12 months correlated significantly with baseline mTSS in both groups (RA $r=-0.37$, $p=0.04$; PsA $r=-0.45$, $p=0.02$) and in the entire cohort ($r=-0.34$, $p=0.01$).

Linear regression analyses indicated that high DXR-BMD at baseline associated with lower mTSS ($\beta=18.26$, $p=0.03$) in PsA and with JSNS and mTSS ($\beta=5.68$, $p=0.04$; $\beta=9.17$, $p=0.04$) in the entire group at 12 months. Change in DXR-BMD over 12 months associated significantly with ES, JSNS and mTSS at 3 and 12 months in the entire group.

Conclusion: To our knowledge this is the first prospective study showing correlations between DXR-BMD and radiographic damage in PsA in the early phase of the disease. Hand DXR-BMD correlated with subsequent radiographic damage in patients with PsA.

Psoriatic Arthritis Mutilans: Clinical and Radiographic Definitions. A Systematic Review. Amir Haddad[1], Mansour Somaily[1], Sindhu R. Johnson[2], Rouhi Fazelzad[3], Amie T. Kron[4], Cathy Chau[5] and Vinod Chandran[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Toronto Western Hospital, Toronto General Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON, [3]University Health Network, Toronto, ON, [4]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON, [5]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, University of Toronto, Toronto, ON.

Background/Purpose: Psoriatic Arthritis Mutilans (PAM) is the most severe form of psoriatic arthritis. Research on PAM has been impeded by the lack of an accepted definition. We performed a systematic review of the literature to identify clinical and radiographic features associated with the definition and manifestations of PAM.

Methods: Medline, Embase, Cochrane Central Register for Controlled trials, Cochrane databases of Systematic Reviews and CINAHL databases from 1946 until March 2013, were searched without language restriction but limited to humans studies. Two investigators independently screened titles and abstracts and included studies that reported information on patients with PAM with clinical or radiographic information. The selected articles were retrieved for extraction of the data. Machine translation software was used to translate articles to English. Two investigators independently used a standardized form to collect items mentioned in the definition of PAM including the presence of shortening of digits, digital telescoping, flail joints, number and type of joints affected, time to joint destruction, the presence of total erosions at both sides of the joint, bone resorption, pencil-in-cup change, ankylosis, and subluxation. Patients demographics, disease characteristics, clinical and radiographic outcomes were also recorded.

Results: 8145 citations were identified of whom 7080 were excluded as they were not related to the topic, 68 were on patients with other rheumatic diseases, 82 had missing or different outcomes and 866 were duplicates. Of the 103 articles selected for full review, 49 were eligible for data abstraction and included 17 review articles, 13 case studies, 12 cohort studies, 6 case series, 2 case-control and 2 cross sectional studies. The most commonly used definition was that by Moll and Wright[i] (78%). The clinical features that were mentioned in the definitions included shortening of digits (38%), presence of digital telescoping (36%) and flail joints (15%). Only 21% of the articles specified the type of joints affected and few commented on time to joint destruction. The radiographic items that were mentioned in the definition included the presence of bone resorption (45%), pencil-in-cup change (17%), ankylosis (21%), total joint erosion (13%) and subluxation (9%). The studies reported a total of 244 patients. Based on data availability, 49% were males and had a mean age of 44.7 $\pm$ 14.7 years, most of the cases had psoriasis before the diagnosis of arthritis with a mean age of psoriasis diagnosis at 25.6 $\pm$ 6 years and psoriatic arthritis at 30.9 $\pm$ 6.7 years. They had invariably one or more of the aforementioned clinical and radiographic features that affected one or more of the small joints in hands and feet within different time intervals.

Conclusion: The systematic review has shown a lack of consensus on the clinical and radiographic items used to define and characterize patients with PAM and advocates a formal definition of PAM.

Efficacy and Safety Of Vaccination Against seasonal 2012 Influenza Virus Among Patients With Psoriatic Arthritis and Psoriasis. Arik Polackek[1], Yuri Korobko[1], Noa Madar-Balakirski[1], Uri Arad[2], David Levartovsky[3], Ilana Kaufman[4], Marina Anouk[5], Irena Litinsky[6], Ella Mendelson[7], Daphna Paran[8], Hagit Matz[9], Dan Caspi[9], Michal Mandelbaum[10] and Ori Elkayam[2]. [1]Tel Aviv Medical Center, Tel Aviv, Israel, [2]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Tel Aviv Medical Ctr, Tel Aviv, Israel, [4]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel-aviv, Israel, [5]Tel Aviv Sourasky Medical Ctr, Tel-Aviv University, Tel Aviv, Israel, [6]Department of Rheumatology, Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine Tel Aviv University, Tel Aviv, Israel, [7]Sheba Medical Center, Ramat Gan, Israel, [8]Tel Aviv Sourasky Medical Ctr, Tel-Aviv university, Tel Aviv, Israel, [9]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [10]Sheba Medical Center, Tel Aviv, Israel.

Background/Purpose: Patients with psoriatic arthritis (PsA) and psoriasis (Pso) are considered to be immunosuppressed and are therefore recommended to receive vaccination against seasonal influenza. However, in this population of patients, data on the efficacy and safety of vaccination

against influenza is scarce.The purpose of this study was to assess the efficacy and safety of vaccination against seasonal influenza in psoriatic arthritis and psoriasis patients.

Methods: Patients with PsA, Pso and healthy controls were vaccinated using the Sanofi Pasteur vaccine recommended by the WHO in 2012 which included 3 serotypes (A/California/7/2009, A/Victoria/361/2011 and aB/Wisconsin/1/2010 influenza virus i.eH1N1, H2N3 and B). Clinical and laboratory assessment were performed on the day of the vaccination and 4–6 weeks later. The immunogenicity of the vaccine was evaluated by hemagglutination inhibition assay. Geometric mean titers and the rate of seroconversion was analyzed in each group. The effect of the vaccine on disease activity was evaluated using 68 tender and 66 joint counts, number of dactylitis, psoriasis area severity index (PASI), patient visual analogue scale (VAS) for pain, physician VAS for pain, c-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).

Results: 67 patients (63 PsA, 4 Pso, mean age 50.1, 37 female, 30 male, 55.2% treated with TNF α blockers, 31.3% on disease-modifying anti rheumatic drugs (DMARDs)) and 30 healthy controls participated in this study. Immunogenicity: The geometric mean titers increased significantly in both the patients and control group for each of the subtypes tested. A substantial and similar proportion of patients in both groups responded to the vaccine. The response rate was not affected by parameters such as age, gender, disease activity or the use of TNF α blockers or DMARDs. Effect of the vaccine on parameters of disease activity: no significant changes were observed in the tender and swollen joint counts, dactylitis, PASI, global evaluation of the patient and physician and ESR, while a raise in CRP was noticed. The most common side effect was transient local inflammation at the site of vaccination, the rate being similar in both groups.

Conclusion: Vaccination against seasonal influenza is safe and induces an appropriate response in patients with psoriatic arthritis and psoriasis, similar to healthy controls.

353

Time Interval Between The Onset Of Psoriasis and The Onset Of Psoriatic Arthritis May Define Disease Subsets. Arane Thavaneswaran, Vinod Chandran and Dafna Gladman. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Psoriatic Arthritis (PsA) is a heterogeneous disease with widely varying clinical features and outcomes. Phenotypic heterogeneity may reflect genetic heterogeneity. We aimed to investigate whether the interval between the onset of psoriasis and PsA could be used to define more homogeneous subsets of PsA.

Methods: Data on the age at onset of psoriasis and PsA, clinical and radiographic features at baseline as well as HLA B*27 and C*06 status was obtained from a large well-phenotyped PsA cohort. Patients were divided into 4 quartiles based on the time interval between the onset of psoriasis and the onset of PsA. The distribution of the above HLA alleles between the 4 quartiles was investigated. Subsequently, the patients were divided into 2 groups by combing the first two and the last two quartiles. Differences between the clinical and radiographic features at baseline (t-tests, chi-squared test, logistic regression) between the two groups were then investigated.

Results: 1202 patients [56.7% males, mean (s.d.) age at first visit 47.4 (13.3) years, duration of psoriasis 18.2 (13.3) years, duration of PsA 10.1 (9.0) years] were distributed into the following 4 quartiles based on the time interval between onset of psoriasis and PsA- quartile 1: <0 years (n=318 patients, 26.5%), quartile 2: 0–5 years (n=291 patients, 24.2%), quartile 3: 5–13 years (n=262 patients, 21.8%) and quartile 4: >=13 years (n=331 patients, 27.5%). The distribution of HLA C*06 by quartile was 15.5%, 23.0%, 29.7% and 36.3% (trend test p-value <0.0001), while that of HLA B*27 was 21.2%, 18.1%, 15.6%, and 13.1% (trend test p-value =0.01), respectively.

At baseline, compared to group 1 (quartile 3 and 4), group 0 (quartile 1 and 2) had a significantly higher proportion of males, older age at onset of psoriasis but lower age at onset of PsA, lower PASI scores, higher prevalence of dactylitis, radiographic joint damage and patients treated with NSAIDs. There was no significant difference in the tender and swollen joint counts, ESR and the proportion of patients treated with DMARDs and biologics (Table 1). Since the proportion of patients positive for HLA B*27 and C*06 were different between the two groups, we examined whether the differences remained after adjusting for HLA status. After adjusting for HLA B*27 positivity there were no significant differences in the proportion of males, age at onset of PsA, and PASI score. When adjusting for HLA C*06 there was no difference in the proportion of males. When adjusting for HLA B*27 and C*06 differences between the two groups in age at onset of psoriasis, age at onset of PsA, PASI score, dactylitis and radiographic damage remained significant ($p<0.05$).

Table 1.

	Group 0 (N=609)	Group 1 (N=593)	P value
Age at first visit	43.38 (13.38)	44.57 (12.75)	0.1147
Males	370 (60.76%)	311 (52.45%)	0.0037
Age at psoriasis onset	35.01 (14.12)	21.92 (12.18)	<0.0001
Age at onset of PsA	35.38 (13.69)	38.93 (12.85)	<0.0001
Tender joint count	9.42 (9.10)	8.40 (8.20)	0.0664
Swollen joint count	5.08 (4.77)	5.18 (5.95)	0.7859
PASI	4.56 (6.86)	7.24 (9.17)	<0.0001
Dactylitis	217 (35.75%)	162 (27.41%)	0.0019
ESR	24.30 (19.83)	23.11 (21.31)	0.3464
Patients with erosions	296 (57.14%)	253 (48.28%)	0.0042
Modified Steinbrocker score	14.44 (34.37)	9.40 (26.45)	0.0082
Patients with at least unilateral sacroiliitis	182 (35.14%)	159 (30.34%)	0.0993
Patients satisfying NY criteria	137 (26.45%)	117 (22.33%)	0.1215
Treatment with NSAIDs	478 (82.84%)	423 (76.35%)	0.0067
Treatment with DMARDs	306 (53.31%)	269 (48.47%)	0.1038
Treatment with biologics	34 (6.19%)	38 (7.22%)	0.499
HLA B*27	93 (19.75%)	63 (14.16%)	0.0245
HLA C*06	90 (19.11%)	149 (33.56%)	<0.0001

*Mean (standard deviation) or proportion.

Conclusion: There are differences in the clinical phenotype of PsA when taking the interval between the onset of psoriasis and PsA into account. These differences are not fully explained by the differences in the HLA -B*27 and –C*06 status between the two groups.

Disease Burden Among Patients With Psoriatic Arthritis Who Have Experienced First Line Tumor Necrosis Factor Inhibitor Regimen Failure In The European Union. Siva Narayanan[1], Yao Lu[2], Richard Hutchings[2] and Amanda Baskett[2]. [1]Ipsos Healthcare, Columbia, MD, [2]Ipsos Healthcare, London, United Kingdom.

Background/Purpose: Data on second line biologic patients who have experienced 1st line tumor necrosis factor inhibitor (TNF) failure and associated disease burden among patients (pts) with Psoriatic Arthritis (PsA) in the European Union (EU) is lacking. We assessed the clinical characteristics of pts with PsA on 2nd line biologics after 1st line anti-TNF failure.

Methods: A multi-country medical chart-review study of PsA pts was conducted among physicians (rheumatologists: 96%) in hospitals/private practices to collect de-identified data on pts recently treated with a biologic as part of usual care. Physicians from UK/Germany/France/Italy/Spain (5EU) were screened for practice duration and pt volume and recruited from a large panel to be geographically representative in each country. Eligible pt charts (>2) were randomly selected from a sample of prospective pts visiting each center/practice during the screening period. Physicians abstracted pt diagnosis, treatment patterns/dynamics and pt symptomatology/disease status. EU sites did not require local ethics reviews owing to de-identified retrospective data collection methodology.

Results: Between Jan2011 and Dec2012, 454 PsA pts (mean age:48.8yrs; female:49.6%) on 2nd line biologic after 1st line anti-TNF failure were identified. Mean time-to-1st line anti-TNF from diagnosis was 51.6 months; mean time on 1st line anti-TNF was 18.3months (pts <6:/7–12/13–24>/24months: 33%/21%/19%/27%). Top-3 1st line anti-TNFs observed were: etanercept (38%), adalimumab (32%), and infliximab (27%). The top-5 reasons for 1st line anti-TNF discontinuation were 'long-term efficacy failure', 'disease worsened', 'side-effects not tolerated', 'insufficient improvement', and 'short-term efficacy failure'. Mean time on current 2nd line biologic was 18.5months (pts <6/7–12/13–24>/24months: 28%/21%/25%/27%). Current 2nd line biologics (top-5) included: adalimumab (39%), etanercept (31%), infliximab (14%), golimumab (11%), abatacept (2%).

Top-5 reasons for choice of 2nd line biologic were 'mechanism of action', 'prevention of structural damage', 'improve signs/symptoms', 'disease worsened', 'positive personal experience'. Key lab measures documented were: ESR-21.7mm/h and CRP-8.3mg/dl. Among pts with available data, current HAQ was 1.1, Swollen Joint Count was 1.9 and Tender Joint Count was 3.4. Current disease severity per physician judgment (mild:moderate:severe) were: 48%:47%:5%. Current disease severity (mild:moderate:severe) by time on 1st line anti-TNF biologic (<6/7–12/13–24>/24months) were 47%:48%:5%/55%:42%:3%/49%:48%:4%/44%:49%:7% respectively.

Conclusion: Among PsA pts on their 2nd biologic who have experienced prior anti-TNF failure, 54% discontinued their 1st line anti-TNF regimen within 12months of initiation. There was considerable disease burden despite current 2nd line biologic. Further research is warranted to assess the effectiveness of switching in PsA pts and optimize the treatment strategies to alleviate disease burden among 1st line anti-TNF failures.

Response To Etanercept With Or Without Methotrexate Combination Therapy In Patients With Psoriatic Arthritis. Bernard Combe[1], Urs Kerkmann[2], Fiona Brock[3] and Gaia Gallo[2]. [1]Hôpital Lapeyronie-Service d'Immuno-rhumatologie, Montpellier, France, [2]Pfizer Europe, Rome, Italy, [3]Quanticate, Hitchin, Hertfordshire, United Kingdom.

Background/Purpose: Randomized controlled trials in psoriatic arthrtitis (PsA) have allowed treatment with TNF inhibitors (TNFi) as monotherapy as well as co-medication with methotrexate (MTX), but no trials have indicated any difference in response to TNFi in subgroups with and without concomitant MTX.[1] Current PsA treatment guidelines do not provide clear recommendations on the use of TNFi as monotherapy or combined with MTX.[2–4] Recent real-life data found no additional benefit in response but a trend towards better drug survival in patients receiving TNFi and concomitant MTX.[5,6] We pooled data (post-hoc) from two clinical trials[7,8] to evaluate clinical and functional outcomes in PsA patients receiving etanercept (ETN) with and without MTX.

Methods: Data from PsA patients with active disease receiving ETN (25 mg twice weekly[7] or 50 mg once weekly[8]) with (ETN+MTX arm) and without MTX (ETN arm) were included in descriptive summaries. Demographic and disease activity characteristics at baseline, PsARC and ACR20, 50, and 70 responses at 24 weeks, and change from baseline to week 24 in DAS28-CRP, HAQ-DI, and PASI were summarized for patients in the ETN arm and in ETN+MTX arm across both studies.

Results: At baseline, patients in the ETN (n=322) and ETN+MTX (n=153) arms had a mean age (SD) of 47.0 (11.7) and 47.3 (11.1) years, respectively; weight of 84.7 kg (18.7) and 87.1 (20.6); 38% and 42% were female. The duration of psoriasis was 18.4 (12.0) and 17.5 (11.0) years, respectively; duration of PsA, 8.2 (7.8) and 8.9 (7.0) years; DAS28-CRP, 4.7 (1.2) and 4.7 (1.1); HAQ-DI, 0.9 (0.7) and 1.1 (0.7); and PASI, 18.3 (10.2) and 16.1 (9.6). Other demographic and baseline disease characteristics were also similar for patients in the ETN arm and ETN+MTX arms. Similar proportions of patients in both arms achieved PsARC and ACR20 responses; numerically, a higher proportion of patients in the ETN arm achieved ACR50 and ACR70 responses than in the combination therapy arm. Little difference between groups was observed in DAS28-CRP, HAQ-DI, and PASI improvement from baseline (Table).

Table. Clinical and functional outcomes in patients in the ETN and ETN + MTX arms across studies[7,8]

	ETN Arm	ETN+MTX Arm
% patients achieving endpoint at week 24 (n/N)		
PsARC	80.3 (240/299)	82.6 (119/144)
ACR20	70.5 (203/288)	69.9 (100/143)
ACR50	54.9 (158/288)	48.3 (69/143)
ACR70	34.7 (100/288)	26.6 (38/143)
Change from baseline to week 24, mean (SD)		
DAS28-CRP	−1.9 (1.3)	−1.8 (1.1)
HAQ-DI	−0.5 (0.6)	−0.6 (0.6)
PASI	−13.6 (9.6)	−12.2 (9.5)

PsARC, Psoriatic Arthritis Response Criteria; ACR20/50/70, American College of Rheumatology 20%, 50%,and 70% improvement; DAS28, Disease Activity Score based on 28-joint count using C-reactive protein; HAQ-DI, Health Assessment Questionnaire-Disability Index; PASI, Psoriasis Area and Severity Index.

Conclusion: Etanercept with or without MTX combination therapy provided similar benefit across clinical and functional outcomes in patients with active PsA at 24 weeks of treatment. Further research is warranted to investigate the effect of concomitant MTX on responses and drug survival in patients with PsA starting their first TNFi.

ACR Poster Session A
Rheumatoid Arthritis - Clinical Aspects I: Comorbidities in Rheumatoid Arthritis
Sunday, October 27, 2013, 8:30 AM–4:00 PM

356

Outcomes Of Patients With Rheumatoid Arthritis and Comorbid Hyperlipidemia. L Rosenblatt[1], JR Curtis[2], G Yang[1] and T Hebden[3]. [1]Bristol-Myers Squibb, Plainsboro, NJ, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Formerly of Bristol-Myers Squibb, Plainsboro, NJ.

Background/Purpose: Patients (pts) with RA have an increased prevalence of cardiovascular disease (CVD). Whether due to comorbidity or related to RA medications, many pts with RA have hyperlipidemia, a risk factor for CVD. Using data from a real-world setting we determined the overall and sex-specific risk of cardiovascular (CV) events in pts with RA, with or without comorbid hyperlipidemia, relative to those in a non-RA cohort.

Methods: This retrospective cohort study using claims data from a US commercial health plan (2005–2011) included pts with ≥2 physician diagnoses of RA (ICD-9: 714.0, 714.2) and a non-RA cohort, matched 3:1 with the RA cohort on demographics (age, gender, region, index year). Follow-up began at the index date, 1 year after initiation of full coverage with medical and pharmacy benefits, and lasted until the first CV event, end of enrollment, or end of data availability. Incidence of the first hospitalized CV event (composite of myocardial infarction and ischemic stroke) or *percutaneous coronary intervention*/coronary artery bypass graft in the post-index period was determined for each cohort and stratified by sex and the presence of hyperlipidemia (defined by the presence of a ICD-9. 272.xx diagnosis claim or antihyperlipidemic agent drug claim during the pre-index period). Cox proportional hazards regression model determined the hazard ratio (HR) for CV events, using the presence of RA as the independent variable, controlling for other baseline covariates (age, sex, hyperlipidemia, diabetes, and hypertension).

Results: The RA cohort consisted of 51,130 pts who were matched with 154,292 non-RA pts (37.9% and 38.7% with hyperlipidemia during baseline, respectively). The incidence of CV events per 1000 person-years was 10.19 for the RA cohort and 6.41 for the non-RA cohort (crude rate ratio [RR]=1.59). Within the RA cohort, incidence was 15.54 for pts with hyperlipidemia and 7.05 for pts without hyperlipidemia (crude RR=2.21); in the non-RA cohort, incidence was 10.55 and 3.82 for those with and without hyperlipidemia, respectively (crude RR=2.76). When controlling for covariates, the HR of CV events for pts with RA was 1.68 (95% CI: 1.50, 1.87) relative to non-RA pts. Among covariates, presence of hyperlipidemia conferred a significant risk of CV events ($p<0.0001$); the interaction between RA and hyperlipidemia was not significant ($p=0.13$). Sex-specific RRs and risk differences are shown.

Cohort	Hyperlipidemia (Yes/No)	Sex	CVD incidence rate (/1000 person-years)	Crude RR (with/without hyperlipidemia)	Crude rate difference (with – without hyperlipidemia)
RA	Yes	M	23.25	1.81	10.4
	No	M	12.85		
	Yes	F	12.32	2.21	6.74
	No	F	5.58		
Non-RA	Yes	M	14.74	2.23	8.13
	No	M	6.61		
	Yes	F	8.66	2.76	5.52
	No	F	3.14		

Conclusion: This real-world analysis demonstrates that pts with RA have an increased risk of CV events and, as seen with the non-RA cohort, CV event rates are incrementally higher for those pts with hyperlipidemia. Therefore, mitigating the increased CV risk associated with hyperlipidemia and optimizing lipid levels are key treatment strategies for pts with RA.

Predictive Value Of Anti Cyclic Citrullinated Peptide and Rheumatoid Factor To The Development Of Rheumatoid Arthritis In a Cohort Of Healthy Relatives Of Patients With Rheumatoid Arthritis. Jose Dionisio Castillo-Ortiz[1] and Cesar Ramos-Remus[2]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara, Mexico.

Background/Purpose: Consanguineous relatives of patients with RA are at a higher risk to develop RA. It is also known that specific antibodies including CCP and RF may occur years prior to the disease onset. To assess the predictive value of serum IgM-RF and anti-CCP to the development of RA in a 5-year prospective cohort of healthy consanguineous relatives of RA patients.

Methods: RA patients (ACR criteria) attending one tertiary- and two secondary-care outpatient rheumatology clinics were asked to invite their consanguineous relatives to participate in the study. All patients and relatives underwent medical history; serum IgM-RF (nephelometry) and anti-CCP antibodies (ELISA II) were determined in patients and healthy relatives at baseline. Thereafter participant relatives were contacted by phone every four months using a structured interview (COPCORD questionnaire). When COPCORD was positive subjects had an in-office rheumatology assessment including physical examination, *erythrocyte sedimentation rate*, and plain x-Ray. The outcome was defined as fulfillment of ACR-EULAR criteria of RA. The Kaplan Meier curve was done to assess the time to the outcome and Cox analysis was used to determine baseline predictors (age, sex, anti-CCP, IgM-RF).

Results: A total of 771 consanguineous relatives from 257 RA patients were included. At baseline, all had COPCORD negative and the mean age was 35 (±12), 69% were females and 33% siblings. Thirteen (2%) subjects were positive to both CCP and RF: 9 (1 %) only to CCP and 16 (2 %) only to RF. Sixteen of 771 subjects (2%) developed rheumatoid arthritis during the 5-yrs follow up (3348 person-years), with an annual rate of 0.5% (Kaplan-Meier). The positive predictive value when CCP and RF are positive was 54% and 56% when only CCP was positive. RF per se had no predictive value (table 1). Cox analysis showed that age at baseline, CCP, RF, and siblings were significant predictors for developing RA over follow-up.

Conclusion: The positivity of CCP may be useful to detect preclinical disease in healthy relatives of RA patients.

Disclosure: J. D. Castillo-Ortiz, None; **C. Ramos-Remus**, None.

Inflammatory Burden Predicts Carotid Plaque Progression and Subsequent Cardiovascular Events In Rheumatoid Arthritis: The 2-Year Prospective Cohort Study. Churl Hyun Im, Sang Hoon Kwon, Jeong Soo Eun, Na Ri Kim, Eon Jeong Nam and Young Mo Kang. Kyungpook National University School of Medicine, Daegu, South Korea.

Background/Purpose: Rheumatoid arthritis (RA) patients have increased prevalence of carotid atherosclerosis, especially plaque formation, which has been associated with inflammatory burden in a previous study. We sought to investigate the risk factors of carotid atherosclerosis progression and cardiovascular events (CVE) in RA patients in a prospective cohort study.

Methods: Progression of carotid atherosclerosis, determined by carotid ultrasound and the incidence of CVE were investigated in a prospective KARRA cohort. All patients and healthy controls were prospectively followed up for 5 y ears or until deaths. Conventional CV risk factors, RA disease activity and severity markers, medication histories, and calculated areas under the curve of erythrocyte sedimentation rate (ESR-AUC) for 2 years follow-up were analyzed.

Results: Mean age and female frequency of RA patients were not different compared with those of healthy controls (54 ± 12 vs. 55 ± 12, 81.6 vs. 78.8%, respectively). The number of carotid plaques increased more rapidly in RA patients compared with controls during 2 years of follow-up (0.3 ± 0.7 and 0.2 ± 0.6, respectively, $P = 0.030$). Frequencies of new carotid plaques among subjects without plaque at baseline were not different between RA patients and controls. However, subjects with increased number of plaques who had plaques at baseline were more frequent in RA patients compared with controls (OR 3.086 [95% CI 1.518–6.276; $P = 0.002$]). RA patients with increased number of plaques who had plaques at baseline were significantly associated with modified health assessment questionnaire, tender and swollen joint counts, DAS28, methotrexate (MTX) dose, and ESR-AUC for 2-year period. In a multivariate analysis, tender joint count 68 (OR 1.129 [95% CI 1.025–1.243; $P = 0.014$]), ESR-AUC (OR 1.001 [95% CI 1.000–1.002; $P = 0.022$]), and MTX dose (OR 1.424 [95% CI 1.103–1.839; $P = 0.007$]) were independently associated with these patients. During the 2-year period, CVE occurred in seven (1.7%) among RA patients compared with one (0.5%) among controls. In RA patients, higher number of carotid plaques was significantly associated with CVE ($P = 0.001$). Furthermore, the incidence of CVE was 4.1% among patients with plaque, compared with 0.4 % among patients without plaque (RR 10.859 [95% CI 1.294–91.095; $P = 0.011$]). In a Cox regression model, two or more carotid plaque presence predicted CVE in RA patients during 2-year period (hazard ratio 27.463 [95% CI 3.306–228.124; $P = 0.002$]).

Conclusion: These prospective data suggest that the incidence of CVE depends on by baseline carotid plaques, the progression of which is strongly associated with time-integrated inflammatory burden in RA patients.

Tocilizumab Treatment Increases Left Ventricular Ejection Fraction and Decreases Left Ventricular Mass Index In Rheumatoid Arthritis Patients Without Cardiac Symptoms: Assessment By Cardiac Magnetic Resonance Imaging At 3.0 Tesla. Hitomi Kobayashi[1], Isamu Yokoe[2], Hiroshi Sato[2], Yasuyuki Kobayashi[3], Kihei Yoneyama[3], Masaharu Hirano[4] and Masami Takei[1]. [1]NIhon University School of Medicine, Tokyo, Japan, [2]Itabashi Chuo Medical Center, Tokyo, Japan, [3]St.Marianna University School of Medicine, Kawasaki, Japan, [4]Tokyo Medical Colleage, Tokyo, Japan.

Background/Purpose: Left ventricular (LV) dysfunction in rheumatoid arthritis (RA) may result, at least in part, from inflammation that may be regional and global. Therefore, therapies that reduce inflammation (anti-IL-6 therapy) may delay onset and/or slow progression of LV dysfunction. Cardiac magnetic resonance imaging (CMR) is a sensitive technique for assessing subclinical LV dysfunction. The overall goal of this pilot study was to prospectively evaluate the effect of inhibition of IL-6 on LV function and structure in patients with RA without cardiac symptoms as assessed by using CMR at 3.0 T.

Methods: Consecutive RA patients (pts) with active disease and healthy controls were enrolled. All subjects had no history or clinical findings of hypertension, cardiovascular disease, diabetes mellitus, or dyslipidemia. The

RA pts who each had inadequate clinical response to methotrexate were prescribed tocilizumab (TCZ; 8 mg/kg IV every 4 wks). All subjects underwent baseline evaluation of LV function and structure, as measured by non-contrast CMR at 3.0 T. The following parameters were measured: global LV function (LV ejection fraction, end-systolic volume, end-diastolic volume, stroke volume, and cardiac output); and LV hypertrophy (absolute LV mass, LV mass index [mass/BSA]). After the baseline (BL) CMR, treatment with TCZ was initiated and pts were followed for 52 wks. Pts underwent follow-up CMR evaluation at 52 wks of treatment with TCZ. We examined differences in LV structure and function between control subjects and RA pts. We compared RA pts at BL and at 52 wks, and determined the association of LV structure and function with disease activity and severity measures.

Results: All RA pts received TCZ treatment for 52 wks. We compared 20 RA pts (100% female; mean age 53.4±10.2 y) at BL and at 52 wks, with 20 non-RA controls (100% female; mean age 54.0±4.6 y). DAS28-ESR, SDAI and swollen joint count were significantly lower in RA pts at 52 wks than at BL ($p<0.0001$, $p<0.0001$, $p<0.0001$, respectively). In RA pts at BL, ejection fraction (EF) was significantly lower than in controls ($p=0.04$), and LV mass Index was also significantly higher than in controls ($p=0.05$). Median EF at BL was 60.5% (25th and 75th percentiles 56.1% and 63.4%, respectively), and TCZ treatment resulted in a significant increase of EF at 52 wks (median value 64.3%; 25th and 75th percentiles 61.6% and 69.0%; $p<0.0001$). Median LV mass index at BL was 59.4 gm/m^2 (25th and 75th percentiles 54.3 gm/m^2 and 63.0 gm/m^2, respectively), and TCZ treatment also resulted in a significant decrease in mass index at 52 wks (median value 48.0 gm/m^2; 25th and 75th percentiles 44.1 gm/m^2 and 52.1 gm/m^2; $p=0.0013$). Percentage change in LV mass index in RA pts was significantly associated with percentage change in SDAI ($r=-0.63$, $p=0.0028$).

Conclusion: TCZ treatment contributed significantly to increasing LVEF and decreasing LV mass. Furthermore, we found a significant relationship between disease activity and measures of LV structure and function. TCZ may reduce progression of LV dysfunction and improve LV structure in association with reduced disease activity. These findings suggest that RA itself may be an important contributor to functional and structural abnormalities of LV.

Visit-To-Visit Variability In Blood Pressure In Patients With Rheumatoid Arthritis (RA) Vs General Population, and Its Impact On Cardiovascular Events and All-Cause Mortality In Rheumatoid Arthritis. Elena Myasoedova, Cynthia S. Crowson, Abigail B. Green, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN.

Background/Purpose: Blood pressure (BP) variability has been associated with increased risk of cardiovascular (CV) disease and death in the general population. The impact of BP variability on CV events and mortality in RA is uncertain. We aimed to examine long-term visit-to-visit BP variability in RA vs non-RA subjects and to assess the impact of BP variability on CV events and all-cause mortality in RA.

Methods: The study included a population-based incident cohort of RA patients (1987 ACR criteria first met between 1980 and 2007) and a cohort of non-RA subjects of similar age and sex. All available clinic BP measures were collected from the medical records. BP variability was defined as within-subject standard deviation (SD) in systolic and diastolic BP. Cox models were used to examine the effect of BP variability on CV events (i.e. hospitalized/silent myocardial infarction, CV mortality, heart failure, ischemic heart disease, angina, or revascularization procedures) and all-cause mortality in RA.

Results: The study included 452 RA patients (mean age 55.5 years, 31% males) and 436 non-RA subjects (mean age 55.7 years, 31% males). During the mean follow-up of 7.1±2.7 years in RA and 7.2±2.6 years in the non-RA cohort there were 13,470 BP measures in RA and 9,476 in the non-RA subjects; median time between the measurements: 30 days in RA vs 27 in the non-RA cohort (p=0.93). The mean systolic BP at RA incidence/index date was higher in RA vs non-RA cohort (131.2±18.7 mmHg vs 128.2±19.3 mm Hg, p=0.018); the mean diastolic BP was similar in RA (75.1±10.9 mm Hg) vs non-RA cohort (75.6±11.0 mm Hg, p=0.53). There were 290 (64%) patients with hypertension in RA vs 241 (55%) in the non-RA cohort at index date. The proportion of hypertensive subjects on antihypertensive drugs was similar in RA and non-RA cohort at index date (35% vs 33%, respectively, p=0.59) and during the follow-up (36% vs 31% at 10 years, respectively, p=0.30). Patients with RA had higher visit-to-visit variability in systolic BP (13.8±4.7 mm Hg), but not diastolic BP, than the non-RA subjects (13.0±5.2 mm Hg, p=0.004). There was a significant decline in systolic BP variability in RA (p<0.001) after RA incidence/index date, adjusting for age, sex and calendar year of RA; no such trend was noted in the non-RA cohort (p=0.73). Diastolic BP variability remained unchanged in RA (p=0.56) and non-RA (p=0.15) cohort. During the follow-up, 33 CV events and 57 deaths occurred in the RA cohort. Adjusting for systolic and diastolic BP, body mass index, smoking, diabetes, dyslipidemia and use of antihypertensives, higher systolic BP variability was associated with increased risk of CV events in RA (hazard ratio [HR] 1.15, 95% confidence interval [CI] 1.02–1.3); higher diastolic BP variability was associated with all-cause mortality (HR 1.14, 95%CI 1.03–1.27).

Conclusion: Patients with RA had higher long-term visit-to-visit variability of systolic BP than non-RA subjects. Systolic BP variability declined significantly after the index date in RA patients, but not in the non-RA subjects. Higher visit-to-visit variability in systolic and diastolic BP was associated with adverse CV outcomes and all-cause mortality in RA.

Risk Of Venous Thromboembolism and Use Of Disease-Modifying Antirheumatic Drugs For Rheumatoid Arthritis. Seoyoung C. Kim[1], Daniel H. Solomon[2], Jun Liu[3], Jessica M. Franklin[4], Robert J. Glynn[1] and Sebastian Schneeweiss[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA, [4]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Recent research suggests that rheumatoid arthritis (RA), an autoimmune systemic inflammatory disease, increases the risk of venous thromboembolism (VTE) including pulmonary embolism and deep vein thrombosis. We compared the risk of VTE in RA patients initiating treatment with biologic disease-modifying antirheumatic drugs (bDMARD), methotrexate (MTX) or non-biologic DMARD (nbDMARD).

Methods: We conducted a population-based cohort study combining three U.S. commercial insurance claims databases (2001–2012). Adult patients with a new diagnosis of RA were identified based on ≥2 RA diagnoses that were ≥7 days apart with a baseline period free of RA diagnosis or DMARD use for ≥1 year. Among these patients, initiators (starting or switching) of various DMARDs were identified. Patients with a history of VTE, malignancy and use of anticoagulants at baseline were excluded. Drug regimens were categorized into three mutually exclusive hierarchical groups: (1) a biologic DMARD with or without nbDMARDs, (2) MTX without a biologic DMARD, or (3) nbDMARDs without a biologic DMARD or MTX. We calculated incidence rates (IR) with 95% confidence intervals (CI) of VTE identified by a previously validated algorithm with inpatient diagnosis codes (PPV 75–90%). Cox proportional hazards models stratified by propensity score (PS) deciles after asymmetric trimming were used for 3 pairwise comparisons, controlling for baseline demographic factors, comorbidities, medications, and health care utilization. Sensitivity analysis limited to 180 days of follow-up and PS-matched analyses were also performed.

Results: A total of 29,481 RA patients with 39,647 treatment episodes were identified. Mean (SD) age was 49 (12) years for bDMARD and nbDMARD groups and 51 (12) for MTX. The crude IR of VTE per 1,000 person-years was higher in the bDMARDs group (5.53, 95% CI 3.67–8.32) compared to nbDMARDs and MTX (**Table**). In the PS decile-stratified Cox regression, the hazard ratio (HR) of VTE associated with initiation of bDMARDs was 1.83 (95% CI 0.92–3.63) compared to nbDMARDs and 1.39 (95% CI 0.73–2.64) compared to MTX. The HR of VTE associated with initiation of MTX versus nbDMARDs was 0.78 (95% CI 0.50–1.21). In a sensitivity analysis limiting the follow-up up to 180 days, bDMARDs was associated with a significantly increased risk (HR 2.48, 95% CI 1.14–5.40). In the PS-matched analyses, the HR was 1.34 (95% CI 0.65–2.75) in bDMARDs vs. nbDMARDs and 1.73 (95% CI 0.90–3.32) in bDMARDs vs. MTX.

Table. Risk of venous thromboembolism associated with initiation of DMARDs: PS decile-stratified 'as treated' analysis

Exposure	Treatment episodes	VTE	Person-years (PY)	IR (95% CI) per 1,000 PY	HR (95% CI)	HR (95% CI) 0-180d only
bDMARDs	4488	23	4157.90	5.53 (3.67–8.32)	1.83 (0.92–3.63)	**2.48 (1.14–5.40)**
nbDMARDs	12859	32	7220.08	4.43 (3.13–6.26)	Ref	Ref
bDMARDs	4597	21	4368.17	4.81 (3.14–7.38)	1.39 (0.73–2.64)	1.80 (0.84–3.85)
MTX	13912	32	9258.12	3.46 (2.45–4.89)	Ref	Ref
MTX	16352	42	11075.60	3.79 (2.80–5.13)	0.78 (0.50–1.21)	0.86 (0.50–1.48)
nbDMARDs	14618	41	8249.97	4.97 (3.66–6.75)	Ref	Ref

Conclusion: Among newly diagnosed RA patients, initiating a bDMARD was associated with a likely increase, but not statistically significant, in the risk of incident VTE compared to those initiating MTX or nbDMARDs, albeit low absolute risks of VTE. Initiation of bDMARDs was significantly associated with a 2.5-times elevated risk of VTE in the first 180 days.

Management Of Hyperlipidemia In Patients With RA: Results From The Corrona Certain Study. Dimitrios A. Pappas[1], Ani John[2], Joel M. Kremer[3], George W. Reed[4], Tanya Sommers[4], Jeffrey D. Greenberg[5], Ashwini Shewade[2] and Jeffrey R. Curtis[6]. [1]Columbia University, New York, NY, [2]Genentech Inc., South San Francisco, CA, [3]Albany Medical College and The Center for Rheumatology, Albany, NY, [4]CORRONA, Inc., Southborough, MA, [5]NYU Hospital for Joint Diseases, New York, NY, [6]7University of Alabama at Birmingham Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background/Purpose: RA is associated with an increased risk for cardiovascular disease (CVD).[1] Patients (pts) with RA share similar risk for CVD with non-RA pts who are 10 years older and with diabetics and may benefit from lipid-lowering therapies such as statins[2]; however, information on management of hyperlipidemia in pts with RA is not well characterized. This study evaluated adequacy of lipid-lowering therapy in a cohort of 779 ptswith RA participating in the CORRONA registry.

Methods: Pts with at least moderate disease activity (CDAI $>$ 10) initiating a biologic DMARD participated in an ongoing comparative effectiveness study (CERTAIN) nested within CORRONA. Lipid levels and information about statin or other lipid-lowering use was obtained at baseline. Clinical and demographic characteristics of pts receiving antihyperlipidemic therapy at baseline were compared with pts with increased lipid levels (LDL $\geq$ 100 mg/dL and LDL $\geq$ 130 mg/dL) who were not receiving lipid-lowering agents.

Results: A total of 779 CERTAIN enrollments were evaluated between November 20, 2010, and July 2, 2012. At baseline, 485 (62.3%) pts had LDL $\geq$ 100 mg/dL (223 [28.6%] with LDL $\geq$ 130 mg/dL), 84 (10.8%) had HDL $<$ 40 mg/dL, 311 (39.9%) had TC $\geq$ 200 mg/dL, 298 (38.3%) had TG $\geq$ 150 mg/dL and 69 (8.9%) had a TC/HDL ratio $>$ 5. Of 779 pts, 191 (24.5%) were already using statins and/or other lipid-lowering therapies at baseline. A total of 408 (52.4%) pts with an LDL $\geq$ 100 mg/dL and 192 (24.6%) pts with LDL $\geq$ 130 mg/dL were not on statin therapy. Pts receiving statins were older (62.1 $\pm$ 11.0 vs 54.1 $\pm$ 12.8 years), less frequently female (66.5% vs 78.4%) and had more frequent history of CVD (22.5 vs 3.4%) and diabetes mellitus (9.4 vs1.7%) compared with pts having LDL $\geq$ 100 mg/dL who were not receiving statins. Similar differences were seen comparing pts on statins with pts with LDL $\geq$ 130 but not on statins.

Conclusion: Consistent with previous reports,[3,4] a considerable proportion of hyperlipidemic RA pts at risk for CVD were not receiving lipid-lowering therapy. Practicing rheumatologists need to be aware of the prevalence of hyperlipidemia and appropriate management to reduce risk for CVD.

363

Comparing Myocardial Infarction Risks Associated With Biologics Of Varying Mechanisms Of Action Among Older Rheumatoid Arthritis Patients. Jeffrey R. Curtis[1], Huifeng Yun[2], Jie Zhang[2], Fenglong Xie[2], Lang Chen[2], Emily Levitan[2], James Lewis[3], Timothy Beukelman[2], Kenneth G. Saag[2] and Iris Navarro-Millan[2]. [1]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Anti-TNF biologics have been associated with a reduced risk for acute myocardial infarction (AMI) in some rheumatoid arthritis (RA) populations. The comparative risks for AMI associated with newer biologics with alternative mechanisms of action other than TNF blockade have not been well characterized.

Methods: Using Medicare data from 2006–2011 for patients with RA, we identified new users of abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. New users were defined specific to each drug using a 12 month 'baseline' period. To increase homogeneity of patients' characteristics to allow comparison with biologics typically not used as first line agents, patients were required to have used another biologic during baseline.

Eligible subjects must have been continuously enrolled in Medicare Parts A, B and D in baseline and throughout follow up and could not have had a hospitalized AMI during baseline. Follow up started from the drug initiation date and ended at the earliest of: AMI (primary position or non-primary), a 30 day gap in current exposure, death, loss of Medicare coverage or Dec 31, 2011. Confounding was controlled through a person-specific risk score. We calculated the incidence rate of AMI for each biologic and risks during follow-up using Cox regression adjusting for risk score decile, disability, baseline glucocorticoid use, methotrexate use, and dual eligible status, and accounting for clustering of biologic exposure treatment episodes within patients.

Results: Of 27,082 new biologic users, 11.3% initiated etanercept, 15.8% adalimumab, 6.1% certolizumab, 4.4% golimumab, 12.6% infliximab, 29.0% abatacept, 14.6% rituximab and 6.3% tocilizumab. Among 24,237 eligible RA patients, we identified 181 hospitalized AMIs, yielding an overall crude incidence rate of 0.88/1000py. After adjustment for potential cofounders and compared to abatacept users, the adjusted hazard ratios of various biologics were not significantly different (Table). Ongoing work is confirming the robustness of the results across a range of sensitivity analyses.

Table. Events, absolute incidence rate and adjusted hazard ratio of hospitalized MI

Biologic Exposures	Events	Crude incidence rate per 100 py	Adjusted Hazard Ratio* (95% CI)
Abatacept	71	0.96	1.0 (referent)
Anti-TNF	70	0.78	0.87 (0.55, 1.36)
Rituximab	34	1.00	0.98 (0.57, 1.68)
Tocilizumab	$<$11	0.374	0.43 (0.13, 1.42)

* Adjusted for age, sex, risk score decile, steroid use during baseline, specific biologic use during baseline, original reason for Medicare coverage and dual eligible status.

Conclusion: Among patients with RA, the risk for hospitalized myocardial infarction was similar between anti-TNF therapies and biologics with other mechanisms of action. The protective effect previously observed with anti-TNF therapies may apply more broadly to newer biologics and may be a consequence of reduction in inflammation rather than a drug-specific effect.

Hyperuricemia As a Risk Factor for Cardiovascular Disease in Patients With Rheumatoid Arthritis. Daniel Kuo, Cynthia S. Crowson, Sherine E. Gabriel and Eric L. Matteson. Mayo Clinic, Rochester, MN.

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of developing cardiovascular disease (CVD). There is growing evidence that serum uric acid plays an important role in CVD in the general population. The purpose of this study was to evaluate whether hyperuricemia is a risk factor for CVD in patients with RA.

Methods: A population-based inception cohort of patients diagnosed between 1980 and 2007 with adult-onset RA according to 1987 ACR guidelines was assembled. A comparison cohort of subjects without RA (non-RA) but with similar age and sex was also assembled. All subjects were followed from inception/index until death, migration, or December 31, 2008. All clinically obtained uric acid values were collected. Per reference ranges, hyperuricemia was defined as serum uric acid >8.0 mg/dl for males and >6.1 mg/dl for females. CVD recorded for each patient included angina, coronary heart disease, revascularization procedures, myocardial infarction (MI) and heart failure (HF). Noncardiac vascular diseases included stroke, thromboembolism, and peripheral arterial disease (PAD). Cox proportional hazards models were used to assess the impact of hyperuricemia on the development of CVD and mortality among RA and non-RA subjects as well as noncardiac vascular disease in RA patients.

Results: The study included 813 patients with RA and 813 subjects without RA (mean age 55.9 years; 68% female in both cohorts). There was no significant difference in the presence of hyperuricemia between the cohorts at baseline (10% in RA vs. 13% in non-RA; p=0.15). Cumulative incidence of hyperuricemia was higher in RA patients (19.1% ± 1.8% at 10 years in RA vs. 12.4% ± 1.5% in non-RA; p=0.005). In patients without RA, after adjusting for traditional cardiovascular risk factors, hyperuricemia was associated with HF (HR: 1.87; 95% CI: 1.08, 3.25) and CVD (HR: 1.79; 95% CI: 1.13, 2.84). In patients with RA, hyperuricemia was not significantly associated with the assessed cardiac outcomes. However, hyperuricemia appeared to be more strongly associated with mortality among RA patients (HR: 1.93; 95% CI: 1.43, 2.60) than among the non-RA subjects (HR: 1.51; 95% CI: 1.06, 2.16). After adjusting for vascular risk factors, in patients with RA, hyperuricemia was significantly associated with PAD (HR: 2.74; 95% CI: 1.28, 5.86).

Conclusion: Patients with RA were more likely to develop hyperuricemia than patients without RA. In patients with RA, hyperuricemia was a significant predictor of increased mortality and PAD but not CVD. Further studies are needed to improve our understanding of the effects of hyperuricemia in RA.

Oral Calcium Supplementation Is Associated With Subclinical Atherosclerosis In Rheumatoid Arthritis. Shanthi Dhaduvai[1], Laura Geraldino-Pardilla[1], Jon T. Giles[2] and Joan M. Bathon[3]. [1]Columbia University Medical Center, New York, NY, [2]Columbia University, College of Physicians & Surgeons, New York, NY, [3]Columbia University, New York, NY.

Background/Purpose: Recent studies in the general population highlight possible adverse cardiovascular effects with calcium supplementation; however, the association between calcium intake and subclinical markers of atherosclerosis has not been explored in patients with rheumatoid arthritis, a group with increased risk for coronary artery disease and cardiovascular mortality.

Methods: Among RA patients participating in a cohort study of subclinical cardiovascular disease (CVD), daily supplemental calcium dose was assessed from prescription and over the counter medications at baseline and at the first follow-up visit (median time from baseline 20 months). Participants underwent 64-slice cardiac multidetector row CT scanning at baseline and at visit 3 (median time 39 months from baseline) to assess coronary artery calcium (CAC), a measure of coronary atherosclerosis. The relationship of average daily intake of calcium (mg/day) with CAC was assessed by multivariable ordinary logistic regression with CAC score dichotomized at 100 units (a level predictive of subsequent CVD events), and adjusting for relevant confounders.

Results: A total of 145 RA patients [38% male, mean age 59±8 years, median RA duration 9 years, mean DAS28 3.6±1.0] had complete longitudinal data. At baseline, 42 (28%) were taking ≥1000mg/d of calcium while the remainder took <1000mg/d. A CAC score ≥100 units was observed in 44 (30%) at baseline and 51 (35%) at follow-up. Age, gender, body mass index (BMI), and use of anti-hypertensives were associated with both CAC and calcium intake, and were considered as relevant confounders in subsequent analyses. At baseline, CAC scores of ≥100 were significantly less frequent in the higher vs. lower dose calcium supplementation groups [OR 0.30 (95% CI 0.12–0.78) (Fig 1a)], and this difference remained significant after adjustment for relevant confounders [OR 0.31 (95% CI 0.97-0.95) (Fig 1a)]. Similarly, at follow-up, CAC scores of ≥100 were also significantly less frequent in the group taking an average calcium supplement dose of ≥1000mg/d vs. those taking <1000mg/d (Fig 1b); however, when adjusted for relevant confounders, there was only a trend to significance [OR 0.40 (95% CI 0.14–1.15) (Fig 1b)]. There was no gender heterogeneity in the association of calcium intake with CAC score. Change in CAC score over time between baseline and follow-up was not statistically significantly different between the two calcium groups.

Conclusion: Calcium supplementation was not associated with a higher risk of coronary atherosclerosis in this RA population, and may have even been protective, a finding with relevant therapeutic implications in the daily treatment of RA patients.

366

Traditional Cardiac Risk Factors Predict Significant Coronary Plaque Burden In Asymptomatic Patients With Rheumatoid Arthritis. George A. Karpouzas, Jennifer Malpeso, Tae-Young Choi, Youngju Pak and Matthew Budoff. Harbor-UCLA Medical Center, Torrance, CA.

Background/Purpose: Computed tomography angiography (CTA) provides prognostic information in patients with suspected but unknown coronary artery disease (CAD); subjects without plaque had no incident major cardiovascular events (MACE) at 52 months. In those with obstructive plaque (>50% stenosis) or significant plaque burden [segment involvement score (SIS)>5, or segment stenosis score (SSS)>5] incident MACE was noted in 69%, 75%, and 80% respectively at 52 months. We evaluated the contributions of demographic, traditional cardiac risk factors (CRF) and rheumatoid arthritis (RA)-associated variables on the risk of having obstructive plaque, SIS>5, or SSS>5 in 150 subjects with RA and no symptoms or diagnosis of CAD compared to 150 age and gender-matched controls.

Methods: Patients and controls underwent CTA; qualitative and quantitative plaque evaluation was carried out using a standard 15-coronary segment American Heart Association Model. Subjects with either obstructive plaque, or SIS>5, or SSS>5 where considered high-risk; the remainder were considered low-risk. Chi-square or Fisher's exact tests evaluated the associations between binary variables and high-risk outcomes while simple logistic regression model was used for continuous variables. The Breslow-Day test assessed homogeneity of OR between two groups.

Results: A higher proportion of RA subjects were classified in the high-risk group: 23 (15.3%) vs. 8 (5.3%) in controls, OR (95%CI)=3.2 (1.4–7.4), p=0.004. Age was a significant determinant of high risk for the entire cohort (n=300) [OR=1.08 (1.04–1.13), p=0.0004], as well as for the RA group [OR=1.09 (1.04–1.15), p=0.001], but not the controls [OR=1.06 (0.98–1.15), p=0.14]. In RA patients, age>55 years was the best predictor of high-risk outcome, followed by male gender, diabetes, and hypertension (table 1); none of the RA-associated parameters predicted such outcome. No demographic or CRF predicted high-risk outcomes in controls. Significant interactions were observed between male gender and hypertension for high-risk outcomes in RA patients (p=0.024, and p=0.04 respectively).

Table 1. Outcome= presence of obstructive plaque (>50% stenosis), or SSS>5, or SIS>5 (High-risk) vs. not (low-risk)

	RA-univariate		Controls-univariate		RA vs. controls-differences in OR (Breslow-Day test)
parameters	OR	p	OR	p	p
Age>(55)	5.93 (2.1–17)	***0.0003***	2.27 (0.5–9.9)	0.3	0.29
Male	5.62 (1.9–16.2)	***0.002***	N/A*	0.6	***0.026***
HTN	2.9 (1.1–7.5)	***0.02***	0.4 (0.09–2.3)	0.47	***0.04***
DM	4.2 (1.56–11.1)	***0.005***	1.56 (0.3–8.2)	0.6	0.3
Dyslipidemia	0.4 (0.09–1.9)	0.37	1.3 (0.3–5.5)	0.7	0.25
smoking	1.0 (0.2–4.86)	1	N/A*	0.6	0.27
FHx	1.1 (0.12–9.95)	1	0.4 (0.1–1.9)	0.3	0.48
RA>5 years	2.35 (0.75–7.3)	0.14	–	–	–
RF (+) & a-CCP (+)	1 (0.2–4.8)	1	–	–	–
DAS28-3v>3.2	1.37 (0.56–3.3)	0.5	–	–	–
Erosions	1.55 (0.57–4.2)	0.47	–	–	–
JRS	1.43 (0.37–5.5)	0.7	–	–	–

*N/A: OR not applicable due to presence of 0 cell value.

Conclusion: Demographic and traditional CRF such as age, male gender, diabetes, and hypertension in decreasing significance predict obstructive or high burden coronary plaque by CTA in patients with RA and no symptoms or diagnosis of CAD. Male gender and hypertension differentially predict such outcomes in RA compared to controls.

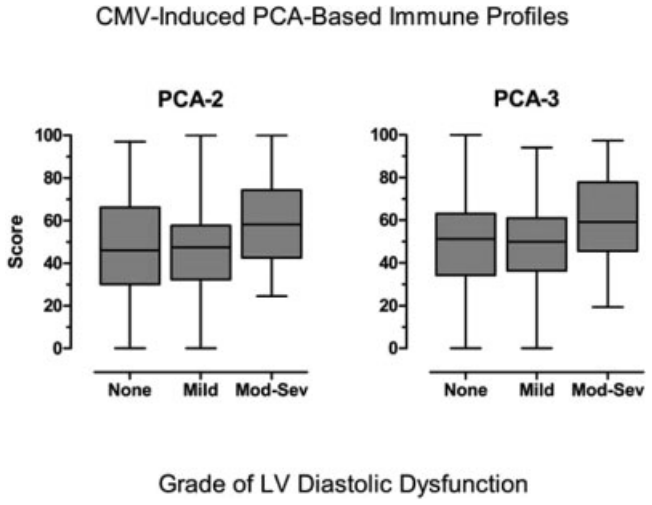
Cytomegalovirus-Related Immunity Correlates With Myocardial Disease In Rheumatoid Arthritis. John M. Davis III, Cynthia S. Crowson, Michael A. Strausbauch, Terry M. Therneau, Eric L. Matteson, Keith L. Knutson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN.

Background/Purpose: We recently discovered correlations between a profile of cytokines produced in response to human cytomegalovirus (CMV), poor treatment outcome, and erosive joint damage. The objective of this study was to determine if a similar CMV-induced cytokine profile would also correlate with myocardial disease in patients with RA.

Methods: A correlative study of 324 patients with RA in our population-based inception cohort was performed. Diastolic function was evaluated using transthoracic 2D/Doppler echocardiography and categorized as normal, mild LVDD, moderate-to-severe LVDD or heart failure, or indeterminate. Immunological profiles of 17 cytokines (IFN-γ, IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-17A, MCP-1, MIP-1β, G-CSF, GM-CSF, TNF-α) produced by peripheral blood mononuclear cells (PBMCs) in response to stimulation with combined cytomegalovirus or Epstein-Barr virus lysates (CMV/EBV) were assessed using multiplex assays. Principal components analysis (PCA) was used to derive robust and informative cytokine profiles based on the 1st, 2nd and 3rd principal components. Mixed effects models were used to normalize the data and test for associations between the CMV/EBV PCA scores and moderate-to-severe LVDD/HF, adjusting for age, sex, cardiovascular risk factors, and RA disease characteristics. Among a separate sample of 64 patients with early RA having available viral serologies, the PCA scores were correlated with CMV or EBV IgG.

Results: The mean age of the subjects was 60.4 years, 74% were female, and the mean RA duration was 9.9 years. 151 (47%) had normal diastolic function, 64 (20%) had mild LVDD, 35 (11%) had moderate-to-severe LVDD or HF, and 74 (23%) were indeterminate. The PCA scores for the 2nd and 3rd principal components (PCA-2 and PCA-3, respectively) were associated with moderate-to-severe LVDD or HF compared to patients with normal diastolic function (odds ratio = 1.28 per 10-unit increase in the 100 point score, p = 0.022 and odds ratio = 1.24, p = 0.067, respectively). The five most informative cytokines in PCA-2 (from highest to lowest importance) were G-CSF, IL-6, IL-8, IL-1β, and GM-CSF and in PCA-3 were TNF-α, MIP-1β, IL-8, IL-1β, and IFN-γ. Among patients with early RA, both PCA-2 (r = 0.25, p = 0.06) and PCA-3 (r = 0.38, p = 0.003) were shown to correlate with CMV IgG whereas neither of the PCA scores were found to correlate with EBV IgG (r < 0.1 for all). A signature incorporating PCA-2 was developed with very good accuracy in predicting advanced myocardial disease (C-statistic = 0.834).



Conclusion: A profile of CMV-related immunity is associated with moderate-to-severe LVDD in persons with RA. The findings are relevant to developing myocardial risk assessment tools and to understanding how perturbations in innate and adaptive immunity in relation to latent CMV infection impact the pathophysiology of myocardial disease in RA.

Detrimental Impact Of Long-Term Cumulative Burden Of Rheumatoid Arthritis (RA) Disease Severity On Cardiovascular Outcomes In RA. Elena Myasoedova[1], Birkan Ilhan[2], Helen Khun[1], Eric L. Matteson[1] and Cynthia S. Crowson[1]. [1]Mayo Clinic, Rochester, MN, [2]Marmara University, School of Medicine, Istanbul, Turkey.

Background/Purpose: Several studies have shown the associations of various measures of rheumatoid arthritis (RA) disease severity with unfavorable cardiovascular (CV) outcomes in RA. The association of cumulative RA severity burden on CV disease has not been investigated in longitudinal population-based studies. We aimed to examine the impact of long-term cumulative burden of RA disease severity on CV outcomes in RA.

Methods: A previously validated Claims-based Index of RA Severity (CIRAS; Ting et al. Arth Res Ther. 2008;10:R95) was used to estimate RA severity in a population-based incident cohort of patients with RA who were >/= 30 years old, fulfilled 1987 ACR criteria between 1/1/1988 and 1/1/2008, and had no history of CV disease. Claims-based data were used to calculate the CIRAS score: number of inflammatory marker tests, platelet counts, and chemistry panels; number of rheumatology visits, rehabilitation visits, assessment of rheumatoid factor, and the presence of Felty's syndrome. CIRAS score was calculated at RA incidence and monthly during the follow-up using 12 months of prior information for each estimate. Data on antirheumatic medications (i.e. methotrexate, hydroxychloroquine, other disease-modifying antirheumatic drugs, biologics and corticosteroids), CV risk factors (i.e. hypertension, diabetes, smoking and dyslipidemia), incident CV events (myocardial infarction, CV death, angina, stroke, intermittent claudication, and heart failure) were collected from the medical records. Cox models with time-dependent covariates were used to assess the association of CIRAS score with the risk of CV events, adjusting for age, sex, calendar year of RA, CV risk factors and antirheumatic medication use.

Results: The study included 526 patients with RA (mean age at RA incidence 54.6 years, 71% female). The mean CIRAS score at RA incidence was 4.5 (standard deviation [SD] 1.9; min 0.6; max 9.5). During the mean follow-up of 7.3 years 103 CV events occurred. There was no apparent association of baseline CIRAS with the occurrence of CV events (hazard ratio [HR] 1.08 per 1 unit increase, 95% confidence interval [CI] 0.96, 1.22, p=0.20). The associations of the highest CIRAS value in the first year (HR 1.14 per 1 unit increase, 95%CI 0.99, 1.31, p=0.063) and monthly CIRAS (HR 1.13 per 1 unit increase, 95%CI 0.98, 1.31, p=0.096) with CV events approached statistical significance. Increase in cumulative moving average of monthly CIRAS was associated with significantly increased risk of CV events (HR 1.34 per 1 unit increase, 95%CI 1.09, 1.66). By cumulative moving percentage of time, patients who spent more time in medium and high CIRAS tertiles were more likely to have an increased risk of CV events vs those who spent more time in the lower tertile (HR 1.07, 95%CI 0.97, 1.17 and HR 1.14, 95%CI 1.03, 1.25, respectively, per 10 unit increase in the amount of time in the tertile).

Conclusion: Higher long-term burden of RA severity as expressed by cumulative moving average of monthly CIRAS and cumulative moving percentage of time in medium and high CIRAS tertiles was associated with significantly increased risk of CV events in RA suggesting accrued detrimental impact of RA severity over time.

Prolongation Of QT Interval In Patients With Rheumatoid Arthritis and Its Impact On Mortality: Results From a Population-Based Study. Krati Chauhan[1], Michael Ackerman[2], Cynthia S. Crowson[1], Eric L. Matteson[1] and Sherine E. Gabriel[1]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester Minnesota, Rochester, MN.

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular morbidity and mortality. This risk persists even when RA disease characteristics are taken into account. Heart rate corrected QT interval (QTc) obtained on standard electrocardiogram (EKG) represents ventricular repolarization. QTc prolongation is related to increased cardiovascular mortality. The primary purpose our study is to determine the impact of QTc prolongation on mortality in patients with RA.

Methods: A population based inception cohort of patients with RA fulfilling 1987 ACR criteria in 1988–2007 was identified, along with an age and sex matched comparison cohort and followed until death, migration or 12–31-2008. Data were collected on EKG variables (heart rate, QRS interval, QT interval, QT interval corrected for heart rate calculated using the Bazett's formula(QTc), atrial fibrillation, atrial flutter, supraventricular tachycardia, bundle branch block, paced rhythm, and ST-T wave changes), medications known to prolong QT interval, electrolytes, cardiovascular risk factors and disease status (hypertension, DM, lipids, BMI, smoking status, myocardial infarction, cardiovascular death, sudden death, heart failure), RA disease characteristics (erythrocyte sedimentation rate [ESR], rheumatoid factor, large joint swelling, joint erosions, destructive changes on radiographs, extraarticular manifestations of RA). Cox proportional hazards models were used as to examine QTc prolongation as predictor of mortality.

Results: Among 650 RA and 650 non RA patients, QTc prolongation prior to RA incidence/index date was similar in RA (15%) and non RA (18%). During follow-up, the cumulative incidence of QTc prolongation was higher among RA (48% at 20 years after RA incidence) than non-RA (38% at 20 years after index date; p= 0.004). This difference remained significant (RA: 22%, non RA: 17% at 20 years, p = .025) after excluding QTc prolongation in the presence of EKG variables, electrolytes and QT prolonging medications. Elevated ESR at RA diagnosis was associated with developing prolonged QTc (Hazard ratio [HR}: 1.14 per 10 mm/hr increase; 95% confidence interval [CI]: 1.03–1.27). QTc prolongation was not significantly associated with all-cause mortality in RA patients (HR: 1.28; 95% CI: −.91-1.81, p=0.16) or coronary heart disease mortality (HR: 1.10; 95% CI:0.43–2.86, p= 0.83) adjusted for age, sex and calendar year of RA incidence/index.

Conclusion: RA patients have a significantly elevated risk of developing prolonged QTc interval. Prolonged QTc was not associated with all cause and coronary heart disease mortality in RA patients. The clinical implications of these findings and their relationship to sudden cardiac death in RA require further study.

Shift In Cardiovascular Risk and Lipid Levels In Rheumatoid Arthritis Patients Using ATP-3 Guidelines: Corrona Certain Study. Dimitrios A. Pappas[1], Ani John[2], Jeffrey R. Curtis[3], George W. Reed[4], Tanya Sommers[4], Jeffrey D. Greenberg[5], Ashwini Shewade[2] and Joel M. Kremer[6]. [1]Columbia University, New York, NY, [2]Genentech Inc., South San Francisco, CA, [3]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, [4]CORRONA, Inc., Southborough, MA, [5]New York Hospital for Joint Diseases, New York, NY, [6]Albany Medical College and The Center for Rheumatology, Albany, NY.

Background/Purpose: RA is associated with an increased risk for cardiovascular (CV) disease. Hyperlipidemia is a recognized risk factor for CVD. This study followed the changes in lipid levels after 3 months of therapy with biologic agents.

Methods: Patients (pts) with at least moderate disease activity (CDAI >10) initiating a biologic DMARD participated in an ongoing comparative effectiveness study (CERTAIN) nested within CORRONA. Characteristics, including lipid values in pts initiating a TNF-α inhibitor (TNFi) or non-TNFi (rituximab [RTX], abatacept [ABA] or tocilizumab [TCZ]), were measured at baseline and 3 months. Adult Treatment Panel III (ATP-3) guideline lipid categories were used to evaluate lipid levels: LDL (optimal < 100), HDL (low < 40), total cholesterol (TC) (desirable < 200) and triglycerides (TG) (normal < 150). TC/HDL ratio (desirable ≤ 5) thresholds were determined by American Heart Association (AHA) recommendations and were used to categorize pts into low/normal risk and elevated risk for CV disease. We describe the proportion of pts who shifted lipid level categories from baseline to 3 months of therapy for each biologic. Pts who started or stopped lipid-lowering therapy between baseline and 3 month follow up visit were excluded from this analysis.

Results: 715 initiations of a biologic were analyzed. Baseline characteristics: age 55.6 ± 13.3, female 76.1%, and baseline CDAI 28.7 ± 12.7. History of prior CVD was present in 7.0% of pts; 3.1% had diabetes mellitus and 39.4% were obese (BMI>30). 55.9% of pts received TNFi, 5.9% RTX, 20.14% ABA and 18.0% TCZ. Changes in lipid levels after three months of therapy and shifts between lipid categories are listed in Table 1. Of all pts with an optimal LDL at baseline, 24.2% had LDL shifted to an above optimal level at 3 months and of those pts with an above optimal LDL at baseline, 12.4% shifted to an optimal level at 3 months; for TC, of pts at a desirable level at baseline, 18.3% shifted to a higher than desirable level at 3 months and of pts at a higher than desirable level at baseline, 20.4% shifted to a desirable level at 3 months. For TC/HDL ratio, of pts at a desirable level at baseline, 41.4% shifted to a higher than desirable level at 3 months whereas of pts with a higher than desirable level at baseline, 4.4% shifted to a desirable level at 3 months. Similar bi-directional changes were noted for all biologics.

LDL	LDL increase from <100 mg/dL at baseline to ≥100 mg/dL at 3 months (% of patients at optimal level)	LDL decrease from ≥100 mg/dL at baseline to <100 mg/dL at 3 months (% of patients above optimal level)
Overall N=715	64/265 (24.2%)	56/450 (12.4%)
TNFi N=400	39/144 (27.1%)	34/256 (13.3%)
Rituximab N=42	5/21 (23.8%)	3/21 (14.3%)
Abatacept N=144	8/58 (13.8%)	10/86 (11.6%)
Tocilizumab N=129	12/42 (28.6%)	9/87 (10.3%)
Total cholesterol (TC)	**TC increase from <200 mg/dL at baseline to ≥ 200 mg/dL at 3 months (% of patients at desirable level)**	**TC decrease from ≥ 200 mg/dL at baseline to <200 mg/dL at 3 months (% of patients above desirable level)**
Overall N=715	79/431 (18.3%)	58/284 (20.4%)
TNFi N=400	36/234 (15.4%)	39/166 (23.5%)
Rituximab N=42	3/24 (12.5%)	4/18 (22.2%)
Abatacept N=144	12/94 (12.8%)	6/50 (12.0%)
Tocilizumab N=129	28/79 (35.4%)	9/50 (18.0%)
TC/HDL ratio	**TC/HDL ratio increase from ≤ 5 at baseline to >5 at 3 months (% of patients at desirable level)**	**TC/HDL ratio decrease from >5 at baseline to ≤ 5 at 3 months (% of patients above desirable level)**
Overall N=715	29/657 (4.4%)	24/58 (41.4%)
TNFi N=400	13/369 (3.5%)	11/31 (35.5%)
Rituximab N=42	2/39 (5.1%)	3/3 (100%)
Abatacept N=144	4/132 (3.0%)	5/12 (41.7%)
Tocilizumab N=129	10/117 (8.6%)	5/12 (41.7%)

Conclusion: In this study, lipid level alterations were noted after three months of therapy with biologic agents. Notably for some pts, lipid levels increased while in others levels decreased over three months. Further studies with long-term follow-up would be needed to determine the clinical significance of lipids and systemic inflammation for CVD risk.

Inflammatory Cell Infiltrates In The Heart Of Patients With Coronary Artery Disease With and Without Inflammatory Rheumatic Disease: A Biopsy Study. Jacqueline Kirsti Andersen[1], Ingvild Oma[2], Ingjerd Lien Kveldstad[2], Knut Mikkelsen[3], Terje Veel[4], Sven M. Almdahl[5], Matthew H. Liang[6], Øystein T. Førre[7], Morten Fagerland[7] and Ivana Hollan[3]. [1]Gjøvik University College, Gjøvik, Norway, [2]Innlandet Hospital Trust, Lillehammer, Norway, [3]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [4]Feiringklinikken, Feiring, Norway, [5]University Hospital of North Norway, Tromsø, Norway, [6]Harvard Medical School, Boston, MA, [7]Oslo University Hospital, Oslo, Norway.

Background/Purpose: Systemic rheumatic diseases (SRDs) are associated with increased cardiovascular (CV) morbidity due to accelerated atherosclerosis. However, SRDs are associated also with cardiac vasculitis that may contribute to the increased CV risk (1). The objective is to examine the occurrence and extent of inflammatory cell infiltrates (ICI) and small vessel

vasculitis in all layers of the right atrium (epicardium, myocardium and endocardium) in patients with coronary artery disease (CAD) with and without SRDs.

Methods: We examined biopsies from the right atrium taken in a standardized way during coronary artery bypass grafting from the edge of the openings for cannulation due to extracorporeal circulation from patients with and without SRD (matched for age, sex and acute coronary syndrome) included in Feiring Heart Biopsy Study (2). The specimens were fixed with paraffin and stained by hematoxylin and eosin, and one 3-mm thick section from each specimen was examined by light microscopy in a blinded manner. The number and extent of ICIs in the three layers of the heart wall were semi-quantified.

Results:

	IRD (n = 40)	Non-IRD (n = 48)	Fisher mid-p test
Age, mean ± SD (years)	66,83 ± 10,5	66,42 ± 10,2	0.85
Male (%)	27 (67,5)	28 (58,3)	0.39
ICIs of epicardium (%)	24 (60%)	27 (56,2)	0.75
ICIs of myocardium (%)	0 (0%)	3 (6,2%)	0.17
ICIs of endocardium (%)	0 (0%)	1 (2,1%)	0.73
Vasculitis (%)	0 (0%)	0 (0%)	1.00

The infiltrates consisted predominantly of lymphocytes. Perivascular infiltrates occurred in all patients except for one. All the infiltrates in the myocardium were perivascular. There was no significant difference in the scores for the size and number of ICIs in the epicardium between the groups.

Conclusion: In patients with CAD, vasculitis was not observed, but the occurrence of ICIs in the right atrium was high, mostly localized around small vessels. The ICIs were found predominantly in the epicardium, and the occurrence and extent of epicardial ICIs was similar in SRD and non-SRD patients. In the myocardium and endocardium, the ICIs occurred in a low frequency, and in the non-SRD group only (but the difference was not statistically significant). In theory, the observed ICIs might be secondary to or independent of cardiovascular disease (CVD), but the inflammation might also contribute to CAD by compromising of the function of epicardial coronary arteries. Interestingly, abnormalities in epicardium (increased mass of epiicardial adipose tissue) are related to CV prognosis, and we propose that inflammation in the epicardium might be of particular importance. Our findings do not support the hypothesis that inflammation in the heart including small vessel cardiac vasculitis is more common in SRD than non-SRD patients. However, this possibility cannot be completely ruled out as the number of examined specimens were small, taken from apparently healthy tissue, and the right atrium was the only site sampled.

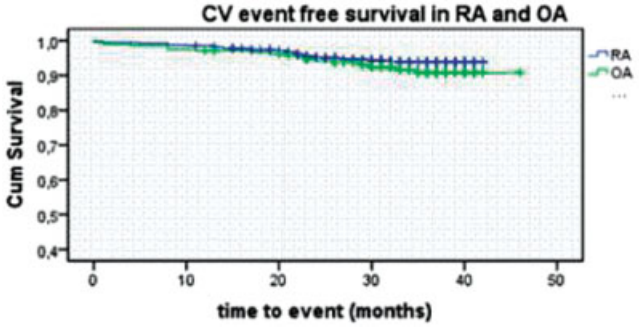
Cardiovascular Risk In Intensively Treated Rheumatoid Arthritis: Comparison To An Osteoarthritis Population. First Prospective Analysis Of The ACT-CVD Cohort. Inger L. Meek[1], Harald E. Vonkeman[2] and Mart A.F.J. van de Laar[2]. [1]Rheumatology Center Twente, Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [2]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) morbidity and mortality. This association is thought to be due to the chronic inflammatory disease process, clustering of lifestyle associated CV risk factors, as well as the use of medication such as non steroidal anti-inflammatory drugs (NSAIDs) and corticosteroids in patients with RA. Most studies on CV risk in patients with RA were performed before the introduction of modern powerful anti-inflammatory therapies and intensive treatment strategies aiming at remission. It is important to obtain more information on CV risk in intensively treated RA.

The objective of this study was to evaluate CV event risk and its predictors in intensively treated RA in comparison with an OA population.

Methods: first prospective analysis of occurrence of CV events (myocardial infarction, acute coronary syndrome, coronary intervention, acute heart failure, acute cardiac death) in a cohort of consecutive patients attending the Arthritis Centre Twente (ACT-CVD). All patients with a diagnosis of RA (n=495) or OA (n=208) without previous CV events were included in this study. Inclusion took place between February 2009 and November 2011, follow up data for this analysis were collected onto November 2012. Incidence of CV events in RA and OA groups was compared by Kaplan Meier survival analysis, potential CV event risk factors (traditional CV risk factors and RA severity markers) within groups were evaluated by COX-regression.

Results: At baseline RA and OA groups did not differ in sex (% female; RA=72, OA=78), age (mean years; RA=59, OA=59) and estimated 10-year risk of CV death (mean %; RA=5.7, OA=5.5). The RA group (mean disease duration 7.5 years, 50 % RF positive) was characterized by low disease activity (mean DAS28 2.5, 72% remission). After a median follow up of 36 months 46 events had occurred (RA=29, OA=17, p=0.25, figure 1). Age, systolic blood pressure and non-use of methotrexate significantly contributed to CV event risk in RA, age and current smoking in OA.



Conclusion: Preliminary data suggest that CV event risk in intensively treated RA equals CV event risk in OA. Use of methotrexate is independently associated with lower CV event incidence in RA.

Menopause Occurs Earlier and Is An Independent Risk Factor For Osteoporosis In Women With Rheumatoid Arthritis. Michael Cocker[1], Alexander Oldroyd[2] and Marwan Bukhari[1]. [1]Royal Lancaster Infirmary, Lancaster, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) and early menopause (<45 years) are recognised risk factors for the development of osteoporosis and form part of the World Health Organisation "FRAX" 10-year fracture risk-stratification tool[1]. It is not known whether age of menopause is an independent risk factor for osteoporosis in women with RA. Evidence exists linking connective tissue diseases to earlier menopause[2]however whether this also occurs in RA is unknown.

This paper aims to establish whether RA is associated with earlier menopause and whether age of menopause is an independent risk factor for osteoporosis in RA.

Methods: Data from female patients with RA attending for dual-energy X-ray absorptiometry (DXA) assessment between 2004 and 2011 was analysed using a nested case-control approach. Control subjects with no pre-defined indication for DEXA assessment were age-matched with RA subjects. Osteoporosis was defined as any hip or lumbar spine (L1-L4) T-score <−2.5. Student's t-test was used to compare age of menopause in the RA and control group. Subjects were divided into 3 tertiles according to age of menopause and logistic regression performed to assess for relationships with osteoporosis. All statistical analysis was performed using STATA v11.2, with results expressed as odds ratios (OR) with 95% confidence intervals (95%CI). P values <0.05 were considered significant.

Results: 397 subjects (median age 69.5 years, interquartile range 62.1,76.5) were matched for age with 397 controls. Mean age of menopause was lower in RA subjects (48.1 years vs. 49.7 years, mean difference 1.6 years) and was significant (p<0.001). After adjusting for age the earliest menopause tertile (median age of menopause 43.9 years) was associated with the highest odds of osteoporosis (OR 1.65 95%CI 1.13,2.41 p=0.01). Odds were increased to a lesser degree in the second-earliest tertile (median menopause age 50.2 years, OR 1.48 95%CI 1.00,2.17 p=0.048). No such associations were seen in controls.

Conclusion: This case-control study has demonstrated for the first time that women with RA experience the menopause earlier, and that earlier age of menopause is an independent risk factor for the development of osteoporosis in this population.

Effect Of Age At Menopause In Women With Early Rheumatoid Arthritis. Lauren Wong[1], Wei-Ti Huang[1], Juan Xiong[2], Gilles Boire[3], Boulos Haraoui[4], Janet E. Pope[5], J. Carter Thorne[6], Carol A. Hitchon[7], Diane Tin[6], Edward Keystone[8] and Vivian P. Bykerk[1]. [1]Hospital for Special Surgery, New York, NY, [2]Mount Sinai Hospital, University of Toronto, Toronto, ON, [3]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [4]Institut de Rhumatologie de Montréal, Montreal, QC, [5]St. Joseph's Health Care, University of Western Ontario, London, ON, [6]Southlake Regional Health Centre, Newmarket, ON, [7]University of Manitoba, Winnipeg, MB, [8]Mount Sinai Hospital, Toronto, ON.

Background/Purpose: Rheumatoid arthritis (RA) preferentially affects women and studies suggest that various hormonal and reproductive factors may affect disease onset and severity. This study assessed how age at menopause affects disease presentation in post-menopausal women with early RA and explored the effects of hormone use.

Methods: Post-menopausal women from the Canadian early ArThritis CoHort (CATCH) under age 65 at time of enrollment were included. Early age at menopause (EM) was defined as age at menopause < 45; usual age at menopause (UM) was defined as age at menopause >/=45. The Wilcoxon rank sum test was applied to continuous variables and Chi-square test to categorical variables. Multivariate logistic regression analysis was used to adjust for age, smoking, education, and use of exogenous hormones.

Results: 534 women met inclusion criteria (see Table 1). The EM group was more likely to report current use of hormone replacement therapy (HRT) and had higher mean patient global scores and pain scores. The EM group was more likely to meet 1987 criteria for RA and have positive serologies for RF and ACPA. There was a non-significant trend for women to have more erosions in the EM group. There was no difference in DAS28. Multivariate logistic regression analysis showed that the EM group was more likely to be RF positive (OR 2.1, CI 1.2–3.6, p=0.01) and current HRT users were less likely to be RF positive (OR 0.5, CI 0.2–0.8, p=0.01). Current smokers were more likely to be RF positive (OR 1.6, CI 1.0–2.6, p=0.03) and ACPA positive (OR 2.5, CI 1.5–4.3, p=0.001). At the time of analysis, 35% of subjects did not have ACPA data available. After confirming that missing data had occurred at random, multiple imputation analysis was used and showed that the EM group was also more likely to be ACPA positive (OR 1.8, CI 1.1–2.9, p=0.03). Sensitivity analysis removing current hormone therapy users did not change these findings.

Table 1: Baseline Characteristics

	All Post-Menopausal Women (n=534)	Age at Menopause <45 (N=93)	Age at Menopause ≥45 (N=441)	P-value
Age at Study Entry	55.5 ± 5.3	55.3 ± 6.0	55.5 ± 5.2	0.98
Age at Menopause	49.4 ± 6.5	38.5 ± 6.5	51.7 ± 3.5	0.001
CRP, mg/l	1.3 ± 1.6	1.3 ± 1.6	1.3 ± 1.6	0.95
DAS28	5.0 ± 1.5	5.0 ± 1.5	5.0 ± 1.5	0.76
ESR, mm/h	28.5 ± 24.6	27.6 ± 24.0	28.7 ± 24.7	0.74
Patient global	5.9 ± 2.8	6.6 ± 2.9	5.8 ± 2.8	0.01
Pain	5.8 ± 2.6	6.5 ± 2.7	5.6 ± 2.6	0.002
Education ≥ High school	264 (49.4%)	31 (33.3%)	233 (52.8%)	0.001
Currently Employed	340 (63.7%)	57 (61.3%)	283 (64.2%)	0.599
Current Smoking	123 (23.0%)	31 (33.3%)	92 (20.9%)	0.01
Current Use of HRT	55 (10.6%)	19 (21.1%)	36 (8.4%)	<0.0001
Current Use of OCP	4 (0.8%)	1 (1.1%)	3 (0.7%)	<0.0001
Meeting 1987 ACR	337 (65.1%)	66 (75.0%)	271 (63.0%)	0.032
Meeting 2010 ACR	428 (80.2%)	77 (82.8%)	351 (79.6%)	0.481
Erosion positive	106 (24.8%)	22/71 (31.0%)	84/356 (23.6%)	0.188
RF positive	284 (57.7%)	58 (71.6%)	226 (55.0%)	0.01
ACPA positive	175 (48.8%)	34/56 (60.7%)	141/303 (46.5%)	0.05

Conclusion: These data suggest that EM compared to UM is associated with different features at disease presentation in early RA, most notably in RF and ACPA positivity. Further research is needed to better understand how changes in hormonal states and exposure to exogenous hormone influence disease in women with rheumatoid arthritis.

Systemic Inflammation Contributes To Depression In Patients With Rheumatoid Arthritis. Mary Margaretten, Laura Trupin, Patricia P. Katz, Gabriela Schmajuk, Jinoos Yazdany, Chris Tonner, Jennifer Barton and Edward H. Yelin. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Prior research suggests that systemic inflammation contributes to the pathogenesis of depression, but longitudinal studies in patients with rheumatoid arthritis (RA) are lacking. Comorbid depression is common in patients with RA and traditional risk factors such as disability, fatigue, and pain explain only a portion of the increased prevalence of depression in RA. We prospectively examined the association between serum C-reactive protein (CRP) and depression to determine whether an increase in CRP precedes an increase in depressive symptoms in adults with RA.

Methods: Participants were patients from a multi-site observational RA cohort. Inclusion criteria for this analysis included age ≥ 18 years of age, meeting the American College of Rheumatology classification criteria for RA, and at least two clinical visits that included a measure of depression, the Patient Health Questionnaire-9 (PHQ-9), and two measurements of serum high-sensitivity CRP**.** In order to calculate a change in CRP that occurred prior to the change in depression score, the first CRP was collected up to 6 weeks prior to the first PHQ-9 score, and the second CRP was collected up to 6 weeks prior to the second PHQ-9 score. Given the non-linear relationship between predictor and outcome, odds ratios were estimated using a restricted cubic spline regression analysis. Post-estimation Wald test confirmed there was a non-linear relationship between changes in CRP and successive PHQ-9 scores.

Results: There were 362 observations for 212 patients with a pair of clinical visits with two serum CRP measurements and a subsequent change in PHQ-9 score measured. The mean ± SD of the 1st CRP and change in CRP were 8.6 ±13 and 0.14 ±12, respectively. With regard to the prevalence of depressive symptoms, 41% of patients scored ≤ 10 on the PHQ-9 during at least one clinic visit, which corresponds to a symptom severity of at least moderate depression. The mean ± SD of the 1st PHQ-9 and change in PHQ-9 was 6 ±5 and −0.2 ±4, respectively corresponding to an initial symptom severity of mild depression. A significant non-linear relationship existed ($p<.001$) between change in CRP and change in depression score in patients with RA (Figure). Adjustment for age, gender, race/ethnicity, body mass index, and socioeconomic status did not significantly alter results.

Conclusion: An increase in systemic inflammation as measured by CRP contributes to an increase in depressive symptoms in a subset of patients with RA. For these patients, further investigation is warranted as to whether treating RA with additional anti-inflammatories may have the extra benefit of decreasing depression.

376

The Risk Of Pneumococcal Infections After Immunisation With Pneumococcal Conjugate Vaccine Compared To Non-Vaccinated Inflammatory Arthritis Patients. Johanna Bengtsson[1], Pierre Geborek[2], Tore Saxne[2], Martin Englund[3], Ingemar F. Petersson[2], Jan-Åke Nilsson[4], Göran Jönsson[5] and Meliha C. Kapetanovic[6]. [1]Section of Rheumatology, Lund University and Skåne University Hospital, Lund, Sweden, Lund, Sweden, [2]Lund University, Lund, Sweden, [3]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [4]Lund University, Malmö, Sweden, [5]Dept of Clinical Sciences Lund, Section of Infectious Diseases, Lund, Sweden, [6]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund University, Lund, Sweden.

Background/Purpose: The purpose was to examine the risk of putative pneumococcal infections between adult arthritis patients on different anti-rheumatic drugs immunised with heptavalent pneumococcal conjugate vaccine (Prevenar7; PCV7) and non-vaccinated individually matched arthritis patients.

Methods: A consecutive cohort of 505 patients with rheumatoid arthritis (RA) and spondylarthropathy (SpA) including psoriatic arthritis, regularly followed at the outpatient Department of Rheumatology Skåne University Hospital in Lund and Malmö, was immunised with a single dose of PCV7 (exposed group). Of these, 497 patients (RA=248; SpA=249) were included. At vaccination, RA patients were treated with methotrexate (MTX) (n=84), anti-TNF+MTX (n=87) or anti-TNF as monotherapy (n=77). SpA patients were treated with anti-TNF as monotherapy (n=81), anti-TNF+MTX (n=82) or NSAIDs/analgesics (n=86). For each vaccinated patient, we identified four reference subjects (n=1988) from the same geographic area (Skåne county, Sweden), individually matched for age, gender, diagnosis and date. These were considered unexposed to conjugate pneumococcal vaccination. The Skåne Health Care Register containing all data on inpatient and outpatient health care was searched for all individuals seeking health care for putative pneumococcal infections using ICD-10 diagnostic codes. All events occurring 4 years before vaccination and up to 4.5 years after vaccination were divided into serious infections; (pneumonia, other lower respiratory infections, meningitis, sepsis, septic arthritis) and non-serious infections; (upper respiratory infections, otitis media and sinusitis). Relative risks (RR) of infections were calculated as events after/events before vaccination. Ratios of relative risk (RRR) were calculated between exposed and unexposed groups of patients. Generalized Estimating Equation was used to handle correlated data for several events in the same individual, PROC GENMOD in the SAS System 9.3.

Results: Although non-significant, the point estimate of RRR suggested a reduced risk of serious infections in vaccinated patients compared to the unexposed group (Table). However, time to first event of all infections before and after vaccination did not differ between the groups. Mean time (CI 95%) to first serious infection was significantly longer for immunised patients compared to the unexposed group [48.5 months (47.9–49.0) and 47.0 (46.7–47.3)], respectively.

RA+SpA	All exposed (vaccinated) (N=497)	All unexposed (non-vaccinated) (N=1988)	RRR (95% CI) (exposed/unexposed)	Risk reduction (%)
Serious infection (event Nr after/before); RR (95% CI)	27/18 1.52 (0.74–3.15)	132/49 2.76 (1.97–3.85)	0.55 (0.25–1.22)	45%
Non-serious infections (event Nr after/before); RR (95% CI)	45/26 1.78 (1.00–3.18)	165/101 1.64 (1.22–2.21)	1.09 (0.57–2.08)	9 % increased risk
All infections (event Nr after/before); RR (95% CI)	72/44 1.69 (1.07–2.69)	297/150 2.06 (1.63–2.60)	0.82 (0.49–1.38)	18%
RA	**RA exposed (vaccinated) (N=248)**	**RA unexposed (non-vaccinated) (N=992)**	**RRR (95% CI) (exposed/unexposed)**	**Risk reduction (%)**
Serious infections (event Nr after/before) RR (95% CI)	23/13 1.84 (0.76–4.46)	91/33 2.84 (1.88–4.28)	0.65 (0.24–1.72)	35%
Non-serious infections (event Nr after/before); RR (95% CI)	28/11 2.60 (1.26–5.38)	100/62 1.63 (1.13–2.36)	1.60 (0.71–3.60)	60% increased risk
All infections (event Nr after/before); RR (95% CI)	51/24 2.25 (1.21–4.20)	191/95 2.13 (1.59–2.86)	1.06 (0.53–2.10)	6% increased risk
SpA	**SpA exposed (vaccinated) (N=249)**	**SpA unexposed (non-vaccinated) (N=996)**	**RRR (95% CI) (exposed/unexposed)**	**Risk reduction (%)**
Serious infection (event Nr after/before); RR (95% CI)	4/5 0.80 (0.21–3.04)	41/16 2.62 (1.47–4.67)	0.31 (0.07–1.31)	69%
Non-serious infections (event Nr after/before); RR (95% CI)	17/15 1.16 (0.47–2.85)	65/39 1.68 (1.02–2.76)	0.69 (0.25–1.93)	31%
All infections (event Nr after/before); RR (95% CI)	21/20 1.08 (0.54–2.16)	106/55 1.98 (1.33–2.93)	0.64 (0.31–1.34)	36%

Conclusion: Vaccination with heptavalent pneumococcal conjugate vaccine tended to reduce the risk of putative serious pneumococcal infections with about 45% compared to unvaccinated patients in this observational cohort study.

377

Risk Factors For Stroke In Patients With Rheumatoid Arthritis. Anja Strangfeld[1], Yvette Meißner[2], Adrian Richter[1], Matthias Schneider[3], Hans Peter Tony[4], Kerstin Gerhold[1], Angela Zink[5] and Joachim Listing[6]. [1]German Rheumatism Research Center, a Leipniz Institute, Berlin, Germany, [2]German Rheumatism Research Center Berlin, Berlin, Germany, [3]University of Duesseldorf, Duesseldorf, Germany, [4]University of Würzburg, Würzburg, Germany, [5]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [6]German Rheumatism Research Center, Berlin, Germany.

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of stroke. This event is associated with considerable sequelae and might result in death or major physical and neurological disability. Despite its clinical relevance data regarding stroke are rare. Our objective was to analyse the impact of different risk factors on the development of stroke within our German biologics register RABBIT.

Methods: RABBIT is an ongoing prospective cohort study. Since 2001 patients have been enrolled at start of an approved biological therapy or a new synthetic DMARD treatment after at least one DMARD failure. At fixed time points at follow-up rheumatologists assess the clinical status, report treatment details and adverse events according to ICH guidelines. We analysed all patients enrolled in the register until 31.08.2012 with at least 3 months of follow-up. All reports of stroke were included, transient ischemic attacks were not. Diagnoses of stroke were re-validated at on-site visits. Medical records as well as hospital reports were analysed. To assess the impact of different risk factors for stroke we performed a multivariate Cox regression analysis. Patients treated with biologics were considered to be exposed to these drugs up to 6 (rituximab: 12) months after the last dose.

Results: 10,159 patients were included. 77% of them were female, the mean age at enrollment was 56 years, mean disease duration 10.4 years, and mean disease activity score (DAS28) 5.5. The mean observation time was 3.5 years. 109 patients experienced a stroke. Older age and male sex were significant risk factors for the development of stroke, as well as hypertension, DAS28 and smoking (see Table). Factors not significantly associated were functional capacity and treatment with antiTNF or other biologics and use of glucocorticoids. As relevant comorbidities we investigated diabetes (db), coronary heart disease (chd), heart failure (hf) and atrial fibrillation (af). All of those were more prevalent in patients who developed a stroke (db 19 vs 10%, chd 17 vs 6%, hf 7 vs 2%, af 3 vs 0.5%). These portions were significantly different in univariate comparisons but did not achieve statistical significance in the multivariate model. DAS28 was a better predictor than erythrocyte sedimentation rate.

Table. Results of the multivariate Cox regression analysis.

	HR	95% CI
Age (by 10 years)	1.7	[1.4; 2.1]
Males vs. females	1.6	[1.0; 2.4]
Hypertension (yes/no)	1.7	[1.1; 2.5]
Atrial fibrillation (yes/no)	2.8	[0.9; 9.1]
DAS28 at follow-up per unit increase	1.6	[1.4; 1.9]
Smoking ever vs. no	1.2	[1.0; 1.4]
antiTNF vs. DMARDs	1.1	[0.8; 1.7]
Other biologics vs. DMARDs	1.3	[0.8; 2.1]

Conclusion: Biologic treatments and glucocorticoids did not have an influence on the risk of stroke. Among traditional risk factors for stroke such as age, male gender, smoking and hypertension, a higher disease activity and atrial fibrillation seem to increase the risk for stroke. This could have implications for the cardiovascular risk assessment in patients with RA.

HBV Reactivation and Consequent Hepatitis In Rheumatoid Arthritis Patients With Different HBV Carring State: A Clinical Observation Follow-Up. Lie Dai, An Qi Liang, Ying Qian Mo, Jian Da Ma, Le Feng Chen, Dong Hui Zheng and Lang Jing Zhu. Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China.

Background/Purpose: Approximate 7.2% Chinese were infected with hepatitis B virus (HBV), and the prevalence of concurrent HBV carriers in Chinese rheumatoid arthritis (RA) patients was 9.4% (Lie D, et al. Clin Rheumatol, 2013). Antiviral prophylaxis is recommmended for HBV carriers with RA during DMARDs treatment except hydroxychloroquine by ACR 2008, similar to the professional guideline of Asian Pacific Association for the Study of the Liver. However, antiviral prophylaxis is not commonly used in China due to high economic burden, poor patient compliance and the efficacy/safety of antiviral drugs. This study was to explore the risk of DMARDs associated HBV reactivation and consequent hepatitis in different HBV carriers with RA and the efficacy of antiviral prophylaxis.

Methods: HBV carriers with RA (HBsAg+ and normal transaminases) were enrolled from July 2007 to December 2012 and patients with ≥6-month's follow-up were qualified for analysis. HBV carriers were divided into inactive group (either HBeAg or HBV-DNA negative) and chronic group (HBeAg and/or HBV-DNA positive). HBV reactivation was defined as a 10-fold rise in HBV-DNA compared to baseline or switch from undetectable to detectable.

Results: (1) 36 HBV carriers with RA were enrolled and 6 of them failed to complete the ≥6-month's follow-up due to home migration or conversion to Chinese herbal therapy. Among the qualified 30 patients, 77% were female, mean age was 48 years (range, 17~80), median disease duration was 19 months (range, 1~360) and mean DAS28 was 4.6 (range, 1.7~7.6). There were no significant differences between inactive group (n=15) and chronic group (n=15) in age, gender, disease duration, disease activity (all P>0.05). (2) During a median follow-up period of 12 months (range, 6–69months), 87% patients received low-dose corticosteriods, 100% received MTX, 17% received leflunomide, 50% received sulfasalazine and 67% received hydroxychloroquine. All patients were treated with combination DMARDs therapy with or without low-dose corticosteriods. (3) The outcome of different HBV carriers with RA was shown in figure 1. 33% developed HBV reactivation and 17% developed the consequent hepatitis. Survival curves showed patients in chronic group tend to develop HBV reactivation and consequent hepatitis earlier than in inactive group (figure not shown). (4) Multivariate logistic regression analyses showed the risk factors of HBV reactivation were leflunomide (OR: 6.376, 95% CI: 1.063–38.227) and poor patient compliance of antiviral drugs (OR: 21.140, 95% CI: 1.309–341.467), the risk factor of the consequent hepatitis was past history of acute hepatitis (OR: 17.334; 95% CI: 1.225–245.267).

Conclusion: Our preliminary results suggest that HBV carriers with RA should avoid leflunomide and antiviral prophylaxis should be prescribed for either chronic or inactive HBV carriers during DMARDs treatment, especially for patients with past history of acute hepatitis.

Osteoporotic Fracture and Post-Operative Clinical and Cost Outcomes In Rheumatoid Arthritis: Results From Two UK Inception Cohorts. Elena Nikiphorou[1], Lewis Carpenter[2], Josh Dixey[3], Peter Williams[4], Patrick D. Kiely[5], David Walsh[6], Richard Williams[7] and Adam Young[8]. [1]ERAS, St Albans City Hospital & University College London (UCL), London, United Kingdom, [2]University of Hertfordshire, Hatfield, United Kingdom, [3]New Cross Hospital, Wolverhampton, United Kingdom, [4]Medway Maritime Hospital, Gillingham, United Kingdom, [5]St George's Hospital, London, United Kingdom, [6]University of Nottingham, Nottingham, United Kingdom, [7]County Hospital, Hereford, United Kingdom, [8]St Albans City Hospital, St Albans, United Kingdom.

Background/Purpose: The risk of osteoporotic fracture is known to be high in RA. Yet less is known about RA related predictive factors for this complication & its associated economic burden.

Methods: The Early RA Study (ERAS, 9 centres) recruited 1465 DMARD naïve patients between 1986–1998 & the Early RA Network (ERAN, 23) 1236 patients, 2002–2012. Standard clinical, radiological & laboratory measures were performed yearly for 25 & 10yrs (median 10 & 3yrs respectively). Major comorbidities & in-patient hospital episodes were recorded yearly, including fracture sites & orthopaedic surgery. Clinical databases were supplemented & validated with national databases: National Joint Registry (data available 2003–2011), Hospital Episode Statistics (1997–2011) & National Death Register (1986–2011). Treatment regimens followed guidelines of the era, mainly conventional DMARD therapies, +/− steroids, & latterly biologics.

Results: A total of 178 (6.6%) patients had 182 fractures, the majority hip (42%), wrist fractures (17.5%), & vertebrae (12%). Other fractures (28.5%) included the distal forearm, foot & ankle. 13 hip fractures resulted in total hip replacements & 57 in dynamic hip screw surgery. None of the procedures were complicated by death in the postoperative period, although hip & vertebral fractures were recorded as contributory causes of death in 12 & 2 respectively. The average length of stay (LoS) varied across procedures, with hip fractures incurring the longest LoS (median 15days in the first decade of the study, 8days in the last). The LoS appeared to drive costs (graphs to demonstrate this). Compared to national data, both LoS & consequently costs were higher in RA patients sustaining osteoporotic fractures, compared to other RA-related intervention or other orthopaedic surgery undertaken nationally by non-RA patients (figure 1). The median time from baseline to hip fracture was 8yrs (IQR 5–15). In hip fracture patients, the mean number of all & major comorbid conditions was increased (3.7 & 1.4) compared to non-fracture (1.8 & 0.9, p <0.001), & survival reduced (48% vs 20%, p<0.0001). Aside from traditional risk factors (age, gender), baseline & 1yr disease activity measures were identified as potential predictors: erosions (OR 2.4, 95%CI 1.4–4.0), high rheumatoid factor (OR 1.7, 95%CI 1.1–2.9), high HAQ (OR 1.7, 95%CI 1.1–2.9), high ESR (OR 1.9, 95%CI 1.1–3.1), low haemoglobin (OR 1.99, 95%CI 1.2–3.1). Steroid use predicted higher risk for fracture: OR 2.7, 95% CI 1.1–6.5.

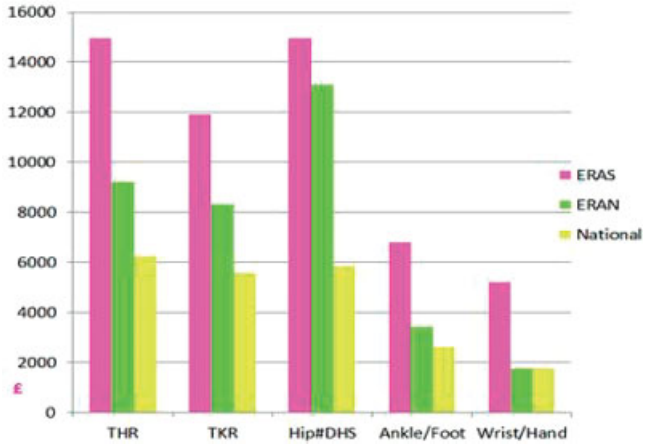

Figure 1.

Conclusion: RA over 25yrs was complicated by osteoporotic fracture in 6.6% patients, mainly hip fractures, which were not a late complication of RA. Most required major orthopaedic surgery, & were associated with comorbidity & reduced survival, as well as high costs. Markers of active disease were associated with a higher risk of fracture, highlighting the need for more active therapies for RA control & bone protection.

Active Rheumatoid Arthritis Is An Independent Risk Factor Of Chronic Kidney Disease. Ryosuke Hanaoka[1], Kazuhiro Kurasawa[2], Ayae Tanaka[3] and Harutsugu Okada[4]. [1]Kamitsuga General Hospital, Kanuma, Tochigi, Japan, [2]Dokkyo Medical University, Mibu-machi, Shimotsuga-gun, Tochigi-ken, Japan, [3]Dokkyo Medical University, Mibu, Tochigi, Japan, [4]Dokkyo Medical University, Mibu-machi, Tochigi-ken, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory disease that affects not only joints but also many organs. RA causes vascular damages to contribute to progression of atherosclerosis. RA itself is a risk factor for cardiovascular diseases as well as hypertension and/or hyperlipidemia that could be induced by medication for RA. However, it has not been determined whether RA itself is a risk factor for chronic kidney disease (CKD). The aim of this study is to determine whether RA is an

independent risk factor for CKD. And if so, to determine whether the disease activity contributes to renal function in RA patients.

Methods: A prospective cohort study was performed. The study included 134 RA patients who met ACR criteria 1987 and were treated at our hospital, and 1156 non-RA individuals who received annual medical screening at the same hospital. Demographic data, general risk factors for CKD, laboratory data, medications and data for RA activity were collected. Estimated glomerular filtration rate (eGFR) was calculated as follows; eGFR = $1.94 \times \text{Cr (mg/dl)}^{-1.094} \times \text{age (year)}^{-0.287} \times$ (1.0 if male/0.739 if female). When patients showed eGFR less than 60 ml/min/1.73m^2 or positive for urinary protein test, they were judged as having CKD. To identify risk factors, univariate and multivariate analysis were conducted.

Results: RA patients were 38 male, and 96 female, mean age; 65.3 year, mean disease duration; 100.1 months, and DAS28 CRP; 2.41. Control individual were 768 male and 388 female and mean age; 53.4 year. At baseline, eGFR were 71.5 ml/min/1.73m^2 in RA and 77.7 ml/min/1.73m^2 in controls, and CKD was found in 33.6 % of RA patients, while 12.6 % of controls had CKD. Annual decline of eGFR was greater in RA group compared with control (−5.81 %, 95%CI. −7.82 to −3.79 vs. 0.71 %, 95%CI. 0.22 to 1.20). Annual incidence of CKD was significantly higher in RA group compared with control (15.7 % vs. 4.6 %, relative risk 1.210, 95%CI. 1.051 to 1.393). Univariate analysis for identification of risk factors for CKD development revealed RA is a risk factor for CKD ($p<0.001$) as well as hypertension, hypercholesterolemia, and anemia. Multivariate analysis using logistic regression analysis showed RA is an independent risk factor of incident of CKD (P = 0.005, relative risk = 2.968, 95%CI. =1.393 to 6.327) as well as hypertension.

Among RA patients, active RA patients showed greater annual decline of eGFR compared to those in remission (−8.89 %, 95%CI. −10.38 to−7.40 in active disease vs. −3.52 %, 95%CI. −4.86 to 2.18 in remision). Significant correlation was found between DAS28CRP at baseline and annual decline of eGFR (correlation coefficient −0.238, P = 0.006). Active group had significantly greater annual decline of eGFR compared to remission group (−8.89 %, 95%CI. −10.38 to −7.40 vs. −3.52 %, 95%CI. −4.86 to 2.18). Multiple regression analysis showed that high DAS28 CRP is correlated with annual decline of eGFR in the patients with RA (coefficients −2.026, 95%CI. −3.909 to −0.142).

Conclusion: RA is an independent risk factors of CKD incident. RA activity is correlated with annual decline of eGFR in patients with RA, suggesting that RA activity, presumably systemic inflammation, could contribute to development of CKD.

Coronary Endothelial Dysfunction Directly Measured By N13 Positron Emission Tomography (PET) Is Detected In Established Rheumatoid Arthritis (RA), But Not Early RA. OM Troum[1], OL Pimienta[1], B Hidalgo[2] and WA Hsueh[3]. [1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]University of Alabama, Birmingham, AL, [3]Weill Cornell Medical College, Houston, TX.

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased risk of cardiovascular (CV) disease. The endothelium is a key regulator of vascular function. Subclinical CV disease and its progression are intimately related to endothelial dysfunction (ED), a preclinical marker of atherosclerosis. Endothelial function has been measured indirectly as the response to hyperemic flow in the peripheral vasculature to identify and monitor CV risk in RA. Positron Emission Tomography (PET/CT) with Cold Pressor Test (CPT) *directly* measures coronary artery endothelial cell function during sympathetic stimulation. This non-invasive index of coronary function predicts atherosclerosis. We evaluated the differences in large and small vessel coronary endothelial reactivity in early RA (< 2 years), established RA (> 2 years) and healthy subjects by PET/CT with CPT.

Methods: Delta percent Myocardial Blood Flow (Delta % MBF) was assessed by cardiac N-13 ammonia PET/CT scan. Myocardial perfusion (MP) was evaluated at baseline (BL) following intravenous (IV) administration of N-13 ammonia. After acquiring BL perfusion images with PET, cold pressor stress was assessed by immersing one hand in ice water while a second dose of N-13 ammonia was injected. MP and blood flow were determined from serially acquired images and left ventricular function was assessed from gated images. 15 non-smoking subjects (87% female) were studied: 5 early RA (mean age 60.8 y, mean disease duration 5.0 months), 5 established RA Methotrexate [MTX] inadequate responders (mean age 46.2 y, mean disease duration 153.6 months), and 5 healthy subjects (mean age 53.8 y). Means were calculated for demographic and physiologic characteristics, with one-way Anova and Kruskall-Wallis to compare differences across groups. Univariate correlations of Delta % MBF were also performed in the RA groups. Studies were controlled for age, body mass index (BMI), gender, and mean arterial blood pressure (MAP).

Results: Characteristics between groups were similar, except for sedimentation rate (P=0.003), and age (P=0.002). Low-density lipoprotein cholesterol (LDLC), and MAP positively correlated with Delta % MBF ($P<0.05$). Delta %MBF was similar in normal and early RA subjects. However, RA > 2 years compared to RA <2years demonstrated markedly decreased endothelial reactivity (mean 34.0 (9.7) vs 61.6 (26.7); P=0.0001) when clinical disease activity index (CDAI) and vascular cell adhesion molecule (VCAM-1) were added to the model.

Conclusion: Premature coronary endothelial dysfunction is present in patients with established RA. CDAI and VCAM-1 impact the difference in endothelial function between established RA and early RA. These results raise the question of whether further disease modifying therapy beyond MTX will be useful to improve endothelial function in established RA patients.

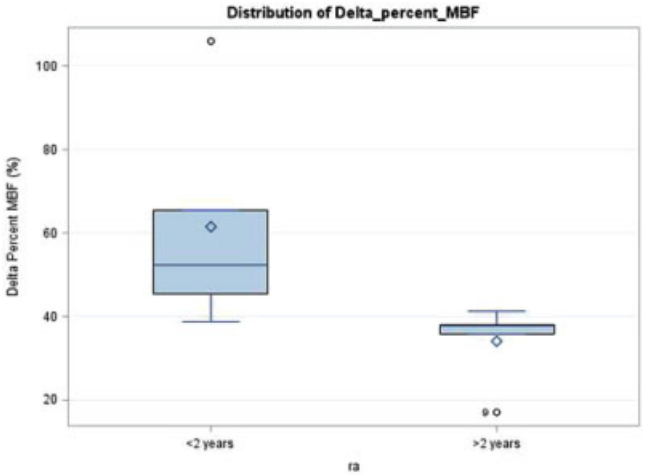

Figure 1. Distribution of Delta % MBF across groups, adjusting for Age, Gender, BMI, MAP and CDAI

382

Effect Of Biologic Disease Modifiers On Cardiovascular Risk Of Patients With Rheumatoid Arthritis – 2 Years Prospective Cohort Study. Majed M. Khraishi[1] and Rana Aslanov[2]. [1]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [2]MD, MSc, Memorial University of Newfoundland, St.John's, NF.

Background/Purpose: People with RA have a higher risk for developing cardiovascular diseases than the general population. The pathogenic mechanisms in RA appear to be complex and multifactorial.

1. To assess the effect of Biologic Disease Modifier Anti-Rheumatic Drugs (BDMARDs) on a 10-year CV event risk in patients with RA after 2 years of follow-up

2. To evaluate the impact of BDMARDs on the incidence of CV events in patients with RA

Methods: Patients with RA receiving biologic therapy were prospectively followed-up. The FRS was used for the assessment of 10-year CVD risk. The presence of CV risk factors was ascertained at the baseline and at every six months of observation up to 24 months. Analyses of the relationships between lipids and inflammatory indices before and after treatment with biologics were performed. Ten-year CVD event risk was assessed by gender and age.

Results: From 228 patients, 2 patients passed away and 6 patients dropped out of the study. Total 220 patients (73% females) with the mean (SD) age of 56.2 (11.6) years were prospectively followed up to 24 months. The mean (SD) age at RA diagnosis was 41.6 (12.9) years with the mean (SD) duration of RA symptoms 14.5 (8.5) years. Nine patients with documented MI and 5 patients with TIA/Stroke had CV events prior to the study. Two male patients had MI during the observation period. Forty-two patients (62% females) smoked at the baseline. Sixty-five patients were on Lipid-lowering treatment, of them 48% started it after the initiation of the treatment with biologics.

TJC and SJC were significantly reduced after 24 months of treatment. TC did not change significantly after 1 year but was significantly reduced after 2 years. HDL increased significantly at 12-month and then significantly reduced at 24-month period. Comparison of LDL measurements at 12 and 24-month periods showed significant improvement from 1.8±1.6 to 1.3±1.5 with p<0.001. The AI was significantly reduced during the two follow-up periods. CRP, ESR and DAS28 were also significantly reduced from the baseline levels (Table).

RA Characteristics	Baseline, mean (SD)	12-month F-Up, mean (SD)	P	24-month F-Up, mean (SD)	P
Total Joint Count (TJC)	12.3 (8.1)	5.3 (4.7)	<0.001	5.1 (5.6)	<0.001
Swollen Joint Count (SJC)	4.3 (3.7)	2.1 (2.6)	<0.001	1.1 (1.9)	<0.001
C-Reactive Protein (CRP), mg/l	15.5 (29.0)	10.1 (15.5)	0.004	4.7 (8.3)	<0.001
ESR, mm/h	29.7 (22.8)	22.9 (20.1)	<0.001	16.4 (17.7)	<0.001
DAS28 score	4.1 (1.2)	3.6 (1.2)	<0.001	3.0 (1.1)	<0.001
CDAI score	18.2 (9.6)	14.2 (9.8)	<0.001	10.7 (7.2)	<0.001
HAQ score	1.2 (0.7)	1.1 (0.7)	0.030	0.9 (0.7)	<0.001
Total Cholesterol, mmol/l	3.0 (2.8)	3.3 (2.7)	0.038	2.0 (2.5)	<0.001
HDL Cholesterol, mmol/l	0.7 (0.7)	0.8 (0.7)	0.001	0.6 (0.7)	0.025
Atherogenic Index (TC/HDL)	4.6 (1.7)	4.1 (1.2)	<0.001	3.8 (0.8)	<0.001
Overall 10-year CV Event Risk (%)	12.5 (9.3)	12.1 (9.0)	0.019	11.9 (8.9)	<0.001

The overall risk of cardiovascular event significantly reduced in 12 months (p=0.019, 95%CI 0.1–0.7) and 24 months of the study (p<0.001; 95%CI 0.3–0.9). Thirty seven patients switched biologics during their treatment course. The analysis of the impact of individual biologic DMARD on 10-year CV event risk showed significant improvement at 24-month period in Tocilizumab (p=0.002) and Abatacept (p=0.042) groups.

Conclusion: Our results showed a trend in reducing a 10-year CV event risk in RA patients treated with BDMARDs. This improvement was influenced by many factors. The study results demonstrated a possible favorable effect of biologic DMARDs on the serum levels of TC, LDL and AI. Good control of the inflammation by BDMARDs effectively decreased inflammation and possibly played a pivotal role in reducing the risk for cardiovascular event in patients with RA.

Increased Incidence Of Low-Energy Fractures In Rheumatoid Arthritis Patients. Kristina Wiberg[1], Marie-Louise Öhman[1], Ulrika Bergström[1] and Solbritt M. Rantapaa-Dahlqvist[2]. [1]Umeå University, Umeå, Sweden, [2]Institution of Public health and clinical medicine/Rheumatology, University of Umeå, Umeå, Sweden, Umea, Sweden.

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased development of osteoporosis. The fracture indicence is not well explored. The aim of this study was to estimate the incidence of low-energy fractures in RA patients identified with a population based register of fractures in northern Sweden.

Methods: The register of patients with RA (ACR criteria) consecutively included since 1995 (n=1178) was coanalysed with the register of Umeå injury data base, Umeå, Sweden of low-energy fractures. This data base was constituted in 1993 and covers six communities with a population at risk of 118000 adults. All individuals admitted to the emergency ward are included. The individuals in this study were followed until fracture or to Jan 1st2011. The standard incidence ratio (SIR) was calculated.

Results: Among the RA patients, 329 individuals (246 females and 83 males) were identified with a fracture. The corresponding figures among controls were 14102 females and 13313 males with fractures. The SIR for a fracture in the RA patients was overall in females OR=1.35 (1.19–1.53) and in males OR=1.70 (1.36–2.11). Stratification for age showed increased SIR in the year group over 65 years of age; females OR=1.39 (1.19–1.62) and males OR=1.88 (1.44–2.42). The highest SIR was for hip fracture; females OR=2.51 (1.21–4.61) and males OR=4.75 (1.74–10.35) with a similar mean age for cases and controls; 72–75 years. The duration of time from diagnosis of RA to the first fracture was during the follow up in females mean (SD) 16.9 (12.4) years and in males 11.7 (9.9) years. The RA patients had similar frequence of fractures in- as out-doors as compared with controls who had significantly higher frequency of fractures outdoors.

Conclusion: RA is associated with a higher incidence for fractures among individuals seeking emergency care. In this study the highest SIR was for hip fractures both in females and males.

Carotid Artery Plaques Are Associated With Coronary Atherosclerosis In Patients With Inflammatory Joint Diseases Independent Of Several Cardiovascular Risk Calculators. Silvia Rollefstad[1], Eirik Ikdahl[1], Inge C. Olsen[1], Tore K. Kvien[2], Anne S. Eirheim[1], Terje R. Pedersen[2] and Anne G. Semb[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]University of Oslo, Oslo, Norway.

Background/Purpose: Patients with rheumatoid arthritis (RA) and carotid plaque (CP) have been shown to have increased risk of future acute coronary syndrome. We have established a cardiovascular (CV) preventive clinic and in a CV risk evaluation it is of clinical value to know if CP is associated with coronary atherosclerosis (CA) in addition to the CV risk algorithms in patients with inflammatory joint diseases (IJD). Our objective was to evaluate if CP was associated with CA in patients with IJD.

Methods: In a preventive cardio-rheuma clinic 157 patients with IJD (98 with rheumatoid arthritis, 42 with ankylosing spondylitis, 17 with psoriatic arthritis) were referred for CV risk evaluation. Traditional CV risk factors were recorded. All patients underwent B-Mode ultrasound of the carotid arteries for evaluation of CP and multidetector computer tomography (MDCT) coronary angiography for evaluation of CA.

Results: In a cross sectional analysis all patient characteristics as age, traditional CV risk factors and CRP/ESR were comparable across the various IJD, apart from gender (p<0.01) and disease duration (p<0.01). The presence of CP was also comparable across the various IJD [RA, n= 76 (77.6%), ankylosing spondylitis: 36 (85.7), psoriatic arthritis 15 (88.2), p=0.38]. A total of 98 (62) had CA, while 59 (37.6) did not have CA and there was no difference between the 3 IJD groups. In logistic regression analyses CP was significantly associated with CA (Table, model 1a, 2a and 3a respectively) independent of the 3 CV risk calculators: SCORE, Framingham and Reynolds. When number of CP was added in the models (Table, model 1b, 2b, 3b), it increased the associations of CP with CA.

Table. Association of carotid plaque (CP) to coronary atherosclerosis

		a	b
Model 1	SCORE	1.17 (1.06, 1.30) p=0.002	
	CP	2.92 (1.18, 7.22) p=0.02	
	SCORE		1.16 (1.05, 1.29) p=0.003
	Number of CP		1.78 (1.25, 2.54) p=0.001
Model 2	Framingham	1.09 (1.04, 1.14) p<0.001	
	CP	2.76 (1.06, 7.19) p=0.04	
	Framingham		1.001 (1.03, 1.13) p=0.001
	Number of CP		1.67 (1.15, 2.40) p=0.04
Model 3	Reynolds	1.08 (1.03, 1.14) p<0.001	
	CP	3.02 (1.20, 7.58) p=0.02	
	Reynolds		1.08 (1.03, 1.14) 0.004
	Number of CP		1.73 (1.21, 2.47) p=0.003

Cardiovascular risk algorithms:
SCORE (Systematic coronary risk evalution), Framingham and Reynolds

Conclusion: CP was independently associated with coronary atherosclerosis. CP can therefore be regarded as CV disease in patients with IJD and has direct clinical implications in CV risk evaluation and prevention.

Systemic Inflammation In Patients With Inflammatory Joint Disease Does Not Influence Statin Dose Needed To Obtain Low Density Lipoprotein Cholesterol Goal In Cardiovascular Prevention. Silvia Rollefstad[1], Eirik Ikdahl[1], Tore K. Kvien[2], Terje R. Pedersen[2], Ingar Holme[3] and Anne G. Semb[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]University of Oslo, Oslo, Norway, [3]Oslo University Hospital-Ullevaal, Oslo, Norway.

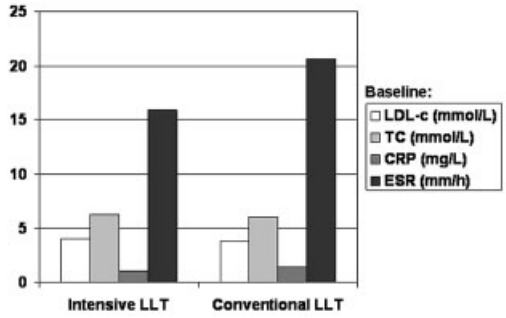
Background/Purpose: There is a lipid paradox in rheumatoid arthritis (RA): despite low lipids influenced by systemic inflammation, there is an increased risk of cardiovascular (CV) disease. Our aim was to describe doses of statins needed to obtain recommended lipid goals in patients with inflammatory joint disease (IJD), including RA, ankylosing spondylitis (AS)

and psoriatic arthritis (PsA). Further, to evaluate if baseline systemic inflammation and lipid levels were associated with statin dose (conventional vs. intensive) needed to obtain guideline recommended low density lipoprotein cholesterol (LDL-c) goal in patients with IJD.

Methods: CV risk stratification was performed at the first consultation in a preventive cardio-rheuma clinic in 202 patients (RA: n=124, AS: n=52, PsA: n=26). The patients were classified to either primary or secondary CV prevention with lipid lowering (LL) treatment, or to have low risk with no indication for medical intervention. LL treatment was initiated with statins and adjusted until at least two lipid targets were achieved. Any side effects/intolerance was recorded. Intensive LL treatment was defined as rosuvastatin ≥ 20 mg, atorvastatin and simvastatin ≥ 80 mg, and conventional LL treatment was defined as all lower doses.

Results: Type or dosage of statins and number of dose adjustments to obtain lipid goals were similar in patients with RA, AS and PsA. There was equal need for change of statin medication across the 3 IJD's due to intolerance/adverse event(s). In a univariate analysis neither systemic inflammation (CRP/ESR: p-value 0.10 and 0.11, respectively) nor lipid levels (LDL-c/total cholesterol (TC): p-value 0.17 and 0.34, respectively) at baseline were associated with the dose of statin needed to achieve LDL-c targets (Figure).

Figure: Doses of lipid lowering treatment (LLT) needed to achieve LDL-c goals



Conclusion: Systemic inflammation or lipid levels did not influence statin dose (conventional or intensive) needed to obtain guideline recommended lipid targets in CV prevention. Whether the background inflammation in IJD patients over time influences the CV risk reduction related to statins is yet unknown.

386

Rheumatoid Arthritis Is Associated With Systemic Inflammation In Coronary Vessels. Inge A.M. van den Oever[1], Alper M. van Sijl[1], Umit Baylan[1], Michael. T. Nurmohamed[1], Alexandre E. Voskuyl[1], Hans W. Niessen[1] and Suat Simsek[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Medical Center Alkmaar (MCA), Alkmaar, Netherlands.

Background/Purpose: Patients with a chronic inflammatory disease (CID), particularly rheumatoid arthritis (RA), have an increased risk of fatal myocardial infarction (MI), as compared to the general population. This risk might be explained, in part, by an increased systemic inflammatory burden in CID causing coronary plaque instability. With tissue specimens of epicardial coronary arteries, we studied whether individuals with CID who died of a fatal MI have an increased influx of inflammatory cells, as compared to individuals without CID but with fatal MI.

Methods: All epicardial coronary artery tissue was collected from 11 individuals with CID (including RA) who had a fatal MI and controls without CID who also had a fatal MI. Controls were matched for age, gender and maximum stenosis of coronaries. Coronary arteries were immunohistochemically stained with specific antibodies against myeloperoxidase (neutrophilic granulocytes), CD45 (lymphocytes), CD68 (macrophages) and tryptase (mast-cells). Intramyocardial coronaries were stained with N-epsilon-(Carboxymethyl)lysine (CML), an advanced glycation end product, visualizing a pro-inflammatory status. Inflammatory cell density (cells/mm2) was calculated for each section of the coronary artery (intima, media and adventitia) for each stain. Subsequently, grade of coronary stenosis (0–100%) was measured. Correlations of grade of coronary stenosis and inflammatory cell density within each of these groups was calculated using the non-parametric Spearman's Rank correlation.

Results: In RA patients, there was a significant correlation between grade of stenosis and inflammatory cell density of macrophages and lymphocytes in the intima of coronaries, with correlation coefficients of 0.313 ($p < 0.05$) and 0.205 ($p < 0.05$), respectively. This was also noted in granulocyte and mast-cell staining, but less strongly. These correlations were not observed in the control group and were also not observed in the media or adventitia of coronaries. Also, in patients with RA, a pro-inflammatory status of intramyocardial coronaries was shown, not only around the infarcted areas, but also in areas of the myocardium distant from MI.

Conclusion: Patients with RA who developed a fatal MI had a significant association between increasing grade of coronary stenosis and influx of inflammatory cells into the intima of all coronary arteries, irrespective of their relationship with the coronary implicated in MI. In particular, an increased influx of macrophages and lymphocytes was noted in the intima of all epicardial coronaries, as well as an increased endothelial activation of intramyocardial coronary vessels. The underlying inflammatory process in RA might drive a more inflammatory form of atherosclerosis, resulting in plaque vulnerability.

Left Ventricular Myocardial Tissue In Rheumatoid Arthritis Shows Systemic Inflammation After Fatal Myocardial Infarction. Inge A.M. van Den Oever[1], Alper M. van Sijl[1], Umit Baylan[1], Michael. T. Nurmohamed[1], Alexandre E. Voskuyl[1], Hans W. Niessen[1] and Suat Simsek[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Medical Center Alkmaar (MCA), Alkmaar, Netherlands.

Background/Purpose: Patients with a chronic inflammatory disease (CID), particularly rheumatoid arthritis (RA), have an increased risk of fatal myocardial infarction (MI) and a diminished survival rate as compared to the general population. This risk might be explained, in part, by the systemic inflammatory process in CID. We investigated whether individuals with CID who developed a fatal myocardial infarction (MI) had an increased influx of inflammatory cells in different areas of myocardial tissue, as compared to individuals without CID.

Methods: Myocardial tissue of 11 individuals with CID (5 with RA, 4 with psoriasis, 2 with an inflammatory bowel disease) who died of a fatal MI were used. Controls were matched for age, gender and time elapsed between myocardial infarction and death. Myocardial tissue was immunohistochemically stained with specific antibodies against myeloperoxidase (neutrophilic granulocytes), CD45 (lymphocytes), CD68 (macrophages) and tryptase (mast-cells). Cell density (cells/mm2) was calculated for the right ventricular (RV) myocardium (internal control; remote area), left ventricular (LV-) myocardium free from MI (internal control) and left ventricular (LV+) myocardium of the MI for each stain. Differences in cell densities between the CID group and controls, and within these groups; between LV+, LV- and RV, were analysed using the non-parametric Mann-Whitney U test.

Results: The CID group and controls showed a similar propensity towards inflammatory cell influx in infarcted myocardium. However, in patients with RA, an increased influx of lymphocytes and macrophages was noted in LV+ as well as LV-, as compared to RV, lymphocyte density: 16.5 ($p < 0.05$) and 14.8 ($p < 0.05$) vs. 7.9, macrophage density: 17.1 ($p < 0.05$)

and 20.3 ($p < 0.05$) vs. 9.9 ($p < 0.05$). These findings were not found in the control group. There was no significant influx of granulocytes or mast-cells in ventricular tissue of patients with RA.

Conclusion: Left ventricular myocardial tissue of patients with RA, showed an increased propensity towards systemic inflammation outside the regions of myocardial infarction. In particular, an increased influx of macrophages and lymphocytes was noted. This underlying inflammatory process in RA might enhance more cytokine release, thereby causing more cardiac depression and tissue damage after myocardial infarction.

Vitamin D Levels and Inflammation In The Aortic Wall Of Patients With Inflammatory Rheumatic Disease and Coronary Artery Disease. Ingvild Oma[1], Jacqueline Kirsti Andersen[2], Torstein Lyberg[3], Øyvind Molberg[4], Jon Elling Whist[1], Ingjerd Lien Kvelstad[1], Terje Veel[5], Morten Fagerland[3], Sven M. Almdahl[6], Knut Mikkelsen[7] and Ivana Hollan[7]. [1]Innlandet Hospital Trust, Lillehammer, Norway, [2]Gjøvik University College, Gjøvik, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]University of Oslo, Oslo, Norway, [5]Feiringklinikken, Feiring, Norway, [6]University Hospital of North Norway, Tromsø, Norway, [7]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway.

Background/Purpose: Vitamin D is involved in immune reactions, and vitamin D deficiency is associated with autoimmune diseases and with cardiovascular diseases. In Feiring Heart Biopsy Study (FHBS), we previously demonstrated a high occurrence of mononuclear cell infiltrates (MCIs) in subintimal layers of the aorta, related to inflammatory rheumatic disease (IRD). In theory, vitamin D deficiency might contribute to vascular inflammation involved in the pathogenesis of cardiovascular disease (CVD) along with the premature and accelerated CVD in IRD.

We looked for differences in plasma levels of $25(OH)D_3$ and $1,25(OH)_2D_3$ in patients with coronary arterial disease (CAD) and CAD+IRD, and examined if the levels of $25(OH)D_3$ and $1,25(OH)_2D_3$ were related to inflammation in subintimal aortic layers in terms of MCIs.

Methods: Plasma levels of $25(OH)D_3$ were examined by radioimmunoassay and $1,25(OH)_2D_3$ by immunoassay in 53 patients with CAD and 68 patients with CAD and IRD from FHBS. The D vitamin levels were then correlated to the number of MCI previously identified in the subintimal aortic layers of these patients (I. Hollan *et.al*., *Arthritis Rheum*, 56 (2007), 2072–9).

Results: From our univariate analysis, we observed no differences in $25(OH)D_3$ and $1,25(OH)_2D_3$ levels between patients with CAD+IRD and patients with CAD only (see Table). Nor did we observe any relationships between vitamin D levels and occurrence of MCIs in the subintimal aortic layers. However, after adjustment for variables with $p<0,20$ (CRP, glucocorticosteroids, daily vitamin and mineral supplementation, group, MCI) and age and sex, there was a significant inverse relationship between $1,25(OH)_2D_3$and the occurrence of MCIs in the subintimal aortic layers (B=−17, p=0.019, CI= −31.3, −2.8).

Table.

	CAD-IRD (n=68)	CAD-nonIRD (n=53)	*P* value
Age – years	67 ± 10	68 ± 10	0.601
Women – no. (%)	26 (38)	19 (36)	0.851
$25(OH)D_3$ – nmol/l	59 ± 20	59 ± 14	0.930
$1,25(OH)_2D_3$ – pmol/l	108 ± 46	96 ± 23	0.055
MCI in aortic adventitia–no. (%)	30 (48)	10 (20)	0.002

Conclusion: Our study does not support the hypothesis that vitamin D deficiency contributes to the premature and accelerated CVD in IRD. However, based on multivariate analyses, low $1,25(OH)_2D_3$ might be related to the presence inflammation in the subintimal layers of the aorta. This fact needs more exploration in future studies. If there is a causal relationship, vitamin d supplementation might represent a simple and cheap treatment for vascular inflammation.

Small Intestine Enteropathy In Patients With Rheumatoid Arthritis and Osteoarthritis, Taking Regularly Non-Steroidal Antirheumatic Drugs. Has The Basic Disease Effect On Incidence and Degree Of Damage? Petr Bradna[1], Ilja Tachecí[2], Drahomira Bastecka[2], Stanislav Rejchrt[2], Jan Bures[3] and Marcela Kopacova[4]. [1]Charles University Prague Faculty of Medicine Hradec Kralove and University Hospital, Hradec Králové, Czech Republic, [2]Charles University Prague Faculty of Medicine Hradec Kralove and University Hospital, Hradec Kralove, Czech Republic, [3]Charles University Prague,Medical Faculty Hradec Kralove and University Hospital, Hradec Kralove, Hradec Kralove, Czech Republic, [4]Charles University Prague, Medical Faculty Hradec Kralove and University Hospital, Hradec Kralove, Czech Republic.

Background/Purpose: The involvement of small intestine is demonstrable up to 72% of patients, using non-steroidal antirheumatic drugs (NSAIDs). Quite a few is known about the influence of the principal diagnosis on incidence and severity of enteropathy. The aim of our study was to compare small bowel enteropathy in rheumatoid arthritis and osteoarthritis patients, which are regularly use NSAIDs.

Methods: Capsule endoscopy is currently the leading method for non-invasive diagnostics of small bowel lesions. This method is safe, reproducible, with high diagnostic yield, discriminating extend localization, severity and character of lesions.

We examined 37 rheumatoid arthritis (RA) patients and 14 patients, using NSAIDs on a regular basis for osteoarthritis (OA). Group of 13 healthy persons, who are not using NSAIDs served as a control group. We excluded people with comorbidities potentially involving the bowel or leading to a blood loss.

We evaluated extend, severity and localizations of lesions. Qualitative data were evaluated by Fisher′s exact test, Armitage test or chi2 test, quantitative data were evaluated by Student′s T-test or Mann Whitney test in case of nonparametric distribution.

Results: We demonstrated enteropathy in 67.5% of rheumatoid arthritis patients, moderate or severe lesions in 20% of RA patients. In osteoarthritis group there were 42.9% patients with enteropathy, severe in 7% of them. In control group there were demonstrated only mild changes in 15% people. Moderate or severe lesions were not demonstrated in NSAIDs non-users. Lesions were equally frequent in ileum and jejunum, duodenum was involved rarely. The same distribution was demonstrated also in moderate and severe lesions.

Conclusion: Rheumatoid arthritis patients, using non-steroidal antirheumatic drugs, have significantly more frequent and more severe lesions of small bowel, then osteoarthritis NSAIDs users.

Jejunum and ileum were involved with equal frequency and severity, duodenal involvement was rare. Next studies should reply, if differences are caused by genetic predisposition, co-medication, or they are caused by direct impact of rheumatoid arthritis.

Autonomic Dysfunction In Rheumatoid Arthritis Improves With Disease Modifying Anti Rheumatic Drugs. Ashit Syngle[1], Inderjeet Verma[2], Pawan Krishan[3] and Nidhi Garg[3]. [1]Healing Touch City Clinic, Fortis Multispeciality Hospital, Chandigarh, India, [2]Punjabi University Patiala, India, Chandigarh, India, [3]Punjabi University Patiala, India, Patiala, India.

Background/Purpose: Autonomic (AN) function is impaired in rheumatoid arthritis (RA) and is a significant risk predictor of sudden cardiac death. However, even half a century after the description of AN dysfunction in rheumatic diseases, we do not know the impact of disease modifying anti-rheumatic diseases (DMARDs). There is need to study the effect of different DMARDs which are routinely employed in the treatment of RA, So we examined the clinical efficacy of DMARDs on AN function in patients with RA.

Methods: We evaluated total 30 RA patients of which 20 were DMARDs naïve; 9 Rheumatoid Factor (RF) RF +ve and 11 RF –ve; mean age 40.5± 7.1 years; disease duration 5.37±6.8; 11/9 (F/M) and 10 biologics naïve; 6 RF +ve and 4 RF -ve; mean age 49.28±6.62; disease duration 9.5±5.1; 4/8 (F/M). 20 aged matched healthy subjects aged 26–57 years were also enrolled as control group. AN function was assessed by applying a battery of 5 non invasive cardiovascular reflex tests according to Ewing and peripheral sympathetic AN function was assessed by Sudoscan. CAN is considered to exist if at 2 two of 5 cardiovascular reflex tests were positive.

Results: Patients with RA had significantly impaired AN function tests compared with healthy controls. After 12 weeks treatment with combination synthetic DMARDs, heart rate (HR) response to standing in RA patients significantly improved. After treatment with different biologic DMARDs there was significant improvement in HR responses to the deep breathing ($p<0.05$), standing up ($p<0.05$) and sustained handgrip (($p<0.05$)) and sudomotor function ($p<0.05$). DMARDs naïve RF +ve patients had more CAN [77% (7/9)] as compared to the RF -ve patients [45.4% (5/11)]. 83 % (5/6) biologics naïve RF +ve and 75% (2/3) RF –ve patients had CAN. 44% (4/9) DMARDs naïve RF +ve patients and 18 % (2/11) RF –ve had sudomotor dysfunction. 66.6% (4/6) biologics naïve RF +ve patients had sudomotor dysfunction while there was no sudomotor dysfunction in RF –ve patients. After 12 weeks treatment with csDMARDs 28% (2/7) RF +ve patients and 20% (1/5) RF–ve patients improved CAN. After treatment with biologic DMARDs, 100% (5/5) RF +ve patients and 66.6% (2/3) RF –ve patients had significantly improved CAN. 75 % (3/4) of the biologics naïve RF +ve patients who had sudomotor dysfunction improved significantly with biologics. There was no significant improvement in sudomotor function in RF +ve and RF−ve DMARDs naïve RA patients. Patients with normal AN function had no change in their autonomic function after treatment with synthetic or biologic DMARDs.

Conclusion: Synthetic DMARDs significantly improved HR response to standing. Biologics DMARDs significantly improved HR response to deep breath, HR response to standing, BP response to handgrip and sudomotor function in RA biologics naïve patients. RF +ve RA patients have more AN dysfunction than RF –ve patients. In this study biologics and csDMARDs improve CAN & sudomotor function but RF +ve biologics naïve RA patients achieved significantly greater reductions in AN dysfunction compared to RF –ve biologics naïve patients.

Insulin Resistance As A Risk Factor For Subclinical Atherosclerosis In Rheumatoid Arthritis. Adel M. Elsayed[1], Samah A. El Bakry[1], S. A. M. Hassan[1], Rehab A. Rahman[1], Rania A. Abo-Shady[1] and Nouran Abaza[2]. [1]Ain Shams University, Cairo, Egypt, [2]Lecturer of Physical medicine, Rheumatology and Rehabilitation, Faculty of Medicine, Ain Shams University, Cairo, Egypt.

Background/Purpose: Insulin resistance (IR) is a state in which a high insulin concentration is associated with an inadequate response to glucose with normal or high levels of glycaemia. It is strongly associated with systemic inflammation. IR is known to be increased in patients with established rheumatoid arthritis (RA) and has been shown to be a risk factor for both clinical CVD and subclinical atherosclerosis. The aim of this study is to estimate the prevalence of IR among RA patients and its relation to disease activity and disease duration.

Methods: Forty RA patients and 10 age and sex matched healthy individuals as controls were included. RA patients were fulfilling the 2010 ACR/EULAR diagnostic criteria for RA. Patients with Diabetes mellitus, Obesity and Hypertension were excluded. For all, detailed medical history and thorough examinations were performed. Fasting plasma sugar and fasting serum insulin were done, RA disease activity assessed using DAS28-ESR score and IR was evaluated by the homeostasis model assessment (HOMA2). Carotid artery intima media thickness (IMT) was evaluated using ultrasound.

Results: RA patients had significantly higher ESR, CRP positivity, fasting plasma sugar and fasting serum insulin, HOMA2-IR levels than the controls. Insulin resistance as defined by HOMA2-IR>1 was seen in 33(82.5%) RA patients while it was present in only one (10%) of the controls ($p=0.001$). RA patients with insulin resistance have significantly longer disease duration ($p=0.003$), higher disease activity ($p=0.000$), greater carotid IMT ($p=0.000$), and have more carotid plaques ($p=0.043$) than those without insulin resistance. Dividing the RA patients according to the cut-off IMT value (0.72 mm), a significant difference was detected in disease duration ($p=0.002$), DAS28 score ($p=0.000$) and HOMA2-IR ($p=0.000$) being higher in RA patients with increased IMT(>0.72).

Conclusion: In patients with RA, IR was significantly higher than that of healthy controls. A significant positive correlation was found between IR with both disease activity and disease duration in RA patients. Our study pointed out a significant association between IR and subclinical atherosclerosis in RA.

M. Ramos Mejía Hospital, School of Medicine, University of Buenos Aires, Buenos Aires, Argentina, [15]Revmatologická ambulance, Terezin, Czech Republic, [16]Hospital Provincial de Rosario, Rosario, Argentina, [17]University of Massachusetts Medical School, Worcester, MA, [18]NYU Hospital for Joint Diseases, New York, NY.

Background/Purpose: Cardiovascular disease (CVD) is a major comorbidity in patients (pts) with rheumatoid arthritis (RA). We explored variations in the prevalence of cardiovascular (CV) risk factors and CVD among patients (pts) in different international regions using data in CORRONA International (C.Intl) and CORRONA US (C.USA) registries.

Methods: The C.Intl registry, launched in September 2011, is a multicenter, observational registry. Adult RA pts have been enrolled from 83 rheumatology practices in 10 countries in 3 regions [Latin America: Mexico, Brazil, Argentina; Eastern Europe: Poland, Czech Republic, Hungary, Romania, Russia, Ukraine; Asia: India]. The only exclusion criteria are functional class IV and age >85 years old.

The C.USA registry was launched in 2001 and enrolls pts from 111 rheumatology practices across the United States. There are no exclusion criteria.

Both registries collect data in a similar manner on demographics, lifestyle characteristics, anthropometry, medication exposures, adverse events and comorbidities from rheumatologists and RA pts at regular clinical encounters.

We present cross-sectional baseline descriptive data for demographic and disease characteristics for the C.Intl regions. We compare this information with cross-sectional data from the most recent visit of C.USA-enrolled pts excluding those with functional class IV and >85 years of age. Prevalence for CV risk factors and CVD are presented crude for C.USA and age/gender-

standardized to the C.USA age/gender distribution (age categories <50, 50-<60, 60-<70, ≥70 years) for C.Intl regions. No formal statistical testing was conducted.

Results: As of March 4 2013, 5696 pts had been enrolled in C.Intl and 20291 pts with functional class <IV and age ≤85 were actively followed in C.USA.

While there are cross-sectional differences across all regions, in general, the greatest differences are between the US and C.Intl overall. There is a higher percentage of male pts in C.USA, disease duration is longer, and pts tend to have lower disease activity, yet are more likely to receive a biologic (Table 1).

After adjusting for age and gender differences by standardization, enrolled pts in India have the lowest BMI, are more rarely smokers and have a low prevalence of hyperlipidemia and CVD compared to other C.Intl regions and C.USA (Table 1). C.USA participants have the highest BMI. Participants from Eastern Europe suffer more frequently from hypertension and hyperlipidemia and have the highest prevalence of all manifestations of CVD (Table 1).

Table 1. *Demographic and disease characteristics, CV risk factors and CVD in RA patients from international regions and from the US

	CORRONA International - regions			
	Latin America	Eastern Europe	Asia	CORRONA US
NUMBER OF PATIENTS (N)	2030	2517	1149	20291
Demographic and disease characteristics				
Females (n,%)	1759 (86.7%)	2099 (83.4%)	982 (85.5%)	15358 (76.6%)
Age/years (mean, SD)	54.2 (12.9)	57.1 (12.2)	47.6 (11.9)	60.3 (12.6)
Disease duration/years (mean, SD)	9.9 (8.7)	9.1 (8.6)	6.3 (5.8)	12 (10.1)
Anti-CCP or RF positive (%)	1695 (83.5%)	1922 (76.4%)	750 (65.4%)	9867 (76%)
CDAI (mean, SD)	14.6 (13.3)	19.1 (14.3)	15.3 (11.8)	10.4 (11.2)
Current RA medications				
On biologic (n,%)	400 (19.7%)	323 (12.8%)	6 (0.5%)	10516 (51.8%)
On DMARD(s) but not on biologics (n,%)	1374 (67.7%)	1782 (70.8%)	1026 (89.3%)	8430 (41.5%)
Corticosteroids (n,%)	842 (41.5%)	690 (27.4%)	304 (26.5%)	4635 (22.8%)
Prevalence of CV risk factors (age/gender standardized)				
Family history of early AMI (<60 years) (n,%)	255 (12.5%)	270 (10.2%)	84 (6.8%)	677 (3.3%)
Family history of early stroke (<60 years) (n,%)	115 (5.4%)	194 (7.2%)	21 (2.1%)	259 (1.3%)
BMI (mean, SD)	27.3 (7.6)	27.4 (6)	24.2 (5.3)	29.4 (7)
Current smoker (n,%)	327 (15.9%)	339 (12.9%)	23 (2.7%)	3015 (15%)
Hypertension (n,%)	655 (39.4%)	1378 (58.1%)	186 (31.7%)	6359 (31.4%)
Hyperlipidemia (n,%)	317 (18.6%)	677 (28%)	33 (5.3%)	1463 (7.2%)
Prevalence of CVD (age/ gender standardized)				
Congestive Heart Failure (n,%)	19 (1.3%)	48 (2.1%)	0 (0%)	44 (1.1%)
Coronary artery disease (n,%)	21 (1.9%)	282 (12.9%)	12 (1.8%)	920 (4.5%)
AMI (n,%)	20 (1.6%)	69 (3.6%)	6 (2.2%)	560 (2.8%)
Unstable angina (n,%)	1 (0.1%)	20 (0.8%)	2 (0.1%)	78 (0.4%)
Peripheral arterial disease (n,%)	4 (0.3%)	26 (1.2%)	0 (0%)	50 (0.2%)
Stroke (n,%)	15 (0.9%)	44 (2.2%)	1 (0.9%)	407 (2%)
TIA (n,%)	9 (0.8%)	38 (1.5%)	2 (0.4%)	175 (0.9%)

* all data are from baseline visits for CORRONA International, and cross-sectional data from the most recent visit of pts enrolled in CORRONA US.
ABBREVIATIONS CCP: Cyclic Citrullinated Peptide; CDAI: Clinical Disease Activity Index; DMARDs: Disease Modifying Anti-Rheumatic Drugs; AMI: Acute Myocardial Infarction; BMI: Body Mass Index; TIA: Transient Ischemic Attack

Conclusion: Data from the C.Intl and C.USA registries reveal variations in disease characteristics, as well as prevalence of CV risk factors and CVD across different regions. Observed differences may be influenced by differences in the composition and treatment of pts populations and should be considered in analyses and evaluation of pts from different geographic origins.

393

Survival In Rheumatoid Arthritis Associated Pulmonary Arterial Hypertension Is Comparable To Idiopathic Pulmonary Arterial Hypertension. Saghar Sadeghi[1], John T. Granton[2], Pooneh Akhavan[3] and Sindhu R. Johnson[4]. [1]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON, [2]Toronto Pulmonary Hypertension Programme, Toronto General Hospital and University of Toronto, Toronto, ON, [3]Early Rheumatoid Arthritis Program, Mount Sinai Hospital and University of Toronto, Toronto, ON, [4]Toronto Western Hospital, Toronto General Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON

Background/Purpose: To evaluate survival in rheumatoid arthritis associated pulmonary arterial hypertension (RA-PAH) compared to idiopathic PAH (IPAH) patients. Secondary outcomes included evaluation of differences in sex predisposition, age of diagnosis, disease severity, co-morbid diseases and pulmonary hypertension treatment.

Methods: A retrospective cohort study of RA-PAH and IPAH seen at the University Health Network Pulmonary Hypertension Programme, Toronto, Canada was conducted. The primary outcome was time to all cause mortality. Unadjusted survival was evaluated using Kaplan-Meier survival curves. Propensity score models were used to adjust for differences in baseline covariates, and to assemble a matched cohort. Cox proportional hazards models were used to estimate survival in the matched cohort.

Results: Screening of 1385 patients identified 18 RA-PAH and 155 IPAH patients. RA-PAH patients had a lower proportion of males (17% versus 30%), and had an older median age of onset (64.0 years versus 53.7 years). RA-PAH patients more frequently had coronary artery disease (33% versus 16%), lower baseline mPAP (43 mmHg versus 51 mmHg), lower proportion of WHO functional class III or IV (39% versus 52%), lower median baseline BNP (58.4 pg/mL versus 95.0 pg/mL), longer 6-minute walk distance (478 m versus 381 m), less calcium channel blocker (22% versus 29%), phophodiesterase-5 inhibitor (11% versus 19%) and prostaglandin analogues (6% versus 15%) use. There were 35 deaths, 2/18 (11%) RA-PAH patients and 33/155 (21%) IPAH patients. The unadjusted 1-year survival for RA-PAH patients was 93% and for IPAH was 94%. The unadjusted hazard ratio comparing RA-PAH to IPAH survival was 1.52 (95% CI 0.16, 2.76). In the matched cohort there were 7 deaths, 2/18 (11%) RA-PAH patients and 5/18 (28%) IPAH patients, with a hazard ratio of 1.53 (95% CI 0.15, 2.84).

Conclusion: PAH is a serious manifestation of RA. Despite milder disease at presentation, survival is comparable to IPAH.

394

Vitamin D Deficiency In Patients With Early Inflammatory Arthritis. Seung-Geun Lee[1], Guen-Tae Kim[2], Joung-Wook Lee[3], Seong-Ho Kim[4] and Seung-Hoon Baek[5]. [1]Divsion of Rheumatology, Department of Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Kosin University College of Medicine, Busan, South Korea, [3]Divsion of Rheumatology, Department of Internal Medicine, Busan St. Mary's Medical Center, Busan, South Korea, [4]Division of Rheumatology, Inje University College of Medicine, Haeundae Paik Hospital, Busan, South Korea, [5]Divsion of Rheumatology, Department of Internal Medicine, Ilsin Christian Hospital, Busan, South Korea.

Background/Purpose: To investigate the status of vitamin D in patients with early inflammatory arthritis (EIA) compared with healthy controls.

Methods: The study included 101 patients with EIA (≥ 1 swollen joint, symptom duration of ≤ 6 months, not explained by another disease) and 101 healthy controls matched for age, gender and the month of serum vitamin D measurements, not receiving vitamin D supplementation, at a university-affiliated rheumatology center in South Korea from March 2012 to February 2013. Serum 25(OH) vitamin D levels were assessed by radioimmunoassay. EIA patients were subdivided into rheumatoid arthritis (RA) and non-RA

according to the 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria.

Results: No significant difference in serum 25(OH) vitamin D levels between EIA and controls was observed (median 14.2 vs 16.3, p=0.229, Table 1). Among 101 EIA patients, 38 subjects (37.1%) were categorized as RA. In subgroup analyses of EIA patients, RA patients had significantly higher swollen joint count (SJC), tender joint count, erythrocyte sedimentation rate, C-reactive protein, rheumatoid factor, anti-citrullinated protein antibody (ACPA) and lower serum 25(OH) vitamin D levels than in non-RA subjects. Serum 25(OH) vitamin D levels in EIA patients were inversely correlated with the titer of ACPA ($\rho=-0.214$, p=0.031), SJC ($\rho=-0.196$, p=0.049) and patient's visual analogue scale ($\rho=-0.202$, p=0.043). Low serum 25(OH) vitamin D levels in EIA patients tended to be related to a greater likelihood of fulfilling the 2010 ACR/EULAR criteria after adjusting age, sex, Health Assessment Questionnaire score and season (OR=0.952, 95% CI=0.905–1.001, p=0.054, Table 2). In particular, multivariable logistic regression analysis showed that severe vitamin D deficiency (25(OH) vitamin D < 10ng/mL) was significantly associated with the diagnosis of RA (OR=3.259, 95% CI=1.137–9.342, p=0.028, Table 2).

Table 1. Demographics and disease characteristics of patients with early inflammatory arthritis and healthy controls

Variables	EIA (n=101)	Controls (n=101)
Age, years	56.5 ± 12.2	56.6 ± 12.1
Female, n (%)	86 (85.1)	86 (85.1)
Serum (OH) vitamin D, ng/mL	14.2 (5.5–67.9)	16.3 (4.6–23.3)
Severe vitamin D deficiency (<10 ng/mL), n (%)	18 (17.8)	15 (14.9)
Diagnosis		
RA, n (%)[1]	38 (37.6)	
Non–RA, n (%)	63 (62.4)	
OA, n (%)	37 (36.7)	
UIA, n (%)	24 (23.1)	
Other, n (%)	2 (2.0)	

EIA, inflammatory early arthritis; RA, rheumatoid arthritis; OA, osteoarthritis; UIA, undifferentiated arthritis.
[1] RA was classified as 2010 ACR/EULAR criteria.

Table 2. Association between serum 25 (OH) vitamin D and the presence of rheumatoid arthritis in early inflammatory arthritis

Variables	Crude OR (95% CI)	p-value	Adjusted OR (95% CI)	p-value
Serum 25 (OH) vitamin D, ng/mL,	0.95 (0.91 – 1.00)	0.054	0.95 (0.91 – 1.00)[1]	0.054
Severe vitamin D deficiency (<10 ng/mL)	3.26 (1.14 – 9.34)	0.028	3.26 (1.14 – 9.34)[1]	0.028
Age, years	1.00 (0.98 – 1.04)	0.612		
Female vs male	0.89 (0.29 – 2.73)	0.837		
HAQ	1.85 (0.96 – 3.53)	0.064		
Season				
Spring	1.0			
Summer	0.37 (0.12 – 1.12)	0.078		
Autumn	0.37 (0.12 – 1.12)	0.078		
Winter	0.31 (0.10 – 1.00)	0.050		

[1] Estimated using multivariable logistic regression analyses with backward selection, adjusted for age, sex, HAQ and season.

Conclusion: Although serum vitamin D levels in EIA patients were similar to those of controls, vitamin D deficiency contributed to the presence of RA in EIA patients.

Sex Differences In Lean Mass Deficits In Rheumatoid Arthritis. Joshua Baker[1], David I. Daikh[2] and Patricia P. Katz[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Significant differences in adiposity between men and women with RA have been observed (1). Another alteration of body composition, rheumatoid cachexia, characterized by low lean mass, is also clinically important because it has been linked to increased risk of disability and mortality (2). Our objective was to identify the extent of lean mass deficits in men and women with RA compared to age- and sex-specific national reference data.

Methods: Subjects were recruited from a university-based cohort of patients with RA. Exclusion criteria were non–English speaking, age >18 years, current daily oral prednisone dose >50 mg/day, pregnancy, and joint replacement within 1 year. Body composition and regional fat and lean mass distribution were assessed with whole body dual energy X-ray absorptiometry (DXA) using a Lunar Prodigy DXA system. Precision error (1 SD) was 1.0 kg for fat mass, and 0.8 kg for lean mass. Appendicular lean mass and overall lean body mass were adjusted for height to create indices (ALMI and LBMI, respectively). Indices for each subject were compared to previously published NHANES reference ranges to generate age- and sex-specific Z-scores according to the guidelines defined by Kelly et al (3). Sarcopenia was defined as an ALMI Z-score <-1 (corresponding to the16th percentile) (4).

Results: DXA was performed for 141 individuals (56 men, 85 women). There were no significant differences in self-reported disease activity, functioning (by Health Assessment Questionnaire), prednisone use, or disease duration. Men had significantly lower ALMI and LBMI Z-scores compared to women (Table). On average among men, ALMI and LBMI were at the 8th and 7th percentiles, respectively. In contrast, average ALMI and LBMI among women were at the 37th and 32st percentiles, respectively. Sarcopenia was present among 55% of men and 25% of women, with the odds of sarcopenia significantly greater for men ([OR 3.78 [1.84–7.78], p<0.001).

Table. Mean lean mass Z-Scores (SD) and percentiles for men and women with RA based on NHANES reference ranges

	Men (n = 56)	Women (n = 85)	p*
Appendicular lean mass index (ALMI) z-score	−1.39 (1.34)	−0.34 (0.92)	< .0001
ALMI percentile	8th	37th	
Overal lean body mass index (LBMI) Z-score	−1.44 (1.36)	−0.47 (0.86)	< .0001
LBMI percentile	7th	32nd	

* p-value from t-tests comparing men and women

Conclusion: Among subjects with RA, men had significantly greater lean mass deficits than women. Combined with previous observations of greater obesity among men with RA, it appears that men with RA may experience greater alterations in body composition than women when compared to normal sex-specific ranges. Further study may help confirm these findings and to clarify the factors leading to these differences.

The Dosage Of Prednisolone Is a Risk Factor For Falls In Rheumatoid Arthritis Patients—The Third Year Results Of The Tomorrow Study. Yuko Sugioka, Tatsuya Koike, Kenji Mamoto, Tadashi Okano, Masahiro Tada, Kentaro Inui and Hiroaki Nakamura. Osaka City University Graduate School of Medicine, Osaka, Japan.

Background/Purpose: Population-based studies suggest an association between musculoskeletal problems and an increased risk of falls. Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at an increased risk of falling. But, no prospective cohort study concerning fall incidence in RA has been performed. This study used a prospective cohort design to determine the incidence of falls and to elucidate their risk factors in patients with RA who participated in the TOMORROW study (UMIN000003876) that was started in 2010.

Methods: We have started the TOMORROW study examining several risk factors affecting RA. The participants in the study consist of 202 RA patients (109 patients receiving biological agents) and 202 age-and sex-matched healthy volunteers were collected through mass media as controls.

As a baseline, all participants completed a self-administered questionnaire on general health status. Laboratory data and anthropometric parameters were also collected. Body composition was determined by whole body dual X-ray absorptiometry. Vertebral fractures using thoracolumbar spine X-rays were evaluated. In addition, incidence of falls was tracked with a "fall calendar" for 3 years and we collected the calendar yearly.

Results: The incidence of having at least one fall during the 3-year period did not significantly differ between the patients and controls (37.1% vs. 30.2%, NS). However, the patients fell significantly more often than controls (2.48 vs.1.74 falls; $p = 0.03$) and had a higher prevalence of vertebral fractures (46% vs. 30%) and semiquantitative (SQ) grade ≥2 (15% vs. 5%) than the controls. After adjusting for risk factors of falls such as age, gender, smoking and BMI, multiple logistic regression analysis identified that a history of falls was the most significant parameter associated with the incidence of falls (odds ratios: all, 2.49, $p < 0.001$; patients, 1.98, $p = 0.047$; controls, 3.60, $p = 0.017$). Existing vertebral fractures and SQ grade ≥2 did not correlate with the incidence of falls. Multiple regression analysis revealed that the number of falls experienced by patients with RA was associated with the dosage of prednisolone (PSL; $\beta = 0.214$, $P = 0.027$,) and matrix metalloproteinase-3 (MMP-3; $\beta = 0.141$, $P = 0.046$) (Table 1.).

Table 1. Association between number of falls and parameters adjusted for potential confounders for falls

Multivariate number of falls	RA patients β	P value
mHAQ	0.071	0.347
Prednisolone (PSL: mg/day)	0.214	0.027
MMP-3	0.141	0.046
Whole BMD (mg/cm^2)	−0.020	0.843
Body fat (kg)	0.181	0.201
Walking period (min/day)	0.044	0.535

Conclusion: We evaluated the associated risk factors for falls in RA patients. Multiple falls in RA patients were significantly higher than in controls over the past three years. In RA patients, history of fall and a prednisolone use were associated with falls. The patients who fell at least once tend to fall again. To prevent falls, various interventions are necessary for the patients.

Does Elevated Disease Activity Or Medication Use Influence The Bone Density Of The Prepubertal Offspring In Pregnant Women With Rheumatoid Arthritis? Florentien D.O. de Steenwinkel[1], Anita C.S. Hokken-Koelega[2], Johanna Hazes[1] and Radboud J.E.M. Dolhain[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus Medical Center-Sophia Children's Hospital, Rotterdam, Netherlands.

Background/Purpose: Elevated rheumatoid arthritis disease activity and prednisone use during pregnancy are both associated with a lower bone mineral density (BMD) of the patients, but both can be inevitable in pregnant women with RA. It is unknown if these variables influence the BMD of their offspring. Our purpose was to investigate whether medication or disease activity during pregnancy in patients with RA, influence the BMD of their prepubertal offspring

Methods: Children were included if their mother participated in a prospective cohort study on RA and pregnancy. In 108 children, approximately 7-years-old, the BMD was assessed by dual-energy X-ray absorptiometry. The bone mineral density was expressed in standard deviation score (SDS) for total body and lumbar spine. Variables of the child known to influence the BMD were taken into account: calcium intake, physical activity, serum 25-hydroxyvitamin D, gender, length and weight. Pre- and postnatal variables known to influence the BMD are gestational age, maternal smoking, birth weight, postnatal tempo of growth and type of feeding. The independent variables were prednisone, sulfasalazine and RA disease activity during pregnancy.

Results: The mean BMD total body SDS was −0.11 (0.10) and the mean BMD lumbar spine SDS was −0.20 (0.99). Both variables were comparable to zero, thus the mean of aged and sexed matched healthy controls. No association was found between prednisone or RA disease activity during pregnancy and BMD of 7-years-old offspring, even after correcting for all known associated variables. Sulfasalazine had a positive effect on the whole body BMD (difference in SDS=0.53; p=0.005).

Conclusion: Neither elevated RA disease activity nor medication use during pregnancy is associated with a lower BMD of the 7-year-old offspring. The results of this study may be a help in balancing the risk and benefits of prescribing medication during pregnancy versus accepting active disease.

Does Elevated Disease Activity Or Medication Use Influence The Body Composition Of The Prepubertal Offspring In Pregnant Women With Rheumatoid Arthritis? Florentien D.O. de Steenwinkel[1], Radboud J.E.M. Dolhain[1], Johanna M.W. Hazes[2] and Anita C.S. Hokken-Koelega[3]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus University Medical Center, Rotterdam, Netherlands, [3]Erasmus Medical Center-Sophia Children's Hospital, Rotterdam, Netherlands.

Background/Purpose: Elevated rheumatoid arthritis (RA) disease activity during pregnancy is associated with lower birth weight and rapid post-natal growth. Lower birth weight and rapid post-natal growth can negatively influence the body composition later in life, creating a negative health profile and hence contribute to cardiovascular disease (CVD) and type 2 diabetes mellitus (T2DM) in adulthood. Glucocorticoids are one of the few medications that can be given safely during pregnancy, but animal studies have shown a negatively influence on the metabolic profile of the offspring. Whether the same holds true for humans is not known. The purpose of the study was to investigate if RA disease activity or medication during pregnancy influences the body composition, or increases the presence of early risk on CVD or T2DM determinants, in the prepubertal offspring.

Methods: Children were included if mother participated in a prospective cohort study on RA and pregnancy. In 108 children, approximately 7-years-old, the body compositions were assessed by dual-energy X-ray absorptiometry. The body compositions was expressed in standard deviation score (SDS) for lean body mass (LBM) and fat mass (FM).The presence of the early risk on CVD or T2DM determinants was determined by assessing the individual components (abdominal obesity, high triglyceride, low high-density lipoprotein, high systolic or diastolic pressure and high fasting glucose) of the metabolic syndrome (MetS) adapted for children Independent variables were prednisone, sulfasalazine and RA disease activity during pregnancy.

Results: The mean LBM SDS was −0.65 (0.70) and FM SDS was, 0.21 (0.94). Both variables were significantly different from 0 SDS, the mean of healthy controls, LBM SDS ($p<0.001$) and FM SDS ($p=0.02$). In multivariate analysis a significant association of gender, birth weight, height and weight was found ($p<0.001$) in LBM and only on height and weight ($p<0.001$) in FM. No association was found between elevated RA disease activity or the presence of medication use during pregnancy. RA disease activity or medication use were also not associated with the individual components of the MetS and only 1 child could be diagnosed with MetS.

Conclusion: The elevated fat mass compared to the low lean body mass points to a relative higher fat distribution in the prepubertal children born from mothers with RA. Since this was not associated with disease activity or medication use during pregnancy, this could implicate that RA during pregnancy has an impact on the body composition of children through other mechanisms. In addition, prednisone use during pregnancy was not associated with the individual components of the MetS. This underscores that in humans, in contrast to animal studies, corticosteroids do not influence the metabolic profile of the offspring and can hence be prescribed safely.

Nausea and Vomiting During Pregnancy and Spontaneous Abortion In Women With Rheumatoid Arthritis. Balambal Bharti[1], Diana L. Johnson[2] and Christina D. Chambers[2]. [1]University of California San Diego, La Jolla, CA, [2]University of California, San Diego, La Jolla, CA.

Background/Purpose: Nausea and Vomiting during Pregnancy (NVP) has been associated with a decreased risk for spontaneous abortion (SAB). However, the Th1/Th2 imbalance that occurs in pregnancy and is accentuated

in women with NVP has not been studied in women with autoimmune diseases (AI) with respect to risk for SAB.

Methods: As part of the ongoing Organization of Teratology Information Specialists Autoimmune Diseases in Pregnancy Project, pregnant women were surveyed regarding 1st trimester vomiting using the Pregnancy Unique Quantification of Emesis (PUQE) questionnaire. Other characteristics assessed included maternal demographics, lifestyle factors and health status, AI status, current pregnancy related characteristics, pregnancy planning, previous pregnancy loss, and outcome of the current pregnancy. The severity of NVP was compared using the mean PUQE scores as well as categories of NVP. Cox proportional hazards regression models were constructed to estimate the adjusted hazard ratios for SAB in those with and without NVP. Separate models were constructed for women with and without AI.

Results: Data were available for 182 women with AI (n = 92) and without AI (n = 90). The mean age of the women at delivery was 33±5 years, with enrollment in the study taking place at an average gestational age of 9±3 weeks. The prevalence of NVP in the entire sample was 65%, with a mean PUQE score of 4.91±1.96. The overall crude rate of SAB was 11%; the rate in women with AI was 13% compared to 9% in those without AI. Women with AI had lower PUQE scores as compared to those without AI, although the difference was not statistically significant (4.7 vs. 5.1; p=0.14). The crude rate of SAB among those with NVP was 9% compared to 16% among those without NVP. The adjusted hazard ratio for SAB among women who had NVP compared to those who did not was 0.61 (95% CI, 0.23–1.62). The adjusted hazard ratios for SAB in women with NVP compared to those without were similar and close to 1 both in women with and without AI (95% CIs, 0.19–2.02 and 0.08–1.47, respectively).

Conclusion: The prevalence of NVP in this cohort of pregnant women with and without AI is comparable to the general population (65% compared to 60–90% in the general population). Women with NVP had a lower risk of SAB compared to those without NVP. The association between NVP and SAB did not differ appreciably between women with and without AI.

Parotid Ultrasound Abnormalities Among Rheumatoid Arthritis Patients: Prevalence and Clinical Correlates. Hong Yang[1], Doquyen H. Huynh[2], Arnold Ceponis[3] and Arthur Kavanaugh[4]. [1]UCSD, San Diego, CA, [2]UC San Diego School of Medicine, San Diego, CA, [3]University of California San Diego, La Jolla, CA, [4]University of California San Diego, San Diego, CA.

Background/Purpose: Sjögren's syndrome (SS) occurs commonly among rheumatoid arthritis (RA) patients. It may be an indicator of, and even a contributor to, increased RA disease activity and severity. Thus, secondary SS may impact outcome assessment in RA. Diagnosis of SS has traditionally depended on signs and symptoms and serologic test, but also invasive procedures such as minor salivary gland biopsy. Work from several independent groups has shown common, consistent and characteristic findings on parotid and minor salivary gland ultrasound (US) among patients with SS. We used US to assess the parotid and submandibular glands of RA patients, and correlated these findings with clinical characteristics.

Methods: Patients with an established diagnosis of RA attending UCSD Arthritis clinics were randomly recruited. Parotid and submandibular glands US were performed using a standardized protocol; a total US score was calculated according to an validated system (1,2). This system assesses gland texture (echogenicity), posterior border appearance, and parenchymal homogeneity. The US score was calculated as summation of the grades of 5 parameters for all four glands (range 0 to 48). From the literature, the optimal cut-off score for diagnosing SS was 17. Demographic and clinical information were collected, including the sicca syndrome questionnaire, standard RA patient demographics, functional status (using HAQ), RA disease activity (using RAPID3), dental health assessment (using the oral health impact profile [OHIP] short form; range of scores 0 to 56), and cigarette smoking status. Serologic testing included RF, ACPA, SS-A, SS-B. Schirmer's test was performed.

Results: Among the initial 20 patients, half had SS related symptoms per sicca questionairre. Also, 45% patients showed significant ultrasonographic changes (score ≥ 17) in their major salivary glands. Among patients with ultrasonographic salivary changes, 78% had sicca symptoms. The mean dental health assessment score from OHIP short form of patient with US changes was 18.2 compared to 3.2 among patients without US changes. The mean HAQ score was 1.2 among patients with US changes and 0.9 among those without. The mean RAPID3 score of patient with and without US changes was 16.3, and 15.1 respectively. Although ~ 66% patients had abnormal results for Schirmer's test, there was not a strong correlation with US changes.

Conclusion: SS related symptoms are common among unselected RA patients, as are abnormalities on parotid and submandibular gland US. Sonographic salivary gland findings correlate with SS related symptoms, and also with overall dental health. Further study to assess the potential correlation between sonographic salivary gland findings and RA disease activity and severity is needed.

Chest Pain Is Not Associated With Coronary Atherosclerosis In Patients With Rheumatoid Arthritis and Ankylosing Spondylitis. Silvia Rollefstad[1], Eirik Ikdahl[1], Inge C. Olsen[1], Jonny Hisdal[2], Tore K. Kvien[3], Anne S. Eirheim[1], Terje R. Pedersen[3] and Anne G. Semb[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Uslo University Hospital-Aker, Oslo, Norway, [3]University of Oslo, Oslo, Norway.

Background/Purpose: During cardiovascular (CV) risk stratification in patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS), it can be difficult to distinguish between chest pain related to coronary atherosclerosis (CA), or to the rheumatic disease itself. The aim was to evaluate associations between chest pain, CV risk factors and CA in RA and AS patients without established CV disease.

Methods: Detailed information concerning chest pain and CV risk factors was obtained in 335 patients with RA and AS. In addition, 119 patients (RA n=86 and AS n=33) underwent multi detector computer tomography (MDCT) coronary angiography.

Results: Thirty-one percent (104/335) reported chest pain. Only 6 patients (1.8%) had atypical angina pectoris (pricking pain at rest). In 50 patients with chest pain, 26 (52.0%) had CA, while in 69 patients without chest pain, 51 (73.9%) did have CA (Fig. 1). In a logistic regression analysis with CA (by CT coronary angiography) as the dependent variable, chest pain was not associated with CA (p=0.28). About 30 % of CA was explained by any of the three following CV risk calculators: SCORE, Framingham and Reynolds in these models (Fig. 2).

Conclusion: Chest pain was surprisingly infrequently reported considering the underlying rheumatic joint disease, but when present, chest pain was of limited value in CV risk evaluation.

Can Modulators Of Inflammation Serve As Biomarkers For Subclinical Atherosclerosis In Rheumatoid Arthritis? Kimberly P. Liang, Douglas P. Landsittel, Suresh R. Mulukutla, Steven E. Reis, Marc C. Levesque, Donald M. Jones, Rachel Gartland, Ali Shoushtari, Flordeliza S. Villanueva, Hunter C. Champion and Larry W. Moreland. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Rheumatoid arthritis (RA) is independently associated with a higher risk of cardiovascular disease (CVD) and premature atherosclerosis. Mechanisms of atherosclerosis include (1) Endothelial dysfunction/activation mediated by intercellular adhesion molecules (e.g., ICAM-1, VCAM-1, E-selectin) and oxidative stress (e.g., through MPO

activity); (2) Inflammation mediated by cytokines (e.g., IL-6); (3) Plaque stability mediated by CD40-CD40L interactions; and (4) Proteolysis/Plaque rupture mediated by proteolytic enzymes (e.g. MMP-9). This study evaluates whether these serum biomarkers are higher in RA subjects, and/or associated with subclinical carotid atherosclerosis.

Methods: Carotid ultrasounds were performed with measurement of intima-media thickness (cIMT, using maximum of both sides) and plaque presence (of either side), and serum biomarkers (ICAM-1, VCAM-1, E-selectin, MPO, IL-6, CD40L, and MMP-9) were measured by ELISA in all subjects (46 RA cases and 70 controls). Each of the biomarkers, cIMT, plaque presence, and demographic data, were tested for differences between cases and controls, using the Wilcoxon rank-sum test (for continuous data) or chi-square test. The relationship between each serum biomarker and cIMT or plaque presence was tested by Spearman correlations or rank-sum test (for IL-6 only, which was categorized as above detection limit [for 21%] or not).

Results: Mean age, BMI, and gender frequency were similar ($p \geq 0.19$) between RA (59.3 years, 28.9, 72% female) and controls (54.7 years, 28.7, 67% female); race was significantly different (4.4% African-American or other in RA vs. 28.6% in controls; $p=0.001$). Mean cIMT and detectable IL-6 presence were higher in RA (0.88 and 31.8%) than controls (0.79 and 14.3%; $p=0.02$ and 0.03). Mean (+/−SD) MPO was lower in RA (594.9+/−670.9) than controls (727.4+/−464.6) ($p=0.01$). Plaque presence was found in 47.8% of RA cases vs. 37.7% of controls ($p=0.28$). None of the other serum biomarkers were significantly different between RA vs. controls.

ICAM-1 ($r=0.36$, $p<0.001$), VCAM-1 ($r=0.28$, $p=0.002$), and E-selectin ($r=0.32$, $p<0.001$) were positively associated with cIMT in the overall group. Mean cIMT was higher in those with IL-6 above detection limit (0.91 vs. 0.80; $p=0.05$). Mean CD40L and MPO were lower in those with plaque presence (8385 for CD40L and 554 for MPO) compared to plaque absence (9433 for CD40L and 754 for MPO). Results were similar when examined in the RA and control groups separately, though the magnitude of the correlations with cIMT was slightly higher in the control group for ICAM-1, VCAM-1, and E-selectin. In the RA group only, mean ICAM-1 was higher (292) in those with plaque than in those without plaque (234) ($p=0.05$).

Conclusion: This study confirms previous observations that cIMT is higher in RA than non-RA subjects. Markers of endothelial dysfunction (ICAM-1, VCAM-1, E-selectin) are significantly associated with higher cIMT in both RA and non-RA subjects. This suggests possible common pathways of atherosclerotic progression as evidenced by cIMT and biomarker elevation. Further studies are needed to determine the predictive ability of these and other serum biomarkers in CVD risk stratification algorithms in RA patients.

Peripheral Blood Biomarkers Of Rheumatoid Arthritis-Associated Interstitial Lung Disease. Juan Chen[1] and Dana P. Ascherman[2]. [1]The First Afflicted Hospital of Xiamen University, Xiamen, China, [2]University of Miami, Miami, FL.

Background/Purpose: Interstitial lung disease (ILD) is a common extra-articular manifestation of rheumatoid arthritis (RA) and a significant cause of morbidity and mortality. Asymptomatic, subclinical RA-associated ILD (RA-ILD) may represent a more treatable precursor to end stage fibrotic lung disease. The objective of this study was therefore to define peripheral blood protein signatures capable of identifying subclinical RA-ILD.

Methods: We analyzed the serum concentration of 37 cytokines, chemokines, and remodeling proteins in 55 RA patients and 24 healthy controls recruited through the First Hospital of Xiamen University. RA patients were independently classified as RA-ILD or RA−no ILD based on the presence/absence of high resolution chest CT (HRCT) abnormalities consisting of ground glass opacification, septal thickening, traction bronchiectasis, and/or honeycombing. Levels of specific serum proteins were then correlated with disease subset as well as pulmonary function tests (percent predicted forced vital capacity (%FVC), total lung capacity (%TLC), and carbon monoxide diffusion capacity (%DLCO)) using non-parametric rank sum analysis and Spearman's correlation coefficients, respectively.

Results: Among the 55 RA patients who generally lacked symptoms of dyspnea or cough (2/55 patients presented with these pulmonary manifestations) at the time of serum assessment, 38 (69%)had HRCT evidence of ILD (RA-ILD), while 17 (31%) had no clinical or radiographic evidence of ILD (RA-no ILD). Within the RA-ILD subgroup, the predominant HRCT abnormality was ground glass opacification (55%) suggestive of nonspecific interstitial pneumonia (NSIP).

Multiplex ELISA demonstrated that concentrations of MMP7, IFNg, IP-10, and IL-2Ra were statistically higher in the sera of RA-ILD relative to RA-no ILD patients (respective means ± SEM: 1739 ± 292.3 vs. 761.5 ± 83.85 pg/ml ($p=0.0317$); 9.084 ± 1.502 vs. 4.419 ± 0.6553 pg/ml ($p=0.0474$); 204.6 ± 34.83 vs. 95.49 ± 13.75 pg/ml ($p=0.0449$); and 157.0 ± 25.16 vs. 71.55 ± 11.04 pg/ml ($p=0.0307$)). By ROC analysis, levels of MMP7, IFNg, and IL-2Ra distinguished RA-ILD from RA-no ILD with optimal sensitivities and specificities of 0.87/0.71/0.95 and 0.71/0.65/0.47, respectively. A composite index based on levels of MMP7, IFNg, IL-2Ra, IP-10, and TNFa further discriminated these subgroups with a sensitivity of 0.76 and a specificity of 0.94. Individual concentrations of MMP7, IFNg, IL-2Ra, and IP-10 correlated significantly with overall disease activity, effectively distinguishing individuals with RA-ILD and RA-no ILD. At the same time, MMP7, IFNg, IL-2Ra, and IP-10 concentrations were negatively correlated with %FVC, %TLC, and %DLCO.

Conclusion: In a cohort of RA patients lacking overt clinical features of pulmonary involvement, MMP7, IFNg, IL-2Ra, and IP10 emerged as serum biomarkers of radiographically defined ILD. Supporting a relationship to underlying pulmonary disease activity, serum levels of these proteins were inversely correlated with various measures of pulmonary function. However, future longitudinal studies will be required to fully assess the capacity of these serum biomarkers to predict disease progression.

Arterial Stiffness Is Associated With Abnormal Left Ventricular Geometry In Patients With Rheumatoid Arthritis. Helga Midtbø[1], Eva Gerdts[2], Inge C. Olsen[3], Tore K. Kvien[3], Einar Davidsen[1] and Anne Grete Semb[3]. [1]Haukeland University Hospital, Bergen, Norway, [2]University of Bergen, Bergen, Norway, [3]Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: Rheumatoid arthritis (RA) predisposes for increased arterial stiffness(1). In hypertension, arterial stiffness is a powerful modulator of left ventricular (LV) geometry(2). Whether this is true in patients with RA is unknown.

Methods: Echocardiography, clinical and laboratory assessment were performed in 134 RA patients without prior myocardial infarction or cardiac surgery and 102 healthy controls. Arterial stiffness was determined by echocardiography as pulse pressure/stroke volume indexed to height$^{2.04}$ (PPSVi). LV geometry was evaluated by relative wall thickness (RWT) and LV mass, and considered concentric if RWT≥0.43.

Results: The RA patients were older, more often female, had higher blood pressure (BP) and PPSVi compared to controls (all $p<0.05$). In univariate analyses, higher PPSVi was associated with having RA, LV concentric remodeling, older age, and higher systolic BP (all $p<0.001$).In multivariate linear regression analysis, having RA was not directly associated with increased arterial stiffness, when adjusted for other variables (Table).

Table. Covariates of arterial stiffness in total study population (n = 236).

	Dependent variable: Arterial stiffness Multiple $R^2=0.50$	
Independent variable	**Beta**	**p-value**
Systolic BP (mmHg)	0.51	<0.001
Concentric remodeling	0.36	<0.001
Age (years)	0.07	0.234
Female gender	−0.03	0.609
RA	0.01	0.909

Multivariate linear regression analysis. Results reported as multiple R^2 for model and standardised beta coefficients for individual variables.

Conclusion: In RA patients without established cardiovascular disease, increased arterial stiffness is mainly associated with higher systolic BP and concentric remodeling of the LV, pointing to the importance of BP control in RA patients.

Gout and RA: Not Such a Rare Coexistence After All. Christina Petsch, Elizabeth Araujo, Matthias Englbrecht, Axel J. Hueber, Georg Schett, Bernhard Manger and Juergen Rech. University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: According to the current rheumatology literature, the simultaneous occurrence of rheumatoid arthritis (RA) and gout is rare and only a few cases have been reported to date (1). However, clinical practice suggests otherwise. The goal of this study was to investigate the coexistence of RA and gout in patients with known RA and identify prognostic factors that could lead to the development of gout in these patients.

Methods: Patients who fulfilled ACR criteria for RA and had a serum uric acid (SUA) level above 6 mg/dl were included. The presence of uric acid deposits in joints was confirmed by means of a dual energy computed tomography (DECT). DECT is a new imaging tool which uses x-ray beams of two different energies to differentiate monosodium urate (MSU) deposits from connective tissues and from calcium containing structures by their absorption properties (2). The following baseline parameters were assessed: gender, age, BMI, duration of disease, DAS 28, current RA therapy, use of medications that interfere with SUA, ESR, CRP, SUA and presence of metabolic syndrome. DECT of patients' feet was performed.

Results: 100 patients (45 females, 55 males) were recruited. 55 patients were seropositive and 45 seronegative. Mean ± SD age was 63.05 ±11.15 years, mean ± SD duration of disease was 8.76 ± 11.15 years, mean ± SD DAS 28 was 3,28 ±1,58. DECT was positive in 16.3% of all scanned patients (9% in seropositive and 24% in seronegative patients). Regarding those, the mean ± SD SUA level was 7,82 ±2,18 mg/dl, mean ± SD age was 63.44 ± 11.71 years, and mean ±SD BMI was 28.06 ±3.45. 88% were male, 20% had a metabolic syndrome and 69% were taking medications that could elevate SUA. According to a logistic regression model analysis, the following parameters showed significance for the presence of uric acid deposits: male gender (Wald x^2 = 3.897, Exp B = 5.678, 95% CI = 1.013–31.844, p=0.048) and seronegativity (Wald x^2 = 4.973, Exp B = 0.171, 95% CI = 0.036–0.807, p=0.026). Interestingly, SUA was not statistically significant.

Conclusion: Our study showed that a considerable number of patients with a diagnosis of RA and elevated SUA level present MSU deposits in typical locations. Male gender and seronegative status are independent variables related to positive findings. Based on this study it is always necessary to think of gout as an additional diagnosis in patients with RA and hyperuricemia.

Cardiovascular Case Fatality In Rheumatoid Arthritis Is Decreasing; Results From a Current Low Disease Activity Rheumatoid Arthritis Cohort and Review Of The Literature. Inger L. Meek[1], Harald E. Vonkeman[2] and Mart A.F.J. van de Laar[2]. [1]Rheumatology Center Twente, Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [2]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) morbidity and mortality. Previous studies, found increased case fatality after myocardial infarction and more frequent sudden death in RA patients compared to non-RA subjects. Trends in case fatality rate in RA after the introduction of potent anti-inflammatory biologic therapies and treat-to-target treatment strategies aiming at remission are not known. The objective of this study was to examine the case fatality rate in current low disease activity RA associated cardiovascular (CV) disease, and to evaluate trends in RA associated CV case fatality over time.

Methods: Prospective study to determine the incidence of fatal and nonfatal CV events in 480 RA patients included in the ACT-CVD cohort between February 2009 and December 2011. Patients with prior CV disease were excluded. Cox regression analysis was performed to determine CV event risk and contributing risk factors over time. The results of the cohort analysis were put into the context of a review of the literature to evaluate trends in RA associated CV fatality rate over time.

Results: The study included 480 RA patients, 72.3% female with a median disease duration of 4.2 years, 72.1% being in clinical remission (Disease Activity Score in 28 joints). During a mean follow up of 2.9 years 29 patients (6%, 21/1000 person years) experienced a first CV event, 2 fatal and 27 non-fatal, corresponding to a 6.9 % case fatality rate. Comparison with previous studies in cohorts with successive enrolment periods showed stable high CV event rates in RA cohorts with enrollment between 1955 and 2011, however CV case fatality in these RA cohorts decreased from 52.9% in 1998 to 6.9% in our study.

Conclusion: CV case fatality in current low disease activity RA is importantly lower than in previous studies. Composite CV event rates remain high, but a trend towards decreasing CV fatality in RA is observed.

Association Between Anti-Cyclic Citrullinated Peptide Antibodies Titres and The Presence and Severity Of Diffuse Interstitial Lung Disease Secondary To Rheumatoid Arthritis. Juan Manuel Ponce-Guarneros[1], Alberto Daniel Rocha Muñoz[2], Jorge Ivan Gámez Nava[3], Soraya Amalí Zavaleta Muñíz[4], Miriam Lizette Díaz Toscano[5], Mario Salazar Paramo[6], Liliana Faviola De La Cerda Trujillo[7], Norma Guadalupe González Montoya[3], Ernesto German Cardona Muñoz[8], Monica Vazquez del Mercado[9] and Laura González López[2]. [1]Hospital General Regional 110, Instituto Mexicano del Seguro Social. Guadalajara., Guadalajara, Jalisco, Mexico, [2]Departamento de Medicina Interna-Reumatología, Hospital General Regional 110, Instituto Mexicano del Seguro Social., Guadalajara, Jalisco, Mexico, [3]Unidad de Investigación en Epidemiología Clínica, Hospital de Especialidades Centro Médico Nacional de Occidente., Guadalajara, Jalisco, Mexico, [4]Universidad de Guadalajara, Guadalajara, Jalisco, México, Mexico, [5]Doctorado en Farmacología, Centro Universitario de Ciencias de la Salud, Guadalajara, Jalisco, Mexico, [6]Instituto Mexicano Del SS, Guadalajara, Mexico, [7]Unidad de Investigación en Epidemiología Clínica del Hospital de Especialidades Centro Médico Nacional de Occidente, IMSS, Guadalajara, Jalisco, Mexico, [8]Departamento de Fisiología, Universidad de Guadalajara, Guadalajara, México, Guadalajara, Jalisco, Mexico, [9]Universidad de Guadalajara, Guadalajara, Mexico.

Background/Purpose: To evaluate the association between anti-cyclic citrullinated peptide antibody titres (anti-CCP) and other clinical factors with the presence and severity of Interstitial Lung Disease in patients with Rheumatoid Arthritis (ILD-RA).

Methods: A total of 81 RA patients were included in a cross-sectional study. Forty-one patients with ILD-RA were compared with 40 Rheumatoid Arthritis without pulmonary involvement (RA w/out). ILD was screened with pulmonary function tests (PFT) and diagnosed by definite findings in the high-resolution computed tomography (HRCT). Clinical impact of ILD was evaluated with PFP, six-minute walk test (6MWT); Borg scale, Saint George's respiratory scale (SGRQ), and severity of ILD according to the HRCT score. Serum anti-CCP levels were measured by ELISA. Multivariate logistic regression was conducted to identify independent risk factors for ILD-RA.

Results: There was no difference in the frequency of smoking history between the group ILD-RA compared with the group of RA w/out (23.1% vs. 31.0% respectively, p = 0.46). The group of ILD-RA has higher score of DAS28 compared with RA w/out (3.59 ± 1.09 vs. 2.77 ± 0.84 respectively, p <0.001), HAQ-Di, (0.90 ± 0.52 vs. 0.58 ± 0.45 respectively, p < 0.05) and higher frequency of positive anti-CCP (100% vs. 64.3%, p < 0.001). Anti-CCP titres correlated with severity of dyspnea (r=0.535, p <0.001), SGRQ symptoms (r = 0.547, p <0.001), SGRQ activity (r = 0.616, p <0.001), SGRQ impact (r = 0.523, p <0.001), HCRT alveolar score (r =

0.695, p <0.001), HCRT interstitial score (r = 0.547, p <0.001) and HCRT total score (r = 0.549, p <0.001). In the multivariate analysis, after adjusting by age, disease duration, smoking status and disease activity anti-CCP titres remained as a risk factor (OR, 1.06; 95%CI, 1.02–1.10; p= 0.001) as well as duration of treatment with methotrexate (OR, 2.82; 95%CI, 1.51–5.29 p = 0.001).

Conclusion: High anti-CCP titers are associated with the severity of the ILD secondary to RA. Follow-up studies are required to identify if patients with higher titers of this antibody are associated with a poor outcome in patients suffering ILD-RA.

Comorbidity In Early Rheumatoid Arthritis.Does Inflammation Matter? Lena Innala[1], Clara Sjöberg[1], Ewa H. Berglin[1], Anna Södergren[1], Bozena Möller[2], Solbritt M. Rantapaa-Dahlqvist[3] and Solveig Wållberg-Jonsson[1]. [1]Institution of Public health and clinical medicine/Rheumatology, University of Umeå, Umeå, Sweden, [2]Department of Rheumatology, Sunderby Hospital, Luleå, Sweden, [3]Institution of Public health and clinical medicine/Rheumatology, University of Umeå, Umeå, Sweden, Umea, Sweden.

Background/Purpose: Patients with rheumatoid arthritis (RA) suffer from comorbidities that contribute to a shortened lifespan. The degree of inflammation is of importance for the development of cardiovascular disease, but little is known on its relationship with other comorbidities in RA. In the present prospective study we examined the prevalence of comorbidities in early RA and the role of inflammation in this context.

Methods: All patients with early RA (symptom duration <12 months) in Northern Sweden are since 1995 included in a study on co-morbidities. By now 950 patients have been included. At the time of this compilation, 715 patients were followed-up of whom 498 had been ill for ≥ 5 years. Data on comorbidities, disease activity, x-ray (hands, feet) and laboratory samples (autoantibodies, inflammatory variables) and pharmacological therapy were collected in record studies and validated using a survey at RA onset (T0) and after 5 years of disease (T5).

Results: 56% had one or more comorbidities at RA onset. After 5 years, 44% developed at least one new comorbidity. At T0, the most common comorbidities were: hypertension (26.7%), obstructive pulmonary disease (13.4%), diabetes (7.1%), hypothyroidism (7.0%) and malignancy (5.2%). At T5, the most common new comorbidities during the first five years of RA were: hypertension (14.3%), malignancy (7.6%), stroke/TIA (5.0%), myocardial infarction (4.8%) and osteoporosis (4.4%). Univariate regression analyses showed that age (p< 0.001), ESR (p< 0.01), extra-articular RA, Larsen score and corticosteroids (p<0.05 for all) were associated with a new comorbidity during 5 years. Female gender and biologics reduced the risk of comorbidity (p<0, 05 for both). In a regression model adjusted for sex, age, corticosteroid treatment and smoking, extra- articular RA was associated with new endocrine disease during 5 years. In another model, adjusted for age, sex and smoking, AUC for DAS28 (24 months) was associated with lung disease ever.

Conclusion: There is substantial comorbidity among RA patients already at disease onset and considerable new comorbidity during the first five years of disease. Measures of disease activity were associated with occurrence of comorbidity.

Rheumatoid Arthritis-Associated Interstitial Lung Disease: Lung Inflammation Evaluated With High Resolution Computed Tomography Scan Is Correlated To Rheumatoid Arthritis Disease Activity. Jorge Rojas-Serrano[1], Renzo Perez-Dorame[2], Heidegger Mateos-Toledo[2] and Mayra Mejia[3]. [1]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico, [2]Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico, [3]Instituto Nacional de Enfermedades Respiratorias Dr. Ismael Cosío Villegas. México DF., México, D.F., Mexico.

Background/Purpose: To describe the association between rheumatoid arthritis disease activity (RA) and interstitial lung damage (inflammation and fibrosis), in a cohort of rheumatoid arthritis-associated interstitial lung disease (RA-ILD) patients.

Methods: A retrospective study of RA patients with interstitial lung disease (restrictive pattern in lung function tests and evidence of interstitial lung disease in high resolution computed tomography (HRCT)). Patients had a complete evaluation to exclude other causes of pulmonary disease. RA disease activity was measured with the CDAI index. Interstitial lung inflammation and fibrosis were determined by Kazerooni scale. We compared Kazerooni ground-glass score with the nearest CDAI score to HRCT date scan. In 18 patients, a bronchoalveolar lavage (BAL) cell profile (lymphocytes cell count, neutrophils cell count and macrophages cell count) was available and was correlated with the nearest CDAI index. In nine patients, we compared the first ground-glass score with a second one after treatment with DMARs and corticosteroids. Spearman's rank correlation coefficient was used to evaluate the association between RA disease activity with the Kazerooni ground-glass and fibrosis scores, and with the BAL cell profiles.

Results: Thirty-four patients were included. A positive correlation between CDAI and ground-glass scores was found (r_s= 0.3767 (P < 0.028). Fibrosis and CDAI scores were not associated (r_s= −0.0747, p < 0.6745). In the 18 patients with BAL lavage, lymphocytes cell count correlated strongly with the CDAI index (r_s= 0.58, p < 0.011). After treatment, a tendency to lowering in ground-glass score was observed (median [IQR]): (2.33 [2–3] vs. 2 [1.33–2.16]), p<0.056, along with lowering in CDAI score (27 [8–43] vs. 9 [5–12]), p<0.063.

Conclusion: there is a correlation between RA disease activity and ground glass in HRCT in RA-ILD patients. Lymphocytic BAL in RA seems to correlate with disease activity. Ground glass may respond to treatment.

Correlation of Carotid Intima Media Thickness With Interleukin-6, Tumor Necrosis Factor-α and Anti-Cyclic Citrullinated Peptides In Rheumatoid Arthritis. Lourdes Nuñez Atahualpa[1], Mauricio Figuroa Sanchez[1], Daniel Alberto Rocha Muñoz[2], Raul Vargas Ramirez[3], Beatriz Teresita Martin Marquez[4], Jorge Ivan Gamez Nava[5], Laura González López[6], Erika Martínez García[3], Esther Sanchez Corona[3], Marcelo Petri[4], Rosa Navarro Hernandez[3], Veronica Gonzalez Diaz[1], Jorge Aguilar Arreola[7], Ana Guisllaine Bernard Medina[1], Alejandra Nuñez Atahualpa[8], Javier Andrade Garduño[8], Eduardo Gomez Bañuelos[3] and Monica Vazquez Del Mercado[7]. [1]Hospital Civil Fray Antonio Alcalde, Guadalajara, Mexico, [2]Unidad de Investigación en Epidemiología Clínica del Hospital de Especialidades Centro Médico Nacional de Occidente, IMSS, Guadalajara, Jalisco, Mexico, [3]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Guadalajara, Mexico, [4]Universidad de Guadalajara, Guadalajara, Mexico, [5]Unidad de Investigación en Epidemiología Clínica, Hospital de Especialidades Centro Médico Nacional de Occidente., Guadalajara, Jalisco, Mexico, [6]Departamento de Medicina Interna-Reumatología, Hospital General Regional 110, Instituto Mexicano del Seguro Social., Guadalajara, Jalisco, Mexico, [7]Hospital Civil Dr Juan I Menchaca, Guadalajara, Mexico, [8]Universidad Autónoma de Guadalajara, Guadalajara, Mexico.

Background/Purpose: The main cause of death in rheumatoid arthritis patients are cardiovascular events which cannot be entirely explained by traditional risk factors, suggesting, that systemic inflammation may accelerate them.Anti-cyclic citrullinated peptides (Anti-CCP) antibodies are well known as predictors and markers of clinical activity in RA. Cytokines play an important role in RA. It has been shown that carotid intima media thickness (IMT) values are higher in patients positive for anti-CCP positive.

The aim of this work is to evaluate the relationship of interleukin-6 (IL-6), Tumor Necrosis Factor α (TNF-α), anti-CCP titers and carotid IMT in patients with RA evaluated by bilateral carotid ultrasound.

Methods: Cross-sectional study. The study population was recruited from 2010 to 2012 and included patients with RA of 18 years or older who met the ACR criteria (1987). For the controls we included blood donators matched by gender and by age range. The exclusion criteria for both groups were history of ischemic cardiovascular disease (CVD), hypertension, diabetes mellitus type II, thyroid disease, liver disease, renal impairment, malignancy, dyslipidemia and premature menopause. We also excluded patients treated with high doses of steroids (>10 mg/day). RA disease activity was measured by the Disease Activity Score 28 (DAS28). Carotid IMT was measured using a high-resolution B-mode ultrasound with a 12-MHz transducer. Both left and right carotid arteries were examined. All measurements were performed by a single operator. Anti-CCP and other laboratory measurements: ESR, mm/h was measured using the Winthrobe method; hs-CRP levels were calculated by the nephelometric method and expressed as milligrams per liter. Triglycerides, HDL-cholesterol and LDL-cholesterol were measured and expressed as milligrams per deciliter. Serum was obtained and stored at −70°C for determination of anti-CCP antibodies, IL-6 and TNFα by ELISA. Statistical analysis. Variables were tested for normality using the Kolmogorov-Smirnov test. Student's t-test or Mann–Whitney U-test was applied for comparison between continuous variables, as well as chi-square or Fisher's exact test for categorical variables. Multiple regression analysis was performed to assess independent associations between carotid IMT and various clinical and laboratory factors that had $p<0.2$. All data were analyzed using SPSS 8.0 software, considering a two-tailed level of $p<0.05$ statistically significant for univariate and multivariate analysis.

Results: Correlation coefficients between carotid IMT and characteristics of the evaluated groups showed a *r* and p values of 0.319 and 0.02 for age, TNF-α 0.791 and <0.001, IL-6 0.794 and <0.001, anti-CCP 0.539 and <0.001. It was also found an increased carotid IMT between blood donors and RA patients of 61.3 vs 90% (<0.001). The patients were classified as negative or positive for anti-CCP antibodies and we found an association of increased carotid IMT with higher anti-CCP titers ($p<0.001$).

Conclusion: Pro-inflammatory cytokines are highly correlated with the presence of anti-CCP antibodies and carotid IMT in RA patients.

Differential Effects of biologics On The Removal Of Amyloid Deposition Between The Kidney and Gastric Tract Of Amyloid A Amyloidosis Patients With Rheumatoid Arthritis. Hiroshi Uda, Tamaki Harada, Ayumi Matsumoto, Aya Mizumoto, Toshirou Takama and Osamu Saiki. Higashiosaka City General Hospital, Higashiosaka, Japan.

Background/Purpose: Several biologics therapy reportedly regress gastric amyloid deposition in amyloid A (AA) amyloidosis patients with rheumatoid arthritis (RA), but it is uncertain whether the biologics therapy can also reduce renal amyloid deposition or not, because it is difficult to repeat a renal biopsy in these patients. We classified renal amyloidosis into two groups, glomerular and vascular types (J. Rheumatology, 2006, 1). In patients with vascular type disease, renal involvements are limited, which enabled us to carry out a follow-up histological study. The main focus of the present study is to compare the regression of amyloid deposition in kidney before and after biologics treatment in patients with vascular type disease.

Methods: The diagnosis of AA amyloidosis was determined by Congo-red stain and anti-AA antibody of gastric biopsy specimen. At first, the RA patients with AA amyloidosis were treated with methotrexate and 5mg of prednisolone, but they did not achieve adequate responses. Subsequently, they were treated with tocilizumab or etanercept for more than three years. Gastric and renal biopsies were performed before and after biologics treatment at least three years' interval. Renal biopsies were examined only in patients with AA amyloidosis of vascular type disease because renal function does not significantly deteriorate (1).

Results: The vascular type of AA amyloid patients with RA received either etanercept or tocilizumab and the clinical symptoms and laboratory data were significantly improved and sustained for more than 3 years during treating with the biologics. Before biologics treatment, renal biopsy specimens showed amyloid deposition around the blood vessels selectively (Figure A). After biologics treatment (mean 4.5 years), however, amyloid deposition did not significantly regress, similar to those observed in the initial study (Figure B). Renal function of the patients was not also changed significantly. The results of AA deposition in kidney were also confirmed by anti-AA antibody. In the gastrointestinal tract, after treatment (mean 4.5 years) with etanercept or tocilizumab, amyloid deposition was markedly regressed (Figure D) compared to the initial study (Figure C) as reported.

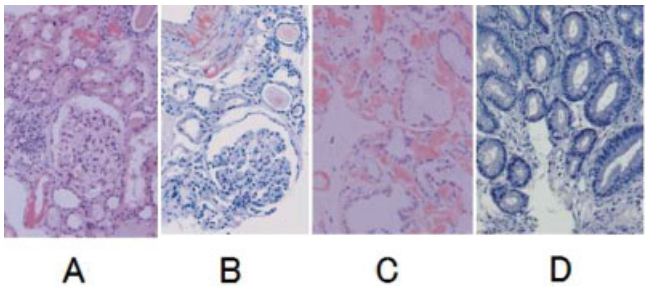

Figure. Results of renal biopsy (**A**, **B**) and gastrointestinal biopsy (**C**, **D**) before therapy (**A, C**) and after therapy (**B, D**) by etanercept. (Congo red stained; original magnification × 200.)

Conclusion: Amyloid deposition of the kidney, unlikely to the gastric tract, does not significantly regress in AA amyloidosis patients with RA by biologics therapy, suggesting that regression of amyloid deposition is differently regulated between the kidney and the gastric tract.

Clinical Characterization Of Extensive Interstitial Lung Disease In Rheumatoid Arthritis Patients. Masaomi Yamasaki. Shin-Yokohama Yamasaki Clinic, Yokohama, Japan.

Background/Purpose: To investigate clinical characteristics of interstitial lung disease (ILD) in rheumatoid arthritis (RA) patients, and to analyze whether high resolutional CT (HRCT) can predict the outcome of ILD in RA.

Methods: 365 patients with RA were treated at our hospital and followed up at least one year. All patients were performed chest radiological examinations at the initial presentation. The HRCT findings which include (1) ground glass opacity, (2) air-space consolidation, linear opacity including (3) septal line and (4) non-septal line, (5) honeycomb lung, (6) traction bronchiectasis, (7)pleural irregularity, and (8)pleural effusion were scored as the CT scoring system. The extent of involvement of each abnormality was assessed independently for each of the three zones of each lung. The HRCT extent score was represented the sum of the score of each lung. HRCT parameters which include the extension score and the clinical features at the initial presentation were retrospectively analyzed.

Results: 177 out of 355 patients had abnormal chest radiological findings which included bronchiectasis, bronchitis and ILD (49.8%). 91 (26 male(39.3%), 65 female(22.4%)) out of 355 patients showed ILD at initial presentation (25.6%). 5 out of 91 patients had shortness of breath and showed a rapidly progressive ILD (5.5%). In HRCT findings, ILD in these 5 cases were widely spread at the initial presentation. The rest of 86 patients showed no progression of ILD and asymptomatic. However there were no difference in the HRCT findings which include nonseptal linear attenuation, ground-glass attenuation and air space consolidation between rapidly progressive ILD group and asymptomatic group, rapidly progressive ILD group showed more higher degree in honeycombing ($p=0.0002$) and extensive ILD ($p=0.007$). Prognosis of the rapidly progressive ILD was variable. The rapidly progressive ILD are treated with immunosuppressive agent which include high dose steroid, cyclophosphamide, azathioprine, cyclosporineA (CsA) and Mycophenolate Mofetil(MMF) for IP. 2 patients treated with CsA and one patient treated with MMF shows improving of ILD on HRCT. But in other 2 patients were resistant to these immunosuppressive agents.

Conclusion: HRCT findings focused on the extension score at the initial presentation is a useful predictor of the outcome of ILD in RA. And this study suggests that RA patients with preexisting honeycombing lung must be aware of rapidly progressive ILD.

A Multiple Cause-Of-Death Study In Rheumatoid Arthritis. Frederico A. G. Pinheiro[1], Deborah C. C. Souza[1] and Emilia I. Sato[2]. [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil.

Background/Purpose: Rheumatoid arthritis (RA) is the most common chronic inflammatory arthritis and has a high standardized mortality ratio when compared to general population. One of the possible ways to assessing mortality is to use the death certificate (DC) that is nationally available and has a broad coverage and further continuity. The evaluation of multiple cause-of-deaths provides beyond the underlying cause of death, the understanding of whole context of death, by the recognition of non-underlying causes of death, which are very important in chronic diseases. The aim of study was to evaluate the mortality profile of RA using the multiple cause-of-death method.

Methods: The DC is established according to World Health Organization recommendation and is composed by two parts: the first presents the sequence of events leading to death, with underlying cause of death stated at last line, and the second part is composed by contributing causes of death.

Death information was provided by the state public center responsible to receive the data from civil registry office. The data about the whole population were obtained from the site of public health care system. Were chosen DC which has had RA (ICD-10: all group M05, M06.1, M06.8 and M06.9) on any line of the medical certification. All DC (N=3938) age above 19 years, for the period of 1996 to 2010 on which RA was listed as an underlying (N=1091) or non-underlying (N=2847) cause of death were analyzed. The variables gender, age and cause of death were analyzed, as well as comparisons between the two sub-periods (1996 –2000 and 2006–2010). To compare the proportional mention of causes of death between the sub-periods, we used chi-square test, performed at SPSS version 20.0. We set the level of significance at $p < 0.05$.

Results: For RA as an underlying cause of death, 251 were males (M) and 840 females (F), with a ratio M/F of 1/3.3. The mean age of death was 67.12 (SD 13.32) years and the main non-underlying causes of death associated with RA were pneumonia (38.86%), septicemia (29.7%), interstitial lung disease (10.91%) and heart failure (9.17%). Comparing the sub-periods, there was an increase of infectious causes (pneumonia and septicemia) and a reduction of heart failure, while interstitial lung disease remained stable.

For RA as a non-underlying cause of death, the mean age of death was 67.92 (SD 13.03) years, with 672 males and 2175 females and a sex ratio of 1/3.2. The most common underlying causes of death were circulatory (35.16%) and respiratory system diseases (21.81%). Comparing the two sub-periods, there was a decrease in respiratory system (all group), pneumonia and cerebral infarction, but an increase in interstitial lung disease in more recent period.

There were 19 cases of tuberculosis (3 as non-underlying and 16 as underlying cause-of-death), but without any type of predominance.

Conclusion: The cardiovascular (CV) disease remains as an important cause of death in RA, justifying a judicious follow-up and treatment of CV risk factors. The infectious diseases are an increasing cause of death in RA patients, bringing the question if infection is related with the vigorous immunosuppressive treatment.

High Prevalence Of Obesity Among Early and Established Rheumatoid Arthritis. Ines Colmegna[1], Maria Celia Bazan Bardales[2], Susan J. Bartlett[2] and Carol A. Hitchon[3]. [1]McGill University Health Centre, Montreal, QC, [2]McGill University, Montreal, QC, [3]University of Manitoba, Winnipeg, MB.

Background/Purpose: Rheumatoid arthritis (RA) is characterized by early, accelerated atherosclerosis leading to increased disability, morbidity and mortality. Inflammation and traditional cardiovascular (CVD) risk factors contribute to poor outcomes, and obesity further increases risks of CVD, diabetes and disability. New sex-specific RA cutpoints for obesity have been proposed. We estimated the prevalence of obesity among Canadian RA patients using the existing and new thresholds.

Methods: Patients receiving care during 2011–13 at two university centers were included. Height and weight were measured and selected demographic (age, sex, tobacco use), RA (duration, RF+, CCP+, ESR, CRP, tender + swollen joints) and patient reported outcomes (patient global, HAQ, morning stiffness) were obtained at the visit. Patients were classified according to WHO criteria and proposed new RA cutpoints, and results were compared with 2008 StatsCan data.

Results: Participants were 200 RA patients (106 from Winnipeg, 94 from Montreal) who were mostly female (76%) with a mean ± SD age of 56.9 ± 15.3 yr, median [IQR] RA duration of 5 [6] yr (29% < 2 yrs) and HAQ of .7 [IQR 1]. 83% were RF+ and 63% anti-CCP+. Groups did not differ between sites by age, sex or BMI, however, patients in Montreal were more likely to have early RA (38 vs 20%; p =.001) and less likely to have smoked (31% vs. 66%, p <.001). Women were significantly younger than men (56 ± 16 vs 61 ± 14; p=.025) and less likely to report tobacco use (47 vs. 68%; p=.023). RA duration, HAQ and BMI was similar between sexes. Using WHO, 34% of the RA patients were obese; women with RA had higher rates of obesity than men (see table). Using the proposed RA cutpoints, 55% were classified as obese, and men with RA had higher rates of obesity than women. Demographic and RA characteristics were not significantly (p>.05) different between obese and non-obese patients. Although HAQ was only weakly associated with BMI (r=.311 p< .001), obese patients had more than twice the odds of HAQ scores ≥ 1 (OR 2.3 95% CI 1.2, 4.2).

	All	Men	Women
Canadian Population (2008)	24.1%	24.3%	23.9%
Rheumatoid Arthritis			
BMI ≥ 30	34%	29%	36%
Risk Ratio (95% Confidence Interval)	1.4 (0.9–2.2)	1.2 (0.8, 1.9)	1.5 (1.0, 2.3)
Proposed RA Cutpoints			
BMI ≥ 24.7 men; 26.1 women	55%	67%	53%
Risk Ratio	2.3 (1.5, 3.4)	2.8 (1.9, 4.1)	2.2 (1.5, 3.3)

Conclusion: Our results suggest that Canadian RA patients are more likely to be obese than their peers and men appear to be at particular risk. Obesity in RA is associated with greater rates of self-reported disability. Identifying and addressing obesity among newly and established RA patients may be relevant to reduce the excess CVD-associated morbidity and mortality associated with this disease.

Disclosure: I. Colmegna, None; **M. C. Bazan Bardales**, None; **S. J. Bartlett**, None; **C. A. Hitchon**, None.

Stability Of Carotid Intima Media Thickness and No Plaque Formation In Inflammatory Arthritis Patients On Biologics Over One Year. Stephanie O. Keeling[1], Asvina Bissonauth[1], Jeff Odenbach[1], Quazi Ibrahim[2] and Michael Sean McMurtry[1]. [1]University of Alberta, Edmonton, AB, [2]EPICORE, Edmonton, AB.

Background/Purpose: Carotid intima media (cIMT) measurement is a validated surrogate measure of cardiovascular (CV) disease. Our aim was to evaluate baseline and follow-up cIMTs in a cohort of northern Alberta inflammatory arthritis (IA) biologic patients to determine if CIMT correlates with traditional CV factors, arthritis activity measures or risk scores.

Methods: CIMT's were performed on 83 IA patients at the Mazankowski Heart Institute as part of their evaluation in the "Cardiovascular Risk Reduction Clinic for Inflammatory Rheumatic Diseases" (CRRC). Univariate and multivariate logistic regression analyses evaluated associations between CV and IA risk factors and the composite outcomes (cIMT > 0.9 mm, presence of plaque or both). Change in cIMT or new plaques were evaluated with repeat cIMT at > 1 year in 13 patients.

Results: CIMTs were performed on 83 IA patients, mean age 60 (SD 12) years, female:male = 58:28. Baseline characteristics included: disease duration 18 (SD 13) years, ESR 16 (SD 16) mm/hr, CRP 6 (SD 8) mg/L, 48 RF/anti-CCP + patients, DAS28 2.92 (SD 1.46). All patients had been on at least one biologic and 59 with past prednisone. Traditional CV risk factors included: 13 current smokers, 6 diabetics, 33 patients with systolic hypertension, 31 patients with dyslipidemia (mean values (mmol/L): total cholesterol 4.80 (SD 1.01), LDL 2.69 (SD 0.78), HDL 1.50 (SD 0.49), total cholesterol/HDL 3.38 (SD 0.91), triglycerides 1.41 (SD 0.76) mmol/L. Twenty-nine patients had family history of premature CVD, 14 patients with personal history of CVD, mean Framingham 12.5% (SD 8.1), mean Framingham with

EULAR adjustment 22.0% (SD 13.4). Mean cIMT was 0.69 (SD 0.15) and 15 patients had one or more plaques. Age > 65 years old was associated with worse cIMT (> 0.9 mm) at baseline (OR 4.58 (95% CI 1.26–16.57). No significant change in cIMT or new plaque formation was seen in 13 patients with repeat cIMT at 1 year or longer. The composite score of cIMT > 0.9 & presence of plaque was associated with moderate Framingham risk score (with EULAR adjustment) (OR 18 (95% CI 1.65–196.35).

Conclusion: Stability of cIMT over time is demonstrated, suggesting possible modification of the increased cardiovascular risk in this small sample of IA patients on biologics. Associations of cIMT with the EULAR-adjusted Framingham risk score requires further study.

Changes In Body Composition On Two Different Glucocorticoid Regimens In Early RA: Experience From The Cobra-Light Trial. Nicole P.C. Konijn[1], Karin Britsemmer[2], Marieke M. ter Wee[1], Debby den Uyl[1], Birgit S. Blomjous[1], Maarten Boers[2], Dirkjan van Schaardenburg[2], Willem F. Lems[2] and Michael T Nurmohamed[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute/Reade, Amsterdam, Netherlands.

Background/Purpose: Prednisolone improves joint inflammation and disease severity in rheumatoid arthritis (RA), but is associated with multiple cardiovascular, metabolic and endocrine side effects and may negatively influence body composition (BC) [1,2]. Rheumatoid cachexia (i.e. loss of lean mass [LM] and gain in fat mass [FM]) is often observed among RA patients, with deleterious effects on morbidity and functional capacity [2]. The net effect of prednisolone on BC in active RA is unknown. The aim of this study was to determine if different dosages of prednisolone have different effects on BC in early RA patients.

Methods: In total, 164 patients with early, active RA were randomised to either COBRA therapy (prednisolone starting at 60 mg/day tapered to 7.5 mg/day in 6 weeks, methotrexate 7.5 mg/week and sulfasalazine 2 g/day; cumulative prednisolone dose at 26 weeks 2.3 g, mean dose: 12.5 mg/day; n = 81) or COBRA light therapy (prednisolone starting at 30 mg/day tapered to 7.5 mg/day in 9 weeks and methotrexate escalated to 25 mg/week in 9 weeks; cumulative prednisolone dose 1.8 g, mean dose: 9.6 mg/day) (n = 83) [3]. Of these, 40 resp. 42 had BC assessments by whole body DXA scans at baseline (BL) and after 26 weeks of treatment. These patients were similar to the other patients with respect to demographics and baseline disease severity (data not shown). Main outcomes of the trial included disease activity (DAS_{44}) and physical functioning (HAQ).

Results: Mean age was 51 years, 67 % were female, median symptom duration was 16 weeks. At baseline, median BMI was above the upper limit of normal in both groups (Table 1); 48% (COBRA) vs. 36% (COBRA light) were classified as overweight, and 15% vs. 19% as obese.

Table 1. Changes in disease activity, physical functioning and body composition parameters after 26 weeks prednisolone treatment

	COBRA group (n=40) (mean pred 12,5 mg/d)		COBRA light group (n=42) (mean pred 9,6 mg/d)	
	Week 0	*Δ after 26 weeks*	*Week 0*	*Δ after 26 weeks*
Disease Activity Score (DAS_{44})	3.87 (0.75)	−2.37 (1.17)*	3.95 (0.91)	−2.22 (1.11)*
Health Assessment Questionnaire (HAQ)	1.25 [0.75]	−0.94 [1.03]*	1.13 [1.12]	−0.57 [0.90]*
Body Weight (Total Body Mass, kg)	76.4 [15.1]	2.4 [2.8]*	72.6 [22.8]	1.3 [4.5]*
Body Mass Index (kg/m^2)	25.7 [4.5]	0.7 [1.2]*	25.1 [7.1]	0.4 [1.8]*
Fat Mass (kg)	23.4 [12.4]	1.5 [2.6]*	23.3 [15.2]	1.8 [3.3]*
- on trunk (kg)	13.0 [8.4]	1.0 [1.8]*	11.3 [10.8]	0.5 [2.4]*
- on arms & legs (kg)	10.0 [4.9]	0.7 [1.3]*	10.5 [4.8]	0.4 [1.1]*
- trunk/arms & legs (truncal distribution) FM (kg)	1.19 [0.70]	0.01 [0.13]	1.10 [0.53]	−0.01 [0.16]
- Fat Mass/Total Mass (% Body Fat)	32% [14%]	1% [3%]*	35% [13%]	1% [3%]*
Lean Mass (kg)	45.4 [10.2]	0.3 [1.6]*	43.7 [15.4]	0.1 [1.3]
- on arms & legs (kg)	20.5 [6.4]	0.2 [1.2]*	19.0 [8.7]	0.1 [0.8]

*Data are presented as mean (SD) for normally distributed variables and as median [IQR] for non-parametric variables;*significant difference between week 0 and 26 within treatment group (p<0.05);*

In both groups, DAS_{44} and HAQ decreased significantly after 26 weeks of treatment. In the COBRA group the effect on HAQ was more prominent at week 13 (data not shown). Both groups gained weight (median 1–2 kg) with slight but significant deterioration in BC parameters: increases in BMI, total FM, truncal FM, FM of arms and legs and BF%, without significant differences between treatment groups. Interestingly, in the COBRA treatment group, total LM and LM of arms and legs increased significantly, with a trend for significant difference between both groups (p=0.058 and p=0.070, resp.).

Conclusion: This study suggests a potentially negative effect of intermediate dose prednisolone treatment on body composition in RA patients, as multiple fat mass parameters indicated a more unfavourable body composition after 26 weeks. The increase of lean mass in the COBRA treatment group also suggests positive effects, possibly explained by a rapid improvement in physical functioning. Results have to be interpreted with caution as most patients were overweight, and body composition before the onset of RA was not recorded.

IIS Princesa, Madrid, Spain, [13]Hospital Universitario de Móstoles, Mostoles, Spain, [14]Institute for Musculoskeletal Health, Madrid, Spain, [15]Hospital Universitario de La Princesa, IIS Princesa, Madrid, Spain.

Background/Purpose: comorbidity in rheumatoid arthritis (RA) is very important because it might delay diagnosis and influence treatment decisions. It is usually related to complications, alters survival, outcomes and confounds analysis. Moreover, managing care for patients with several chronic conditions currently represents one of the greatest challenges to health care systems. The aim of this study was to to develop evidence based recommendations for the diagnosis and management of comorbidity in RA in daily practice

Methods: four systematic literature reviews, following the guidelines of the Cochrane Collaboration were performed by 4 evidence reviewers, a librarian and two methodologists, to identify comorbidity indexes or scales and to assess the prevalence, mortality, impact on quality of life and costs of comorbidity in RA. Evidence from other consensus, relevant publications and available clinical guidelines was also revised. Comorbidity included co-existent diseases as well as complications of RA or RA therapies. This evidence was discussed in two different meetings, summarized and recommendations were finally formulated by a task force comprising 16 expert rheumatologists and 2 methodologists. The level of evidence and strength of recommendation were classified according to the Center for Evidence Based Medicine of Oxford. The level of agreement was established through Delphi technique.

Results: the consensus covers: 1) which comorbidities and how they should be identified in clinical practice in the first and following visits (including treatments, risk factors and/or patient′s features that might interfere with RA management); 2) specific recommendations on comorbidities related and not to RA, including major adverse events of RA treatment; 3) disease prevention and health promotion (general and musculoskeletal health); 4)

when comorbidities management should be referred and/or shared with other specialities and who with: primary care, other specialists, etc.; 5) specific recommendations to assure an integral care approach for RA patients with any comorbidity: health care models for chronic inflammatory patients, early arthritis units, primary care relationships, specialized nursing care, self-management.

Conclusion:these recommendations are intended to provide rheumatologists, patients and other stakeholders with a consensus on the diagnosis and management of comorbidity in RA, in order to improve the final disease outcomes.

Assessment Of Treatment Effect Over Insulin Resistance and Adipokines In Patients With Early Rheumatoid Arthritis: A 6 Months Longitudinal Observational Study. Sara Manrique-Arija[1], José Rioja[2], Pedro Valdivielso[2], María América López-Lasanta[3], Pilar Espiño[4], Inmaculada Ureña[4], Francisco G. Jiménez-Núñez[4], Carmen M. Romero-Barco[4] and Antonio Fernández-Nebro[1]. [1]Hospital Carlos Haya. University of Malaga. IBIMA, Malaga, Spain, [2]Department of Medicine. University of Malaga, Malaga, Spain, [3]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [4]Hospital Carlos Haya. University of Malaga, Malaga, Spain.

Background/Purpose: To analyze treatment effects over insulin resistance (IR), adipokines, inflammatory cytokines and clinical and laboratory characteristics in patients with early rheumatoid arthritis (RA).

Methods: A 6 month prospective longitudinal observational cohort study. Patients with early untreated RA (disease duration <1 year) according to 2010 ACR/EULAR criteria, in follow-up by Rheumatology service of HRU Carlos Haya of Málaga(Spain) were included. After a baseline blood test, treatment for RA was initiated. At six months, another blood test was done. Exclusion criteria: Patients with Diabetes (2010 ADA Criteria) or patients in treatment with glucocorticoids or DMARDs were excluded. All subjects provided written informed consent. Outcome 1°: changes in Insulin Resistance (IR),after starting treatment for RA,estimated by the Homeostasis Model Aassesment for insulin resistance (HOMA-IR), by HOMA β, McAuley and by QUICKI index. Secondary Variables:Changes in the follow variables:Glucose, lipid profile,blood pressure, RF, antiCCP and ESR were measured. Insulin,CRP, IL6, TNFα,resistin, adiponectin, and leptin were determined in frozen serum stored at −80°C. Measurement of waist and hip circumference was performed. *Statistical analysis:* Baseline comparisons between groups were performed using Chi-square, T-test or Mann Whitney test. To analyse the changes Mc Nemar, paired sample T-Test and Wilcoxon tests were used. Multiple linear regression was carried out.

Results: A total of 103 subjects were investigated.12 were excluded (6 other types of arthritis,6 Diabetics) and finally, 91 subjects were included in the study; 46 RA and 45 healthy controls. Most of them were women (76.1% in RA). Cases and controls were similar in age, sex and BMI. Regarding baseline characteristics of patients with RA, the mean time duration of RA was 5.9 (SD± 3.5) months, and more than 70% of patients had positive RF and/or AntiCCP. CRP and ESR were higher in RA patients than in controls ($p<0,001$). In baseline evaluation no differences were found in IR estimated by different index. In multiple linear regression noted a positive correlation between HOMA IR and AR evolution time to diagnosis.After baseline evaluation, all patients were treated with DMARDs. After 6 month of follow–up, a non-significant increase in BMI was observed. The blood pressure and the metabolic characteristics, including lipid profile, fasting glucose, fasting insulin, HOMA-IR, HOMA-B, and QUICKI, remained steady. However, an improvement was observed in all variables related with activity index: hsCRP(12.3 Vs5.6), ESR(32.9(21.4)Vs 18.7(12.0), joint counts, patient's assessment of disease, DAS28(5.5(1.3)Vs3.2(1.4)), and HAQ(1.3(0.7)Vs 0.548(0.567)) with ($p<0.001$). Both cytokines and adipokines decreased after the treatment.

Conclusion: The patients with untreated early RA still do not show insulin resistant observed in patients with established RA despite having high levels of activity index a inflammatory cytokines. Lack of association in baseline evaluation between AR and IR indexes might be due to the short course of the disease but after six months of follow up, we do not find IR which could be due to inflammatory activity is controlled in most of them.

A Long Term Observation Of Rheumatoid Arthritis Who Developed Methotrexate Related Lymphoproliferative Disorders. Yukiko Kamogawa, Kyohei Nakamura, Ryu Watanabe, Tsuyoshi Shirai, Yoko Fujita, Yuko Shirota, Noriko Fukuhara, Hiroshi Fujii, Shinichiro Saito, Tomonori Ishii and Hideo Harigae. Tohoku University, Sendai, Japan.

Background/Purpose: Methotrexate (MTX) has been increasingly administered by patients with rheumatoid arthritis (RA). In rare cases, we experience development of malignant lymphoma in patients treated with MTX, resulting as methotrexate-associated lymphoproliferative disorders (MTX-LPDs). However, there are few reports about analyzing relation between lymphoma chemotherapy and RA prognosis. We tried to show how anti-tumor therapies affect the activity of RA.

Methods: We retrospectively enrolled 14 RA patients (4 males and 10 females) who had taken MTX and developed lymphoproliferative disorders in Tohoku University Hospital between 2008 and 2013. Then we analyzed the RA disease duration, period of MTX administration, histology of lymphoma including EBER-1 in situ hybridization for Epstein-Barr virus (EBV), chemotherapies, prognosis of RA and how RA was treated thereafter.

Results: The median age of patients at the time of lymphoma diagnosis was 69 years (57–83). The average period of MTX administration was 6.4 years. 7 of 13 patients were diagnosed as diffuse large B-cell lymphoma (DLBCL), 3 as MALT lymphoma (MALT), 1 as peripheral T-cell lymphoma (PTCL), 2 as Hodgkin lymphoma (HL), 1 as Follicular lymphoma (FL). EBER-1 in situ hybridization for EBV showed positive signals in tumor cells in 4 of 11 cases. After withdrawal of MTX, 2 cases of DLBCL, 1 case of PTCL, and 1 case of MALT showed spontaneous regression of tumors. The 10 patients with LPD persisted after MTX withdrawal treated with R-CHOP (n=4), R-VP+R-COP (n=1), Rituximab (n=3) or ABVD (n=2). 7 out of 14 patients presented RA relapse and treated with prednisolone (PSL), Tacrolimus, Iguratimod, Etanercept, or Tocilizumab. 6 out of 8 patients treated with Rituximab kept remission and other 2 relapsed patients showed weak RA activity, required only small amount of PSL but no DMARDs or Biologics.

Conclusion: Administration of Rituximab toward MTX-LPDs thought to have assisted to keep the RA activity low unexpectedly by suppressing auto-reactive B cells "and "non-remission" in both treatment arms. Autoantibody profiles measured before treatment were then correlated with the status "remission" and "non-remission".

Results: A previously identified diagnostic panel of six novel antigens allowed to distinguish ERA HITHARD samples from age and sex-matched healthy controls with an AUC=0.94. Comparing pre- and post-treatment samples, a small, but significant reduction (−1.3 fold) of autoantibody reactivities towards two antigens was detected in both treatment arms, even though levels were not normalized compared to healthy controls. A specific autoantibody signature was identified in a subgroup of ERA patients who achieved clinical remission after 24 weeks under ADA/MTX combination therapy. A classification biomarker panel of 5–10 autoantigens appears to be sufficient to identify RA patients who will achieve clinical remission upon ADA/MTX therapy. This panel was independent of anti-citrullinated protein antibody (ACPA) positivity. A different set of up to nine antigens was identified that could predict remission in RA patients upon PLACEBO/MTX therapy.

Conclusion: We identified autoantibody patterns in ERA patients associated with clinical response to an induction therapy and identified two independent marker panels that, if further developed into a screening test, could help to guide future treatment selection for MTX alone or a combined use of MTX/ADA.

Lean Body Mass (LBM) Distribution Negatively Impacts On Health Related Quality Of Life (HRQoL) In Patients With Rheumatoid Arthritis (RA). Rocio V. Gamboa-Cardenas[1], Manuel F. Ugarte-Gil[1], Erika Noriega[1], Mariela Medina-Chinchon[1], Francisco Zevallos-Miranda[1], J. Mariano Cucho-Venegas[1], Jose L. Alfaro-Lozano[1], Zoila Rodriguez-Bellido[2], Risto A. Perich-Campos[2], Karim E. Diaz-Deza[1] and Cesar A. Pastor-Asurza[2]. [1]Hospital Almenara, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru.

Background/Purpose: Sarcopenia is more frequent in RA patients than in general population, probably due to persistent inflammatory state. The impact of inflammatory burden seem to be higher in appendicular lean mass than in trunk lean mass, and it could be evaluated using the trunk-to-appendicular lean mass ratio. The aim of this study was to determine whether LBM distribution, in particular trunk-to-appendicular lean mass ratio, is associated with HRQoL in RA patients.

Methods: This cross-sectional study was conducted in consecutive RA patients seen in our Rheumatology Department from January 2012 to June 2013. An interview, chart review, physical examination, laboratory tests and dual energy X-ray absorptiometry (DXA) were performed. RA was defined using the ACR criteria; LBM was determined by DXA and it was analyzed as subtotal LBM (whole body excluding the head), trunk LBM, appendicular LBM and trunk to appendicular lean mass ratio. Socioeconomic status was evaluated according to Graffar′s scale. HRQoL was ascertained using the SF-36. Disease activity was ascertained using the DAS28CRP and disease damage with the Sharp van der Heidje score. Use of prednisone was recorded as current dose of prednisone. The association between HRQoL and LBM was evaluated using Pearson's correlation. Subsequently, a linear regression model was performed to evaluate the association between the SF-36 subcategories and LBM, adjusted for age, socioeconomic status, rheumatoid factor, disease duration, disease damage, disease activity and use of prednisone.

Results: Two-hundred and thirty six patients were evaluated; their average (SD) age was 57.4 (12.8) years. Disease duration was 14.0 (10.4) years; almost all patients were mestizo. 204 (87.9%) were rheumatoid factor positive. DAS28CRP was 4.0 (1.2), the Sharp van der Heidje total score was 99.5 (80.9), the current dose of prednisone was 4.7 (3.2) mg/d. Percentage of subtotal LBM was 58.2 (5.9), percentage of trunk LBM was 60.7 (6.8) and of appendicular LBM was 53.4 (6.3); trunk to appendicular lean mass ratio was 1.4 (0.1). Physical component summary (PCS) was 38.5 (16.9) and mental component summary (MCS) was 45.3 (16.6). In the univariate analysis, trunk to appendicular lean mass ratio was associated with lower PCS (Rho: −0.18); MCS (Rho: −0.21), physical function (Rho: −0.12), general health (Rho: −0.14), vitality (Rho: −0.18), social functioning (Rho: −0.17), role emotional (Rho: −0.15) and mental health (Rho: −0.15). In the adjusted model trunk to appendicular lean mass ratio was associated with PCS (standardized β: −0.17), MCS (β: −0.18), physical function (β: −0.19), general health (β: −0.17), vitality (β: −0.19), social functioning and mental health (β: −0.16); $p<0.05$ in all analyses.

Conclusion: There was a negative association between trunk to appendicular lean mass ratio and the components of HRQoL independent of age, socioeconomic status, rheumatoid factor, disease activity, joint damage, disease duration and use of steroids in our RA patients. The preservation of LBM should be part of the overall goals in the management of RA patients.

Enhanced Cardiovascular Risk Factor Screening In Rheumatoid Arthritis: Does This Have a Sustained Impact? Mark J Ponsford[1], Jennifer K. Cooney[2], Bethany Anthony[2], Fflur A. Huws[2], Lauren Evans[1], Jeanette Thom[2] and Yasmeen Ahmad[1]. [1]Peter Maddison Research Centre, Llandudno, United Kingdom, [2]School of Sport, Health and Exercise Sciences, Bangor University, George Building, Bangor, Gwynedd, LL57 2PZ, UK., Bangor, United Kingdom.

Background/Purpose: Rheumatoid Arthritis (RA) patients face a burden of cardiovascular disease (CVD) twice that of the general population. RA patients have reduced physical fitness, a risk factor for CVD not routinely measured or addressed. Enhanced risk profiling was performed in 100 RA patients between October 2010 and March 2011 combining traditional risk factors with a novel assessment of physical fitness. Patients were given written feedback on lifestyle modification, smoking cessation, where appropriate offered statin or antihypertensive medications, and invited to an 8-week aerobic training research programme. Here we examine the impact on CVD risk and fitness 2 years on.

Methods: All 100 RA patients (69 female, 31 male) were invited for reassessment between February and June 2013. Of these, 58 did not participate (3 died, 28 opted-out, 23 unable to attend, 4 not eligible). Forty-two patients returned for assessment of RA activity scores (DAS-28), CVD risk factors, anthropometric measures, 10-year Framingham and QRISK2–2013 risk score, and physical fitness using the Siconolfi Step Test. Assessments using the Health Assessment (HAQ), International Physical Activity (IPAQ) and study specific questionnaires were completed. Statistical analysis was performed in SPSS v21 and GraphPad.

Results: During the follow-up period (median 2.2 years) there were no cardiovascular events. Results are outlined in table 1. Patients found feedback on CVD risk and fitness useful in 76% cases, citing it prompted an increase in exercise for 48% and to pursue a low fat diet in 63%. Lifestyle modification occurred with smoking cessation in 4 of 7 active smokers and greater engagement with lipid-lowering and antihypertensive agents. A significant rise in physical activity was reported, however observed physical fitness decreased ($p = 0.026$) and body mass index rose ($p = 0.014$).

The QRISK2 10-year CVD risk estimate rose slightly, whereas Framingham risk scores did not significantly change. Ageing increases CVD risk, and Framingham 10-year risk at reassessment (15%) was significantly lower than that predicted by age-adjusted initial CVD risk factor data (18%). Diastolic pressures fell, and a similar trend in systolic blood pressure was seen.

Table 1. Two-Year Follow-up Data: Changes in CVD Risk, Physical Fitness and RA Status

	Initial Assessment	Reassessment	Probability (2-tailed)
Number	42	42	–
Age	62.3 ± 9.3	64.6 ± 9.3	–

Paired T-Test unless otherwise stated. †- Fisher's Exact Test, ††- Chi Squared
* - Significant at 5%, **- Significant at 1%

Conclusion: Our study showed providing patients with an assessment of CVD risk factors and physical fitness had a positive impact on smoking, uptake of risk modifying medications, and perceived physical activity and healthy diet. CVD risk increased but less than that expected with ageing. Disappointingly this was not reflected in body composition or physical fitness, and uptake of a training programme was low (19%) - even in this returning cohort. Behavioural modification such as improving physical activity is fundamental to improving cardiac risk and functional status. Further work is needed in how these changes can be introduced and maintained as pharmacological and prescriptive interventions alone are inadequate.

Disease Activity In Rheumatoid Arthritis Is Associated With Abnormal Left Ventricular Geometry. Helga Midtbø[1], Eva Gerdts[2], Inge C. Olsen[3], Tore K. Kvien[3], Einar Davidsen[1] and Anne Grete Semb[3]. [1]Haukeland University Hospital, Bergen, Norway, [2]University of Bergen, Bergen, Norway, [3]Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: Disease activity is related to risk of cardiovascular (CV) disease in rheumatoid arthritis (RA) patients[1,2]. Left ventricular (LV) geometry strongly predicts CV mortality and morbidity. Less is known about the relation between LV geometry and RA disease activity. Our objective was to study if RA or RA disease activity was associated with abnormal LV geometry measured as increased LV relative wall thickness (RWT) or LV mass.

Methods: Echocardiography, clinical and laboratory assessments were performed in 129 RA patients without prior myocardial infarction or valvular disease and 102 healthy controls. Age-adjusted RWT (LV posterior wall thickness to internal LV radius ratio) and LV mass were calculated by validated equations.

Results: The RA group was older, had higher blood pressure (BP) and included more women compared to controls (all $p<0.05$).

Among RA patients, higher RWT correlated with higher systolic BP, wall stress, and RA disease activity measured by Modified Health Assessment Questionnaire (MHAQ), Clinical Disease Activity Index (CDAI), Simple DAI (SDAI) and Disease Activity Score in 28 Joints (DAS28) in univariate analyses (all $p<0.05$). Wall stress and systolic BP were the main covariates of higher RWT in multivariate analyses both among RA patients and controls (both $p<0.001$) (Table). However, the analyses showed that among RA patients, RWT was associated with higher RA disease activity independent of gender, systolic BP and wall stress (Table). Higher LV mass was independently associated with higher systolic BP, age and body weight, male gender and lower LV ejection fraction (all $p<0.05$), but was not associated with any marker of RA disease activity (data not shown).

Table. Covariates of RWT for RA patients and controls. Multivariate linear regression analyses, results are reported as standardised beta coefficients for individual variables and multiple R^2 for models.

	RA group n=129								RA and control group n=231	
	Model with CDAI		Model with SDAI		Model with DAS 28		Model with MHAQ			
Multiple R^2 for model	0.32	<0.001	0.32	<0.001	0.30	<0.001	0.32	<0.001	0.24	<0.001
Variable	**Beta**	**P**	**Beta**	**P**	**Beta**	**P**	**Beta**	**P**	**Beta**	**P**
CDAI score	0.19	0.01								
SDAI score		0.19	0.01							
DAS 28 score					0.16	0.04				
MHAQ score							0.19	0.01		
Systolic BP (mmHg)	0.43	<0.001	0.43	<0.001	0.44	<0.001	0.44	<0.001	0.32	<0.001
Wall stress (dynes/cm^2)	−0.55	<0.001	−0.54	<0.001	−0.54	<0.001	−0.54	<0.001	−0.44	<0.001
Female gender	0.00	0.99	0.01	0.88	0.02	0.78	0.04	0.64	−0.04	0.55
Anti-hypertensive medication									0.20	<0.01
RA									−0.09	0.21

Conclusion: Abnormal LV geometry was independently associated with markers of increased disease activity in RA, pointing to the importance of disease activity control in RA patients.

Serological Biomarkers For The Development Of Rheumatoid Arthritis Related Interstitial Lung Disease. Elena Nikiphorou[1], Esther Chan[2], Vadivelu Saravanan[2], Julie Dawson[3], Navtej Sathi[4], Felix Woodhead[5], Mohamed Nisar[6], Subhashini Arthanari[6], Yasmeen Ahmad[7], Adam Young[8] and Clive Kelly[2]. [1]ERAS, St Albans City Hospital & University College London (UCL), London, United Kingdom, [2]Queen Elizabeth Hospital, Gateshead, United Kingdom, [3]St Helens Hospital, St Helens, United Kingdom, [4]Wrightington Hospital, Wigan, United Kingdom, [5]University Hospitals Coventry and Warwickshire, Coventry, United Kingdom, [6]Burton Hospital, Burton-on-Trent, United Kingdom, [7]Peter Maddison Research Centre, Bangor, United Kingdom, [8]St Albans City Hospital, St Albans, United Kingdom.

Background/Purpose: Interstitial Lung Disease (ILD) is the commonest manifestation of lung disease in Rheumatoid Arthritis (RA) and the only complication reported to be increasing in prevalence, accounting for 6% of all RA deaths. High resolution computed tomography (HRCT) confirmed 25% of RA patients had radiological evidence of ILD. This study examines predictive factors for RA-ILD in a large multi centre UK cohort.

Methods: Data from 14 UK centres was collected using a standard form for patients with both RA and ILD diagnosed over a 25 year period (1987–2012). Analysis included gender, age, duration of both RA and ILD, smoking history, rheumatoid factor (RF) and cyclic citrullinated peptide (CCP) antibody status. Results were compared to age and gender matched RA patients with neither clinical nor radiological evidence of lung disease.

Results: A total of 230 patients with proven RA-ILD were identified: 110 male patients (48%), median (range) age at diagnosis of RA-ILD was 64 (42–83) years, no significant difference between males and females. Articular disease predated ILD in 191 patients (82%), lung disease predated RA in 22 (10%) and synchronous in 17 (7%). The median (range) duration of RA at the time of diagnosis of ILD was 9 (0–31) years. Median age at diagnosis of RA was 56 (23–76) years. 154 patients (67%) were past (121) or present (33) smokers, with a median (range) of 26 (5–88) pack years. Smoking was significantly more frequent among males (75%) than females (60%), odds ratio 1.95 (95%CI 1.11–3.43).The median number of pack years was greater in males (35) than females (20) [p=0.01]. Smoking was less prevalent among RA controls (60%) and median pack year consumption was lower at 21 (5–60) [p=0.03].Although CCP was only available in a subset of RA-ILD patients (n=100), CCP antibody titres were significantly higher in patients with RA-ILD. The table shows univariate analysis (odds ratios & 95% confidence intervals) and multivariate logistic regression (LR) with & without anti-CCP.

	Univariate Analysis		LR without CCP		LR model with CCP	
	OR	95% CI	OR	sig	OR	sig
Sex	1.67	1.2–2.2	.63	.006	.75	.284
Age	2.14	1.4–3.1	.61	.031	.49	.062
RF	2.81	1.8–4.1	.27	.000	.36	.008
Smoker	1.91	1.3–2.7	.62	.011	.72	.279
ACCP	4.00	2.0–7.8			.33	.003

Conclusion: This is the largest and longest multicentre study of factors associated with RA-ILD in the UK. RF and anti-CCP antibodies were both strongly associated with RA-ILD, and may predate articular disease, especially in smokers, with anti-CCP an important and easily measured risk factor for RA-ILD. As smoking is both more prevalent and heavier in males, it may contribute to the increased frequency of RA-ILD in men. As lung abnormalities may also develop before articular symptoms occur, tobacco smoking may precipitate site specific citrullination in the lungs leading to the generation of anti CCP antibodies in early RA. This may alter enzyme expression in the lungs and trigger an abnormal response in genetically susceptible individuals. This suggests a causal role for B cell activation, possibly induced by smoking, in the development of RA-ILD in some patients. A detailed smoking history and titres of anti-CCP antibody should therefore be documented in all RA patients.

2-Year Results From The Ample (Abatacept versus Adalimumab Comparison in Biologic-Naïve RA Patients with Background Methotrexate) Trial: Changes In Patient-Reported Outcomes In Response To Subcutaneous Abatacept Or Adalimumab In Rheumatoid Arthritis. R Fleischmann[1], ME Weinblatt[2], M Schiff[3], D Khanna[4], MA Maldonado[5], A Nadkarni[5] and D E Furst[6]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [3]University of Colorado, Denver, CO, [4]University of Michigan, Ann Arbor, MI, [5]Bristol-Myers Squibb, Princeton, NJ, [6]University of California at Los Angeles, Los Angeles, CA.

Background/Purpose: RA is a debilitating disease that can impact health-related quality of life (HRQoL) through impairment of activity, loss of independence and reduced work productivity. Year 1 data from the 2-year head-to-head AMPLE study showed comparable improvements in HRQoL and similar onset of response with subcutaneous abatacept and adalimumab on background MTX for multiple patient-reported outcomes (PROs).[1] Longer term data are important to assess maintenance of response over time. Here, we present PRO data from 2 years of the AMPLE study.

Methods: AMPLE is a Phase IIIb, randomized, investigator-blinded study. Biologic-naïve patients with RA and an inadequate response to MTX were randomized to 125 mg abatacept weekly or 40 mg adalimumab bi-weekly, with background MTX. Pain, fatigue, and patient global assessment (PtGA) were measured by 100 mm visual analog scales. Physical function was evaluated using the Health Assessment Questionnaire-Disability Index (HAQ-DI). HRQoL was assessed using the Short Form-36 (SF-36; including Physical and Mental Component Summary subscores [PCS and MCS]). The Activity Limitation Questionnaire (ALQ) measured the number of days patients were unable to perform usual activities during the past 30 days. Psychosocial independence was assessed using the ALQ plus the Role Emotional, Social Functioning and Role Physical subscale items from the SF-36 survey. Physical independence was evaluated using 15 items from the HAQ-DI. The Work Productivity and Activity Impairment questionnaire assessed work productivity. Data are mean (SE) improvements from baseline, unless stated otherwise.

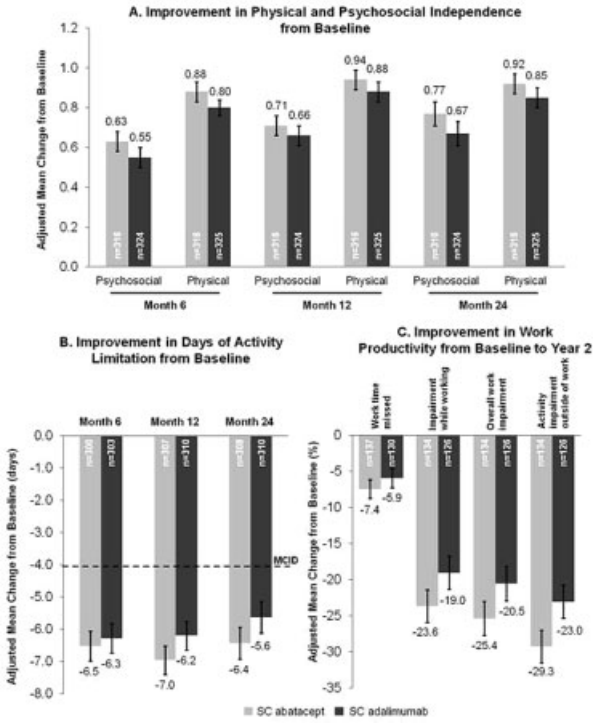

Figure. Mean change in independence, activity limitation, and work productivity over 2 years. Error bars=SE. MCID=minimal clinically important difference.

Results: 646 patients were randomized and treated with abatacept (n=318) or adalimumab (n=328) on background MTX. Baseline characteristics were balanced between the two treatment arms. A similar proportion of abatacept- and adalimumab-treated patients (54.1% and 48.8%, respectively) achieved a HAQ-DI response (improvement of ≥0.3 units from baseline) at 2 years. Improvements [% (SD)] in PtGA at 2 years were 43.5 (3.7) vs 40.6 (3.6)% for abatacept and adalimumab, respectively. Improvements in all domains of the SF-36 observed at 1 year were maintained at 2 years (PCS: 9.3 [0.6] vs 8.6 [0.6]%; MCS: 4.1 [0.6] vs 3.3 [0.6]%, abatacept vs adalimumab at Year 2). Comparable improvements in activity limitation, independence, and work productivity were observed between the two treatments (Figure).

Conclusion: Year 2 data from this head-to-head study show that the improvements in PROs, including productivity and independence, with both SC abatacept plus MTX and adalimumab plus MTX observed at Year 1 are maintained up to Year 2, with similar onset and durability of response.

Efficacy, Pharmacokinetics, and Safety of Different Doses of Methotrexate in Combination With Adalimumab: Results From the Concerto Trial. Gerd R. Burmester[1], Alan J. Kivitz[2], Hartmut Kupper[3], Udayasankar Arulmani[4], Stefan Florentinus[5], Sandra Goss[4], Suchitrita S. Rathmann[4] and Roy Fleischmann[6]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie, Rungis, France, [6]University of Texas Southwestern Medical Center, Dallas, TX.

Background/Purpose: Anti-TNF plus methotrexate (MTX) is more effective than either as monotherapy. Thus far, no controlled data are available on the benefit:risk of different doses of MTX in combination with anti-TNF. The purpose of this study was to determine the effect of MTX dose in combination with adalimumab (ADA) on efficacy, pharmacokinetics, and safety in patients (pts) with early rheumatoid arthritis (RA).

Methods: CONCERTO was a 26-week (wk), double-blind, parallel-arm trial in MTX and biologic-naive pts with active RA [DAS28(CRP) ≥3.2; CRP ≥1.5 mg/dL or ESR ≥28 mm/hr; ≥1 erosion or RF+ or ACPA+] of <1 year duration. Pts were randomized 1:1:1:1 to wkly oral MTX (2.5, 5, 10, or 20 mg) and received open-label (OL) ADA 40 mg every other wk (eow). Pts in the 20 mg arm began 10 mg and escalated 2.5 mg eow to 20 mg. The primary endpoint was the achievement of low disease activity [LDA, defined as DAS28(CRP) <3.2] at wk 26. Secondary endpoints included DAS28(CRP) (<2.6), ACR50/70/90, SDAI (≤3.3)/CDAI (≤2.8) remission, radiographic nonprogression (ΔmTSS ≤0.5), and ΔHAQ-DI ≤-0.22 at wk 26. Dose-response was assessed via Cochran-Armitage linear trend test. Non-responder imputation was used for missing data. Serum samples for pharmacokinetics were collected prior to baseline and at all study visits. Safety was assessed in terms of adverse events (AEs) for all pts who received ≥1 dose of study drug.

Results: Of the 395 randomized pts, 358 (83, 93, 93, and 89 from the 2.5, 5, 10, and 20 mg arms, respectively) completed 26 wks. At wk 26, there was a statistically significant trend in the proportion of pts achieving DAS28(CRP) <3.2 with increasing dose of MTX in combination with OL ADA (**Table**). Significant trends were noted as early as wk 12 and sustained through wk 26. Similar results were observed for ACR50/70/90 and DAS28(CRP) < 2.6, SDAI/CDAI remission. Numerically increasing trends were also apparent in the proportions achieving radiographic nonprogression and ΔHAQ-DI ≤-0.22 at wk 26. Clinical and radiographic outcomes generally appeared comparable between the 10 and 20 mg arms. ADA serum concentrations were similar in the 10 and 20 mg MTX arms, with slightly lower mean ADA serum concentrations in the 2.5 and 5 mg arms. AEs were consistent with the known profile of anti-TNF and were generally consistent between arms, occurring most frequently in the 20 mg arm.

Parameter[a]	2.5 mg MTX + OL ADA	5 mg MTX + OL ADA	10 mg MTX + OL ADA	20 mg MTX + OL ADA	*P* value
DAS28(CRP) <3.2, n/N (%)	42/98 (43)	44/100 (44)	56/99 (57)	59/98 (60)	.005
DAS28(CRP) <2.6, n/N (%)	27/98 (28)	32/100 (32)	37/99 (37)	44/98 (45)	.008
SDAI ≤3.3, n/N (%)N (%)	11/98 (11)	22/100 (22)	28/99 (28)	29/98 (30)	.005
CDAI ≤2.8, n/N (%)	12/98 (12)	22/100 (22)	29/99 (29)	27/98 (28)	.02
ACR50/70/90, %	46/24/7	51/34/10	54/41/17	62/46/16	.02/.003/.04
ΔmTSS ≤0.5, n/N (%)	63/98 (64)	72/100 (72)	76/99 (77)	76/98 (78)	.06
ΔHAQ-DI ≤-0.22, n/N (%)	67/98 (68)	70/100 (70)	73/99 (74)	76/98 (78)	.12

[a]Non-responder imputation.

Conclusion: MTX and biologic-naïve pts with early RA demonstrated robust and dose-dependent clinical responses with increasing doses of MTX in combination with OL ADA through 26 wks. Interestingly, clinical responses and ADA serum concentrations generally appeared similar between the 10 and 20 mg MTX arms.

Characteristics of Protocol-Specified Responders/Non-Responders Treated With Etanercept Plus Methotrexate in Period 1 of the Prize Study. Paul Emery[1], Annette Szumski[2], Jack Bukowski[3], Eustratios Bananis[2] and Lisa Marshall[2]. [1]Institute Rheumatic and Musculoskeletal Medicine University of Leeds, Leeds, United Kingdom, [2]Pfizer Inc., Collegeville, PA, [3]Pfizer Inc, Collegeville, PA.

Background/Purpose: Although frequently effective, treatment with synthetic or biologic disease-modifying antirheumatic drugs (DMARDs) does not adequately control disease activity in all patients. Prompt identification of patients unlikely to achieve long-term therapeutic targets is a clinically relevant strategy that may allow for timely alterations in treatment and optimal outcomes. The objective of this subanalysis was to determine disease characteristics of responders and non-responders to treatment with etanercept (ETN) plus methotrexate (MTX) in patients with early, active moderate-to-severe RA participating in Period 1 of the PRIZE study.

Methods: MTX- and biologic-naïve RA patients (DAS28 >3.2; symptom onset ≤12 months from enrollment) received ETN 50 mg QW and MTX (ETN50/MTX) for 52 wk. At the investigator's discretion, the initial 10 mg/wk MTX dose was titrated to a maximum 25 mg/wk; corticosteroid boosts were administered to patients not achieving low disease activity (LDA; DAS28 ≤3.2) at week 13 and/or 26. Prior DMARD, NSAID, and corticosteroid use and disease characteristics were analyzed in responders at week 39 and 52 (defined as patients with DAS28 ≤3.2 and DAS28 <2.6, respectively) and non-responders at week 39 and 52 (defined as patients with DAS28 >3.2 and DAS28 ≥2.6, respectively, or unsatisfactory response due to efficacy [based on investigators' judgment]), as specified by the study protocol and using a last observation carried forward approach.

Results: Of 306 patients receiving ETN50/MTX in Period 1, 30 (9.8%) and 24 (7.8%) were non-responders at wk 39 and 52, respectively; 7 (2.3%) had an unsatisfactory response. Among responders (n=194) and non-responders (n=61), 33 (17.0%) and 3 (4.9%) received prior DMARDs, respectively (P=0.018); 80 (41.2%) and 22 (36.1%), prior corticosteroids (P=0.472); and 129 (66.5%) and 31 (50.8%), prior NSAIDs (P=0.027). A lower proportion of responders received corticosteroid boosts than non-responders at week 13 (29.0% v 63.9%) and week 26 (17.0% v 61.7%). DAS28, SDAI, and HAQ values were significantly higher in non-responders at baseline (P<0.01) and from weeks 2–52 (P<0.0001; Table). Significantly lower proportions of non-responders had normal HAQ (≤0.5) vs responders from week 2–52 (P<0.0001). Both responders and non-responders had improved disease activity and function with treatment over time, but non-responders had slower rates of response. Both groups appeared to achieve a steady state by week 39.

Table. Differences in disease characteristics at baseline (BL) and weeks 39 and 52 in protocol-specified responders and non-responders to ETN50/MTX at week 52 (LOCF)

Characteristic	Mean (SD)/Adjusted Mean Change (SE) Responders	Non-Responder	Mean Difference (95% CI)	P Value
DAS28 at BL	5.9 (1.1)	6.3 (1.1)		0.004
Week 39	2.0 (0.7)/−4.0 (0.06)	3.8 (1.5)/−2.3 (0.12)	−1.6 (−2.0, −1.4)	<0.0001
Week 52	1.8 (0.6)/−4.1 (0.06)	4.1 (1.4)/−2.0 (0.11)*	−2.1 (−2.3, −1.8)	<0.0001
SDAI at BL	36.4 (13.5)	41.8 (14.7)		0.008
Week 39	2.8 (2.8)/−34.5 (0.6)	15.8 (15.8)/−23.0 (1.0)	−11.5 (−13.9, −9.2)	<0.0001
Week 52	2.0 (1.9)/−35.4 (0.6)	16.6 (15.8)/−22.3 (1.0)*	−13.1 (−15.4, −10.8)	<0.0001
HAQ at BL	1.2 (0.6)	1.5 (0.7)		0.0007
Week 39	0.3 (0.4)/−0.9 (0.0)	0.9 (0.7)/−0.5 (0.1)	−0.5 (−0.6, −0.3)	<0.0001
Week 52	0.3 (0.4)/−1.0 (0.0)	0.9 (0.7)/−0.5 (0.1)*	−0.5 (−0.6, −0.4)	<0.0001
	% of Patients (95% CI)			P Value
Normal HAQ (≤0.5)				
Week 39	77.8 (16.5, 28.7)	34.4 (52.3, 77.3)		<0.0001
Week 52	81.4 (75.2, 86.7)	36.1 (50.6, 75.8)*		<0.0001

* ≥50% of patients were discontinued at week 39 and were carried forward to week 52.

Conclusion: In Period 1 of the PRIZE trial, patients with early, moderate-to-severe RA who did not meet protocol-specified response criteria after treatment with etanercept plus methotrexate showed higher levels of disease activity and greater functional disability at baseline and throughout the period, and were more likely to require corticosteroid boosts, compared with patients who satisfied response criteria.

US Veterans With Rheumatoid Arthritis Who Switch Among Tumor Necrosis Factor Blocking Agents Have No Additional Clinical Benefit With The Change In Therapy and Incur Higher Costs. Grant W. Cannon[1], Scott L. DuVall[2], Candace L. Hayden[2], Liron Caplan[3], Jeffrey R. Curtis[4], Kaleb Michaud[5], Ted R. Mikuls[6], Andreas M. Reimold[7], David H. Collier[8], George Joseph[8], David J. Harrison[8] and Brian C. Sauer[9]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]VA Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [3]Denver Veterans Affairs Medical Center, Denver, CO, [4]University of Alabama at Birmingham, Birmingham, AL, [5]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE, [6]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [7]Dallas VA and University of Texas Southwestern, Dallas, TX, [8]Amgen Inc., Thousand Oaks, CA, [9]George E. Wahlen Veteran Affairs Medical Center, Salt Lake City, UT.

Background/Purpose: While tumor necrosis factor (TNF) blockers can be effective in treating rheumatoid arthritis (RA), the benefit of switching among TNF blockers is not clear. The objective of this study was to compare clinical outcomes and costs in US veterans who switch between adalimumab (ADA), etanercept (ETN), and infliximab (INF) to patients treated with the same TNF blocker.

Methods: The Veterans Affairs Rheumatoid Arthritis (VARA) registry is a longitudinal, observational, cohort study of US veterans with RA. It links to VA pharmacy and administrative data and documents longitudinal assessments of RA disease activity and outcomes. VARA patients initiating ADA, ETN, or INF from March 2003 (the date after which all agents were available within VA) to Sept 2010 were identified and followed until Sept 2011. A treatment course was defined as continuous TNF blocker use without a ≥90-day gap in treatment. The cost of TNF blockers with associated drug administration costs was determined for the first course initiated within the VA and compared to the second course with the same or a different TNF blocker.

Results: Data from 563 RA patients (204 ADA, 290 ETN, 69 INF) initiating TNF-blocker therapy were analyzed. All groups had a similar decrease in DAS28 during their first TNF-blocker course; however, baseline DAS28 prior to treatment and during treatment was higher during the first course for patients who eventually switched TNF blocker therapy. In the 61 patients who had 2 courses of therapy with DAS28 measurements available during both courses of treatment, there were no significant differences

between mean DAS28 during the first and second TNF-blocker courses. Thus, patients who switched TNF-blocker therapies had higher DAS28 prior to and during TNF-blocker treatment compared with patients with a single TNF-blocker course or patients who had 2 courses with the same therapy interrupted by a ≥90-day gap; however, the relative change in DAS28 was the same in all groups during TNF-blocker treatment. While annualized costs were similar in all groups during the first course of therapy, these costs were significantly higher during the second course in patients who switched than for patients who restarted their initial TNF blocker ($P<0.05$).

Conclusion: In VARA patients receiving 2 courses of TNF-blocker therapy, improvements in DAS28 scores were not significantly different in patients treated with a different second agent than re-starting the initial agent. Patients who switched TNF blockers had higher DAS28 scores during the initial course and higher costs overall than patients who remained on the same TNF-blocker therapy. Because of potential confounding factors inherent in observational studies, more research is needed to understand reasons for switching and the effects of switching TNF blockers on overall outcomes in RA.

Table. Comparison of patients with a single vs a second course with and without switching

	Single course (N=264)		Second course, same TNF blocker (N=143)		Second course, different TNF blocker (N=156)	
	Mean	95% CI	Mean	95% CI	Mean	95% CI
Age at start of Rx (yrs)	63.1	61.9, 64.3	57.7	55.6, 59.8	59.0	57.5, 60.5
RA disease duration at Rx (yrs)	10.6	9.3, 11.9	10.9	9.1, 12.7	9.9	8.4, 11.3
Male sex, n (%)	234 (89)	(85, 92)	131 (92)	(88, 97)	142 (91)	(87, 96)
First TNF-Blocker Course						
Course duration (mos)	34.1	30.7, 37.5	18.1	15.4, 20.9	18.0	14.9, 21.1
Annual drug and admin costs (US $ × 1000)	13.8	13.4, 14.2	13.2	12.1, 14.3	14.2	13.4, 14.8
DAS28 before Rx	4.5	4.3, 4.7	4.6	4.3, 4.9	5.3	5.0, 5.6
DAS28 after ≥90 days on Rx	3.5	3.3, 3.7	3.5	3.3, 3.8	4.3	4.0, 4.6
Change in DAS28 on Rx	−0.9	−1.2, −0.7	−1.1	−1.5, −0.6	−0.8	−1.3, −0.4
Second TNF-Blocker Course						
Course duration (mos)	N/A	N/A	15.6	12.8, 18.5	17.7	14.9, 20.5
Annual drug and admin costs (US $ × 1000)	N/A	N/A	12.9	12.1, 13.6	15.1	13.6, 16.5
DAS28 after ≥90 days on Rx	N/A	N/A	3.4	3.1, 3.8	4.2	3.9, 4.5
Change in DAS28 1st to 2nd course	N/A	N/A	−0.2	−0.6, 0.1	−0.2	−0.6, 0.1

CI, confidence interval; Rx, treatment; DAS28, disease activity score based on 28 joints

Correlation Between Objective and Patient Self-Reported Clinical Improvement After Multiple Courses of Rituximab in Rheumatoid Arthritis Patients With Inadequate Response to Tumour Necrosis Factor Inhibitors: Data From Repeat Study. Ioan Ancuta[1], Catalin Codreanu[2], Ruxandra Ionescu[3], Magda Parvu[4], Dan Nemes[5], Rodica Chirieac[6], Paulina Ciurea[7], Maria Suta[8], Andra Balanescu[9], Eugenia Mociran[10] and Elena Rezus[11]. [1]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [2]"Dr. I. Stoia" Center for Rheumatic Diseases, Bucharest, Romania, [3]Clinic Hospital Sf. Maria, Bucharest, Romania, [4]"N.Gh. Lupu" Clinical Hospital, Bucharest, Romania, [5]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [6]C.M.I. Rodica Chirieac, Iasi, Romania, [7]Emergency County Hospital, Craiova, Romania, [8]Emergency County Hospital, Constanta, Romania, [9]University of Medicine and Pharmacy, Bucharest, Romania, [10]Emergency County Hospital Dr Constantin Opis, Maramures, Romania, [11]Recovering Clinical Hospital, Iasi, Romania.

Background/Purpose: Rituximab (RTX) has been evaluated in many clinical trials and objective assessment of rheumatoid arthritis (RA) activity must comply with Treat to Target principles. Little is known about the relationship between objective clinical outcomes and self-reported health status in RA patients treated with repeated courses of biologics over extended periods of time.

We wanted to compare evolution of clinical outcome measures and self-perceived health status in patients with severe active RA treated with multiple courses of RTX in Romania.

Methods: In this open-label, multicentre, prospective observational study, patients were treated with initial (2×1000 mg IV, at 2 weeks apart) and subsequent RTX courses. Clinical assessments including 28-joint disease activity score (DAS-28) were performed at baseline (before treatment initiation), and after each retreatment course at 6, 12, 18 and 24 months. A visual analogue scale (VAS; 0=best, 100=worst) allowed patients to report health status at each clinical assessment. Delta DAS-28 and delta VAS were calculated as difference between values found at two consecutive evaluations and tested with unpaired t-tests and Pearson correlation coefficients R^2. Linear regression models were estimated at baseline, 6, 12, 18, and 24 months with the DAS-28 as the outcome variable and the VAS as a predictor. Statistical analyses were performed with STATA SE 11.0 software.

Results: A total of 943 adult (>18 years) patients with active RA and inadequate response to at least one TNF inhibitor received initial RTX treatment. In our study, 805 (85.37%) patients had only one anti-TNF treatment and 138 (14.63%) had more than one, with a median duration of anti-TNF treatment of 21 and 47 months, respectively. Median DAS-28 and VAS scores steadily decreased after each retreatment:

Evaluation	DAS-28	VAS
1st (baseline)	5.67	50
2nd (6 months)	3.87	20
3rd (12 months)	3.38	12
4th (18 months)	2.96	10
5th (24 months)	2.80	10

Sustained, statistically significant delta DAS-28 changes ($p<0.00001$, $p<0.0005$ and $p<0.0128$) and delta VAS changes ($p<0.00001$, $p<0.0026$ and $p<0.0005$) were found at 12, 18 and 24 months, respectively. Linear regression analysis showed DAS-28 and VAS scores significantly correlated in all evaluations, with R^2Pearson correlation coefficients of 0.7291, 0.5651 (n=877), 0.3951 (n=580), 0.3169 (n=302), and 0.2754 (n=112), at baseline, 6, 12, 18, and 24 months, respectively ($p<0.0001$ in all). Taken together, our results indicate that VAS score can have predictive value for clinical outcome.

Conclusion: We found strong correlation between objective clinical outcomes and self-reported health status, with clinical response maintained or improved after each fixed interval retreatment with Rituximab, even in patients with a long history of inadequate response to TNF inhibitors. Major improvements occurred early in our study, at 6 months, and were appreciated by patients. This synergy is important for doctor-patient relationship, increased patient confidence and treatment compliance, key factors for a successful therapy.

429

Sustained Clinical Efficacy After Multiple Courses of Rituximab in Rheumatoid Arthritis Patients With Inadequate Response to Tumour Necrosis Factor Inhibitors: 2-Year Data From the Repeat (Repeated Courses in Routine Clinical Practice) Study. Catalin Codreanu[1], Ioan Ancuta[2] and Ruxandra Ionescu[3]. [1]"Dr. I. Stoia" Center for Rheumatic Diseases, Bucharest, Romania, [2]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [3]Clinic Hospital Sf. Maria, Bucharest, Romania.

Background/Purpose: In the last decade, biologic therapy changed dramatically treatment options for rheumatoid arthritis (RA). However, a significant number of patients failed to maintain the initial response to a TNF blocker. More information is needed regarding efficacy and safety of multiple courses of biologics administered over extended periods of time.

We tried to assess clinical efficacy of subsequent courses with Rituximab (RTX) in patients with moderate-severe active RA despite treatment with a TNF inhibitor in routine clinical practice in Romania.

Methods: In this open-label, multicentre, prospective observational study started in 2010, patients were treated with RTX at each 6 months. Clinical efficacy was assessed at baseline and after each retreatment course at 6, 12, 18 and 24 months. Clinical assessments included DAS-28, SDAI and CDAI. Δ DAS-28, Δ SDAI and Δ CDAI were calculated based on two consecutive evaluations. Statistical analyses: STATA SE

11.0 software, unpaired t-tests and Pearson correlation coefficients R2 in regression analysis (for Δ DAS-28, Δ SDAI and Δ CDAI) and Cuzick non-parametric trend tests across ordered groups (for disease activity state).

Results: 943 adult (>18 years) patients with active RA and inadequate response to at least one TNF inhibitor received initial RTX treatment. Median clinical disease activity scores steadily decreased after each retreatment indicating improvement in clinical response:

Evaluation	DAS-28	SDAI	CDAI
Baseline	5.67 (n=943)*	27.68 (n=935)**	26 (n=943)
6 months	3.87 (n= 877)	10.98 (n=862)	10 (n=877)
12 months	3.38 (n=580)	7.40 (n=564)	6 (n=580)
18 months	2.96 (n=302)	4.70 (n=299)	3.80 (n=302)
24 months	2.80 (n=118)	4.44 (n=116)	3 (n=118)

* Patient's number (n) decreases in time because of the enrolment timeframe and represents the number of patients who reached each evaluation (data cut-off 1st of December 2012)
** SDAI patient's number is lower as CRP was not dosed to all patients analysed

Remission rate progressively increased after each retreatment course: 10.95%, 18.79%, 35.1% and 39.83%, whereas initial percentage of patients showing high disease activity (HDA) (63.94%) steadily decreased to 16.65%, 3.62%, 1.66% and 0.85% at 6, 12, 18 and 24 months, respectively. Similar trends were observed in SDAI and CDAI scores. In SDAI, remission rate increased from 4.28% to 11.02%, 18.79%, 31.44% and 35.34%, whereas initial proportion of patients with HDA (53.48%) decreased to 9.63%, 1.67%, 1.42% and 0%. Similarly, in CDAI, remission rate increased from 4.24% to 11.4%, 20.17%, 36.75% and 37.29%, with steadily decreased HDA after each retreatment, from 58.43% to 14.25%, 2.59%, 2.32% and 0%, respectively. All Δ DAS-28, Δ SDAI and Δ CDAI changes, as well as DAS-28 vs. SDAI and DAS- 28 vs. CDAI comparisons were statistically significant ($p<0.0001$).

Conclusion: Our study showed a sustained improvement of clinical response after each retreatment course with RTX (at 6 months interval), regardless of assessment tool used (DAS28, SDAI or CDAI). Each RTX course led to an increased and cumulative clinical response versus the previous one with respect to Treat to Target principles and EULAR/ACR recommendations.

Comparing abatacept to Adalimumab, Etanercept and Infliximab As First Or Second Line Agents in Patients With Rheumatoid arthritis: Experience From the rhumadata® Clinical Database and Registry. Denis Choquette[1], Diane Sauvageau[1], Louis Bessette[2], Boulos Haraoui[1], Jean Pierre Pelletier[1], Jean-Pierre Raynauld[1], Edith Villeneuve[1] and Louis Coupal[1]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC.

Background/Purpose: The order of use of biologic agents is still a question for debate. Phase III trial data in MTX-IR patients show comparable efficacy results across biologic agents and limited head-to-head studies have been published. Prospective registries offer a unique opportunity to observe the effectiveness of these agents in a clinical setting. Our objectives are to evaluate if patients with rheumatoid arthritis (RA) treated with abatacept after failure to either a first line agent (MTX-IR) or a second line anti-TNF agents (TNF-IR) have a different drug survival rate than patients similarly treated with adalimumab, etanercept or infliximab. A secondary objective is to explore the role of MTX co-prescription.

Methods: RA patients prescribed a first biologic agent after January 1st 2007 were included in the present analysis. Two cohorts were extracted, the first included all patients prescribed their first biologic agent, abatacept (ABA), adalimumab (ADA), etanercept (ETA) or infliximab (INF); the second included all patients failing their first biologic agent and switching to a second one. Baseline demographics for both cohorts included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluation (VAS), TJC, SJC, DAS 28 ESR and SDAI. Person-years of treatment were also compared across biologic agents. Statistical analysis was performed using SAS version 9.3. RHUMADATA® is a clinical database and registry used daily in clinical practice at the IRM and the CORQ.

Results: A total of 493 patients were analysed, 339 were included in the first cohort and 154 composed the second cohort. No significant differences in baseline characteristics were noted between treatment groups. The 5 year retention rate of ABA, ADA, ETA and INF post MTX failure were 66%, 44%, 47% and 50% without significant statistical differences (Log-Rank $p=0.35$). When combining all biologics, the use of DMARDs did exhibit better drug survival than biologic monotherapy, 50% (combination therapy) vs. 33% (monotherapy). This difference however did not reach statistical significance (Log-Rank $p=0.09$). However, patients having failed a first anti-TNF agent had a better 5 years drug survival rate if treated with ABA than those treated with ADA, ETA or INF as demonstrated by rates of 47% (ABA), 28%(ADA), 27% (ETA) and 13% (INF) (Log-Rank $p=0.01$).

Conclusion: Abatacept, adalimumab, etanercept and infliximab after MTX failure have similar 5-years retention rates. Combination with methotrexate did not, however, demonstrate statistically significant improved 5-year retention. Prescribing abatacept after a previous TNF agent failure seems to offer a more favorable outcome.

Prediction Of Week 52 Treatment Response Based On A Week 12 Assessment In Rheumatoid Arthritis Patients Receiving Certolizumab Pegol: Comparison Of A Patient-Reported Instrument Versus Physician-Based Disease Activity Assessment. Jeffrey R. Curtis[1], Willem Koetse[2], Jeymi Tambiah[3], Lucian Ionescu[4] and Yusuf Yazici[5]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]UCB Pharma, Raleigh, NC, [3]UCB Pharma, Smyrna, GA, [4]UCB Pharma, Brussels, Belgium, [5]New York University Hospital for Joint Diseases, New York, NY.

Background/Purpose: Guidelines support early intervention in rheumatoid arthritis (RA).[1,2] The aim was to prospectively test whether outcome assessment at 12 weeks (wks) using a patient-reported tool (RAPID3) was comparable with investigator-based assessment (CDAI) in RA patients (pts) treated with certolizumab pegol (CZP) for predicting attainment of low disease activity (LDA) or better at Wk 52. Both scoring tools are used as clinical measures of disease activity in the absence of inflammatory laboratory markers.

Methods: In this 52-wk study (PREDICT; NCT01255761) pts received CZP standard dosing regimen (400mg at Wks 0, 2, 4 [loading dose] then 200mg Q2W). Pts were ≥18 yrs with adult onset active RA, unsatisfactory response to ≥1 DMARD and ≤2 prior TNF inhibitors. Pts were randomized 1:1 to RAPID3 or CDAI for classification as responder/non-responder at Wk12. Treatment decision at Wk12 was based upon randomization arm (RAPID3 responder, ≤6 or 20% improvement from baseline [BL]; CDAI responder, ≤10 or 20% improvement from BL). Pts who showed no improvement by Wk12 (<1 point improvement in CDAI or no improvement in RAPID3) were classified as failures and withdrawn. All other pts continued CZP 200mg Q2W unless they reached high disease activity (HDA; CDAI>22 or RAPID3>12) at 2 consecutive visits, at which point they escaped. Pts were permitted concomitant DMARDs if their regimen was unmodified between Wks 0 and 12. Long-term treatment success was defined as DAS28(ESR) ≤3.2 (LDA or better) at Wk52. Safety was monitored. The results are presented for the full analysis set (FAS; all pts who had valid BL and post-BL measurements) and both arms were adjusted for baseline DAS28(ESR) scores. Non-responder imputation (NRI) was applied.

Results: Enrolled pts (FAS; N=733) had longstanding disease (mean±SD 8.9±9.1 years), HDA (mean±SD DAS28[ESR] 6.3±1.1, RAPID3 16.1±5.6, CDAI 40.2±13) and over half (55.5%) were prior TNF inhibitor failures.

At Wk12, 64.7% (238/368) and 76.4% (279/365) of pts randomized to RAPID3 and CDAI, respectively, were classed as responders (Table 1). At

Wk52, 31.5% (75/238) of Wk12 RAPID3 responders, and 32.3% (90/279) of Wk12 CDAI responders, achieved DAS28(ESR) LDA or better (Table 1) demonstrating similar positive predictive values of these measures. No new safety signals were observed.

Table 1. Response at Wkl2, proportion of Wkl2 responders with DAS28 (ESR) LDA at Wk52, and DAS28(ESR) remission/LDA at Wk 12 and Wk52 (FAS, NRI)

Response at Wkl2	**RAPID3**	**CDAI**
N	368	365
Yes, n (%)	238 (64.7)	279 (76.4)
Difference in proportion of Wk12 responders [a]		
RAPID3 − CDAI	−0.12	
(95% CI)	(−0.18, −0.05)	
Wkl2 responders who achieved DAS28(ESR) LDA at Wk52 [b]	**RAPID3**	**CDAI**
N	238	279
Yes, n (%)	75 (31.5)	90 (32.3)
Difference in proportion of Wk12 responders [a]		
RAPID3 − CDAI	−0.01	
(95% CI)	(−0.09, 0.07)	
DAS28(ESR) Remission [c]	**RAPID3**	**CDAI**
% pts DAS28(ESR) Remission at Wk 12 (n/N)	12.8% (47/368)	15.6% (57/365)
% pts DAS28(ESR) Remission at Wk 52 (n/N)	14.9% (55/368)	17.8% (65/365)
DAS28(ESR) LDA [d]	**RAPID3**	**CDAI**
% pts DAS28(ESR) LDA at Wk 12 (n/N)	25.0% (92/368)	28.2% (103/365)
% pts DAS28(ESR) LDA at Wk 52 (n/N)	21.5% (79/368)	24.9% (91/365)

[a] The difference in proportion (RAPID3 − CDAI) was analyzed using non-parametric ANCOVA with assessment tool as factor and baseline DAS28(ESR), gender, age, prior TNF inhibitor use and duration of RA (<2 or ≥2 years) as covariates; [b] = positive predictive value; [c] DAS28(ESR) <2.6; [d] DAS28(ESR) ≤3.2.

Conclusion: In pts with chronic, severe RA the physician-based assessment detected greater CZP response at Wk12 compared with the patient-reported tool. Although the two outcome measures were not statistically comparable at Wk12, the positive predictive value for LDA at Wk52 for both assessments was similar. Further analysis is needed to evaluate the sensitivity and specificity of these measures for clinical disease activity assessments and treatment decisions in RA.

Use Of Rituximab As Second Line Biologic Agent Compared With Adalimumab, Etanercept and Infliximab In Patients With Rheumatoid Arthritis. A Report From The Rhumadata® Clinical Database and Registry. Louis Bessette[1], Denis Choquette[2], Diane Sauvageau[2], Boulos Haraoui[2], Jean Pierre Pelletier[2], Jean-Pierre Raynauld[2], Edith Villeneuve[2] and Louis Coupal[2]. [1]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC, [2]Institut de Rhumatologie de Montréal, Montreal, QC.

Background/Purpose: The order of use of biologic agents after failing a TNF inhibitor is still a question for debate. Phase III trial data in TNF-IR patients show comparable efficacy results across biologic agents and limited head-to-head studies have been published. Prospective registries offer a unique opportunity to observe the effectiveness (combined evaluation of efficacy and safety profile over time) of these agents in a clinical setting. Our objectives is to evaluate if patients with rheumatoid arthritis (RA) treated with rituximab after failing a first anti-TNF agents (TNF-IR) have a different drug retention rate than patients similarly prescribed adalimumab, etanercept or infliximab.

Methods: Data from TNF-IR RA patients prescribed adalimumab (ADA), etanercept (ETA), infliximab (INF) or rituximab (RIT) as a second biologic agent on or after January 1st 2007 was extracted. Baseline demographics included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluations (VAS), TJC, SJC, DAS 28 ESR and SDAI. Person-years of treatment were also compared across biologic agents. Five-year drug retention rates were estimated and compared using Kaplan-Meier survival estimates. Statistical analysis was performed using SAS version 9.3. RHUMADATA® is a clinical database and registry used in daily clinical practice at the IRM and CORQ.

Results: The data from 126 RA patients were extracted. No significant differences in baseline variables were observed between treatment groups. The 5 year retention rates of ADA, ETA, INF and RIT after failing second line anti-TNF agent were 28%, 27%, 13% and 66% with significant statistical differences (Log-rank $p<0.001$).

Conclusion: As a second line agent in TNF-IR patients rituximab demonstrate a better 5 year retention rate than the comparator agents.

Retrospective Analysis Of Certolizumab Pegol Use During Pregnancy: Update Of Impact On Birth Outcomes. Megan E. B. Clowse[1], Douglas C. Wolf[2], Frauke Förger[3], John J. Cush[4], Christian Stach[5], Gordana Kosutic[6], Susan Williams[6], Chidi Maduka[6] and Uma Mahadevan[7]. [1]Duke University Medical Center, Durham, NC, [2]Atlanta Gastroenterology Associates, Atlanta, GA, [3]University of Bern, Bern, Switzerland, [4]Baylor Research Institute and Baylor University Medical Center, Dallas, TX, [5]UCB Pharma, Monheim, Germany, [6]UCB Pharma, Raleigh, NC, [7]UCSF Medical Center, San Francisco, CA.

Background/Purpose: Certolizumab pegol (CZP) is a PEGylated Fc-free anti-TNF approved in 45 countries for the treatment of rheumatoid arthritis (RA) and/or Crohn's disease (CD). An earlier analysis of pregnancies reported to the UCB Pharma global safety database[1] suggested pregnancy outcomes after maternal CZP exposure are similar to those reported for the US general population (65% live births, 17% fetal losses and 18% elective terminations; data from 6,578,000 pregnancies, 1990–2008).[2] The aim was to provide an updated analysis of pregnancy outcomes after CZP exposure by including new reports and ongoing pregnancies since the last retrospective analysis.[1]

Methods: The UCB Pharma global safety database was searched retrospectively for all medically confirmed cases of pregnancy, including both clinical trial (incidental exposures as all trial protocols exclude pregnant women and those not receiving reliable contraception) and post-marketing reports, through March 28 2013. The number of live births, spontaneous miscarriages and elective terminations for neonates exposed to CZP (maternal and paternal exposure) before and during pregnancy was examined. Congenital abnormalities, neonatal deaths and maternal demographics were also investigated.

Results: As of March 28 2013, 337 pregnancies were reported: 17/337 (5.0%) occurred following paternal exposure and 320/337 (95.0%) occurred following maternal exposure to CZP. Within the 320 maternal exposure pregnancies, 234 were reported from the US and 86 from the rest of the world. The underlying maternal conditions were CD (219/320) and RA (52/320), and the majority of mothers were <35 years old (192/320). For pregnancies following maternal CZP exposure (Table 1), outcomes were unreported for 67/320 (20.9%) and known outcomes were available for 253/320 (79.1%): 191/253 (75.5%) resulted in live births, 37/253 (14.6%) in spontaneous miscarriages and 25/253 (9.9%) women had elective terminations. Within the 191 live births after maternal CZP exposure there were 3 reported cases of congenital disorder: one infant had vesicoureteric reflux, one infant was born with congenital morbus hirschsprung and club feet, and one infant had a high aortic arch with aberrant left subclavian. None of the treating physicians considered these events related to CZP administration. A single neonatal death was reported after maternal exposure in one of a set of twins delivered before 26 weeks gestation.

Table 1. Maternal demographics and pregnancy outcomes for pregnancies after maternal exposure to CZP (N=320)

	Live birth [a]	Miscarriage [a]	Elective termination [a]	Outcome unreported
All pregnancies, n (%) [b]	191 (75.5%)	37 (14.6%)	25 (9.9%)	67
Clinical trial pregnancies (n=104), n (%) [b]	56 (57.1%)	21 (21.4%)	21 (21.4%)	6
Maternal medical condition (n where known)				
Crohn's disease				
All pregnancies (n=219)	133	28	8	50
Clinical trial pregnancies (n=64)	40	14	7	3
Rheumatoid arthritis				
All pregnancies (n=52)	30	7	9	6
Clinical trial pregnancies (n=29)	12	6	8	3
Other [c]				
All pregnancies (n=14)	7	1	5	1
Clinical trial pregnancies (n=7)	1	1	5	0
Mean age of mother at conception, [d] years (SD)[e]	29.3 (5.7)	33.0 (6.5)	30.9 (7.0)	30.0 (5.6)
n (where age reported)	151	34	22	48

[a] Reported outcomes were categorized based on MedDRA 15.1 preferred terms followed by manual validation; [b] Expressed as % of pregnancies with known outcomes (N = 253); [c] Other category includes, but is not limited to, psoriatic arthritis, axial spondyloarthritis, juvenile idiopathic arthritis, unspecified colitis and psoriasis; [d] Conception date was estimated based on a combination of various available data, such as estimated delivery date and date of last menstruation, using an algorithm-based calculation; [e] Age, as reported in global drug safety database, was only reported for 255 pregnancies.

Conclusion: Updated analysis of pregnancy outcomes after exposure to CZP supported previous reports[1] suggesting no obvious/apparent impact of maternal CZP exposure on pregnancy outcomes. Additional data from large numbers of pregnant women are required to fully evaluate the safety and tolerability of CZP in pregnancy.

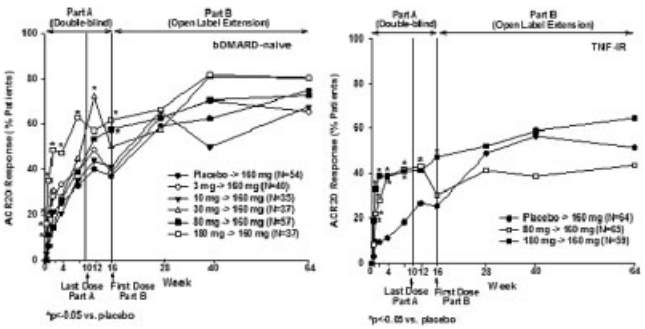
Results Of 64 Weeks Of Treatment With An Anti-IL-17 Antibody, Ixekizumab, In Patients With Rheumatoid Arthritis In a Phase 2 Study.

Mark C. Genovese[1], Hilde Carlier[2], Janelle Erickson[2], Daniel Braun[2] and Subhashis Banerjee[2]. [1]Stanford University, Palo Alto, CA, [2]Eli Lilly & Company, Indianapolis, IN.

Background/Purpose: Ixekizumab, a monoclonal antibody that neutralizes IL-17A with high affinity and specificity, has been evaluated in patients (pts) with moderate to severe rheumatoid arthritis (RA) who were naïve to biologic therapy (bDMARD-naïve) or were inadequate responders to TNF inhibitors (TNF-IR) in a Phase 2 study. The primary endpoint at 12 weeks was achieved, and significant improvements versus placebo (PB) were observed in both populations[1]. The long-term safety and efficacy after 64 weeks of ixekizumab treatment in the two populations were evaluated in an optional open-label extension (OLE) of the study.

Methods: In this randomized, double-blind study, PB or ixekizumab was administered subcutaneously (SC) to 260 bDMARD-naïve pts (ixekizumab 3, 10, 30, 80, or 180 mg) and 188 TNF-IR pts (ixekizumab 80 or 180 mg) at Weeks 0, 1, 2, 4, 6, 8, and 10 receiving concomitant conventional DMARD therapy (Part A). After a treatment hiatus between Weeks 10 to 16, 232 bDMARD-naïve and 158 TNF-IR pts elected to participate in the OLE period, receiving ixekizumab 160 mg SC at Weeks 16, 18 and 20 and then every 4 weeks (Q4W) through Week 64 (Part B).

Results: A total of 202 bDMARD-naïve (87%) and 99 TNF-IR (62%) pts completed the OLE period. ACR20 response rates observed at Week 16 were maintained or improved after switching to 160 mg Q4W through Week 64 (Figure). Similar maintenance or improvement was observed for ACR50 and ACR70 responses as well as for DAS28-CRP in both populations. Among bDMARD-naïve pts with an ACR20 (n=107), ACR50 (n=39), or ACR70 (n=13) response at Week 16, this response was maintained in 89%, 77%, and 69% pts, respectively. Among TNF-IR pts with an ACR20 (n=41), ACR50 (n=18) or ACR70 (n=11) response at Week 16, this response was maintained in 76%, 67%, and 44% pts, respectively. Similar maintenance of response was observed for EULAR responses. For pts on PB in Part A, disease activity decreased in Part B to levels comparable with pts originally assigned to ixekizumab groups in Part A. DAS28<2.6 was achieved in 23% bDMARD-naive (n=46) and 22% TNF-IR pts (n=23) after 64 weeks of ixekizumab treatment. Adverse events (AEs) occurred in 73% (n=283) pts during Part B. Most AEs were mild to moderate in severity and did not lead to study discontinuation. Serious AEs were reported in 9% (n=35) pts including 2% (n=9) cases of serious infections. No mycobacterial or systemic fungal infections were reported.



Conclusion: Clinical improvements observed with ixekizumab treatment in the double-blind phase were maintained or improved in the pts that participated in the open label extension period through Week 64. Ixekizumab was well-tolerated, and there were no unexpected safety findings observed in Part B relative to Part A.

Final 5-Year Safety and Efficacy Results Of a Phase 3, Randomized, Placebo-Controlled Trial Of Golimumab In Methotrexate-naïve Patients With Rheumatoid Arthritis.

Paul Emery[1], Roy M. Fleischmann[2], Ingrid Strusberg[3], Patrick Durez[4], Peter Nash[5], Eric Amante[6], Melvin A. Churchill[7], Won Park[8], Bernardo Pons-Estel[9], Chenglong Han[10], Timothy A. Gathany[10], Yiying Zhou[11], Stephen Xu[11] and Elizabeth C. Hsia[12]. [1]University of Leeds, Leeds Institute of Molecular Medicine and NIHR LMBRU, Leeds, United Kingdom, [2]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [3]Instituto Reumatológico Strusberg, Cordoba, Argentina, [4]Pôle de Recherche en Rhumatologie, Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain, Brussels, Belgium, [5]University of Queensland, Brisbane, Australia, [6]University of Phillipines General Hospital, Manila, Philippines, [7]Arthritis Center of Nebraska, Lincoln, NE, [8]Inha University Hospital, Incheon, South Korea, [9]Sanatorio Parque, Rosario, Argentina, [10]Janssen Global Services, LLC., Malvern, PA, [11]Janssen Research & Development, LLC., Spring House, PA, [12]Janssen Research & Development, LLC./U of Penn, Spring House/ Philadelphia, PA.

Background/Purpose: Final 5yr safety and efficacy results of subcutaneous golimumab (GLM)+/−MTX evaluated in a phase 3 trial (GO-BEFORE) of MTX-naïve pts with rheumatoid arthritis (RA) are reported.

Methods: Pts in GO-BEFORE were randomized to placebo (PBO)+MTX, GLM 100mg+PBO, GLM 50mg+MTX, or GLM 100mg+MTX q4w. PBO+MTX pts crossed over to GLM+MTX at wks 28 (blinded early escape)

or 52 (pts with ≥1 swollen/tender joint). Pts continued treatment at wk52 (start of long-term extension). After the last pt completed wk52 and unblinding occurred, PBO+MTX pts could switch to GLM 50mg+MTX, MTX and corticosteroid use could be adjusted, and a one-time GLM dose change (50–100mg or 100–50mg) was permitted at investigator's discretion. The last GLM injection was at wk252. Observed efficacy results (ACR20/50/70, DAS28-CRP, HAQ-DI, radiographic) by randomized treatment group and cumulative safety data are reported through wks 256 and 268, respectively.

Results: Of 637 randomized pts, 3 were never treated; 419 continued treatment through wk252, and 215 pts withdrew (111 for AE, 23 for lack of efficacy, 20 lost to follow-up, 53 for other reasons, 8 deaths). 402 pts completed the safety follow-up through wk268. Efficacy results are presented in the table. At wk 256, 84.3% of all pts had an ACR20, 93.9% had DAS28-CRP EULAR response, and 80.6% had improvement in HAQ-DI ≥0.25. Mean changes from baseline in total vdH-S score were small and 64% of pts randomized to GLM+MTX had no radiographic progression (DvdH-S≤0). The most common AEs were upper respiratory tract infection(29.4%), nausea(19.6%), bronchitis(16.6%), and increased alanine aminotransferase (16.1%); 11.9% of pts had an injection-site reaction. Through wk268, 204/616 (33.1%) pts had an SAE; 17.5% of pts discontinued study agent due to AEs. Overall rates of serious infections, malignancies, and death were 12.2%, 3.4%, and 1.9%, respectively. Of 595 pts with available samples, 58 (9.7%) were positive for antibodies to GLM.

Efficacy results at wk256	PBO+MTX[a,b]	GLM 100mg+PBO[b]	GLM 50mg+MTX[b]	GLM 100mg+MTX[b]	Total
ACR20	87/110 (79.1%)	89/105 (84.8%)	92/108 (85.2%)	87/98 (88.8%)	355/421 (84.3%)
ACR50	68/110 (61.8%)	68/105 (64.8%)	72/108 (66.7%)	73/98 (74.5%)	281/421 (66.7%)
ACR70	53/110 (48.2%)	47/105 (44.8%)	47/108 (43.5%)	52/98 (53.1%)	199/421 (47.3%)
DAS28-CRP EULAR Response	96/106 (90.6%)	98/103 (95.1%)	99/106 (93.4%)	94/97 (96.9%)	387/412 (93.9%)
DAS28-CRP <2.6	56/106 (52.8%)	50/103 (48.5%)	59/106 (55.7%)	60/97 (61.9%)	225/412 (54.6%)
SDAI ≤3.3	42/106(39.6%)	33/103(32.0%)	35/106(33.0%)	38/98(38.8%)	148/413(35.8%)
HAQ-DI improvement ≥0.25	90/109 (82.6%)	86/104 (82.7%)	78/106 (73.6%)	83/99 (83.8%)	337/418 (80.6%)
Radiographic results at wk256					
Estimated annual progression rate at baseline[c]	8.8 ± 20.2	8.8 ± 29.0	10.1 ± 26.2	6.8 ± 14.9	8.6 ± 23.2
Mean ± SD annual rate of progression through 5yrs[d]	0.5±1.5	0.3 ± 1.3	0.2 ± 0.8	0.1 ± 0.6	0.3 ± 1.1
Mean ± SD change in vdH-S score	2.3 ± 6.7	1.8 ± 6.8	0.7 ± 3.7	0.6 ± 2.9	1.4 ± 5.3
Change in vdH-S score ≤0	65/120 (54.2%)	64/113 (56.6%)	75/120 (62.5%)	73/112 (65.2%)	277/465 (59.6%)

[a]Pts randomized to PBO who switched to GLM at wk28 or 52.
[b]After wk52 pts could receive GLM50 mg or 100mg, and MTX could be added/adjusted.
[c]Estimated as vdH-S score divided by the disease duration per pt.
[d]Estimated as change in vdH-S score divided by GLM treatment duration per pt.

Conclusion: The retention rate was high (66.1%) through 5yrs. GLM+MTX therapy resulted in maintained improvements in signs/symptoms of RA and in physical function, and inhibited structural damage progression long-term. No new safety signals were detected through 5 years in MTX-naïve RA pts.

Efficacy and Safety Study Of a Sequential Therapy Of Tocilizumab and, If Initially Inadequately Responded To Tocilizumab, Followed By Rituximab In Patients With Rheumatoid Arthritis and Inadequate Response To Traditional Disease Modifying Anti-Rheumatic Drugs (MIRAI)-Interim Analysis 2.

Thomas Doerner[1], Hans Peter Tony[2], Hendrik Schulze-Koops[3], Jörg Kaufmann[4], Peter Kaestner[5], Herbert Kellner[6], Reiner Kurthen[7], S. Wagner[8], Marvin A. Peters[9] and Christof Iking-Konert[10]. [1]Humdoldt Univ, Berlin, Germany, [2]University of Würzburg, Würzburg, Germany, [3]University of Munich, Munich, Germany, [4]Rheumatologist, Ludwigsfelde, Germany, [5]Ambulantes Rheumazentrum Erfurt, Germany,, Erfurt, Germany, [6]Centre for Inflammatory Joint Diseases, Munich, Germany, [7]Rheumapraxis, Aachen, Germany, [8]Internistische Schwerpunktpraxis für Rheumatologie, Halle, Germany, [9]Roche Pharma AG, Grenzach-Wyhlen, Germany, [10]University Hospital Hamburg Eppendorf, Hamburg, Germany.

Background/Purpose: The MIRAI study evaluates a sequential exposure to two defined biologics under rigorous study conditions within a homogeneous population of patients (pts) who inadequately responded to traditional disease modifying anti-rheumatic drugs (DMARD-IR). This study investigates the early response to the IL-6 inhibitor tocilizumab (TCZ) in rheumatoid arthritis (RA) patients; non-responders to TCZ will subsequently receive 1 cycle of rituximab (RTX; anti-CD20 therapy).

Methods: We report the results of a 2nd interim analysis (first-pat-in: MAR-2011; last-pat-in: FEB-2013) of MIRAI (NCT01332994), an ongoing, German, multicenter, two-arm, open-label, phase-III-study in DMARD-IR pts with moderate to severe active RA, DAS28>3.2, biological naïve and on ≥1 concomitant traditional DMARD. All pts received 4 TCZ infusions (8 mg/kg, q4w; 1st treatment period) until week 16. Partial responders (ΔDAS28<1.2 or DAS28≥2.6 and ≤3.2) received further 4 TCZ infusions (8 mg/kg, q4w); non-responders (ΔDAS28<1.2 and DAS28>3.2) received a subsequent biological treatment with RTX (1g each at weeks 16 and 18). All pts with a 2nd treatment period (TCZ or RTX) will complete study at week 32. Primary endpoint: patients in remission (DAS28<2.6) at week 16. Secondary endpoints include: DAS28<2.6 at week 32, ACR response, adverse events (AE).

Results: 510 pts (ITT-Main; mean age: 56 years, females 68.2%) entered the first treatment period and received TCZ. All pts had previously received DMARDs (mostly methotrexate, 412 pts). 432 pts (85%) completed week 16, 155 pts (30%) completed week 32. At week 16, 186 pts (36%) initiated a second TCZ treatment period (ITT-TCZ2) and 24 pts (4.7%) received a subsequent RTX therapy (ITT-RTX). At week 16, efficacy parameters had improved considerably in the ITT-Main population. At week 32, further improvement was seen in all efficacy parameters under continued TCZ therapy (ITT-TCZ2); up to now, the few pts who received a subsequent RTX therapy showed slight improvements (ITT-RTX).

Parameter	Baseline	Week 16	Week 32

Data are presented "as-observed".
DAS = Disease Activity Score; HAQ-DI = Health Assessment Questionnaire-Disability Index; SD = Standard Deviation; SJC28 = Swollen Joint Count (28 joints); VAS = Visual Analogue Scale.

The total incidence of AEs/serious AEs with a suspected causal relationship to treatment is 30.4%/4.1%. SAEs suspected to be causally related to TCZ include 2 cases each of diverticulitis, pneumonia and elevated liver enzymes; 1 case each of atrial fibrillation; neutropenia plus leucopenia; thrombopenia. One death with a suspected causal relationship to TCZ was reported (fall plus craniocerebral injury). Up to now, no SAEs suspected to be causally related to RTX have been reported.

Conclusion: Early response to TCZ was demonstrated by a substantial improvement in all efficacy parameters within the first 16 weeks of treatment. Initially partial responders to TCZ benefited from a continued TCZ therapy. Notably, the proportion of TCZ non-responders who received a subsequent RTX-treatment was low.

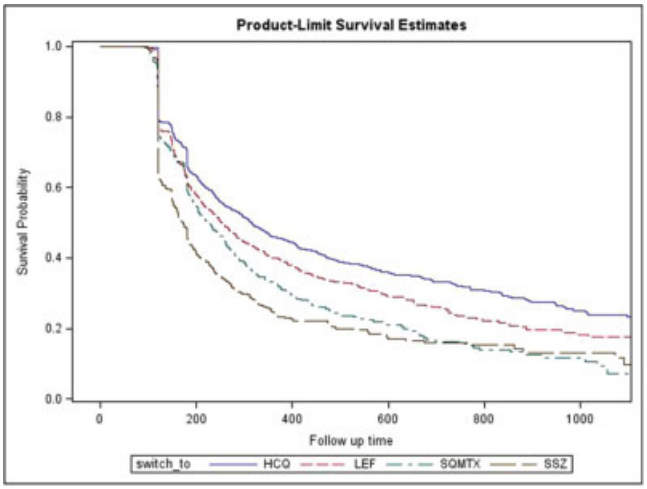
Patterns Of Use Of Oral and Subcutaneous Methotrexate Use In Rheumatoid Arthritis Patients Enrolled In The U.S. Medicare Program.

Jeffrey R. Curtis[1], Fenglong Xie[1], Jie Zhang[1], Lang Chen[1], Huifeng Yun[1], Michael H. Schiff[2], David Mackey[1] and Seth Ginsberg[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Colorado, Denver, CO, [3]Creaky Joints, New York, NY.

Background/Purpose: Although methotrexate (MTX) is the cornerstone of RA treatment, use of oral and subcutaneous (SC) preparations in real-world settings is not well characterized.

Methods: Using national data from the U.S. Medicare program 2006–2010, we identified RA patients (pts) on the basis of 2 physician diagnosis codes initiating oral MTX (no prior use ever, minimum of 6m clean period) who had no use of hydroxychloroquine (HCQ), sulfasalazine (SSZ), or leflunomide (LEF) in the previous 6 mo with no prior biologic use. During follow-up (>=1 year required), dose escalation of oral MTX and switch to SC MTX, HCQ, SSZ, and LEF were characterized. Persistence with each was examined and defined as a gap > 90 days after the end of the days' supply. Subsequent use and timing of addition of biologics was examined among those who had at least one switch, adjusting for multiple potential confounders using Cox proportional hazards models, using the switch date as the time axis.

Results: New oral MTX users (n=20406) were 76.9% women, had mean +- SD age of 69.7 + −11.7 years and contributed a median (IQR) follow-up of 2.6 (1.7, 3.5) years; 32.1% never changed dose of oral MTX and remained at their starting dose (most common dose: 7.5mg, 22%; and 10.0mg, 23%). Of all patients, only 39.4% used oral doses of >= 20mg/week at any time. At 1 year and beyond, 75.8% stayed on oral MTX (with or without dose increase) and did not add or switch to HCQ, SSZ, LEF, or SC MTX. The remainder switched or added HCQ (11.9%), SSZ (5.0%), LEF (9.3%) or switched to SC MTX (3.9%). The median (IQR) dose of oral MTX prior to switch to SC was 15.0 (12.5, 20.0) mg/wk and occurred at a median (IQR) of 292 (133,557) days. Persistence with SC MTZ, HCQ, SSZ, and LEF was similar (figure) and was lower than with oral MTX.



Overall, 19.1% of the cohort starting oral MTX initiated a biologic, mostly (84.7%) anti-TNF therapy. Of these individuals, 55.5% had never used MTX at a dose of >= 20mg prior to biologic use; 32.8% never used MTX at a dose of >= 15mg. Among pts who used biologics after a switch to SC MTX, the median (IQR) interval of time between switching to SC MTX and initiation of a biologic was 165 (66, 336) days. Among patients who increased oral MTX dose or switched to SC MTX or other nbDMARDs (n=12,652) and after multivariable adjustment, there were no significant differences in use of biologics between patients who switched to SC MTX vs. added or switched to SSZ or LEF. Pts who added HCQ were less likely to require biologics (hazard ratio 0.53, 95% CI 0.37–0.77), with some evidence suggesting that HCQ use was a proxy for less severe RA (not shown).

Conclusion: Titration to higher doses of oral MTX and use of SC MTX preparations among Medicare pts with RA is infrequent and may be underutilized. Further work to optimize MTX dosing before pts are switched to a biologic may be warranted.

Tofacitinib, An Oral Janus Kinase Inhibitor, In A Rheumatoid Arthritis Open-Label Extension Study Following Adalimumab Therapy In A Phase 3 Randomised Clinical Trial.

M. C. Genovese[1], R. F. van Vollenhoven[2], B. Wilkinson[3], L. Wang[3], S. H. Zwillich[3], D. Gruben[3], B. Benda[4] and T. V. Jones[4]. [1]Stanford University, Palo Alto, CA, [2]The Karolinska Institute, Stockholm, Sweden, [3]Pfizer Inc, Groton, CT, [4]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of rheumatoid arthritis. Here, we describe the efficacy and safety for adalimumab (ADA) patients (pts) transitioning to tofacitinib open-label extension (OLE) without washout. These data were presented previously.[1]

Methods: In the Phase 3 randomized controlled trial (RCT, NCT00853385) ORAL Standard, pts on background methotrexate received tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, ADA 40 mg subcutaneous injections (every other week [Q2 Wk]), placebo (PBO) advanced to tofacitinib 5 mg BID, or PBO advanced to tofacitinib 10 mg BID (4:4:4:1:1). Primary results were reported.[2] Eligible pts from the RCT were permitted to enroll in an OLE receiving tofacitinib 10 mg BID without washout (last RCT ADA dose to first OLE tofacitinib dose ≤1 Wk). In this post-hoc analysis, results are described for ADA pts 4.5 months (Mo) before and at end of the RCT, and 4.5 Mo after transition to tofacitinib in OLE. Data for tofacitinib 10 mg BID during RCT and OLE are shown at the same time points.

Results: 145/204 pts randomized to ADA were eligible and enrolled in OLE; 125 started tofacitinib without washout. There were 8 (6.4%) discontinuations during the first 4.5 Mo of OLE (3 drug-related adverse event [AE], 1 unrelated AE, 1 pregnancy, 1 death, 2 other reasons). 148/201 pts randomized to tofacitinib 10 mg BID were eligible and enrolled in OLE; 124 took their first dose of tofacitinib in the OLE ≤1 Wk after their last dose of tofacitinib in the RCT. There were 9 discontinuations in the first 4.5 Mo of OLE (1 drug-related AE, 2 unrelated AE, 6 other reasons). American College of Rheumatology (ACR)20 response rate in ADA to tofacitinib pts (N=124) was 74.2% at 4.5 Mo before end of RCT, 76.6% at end of RCT, and 90.5% at 4.5 Mo after transition to tofacitinib. ACR50 response rates (44.4%, 50.8%, 65.5%) and ACR70 response rates (16.1%, 21.0%, 36.2%) at the same time points showed a similar pattern. Mean change from baseline in health assessment questionnaire-disability index (HAQ-DI) was −0.55, −0.60, and −0.70 at the same time points. Results in tofacitinib to tofacitinib pts were similar at the same time points and showed a similar pattern of increases from RCT to OLE.

	ADA to Tofacitinib (N=125)		Tofacitinib to Tofacitinib (N=124)	
	Last 4.5 Mo, RCT	First 4.5 Mo, OLE	Last 4.5 Mo, RCT	First 4.5 Mo, OLE
Discontinuations due to AEs, pts (%)	Not applicable	4 (3.2)	Not applicable	3 (2.4)
Serious AEs, pts (%)	1 (0.8)	9 (7.2)	4 (3.2)	9 (7.3)
Serious infection, pts (%)	0 (0)	3 (2.4)	1 (0.8)	3 (2.4)

ADA, adalimumab; AE, adverse event; Mo, month; OLE, open label extension; RCT, randomized controlled trial

Conclusion: Changing directly from ADA in RCT to tofacitinib in OLE resulted in sustained clinical response, with numerical improvements in ACR 20, 50, and 70 response rates and mean change in HAQ-DI from baseline. Safety-related events appeared to increase post-transition from

ADA to tofacitinib; however, similar increases were seen in tofacitinib-treated pts in the RCT after they transitioned to OLE tofacitinib. The increase in safety-related events in both groups suggests that the increase was not simply the result of overlapping immunomodulatory effects of ADA and tofacitinib.

Tofacitinib, An Oral Janus Kinase Inhibitor: Analysis Of Gastrointestinal Adverse Events Across The Rheumatoid Arthritis Clinical Program.

E. B. Lee[1], J. R. Curtis[2], R. Riese[3], C. A. Connell[3], R. Chew[3], M.G. Boy[3], E. Maller[4], C. Su[4] and L. Wang[3]. [1]Seoul National University, Seoul, South Korea, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Pfizer Inc, Groton, CT, [4]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator in rheumatoid arthritis (RA). This analysis aimed to describe and report the incidence of gastrointestinal (GI) adverse events (AEs) that occurred in the tofacitinib RA program up to 29 March 2011. These data were presented previously.[1]

Methods: Data from 5 randomised Phase 3 (P3) studies or 2 open-label long-term extension (LTE) studies were pooled. Patients (pts) were treated with tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, placebo (PBO; P3 only), or adalimumab (ADA; P3 only). Analyses of integrated safety data were from 3315 (P3; 2480 pt-y) and 3227 pts (LTE; 3118 pt-y) (LTE pts rolled over from P2 and P3). GI perforation data were analyzed from P2 (1608 pts), P3, and LTE studies.

Results: In P3 studies, exposure-adjusted event rates (EAER) (per 100 pt-y) of AEs (regardless of causality) coding to the GI System Organ Class and MedDRA preferred term, Month (Mo) 0–12, was numerically lower in pts receiving tofacitinib 5 mg BID (33.48), 10 mg BID (31.03) and ADA (21.23) vs PBO (49.87). In LTE, EAERs of GI AEs were 17.52 and 25.26 in the 5 and 10 mg BID groups, respectively. GI AEs included gastritis, constipation, diarrhea, abdominal pain, dyspepsia, nausea and vomiting; diarrhea (3.4%) and nausea (2.3%) were the most frequently reported with tofacitinib. EAERs for discontinuations (DCs) due to GI AEs in P3 (Mo 0–3, PBO-controlled period) were similar for tofacitinib (doses combined) (1.52) and PBO (1.93); EAER for ADA was 4.26. EAERs for DCs due to GI AEs for Mo 3–6 and > Mo 6 were similar to Mo 0–3. EAERs for DCs due to GI AEs in LTE were numerically lower vs P3: 0.72 (5 mg) and 0.34 (10 mg). Abdominal pain was the most common GI cause leading to DC (0.1%) with tofacitinib. Serious adverse events (SAEs) (all causality) due to GI disorders were uncommon in P3 and LTE. In P3, no GI SAE occurred in more than one pt in any dose group during Mo 0–3, 3–6 and >6. In LTE the most common abdominal SAEs were pancreatitis (4 pts, 0.12%) and cholecystitis (5 pts, 0.15%). To assess the occurrence of GI perforations, potential cases were retrospectively reviewed by Pfizer gastroenterologists based on pre-specified criteria. Ten cases of probable or definite perforation occurred in tofacitinib-treated pts; one resulted in death associated with appendicitis and sepsis. The overall GI perforation incidence rate was 0.18 (95% CI 0.095, 0.329) events per 100 pt-y. GI perforations primarily involved the lower GI tract (9 pts), and generally occurred in pts with other underlying risk factors, eg non-steroidal anti-inflammatory drugs (7 pts), glucocorticoid use (8 pts), or comorbidity of diverticulitis (3 pts).

Conclusion: GI AEs occurred commonly in all treatment groups including PBO, but were uncommon causes for DCs. Serious GI AEs were uncommon. The rate of GI perforation falls between the rates reported for pts treated with tocilizumab (0.19) and TNF inhibitors (0.13).[2]

Cardiovascular Safety Findings In Rheumatoid Arthritis Patients Treated With Tofacitinib, A Novel, Oral Janus Kinase Inhibitor.

C. Charles-Schoeman[1], P Wicker[2], M. A. Gonzalez-Gay[3], S. P. Wood[4], M.G. Boy[4], J. Geier[5], D. Gruben[4], K. Soma[4] and R. Riese[4]. [1]University of California, Los Angeles, CA, [2]PW Consulting LLC, Mystic, CT, [3]Hospital Marques De Valdecilla, Santander, Spain, [4]Pfizer Inc, Groton, CT, [5]Pfizer Inc, New York, NY.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Here we evaluated the cardiovascular (CV) event rates and changes in blood pressure (BP) in the tofacitinib Phase 3 (P3) and long-term open-label extension (LTE) studies up to March 29, 2011. These data were presented previously.[1]

Methods: Five P3 studies in patients (pts) with inadequate response to nonbiologic/biologic disease-modifying anti-rheumatic drugs (DMARDs) and 2 LTE studies were included. Tofacitinib was administered as monotherapy or with background nonbiologic DMARDs, predominantly methotrexate. One P3 study included adalimumab (ADA) as active control. An independent CV Safety Endpoint Adjudication Committee performed blinded adjudication of deaths, potential major adverse CV events (MACE), and events of congestive heart failure (CHF). MACE was defined as CV death and non-fatal CV events.

Results:

		All P3 Studies (0–12 Months)			LTE Studies
		PBO (N=681)	*All Dose tofacitinib (5 and 10 mg BID) (N=3030)	ADA 40 mg SC q2w (N=204)	All Dose tofacitinib (5 and 10 mg BID) (N=3227)
Exposure		202.6 pt-y	2098.2 pt-y	178.9 pt-y	2622.2 pt-y
MACE	Events (n)	2	14	3	5
	IR per 100 pt-y (95% CI)	0.99 (0.25, 3.95)	0.57 (0.33, 1.01)	1.68 (0.54, 5.20)	0.19 (0.08, 0.46)
CV Mortality	Events (n)	0	2	1	**1**
	IR per 100 pt-y (95% CI)	0	0.10 (0.02, 0.38)	0.56 (0.08, 3.97)	0.04 (0.01, 0.27)
Non-fatal myocardial infarction	Events (n)	0	4	2	**1**
	IR per 100 pt-y (95% CI)	0	0.19 (0.07, 0.51)	1.12 (0.28, 4.47)	0.04 (0.01, 0.27)
Non-fatal cerebrovascular accidents	Events (n)	2	8	0	3
	IR per 100 pt-y (95% CI)	0.99 (0.25, 3.95)	0.33 (0.16, 0.70)	0	0.11 (0.04, 0.36)
CHF	Events (n)	0	7	0	3
	IR per 100 pt-y (95% CI)	0	0.29 (0.13, 0.64)	0	0.08 (0.02, 0.31)

* Pts advanced from PBO to tofacitinib are 'PBO' until advanced and only in 'All Dose' post-advancement

MACE IRs (per 100 pt-y) in placebo (PBO) and tofacitinib groups in P3 were low. IR in the LTE studies in the tofacitinib All Dose group (0.19) was lower than in P3 (0.57). IRs of CHF in tofacitinib groups were low. In P3, mean changes from baseline at Month 3 for systolic and diastolic BP, respectively, were 0.1 mmHg and −0.8 mmHg for PBO and −0.2 and 0.3 mmHg for tofacitinib. Mean BP changes at Months 6 and 12 and in the LTE studies remained stable.

Conclusion: Incidence rates of MACE were similar across groups in P3 with lower rates in LTE, suggesting no increased risk over 3 years of follow up. Tofacitinib was not associated with clinically meaningful increases in BP. Although the number of events has been few and longer observation periods are warranted, CV risk does not appear to be increased with tofacitinib treatment, and rates of CV events are consistent with those observed among patients with RA of similar disease severity.[2–4]

Tofacitinib, An Oral Janus Kinase Inhibitor: Safety Comparison In Patients With Rheumatoid Arthritis and An Inadequate Response To Nonbiologic Or Biologic Disease-Modifying Anti-Rheumatic Drugs.

G. R. Burmester[1], C Charles-Schoeman[2], J. D. Isaacs[3], T. Hendrikx[4], K. Kwok[5], S. H. Zwillich[6] and R. Riese[6]. [1]Charité University Medicine Berlin, Berlin, Germany, [2]University of California, Los Angeles, CA, [3]Newcastle University, Newcastle-upon-Tyne, United Kingdom, [4]Pfizer Inc, Capelle aan den IJssel, Netherlands, [5]Pfizer Inc, New York, NY, [6]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). This analysis provides comparative safety data on the incidence of safety events for patients (pts) with an inadequate response (IR) to a nonbiologic disease-modifying antirheumatic drug (DMARD-IR) versus pts with an IR to a biologic DMARD (bDMARD-IR). These data were presented previously.[1]

Methods: The primary comparison was performed on pooled data from 5 randomized, controlled Phase 3 (P3) studies in RA pts treated with tofacitinib 5 mg or 10 mg BID for 6 to 12 months. Supportive analyses were conducted on 2 pooled open-label long-term extension (LTE) studies. All pts enrolled were nonbiologic or biologic DMARD-IR.

Results: In the pooled P3 studies, 2389 tofacitinib-treated pts with 1783 pt-years (pt-yrs) of exposure were analyzed in the DMARD-IR population and 641 pts with 315 pt-yrs of exposure in the bDMARD-IR group. Baseline demographics were generally similar, albeit the bDMARD-IR group was generally older, heavier and had fewer Asian pts. Compared with the DMARD-IR, the bDMARD-IR population exhibited increases in the rate (events/100 pt-yrs) of serious adverse events (SAEs) (12.3 [95% confidence interval (CI) 9.0, 16.9] vs 9.9 [8.6, 11.5]) and discontinuations due to adverse events (AE DC) (15.0 [95% CI 11.3, 20.0] vs 9.6 [7.7, 12.1]) in both tofacitinib treatment arms and in placebo. There were four adalimumab pts (and 0 events) that were bDMARD-IR. The rates of deaths, serious infections (SI), malignancies and major adverse cardiovascular events were similar across the populations (Table). LTE studies included 2715 pts with 3588 pt-yrs of exposure in the DMARD-IR population and 566 pts with 514 pt-yrs of exposure in the bDMARD-IR group. As compared with the DMARD-IR, the bDMARD-IR population showed increases in rates (events/100 pt-yrs) of SAEs (14.6 [95% CI 11.6, 18.4] vs 10.2 [9.2, 11.3]), AE DC (10.0 [95% CI 7.6, 13.1] vs 6.8 [6.0, 7.7]) and SIs (4.7 [95% CI 3.1, 7.0] vs 2.7 [2.2, 3.3]). The rates of the other safety events were similar.

	DMARD-IR Incidence Rate (95% CI) [number of pts with event]				bDMARD-IR Incidence Rate (95% CI) [number of pts with event]				
	Tofacitinib					Tofacitinib			Placebo n=181

*Tofacitinib All group comprises pts randomized to tofacitinib 5 or 10 mg BID at study start plus placebo pts advanced to tofacitinib treatment per protocol design. Placebo pts advanced to tofacitinib are counted in placebo until advancement and in the "Tofacitinib All" group after advancement.
†NMSC, nonmelanoma skin cancer.
$^{\Psi}$MACE, major adverse cardiovascular events. All data as of 29 Sep 2011

Conclusion: Event rates for important safety events for both DMARD-IR and bDMARD-IR pts are within the ranges observed with biologic therapies approved for treatment of RA with some differences noted in SI (LTE only), SAE and AE DC favoring the DMARD-IR population.

Tolerability and Non-Serious Adverse Events In Rheumatoid Arthritis Patients Treated With Tofacitinib As Monotherapy Or In Combination Therapy.

A. Dikranian[1], K. Soma[2], R. Riese[2], D. Gruben[2] and T. V. Jones[3]. [1]San Diego Arthritis Medical Clinic, San Diego, CA, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Tolerability remains an ill-defined construct in clinical trials. Most commonly the term is used to refer to non-serious adverse events (AEs) that despite being non-serious may still impact the patient's experience taking a drug, potentially affecting satisfaction and adherence. The objective of this analysis is to describe occurrence of the most common non-serious AEs (excluding infections and laboratory test abnormalities) in patients treated with tofacitinib as monotherapy or in combination with nonbiologic DMARDs.

Methods: The most common non-serious investigator-reported AEs (those with an incidence rate (IR) ≥5 per 100 patient-years and IR exceeding that for patients taking PBO for both doses of tofacitinib combined) were evaluated in a post-hoc pooled analysis of five DMARD inadequate responder Phase 3 studies. IRs were computed for patients taking placebo (PBO) or tofacitinib 5 or 10 mg twice daily (BID) using the data from all five Phase 3 studies. Additionally, the proportion of patients experiencing an AE were computed for each group within the first three months of exposure for the monotherapy study and for the combined four studies in which tofacitinib was taken with nonbiologic DMARDs.

Results: The most commonly reported non-serious AEs (excluding infections and laboratory test abnormalities) were headache, diarrhea, hypertension, dyspepsia, back pain, upper abdominal pain, and constipation. Incidence rates per 100 patient-years for tofacitinib 5 mg BID, 10 mg BID and PBO, respectively, from the pooled Phase 3 data were: headache: 21, 15 and 11; diarrhea: 16, 12, and 10; hypertension: 7, 9, and 4; dyspepsia: 7, 9, and 7; back pain: 6, 7, and 3; upper abdominal pain: 8, 5, and 3; constipation: 6, 6, and 4. The proportion of patients with one or more events in the first three months was <5% for all AEs except headache in patients taking tofacitinib 5 mg BID (see Table).

Table. Non-serious, non-infectious treatment-emergent AEs (excluding infections and laboratory test abnormalities) in Phase 3 studies (Months 0–3)

	Monotherapy			Combination therapy		
AE	5 mg BID N=243	10 mg BID N=245	PBO N=122	5 mg BID N=973	10 mg BID N=969	PBO N=559
Headache, %	5.3	4.5	2.5	4.2	2.8	2.1
Diarrhea, %	4.5	3,7	2.5	3.5	2–6	3.0
Hypertension. %	0.8	2.9	1.6	1.7	2.0	0.9
Dyspepsia, %	2.1	2.4	3.3	1.4	2.0	1–3
Back pain. %	2.1	2.0	1.6	1.1	1.3	0,5
Upper abdominal pain. %	2.5	1.6	0.0	1.7	0.9	0.9
Constipation, %	2.1	2.0	2.5	1.1	1.1	0.5

Conclusion: The most common non-serious AEs (excluding infections and laboratory test abnormalities) were headache, hypertension, back pain and abdominal pain, and selected gastrointestinal events. A rate of 10 or more events per 100 patient-years for at least one dose of tofacitinib was observed for headache and diarrhea. Overall, the proportions of patients experiencing non-serious, non-infectious AEs were similar for patients receiving tofacitinib as monotherapy or in combination with nonbiologic DMARDs.

Efficacy and Safety Analyses Of Tofacitinib From Pooled Phase 2, Phase 3 and Long-Term Extension Rheumatoid Arthritis Studies: US Compared With Non-US Populations.

S. B. Cohen[1], R. M. Fleischmann[1], J. M. Kremer[2], A. Koenig[3], K. Kwok[4], L. Wang[5], C. A. Mebus[5], R. Riese[5] and T. Robinson[3]. [1]Metroplex Clinical Research Center, Dallas, TX, [2]Albany Medical College and The Center for Rheumatology, Albany, NY, [3]Pfizer Inc, Collegeville, PA, [4]Pfizer Inc, New York, NY, [5]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor approved in the US for the treatment of rheumatoid arthritis at 5 mg BID.

Phase (P) 3 studies demonstrated efficacy of tofacitinib and elucidated its safety profile at 5 and 10 mg twice daily (BID). These post-hoc analyses of pooled P2, P3 and long-term extension (LTE) data assessed whether there were differences in efficacy and/or safety between the patient (pt) populations in the United States (US) and the Rest of World (ROW, non-US).

Methods: Data from DMARD-inadequate responder pts receiving tofacitinib 5 or 10 mg BID ± background nonbiologic DMARDs were pooled from six P2 and five P3 randomized studies and two open-label LTE studies for safety analyses: comparisons evaluated the incidence rates (IRs) (events/100 pt-years) for all tofacitinib groups combined for events of special interest. Pooled P3 data were assessed for efficacy comparisons of tofacitinib 5 and 10 mg BID and placebo (PBO) at Month 3 (PBO could be rescued at Month 3); descriptive statistics are presented.

Results: Data from 664 (US) and 2447 (ROW) pts were included in the efficacy analyses; 974 (US) and 3815 (ROW) pts were included in the safety analyses. Pts in the US and ROW had similar demographics other than a greater proportion of Caucasians seen in the US (PBO, 83.1%; 5 mg BID, 81.1%; 10 mg BID, 82.0%) compared with ROW (PBO, 58.7%; 5 mg BID, 55.3%; 10 mg BID, 55.5%). At Month 3, there were slight differences in the efficacy of tofacitinib between the US and ROW by ACR criteria with the PBO-adjusted response rate very similar for ACR20/50/70 (Table). DAS28-defined remission (DAS28-4(ESR)<2.6) at Month 3 was achieved in numerically more (5 mg) and fewer (10 mg) pts treated with tofacitinib in the US compared with ROW. The HAQ-DI score achieved similar improvement from baseline in the US and ROW. The IRs for safety events in the US and ROW demonstrated numerical differences with higher rates for tuberculosis, herpes zoster (HZ) and lymphoma in ROW compared with the US but higher rates of serious infection events, malignancies and deaths in the US (Table); 95% confidence intervals were largely overlapping. There were no cases of lymphoma or serious HZ in the US.

Table. Efficacy and Safety in the US and ROW patient populations (observed data)

Lymphoma	0	0.06 (0.02, 0.16) [4]

†Includespts receiving 5 and 10 mg BID; ††Data as of April 19 2012; ‡the one case of TB and the one OI were the same event; §includes those events occurring within 30 days of Last Dose of study drug
ACR, American College of Rheumatology; DAS. disease activity score; HAQ-DI, Health Assessment Questionnaire - Disability Index; TB. tuberculosis

Conclusion: US study pts achieved similar delta change in ACR responses at both tofacitinib 5 and 10 mg BID in P3 at Month 3 compared with ROW study pts; there was a difference in achieving DAS-defined remission. There were differences seen with respect to safety events of interest, particularly with fewer selected infections of significance in the US. Conclusions are limited by the difference in population sizes.

Reversibility Of Pharmacodynamic Effects After Short- and Long-Term Treatment With Tofacitinib In Patients With Rheumatoid Arthritis.

M. C. Genovese[1], T. Kawabata[2], K. Soma[2], S. Menon[2], J.D. Clark[3], J. Hodge[4], L. Takiya[4], R. Riese[2] and S. Krishnaswami[2]. [1]Stanford University, Palo Alto, CA, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Cambridge, MA, [4]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is a novel oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). It has a short pharmacokinetic (PK) half-life of 3 hours, with systemic concentrations falling below pharmacologically active levels within 24 hours after cessation of therapy. This analysis investigated the reversibility of the pharmacodynamic (PD) effects of tofacitinib over a range of biomarkers. Phosphorylation of signal transducer and activator of transcription (STAT)5 was measured as a direct read-out of JAK1/3 dependent signaling. In addition, changes reflecting downstream events such as interferon-inducible protein-10 (IP-10), lymphocyte subsets (natural killer (NK) and B cells), neutrophils, C-reactive protein (CRP), and clinical efficacy were monitored.

Methods: Data following discontinuation (dc) of tofacitinib from 2 randomized Phase 2 (P2) studies of 4–6 weeks' treatment duration, and temporary withdrawal from 1 long-term extension (LTE), were assessed. In P2 study A (NCT00976599), tofacitinib 10 mg twice daily (BID) or placebo were administered to 29 RA patients (pts) on stable methotrexate for 4 weeks and blood samples were collected during therapy and ≤1 week post-dc. In P2 study B (NCT00147498), tofacitinib 5, 15, or 30 mg BID or placebo were administered to 264 RA pts as monotherapy for 6 weeks and blood samples were collected during therapy and 2 and 6 weeks after dc. In the LTE study (NCT00413699), after a median of approximately 22 months of exposure, CRP, disease activity score defined using 28 joint counts (DAS28) and Health Assessment Questionnaire Disability Index (HAQ-DI) were assessed in pts in whom tofacitinib was administered continuously throughout the study or in whom tofacitinib was withdrawn for a 2-week period.

Results: After short-term tofacitinib treatment (4–6 weeks), mean and median pSTAT5 levels fully reversed to baseline within 24 hours after dc, while serum IP-10 levels and NK and B cell counts completely reversed to baseline levels 1–2 weeks after dc; mean CRP and neutrophil counts partially reversed over 2–4 weeks after dc. After temporary withdrawal from longer-term tofacitinib treatment, B cell counts decreased and CRP, DAS28 and HAQ-DI values increased after 1–2 weeks (Table).

Table. Reversibility of Pharmacodynamic Endpoints After Tofacitinib Treatment is Discontinued

	Biomarker	Change during treatment	Time to reversal (weeks)
Phase 2 RCT	pSTAT5[a]	↓	<1
	IP-10[a]	↓	1
	CRP[b]	↓	2
	B cells[b]	↑	2
	NK cells[b]	↓	2
	Neutrophils[b]	↑	4
LTE*	B cells	↑	1
	CRP	↓	1
	DAS28-4(ESR)	↓	1
	HAQ-DI	↓	2

RCT, randomized controlled trial; [a]P2 study A (4 weeks); [b]P2 study B (6 weeks); *LTE, long-term extension study (median 22 months)

Conclusion: The PD effects of short- or long-term tofacitinib treatment are reversible, after approximately 2 weeks of dc. These data provide a scientific basis for a 2-week dc of tofacitinib to reverse many of the pharmacologic effects of the agent.

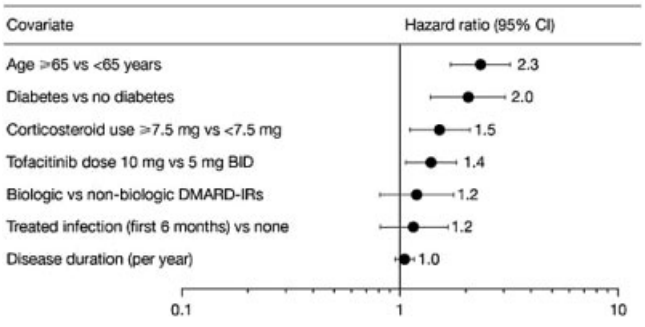
Post-Hoc Analysis Of Serious Infection Events and Selected Clinical Factors In Rheumatoid Arthritis Patients Treated With Tofacitinib. J. J. Gomez-Reino[1], A. Hazra[2], C. Fosser[2], S. Menon[2], S. H. Zwillich[2], R. Riese[2] and S. Krishnaswami[2]. [1]Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [2]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Serious infections (requiring hospitalization or parenteral antibiotics; SIEs) have been reported at an incidence of approximately 3 events per 100 patient-years (pt-y) in tofacitinib-treated RA patients (pts). This retrospective analysis incorporating Phase (P) 2, 3 and long-term extension (LTE) safety data assessed the relationship between selected clinical factors and SIE occurrence.

Methods: Data from pts receiving tofacitinib were pooled from five randomized P2, five randomized P3 and two open-label LTE studies. Clinical factors in the analysis were a) age (≥65 years vs <65 years), b) diabetes status (yes/no), c) concomitant baseline glucocorticoid use (≥7.5 mg vs <7.5 mg), d) tofacitinib dose (as a continuous variable incorporating dose changes over time), e) prior treatment (inadequate responders; IR) with biologic vs non-biologic disease modifying anti-rheumatic drugs (DMARDs), f) pts experiencing a treated infection (i.e. infection requiring antimicrobial therapy) within the first 6 months of treatment vs none, and g) duration of disease (RA) at baseline (as a continuous variable). SIE data were analyzed using a Cox Proportional Hazards model with time dependent covariates (dose), with simultaneous inclusion of the above covariates. Separate interaction tests between tofacitinib dose and age, diabetes or glucocorticoid dose were performed. Results were expressed as hazard ratios with 95% confidence intervals (CIs).

Results: Based upon the exclusion of 1 for 95% CI of hazard ratios, age (elderly), corticosteroid dose ≥7.5 mg, diabetes and tofacitinib dose were identified as independent factors associated with the risk of SIE (Figure). Elderly pts had an estimated 2.3 times increased risk of SIE. Pts with diabetes had 2 times increased risk of SIE, while a separate infections analysis irrespective of severity did not show noticeable differences (data on file). There was a 50% increase in SIE risk in pts receiving corticosteroid doses ≥7.5 mg and 40% increased risk of SIE with 10 mg vs 5 mg tofacitinib. Interaction tests did not show an increase in tofacitinib risk in the above sub-populations. Relative to non-biologic DMARD IRs, biologic DMARD IRs showed a hazard ratio of 1.2, with CIs including 1.

Figure: Hazard Ratios for Serious Infections, Cox Proportional Hazards Model



Data as of 29 Sept 2011; Post-hoc anaylsis of tofacitinib-treated patients

Conclusion: Identification of age, diabetes and corticosteroid dose as independent risk factors is consistent with reports from multiple RA pt databases (Listing et al., 2013; Strangfeld A, et al. 2011) of biologic DMARDs. Tofacitinib dose was an independent risk factor for SIEs. However, interaction tests suggest that the identified risk factors are reflective of underlying characteristics of the RA population, particularly DMARD-treated pts, rather than tofacitinib.

Remission Rates During Golimumab Treatment For Rheumatoid Arthritis Are Associated With Differences In Baseline Disease States Across Geographic Regions. P Durez[1], K Pavelka[2], M Lazaro[3], A Garcia Kutzbach[4], R Moots[5], H Amital[6], R Yao[7], M Govoni[8], N Vastesaeger[9] and HH Weng[7]. [1]Université Catholique de Louvain and Cliniques Universitaires Saint-Luc, Brussels, Belgium, [2]Revmatologicky Ustav, Praha, Czech Republic, [3]Instituto de Asistencia Reumatológica Integral, San Fernando, San Fernando, Argentina, [4]Universidad Francisco Marroquin Guatemala School of Medicine, Guatemala City, Guatemala, [5]University Hospital Aintree, Liverpool, United Kingdom, [6]Sheba Medical Center, Tel-Hashomer, Israel, [7]Merck Sharp & Dohme, Kenilworth, NJ, [8]Merck Sharp & Dohme, Rome, Italy, [9]Merck Sharp & Dohme, Brussels, Belgium.

Background/Purpose: Regional differences in practice patterns and access to biologic treatment for rheumatoid arthritis (RA) may lead to regional differences in baseline disease characteristics, which could influence response to biologic treatments. The purpose of this analysis of the GO-MORE study was to compare across geographic regions the baseline disease levels and remission rates among biologic-naïve RA patients during 6 months of add-on golimumab (GLM) treatment.

Methods: GO-MORE was an open-label, multinational, prospective study in biologic-naïve patients with active RA (DAS28-ESR ≥3.2) despite nonbiologic disease-modifying antirheumatic drug treatment. Patients received 50-mg SC GLM once monthly for 6 months. In planned and post hoc analyses, baseline disease activity, disease duration, and DAS28-ESR remission rates were evaluated across geographic regions.

Results: Baseline disease activity varied across regions (table), with high EULAR disease activity most prevalent in South Africa, Asia, and Latin America. Disease duration was longest in Latin America and South Africa. Overall, after 6 months of GLM treatment, DAS28-ESR remission rate was approximately 25%. Remission rates varied substantially by region, with lower remission rates generally found in the regions with the greatest initial disease activity and disease duration, with the exception of South Africa. Within the European region, the largest population in the study, the countries with the lowest remission rates were Russia and Romania (6.8% and 7.8% at month 6, respectively), also had high rates of baseline disease activity (96.6% and 86.3% of patients had high disease activity, respectively; mean DAS28-ESR 6.4 and 6.2, respectively). In the European countries with the highest remission rates, Belgium and Austria (43.1% and 40.2% at month 6, respectively), much lower baseline disease activity was observed (40.2% and 59.8% of patients had high disease activity, respectively; mean DAS28-ESR 5.0 and 5.2, respectively). Regardless of geographic region, patients with moderate baseline disease activity were more likely to achieve remission than those with high baseline disease activity (43.4% and 18.5%, respectively, $P<.0001$).

Geographic Region	Baseline EULAR Disease Activity[a] n (%)		Baseline Disease Duration, y Mean (SD)	Baseline DAS28-ESR Mean (SD)	Month 6 DAS28-ESR Remission[b] n (%)
	Moderate	High			
South Africa, N=117	10 (8.5)	107 (91.5)	7.6 (7.9)	6.7 (1.1)	34 (29.1)
Asia, N=133	10 (7.5)	123 (92.5)	5.4 (4.8)	6.2 (0.8)	20 (15.0)
Europe, N=1818	525 (29.0)	1286 (71.0)	7.4 (7.8)	5.7 (1.0)	507 (27.9)
Latin America, N=906	84 (9.3)	821 (90.7)	8.6 (8.2)	6.4 (1.0)	156 (17.2)
Middle East, N=88	19 (21.8)	68 (78.2)	6.9 (7.0)	6.0 (1.0)	24 (27.3)
Canada, N=218	50 (23.0)	167 (77.0)	6.6 (8.4)	5.9 (1.1)	43 (19.7)

[a]Moderate disease activity: DAS28-ESR 3.2–5.1; high disease activity: DAS28-ESR >5.1. [b]Remission: DAS28-ESR <2.6.

Conclusion: After 6 months of GLM treatment, patients in South Africa, Europe, and the Middle East had higher remission rates than those in Latin America and Asia. This pattern may be due to differences in baseline disease activity and duration, which may reflect differences in practice patterns and access to biologic treatments. Overall, patients with moderate baseline disease activity were more likely to achieve remission than those with high baseline disease activity.

High Levels Of Memory B CELLS ARE Associated With Response To A First ANTI-TNF Drug In Patients With Rheumatoid Arthritis. Claire I. Daien[1], Sarah Gailhac[2], Thibault Mura[3], Bernard Combe[1], Michael Hahne[4] and Jacques Morel[1]. [1]Lapeyronie Hospital, Montpellier, France, [2]CNRS, Montpellier, France, [3]Hopital Gui De Chauliac, Montpellier, France, [4]IGMM, CNRS UMR5535, Montpellier, Montpellier, France.

Background/Purpose: Tumor necrosis factor (TNF) inhibitors (TNFi) are effective treatments for rheumatoid arthritis (RA). Some reports suggested that TNFi affect B cell homeostasis. We studied the effect of TNFi on peripheral B cells and elucidated B cell related biomarkers to predict TNFi response.

Methods: Peripheral B cells were analyzed for expression of CD19, CD27, CD38, IgD in 31 healthy donors and 96 RA patients, including 21 patients who were followed 3 months after TNFi introduction. We compared B cell subsets between patients with RA and controls; TNFi and non TNFi users as well as before and after TNFi introduction in RA patients. We also aimed to identify phenotypes associated with EULAR response.

Results: B cell subsets in blood were influenced by age and glucocorticoids doses. After adjustment on age, gender and glucocorticoid doses, patients with RA were found to have similar B cell subset frequencies as controls. No significant effect of TNFi on B cell repartition was found when comparing TNFi and non TNFi users at baseline or patients before and after TNFi introduction. TNFi responders at 3 months had significantly higher percentage of $CD27^+$ memory B cells at baseline and those with $CD27^+$ above 26% at inclusion were 4.9 (1.3–18.6) more likely to respond TNFi treatment. $CD27^+$ cells produced 3 times more TNF alpha than naïve B cells which was correlated with IFN gamma-producing $CD4^+$ in patients free of TNFi.

Conclusion: High levels of memory B cells at baseline were associated with response to TNFi which may be related to the activation of the Th1 pathway in a TNFa depending manner.

Inflammatory Diseases (ClinTrid), Karolinska Institute, Stockholm, Sweden, [9]Karolinska Institute, Stockholm, Sweden, [10]ARBITER, Institute of Rheumatology, Moscow, Russia, [11]Institute of Rheumatology, Moscow, Russia, [12]ROB-FIN, Helsinki University Central Hospital, Helsinki, Finland, [13]Diakonhjemmet Hospital, Oslo, Norway, [14]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [15]Instituto de salud Musculoesqueletica, Madrid, Spain, [16]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Tocilizumab (TCZ) is efficacious in monotherapy and in combination with methotrexate (MTX) or other DMARDs. However, longitudinal data from large registry populations are missing. To examine the effectiveness of TCZ administered alone or in combination with DMARDs in the TOcilizumab Collaboration of European Registries in RA (TOCERRA).

Methods: All RA patients treated with TCZ having a baseline (BL) visit were considered. Patients were assigned to groups: TCZ monotherapy (TCZ), TCZ+MTX, TCZ+MTX+other DMARDs (TCZ+MTX+other), and TCZ+other DMARDs based on BL information. Effectiveness was measured in terms of percentages of patients achieving DAS28 and CDAI remission and according to changes in DAS28 and CDAI at around 6 and 24 months post TCZ start. Groups were compared by time point using Fisher's exact test or a Kruskal-Wallis test. A covariate-adjusted non-linear mixed effects model with an exponential decrease over time was fitted to the longitudinal DAS28 and CDAI data for patients with complete covariate information, including country, sex, age, disease duration, number of prior biologics, corticosteroid use, seropositivity and use of co-DMARDs.

Results: 1515 RA patients with 1537 treatment courses (TCs) were retrieved. 26% were treated with TCZ, 52% with TCZ+MTX, 9% with TCZ+MTX+other, and 13% with TCZ+other. Group frequencies varied significantly among countries (P=0.0005). For 78% of TCs DMARD co-therapy did not change over time. Median TCZ treatment duration was 0.75 years (IQR: 0.31 – 1.60 years, max: 4.25 years). BL characteristics of patients are described in Table 1. Number of TCs with a value for DAS28 and CDAI were 631 and 470 at 6 and 170 and 148 at 24 months. DAS28 and CDAI remission at 6 and 24 months in the different groups ranged from 47 to 52% and from 62 to 73% for DAS28 and from13 to 21% and from 18 to 30% for CDAI, respectively. Differences were not significant (all P>0.05). In all groups mean DAS28 and CDAI had decreased rapidly (to 2.7–3.0 and 9.8–14.1, respectively) by 6 months and leveled off thereafter, at 2.4–2.5 and 8.2–10.0 by 24 months, respectively (all P>0.05). There was no indication for an effect of DMARD use on the decrease of DAS28 and CDAI from the mixed effects analysis including 7096 and 6050 observations from 1251 and 985 TCs (with comparable percentages of groups as above), respectively (both P>0.05). However, country as well as use of prior biologics (in terms of none, 1, or ≥ 2) were found to significantly affect DAS28 and CDAI decrease (all P<0.001).

Work Instability In Early Rheumatoid Arthritis With Elevated Risk Of Employment Loss: Effects Of Adalimumab/Methotrexate Combination Therapy Versus Methotrexate In a Randomized Clinical Trial. Arthur Kavanaugh[1], Josef S. Smolen[2], Arijit Ganguli[3], Hartmut Kupper[3], Mary Cifaldi[3], Naijun Chen[3] and Dennis Revicki[4]. [1]University of California, San Diego, La Jolla, CA, [2]Medical University of Vienna, Vienna, Austria, [3]AbbVie Inc., North Chicago, IL, [4]United BioSource, Bethesda, MD.

Background/Purpose: Intensive treatment of early rheumatoid arthritis (RA) has been shown to reduce functional disability over time and to positively impact employment outcomes. Adalimumab (ADA) is approved

for the treatment of RA and has demonstrated improvements in clinical, patient-reported, and work productivity outcomes.[1,2] We aimed to evaluate the effects of combination therapy with ADA plus methotrexeate (MTX) compared with MTX monotherapy on work instability outcome, a significant predictor of employment loss, among patients at elevated risk for job loss.

Methods: A secondary analysis was conducted using data from the 26 week, randomized, double-blind period of OPTIMA, a study designed to compare the safety and efficacy of ADA plus MTX to placebo plus MTX in subjects with early (<1 year duration), active RA. Work instability was assessed using the Rheumatoid Arthritis-Work Instability Scale (RA-WIS) (range 0–23), where scores of ≥17, ≥10 to <17, and <10 represent high-, medium-, or low-risk for job loss. To meet study objectives, only employed patients with baseline RA-WIS score ≥10 (moderate to high risk) were included in this analysis. Improvements of 5 points in RA-WIS has been determined to be clinically meaningful. Chi-square tests were used to assess treatment group differences in the percentage of patients who: a) demonstrated improvement by at least 1 risk category; and b) achieved improvements of ≥5, ≥7 or ≥9 points, at Weeks 4, 12 and 26 from baseline. Missing values were imputed using NRI method. As sensitivity analysis, responders were defined as patients with both improvement by at least 1 category and a ≥5 point change.

Results: A total of 320 patients (146 ADA plus MTX; 174 PBO plus MTX) were included in the analysis sample (mean age: 46; females: 69%). The mean baseline RA-WIS score was 16.7(±3.8). Significant differences favoring ADA were observed among patients who improved by at least 1 risk category at Weeks 4, 12, and 26 (50% vs 33%; P=.0025, 62% vs 44%; P=.0019, and 58% vs 47%; P=.048, respectively). A significantly greater percentage of ADA treated patients also improved by 5 points (42% vs 23%; P=.0003, 58% vs 43%; P=.010, and 56% vs 43%, P<.027 at Weeks 4, 12, and 26, respectively), 7 points (29% vs 16%; P=.004, 45% vs 33%; P=.031, and 47% vs 36%; P=.035 at Weeks 4, 12, and 26, respectively), or 9 points (23% vs 9%; P=.0008, 34% vs 23%; P=.036, and 42% vs 26%, P=.004 at Weeks 4, 12, and 26, respectively) compared to patients receiving MTX monotherapy. Sensitivity analysis also showed significant differences favoring patients treated with ADA at Weeks 4, 12 and 26 (38% vs 21%; P<.001, 53% vs 38%; P<.001, and 53% vs 41%; P=.031, respectively).

Conclusion: Among early RA patients with elevated risk of employment loss, combination therapy with ADA plus MTX was associated with clinically meaningful greater improvements in RA-WIS compared with MTX monotherapy.

Tocilizumab Monotherapy Compared With Adalimumab Monotherapy In Patients With Rheumatoid Arthritis: An Evaluation Of High-Density Lipoprotein Composition. Cem Gabay[1], Katie Tuckwell[2], Jennifer Green[2], Micki Klearman[3] and Arthur Kavanaugh[4]. [1]SCQM registry, University Hospitals of Geneva, Geneva, Switzerland, [2]Roche, Welwyn Garden City, United Kingdom, [3]Roche, South San Francisco, CA, [4]University of California, San Diego, La Jolla, CA.

Background/Purpose: Rheumatoid arthritis (RA) patients (pts) are at increased risk for cardiovascular (CV) disease. Although analysis of lipids such as LDL-C and HDL-C is useful in the general population to estimate CV risk, disease-associated inflammation also contributes to CV risk among RA pts. Chronic inflammation in RA is associated with low HDL-C and altered HDL composition. HDL particles may become atherogenic due to association with acute-phase reactants (ie, serum amyloid A [SAA] and secretory phospholipase A_2 [sPLA2]), thereby losing their ability to protect LDL from oxidation. Elevated serum HDL-associated SAA (HDL-SAA) and sPLA2 have been identified as markers of increased CV risk.[1] We conducted a post hoc analysis of HDL-SAA and sPLA2 to investigate changes in HDL composition in RA pts after initiation of 2 biological therapies with different mechanisms of action.

Methods: ADACTA was a phase 4, randomized, double-blind study in RA pts (tocilizumab [TCZ], n=163; adalimumab [ADA], n=163).[2] Pts received TCZ 8 mg/kg IV Q4W or ADA 40 mg SC Q2W for 24 wks, both as monotherapy. Available serum samples were analyzed at baseline (BL) and wk 8 for HDL-C, HDL-SAA, and sPLA2. Change from BL to wk 8 was analyzed by ACR20 response (responders [R]/nonresponders [NR]) at wk 24. Change from BL to wk 8 in median HDL-SAA and sPLA2 was compared using nonparametric Kruskal-Wallis analyses. Spearman rank correlation coefficients were used to determine associations between changes in these parameters and C-reactive protein (CRP) and apolipoprotein A-1 (apoA-1) collected during the trial.

Results: A greater increase in HDL-C was observed after treatment with TCZ vs ADA (TCZ, 0.14 mmol/L, n=129; ADA, 0.07 mmol/L, n=137). Reductions in HDL-SAA and sPLA2 were seen in both arms, with a greater response with TCZ (Table). Larger reductions in sPLA2 were seen with TCZ for ACR20-R. For ACR20-NR, smaller reductions were seen in both arms, also in favor of TCZ. There were similar reductions in HDL-SAA for ACR20-R and -NR, but again reductions were greater with TCZ (Table); the same effect was seen for EULAR good responders (data not shown). In both arms, a moderate positive correlation was seen between HDL-SAA and sPLA2 (TCZ, r=0.57, p<0.0001; ADA, r=0.54, p<0.0001). A stronger correlation was observed between HDL-SAA and CRP (TCZ, r=0.58, p<0.0001; ADA, r=0.69, p<0.0001) and sPLA2 and CRP (TCZ, r=0.66, p<0.0001; ADA, r=0.74, p<0.0001). There was a weak negative correlation between HDL-SAA or sPLA2 and apoA-1 with TCZ (HDL-SAA, r=–0.27, p=0.05; sPLA2, r=–0.25, p=0.04) and a weaker correlation with ADA (HDL-SAA, r=–0.19, p=0.13; sPLA2, r=–0.16, p=0.14).

Table. Change From Baseline to Week 8 in HDL-SAA and sPLA2

		HDL-SAA mg/L		SPLA2 ng/mL	
Subgroup	**Statistic**	**ADA 40 mg**	**TCZ 8 mg/kg**	**ADA 40 mg**	**TCZ 8 mg/kg**
Allpatients	n	62	55	86	73
	Mean (SD)	−4.4 (12.3)	−9.3 (18.3)	−1.8 (9.2)	−7.8 (12.8)
	Median	−1.1	−3.2	−1.3	−4.1
	Quartiles (25%, 75%)	−7.1, 0.6	−11, −1.0	−2.9, 0.8	−7.8, −1.1
	P^a	0.0077		<0.0001	
ACR20 responders	n	32	39	47	52
	Median	−1.0	−3.3	−1.3	−4.8
	Quartiles (25%, 75%)	−6.8, 0.6	−10, 1.0	−3.2, 0.7	−9.5, −1.3
	P^a	0.0475		<0.0001

	Median	−1.1	−3.1	−0.6	−3.1
	Quartiles (25%, 75%)	−8.7, 1.2	−13, −1.2	−2.8, 1.9	−4.9, −1.0
	P^a	0.0816		0.0012	

The table includes patients for whom samples and valid results were available for HDL-SAA and SPLA2.
[a] Analysis was performed using the Kruskal-Wallis test. The descriptive p value is presented, and no adjustment was made for multiple testing.

Conclusion: TCZ had a greater effect than ADA on reducing HDL-SAA and sPLA2 levels, suggesting a greater positive impact of TCZ on the antiatherogenic properties of HDL.

Evaluation Of Disease Activity By The Routine Assessment Of Patient Index Data 3 In Patients With Rheumatoid Arthritis Receiving Tocilizumab. Yu F. Asanuma, Takashi Maruyama, Maiko Yanagisawa, Kazuhiro Yokota, Yoshihiro Yoshida, Hiroshi Kajiyama, Kojiro Sato, Yuji Akiyama and Toshihide Mimura. Saitama Medical University, Saitama, Japan.

Background/Purpose: Interleukin-6 (IL-6) has been demonstrated to play a pathological role in rheumatoid arthritis (RA). IL-6 strongly induces production of C-reactive protein (CRP) and fibrinogen in hepatocytes. Marked decrease of serum CRP level and erythrocyte sedimentation rate (ESR) has been shown soon after administration of IL-6 antagonist, tocilizumab (TCZ). Therefore, usual disease activity scores using clinical data including CRP or ESR may not reflect real clinical response to the treatment with TCZ in patients with RA. RAPID3 includes the 3 patient-reported RA core data set measures: physical function, pain, and patient global estimate without formal joint counts and laboratory test, ESR or CRP. We investigated the usefulness of RAPID3 to evaluate disease activity and functional disability in RA patients receiving TCZ.

Methods: Twenty four patients with RA were enrolled in this prospective, IRB proven study. The patients were started on TCZ therapy at Saitama Medical University Hospital from 2010 to 2012. TCZ was infused every 4 weeks at a dose of 8 mg/kg. All patients were followed up to week 52. RAPID3 was calculated from a multidimensional health assessment questionnaire, pain and patient global estimate. The primary outcomes were the DAS28-ESR, CDAI, SDAI, HAQ and RAPID3 at week 52 of TCZ treatment. Secondary outcomes included proportion of patients in remission of RAPID3 or other indices to assess patients with RA. The association between RAPID 3 and other indices at week 52 was also examined.

Results: Mean age of patients was 53 years, 71 percent of patients were female, the mean duration of disease was 10 years and 75 percent of patients had received prior treatment of other biologics. Seventy one percent of patients were methotrexate users and 67 percent were corticosteroid users. Significant reduction of DAS28-ESR, CDAI, SDAI and RAPID3 were observed at week 52 compared to baseline ($P<0.05$). Remission rate of RAPID3 (29%) was not significantly different with that of CDAI (17%), SDAI (25%), ACR/EULAR Boolean (17%) and HAQ (38%) in patients receiving TCZ for 52 weeks, although the remission rate of RAPID3 was lower than that of DAS28-ESR (54%) ($p=0.07$). RAPID3 scores were correlated significantly with those of DAS28-ESR (rho = 0.66), CDAI (rho = 0.79), SDAI (rho = 0.78) and HAQ (rho = 0.85) (all $P<0.001$) at week 52.

Conclusion: RAPID3 may be useful for evaluating disease activity and functional disability without formal joint counts and laboratory tests in RA patients receiving TCZ.

What Are The Implications Of Concomitant and Pre-Medication On Infusion Reactions To Infliximab: Results From "RemiTRAC Infusion", a Prospective Real-World Community Registry. Denis Choquette[1], Rafat Y. Faraawi[2], Merlin Njoya[3], Andrew Chow[4], William G. Bensen[5] and Francois Nantel[6]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]Rheumatologist, KW Musculoskeletal Research Inc., Kitchener, ON, [3]McKesson Canada, Toronto, ON, [4]Credit Valley Rheumatology, Mississauga, ON, [5]St. Joseph's Hospital and McMaster University, Hamilton, ON, [6]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Infliximab (IFX) is a therapeutic monoclonal antibody targeting TNFa indicated in the treatment of a number of chronic inflammatory diseases. IFX is administered by intravenous infusion and may be associated with infusion reactions (IRs).

Methods: RemiTRAC Infusion is a prospective observational registry conducted in 12 Canadian sites from 2005–2012. IFX infusions were followed to document IRs and their management, pre-medication use and adverse events. An IR was defined as any AE occurring during the infusion or within 1 hour post-infusion. The effects of concomitant medication and pre-medication prior to infusions on the incidence of IRs were evaluated by propensity score adjusted analysis using a Multilevel logistic regression model with the following variables as predictors: Patient age, weight and gender; prior enrolment use of IFX, any prior biologic use; indication; season and year of infusion; patient eligibility; dose; time since the last infusion and number of previous IRs.

Results: 1632 patients were enrolled and 24,852 infusions were recorded. The majority (63%) of patients in this cohort are treated with IFX for rheumatologic conditions such as RA (40%), AS (18%) and PsA (6%). 201/1632 (12.3%) patients reported at least one IR. Of 24,852 infusions, 322 resulted in an IR (1.3%) and most IRs were mild to moderate in severity (95%). The most common IR was pruritus, occurring in 19.9% of infusion reactions. Flushing (9.9%) and dyspnoea (6.2%) are the only other infusion AEs occurring in ≥5% of IRs. Four serious IRs (fever, itching/flushing, chest pain, chest pain/flushing) and no serious anaphylactic reactions occurred.

The effects of concomitant medications and pre-medication are shown in table 1. Neither immunosuppressive agent overall, nor do MTX or corticosteroids have any effect in reducing the incidence of IRs. In contrast, pre-medication with anti-histamines and/or steroids were associated with a significant increase in the incidence of IRs. Only the use of acetaminophen monotherapy was associated with a significant reduction in the incidence of IRs.

Table 1. Effect of concomitant medication and pre-medication on the incidence of IRs (Propensity scores adjusted effect).

S + AH + AA	2101	8.45%	37	1.76%	1.44	(0.97, 2.15)	0.0701

Conclusion: This registry shows that in community-based infusion clinics, IR to IFX are uncommon and largely mild to moderate in nature. Anti-histamines, intravenous steroids and acetaminophen have been widely used to decrease the odds of IRs. However, the results of this registry demonstrate that anti-histamines[1] and steroids[2]are ineffective as prophylactic pre-medication. The effectiveness of acetaminophen as pre-medication suggests that most IRs are of a non-immunological mechanism.

Impact Of Inadequate Adherence On Clinical Outcomes: Results From The Biologics In Rheumatoid Arthritis Genetics and Genomics Study Syndicate Cohort. James Bluett[1], Catharine Morgan[1], Layla Thurston[2], Darren Plant[1], Ann W. Morgan[3], Anthony G. Wilson[4], John Isaacs[5], Kimme L. Hyrich[1], Lis Cordingley[1] and Anne Barton[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Manchester Medical School, The University of Manchester, Manchester, United Kingdom, [3]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [4]Department of Infection and Immunity, University of Sheffield, Sheffield, United Kingdom, [5]National Institute for Health Research, Newcastle Biomedical Research Centre, Newcastle Hospitals Foundation Trust and Newcastle University, Newcastle Upon Tyne, United Kingdom.

Background/Purpose: Biologic therapy has revolutionised patient prognosis in rheumatoid arthritis (RA). In the UK, continuing biologic therapy requires a sustained response as determined by the 28 joint-count disease activity score (DAS28). Adherence to DMARDs is low but little is known about adherence to biologic therapies and its relationship to treatment response.

The purpose of this study is to investigate the association of adherence to subcutaneous (SC) biologics and EULAR response criteria in subjects with RA.

Methods: Participants were recruited to the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS), a large UK multicentre prospective observational cohort study. Demographic

information for patients receiving SC biologic therapy and disease characteristics were assessed at baseline. Self-reported adherence was recorded at 3 and 6 months if the biologic was taken on the day agreed with the healthcare professional. Non-adherence was defined as 'ever non-adherent' for these periods. DAS28 was recorded at baseline and following 3 and 6 months of therapy and categorised according to the EULAR response criteria. Descriptive statistics, Student's t-test, chi-squared test and Mann-Whitney U test statistics were used to analyse the data.

Results: Data were collected for 390 patients with median disease duration of 7 years (IQR 3–15). Adherence data were collected in 286 patients. 27% reported non-adherence with biologic therapy according to our criteria. There were significantly smaller changes in DAS28, ESR and poorer EULAR response in patients reporting non-adherence as shown in table 1. There were no differences between the adherent and the non-adherent group in terms of other DAS components; tender or swollen joint counts nor patient visual analogue scale. Age, disease duration and baseline DAS28 were not significantly associated with adherence status in this cohort; however it was associated with gender with self-reported adherence lower in women.

	Total sample	Adherent group	Non-adherent group	*P*-value
Age in years: mean (SD)	57.2 (11.5)	57.7 (11.4)	56.1 (12.0)	0.205
Gender F: n (%)	291 (74.6)	146 (69.9)	64 (83.1)	**0.024**
Change in DAS28 at 6 months: median (IQR)	−2.9 (−1.7 to −3.8)	−3.1 (−2.0 to −3.8)	−2.35 (−1.1 to −3.7)	**0.025**
Change in ESR at 6 months: median (IQR)	−8.5 (0 to −20)	−10 (−1 to −25)	−3.5 (4 to −14)	**0.004**
EULAR non response: n (%)	26 (11.0)	13 (7.6)	13 (20.3)	
EULAR moderate response: n (%)	91 (38.6)	66 (38.4)	25 (39.1)	
EULAR good response: n (%)	119 (50.4)	93 (54.1)	26 (40.6)	**0.014**

Conclusion: RA patients who reported not taking their biologic on the day agreed with their healthcare professional showed poorer clinical outcomes than their counterparts, emphasising the need for strict adherence to biologics in patients with RA. Female gender was a baseline predictor of patient reported non-adherence.

Antibody Response To Pneumococcal and Influenza Vaccination In Patients With Rheumatoid Arthritis Receiving Subcutaneous Abatacept. MC Genovese[1], CO Bingham 3rd[2], S Cohen[3], L Calabrese[4], JR Curtis[5], A Block[6], J Fay[6], S Kelly[6], A Luo[6], D Wong[6] and R Alten[7]. [1]Stanford University, Palo Alto, CA, [2]Johns Hopkins University, Baltimore, MD, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Cleveland Clinic, Cleveland, OH, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Bristol-Myers Squibb, Princeton, NJ, [7]Schlosspark-Klinik, University Medicine Berlin, Berlin, Germany.

Background/Purpose: Previous small studies have suggested that responses to some immunizations may be attenuated by intravenous abatacept but remain clinically meaningful.[1,2] We investigated the magnitude of antibody response to the standard 23-valent pneumococcal polysaccharide vaccine (PPV23) and the 2011–2012 seasonal influenza trivalent vaccine in a large number of adult patients (pts) with RA receiving subcutaneous (SC) abatacept and background DMARDs.

Methods: Two multicenter, open-label sub-studies of PPV23 and seasonal influenza vaccine enrolled pts in the ACQUIRE (pneumococcal and influenza) or ATTUNE (pneumococcal) studies. Pts were enrolled at any point during their SC abatacept treatment cycle after completion of ≥3 months' abatacept treatment. All pts received fixed-dose SC abatacept 125 mg/week with background DMARDs. A pre-vaccination blood sample was collected and vaccines administered, while continuing background SC abatacept and DMARDs. After 28 ± 3 days, a final post-vaccination blood sample was collected. For PPV23, the primary endpoint was the proportion of pts achieving an immunologic response, defined as a ≥2-fold increase in post-vaccination titers to ≥3 of 5 evaluated pneumococcal antigens (9V, 14, 18C, 19F, and 23F) in the vaccine at Day 28 in the subgroup of pts without a protective antibody level (titer ≥1.6 μg/mL to ≥3 of 5 pneumococcal antigens) to these antigens at baseline. For influenza vaccination, the primary endpoint was the proportion of the subgroup of pts achieving an immunologic response, defined as a ≥4-fold increase in post-vaccination titers to ≥2 of 3 evaluated 2011–2012 influenza antigens (H1N1, H3N2, and Brisbane) at Day 28 in pts without a protective antibody level (titer ≥1:40 to ≥2 of 3 influenza antigens) to these antigens at baseline. Safety and tolerability were assessed throughout the studies.

Results: Pre- and post-vaccination titers were available for 113/125 and 186/191 enrolled pts receiving the pneumococcal and influenza vaccines, respectively. Among vaccinated pts, 47/113 pneumococcal and 121/186 influenza pts were without protective antibody levels at baseline. Of these pts, 73.9% (34/46) and 61.3% (73/119) met the primary endpoint and demonstrated an immunologic response to PPV23 or influenza vaccine, respectively. In all pts who received the vaccine and had pre- and post-vaccination antibody titers available at 4 weeks post-vaccination, 83.9% (94/112) demonstrated protective antibody levels with PPV23 (titer ≥1.6 μg/mL to ≥3 of 5 pneumococcal antigens), and 82.1% (151/184) in the influenza study demonstrated protective antibody levels (titer ≥1:40 to ≥2 of 3 influenza antigens). Vaccination during SC abatacept administration was well tolerated, with no new safety signals identified.

Conclusion: In this group of pts with RA on SC abatacept and background DMARDs, most pts without protective antibody levels at baseline were able to mount an immune response to the PPV23 and influenza virus vaccines, and vaccination was well tolerated. These data are consistent with previous smaller studies.

Oskira-2: A Phase III, Multicenter, Randomized, Double-Blind, Placebo-Controlled Parallel-Group Study Of 2 Dosing Regimens Of Fostamatinib In Rheumatoid Arthritis Patients With An Inadequate Response To Disease-Modifying Antirheumatic Drugs. Peter Dawes[1], Aleksandar Dimic[2], Mark C. Genovese[3], Désiréé van der Heijde[4], Martin Jenkins[5], Chris O'Brien[6], Barry Oemar[7], Jiri Vencovsky[8] and Michael Weinblatt[9]. [1]University of North Staffordshire NHS Trust, Stoke-on-Trent, United Kingdom, [2]Rheumatology Institute, Niška Banja, Serbia, [3]Stanford University, Palo Alto, CA, [4]Leiden University Medical Center, Leiden, Netherlands, [5]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [6]AstraZeneca R&D Wilmington, Wilmington, DE, [7]AstraZeneca R&D Boston, Boston, MA, [8]Institute of Rheumatology, Prague, Czech Republic, [9]Division of Rheumatology, Brigham & Women's Hospital, Boston, MA.

Background/Purpose: Fostamatinib (Fosta) is a novel spleen tyrosine kinase (SYK) inhibitor. The Phase II TASKi studies showed benefit in patients (pts) with active rheumatoid arthritis (RA). A formal, prospective, international, phase III research program (OSKIRA) was initiated in 2010. This 52-wk study, (OSKIRA-2) evaluated Fosta in pts with active RA who had an inadequate response to DMARDs.

Methods: 908 pts who fulfilled 1987 ACR criteria were randomly allocated to 1 of 3 groups: Fosta 100 mg bid (Group A, n = 308); Fosta 100 mg bid for 4 wks then Fosta 150 mg qd (Group B, n = 298); or placebo (PBO) for 24 wks then Fosta 100 mg bid (Group C, n = 302). All

treatment regimens were taken in combination with DMARDs. Non-responders at Wk 12 could leave the study and enter an active extension. The primary endpoint was the proportion of pts achieving ACR20 at Wk 24. Secondary endpoints evaluated efficacy, safety and tolerability up to 52 wks.

Results: There were no notable imbalances in demographics, disease duration and activity/disability/erosions or concomitant medications at baseline between the 3 groups (mean age: 53 yrs; 82% female; mean disease duration: 7.5 yrs; RF seropositive: 78%; erosive score ≥ 3: 80%; mean DAS28-CRP score: 5.6). Background medications included methotrexate (83% of pts) and sulfasalazine, hydroxychloroquine or chloroquine (17% of pts). There were statistically significant improvements in ACR20 at Wk 24 for both Fosta groups vs PBO ($p < 0.001$ for both groups; Table). For all the key secondary endpoints evaluating RA signs and symptoms up to Wk 24, Fosta Group A achieved statistically significant differences vs PBO ($p < 0.001$ for all; Table) and there were statistical differences from PBO for these endpoints for Group B ($p < 0.001$), except ACR70 (Table). Changes in ACR20 were seen as early as Wk 1. Change in mTSS at Wk 24 did not show a significant difference compared with PBO for either Fosta group ($p = 0.904$; $p = 0.342$, respectively).

Table. Patient discontinuations, primary endpoint and key secondary endpoints at or up to Wk 24

Endpoint*	Group A	Group B	Group C
	Fosta 100 mg bid (n = 308)	Fosta 100 mg bid for first 4 wks then 150 mg qd (n = 298)	Placebo for 24 wks then Fosta 100 mg bid (n = 302)
Patients discontinuing treatment up to Wk 24	100 (32.5%)	105 (35.0%)	155 (50.8%)
ACR20 at Wk 24 (primary endpoint)	122 (39.6%)	118 (39.6%)	74 (24.5%)
ACR50 at Wk 24	64 (20.8%)	54 (18.1%)	25 (8.3%)
ACR70 at Wk 24	28 (9.1%)	18 (6.0%)	8 (2.6%)
ACR20 at Wk 1	97 (16.0%)		25 (8.3%)
DAS28-CRP < 2.6 at Wk 12	53 (17.2%)	32 (10.7%)	9 (3.0%)
DAS28-CRP < 2.6 at Wk 24	44 (14.3%)	3S (12.8%)	7 (2.3%)
HAQ-DI reduction ≥ 0.22 at Wk 24	142 (46.1%)	126 (42.3%)	80 (26.5%)
	(n = 266)	(n = 260)	(n = 260)
Change from baseline in mTSS score at Wk 24	0.64	0.37	1.16

* Patients who withdrew for any reason, including non-response at Wk 12, or had an increased dose of their background DMARD or any DMARD initiated were considered non-responders at all subsequent visits. Non-responders at Wk 12 could be transferred to an extension study to receive Fosta 100 mg bid; however, the treatment arm to which they were initially randomized remained blinded for the duration of the study. Patients who successfully completed the scheduled treatment period could also enter the extension study.

The most frequently reported AEs in Fosta-treated pts included hypertension, nasopharyngitis, diarrhea and hepatic enzyme increases. No major differences in serious AEs were encountered between the 3 groups (6.8%, 4.7% and 3.3% of pts, respectively). As expected, patients developed elevated blood pressure with Fosta, with elevated BP (≥ 140/90 mmHg) observed in 49.8% and 48.1% (Groups A and B), vs. 29.5% of pts (PBO) at ≥ 1 visit during the first 24 wks.

Conclusion: Fosta had an early beneficial effect on signs and symptoms, disease activity and physical function in RA vs. PBO. The overall level of response with Fosta was not as large as observed in the phase ll (TASKi) program. Treatment at the higher dose (100 mg bid) generally showed a more consistent improvement in signs and symptoms. However, Fosta failed to show benefit in mTSS. Safety and tolerability findings were consistent with the profile observed in earlier Fosta studies.

Oskira-3: A Phase III, Multicenter, Randomized, Double-Blind, Placebo-Controlled Parallel-Group Study Of 2 Dosing Regimens Of Fostamatinib In Rheumatoid Arthritis Patients With An Inadequate Response To a Tumor Necrosis Factor-α Antagonist.

Mark Genovese[1], Désiréé van der Heijde[2], Edward Keystone[3], Alberto Spindler[4], Claude-Laurent Benhamou[5], Arthur Kavanaugh[6], Edward Fudman[7], Kathy Lampl[8], Chris O'Brien[8], Emma Duffield[9], Jeffrey Poiley[10] and Michael Weinblatt[11]. [1]Stanford University, Palo Alto, CA, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University of Toronto, Toronto, ON, [4]Centro Medico Privado de Reumatologia, Tucuman, Argentina, [5]Centre Hospitalier Régional d'Orléans, Orleans, France, [6]University of California San Diego, San Diego, CA, [7]Austin Rheumatology Research PA, Austin, TX, [8]AstraZeneca R&D Wilmington, Wilmington, DE, [9]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [10]Arthritis Associates, Orlando, FL, [11]Division of Rheumatology, Brigham & Women's Hospital, Boston, MA.

Background/Purpose: Fostamatinib (Fosta) is an oral SYK inhibitor. This 24-wk study (NCT01197755) compared Fosta vs placebo (PBO) on methotrexate (MTX) treatment in patients (pts) with active RA and an inadequate response to a single TNF-α antagonist.

Methods: Adult pts on MTX were randomized (1:1:1) to Fosta (100 mg bid for 24 wks [n = 105; Group (Gp) A] or 100 mg bid for 4 wks then 150 mg qd [n = 108; Gp B]) or to PBO (n = 109; Gp C) for 24 wks. Non-responders at Wk 12 could leave the study and enter an active extension study. The primary endpoint was the proportion of pts achieving ACR20 response at Wk 24. Secondary endpoints evaluated efficacy, safety and tolerability up to 24 wks.

Results: Baseline characteristics were well balanced across gps. Fosta Gp A, but not Gp B had significantly more pts achieving ACR20 at Wk 24 vs PBO (Table, p=0.004; p=0.168 respectively). At Wk 24, 36.2% of pts in Gp A, 27.8% of pts in Gp B, and 21.1% of pts on PBO achieved ACR20 (Table). Improvement was seen as early as Wk 1 (Table). Secondary endpoints were not tested statistically for Gp B due to failure of the primary endpoint. Fosta Gp A did not show a difference in radiographic outcomes at Wk 24 vs PBO. Frequently reported adverse events (AEs) in Gps A, B and PBO were diarrhea (20.0%, 26.9%, 6.4%), hypertension (13.3%, 13.9%, 8.3%) and headache (7.6%, 8.3%, 10.1%). Serious AEs occurred in 6.7%, 6.5% and 5.5% of pts. AEs leading to discontinuation (DAE) occurred in 9.5%, 10.2% and 8.3% of pts, the most frequent being diarrhea, abdominal pain, and vomiting. Elevated BP (≥ 140/90 mmHg) was observed in 46.7%, 51.9%, and 26.6% of pts at ≥ 1 visit.

Table. Patient discontinuations and secondary endpoints at or up to Wk 24

Endpoint*	Group A	Group 8	Group C
	Fosta 100 mg bid + MTX (n = 105)	Fosta 100 mg bid + MTX for the first 4 wks then 150 mg qd + MTX (n = 108)	PBO + MTX (ns 109)
Patients discontinuing treatment up to Wk 24	38 (36.2%)	43 (39.8%)	54 (49.1%)
ACR20 at WK 24	38 (36.2%)	30 (27.8%)	23 (21.1%)
ACR50 at Wk 24	19 (18.1%)	14 (13.0%)	9 (8.3%)
ACR70 at Wk 24	15 (14.3%)	3 (2.8%)	3 (2.8%)
HAQ-DI reduction ≥ 0.22 at Wk 24	44 (41.9%)	34 (31.5%)	26 (23.9%)
ACR20 at Wk 1	54 (25.4%)		4 (3.7)
DAS ≤ 3.2 at Wk 12	19 (18.1%)	22 (20.4%)	6 (5.5%)
DAS < 2.6 **at** Wk 24	12 (11.4%)	8 (7.4%)	4 (3.7%)
	(n = 81)	**(n = 87)**	**(n = 88)**
Mean change from baseline in mTSS score at Wk 24	0.80	**0.18**	0.84
Patients with mTSS change ≤ 0.5 **from** baseline at Wk 24	**56 (69.1%)**	**72 (82.8%)**	**63 (71.6%)**

*Pts who withdrew for any reason, or had an increased MTX dose or had any DMARD initiated were considered non-responders at all subsequent vi sits. Non-responders at WK 12 could be transferred to an extension study to receive Fosta 100 mg bid, however, the treatment arm to which they were initially randomized remained blinded for the duration of the study. Overall exposure up to 24 wks was 35.60 patient-years (PY) for PBO and 79.36 PY for Fosta.

The majority of pts' hypertension could be managed per protocol. 30/187 pts without baseline hypertension started antihypertensives during

the study (10, 15, and 5 in Gps A, B and C, respectively). In pts on baseline antihypertensives, 50/135 pts had an increase in baseline medication and/or a new therapy (21, 18, and 11 in Gps A, B and C, respectively). Three pts (2 Gp A; and 1 in Gp B) had a DAE due to hypertension.

There were 3 adjudicated CV events in Fosta Gp B (cardiopulmonary arrest with fatal myocardial infarction [2.4/100 PY]; heart failure; syncope). One event in PBO was adjudicated as indeterminate (2.7/100 PY; sudden death, unknown etiology). These were the only two deaths in the trial. There was 1 malignancy (2.4/100 PY; renal cell carcinoma) in Fosta Gp B.

Conclusion: In this phase III study in pts with an inadequate response to a single TNF-α antagonist, Fosta 100 mg bid but not Fosta 100 mg bid for 4 wks then 150 mg qd achieved statistical improvements in ACR20 response rate at 24 wks vs PBO. The overall level of response was not as large as had been anticipated based on evaluation of Phase 2 results (eg the TASKi program). Safety and tolerability findings were consistent with the profile observed in earlier Fosta studies.

Pharmacodynamic Effect Of Intravenous Golimumab By Messenger Ribonucleic Acid Expression Profiling. Yauheniya Cherkas, Carrie Brodmerkel, Mark Curran and Sarah Lamberth. Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: RA is a chronic systemic autoimmune disease resulting in joint inflammation and damage. Despite the current therapies available, only a small percentage of RA pts achieve remission. To improve care and treatment for RA pts, a deeper understanding of the mechanisms that drive disease and response to therapy are desirable. The molecular understanding of disease and treatment mechanisms of RA continues to evolve. To explore the utility of peripheral blood expression profiling for informing disease and treatment mechanisms, samples derived from the GO-FURTHER golimumab study in RA were evaluated. This study examines if whole blood (WB) gene expression profiles can be utilized to: identify a baseline disease profile (DP) for pts with moderate-to-severe RA elucidate the pharmacodynamic (PD) and response profile of golimumab IV treatment, and delineate the peripheral biological processes dysregulated in RA and modulated by golimumab IV.

Methods: mRNA from 487 WB samples collected in a Phase III study of golimumab IV (GO-FURTHER) in pts with active RA despite methotrexate (MTX) therapy was isolated and profiled using the Affymetrix HT HG-U133+ PM Array (Santa Clara, CA). Samples were collected at Wks 0 and 14 from pts treated with IV placebo + MTX (PBO; n= 161) or IV golimumab 2mg/kg + MTX (GLM; n=326) administered at Wks 0, 4, and every 8 wks thereafter. Non-RA WB samples (healthy controls; n=22) were obtained from Bioreclamation (Hicksville, NY).

Results: A disease profile comparing baseline gene expression profiles of RA to healthy controls yielded about 2000 differentially expressed genes (DEGs), while comparison of post-treatment to pretreatment samples generated a PD profile of about 3000 DEGs. Over 70% of genes in the DP are downregulated as well as humoral immune response and B and T cell receptor signaling pathways. Pathways upregulated in the DP include innate immune response, Toll-like receptor (TLR), and cell activation. Treatment with golimumab modulates more than 30% of the disease profile, while just over 25% of PD effect is shared with the DP. The above mentioned pathways are common between the DP and PD profiles and are reversed, in part, through changes in peripheral cell populations post-golimumab treatment. A significant decrease in neutrophils and increase in lymphocytes was observed in the periphery at Wk 12 and in gene expression profiles representative of these cells at Wk 14 post-treatment. In addition, response to golimumab at Wk 14 was associated with more gene changes in B and T cell receptor signaling pathways in comparison to nonresponders.

Conclusion: Gene expression from the periphery of RA pts can be used for identification of a DP as well as the PD effect and response profile to golimumab IV. The most significant biological pathways and functions associated with the DP or PD effect are related to immune response and function. At baseline, RA pts had an increased innate and decreased adaptive immune profile in the periphery and majority of these processes were reversed by treatment with golimumab IV. Defining the pathways dysregulated in RA and modified by effective treatment as well as those that remain dysregulated aids in defining novel areas for potential therapeutic intervention.

High Levels Of Natural Killer CELLS ARE Associated With Response To Tocilizumab In Patients With Severe Rheumatoid Arthritis. Claire I. Daien[1], Sarah Gailhac[2], Rachel Audo[3], Thibault Mura[4], Michael Hahne[3], Bernard Combe[1] and Jacques Morel[1]. [1]Lapeyronie Hospital, Montpellier, France, [2]CNRS, Montpellier, France, [3]IGMM, CNRS UMR5535, Montpellier, Montpellier, France, [4]Hopital Gui De Chauliac, Montpellier, France.

Background/Purpose: Inhibition of interleukin 6 (IL-6) receptor with tocilizumab (TCZ) is effective for rheumatoid arthritis (RA). However, the effect of TCZ on lymphocytes remains poorly studied. We analyzed the effect of TCZ on proportion of B, T, natural killer (NK) and NK T (NKT) cells in patients with RA and healthy controls and cell type predictors of disease activity response (disease activity in 28 joints [DAS28]). Secondary objectives were association of NK cells and disease activity in patients with RA, effect of TCZ on NK-cell cytotoxicity and effect of anti-tumor necrosis factor (anti-TNF) therapy on NK-cells.

Methods: Included patients had to meet 2010 ACR/EULAR criteria, be receiving steroids with stable doses $<$ 10 mg per day and not have received rituximab in the previous year. Healthy subjects were recruited. Patients with TCZ introduced at baseline were followed at 3 and 6 months. Different B and T cell subsets, NK and NKT were assessed by flow cytometer as well as perforin A and granzyme B to estimate NK-cell cytotoxicity.

Results: We included 25 controls and 92 RA patients, including 20 requiring TCZ treatment and 15 requiring anti-TNF drugs. At baseline, patients with RA had significantly lower proportion of regulatory T cells (Tregs), as defined by $CD4^+CD25^{hi}CD127^{lo}$, than controls ($p=0.003$), and the proportion of $CD56^{dim}CD16^+CD3^-$ NK cells was inversely correlated with DAS28. The proportion of Tregs was increased at 3 months but not 6 months. Baseline proportion of $CD3^-CD56^+$ NK cells was inversely correlated with change in DAS28 score at 3 months, and the proportion was three-fold greater for patients with DAS28 $<$ 2.6 (disease remission) at 3 months than other patients. Change in proportion of $CD56^{bri}CD16^-$ NK cells was linearly correlated with change in DAS28 at 3 months. The baseline proportion of NK cells did not predict change in disease activity at 3 months with anti-TNF therapy. Perforin content in NK cells was increased with TCZ treatment.

Conclusion: This study supports NK cell involvement in RA. TCZ transiently increased the proportion of Tregs and increased perforin content in NK cells. NK cells at baseline could be a predictive factor of TCZ response if results are confirmed.

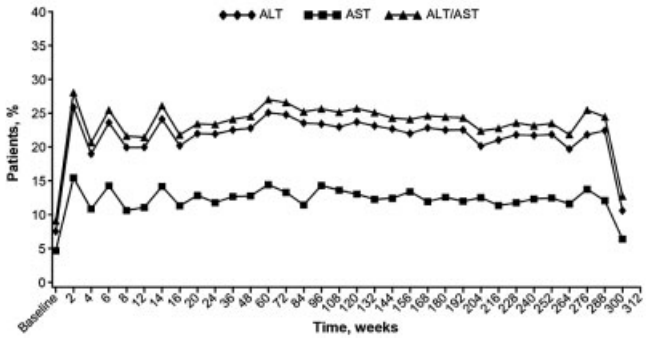
Transaminase Levels and Hepatic Events Observed During Tocilizumab Treatment: Pooled Analysis Of Long-Term Clinical Trial Safety Data In Patients With Rheumatoid Arthritis. Mark C. Genovese[1], Joel M. Kremer[2], Ronald F. van Vollenhoven[3], Rieke Alten[4], Juan José Scali[5], Ariella Kelman[6], Lucy Rowell[7] and Laura Pitts[7]. [1]Stanford University Medical Center, Palo Alto, CA, [2]Center for Rheumatology, Albany Medical College, Albany, NY, [3]Karolinska Institute, Stockholm, Sweden, [4]University of Berlin, Berlin, Germany, [5]Durand University Hospital, Buenos Aires, Argentina, [6]Genentech, South San Francisco, CA, [7]Roche, Welwyn Garden City, United Kingdom.

Background/Purpose: The interleukin-6 receptor inhibitor tocilizumab (TCZ) has demonstrated efficacy in improving signs/symptoms, reducing joint damage, and improving function and is well tolerated in patients (pts) with rheumatoid arthritis (RA). Elevated transaminase levels can occur, and, therefore, routine monitoring is recommended with TCZ treatment. This analysis examined the effect of TCZ on transaminase levels and evaluated hepatic serious adverse events (SAEs) observed in the clinical trial program.

Methods: Analyses were performed in all pts who received ≥1 dose of TCZ in 1 of 5 phase 3 placebo-controlled studies (OPTION, TOWARD, RADIATE, AMBITION, LITHE), a clinical pharmacology study, a phase 4 TCZ monotherapy study (ADACTA), or long-term extension studies. Pts with ALT/AST >1.5×ULN were excluded from the studies. Per protocol and consistent with recommendations in the USPI, DMARDs and TCZ dose were modified for ALT/AST elevations. Data were pooled and analyzed from initial TCZ exposure to May 2, 2012.

Results: In total, 4171 pts were included. Mean (median [range]) duration was 3.9 y (5.1 [0.0–6.8]); observation time was 16204.8 pt-y (PY). At baseline, 92.2%/95.2% of pts had ALT/AST levels within the normal range. Most pts were taking concomitant methotrexate at baseline or during the studies. Mean and median ALT/AST levels increased within the normal range after initiation of TCZ and remained stable at the higher level thereafter. ALT/AST levels increased from normal at baseline to >ULN at least once in 70.6% (2712/3839) and 59.4% (2357/3965) of pts, respectively, during the study period. In most of these pts, the highest postbaseline value was >1-≤3×ULN; elevations to >5×ULN occurred in 2.9% and 0.9% of pts, respectively. There was no trend for increased risk of transaminase level elevations over time (Figure). Analysis of ALT/AST increases >3×ULN over time showed that the elevations were single occurrences in most pts; at most, 0.2% of pts sustained elevations in ALT/AST during any 12-month study period. Elevated transaminase levels led to withdrawal in 2.5% of pts (105/4171); most withdrawals occurred during the first 12 months of treatment. There were 7 cases of hepatic SAEs (overall rate: 0.04/100 PY [95% CI: 0.02, 0.09]). Events were variable in nature with no pattern over time, and the rate was consistent with the background rate of hepatic SAEs estimated for RA pts treated with other biologic and conventional DMARDs.[1, 2]

Figure. Rate of ALT and AST Elevations >ULN to 3×ULN (All Exposure Population).



Conclusion: Mean transaminase levels increased early in TCZ treatment, and the proportion of pts with elevations did not increase with continued TCZ exposure. In most pts, the elevations were single occurrences ≤3×ULN. To date, there is no evidence of increased rate of hepatic SAEs in pts treated with TCZ.

Comparative Efficacy Of Novel Disease-Modifying Antirheumatic Drugs As Monotherapy and In Combination With Methotrexate In Rheumatoid Arthritis Patients With An Inadequate Response To Traditional Disease-Modifying Antirheumatic Drugs: A Network Meta-Analysis. Felicity Buckley[1], Axel Finckh[2], Thomas W.J. Huizinga[3], Fred Dejonckheere[4] and Jeroen P. Jansen[1]. [1]MAPI Consultancy, Boston, MA, [2]University of Geneva, Geneva, Switzerland, [3]Leiden University Medical Center, Leiden, Netherlands, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland.

Background/Purpose: To compare ACR responses of novel DMARDs as monotherapy or in combination with methotrexate (MTX), including subcutaneous (SC) abatacept and SC tocilizumab (TCZ), in RA patients with an inadequate response to conventional DMARDs (DMARD-IR).

Methods: A systematic literature review identified randomized clinical trials (RCTs) that evaluated abatacept (intravenous [IV] and SC), anakinra, adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, tofacitinib, and TCZ (IV and SC). Thirty RCTs were identified. Reported treatment effects in terms of ACR responses at 24 weeks were synthesized by means of Bayesian network meta-analyses to allow comparisons of the different treatments as monotherapy and combination therapy. Based on previous reviews[1,2] an assumption was made that the effects of anti-tumor necrosis factor (aTNF) therapy were exchangeable. Given this, and the limited data identified for these therapies in monotherapy, aTNF data were pooled.

Results: aTNFs + MTX, tofacitinib + MTX, abatacept IV/SC + MTX, and TCZ IV/SC + MTX demonstrated comparable ACR responses while anakinra + MTX was less efficacious. Among biologic monotherapies, greater ACR20/50/70 responses were observed with TCZ IV than with aTNFs and tofacitinib (Figure 1). When comparing biologics + MTX with biologic monotherapies, ACR20, ACR50, and ACR70 responses with TCZ + MTX were similar to TCZ as monotherapy (OR=1.04, 95% CI, 0.39–2.80; OR=1.28, 95% CI, 0.46–3.51; OR=0.97, 95% CI, 0.38–2.49, respectively), whereas with aTNF + MTX greater ACR20/50/70 responses were observed than with aTNF monotherapy (OR=2.22; 95% CI, 0.46–10.83, probability better=84%; OR=3.12, 95% CI, 0.60–16.32, probability better=92%; OR=1.39, 95% CI, 0.26–6.78, probability better=68%, respectively). For tofacitinib, sensitivity analyses showed conflicting results for the indirect comparison of tofacitinib + MTX versus tofacitinib.

Conclusion: Results of this meta-analysis suggest that most available novel DMARDs, in combination with MTX, have similar levels of efficacy in DMARD-IR patients. As monotherapy, TCZ is likely to have a greater response than aTNFs and tofacitinib. TCZ monotherapy also shows comparable efficacy compared to TCZ + MTX, whereas aTNFs in combination with MTX showed greater ACR responses compared with aTNF monotherapy at 24 weeks.

Higher TNFi Dosing Is Not Associated With More Serious Infectious Events (SIE), Elevated AST/ALT Or WBC. Daniel Furst[1], Mei Liu[2], Jeffrey D. Greenberg[3] and Joel M. Kremer[4]. [1]David Geffen School of Medicine, UCLA, Los Angeles, CA, [2]CORRONA, Inc, Southborough, MA, [3]NYU Hospital for Joint Diseases, New York, NY, [4]Albany Medical College and The Center for Rheumatology, Albany, NY.

Background/Purpose: There is a perception that higher TNFi doses result in increased adverse events (AEs) in selected AEs such as SIE, increased ALT/AST or WBC<1.5. We examined this perception in the USA CORRONA database.

Hypothesis: Higher doses of TNFi are associated with an increased incidence of SIE, increased ALT/AST and/or WBC<1.5.

Methods: We examined the US CORRONA registry between Oct 1, 2001 and Feb 15, 2013. This registry is an independent, prospective, observational cohort of rheumatic disease patients (in this case rheumatoid arthritis (RA) patients (pts)) among 159 sites in the United States.

Inclusions Patients with a diagnosis of RA who started their first TNFi without prior biological use, with TNFi doses recorded and followed for ≥ 3 months.

High-dose TNFi was defined as: ≥ 5 mg/kg infliximab q8wks, > 50 mg etanercept wkly, 40 mg adalimumab wkly, >400 mg certolizumab q4wk or > 50 mg golim. q4wk for at least 3 months.

Adverse Events (AEs) were defined as: SIE (infection requiring hospitalization or IV antibiotic), AST+/−ALT > upper limit of normal or WBC<1.5.

Analysis Descriptive statistics were done. A Cox proportional hazards model assessed the association of TNFi AEs of interest; if P≤0.2 in the univariate model, the variables were included in the multivariable model. For WBC, hazard ratio (HR) from the univariate Cox regression was used because there were too few instances for multivariate analysis.

Results: Of 4195 TNFi-starter RA patients naïve to other biologics, 2688 met inclusion criteria and constituted the test set. There were 388 high dose (14.4%), versus 2300 low dose (85.6%) pts.

The High dose group was older and generally had more active, severe disease (High versus Low P value): Age: 60 vs. 56 yrs; CDAI: 17.2 versus 14.5; erosion: 41.1 versus 18.8%; RF/CCP pos.: 80.1 versus 74.6%-all P <0.05–0.001. Shorter F/U for the High dose group (35.8±27.9 vs. 39.7±30.0 mos; P= 0.02) was not clinically significant (10%). The incidence rates and dose effects for SIEs, ALT/AST and WBC<1.5 are shown in table 1.

		SIE	ALT/AST	WBC < 1.5
% event (High + Low)		3.3	26.7	0.6
Incidence/100 pt-yrs	High*	0.7	9.8	0.20
	Low**	1.1	11.8	0.23
Person yrs f/u × 100	High	11.6	8.6	10.0
	Low	76.1	53.8	69.5
Dose comparison HR (95% CI)		0.52 (0.24, 1.12)	0.77 (0.59, 1.02)	0.91 (0.21, 3.95)

*High dose n= 388
**Low dose n= 2300

Discussion: In this real-life cohort of RA pts, higher dose users had more active, severe disease. Since the high-dose group had lower BMI (P< 0.05), the High dose users were especially likely to be using higher milligrams/m2 doses, supporting the credibility of the results. As in all registries, however, some selection bias may have contributed to the lack of differences found in High vs. Low dose TNFi users.

Conclusion: High dose TNFi users with RA did not seem to be subject to more SIE, AST/ALT elevations or WBC<1.5 than Low dose users, within the limits of TNFi doses used within usual clinical practice in this real-life cohort of patients in the USA.

Reduced Response To Biologic Treatments in Rheumatoid Arthritis Patients Affected By Arterial Hypertension. Marco Antivalle[1], Michel Chevallard[2], Michele Battellino[2], Alberto Batticciotto[1], Maria Chiara Ditto[2], Alessandra Mutti[2], Federica Rigamonti[2], Valentina Varisco[2], Sara Bongiovanni[2], Fabiola Atzeni[3] and Piercarlo Sarzi-Puttini[1]. [1]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy, [2]Rheumatology Unit, L. Sacco University Hospital, Milano, Italy, [3]Rheumatology Unit, L. Sacco University Hospital, MiIano, Italy.

Background/Purpose: Several reports show that the presence of comorbidities negatively influences both functional status (1) and quality of life (2) in rheumatoid arthritis (RA). No published study, however, has addressed the impact of comorbidities on the response to biologic treatments. Aim of the present study was to assess whether the presence of arterial hypertension influences the clinical response to biologics in RA.

Methods: The study population consisted of 526 patients affected by RA (416 F 110 M, mean age 53.8±14.27 yrs) treated with first-line biologic treatments. 349 (66.3%) patients were normotensive (NT), and 177 (33.7%) hypertensive (AH). Disease activity was evaluated by DAS28. The 6-month response to biologic treatments was evaluated by EULAR response criteria, and by the percentage of patients in low disease activity (DAS28 <3.2) and in remission (DAS28<2.6). The differences in the percentage of responders between the 2 groups were analyzed by generalized linear models, correcting data for confounder variables (age, sex, baseline disease activity, disease duration), and for the presence of other comorbidities (diabetes, dyslipidemia, ischemic heart disease, osteoporosis, fibromyalgia, thyroid disease and COPD). In the following test, the observed percentages are reported, while statistical significance (p values) refers to corrected values. All statistical analyses were performed with the IBM SPSS 20.0 software.

Results: The vast majority of patients were treated with anti-TNF biologics in both groups (AH 94.5%, NT 90.6%, p=0.177). The percentage of females (AH 82% NT F 78%, p=0.586) was not significantly different in the 2 groups, while mean age was significantly higher in AH patients (59.85±12.53 vs 51.29±14.29 yrs, p=0.000), and disease duration in NT patients (4.4±6.4 vs 2.5±5.1 yrs, p=0.001). Among the other comorbidities, only the prevalence of dyslipidemia, osteoporosis, and COPD was significantly higher in AH group (p<0.05). Biologic treatment was stopped or switched in 192/526 (36.5%) patients before the 6th month, without a significant difference between the 2 groups (AH: 75/177 (42.4%); NT 117/349 (33.5%), p=0.361). Baseline DAS28 was higher in AH patients (5.73±1.11 vs 5.18±1.34, p=0.000). EULAR response at 6 months (Fig. 1), and the percentage of patients in low disease activity (14/102 (13.7)% vs 71/232 (30.6%), p=0.000) and in remission (8/102 (7.8%) vs 48/232 (20.7%), p=0.001) (Fig. 2) were significantly lower in AH patients.

Fig 1. EULAR response after 6 months of treatment with biologics in normotensive and hypertensive RA patients

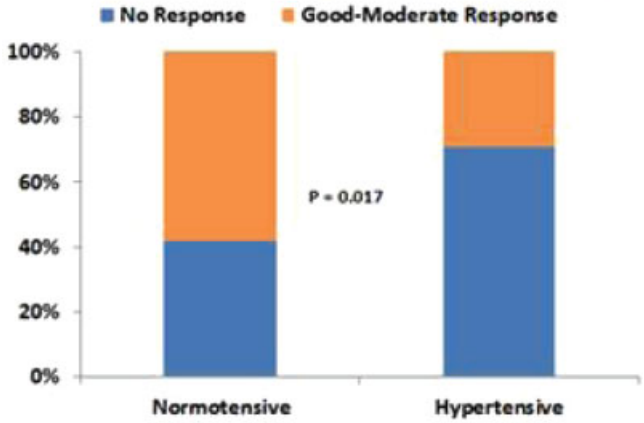

Fig 2. Percentage of patients in low disease activity and remission after 6 months of treatment with biologics

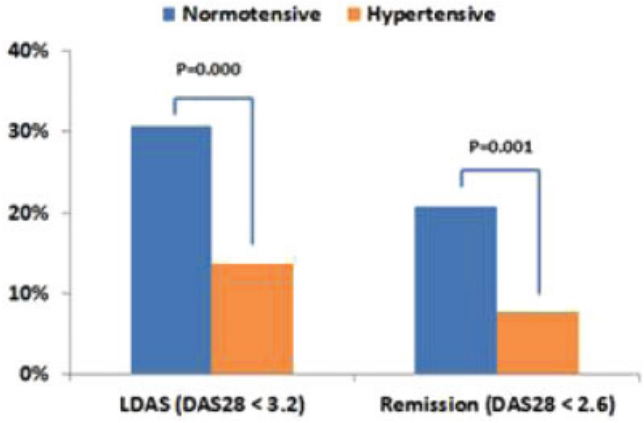

Conclusion: Concomitant arterial hypertension influences negatively the response to biologic treatments in rheumatoid arthritis. The presence of comorbidities should be taken into account in the evaluation of the clinical response to biologic treatments.

An Indirect Comparisons Analysis Between Biologic Disease Modifiers in The Treatment Of Rheumatoid Arthritis To Evaluate For Efficacy and Safety. Aaron C. Garza Romero, Elie Donath, Hernan Osorno and Suresh Kumar. University of Miami Miller School of Medicine Palm Beach Regional Campus, Atlantis, FL.

Background/Purpose: There are primarily six groups of biologic disease modifiers (BDM) for treatment of rheumatoid arthritis (RA): tumor necrosis factor inhibitors (infliximab (IFX), etanercept (ETN), adalimumab (ADM), certolizumab pegol (CZP) and golimumab (GLM), B-Cell depleting anti CD20 antibodies (rituximab), selective coestimulator blocker (abatacept (ABT), interleukin 6 inhibitor (tocilizumab (TCZ), interleukin 1 receptor antagonist (anakinra) and Janus associated kinase inhibitor (tofacitinib). BMD are known to interfere in the immune system leading to concerns on their safety. In general, patient/physician preference is what mandates the choice of drug. This is partially due to lack of evidence comparing these drugs to one another (the majority of evidence is based on randomized controlled trials (RCT's) that are compared to methotrexate (MTX). The objective of this research is to perform a network meta-analysis among these drugs, using the MTX group as a common comparator, to determine their efficacy and safety.

Methods: Studies were extracted from a computerized literature search of MEDLINE and EMBASE of all relevant RCT's. 41 RCT's, including 12,487 patients, were identified. There were three outcomes of interest for efficacy: ACR20, ACR50 and ACR70 response. There were several outcomes of interest for safety, primarily serious infections requiring intravenous antibiotics or hospitalization: pneumonia, cellulitis, skin abscess, sepsis, septic arthritis, urinary tract infection, TB and opportunistic infections, sudden cardiac death and death. For each outcome, a fixed-effects meta-analysis was employed to compare each drug to MTX. A mixed-treatment comparisons analysis was then used to compare each of these drugs to one another indirectly. Calculation of the probability that each treatment is best was implemented using the Bayesian Markov chain Monte Carlo method.

Results: In terms of ACR20 response, patients taking IFX (10mg/kg) had a highly statistically significant likelihood of achieving response compared to ADM (RR 0.33, 95% CI 0.11 – 1.00) and a similar benefit was seen in patients taking CZP compared to ADM (RR 0.21, 95% CI 0.06 – 0.69). In terms of ACR50 response, patients taking CZP had a statistically significant increased likelihood of achieving response compared to ABT (RR 0.32, 95% CI 0.11 – 1.04). In terms of ACR70 response, patients taking IFX (10 mg/kg) had a statistically significant higher likelihood of response compared to ABT (RR 0.31, 95% CI 0.09 – 0.90), ADM (RR 0.30, 95% CI 0.09 – 0.82), ETN (RR 0.22, 95% CI 0.06 – 0.70) and GLM (RR 0.29, 95% CI 0.07 – 0.98) and a similar benefit was seen in patients taking TCZ compared to ABT (RR 0.30, 95% CI 0.10 – 0.99), ADM (RR 0.29, 95% CI 0.09 – 0.87) and ETN (RR 0.21, 95% CI 0.06 – 0.80). Patients taking IFX (3mg/kg) had a statistically significant decreased risk of death compared to ADM (RR 0.09, 95% CI 0.01 – 0.97. The degree of incoherence (measuring how closely the network fits together) was low for all outcomes.

Conclusion: This was the first attempt to include all BDM used in the treatment of RA in a network meta-analysis. Important results on safety and efficacy outcomes were discovered, future research is required to better elucidate these findings.

The Efficacy and Safety Of Tocilizumab Subcutaneous Versus Tocilizumab Intravenous, In Combination With Traditional Dmards In Patients With RA At 49 Weeks (SUMMACTA). Gerd R. Burmester[1], Andrea Rubbert-Roth[2], Alain G. Cantagrel[3], Stephen Hall[4], Piotr Leszczynski[5], Daniel Feldman[6], Madura J. Rangaraj[7], Georgia Roane[8], Charles L. Ludivico[9], Eduardo F. Mysler[10], Chris Wells[11], Melanie Bennett[12] and Ivana Vranic[12]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Klinikum der Universität zu Köln, Köln, Germany, [3]Centre Hospitalier Universitaire de Toulouse, Toulouse, France, [4]Cabrini Medical Centre, Malvern, Australia, [5]J. Strus Poznan Municipal Hospital, Poznan University of Medical Sciences, Poznan, Poland, [6]Universidade Federal de São Paulo, Sao Paulo, Brazil, [7]Arthritis & Diabetes Clinic, Inc., Monroe, LA, [8]Rheumatology Associates of South Carolina, Charleston, SC, [9]East Penn Rheumatology Associates, PC, Bethleham, PA, [10]Organización Médica de Investigación, Buenos Aires, Argentina, [11]Roche, Welwyn Garden City, United Kingdom, [12]Roche Products Ltd., Welwyn Garden City, United Kingdom.

Background/Purpose: The efficacy and safety of subcutaneous tocilizumab (TCZ SC) were demonstrated in a 24 week (wk) randomized clinical trial (SUMMACTA). The cumulative safety, immunogenicity and continued efficacy in patients (pts) with RA who were rerandomized to receive either TCZ SC or TCZ IV in the open label (OL) period was evaluated at 49 wks.

Methods: SUMMACTA is a 2-year, Phase 3 trial, which is a randomized, active controlled, parallel group study that includes a 24 wk double-blind (DB) period, followed by a 72 wk OL phase. During the DB period, pts were

randomized 1:1 to receive TCZ SC weekly (qw) or TCZ IV every 4 wks (q4w) in combination with traditional DMARDs. After the DB period, pts who initially received TCZ SC 162 mg qw were re-randomized 11:1 to receive TCZ SC 162 mg qw or TCZ IV 8mg/kg q4w and pts who initially received TCZ IV 8mg/kg q4w were re-randomized 2:1 to receive TCZ IV 8mg/kg q4w or TCZ SC 162 mg qw.

Results: A total of 1262 pts were initially enrolled (TCZ SC, n = 631; TCZ IV, n = 631). At Wk 25, 521 pts continued TCZ SC and 372 pts continued TCZ IV; 48 pts switched from TCZ SC to TCZ IV and 186 pts switched from TCZ IV to TCZ SC. 61 (12%) pts in the TCZ SC group and 43 (12%) pts in the TCZ IV group withdrew from the study in the OL period; most commonly due to safety. The percentage of pts who continued TCZ SC and TCZ IV who achieved ACR20/50/70 responses, DAS28 remission and an improvement from baseline in HAQ-DI ≥ 0.3 were sustained up to 49 wks and were comparable between the groups (Table). Efficacy in pts after switching from TCZ IV to TCZ SC or TCZ SC to TCZ IV was comparable to pts who received continuous TCZ SC or TCZ IV. Rates of adverse events (AE), serious AEs, serious infections and malignancies for TCZ SC and TCZ IV were comparable between 24 and 49 wks (Table). The rate of injection site reactions (ISRs) decreased over time, but remained higher for pts receiving TCZ SC compared with pts receiving TCZ IV, as previously reported for wk 24. There were 3 deaths each in the TCZ SC and TCZ IV groups that occurred between wks 24 to 49. AntiTCZ antibody development remained low to wk 48 and no anaphylaxis occurred. The safety profile of pts who switched from TCZ IV to TCZ SC and vice versa were similar to pts who received continuous TCZ SC or TCZ IV.

[a] The Week 24 ITT population contained all patients who received a dose of TCZ, and groups are presented according to the treatment randomized at baseline. The Week 49 ITT Population contained all patients who received a dose of TCZ post week 24 and groups contain patients who were re-randomized to the same treatment they were allocated at baseline.
[b] The per protocol population is the primary efficacy analysis for week 24.
[c] Excludes tuberculosis (TB). Up to Week 49 data cut, there was 1 case of latent TB in the TCZ SC arm and none in other treatment groups.
[d] All malignant and unspecified tumors were included.
[e] SAEs occuring during or within 24 hours of the injection/infusion, excluding ISRs, and that were not deemed to be unrelated to treatment by the investigator.

Conclusion: These data demonstrate that efficacy rates for pts continuing on TCZ SC over 49 wks are maintained and remain comparable to TCZ IV, as shown at Wk 24. The wk 49 cumulative safety profiles of pts on TCZ SC were consistent with Wk 24 data and to TCZ IV, with the exception of ISRs, which were lower in the TCZ IV group. The efficacy and safety profile of pts who switched from TCZ IV to TCZ SC and vice versa was similar to pts who remained on TCZ SC or TCZ IV. AntiTCZ antibody (including IgE isotype) development did not correlate with AEs or loss of efficacy with prolonged TCZ SC exposure. TCZ SC formulation could provide an additional, more convenient administration route for pts with RA.

Higher Titer Of Anti-Citrullinated Protein Antibodies In Biologic-Naïve Rheumatoid Arthritis Patients Are Candidate Biomarkers To Predict Sensitivity Leading To Clinical Remission With Abatacept; Data From The Abroad Study.

Takao Fujii[1], Masahiro Sekiguchi[2], Kiyoshi Matsui[2], Masayasu Kitano[2], Motomu Hashimoto[1], Koichiro Ohmura[1], Aihiro Yamamoto[3], Hideko Nakahara[4], Keiji Maeda[4], Akira Yokota[5], Kenji Miki[6], Naoki Shimmyo[7], Takanori Kuroiwa[8], Kosaku Murakami[1], Yoshio Ozaki[9], Kenshi Higami[10], Ichiro Yoshii[11], Yuji Nozaki[12], Takashi Ikawa[13], Satoshi Morita[14], Yutaka Kawahito[3], Norihiro Nishimoto[15], Tsuneyo Mimori[1] and Hajime Sano[2]. Background/Purpose: Biomarkers to predict each rheumatoid arthritis (RA) patient's sensitivity for biologic disease modifying anti-rheumatic diseases, especially for the only T cell modulator abatacept (ABT), is of high interest from the points of view of medication and medical economy. The purpose of this study is to determine the predicting factors of clinical remission by ABT in biologic-naïve RA patients.

Methods: Efficacy and safety of ABT are being investigated with Japanese biologic-naïve RA patients (N=155) in the ABROAD study (ABatacept Research Outcomes as a first-line biological Agent in the real worlD, an ongoing, prospective, multicenter cohort study in the west side of Japan, female = 83.2%, mean age at the ABT initiation = 61.3 years old, and disease duration = 8.1 years). In this study, simplified disease activity index (SDAI) remission (μ3.3) rate at 24 wks is defined as a goal of treatment and a merkmal of patient's sensitivity to ABT. Correlation between the SDAI remission rate and other clinical indexes before ABT treatment were analyzed by the univariate analysis method. During the analysis, anti-citrullinated protein antibodies (ACPA) titer values before treatment were classified into 4 groups; negative (less than the upper limit of normal [ULN], <4.5 U/mL), low-positive (less than 3 times of the ULN, 4.5–13.5 U/mL), high-positive (less than 22 times of the ULN, 13.6–99 U/mL), and very high-positive (equal or more than 22 times of the ULN, μ99 U/mL), and each group was studied independently.

Results: SDAI remission at 24 wks was achieved in 16% of the patients. Very high-positive ACPA (Odds ratio [OR] = 4.44, 95% confidence interval [CI] = 1.28–15.38, p = 0.019) were significantly associated with the SDAI remission. High-positive group was slightly inclinable but insignificant. Low-positive and negative groups had no correlations. As the reference, short disease duration (<1 year) (OR =2.79, 95% CI = 1.02–7.61, p = 0.045 vs. μ1 year) and moderate disease activity at baseline defined by DAS28-CRP (OR = 4.39, 95% CI = 1.55–12.5, p = 0.005 vs. high disease activity) were also significantly associated with the SDAI remission at 24 wks, and male gender (OR = 2.76, 95% CI = 0.91– 8.40, p = 0.072 vs. female) appeared to be linked. While age at ABT initiation, concomitant use of methotrexate, CRP level at baseline, and the 1987 ACR criteria fulfillment were not statistically associated with the SDAI remission. ACPA positivity association with a better response to ABT observed in this study sustained French report of the ORA registry (Gottenberg JE, *et al, ARD* 2012;71:1815).

Conclusion: Higher titer of ACPA in biologic-naïve RA patients, in whom T and B lymphocytes are possibly activated, could be a candidate biomarker to predict sensitivity for ABT.

Biologic Monotherapy in French Rheumatoid Arthritis (RA) Patients From a Real-Life Clinical Practice Compared To Patients Treated with a Combination Therapy (Biologic + DMARD). Philippe Dieude[1], Chantal Deslandre[2], Emilie Desfleurs[3], Jeanne Antheaume[3] and Jean-Charles Balblanc[4]. [1]Rheumatology departement & INSERM U699, Paris Diderot university, APHP, Bichat hospital, Paris, France, [2]Cochin Hospital, Paris, France, [3]Roche SAS, Boulogne-Billancourt, France, [4]Centre Hospitalier Général de Belfort, Belfort, France.

Background/Purpose: Combination therapy (Biologic+non-biologic (nb)DMARDs) is the recommended therapeutic strategy in biologic-based RA treatment. However, biologics in montherapy represent around 30% of the biologic-treated patients (1–3).

Objectives: Evaluate in a real life setting the rate of patients treated with biologics as monotherapy (Mono) vs in combination with a nbDMARD (Combo) and compare the characteristics of these two populations.

Methods: 15-week prospective survey among 121 French representative rheumatologists (region and activity) treating RA patients with biologics in Mono or in Combo. Each physician completed a short record-sheet for biologic-treated RA patients seen in Q4 2012 (CENSUS). A more detailed record sheet was filled-in for the 5 next Mono patients and the 5 next Combo patients (FOCUS). Reported data were patients' and disease characteristics, current and previous treatment and therapeutic strategy.

Results: 1949 patients were included in the CENSUS. Patients characteristics were as followed: mean age 54,2 years, 72% female, mean disease duration 12,5 years, 81% ACPA positive and 68% erosive RA. Regarding disease activity, 40% were in DAS28 remission (<2,6) and 36% presented a low disease activity (DAS<3,2).The survey showed that 34% (n=662) of these patients were on biologic Mono. Patients treated by an office-based rheumatologist (n=404) were more often on a biologic in Mono (43% vs 32%, $p<0.01$) than patients treated at hospital. No differences in terms of patients characteristics were observed between Mono and Combo patients except for a negative ACPA serology (22% Mono patients vs 14% Combo, $p<0.01$) and corticosteroids which were more frequently used in Mono patients (64% vs 58%, $p=0.02$). The main biologics prescribed in Combo were Etanercept (ETN, 35%) and Adalimumab (ADA, 24%) and in Mono ETN (34%), ADA (23%) and Tocilizumab (TCZ, 19%). Compared to the other biologics, TCZ appeared to be more frequently used in Mono than in Combo with 54% of TCZ-patients treated in Mono vs 33% for both ETN- and ADA-patients. The survey also showed that among patients treated with a biologic without Mono label, approximately 1/3 received it in Mono. The majority (86%) of Combo patients were on MTX at a median dosage of 15mg/week. The FOCUS included 445 patients on Combo and 369 patients on Mono, who were representative of the CENSUS patients (no difference observed between both parts). For patients treated currently with a biologic in Mono, main reasons for stopping DMARDs were: intolerance 43%, lack of efficacy 31%, remission 18%, and patients' refusal 12%.

Conclusion: This survey showed that in a French real life clinical practice, 34% of RA patients treated with a biologic received it in Mono. This result is concordant with French and European registries (1–3) data. Surprisingly, no relevant difference was observed in terms of characteristics between patients treated in Mono and patients treated in Combo, except for ACPA status.

467

Adherence To Conventional Disease Modifying Anti-Rheumatic Drugs (cDMARDs) In Rheumatoid Arthritis (RA) Patients Treated In Association With a Biologic: A French Cross-Sectional Survey. Jean-Charles Balblanc[1], Philippe Dieude[2], Emilie Desfleurs[3], Jeanne Antheaume[3] and Chantal Deslandre[4]. [1]Centre Hospitalier Général de Belfort, Belfort, France, [2]Rheumatology departement & INSERM U699, Paris Diderot university, APHP, Bichat hospital, Paris, France, [3]Roche SAS, Boulogne-Billancourt, France, [4]Cochin Hospital, Paris, France.

Background/Purpose: A recent meta-analysis of aTNF and abatacept clinical trials established in those drugs that the efficacy of combination therapy with biologic is superior to methotrexate for remission (1). Therefore, non-adherence to cDMARDs prescribed in combination with a biologic may reduce the benefit obtained with these agents.

Objectives: To evaluate the adherence to cDMARDs and biologics in RA patients from both a rheumatologist's and patient's perspective.

Methods: A panel of French representative rheumatologists (rheums) were questioned on their perception of their patient's adherence to cDMARDs and were asked to collect data (age, gender, disease duration, disease activity, treatment characteristics) on their five next patients treated with biologic in combination with cDMARDs and in monotherapy and seen between Nov. 12, 2012 –Feb. 21, 2013. Each included RA patient was invited to complete a self-administered questionnaire (SAQ) on treatment adherence. Adherence to cDMARDs and BT was assessed by the Morisky Medication Adherence Scale (MMAS-4)(2).

Results: This survey included 121 physicians, who collected data on 814 biologic-treated RA patients of whom 445 were treated in combination with cDMARDs. SAQ was returned by 82% (n=365) of these 445 patients. Regarding non-adherence to cDMARDS, 21% of rheums estimated this situation as frequent. In concordance with that, rheums considered that, among their RA patient pool, the mean proportion of patients non-adherent to cDMARDs was 17%. In contrast, the MMAS-4 showed that 35% of patients presented a medium/low adherence (2) to cDMARD. No differences in terms of age, gender, disease duration and disease activity were observed between high adherent and medium/low adherent patients. Patients highly adherent to cDMARD were significantly more often highly adherent to their biologic (90% vs 61%) compared to medium/ low adherent patients. Additionally, the main reasons for cDMARD dose reduction or dose spacing from a patient's perspective were adverse events (27%), on physician's advice (24%), forgotten (24%), convenience (23%) and lassitude (17%). Reasons given by rheums were intolerance (72%), lassitude (48%) and disease remission (36%). Over 90% of interviewed rheums evaluated their patients' adherence, mainly by questioning the patient; 61% did it systematically and 31% frequently. While 23% of patients declared informing their treating rheums of their lack of adherence to cDMARDs, rheums declared being informed only by 17% of their patients.

Conclusion: Adherence to cDMARD in RA patients treated in combination with a biologic should be taken into consideration in patient management as this survey showed that it concerns around 35% of these patients, which is a more frequent situation than expected by their treating rheums. Tools to evaluate patients' adherence should be developed to help physicians to detect this situation.

The Differential Role Of T Helper Cells In The Pathogenesis and Responsiveness To Abatacept Therapy In Rheumatoid Arthritis. Shunsuke Fukuyo[1], Shingo Nakayamada[1], Kunihiro Yamaoka[1], Satoshi Kubo[1], Shigeru Iwata[2], Kazuyoshi Saito[1] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]University of Occupational and Environmental Health, Kitakyushu, Japan, Kitakyushu, Japan.

Background/Purpose: Abatacept (ABT) works through a different mechanism of action from TNF inhibitors in the treatment of rheumatoid arthritis (RA). ABT decreases T cell responses by limiting CD28 mediated signaling that is required for T cell activation and differentiation. However,

little is known about T cell populations targeted by ABT. We investigated the relevance of the phenotype of $CD4^+$ helper T cells to disease activity in patients with RA and responsiveness to treatment, elucidating targets to ABT.

Methods: Heparinized whole blood samples were obtained from 19 patients with RA and 15 healthy donors (HD). All patients were treated with ABT at baseline, week 2 and every 4 weeks, and blood samples were taken at baseline and week 24 after treatment. The phenotype of T cells was determined by flow cytometry and the results were correlated with the clinical disease activity with simplified disease activity index (SDAI), disease activity score based on 28 joints and Erythrocyte Sedimentation Rate (DAS28 (ESR)), anti-cyclic citrullinated peptide (CCP) antibody and rheumatoid factor (RF).

Results: The proportion of $CD28^-$ cells among $CD4^+$ cells increased in RA, compared to HD ($p=0.04$). Baseline levels of CD28 on $CD4^+$ cells have positively correlated with DAS28 ($p=0.00$) and SDAI ($p=0.03$) at baseline as well as‡™DAS28 ($p=0.0115$) and ‡™SDAI ($p=0.0574$) in response to ABT for 24 weeks. By contrast, baseline proportion of $CD4^+CD28^-$ cells was higher in patients who failed to achieve a remission at 24 week after treatment. The proportion of $CD4^+$ $CXCR5^+$ Tfh ($p=0.00$) and $CD4^+CXCR3^+$ Th1 ($p=0.08$) cells increased in RA compared to HD. Those cells also expressed active surface markers such as CD38. $CD4^+CD28^+$ cells consisted of activated Tfh and Th1 in naïve and central memory phase: the proportion of Tfh cells increased in anti-CCP antibody-positive patients ($p=0.05$), whereas that of Th1 cells tended to be correlated with disease activity ($p=0.07$). $CD4^+CD28^-$ cells consisted of Th1 in effector memory phase, showing no correlation to disease activity and antibody production. Finally, the proportion of Tfh cells was significantly decreased after ABT treatment ($p=0.03$), but those of Th1 cells was not changed ($p=0.26$).

Conclusion: These results imply that $CD4^+CD28^+$ cells, which consist of Tfh cells in central memory phase associated with production of anti-CCP, are target of ABT, whereas $CD4^+CD28^-$ cells, which consist of terminally differentiated Th1 cells, might be associated with refractoriness to ABT therapy. The evaluation of T cell phenotype may serve to predict to the response to ABT therapy in advance in patients with RA.

Anti-TNF Therapy Induces Positive Changes In The Lipoprotein Profile Of RA Patientes. Results Of a Prospective Study. Jaime Calvo-Alén[1], Carmela Baamonde[1], Ignacio Villa[1], Víctor Martínez-Taboada[2], Mario Agudo[3] and Juan Gómez-Gerique[2]. [1]Hospital Universitario Sierrallana, Torrelavega, Spain, [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [3]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain.

Background/Purpose: Anti-TNF therapy induces elevations in total cholesterol levels although does not seem to modify the atherogenic index. Otherwise, it appears to have a cardiovascular protective effect. We have tried to study in depth the effect of this therapy in the lipidic metabolism through a comprehensive analysis of the lipid and lipoprotein induced modifications.

Methods: RA patients naive to any type of biologic therapy starting anti-TNF therapy, were evaluated at two points (first, just before the first dose of the anti-TNF agent and second, at six months of stable anti-TNF therapy) according to a pre-established protocol including the following assessments of lipidic metabolism: Lipoprotein, and apolipoprotein A1 (ApoA1) and B (ApoB) levels (total and lipoprotein specific), levels of paroxonase 1 (PON1), HDL, LDL, VLDL and total cholesterol, triglycerides and phospholipids levels, as well as number of molecules of these lipids (mc, mt and mf respectively) in each lipoprotein, total mass (M) and number of particles (np) of the afore mentioned lipoproteins and levels of PCSK9 receptor. Inflammatory markers (ESR, hsCRP, Pentraxina 3 and SAA) and disease activity by joints counts and DAS28 index were also performed. Standard statistical tests were used for comparing both assessments.

Results: Nineteen RA (mean age±SD: 60.7±13.2 years; disease duration±SD: 124.3±296.8 months; 68% women; 47% seropositive and mean±SD DAS28 at first evaluation: 5.5±1.2) patients were evaluated. As expected patients showed a decrease in disease activity (4.6±1.4; p=0.08)). Regarding to the lipidic determinations, although the total cholesterol increased (191 mg/dl ±25 vs 208 mg/dl ±24; p=0.07) without modifying the atherogenic index, anti-TNF induced several biochemical and structural lipoprotein changes with a final positive balance including the following: increase levels of total and HDL ApoA1 (p=0.05 and 0.04), decrease of LDL ApoB (p=0.08) with increase of ApoB VLDL (p=0.08) increase of MHDL (p=0.003) and HDL triglyceride (p=0.035) and protein (p=0.0003) content, decrease in np LDL (p=0.08) and increase of np VLDL which are less atherogenic.

Conclusion: Anti-TNF therapy induces global positive lipoprotein balance with increases of ApoA1 levels and a metabolic shift towards HDL and VLDL molecules instead of LDL. Future studies with larger samples and times of follow up will help us to better define this modifications.

Sarilumab, a Subcutaneously Administered, Fully Human Monoclonal Antibody Inhibitor Of The IL-6 Receptor Alpha: Relationship Between Inflammation Suppression and Changes In Cholesterol Levels. Christina Charles-Schoeman[1], Steven P. Weinstein[2], Janet van Adelsberg[3], Tanya Momtahen[4], Richard Wu[5], Neil Graham[5] and Stefano Fiore[4]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Regeneron Pharmaceuticals Inc, Tarrytown, NY, [3]Regeneron Pharmaceutials, Inc., Tarrytown, NY, [4]Sanofi, Bridgewater, NJ, [5]Regeneron Pharmaceuticals, Inc., Tarrytown, NY.

Background/Purpose: Sarilumab (SAR) is a fully human monoclonal antibody directed against the alpha subunit of the IL-6 receptor (IL-6Rα) which is currently being evaluated for treatment of rheumatoid arthritis (RA). Patients with active RA have increased CV risk despite lower levels of total cholesterol (TC) and low density lipoprotein cholesterol (LDL-C) as well as high density lipoprotein cholesterol (HDL-C) associated with active inflammation. The current work explores further the acute phase relationship of cholesterol levels in relation to measures of inflammation in RA. In particular we evaluated the changes in cholesterol levels following SAR treatment as well as their relationship to decreases in inflammation using data from a 12-wk phase 2 study (MOBILITY Part A [NCT01061736]) of SAR + methotrexate in patients with RA.

Methods: Patients with RA (n=306) were randomized to one of the following 6 treatment groups: Placebo (PBO), SAR 100, 150, 200 mg every other week (q2w) or 100, 150 mg weekly (qw). Changes from baseline to wk 12 in TC, LDL-C, and HDL-C were assessed in the intent-to-treat (ITT) population (n= 306 patients). These changes, and changes in C-reactive protein (CRP) and serum amyloid A (SAA) levels, were assessed according to tertiles of baseline CRP and SAA levels in the 2 SAR dose groups whose dose regimens were subsequently chosen for study in phase 3 trials (150 mg and 200 mg q2w).

Results: At wk 12, changes in TC and LDL-C but not HDL-C were statistically significantly greater in the SAR group compared with PBO (TABLE). Patients with the highest baseline levels of inflammation as assessed by the top tertiles of CRP and SAA, showed the largest decreases in inflammation and the largest increases in TC with SAR treatment. Similar trends were observed for LDL-C (TABLE).

Mean SAA, hsCRP, TC, LDL-C, and HDL-C changes from baseline to 12 weeks grouped by tertiles of baseline SAA and CRP, ITT population, MOBILITY Part A, placebo vs. pooled SAR 150mg and 200 mg q2weeks

Mean Change from Baseline to 12 weeks in Biomarker	Placebo (n=52)	Pooled SAR (n=103)	Pooled SAR: Tertile of Baseline ≤12.7 (n=29)	>12.7–≤45.9 (n=32)	>45.9 (n=29)	P-trend
hsCRP (mg/L)	−2.5	−24.2*	−5.1	−15.6	−27.9	<0.0001
SAA (mg/L)	−0.7	−59.1*	6.8	−18.5	−99.1	<0.0001
TC (mmol/L)	0.07	0.61*	0.31	0.53	0.82	0.0679
LDL-C (mmol/L)	0.06	0.42*	0.19	0.43	0.57	0.0489
HDL-C (mmol/L)	0.06	0.10	0.09	0.03	0.14	0.2175
			Pooled SAR: Tertile of Baseline CRP (mg/L)			
	Placebo (n=52)	Pooled SAR (n=103)	≤14.2 (n=33)	>14.2–≤27.5 (n=34)	>27.5 (n=33)	P-trend
hsCRP (mg/L)	−2.5	−24.2*	−3.3	−16.6	−54.0	<0.0001
SAA (mg/L)	−0.7	−59.1*	−8.3	−34.8	−142.3	<0.0001
TC (mmol/L)	0.07	0.61*	0.36	0.61	0.84	0.0247
LDL-C (mmol/L)	0.06	0.42*	0.23	0.52	0.49	0.0338
HDL-C (mmol/L)	0.06	0.10	0.04	0.08	0.17	0.4505

P-trend is value for nonparametric signed-rank test across the SAR tertiles; * P value ≤0.05 vs. placebo

Conclusion: Treatment with sarilumab at either 150 mg or 200 mg every other week in the phase 2 study MOBILITY Part A was associated with increases in TC and LDL-C compared to placebo. These increases in TC and LDL-C observed with sarilumab were associated with both the baseline burden of inflammation assessed by SAA and CRP, as well as the degree of suppression of inflammation by sarilumab. Further investigation of additional CV biomarkers which are less sensitive to the acute phase response and adequately assess CV risk in the setting of high levels of systemic inflammation from active RA may be warranted. The effect of sarilumab on markers of inflammation and lipid parameters will be further evaluated in the Phase 3 program.

Etanercept 25 Mg Once Weekly Program For Rheumatoid Arthritis, Psoriatic Arthropathy and Ankylosing Spondylitis Patients In Sustained Clinical and Radiological Remission. Joaquín Borrás-Blasco[1], Antonio Gracia-Pérez[1], Dolores-Elvira Casterá[1], J. Dolores Rosique-Robles[1], Javier Abad[1] and Alejandro González Álvarez[2]. [1]Hospital de Sagunto, Sagunto, Spain, [2]Hospital Obispo Polanco, Teruel, Spain.

Background/Purpose: Etanercept 50mg/week (ETN50) has demonstrated efficacy in patients with rheumatoid arthritis (RA), psoriatic arthropathy (PA) and ankylosing spondylitis (AS). In certain patients in sustained clinical remission with ETN 50, a dose reduction to etanercept 25 mg/week (ETN25) could be done. This strategy of dose reduction could have advantages in terms of safety and costs. The aim of the study is determine the clinical and economic impact of the use of ETN25 in RA, PA and AS patients in sustained clinical remission.

Methods: Observational, retrospective cohort of patients in an off-label program receiving ETN25 for at least 6 months between January 2006 and June 2013. Inclusion Criteria: patients treated with ETN50 that achieve and maintain clinical remission (DAS28<2.6 or BASDAI<2) during 1 year and slow worsening of structural changes were selected to change their standard dose of ETN50 to ETN25. We collected age, sex, indication, duration (in years) of ETN25 during the study period. In these patients, we simulated the cost of treatment with etanercept as if they had received ETN50 during their ETN25 respective periods. Economic impact was assessed using Enbrel® Spanish official prices.

Results: From Jan 2006 to 1st Jun 2013, 39 patients (18 women; age 53±7 years; 24 RA, 7 PA, 8 AS) received ETN25 for at least 0.5 years (2.6±2.0 years; range 0.5–7.3 years). At 1st Jun 2013, 29 (74%) patients continued on ETN25 (17 RA, 4 PA and 8 AS). Table 1 shows associated clinical data of these patients. 10 (26%) patients discontinued due to: RA patients: 5 patients due to reactivation of RA (4 switched to ETN50 and 1 switched to adalimumab, all patients achieved clinical remission) and 2 patients due to adverse reactions; PA patients: 2 patients due to reactivation of PA (switched to ETN50 and achieved clinical remission) and 1 patient due to adverse reactions. All AS patients continued on ETN25 (Table 1). Total associated costs of this low dose strategy throughout the observation period were 622.073€. If these patients had been treated with ETN 50, the total cost of therapy would have been 1.224.146€. The implementation of the once-weekly ETN25 in these patients saved 622.073€ during 7 years. This cost savings achieved with an ETN25 regimen could lead to treat approximately 52 additional patients with RA, PA or AS for a year without increasing the total cost of etanercept therapy.

Conclusion: ETN25 produces important cost savings when used in patients with slow worsening of structural changes who maintain clinical remission for at least 1 year with ETN50. Reducing the dosage in selected patients could make treatment more cost-effective and allow physicians to treat more patients with a fixed budget.

Clinical Efficacy Rate Of The Non-Specific Effect (the placebo effect) In The Tumour Necrosis Factor Inhibitors For Rheumatoid Arthritis Treatment After Methotrexate Failure: Meta-Analysis. Julie Azaïs[1], Thomas Barnetche[2], Pascale Vergne-Salle[3], Christine Bonnet[1], Carine Dufauret-Lombard[1], Richard Treves[1] and Philippe Bertin[1]. [1]CHU Dupuytren Limoges, Limoges, France, [2]CHU Bordeaux Pellegrin, Bordeaux, France, [3]CHU Dupuytren Limoges, limoges, France.

Background/Purpose: Therapeutics generate non-specific effects (the placebo effect), and specific ones, like the 5 tumor necrosis factor (TNF) inhibitors used in the treatment of Rheumatoid Arthritis (RA). Few abstracts deal with the placebo effect. Its role in clinical responses to treatments has not been clearly accounted for. A systematic review must henceforth be conducted to appraise its rate in TNF-blockers treatments. This rate seems quite important in the first 3 months of treatment. The aim of this study was to estimate the placebo effect in ACR 20, 50 and 70 responders in patients suffering from RA and being treated by TNF-blockers after MTX failure.

Methods: A systematic literature review was conducted using PubMed, Embase and Cochrane library databases. The articles selected till March 2013 reported on double-blind RCTs of TNF-blockers versus placebo with patients receiving concomitant MTX. These patients, suffering from RA according to ACR 1987 criteria, were naive of biotherapies. MTX therapy with a minimum dosage of 10 mg/week had proved unsuccessful for at least 6 months. The data collected dealt with RA patients and the rates of ACR 20, 50 and 70 responders in each group at week 24. A meta-analysis was conducted using Methodomics for global responders, each molecule and injection method.

Results: Twenty-two RCTs out of 1,386 were included in the systematic review and meta-analysis: 6 studied infliximab, 5 etanercept, 4 adalimumab, 3 certolizumab, and 4 golimumab. ACR 20 responses at W24 were available in 13 RCTs. The placebo effect was 24.70% on the whole (IC95% [0.192; 0.301] p=0) with significant statistical results for adalimumab: 26.70% (IC95% [0.161;0.373] p=0.001), certolizumab: 16.40% (IC95% [0.068;0.26] p=0), infliximab: 31.90% (IC95% [0.154;0.485] p=0.001). The subgroup analysis concerning the injection method showed 31.90% vs. 23.30% for the IV route (IC95% [0.154;0.485] p=0.001). The ACR 50 non-specific response at W24 was 10.90% (IC95% [0.074;0.144] p=0) for the 14 RCTs. It was only significant for adalimumab, estimated at 15.40% (IC95% [0.026; 0.281] p=0). It was not increased by the IV relative to the SC routes. The ACR 70 placebo effect response at W24 was estimated at 3.40% (IC95% [0.019;0.049] p=0) in 13 studies. No result was statistically significant. The more the ACR criteria were stringent, the more the placebo effect decreased. Heterogeneity was important due to both MTX and TNF-blockers different dosages and administration frequencies. The rates were analysed by the random model.

Conclusion: Even if RCTs showed that TNF-blockers were more efficient than MTX alone, this meta-analysis shows that the non-specific effect must be taken into account. It is estimated at about 20% even if patients are in failure with the treatment. Adalimumab, certolizumab and infliximab rose above others in placebo effect responses, as well as for the IV route. This placebo effect seems to decrease with strict evaluation criteria. It would be interesting to better consider its role in clinical responses aspects and to take into account the cost margin.

Real-World Effectiveness and Safety Of Infliximab In The Treatment Of Rheumatoid Arthritis Over 5 Years: The Canadian Experience. Denis Choquette[1], William Bensen[2], Andrew Chow[3], John T. Kelsall[4], Maqbool K. Sheriff[5], Jude F. Rodrigues[6], Emmanouil Rampakakis[7], John S. Sampalis[7], May Shawi[8], Francois Nantel[8], Susan M. Otawa[8] and Allen J. Lehman[8]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]St. Joseph's Hospital and McMaster University, Hamilton, ON, [3]Credit Valley Rheumatology, Mississauga, ON, [4]Mary Pack Arthritis Centre, Vancouver, Vancouver, BC, [5]Nanaimo Regional General Hospital, Nanaimo, BC, [6]Rheumatology, Windsor, ON, [7]JSS Medical Research, St-Laurent, QC, [8]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Efficacy and safety of anti-TNF in rheumatoid arthritis (RA) management has been demonstrated in numerous controlled clinical trials. Longitudinal observational studies assessing the real-world effectiveness and safety of anti-TNF agents are essential to demonstrate the true population-based benefit-risk ratio. The purpose of this study was to assess in Canadian routine clinical practice the long-term effectiveness and safety profile of infliximab (INF) in RA patients.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of rheumatology patients initiating INF or golimumab treatment as first biologics or after having been treated with a biologic < 6 mos. RA patients treated with INF who enrolled between 2002 and 2011 and had at least one follow-up assessment were included in the

effectiveness analysis (N=628), while the safety population comprised all patients treated with INF during that period (N=838). Adverse events (AEs) were classified as per the Medical Dictionary for Regulatory Activities and were counted once per System Organ Class and Preferred Term.

Results: Mean (SD) age and disease duration among the effectiveness population were 55.8 (13.6) yrs and 10.2 (10.0) yrs, respectively. At the time of the analysis, 96 (15.3%) had completed 5 yrs of followup. At treatment initiation, 90.9% were treated with DMARDs, 56.1% with NSAIDs, and 40.0% with steroids. Mean (SD) patient parameters at baseline: C-reactive protein (CRP) = 19.5 (24.9) mg/L, erythrocyte sedimentation rate (ESR) = 32.2 (24.0) mm/hr, morning stiffness = 70.4 (43.6) min, tender joint count (TJC28) = 12.5 (7.9), swollen joint count (SJC28) = 10.6 (7.1), health assessment questionnaire (HAQ) = 1.7 (0.7), patient global assessment of disease activity (PtGA) = 6.0 (2.4) cm, physician global assessment of disease activity (MDGA) = 6.6 (2.1) cm, and DAS28-CRP = 5.4 (1.3). Upon 6 mos of treatment, statistically significant ($P<0.05$) and clinical meaningful improvements were observed in all parameters analyzed, which were sustained over 60 mos of treatment.

A total of 1,740 AEs were reported for 43.3% patients in the safety population (110.24 events / 100 patient yrs (PYs)), the majority of which (92.3%) were non-serious as per the judgment of the treating physician. Most frequently reported AEs included arthralgia (5.3% of patients), headache (3.8%), and upper respiratory tract infections (3.8%). There were 134 serious AEs reported for 84 (10.0%) patients (8.49 events/100 PYs). The incidence of serious infections and neoplasms was 1.96 and 0.70 events per 100 PYs, respectively. Five deaths (pulmonary fibrosis, miliary tuberculosis, severe arteriosclerotic heart disease, intestinal gangrene, and atrial fibrillation with hypotension and interstitial lung disease) were reported during the study, of which three (pulmonary fibrosis, intestinal gangrene, atrial fibrillation with hypotension and interstitial lung disease) were judged by the treating physician as unlikely related to INF.

Conclusion: The results of this Canadian longitudinal observational study have shown that INF is well tolerated and effective in reducing symptom severity and improving outcomes in RA patients over a 5-yr period.

HM-0523, a Novel Syk Inhibitor Significantly Ameliorates The Severity Of Arthritis In Rodents. Yu Cai, Zhong Cui Sun, Ping Ren, Lei Fang, Xiaoming Dai, Zhipeng Wu, Qianqian Dong, Xinrong Wang, Jian Wang, Yang Sai, Xiong Li and Weiguo Su. Hutchison Medipharma Limited, Shanghai, China.

Background/Purpose: Spleen tyrosine kinase (SYK) is a key mediator of signaling events downstream of a wide array of receptors important for immune function, including the B cell antigen receptor, immunoglobulin receptors bearing the Fcg or Fce chain, and other ITAM-containing C-type lectin and integrin receptors. Therefore, Syk inhibition has attracted considerable interest for treatment of autoimmune and allergic diseases. In this report, we present a highly potent and selective, orally available Syk inhibitor and its efficacies in rodent models of rheumatoid arthritis.

Methods: Utilizing a series in vitro biochemical and cellular assays and in vivo pharmacological models of rheumatoid arthritis, Syk inhibitors were designed and evaluated to identify a drug candidate with excellent potency, selectivity, and drug-like properties.

Results: HM-0523 demonstrated high potency against Syk enzyme activity (IC_{50}=20 nM) in vitro. The compound also exhibited its high kinome selectivity, although it cross-inhibited several kinases such as Flt3 with IC_{50}=63 nM. HM-0523 also displayed functional activities in multiple cellular assays in various human cell types. It blocked FceR crosslinking-induced degranulation in mast cells (IC_{50}=30 nM), FceR engagement-mediated TNF-a and IL-6 production in BMMC (IC_{50}=52 and 78 nM, respectively), FcgR engagement-mediated TNF-a production in monocytes (IC50=54 nM). In human whole blood, HM-0523 potently inhibited BCR mediated B cell activation (IC_{50}=120 nM) and FcεR1 mediated basophil degranulation (IC_{50}=145 nM). HM-0523 was further evaluated in the models of rheumatoid arthritis. In mice collagen-induced arthritis model, treatment with HM-0523 after disease onset significantly reduced disease severity in a dose dependent manner with estimated ED_{50}=4~5 mg/kg QD. Consistent with its efficacy in mice, HM-0523 also suppressed paw swelling with ED_{50}=1.4 mg/kg QD in rat collagen-induced arthritis model. Furthermore, HM-0523 inhibited synovial proinflammatory cytokine production and inflammatory markers in the blood, suggesting its mechanism of action correlated with its clinical benefits in those models of rheumatoid arthritis. In addition, HM-0523 has demonstrated its superior in vitro potency, selectivity, in vivo efficacy and PK profile in preclinical animal models to current clinical lead fostamatinib that is under evaluation in Phase III clinical trials for Rheumatoid Arthritis.

Conclusion: Our data demonstrated that HM-0523, acting through selective inhibition of Syk activation, exhibited significantly beneficial effects in rodent models of rheumatoid arthritis. These results strongly support further development of HM-0523 as a promising new agent for the treatment of rheumatoid arthritis.

Alteration Of Aortic Distensibility Within 6 Months Of Treatment In RA Patients: An Observational Comparison Of Infliximab and Synthetic Dmards. Birgul Ay[1], Dilek Keskin[1], Goksal Keskin[1] and Ayhan Dinc[2]. [1]DYB Research and Training Hospital, Ankara, Turkey, [2]Patio Clinic, Ankara, Turkey.

Background/Purpose: The proximal aorta accounts for most of the global arterial stiffening and subsequent complications. Aortic stiffness can be demonstrated by changes in aortic dimensions such as strain (proportional change of aortic area to the minimum area) and, when combined with pressure, distensibility (relative dimensional change related to changes in local pressure). We report aortic size and stiffness changes over 6 months after treatment with infliximab or synthetic DMARDs in a group of RA patients.

Methods: The study comprised thirty-eight female patients with RA and 30 otherwise healthy female individuals. Those with stable co-morbidities were allowed, but not with a documented cardiovascular disease. According to the clinical decision of attending physicians (blinded to study protocol), 20 patients received infliximab, while 18 patients received single or combined synthetic DMARDs during the study period.

At baseline and six months later (prior to first and last infusions), all subjects underwent, complete 2-dimensional transthoracic echocardiography, and systolic and diastolic ascending aortic diameters (SD and DD) were recorded in M-mode 3 cm above the aortic valve from a parasternal long-axis view. Aortic elastic properties were calculated using aortic data and forearm blood pressure values.

Results: Regarding baseline demographic features and comorbid conditions, all patients and healthy controls, were comparable. Baseline treatment profiles and disease activity scores were also similar between two RA groups. Echocardiographic parameters were normal in all subjects, none having significant valvular heart disease, segmental wall motion abnormalities or myocardial hypertrophy.

All groups had similar aortic diameters, but RA groups had significantly reduced aortic strain and distensibility, compared with healthy controls. In both treatment arms, a significant and comparable DAS28 response was achieved at six months.

At the end of study, infliximab-treated group showed significant improvement in either aortic strain (4,3±3,2 vs. 9,2±5,7, %, $p<0,01$) or aortic distensibility (0,18±0,14 vs. 0,44±0,28, cm^2/dynes/103, $p<0,01$), whereas synthetic DMARD-treated group did not show a significant change. Correlation analysis revealed that, this achievement, significantly associated with changes in DAS28 and hs-CRP values.

Conclusion: RA patients have impaired aortic elasticity, which could be improved with infliximab, but not with synthetic DMARDs, over six months.

Two-Year Results From The Ample Trial: Low Disease Activity and Association Between Remission and Changes In Physical Function and Radiographic Outcomes With Subcutaneous Abatacept Or Adalimumab. R Fleischmann[1], M Schiff[2], M E Weinblatt[3], M Maldonado[4], E Massarotti[5] and Y Yazici[6]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Colorado, Denver, CO, [3]Brigham & Women's Hospital, Boston, MA, [4]Bristol-Myers Squibb, Princeton, NJ, [5]Brigham and Women's Hospital, Boston, MA, [6]New York University Hospital for Joint Diseases, New York, NY.

Background/Purpose: Remission and low disease activity (LDA) are now more achievable goals in RA. Year 1 data from the head-to-head AMPLE (Abatacept vs Adalimumab Comparison in Biologic-Naive RA Patients with Background MTX) study showed comparable rates of remission and LDA for patients treated with subcutaneous (SC) abatacept or adalimumab.[1] To assess whether these responses are maintained over time and to evaluate the relationship with functional and radiographic outcomes, we report Year 2 data from AMPLE.

Methods: AMPLE is a 2-year, Phase IIIb, randomized, investigator-blinded study. Biologic-naïve patients with RA and an inadequate response to MTX were randomized to 125 mg SC abatacept weekly or 40 mg SC adalimumab bi-weekly, with background MTX.[1] The proportions of patients achieving remission (defined as Disease Activity Score [DAS]28 [C-reactive protein; CRP] <2.6, Clinical Disease Activity Index [CDAI] ≤2.8, Simplified Disease Activity Index [SDAI] ≤3.3, Routine Assessment of Patient Index Data [RAPID]3 <3, Boolean score ≤1) or LDA (defined as DAS28 [CRP] ≤3.2, CDAI ≤10, SDAI ≤11, RAPID3 ≤6) are presented. Physical function (assessed with the Health Assessment Questionnaire-Disability Index [HAQ-D]I; responders defined as an improvement of ≥0.3) and radiographic non-progression (defined as change in modified total Sharp score of ≤ smallest detectable change) were analyzed in patients achieving remission at 2 years.

Results: A total of 646 patients were randomized and treated with abatacept (n=318) or adalimumab (n=328) on background MTX. Baseline clinical characteristics were balanced between treatments. The proportions of patients in remission or LDA at Year 2 were comparable for both treatments (Table), and were higher than those reported at Year 1.[1,2] More patients achieved DAS28 (CRP) remission compared with CDAI, SDAI, and RAPID3 remission, with the smallest proportion achieving Boolean remission. Depending on the criteria used to assess remission, 65.9–80.2% of adalimumab-treated patients and 72.7–81.2% of abatacept-treated patients who were in remission at Year 1 were maintained in a state of remission at Year 2. Across all criteria, >70% of patients in remission at Year 2 were also HAQ-DI responders, and >85% were radiographic non-progressors at Year 2. Improvement in physical function and radiographic outcomes at Year 2 were consistent between the two treatments.

	SC abatacept + MTX n/N (%)	**SC adalimumab + MTX** n/N (%)
Remission criteria		
DAS28 (CRP) <2.6	127/251 (50.6)	130/244 (53.3)
CDAI ≤2.8	80/250 (32.0)	74/244 (30.3)
SDAI ≤3.3	78/250 (31.2)	79/243 (32.5)
RAPID3 (0–30) ≤3	77/248 (31.0)	61/233 (26.2)
Boolean	52/251 (20.7)	50/244 (20.5)
Low disease activity criteria		
DAS28 (CRP) ≤3.2	164/251 (65.3)	166/244 (68.0)
CDAI ≤10	164/250 (65.6)	165/244 (67.6)
SDAI ≤11	163/250 (65.2)	168/243 (69.1)
RAPID3 (0–30) ≤6	123/248 (49.6)	116/233 (49.8)

Conclusion: Over 2 years of the AMPLE study, rates of remission and LDA increased over time across all criteria and remained comparable for SC abatacept and adalimumab. All remission criteria demonstrated high correlation with physical function and radiographic outcomes, with similar improvements in each treatment group at Year 2. **References:** 1. Golimumab Improves Patient-Reported Outcomes In Patients With Active Rheumatoid Arthritis. B Dasgupta[1], P Bertin[2], L Settas[3], JE Fonseca[4], V Wolff[5], R Yao[6], M Govoni[7], N Vastesaeger[8] and HH Weng[6]. [1]Southend University Hospital, Westcliff-on-Sea, United Kingdom, [2]Hôpital Dupuytren, Limoges, France, [3]AHEPA University Hospital of Thessaloniki, Thessaloniki, Greece, [4]Lisbon Academic Medical Centre, Lisboa, Portugal, [5]Hospital del Salvador, Santiago, Chile, [6]Merck Sharp & Dohme, Kenilworth, NJ, [7]Merck Sharp & Dohme, Rome, Italy, [8]Merck Sharp & Dohme, Brussels, Belgium.

Background/Purpose: Rheumatoid arthritis (RA) has a substantial impact on patient quality of life (QOL), physical functioning, and other outcomes important to patients. This subanalysis of the GO-MORE study aimed to evaluate patient-reported outcomes (PROs) and their associations with disease characteristics in RA patients receiving add-on subcutaneous (SC) golimumab (GLM).

Methods: GO-MORE was a large, open-label, multinational, prospective study in biologic-naïve patients with active RA (DAS28-ESR ≥3.2) despite non-biologic disease-modifying antirheumatic drug (DMARD) treatment. Patients received 50-mg SC GLM once monthly for 6 months in addition to their current DMARD treatments. Clinical responses and PROs were assessed, including Health Assessment Questionnaire-Disability Index (HAQ-DI); patient's global assessment (PGA) of disease activity; patient assessments of pain, disease state, and fatigue; EuroQol 5-dimension (EQ-5D) index and health state; and patient acceptable symptom state (PASS). Associations between PROs and several baseline disease and treatment history characteristics were tested with chi-square tests.

Results: After 6 months of add-on GLM therapy, 82.1% of 3280 efficacy-evaluable patients attained a good or moderate EULAR response. Substantial improvement occurred in pain/discomfort, disease activity, fatigue, and QOL at month 6 (table). 37.4% of patients achieved minimal or no functional impairment (HAQ-DI ≤0.5), and the percentage of patients with PASS improved from 13.9% at baseline to 66.0% at month 6. Patients in the upper 2 tertiles of baseline rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) had greater improvements in PASS and EQ-5D health state than patients in the lowest tertile. Most of these effects met the predefined $P<.001$ criterion early in treatment, but not at month 6. Early in treatment, the PASS rate was highest in patients with the longest disease duration (>10 years).

	Baseline, Mean (SD)	**Month 6, Mean (SD)**
HAQ-DI	1.44 (0.672)	0.88 (0.690)
PGA Disease Activity (0–100 mm VAS)	65.5 (19.50)	35.4 (25.37)
Pain/Discomfort (0–100 mm VAS)	64.5 (20.55)	34.9 (26.54)
Fatigue (1–4 scale)	2.9 (0.86)	2.2 (0.89)
Disease State (1–5 scale)	4.1 (0.90)	2.7 (1.14)
EQ-5D QOL Index (index range –0.59 to 1.0)	0.42 (0.33)	0.67 (0.262)
EQ-5D Health State (0–100 mm VAS)	46.6 (21.12)	68.7 (22.20)

Note: Lower scores indicate better outcomes, except for the EQ-5D. VAS, visual analog scale.

Conclusion: In patients with active RA despite DMARD treatment, 6 months of add-on GLM treatment led to substantial improvement in PROs, including QOL, pain, fatigue, PASS, and functioning. Higher baseline levels of RF and anti-CCP may be associated with better early response to GLM as assessed by PROs.

Analysis Of The JAK1 Selectivity Of GLPG0634 and Its Main Metabolite In Different Species, Healthy Volunteers and Rheumatoid Arthritis Patients. René Galien[1], Béatrice Vayssière[1], Steve de Vos[2], Marielle Auberval[1], Nick Vandeghinste[2], Sonia Dupont[1], Philippe Clément-Lacroix[1], Philippe Delerive[1], Frédéric Vanhoutte[2], Reginald Brys[2], Annegret Van der Aa[2], Luc Van Rompaey[2] and Gerben van 't Klooster[2]. [1]Galapagos SASU, Romainville, France, [2]Galapagos NV, Mechelen, Belgium.

Background/Purpose: The 4 Janus kinases (JAK1, JAK2, JAK3 and TYK2) are cytoplasmic tyrosine kinases that transduce intracellular signaling for cytokines including interleukins and interferons, and for growth factors

such as erythropoietin. GLPG0634 is a JAK inhibitor that has been shown to be selective for JAK1 over JAK2 in human whole blood and over JAK3 and TYK 2 in biochemical assays. GLPG0634 showed a favorable safety and efficacy profile in two 4-week Phase 2A studies in patients with rheumatoid arthritis (RA). Its activity is supported by an active metabolite that shows a high plasma exposure in humans. Here, we have evaluated the JAK1 selectivity of GLPG0634 and its main metabolite in animals, healthy volunteers and RA patients.

Methods: JAK selectivity of GLPG0634 and its metabolite was evaluated by measuring STAT phosphorylation (pSTAT) in whole blood from humans, dogs and monkeys incubated with triggers that activate JAK-dependent pathways by flow cytometry. STAT phosphorylation measurement in cells transfected with JAK siRNA was performed using SureFire technology. Effects on JAK–dependent gene signatures in blood incubated with or without triggers were assessed by QRT-PCR. Sources of blood were from healthy volunteers (untreated or following 10 days of GLPG0634), RA patients (4-week GLPG0634 treatment), untreated animals and mice subjected to CIA (2-week treatment with GLPG0634).

Results: An approximately 30-fold selective inhibition of JAK1 over JAK2 by parent GLPG0634 using the IL6/pSTAT1 assay for JAK1 and GM-CSF/pSTAT5 for JAK2 was similarly found with its metabolite. However, the metabolite displayed an >10 fold lower JAK inhibition potency. In cellular knock-down experiments with siRNA we confirmed IL-6-induced pSTAT1 to be an exclusive JAK1-driven event. The JAK1 selective inhibition by GLPG0634 and its metabolite was confirmed in complementary whole blood assays for alternative pathways: IL-2/pSTAT5 (JAK1/JAK3) and IFNα/pSTAT1 (JAK1/TYK2). In these pathways, where JAK1 partners with other JAKs, a 10-fold selectivity over the inhibition of JAK2-driven signalling was found in human, dog and monkey blood. Transcriptional profiling was applied to assess selectivity of GLPG0634 using genes such as MX1, MX2 and GBP1 (IFNα-induced) and HRH4 (GM-CSF-induced) in human whole blood. In samples from human healthy volunteers exposed to GLPG0634 (and its metabolite as formed), gene expression analysis showed that selectivity was conserved up to the highest dose (450 mg QD). In addition, JAK1 selectivity over JAK2 was confirmed in blood from mice with collagen-induced arthritis (CIA) treated with GLPG0634, as well as from RA patients administered GLPG0634 at the doses of 100 mg BID and 200 mg QD.

Conclusion: These data demonstrate that GLPG0634 and its metabolite are highly selective JAK1 inhibitors in humans and animal species, using various technologies. The disease status did not alter selectivity, as a similar JAK inhibition profile was observed in blood from either healthy subjects or RA patients. Longer-term clinical studies are ongoing to confirm a favorable risk-benefit by selective inhibition of JAK1 and avoiding effects related to JAK2, such as anemia.

Attainment Of Remission, Functional, and Quality Of Life Improvements With Golimumab Treatment In Rheumatoid Arthritis Are Associated With Patient Expectations. B Dasgupta[1], B Combe[2], I Louw[3], J Wollenhaupt[4], C Zerbini[5], A Beaulieu[6], H Schulze-Koops[7], P Durez[8], V Wolff[9], R Yao[10], HH Weng[10], M Govoni[11] and N Vastesaeger[12]. [1]Southend University Hospital, Westcliff-on-Sea, United Kingdom, [2]Hôpital Lapeyronie, Montpellier, France, [3]Panorama Medical Centre, Cape Town, South Africa, [4]Schön-Klinik, Hamburg, Germany, [5]Hospital Heliópolis, Serviço de Reumatologia, São Paulo, Brazil, [6]Centre de Rhumatologie, St-Louis, QC, [7]University of Munich, Munich, Germany, [8]Université Catholique de Louvain and Cliniques Universitaires Saint-Luc, Brussels, Belgium, [9]Hospital del Salvador, Santiago, Chile, [10]Merck Sharp & Dohme, Kenilworth, NJ, [11]Merck Sharp & Dohme, Rome, Italy, [12]Merck Sharp & Dohme, Brussels, Belgium.

Background/Purpose: Golimumab (GLM) and other tumor necrosis factor antagonists are used as add-on therapy for patients with rheumatoid arthritis (RA) who have not responded to disease-modifying antirheumatic drugs (DMARDs). Comprehensive management of RA involves clinical goals such as remission and outcomes important to patients such as daily functioning and improvement in quality of life (QoL). After DMARD failure, patients may have low treatment expectations, which could affect outcomes. This subanalysis of the GO-MORE study investigated relationships between patient expectations and GLM treatment outcomes.

Methods: GO-MORE was an open-label, multinational, prospective study in biologic-naïve patients with active RA despite DMARD treatment. Patients received 50-mg subcutaneous GLM once monthly for 6 months. At baseline and month 3, patients rated their expectation of how well their treatment would control RA symptoms and improve QoL 3 months later using 5-point Likert scales (1=good outcome, 5=poor outcome). Patients were divided into tertiles of expectation scores: most positive ($\leq$1.5), intermediate (>1.5 to <1.86), or least positive ($\geq$1.86). Efficacy outcomes were compared among tertiles using ANCOVA; *P* values were calculated for pairwise differences from the comparator group.

Results: At baseline, 3280 efficacy-evaluable patients had moderate (21.3%) or high disease activity (78.7%), mean age 52.3 (SD=12.8) years, mean disease duration 7.6 (SD=7.9) years, mean Health Assessment Questionnaire Disability Index (HAQ-DI) 1.44 (SD=0.67), and mean EQ-5D 0.42 (SD=0.33). Overall, patients had high expectations, with a mean expectation score of 1.4 (1=good expectation, 5=poor expectation) at baseline. Higher expectations were observed in patients who had failed fewer DMARDs (1 vs 2 failures, $P=.0039$; 1 vs $\geq$3 failures, $P<.0001$) and patients who had high baseline disease activity (moderate vs high disease activity, $P=.0014$). Patients expected improvement in physical (pain, joint swelling, fatigue) and functional (ability to participate in activities) outcomes. After 6 months of GLM, patients with the most positive expectations had higher remission rates ($P<.0001$). More positive expectations were also associated with greater improvements in functional impairment and EuroQoL Questionnaire (EQ-5D) scores (table).

Table. Relationship Between Patient Expectations and GLM Treatment Outcomes

	Patient Expectations at Baseline		
Treatment Outcome at Month 6	**Most Positive n=1212**	**Intermediate n=1009**	**Least Positive n=1054**
Remission 28-joint Disease Activity Score (DAS28-ESR)<2.6, n (%)	339 (28.0)	236 (23.4)	209 (19.8) $P<.0001$[a]
Minimal Functional Impairment HAQ-DI ≤0.5, n (%)	562 (46.4)	368 (36.5) $P<.0001$[a]	294 (27.9) $P<.0001$[a]
Change in EQ-5D Score Mean (SD)	0.28 (0.35)	0.25 (0.33)	0.21 (0.34) $P<.0001$[a]

[a]*P* values for comparison with most positive expectation group. *P* values >.001 not reported.

Conclusion: Patients had high expectations for add-on GLM treatment despite previous treatment failures. Patients with more positive expectations had better outcomes and better comprehensive control of their RA than those with less positive expectations, as evidenced by higher DAS28 remission rates and improvement in patient-reported measures, such as physical function and QoL.

Levels Of Circulating Mirnas Before and After 12 Months Therapy With Dmards In Patients With Early Rheumatoid Arthritis. Mária Filková[1], Borbala Aradi[2], Ladislav Senolt[3], Klara Prajzlerova[4], Serena Vettori[2], Herman F. Mann[5], Jiri Vencovsky[4], K. Pavelka[6], Beat A. Michel[7], Renate E Gay[2], Steffen Gay[2] and Astrid Jüngel[2]. [1]Institute of Rheumatology and Department of Rheumatology of the First Faculty of Medicine, Charles University in Prague, Czech Republic, Prague, Czech Republic, [2]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [3]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [4]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [5]Institute of Rheumatology, Prague, Prague, Czech Republic, [6]Department of Clinical and Experimental Rheumatology, Charles University, Prague, Czech Republic, [7]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: The altered expression of cellular miRNAs in the immune and resident cells involved in the pathogenesis of rheumatoid arthritis (RA) has been shown to contribute to the maintenance of pathognomic features typical of RA. Differential levels of circulating miRNAs in plasma were reported between patients with RA and osteoarthritis. Our aim was to analyze the effect of therapy on levels of circulating miRNAs in sera of patients with early RA (ERA).

Methods: Sera were obtained from patients with ERA (n=34, disease duration <8 months, fulfilling 2010 EULAR/ACR criteria) at baseline and correspondingly after 3 (M3) and 12 (M12) months therapy with disease modifying antirheumatic drugs (DMARDs, methotrexate n=28, sulphasalazine n=4, leflunomide n=1) and glucocorticoids (n=30). In addition, sera were obtained also from patients with established RA (estRA, n=28, disease duration 9.28±6.52 years, fulfilling 1987 revised ACR criteria) treated with DMARDs (methotrexate n=14, sulphasalazine n=2, leflunomide n=8), glucocorticoids (n=6) or biologics (n=19). Total RNA was isolated using phenol-chloroform extraction and the levels of RA-associated miR-155, 223, 16, 146a, 132, 203 and 124a were analyzed using specific primers by TaqMan Real-Time PCR. dCt method was used for relative quantification using let-7a as a normalization control (with a detection limit at Ct= 40).

Results: MiR-155 in sera of treatment naïve ERA patients showed significantly lower levels than in patients with estRA (dCt −6.31±1.05 v.s. −4.68±1.86, $p<0.001$). Treatment in ERA did not change the levels of miR-155 at M3 (dCt −6.13±1.62) or M12 (dCt −6.99±1.54). Interestingly, levels of miR-155 dropped below the detection limit in 14 ERA patients at M12. Levels of miR-223 were comparable between treatment naïve ERA and estRA (dCt 5.67±1.04 vs. 6.23±1.45) and did not change after M3 following treatment initiation in ERA (dCt 5.12±0.91). Most impressively, miR-223 in ERA showed significantly lower levels at M12 (dCt 4.34±0.78) in comparison with baseline ($p<0.001$) as well as M3 ($p<0.01$). MiR-16 was found at significantly lower levels in treatment naïve ERA patients compared with estRA (dCt 4.93±0.91 v.s. 6.10±1.22, $p<0.001$). During treatment levels of miR-16 in ERA did not change after 3 months (M3: dCt 5.71±1.27) but they significantly decreased after 12 months (M12: dCt 3.85±1.37 in comparison with baseline ($p<0.05$) and M3 ($p<0.001$). The levels of miR-146a were significantly lower in ERA sera in comparison with estRA (dCt 0.44±0.93 v.s. 1.20±1.00, $p<0.01$) but were not changed upon treatment in ERA (dCt 0.50±0.64 at M3, 0.02±1.97 at M12 respectively). The levels of miR-132 in ERA before treatment were comparable with estRA (dCt −4.31±0.90 v.s. −3.76±1.07) and were not affected by therapy over time (dCt −4.47±0.0.91 at M3, −4.94±1.83 at M12, 4 were undetectable). MiR-124a and miR-203 in sera were present in negligible amounts close to the detection limit and were therefore excluded from further analysis.

Conclusion: We show here that the levels of circulating miRNA-16 and −223 are changed upon therapy such as MTX combined with glucocorticoids in patients with ERA after 12 months suggesting miRNAs as potential biomarkers in ERA.

Down-Titration of Biological Therapies In Rheumatoid Arthritis In Daily Clinical Practice. Miguel Arredondo, Iciar Cañamares, Esther Ramírez-Herráiz, Isidoro Gonzalez-Alvaro, Alberto Garcia-Vadillo, Alberto Morell, Rosario Garcia-Vicuña and Jose María Alvaro-Gracia. Hospital Universitario de La Princesa, Madrid, Spain.

Background/Purpose: One of the limiting factors for the use of biological therapies (BT) is cost. For this reason, the development of cost optimization strategies without compromising effectiveness is becoming increasingly frequent in clinical practice. Herein, we report our experience with titration of biological therapies in rheumatoid arthritis (RA) in daily clinical practice, and a comparison between two different periods of time.

Methods: An observational transversal study was performed including all patients with RA under BT (except anakinra and rituximab) in a University Hospital setting. First three months of 2011 and 2013 were included for comparison. Analyzed parameters included: dose, intervals and cost. Data were extrapolated to one year. Patients were considered as down-titrated when the quarterly dose of BT was ≤ 83% of approved dose. Effectiveness was measured by DAS28. Statistical comparison of both periods was performed by T-test and Chi-squared test.

Results: 211 and 265 patients were studied in 2011 and 2013 respectively. Percent of patients down-titrated, total mean dose and mean dose in the titrated group are shown in Table. Our data show an average decrease in total cost of 16.19% in 2013, in comparison with 9.44% in 2011. These data ranged from 0 to 34.75% with the different BT. Paired analysis of DAS28 revealed no significant differences between both time periods, 2.94 (2.05–3.84) vs 2.88 (1.80–3.96) ($p=0.742$).

	2011				2013			
	n	% pdt*	Total mean dose (%)	Mean dose in down-titrated (%)	n	% pdt*	Total mean dose (%)	Mean dose in down-titrated (%)
TOTAL	211	32.54†	88.87†	58.82††	265	41.06	83.90	59.01
Adalimumab	86	39.53	86.01	64.61	91	47.20	83.10	64.30
Etanercept	58	39.66	80.01	52.85	80	53.70	74.20	52.06
Certolizumab	14	0	100	-	35	17.10	93.40	61.48
Infliximab	23	21.73	115.64	65.07	18	5.16	107.39	82.35
Golimumab	1	0	100	-	3	0	100	-
Tocilizumab	19	31.57	85.74	54.20	20	55.00	77.28	56.70
Abatacept	10	20.00	93.33	66.67	18	11.1	96.30	66.67

* % pdt = percentage of patients down-titrated.
† $p<0.05$ compared to 2013.
†† $p>0.05$ compared to 2013.

Conclusion: Down-titration of BT in RA is feasible and occurs with increasingly frequency in daily clinical practice. This results in cost containment and contributes to rational use of these therapies.

Methotrexate Use At Infliximab Initiation and Impact On Treatment Outcomes: An Analysis From A Canadian Registry. Denis Choquette[1], J. Carter Thorne[2], John T. Kelsall[3], Michel Zummer[4], Michael Starr[5], Maqbool K. Sheriff[6], William G. Bensen[7], Andrew Chow[8], Philip Baer[9], Emmanouil Rampakakis[10], John S. Sampalis[10], Francois Nantel[11], Allen J. Lehman[11], Susan M. Otawa[11] and May Shawi[11]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]Southlake Regional Health Centre, Newmarket, ON, [3]Mary Pack Arthritis Centre, Vancouver, Vancouver, BC, [4]Ch Maisonneuve-Rosemont, Montreal, QC, [5]Montreal General Hospital, Montreal, QC, [6]Nanaimo Regional General Hospital, Nanaimo, BC, [7]St. Joseph's Hospital and McMaster University, Hamilton, ON, [8]Credit Valley Rheumatology, Mississauga, ON, [9]Rheumatology, Scarborough, ON, [10]JSS Medical Research, St-Laurent, QC, [11]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Clinical trials of anti-TNF therapies have shown that concurrent methotrexate (MTX) therapy enhances the efficacy of infliximab (IFX)[1]. Data on the benefits of combination therapy with MTX and IFX in a real-life clinical setting are scarce. The objective of this analysis is to describe changes in the use of MTX at IFX initiation in patients enrolled in routine clinical practice and assess the impact of the MTX dose on the real-life effectiveness of IFX.

Methods: BioTRAC is an ongoing, prospective registry of RA, AS or PSA patients initiating treatment with IFX or golimumab as first biologics or after having been treated with a biologic <6 mos. Data from RA patients treated with IFX between Jan 2002 and Jun 2011 were analysed. Patients were stratified based on the use of MTX (0mg of MTX,≤10mg/week, 10.1–24.9mg/week, ≥25mg/week) or by the 3-yr period of enrolment (01/2002–06/2005,07/2005–06/2008,07/2008–06/2011). Cox regression was used to examine time-dependent association between the attainment of disease remission as per the DAS28, CDAI and SDAI criteria and MTX dose.

Results: 790 RA patients were included with a mean (SD) age of 55.75 (13.46) yrs, mean (SD) disease duration of 10.15 (10.08) yrs. The concomitant use of MTX at infliximab initiation increased across enrolment periods (66.5% vs. 73.3% vs. 77.6%; P=0.022) which was also associated with decreased disease activity at baseline. Concomitant use of azathioprine (5.2% vs. 0.2%; P<0.001) and leflunomide (46.1% vs. 14.5%; P<0.001) at baseline, and prior past use of MTX (77.8% vs. 65.7%; P=0.001) was more frequent in patients not treated with MTX at infliximab initiation than those treated with MTX. Among patients treated with MTX at baseline the most common MTX dose category was 10–25mg/week (66.3% of patients). A trend towards higher MTX doses was observed over time with more patients treated with >25mg/week of MTX in recent yrs. Survival analysis shows that, upon adjusting for baseline disease activity, use of MTX over time was associated with an increased hazard ratio [HR (95%CI)] of attaining disease DAS28-CRP [1.35 (1.06–1.71)], CDAI [1.33 (1.02–1.72)], and SDAI [1.62 (1.14–2.32)] remission. This effect was observed across all MTX dose categories except for DAS28-CRP and CDAI in the >25mg/week dose category.

Conclusion: Clinical practice has changed over time with physicians using concomitant MTX at IFX initiation more frequently in recent years despite lower disease activity in patients today. The data support improved outcomes among patients treated with IFX in routine clinical care when receiving concomitant MTX. This is consistent with the current label and recent recommendations of the Canadian Rheumatology Association.

Adalimumab and Methotrexate Pharmacokinetics Following Combination Therapy With Different Methotrexate Doses in Methotrexate and Biologic-Naïve Rheumatoid Arthritis Patients: Concerto Study. Sandra L Goss[1], Cheri E Klein[1], Hartmut Kupper[2], Gerd R Burmester[3] and Walid Awni[1]. [1]AbbVie Inc., North Chicago, IL, [2]AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany, [3]Charité-Universitätsmedizin Berlin, Free University and Humboldt University of Berlin, Berlin, Germany.

Background/Purpose: Higher exposure and lower immunogenicity rates have been observed for adalimumab when co-administered with methotrexate (MTX) compared to adalimumab monotherapy. The CONCERTO study was designed to evaluate the effect of fixed MTX doses on adalimumab exposure and to assess the pharmacokinetics of MTX polyglutamates 1, 2, 3, 4 and 5 (PG1–5) in red blood cells in MTX and biologic-naïve RA patients. The efficacy and safety from the CONCERTO study was previously reported.

Methods: CONCERTO was a Phase 4, 26-wk, double-blind, and parallel-arm trial in MTX and biologic-naive patients with active RA. Subjects were randomized 1:1:1:1 to blinded weekly oral MTX doses (2.5, 5, 10, or 20 mg). MTX dose remained constant throughout the entire study for the 2.5, 5 and 10 mg per wk MTX groups. Subjects in the 20 mg MTX group started on 10 mg MTX per wk which increased every two wks by 2.5 mg until reaching 20 mg per wk at Wk 8-Wk 26. All subjects received open-label adalimumab 40 mg sc every other wk and took 5 mg weekly supplement of oral folate. Blood samples were collected at baseline and prior to dosing at Wks 2, 4, 8, 12, 16, 20 and 26 for analysis of adalimumab and anti-adalimumab antibodies (AAA) in serum and analysis of MTX PG1–5 in red blood cell (RBC). Adalimumab and AAA were determined using validated ELISA methods. MTX PG1–5 concentrations were measured using a validated LC-MS method. A patient was considered AAA+ if at least one sample had measured AAA greater than 20 ng/mL and was confirmed by the confirmatory assay within 30 days after an adalimumab dose.

Results: Adalimumab trough concentrations appeared to reach steady state by Wk 16. At Week 26, mean adalimumab concentration in the 2.5 and 5 mg per week MTX dose groups was 4.4 μg/mL (N=98) and 5.7 μg/mL (N=100), respectively. Mean adalimumab concentration at higher MTX doses (10 to 20 mg weekly) was approximately 6.5 μg/mL (N=98 for each group) at Wk 26. Forty six patients (46/394, 12%) were classified as AAA+ during the study. The percents of subjects with at least one AAA+ sample for the 2.5, 5, 10 and 20 mg MTX per week dose group were 21%, 13%, 6%, and 6% respectively. At Week 26, mean MTX PG1–5 concentrations in RBC were 19.4, 34.2, 62.8, and 119 nM for the 2.5, 5, 10 and 20 mg MTX dose groups, respectively. Time to achieve steady state PG concentration was shorter for short chain PG1–2 (4 weeks) compared to longer chain PG3–5 (20- >26 weeks), leading to longer times to reach steady state as MTX dose increased. Higher MTX doses resulted in higher percentages of longer chain PG3–5. Short-chain PG1–2 were less than dose proportional and longer chain PG3–5 were greater than dose proportional.

Conclusion: In MTX and biologic-naive patients with active RA who received a fixed dose of MTX, the mean adalimumab exposure increased with increasing MTX dose from 2.5 to 10 mg MTX; adalimumab exposure was similar following 10 or 20 mg MTX. The percent of subjects with at least one AAA positive sample decreased with increasing MTX dose up to 10 mg MTX. Time to MTX steady state is dependent on MTX dose and is longer for higher MTX doses. As MTX dose increases, the percentage of PG1–2 increases less than dose proportionally while the percentage of PG3–5 increases more than dose proportionally.

Response To Biologic Disease-Modifying Anti-Rheumatic Drugs After Discontinuation Of Anti-Tumor Necrosis Factor Alpha Agents In Rheumatoid Arthritis Patients. Eric Elkin[1], Max I. Hamburger[2], Tripthi Kamath[3], Sarika Ogale[3], Adam Turpcu[3], Jae Oh[4], Kristin King[4], Monarch Shah[1] and Martin J. Bergman[5]. [1]ICON Clinical Research, San Francisco, CA, [2]Rheumatology Associates, Melville, NY, [3]Genentech, South San Francisco, CA, [4]ICON Late Phase and Outcomes Research, San Francisco, CA, [5]Taylor Hospital, Ridley Park, PA.

Background/Purpose: Rheumatoid arthritis (RA) patients who have failed an anti-TNF agent as their first biologic agent have the option of switching to a second aTNF agent or a biologic with other mechanism of action (oMOA), either abatacept, tocilizumab, or rituximab. An exploratory analysis was undertaken to compare the routine assessment of patient index data 3 (RAPID3) response of aTNFs vs. biologics with oMOA used as a second biologic in RA patients with a history of aTNF treatment as their first biologic DMARD.

Methods: An observational, non-interventional, retrospective chart review study was conducted in 8 community-based rheumatology practices in the United States from February to September 2012. Patient charts were eligible if the patient's first biologic DMARD was an aTNF; they were 18 years or older at time of the second DMARD; they were prescribed a second biologic DMARD during the period July 1, 2006 and October 1, 2011. Patients were also required to have a RAPID3 score at baseline (up to 6 weeks prior to the second DMARD start) and at 6 months on therapy (+/−8 weeks). The RAPID3 score ranges from 0 to 30 with higher scores indicating more severe disease. A poor response was defined as a decrease of <1.8 points and/or a follow-up score >12. In addition, if a patient discontinued therapy prior to 6 months they were classified as having a poor response. A good response was a decrease in RAPID3 score >3.6 points and a follow-up score <6. The remainder of the patients had a moderate response. The percent of patients with a good response and a poor response was compared between treatment groups using the chi-square test and mean change in RAPID3 by t-test.

Results: A total of 144 charts were available for this analysis (mean age = 59.9 years, 76% female). The second biologic DMARD was an aTNF for 101 patients and oMOA for 43 patients. At baseline, mean scores were similar (14.8±6.2 for aTNF and 15.2±6.0 for oMOA, p=0.74). A good RAPID3 response was achieved for 9.9% of aTNF patients and 18.6% of other MOA patients (p=0.15). In addition, aTNF patients had a greater percent with a poor response (69.3% vs. 46.5%, p=.01). The mean change from baseline to 6 months was also different between the two treatment

groups: −1.1±5.9 for aTNF vs. −4.6±5.2 for oMOA (p<.01). These results were similar for the third biologic DMARD.

Conclusion: In this exploratory analysis of RA patients who had discontinued their first aTNF agent, those receiving a second biologic DMARD with another MOA were more likely to have a good or moderate RAPID3 response and had a greater decrease in RAPID3 scores, compared with patients receiving a second aTNF. We did not examine RAPID3 response to individual treatments due to small numbers. In patients who have already failed an aTNF agent, physicians should consider using a biologic agent with a different mechanism of action.

Safety Of Biologic Therapy In Veterans With Rheumatoid Arthritis and Chronic Hepatitis B Infection. Jeffrey R. Curtis[1], Mary J. Burton[2], Shuo Yang[3], Lang Chen[3], Ted R. Mikuls[4], Kevin L. Winthrop[5] and John Baddley[3]. [1]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, [2]VA Hospital, Jackson, MS, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [5]Oregon Health & Science University, Portland, OR.

Background/Purpose: Among patients with rheumatoid arthritis and hepatitis B infection, the impact of biologic therapy on hepatotoxicity has received limited study.

Methods: Using 1997–2011 national data from the U.S. Veteran's Health Administration, we identified a cohort of 38,453 rheumatologist-diagnosed RA patients. Patients who had hepatitis B infection (defined by detectable hepatitis B surface antigen, hepatitis B core antibody or hepatitis B DNA), initiated a new biologic (anti-TNF: infliximab, adalimumab, etanercept; vs. rituximab) that they had never been on previously and had a baseline ALT < 1.5× the upper limit of laboratory normal within 90 days prior to starting biologic therapy were eligible for analysis. Patients could contribute more than one biologic treatment episode provided they switched to a new biologic they had not previously used, or switched to a previously used biologic they had not used in the past year. The main outcome of interest was hepatotoxicity, defined as ALT elevation > 100 IU/L (corresponding to 3× ULN for women and 2.5 ULN for men). Hepatotoxicity was examined within the first year of biologic use. Current exposure was defined as-treated based on day supply (injection biologics) or usual dosing intervals (infused biologics). Results were reported as the cumulative incidence of patients achieving pre-defined hepatotoxicity at 3, 6 and 12-months post biologic exposure.

Results: 248 RA patients with hepatitis B were identified and contributed 322 new biologic treatment episodes. Mean age was 60.2 years and 91.7% were male. Overall, ALT elevations were uncommon, with 10 hepatotoxicity events (ALT > 100 IU/L) occurring among 322 episodes (3.1%) within 12-months. Most hepatotoxicity events (7/10, 70%) occurred within 90 days of initiation of biologic. The highest proportion of hepatotoxicity occurred in patients receiving rituximab (4/35, 11.4%) (p = 0.013 vs. anti-TNF).

Drug	Pts	Episodes	3-month Failures	6-month Failures	12-month Failures
ADA	122	126	1 (0.8%)	2 (1.6%)	2 (1.6%)
ETA	126	128	3 (2.3%)	4 (3.1%)	4 (3.1%)
INF	30	33	0 (0.0%)	0 (0.0%)	0 (0.0%)
RIT	25	35	3 (8.6%)	3 (8.6%)	4 (11.4%)
Total	248	322	7 (2.2%)	9 (2.8%)	10 (3.1%)

ABA=abatacept; ADA=adalimumab; ETA=etanercept; INF=infliximab; RIT=rituximab

Conclusion: In US Veterans with hepatitis B receiving biologic therapy for RA, the proportion of episodes of hepatotoxicity (ALT >100 IU/L after initiation of biologic) was low, with the highest incidence occurring in patients receiving rituximab. Among those who failed, most failures occurred early (<91 days) after biologic initiation.

The Cost Savings Associated With a Departmental Etanercept Dose Reduction Pathway For Patients With Rheumatic Diseases and Maintained Low Disease Activity. Richard CJ Campbell, Emma Sanders, Francesca Leone, Emma Gilgeours, Margaret Sibley and Patrick D. Kiely. St George's Hospital, London, United Kingdom.

Background/Purpose: Clinical trials have previously demonstrated that it is safe and effective for some rheumatoid arthritis (RA) patients with low disease activity on full dose Etanercept to switch to half dose Etanercept (25mg per week)[1]. We decided to test the feasibility of this in clinical practice by developing a departmental Etanercept dose reduction algorithm. We also considered the associated cost savings.

Methods: Patients with inflammatory rheumatic diseases were eligible to enter the treatment pathway provided they had been on full dose Etanercept for more than one year and had low disease activity according to two assessments at least one month apart (DAS 28 <3.2 for rheumatoid arthritis (RA), Bath Ankylosing Spondylitits Disease Activity Index (BASDAI) <4 for ankylosing spondylitis (AS) and zero tender/swollen joint for psoriatic arthritis (PSA)). After switching to half dose Etanercept, patients attended for clinical assessments at 1, 3 and 6 months. Patients were switched back to full dose Etanercept if they no longer met criteria for low disease activity (termed 'flare'). Patients could choose to switch back to full dose Etanercept at any point without giving a reason.

Results: 31 patients (15 RA, 4 AS, 10 PSA, 1 adult JIA and 1 reactive arthritis) were switched to half dose Etanercept. Patient and disease criteria are shown in the table. 16 patients left the pathway early and had their dose increased for the following reasons: flare of disease (13), patient choice without objective evidence of flare (2) and device preference (1). After 6 months, 15 of the patients (48%) (9 RA, 3 AS, 2 PSA and 1 adult JIA) maintained low disease activity (see table) and so met criteria to continue on reduced dose Etanercept. A much smaller proportion of the patients with psoriatic arthritis (20%) maintained low disease activity compared with those with RA (60%). The total cost savings for the patients that completed 6 months on the pathway (90 patient-months) was $49,562 (£32,175).

Table. Patient Characteristics and Summary Data

	RA	*AS*	*PSA*	*Other*
Number of Patients	15	4	10	2
Gender (female)	11	0	2	1
Mean Age Yrs (SD)	56 (15)	50 (16)	48 (15)	32 and 22
Disease Duration Yrs (SD)	11 (6)	18 (19)	8 (5)	6.5
Concomitant DMARDS	MTX 9, HCQ 2, SSZ 1	None	3 MTX, 2 LFD, 1 ciclosporin	None
Duration Etanercept Yrs (SD) Pre Reduction	3.3 (2.0)	4.1 (1.8)	3 (0.9)	5.5
Mean Baseline Disease Activity (SD)	*DAS 28:* 2.5 (0.6)	*BASDAI:* 2.0 (0.4); *Spinal VAS:* 1.1 (0.6)	*All meeting criteria*	*Clinician remission*
Mean Disease Activity (SD) at 6 months (of those remaining	DAS 28: 2.1 (1.2)	*BASDAI: 0.9 (1.3) Spinal VAS: 0.0 (0.0)*	*All meeting criteria*	*Clinical Remission*
Mean Time (months) to Exit Pathway (For Those Exiting)	1.8 (1.3)	1	1.8	2
Number Completing 6 months	9	3	2	1

Conclusion: We were able to reduce Etanercept dose for a large proportion of our patients with low disease activity and maintain low disease activity without flares of disease. This represented significant cost savings. When developing future guidance, national prescribing bodies could take this into account when determining the relative positioning for different biologic therapies.

488

The Effect Of Methotrexate On Adalimumab Pharmacokinetics: Pooled Analysis Of Adalimumab Pharmacokinetics In Patients With Rheumatoid Arthritis After Subcutaneous Administration. Walid Awni[1], Sabine Pilari[2], Ghada Ahmed[3] and Peter Noertersheuser[2]. [1]AbbVie Inc., North Chicago, IL, [2]AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany, [3]AbbVie, North Chicago, IL.

Background/Purpose: Co-administration of methotrexate (MTX) has a significant effect on the pharmacokinetics (PK) of adalimumab (ADAL). MTX may impact the PK of other drugs by multiple mechanisms including immunosuppressant and anti- inflammatory effects. This pooled analysis was conducted to examine the effect of MTX and other factors on ADAL PK.

Methods: Individual subjects' PK and demographics data from 9 ADAL Phase II and III studies in patients with Rheumatoid Arthritis (RA; n=1991) after SC administration of different ADAL dosing regimens were pooled. 642 patients were on 40 mg ADAL every other week dosing regimen. Serum samples were collected prior to dosing and at several time points for up to 1 year for measurement of ADAL and anti-ADAL antibodies (AAA) using ELISA methods. All patients with at least one measurable ADAL were included. A patient was considered AAA+ if at least one sample had AAA > 20 ng/mL within 30 days after an ADAL dose. Analyses were conducted utilizing measured ADAL concentrations and population PK (PopPK) modeling.

Results: The median (range) age and weight of patients (77% F, 23%M) were 54 (4–87) yrs and 69.7 (13–186) kg. 48.8% were on a stable dose of concomitant MTX (10 to 30 mg/wk) and 51.2% received ADAL as monotherapy. 91.4% were adults and 8.6% were children (4 to 17 yrs). Patients on a stable dose of MTX at study start had lower baseline C-Reactive Protein (CRP) and Rheumatoid Factor (RF) compared to patients who were not on MTX. Median baseline CRP was 11.0 and 33.5 mg/L with and without MTX. Median baseline RF was 68 and 148 IU/mL with and without MTX. Overall, 8.8% of patients across all 9 studies, with 3.3% of patients on MTX co-medication and 14.7% of patients on ADAL monotherapy, had at least one AAA+ sample. PopPK indicated that MTX had the most significant impact on ADAL apparent clearance (CL) in all patients (AAA+ and AAA-), and even when patients with AAA+ were excluded from the analysis. ADAL clearance (CL) was 10.6 and 20.6 mL/hr with and without MTX in all patients and was 10.1 and 17.5 mL/hr with and without MTX in AAA- patients. Median ADAL CL was similar in patients receiving MTX doses of 10 mg/wk and up to 30 mg/wk. After accounting for MTX effect, body weight, baseline CRP and baseline RF were also factors that influence the variability in ADAL PK. ADAL CL increased with increase in body weight, and higher baseline levels of CRP or RF. After accounting for the differences in body weight, ADAL CL, with and without MTX, were similar in males and females, across races, and from 4 to 87 yrs of age.

Conclusion: Pooled analyses of data from nine ADAL Phase II and III studies in patients with RA after SC administration indicate that MTX has significant effects on ADAL PK in all patients and in AAA- patients. MTX effects on ADAL PK may potentially be by multiple mechanisms including an anti-inflammatory effect in addition to the immunosuppressant effect by reducing the development of AAA. After accounting for MTX effect and AAA+ status, body weight, baseline CRP and RF are additional factors that influence the variability in ADAL PK. ADAL PK were similar regardless of patient sex, race and age.

Combining Methotrexate To Etanercept Does Not Improve Its Retention Rate In Rheumatoid Arthritis Patients When Compared To Etanercept Monotherapy. A Report From The Rhumadata® Clinical Data Base and Registry. Denis Choquette[1], Louis Bessette[2], Boulos Haraoui[1], Diane Sauvageau[1], Jean Pierre Pelletier[1], Jean-Pierre Raynauld[1], Edith Villeneuve[1] and Louis Coupal[1]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC.

Background/Purpose: Etanercept (ETA) has demonstrated good retention in both mono and combination therapy in clinical trials of rheumatoid arthritis patients followed over short observation periods (less than 2 years). Studies evaluating the efficacy of anti-TNF have provided better results when it is used with methotrexate compared to monotherapy. Data from registries have also demonstrated that methotrexate significantly influence the retention on anti-TNF. The rationale of this analysis is to explore the impact of combining methotrexate with etanercept on retention vs. monotherapy usage over a prolonged observation period in the Rhumadata® clinical database and registry.

Methods: RA patients prescribed ETA as a first biologic agent after January 1st 2004 were included in the present analysis. Baseline demographics for both cohorts included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluation (VAS), TJC, SJC, DAS 28 ESR and SDAI. The drug retention rate of subjects on ETA monotherapy (n=45) were estimated and compared to the retention rate of subjects also receiving a DMARD (n=211) using Kaplan-Meier survival estimates. Six month and yearly estimates (up to 5 years) were obtained. Statistical analysis was performed using SAS version 9.3. RHUMADATA® is a clinical database and registry used in daily clinical practice at the IRM and CORQ.

Results: At six months, drug retention for ETA monotherapy and combination therapy was estimated at 87%. Yearly drug retention rates for subjects on monotherapy ranged from 64% at year 1 to 36% at year 6. Estimates for subjects on combination therapy ranged from 78% to 53%.

Therapy	6 months	Year 1	Year 2	Year 3	Year 4	Year 5
Monotherapy (n=45)						
Mean retention time in days (StdD)	166.9 (6.9)	301.2 (16.1)	520.6 (39.8)	713.6 (65.1)	897.6 (91.2)	1053.55 (115.0)
% retention (StdE)[1]	87% (5%)	64% (7%)	55% (8%)	52% (8%)	49% (8%)	36% (6%)
Combination therapy (n=211)						
Mean retention time in days (StdD)	170.7 (2.3)	322.0 (6.5)	591.2 (16.5)	832.8 (27.3)	1057.6 (38.8)	1260.4 (50.32)
% retention (StdE)	87% (2%)	78% (3%)	71% (3%)	64% (3%)	58% (4%)	53% (4%)
Log-rank p-value	0.10	0.34	0.13	0.36	0.43	0.06

[1] Product-limit survival estimates

Conclusion: Etanercept with and without methotrexate discloses statistically similar retention rates from 6 months up to 5 years. It is worth noting that combination therapy remains numerically superior to the monotherapy over the 5 year observation period.

Disclosure: D. Choquette, None; **L. Bessette**, None; **B. Haraoui**, None; **D. Sauvageau**, None; **J. P. Pelletier**, None; **J. P. Raynauld**, None; **E. Villeneuve**, None; **L. Coupal**, None.

Does Low Disease Activity At Six Months Predict Remission At 12 Months In Rheumatoid Arthritis Patients Treated With Biologics In a Real–World Setting? Philip Baer[1], William G. Bensen[2], Andrew Chow[3], Rafat Y. Faraawi[4], Denis Choquette[5], Isabelle Fortin[6], John T. Kelsall[7], Dalton E. Sholter[8], Emmanouil Rampakakis[9], John S. Sampalis[9], Francois Nantel[10], Allen J. Lehman[10], May Shawi[10] and Susan M. Otawa[10]. [1]Rheumatology, Scarborough, ON, [2]St. Joseph's Hospital and McMaster University, Hamilton, ON, [3]Credit Valley Rheumatology, Mississauga, ON, [4]Rheumatologist, KW Musculoskeletal Research Inc., Kitchener, ON, [5]Institut de Rhumatologie de Montréal, Montreal, QC, [6]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [7]Mary Pack Arthritis Centre, Vancouver, Vancouver, BC, [8]Rheumatology Associates, Edmonton, AB, [9]JSS Medical Research, St-Laurent, QC, [10]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Remission is considered the treatment goal in the management of patients with rheumatoid arthritis (RA). The objective of this analysis was to determine if low disease activity (LDA) at 6 months is a predictor of remission at 12 months in patients with RA treated with infliximab or golimumab in a Canadian real–world setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. Patients with RA treated with infliximab or golimumab who were enrolled between 2002 and 2012 and had 12 months of follow-up were included in this analysis.

Results: A total of 436 patients with a mean (SD) age of 56.1 (13.1) years and disease duration of 10.4 (9.9) years were included in the analyses. Mean (SD) DAS-ESR, DAS-CRP, CDAI, and SDAI at baseline were 5.7 (1.5), 5.3 (1.3), 34.3 (16.0), and 36.9 (16.7), respectively. At 12 months 25.3%, 32.5%, 15.9% and 16.5% had DAS-ESR, DAS-CRP, CDAI and SDAI remission, respectively. Significant predictors of DAS-ESR remission at 12 months were LDA at 6 months [OR (95%CI) = 7.9 (4.5, 14.1)], change in SJC [OR (95%CI) = 1.1 (1.0, 1.1)] and DAS-ESR [OR (95%CI) = 0.8 (0.7, 1.0)] at 6 months. For DAS-CRP remission at

12 months, significant predictors were LDA at 6 months [OR (95%CI) = 8.0 (4.3, 14.9)] and change in DAS-CRP [OR (95%CI) = 0.7 (0.6, 0.9)] at 6 months. For CDAI remission at 12 months, significant predictor was LDA at 6 months [OR (95%CI) = 9.4 (4.6, 19.4)]. For SDAI remission at 12 months, significant predictor was LDA at 6 months [OR (95%CI) = 9.9 (4.3, 22.8)]. See Figure 1. Changes in CDAI, SDAI, TJC and SJC from baseline to 6 months were not associated with CDAI and SDAI remission at 12 months.

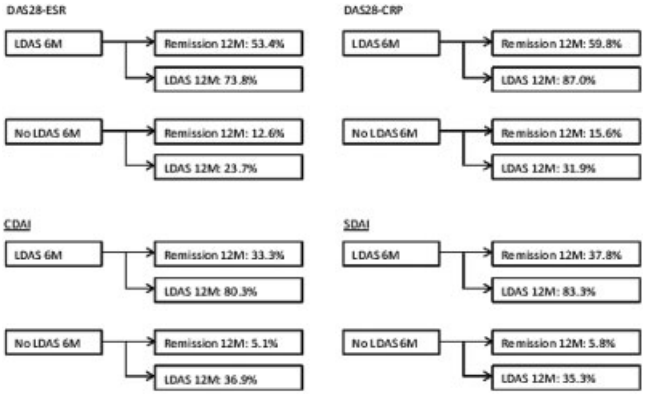

Figure 1. Proportion of LDA Patients at 6 Months in LDA and Remission at 12 Months

Conclusion: The results of this Canadian longitudinal observational study have shown that LDA at six months is a significant predictor of remission at 12 months. For patients achieving a low disease activity state at 6 months, there is a 7.9 to 9.9 odds ratio of achieving remission at 12 months. Data from this real-world registry suggest that a significant proportion of patients with LDA who had not achieved a therapeutic target of remission at 6 months do so at 12 months while maintained on the same biologic treatment.

Infection Risk Among Patients Receiving Concurrent Denosumab and Biologic Or Non-Biologic DMARD Therapy: An Analysis Of The Consortium Of Rheumatology Researchers Of North America (CORRONA) Registry.

Vance J. Bray[1], Adam W. Bagley[2], Sterling G. West[2], Carol J. Etzel[3], Joel M. Kremer[4] and Jason R. Kolfenbach[2]. [1]Denver Arthritis Clinic, Denver, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]UT MD Anderson, Houston, TX, [4]Albany Medical College and The Center for Rheumatology, Albany, NY.

Background/Purpose: RANKL is a cytokine member of the tumor necrosis family that mediates osteoclastic bone resorption. Denosumab prevents RANKL from activating RANK on the cell surface of osteoclasts, resulting in decreased bone resorption. RANK/RANKL also plays a role in the immune system, with RANK receptors found on macrophages and dendritic cells; as such, denosumab may interfere with normal immune pathways. Infections (including serious events such as endocarditis) have been reported in clinical trials of denosumab. Data on the potential infectious complications of denosumab in patients with autoimmune disease is lacking, despite higher baseline rates of infection among this group. We sought to identify the rate of infection among patients with autoimmune disease and recent initiation of denosumab.

Methods: We utilized the CORRONA registry to calculate the infection rate among patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) following initiation of denosumab. Eligible patients had visit data ≥ 6 months prior to the start of denosumab and at least 1 follow-up visit post drug initiation. Data between 8/2009 and 2/2013 were included. Age, sex, disease activity, prior infection history, comorbid disease, and disease specific medication use (biologic DMARD: bDMARD, non-biologic DMARD: nbDMARD and prednisone) were recorded. Overall incident and serious infections (requiring hospitalization or IV antibiotics) were recorded. Rates of incident and serious infections per 100 person-years were calculated. Cox proportional hazard analysis was performed to identify factors associated with infection risk.

Results: 33,288 patients had ≥ 2 study visits (28,852 RA + 4436 PsA); 96 were eligible for this analysis. Demographic data is presented in Table 1. Data regarding incident and serious infections are presented in Table 2. Prednisone use was associated with an increased incidence of infection (HR 3.73; [1.29–10.77]) in univariate analysis. No other variable demonstrated a significant association.

Table 1. Baseline characteristics among RA and PsA patients on denosumab

	All Patients N=96	RA Patients N=90 (93.8)	PsA Patients N=6 (6.3)
Age (years, SD)	73.3 ± 10.7	73.3 ± 10.7	73.2 ± 10.5
Female (%)	94 (97.9)	88 (97.8)	6 (100.0)
Caucasian (%)	88 (91.7)	82 (91.1)	6 (100.0)
Disease Duration (years, SD)	17.0 ± 12.8	16.7 ± 12.3	21.5 ± 20.0
Disease Activity	7.7 ± 8.4	7.8 ± 8.5	6.7 ± 7.5
CDAI (mean, SD)	71 (74.0)	67 (74.0)	4 (66.7)
Low Disease activity[1] (%)			
Drug Therapy	7 (7.3)	7 (7.8)	0 (0.0)
Denosumab alone (%)	46 (47.9)	42 (46.7)	4 (66.7)
nbDMARD[2] (%)	43 (44.8)	41 (45.5)	2 (33.3)
bDMARD[3] ± nbDMARD (%)			
Prednisone Use	30 (31.3)	28 (31.1)	2 (33.3)
Current (%)	56 (58.3)	51 (56.7)	5 (83.3)
Prior (%)			
Prior Serious Infections (%)	10 (10.4)	10 (11.1)	0 (0.0)

Abbreviations: SE: standard error. CDAI: clinical disease activity index
[1] Low disease activity defined as CDAI ≤ 10
[2] nbDMARD: leflunomide, methotrexate, cyclosporine, azathioprine
[3] bDMARD: certolizumab, anakinra, etanercept, adalimumab, golimumab, infliximab, abatacept, rituximab, or tocilizumab

Table 2. Infection Rates among Patients on Denosumab*

	Events (%)	Person-Years At Risk	Infection Rate per 100 Person-Years** (95% CI)
Incident Infections+ (N=96)	14 (14.6)	58.9	24.0 (14–40)
Denosumab alone (N=7)	0 (0)		NC
nbDMARD (N=46)	6 (13.0)		NC
bDMARD (N=10)	1 (10.0)		NC
bDMARD **and** nbDMARD (N=33)	7 (21.2)		NC
Serious Infections++ (N=96)	3 (3.1)	58.9	5 (2–16)

Incident infections: septic arthritis/bursitis, cellulitis, sinusitis, diverticulitis, sepsis, pneumonia bronchitis, gastroenteritis, meningitis, UTI, URI or other specified site
*Table includes 90 patients with RA and 6 with PsA. Among the PsA cohort, 2 total infections (1 serious) were recorded
Historical rates of infection among RA patients in CORRONA (Au et. al; *Ann Rheum Dis* 2011;70:785–791): **31.2 outpatient infections per 100 person-yrs; 0.8 hospitalized infections per 100 person-yrs
+ Kaplan-Meier estimate of incident infection 3 months post denosumab start: 2.5% (95% CI 0.6–9.3); at 6 months: 12.0% (95% CI 6.4–22)
++ Kaplan-Meier estimate of serious infection 3 months post denosumab start: 1.2% (95% CI 0.1–8.3); at 6 months 2.5% (95% CI 0.6–9.7)

Conclusion: The infection rate appears to be low among patients on denosumab and concurrent DMARD therapy. Compared to historical incidence rates for infection within the larger CORRONA database (and other historical cohorts), the rates observed herein appear comparable. Univariate analysis was limited by cohort size, but did not identify an association with nbDMARD or bDMARD use and subsequent infection. Additional study will be necessary to further delineate the risk for infection in patients exposed to denosumab.

Distinction Between Glucocorticoid-Responders and Non-Responders In Rheumatoid Arthritis: A New Role For Endoplasmic Reticulum Aminopeptidase 2. Ruth Fritsch-Stork, Sandra Cardoso, Jasper Broen, Marian Groot-Koerkamp, Arno Concepcion, Floris Lafeber and Johannes W.J. Bijlsma. University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Glucocorticoids (GC) have been a cornerstone of Rheumatoid arthritis (RA)-therapy for the last decades. However, about a third of RA-patients do not respond adequately. As monocytes and T-cells play an important role in RA-pathogenesis, the differential gene expression of these cells before and 24 hours after start of pulse therapy with methylprednisolone was evaluated in order to find potential predictors of GC-response.

Methods: CD14-positive and CD4-positive cells were isolated by MACS sorting from five GC-Responders meeting the European League against Rheumatism (EULAR) response criteria and five Non-Responders. The clinical response was measured by disease activity score (DAS28) at the end of pulse therapy (3× 1000mg Methylprednisolone) at day 5. Labeled cRNA was hybridized to Agilent 4×44K microarrays and differentially expressed genes were determined by MAANOVA. False discovery rate was used as multiple testing correction and set at 5%. Genes were validated by quantitative real-time PCR (qPCR).

Results: We found eight known genes differentially expressed in CD14-cells and 4 in CD4-T-cells of GC-Responders compared to Non-Responders before start of therapy using microarrays. After 24 hours, 13 known genes were seen differentially expressed in CD14-cells and CD4-T-cells each. Higher expression of ERAP2 in monocytes and CD4-cells (fold change (FC) Responders vs. Non-Responders: 6.6 and 4.9; $p<0.007$ and $p<0.02$) and LST1 and FAM26F in CD4-Tcells of GC-Responders (FC: 2.54 and 4.4; $p<0.06$ and $p<0.009$) before start of therapy was verified by qPCR and correlated with DAS28 at day 5. In both cell types ERAP2 (CD14-cells: FC: 4.9; $p<0.01$; CD4-cells: FC: 7.5; $p<0.003$) and FAM26F (CD14-cells: FC: 4.2; $p<0.007$; CD4-cells: FC: 8.0; $p=0.058$) were also significantly higher after 24 hours in GC-Responders measured by qPCR. Additionally, CCNB2 (FC: 0.49; $p<0.008$) was significantly and TMP4 (FC: 0.62; $p=0.058$) marginally lower in CD4-Tcells and CEP350 and DICER were marginally higher (FC: 1.8; $p=0.054$ and FC: 1.55; $p=0.063$) in CD14-cells of GC-Responders compared to GC-Non-Responders.

Conclusion: We found several differentially expressed genes in GC-Responders versus GC-Non-Responders before and 24 hours after start of pulse therapy. The most striking difference is the significantly higher expression of ERAP2 in T-cells and monocytes of GC-Responders. ERAP2 constitutes a susceptibility locus in autoimmune disease, and functions as proteolytic enzyme implicated in antigen presentation. Its homologue is also known to cleave cell surface receptors (TNFR1, IL1R2, IL6Ra). The increased expression in GC-Responders compared to GC-Non-Responders may thus constitute not only a potential predictor of the clinical response to GC in RA, but also warrants further investigation to elucidate the possible role in the inflammatory process of RA.

A Real-World Risk Analysis Of Biological Treatment (Adalimumab and Etanercep) In Country With High Prevalence Of Tuberculosis and Hepatitis B/C. Ying-Ming Chiu[1], Chao-Hsiung Tang[2], Sheng-Tzu Hung[3], Ya-Wen Yang[4], Chi-Hui Fang[4] and Hsiao-Yi Lin[5]. [1]Changhua Christian Hospital, Changhua City, Taiwan, [2]Taipei Medical University, Taipei, Taiwan, [3]Formosa Biomedical Technology Corp., Taipei, Taiwan, [4]Pfizer Limited, Taipei, Taiwan, [5]Taipei Veterans General Hospital, Taipei, Taiwan.

Background/Purpose: Biologics have been widely utilized in many rheumatic diseases. Risks associated with the use of biological treatments are revealed in many published studies. Nevertheless, it was lacking investigations in countries with high prevalence of tuberculosis (TB) and hepatitis B/C (HBC). This research aimed to analyze the difference of risk for adalimumab and etanercept in endemic areas.

Methods: National Health Insurance (NHI) Research Database was applied, which consists of administrative and claims records; covers over 99% of entire population in Taiwan. Patients who had used adalimumab or etanercept in between 2003 and 2011 were eligible for this analysis. Exposure of adalimumab or etanercept was quantified in treatment episode. Each patient could have multiple treatment episodes with different biologics. With same biologic, a new treatment episode was initiated when 6 months apart. The incidence rates of TB, HBC, acute myocardial infarction/heart failure (AMI/HF), infection hospitalization (IHP), herpes zoster (HZ) and lymphoma (Lym) were calculated in person year. All events were defined by corresponding ICD codes, medications related to events and diagnosis during hospitalization. Event was captured within 30 days posterior to the end of each treatment episode. Time to event was summarized by Kaplan-Meier curves. The Cox proportional model was conducted to estimate the hazard ratio (HR) with 95% confidence interval (CI) by adjusted covariates.

Results: From 2003 to 2011, there were 3,844 patients (4,049 episodes) treated with adalimumab and 5,933 patients (7,056 episodes) treated with etanercept. The average age of adalimumab and etanercept users were 50.8 (SD 14.58) and 51.5 (SD 15.29); about 61.4% and 73.1% were female respectively. In adalimumab group, incidence rates of TB, HBC, AMI/HF, IHP, HZ and Lym were 1.62, 0.75, 0.38, 3.05, 0.62 and 0.11 per 100 person-years. Conversely, incidence rates of TB, HBC, AMI/HF, IHP, HZ and Lym were 0.68, 0.4, 0.23, 2.16, 0.64 and 0.11 in etanercept group. Comparing adalimumab to etanercept, the crude HR of TB, HBC, AMI/HF, IHP, HZ and Lym were 2.03 ($P<0.0001$), 1.61 (0.03), 1.56 (0.14), 1.32 (0.01), 0.94 (0.78), 0.96 (0.94). The adjusted HR of TB, HBC, AMI/HF, IHP, HZ and Lym were 1.53 ($P=0.01$), 1.31, 1.27 (0.43), 1.12 (0.27), 0.90 (0.62), 0.76 (0.58).

Table 1. Incidence rates and Hazard ratios

	Adalimumab			Etanercept		
	# person-year	# event	Incidence Rate	# person-year	# event	Incidence Rate
TB	5,317	86	1.62	13,143	89	0.68
HBC	5,311	40	0.75	13,148	53	0.4
AMI/HF	5,315	20	0.38	13,134	30	0.23
IHP	5,244	160	3.05	12,924	279	2.16
HZ	5,299	33	0.62	13,042	83	0.64
Lym	5,324	6	0.11	13,146	14	0.11

	COX Proportion Hazard Model					
	Before Adjusted			After Adjusted		
	cHR[3]	95% CI	P value	aHR[4]	95% CI	P value
TB	2.03	1.50 ~ 2.74	<.0001	1.53	1.13 ~ 2.06	0.0058
HBC	1.61	1.06 ~ 2.44	0.0262	1.31	0.86 ~ 1.99	0.2076
AMI/HF	1.56	0.87 ~ 2.79	0.1362	1.27	0.71 ~ 2.28	0.4273
IHP	1.32	1.09 ~ 1.62	0.0058	1.12	0.92 ~ 1.37	0.2688
HZ	0.94	0.62 ~ 1.42	0.7783	0.9	0.59 ~ 1.37	0.6185
Lym	0.96	0.37 ~ 2.54	0.9404	0.76	0.29 ~ 2.00	0.5781

Note: 1. Per 100 person year
2. Hazard ratios were calculated for adalimumab versus etanercept (reference)
3. cHR: crude hazard ratio
4. aHR: adjusted hazed ratio; demography, disease severity, disease history/duration were used for adjustment.

Conclusion: Across different events, patients with adalimumab treatment tended to have an adverse event in a shorter time period relative to etanercept. Patients had a significant higher risk of TB if used adalimumab.

Autoantibody Profiles Predict Responsiveness To Methotrexate and Anti-TNF Therapy In Early Rheumatoid Arthritis. Petra Budde[1], Angelika Lueking[1], Carmen Theek[1], Peter Schulz-Knappe[1], Jacqueline Detert[2], Gerd R Burmester[3] and Matthias Schneider[4]. [1]Protagen AG, Dortmund, Germany, [2]Charité - Universitätsmedizin Berlin, Berlin, Germany, [3]Charité-Universitätsmedizin Berlin, Free University and Humboldt University of Berlin, Berlin, Germany, [4]Heinrich-Heine-University, Duesseldorf, Germany.

Background/Purpose: Novel therapeutic concepts in early rheumatoid arthritis (ERA) are aiming for an early intervention and effective control of disease activity reaching remission. Most current guidelines recommend methotrexate (MTX) as the first DMARD even though at least for half of these patients MTX alone is not sufficient to achieve this goal. Currently, the clinical response to the first and probably second DMARD is used to decide

further therapeutic approaches. Here we evaluated the autoantigen repertoire as a prospective predictive tool in ERA patients treated with MTX alone or combined with Adalimumab (ADA) in an induction trial (HITHARD study, Detert et al. ARD 2012).

Methods: Luminex-based SeroTag technology was applied to perform large-scale studies in order to define the most prevalent autoantibodies in RA and other connective tissue diseases. 6,000 different human proteins from our huPROT library were incubated with patient sera to screen for autoantibody reactivities and disease or treatment induced alterations using univariate and multivariate statistical algorithms. The DAS28 score was defined as the clinical endpoint, and patients were grouped into those achieving DAS28<2.6 "remission" and "non-remission" in both treatment arms. Autoantibody profiles measured before treatment were then correlated with the status "remission" and "non-remission".

Results: A previously identified diagnostic panel of six novel antigens allowed to distinguish ERA HITHARD samples from age and sex-matched healthy controls with an AUC=0.94. Comparing pre- and post-treatment samples, a small, but significant reduction (−1.3 fold) of autoantibody reactivities towards two antigens was detected in both treatment arms, even though levels were not normalized compared to healthy controls. A specific autoantibody signature was identified in a subgroup of ERA patients who achieved clinical remission after 24 weeks under ADA/MTX combination therapy. A classification biomarker panel of 5–10 autoantigens appears to be sufficient to identify RA patients who will achieve clinical remission upon ADA/MTX therapy. This panel was independent of anti-citrullinated protein antibody (ACPA) positivity. A different set of up to nine antigens was identified that could predict remission in RA patients upon PLACEBO/MTX therapy.

Conclusion: We identified autoantibody patterns in ERA patients associated with clinical response to an induction therapy and identified two independent marker panels that, if further developed into a screening test, could help to guide future treatment selection for MTX alone or a combined use of MTX/ADA.

The Impact Of Inadequate Response To Prior Biologic Agents On Abatacept Drug Retention In Rheumatoid Arthritis Patients. A Pan-European Analysis Of RA Registries. Axel Finckh[1], Florenzo Iannone[2], Juan Gomez Reino[3], David Neto[1], Elisabeth Lie[4], Piet van Riel[5], Merete Lund Hetland[6], Karel Pavelka[7], Carl Turesson[8], Xavier Mariette[9] and Jacques-Eric Gottenberg[10]. [1]University of Geneva, Geneva, Switzerland, [2]D.I.M.I.M.P, Rheumatology Unit - University of Bari, Bari, Italy, [3]Hospital Clínico de Santiago, Santiago de Compostela, Spain, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [6]The Danish Rheumatologic Database (DANBIO), Glostrup Hospital., Copenhagen, Denmark, [7]Department of Clinical and Experimental Rheumatology, Charles University, Prague, Czech Republic, [8]Lund University, Malmö, Sweden, [9]Bicêtre University Hospital, Le Kremlin Bicetre, France, [10]Strasbourg University Hospital, Strasbourg, France.

Background/Purpose: In rheumatoid arthritis (RA), abatacept (ABA) may be used in biologic naïve patients (pts) or after failure to an anti-TNF or other biologic agents (BIO-IR). Drug retention is a useful overall measure of effectiveness, integrating both clinical response and tolerance. For several biologic antirheumatic agents (BIO), it has been demonstrated that a history of BIO-IR strongly decreases subsequent drug retention. The impact of BIO-IR has been less studied with ABA.

The objective of this study was to compare drug retention of ABA in BIO-IR pts.

Methods: This is an observational cohort analysis of 8 prospective, longitudinal, European cohorts of RA pts (ARTIS (Sweden), ATTRA (Czech Republic), BIOBADASER (Spain), DANBIO (Denmark), GISEA (Italy), NORDMARDS (Norway), ORA (France), SCQM (Switzerland)). We included all RA pts treated with ABA in real life settings. The primary end point was drug retention of ABA. Secondary endpoint was ABA discontinuation for ineffectiveness. Time to discontinuation was defined as the time between drug initiation and last administration plus one dispensation interval. Drug discontinuation was analyzed using a Cox proportional hazards model, adjusting for potential confounders, such as calendar year of treatment initiation, patient demographics and disease characteristics.

Results: We identified 3783 pts initiating ABA contributing 5980 patient-years of follow-up. Of these, 1159 pts were BIO-naïve, 883 pts had 1 prior BIO-IR, 861 pts had 2, 555 pts had 3 and 325 pts had 4 or more prior BIO-IRs. 85% of pts in the BIO-IR group had failed an anti-TNF agent as last biotherapy. Pts were mostly female (81%), with a mean age of 57 yrs, long disease durations (mean 12.1 yrs), and active, severe disease at baseline (mean values for DAS28: 5.1, ESR: 33 mm/hr, HAQ: 1.3).

In the 1977 ABA discontinuations, 72% were motivated by ineffectiveness, 24% by adverse events, 2% by remission and 2% by other reasons, when the reason for discontinuation was indicated. Drug retention differed significantly by prior BIO-IRs ($p<0.001$, logrank test). BIO-naïve pts had the highest drug retention (reference Hazard Ratio (HR): 1), pts with 1–3 prior BIO-IRs had lower retention (HR: 1.2–1.3, $p<0.01$), and pts with 4 or more BIO-IRs had the lowest retention (HR: 1.4, $p < 0.001$). A similar trend was observed when examining treatment discontinuation for ABA ineffectiveness ($p< 0.001$, logrank test). Drug discontinuation for ineffectiveness was uncommon in BIO-naïve pts (reference HR: 1), higher in pts with 1–2 prior BIO-IRs (HR: 1.2, $p<0.05$) and highest in pts with 3 or more BIO-IRs (HR: 1.5–1.6, $p<0.01$). Other strong predictors of drug retention were calendar year of ABA initiation, with significantly shorter drug retention in recent years (≤2007: HR=1; 2008–9: HR=1.2; ≥2010: HR: 2.2) and country of origin.

Conclusion: Drug retention of ABA is strongly influenced by a history of prior BIO-IR, with higher discontinuation rates in pts having experienced more BIO-IRs, which suggests a progressive selection of pts with more resistant disease. However, some pts with a history of several BIO-IRs remained on ABA for an extensive time, suggesting some benefit of switching modes of action after anti-TNF-IR.

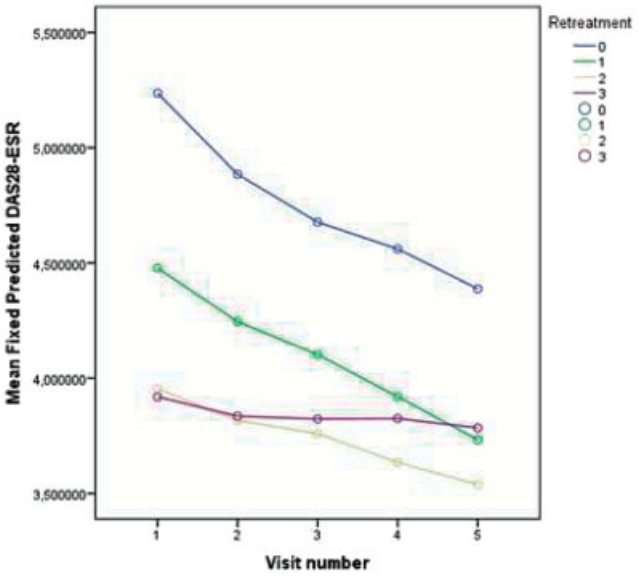
Background/Purpose: Retreatment with rituximab (RTX) is common clinical practice, although several aspects regarding retreatment, such as frequency, need to be further elucidated. The aim of this study was to describe the effectiveness of repeated courses of RTX in a large observational cohort of real-life patients with RA.

Methods: Pooled data from the Collaborating European Registries for Rituximab in RA (CERERRA) project were used. Patients with RA who received at least 4 cycles with RTX were identified and included in the analysis. A covariate-adjusted mixed effects model was fitted to the longitudinal DAS28 for patients with complete covariate information, including country, sex, age, anti-CCP status, number of prior biologics and concomitant DMARD treatment.

Results: 340 patients met the eligibility criteria for these analyses. At baseline (start of RTX) the mean (SD) age was 53.5 (12.6) years and the mean (SD) disease duration was 12.1 (8.2) years. Patients were 83% females, 79%

RF positive and 74% anti-CCP positive. 60% were treated with corticosteroids and 84% with concomitant DMARD. Patients had failed 2.7 (1.5) prior DMARDs and 1.1 (1.0) prior biologic agents. The baseline DAS28 was 6.0 (1.4). In figure 1 the mean fixed predicted decrease of DAS28 after the first cycle and after each retreatment (1st, 2nd and 3rd) is shown. Significant improvement in DAS28 ($p<0.001$) was observed for each course of RTX. Comparison between curves (based on estimated marginal means) revealed significant difference between the first cycle (0) and the fourth (3rd retreatment), $p<0.0001$, and borderline significant difference between first cycle and 2nd retreatment ($p=0.05$).



Conclusion: Repeated retreatment with RTX can lead to further clinical improvement after the first course of RTX.

Development Of a Novel Bispecific Therapeutic For Arthritic Diseases. Mathieu Ferrari[1], Shimobi Onuoha[1], Tahereh Kamalati[2], Daniele Sblattero[3] and Costantino Pitzalis[4]. [1]William Harvey Research Institute, Barts and the London School of Medicine and Dentistry Queen Mary University of London, London, United Kingdom, [2]University College of London, London, United Kingdom, [3]University of Eastern Piedmont, Novara, Italy, [4]William Harvey Research Institute, QMUL, London, United Kingdom.

Background/Purpose: Despite the obvious success of current biological agents for treatment of rheumatoid arthritis (RA), achievement of broader efficacy and improved safety profile remains an unmet need in RA therapy. There is significant evidence demonstrating molecular heterogeneity within the endothelium of different tissues, conferring organ tropism to migrating lymphocytes subsets by direct interaction with specific homing receptors. We have previously reported the isolation of a single chain Fv (scFv A7) antibody with specificity for synovial arthritic microvasculature, following an in vivo phage display selection on SCID mice grafted with human arthritic synovium[1]. The aim of the present study was to develop the scFv A7 as a tissue specific therapeutic in arthritic disease conditions.

Methods: In order to obtain a bivalent molecule with increased avidity and serum half-life, the scFvA7 was subcloned in fusion with the CH2-CH3 domain of the human IgG (scFv A7-Fc). In addition, scFv A7-Fc was coupled with the scFv-Fc of the Adalimumab anti-TNF antibody, via a monocistronic RNA approach, to form a bispecifc antibody (BsAb) using the Knobs-into-Holes technology[2] (A7/Adalimumab). The reactivity in frozen and paraffin embedded tissue sections was investigated using immunohistochemistry and immunofluorescence analysis. *In vitro* functionality and biological activity was assessed in TNF-ELISA and TNF cytotoxicity assay on L-929 cell line.

Results: The scFv-Fc fusion protein of Adalimumab showed analogous anti-TNF properties with the parent antibody, EC50 0.008nM (Adalimumab 0.006nM), proving the validity of the scFv format. The BsAb A7/Adalimumab achieved a high degree of efficient heterodimerisation showing only 3% Adalimumab homodimer and was able to selectively bind TNFα *in vitro* with similar efficacy to the TNF blocker with a 0.01nM EC50. Despite the monovalency for the anti-TNF activity, the BsAb showed a dose dependent rescue of TNF induced cytotoxicity in L-929 cell line comparable to Adalimumab with a 0.4nM IC50 (Adalimumab 0.16nM), demonstrating the biological functionality of the construct. In addition, the A7/Adalimumab antibody proved to efficiently and specifically target the stromal compartment of human arthritic synovial microvasculature, maintaining unaltered the organ tropism of the original scFv A7.

Conclusion: Our results demonstrate that the reactivity of scFv A7 is specific to the microvasculature of human arthritic synovium. This specific reactivity suggests that the target molecule for scFv A7 may have potential as a biomarker in arthritis and also have applications as an immunotherapeutic target. The bispecific antibody format developed showed unaltered TNF blocking capacity and synovial specificity, that may allow reduction in the dosage and/or administration frequency, with the ultimate goal to reduce the systemic exposure and achieve a better therapeutic index and decreasing health care costs.

A Systematic Review and Meta-Analysis Comparing Low- Versus High-Dose Rituximab For Rheumatoid Arthritis. Markus Bredemeier, Fernando K. de Oliveira and Claúdia M. Rocha. Hospital Nossa Senhora da Conceição - Grupo Hospitalar Conceição, Porto Alegre, Brazil.

Background/Purpose: The approved dose of rituximab (RTX) for rheumatoid arthritis (RA) is 2×1000 mg infusions given 2 weeks apart. There is contradictory evidence regarding the effectiveness of a lower dose regimen (2×500 mg) of RTX. Our aim was to compare the efficacy and safety of low- and high-dose RTX and to test the non-inferiority of the low-dose scheme.

Methods: A systematic literature review searching for randomized controlled trials (RCTs) was conducted using Embase, PubMed, Cochrane and Web of Science databases. Additional studies were hand searched in ClinicalTrials.gov, Clinicaltrialsregister.eu, and Roche-trials.com websites. The meta-analysis was conducted according to the recommendations of the PRISMA statement. The primary endpoints were ACR20, ACR50, and ACR70 responses and DAS28 score at 24 and 48 weeks. Secondary endpoints were patient reported outcomes (PRO; HAQ, SF-36, and FACIT-F scores) and adverse events. For the primary dichotomous efficacy outcomes, non-inferiority of low-dose RTX was confirmed present when the lower boundary of the 95% CI of the risk ratio (RR) was ≥ 0.80. For DAS28 and PRO, non-inferiority was confirmed when the upper boundary of the 95% CI of the standardized mean difference between low- and high-dose RTX was ≤ 0.25 (i.e., within the margin of a small effect size).

Results: Six RCTs were identified (1–6). Four RCTs (1–4) were included in the meta-analysis of efficacy outcomes, which showed no significant differences in the primary outcomes between low- and high-dose RXT (Table). Non-inferiority criteria of low-dose RTX were met for ACR20, ACR50, DAS28, and PRO (at weeks 24 and 48) (Table). The results of the efficacy outcomes of the Score trial (5), a double-blind RCT, were not extractable, but there were similar improvements in ACR20 and ACR50 responses in both RTX groups at week 52. The DAS28 and the HAQ scores at 24 and 52 weeks showed statistically significant improvements (comparing to placebo) only in the low-dose RTX group. The Results of the Smart study (6), an open-label RCT that included only anti-TNF experienced patients, demonstrated non-inferiority of low-dose RTX for DAS28-CRP in patients that initially responded to standard-dose RTX. Serious adverse events did not differ significantly, but first infusion reactions were less frequent with low-dose RTX (Table).

Table. Comparison of the efficacy and safety outcomes between low- and high-dose rituximab (RTX).

Efficacy and Safety Of Infliximab Or Adalimumab Vs Abatacept In Patients With Rheumatoid Arthritis and An Inadequate Response To Methotrexate: Attest-Ample Network Randomized Trial. Robin Christensen[1], Simon Tarp[1], Daniel E. Furst[2], Lars E. Kristensen[3] and Henning Bliddal[1]. [1]Musculoskeletal Statistics Unit, The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [2]David Geffen School of Medicine, University of California, Los Angeles, CA, [3]Department of Clinical Sciences, Lund, Section of Rheumatology, Lund University, Lund, Sweden.

Background/Purpose: Using combined data from the ATTEST [1] and AMPLE [2] study comparing infliximab and adalimumab with abatacept in patients with rheumatoid arthritis (RA), we sought to assess the relative effectiveness of infliximab, adalimumab, and abatacept in patients with RA and an inadequate response to methotrexate.

Methods: The meta-dataset included results from the ATTEST (NCT00095147) and AMPLE (NCT00929864) studies. Both trials included patients who met the American College of Rheumatology (ACR) criteria for RA, were at least 18 years of age, and had an inadequate response to MTX. Major outcomes concerned the benefits and harm after 1 year on therapy, American College of Rheumatology 50% (ACR50) criterion extracted from the papers and the number of withdrawals related to adverse events (AEs), respectively. All analyses were performed using the modified intention to treat population: all patients who were randomized and received at least one dose of study drug. Patients who discontinued the study prematurely were considered non-responders subsequent to the time of discontinuation. Statistical analyses were based on mixed-effects logistic regression using an arm-based, random-effects model respecting randomization within each study [3].

Results: Compared with infliximab (IV), abatacept (IV/SC) and adalimumab SC were associated with a statistical significantly higher likelihood of achieving an ACR50 response (abatacept: OR 1.49, 95% CI: 1.03 to 2.15; P = .032; Adalimumab: OR 1.49, 95% CI: 1.02 to 2.19; P = .041). In contrast,the ACR50 responses for abatacept and adalimumab were comparable (OR 1.00, 95% CI: 0.75 to 1.32; P = .99). Abatacept was less likely than infliximab to result in discontinuation due to adverse events (OR 0.45, 95% CI: 0.21 to 0.96; P = .040) while infliximab and adalimumab were similar in this respect (OR 0.83, 95% CI: 0.39 to 1.74; P = .62)

Table. Summary of the findings of ATTEST-AMPLE network trial of selected biologics for rheumatoid arthritis

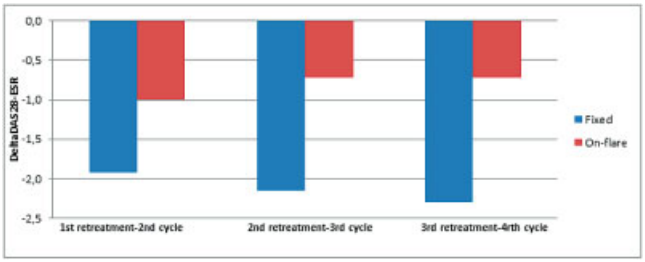
Inflammatory Diseases (ClinTrid), Karolinska Institute, Stockholm, Sweden, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]ARBITER, Institute of Rheumatology, Moscow, Russia, [4]DANBIO, Department of Rheumatology, Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [5]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [6]Department of Clinical and Experimental Rheumatology, Charles University, Prague, Czech Republic, [7]SCQM registry, University Hospitals of Geneva, Geneva, Switzerland, [8]ROB-FIN, Helsinki University Central Hospital, Helsinki, Finland, [9]Instituto de Medicina Molecular, Rheumatology Research Unit, Rheumatology Research Unit, on behalf of the Rheumatic Diseases Portuguese Register, Lisbon, Portugal, [10]BioRx.si, University Medical Centre Ljubjana, Ljubljana, Slovenia, [11]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [12]Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [13]Cantacuzino Hospital, Bucharest, Romania.

Background/Purpose: The data on how to optimally retreat patients with RA with rituximab (RTX) have been limited so far. The aim of this analysis was to compare two common retreatment strategies: A fixed retreatment approach (before flare) and retreatment when a flare occurs.

Methods: Pooled data from the Collaborating European Registries for Rituximab in RA (CERERRA) project were used. RA patients who received at least 2 retreatments (3 courses) with RTX and for whom information about the strategy for retreatment was available (according to the physician's opinion) were identified. The two retreatment strategies were compared by applying an adjusted mixed model analysis with DAS28 improvement as the dependent variable.

Results: A total of 800 patients were retreated at least 2 times: 616 retreated because of a flare (442 at 1st and 174 at 2nd retreatment) and 184 receiving fixed retreatment (128 at 1st and 56 at 2nd retreatment). Baseline characteristics (incl. age, sex, seropositivity, disease duration, number of prior DMARDs and biologics) at first course of RTX did not differ significantly between the two groups. However, patients retreated on flare had a significantly higher DAS28-ESR at the time of 1st retreatment (5.1±1.3 vs. 4.1±1.4, p<0.0001), and a higher HAQ (1.5±0.7 vs. 1.3±0.8, p=0.001), as expected. They had also a higher baseline (at the time of RTX start) DAS28 (6.3±1.0 vs. 6.1±1.2, p=0.03). Those retreated on flare were also more likely to be treated with corticosteroids (58% vs. 46%, p=0.01) but less likely to receive concomitant DMARDs (82% vs. 92%, p=0.005).

In figure 1 the baseline (=start of each cycle) DeltaDAS28 (compared to the DAS28 at the time of RTX start) for the two groups is shown. Patients receiving fixed retreatment had a significantly higher (in absolute number) DeltaDAS28 (p<0.0001) at the start of each cycle, compared to those retreated on-flare. In the adjusted mixed model analysis, we compared the two retreatment groups for the 1st and the 2nd retreatment separately using estimated marginal means. For the 1st retreatment a fixed retreatment yielded significantly better results than the "on-flare": mean DeltaDAS28=−2.4 (95% CI: −3.0; −1.7) vs. −1.8 (95% CI: −3.6; −0.03), p<0.0001. Similar results were found for the 2nd retreatment: mean DeltaDAS28=−2.6 (95% CI: −3.1; −2.2) vs. −1.6 (95% CI: −1.8; −1.4), p<0.0001.



Conclusion: A fixed retreatment strategy with RTX in RA seems to be more effective than the retreat 'on-flare' strategy.

A Randomized Placebo-Controlled Phase 2 Study To Evaluate Efficacy, Safety and Tolerability Of Two Secukinumab Loading Dose Regimens In Subjects With Active Rheumatoid Arthritis Despite Treatment With Methotrexate.

Silvano Adami[1], André Beaulieu[2], Proton Rahman[3], Bruno Seriolo[4], Janet S. Lee[5], Gerhard Krammer[6], Brian Porter[6], Anuradha Thulasiraman[6] and Hanno B. Richards[6]. [1]Rheumatology Clinic, University of Verona, Verona, Italy, [2]Faculty of Medicine, Laval University, Quebec, QC, [3]Memorial University, St. Johns, NF, [4]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [5]Novartis Pharma AG, East Hanover, NJ, [6]Novartis Pharma AG, Basel, Switzerland.

Background/Purpose: To evaluate the efficacy, safety and tolerability at week 12 of two loading regimens of secukinumab (AIN457), a fully human anti-interleukin-17A monoclonal antibody, compared to placebo and to determine whether i.v. and s.c. loading doses of secukinumab offer comparable results for patients with active RA despite treatment with methotrexate.

Methods: This was a randomized, double-blind, 12-week, phase 2 study in subjects with active RA despite stable methotrexate treatment. Subjects were randomized (2:2:1) to receive secukinumab i.v. loading (10 mg/kg week 0, 2 and 4, followed by 150 mg s.c. week 8), secukinumab s.c. loading (150 mg week 0, 1, 2, 3, 4 and 8) or placebo. The primary objective was to demonstrate the superior efficacy of pooled secukinumab compared to placebo using ACR20 criteria at week 12. Secondary efficacy objectives included ACR20/50/70, ACR components and DAS28 for pooled and individual secukinumab treatment arms.

Results: A total of 221 subjects were randomized: 88 to i.v. loading, 89 to s.c. loading and 44 to placebo. All subjects were included in efficacy and safety analyses. Subjects were mainly from Eastern Europe (78%) and had a median of 12 swollen and 20 tender joints at baseline. All were positive for either anti-CCP or RF, with a CRP ≥ 10 mg/L or ESR ≥ 28 mm/1st hr. ACR20 response rate at week 12 was numerically but not statistically significantly greater with pooled secukinumab (49.2%) compared to placebo (40.9%). Reductions of DAS28-CRP were significantly greater for both secukinumab arms compared to placebo at all visits (except i.v. loading week 8) (Figure). No statistically significant differences in ACR20, DAS28-CRP or other efficacy outcomes were observed between the i.v. and s.c. loading regimens. The safety profile was similar to that in previous secukinumab RA trials. The proportion of pooled secukinumab-treated subjects vs. placebo-treated subjects was 41.2% vs. 38.6% for any AE, 2.8% vs. 2.3% for serious AEs, and 1.7% vs. 0% for AEs leading to discontinuation.

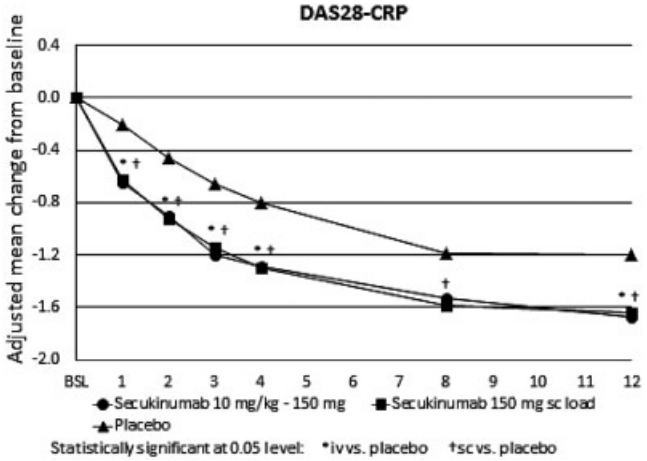

Figure. DAS28-CRP response rates by treatment arm through week 12

Conclusion: Secukinumab demonstrated improved efficacy in reducing disease activity over placebo as measured by DAS28-CRP, but not ACR20 at week 12 (primary endpoint). Reductions in disease activity were very similar for the i.v. and s.c. secukinumab loading regimens. The AE profile of secukinumab was comparable to placebo. Phase 3 studies in RA patients with inadequate response to anti-TNF treatments are ongoing.

Early Introduction Of Biologic Treatment Is An Important Predictor Of Sustained Favorable Outcome Including Clinical Remission In Early Arthritis But Not Of Sustained Favorable Outcome On Structure and Function Only: Results From The Espoir Cohort.

Cécile Gaujoux-Viala[1], Laure Gossec[2], Maxime Dougados[3], Francis Guillemin[4] and Bruno Fautrel[2]. [1]EA 2415, Montpellier I University, Nîmes University Hospital, Rheumatology Department, Nîmes, France, [2]Paris 6–Pierre et Marie Curie University; AP-HP, Rheumatology, Pitié-Salpêtrière Hospital, -GRC-UPMC 08–EEMOIS, Paris, France, [3]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [4]CHU Nancy, Clinical Epidemiology and Evaluation, Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, Nancy, France.

Background/Purpose: The relevant elements to evaluate health states in RA should include remission, good functional ability and structural stability [1]. The concept of favorable outcome could then be defined by the association of these 3 elements. An alternative definition of favorable outcome keeps only the last 2 criteria: function + structure.

Objective: To assess which variables at baseline are associated with sustained favorable outcome over 3 years in early arthritis (EA) in daily clinical practice.

Methods:- *Patients*: from the French cohort of EA ESPOIR (at least 2 swollen joints for less than 6 months and suspicion of RA) fulfilling the new ACR-EULAR criteria for RA at baseline.

Outcome: favorable outcome was defined by a criterion representing good functional ability (HAQ ≤0.5 and HAQ deterioration ≤0.25) and a criterion representing structural damage (absence of progression of the Sharp score over 1 year) with or without remission according to the new criteria of ACR/EULAR. Patients with sustained favorable outcome (according to the two definitions, ie using 2 and 3 criteria) over 3 years were analyzed.

Analysis: multinomial and ordinal logistic regression were used to determine which variables at baseline were independently associated with sustained favorable outcome. Sensitivity analyses on different definition of 'sustained' favorable outcome (sum, continuity rewarded score [2]) and on the timing of the treatment's introduction were performed.

Results: 643 patients were analyzed (mean age of patients 48±12 years; 78% were women; mean DAS28 5.4±1.2). In all, 97 patients presented sustained favorable outcome using 2 criteria (function+structure) at least at 2 time-points and 29, sustained favorable outcome using 3 criteria. (function+structure+remission). In the logistic regression models, only low HAQ and morning stiffness were always associated with sustained favorable outcome whatever the definition used (3 or 2 criteria). Being younger, living with a partner (being married/in a common-law relationship) and biological treatment during the first 6 months were associated with sustained favorable outcome using the 3 criteria (including remission). Being male, low Sharp score and no synthetic DMARD during the first year were associated with sustained favorable outcome using the 2 criteria (function+structure) (Table). To note the introduction of biological treatment after 6 months was not associated with sustained favorable outcome.

Variable at J0	OR [95%CI] Sustained favorable outcome structure+function+remission	OR [95%CI] Sustained favorable outcome structure+function
Low age	1.17 [1.07; 1.28]	NS
Low TJC	1.24 [1.01; 1.54]	NS
Living with a partner	16.67 [1.04; 250]	NS
Biological treatment during the first 6 months	28.6 [1.92; 500]	NS
Low HAQ	31.25 [3.08; 333.3]	2.38 [1.45; 3.93]
Morning stiffness >1h	6.80 [1.46; 31.2]	3.09 [1.99; 4.78]
Low Sharp score	NS	1.03 [1.005; 1.06]
Male	NS	1.70 [1.05; 2.77]
No synthetic DMARD during the first year	NS	1.70 [1.06; 2.72]

Conclusion: Early initiation of biological treatment is an important predictor of sustained favorable outcome (function+structure+remission) but not of sustained favorable outcome on structure and function only.

ACR Poster Session A
Sjögren's Syndrome: Clinical Aspects
Sunday, October 27, 2013, 8:30 AM–4:00 PM

503

Sjögren's Syndrome In American Ethnic and Racial Minorities. Ann Igoe[1], Christopher J. Lessard[1], Juan-Manuel Anaya[2], Astrid Rasmussen[1], Kiely Grundahl[3], Biji T. Kurien[4], Jacen S Maier-Moore[5], Lida Radfar[6], John A. Ice[1], Glen D. Houston[6], David M. Lewis[6], Donald U. Stone[6], Kimberly S. Hefner[7], Kathy L. Sivils[1] and R. Hal Scofield[8]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia, [3]Oklahoma Medical Research Foundation, oklahoma CIty, OK, [4]U.S. Department of Veterans Affairs Medical Center, Oklahoma City, OK, [5]University of Oklahoma Health Sciences Center, Oklahoma Medical Research Foundation, Department of Veterans Affairs, Oklahoma City, OK 73104, Oklahoma City, OK, [6]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [7]Hefner Eye Care and Optical Center, Oklahoma City, OK, [8]US Department of Veterans Affairs Medical Center, Oklahoma City, OK.

Background/Purpose: Examine the racial and ethnic make-up of a large cohort of Sjögren's syndrome (SS) gathered in the USA compared to the make-up found among SLE patients, as well as the clinical manifestations of SS in Black- and Hispanic-Americans.

Methods: Consecutive subjects, all of whom had dry eyes and mouth, attending a comprehensive sicca evaluation clinic underwent dental, ophthalmological and medical examinations. Subjects were classified according to the American-European Consensus Group Criteria (AECG) as well as the SICCA/ACR criteria. Furthermore, race and ethnicity were recorded based on self-report as well as NIH-defined race and ethnicity. Laboratory and serological studies included determination of anti-Ro/La by multiple methods.

Results: Among 256 subjects classified as primary Sjögren's syndrome, 9 (3.5%) were African-Americans and 9 (3.5%) were Hispanic-Americans. This was substantially below the representation of these minorities in the general population of the region (about 10% each), but was no different than that found among 273 subjects not classified as SS who had no anti-Ro/La and a focus score of 0.0. Compared to 152 non-Hispanic white Americans classified as SS, the blacks Americans with SS were less likely to have an abnormal Schirmer's test (1 of 9 versus 79 of 152, Fisher's p=0.03). Other clinical manifestations were similar between non-Hispanic whites and Blacks- or Hispanic Americans. Both Hispanic and black SS subjects were more likely to have anti-Ro (or SSA) than non-Hispanic white SS, and black SS were also more likely to have anti-La (or SSB) (6 of 9 versus 44 of 152, Fisher's p=0.026). We also compared the race and ethnicity of the SS cohort to a cohort of SLE patients collected in the same geographic area. Of 477 SLE patients, 106 were black. This was statistically different compared to SS (9 of 152 versus 106 of 447, $\chi 2=42.7$, p>0.001, odds ratio=7.8 (95% CI=3.9–15.8)). There were 32 Hispanics among the SLE group, and this difference almost reached statistical significance ($\chi 2=3.27$, p=0.07, OR=0.99–4.6).

Conclusion: Neither Black-Americans nor Hispanic-Americans were commonly found among a cohort with Sjögren's syndrome. Further, SS was not more severe in either Blacks or Hispanics. This is in contrast to SLE, where both these minority groups were over-represented among SLE, and disease is more severe. These findings may well represent a biological difference between Sjögren's and SLE, but socioeconomic factors impacting upon access to care and referral could be important.

Raynaud's Phenomenon and African American Race Are Independently Associated With Non-Hodgkin's Lymphoma In Sjogrens Syndrome Patients: Findings From a United States National Study. Bella Mehta[1], Neville Jadeja[2], Marjan Mujib[3] and Petros V. Efthimiou[4]. [1]Westchester Medical Center at New York Medical College, Valhalla, NY, [2]Jacobi Medical Center, New York, NY, [3]New York Medical College, Valhalla, NY, [4]LM&MHC/Weill Cornell MC, New York, NY.

Background/Purpose: Higher incidence of lymphoma in sjogrens syndrome has been reported since more than 5 decades now. Non Hodgkin's Lymphoma (NHL) ranks as the seventh leading cause of cancer diagnosis in United States. There are numerous reports of Raynaud's syndrome being an early paraneoplastic manifestation of occult malignancies.

Objectives: To investigate the associations of rheumatologic and immunologic conditions with NHL in hospitalized patients with Sjogrens disease from a large nationwide hospital registry database.

Methods: All hospitalized patients included in the nationwide inpatient sample (NIS) 2010 database with a confirmed discharge diagnosis of Sjogrens disease, as per the ICD-9-CM code 710.2 were identified. NIS is the largest all-payer inpatient care database in the United States. Multivariable logistic regression models were used to determine the associations of rheumatic diseases and demographics of the population with Non-Hodgkin's lymphoma among these patients. Discharge weight was used to measure national estimates.

Results: From 7,800,441 hospitalizations in NIS 2010 database, 7,734 Sjogrens syndrome patients were identified. Patients had a mean age of 63.47 (±16.03) years, 91.14% (7,049) were women. We used weighted analysis to estimate the national values. 38677 sjogrens syndrome patients were thus analyzed. 34923(90.29%) had no NHL or Raynaud's, 758 (1.96%) had no Raynaud's but had NHL. 2843 (7.35%) had Raynaud's present but no NHL. 153(0.4%) had both NHL and Raynaud's. Models were adjusted for Age, Sex, Vasculitis, Systemic Lupus Erythematosus, HIV, Rheumatoid Arthritis, Dermatmyosisits, Polymyositis, Connective tissue disease, Polymyalgia Rheumatica, Systemic sclerosis, Celiac Disease, Hypthyroidism, Autoimmune hepatitis, Hepatitis C virus infection, Smoking history and African American race. African american race was independently associated with presence of NHL(adjusted odds ratio, 2.217; 95% confidence interval, 1.791–2.745; p<0.005) Raynaud's syndrome was found to be independently associated with NHL (adjusted odds ratio, 2.854; 95% confidence interval, 2.357–3.456; p<0.005) (Table 1).

CHARACTERISTICS	Adjusted Odds Ratio	95% C.I.for OR Lower	Upper	P Value
AGE	1.010	1.006	1.015	.000
SEX(FEMALE)	1.330	1.080	1.638	.007
AFRICAN AMERICAN	2.217	1.791	2.745	.000
SLE	.716	.588	.873	.001
RHEUMATIOD ARTHRITIS	0.335	0.265	0.423	.000
RAYNAUD'S	2.854	2.357	3.456	.000
VASCULITIS	1.684	1.139	2.490	.009
POLYMYOSITIS	3.606	2.172	5.987	.000
CONNECTIVE TISSUE DISEASE	1.274	.671	2.418	.458
SYSTEMIC SCLEROSIS	0.866	0.618	1.214	.405
CELIAC DISEASE	2.203	1.313	3.695	.003
HYPOTYROIDISM	.753	.636	0.893	.001
AUTOIMMUNE HEPATITIS	0.999	.516	1.935	.997
HEPATITIS C VIRUS	1.402	.573	3.430	.459
SMOKING HISTORY	0.227	0.124	0.416	.000

Conclusion: In this large national database, African american race and Raynaud's syndrome was independently associated with non-hodgkins lymphoma among hospitalized Sjogrens patients. The presence of Raynaud's syndrome in patients with Sjogren's should arouse clinical suspicion for this feared complication. Further prospective studies and are needed to understand this relationship in this high-risk population.

Damage Accrual In a Single Centre Cohort Of Patients With Primary Sjögren's Syndrome Followed Up For Over 10 Years. Chiara Baldini[1], Francesco Ferro[1], Pasquale Pepe[2], Nicoletta Luciano[1], Francesca Sernissi[1], Carlotta Cacciatore[1], Daniela Martini[1], Antonio Tavoni[3], Marta Mosca[4] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Institute of Clinical Physiology, National Research Council, Pisa, Italy, [3]Immunoallergology unit, Pisa, Italy, [4]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: 1) To describe the progression and cumulative prevalence of damage accrued over the time in a single center cohort of patients with primary Sjögren's Syndrome (pSS) 2) to explore the influence of the patients' clinical and serologic profile on damage accrual.

Methods: Consecutive unselected pSS patients (AECG criteria) were enrolled in this study between September 2012 and April 2013. Demographic, clinical, serologic, histological and therapeutic data of the patients enrolled were collected. Damage scores were assessed at 1, 3, 5 and 10 years post-diagnosis of pSS using both the Sjogren's Syndrome Damage Index (SSDI) and the Sjögren's Syndrome Disease Damage Index (SSDDI). The category/item of damage was also noted. Friedman test and Wilcoxon signed-rank test were used to evaluate damage progression over the follow-up.

Results: The study cohort consisted of 155 pSS patients (7M:148F; median age at diagnosis= 49 years, IQR 40–58 years; median follow-up=5 years, IQR 3–10 years). The total increase of patients with damage was 28% after 1 year, 44% after 3 years, 74% after 5 years and 83% at the end of ourstudy. Median SSDI and SSDDI total damage scores steadily increased over the 10 years from 0 (IQR 0–1) to 2 (IQR 1–4) and from 0 (IQR 0–1) to 2 (IQR 1–3), respectively, with a significant correlation between SSDI and SSDDI scores (p=0.000). The domains mainly contributing to the total damage were the oral and the ocular items. More specifically, over the follow-up, 77/155 (49.5%) patients presented teeth loss and/or caries and 53/155 (34%) showed salivary flow impairment. Persistent salivary gland swelling was detected in 22/155 patients (14%) and was associated with a lower age at pSS diagnosis (p=0.002), anti-Ro/SSA (p=0.03), cryoglobulinemia (p=0.05), low C4 (p=0.04), hypergammaglobulinemia (p=0.000) and lymphocytopenia (p=0.000). Ocular damage was observed in 35/155 patients (22.6%) with corneal ulcers in 17/155 (11%) and tear flow impairment in 31/155 subjects (20%). Systemic damage manifestations were observed in 21/155 patients (13.5%) and correlated with the ESSDAI scores at the baseline (p=0.000), low C4 levels (p=0.005) and lymphocytopenia (p=0.01). Lymphoproliferative disorders were detected in 7/155 patients (4.5%) and malignancy in 14/155 (9%) cases.

Conclusion: This study demonstrated that the vast majority of pSS patients developed damage within 10 years. Damage accrued mostly in the oral and ocular domains, however systemic damage manifestations and malignancy might be observed in the 10–15% of the patients.

506

Hospitalization In Patients With Primary Sjögren's Syndrome. Yemil Atisha-Fregoso, Yahaira Rivera and Gabriela Hernandez-Molina. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico City, Mexico.

Background/Purpose: There is scant information on the frequency, main causes and associated risk factors of hospitalization in patients with primary Sjögren syndrome (PSS).We aimed to identify the causes and risk factors for hospitalization of PSS patients who attended a tertiary referral center.

Methods: We identified all PSS patients who regularly attend our Rheumatology clinic from Jan 2000 to Apr 2013 and retrospectively collected demographic, clinical (parotid enlargement and extraglandular features) and serological (anti-Ro/SSA, anti-La/SSB, RF, low C3 or C4 ever and maximum globulin levels) data from medical records. Patients who required at least one hospital admission were compared with those who never were hospitalized. The Disease Damage Index (SSDDI) (excluding the oral and ocular items) and the Charlson comorbidity Index were also assessed. We used a logistic regression analysis.

Results: We included a total of 170 patients (162 females, 95%). Fifty five (32%) patients were hospitalized, representing a total number of 111 hospitalizations (28 patients had more than one hospital admission). The hospitalization incidence density rate was 6.49/100 patient years. The median length of hospital stay was 9 days (IQR 6–15). There were 7 ICU admissions and 6 deaths. The main causes of admissions were disease activity in 37 cases (33.3%), infections in 36 patients (32.4%) and miscellaneous causes in 42 patients (34.3%). When compared to patients seen during the same time period and not admitted to hospital, those admitted had a shorter disease duration (6.3 [IQR 1.6–12.1] vs. 8.2 [IQR 4.6–14-1], p=0.015), similar age (55.97 ± 16.6 vs. 56.1 ± 14.2, p=0.96), a higher median SSDDI score (2 [IQR 0–2] vs. 0 [IQR 0–2], p=0.001) and higher proportion of patients with a Charlson comorbidity index ≥ 2 (36.4% vs. 15.6%, p=0.003).

The variables associated with hospitalization at the univariate analysis were vasculitis (20% vs. 7%, p=0.01), glomerulonephritis (9.1% vs. 0%, p=0.03), neurologic manifestations (polyneuropathy, mononeuritis or myelitis) (43.6% vs. 25.2%, p=0.02), hepatic involvement (primary biliary cirrhosis, autoimmune hepatitis and overlap syndrome) (21.8 vs. 5.2%, p=0.002) and hyperviscosity syndrome (7.2% vs. 1%,

p=0.038). Hospitalized patients had higher median levels of globulins (4.2 [IQR 3.4–5.7] vs. 3.8 [IQR 3.4–44], p=0.03), a higher prevalence of low C4 (16/41, 39% vs. 13/86, 15.1%, p=0.006) and less use of antimalarials (9.1% vs. 56.5%, p<0.001) and methotrexate (5.5% vs. 17.4%, p=0.03). At the multivariate analysis we identified the hepatic involvement (OR=5.01, 95% CI 1.02–24.39, p=0.046), globulin levels (OR=1.51, 95% CI 1.06–2.13; p=0.02) and low C4 (OR=4.85, 95% CI 1.54–15.30, p=0.007) as risk factors for hospitalization, whereas the use of antimalarials (OR= 0.08; 95% CI 0.02–0.27, p<0.001) was protective.

Conclusion: Major causes for admission were disease activity and infection. The presence of serologic activity parameters such as higher levels of globulins, low C4 as well as the presence of hepatic involvement were risk factors associated with hospitalization; while the use of antimalarial seemed to protect.

Level Of Agreement Of The AECG 2002 and ACR 2012 Classification Criteria For Sjögren's Syndrome In The Brittany Cohort: Clues To Understand Discrepancies. Divi Cornec[1], Alain Saraux[2], Jacques-Olivier Pers[1], Sandrine Jousse-Joulin[3], Yves Renaudineau[1], Beatrice Cochener[1], Thierry Marhadour[4] and Valerie Devauchelle-Pensec[5]. [1]Brest Occidentale University, Brest, France, [2]CHU Brest et Université Bretagne Occidentale, Brest, France, [3]Brest university medical school, EA 2216, UBO and CHU de la Cavale Blanche,, Brest, France, [4]CHU de la Cavale Blanche, Brest, France, [5]Brest Occidentale university, Brest, France.

Background/Purpose: New classification criteria for primary Sjögren's syndrome (pSS) have been proposed in 2012 and approved by the ACR. They differ substantially from the currently used AECG criteria in that 1) they do not include subjective ocular and buccal symptoms nor functionnal or morphological tests for salivary glands, 2) they use a new Ocular Staining Score (OSS) as the sole evaluation for ocular involvement, and 3) they consider the association of antinuclear antibody (ANA) titer ≥1:320 and rheumatoid factor (RF) positivity as equivalent to anti-SSA/SSB positivity. The aim of this work was to evaluate the agreement between the two sets of criteria, and to determinate the factors leading to an eventual discrepancy.

Methods: This study was conducted in the Brittany monocentric cohort of patients with suspected pSS, included between November 2006 and March 2013. All patients were evaluated by an ophtalmologist who used fluorescein and Lissamine green to evaluate the presence of keratoconjunctivitis sicca, allowing the subsequent calculation of the OSS. All cases were reviewed by a panel of 3 experts, who determined a clinical diagnosis of pSS or other cause of sicca symptoms. The agreement between the different criteria or tests was studied using Cohen's κ coefficient.

Results: 105 patients have been included in the study. 47 (44.8%) patients had a clinical diagnosis of pSS, 42 (40.0%) fulfilled AECG criteria and 35 (33.3%) ACR criteria. 27 patients fulfilled both classification criteria, 15 patients only AECG, 8 patients only ACR, and 55 none of them. The agreement between the two criteria was moderate (κ = 0.53). Xerophtalmia and xerostomia were noted respectively in 92.4% and 94.3% of the patients, suggesting no discriminating capacity between pSS and non-pSS patients. Only 3 patients had ANA≥1:320 and RF but no anti-SSA, but all of them fulfilled both AECG and ACR criteria. The agreement between OSS ≥3 and Schirmer's test ≤5mm/5min was very low (κ = 0.14). The agreement with SGB was lower for OSS than for Schirmer's test (κ = 0.14 and 0.35 respectively); they both displayed poor agreement with SSA/SSB positivity (κ = 0.21 and 0.27 respectively).

Conclusion: ACR 2012 and AECG criteria have a moderate agreement, suggesting that cohorts of pSS patients selected using different classification criteria would not be comparable. The main part of this discrepancy is caused by the differences between OSS and Schirmer's test. More precise evaluation of the diagnostic value of these ocular tests has to be performed.

Background/Purpose: Ultrasonography (US) of salivary glands is a relatively new test to diagnose primary Sjögren syndrome (pSS)[1–6]. In 2012, an international group of interest was formed to address the metric qualities of US as a potential outcome measure. A preliminary systematic review highlighted the deficiencies in the literature, particularly with regard to the reliability of interpreting and acquiring images and to delineate which abnormalities should be scored. The purpose of this study group is to improve reliability and to evaluate several US abnormalities in salivary gland according to the diagnosis or not of primary Sjögren syndrome (pSS).

Methods: We report here the first part of the study by the group that was conducted between November 2012 and june 2013 with an international group of 12 experts in ultrasonography of the salivary gland in pSS and aims were 2-fold: first to assess the interobserver reliability among experts and second to better define salivary gland abnormalities. 28 scanned imaged of parotid gland in longitudinal and transverse plans were scoredwithout preliminary training but based on experts experienced concerning salivary gland in pSS. US-GS scoring was evaluated using a 4-grade scale derived from De Vita, with the following subjective definitions for each category of homogenicity of the parenchyma: grade 0 = normal gland; grade 1:small hypoechogenic areas without echogenic bands; grade 2: multiple hypoechogenic areas measuring <2 mm with echogenic bands; grade 3, multiple hypoechogenic areas measuring 2–6 mm with hyperechogenic bands; and grade 4, multiple hypoechogenic areas measuring >6 mm. And for two grades concerning echogenicity of the parenchyma: normal or decreased. PD was not yet used for this first step. Interobserver agreement was estimated using the kappa index.

Results: Concerning hypoechogenicity the mean kappa was low: 0.3 (0.12–0.8). For homogenicity the mean kappa were respectively:0.6 (range: 0.4–0.8); 0.4 (range: −0.1–0.7) and 0.6 (range: 0.5–0.9) for grade 1, 2 and 3. The low agreement for homogenicity could be due to the absence of reference to normal parenchyma scanned image of the thyroid gland used as reference or to the absence of well defined consensus. In the absence of previous training session a relative good agreement was found between ultrasonographers. Grade 3 is related to the diagnosis of pSS. New definition of each abnormality was elaborated by the experts.

Conclusion: In the absence of well defined consensus, ultrasonography has an acceptable agreement for homogenicity of the parenchyma but not for echogenicity. Diagnosis based on grade 3 is reliable between observers. Training sessions are required and further studies will assess the scoring system and the value of US in clinical trials fro pSS.

A Novel Screening Tool Indicative Of Primary Sjogren's Syndrome Versus Sicca Symptoms. Gerard Dumancas[1], Michael Brown[1], Indra Adrianto[1], Christopher J. Lessard[1], Jennifer A. Kelly[1], Kiely Grundahl[2], Astrid Rasmussen[1], R. Hal Scofield[3], Courtney Montgomery[1] and Kathy L. Sivils[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, oklahoma CIty, OK, [3]US Department of Veterans Affairs Medical Center, Oklahoma City, OK.

Background/Purpose: Sjogren's syndrome (SS) is a chronic, progressive disease characterized by dry eyes and dry mouth resulting from lymphocytic infiltration of the lacrimal and salivary glands, respectively. Although SS is defined by keratoconjunctivitis sicca and xerostomia (dry eyes and mouth), the full spectrum of disease can involve a complex myriad of systemic symptoms similar to other rheumatic diseases. The American-European Consensus Group (AECG) classification criteria for SS require serologic and hematologic tests as well as the expertise of at least two clinical specialties for diagnosis. As such, proper diagnosis of SS is often challenging.

Methods: In order to develop a model to better predict SS, we first assessed the predictive value of a commonly used screening tool, the AECG six-question phone interview, in 379 European American (EA) individuals with dry eyes and mouth using structural equation modeling (SEM) and logistic regression (LR). Then, using responses to 440 general health and medical history questions in addition to the six-question phone interview from the same participants, we developed a novel predictive model using genetic algorithm (GA), k-nearest neighbor and forward selection model.

Results: The six-question phone interview, which in our experience results in ~36% classification of SS, yielded an ill-fitting model with low prediction accuracy (~56% under violated assumptions) *in silico.* Our novel model generated from the general health, medical history questionnaire, and six-question phone interview data obtains an accuracy of ~61% in the test set and ~64% in the unknown set. The generated model considered clinically substantive consisted of 9 questions relating to autoimmunity, difficulty swallowing, mouth/tongue dryness, aching, and disorientation.

Conclusion: The six-question phone interview, which in our experience results in ~36% classification of SS, yielded an ill-fitting model with low prediction accuracy (~56% under violated assumptions) *in silico.* Our novel model generated from the general health, medical history questionnaire, and six-question phone interview data obtains an accuracy of ~61% in the test set and ~64% in the unknown set. The generated model considered clinically substantive consisted of 9 questions relating to autoimmunity, difficulty swallowing, mouth/tongue dryness, aching, and disorientation.

Multicentric Analysis Of Inter and Intra Observer Reliabilities For Histopathological Abnormalities In Salivary Gland Biopsy In Primary Sjögren Syndrome. Background/Purpose: Histopathologic evaluation of minor labial salivary gland (MLSG) is a major goal for the classification of patients with a primary Sjögren syndrome (pSS) [1,2]. The standard focus score has been described by Daniels et al [3] but several other histopathological abnormalities have been described. However, their intra and inter reliabilities have been poorly investigated.

Our objective was to examine associations between MLSG histopathology and their reliabilities in the TEARS (Tolerance and efficacy of Rituximab in primary Sjogren Syndrome) study, a randomised multicenter study evaluating efficacy of rituximab in pSS. We studied inter and intra-observer agreement concerning the focus score and other histopathological items. We also tested agreement in the estimation of B and T cells lymphocytes ratio using doubled staining immunohistochemistry.

Methods: All MLSG biopsies available from the TEARS study were reviewed and scored by an independent pathologist (SC) at two different times, after a training session (SC, IQR). All patients fulfilled the American-European Consensus Group criteria for pSS, and had an active disease. We compared with the baseline focus score, established at the patient's inclusion. We used Daniels et al's protocol to re-evaluate the MLSG. As previously described, the agreement rate was calculated for the dichotomized focus score (separating focus <1 from $\geq 1/4mm^2$) and for each following item: focal lymphocytic sialadenitis, non-specific chronic inflammation, presence of confluent foci, presence of germinal centers, acinar depletion, duct dilatation, fibrosis, and adiposis. B and T lymphocytes cells ratio was also measured after double staining in immunohistochemistry. Inter and intra-observer agreements were estimated using the kappa index.

Results: Inter observer reliabilities were evaluated in 77 MLSG biopsies and intra observer in 89 independant MLSG biopsies. MLSG specimens included 50% with focal lymphocytic sialadenitis and 41 % with non-specific or sclerosing chronic sialadenitis. For the dichotomized focus score, the inter-observer agreement was good $k = 0.70$ (95% CI 0.62–0.78). 66/77(86%) MLSG biopsies had concordant focus scores. For focal lymphocytic sialadenitis, non-specific chronic inflammation and fibrosis, reliabilities were moderate, respectively, $k = 0.63$ (95% CI 0.54–0.72); 0.42(95% CI 0.33–0.51) and 0.22 (95% CI 0.13–0.33). Intra observer reliabilities for focus score was good with a $k = 0.77$ (95% CI 0.71–0.84). Reliability for fibrosis was moderate, $k= 0.44$ (95% CI 0.34–0.53). The agreement for B/T lymphocyte ratio was excellent $k = 0.87$ (95% CI 0.82–0.92).

Conclusion: Although focus score reliability seems good, there is disparity in the way to determine the focus score. Daniels et al' s protocol fails to be systematically applied. This could result in an over estimation of the focus score. Evaluation of B and T cells infiltrate is accurate.

Salivary Gland Lymphocyte Pattern Associated With Response To Belimumab In Primary sjogren'ssyndrome: Results Of The Beliss Study. Raphaèle Seror[1], Thierry Lazure[2], Frederic Desmoulins[3], Stephan Pavy[4], Corinne Miceli-Richard[5], Gabriel Baron[6], Philippe Ravaud[7] and Xavier Mariette[8]. [1]Université Paris Sud, Le Kremlin Bicêtre, France, [2]INSERM U1012 - Université Paris XI, Le Kremlin Bicêtre, France, [3]Université Paris-Sud, Le Kremlin Bicêtre, Le Kremlin Bicetre, France, [4]Hopital Bicetre, Paris, France, [5]Université Paris-Sud 11, Bicêtre Hospital,, Kremlin Bicêtre, France, [6]Epidemiology, Paris, France, [7]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [8]Bicêtre University Hospital, Le Kremlin Bicetre, France.

Background/Purpose: To address the change in labial salivary gland (LSG) inflammation after Belimumab (biological treatment inhibiting soluble BAFF/BLyS) therapy in pSS patients and identify predictor of response to treatment.

Methods: Patients were included in 2 parallel and identical studies in 2 European centers. Patients had to fulfill AECGcriteria, to be anti-SSA/SSB positive and had to have at the time of inclusion either systemic complications or early disease (<5 yrs of symptoms), or the presence of biomarker of B-cell activation. The patients were treated with belimumab 10 mg/kg W0, W2, W4 and then every four weeks until W24. Minor labial salivary gland (LSG) biopsies of the 15 patients (all female, mean age=50 yrs, mean disease duration= 5 yrs)from the French center, performed at W0 and W28, were analyzed for estimating the focus score, the B-cell/T-cell ratio, BAFF expression and NK infiltrate.

Response to treatment was defined according to a composite primary end-point and systemic response according to a decrease of the ESSDAI≥3 points.

Results: Before treatment, significant lymphocytic sialadenitis (focus score >1) was observed in 11 (78.6%) patients, five of whom became negative at w28 ($p=0.07$). The median focus score decreased from 1.6 to 0.5 ($p=0.39$) and Chisholm score from 4 to 2 ($p=0.01$). Median B-cell/T cell ratio decreased decreased from 0.58 to 0.50, $p=0.055$. Before treatment, a

BAFF staining was detected in 11/14 (78.6%) patients, and in only 7/14 (50.0%) after belimumab (p=0.07). The median percentage of BAFF positive cells in foci significantly decreased from 27.5% to 5% after belimumab therapy (p=0.03).NKp46 staining revealed that NK cells infiltrate was predominantly located in interstitium rather than in foci (p=0.0003), and did not change after belimumab.

8/15 patients (53%) achieved the primary end-point, and 6 (40%) patients had a significant systemic improvement. The only histological parameter associated with response to belimumab was the NK infiltrate in periphery of the foci which was lower in responders than in non-responders (median number of NK cells 21.4 vs 29.4; p=0.028) Also, there was a trend to observe lower focus score in responders than in non responders (median number of foci 1.37 vs. 3.0; p=0.08). Likewise, low NK infiltrate was also associated with improvement of systemic activity (p=0.019). The rate of salivary BAFF-positive cells was not associated with the response. Dosage of serum BAFF levels and their association to response to belimumab will be presented at the meeting.

Conclusion: After belimumab therapy, there was a clear tendency in favour of a decrease of lymphocytic infiltration BAFF-expressing cells and of B-cell/T-cell ratio within LSG. Also the percentage of BAFF positive cells significantly decreased, that could be interpreted as a decrease of the BAFF expressing cells, but also as a decrease in B cells expressing BAFF receptors linked to soluble BAFF passively stained by the anti-BAFF antibody.

The patients with a higher number of foci and a higher number of NK cells at the periphery of the foci had a poor response to Belimumab, suggesting that these forms of the disease may be more linked to the IL-12/IFNg TH1/NK axis and less linked to BAFF/B-cell axis than others
